Conclusions: PD utilization increases with increasing driving distances from the nearest dialysis providing units (HD or PD). Using driving distance, but not straight line distance affects data analysis and outcomes. Increasing the number of PD units may have a limited impact on increasing PD utilization.
Change in Physical Activity and Function in Patients with Baseline Advanced Non-Dialysis CKD

Background: Progressive declines in physical activity and function are common in individuals with worsening chronic kidney disease (CKD). However, little is known about whether the transition to dialysis is associated with accelerated decline. We aimed to assess temporal rates of change in physical activity level and physical function in people with advanced CKD to determine whether the transition to dialysis was associated with accelerated decline.

Methods: Individuals with advanced CKD stages G4-G5 from the Canadian Frailty Observation and Interventions Trial (CanFIT) were included. Outcomes included change in physical activity level measured using the Physical Activity Scale for the Elderly (PASE) and physical function measured using the chair stand test, 4-meter gait speed, and grip strength. Unadjusted and adjusted generalized linear regression models were conducted to determine whether progression to dialysis was associated with greater decline in physical activity or physical function.

Results: Of 386 individuals, 162 individuals progressed to dialysis during the study period, whereas 224 did not. Both groups experienced statistically significant declines in self-reported physical activity, increased chair stand test times, and decreased gait speed. Compared to individuals with advanced nondialysis CKD, progression to dialysis was associated with greater increase in chair stand test time in unadjusted (beta estimate 6.05 seconds, 95% CI 2.36 – 9.74, p=0.001) and adjusted (beta estimate 5.23 seconds, 95% CI 0.75 – 9.71, p=0.02) models.

Conclusions: Although individuals with advanced CKD experience declines in physical activity and function over time, progression to dialysis is associated with accelerated decline in physical function as measured by the chair stand test. Future studies on interventions to delay or prevent declines associated with CKD progression and dialysis initiation are needed.

Validation of the Surprise Question in an Ethnically Diverse Population

Background: The “Surprise Question” (SQ) asks: “If you died in the next six months, would you be surprised?”—to estimate prognosis for dialysis patients has been largely limited to studies of older populations. We sought to evaluate the SQ as a clinical tool for predicting mortality in a large, real-world population of dialysis patients.

Methods: We recruited 10 dialysis centers (6 in NYC, 3 in Denver, CO, and 1 in Dallas, TX) with 1,507 patients. Dialysis staff screened patients monthly for 14 months (May 2019-June 2020) with the SQ to identify those who were SI and recorded outcomes including the number screened and number SI. In this rolling population of patients, we calculated the mortality risk per month of follow-up for SI and not SI and determined the annualized mortality risk was 41.9% for SI and 135 (50.2%) not SI. The annualized mortality risk was 41.9% for SI and 135 (50.2%) not SI. The annualized mortality risk was 41.9% for SI and 135 (50.2%) not SI.

Results: Of 386 individuals, 162 individuals progressed to dialysis during the study period, whereas 224 did not. Both groups experienced statistically significant declines in self-reported physical activity, increased chair stand test times, and decreased gait speed. Compared to individuals with advanced nondialysis CKD, progression to dialysis was associated with greater increase in chair stand test time in unadjusted (beta estimate 6.05 seconds, 95% CI 2.36 – 9.74, p=0.001) and adjusted (beta estimate 5.23 seconds, 95% CI 0.75 – 9.71, p=0.02) models.

Conclusions: Although individuals with advanced CKD experience declines in physical activity and function over time, progression to dialysis is associated with accelerated decline in physical function as measured by the chair stand test. Future studies on interventions to delay or prevent declines associated with CKD progression and dialysis initiation are needed.

Feasibility and Acceptability of Electronic Patient-Reported Outcome Measures (e-PROMs) Collection and Feedback in Hemodialysis Patients

Background: The “Symptom monitoring With Feedback Trial” (SWIFT) will assess whether 3-monthly symptom monitoring using the IPOS-Renal questionnaire with feedback to patients and clinicians with evidence-based symptom management recommendations, can improve health-related quality of life for adults on hemodialysis with kidney failure and improve adherence and health outcomes in these vulnerable patients.

Methods: We identified four themes: enabling efficient, systematic and multidisciplinary data collection into routine care, assistance to enhance uptake, clarity about e-PROMs purpose and utility of MI to address these obstacles. Verbatim transcripts and an iterative inductive/deductive approach were used to develop a hierarchical coding system. Two researchers independently identified and coded themes informed by social cognitive theory and the social ecological framework.

Results: See table below:

PO089
Perspectives on Motivational Strategies to Improve Hemodialysis Treatment Adherence in African Americans: A Qualitative Study

Background: Compared to White patients, African American (AA) patients have a four-fold higher prevalence of kidney failure and higher hemodialysis non-adherence. Adherence behaviors are influenced by psychosocial factors, including personal meaning and behavior, and self-confidence. It is not clear how these factors can be improved. We assessed perspectives of patients, family physicians and professionals on using motivational interviewing (MI), an evidence-based intervention to improve these psychosocial factors, hemodialysis adherence, and outcomes in AAs.

Methods: Self-identified AA hemodialysis patients (n=21), dialysis clinicians (MDs, NPs, FTE, CNWs and RDs) and health equity researchers (n=30) watched a brief video describing MI and then completed a semi-structured interview. Planned questions targeted unique barriers to hemodialysis adherence faced by AAs, and the perceived utility of MI to address these obstacles. Verbatim transcripts and an iterative inductive/deductive approach were used to develop a hierarchical coding system. Two researchers independently identified and coded themes informed by social cognitive theory and the social ecological framework.

Results: See table below:

and competing interests and barriers to PROMs data collection (physical limitations encompassing survey completion, low educational attainment and language limitations; fitting in with existing routines, and survey fatigue).

**Conclusions:** Clinicians and patients support the use of e-PROMs with feedback in HD. Clinician engagement and patient support, reliability of technology, timely symptom feedback, and interventions undertaken to address symptom burden are likely to improve acceptability and impact of symptom monitoring.

Symptom Clusters in a Diverse Prospective Hemodialysis Cohort

Amy S. You,1 Sara S. Kalantar,

Keith C. Norris,1 Rene Amel Peralta,1 Yoko Narasaki,1 Ronald A. Fischman,4 Michael A. Fischman,4 Avedik Semerjian,9 Zahra Azadbadi,1 Danh V. Nguyen,1 Kamary Kalantar-Zadeh,1 Connie Rhee,1 University of California Irvine, Irvine, CA; University of California Berkeley, Berkeley, CA; University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; Southland Renal Medical Group, Long Beach, CA.

**Background:** Hemodialysis (HD) patients experience a high symptom burden similar to that of patients with malignancy, which may adversely impact their quality of life and well-being. Given that emerging data in other fields (oncology) show that symptoms often occur in clusters, we examined the presence of symptom clusters in a diverse prospective HD cohort.

**Methods:** In 122 HD patients from the prospective Malnutrition, Diet, and Racial Disparities in Chronic Kidney Disease study recruited across 16 outpatient dialysis clinics, the presence of CKD-associated symptoms was ascertained by the Dialysis Symptom Index (DSI), a 30-item validated survey that assesses symptom severity (score range, 0-40; higher score indicating greater severity), over 7/2020-8/2020. Using the DSI surveys, we examined the presence of symptom clusters (2 symptoms related to each other and occurring together) across domains categorized by organ system.

**Results:** The mean ±SD age of the cohort was 60 ±13 yrs, among whom 51% were female, 22% were Black, and 62% were Hispanic. Across the 30-item DSI survey, the most common individual symptoms included feeling tired/lack of energy (71%), dry skin (61%), itching (42%), muscle cramps (42%), and numbness/tingling in feet (41%). Upon examining co-existing symptoms, there was a high prevalence of symptom clusters, with the most common pairings including: 1) having trouble falling asleep + feeling tired/lack of energy or trouble staying asleep, 2) having trouble staying asleep + feeling tired/lack of energy or trouble staying asleep, 3) dry skin + itching, 4) dry skin + dry mouth, and 5) decreased interest in sex + difficulty becoming aroused.

**Conclusions:** We observed a high prevalence of symptom clusters in a well-defined, diverse prospective HD cohort. Further studies are needed to determine the physiologic underpinnings of concurrent symptoms in order to identify targeted therapies that can ameliorate the high symptom burden of HD patients.

Implementation and Effectiveness of a Supportive Care Learning Collaborative for Hemodialysis

Manjula Kurella Tamura,1,2 Margaret R. Stedman,1 Jialin Han,1 Steven M. Asch,2 Alvin H. Moss,3 Annette Aldous,2 Glenda Harbert,1 Amanda C. Nicklas,2 Dale Lupu,1 Laura Holdsworth,1 Stanford Medicine, Palo Alto, CA; VA Palo Alto Health Care System, Palo Alto, CA; West Virginia University Health Sciences, Morgantown, WV; Washington University Milken Institute of Public Health, Washington, DC; The George Washington University School of Nursing, Ashburn, VA; Stanford University, Stanford, CA.

**Background:** The objective of this study was to determine whether a learning collaborative for hemodialysis providers improved delivery of supportive care best practices.

**Methods:** Ten U.S. hemodialysis centers participated in a hybrid implementation-effectiveness pre-post study targeting seriously ill patients between April 2019 and September 2020. The collaborative educational bundle consisted of learning sessions, communication training and implementation support. The primary outcome was change in proportion of seriously ill patients with complete advance care planning (ACP) documentation. Healthcare utilization was a secondary outcome and implementation was assessed qualitatively.

**Results:** One center dropped out during the COVID-19 pandemic. Among the remaining nine centers, 22.9% (320/1395) of patients were identified as seriously ill in the pre-intervention period and 18.0% (226/1254) were identified in the post-intervention period. From the pre-intervention to post-intervention period, the proportion of patients with complete ACP documentation increased, and hospitalizations and emergency department visits decreased (Table). There was no difference in mortality, palliative dialysis, hospice referral or dialysis discontinuation. Screening for serious illness was widely and sustainably adopted. Goals of care discussions were adopted with variable integration and maintenance.

**Conclusions:** Supportive care best practices were feasible to implement in hemodialysis centers and largely sustained during the COVID-19 pandemic. We observed increased documentation of ACP and lower healthcare utilization after the intervention which could reflect a combination of collaborative and pandemic effects.

**Funding:** Private Foundation Support

Implementing a Patient-Centric Educational Handout to Provide the Knowledge of Kidney Disease and Dialysis, Promote Self-Care, and Improve Quality of Life in Patients Starting Hemodialysis

Jennifer Griffiths, Kiran Shivaraj, Shrutir Kure, Michael D. Klein, Savnneek S. Chugh. Westchester Medical Center, Valhalla, NY.

**Background:** In the United States about 700,000 people need hemodialysis with most of them starting in the hospital. While patients on hemodialysis account for only 1% of Medicare beneficiaries, they account for 7% of total Medicare spending. While the cost of care is high among dialysis patient, the morbidity and mortality remain elevated with majority of deaths in the first 90 days of the start of dialysis. Studies has shown, lack of education in these patients about their treatments, dietary modification, fluid intake and vascular access. Early educational intervention of dialysis patient results in reduced re-hospitalizations and 90 days mortality in this vulnerable population

**Methods:** Extensive Pubmed search was performed to identify a validated clinical tool which will assess the pre-existing knowledge and post-interventional knowledge. Chronic Hemodialysis Knowledge Survey (CHEKS) was identified as a test and post-test questionnaire to assess the efficacy of the project. CHEKS was distributed to 10 new-start hemodialysis patients admitted at Westchester Medical Center. An evidence based educational handout was prepared and provided. Blood pressure, weight, and new-start hemodialysis patients. Educational material were given to read independently as well. As post-test was performed group of days later or at the time of discharge using the same CHEKS questionnaire. The mean and median pre-test and post-test scores were analyzed and efficacy of educational intervention was analyzed.

**Results:** The initial pre-test educational questionnaire on 10 patients showed a median score of 38.4% (5 out of 13 correct) and a mean score of 43.79%. The post-test score showed a median score of 92.3% (12 out of 13 correct) or a mean score of 90.9%. These results showed a 51.8% increase in educational score after the intervention was performed. Highest increase in patient’s knowledge were related to renal diet and fluid restrictions.

**Conclusions:** This study showed that the institution of structured educational activity can result in higher knowledge in dialysis patients, leads to better adherence to dialysis prescription and dietary recommendations. This along with limiting excessive fluid intake can result in reduce re-hospitalization and better self-care.

Anxiety, Comorbid Depression, and Dialysis Symptom Burden

Daniel Cukor,1 Stephanie Donahue,1 Sri Lekha TummalaUppal,1,2 Andrew Bohmert,1 Jeffrey I. Silberzweig,1,2 Rognos Institute, New York, NY; 2Well Cornell Medicine, New York, NY, New York, NY.

**Background:** Anxiety is an understudied construct in patients with kidney failure. Its relationship to dialysis and its comorbidities, including symptom burden, is not well known. ‘Anxiety’ describes a category of diagnoses and it is unknown if its components of general worry, somatic anxiety, and anxiety sensitivity have differential relationships with outcomes. It is also not known if depressive affect moderates these relationships.

**Methods:** In this single center survey study, 100 participants completed an assessment of depressive affect (Patient Health Questionnaire-9, PHQ-9), worry (Generalized Anxiety Disorder-7, GAD-7), somatic anxiety (Beck Anxiety Inventory, BAI), anxiety sensitivity

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
(Anxiety Sensitivity Index, ASI), and dialysis symptom burden (Dialysis Symptom Index – DSI). Medical charts were abstracted for demographic information, number of missed dialysis sessions in the past 30 days (not rescheduled or due to hospitalization), and average interdialytic weight gain over the past 3 dialysis treatments. Results: The characteristics of the sample are found in the table below. People with elevated somatic anxiety (BAI > 15) had significantly higher rates of depression, worry, anxiety sensitivity, and dialysis symptom burden (p<.001, all cases). In a predictive model of symptom burden, age, race, and gender were not associated with symptom burden, and only somatic anxiety remained significant once adjusting for depression. In the final model, depression accounted for 40% of the variance and somatic anxiety accounted for an additional 37%. Conclusions: It appears that the impact on symptom burden of depression and worry/ anxiety sensitivity overlap significantly, but somatic anxiety, commonly found in panic disorder, may be a unique contributor to excess symptom burden.

Results: 19 patients completed KDQOL-36 at baseline and at 3 months; 15 also participated in an interview. Patients with high clinical levels of pain reported more overall symptom burden (p<0.001) and had significantly increased scores on all measured domains of the KDQOL-36 were observed from baseline to three months: “Symptoms” [mean difference (MD)=14.9, p<0.01]; “Effect” (MD=14.3, p<0.01); “Burden” (MD=7.3, p=0.04); “PCS” (MD=7.5, p<0.01); “MCS” (MD=7.2, p<0.04). These patterns of change are consistent with both incident and prevalent patients and across the different types of transitions. The qualitative interviews identified the following themes: 1) adapting to new circumstances (tackling change, accepting change), 2) adjusting together 3) trade offs, and 4) challenges of chronicity (the impact of dialysis, living with a complex disease, planning with uncertainty. Conclusions: The transition to a new or different type of dialysis is associated with improvements in HRQOL. In addition, qualitative data provided an in depth understanding of the transition experience, and revealed significant emotional and psychosocial processes that need to be considered during both incident and prevalent dialysis transitions.

PO0834
Prevalence and Demographic Correlates of Pain, Depression, Fatigue, and Readiness to Seek Treatment for These Symptoms in Hemodialysis Patients
Susan M. Devanar,1 Jonathan Yabes,1 Maria-Eleni Roumelioti,2 Jennifer L. Steel,1 Sarah J. Erickson,2 Mark L. Unruh,3 Manisha Jambh,4 1University of Pittsburgh Department of Medicine, Pittsburgh, PA; 2University of New Mexico School of Medicine, Albuquerque, NM.
Background: Patients with End Stage Renal Disease on hemodialysis (HD) experience a high burden of pain, fatigue and depressive symptoms. This study aims to better understand demographic differences in symptom burden and readiness to seek treatment among HD patients being recruited for an ongoing multi-center randomized controlled trial (TACare).
Methods: Patients in on-center HD were screened for clinical levels of pain (Likert scale ≥4), fatigue (Likert scale ≥3), and depression (Patient Health Questionnaire-9 score ≥10) within the last 2 weeks. Patients with at least one clinical symptom were then screened to assess readiness for seeking treatment for symptoms, and eligible to enroll if they were at least in the contemplation stage of Readiness for Behavior Change. Demographic differences in symptom screening and readiness to change (yes/no) were assessed through t-tests (age) and Chi-Square or Fisher’s Exact tests (race, ethnicity, gender). Symptom burden by readiness to change status was assessed using Chi-Square tests.
Results: Of the 390 patients who met eligibility criteria (mean age 59 years, 45% females, 15% Black, and 32% American Indian/Alaska Native, 29% Hispanic), 303 (78%) displayed at least one clinically significant symptom - pain, fatigue, or depression. Of these experiencing symptoms, 39% reported experiencing 1 clinically significant symptom, 35% reported 2, and 26% reported 3. There were no statistically significant differences by age, race, ethnicity, or gender in those reporting symptoms versus those who were not ready to seek treatment (80%) versus those not ready to seek treatment (20%). Of those who were experiencing symptoms, the percentage of patients willing to receive treatment increased as the number of symptoms increased (71%, 86% and 90% willing to receive treatment with 1, 2 or 3 symptoms respectively, p<.01).
Conclusions: The majority of HD patients report experiencing at least one clinically significant symptom and experiencing more of these symptoms increased readiness to seek treatment. Demographic difference in symptom burden and readiness for treatment were not evident in this sample and should continue to be the focus of additional research.
Funding: NIDDK Support

PO0835
Latino Patients’ Perspectives on Their Kidney Disease Education and Recommendations for Improvement: A Qualitative Study
Teresa K. Novick,1 Santiago Diaz,1 Kaydoo D. Choudhury,1 Doris A. Cubas,1 Francisco A. Barrios,1 Lilia Cervantes,1 Elizabeth A. Jacobs,2 1The University of Texas at Austin Dell Medical School, Austin, TX; 2University of Colorado, Denver, CO.
Background: In most states, Latinx immigrants with kidney failure receive dialysis in acute care settings on an emergency-only basis. What and how much kidney disease education they receive, and how to improve kidney disease education and outreach among Latinx populations is unknown. The objective of this study was to understand the kidney disease educational gaps of Latinx individuals who need but lack access to scheduled outpatient dialysis.
Methods: We conducted a qualitative, semi-structured interview study in a Texas hospital system from March 2020 to January 2021 with 15 individuals who received emergency-only dialysis when they were first diagnosed with kidney failure. We collected demographic information, and performed thematic analysis using the constant comparative method on interviews after they were audio-recorded, translated and transcribed verbatim.
Results: All 15 persons interviewed (60% male; mean age 51 years) identified as Hispanic, Mexican, andied knowing about their kidney disease more than 6 months before starting dialysis. The themes were: 1) lack of kidney disease awareness; 2) education provided was incomplete and poor quality; 3) lack of culturally concordant communication and care; 4) elements Latínx patients receiving emergency-only dialysis want in their education; 5) facilitators of patient activation and coping; and 6) Latínx patient recommendations to improve community outreach.

PO0832
Palliative and Conservative Care Consultation in Hemodialysis: A Survey
Karen Cohen,1 Geoffrey S. Techan.2 1Philadelphia College of Osteopathic Medicine, Philadelphia, PA; 2Lankenau Medical Center, Wynnewood, PA.
Background: Prior to initiating dialysis for patients with End Stage Renal Disease (ESRD), options other than dialysis such as conservative or palliative care are under-utilized. There may be a subset of patients who may not be ideal candidates for dialysis. Conservative kidney management can address the symptoms of kidney failure and can articulate goals of care with or without dialysis. Given the costs of healthcare, high morbidity and mortality in the ESRD population, we believe greater attention to conservative care prior to dialysis would result in patients having more comprehensive information prior to initiating dialysis.
Methods: Patients were surveyed at a large for-profit dialysis center in the suburban Philadelphia area in late December 2020. They were administered a 5 question survey about recalled experiences regarding referral patterns prior to dialysis. Potential responses were “yes,” “no,” or “do not recall.” Results: 37 patients were surveyed. Mean age was 63 years +/- 14, 70% were male, 95% were black. 24% of subjects reported discussing hospice and palliative care prior to dialysis initiation. 25% of patients >65 years old and 22% of patients <65 years old had such discussions. Chi square analysis was not statistically significant.
Conclusions: Only a small percentage of patients with ESRD on hemodialysis recall recommendations to improve community outreach. (6) Latinx patient recommendations to improve community outreach.

PO0833
Health-Related Quality of Life During Dialysis Modality Transitions: A Mixed-Methods Study
Chance S. Dumaing,1 Danielle E. Fox,2 Pietro Ravani,2 Maria Jose Santanta,2 Jennifer M. MacRae.2 1University of Saskatchewan, Saskatoon, SK, Canada; 2University of Calgary Cumming School of Medicine, Calgary, AB, Canada.
Background: Dialysis transitions may have an impact on health related quality of life (HRQOL), a patient defined priority for research and clinical care. We measured HRQOL and explored perceptions of adults who were initiating dialysis for the first time or transitioning to a new dialysis modality in a large urban centre in Canada.
Methods: In this prospective convergent parallel mixed-methods study we recruited eligible patients who were transitioning to dialysis from pre-care (n=9, incident) or undertaking a dialysis modality change (n=10, prevalent) between July and September 2017. Patients completed the five domains of the Kidney Disease Quality of Life (KDQOL-36) survey on their first day of dialysis treatment or first day of home dialysis training and underwent a semi-structured interview and follow up KDQOL-36 survey at 3 months.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Latinx adults receiving emergency-only dialysis are usually unaware of their kidney disease until shortly before or after they start dialysis, and the education they receive is poor quality, and often not culturally tailored. Participants made feasible recommendations on how to improve education and outreach among Latinx communities.

Results: Of the 166 eligible patients, 101 consented to the study, and 97 completed all 12 surveys. The mean age was 56±14 years, 52% were female, and 52% were Black. The most common symptoms reported by the patients were fatigue (61%), cramping (59%), and dry skin (53%) (Figure 1). Nurses under-recognized 17/21 symptoms, mean relative difference of 34±33%. Physicians under recognized 16/21 symptoms, by a mean difference of 23±36%. Symptoms with the largest degree of under-recognition by nurses were dry skin (difference of 51 percentage points) and fatigue (difference of 42 percentage points). Physicians struggled most with recognition of cramping (difference of 39 percentage points) and fatigue (difference of 34 percentage points).

Conclusions: Patient symptoms were generally under-recognized by both dialysis nurses and physicians. While several symptoms such as shortness of breath, nausea, and vomiting were well recognized by nurses and physicians, nurses under-recognized dry skin and fatigue and physicians under-recognized cramping and fatigue.

PO0836
Improving Education and Satisfaction of Hemodialysis Patients Through Anonymous Feedback
Arun Rajasekaran, Anand Prakash, Spencer Hatch, Yan Lu, Abolfazl Zarjou.
The University of Alabama at Birmingham, Birmingham, AL.

Background: Patients on outpatient hemodialysis (OHD) are a particularly vulnerable population who may not feel comfortable sharing their experience given the complex and frequent nature of their care. This could lead to conceivable gaps in knowledge pertaining to improving their satisfaction and education. To account for this potential limiting factor and to build on previous surveys performed on OHD patients we conducted a study in nine of our university affiliated OHD units.

Methods: The study had 3 major objectives: 1) apprehend the level of satisfaction of patients with varying aspects of OHD related care, 2) evaluate level of understanding and education of patients regarding issues that pertain to their health and wellbeing, 3) identify potential avenues for improvement based on patients’ input. The survey was in English, paper based, with individual answer choices graded using a 1-5 rating scale [1:very poor, 2:poor, 3:neutral, 4:good, 5:excellent]. To ensure anonymity, the completed surveys were folded and dropped into a box.

Results: Among 516 screened patients 228 did not participate. Additional 35 patients were excluded for ≥ 1 reasons: legally blind, unable to read/write/speak English, advanced dementia, too frail. 253 eligible patients completed the survey. While the overall results were reassuring with 18 out of 24 questions yielding an average of ≥ 4.2 per question, we found specific areas for improving care and education. These included providing additional resources and information regarding palliative care, mental health, cardiovascular diseases, transplant process, addressing discomfort during OHD, improving privacy, and improving the time that the nephrologist spends with patients.

Conclusions: The US centers for Medicare and Medicaid services ESRD prospective payment system and quality incentive program requires that dialysis centers meet predefined criteria for quality of patient care to ensure future funding. We took advantage of an anonymous survey to further reflect on the potential needs of this patient population to enhance their quality of life and education. Despite specific limitations, our survey demonstrated patients undergoing OHD were overall satisfied and had a good understanding about their overall health. However, we identified several aspects to improve upon as requested by our respondents.

PO0838
Improving Food Insecurity in Patients with ESKD on Hemodialysis: Partnership with Local Food Bank
Elaine T. McCull, Emaad M. Abdel-Rahman. University of Virginia, Charlottesville, VA.

Background: Nutrition plays an important role in the management of ESKD on HD. Barriers to appropriate nutrition include medical, behavioral and socio-economic factors. Socio-economic factors may include poor purchase power and problems with transportation. Poverty rate at the area of University of Virginia (UVA) is 12.9%, which is 1.3 times the state average.

Methods: UVA partnered with the local food bank to meet the basic nutritional needs of our patients by delivering renal appropriate diet to patients at the dialysis unit, with an aim of reducing individual food insecurity.

Results: The current UVA food bank collaboration program distributes more than 50 bags each month and roughly 80% of the entire dialysis program has received at least one bag since the inception of the program. Presently 34 patients consistently received bags each month (bi-monthly or greater distribution of bags). There was no significant changes in weight, serum albumin, calcium, phosphorus or potassium between baseline and 6 months of consistently receiving food bags. 28/34 (82.4%) patients responded to a survey. Patients were 64.3% African American with 57.1% females with average age of 61.3 years. Average household of these patients were 2.2, receiving 2.3 bags/week with an average of 3.3 meals/week. While 50% of patients reported satisfaction with the program, 32.5% were very satisfied, 32.1% neutral and 3.6% were unsatisfied. 57.1% viewed the food as healthy, with 21.4% perceived food to be very healthy, 17.8% were neutral and 3.6% viewed the food to be unhealthy. The majority of the patients reported improved nutrition with these food items (82.1%). While only 10.7% of the patients reported they had to skip a meal because of being short on food, 85.7% reported that these bags helped them eat more meals on a regular basis.

Conclusions: Partnership with local food banks helps decrease food insecurity and improved satisfaction in patients on hemodialysis. Nutritional parameters did not improve, which may be due to consumption of supplemental food outside of the program. Expanding such programs to other dialysis units and to include fruits, vegetables, and meats could help decrease dependence on external sources of highly processed foods that contain high levels of potassium and phosphorus and may improve patients’ outcomes.

PO0839
Medication Burden and Prescribing Patterns Among ESKD Patients on Hemodialysis in the United States, 2013-2017
Julie M. Pauk, Min Zhuo, Seooyoung C. Kim, Rishi J. Desai. Brigham and Women’s Hospital, Boston, MA.

Background: The medication burden of patients with ESKD on HD is amongst the highest of any of the chronic diseases. This study describes the medication burden and prescribing patterns in a contemporary cohort of patients with ESKD on HD in the U.S.

Methods: We used the United States Renal Data System database from January 1, 2013 and December 31, 2017 to quantify the medication burden of patients on HD aged ≥18 years. We included patients who had continuous Medicare parts A, B, and D coverage with at least one Medicare part D prescription drug plan, were alive, and had complete medication data.

Results: Of the 166 eligible patients, 101 consented to the study, and 97 completed all 12 surveys. The mean age was 56±14 years, 52% were female, and 52% were Black. The most common symptoms reported by the patients were fatigue (61%), cramping (59%), and dry skin (53%) (Figure 1). Nurses under-recognized 17/21 symptoms, mean relative difference of 34±33%. Physicians under recognized 16/21 symptoms, by a mean difference of 23±36%. Symptoms with the largest degree of under-recognition by nurses were dry skin (difference of 51 percentage points) and fatigue (difference of 42 percentage points). Physicians struggled most with recognition of cramping (difference of 39 percentage points) and fatigue (difference of 34 percentage points).

Conclusions: Patient symptoms were generally under-recognized by both dialysis nurses and physicians. While several symptoms such as shortness of breath, nausea, and vomiting were well recognized by nurses and physicians, nurses under-recognized dry skin and fatigue and physicians under-recognized cramping and fatigue.

Underline represents presenting author.
for at least 3 months prior to January 1 of the respective year and excluded patients with a history of dementia or secondary diagnosis to this. Patients could contribute data to multiple yearly cohorts. We calculated the average number of prescription medications per patient during each respective year, number of medications within classes, including potentially harmful medications, and trends in the number of medications and classes over the study period.

**Results:** We included 163,228 to 176,133 patients from 2013 to 2017. In 2013, the mean age was 63.5 years and increased to 65.1 years by 2017. The percentage in the age 18-64 years category decreased (51.3% in 2013 compared with 45.9% in 2017) and the percentage in the older age categories all increased. In 2013, 51.8% were male and 48.2% were female, compared with 53.6% male and 46.4% female in 2017. The overall burden of medications decreased prescribed, from a mean of 7.4 (SD 3.8) in 2013 to 6.8 (SD 3.6) medications in 2017. Prescribing of potentially harmful medications decreased over time (74.0% with at least one harmful medication class in 2013 to 68.5% in 2017). In particular, the prescribing of non-benzodiazepine hypnotics, benzodiazepines, and opioids decreased from 2013 to 2017 (12.2% to 6.3%, 23.4% to 19.3%, and 60.0% to 53.4%, respectively). This trend was consistent across subgroups of age, sex, race, and low-income subsidy status.

**Conclusions:** Patients with ESKD on HD continued to have a high overall medication burden, with a slight reduction over time accompanied by a decrease in prescribing of several classes of harmful medications. Continued emphasis on assessment of appropriateness of high medication burden in patients with ESKD is needed to avoid exposure to potentially harmful or futile medications in this vulnerable patient population.

The Impact of Late Initiation of Chronic Dialysis on Mortality: A National Longitudinal Study

George L. Worthen,1,2 David Clark,1,2 Keigir More,1,2 Amanda J. Vinson,1,2 Karthik K. Tennakone,1,2 Dalhouse University, Halifax, NS, Canada; ‘Nova Scotia Health Authority; Halifax, NS, Canada.

**Background:** Current Canadian guidelines recommend deferring dialysis initiation in asymptomatic patients until the glomerular filtration rate (GFR) reaches 6 mL/min/1.73m2, an “intent-to-defer” strategy. However, little is known about how dialysis initiation and post-dialysis outcomes are impacted when patients start at or below this threshold.

**Methods:** We sought to characterize the impact of starting dialysis at or below 6 mL/min/1.73m2 in a national retrospective cohort study of incident dialysis patients from 2004-2019. Dialysis data (excluding Manitoba and Quebec) was acquired from the Canadian Organ Replacement Register (CORR) and linked to hospitalization data using the well-established discharge abstract database (DAD). The cohort was restricted to only those who initiated dialysis as an outpatient and with previous nephrology follow-up of three months or more. Time to death was compared for those starting at or below 6 mL/min/1.73m2 (using the CKD-EPI formula) to those initiating between an eGFR of 6-15 mL/min/1.73m2 and analyzed using an adjusted cox proportional hazard model.

**Results:** A total of 63327 unique patients started dialysis from 2004-2019, of whom 39696 patients started dialysis as an outpatient after at least three months of nephrology follow-up. The mean age was 63.1/4, 68% were white, and 61% were male. 24% of the population started dialysis at an eGFR by CKD-EPI at or below 6 mL/min. Patients starting at 6 mL/min/1.73m2 or below were more likely to start dialysis with a CVC (59% vs 50%, p=0.001). During the study period 18979 patients died (48%). Starting dialysis at or below 6 mL/min/1.73m2 was associated with a longer time to death (HR 0.87; 95% CI 0.84-0.90) after adjusting for sex, race, age, dialysis access, diabetic kidney disease, and other comorbidities.

**Conclusions:** In this cohort of incident dialysis patients, those with an eGFR at or below 6 mL/min/1.73m2 had a lower risk for mortality compared with those starting with a higher eGFR. These findings support deferral of dialysis initiation beyond the threshold of 6 mL/min/1.73m2 in the absence of traditional indications.

Hurricane Harvey Increased Need for Emergency Care in Patients with ESKD

Frederick I. Lemaitre1, Caroline M. Schafer2, Donald A. Molony1. Johns Hopkins Medicine, Baltimore, MD; 1The University of Texas Health Science Center at Houston, Houston, TX; 2The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

**Background:** During natural disasters, end-stage kidney disease (ESKD) patients may represent a particularly vulnerable population due to interruption in care. We hypothesized that mortality and medical complications significantly increased in ESKD patients as a result of the disruptions in care related to Hurricane Harvey (HH).

**Methods:** Ten outcome variables for patients receiving outpatient, inpatient and home dialysis were evaluated at any time prior to the year of interest. Inclusion criteria were patients identified with ESKD by Medicare, had received at least one dialysis treatment within the observed timeframe, and had at least one year of follow-up before and four months before and/or four months after HH. All-cause mortality, patient admitted, admissions, emergency department (ED) visits, and diagnosis of complications.

**Results:** Using deidentified Medicare Claims data we identified 7,362 patients in the outpatient, 362 in the inpatient setting, and 810 in the home setting and compared outcomes in approximately stable populations in the years 2016 and 2018. Odds of ED visit was 31% greater (OR= 1.19, CI= [1.10, 1.29]) in 2017, compared to 2016 and 25% greater (OR= 1.25, CI= [1.14, 1.38]) compared to 2018. Odds of hyperkalemia was 37% greater in 2017 compared to 2016 and 15% greater in 2018 than 2016. Non-Hispanic black patients and men experienced lower odds of the outcomes of interest compared to white patients and women. Odds of gastrointestinal infection was 2.34 times more likely (OR = 2.33, CI = [1.32, 4.12]) in 2017 versus 2018. Black patients experienced increased odds of cerebrovascular accident (2.37 times more likely, CI = [1.20, 4.71]) in 2018 than in 2016. Non-Hispanic white women experienced increased odds of emergency department visit (1.42 times more likely, CI = [1.05, 1.95]) in 2017 than in 2016. Non-Hispanic white men experienced increased odds of emergency department visit (1.32 times more likely, CI = [1.00, 1.74]) in 2018 than in 2016.

**Conclusions:** Using Medicare claims data we found significant differences in Emergency Department (ED) visits and incidence of hyperkalemia in HH exposed patients compared to receiving outpatient dialysis in 2016 and 2018. Catastrophic events require special considerations for ESKD populations with increased risk of complications and burdens on the healthcare system. Better preparation for natural disasters may improve health outcomes associated with limited access to dialysis.

Tuscany Network Program for Evaluation of Functional Status in Hemodialysis: The Rehabilitation in Hemodialysis Area Centro Tuscany (REACT) Study

Alessandro Capitanini, Fiammetta Ravaglia, Giuseppe L. Spatoliatore, Matteo Paci, Alessandro M. Pacini, Alberto Rosati. Nephrology and Dialysis Unit, USL Toscana Centro, Italy, Firenze, Italy.

**Background:** Frailty is associated with adverse outcomes among hemodialysis patients. The study session represents an opportunity to reassess functional status, to plan and monitor long-term physical exercise, leading to considerable improvement of quality of life and physical performance. The objective of our study is to assess the prevalence and predictors of frailty among a cohort of prevalent dialysis patients in our unit (RD ACT Study).

**Methods:** A regional program was designed to evaluate functional status in all patients performing hemodialysis in the 11 Dialysis Units of USL Toscana Centro. All patients are screened through the following tests: Short Form Health Survey (SF12); Elderly Falls Screening Test; Short Physical Performance Battery (SPPB); Handgrip test. Patients were assigned to three groups on the basis of the SPPB score: poor (SPPB < 5-6), moderate (SPPB 7-9) and good performers (SPPB >9).

**Results:** Of the 920 hemodialysis patients assessed for eligibility, 446 were enrolled and divided in 3 groups on the basis of SPPB score: Characteristics of the participants and functional status evaluation are shown in Table 1. SPPB score shows a significant correlation with handgrip of right arm (r = 0.48, p < 0.001), with handgrip of left arm (r = 0.21, p < 0.001), with Elderly Falls Screening Test (r = 0.48, p < 0.001), with SF12 physical component (r = 0.43, p < 0.001), with SF12 mental component (r = 0.46, p < 0.001). Principal predictors of SPPB score are Elderly Falls Screening Test (adjusted R² = 0.36), and age (cumulative adjusted R² = 0.71).

**Conclusions:** In our hemodialysis population, SPPB allowed identification of 3 frailty phenotypes. The information needed to determine patients’ degree of frailty can be gathered relatively easily, making frailty assessment a routine activity in hemodialysis patients’ evaluation.

Functional Prognosis Following Cerebral Hemorrhage in Patients on Hemodialysis

Yusuke Watanabe, Tsutomu Inoue, Hirokazu Okada. Sattama Ika Daigaku Igakubu Daigakuen Igaku Kenkyuka, Iruma-gun, Japan.

**Background:** It has been reported that patients on hemodialysis have a higher morbidity and mortality for hypertensive cerebral hemorrhage. However, little is known about the functional outcomes in the surviving patients.

**Methods:** We retrospectively analyzed 62 consecutive patients on hemodialysis who developed hypertensive cerebral hemorrhage between 2016 and 2020. Patient background data, data on the clinical presentation of cerebral hemorrhage, and details of the lifesaving brain surgery (craniotomy for removal of hematoma and ventricular drainage) were reviewed. The outcomes evaluated were in-hospital mortality and Glasgow Coma Scale (GCS), modified Rankin Scale (mRS), and Functional Independence Measure (FIM) scores at discharge.

**Results:** The median age of the patients was 66.5 years (interquartile range [IQR] 61, 72.5), and the median GCS score at admission was 13 (IQR 6, 14). Ventricular perforation was observed in 46.8% of patients. The median estimated hemotoma volume...
Carnitine is an important co-factor in long-chain fatty acid metabolism, and is involved in transport of long chain fatty acids into the mitochondria. Carnitine deficiency can present with hyperammonemia. We present a patient with ESRD with hyperammonemia and encephalopathy.

**Case Description:** This is a 48-year-old man with End Stage Renal disease due to nephrocalcinosis secondary to treatment complications due to X-Linked Hypophosphatemic rickets, presented to emergency room with nausea vomiting and severe confusion. He had a history of atherosclerotic disease disorder and was not on valproate or any other psychotropic medications. His liver enzymes were normal, ALT, albumin levels but he had persistently elevated alkaline phosphatase of 313 unit / L (40-130). PCO2 levels were normal, L. His ammonia level of 578 micro mol/L. There was no intracranial abnormalities imaging. Free carnitine (FC) levels came back as 26 nmol/ml (25-54), Acyl Carnitine (AC) 13 nmol/ml (5-30) AC/FC ratio of 0.5. Even though he had low normal FC levels, his AC/FC ratio was elevated and it has been proposed that car/acyl car ratio greater than 0.4 represents carnitine deficiency. Patient initiated on IV L carnitine 20 mg/Kg three times weekly without repeat episode of hyperammonia. It was also noted that patient no longer experienced intracranial hypotension.

**Discussion:** Carnitine deficiency causes accumulation of non-oxidized fatty acyl-coenzyme A in the mitochondria, which inhibits degradation of ammonia. This typically results in hyperammonemia, and clinicians should have high index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment is directed at replacement with intravenous Carnitine. Oral preparation index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment reduce the ammonia levels in valproate induced hyperammonemia.

**Conclusion:** In our single-center experience, a lower level of consciousness at admission associated with high mortality in patients on hemodialysis with cerebral hemorrhage. Survivors who underwent the lifesaving brain surgery had very poor functional outcomes at discharge.

**PO0844**

Hyperammonemia in an ESRD Patient

Roi Rajaian, Kimberly J. Manzella, Charles W. Hopley. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.

**Introduction:** Carnitine is an important co-factor in long-chain fatty acid metabolism, and is involved in transport of long chain fatty acids into the mitochondria. Carnitine deficiency can present with hyperammonemia. We present a patient with ESRD with hyperammonemia and encephalopathy.

**Case Description:** This is a 48-year-old man with End Stage Renal disease due to nephrocalcinosis secondary to treatment complications due to X-Linked Hypophosphatemic rickets, presented to emergency room with nausea vomiting and severe confusion. He had a history of atherosclerotic disease disorder and was not on valproate or any other psychotropic medications. His liver enzymes were normal, ALT, albumin levels but he had persistently elevated alkaline phosphatase of 313 unit / L (40-130). PCO2 levels were normal, L. His ammonia level of 578 micro mol/L. There was no intracranial abnormalities imaging. Free carnitine (FC) levels came back as 26 nmol/ml (25-54), Acyl Carnitine (AC) 13 nmol/ml (5-30) AC/FC ratio of 0.5. Even though he had low normal FC levels, his AC/FC ratio was elevated and it has been proposed that car/acyl car ratio greater than 0.4 represents carnitine deficiency. Patient initiated on IV L carnitine 20 mg/Kg three times weekly without repeat episode of hyperammonia. It was also noted that patient no longer experienced intracranial hypotension.

**Discussion:** Carnitine deficiency causes accumulation of non-oxidized fatty acyl-coenzyme A in the mitochondria, which inhibits degradation of ammonia. This typically results in hyperammonemia, and clinicians should have high index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment is directed at replacement with intravenous Carnitine. Oral preparation index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment reduce the ammonia levels in valproate induced hyperammonemia.

**Conclusion:** In our single-center experience, a lower level of consciousness at admission associated with high mortality in patients on hemodialysis with cerebral hemorrhage. Survivors who underwent the lifesaving brain surgery had very poor functional outcomes at discharge.

Neurocognitive Function with Convventional Hemodialysis vs. Post-Dilution Hemofiltration as Initial Treatment: A Randomized Controlled Trial (The DA-VINCI Study)

Enzo C. Vasquez Jiménez,1,2 María Guadalupe C. Núñez,1 Salvador L. Gil,1 Abel V. Lerma Talamanes,2 Claudia V. Lerma Gonzalez,2 Aloha V. Meave Gonzalez,2 Magdalena Madero.1 Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico; Instituto de Seguridad Social del Estado de Mexico y Municipios, Toluca, Mexico; Universidad Autonoma del Estado de Hidalgo Instituto de Ciencias de la Salud, Pachuca, Mexico.

**Background:** The ideal modality choice and dialysis prescription during the first renal replacement therapy (RRT) session remains controversial. We conducted a pilot study to determine the safety risk for hemodialysis versus hemofiltration and its relationship with neurocognitive assessment.

**Methods:** Twenty-four incident RRT patients were included. Patients were randomized to the conventional HD group or the post-dilution HF group. MMSE and MOCA tests were applied in all patients before and after RRT and brain MRI was performed in 7 patients from each group before and after the intervention.

**Results:** Baseline characteristics were similar between groups. Compared to conventional HD, post-dilution HD had longer treatment time and blood volume. There were no significant changes in blood pressure after RRT in both groups. The MMSE test showed no significant differences between groups or within groups. The MOCA test showed an increase in the total score for the post dialution HF group with no significant changes between groups. The magnetic resonance image (MRI) evaluation showed no differences between or within groups.

**Conclusions:** Post-dilution hemofiltration is a safe alternative for the first hemodialysis session in incident RRT; it allows longer treatment time if ultrafiltration is required has a similar neurological risk than conventional HD.

**Hemodialysis and hemodynamic variables.**

Data are shown as mean ± standard deviation, median (percentile 25, percentile 75) or absolute frequency (percentage).

Intradialytic Yoga-Based Breathing and Relaxation to Improve Anxiety, Depression, and Quality of Life: A Pilot Feasibility Study

Fran Conway,1 Martha N. Desta,2 Young sun Jung,2 Daniel M. Levine,2 Andrew Bohmert.1 Well Cornell Medicine, New York, NY; 2Rogisio Institute, New York, NY.

**Background:** In-center hemodialysis patients have high rates of depression and anxiety. Pharmacologic interventions to ameliorate psychological burdens have proven to be limited in efficacy. Alternative therapies are increasingly used for those with chronic disease. A small number of studies have looked at the impact of meditation and yoga to improve symptoms of anxiety and depression and to promote a better quality of life. The aim of this study was to test the feasibility of implementing a chairside intradialytic yoga-based breathing and relaxation technique. A secondary goal was assessing the efficacy of such an intervention.

**Methods:** Eligible subjects were patients with a below average score on the Mental Component Summary (MCS) of a previously completed Kidney Disease Quality of Life (KDQOL™-36) survey both at the start and the end of the study. A Likert scale to measure anxiety was completed at each dialysis treatment both pre- and post-intervention.

**Results:** 11 subjects were enrolled over a 10-month period in 2020; 10 completed the study. As measured by the Likert scale, anxiety was significantly reduced after listening to the recording. Notably, there was a larger reduction in anxiety in patients who started dialysis in the year before the COVID-19 pandemic compared to the pre-pandemic period. Over the study period, there was a significant improvement in the scores of the Effects of Kidney Disease on Quality of Life component of the KDQOL™-36, and a trend toward significant improvement in the Mental Component Summary (MCS).

**Conclusions:** A chairside intradialytic breathing and relaxation program can be integrated into a dialysis treatment session. The study demonstrates an improvement in scores related to anxiety, depression, and measures of quality of life. Larger and randomized trials using this intervention are needed to better understand its benefits and adverse effects, as well as the obstacles to large scale implementation.

**PO0847**

Quality of Life and Symptom Burden Before and After Start of Dialysis in Older Patients

Esther N. de Rooij,1 Yvette Meuleman,1 Johan W. De Fijter,2 Kitty J. Jager, Nicholas C. Chennay,3 Christoph Wanner,4 Friedo W. Dekker,5 Ellen K. Hoogven.1 The EQUAL Study investigators1 Leids Universitair Medisch Centrum, Leiden, Netherlands; 2Amsterdam UMC Locate AMC, Amsterdam, Netherlands; 3Jeroen Bosch Ziekenhuis, ‘s-Hertogenbosch, Netherlands; 4Universitatsklinikum Wurzburg, Wurzburg, Germany.

**Background:** The number of ESKD patients ≥65 starting chronic dialysis increases. Many of these patients have low quality of life (QoL) and high symptom burden. Little is known about the effect of dialysis initiation on QoL and symptoms. Therefore, we studied QoL and symptoms before and after start of dialysis in older patients.

**Methods:** The European Quality (EQUAL) study is an ongoing prospective multicenter cohort study in late stage 4/5 CKD patients ≥65 years. For this analysis, we included all patients who started dialysis. QoL was assessed every 3-6 months using the SF-36, resulting in a physical (PCS) and mental (MCS) component score, with higher scores meaning better QoL. Symptom number and severity were assessed every 3-6 months using the symptom index (DIS), with higher scores meaning higher burden. With linear mixed models we examined the effect of physical QoL, symptom number and severity in the year before and after dialysis start.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: We included 571 older patients at dialysis start. Mean (SD) age was 77 (6) years, 74% were men, 45% had diabetes or cardiovascular disease and mean eGFR was 8.2 (3.7) ml/min/1.73m2. In the year before dialysis MCS decreased by -15.7 (95% CI: -19.5 to -11.8), PCS by -12.0 (-15.7 to -8.2), symptom number increased by +3.5 (±2.5 to +4.0) and severity by +14.8 (+10.9 to +18.8). In the year after, MCS increased by +1.9 (-2.7 to +6.4), PCS decreased by -2.1 (-6.9 to +2.7), symptom number by -0.9 (-2.1 to -0.3) and severity by -6.0 (-10.4 to -1.7).

Conclusions: Mental and physical QoL, symptom number and severity, worsened considerably in the year before dialysis, but stabilized after dialysis initiation. These results could inform older ESKD patients who consider starting dialysis.

PO0849
Fetal and Non-Fetal Gastrointestinal Events with Sodium Polystyrene Sulfonate Use in Hemodialysis: DOPPS
Ana C. Farfan Ruiz, Greg A. Knoll, Emily Rhodes, Manish M. Sood
University of Ottawa Faculty of Medicine, Ottawa, ON, Canada.

Background: There are increasing concerns regarding the gastrointestinal (GI) safety of sodium polystyrene sulfonate (SPS), a medication commonly used in the management of hyperkalemia. The objective is to compare the risk for fatal, non-fatal and their composite GI events following initiation of SPS in patients on hemodialysis compared to non-use.

Methods: An international registry of adults (≥18) on chronic intermittent hemodialysis (Dialysis Outcomes and Practice Patterns Study, DOPPS, Phases 2-6 from 2002 to 2018, 17 countries, n=229,295) who were prescribed SPS (n=24,668, 10.76%) were compared with non-users of SPS. Individual patient and facility-level analysis of fatal and non-fatal GI events were examined using weighted models.

Results: Country-level variation in SPS use ranged from 0.74% (UK) to 47.42% (France). 934 fatal, and 837 non-fatal events occurred [3-year cumulative incidence for fatal GI events: SPS 9.0% vs. no SPS 7.6%; non-fatal: SPS 0.4% vs. non-use 0.3%]. The weighted risk of fatal and composite GI events was elevated with SPS use compared to non-use (fatal HR 1.18 95%CI 1.05-1.32, non-fatal HR 0.73 95%CI 0.64-0.84, composite HR 1.02 95%CI 0.82-1.26). Younger age (<65), men, country (France, Belgium, Japan), dialysis vintage (>4 years), shorter HD treatment time (<3.5 hours) and a higher K gradient (serum potassium – dialysate potassium) were associated with a higher risk of a fatal GI event with SPS. The findings were consistent when limited to individuals with known vascular access (n=135, 62% ) and in an analysis examining the fraction of SPS use by facility.

Conclusions: SPS use in patients on hemodialysis is associated with a higher risk of fatal GI events.

Funding: Private Foundation Support

PO0850
Improved One-Year Survival and Decreased Hospitalization Rate in Incident Hemodialysis Patients with Incremental as Compared to Standard Hemodialysis Regimen: A Single-Centre Experience
Patrick Sadaun, David A. Jaques, Cyrielle Alves, Pierre-Yves F. Martin.
Nephrology Unit, Geneva University Hospitals, Geneva, Switzerland.

Background: Preservation of residual kidney function (RKF) in maintenance hemodialysis (HD) patients is associated with better survival and quality of life. RKF may be better preserved with an incremental HD regimen in patients starting HD. Since 2013, incremental HD (frequency < 3x/week) has been used in our center.

Methods: Incremental HD is implemented in incident HD patients who have a daily residual diuresis > 600 ml, a urea clearance ≥ 2 ml/min and an interdialytic weight gain < 2.5 kg. Patients are clinically assessed every week and a 24 hr-urine sample is collected every other month in order to measure RKF.

Results: From January 2013 to March 2020, 295 patients started chronic dialysis in our center, of whom 221 were on hemodialysis. Among them, 63 patients started maintenance HD with an incremental regimen. These patients did not differ significantly from those with a thrice-weekly HD regimen in terms of age, gender and comorbidity score. Residual diuresis, eGFR and urea clearance at incremental HD initiation were respectively 1842 ± 749 ml/day, 6.7± 3.1 ml/min and 4.0 ± 1.8 ml/mm. Among those 63 patients, four could retrieve a sufficient RKF to become dialysis-independent after a mean 6-month duration of incremental HD and 2 were transplanted while on incremental dialysis. Among the remaining 57 patients, mean duration of incremental HD until transition to a thrice-weekly HD regimen or death was 12 ± 12 months (median, IQR: 10, 6-20). Within the first dialysis year, survival and hospital-free days (median, IQR) were higher in patients starting with incremental HD than in patients with a thrice-weekly HD regimen (91 vs 77%; p=0.02 and 344 (318-360) vs 338 (295-354) days; p=0.03).

Conclusions: These preliminary results show that incremental HD can be implemented in incident HD patients as long as regular clinical and RKF assessments are performed adequately. However, randomised clinical trials assessing long-term survival and quality of life in incremental HD are necessary prior to its large-scale implementation.

PO0851
Association Between Systolic Blood Pressure Changes and Residual Kidney Function Decline Among Hemodialysis Patients After 1 Year
Miguel A. Morillo,1 Jui-Ting Hsiung,1 Csaba P. Kovácsdy,2,3 Kamyar Kalantar-Zadeh,1 Elani Streja.1 1University of California Irvine, Irvine, CA; 2VA Memphis Medical Center, Memphis, TN; 3The University of Tennessee Health Science Center, Memphis, TN.

Background: For patients undergoing hemodialysis, large changes in systolic blood pressure (SBP) from before to after the dialysis has been associated with worse survival. Declines in residual kidney function has also been associated with worse survival. However, the association between SBP changes and residual kidney function decline has not yet been examined.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

293
Methods: We constructed a retrospective cohort of 6659 hemodialysis patients who started dialysis between 2007 and 2011 with baseline changes in SBP and renal urea clearance (KRU) at the 1st and 5th patient quarter (91 day interval from dialysis start). KRU difference was measured as KRU difference between 5th minus 1st patient quarter. The association between baseline average changes in SBP and KRU difference was examined using linear regression analyses. Covariates included age, sex, race, BMI, dialysis modality type, and comorbidities.

Results: Linear regression analysis indicated a linear relationship between change in SBP in KRU and decline even after adjusting for covariates. Trends across all models showed hemodialysis patients with increased systolic blood pressure showed increased residual kidney function compared to the reference (-10 to -0 mmHg). After adjusting for covariates, hemodialysis patients with SBP levels that increased by 10mmHg or more had the greatest increase of KRU (0.12, 95% CI (-0.39, -0.62)), while patients with a decrease of SBP by 10-20mmHg had the greatest decline (-0.31, 95% CI (-0.60, 0.02)). Models adjusting for SBP measures showed similar trends, while the model without low-SBP and post-SBP showed an increased in KRU when SBP decreased by 10-20mmHg (0.23, 95% CI (0.01, 0.05)).

Conclusions: Increase in SBP was associated with a greater KRU decline in hemodialysis patients. Further studies should examine the underlying causes of this association and determine if modifications to dialysis treatments can improve preserving KRU and patient survival.

PO0853
Variability of Plasma Refill Rate and Risk of Intradialytic Hypotension During Maintenance Hemodialysis
Hao Wang,1 Dan Negoina,1 Hanjie Zhang,2 Sabrina Rogg,3 Jesse Y. Hsu,4 Peter Kotanko,5,6 Jochen G. Raimann,2 Laura M. Dembert,1,3 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Renal Research Institute, New York, NY; 3Lehigh School of Medicine at Mount Sinai, New York, NY; 4 Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Continuous hemotocrit data can be combined with time-updated ultrafiltration data to non-invasively estimate a semi-instantaneous plasma refill rate (PRR) throughout hemodialysis. The PRR is a dynamic metric that varies throughout hemodialysis, even during periods of constant rates of ultrafiltration, and is influenced by oncotic and hydrostatic forces. We aimed to determine whether variability in PRR is associated with intradialytic hypotension (IDH).

Methods: We used data from continuous hemotocrit monitoring performed at 17 dialysis units from January 2017-October 2019 to calculate intradialytic plasma refill rates standardized to weight and height. PRR variability was defined as the coefficient of variance in PRR (PRRcov) every 15 minutes and categorized into three groups: low (PRRcov < 0.1), moderate (PRRcov 0.1-0.2) and high (PRRcov > 0.2). IDH was defined in three ways: (1) nadir systolic blood pressure (SBP) < 90 mmHg, (2) SBP < 90 mmHg or associated symptoms, and (3) either drop in SBP of 20 mmHg or mean arterial blood pressure of 10 mmHg with associated symptoms. Cox proportional hazard regression was used to assess the impact of starting PRR variability on time to first IDH. Marginal structural modeling was used to assess the impact of time-updated plasma refill rate variability on the risk of IDH.

Results: Among 2350 patients and 184,453 hemodialysis sessions, mean session time was 220 ± 26 min and ultrafiltration rate was 9.0 ± 3.3 ml/kg/min. Median PRRcov was 1.20 (IQR 0.68, 2.18) across all sessions. Compared to hemodialysis sessions with low PRRcov sessions with high PRRcov in the first 15 minutes of treatment were associated with a 1.14 hazard of intradialytic hypotension (95% CI 1.05, 1.24). Accounting for repeated measures and changes in systolic blood pressure and ultrafiltration, sessions with high PRRcov throughout the duration of hemodialysis were associated with an increased risk of IDH based on a definition 1 OR 1.29, 95% CI 1.16, 1.43). For definition 2 (OR 1.85, 95% CI 1.77, 1.94) and definition 3 (OR 1.87, 95% CI 1.78, 1.98).

Conclusions: PRR variability was associated with higher risk of IDH, independent of time-varying confounding from SBP and UFR. PRR variability could be a promising bedside metric for hemodynamic instability during hemodialysis.

PO0854
Systemic Parameters of the Renin-Angiotensin-Aldosterone System Remain Unaffected by Changes in Fibroblast Growth Factor 23 Levels Across Hemodialysis Patients
Katharina Dörö,1 Michael Kammer,1 Roman Reinidl-Schwaighofer,1 Matthias Lorenz,2 Rodrig Murcelcuscu,1 Marko Poglitsch,2 Rainer Oberbauer,1 1Medizinische Universität Wien, Wien, Austria; 2Attoquant, Vienna, Austria.

Background: Fibroblast growth factor 23 (FGF23) is elevated in patients with chronic kidney disease and promotes the development of left ventricular hypertrophy (LVH). Decreasing the levels of FGF23 with the calcimimetic drug etelcalcetide can abate these changes in hemodialysis patients. Whether the antihypertrophic effect of FGF23 is modified by the renin-angiotensin-aldosterone system (RAAS) is unknown. The aim of the analysis was to determine whether changes in FGF23 levels are associated with differences in RAAS-parameters in hemodialysis patients, possibly explaining its influence on LVH.

Methods: Serum samples were obtained at baseline and one year from participants in the randomized EtECAR-HD trial. In this study 62 hemodialysis patients were treated with either calcimimetic or vitamin D treatment, which have opposite effects on FGF23. We analyzed PRA-S as the angiotensin-based marker for renin activity, angiotensin II (AngII), angiotensin-converting enzyme-2 (ACE2) and aldosterone using a high throughput mass spectrometry assay.

Results: The median levels of FGF23 were 2386 pg/ml (1st to 3rd quartile 819–1566) and 1386 pg/ml (288–4068) at baseline and end of study, respectively. The association of changes between baseline and end of study in FGF23 with the levels of the RAAS-components (i.e. PRA-S, AngII, ACE2, aldosterone) estimated by linear regression models was weak, with effect sizes for log2-fold-change in FGF23 close to zero. The median overall levels of PRA-S were 130 pg/ml (1st to 3rd quartile 76-269), of AngII 137 pg/ml [76-201], of aldosterone 335 pg/ml [139-454], of ACE2 1.38 ng/ml (1.1-1.8), as compared with healthy controls (PRA-S 196 pg/ml [98-238], AngII 137 pg/ml [76-201], aldosterone 335 pg/ml [139-454], ACE2 1.17 ng/ml [1.1-1.65]).

Conclusions: In the present study we were able to show that systemic RAAS activity was grossly unaffected by the treatment induced changes in FGF23 levels in this cohort. Overall, the levels of PRA-S, AngII and aldosterone were well below the ranges measured in healthy controls suggesting that the RAAS is not systemically activated in hemodialysis patients.

**Prediction of Left Ventricular Function Using Electrocardiogram Data in Patients on Hemodialysis**

Akhil Vaid, 1 David M. Charytan, 2 Lili Chen, 1 Girish N. Nadkarni. 1 Icahn School of Medicine at Mount Sinai, New York, NY; 2 NYU Langone Health, New York, NY.

**Background:** Left ventricular (LV) systolic dysfunction is common in patients on maintenance hemodialysis (HD). Early identification of patients with depressed left ventricular ejection fraction (LVEF) can facilitate disease modifying treatment. Electrocardiograms (ECGs) are routinely performed in patients on HD, however they have not been used for estimating LVEF in this population.

**Methods:** We analyzed data from five Mount Sinai facilities. Patients on HD with a transthoracic echocardiogram within 7 days of an ECG were identified using diagnostic and procedure codes. ECG data were preprocessed to remove recording artifacts, plotted to an image, and along with patient demographics were analyzed using a model comprised of a Multi-Layer Perceptron and a Convolutional Neural Network. We developed three models: 1) trained from scratch in only HD patients, 2) pre-trained on natural images (Imaginet), and 3) pre-trained on all LVEF-ECG pairs (n=698,890) excluding those for ESRD patients. Models 2 and 3 leverage transfer learning, which reuses knowledge gained from a task to perform a similar task. All models were trained/tested on LVEF-ECG pairs for ESRD patients within a Group Stratified K Fold (K=5) Cross Validation design, and performance was compared per Area Under Receiver Operating Characteristic curve (AUROC) for each category of LVEF ≥40%, 41 to ≤50%, and >50%.

**Results:** We extracted 18,626 LVEF-ECG pairs for 2,168 ESRD patients. For detection of LVEF ≤40%, models trained from scratch and pre-trained on Imaginet had AUROCs of 0.74 (95% CI: 0.67-0.80) and 0.71 (95% CI: 0.65-0.77) respectively. These were outperformed by the model pre-trained on ECG data [AUROC of 0.91 (95% CI: 0.88-0.93)]. Similar results were seen at detection of LVEF ≥40% with the AUROC being 0.85 (95% CI: 0.89-0.96) for both the model trained from scratch and the Imaginet model, while the model pre-trained on ECG data achieved an AUROC of 0.82 (95% CI: 0.78-0.87).

**Conclusions:** A model pre-trained on non-HD LVEF-ECG pairs using transfer learning performed better than output models trained from scratch or pre-trained on Imaginet. This model facilitates identification of LV systolic dysfunction in patients on HD.

PO0858

**Clinical Outcomes of Bioimpedance Analysis-Guided Hemodialysis: A Meta-Analysis of Randomized Controlled Trials**

Panupong Hansrivit1, Chchen Chen, 1 Sumit Mohan, 2 UPMC Pinnacle, Harrisburg, PA; 2 University of Southern California, Los Angeles, CA.

**Background:** Determination of fluid status in hemodialysis patients could be a great challenge for providers. Body composition monitoring using bioimpedance analysis (BIA) is an emerging tool in guiding fluid removal in hemodialysis population. However, although there are some randomized controlled trials (RCT), the reported outcomes remain heterogeneous and inconclusive across studies.

**Methods:** Ovid MEDLINE, EMBASE, and the Cochran Library were searched for eligible articles through May 2021. Inclusion criteria were: 1) RCT comparing BIA against clinical assessment, 2) sample size ≥ 50, 3) adults ≥ 18 years on hemodialysis (HD), 4) clinical outcomes were reported. No publication bias detected by Egger's regression intercept analysis.

**Results:** A total of seven RCTs (n = 1029 total; 519 BIA, 510 control), dated from 2010 to 2019, with a mean follow-up duration of 15.0±6.10 months were identified. There was no difference in mortality between BIA and clinical group (odds ratio [OR] 0.79; 95% CI 0.431, 1.472; I2 12.5%). BIA group had significantly lower weight change during follow-up duration compared to clinical group (standard means difference [SMD] -0.270; 95% CI -0.532, -0.018; I2 9.6%). Clinical group had significantly higher systolic blood pressure compared to BIA group (SMD 0.157; 95%CI 0.034, 0.280; I2 12.3%) with a mean difference of 0.052 mmHg (95% CI 0.513, 0.532; I2 0%). Clinical group had significantly higher diastolic blood pressure compared to BIA group (SMD 0.217; 95%CI 0.105, 0.326; I2 52.8%). Clinical group had significantly higher pre-HD body weight (SMD 0.280; 95% CI 0.130, 0.430; I2 48.1%) with a mean difference of 0.370 kg (95% CI 0.178, 0.563; I2 47.8%) compared to BIA group. There was no difference in post-HD body weight between the two groups (SMD 0.156; 95% CI 0.005, 0.306; I2 0%).

**Conclusions:** There was no mortality benefit to BIA-guided HD compared with clinical-guided HD. However, BIA-guided HD improved systolic blood pressure and weight gain compared to clinical-guided HD. Pulse wave velocity, which represents arterial stiffness, was also lower in BIA group. Although our findings suggest some non-mortality benefits to BIA-guided HD, however, the clinical impact of BIA-guided HD on cardiovascular events, intradialytic complications, and patients' quality of life remain to be elucidated in future RCTs.

**Point-of-Care Ultrasound Measurements to Predict Intradialytic Hypotension: A Cross-Sectional Pilot Study**

Chrystel Pawly, 1 Wael Azzam, 1 Christy Costanian, 1 Gonzalo Matzumura Umemoto, 1 Enyo Ablordepey, 2 Fadi Tohme. 1 Lebanon American University, Beirut, Lebanon; 2 University of Southern California, Los Angeles, CA; 3 Washington University in St Louis, St Louis, MO.

**Background:** Intradialytic hypotension (IDH) results from excessive ultrafiltration in patients on chronic hemodialysis (HD) and has been linked to increased mortality. Prescribing the right amount of ultrafiltration can be challenging, partly due to the poor sensitivity of physical examination for detection of volume overload in HD patients. POCUS is emerging as a valuable tool in the assessment of volume status. The goal of this study is to determine whether pre-dialysis POCUS measurements are associated with development of IDH.

**Methods:** Patients >18 years old on HD for at least 6 months and ordered for 2 or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e’, portal vein (PV) pulsatility and IVC size. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fischer’s and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

**Results:** There was no association between age, sex, ethnicity, BMI, dialysis vintage, Charlson comorbidity index, interdialytic weight gain, IVC size, PV pulsatility, septal E/e’ and the primary outcome. There was a significant association between lateral E/e’ and IDH events or post HD orthostasis (p=0.05).

**Conclusions:** In this pilot study, an elevated lateral E/e’ was associated with lower rates of HD events or post HD orthostasis. The role of POCUS in guiding fluid removal during HD warrants further exploration.
PO0859
Relationship Between Fluid Overload and Hemoglobin Concentration in Hemodialysis Patients: A Longitudinal Analysis
Lemuel Rivera Fuentes,1 Ariolla E. Mermelstein,1 George A. Kayser,2 Jochen G. Raimann,1 Ulrich Moissl,1 Stephan Thijssen,1 Peter Kotanko,1 Renal Research Institute1, Renal Research Institute, New York, NY; 2University of California-Davis, Davis, CA; 1 Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Quantification of fluid status by bioimpedance spectroscopy (BIS) has become routine outside United States (US). We performed the first assessment of fluid status in US hemodialysis (HD) clinics using a BIS device. We studied the longitudinal association between fluid overload (FO) and hemoglobin (Hgb) concentration adjusting for inflammation and erythropoiesis-stimulating agents (ESA).

Methods: Measurement of FO [Body Composition Monitor (BCM); Fresenius Medical Care] was conducted cross-sectionally in chronic HD patients in 4 HD clinics in New York. We built linear mixed effects models with Hgb as the dependent variable and calculated FO longitudinally to include as a fixed effect. We tested the robustness of the association to account for the influence of inflammation by including the neutrophil-lymphocyte ratio (NLR) as an additional fixed effect. As a subset analysis 2 separate models were built in subjects with or without ESAs. To corroborate the dilutional effect of FO we exchanged Hgb for albumin as a fixed effect.

Results: We studied 169 patients (Figure 1). FO was inversely associated with Hgb [Estimate -0.16 (-0.20 to -0.12) g/dl per 1L of FO], a significant fixed effect that remained unchanged in magnitude even after inclusion of NLR [Estimate 0.04 (-0.05 to 0.06) g/dl per 1 unit of NLR]. The effect was larger in patients without ESA prescription [Estimate -0.22 (-0.32 to -0.12) g/dl per 1L of FO]. FO was a significant determinant of albumin [Estimate -0.02 (-0.03 to -0.01) g/dl per 1L of FO] with NLR being a significant fixed effect [Estimate -0.03 (-0.04 to -0.01) g/dl per 1 unit of NLR].

Conclusions: Hgb is inversely affected by FO, a significant effect independent of inflammation (NLR). The impact of FO on Hgb concentration is larger in those with no ESA treatment emphasizing that fluid status has to be considered in anemia management. The effect of FO on albumin supports hemodilution as the principal cause for the changes seen on Hgb.

Interpreting Home Blood Pressure Measurements in Haemodialysis: A Post Hoc Analysis of a Randomized Cross-Over Study
Vicki K. Sandys,1 Lavleen Bhat,1 Emer C. O’Hare,1 Conall M. O’Seaghdha,1 Donal J. Sexton,2 Royal College of Surgeons in Ireland, Dublin, Ireland; 2The University of Dublin Trinity College, Dublin, Ireland.

Background: Home BP correlates better with ambulatory BP, target organ damage and mortality in dialysis patients. We aimed to determine the agreement of in-centre BP with home BP.

Methods: A post-hoc analysis of a pilot-scale, randomised two-period cross over study comparing self-monitoring of BP over 4 weeks with usual care in 41 haemodialysis patients. www.clinicaltrials.gov. NCT0340349. Dialysis clinic BP and home BP (using average real variability (ARV). Mixed effects models for repeated measures with a moving average window of 2 weeks were used to examine associations with BP and ARV.

Results: 33 out of 41 participants had sufficient home BP measurements for inclusion (mean age 63.7 years, 52.1% male). Post-dialysis SBP had moderate agreement with in-home SBP measurements (K = 0.6) compared with pre-dialysis SBP measurements (K = 0.4). The mean bias between home SBP and post SBP measurements was -4.15 mmHg (95% CI 23.5 to -31.8 mmHg) (Figure 1). Home SBP ARV (16 +/- 5) was as high as pre SBP ARV (14 +/- 5) and post SBP ARV (13 +/- 5). In univariate analysis only calcium channel blockers were consistently associated with pre-dialysis (P = 0.02), post-dialysis and home SBP (both P<0.001).

Conclusions: Post-dialysis SBP demonstrates moderate agreement with home BP when two week BP averages are used. Home BP measurements are as variable as clinic BP measurements and isolated measurements may lack interpretability. Averaging the home BP over two weeks may improve the utility of home BP monitoring.

PO0861
Increased Tricuspid Regurgitation Jet Velocity as a Predictor of Acute Decompensated Heart Failure in ESRD Patients on Maintenance Hemodialysis
Youngchan Park,1 Ye na Kim,1,2 Ho Sik Shin,1,2 Yeonsoon Jung,1,2 Hark Rim,1,2 Kosin University Gospel Hospital, Busan, Busan, Republic of Korea; 2Transplantation Research Institute, Kosin University College of Medicine, Busan, South Korea, Republic of Korea.

Background: Many patients with end-stage renal disease (ESRD) on hemodialysis (HD) experience left ventricular hypertrophy and reduced vascular compliance and are likely to develop heart failure (HF). We aimed to determine the hemodynamic factors associated with acute decompensated events among ESRD patients undergoing HD.

Methods: We retrospectively investigated ESRD patients on HD through a medical record review. We excluded patients with significant ischemic heart disease (IHD), percutaneous coronary intervention or coronary artery bypass graft, significant valvular heart disease (VHD), or malignancy. We divided patients into those experience who experienced any admission due to acute decompensated HF (ADHF) and those who did not.

Results: Of the 188 ESRD patients on HD, 87 were excluded, and 101 were enrolled (mean age: 63.7 years, 52.1% male). The ADHF group demonstrated significantly higher tricuspid regurgitation (TR) jet velocity (2.9 ± 0.6 vs. 2.5 ± 0.4 m/s, respectively; p=0.004) than the non-ADHF group. Multivariate logistic regression analysis demonstrated that TR jet velocity (odds ratio: 8.356, 95% confidence interval: 1.806-38.658; p=0.007) was an independent predictor of ADHF after adjusting for age and sex, while LVEF and E/E’ were not. Per receiver operating characteristic curve analysis, TR jet velocity > 2.8 m/s was associated with ADHF with 47.7% sensitivity and 76.4% specificity (area under the curve: 0.656).

Conclusions: Our data showed that increased TR jet velocity was an independent predictor of ADHF events in ESRD patients on HD, but LVEF and E/E’ were not.

Benefit of More Frequent Dialysis on Dialysis Recovery Time in Nursing Home Patients with ESRD
Alice Hellebrand,1 Eran Y. Bellin,1,2 Steven M. Kaplan,1 Jordan Ledvina,1 William Markis,2 Nathan W. Levin,2 Allen Kaufman,1 Dialyze Direct Brooklyn, Brooklyn, NY; 2Albert Einstein College of Medicine, Bronx, NY.

Background: Dialysis patients admitted to a skilled nursing facility (SNF) are characterized by advanced age, frailty, and multiple comorbidities. Based on prior studies, which demonstrated shortened dialysis recovery time (DRT) with more frequent dialysis (MFD) in populations aged ~50s living at home (FREEDOM Study 2010, FHN trial 2006), it was postulated that dialysis patients in a SNF would benefit from MFD.

Methods: Patients studied were admitted to SNFs in OH, TX, FL, NY, and PA from November-December 2019 (pre-COVID) and could reliably answer questions about DRT. 80% were undergoing subacute rehabilitation and 20% were permanent residents of the SNF. Patients received NxStage on-site staff assisted MFD 5x (80%) or 4x (20%) per week. MFDV (V/>2.1. At every dialysis, patients were asked by their RN caregiver “How long did it take you to recover from your last HD session?” Responses were deemed unreliable if a patient had cognitive impairment. Reliable responses were used for outcome analysis. In the present study, DRT data was collected by a caregiver nurse, differing from the methodology of the FREEDOM/FHN studies which collected DRT data via KDQOL form or phone interview. The implications of these differences in data collection methods are currently unknown.

Results: 485 unique patients were included in the study. Demographics included 53% males, mean age 67.5 +/- 13 years, African American 19%, Caucasian 25%, Hispanic 5%, Asian 0.4%, unknown or other 51%. Mean DRT was 1.5 +/- 2.6 hours. Mean DRT was calculated using the midpoint recovery time for intervals, or 18 hours when DRT was the next morning or beyond. In 69%, DRT was < 2 hours.

Conclusions: In the FREEDOM and FHN conventional HD 3x per week study arms, DRT averaged 6-8 hours. MFD reduced DRT to ~1.0 hour in those relatively young patients living at home. In our study, HD patients residing in a SNF and receiving MFD experienced DRT of 1.5 hours. Age, frailty and comorbid conditions therefore do not prevent DRT benefits of MFD. DRT benefits could stem from more effective, gentler fluid management by MFD. Further studies are needed to fully explore the impact of shortened DRT on rehabilitation scores, hospitalizations and deaths in elderly patients residing in SNFs.

PO0863
The Combination of Arterial Stiffness and Peripheral Vascular Disease Aggravates Survival Among Hemodialysis Patient Using Competing Risk Analysis
Adisorn Pathumrak,1 Kanin Thammavarunucut, Chaggiya Kitayakara, Arkorn Nongmuang, Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: The survival in end stage renal disease (ESRD) patient is unacceptable high. The Skin autofluorescence (SAF) for advance glycation end products (AGEs), peripheral vascular disease (PVD) (ankle-brachial index, ABI ≤0.9) and arterial stiffness (cardio ankle vascular index, CAVI>9) were reports as predictors of mortality. However, kidney transplantation (KT) competes the mortality outcome. We aim to explore these markers for precisely prediction of mortality using competing risk method.

Methods: Retrospective chart review in chronic hemodialysis patients was done in 3 hemodialysis centers in North Bangkok during November 2015 and March 2016. Arterial stiffness, SAF, IMAR and PVD were collected as a clinical predictor. Cumulative incidence of mortality was used as was a primary outcome. Logistic regression with competing risk model was used to analyze the factor affecting mortality.

Results: A Total of 176 patients were eligible and classified into 4 groups according to PVD and stiffness status. During follow up 44.5±14.8 months, the overall mortality rate was 27% which is 13.2, 28.6, 31.5 and 61.9% in no PVD and stiffness, exclusively PVD, exclusively stiffness, and combine group respectively. The PVD (HR 2.93, CI 1.2 to 7.14, P=0.018) and stiffness (HR 2.57, CI 1.1 to 5.73, P=0.021) were independent predictors of mortality. In competing risk method, the combination of PVD and stiffness associate with highest mortality (P=0.0002139), while the patients who no PVD and stiffness had the highest rate for KT (P=0.0050275).

Conclusions: The PVD and stiffness were an independent risk of mortality among hemodialysis patients. The combination of PVD and stiffness may stratify risk of mortality in hemodialysis patient using competing risk method.

PO0865
Consistency of the Dry Weight of Hemodialysis Patients Predicted Using Bioelectrical Impedance Analysis Between Standing and Lying-Down Positions
Hyunsuk Kim,1 Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-do, Republic of Korea; 2Chungham National University Sejong Hospital, Sejong, Republic of Korea.

Background: Accurate dry weight (Dw) estimation is important for hemodialysis patients. Although bioimpedance spectroscopy (BIS) is commonly used to measure Dw, the BIS-based Dw frequently differs from the clinical Dw.

Methods: We analyzed the characteristics of patients whose BIS-based Dw were over- and underestimated. In this retrospective cohort study, we evaluated 1,555 patients undergoing maintenance hemodialysis in Chungham National University Hospital. The gap (Dwclinical-DwBIS) was calculated by comparing the BIS and clinical Dws.

Results: We analyzed the clinical characteristics of patients with positive (n = 835) and negative (n = 720) gaps. Compared with other patients, the Dwclinical-positive group was taller, had higher extracellular water (ECW) level and extracellular/intracellular water index (ECI); and had lower weight, body mass index (BMI), lean tissue index (LTI), fat tissue index (FTI), fat mass (FAT), and adipose tissue mass (ATM), as well as lower levels of hemoglobin, total protein, albumin, and phosphorous. The Dwclinical-negative group exhibited higher levels of hemoglobin, total protein, albumin, and phosphorous, as well as elevated BMI, FTI, FAT, and ATM, however, it had lower height, ECW, and ECI. Linear regression analysis revealed that FAT significantly predicted Dwclinical accuracy.

Conclusions: The clinical Dw of patients with malnutrition and a low fat mass tended to be underestimated, while the clinical Dw of patients with comparatively large fat reserves tended to be overestimated. These characteristics of dialysis patients will aid in the correction of BIS-associated Dw errors.
PO0866

Use of Crit-Line to Reduce Intradialytic Hypotension in Hospitalized Patients Receiving Dialysis

Background: Intradialytic hypotension (IDH) is a frequent complication of hemodialysis in hospitalized patients with acute kidney injury (AKI) and end stage kidney disease (ESKD). Crit-Line is a device that monitors absolute hematocrit and oxygen saturation during dialysis and reads out the percent blood volume change. Whether the use of Crit-Line during HD in hospitalized patients results in less IDH is unknown.

Methods: We performed a time series study in all hospitalized adult AKI/ESKD patients undergoing acute HD at the University of Colorado. During the control period baseline data was collected. During the intervention period, Crit-Line was used on all hospitalized patients undergoing HD including those receiving portable HD treatments in the ICU. During both time periods, nurses recorded number of hypotensive events, patient symptoms and modifications that were made to the dialysis prescription. The primary outcome was number of IDH events defined by the NKF KDOQI Guidelines.

Results: 328 patients were included, 161 from the control period and 167 from the intervention period. Patient characteristics were similar in both time periods and are shown in Table 1. IDH occurred in 23.5% of treatments during the control period and 18.7% during the intervention period, but the difference was not significant, p=0.22 (Figure 1). When examining portable dialysis treatments in the ICU, there was a significant reduction in IDH with Crit-Line compared to control (Odds Ratio 0.71 95% CI 0.51-0.99, p=0.04).

Conclusions: Use of Crit-Line in hospitalized patients undergoing dialysis in the ICU resulted in less IDH.

Dry Weight Adjustments for Hemodialysis Patients Using Machine Learning
Hae Ri Kim,1 Jae wan Jeon,1 Youngrok Ham,1 Kiryang Na,2 Kang Wook Lee,2 Yoon-Kyung Chang,2 Dae Eun Choi.1 Chungnam National University Sejong Hospital, Sejong, Republic of Korea; 2Chungnam National University, Daejeon, Daejeon, Republic of Korea; 1Daejeon Saint Mary's Hospital, Daejeon, Daejeon, Republic of Korea.

Background: Knowledge of the proper dry weight plays a critical role in the efficiency of dialysis and the survival of hemodialysis patients. Recently, bioimpedance spectroscopy (BIS) has been widely used for set dry weight in hemodialysis patients. However, BIS is often misrepresented in clinical healthy weight. In this study, we tried to predict the clinically proper dry weight (DW_py) using machine learning for patient’s clinical information including BIS. We then analyze the factors that influence the prediction of the clinical dry weight.

Methods: As a retrospective, single center study, data of 1672 hemodialysis patients were reviewed. DW_py data were collected when the dry weight was measured using the BIS (DW_BIS). The gap between the two (Gap_DW) was calculated and then grouped and analyzed based on gaps of 1 kg and 2 kg.

Results: Based on the gap between DW_BIS and DW_py, 972, 303, and 384 patients were placed in groups with gaps of <1 kg, ≥1kg and <2 kg, and ≥2 kg, respectively. For less than 1 kg and 2 kg of Gap_DW, it can be seen that the average accuracies for the two groups are 83% and 72%, respectively, in using XGBoost machine learning. As Gap_DW increases, it is more difficult to predict the target property. As Gap_DW increases, the mean values of hemoglobin, total protein, serum albumin, creatinine, phosphorus, potassium, and the fat tissue index tended to decrease. However, the height, total body water, extracellular water (ECW), and ECW to intracellular water ratio tended to increase.

Conclusions: Machine learning made it slightly easier to predict DW_py based on DW_BIS under limited conditions and gave better insights into predicting DW_CFR Malnutrition-related factors and ECW were important in reflecting the differences between DW_BIS and DW_CFR.

Interdialytic Weight Gain in Long Intervals and Mortality Among Maintenance Hemodialysis Patients
Yoshikazu Miyasato,1,2 Tsuyoshi Miyagi,1 Yoko Narasaki,1 Hiroshi Kimura,1 Elani Streja,1 Kamyar Kalantar-Zadeh.1 University of California Irvine, Irvine, CA; 2Kumamoto Daigaku, Kumamoto, Japan.

Background: Interdialytic weight gain (IDWG) is an important factor for sudden death on the first dialysis day right after long interdialytic intervals (i.e. 2-day breaks between dialysis treatments) in hemodialysis patients. We defined IDWG in long intervals (IDWGL) as the IDWG during 2-day breaks. In this study we examined the association between IDWGL and medium-term mortality.

Methods: This retrospective cohort study included patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWGL and all-cause mortality using Cox regression model. Seven categories of IDWGL were as follows: 0<−1%, 1−<2%, 2−<3%, 3−<4%, 4−<5%, 5−<6%, and ≥6%. We also examined continuous associations between IDWGL and mortality using restricted cubic spline analysis.

Results: We examined mortality in 35225 patients. The mean age (and standard deviation) was 62±15 years, and 8112 died during the median follow-up period of 1.4 years. Higher categories of IDWGL were associated with increased risk of mortality. The hazard ratios (95% confidence intervals) of all-cause mortality for 3−<4%, 4−<5%, 5−<6%, and ≥6% were 1.09 (1.03-1.16), 1.14 (1.06-1.23), 1.17 (1.06-1.29), and 1.25 (1.14-1.38) (Reference: 2−<3%) (Figure a). The restricted cubic spline analysis showed that risk of mortality increased when IDWGL exceeded 2% (Figure b).

Conclusions: IDWGL exceeded 2% was associated with higher risk of mortality. Our results suggest IDWGL can be a risk parameter for medium-term mortality.

PO0869
Coronary Artery Calcification Is a Risk Factor for Intradialytic Hypotension in Hemodialysis Patients
Sonoo Mizui,1 Yoshiko Nishizawa,1 Toshiki Doi,1 Kazuomi Yamashita,1 Kenichiro Shigemoto,1 Koji Usui,2 Michiko Arita,3 Takayuki Naito,4 Shigehiro Doi,5 Takao Masaki5 1Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; 2Hiroshima Daigaku Byoin, Hiroshima, Japan; 3Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; 4Ichiyokai East Clinic, Hiroshima, Japan; 5Ichiyokai Yokogawa Clinic, Hiroshima, Japan.

Background: Vascular calcification and intradialytic hypotension (IDH) share common risk factors in hemodialysis (HD) patients, but there are few reports about the association. We investigated the association between IDH and coronary artery calcification (CAC) and their effects on mortality in HD patients.

Methods: Subjects were consecutive maintenance HD patients. IDH was defined as nadir systolic blood pressure <100 mmHg, or the requirement for bolus infusion of saline and vasopressor (ethylene glycol solution) during at least two of 10 HD sessions. Laboratory data and Agatston coronary artery calcium score (CAC) were obtained at baseline. Logistic regression analyses for CACs and Cox analyses for mortality were conducted.

Results: In all subjects (n=173), age and dialysis vintage were 66±12 years and 102±9 months, respectively. IDH occurred in 37 patients (21.4%), and CACs was higher in the IDH group than in the non-IDH group [1,845 (243–3,774) vs. 884 (161–2,465)]. IDH was significantly (P<0.05) associated with CACS [odds ratio (OR): 1.01], diabetes (OR: 2.98), mean predialysis systolic blood pressure (OR: 0.93), mean ultrafiltration (P<1.92), K/Vurea (OR: 11.27) and erythropoietin responsive index (ERI) (OR: 0.91), but not with serum albumin or use of calcium channel blockers. For 3-year all-cause mortality, the cut-off value of CACs, determined by receiver operating characteristics curve analysis, was 1,829 with sensitivity of 69% and specificity of 77%. Of the 173 subjects, 45 all-cause mortality and 19 cardiovascular events occurred for 3 years. Patients with both IDH and CACs ≥1,829 had the highest 3-year cumulative CV death rate (33.3%, P<0.01) compared with 19.7%, 11.5%, and 4.5% in those with CACs ≥1,829 only, IDH only, and neither, respectively. In Cox models including age, sex, diabetes, albumin, phosphate, CRP, ERI and FGF23, hazard ratios (HRs) for 3-year all-cause mortality of IDH, CACs ≥1,829, or IDH or CACs ≥1,829 were similar, but HR for 3-year CV mortality was the highest in CACs with ≥1,829 (OR: 0.01) compared with 7.29 (P<0.01) and 6.77 (P<0.01), in those with CACs ≥1,829 only, and IDH only. CACs ≥1,829 independently predict CAC risk for HD patients, and CACs provide additional risk discrimination over IDH for CV mortality in HD patients.

PO0870
Cardiac Arrests During Hemodialysis Among Maintenance Hemodialysis Patients in a Large Dialysis Network in India

Background: Cardiac arrest (CA) during a HD session carries a high mortality and is reported associations include age, comorbidity, dialysis characteristics. Since much is unknown in India, we aimed to study Incidence of CA, prediposing factors and outcome of CPCR following intra HD cardiac arrests.

Methods: Consecutive CA in a large dialysis network from July 2019 to March 2020 were reviewed for age, gender, HD frequency, adequacy, vascular access, HD facility location, size, nephrologist coverage, b/o DM and IHD, HD session timing, duration of HD session & hospitalization in recent past & ultrafiltration rate. Survivors vs non-survivors of CPR were compared with t-test, Chi-square test or Fisher’s exact statistic and risk ratio (RR) for significance of associated factors were analyzed using STATA, v 14.2.

Results: 122 CA occurred among 2,981,759 sessions; rate of 1/24441. 71 survived CA were reviewed for age, gender, HD frequency, adequacy, vascular access, HD facility location, size, nephrologist coverage, b/o DM and IHD, HD session timing, duration of HD session & hospitalization in recent past & ultrafiltration rate. Survivors vs non-survivors of CPR were compared with t-test, Chi-square test or Fisher’s exact statistic and risk ratio (RR) for significance of associated factors were analyzed using STATA, v 14.2.

Conclusions: Incidence of CA in India is developed countries experience; larger facilities & smaller cities form a high proportion of events. Age > 80 risk of death. Female, ↓ Hb or adequacy, UFR >10ml/kg/hour, low HD freq in 2 months prior to CA show tendency to higher risk for non survival. Limitation includes lack of analysis of CPR and post CPR hospitalization course

PO0871
Clinical Significance of Plasma Matrix Metalloproteinase-2 and Matrix Metalloproteinase-9 Levels to Assess the Cardiovascular Risk in Hemodialysis Patients
Yu ho Lee,1 So-young Lee,1 Hyeyun Jeong,1 Yang gyun Kim,2 Ju young Moon,1 Sangho Lee,2 Jin sug Kim,1 Kyung Iwan Jeong,1 Shin-Young Ahn,1 Dong-Young Lee,1 Hyeon Seok Hwang,1 1CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; 2Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea; 3Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; 4Korea University, Seongbuk-gu, Seoul, Republic of Korea; 5Seoul Veterans Hospital, Gangdong-gu, Seoul, Republic of Korea.

Background: Matrix metalloproteinases (MMPs) are endopeptidases that control extracellular matrix synthesis and degradation. Two MMP subtypes, MMP-2 and MMP-9, are known to play important roles in the development and progression of cardiovascular (CV) disease, but its clinical relevance as predictors of cardiovascular events is unclear in hemodialysis patients.

Methods: We prospectively enrolled 435 patients undergoing maintenance hemodialysis from K-cohort between June 2016 and April 2019. Plasma MMP-2, MMP-9 levels, and several biomarkers were measured at the time of study data entry. Primary endpoint was defined as a composite of cardiovascular events.

Results: Plasma MMP-2 level were increased in patients with incident CV events than those without CV events, whereas plasma MMP-9 levels were not different between groups. MMP-2 levels were positively correlated with circulating cardiac markers including brain natriuretic peptides (BNP), N-terminal proBNP, and heart-type fatty acid binding protein. The cumulative event rate of the composite of CV events was significantly greater in patients with higher MMP-2 tertile 3 than in those with other MMP-2 tertile 1 (p = 0.015). MMP-2 tertile 3 was associated with a 2.77-fold higher risk of the composite of CV events (95% CI, 1.40–5.45) and 4.67-fold higher risk of cardiac events (95% CI, 2.06–10.56) after multivariable adjustments. However, plasma MMP-9 levels were not positively correlated with circulating cardiac markers, and not associated with risk of incident CV events.

Conclusions: Higher plasma MMP-2 levels, but not MMP-9 levels, had the positive relationship with circulating levels of cardiac pathology markers, and were associated with increased risks of incident CV events and cardiac events among hemodialysis patients.

PO0872
Utility of CHA2DS2-V ASc score to Predict Mid-Term Clinical Outcomes in Hemodialysis Patients
Aiko Okubo,1 Toshiki Doi,1,2 Yoshiko Nishizawa,1 Kenichiro Shigemoto,1 Sonoo Mizui,1 Takao Masaki,1 Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; 2Ichiyokai Yokogawa Clinic, Hiroshima, Japan.

Background: The CHA2DS2-V ASc score has been widely used as a predictive score for stroke in patients with atrial fibrillation (AF). Recently, it was reported that the CHA2DS2-V ASc score is useful for predicting cardiovascular disease (CVD) or all-cause mortality in patients with or without AF. However, few reports have examined the association between this score and mortality in hemodialysis patients.

Methods: We analyzed 525 consecutive patients who started hemodialysis at our facilities from March 2006 to October 2017. CHA2DS2-V ASc score was calculated at time of initiation of hemodialysis. Multivariate Cox proportional hazards analysis was used to assess independent risk factors for 3-year all-cause mortality.

Results: During the 3-year follow-up period, 153 (29.1%) patients died (cardiovascular death, n=88). According to multivariate analysis, serum albumin [hazard ratio (HR) 0.62, 95% confidence interval (CI) 0.43–0.89, P=0.01], creatinine (HR 0.81, 95% CI 0.71–0.99, P=0.04), and CHA2DS2-V ASc score (HR 1.31, 95% CI 1.21–1.46, P<0.001) were associated with 3-year all-cause mortality. Patients with CHA2DS2-V ASc score ≥4 had higher risk of all-cause and CVD mortality than those with CHA2DS2-V ASc score <4 (all-cause mortality: HR 2.20, 95% CI 1.42–3.71, P=0.015; CVD mortality: HR 2.83, 95% CI 1.37–5.44, P<0.001).

Conclusions: The CHA2DS2-V ASc score is a useful predictor of 3-year all-cause and CVD mortality in incident hemodialysis patients.
NT-ProBNP for Heart Function and Volume Status in Hemodialysis Patients
Kyung Ho Lee, Young seung Oh, Byung chul Yu, Moo Yong Park, Jin kook Kim, Seung D. Hwang, Soo Jeong Choi. Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: N-terminal pro brain natriuretic peptide (NT-proBNP) is a biomarker that predicts heart failure and evaluates volume status in Hemodialysis (HD) patients. However, it is difficult to determine the cutoff value of NT-proBNP in HD patients. In this study, we analyzed whether NT-proBNP helps with predicting heart function and volume status in HD patients.

Methods: Retrospective study was conducted on 96 end-stage renal disease patients with HD. All patients underwent echocardiography and Bioelectrical Impedance Analysis (BIA) after a post HD session. Overhydration (OH) was measured by BIA. Laboratory data were obtained on preHD during the mid-week HD sessions. Serum NT-proBNP was measured after HD.

Results: There was an inverse correlation between NT-proBNP and ejection fraction (EF) (β = -0.34, P = 0.001). Overhydration (OH) (β = 0.33, P = 0.001) and presence of diastolic dysfunction (β = 0.226, P = 0.027) had positive correlations with NT-proBNP. In the subgroup analysis with diastolic dysfunction grade, NT-proBNP increased as the dysfunction grade increased. diastolic dysfunction grade 0: 4177(2637-10391), grade 1: 9736 (5471-21110), grade 2, 3: 24627(16975-44988) Elevation of NT-proBNP above 4058 pg/ml was associated with the presence of diastolic dysfunction (p = 0.001) and Left ventricular hypertrophy (LVH) (p < 0.004). Elevation of NT-proBNP above 1157 pg/ml was associated with the presence of diastolic dysfunction (P < 0.004), LVH (p = 0.001) as well as EF<55% (p = 0.07). The group with lowered dry weight followed up NT-proBNP one month later, compared to the group with no change in dry weight, NT-proBNP showed a tendency to decrease, and the group with no change in dry weight showed a relatively low level of NT-proBNP variability. (-210 (-12899 - 3142) x 330 (10900 - 3858); interquartile range, p = 0.104)

Conclusions: We confirmed that NT-proBNP is associated with volume status as well as heart functions such as diastolic dysfunction, LVH and EF in HD patients.

Heart function according to NT-proBNP level

PO0875
Dysregulation of Fatty Acid Binding Protein and Their Relationship with Inflammatory Biomarkers in ESRD
Emily Bontekoe, Vinod K. Bansal, Fakika Siddiqui, Omer M. Iqbal, Jawed Fareed. Loyola University Health System, Maywood, IL.

Background: End stage renal disease (ESRD) patients are at high risk of cardiovascular disorders and hemostatic complications. Fatty acid binding proteins (FABPs) regulate the transport of fatty acids and other lipophilic mediators such as eicosanoids and retinoids by both intracellular and extracellular mechanisms. While upregulation of FABPs have been reported in ESRD, their relationship with inflammatory biomarkers is not fully understood. Liver fatty acid binding protein (L-FABP) also known as FABP-1 is a 14kDa protein expressed in the liver. This protein is also expressed in tubular kidney cells. Kidney damage and other pathologic conditions result in the marked upregulation of this protein.

Methods: Citrated blood samples from 95 ESRD patients undergoing maintenance hemodialysis were collected prior to hemodialysis. For comparison purposes normal human plasma collected from 50 normal healthy male and female individuals were used. Plasma prepared from these patients and normal individuals was analyzed for FABP-1 and such inflammatory biomarkers as IL-6, TNFa and inflammasomes as using commercially available ELISA methods. All results were compiled and correlation analysis between FABP-1 levels and biomarkers of inflammation was carried out using GraphPad prism software.

Results: The ESRD patients showed a marked increase in FABP levels (106 ng/ml ± 18ng/ml SEM) with a broad range (8 – 974 ng/ml) in comparison to normal (5.1 ± 0.2ng/ml SEM) with a range of (3.4 – 9.2 ng/ml). Marked increases in IL-6, TNFa and inflammation were also noted (2 – 4 fold). FABP-1 showed varying degrees of positive correlation with inflammatory biomarkers.

Conclusions: These studies suggest that plasma levels of FABP-1 is markedly increased (up to 10 fold) in ESRD patients undergoing maintenance hemodialysis. Other biomarkers of inflammation are also upregulated and demonstrate varying degrees of correlation suggesting inter-relationship between FABP-1 and inflammatory processes. These results also suggest that impaired renal function and tubular damage contribute to the marked increase of L-FABP in ESRD patients. Simultaneous measurement of L-FABP with biomarkers of inflammatory responses and kidney damage may be helpful in the risk stratification and prediction of the adverse outcome in ESRD patients.

Funding: Private Foundation Support
Transcapillary Refilling Rate Profile in Hemodialfiltration
Juan P. Rivas de Noriega, Gerardo Medina, Salvador L. Gil. Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Reaching dry weight in end-stage kidney disease (ESKD) patients is subject to high ultrafiltration rates (UFR) during their hemodialfiltration (HDF) sessions. We seek to profile the transcapillary refill kinetics rate (TRR) during HDF, which we infer to be an important protective factor against intradialytic hypotension (IH).

Methods: We studied 30 patients in HDF scheduled 3 times a week. Absolute blood volume was measured with the dilutional method and plasma volume was calculated based on the patient’s hematocrit. Each session was divided in 18 intervals of 10 minutes each. Overall UFR and UFR at each one were measured to calculate the expected plasma volume. Real plasma volume at the end of each interval was calculated on the basis of the relative blood volume. The difference between the real and the expected plasma volume was the plasma refill volume, which divided by the time of each interval gave us the TRR. The HDF session prescription was determined by the nephrologist in charge of the HDF clinic.

Results: 84 HDF sessions were recorded. Mean age was 44 years (40 to 48), 66% were female. TRR:UFR ratio difference between patients with and without IH was statistically significant (p < 0.001, CI 95%), as well as the UFR-TRR delta (p < 0.001, CI 95%). This ratio achieved stability after 30 minutes. Eight patients (27%) presented an IH episode during HDF, in a total of 9 sessions (10.75%); 8 (89%) occurred in the final hour and 1 (11%) occurred in the first 10 minutes and corresponded to a patient who presented fever and bacteremia.

Conclusions: Both the TRR:UFR ratio and UFR-TRR delta were statistically significant for predicting IH. Understanding each patient’s TRR will help us plan interventions in order to try and optimize it and reduce the risk of IH.

Impact of Hydration Status Measurement by Bioimpedance Analysis (BIA) on Haemodialysis Patients
Nasreen Samad,1 Farel Ave,2 Sara Z. Khan,2,3 Jerilyn Lalv.1 Barts Health NHS Trust, London, United Kingdom; American University of Antigua College of Medicine, Saint John’s, Antigua and Barbuda; New Hyde Park, NY.

Background: Volume status in haemodialysis patients is an important prognostic factor. Overhydration is associated with a higher frequency of mortality while diuresis-induced volume depletion is also an independent mortality risk factor. Clinical indices do not always accurately reflect volume status. Bioimpedance analysis (BIA) is used as a simple, noninvasive method which can measure normovolemic status in haemodialysis patients by measurement of height, weight, and body composition. Fluid overload is calculated by subtracting the normovolemic status from the overhydration status.

Methods: All patients at Queens satellite dialysis unit, Romford, United Kingdom, which has a prevalent population of 106 patients had BIA based assessment of fluid status every 3 months from July 2020 to May 2021 and dry weight adjusted accordingly. Outcomes were noted for blood pressure, overhydration, Interdialytic weight gains, intradialytic hypotension, hospitalisation and mortality.

Results: 121 haemodialysis patients were followed with male to female ratio of 55:46, mean age of 62 (25-87) of whom 46 were diabetics. By end of assessment period, 21 patients had died (13 due to COVID related illness). In July 2020, 31 patients had overhydration of 2 litres or more, which reduced to 20 patients, in May 2021. The number of patients who had underhydration of -1 litre or more remained similar with 12 patients in July 2020 compared to 11 in May 2021 in spite of more aggressive approach to reduction in dry weight. The dialysis population had high turnover due to deaths as well and 2 transfers out of the unit. During the time of study 15 patients were admitted to hospital with features of fluid overload.

Conclusions: Bioimpedence analysis (BIA) is a simple, non invasive tool helpful in assessing fluid status in haemodialysis patients. It is easier to convince a patient about their volume status by providing a machine assessed figure rather than clinical parameters. There was significant improvement in overhydration without increasing the number of deaths in patients. The high mortality in prevalent patients during COVID pandemic highlights the need for continued body composition measurements in a larger population once COVID cases subside to come to a significant conclusion about the impact of BIA in improving patient outcomes including effect on residual renal function.

Association of Different Definitions of Intradialytic Hypertension with Long-Term Mortality in Hemodialysis
Anuka T. Singh,1,2 Sushrut S. Waikar,1,4 Finnian R. McCausland,1,2 Brigham and Women’s Hospital, Boston, MA; Harvard Medical School, Boston, MA; Boston Medical Center, Boston, MA; Boston University Renal Section, Boston, MA.

Background: Hypertension is common in patients receiving maintenance hemodialysis (HD). A subset of patients experience increases in systolic blood pressure (SBP) from pre- to post-HD (intradialytic hypertension). This phenomenon is known to be associated with adverse short and long-term outcomes, but there is little consensus on an evidence-based definition.

Methods: In a retrospective cohort of 3,198 HD participants, unadjusted and adjusted Cox proportional hazards models were fit to examine the association of various definitions of intradialytic hypertension (≥30% of baseline sessions with an increase in pre- to post-HD SBP of 1) ≥ ± 10 mmHg [Hyper0]; 2) ± 20 mmHg [Hyper10], or 3) ≥ 20 mmHg increase [Hyper20]) with all-cause mortality. Interaction terms were used to assess for effect modification according to pre-specified demographic (age, sex), HD-related (pre-HD SBP, ultrafiltration rate), and comorbid disease variables (diabetes, heart failure, and peripheral vascular disease [PVD]).

Results: At baseline, mean age was 62 ± 15 years, 57% were male, and 14% were Black. Average change in BP from pre- to post-HD was 13 ± 16 mmHg (median 12 [3 to 22] mmHg). During the baseline period, 47% of individuals met the Hyper0 definition and were at a 29% (HR 1.29; 95%CI 1.05 to 1.62) higher adjusted risk of death, compared with participants with no SBP increase. Hyper10 was present in 21.2% and associated with a 21% higher adjusted risk of death (HR 1.21; 95%CI 0.96 to 1.51). Hyper20 was present in 6.8% and associated with a 5% higher risk of death (HR 1.05; 95%CI 0.76 to 1.46). There was evidence for effect modification by age and PVD (Interaction=0.02 for both), with a higher risk of death in those aged 45-70 years and those without PVD. Funding: NIDDK Support.
had more pericardial effusions (12.5% vs 2.3% p = 0.048) and more GIB (12.5% vs 2.2% p = 0.046) (Table 1). There were no differences in in-hospital mortality, hospital length of stay (LOS), ICU LOS, and sternal wound infections between groups across the different surgeries. 16 PD patients were converted to HD post-surgery, intent to treat analysis was applied for these patients.

**Conclusions:** In patients on maintenance dialysis, patients who underwent CABG, VS, and combined surgery had similar outcomes. PD patients appeared to experience more GIB and pericardial effusions requiring intervention in the CABG group.

**Prevalence and Risk Factors for Development of Cardiac Arrhythmias and Electrocardiographic Abnormalities in Hemodialysis Patients: A Single-Center Experience in Mexico.**

**Andrea San-German Morales, 1 Pedro A. Escamilla Galindo, 2 Armando Castillo Garcia, 3 Paulina Paniagua, 4 Juan M. Ardavin Ituarte, 2 Mario Jimenez Hernandez 1, 2 Universidad de las Americas Puebla, Cholula, Mexico; 3 Medica Santa Carmen, Puebla, Mexico.**

**Background:** Mexico is among the countries with the highest number of patients on kidney replacement therapy (RRT). Despite this, the incidence and prevalence of CKD in Mexico is unknown, due to the lack of a national registry as a result we do not know risk factors associated to this population. Electrocardiographic abnormalities or arrhythmias are among the most frequent cardiovascular pathologies, being the first cause of death during the first month in RRT. That is why the present study aims to identify the prevalence of arrhythmias in a group of Mexican patients on hemodialysis as well as their associated risk factors.

**Methods:** A non-experimental, observational, descriptive, and cross-sectional study was carried out in the period from March to July 2020 with Mexican patients older than 18 years in maintained hemodialysis. The electrocardiograms and blood test analysis were taken on the day of hemodialysis therapy.

**Results:** The mean age of the population was 42.37 years, 57% were male. Arrhythmias were found in 50 patients (41.67%), the prevalence of arrhythmias found was bundle branch block (17.50%), sinus tachycardia (12.50%), sinus bradycardia (7.50%), atrial fibrillation (2.50%), extrasystoles (1.67%). A significant difference in mean ages was found between patients with (47.14) and without arrhythmia (38.97) (P = 0.041). A history of heart disease (OR 7.54 95% CI 1.05-184.7), and the diagnosis of chronic renal failure secondary to diabetic nephropathy (OR 2.5459 95% CI 1.1026-5.8785) were identified as risk factors. The diagnosis of chronic renal failure secondary to arterial hypertension was not related as risk factor (p=0.86). No laboratory study was identified as a risk or protective factor for the development of arrhythmia either the vascular access type.

**Conclusions:** The studied population presented similar characteristics to the described previously, a high prevalence of electrocardiographic abnormalities was identified, laboratory studies were not related to the presence of arrhythmias. History of heart disease and kidney disease secondary to diabetic nephropathy were associated as a risk factors, while the presence of arterial hypertension was not identified as risk factor.

Knowledge and Practice of Incremental Dialysis: A Survey of Canadian Nephrologists

Background: Incremental hemodialysis, a strategy to individualize dialysis prescription at initiation, is being linked to enhanced quality of life and acceptability by patients and decreased health care costs. We aimed to explore knowledge and practice pattern regarding facility-based incremental hemodialysis in Canada.

Methods: A web-based survey of nephrologists, elicited current incremental hemodialysis (HD) prescribing practices, clinical and patient factors used to determine suitability for treatment, and potential barriers to implementation. The survey was circulated over a period of six weeks (September 21, 2020 and October 30, 2020).

Results: The overall response rates 35% (243/691 nephrologists surveyed). Majority (66/111, 59%) of respondents prescribed incremental HD using an individualized approach at the discretion of the nephrologist. Most centers (200/203, 98%) did not report policy or guidance for implementation. Residual urine output was identified as the most important factor for eligibility (112/172, 65%), electrolyte stability (76/172,44%) and existing patient goals of care (69/117, 46%). The majority of nephrologists agreed that dialysis prescriptions are dynamic and should take residual kidney function into consideration; however, 74% of nephrologists did not think there was strong evidence supporting incremental dialysis. Potential barriers identified were patient safety, logistics of scheduling, limited evidence, and acceptance of dose escalation. Despite these barriers, 82% of participants felt that this facility-based incremental dialysis is feasible with their current resources and 78% agreed that with specific exclusion and inclusion criteria, incremental dialysis is a safe option.

Conclusions: Incremental hemodialysis is commonly practiced amongst Canadian nephrologists despite a lack of formal criteria for initiation and treatment escalation. This highlights a need for research to guide policy and practice for incremental hemodialysis in Canada.

PO0884

Thrice vs. Twice Weekly Hemodialysis in a Rural Community Center

Paavan Bonagiri,1 Namrata Singhnia,1 Girish Singhnia,2 Abutaleb A. Ejaz,3 1University of Virginia, Charlottesville, VA; 2University of Utah Health, Salt Lake City, UT; 3Mount Carmel East Hospital, Columbus, OH; 4University of Florida, Gainesville, FL.

Background: Converting stable ESRD patients from thrice to twice weekly HD sessions is a well-accepted strategy in the dialysis community. Present study aimed to determine the feasibility, practicality and impact of this approach at the discretion of the nephrologist. Most centers (200/203, 98%) did not report policy or guidance for implementation. Residual urine output was identified as the most important factor for eligibility (112/172, 65%), electrolyte stability (76/172,44%) and existing patient goals of care (69/117, 46%). The majority of nephrologists agreed that dialysis prescriptions are dynamic and should take residual kidney function into consideration; however, 74% of nephrologists did not think there was strong evidence supporting incremental dialysis. Potential barriers identified were patient safety, logistics of scheduling, limited evidence, and acceptance of dose escalation. Despite these barriers, 82% of participants felt that this facility-based incremental dialysis is feasible with their current resources and 78% agreed that with specific exclusion and inclusion criteria, incremental dialysis is a safe option.

Conclusions: Incremental hemodialysis is commonly practiced amongst Canadian nephrologists despite a lack of formal criteria for initiation and treatment escalation. This highlights a need for research to guide policy and practice for incremental hemodialysis in Canada.

PO0885

Impact of the Ratio of Monocyte to High-Density Lipoprotein Cholesterol on Cardiovascular Outcome in Incident Dialysis Patients

Background: Monocyte count to high-density liprotein ratio (MHR) is a well known risk factor of cardiovascular event-free survival rate between the low MHR group and the high MHR group. The secondary outcome included all-cause mortality, overall CV mortality and possibility of MHR as an independent risk factor for CV complication.

Methods: The medical records of 719 ESKD patients who started maintenance dialysis between January 2006 and July 2017 were reviewed. Patients were divided into low MHR and high MHR groups based on the median MHR value.

Results: Overall CV event was 130 cases, 55 in the low MHR group and 75 in the high MHR group, respectively. The CV event-free survival rate was significantly lower in the high MHR group compared to the low MHR group (47.6% vs. 57.5%, P = 0.017). Of the 577 enrolled patients, there was no statistical difference in all-cause mortality between the two groups during a mean follow-up of 3.2 years (P = 0.371). Overall CV mortality rate was also comparable between the two groups (~0.615). In multivariate Cox regression analysis, high MHR was an independent predictor for CV events (HR 1.463, 95% CI, 1.019 – 2.102, P < 0.039) even after adjustment for age, smoking, diabetes, body mass index, C-reactive protein, and previous CV disease.

Conclusions: In conclusion, high MHR at the time of dialysis initiation in the incident ESKD patients may be a simple and useful method for predicting development of CV complication.

PO0886

Differences in Clinical Characteristics and Outcomes Between Hemodialysis-Dependent and Non-Hemodialysis-Dependent Patients with Gram-Negative Bacteremia

Matthew B. Sinclair,1,2 Joshua T. Thaden,1 Felicia Ruffin,1 Lawrence Park,1 Michael M. Dogher,1 Christina M. Wyatt,1 Vance G. Fowler,1,2 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3Duke University Hospital, Durham, NC; 4Duke Global Health Institute, Durham, NC.

Background: Gram-negative bacteremia (GNB) is a common and potentially lethal infection among hemodialysis (HD)-dependent patients. The determinants of clinical outcomes in HD-dependent patients with GNB are incompletely understood. We compared clinical characteristics and outcomes between HD- and non-HD-dependent patients with GNB in a large cohort of hospitalized patients and subsequently examined associations between specific characteristics and all-cause mortality among HD-dependent patients.

Methods: Hospitalized, non-neutropenic adults with GNB were prospectively enrolled from Jan 1, 2002 to July 1, 2015. Clinical characteristics and outcome data were collected. Differences between HD- and non-HD-dependent patients were estimated using means/standard deviations or counts/percentages with statistical significance evaluated with independent sample T-tests or Pearson’s chi-squared test. Associations between clinical characteristics and outcomes were estimated using logistic regression.

Results: Among 1,827 unique participants, 180 were HD-dependent (9.9%). Compared to non-HD-dependent patients, HD-dependent patients were younger (58.6 vs 61.0 years, p=0.05) and more likely to be Black (55.6% vs 26.4%, p<0.001), to have diabetes (56.1% vs 32.1%, p<0.001), and to die prior to hospital discharge (28.9% vs
19.9%, p=0.01). Among HD-dependent patients, having a higher total APACHE II score (Odds ratio [OR] 1.15, Confidence Interval [CI] 1.08-1.23), non-central venous access, source of infection (OR 8.00, CI 2.71-23.60) or hospital-acquired infection (OR 4.46, CI 2.19-9.09) were associated with in-house mortality, while Black race (OR 0.31, CI 0.16-0.63) was inversely associated with mortality.

**Results:** A total of 24 clinical characteristics and outcomes differed significantly between HD- and non-HD-dependent patients with GNB. Mortality among HD-dependent patients may be partially explained by source of infection, site of acquisition, and severity of illness at time of infection. The association between race and patient outcome requires further study.

PO0887

**Predictors of Hyperkalemia Among Chronic Hemodialysis Patients Transferred to the Emergency Department**

Karlikh T. Tennakone,1,2 David Clark,1,2 Patrick T. Fok,1,3 Judith Goldstein,1,2 Keigan More,1,2 Megi Nallbani,2 Amanda J. Vinson,1,2 Hana Wiener,1,2 Wayel Zanjir,1,2 Dalhousie University, Halifax, NS, Canada; Nova Scotia Health Authority, Halifax, NS, Canada.

**Background:** Chronic hemodialysis (HD) patients often present to the emergency department (ED) with hyperkalemia, which in turn, is associated with morbidity and mortality. In this study we sought to identify pre-hospital predictors of hyperkalemia in patients transported to the ED via ambulance (ambulance-ED).

**Methods:** We analyzed all ambulance-ED transports in a cohort of chronic hemodialysis patients from 2014-2018 (using a province-wide emergency medical services database). The outcome was severe hyperkalemia using the first blood draw after ambulance-ED transport defined as ≥6 mmol/L. Characteristics of interest included vital signs prior to transport, days from last dialysis and prehospital electrocardiograms (ECGs) interpreted by paramedics prior to transport. The association between prehospital factors and hyperkalemia was analyzed using adjusted logistic regression.

**Results:** Of 370 chronic HD patients transferred by ambulance-ED, 16% had severe hyperkalemia (≥6 mmol/L). Compared to non-hyperkalemia patients, hyperkalemic patients were more likely to have pre-dialysis vital signs consistent with hypotension (45% vs 19%, p<0.001), hypoxia (34% vs 21%, p=0.001), and a slower heart rate (37% vs 23%, p=0.001), and more likely to be transferred to the ED during the daytime (70% vs 55%, p=0.01). Patients with severe hyperkalemia had a greater emergency department (ED) length of stay (5.2 hours vs 3.7 hours, p=0.001), and were more likely to be re-transported to ambulance-ED (24% vs 14%, p=0.01) or admitted to hospital (73% vs 61%, p=0.001) compared to non-hyperkalemia patients. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemic patients versus 24% of non-hyperkalemic patients required re-transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

**Conclusions:** A total of 24 clinical characteristics and outcomes had 94% in univariate logistic regression analysis

**Adjusted predictors of severe hyperkalemia after transport to the emergency department (n=609)*

| Age at ED (each year) | 0.07 | 0.095-0.009 | 0.009 |

**Efficacy of Patiromer and Sodium Polystyrene Sulfonate on Potassium Levels in Chronic Hemodialysis Patients**

David A. Jaques,1 Fabien Stucker,2 Thomas Emanande,2 Cyrielle Alves,1 Pierre-Yves More,1 Patrick Saudan,1 Hopitaux Universitaires Geneve, Geneve, Switzerland; Réseau hospitalier neuchatelois, Neuchatel, Switzerland; 1Hôpital de La Tour, Meyrin, Switzerland.

**Background:** While hyperkalemia is frequent in haemodialysis (HD) patients and is associated with increased mortality, evidences regarding treatment options are limited. We compared the effect of sodium polystyrene sulfonate (SPS) and patiromer on potassium control in this population.

**Methods:** We screened 180 prevalent chronic HD patients, and included 52 patients with pre-HD potassium >5.1 mmol/L without potassium binder in a cross-over trial comparing on non-dialysis days SPS 15 g before each meal to patiromer 16.8 g once a day. Treatment duration was four weeks with a 2-week intermediate wash-out period. Treatment attribution order was randomized. Pre-HD potassium level was measured at each dialysis session and tolerability assessed on a semi-quantitative scale from 0 to 10. Results: 45 patients terminated the study without missing values on considered variables. Mean age was 66.3 +/- 19.2 with 74 % male and 44% diabetic patients. Mean pre-dialysis potassium were 4.5 +/- 0.7 mmol/L and 5.0 +/- 0.5 mmol/L under SPS and patiromer respectively. In mixed linear regression, treatment with SPS was associated with a decrease of 0.47 mmol/L in mean weekly pre-HD potassium compared to patiromer (p=0.001). Tolerability score was 6.0 +/- 2.4 and 7.0 +/- 1.8 under SPS and patiromer respectively (p=0.001). Conclusion: In chronic HD patients, SPS 15 g before each meal on non-dialysis days resulted in lower pre-dialysis potassium values as compared to patiromer 16.8 g once a day, although tolerability was poorer. Those findings as well as dose titration need to be tested in larger randomized trials.

PO0890

**Associations of Serum and Dialysate Potassium Concentrations with Incident Atrial Fibrillation in Older US Persons Initiating Hemodialysis for Kidney Failure**

Austin Hu,1 Sai Liu,1 Maria E. Montez-Rath,1 Pascale Hairallahl,2 Jingbo Niu,2 Tara I. Chang,1 Wolfgang C. Winkelmaeyer.1 Stanford University School of Medicine, Stanford, CA; Baylor College of Medicine, Houston, TX.

**Background:** Atrial fibrillation (AF) is the most common arrhythmia and affects more than a third of U.S. patients with kidney failure on hemodialysis (HD). Hyperkalemia is a common concern in the HD population and been associated with higher mortality, especially sudden death. However, little is known about the associations of serum potassium (S-K) and dialysate potassium (D-K) concentrations with incident AF in persons on HD.

**Methods:** We used health records data of a large dialysis provider merged with the US Renal Data System (2006-11). We identified persons ages 67+ years initiating HD who had ≥2 years of prior Medicare coverage and not been diagnosed with AF by day 120 after start of HD. Subsequent 30 day periods were created during which S-K measurements were averaged; the most recent D-K in the preceding 30 day window was also recorded. Demographic, comorbidity, and health utilization variables were defined as other laboratory/biometric characteristics. The outcome, newly-diagnosed AF during the subsequent 30 days, was recorded from claims. This process was repeated after frame-shifting all measurements by 30 day increments. Cox regression was used to estimate hazard ratios.
Results: We studied 15,190 persons on HD without prior AF diagnosis; average age was 76 yrs, 49% were male; 69% were white, 26% black, and 8% Hispanic. At baseline, 7137 persons had a S-K+ ≥4.5 and 6988 ≤4.5 mEq/L. With the exception of race and ethnicity, all other characteristics, including D-K+, which was 2 mEq/L in 52% and 3 mEq/L in 34%, were balanced between groups. During a mean follow-up of 327 days the overall incidence of AF was 13/100 person-years. S-K+ and D-K+ were positively correlated, but not with higher S-K+ concentrations unless extreme values >6.5 mEq/L were reached. D-K+ of 3 mEq/L vs. 2 mEq/L, was associated with 14% (95% CI: 5-24%) lower adjusted rates of AF. No interaction between S-K+ and D-K+ was observed.

Conclusions: Hypokalemia was strongly and independently associated with incident AF whereas hyperkalemia was not. However, choice of D-K+ of 2 mEq/L vs. 3 mEq/L did not associate with higher AF rates, independent of S-K+ and other measured characteristics.

Serum Potassium Changes in US Veterans Receiving Patiromer with Dialysis-Dependent ESKD and Hyperkalemia
Christopher Csaba1, Elvira O. Gosmanova,2 Steven D. Woods,3 Christopher G. Rowan,4 Jared Hansen,5 Brian C. Sauer. The University of Tennessee Health Science Center, Memphis, TN; 1Albert Medical College, Albany, NY; 2Vifor Pharma, Inc., Redwood City, CA; 3COHRDATA, San Clemente, CA; 4Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT.

Background: Patiromer is a sodium-free, non-absorbed, potassium (K+) binding polymer approved for the treatment of hyperkalemia (HK). This retrospective cohort study aimed to describe serum K+ changes in Veterans with HK and end-stage kidney disease (ESKD) receiving dialysis who initiated patiromer.

Methods: Serum K+ concentrations were evaluated pre- and post-patiromer initiation using the National VA Corporate Data Warehouse (1/1–6/31/18). Changes in mean serum K+ concentration were compared at 1, 3, and 6 months following first patiromer dispensing (index date) using the paired t-test (pre K+ versus post K+). All patients had a baseline K+ ≥5.1 mEq/L and ESKD. Patients with continuous exposure to patiromer were analyzed. Follow-up began on the index date and ended at first censoring event (discontinuation or switch of index K+ binder, death, end of follow-up, or 6 months post-index).

Results: 98 patients with ESKD requiring dialysis and HK initiated patiromer. Patient characteristics at baseline were median age 66 years, African-American race 39%, diabetes 71%, heart failure 40%, and mean K+ value of 6.1 mEq/L (standard deviation = 0.7). The initial dose of patiromer was 8.4 g in 96% of patients with few observed increases in unit dose during the follow-up period. Following patiromer initiation, statistically significant reductions in serum K+ concentration were observed at 1 month (~1.24 mEq/L), 3 months (~1.15 mEq/L), and 6 months (~1.36 mEq/L, Figure). No significant change was observed from baseline to 12 months of patiromer use. Patients with HK, as squarer, was associated with clinically relevant reductions in serum K+ concentrations at all study time points. These findings warrant additional investigation in a larger dialysis cohort with HK.

PO0892
Hyperkalemia: Medical Management vs. Hemodialysis
Joseph A. Gotesman, Mario V. DeVita. Lenox Hill Hospital, New York, NY.

Background: Hyperkalemia is a life-threatening electrolyte disorder for which there exists a paucity of data regarding benefit of urgent hemodialysis over medical management. We hypothesized there would be no difference in potassium levels among hyperkalemic patients who received only medical management compared to those who received hemodialysis, with or without hemodialysis.

PO0893
Metabolic Alkalosis in Hemodialysis Patients
Sitarama Arvind Mudunuru, Jose E. Navarrete, W. Charles O'Neill. Emory University School of Medicine, Atlanta, GA.

Background: Hemodialysis (HD) typically employs a high dialysate alkali concentration to counteract interdialytic acid production. Since acid production varies due to the amount and type of protein consumed, some patients may remain alkalotic throughout the interdialytic period and be more alkalotic during HD. This could have adverse effects including arrhythmias, hypotension, hyperventilation, and vascular calculation but dialysate alkali is rarely adjusted. Pre-HD alkalosis is usually ascribed to chronic illness and poor nutrition, but this has not been carefully examined.

Methods: We conducted a retrospective case-control study of all in-center HD patients from 2010 - 2020 at 4 outpatient HD units using citrate-containing dialysate (34.6 meq/L HCO₃, 0.4 meq/L acetate, 2.4 meq/L citrate; citrasate, Fresenius). Interaldialytic alkalosis was defined as pre-HD serum [HCO₃] ≥26 in ≥ 7 months of any 12-month period. Patients with persistent alkalosis defined as interdialytic alkalosis in every subsequent 12-month period. Patients with serum [HCO₃] 19-23 in ≥ 7 months of every 12-month period constituted the control cohort.

Results: Of 1271 patients with at least 12 months of HD, 444 met the alkalosis criteria for at least one 12-month period and 73 had persistent alkalosis. 189 patients met the control criteria for every 12-month period. Patients with persistent alkalosis were older (66 vs 55 years, p<0.001) and weighed less (69 vs 82 kg, p=0.003), but the prevalence of comorbidities including cardiovascular disease, neoplasia, and diabetes was not increased. HD dose (kT/V) was greater (1.47 vs 1.37, p<0.001), protein catabolic rate was lower (0.85 vs 0.96 g/kg/day, p<0.001), and interdialytic weight gain was less (1.62 vs 2.28 kg, p<0.001). Despite significant weight loss over time (7 ± 13 vs 0 ± 9 kg, p<0.001), mortality was not increased when adjusted for age, serum albumin was only slightly lower (3.71 vs 3.80 g/dl, p=0.05), and cause of primary morbidity/chronic illness such as serum cholesterol and hemoglobin did not differ from control patients.

Conclusions: Persistent interdialytic alkalosis was common in this HD population and persistent alkalosis was not rare (~5%). Alkalosis appeared to result from a greater dialysis dose and lower protein intake but not chronic illness. Further studies are needed to determine whether this alkalosis is detrimental and adjustment of dialysate [HCO₃] is indicated.

PO0894
Metabolic Alkalosis in Hemodialysis Patients: Worse Outcomes

Background: The ideal serum bicarbonate levels in prevalent hemodialysis (HD) patients is still debatable. Metabolic alkalosis in these patients has been associated with increased morbimortality. The aim of this study was to evaluate the association between serum bicarbonate and nutritional and cardiovascular risk markers, hospitalizations and mortality.

Methods: This was a single-center, retrospective study, of a cohort of 158 in-center HD patients, with a duration of 24 months. Serum bicarbonate levels were evaluated predialysis every 3 months. Body Composition Monitor was used to assess nutritional and biomarkers. Electrocardiogram and echocardiography data were obtained to calculate the QTc interval and the left ventricular mass index, respectively. Vascular calcifications were assessed using the Adragao score (SVCS).

Results: Mean age of the population was 69±12.6, 73% were male and 45% had diabetes. Mean HD vintage was 69 months (IQR: 65 months). Mean body mass was 23.5±1.57 mEq/L. There was no inverse association between serum bicarbonate and body mass index (r=-0.22, p=0.006), lean tissue index (r=-0.35, p<0.001), hemoglobin (r=-0.19, p=0.016), albumin (r=-0.30, p=0.001), phosphorus (r=-0.33, p<0.001) and nPCR.
Dysfunction. The proinflammatory response in COVID-19 produces dysfunction and understood. Reported cases of PRES have been linked with hypertension, autoimmune Nicardipine drip was weaned, and he was transitioned to oral blood pressure medications. Patient was found to be positive for COVID-19 and did not receive treatment for it as his to 166/105 mmHg. His vision restored fully without further episodes of vision loss. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure of all-cause mortality (p<0.004) in a model adjusted for age, dialysis vintage and the presence of diabetes.

Conclusions: In this population, higher serum bicarbonate was associated with a worse nutritional status and a higher cardiovascular risk, assessed by Adragão score. There was an association with an increased number of infection-related hospitalizations and mortality, as well as higher all-cause mortality. Serum bicarbonate levels ≥24.5 mEq/L were associated with lower survival at 24 months. Prospective studies are needed to determine the ideal serum bicarbonate levels in HD patients.

PO0895
The Use of Caffeine to Treat Intradialytic Hypotension
Indrani G. Das,1 Shah E Gul Rahim,2 Sri Lekha Tummalapally.3 Weill Cornell Medicine, New York, NY; New York-Presbyterian Healthcare System Inc, New York, NY.

Introduction: Intradialytic hypotension (IDH) affects over 10% of individuals on hemodialysis (HD) and can cause long-term multisystemic ischemic damage. One proposed mechanism for IDH is the accumulation of local adenosine causing vasodilation. Agents such as midodrine and caffeine counter these vasodilatory effects. Herein we present a case of IDH where the ingestion of caffeine prior to HD sessions significantly reduced the severity of IDH.

Case Description: A 77-year-old female with CKD-5, longstanding hypertension, and type 2 diabetes mellitus was admitted for initiation of HD. During her 1st HD session, she experienced IDH with a sudden drop in her systolic blood pressure (SBP) from the 193 to 113, accompanied by loss of consciousness and convulsions of the bilateral upper extremities. She recovered consciousness without a postictal state and no significant changes on ECG. Echocardiography ruled out pericardial effusion. On subsequent HD sessions, the patient continued to experience IDH with average decreases of over 100mmHg in her SBP. Initial management by lowering blood flow rate, lowering dialysate temperature, and holding the patient’s pre-dialysis antihypertensive regimen had only a mild effect in preventing IDH. Given previous studies showing the efficacy of 250 mg caffeine capsules in preventing IDH, we tested the effect of caffeine on this patient’s IDH. 30 minutes prior to her next inpatient HD session, we administered 10 oz of coffee (150 mg of caffeine). Her drop in SBP during that session was markedly reduced from 187 to 149.

Discussion: Non-pharmacological measures to prevent IDH have been previously implemented but lack well-powered clinical trial evidence. Using coffee as a vehicle for caffeine administration was an effective preventive measure for IDH in our patient. We hypothesize that this effect is adenosine inhibition mediated. Adenosine is released by cells undergoing localized ischemia during HD, causing vasodilation. Studies show an increase of serum adenosine during IDH. Caffeine is a non-selective adenosine receptor antagonist, and can prevent sudden vasodilatation during dialysis. Thus, coffee may be an effective alternative to midodrine for the prevention of IDH. In conclusion, coffee provided a readily available, inexpensive, patient-centered, non-pharmacological measure to reduce IDH while also decreasing the risk of polypharmacy.

PO0896
A Case of Posterior Reversible Encephalopathy Syndrome (PRES) in an ESKD Patient with COVID-19
Viktor J. Martinez,1 Daranee Chewaprung. Albert Einstein Medical Center, Philadelphia, PA.

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a clinicoradiological syndrome first reported in 1996 which describes the presence of a wide range of neurological symptoms, and posterior brain white matter edema on imaging studies which may be reversible. The clinical presentation is characterized by headaches, altered consciousness, visual disturbances and seizures; hypertension is frequent, although not invariable.

Case Description: A 37-year-old male with past medical history of hypertension and unknown etiology hypertension, being on hemodialysis with shortness of breath, occipital headache, altered consciousness, visual disturbances and seizures; hypertension is frequent, although not invariable. On admission, he was afibrile with a blood pressure of 274/147 mmHg, RR of 16, HR 98 bpm and oxygen saturation of 89% on room air. Due to acute vision loss, a stroke alert was initiated. A head CT scan showed subcortical hypodensities in the bilateral occipital lobes consistent with PRES. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure to 166/105 mmHg. His vision restored fully without further episodes of vision loss. Patient was found to be positive for COVID-19 and did not receive treatment for it as his shortness of breath and hypertension was resolved. The patient received maintenance dialysis using Nicardipine drip was weaned, and he was transitioned to oral blood pressure medications.

Discussion: The relationship between kidney disease and PRES is not fully understood. Reported cases of PRES have been linked with hypertension, autoimmune disorders, and immunosuppressive states, common conditions in ESKD. The pathophysiology of PRES appears to be related to cerebral blood flow dysregulation and endothelial cell dysfunction. The proinflammatory response in COVID-19 produces dysfunction and death of endothelial cells which may increase vascular permeability, promoting the cerebral edema seen in PRES. The estimated prevalence of PRES in COVID-19 patients is between 1-4%. Reports of PRES in ESKD are rare. PRES may not be readily recognized given the heterogeneity of presentation. Therefore, high index of suspicion is needed in the ESKD population.

PO0897
Eye Pain During Hemodialysis: Ocular Dialysis Disequilibrium? Sarah Abbass Massali,1 Monika Aggarwal (Gupta).3 Virginia Commonwealth University Health System, VA; 4 Victoria Richmond Medical Center, Richmond, VA.

Introduction: Changes in Intraocular pressure (IOP) during hemodialysis (HD) are underrecognized. We report a case of increased IOP during HD, successfully treated with adjustments to dialysis prescription.

Case Description: 39-year-old African American man with End Stage Renal Disease (ESRD) secondary to diabetic nephropathy on HD since 2017, presented with exorucing right eye pain during HD for 2 weeks. He described increasing right eye pain during HD, requiring early termination of dialysis after 3 hours. He has known right eye glaucoma with no vision. He was on atropine sulfate, prednisolone acetate, latanoprost, dorzolamide/timolol, and brimonidine tartrate eye drops. IOP in right eye was 63 and 80 mm of Hg, before and after hemodialysis, respectively. Left eye IOP were < 20 mm of HG and did not change significantly with dialysis. Due to concerns for ocular dialysis disequilibrium; blood flow rate, dialysate flow rate, dialysate temperature, and dialysate sodium were changed to 400 ml/minute from 450 ml/minute, 500 ml/minute from 800 ml/minute, 35.6°C from 37°C, and 145 mEq/L from 140 mEq/L, respectively. Subsequently to changes to dialysis prescription, patient was able to complete dialysis with no worsening of right eye pain and IOP (62 and 64 mm of Hg before and after dialysis, respectively).

Discussion: Increase in IOP during HD is thought be due to rapid decline in plasma osmolality relative to aqueous humor, creating an osmotic gradient that causes movement of water into the eye. Patients with normal eye outflow have minimal rise in IOP as aqueous humor is drained simultaneously. However, patients with glaucoma are not able to drain excess water, causing increase in IOP and eye pain. Older age, diabetes mellitus, and African-American race are risk factors for ESRD and Glaucoma. Early recognition of ocular dialysis syndrome can allow for safe delivery of dialysis in patients with glaucoma. While acetazolamide is an effective treatment for raised IOP, it’s efficacy and safety in ESRD remains unknown. Similarly role of Mannitol in mitigation of ocular dialysis disequilibrium is unclear. Our patient had resolution of ocular dialysis disequilibrium with decrease in blood and dialysate flow rates, increase in dialysate sodium, and decrease in dialysate temperature. Increase in ultrafiltration may also reduce risk of ocular dialysis disequilibrium by raising extracellular oncotic pressure.

PO0898
The Association of Interdialytic Weight Gain in Long Intervals with Residual Renal Function Decline
Yoshikazu Miyasato,1,2 Tsuyoshi Miyagi,1 Yoko Narasaki,1 Hiroshi Kimura,1 Kamyar Kalantar-Zadeh,1 Elani Sirieja.3 University of California Irvine, Irvine, CA; 1Kumamoto Daigaku, Kumamoto, Japan.

Background: Preservation of residual renal function (RRF) in dialysis patients is important for better prognosis. The effect of interdialytic weight gain (IDWGL) on change of RRF has not been investigated well. We examined the association of IDWGL in long intervals (i.e. 2-day breaks between dialysis treatments) with rapid decline of RRF.

Methods: This retrospective cohort study included 6425 patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWGL in long intervals (IDWGL) and rapid decline of RRF using logistic regression model. Rapid decline of RRF was defined as the percent decline in renal urea clearance (KRU) greater than the median value of the cohort in the first year after dialysis initiation. Seven categories of IDWGL were as follows: 0<1%, 1~2%, 2~3%, 3~4%, 4~5%, 5~6%, ≥6%. We also examined continuous associations between IDWGL and rapid decline of RRF using restricted cubic spline analysis.

Results: Higher categories of IDWGL were associated with increased risk of rapid decline of RRF. The odds ratios (95% confidence intervals) of rapid decline of RRF for 3~4%, 4~5%, 5~6%, and ≥6% were 1.04 (0.90-1.20), 1.31 (1.09-1.56), 1.19 (0.94-1.51), and 1.30 (1.14-1.97) (Reference: 2~3%) (Figure a). The restricted cubic spline analysis showed that risk of rapid decline of RRF increased when IDWGL exceeded 2% (Figure b).

Conclusions: Our results showed higher IDWGL was associated with higher risk of rapid decline of RRF. IDWGL exceeded 2%, especially ≥4%, seems to be thresholds for higher risk of RRF decline.
Prevalence of Anti-Erythropoietin Antibodies in Patients with ESRD on Regular Hemodialysis: A Single-Centre Experience
Kevin T John Keeppallil, Manikantan Shekar, Ramprasad Elumalai. Sri Ramachandra Institute of Higher Education and Research, Chennai, India.

Background: Recombinant human erythropoietin (rHuEPO) is a glycoprotein that acts as a biological substitute for the endogenous substance used to treat anaemia in individuals with end-stage renal failure. Patients with rHuEPO resistance have been described, requiring higher and higher dosages of the drug to maintain an appropriate haemoglobin level. These antibodies probably cross react with the patient’s endogenous EPO and lead to anaemia that can be more severe than even before the onset of EPO therapy. The prevalence of anti-erythropoietin antibodies in renal patients who respond poorly to erythropoietin is unknown.

Methods: We screened 262 patients who were on maintenance haemodialysis and excluded patients who were malnourished and had chronic liver disease, hypothyroidism, ongoing active autoimmune disease, active infection, on steroid therapy, with bleeding or hemolysis and elderly. 96 ISRD patients who were on recombinant human erythropoietin > 6 months and haemoglobin < 10 g/dL were included. Serum anti-EPO antibodies were detected by enzyme-linked immunosorbant assay technique. All patients were subjected to full history taking and clinical examination. Complete blood count, reticulocyte count, serum creatinine, blood urea, serum albumin, serum ferritin, and haematocrit markers were performed for all patients.

Results: Results showed that 26 patients (27.08%) had the anti-EPO antibodies in their blood, while 70 patients (72.91%) did not have the circulating antibodies. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.4 g/dL ± 1.52) than in the antibody negative group (9.68 g/dL ± 1.14) (P = 0.000). The dose of EPO administered in both studied groups were significantly different. Logistic regression analysis also revealed that gender or age were not associated with any significant variation of serum antibody level. High levels of serum antibodies to EPO are a risk factor for EPO resistance.

Conclusions: Many anaemic ISRD patients treated with recombinant human erythropoietin have a low-affinity immune response to the recombinant protein that is readily detected. Antibodies to rHuEPO were shown to be greater in patients who received high EPO weekly dose. More research into anaemia management protocols in ISRD patients with positive anti-EPO antibodies is needed.

Ocular Dys-equilibrium with Eye Pain During Hemodialysis

Introduction: Eye complications may occur in ESRD patients with glaucoma. Hemodialysis (HD) may lower plasma osmolality at a faster rate than changes in ocular osmolality can adapt. Here we are presenting two cases of ESRD patients who repeatedly develop eye pain only during HD.

Case Description: A 54 y/o Hispanic male with ESRD, right eye blindness & glaucoma who developed right eye pain only during dialysis treatments. The maintenance HD prescription was with duration of 4.5 hr, blood flow rate (BFR) 450mL/min, dialysate flow 800 mL/min, Sodium (Na) 138 mmol/L, Calcium 2.7 mmol/L, Potassium 4.3 mmol/L, Calcium 107 mEq/L, CO2 30mmHg, & an average 2L fluid removal per HD. His BP was 130/140mmHg 80-90 mmHg. In response to the eye symptoms, the BFR was reduced to 350 mL/min & time was increased to 4.5 hr. This change gave the patient initial relief from intradialytic eye pain. Ophthalmologist was able to perform a surgical procedure which would eliminate the intradialytic eye pain. The 2nd case was a 64 y/o AA female with ESRD and glaucoma who developed recurrent left eye pain with headaches only during HD. She went to her Ophthalmologist who renewed her glaucoma medications. This relieved her eye symptoms, and normalized her intradialytic pressure off of dialysis. By taking her eye medications, she no longer developed eye pain or headaches during HD.

Discussion: Glaucoma is an ocular disorder where there is an increased IOP most commonly >22mmHg, this elevated pressure can cause blinding optic neuropathy. The current hypothesis for the rise of IOP during HD is related to an osmotic disequilibrium between the plasma & IO fluid, where the IO fluid is slightly hypertonic compared to plasma. Several medical therapies have been reported to mitigate the IOP increase during HD, such as the use of daily acetazolamide, mannitol infusion or 20% hyperosmolar glucose solution, or modified dialysis parameters with colloid infusion to raise plasma tonicity and decrease fluid shift during HD. However, these maneuvers have not been proven to relieve ocular symptoms. In general, use of higher dialysate Na conc. at hemodialysis are not considered a long term solution to intradialytic ocular hypertension, due to the tendency for increased fluid intake between HDs. Lower BFR with longer duration of hemodialysis treatments has been beneficial in some cases.

Caffeine Overdose Requiring Extracorporeal Mechanical Oxygenation
Lundeen, Connie. WVU Nephrology, Morgantown, WV.

Introduction: Acute on chronic angle-closure glaucoma with elevated intraocular pressure was well-established etiology of severe eye pain and profound vision loss, if not treated urgently. This case is a recurrent and episodic eye pain with transient visual loss during HD.

Case Description: 64 year-old Caucasian female with comorbidities including poorly controlled insulin dependent type 2 diabetes, uncontrolled hypertension, obesity. She is on intermittent hemodialysis three times weekly the last 5 years. She was previously followed by a retina specialist for proliferative diabetic retinopathy with subsequent neovascular glaucoma. Initial onset approximately 1 year prior, with episodic eye pain, decreased visual acuity, and increased intraocular pressure. The right eye had well-documented hypotony and decreased visual field post dialysis. She had a refractive surgical procedure performed for phacoemulsification with IOL implantation. Her visual acuity improved in the right eye. However, she subsequently developed eye tenderness only during HD. Hemodialysis (HD) may lower plasma osmolality at a faster rate than changes in ocular osmolality can adapt. Here we are presenting two cases of ESRD patients who repeatedly develop eye pain only during HD.

Discussion: The effect of hemodialysis (HD) on intraocular pressure (IOP) is variable and the exact mechanisms are still not clear. Previous reports in the literature suggest both increased and decreased intraocular pressure during fluid shifts associated with hemodialysis. Argon Laser Photocoagulation is known to reduce angle neovascularization induced by peripheral retinal ischemia in Neovascular glaucoma patients, IOP reduction is typically achieved with topical and systemic medications. Shunting and filtering procedures, including glaucoma valve implants and trabeculectomy surgery, may restore outflow and reduce IOP. After appropriate surgical intervention, the patient reported resolution of symptoms and improved tolerance to dialysis sessions.
Case Description: A 33-year-old female weighing 63kg presented after ingestion of approximately 100g of guanua powder (22g of caffeine). She presented with tachycardia (140-170 BPM) and severe hypotension (blood pressure 50/40 mmHg) resistant to 4 vasopressors at maximal dose. She required extracorporeal membrane oxygenation (ECMO). Baseline renal function was normal. IHD was initiated with blood flow rate (BFR) 200ml/min and dialysate flow rate (DFR) 500ml/min, which was gradually increased over 4 hours to a BFR of 400ml/min and DFR of 800ml/min; IHD continued for an additional 4 hours at this rate. During this 8-hour IHD treatment, her initial 4 pressor doses were halved, and she was transitioned to CVVHDF; the caffeine level was pharmacologically unavailable. However, after 12 hours of CVVHDF, the patient did not experience continued hemodynamic improvement, so IHD was reinstituted for 12 hours. Following this second prolonged session of IHD, she was weaned down to moderate doses of just two pressors. She was then transitioned back to CVVHDF for an additional 36 hours, at which time she was able to come off ECMO and all pressors. She had a full neurologic recovery. We later received a serum caffeine level of 425mg/L (drawn soon after arrival at the hospital), which is the second-highest level ever reported; the established lethal concentration is 80ng/mL.

Discussion: Despite continuous dialytic therapies being generally favored in patients with severe hemodynamic instability, a combination of IHD and CVVHDF may be used for hemodynamically unstable patients who ingest extremely high dose of caffeine. However, in such patients, continuous therapies are unlikely to supplant prolonged and repeated IHD treatment sessions.

PO0904
Anaphylaxis Secondary to Citric Acid Allergy in ESKD Patients
Hassan Hitkhah, George Jarad. Washington University in St Louis, St Louis, MO.

Introduction: Dialysis reactions are common in ESKD patients undergoing hemodialysis (HD). We report first case of anaphylaxis related to citric acid solution used for dialysis disinfection & descaling.

Case Description: 61-year-old male with history of ESKD on HD for 7 years, presented after missing dialysis. Patient underwent urgent HD upon presentation and developed signs of angioedema within first 30 minutes, requiring nasal intubation & treatment with epinephrine, steroids & antihistamine. While intubated and hypotensive, patient had uneventful Slow Low Efficiency Dialysis. Angioedema was presumed secondary to anitiemetics, which patient required due to severe nausea shortly after starting HD. Post extubation, patient developed similar reaction with milder symptoms with HD that responded to stopping HD and medical therapy. He had normal complement and mildly elevated tryptase. He was presumed to have a dialyzer reaction therefore, the dialyzer was changed from Revaclear to REXEED & it was tolerated well. He had similar severe reaction a week later while using the REXEED dialyzer. Investigations showed elevated anti-ethylene oxide antibodies (ETO) but clinical significance was questionable given the reaction only developed in inpatient setting. Later we discovered that dialysis machines are disinfected/descaled differently between inpatient & outpatient dialysis, even though both utilize citric acid, which might have led to more exposure to citric acid solution in inpatient setting. For next 2 weeks, patient was dialyzed using different combinations of dialysis machines, dialyzer & dialysis circuits including ones sterilized with ETO, however, all machines were disinfected/descaled using a combination of bleach & heat. After elimination of citric acid, patient had no further anaphylactic reaction.

Discussion: Dialyzer membrane reactions have been commonly described as Type A reactions mediated by dialyzer membrane (IgG mediated) and Type B membrane reactions mediated by complement activation. In our case clinical significance of ETO antibody was not clear, & angioedema was eliminated after removing citric acid from the machine disinfection process. Industrial citric acid mediated angioedema has not been reported before, & it might be an important mediator of allergy in ESRD, & careful review of the dialysis machine preparation should be reviewed in every case of severe allergic reaction.

PO0905
An Unexpected Cause of Colitis
Alon Bnaya, Ofer Benjamoin, Eyal Itzkowitz, Jawad Atrash, Omar Abu Lybdeh, Mhsen Abu Alfeiat, Linda Shavit. Shaare Zedek Medical Center, Jerusalem, Israel.

Introduction: Gastrointestinal manifestations are common among patients with advanced kidney disease. However, uremia associated colitis is rarely described in patients with ESKD. We present a unique case of uremic pancolitis in a patient with ESKD of unknown cause.

Case Description: An 18-year-old male with a history of asthma was admitted with nausea, vomiting and diffuse abdominal pain. He had no fever, arthralgias, rash, respiratory symptoms, or diarrhea. Mild peripheral edema and flapping tremors were noted on physical examination. Laboratory blood tests revealed severe kidney injury (creatinine 18.2 mg/dL, BUN 129 mg/dL). Urinalysis was positive for blood and protein. Immunologic and infectious serologies were unremarkable. An abdominal CT scan detected two small atrophic kidneys and diffuse severe bowel wall thickening of the colon with thumb printing noted (Figure 1), mimicking a pseudomembranous colitis pattern. Abdominal ultrasound revealed severe edema along with high vascularization of the colon wall. Uremia associated colitis was suspected due to the patient’s extreme uremic state and hemodialysis was initiated. Following three weeks of hemodialysis, an abdominal ultrasound showed a significant improvement in edema and vascularization of the colon wall.

Discussion: Patients with advanced CKD often have a variety of gastrointestinal symptoms. However, severe uremic colitis mimicking pseudomembranous pattern is extremely rare in ESKD. Extensive literature review revealed only single case report of uremic pancolitis in a patient with severe kidney injury related to IgA nephropathy. With the improvement of care of patients with kidney disease, uremic colitis is rarely seen in the routine nephrology practice. However, it should be included in the differential diagnosis and evaluation of patient with ESKD, particularly if other more frequent etiologies of colitis have been excluded.

PO0906
Reverse Shoulder Arthroplasty in Dialysis Amyloidosis
Jessica Schilling,1 Srinath Kamineni,2 Dana Richards,2 Marie-Claude M. Faugere,1 Florence Lima,1 B. Peter E. Sawaya,2 Madhumathi Rao,2 1University of Kentucky College of Medicine, Lexington, KY; 2University of Kentucky Medical Center, Lexington, KY.

Introduction: The use of high-flux over cuprophane dialyzers, has led to Beta-2 microglobulin amyloidosis (B2M) becoming rare in long term hemodialysis (HD) patients. Amyloid fibers embed systemically, skeletal involvement producing bone cysts, tendinopathy and fractures.

Case Description: A 65-yr male on chronic HD for 30 years presented with progressive, right (R) shoulder intractable pain and limited range of movement (ROM). X-ray/MRI identified severe glenohumeral osteoarthritis (OA), tendinopathy and large irreparable rotator cuff tear. Past history included heart failure, pulmonary hypertension, hepatitis C, severe secondary hyperparathyroidism and chronic anemia. Surgical history included bilateral (b/l) total hip arthroplasties, b/l carpal tunnel release, R nephrectomy for renal cell carcinoma in renal cystic disease. Due to the intractable pain, disability and failure of physical therapy and corticosteroid injection therapy he underwent reverse shoulder arthroplasty. Operative findings showed large soft tissue deposits about the subscapularis, glenoid and labrum, attributed to amyloid. Histology of intra-articular soft tissue, labrum and synovium confirmed amyloid (apple-green birefringence by Congo Red Staining) with focal calcium pyrophosphate deposition. Undecalcified histology of humeral head showed moderate secondary hyper-parathyroid bone disease with peri-articular amyloid deposits. Following surgery patient noted marked improvement in pain and partial improvement in shoulder ROM.

Discussion: No treatment exists for HD patients with B2M, ineligible for kidney transplant. Physicians are tasked with treating clinical manifestations that severely impact quality of life (QOL). Concern for adverse outcomes and paucity of surgical precedent should not deter appropriate surgical intervention. This patient illustrates the clinical and surgical decision-making targeted to improving (QOL).

Prediction of Severe Gastrointestinal Bleeding Events in Hemodialysis: Collaborative Development of Machine Learning Model Within INSPIRE

Suman K. Lama,1 Sheetal Chaudhuri,1 Joanna Willetts,1 John W. Larkin,1 Anke Winter,2 Manuela Stauss-Grabo,2 Len A. Usuyat,1 Jeffrey L. Hynes,1 Franklin W. Maddux,3 David C. Wheeler,1 Peter Stenvinkel,1 Jürgen Floege,3 On behalf of the INSPIRE Core Group1 Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; 3University College London, London, United Kingdom; 4Karolinska Institutet, Stockholm, Sweden; 5RWTH Aachen University Hospital, Aachen, Germany; 6Fresenius Medical Care AG and Co KGaA, Bad Homburg, Germany.

Background: INSPIRE is an initiative on advancing patients’ outcomes in renal disease (INSPIRE) is an academia and industry collaboration set forth to identify critical investigations/models needed to advance the practice of nephrology. As an inaugural effort, INSPIRE group aims to develop a machine learning (ML) model that can identify a hemodialysis (HD) patient’s 30-day risk for hospitalization due to gastrointestinal (GI) bleeding.

Methods: We used data from adult (age ≥18 years) HD patients (Jan 2017-Dec 2020) in the United States to build a XGBoost model considering 2,292 variables for classification of 30-day GI bleed hospitalization risk. Data were randomly split in 50%:20%:30% ratio for model training, validation, and testing. Unseen data by model classification of 30-day GI bleed hospitalization risk. Data were randomly split in 50%:20%:30% ratio for model training, validation, and testing. Unseen data by model (testing) was used for assessing performance via area under the curve (AUC) and feature importance of predictors via Shapley (SHAP) values.

Results: Among 58,187 HD patients included in the testing dataset, 1,150 had a GI bleed hospitalization event. The model showed AUC=0.67 and top predictors of a GI bleed hospitalization in 30 days were the minimum hemoglobin level in prior 180 days, time since prior GI bleed hospitalization, and higher vitamin D levels (Figure 1).

Conclusions: ML model appears to have suitable performance for identifying a patient’s 30-day risk for GI bleed hospitalization. Albeit further model iterations/tuning are needed, ML techniques that account for collinearity and missingness hold promise for early detection of potentially avoidable GI bleeding admissions. Model identified an important association between higher vitamin D levels and GI bleeding events, which is consistent with the increasing evidence suggesting antithrombotic and anticoagulant actions of vitamin D derivatives.

Artificial Intelligence-Driven System to Automatically Identify Arterial Oxygen Saturation Saw-Tooth Pattern in Hemodialysis

Hanjie Zhang,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Sleep apnea (SA) is a condition where normal respiration is disrupted by episodes of apnea because of disturbed respiratory control (central SA) or upper airway obstruction (obstructive SA). Arterial oxygen saturation (SaO2) saw-tooth pattern indicate respiratory instability. We aimed to automatically identify patients with repetitive episodes of intermittent SaO2 saw-tooth pattern.

Methods: The analysis was based on SaO2 recordings taken at a frequency of 0.1 by the Crit-Line® device (Fresenius Medical Care, Waltham, MA). Segments of 30 consecutive SaO2 recordings (i.e., 5 minutes of SaO2 time series) were adjudicated and categorized as (a) no saw-tooth pattern; (b) mild saw-tooth pattern; and (c) severe saw-tooth pattern (examples shown in Figure 1). We used one-dimensional convolutional neural networks (1D-CNN) for time series classification. We randomly assigned SaO2 time series segments to training (80%) and validation (20%) sets, respectively.

Results: We analyzed 89 hemodialysis (HD) treatments with 4,075 adjudicated SaO2 time series segments. Their distribution across the 3 categories was 78% (a), 11% (b), and 11% (c), respectively. In the validation data set of 815 SaO2 time series segments, we achieved an accuracy of 93.9%, 95.8% of category (a), 91.2% of category (b) and 82.8% of category (c) pattern were classified correctly by our 1D-CNN.

Conclusions: Our 1D-CNN algorithm accurately classifies saw-tooth pattern in SaO2 time series recorded in HD patients. The SaO2 pattern classification could be performed in real time during an ongoing HD treatment and provide timely alert in the event of respiratory instability.

Funding: Commercial Support - Fresenius Medical Care North America

Panel A: Intradialytic SaO2 saw-tooth pattern. Panel B to D: SaO2 time series with no saw-tooth pattern (B); mild saw-tooth pattern (C); severe saw-tooth pattern (D)

PO0909

Leveraging Dynamic Data to Predict Mortality Risk in Patients Undergoing Chronic Hemodialysis

Benjamin A. Goldstein,1 Anna Xu,1 Jonathan A. Wilson,1 Patti Ephraim,2 Daniel E. Weiner,1 Tariq Shafi,1 Julia J. Scialla,1 Duke University, Durham, NC; 2Johns Hopkins University, Baltimore, MD; 3Tufts University, Medford, MA; 4University of Mississippi, University Park, MS; 5University of Virginia, Charlottesville, VA.

Background: Predictive models of mortality on HD typically use data collected at HD initiation. This is a missed opportunity that does not leverage the regularly collected data at HD treatments and is not reflective of how models would be used in practice. We compare performance of a risk model that uses static baseline data at incidence vs data at HD treatments and is not reflective of how models would be used in practice.

Machine Learning Classification of Tweets for Patient Dialysis Experience
Alexander S. Leider, Hawkins Gay, Bing Ho. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Popular microblog (e.g. Twitter, Facebook) services provide a continuous stream of public health information. This data has been used to monitor viral spread, medication adherence, and false health information. There are thousands of posts on Twitter daily regarding personal dialysis experience, access, and side effects. While these posts include valuable public health information, evaluating these posts to meaningfully assist dialysis patients is difficult as there are even more tweets mentioning dialysis in a professional context. We aimed to modify a state of the art natural language model to classify posts about dialysis as personal or professional.

Methods: We filtered posts containing the word dialysis. Posts were manually labeled as personal or professional by a nephrologist depending on the context dialysis was mentioned. The data was randomized and split for 60% training, 20% validation, and 20% testing. The text was preprocessed to remove extraneous characters and input into a Bidirectional Encoder Representations from Transformers (BERT) model for fine tuning, and a term frequency inverse document frequency vectorized Multinomial Naive Bayes Classifier.

Results: We collected 6011 tweets from May 3, 2021 to May 14, 2021. 1000 tweets were randomized and labeled. 57% were categorized as personal. BERT and Naive Bayes models attained 88% and 82% accuracy, respectively, on the testing data. The BERT model classified far less false negatives with a small increase in false positives (Figure 1).

Conclusions: BERT’s semantically rich word embeddings can enhance social media mining algorithms on dialysis content. We show superiority of a BERT model over a traditional count-based language model. This method can be easily applied as a pre-processing step to remove noisy posts to better study dialysis and other health trends in social media. This novel processing task and pipeline have broad clinical and public health implications for reducing the amount of data and time required for accurate, real-time monitoring of patient level posts.

PO0911
Automating Dialysis Machine Alarms During Sustained Low-Efficiency Dialysis (SLED)
Gerard Zasuwa, Jerry Yee, Stanley Frnak. Henry Ford Health System, Detroit, MI.

Background: Sustained low-efficiency dialysis (SLED) with regional citrate anticoagulation (RCA) is frequently employed at our institution. RCA requires constant monitoring because a dialysis machines alarm that stops the blood pump (BP) or bypasses dialysate leads to an increased rate of citrate infusion into the patient, with consequence of ionized hypocalcemia. To enhance safety and surveillance efficiency, we developed an innovative computer/phone system that identifies SLED machine alarms and notifies clinical care staff directly via proprietary phone network.

Methods: In 2017, we linked onboard SLED computer Wi-Fi systems to the hospital’s internal phone network (ASCOM). An alarm recorded by the SLED machine’s computer delivers an email to a dedicated email account that is subsequently transmitted to the ASCOM MailGate System. Mailgate produced and relayed text message alerts to dedicated ASCOM phones of dialysis technicians or nurses. Importantly, no additional training or changes in workflow are required for adoption of this method.

Results: This innovation has increased safety and efficiency. Response times for machine alarms improved and downtimes on dialysis were reduced, increasing dialysis dose of dialysis. To ascertain end-user satisfaction of the automated alarming system, we conducted a survey that demonstrates high-level satisfaction with the system (Table 1.)

Conclusions: Currently, no medical alert companies connect dialysis machine information to a medical alert phone system. ASCOM provides wireless messaging systems for dedicated hospital applications. Notably, ASCOM does not directly connect to dialysis machines. In addition, Email Alerts can be browsed by managers for archival retrieval, quality and safety report generation, and investigation of unanticipated events.

Users of a Web-Based Communications Platform for Care Coordination of Hospitalized Dialysis Patients
Laura Plantinga,1 Courtney E. Hoehn,1 Janice P. Lea,1 Christopher M. O’Donnell,1 Ann E. Vandenbarg,1 Kyle P. James,1 Tahsin Masud,1 Bernard G. Jaar,2 Carol A. Gray,1 Rich Mutell,3 Emory University, Atlanta, GA; 2Johns Hopkins University, Baltimore, MD; 3ApeX Health Innovations, Williamsburg, VA.

Background: Better care coordination between dialysis clinics and hospitals may improve outcomes among hospitalized dialysis patients. To fill the gap created by separate electronic health record systems across the two settings, we rolled out a web-based communications platform (“DialysisConnect”) in four dialysis clinics and one hospital in Atlanta. Here, we examine usage patterns of DialysisConnect.

Methods: DialysisConnect included automatically uploaded clinical information from dialysis clinics, forms for entering critical admission and discharge information, and a direct communications channel. Two nephrologists and two hospitalists served as project champions at the dialysis clinics and hospital, respectively. DialysisConnect was made available to 106 potential users (hospitalists, nephrologists, advanced practice providers (APPs) at the hospital and dialysis clinics, care coordinators (hospital), and nurses/nurse managers (dialysis clinic)) starting 10/29/20. Descriptive statistics were used to describe patterns overall and by user role through 4/15/21.

Family-Friendly, Work-Friendly, Home-Hemodialysis and In-Center Hemodialysis Hybrid: The First of Its Kind

Adam Locke, Macaulay A. Onuigbo. University of Vermont College of Medicine, Burlington, VT.

Introduction: Hybrid dialysis is traditionally defined as the combination of peritoneal and hemodialysis (HD) in patients with end-stage renal disease. Its reported use is quite limited outside of Japan. We recently encountered major family-related and employment-related constraints that prevented a 39-yo man with ESRD on home HD from completing the four-times weekly HD treatments with HD inadequacy and worsening of patient’s physiology. We successfully switched him to a new hybrid of twice-weekly HD + twice weekly In-Center HD. This is the first such report.

Case Description: A 41-yo male with ESRD secondary to SLE and hypertension on home HD, 4 x weekly, for some years experienced family-related constraints including non-availability of day-care for two young children due to COVID-19 pandemic, spousal illness and non-family-related challenges with morning travel and was missing his HD sessions. The result was inadequate HD delivery and worsening laboratory indices. He now receives 2 in-center HD treatments on Tuesdays and Thursdays, and 2 home HD treatments, once during the weekend and once during the week. This was started in February 2021. Each HD session lasts for 3.5 hours, 2000 units Heparin bolus, and his left brachiocephalic AVF is accessed by the button-hole method. The Home Dialysis Staff coordinates his dialysis care. Standardized Kt/V for May 2021 was 2.6.

Discussion: Hybrid dialysis is traditionally defined as the combination of peritoneal and HD in patients with ESRD. A 2020 Italian report described another type of hybrid dialysis that consisted of once-weekly in-hospital HD and home peritoneal dialysis to limit patient exposure to the hospital environment during the COVID-19 pandemic. We have described the successful application of a new Hybrid HD system that combined Home HD + In-center HD. To our knowledge, our report is the first of its kind and was designed and implemented primarily for the purpose of overcoming increasing family and employment demands on the patient. This new hybrid dialysis option was designed to facilitate a family-friendly work-friendly HD on a long-term continuous basis. The patient’s family members, two young children and his employers are happy and very satisfied. Simultaneously, the patient has continued to do well with adequate dialysis and meeting all the required goals of management in the past 3 months.

PO0914

Triple I Study: Hubs of Care Survey

Melanie D. Telson,1 Marcello Tonelli,2 Clara Bohm.1 Can-SOLVE CKD Triple I Study Team 1University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; 2University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: The Can-SOLVE CKD Triple I Study identified continuity of care; access to a primary care provider (PCP) in the hemodialysis (HD) unit; and access to care for other medical conditions as key challenges to in-centre HD care (www.betterkidneycare.ca). The Hubs of Care project aims to address these challenges by incorporating health care providers (HCPs) from other settings in the HD unit; firstly, we identify current practice, potential interest and need and desire for different HCPs in HD.

Methods: A cross-sectional self-reported survey administered Feb-May 2021 with HD patients and staff at four academic sites across Canada. Eligible participants included adults fluent in English or French who could complete the survey independently. The survey asked which HCPs are currently in HD units, which additional HCPs would like to see a PCP in the HD unit; of those, 87% prefer in-person and 13% prefer virtual. Qualitative analysis reveals privacy concerns due to the open concept of HD Units; however, the concept of bringing HCPs into the HD unit is regarded as beneficial and time-saving.

Conclusions: In this cross-sectional survey both HD patients and staff identified that, despite privacy concerns, bringing HCPs that provide foot, diabetic and mental health care into the HD unit was a priority with potential for benefit.

PO0016
Impact of Medication Reconciliation by a Dialysis Pharmacist
Summer Dyer, Linda Awidush, Sally Rafie, Victoria T. Nguyen. University of California San Diego, La Jolla, CA.

Background: Medication reconciliation (MR) improves patient outcomes, reduces cost, and is a reporting measure for the CMS End-Stage Renal Disease Quality Incentive Program. Most dialysis facilities do not have a clinical pharmacist to perform MR. The purpose of this study is to evaluate the impact of a pharmacist performing MR and medication management for patients receiving outpatient chronic hemodialysis at an academic institution.

Methods: We conducted a retrospective study from 10/1/18 to 11/2/20 to determine if MR by a pharmacist reduced medication discrepancies (MDs) and medication related problems (MRPs) over time. Secondary outcomes were to describe the type of MDs, type and severity of MR, impact of a pharmacy delivery service, and number of emergency department (ED) visits and hospitalizations pre- and post-pharmacist integration.

Discrepancies were categorized as: unintentional discrepancy, unintentional intentional discrepancy, and MRPs. MRPs severity was categorized using the National Coordinating Council for Medication Error Reporting and Prevention index. Descriptive statistics were calculated for each variable and a repeated measures ANOVA test was conducted to determine if MDs or MRPs changed over time.

Results: A total of 135 patients with 479 unique pharmacist encounters were included. The mean (SD) age was 61.7 (14) years, 58% were male, 65% caucasian, mean (SD) time on dialysis was 12.6 (6.4) years and most common comorbidities were diabetes and hypertension. The pharmacist conducted 3.5 MR/ patient with a mean time spent of 39.7 (16) minutes and 16% required an interpreter. Unintentional discrepancies were noted in 53% encounters, undocumented intentional discrepancies in 71%, MRPs in 59% but decreased significantly from the first to the second encounter (1.9 vs 0.9, 1.9 vs 1.2, and 1.1 vs 0.5 per patient, respectively, p<0.05). Most common MRPs types included non-adherence, prescription renewals, and excessive drug doses. Over half (54%) were enrolled in a pharmacy delivery service and had significantly fewer undocumented intentional discrepancies compared to non-enrollees (p<0.05). ED visits and admissions pre- and post-pharmacist integration were not statistically different.

Conclusions: Integrating a pharmacist into a hemodialysis unit enabled effective medication reconciliation and management to significantly reduce medication discrepancies and problems, and improve safety.

PO0098
Feasibility Study of Wrist-Based Wearable Activity Tracker in Hemodialysis Patients
Maggie Han,1 Ohmar Thwin,1 Xia Tao,1 Lemuel Rivera Fuentes,1 Amrish U. Patel,1 Nadja Grobe,1 Priscila Preciado,1 Leticia M. Tapia Silva,1 Mohamad I. Hakim,1 Stephan Thijssen,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Increased physical activity (PA) is associated with reduced risk of cardiovascular disease which is prevalent in hemodialysis (HD) patients. Wearable activity trackers (WAT) allow remote monitoring of PA. We aim to explore the feasibility of using a WAT for 1 year in HD patients.

Methods: HD patients from 4 NYC clinics were enrolled on a rolling basis starting June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use the Fitbit Charge 2. A stepwise intervention plan was used to assess feasibility (Figure 1). We used Kaplan-Meier analysis to determine mean and median time to withdrawal for non-compliance (TW) and predictors of TW were assessed by univariate Cox Regression.

Results: 119 patients were enrolled into the study. Patients were 54±12 years old, 59% African American, 37% lived alone, and 54% had an education level of college and above. 16% of patients were withdrawn for non-compliance. Mean and standard deviation TW was 175 ± 103 days. Median and interquartile range of TW was 133 and 181 days (98 to 280 days), respectively. The probability of not being withdrawn for non-compliance is shown in Figure 2. Age, gender, race, living status, and education were not associated with non-compliance.

Conclusions: A small portion of patients were continuously non-compliant with wearing/syncing their Fitbit devices in our study. Based on a low risk (<20%) of being withdrawn for non-compliance, we determined that it is feasible to use a wrist-based wearable device in HD patients for up to a year. However, prolonged use of these devices may require additional counseling to patients.

PO0917
Interim Analysis of the Extension of Tablo Treatment Duration (XTEND) Study
Yaadveer Chahal, Josh Schumacher, Michael A. Aragon. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission and is approved for use in the acute, chronic and home settings. Prior reports have demonstrated Tablo’s ability to achieve clinical goals, seamlessly integrate into hospitals and reduce cost across a wide range of treatment times. Extension of the Tablo cartridge to 24 hours (extended therapy; “XT”) allows even greater flexibility for prescribers in the acute setting. The objective is to report on the experience with Tablo extended therapy between 12 and 24 hours utilizing an interim review of the XTEND study (NCT04912050).

Methods: Nursing staff were trained during a single training session on Tablo XT. After a run-in period of 5 treatments, Tablo data were collected via real-time transmission to a cloud-based, HIPAA compliant platform and reviewed by site staff. Clinical treatment success was defined as either ending within 10% of prescribed time or site investigator assessment that all patient treatment goals were met.

Results: Fifty (50) Tablo XT treatments had a median prescribed treatment time of 24 hours and a median achieved treatment time of 23.5 hours. Median cartridge use was 1.0 per treatment. Clinical treatment success was 84%. Treatments ended due to clotting/ clogging were 4% (2 of 50). Median total ultrafiltration (UF) rate was 1.7 mL/kg/hr. Clinically significant alarms occurred at a median rate of 7 per treatment with a resolution time of 14 seconds. Most frequent alarms experienced were arterial and venous pressure (39% and 58%, respectively), of which none resulted in an end treatment.

Conclusions: Tablo’s XT successfully achieves prescribed treatment time and favorable ultrafiltration rates with minimal therapy interruptions from alarms or cartridge changes. This data demonstrates the effectiveness of Tablo’s newly expanded versatility in achieving personalization of treatments necessary for unstable patients and enabling successful delivery of extended therapy with minimal clotting. Tablo’s 24-hour therapy meets the needs of critically ill patients that require renal replacement therapy for greater than 12 hours.

Glycemic Status Ascertained by Continuous Glucose Monitoring in a Prospective Hemodialysis Cohort

Background: Hemodialysis (HD) patients with diabetes are at heightened risk of hypo- and hyperglycemia due to multiple pathways. While self-monitored blood glucose is the standard approach for glucose assessment in HD patients, it may not adequately capture glycemic status given its infrequent nature. We thus sought to measure glucose levels using continuous glucose monitoring (CGM) as a more frequent (every 5-minutes), convenient, and automated method of glycemic status in a prospective HD cohort with diabetes.

Methods: Among 18 HD patients with diabetes hospitalized during 10/2020-5/2021, we conducted simultaneous protocolized glucose measurements using 1) CGM measured by Dexcom G6 devices vs. 2) blood glucose levels using capillary fingertip or venous blood glucose, with the latter measured 4± times per day (before each meal and at night), plus every 30 minutes during HD (total of 6-8 measures during HD). Using American Diabetes Association (ADA)-defined CGM targets, we examined the prevalence of patients achieving the recommended percentage (%) of CGM levels in the ranges of <54, ≥70, 70-180, ≥180, and ≥250mg/dL (ADA target % of glucose levels <1%, <4%, >70%, <25%, and >5%, respectively).

Results: Whereas 64% of CGM measurements (N=9444) were within target glucose range (time in range [TIR] 70-180mg/dL), 80% of blood glucose levels (N=100) were within TIR. The proportion of patients achieving the recommended % of CGM measurements within ADA-defined glycemic ranges of ≥250, >180, 70-180 (target range), <70, and <54mg/dL were 67%, 44%, 44%, 89%, and 78, respectively.

Conclusions: In a cohort of hospitalized diabetic HD patients who underwent concomitant CGM and blood glucose measurements using the Dexcom G6 remote access system, blood glucose testing overestimated the % of time patients were in target glycemic range as compared with CGM. CGM showed that less than half of patients achieved the recommended % of CGM measurements within target range. Further studies are needed to determine whether CGM can improve the glycemic management of HD patients compared to conventional approaches.

Validation of Automated Sodium Control in a Novel Dialysis System

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To test an automated feedback program designed to regulate the infusion of an alkali needed to maintain proper sodium concentration in a dialysate solution

Methods: A 125L volume of simulated dialysate was circulated at ~400 mL/min and ~37 C through a sorbent cartridge which removed the urea from the solution. The fluid exiting the cartridge had no Ca, Mg or K. These chemicals were reinfused through a pump in a solution containing Ca, K and Mg salts. A conductivity sensor (cond) was used in a feedback control of the alkali infusion pump. The feedback control adjusted the pump flow rate to maintain the conductivity of the infusate at 14.1 mS/cm. The sensor was programmed from a curve model of the alkali over time from previous experiments. Occasional spikes of Na+ were programmed from a curve model of the alkali over time from previous experiments.

Results: The results are depicted in table 1. TP1, the mean sodium concentration [Na+] in the dialysate at pump 1, after mixing in a 125L tank was in the range 139.8 – 141.7 mEq/L. TP2, the mean dialysate [Na+] at pump 2 after leaving the sorbent filter was 124.2 (+/-2.4) mEq/L. This correlates with cond1 and was 12.8 (+/-0.4) mS/cm. TP3, the mean dialysate [Na+] after being replenished with the alkali solution immediately prior entering the tank for remixing was 139.5 (+/- 1.9) mEq/L and correlated with cond2 of 14.1 mS/cm.

Conclusions: The results validate the accuracy of the conductivity sensor in correctly regulating the alkali infusion.

Diffusion of Therapeutic Effects Between Roxadustat and Daprodustat, HIF-PH inhibitors, Depending on the Blood Type in Hemodialysis (HD) Patients

Satoshi Funakoshi,1 Takashi Harada,1 Jyunichiro Hashiguchi,1 Kenji Sawascie,1 Akihiro Mackawa,1 Tayo Kawazu,1 Asami Nakamura,1 Tomoya Nishino,2 1Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki University Graduate School of Medicine, Nagasaki, Japan.

Background: Human blood group antigens are glycoproteins and glycolipids expressed on the surface of red blood cells and a variety of human tissues. This study aimed to determine if there is an association between ABO blood type and the efficacy of HIF-PH inhibitors. Roxadustat and daprodustat are potent inhibitors of HIF-PH and capable of stimulating erythropoiesis in patients with impaired renal function. These two compounds are reported to act mechanistically similar but display differences in their effects on cells, and the differences may affect their efficacy in the treatment of renal anemia in HD patients. In this study we compared the response rate by blood type of roxadustat and daprodustat, respectively.

Methods: Sixty-eight HD patients treated with roxadustat (20-100mg, 3/week) and ninety-five treated with daprodustat (1-12mg, daily) were recruited in our observational study. We defined >1.5g/dL increase in hemoglobin as effective, and <1.5g/dL decrease as ineffective.

Results: As shown in the figure, type A had the highest response rate at 47% in HD patients treated with roxadustat. On the other hand, type O had the highest response rate at 55% in those who were treated with daprodustat.

Conclusions: We found the association in the effectiveness of roxadustat on the treatment for anemia in HD patients in type A, while the effectiveness was higher in type O treated with daprodustat. The results suggest that the therapeutic effect of HIF-PH inhibitors may differ depending on the blood type.

Nanostructured Capillary Membranes for Size-Selective Hemofiltration
Peifu Cheng,1 Francesco Fornasier,2 Nicholas J. Ferrell,3 Shuvo Roy,2 William H. Fissell,1 Piran Kidambi,1 1Vanderbilt University, Nashville, TN; 2University of California San Francisco, San Francisco, CA; 3Lawrence Livermore National Laboratory, Livermore, CA.

Background: Size-selective separations offer potentially transformative advances for hemofiltration. In the context of hemodialysis, the tradeoff between selectivity and permeability often results in large package sizes and high driving pressures that limit wearable and implantable options of therapy. Here, we report on composite membranes with vertically aligned precise nanoscale capillaries with improved permeability.

Methods: Arrays of carbon nanotubes (CNTs) were synthesized via chemical vapor deposition and the catalyst composition was carefully selected to achieve a uniform distribution of diameters. The area between the CNTs was filled with a polymer to form a membrane. The CNT membranes were backed with microporous silicon supports and mounted into a filtration cell. Hydraulic permeability was calculated from gravimetric flow rates at stepped transmembrane pressures. Size-selectivity was measured by filtering fluorescently-labeled polydisperse Ficoll in phosphate-buffered saline. Size-specific Ficoll concentrations in feed and filtrate were measured by size-exclusion chromatography.

Results: CNT membranes membrane exhibited a cut-off of 6nm and the measured hydraulic permeability was 102.3 ml h⁻¹ m⁻² mmHg⁻¹ compared to published data of 30 ml h⁻¹ m⁻² mmHg⁻¹ for conventional high flux dialyzers. CNT membranes retained large molecules while passing small and medium-sized molecules. Sieving coefficient at 2 nm, approximately the size of β2 microglobulin, was unity (Figure).

Conclusions: The CNT membranes provide excellent middle molecule clearance and hydraulic permeability multiples of conventional membranes. Further research is necessary to move to clinically implement this technology.

PO0923

Delivered Dialysate Potassium Is Higher Than What Is Prescribed When High Sodium and Low Bicarbonate Are Prescribed
Saiedy W. Ali, Andrew I. Chin. University of California Davis Department of Internal Medicine, Sacramento, CA.

Background: Most hemodialysis machines utilize the 3-stream method of making dialysate. In hospital settings, dialysate prescriptions are customized to the clinical setting. We determined the differences between delivered and prescribed dialysate K⁺ in unusual prescriptions.

Methods: Dialysate samples drawn 15 minutes into HD were analyzed via indirect ion-specific electrodes for Na⁺, K⁺, and HCO₃⁻. 5200 HDs with extremes of ordered Na⁺ and HCO₃⁻ were analyzed. Outcome was measured versus ordered K⁺. Analysis used ANOVA using SPSS.

Results: Means of the difference between measured and ordered K⁺ and Na⁺ are shown in figure 1. For K⁺ there was significant difference amongst the groups (p<0.001). There were no differences amongst the groups for Na⁺.

Conclusions: When a very high Na⁺ is prescribed along with a low HCO₃⁻ the dialysate K⁺ remains close to prescribed Na⁺. As the acid concentrate contains both Na⁺ and K⁺, a high Na⁺ and low HCO₃⁻ prescription will use a relatively more of the acid concentrate and less of the bicarbonate concentrate. Dialysate prescriptions with a high Na⁺ and low HCO₃⁻ increased delivered dialysate K⁺ by an average of 0.5 mEq/L; we observed some HDs where dialysate K⁺ was 1 mEq/L higher than prescribed.

Figure 1: Means of the difference between measured and ordered K⁺ and Na⁺.

PO0924

Urea Clearance Performance in a Modified Batch Dialysis System

Background: Urea clearance is the key measure of dialysis adequacy. The Diality Hemodialysis Machine will provide good clearance performance to ensure an adequate dose of dialysis. Specific Aims: To assess clearance performance during simulated dialysis utilizing a novel modified batch process. In this setup, dialysis was conducted by alternating dialysate delivery from subsequent two-liter reservoirs.

Methods: Simulated dialysis sessions were conducted utilizing blood flowsrates of 300 ml/min, dialysate flowsrates of 500 ml/min and no ultrafiltration. Dialysis occurs off of a two-liter batch of dialysate. Once two liters of dialysate has been circulated through the dialyzer, the spent dialysate is discarded and dialysis switches to a separate two-liter reservoir of dialysate while the first reservoir is drained and filled with fresh dialysate. A single compartment simulated patient was created by combining 50 L of DI water with a 20mM concentration of urea. Simulated blood samples were collected at the dialyzer inlet and outlet and dialysate samples collected at the dialyzer outlet to determine urea concentrations over the course of the simulated treatment.

Results: The results are provided in Figure 1. The urea concentrations in the blood decreased over the course of treatment as expected given the stated clearance values of the dialyzer used in the simulated treatment.

Conclusions: The initial experiments using a modified batch system show promising urea clearance. Future tests will better characterize performance compared with conventional devices that do not use a modified batch configuration.

Comparative Effectiveness Between Novel Medium Cut-Off Membrane Hemodialysis and Mixed-Dilution Online Hemodiafiltration on Middle Molecule Uremic Toxins Reduction: A Prospective Cross-Over Study
Jirarat Eiamcharoenying, Pajaree Charityavilaskul, Kullaya Takivakatkarn, Paweesa Susantitaphong, Yingyos Avihingsanuk, Somchad Eiam-On, Khajohn Tiranathanagul. King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

Background: Mixed-dilution online hemodiafiltration(mixed HDF), one of the best hemodialysis(HD) modes, provides superior removal of middle molecule uremic toxins to standard HD using high flux dialyzer. Due to the limited availabilities and high cost of HDF, we performed standard HD utilizing a novel medium cut-off membrane with a larger pore size and compared the effectiveness in removal of middle molecule uremic toxins with mixed HDF.

Methods: A prospective cross-over randomized controlled trial was conducted in 14 prevalent HDF patients who were randomly allocated into group1 (n=7): mixed-dilution online HDF with high flux dialyzer ELISIO21H and group2 (n=7): standard HD with MCO membrane, Theranova 500. In this 8-week study, the primary outcome was a reduction ratio( RR) of Beta2-microglobulin (B,M). Other small to middle molecules and protein-bound uremic toxins reduction ratio, dialysate albumin loss, and nutritional parameters were also compared.

Results: In this 8-week study, B,M RR from both modalities was higher than the survival benefit cut-point of 80%. In comparison, B,M RR was slightly lower but significant in MCO HD than mixed HDF (82.57±5.34% vs 85.12±3.87%, respectively) with the mean difference of 2.59 (95% confidence interval [CI], -0.07 to -1.03; P<0.001).

The spKt/Vurea and URR, a small uremic toxin removal marker, were comparable. kFLC and Indoxyl sulfate RR also were similar in mixed HDF and MCO HD. Whereas RR of the larger middle molecule uremic toxin, Alpha_M and JFLC was lower with mixed HDF compared to MCO HD (30.13±15.90 vs 41.49±11.46 and 40.85±13.92 vs 50.81±13.18, respectively; P<0.001).

Conclusion: Mixed HDF and MCO HD provided the RR values of B,M and small uremic toxins above the respective cutpoint. Despite mixed HDF provided higher B,M RR, MCO HD also provided more performance in the clearance of the larger middle molecules, particularly Alpha_M and JFLC. However, mixed HDF loss lower albumin than MCO HD. Therefore, both techniques can be used as alternative options.

PO0927

Clearance of Protein-Bound Uremic Toxins on the Tablo Hemodialysis System
Logun Rivas, Dean Hu, Michael A. Aragon. Outset Medical, San Jose, CA.

Background: The Tablo Hemodialysis system (Tablo) is an all in one, easy-to-learn device. While clearance of small and middle molecules has been documented in modern dialysis, the clearance of Protein Bound Uremic Toxins (PBUTs) merits further exploration. Clearance of albumin bound toxins such as indoxyl sulfate (IS) and p-cresol sulfate (PCS) can be limited in dialysis where removal is based on molecular size. Although a clear association has yet to be demonstrated, PBUTs have been considered to be a possible cause of adverse outcomes in patients requiring renal replacement therapy.

Methods: A simulated hemodialysis treatment using Tablo was performed with solution of bovine serum albumin and urea. PCS and IS were added to the solution to maintain a constant concentration. A screening design of experiment was performed utilizing the factors of dialysis flow rate (Qd), blood flow rate (Qb), and ultrafiltration rate (UF). After each factor was changed and allowed to equilibrate, samples were collected from the venous, arterial and spent dialysate lines. Samples of Urea, PCS and IS were utilized for determining cut-point. Despite mixed HDF provided higher clearance, albumin levels were not different.

Conclusions: Mixed HDF and MCO HD provided the RR values of B,M and small uremic toxins above the respective cut-point. Despite mixed HDF provided higher B,M RR, MCO HD also provided more performance in the clearance of the larger middle molecules, particularly Alpha_M and JFLC. However, mixed HDF loss lower albumin than MCO HD. Therefore, both techniques can be used as alternative options.

Dialysis Disequilibrium Syndrome (DDS) in Hemodialysis Patients: Systematic Review
Rupesh Rama,1,2 Siddhartha S. Singh,1,2 Ronith Chakraborty,1,2 Cleveland Clinic, Akron, OH; 3Akron Children’s Hospital, Akron, OH.

Background: Dialysis disequilibrium syndrome (DDS) affects patients who have missed multiple dialysis treatments, especially new initiates of hemodialysis (HD), and presents as a rare neurological complication. The conceptual pathogenesis of DDS is likely a result of multiple physiological abnormalities which we explore in this systematic review alongside preventive measures with focus on effective management strategies.

Methods: A literature search was conducted on PubMed/Medline and Embase and included studies if the patient developed DDS irrespective of age and gender. Two independent reviewers conducted the process of article selection with a third reviewer present to resolve any conflicts. The data was analyzed and a summary table was extracted with the following variables: study type, population group, age, patient characteristics, blood and dialysate flow rate, and study outcome. A descriptive analysis was performed analyzing the population size and frequency of symptoms and treatments utilizing the R software.

Results: A total of 49 studies (321 samples) were identified and analyzed. There were 72.4% of patients (based on 48 studies) who reported having DDS with most common symptoms of headache (39.4%), nausea (40.4%), vomiting (39.1%), confusion (66.7%) and seizure (78.6%). Within this sample, 12 studies switched from HD to alternative dialysis modalities including continuous venovenous hemofiltration/haemodiafiltration (CVVH/UVHDF) or peritoneal dialysis (PD) with no further reported DDS symptoms.

Conclusions: We have provided a comprehensive clinical practice points for both the pediatric and adolescent and young adult population; interestingly, DDS was reported more often in the early dialysis era prior to recent advances and improvement of resource allocation. Existing literature shows it is crucial to recognize symptoms of DDS and implement timely prevention to improve outcomes.

PO0929

Protein Loss with Medium Cut-Off and High Flux Dialyzer: A Proteomic Analysis
Xiaoling Wang,1 Xia Tao,1 Leticia M. Tapia Silva,1 Amrish U. Patel,1 Mohamad I. Hakim,1 Nadja Grobe,1 Stephan Thijssen,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Hemodialysis (HD) patients frequently suffer from low serum albumin levels, making dialytic albumin and protein loss a concern. Medium cut-off (MCO) dialysis membranes reportedly show a greater albumin loss compared to high-flux (HiFlux) membranes. To better understand the spectrum of proteins cleared with MCO membranes, we set up an ex vivo dialysis system and perform proteomic analysis of the dialysis membranes.

Methods: Eight liters of human plasma (EDTA added) are split into two 4-liter batches and dialyzed for 4 hrs in single-pass, either with an MCO (Theranova 400) or HiFlux dialyzer (Optiflux F180NR) using a Fresenius 2008T machine. Blood flow was 400 ml/min. Dialysate flow was 600 ml/min for the first 3 hrs and zero for the 4th hr. Ultrafiltration rate was zero for the first 2 hrs and switched to 1 L/hr thereafter. This design allowed us to study three HD modes: diffusion only (2 hrs); diffusion with convection only (1 hr); convection only (1 hr). Dialysates were sampled at multiple time points (Fig 1B).

Results: Three µg of initial plasma and 23 µl dialysate were loaded on an SDS-page gel and silver stained (Fig 1A). Lanes 3 and 4 were from MCO, lanes 4 and 6 from HiFlux. Lanes 3 and 4 were collected 15 mins into dialysis, lanes 5 and 6 at 240 mins. Results show that dialysates contain less high molecular weight proteins compared to plasma, and MCO dialysates contain much more proteins compared to HiFlux dialysates. The strong band at ~62 kD is most likely albumin. Using mass spectroscopy, we can identify 56 different protein species in MCO dialysate. Dialysate protein levels (measured by Bradford assay) with the 3 dialytic modalities are shown in Fig 1B, the total protein losses are listed in Fig 1C. The ratio of protein loss between MCO and HiFlux dialyzers is 17-fold in the convection only mode.

Conclusions: Our results show a higher diffuse and convective protein loss with MCO compared to HiFlux membranes. Further characterization and quantitation of proteins cleared in vivo during HD are necessary to better understand the clinical impact of our ex vivo observations.

Intradialytic and Interdialytic Urea Dynamics in Blood and Cerebrospinal Fluid in Hemodialysis Patients
Xia Tao,1 Lin-Chun Wang,1 Xin Wang,1 Ohnmar Thwin,1 Nadja Grobe,1 Amrish U. Patel,1 Stephan Thijssen,1 Joshua E. Chat,1 Ludovic Debure,3 Thomas Wasienski,2 Peter Kotanko,1,2 Renal Research Institute, New York, NY; ‘NYU School of Medicine, New York, NY; ‘Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Modern, highly efficient hemodialysis (HD) results in rapid decline of blood urea. Urea gradients across the blood-brain barrier (BBB) can drive water movements. A positive urea gradient, i.e. brain urea to plasma urea, can result in brain swelling and impair brain function. We explored the dialytic changes of urea in blood and cerebrospinal fluid (CSF) to better understand intradialytic osmotic gradients across the BBB and provide insights that support the development of brain-protective HD.

Methods: Two HD patients (39 and 26 years old) with ventriculo-peritoneal (VP) shunts were enrolled into this one-week IRB-approved study with a Monday/Wednesday/Friday dialysis schedule. CSF was collected via VP shunt tap 2 hrs before and 2 hrs after HD (Wednesday and Friday), and Tuesday and Thursday. Plasma samples were collected concurrently with CSF and during HD. In addition, the patients underwent test of executive function (Trail Making Test Part B; TMT B) and global cognitive function (Montreal Cognitive Assessment; MoCA) on Monday.

Results: Urea was removed efficiently from patients’ blood by HD. While patient A showed a small post-HD plasma-to-CSF urea gradient, it was highly positive (~ 60 mg/dL) in patient B (Fig 1). TMT B and MoCA score were normal for patient A but not patient B (TMT B 415 sec; TMT B error count: 2; MoCA score: 11).

Conclusions: Our patients showed very different post-HD plasma-to-CSF gradients. Theoretically, the positive gradient in patient B would favor intradialytic brain swelling. Patient B showed impaired neurological testing results which are not related to patient’s pre-existing neurological conditions. We can only speculate if and to what extent trans-BBB water movements driven by dialytic urea dynamics may have impacted the patient’s cognitive functions. We believe that patient-specific levels of osmotic stress need to be considered when developing neuro-protective HD technologies.

Figure 1: Urea concentrations in plasma (black line) and CSF (red line) (left panel: patient A; right panel: patient B).

PO0931
High-Throughput Analysis of Changes in Protein Biomarkers During Hemodialysis
Matthew B. Lanktree,1 David T. Collister,2 Guillaume Pare,3 Michael Walsh,4

1McMaster University, Hamilton, ON, Canada; 2University of Manitoba, Winnipeg, MB, Canada.

Background: The impact of hemodialysis on the concentration of circulating protein biomarkers remains unclear. Biomarkers may decrease in concentration due to filter adsorption, diffusive clearance, or convective clearance, while others may increase in concentration due to production and secretion or intracellular release. Ultrafiltration of water is also expected to increase biomarker concentration. We sought to evaluate the impact of hemodialysis on 1,163 protein biomarkers in a high-throughput fashion.

Methods: A nested cohort of 44 patients (25 male, 19 female) including 29 with intradialytic hypotension and 15 without were selected from the prospective Hemodialysis Outcomes and Symptoms assessment (HOST) cohort. Intradialytic hypotension was stringently defined as a 60 mmHg drop in systolic blood pressure or a nadir systolic blood pressure of less than 70 mmHg during hemodialysis treatment. All hemodialysis treatments were done using the same hemodialysis filter type. 1,163 unique biomarkers were measured in each patient before and after a hemodialysis session using the Olink proximity extension assay (www.olink.com). Paired sample t-tests were used to compare pre- and post-dialysis concentrations with a Bonferroni-corrected significance threshold (P < 5 x 10^-6).

Results: 54 biomarkers (5%) significantly increased during hemodialysis treatment, while 243 (24%) significantly decreased. Change in biomarker concentration was significantly correlated with biomarker molecular weight (r = 0.37, P = 2.8 x 10^-10), isoelectric point (r = -0.26, P = 6.4 x 10^-4), and pre-dialysis concentration (r = -0.21, P = 3.0 x 10^-4). There was a significant enrichment of cardiovascular biomarkers in the top 20 biomarkers associated with a drop in systolic blood pressure (P = 2.8 x 10^-7), including Kidney Injury Molecule 1 (KIM1, P = 0.005).

Conclusions: Hemodialysis is associated with significant changes in protein biomarker concentrations related to protein properties and clinical events during treatment. These changes are measurable on a high-throughput platform. Further high-throughput biomarker studies could assess dialysis adequacy, test biomarker-symptom associations, and improve risk prognostication.

Feasibility of Allo-Hemodialysis: First Experience from Porcine Studies
Xin Wang,1 Amrish U. Patel,2 Anil K. Gothi,3 Dejan Nikolic,4 Alexander Heide,5 Jianning Dong,1 Hao Zhang,6 Vaibhav Maheshwari,7 Nadja Grobe,8 K S Nayak,8 Peter Kottan,9 1 Renal Research Institute, New York, NY; 2Vivo Bio Tech Ltd, Hyderabad, India; 3Fresenius Medical Care Shanghai Co Ltd, Shanghai, China; 4Icahn School of Medicine at Mount Sinai, New York, NY; 5Vijivini Hospital, Hyderabad, India; 6Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Annually, millions of kidney patients, predominantly in low and low-middle income countries, die prematurely because of unavailability of affordable kidney replacement therapy. We previously demonstrated through mathematical modeling and bench testing the feasibility of alloHD, an alternative low-cost hemodialysis treatment approach where the blood of a kidney failure patient flows counter-current to that of a healthy donor (“buddy”) through a dialyzer. Herein we report first results from an alloHD feasibility study in a porcine model. We aimed to specifically address questions around hemolysis and coagulation of the dialysate compartment.

Methods: Ethics protocol was approved by Committee for the Purpose of Control and Supervision of Experiments on Animals, India. Under general anesthesia, healthy male female white Yorkshire pigs of 30 to 80 kg with central venous catheter as vascular access were dialyzed 1-3x weekly for 2-4 hours. Ultrafiltration volume goals were set between 0 and 1000 mL. “Patient” and “buddy” pigs were connected to the dialysate and blood compartments, respectively, of a Nipro Cellenta 171 (Fig. 1). Pigs were anticoagulated with 5000 IU heparin per hour. Pre- and post-treatment blood samples were collected for biochemical measurements.

Results: We successfully completed 10 alloHD sessions. No coagulation was observed. Visual inspection of plasma samples indicated no signs of hemolysis. This was further corroborated by measurements of lactate dehydrogenase and haptoglobin, which were available in seven experiments (Fig. 2).

Conclusions: We found no indication of hemolysis and dialysate compartment coagulation in our experiments. Upcoming studies in a porcine renal failure model will address in vivo solute clearances by alloHD.

Funding: Commercial Support - Renal Research Institute

Can Plasma Filters Be Reused for Plasmapheresis in Resource-Poor Settings? Experience from a Tertiary Care Hospital
Priti Meena, Sandip Panda, Rishita Mondal, Swati Das. All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India.

Background: Therapeutic plasma exchange (TPE) is used in the management of various life-threatening illnesses. It is widely performed by nephrologists, intensivists, pathologists, or experts of transfusion medicine worldwide. However, the costs of TPE sessions are exceedingly high and it has a huge impact on patients’ financial burden. Most of the patients cannot afford such a high-cost treatment. Herein, we investigated the outcomes of reuse of plasma filters in TPE for several occasions

Methods: This was an ambidirectional study that included retrospective analysis of patients receiving TPE from January 1, 2021, to December 31, 2020, whereas the patients receiving TPE from January 1, 2021, to April 30, 2021, were prospectively analysed. The procedure was performed in our hospital’s dialysis unit. Formulation of 4% peracetic acid and 24% hydrogen peroxide acid with RO water was used for reprocessing. Fresenius Plasma Flux P2 (0.6 m2) was used in the study. Clinical outcomes, risks, and cost-benefit were evaluated and compared between the plasma filter reuse group (GP-1) and no reuse group (GP-2).

Results: 46 patients were included in the study. 26 patients were in the Plasma filter reuse group. 122 and 119 TPE sessions were performed in GP-1 and GP-2 respectively. A total of 58 plasma filters were used in GP-1. In six patients single plasma filter was used on 3 occasions whereas, it was used for 2 occasions in other patients. The most common indication for TPE in both groups was Guillain barre syndrome. The rates of clinical improvement in disorders for which the TPE were performed were similar in both GP-1 and GP-2 (88 % vs 90%, p=0.4). None of the patients in either group had clotting of plasma filter, any allergic reaction, or increased bleeding risk. No higher chances of sepsis were noticed in GP-1 (P=0.08). No difference in patient survival was noticed between the two groups (97% vs 96%, p=0.5). The cost of overall treatment was 2.5 times higher in GP-2, (P=0.003).

Conclusions: Reuse of plasma-filter is a safe and effective method for cost minimization in patients requiring TPE. This method can effectively be utilized in resource-poor settings without any increased risk of adverse effects

A Forgotten Technique of RRT for Correction of Severe Hypotension in CKD: Case Report
Rodolfo A. Moreno,1,2 Alexandra M. Trochez,1,2 Pedro Gonzales,1,2 Antonio J. Palma,1,2 Lidia B. Sanchez,1,2 Rafael J. Hernandez,1,2 Jorge A. Hernandez,1 Centro Medico Militar, Guatemala, Guatemala; Universidade Mariano Galvez Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala.

Introduction: Patients with chronic kidney disease (CKD) present electrolyte disorders. This represents a challenge when hypotension is below 125 mmol/L, associated with any criteria for urgent renal replacement therapy (RRT) with conventional hemodialysis because of higher risk of over correction above the security threshold of 10 mmol/L/day and osmotic demyelination syndrome.

Case Description: A 49-year-old Guatemalan female with history of 15 days of edema and slurred speech. Only history of T2DM. Was brought to the ER with BP 100/80 mmHg and anaerusa. Initial laboratory tests: negative COVID-19Ag, Cr 5.12 mg/dL, (previous 2mg/dL) BUN 105mg/dL, glucose 156mg/dL, Na 108mmol/L, K 5.2mmol/L, Cl 70mmol/L, SO4 224mmol/L, pCO2 35mmol/kg, UNa 28mmol/L. Because of neurologic symptoms, received a 150ml bolus of 3% saline twice with a rise to 112mmol/L. After the bolus, we initiated a 24-hour infusion with 3% hypotonic solution reaching a rise of Na up to 119mmol/L in 48 hours, but because of persistence of neurologic symptoms plus fluid overload >10% of body weight and hyperkalemia, we initiated RRT. In the absence of CRRT or CVVH we planned a conventional HD with blood flow of 100mL/min, dialysate flow 600mL/min, dialysate Na 130mmol/L (the lowest Na possible) and 3 hours duration. After the first session had neurologic and edema improvement. After two sessions with an interdialytic period of 48 hours, Na control of 122mmol/L and 132mmol/L respectively with resolution of uremic syndrome. Later was diagnosed with hospital-acquired pneumonia receiving antibiotic treatment for 14 days and was discharged home with ambulatory HD.

Discussion: In undeveloped countries where the access to CRRT or CVVH is unavailable, conventional modalities can be used with low blood flows and modification of the dialysate Na to a minimum (130mmol/L) offering a safe option to Na correction for patients with severe hypotension and any other HD criteria.

PO0936
Green Hemodialysis: Is It Really Possible to Save Water and Plastic Without Affecting the Quality of the Treatment? Ismael A. Gómez Ruiz, Geovana Martin-Alemalhy, Juan M. Ardavin Iruarte, Rossana Olmedo Ocampo, Santa Carmen Médica Santa Carmen, Ciudad de México, Mexico.

Background: Hemodialysis (HD) is essential for the preservation of life in many patients but represents a complex issue in ecology producing a large waste load that affects the environment. Sustainable waste management policies are scarce. The aim of the present study was to show the particular water and plastic savings in a mexican HD center that practices the reuse of dialyzers and reject water (RW) without affecting the quality of care provided for patients.

Methods: Prospective cohort study performed between January and May 2021 in a HD center with 90 patients (AK 98 Baxter®). HD center has 15 employees, 5 bathrooms and 12 sinks. Volumes of produced and reused RW were measured by flow meters. A detailed analysis of the residual biochemical content of RW was performed. The weight of plastic waste was compared between patients with reused membranes and patients without reusing the membranes. Finally, to evaluate the quality of the HD treatment in reused dialyzers (1-12 reuses), the difference between 5 monthly measurements of the spKt/V was determined using a repeated measure ANOVA considering a p>0.05 for no difference.

Results: During the study period 4158 HD sessions were provided, 394 m3 of RW were produced, 312 m3 (79%) were reused for all center sanitation purposes. Analysis of the residual biochemical content of RW is shown in Table 1. A total of 1902 HD sessions were performed with reused dialyzers. With each dialyzer reuse (Revaclear Baxter®) 0.88 lbs of plastic waste was spared. This translates into 1.53 tons less waste. No adverse effects were observed. No statistical significance difference was observed in single pool Kt/V between treatments with reused filters.

Conclusions: These results suggest that reuse of RW in the sanitation of the centers and dialyzer reuse resulted in significant savings in water and plastic without affecting the quality of treatment received by patients.

Single-Bolus Tinzaparin Anticoagulation in Extended Hemodialysis Sessions: A Feasibility Study
Benoit Harvey,1 Simon Léger,2 Naoul Elfoutouh,3 Michel Vallette,3 Louis-Philippe Laurin,2 Annie-Claire Nadeau-Fredette,3 Université de Montréal, Montreal, QC, Canada; Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Few studies have assessed the use of low-molecular weight heparins for anticoagulation during extended hemodialysis (HD) sessions. This study aimed to evaluate the safety and efficacy of tinzaparin for anticoagulation of the extracorporeal circuit and dialyzer in extended, 8-hour, sessions.

Methods: This single-center study included all patients who underwent a single in-centre 8-hour session as part of their nocturnal home HD training between 2009 and 2020. Tinzaparin was delivered as a single bolus injection at time 0 with dosing based on the patient’s weight and doubling of standard 4-hour session dose. Tinzaparin safety effects were observed. No statistical significance difference was observed in single pool Kt/V between treatments with reused filters.

Conclusions: These results suggest that reuse of RW in the sanitation of the centers and dialyzer reuse resulted in significant savings in water and plastic without affecting the quality of treatment received by patients.

Targeted Alteplase Administration to Improve Hemodialysis Catheter Patency: A Quality Improvement Pilot Study
Jason T. Bau, Tyrone Harrison,1,3 Kokak Younis,2 Nathan Gallagher,2 Julliya Hemmett,1 Elena Qirjazi.1 1University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2Alberta Health Services, Calgary, AB, Canada; 3University of Calgary Department of Community Health Sciences, Calgary, AB, Canada.

Background: Catheter dysfunction (CD) is a frequent complication during the provision of hemodialysis. Thrombolytic agents (i.e. alteplase) are the mainstay for resolving CD, however, alteplase usage has increased 16% (~$440,000CD) annually in the Alberta Kidney Care South program without improved patient or dialysis outcomes. We assessed the implementation of a protocolized algorithm to reduce alteplase usage.

Methods: In this pilot quality improvement study, we designed an algorithm where CD was treated with high-dose (2mg) alteplase therapy to the problematic lumen only, after meeting pre-specified criteria (Fig 1). This protocol was implemented in a satellite hemodialysis unit (~110 patients) from Jan 2021 to Mar 2021. The baseline comparison period was Jan 2020 to Dec 2020 when CD was treated with low-dose 1mg/lumen alteplase. Outcome measures included total alteplase usage, changes in Kt/V, recirculation, clearance, line interventions and hospitalization rates. Statistical analysis was completed using Mann-Whitney and Z-score calculations.

Results: Sixty-nine alteplase administrations occurred over the two-month period, versus 438 in the baseline period. Patients in the 2mg group were more likely to achieve an increase in Kt/V of at least 10% in the next dialysis session (34.7% vs 28.9% p=0.04). Otherwise the 2mg alteplase with our protocol was not inferior to baseline with respect to blood flow rate processed (26.1% vs 20.1% p=0.13) and average clearance (37.7% vs 28.5% p=0.37). A 12% decrease (88 vs 100mg/mo p=0.05) in alteplase use was observed with no differences in frequency of hospitalizations (8% vs 5.9% p=0.39) or line interventions (12.3% vs 7.3% p=0.20).

Conclusions: Our protocol with 2mg alteplase therapy to the problematic lumen was not inferior with respect to patient outcomes compared to baseline practices and resulted in lower alteplase use. An expanded multi-center prospective study is underway to further assess the broader applicability of these findings.

Implement alteplase administration protocol.

The Effect of Predilution Online Hemodiafiltration on Body Composition, Nutritional Status, and Mortality
Sannoo Miziari,1 Yoshiko Nishizawa,2 Aiko Okubo,3,4 Toshiaki Doi,5 Kazumi Yamashita,1 Kenichiro Shigemoto,3 Koji Usui,3 Michiko Arita,1 Takayuki Naito,1 Shigehiro Doi,2 Takao Manaki,3 Iryo Higai Ichiyokai Harada Byoin, Hiroshima, Japan; 2Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; 3Ichiyokai East Clinic, Hiroshima, Japan; 4Ichiyokai Yokogawa Clinic, Hiroshima, Japan; 5Hiroshima Daigaku Byoin, Hiroshima, Japan.

Background: We evaluated the effect of predilution online hemodiafiltration (HDF) on body composition, nutritional status and all-cause and cardiovascular (CV) mortality in maintenance dialysis patients.

Methods: All subjects (n=215) had blood flow rate of ≥200 mL/min and underwent HDF with a convective volume of 40 L/session or hemodialysis (HD), 4h/session, 3 times/week. Predialysis clinical data and same day postdialysis body composition parameters were subjected to machine learning methods to predict intradialytic SAS, as quantified by the ODD value and the SAS classification by the American Sleep Disorders Association.

Results: We examine intradialytic SAS severity in 16 patients (age of 54±11 years, 63% males, 39% Black) with arteriovenous vascular access. Mean SaO2 was 94.3±2.1%. Figure 1A shows a typical SaO2 annotated with the SAS intensity assessed by ODD. Two calculated metrics are plotted in Figs. 1C-D. The results reveal dynamic characteristic patterns of SAS with differential severity scores during HD. Figures 1E-G show the ROC for the classifiers when considering episodes of at least mild, moderate, or severe SAS, respectively. The maximum AUC is 0.93 for severe SAS episodes.

Conclusions: Our analysis suggests that entropy and recurrent-based quantifiers could be used as predictive indicators of intradialytic SAS. However, further studies are needed to assess their relationships to clinical outcomes.

Leveraging Technology and Innovation to Predict Events and Improve Dialysis Delivery

DENALI, a Phase 3b Multicenter, Open-Label Single-Arm Study of Roxadustat: Operational Learnings Within US Dialysis Organizations
Arnold L. Silva,1 Gopal Saha,2 Jeffrey L. Hymes,3 Lynda Szczecz,2 Yemisi Oluwatotin,2 Zhiqun Gong,2 Kenny Cooper,3 John W. Larkin,1 Boise Kidney & Hypertension Institute, Meridian, ID; 2FibroGen Inc, San Francisco, CA; 3Fresenius Medical Care North America Nashville, Nashville, TN; 4AstraZeneca, Wilmington, DE; 5Fresenius Medical Care North America, Waltham, MA.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitor that promotes erythropoiesis and improves iron availability in patients with anemia of chronic kidney disease (CKD). This trial aims to provide practical data on roxadustat use in dialysis patients with anemia via a semi- pragmatic evaluation of introduction into providers’ practices (Fresenius Medical Care).
Methods: This open-label, single-arm study assesses the efficacy and safety of roxadustat in correcting/maintaining hemoglobin (Hb) in patients with CKD-related anemia receiving in-center hemodialysis at nine US sites (NCT04410198). Initial roxadustat dose is weight-based (erythropoiesis-stimulating agent [ESA]- naïve patients) or guided by an ESA dose-conversion algorithm (ESA patients), in this trial targeting Hb=11±1 g/dL. Roxadustat dose is titrated every 4 weeks based on Hb level or rate of change, with 24-week treatment duration and up to 1-year extension. Efficacy is assessed by change from baseline in Hb and proportion of patients achieving mean Hb ≥10 g/dL averaged over weeks 16-24. Exploratory endpoints include time to first red blood cell transfusion, proportion of patients achieving mean Hb ≥10 g/dL in first 8 weeks, intravenous use, and dosing adherence. Safety endpoints include treatment-emergent adverse events (AE), with COVID-19 positivity an AE of special interest.

Results: This ongoing trial was successfully initiated and enrolled (n=203) during the COVID-19 pandemic, with modifications for home dialysis. Baseline characteristics appear representative of the US dialysis population (Table).

Conclusions: This trial adds to phase 3 studies of roxadustat by evaluating its use in treating anemia of CKD in home/in-center dialysis patients during the COVID-19 pandemic, while providing a view into operationalization and ease of real-world use. Full study results will be presented.

Funding: Commercial Support - FibroGen and AstraZeneca

Table: Key Baseline Characteristics in DENALI Patient Population.

PO0942
Validation of Urea Removal in Novel Sorbent Dialysis System

Background: The Diallyt Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aim: To assess urea mass removal during a simulated dialysis utilizing a novel sorbent filter.

Methods: Nine simulated dialysis sessions were conducted utilizing between 50L and 125L volumes of dialysate circulated at approx. 400 mL/min & 37°C through a sorbent cartridge with a standard dialysate. (Table 1) It is expected that with each pass through the filter the dialysate urea mass will decline. The experiment is continued until breakthrough occurs or the infrusate outlet reaches 10 ppm of NH3. A solution containing K2, Ca and Mg salts were constantly infused to replenish electrolytes lost in each pass. Another solution was infused at a variable rate as determined by conductivity to maintain Na Balance.

Results: The results are provided in table 1. The average URR was 63.8 % ranging from 53.3 to 87.0 %. The average starting HUN was 48.2 mg/dL and the average ending HUN was 16.8 mg/dL.

Conclusions: The initial experiments using a sorbent filter demonstrate a URR of near 65 is feasible. Future design changes will be scaled to handle larger amounts of urea and provide acceptable clearances.

Funding: Commercial Support - Diallyt Inc

PO0943
Effect of Hemodialysis on Amyloid-β in Cerebrospinal Fluid and Plasma
Lin-Chun Wang,1 Ohnmar Thwin,1 Joshua E. Chao,1 Amruth U. Patel,1 Ludovic DeBarre,2 Nadja Grobe,3 Xia Yao,3 Hanjie Zhang,3 Stephan Thijssen,3 Thomas Wisniewski,3 Peter Kotanko.1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY; 2NYU Langone Health, New York, NY.

Background: Hemodialysis (HD) can reduce amyloid-β(Aβ) species in whole-body circulation by 30 to 50%. Due to the dynamic exchange of Aβ between the brain and the blood, we hypothesized that HD might lower Aβ levels in the cerebrospinal fluid (CSF).

Methods: In a dialysis network with over 160,000 patients, we identified three maintenance HD patients (age 36±9 years) with ventriculo-peritoneal (VP) shunts who were subsequently recruited for this IRB-approved research study. Study subjects were dialedyzed on Monday, Wednesday, and Friday. Plasma samples were collected at 6 timepoints during the 3 HD sessions. One subject was withdrawn over safety concern related to the VP shunt tap procedure. Two subjects further underwent VP shunt taps for CSF sample collection before and after the Wednesday and Friday HD sessions, and once on interdialytic days (Tuesday, Thursday). Aβ1-42 and Aβ1-40 were quantified by Neuro 3-Plex SIMOA assays (Quanterix, MA, USA).

Results: HD effectively reduced plasma Aβ1-42 by 41% and Aβ1-40 by 34% (Fig 1a and 1b, p < 0.01). In CSF, levels of Aβ increased after Wednesday HD sessions in subject 1 (Aβ1-42: 4.2-fold, Aβ1-40: 5.5-fold) and subject 2 (Aβ1-42 and Aβ1-40: 1.06-fold), while Aβ1-40 decreased after Friday HD sessions in both subject 1 (Aβ1-42: 0.1-fold, Aβ1-40: 0.7-fold) and 2 (Aβ1-40: 0.7-fold, Aβ1-40: 0.7-fold) shown in Figure 1c–f.

Conclusions: This is the first report of Aβ dynamics in the CSF and plasma of HD patients. While plasma levels were in similar ranges, we found high inter-individual variations of CSF levels. Different plasma-to-CSF ratios after HD may reflect individual brain Aβ pools that are accessed by HD. We corroborate previous reports demonstrating the removal of Aβ from the blood compartment by HD.

**Circulating Microbiome and Cardiovascular Death in Patients with ESRD**

Keichi Sumida, Joseph F. Pierre, Zhongji Han, Tahliyah S. Mims, Praveen Kumar Potukuchi, Susmita Datta, Csaba P. Kovacs. The University of Tennessee Health Science Center, Memphis, TN; University of Florida, Gainesville, FL.

**Background:** Patients with end-stage renal disease (ESRD) suffer from disproportionately high cardiovascular (CV) mortality. Accumulating evidence suggests a role for the circulating microbiome (CM) in the pathogenesis of CV disease; however, little is known about its association with premature CV mortality in ESRD.

**Methods:** In a pilot case-control study of 17 hemodialysis (HD) patients who died of a CV event and 17 matched HD controls who remained alive during a median follow-up period of 2.0 years, we compared the levels and composition of CM, including Bacteria, Archaea, and Fungi in serum samples by quantitative PCR and 16S or Internal Transcribed Spacer (ITS) ribosomal RNA (rRNA) sequencing, respectively. Association of the CM with CV death were examined using multivariable conditional logistic regression.

**Results:** 16S and ITS rRNA was detectable in all (except 3 for ITS) examined patients’ serum samples. Despite no significant difference in 16S rRNA levels and diversity between cases and controls, taxonomic analysis demonstrated differential community membership between groups, with significantly greater Actinobacteria and less Proteobacteria observed in cases than controls at the phylum level. At the genus level, Staphylococcus was numerically higher in cases than in controls, albeit not significantly.

**Conclusions:** Alterations of the CM may be associated with a higher risk of premature CV mortality in ESRD patients. Supported by NIDDK.

**Dysregulation of Fibrinolytic Process Contributes to the Thrombotic and Bleeding Complications in ESRD Patients**

Faksha Siddiqui, Vinod K. Bansal, Omer M. Iqbal, Emily Bontekoe, Jawed Fareed. Loyola University Health System, Maywood, IL.

**Background:** End stage renal disease (ESRD) is a complex syndrome involving both cellular and humoral mechanisms. Both thrombotic and bleeding complications are observed which may result in cardiovascular and cerebrovascular adverse outcomes. Fibrinolytic system placed an important role in the regulation of hemostatic process. A comprehensive profiling of the components of fibrinolytic process may provide additional understanding of the bleeding and thrombotic complications in ESRD.

**Methods:** Citrated whole blood samples were collected from a cohort of ESRD patients (n=95). Normal citrated plasmas were obtained from healthy male and female individuals. These samples were analyzed for prothrombin time (PT), activated partial thromboplastin time (aPTT), prothrombinase-induced clotting time (PicT) and thrombin time (TT) using clot based technique. Fibrinolytic parameters such as urinokinase type plasminogen activator (uPA), plasminogen activator inhibitor-1 antigen (PAI-1), and D-Dimer were measured by using ELISA method. Functional PAI-1 was measured by using an amyodylthactic method. All results were compiled as group means ± SEM and respective ratios were calculated.

**Results:** All of the clotting results showed varying levels of elevated values in comparison to normal plasma. uPA levels showed wide variations and were increased (1.6 fold). D-Dimer was markedly increased in the ESRD patients (11.53 fold). Both functional (1.2 fold) and antigenic (3.07 fold) levels of PAI-1 were increased. Interestingly, the PAI-1 antigen levels was much higher in contrast to the functional levels suggesting a progressive consumption of this mediator.

**Conclusions:** These results suggest that the overall hemostatic system in ESRD patients is dysregulated due to the imbalance of the inhibitors such as PAI-1. The persistent activation of fibrinolysis is due to the increase production of uPA which facilitates endogenous fibrinolysis resulting in the elevation of D-Dimer. The generation of fibrinolytic enzymes results in increased fibrin/fibrinogen degradation products which may contribute to the observed intrinsinc and extrinsic coagulation defects as measured by the prolongation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting test may be helpful in the risk stratification and prediction of adverse outcomes in ESRD patients.

**PO0946**

**Successful Treatment of Systemic Calciumis in a Teenager on Hemodialysis**

Naile Tufan pekkucuksen, Mohammed Al-Humiari, Sai Sudha Mannemuddu, Lawrence R. Shoemaker. University of Florida, Gainesville, FL; East Tennessee Children's Hospital, Knoxville, TN.

**Introduction:** Systemic calcinosiis is rare in pediatric ESKD patients compared to adults. The subcutaneous tissues are most frequently involved. We present teenager in whom calcinosiis was detected incidentally on chest radiograph, and review its successful treatment.

**Case Description:** A 15 yo anuric female who had received hemodialysis(HD) for 18 months after renal transplant failure, was treated for progressive respiratory distress in the ICU. Significant history included osteoporosis, hypertensive cardiomyopathy, and renal failure since age 1. Chest-XR revealed bilateral pulmonary infiltrates and calcified lesions. Thoracic CT scan demonstrated calcified tracheal and bronchial cartilage rings. Flexible bronchoscopy revealed diffuse white/grey nodules throughout the wall of tracheobronchial tree. All cultures were negative. When notified of the finding of calcifications on CT scan, patient’s mother also asked about the firm nodules in the space between patient’s fingers. Dialytic phosphate (P) clearance, and non-calcium(Ca), non-aluminum(Al) based binder use were maximized, using sevelamer and lanthanum carbonate. Sodium thiosulfate and etalcalcetide were given iv post each dialysis. Dialysate Ca varied between 1.60-2.53 mg/dL, to avoid hypocalcemic stimulation of PTH and high CaXP. Lanthanum was discontinued after 3 months, once P levels declined. Other therapies were continued for 10 months; with monthly dose adjustment. PTH level decreased and P levels normalized. Etalcalcitide was reduced to maintain normal Ca level. After 10 months, is panimidoste was initiated to prevent further demineralization. This led to transient marked elevation in PTH. Combined therapies led to resolution of calcinosiis. However, tracheobronchial calcifications have not been reassessed, since neither chest imaging nor bronchoscopy have been clinically indicated.

**Discussion:** Calcinosiis is uncommon, yet treatable condition in pediatric dialysis patients. Combined use of old and new therapies was successful. Reversed side effects of therapies affects aging. Ectalcalcitide often causes hypocalcemia. Thiosulfate use is associated with nausea. Lanthamum is an effective metal Ca binder, but prolonged use may lead to accumulation and systemic deposition. The emergence of new P binders: ferric citrate, sucroferric oxyhydroxide, and bixalomer will offer exciting new treatment options.
Severe Thrombocytopenia due to Electron-Beam Sterilized Polysulfone Dialyzer Membrane Reaction

Zachary Chandler, Iritza Hasan, Vishal Jaikaransingh, University of Florida Health Science Center Jacksonville, Jacksonville, FL

Introduction: We describe a case of severe thrombocytopenia due to reaction with an electron-beam sterilized polysulfone (PS) membrane. This phenomenon has been previously described but is rarely reported. E-beam sterilized PS membranes are classically more biocompatible than cellulose-based membranes but adverse reactions may occur as demonstrated in our case.

Case Description: A 74 y.o. woman with CKD Stage 4 and secondary hyperparathyroidism presented for evaluation of generalized weakness, anorexia, and weight loss. Her past medical history included gout, short bowel syndrome following prior bowel resection and osteoporosis. Home medications were allopurinol, calcitriol, gabapentin, fluoxetine, and mirtazapine. She was started on hemodialysis (HD) for suspected progression to ESRD. She developed progressive thrombocytopenia (Figure 1) that was more following HD1 with improvements on non-HD days. Evaluation of usual culprits of thrombocytopenia was unrevealing. Reaction to the polysulfone filter was suspected and she was switched to a cellulose-based filter with resolution of her thrombocytopenia. She was dialyzed with a PS membrane on HD20 as proof of concept with recurrent thrombocytopenia following HD2. She was dialyzed with cellulose-based filter thereafter with no further thrombocytopenia.

Discussion: We describe a case of PS-membrane induced thrombocytopenia. It is hypothesized that e-beam radiation may affect membrane integrity or structure, or produce intermediary products which may cause platelet activation, aggregation, and adhesion and therefore thrombocytopenia. This entity should be considered in the differential diagnosis of patients undergoing HD who develop thrombocytopenia. Early recognition may reduce incidence of bleeding and need for blood products in these patients.

The frequency of treatments reported on a Saturday was only 92% of that on a Tuesday. The frequency of by-pass (or alerts) was not related to day of the week.

Conclusions: The variation in frequency of treatment by the day of week suggests “social” causes — i.e. a “night off” is more frequent on the weekend. Either some form of treatment event or alert is present in a substantial minority of APD sessions. The relationship of these events with technique survival is important, but not yet known. In this time linked data will allow examination of events recorded during treatment with patient outcomes.

Feasibility of a Staff-Assisted Peritoneal Dialysis Program in the United States: Results of a Pilot Study

Wael F. Hussein,1,2 Graham E. Abra,1,2 Paul N. Bennett,1,3 Jugjeet Atwal,1 Veronica Legg,1 Brigitte Schiller,1,2 Satellite Healthcare, San Jose, CA; Stanford University School of Medicine, Stanford, CA; University of South Australia, Adelaide, SA, Australia.

Background: Staff-assistance can support patients to utilize peritoneal dialysis (PD) and is available in many countries but not in the US. We report on the initial experience from a feasibility study for staff-assisted PD in the US.

Methods: An assisted PD program was initiated at one home dialysis center in Aug 2020, and expanded to a total of 6 centers by Feb 2021. Home assistance by non-registered nurse staff was offered to patients with barriers to self-care with the aim to support patients and families to become independent from staff assistance.

Results: Participating centers referred 33 patients (range: 0 – 16 referrals) (16 referrals were cancelled [admission from HD to the home program cancelled (3 referrals), treatment not tolerated (2), patient preferred to continue HD (5), death (3)]). Of the 17 referred, 15 patients started staff assistance (less than 3 months of assistance (8), and death (1)), 3 referrals are pending, and 14 patients received staff assistance at home. Of those who received assistance, median age was 72 years (34-87 years), and 8 were new to PD. Indications included: physical weakness (10 patients), cognitive difficulties, and psychosocial issues (7). One prevalent PD patient required assistance following a PD peritonitis episode. Anxiety and lack of confidence were common among referred patients. Staff member attending the patient’s home assisted with removal and replacement of PD bags (5 patients), machine setup (9), dressing of exit site (7), checking the blood pressure (2), and other requests (8) such as documentation. Assisting staff worked with patients to build problem-solving skills, gain self-confidence, and arrange a safer home environment. Median length of time on the service was 17 [IQR: 6 – 23, range: 2 – 49 days], and median number of visits was 15 (range: 4 – 38, IQR: 5 – 26) visits/patient. Median revisit duration was 45 (range: 15 – 90) minutes. Seven of the patients who finished are more than 90 days after starting assistance. Six of them remain on PD and one patient transferred to HD.

Conclusions: Staff-assistance can support patient transition to, and maintenance on, PD. Such programs are operationally feasible with non-RN staff in the US and should be supported by Medicare and regulatory agencies.

Increasing the Prevalent Peritoneal Dialysis Patient Population Can Be Challenging

Hari Dukka, Emma Edwards, Anil Jain, Dhawal Arora. University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.

Background: Peritoneal dialysis (PD) can provide better quality of life for patients requiring renal replacement therapy compared to in centre dialysis. It can be challenging to increase prevalent patient population on PD after a certain number is reached. We did a retrospective analysis to assess the turnover of patients on PD over a 8 year period and to understand the reasons for a stagnant prevalent PD population in the renal unit in Royal Derby Hospital.

Methods: Electronic medical records were used to track the number of prevalent PD patients enrolled each year from 2009 to 2017. Reasons for stopping PD and duration of technique survival were noted. If technique failure resulted in conversion to haemodialysis, it was noted for more than 3 months, the cause of the failure was also noted. Patients who converted to HD for less than 3 months were excluded from the study.

Results: The number of patients starting (n=324) and dropping off PD (n=322) was similar for each year between 2013 to 2020. Modality switch to haemodialysis accounted for 40-60% of patients stopping PD, followed by death (15-30%) and patients receiving renal transplantation (10-35%). Modality switch to haemodialysis was primarily due to infection (60-80%), poor clearances and ultrafiltration failures (10-30%), social reasons (10-15%). Among patients who switched to HD due to an infection, peritonitis accounted for 75-85% of the cases followed by exit site and tunnel infections (15-25%).

Conclusion: Increasing the prevalent population on PD can be challenging even with a high incident PD population. Having mechanisms which prevent infections, early identification and treatment of infections may help increase prevalent PD population.

PO0952

Disparities in Kidney Care: Where Care Needs to Be Equal

Background: Disparities in kidney care are widespread and gaining more attention. This research focuses on care differences that existed between home hemodialysis (HHHD) and in-center hemodialysis (ICHD) patient from 2017 to 2020.

Methods: Using a HIPAA-compliant, online chart review tool, nephrologists submitted de-identified clinical and non-clinical demographic information beginning at the time of patient referral and concluding with details from the most recent visit. These data, from 2017 through 2020, were then merged with the physician demographic profile and attitudinal responses. The full data set of 4,062 patient charts submitted from 1,021 nephrologists was analyzed in SPSS.

Results: Given the efforts to promote home modalities, nephrologists are following status quo and continue to initiate new dialysis patients on in-center hemodialysis. Nephrologists' current patient loads consist of, on average, 5 HHHD patients and 9 ICHD patients. On average, they initiate one new patient on HHHD compared to 17 new ICHD patients per year. When comparing HHHD and ICHD patient charts there are substantial differences between the two patient types. ICHD patients tend to be Caucasian and from higher education and socioeconomic levels: 52% are Caucasian and 25% are African American, 37% have some college (14% have an advanced degree), and 67% are middle or upper class. Conversely, ICHD patients tend to be more diverse (40% are Caucasian, 40% are African American), less educated (24% have some college and 5% have an advanced degree) and from lower socioeconomic classes (44% are lower or lower-middle class). Further, 40% of patients on home modalities are employed part- or full-time, versus 18% of patients on ICHD. Insurance coverage – both at dialysis initiation and current – influence modality choice as well. Notably, 70% of patients on home modalities were followed prior to dialysis, whereas only 48% of patients on ICHD were followed pre-dialysis, and patients on home modalities are substantially more likely to be on the transplant list versus ICHD patients (62% versus 37%).

Conclusions: Disparities in care exist between patients receiving home hemodialysis versus in-center home hemodialysis. As kidney care continues to evolve, physicians will need to account for these differences in their treatment paradigms to ensure they provide comparable care across patients.

PO0953

Characteristics and Treatment Patterns of Dialysis Providers Randomly Assigned to the Medicare ESRD Treatment Choices Model

Adil G. Thosar, Kelsey M. Drewrey, Zhong Yang,1 Rebecca Thorsness,2 Amal Trivedi,3 Rachel E. Patez,4 Hennepin County, Minneapolis, MN; 1University of Pennsylvania, Philadelphia, PA; 2Brown University, Providence, RI.

Background: In January 2021, Medicare’s End-stage Renal Disease Treatment Choices (ETC) model randomly assigned 30% of US dialysis facilities to receive financial bonuses and penalties on the basis of their home dialysis use, waitlisting, and living-donor transplantation among their patients, compared with benchmarks from non-ETC-assigned facilities. We assessed whether sampling variance may influence ETC performance by comparing pre-ETC treatment use among ETC-assigned and non-assigned facilities.

Methods: We compared rates of transplantation (living and deceased donor transplantation) and home dialysis use (peritoneal dialysis, home hemodialysis) at 12 months among patients with incident kidney failure during July 2014-June 2018 in future ETC and non-ETC dialysis facilities (n=7527 facilities, n=192755 patients). In logistic regression models with region random effects and Bonferroni-adjusted robust standard errors, we assessed associations between ETC assignment and patient and facility characteristics (ownership, home dialysis offerings, staffing), patient case-mix (demographic, clinical, and insurance characteristics; mortality), and area-level socioeconomic status (e.g., median household income).

Results: Prior to ETC, patients in ETC-assigned facilities had 22% (0.71 pp) higher rates of living-donor transplant receipt (p<0.005), 24% (0.89 pp) higher rates of deceased-donor transplant receipt (p=0.001), and 9% (3.3 pp) lower mortality rates (p<0.001) at one year versus in non-assigned facilities. Rates of home dialysis use were similar for ETC-assigned and non-assigned facilities, 21% (2.0 pp) more likely to be owned by a small-for-profit chain and 16% (5.8 pp) more likely to be owned by the second largest dialysis organization (p=0.001). Adjusting for other factors, dialysis facilities were more likely to be ETC-assigned if their patients were younger and if they had a lower percentage of patients who were Hispanic (both p<0.001).

Conclusions: Due to sampling variance, ETC-assigned facilities may be disproportionately likely to receive bonuses (vs penalties) under the model, even if they do not increase home dialysis treatment and transplant receipt among their patients.

PO0954

Novel Transitional Care Unit Design Achieves >50% Home Dialysis Choice in Incident ESRD Patients

Background: In 1983 Eschbach reported that a 6 station Home Dialysis (HD) Orientation Unit at Northwest Kidney Center had a 62% success rate in incident ESRD pts choosing HD. The RV CARE study of intensive in center HD education during routine thrice weekly dialysis had 38% of pts chose HD. Satellite Dialysis found that with their Transitional Care Unit (TCU) 30 % of pts chose HD.

Methods: We designed a 6 station dedicated TCU staffed with the added benefit of its main teaching nurse having 4 years each of being a home hemodialysis (HHD) & peritoneal dialysis (PD) nurse coordinator. The unit contains 3 NxStage & 2 Liberty Select Peritoneal cyclers. Pts are dialyzed 4 times weekly on the Nxstage or eventually the cyclers. Additional support is given by dialysis nurses trained in HHD & PD as are the social worker and dietitian educators. Intensive education with a defined curricula in all forms of HD are given including shared decision making with families. A medical director highly skilled in HD therapies also re-enforces the education delivered by the entire team every week. All 67 of our pts starting dialysis since July 2020 received standard dialysis education with several phone or virtual education sessions from our outpatient CKD coordinator, description of the TCU, plus a home visit by one of our HD coordinators.

Results: Since July, 2020 67 pts have started ESRD therapy, with 35 choosing not to enter the TCU and 32 choosing the TCU. Only 7 of 35 pts received the standard way chose HD, 4 PD & 3 HHD but 17 TCU pts out of 32 chose HD, 10 HHD & 7 PD, 53%, p=004 compared to standard education. There were no significant differences in duration of nephrology followup, age, sex or causes of ESRD between the 2 groups.

Conclusions: We conclude the success of our TCU is due to the following: 1) Pre-ESRD education about the benefits of starting dialysis in a TCU & 2) Most importantly having a skilled and experienced home HD and PD nurse coordinator to be the main educator and pt champion for both HHD adn PD. 3) Utilizing a HD skilled medical doctor & social worker using shared decision making adds confirmatory education on the benefits of HD.

Home Hemodialysis with the Tablo System: The First 1000 Real-World Treatments

Michael A. Aragon, Yadaveer Chahal, Brittany Lim, Josh Schumacher. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System is an all in one, easy-to-learn device capable of achieving clearance goals in as little as three treatments per week. It features integrated water purification, on demand dialysate production and two-way wireless data transmission. Tablo obtained FDA clearance for home hemodialysis (HHD) in March 2020. Approval was based on a prospective, crossover trial (in-center and at dialysis) where Tablo successfully met all safety and effectiveness endpoints, reported high rates of treatment adherence and patient retention, with greatly reduced training time (NCT02460263). The objective is to report on the first 1,000 treatments performed on Tablo by patients at home in the real-world.

Methods: Incident and prevalent patients currently performing in-center dialysis, PD, or HHD were initiated on Tablo at participating Home Dialysis programs. Patients were initiated by facility nurses on the Tablo device prior to beginning treatments at home. Data on the first 1000 treatments was obtained wirelessly via Tablo's data platform along with corresponding patient training data.

Results: The first 1000 treatments occurred in 20 patients, with a mean follow-up duration of 3.4 months. Patient training on Tablo was completed over an average of 7.4 training sessions. Retention was 98% for patients initiating treatment on Tablo. Mean prescribed treatment time was 3.2 hours with a mean frequency of 3.7 treatments.
per week. Mean total UF per treatment was 1.9 L. Mean UF rate per treatment was 7.3 mL/kg/h. Treatment adherence was 93%, with 95% of treatments completing within 10% of prescribed time. The mean number of clinically significant alarms per treatment was 1.0 (± 3.0), with an average time to resolution of 10.7 (± 18.5) seconds.

**Conclusions:** Results from the Tablo IDE demonstrating reduced training time, increased treatment adherence, high treatment success rate and a low occurrence of treatment alarms are reproducible in the real world at a frequency of 3-4 treatments/week. This data supports that Tablo is capable of successfully achieving clinical goals while reducing the overall patient burden often associated with HHD.

**Recent Trends in Utilization of Home Dialysis Modalities, Overall and by Duration of ESKD**

**Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen.1 (Hennepin Healthcare Research Institute, Minneapolis, MN; University of Minnesota Twin Cities, Minneapolis, MN.**

**Background:** The Executive Order on Advancing American Kidney Health and the End Stage Renal Disease Treatment Choices payment model have focused attention on increasing utilization of home dialysis. We assessed trends in home dialysis utilization between 2016 and 2021, including variability in trends among strata defined by duration of end stage kidney disease (ESKD).

**Methods:** We analyzed dialysis facility admission and discharge data extracted from the End Stage Renal Disease Quality Reporting System in May 2021. During the epidemiologic week of each year from 2016 to 2021, we identified patients undergoing maintenance dialysis at the beginning of the week. For each patient, we identified the current dialytic modality. We estimated trends in utilization of each modality, overall and by duration of ESKD at the beginning of the week (<2, ≥2, 4, 5-9, and ≥10 years).

**Results:** Between 2016 and 2021, home dialysis utilization increased from 11.5% to 14.3%, with the majority of growth occurring since the beginning of 2019 (figure). Concurrently, HHD utilization increased from 1.57% to 2.23%, whereas PD utilization increased from 10.0% to 12.0%. Among patients with ESKD duration <2 years, home dialysis utilization increased from 14.8% in 2016 to 20.0% in 2021, with >90% of utilization in this stratum due to PD. Among patients with ESKD duration 2-4 years, home dialysis utilization increased from 11.7% in 2016 to 13.7% in 2021. Among patients with ESKD duration ≥10 years, home dialysis utilization hovered around 9%, although HHD utilization reached a high of 3.65% in 2021, representing nearly 40% of home dialysis utilization in this stratum.

**Conclusions:** Growth of home dialysis utilization has accelerated since 2019, with greater absolute growth of PD and greater relative growth of HHD. Longer duration of ESKD is associated with lower utilization of PD, but higher utilization of HHD.

**PO0957**

**The Impact of Seasonality on Crash Starts and Home Dialysis Use**

**Eugene Lin,1,2 Kristhina I. Lung,2 Darius Lakdawalla.1 (University of Southern California Keck School of Medicine, Los Angeles, CA; University of Southern California Leonard D Schaeffer Center for Health Policy and Economics, Los Angeles, CA.**

**Background:** The US has made a concerted effort to increase home dialysis use. Dialysis “crash starts,” when patients emergently initiate dialysis in the hospital, are a barrier to home dialysis because they often preclude successful planning. We studied whether the season of the year was associated with crash starts and with home dialysis use among incident patients with end-stage kidney disease (ESKD).

**Methods:** From the United States Renal Data System, we identified all adults with at least 30 days of continuous Medicare Parts A and B coverage initiating dialysis from 2007-2017. We identified home dialysis use and whether patients were hospitalized within 14 days prior to the first outpatient dialysis treatment (i.e., “crash start”). Using multivariable logistic regression, we studied the association between season, likelihood of crash start, and starting dialysis at home. We used a Cox model to study whether crash starts were associated with ever using home dialysis in the first year. We adjusted for demographics, comorbidities, facility and geographic characteristics, and year of dialysis start.

**Results:** After adjusting for confounders and year of dialysis start, patients were less likely to start dialysis in the winter versus the summer (OR: 0.86, 95% CI: 0.82, 0.90). Conversely, patients were more likely to “crash start” into dialysis in the winter versus the summer (OR: 1.14, 95% CI: 1.11, 1.17). Patients with a crash start were substantially more likely to initiate with home hemodialysis (OR: 0.16, 95% CI: 0.15, 0.16) and were less likely to ever use home dialysis in the first year (HR: 0.41, 95% CI: 0.40, 0.42).

We observed seasonal heterogeneity in the admission diagnoses. Hospitalizations due to pneumonia, myocardial infarction, and congestive heart failure were 1.6, 1.4, and 1.3 times more likely to occur in the winter versus the summer, respectively. Hospitalizations due to diabetes, complications of devices, and chronic kidney disease were 1.05, 1.08, and 1.08 times more likely to occur in the winter, respectively.

**Conclusions:** We observed more dialysis crash starts in the winter and a subsequent decrease in home dialysis use in the first year. Winter hospitalizations were more often associated with cardiovascular and pulmonary etiologies. Clinicians should remain vigilant that patients may be prone to crash starts in the winter and should accelerate dialysis planning accordingly.

**Comorbidity Is Not Associated with Home Dialysis Choice**

**Sanne Vonk,2 Anna A. Benonkamp,1 Yolande Vermeerden,1 Anita van Eck van der Sluijs,1 Tiny Hoekstra,1 Aflonso C. Abrahams,2 Frans J. van Itersum,1 Brigit C. van Jaarsveld,1 DOMESTICO ‘Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; ‘University Medical Center Utrecht, Utrecht, Netherlands; ‘Department of Internal Medicine, Apeldoorn, Netherlands.**

**Background:** Over the past 15 years the proportion of Dutch home dialysis patients has decreased markedly. In addition, the rate of home dialysis varies significantly among centers. It is unclear whether this is the result of increased comorbidity, other patient characteristics or because dialysis centers perceive barriers for home dialysis differently. Our aim was to investigate the association between comorbidity and home dialysis choice.

**Methods:** The DOMESTICO study is a multicenter retrospective cohort study on home dialysis and randomly selected in-center hemodialysis patients. Comorbidity data was collected of patients who started dialysis between 2012 and 2017, including those who had previously received dialysis or obtained a kidney transplant. Patients who stopped dialysis or died within 30 days were excluded. Comorbidity was assessed with the Charlson comorbidity index (CCI). Home dialysis was defined as any peritoneal dialysis or home hemodialysis treatment during follow-up. Patients were followed until kidney transplantation, wish to stop dialysis, death or study end on 1 January 2017. Multivariable logistic regression analysis was used to assess the association between comorbidity and home dialysis, with a mixed model approach to adjust for dependency of patients within dialysis centers and for other patient characteristics including age, sex, and body mass index (BMI).

**Results:** Of 1358 included patients, 46% were treated with home dialysis. A high comorbidity score (CCI ≥5) was associated with a lower probability to receive home dialysis compared to patients without comorbidities (unadjusted OR 0.74, 95% CI 0.54–1.00). After adjustments for patient characteristics including age and BMI, there was no association between comorbidity and home dialysis. Only obese patients (BMI ≥30 kg/m²) with comorbidities had a significant lower likelihood to receive home dialysis compared to obese patients without comorbidities (medium comorbidity score (CCI 1-4) adjusted OR 0.40, 95%CI 0.18–0.86 and high comorbidity score (CCI ≥5) adjusted OR 0.43, 95%CI 0.20–0.93).

**Conclusions:** Comorbidity is not associated with home dialysis, after adjustment for several confounding factors including age and BMI. Future studies should aim at unraveling the center-specific characteristics that play a role in dialysis treatment.

**Funding:** Commercial Support - Nierstichting/Dutch Kidney Foundation – non-profit organisation. Grant no: AZ4DP02.
Reducing Routine Bloodwork in Home Dialysis Patients: A Quality Improvement Initiative

Epsita Shone-Vasanthan, Sophia Chou, David Ward, Juliya Hemmert, Jennifer M. MacRae, Elena Qirjazi. University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: There is a paucity of evidence for routine bloodwork frequency in maintenance dialysis patients to assess and manage complications such as anemia and mineral bone disease (MBD). Recent studies showed that decreasing the frequency in conventional in-center hemodialysis (ICHHD) patients had no negative impacts. Given the strain on lab services from the COVID-19 pandemic, Alberta Kidney Care-South (AKC-S) decreased the frequency of routine labs from monthly to every 2 months in home hemodialysis (HHHD) and peritoneal dialysis (PD) patients. We studied the effect of this change on patient outcomes.

Methods: We retrospectively compared prevalent home dialysis patients (>3 months) in AKC-S over two 6-month periods: a) Pre-pandemic May-Oct 2019 and b) Pandemic May-Oct 2020. Primary outcomes were number of routine bloodwork days and percentage of patients within target for anemia (hemoglobin, iron saturation) and MBD (calcium, phosphorus, parathyroid hormone). We also compared hospitalizations, mortality, technique failure (defined as transition to ICHD for >60 days), and cost.

Results: There were 366 home dialysis patients in 2019 (270 PD, 96 HHHD) and 400 in 2020 (296 PD, 104 HHHD). The number of routine bloodwork days decreased in 2020 compared to 2019 (p=0.01) (Fig 1). The proportion of patients who achieved anemia (33% vs 35%, p=0.44) and MBD (34% vs 28%, p=0.1) targets was similar. There was no difference in the number of hospitalizations (155 vs 141, p=0.34), deaths (13 vs 17, p=0.71) or technique failure (8% vs 5%, p=0.06). Projected cost savings were $102 per patient year from reduced labs.

Conclusions: AKC-S reduced the frequency of routine labs during the pandemic in home dialysis without negative consequences on patient biomarkers or outcomes. Our study suggests that bloodwork frequency in home dialysis patients may be safely reduced.

On-Demand Automated Peritoneal Dialysis Solution Generation

Jaine Uribari,1 Nabeel Aslam,2 Clinton Edwards,1 Lara M. Yamagata,4 Anders J. Wellings,2 Alyssa Wilmington,1 Ha Tran,1 Icahn School of Medicine at Mount Sinai, New York, NY; 2Mayo Clinic’s Campus in Florida, Jacksonville, FL; 3Saint Bernards Healthcare, Jonesboro, AR; 4Baxter Healthcare Corporation, Deerfield, IL.

Background: While automated peritoneal dialysis (APD) is an effective treatment for kidney failure, ordering, delivery and storage of supplies can be challenging. The APD Solution Generation System (SGS) allows for dialysate solution generation using tap water in a patient’s home with fewer supplies (Figure 1).

Methods: A 12-week single-arm, prospective, descriptive study was conducted with in-home APD patients. Patients were screened, trained and treated with the SGS. Endpoints included testing the final product against specifications for Dianeal and water purification ISO Standard 13959 and measuring PD adequacy. Adverse events and device deficiencies were collected.

Results: 22 patients were enrolled; 14 patients completed the study. Demographics are shown in Table 1. See Figure 1 for primary efficacy and safety endpoint results. All tested post-sterilization filter and final dialysis solution samples passed. Missing data for water purity attributed to only 56.9% of samples passing. Mean (SD) change from baseline for Kt/V was -0.15 (0.370). There were 2 peritonitis events (0.43 episodes per patient-year), 1 occurring in a patient with HIV. There were no safety signals.

Conclusions: The SGS has the technical capability to accurately and safely generate dialysate at the point of care, maximizes dialysis performance, and optimizes treatment protocol. Remote monitoring capability by SGS allows remote supervision and management, an efficient choice especially in Covid-19 times.
PO0962
Animal Trial of Sorbent Cartridge for Portable Artificial Kidney (PAK) In Vivo Maintenance Peritoneal Dialysis Using a Sorbent-Based PD Device in a Porcine Model
Suresha R. Duan,1 Yen N. Koh,1 Chieh-suai Tan,2 Kenneth Chen,2 Kun D. Zhuang,1 Dialysis Pte Ltd, Singapore, Singapore; 2Singapore General Hospital, Singapore, Singapore.

**Background:** The NextKidney/Dialysis HD Sorbent Cartridge (SC) uses a novel type of sodium-neutral sorbent to regenerate spent dialysate for standard hemodialysis (HD) therapies. The SC is intended to be used with the NextKidney sorbent HD device, where it produces fully physiological dialysate meeting today’s industry standards. We tested the safety and efficacy of the sorbent system in a total failure kidney pig model. The animals were maintained exclusively on sorbent HD for up to 2 weeks.

**Methods:** Three highly uremic pigs (60–75Kg) underwent a total of 14 alternate-day, 4h sorbent HD therapy sessions. Total renal failure was induced via bilateral renal artery embolization (pig #1), or bilateral laparoscopic ligation of renal arteries (pigs #2 and 3). A palindromic catheter provided blood flow rates of 200 – 300mL/min. A hemoperfusion machine was used for the blood circuit, coupled with a prototype device controlling the dialysate circuit. Dialysate was continuously purified in the SC at a flow rate of 300 mL/min. Therapy efficacy and mass balances were calculated from blood and dialysate samples collected before and after the dialyzer at specific time points.

**Results:** The animals tolerated the therapies well. The incision site at the femoral artery and vein was noted during internal bleeding and loss of the animal. Fourteen 4hr dialyses were averaged to calculate toxin removal efficacy and mass balances. The average clearances for urea, creatinine and phosphorus were 139, 146 and 141mL/min, respectively. Dialysate sodium and bicarbonate concentrations remained within the permissible deviations of +/-5% and +/-25%, respectively.

**Conclusions:** The biocompatibility of the sorbent system has been confirmed in fourteen 4h HD therapies conducted on three highly uremic pigs. The sorbent system was able to maintain the highly uremic animals. There were no severe adverse events related to the sorbent HD therapy. We currently plan to proceed to a first-in-human trial to evaluate the safety and efficacy of the sorbent cartrige for human use.

Thirty Days of Maintenance Peritoneal Dialysis Using a Sorbent-Based Automated Wearable Artificial Kidney (AWAK) PD Device in a Porcine Model
Manoj W. Foo,1 Hayi Huy,1 Edwina A. Brown,2 Sridhar Chirimarry,3 Marcin Pawlak,2 Siti N. Huda,1 Jason T. Lim,1 Sanjay Singh,1 Mandar Gori,1 Suressa B. Venkatary,1 Arsh Jain,4 Singapore General Hospital, Singapore, Singapore; 2Hammersmith Hospital, London, United Kingdom; 3AWAK Technologies Pte Ltd, Singapore, Singapore; 4Western University, London, ON, Canada.

**Background:** In sorbent-based PD, spent dialysate is processed and clean dialysate is re-introduced into the abdomen. Our aim was to determine if AWAK dialysis can maintain euvolemia and biochemistry for 30 days in a porcine model.

**Methods:** The study was conducted in a 5:6 nephrectomised pig (Sus Scrofa, male). Post nephrectomy, the animal was treated with CAPD (14 weeks) before commencing sorbent-based PD for 7 hour per day with initial fill of 2L 1.5% Dianeal for 30 consecutive days. Thereafter, the animal was maintained on standard of care (SOC) for 3 days (5x2L exchanges over 10 hour APD, with 1L last fill, 2.5% Dianeal).

**Results:** Stable serum concentration of toxins, electrolytes and inflammatory markers were noted during AWAK therapy (Table); with no significant change after switch to SOC. pH of regenerated dialysate was consistent with biocompatible solutions (figure 1) and appropriate change in ultrafiltration was observed in response to glucose infusion (figure 2).

**Conclusions:** AWAK PD therapy successfully treated a CKD animal model for 30 days, without adverse impact on volume status or clinical parameters. Future long-term human studies are needed for device enhancement.

**Funding:** Commercial Support - AWAK Technologies Pte Ltd

**PO0964**

**Smartphone Application to Assist Peritoneal Dialysis Patients for Timely Detection of Peritonitis**
Mia Garbaccio,1 Xia Tao,1 Xiaoling Wang,1 Xin Wang,1 Zahir S. Haq,1 Amrish U. Patel,1 Lela Tisdale,1 Ohnmih Thwin,1 Lin-Chun Wang,1 Nadja Grobe,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Timely detection of peritonitis in patients undergoing peritoneal dialysis (PD) is critical to lower the risk of catheter loss, morbidity and mortality (Mufuucumaran, 2016). Current practice of screening potential peritonitis events at home relies on patients’ visual detection of turbid spent dialysate and symptoms recognition. To assist patients with the timely capture of a potential peritonitis episode, we developed a smartphone app, which uses light detection to quantify cloudiness and estimate white blood cell (WBC) count in PD effluent (PDE). The app uses the built-in light sensor and compares measurements taken from the ambient light (Lambient) and light through PD bags (Lbag) to estimate dialysate cloudiness. PDE samples were obtained as part of two IRB-approved clinical studies over a period of 6 months. Cloudiness of each sample was measured 3x with the app. Cloudiness (in %) was calculated as (1 - Lbag/Lambient) x 100. WBC were counted using a hematology analyzer (Horiba 80XL).

**Results:** Patients maintained a stable baseline cloudiness of 2.5% (Fig 1). A peritonitis episode (subject PDMET0002) increased the cloudiness to 40%, which is 32 percentage points over the patient’s peritonitis-free baseline. One suspected peritonitis sample (albeit WBC’s <100 cells/mL) showed slightly higher cloudiness than non-peritonitis samples (Fig 2).

**Conclusions:** Our smartphone app can distinguish peritonitis from normal PD samples. Smartphone-enabled detection of cloudiness in PDE samples using light transmission is possible and has the potential to easily monitor and diagnose patients at risk for peritonitis. Studies to define diagnostic performance in a large patient cohort are underway.

Remote Monitoring of Patients with Automated Peritoneal Dialysis May Improve Clinical Outcomes: Analysis by Competing-Risk Regression Models
Ramón Paniagua, Marcela Avila, Alfonso Ramos, Abdul Rashid T. Qureshi, Bengt Lindholm, Mexican Nephrology Collaborative Study Group, Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; Baxter Novum CLINTEC, Karolinska Institutet, Stockholm, Sweden; Baxter Mexico, Mexico City, Mexico.

Background: Current information technologies allow remote monitoring (RM) of patients on automatic peritoneal dialysis (APD) and the adoption of proactive behaviors to prevent complications and improve treatment quality. We analyzed the effect of RM-APD on survival and preventable complications through a controlled clinical trial.

Methods: In a two-branched cluster RCT, hospitals with >100 prevalent, >50 new patients per year, and >5 years APD experience were randomly assigned to perform RM-APD or conventional APD with equivalent APD-equipment in adults beginning APD. The primary outcome was a composite index (CI) of death, first adverse event (AE) or first hospitalization. Secondary outcomes were the same variables considered individually and for their specific causes. All-cause and cardiovascular disease (CVD) mortality risk and AEs were analyzed with competing-risk regression with transplantation as competing risk.

Results: Eleven hospitals per arm were included and 815 patients were followed-up by at least one year, 417 using RM-APD and 398 on APD. Patients in hospitals using APD reached earlier the CI as well as its individual components. Patients with APD as compared to RM-APD were older, more inflamed, and had higher all-cause and CVD mortality. In competing risk analysis, after adjusting for age, sex, presence of smoking, hypertension, CVD and diabetes, APD as compared with RM-APD associated with higher subdistribution hazard ratio (sHR) for all-cause mortality (sHR 1.79, 95%CI (1.15-2.81); p=0.01), CVD-related mortality (sHR 2.21, 95%CI (1.07-4.38); p=0.03) and AE (sHR 1.74, 95%CI (1.34-2.25); p=0.001).

Conclusions: Use of RM-APD may improve survival and prolong the time to first AE and hospitalization in comparison with APD, suggesting that RM-APD may improve clinical outcomes in APD patients.

PO0966
Peritoneal Dialysis Discontinuation: Trends and Risk Factors

Background: Increasing use of dialysis home modalities among ESRD patients is a Centers for Medicare and Medicaid Services priority. This can be accomplished by increasing use of home dialysis among incident patients or by reducing PD discontinuation.

Methods: We identified incident ESRD patients from 2008 to 2018 who received peritoneal dialysis in their third month of ESRD treatment. We used data from CROWNWeb and Medicare claims to determine the patient’s modality 1, 2, and 3 years after initiation of ESRD treatment. We summarize trends in share of incident PD patients who were treated with PD at each follow up and describe differences by patient and facility characteristics.

Results: From 2008 to 2017, approximately 70 percent of incident PD patients remained on PD after 1 year of dialysis, 50 percent after 2 years, and 30 percent after 3 years of dialysis (figure 1). Over these years the percentage of incident PD patients treated with PD after two years rose from 47.9 to 52.3 percent. The rate of two-year PD persistence has declined modestly since a peak of 53.1 percent in 2013. PD patients treated at DaVita facilities were more likely than those treated at FMC or independent facilities to remain on PD after two years. PD patients treated at facilities with a higher share of PD patients were more likely to remain on PD after two years. Among incident PD patients, the rate of peritonitis during the first year of dialysis declined from 33.5 to 21.7 between 2010 and 2018. Peritonitis was more common among dual eligible patients, Black and American Indian/Alaska Native patients, and overweight or obese patients.

Conclusions: Differences in PD discontinuation and peritonitis incidence across patient and facility subgroups represent opportunities for future quality improvement efforts.

PO0968

Contemporary Incidence of Peritoneal Dialysis Attrition and Variability Therein Among Age Strata

Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen,1 Hennepin Healthcare Research Institute, Minneapolis, MN; University of Minnesota Twin Cities, Minneapolis, MN.

Background: With an increasing percentage of patients performing dialysis in the home setting, quality measurement systems should increase focus on home dialysis outcomes. Considering the central role of peritoneal dialysis (PD) in home dialysis, an important and readily estimable measure is the duration of PD before initiation of hemodialysis. We estimated the cumulative incidence of attrition due to initiation of hemodialysis among patients who recently initiated PD in the United States and assessed variability of incidence among age strata.

Methods: We analyzed United States Renal Data System Standard Analysis Files. We identified all patients who initiated PD in the home setting between January 1, 2011, and September 30, 2018, and within one year after diagnosis of end stage kidney disease (ESKD). We classified patients into cohorts of age 18-44, 45-64, 65-74, and ≥75 years. Overall and within age strata, we estimated the 5-year cumulative incidence of conversion to hemodialysis, with accounting for the competing risks of death and kidney transplantation.

Results: The cohort included 111,464 patients who initiated PD. The cumulative incidence of conversion to hemodialysis was 22.4% at 1 year, 33.9% at 2 years, 41.4% at 3 years, 46.3% at 4 years, and 49.4% at 5 years (figure). During those 5 years, 25.4% of patients died while receiving PD and 12.8% received a kidney transplant, thereby resulting in only 12.4% of patients still performing PD after 5 years. Among patients aged 18-44 years, 1-year (5-year) cumulative incidence of conversion to hemodialysis was 23.3% (51.1%); corresponding estimates were 22.3% (52.0%) among patients aged 45-64 years (48.3%), 21.9% among patients aged 65-74 years, and 22.5% (41.6%) among patients aged ≥75 years.

Conclusions: Regardless of age, between 22% and 23% of patients who initiated PD during the first year of ESKD transferred to hemodialysis within one year. Patient training is a critical component of the peritoneal dialysis (PD) program to ensure safe dialysis outcomes. However, there is a lack of clarity on how long patients should be trained before initiating PD at home. In this analysis, we evaluate the associations between the length of PD training and patient outcomes (early treatment attrition, peritonitis, and hospitalizations) among patients prescribed automated PD (APD).

PO0969

Length of Peritoneal Dialysis Training and Risk of Early Treatment Attrition

Harold E. Giles,1 Vidhya Parameswaran,2 Linda Ficocelli,2 Claude Mullon,2 Dinesh K. Chatoth,2 Michael A. Kraus,2 Michael S. Anger,2 Robert J. Kossmann,2 Nephrology Associates PC, Nashville, TN; Fresenius Medical Care, Global Medical Office, Waltham, MA; University of Colorado, School of Medicine, Denver, CO.

Background: Patient training is a critical component of the peritoneal dialysis (PD) program to ensure safe dialysis outcomes. However, there is a lack of clarity on how long patients should be trained before initiating PD at home. In this analysis, we evaluate the associations between the length of PD training and patient outcomes (early treatment attrition, peritonitis, and hospitalizations) among patients prescribed automated PD (APD).

Methods: Adult patients who initiated APD between 2017-2019 and received PD training at Fresenius Kidney Care facilities within 30 days of home treatments were included. Crude and case-mix adjusted risk of early PD attrition (discontinuation from PD within 3 months of enrollment due to switch to HD, death, or loss to follow-up) were compared between patients with a shorter (≤5 days), medium (6 to 10 days), and longer (>10 days) lengths of training. Early rates of peritonitis and hospitalizations were compared between patients with ≤10 days vs >10 days of training.

Results: 11,039 patients who received training ≤30 days prior to APD initiation were included. Compared to patients with a shorter PD training (n=3,333), patients with a medium length of training (n=6,310) had no significant difference in the risk of early attrition (Figure 1). Patients with longer PD training (n=1,396) had a lower risk of early attrition when compared to shorter PD training patients in the crude analysis, and no significant difference when controlled for case-mix variables (significant confounders: vintage, residual kidney function, and body surface area). There were no differences in the early rates of peritonitis and all-cause and peritonitis-related hospitalizations between patients receiving training for >10 days vs ≤10 days.

Conclusions: There were no significant associations between length of PD training and risk of early treatment attrition, hospitalizations, or peritonitis among automated PD patients.

PO0970

Identifying Patients on Peritoneal Dialysis at High Risk of Transfer to Hemodialysis Using a Modified Surprise Question

Ayesha Anwaar,2,1 Graham E. Abra,2,1 Hatsumi Nielsen,2 Sumi J. Sun,2 Sai Liu,1 Maria E. Montez-Rath,1 Brigitte Schiller,2,1 Wael F. Hussein,2,1 Stanford University School of Medicine, Stanford, CA; Satellite Healthcare, San Jose, CA.

Background: Transfer from peritoneal dialysis (PD) to hemodialysis (HD) is associated with poor outcomes. Available prediction models of modality transfer are limited to the incident PD population. Simple predictive tools are needed to help guide risk stratification and subsequent clinical interventions to avoid unwanted modality transfer. We report on the correlates of nurse prediction of high risk using the question “Would you be surprised if this patient transfers to HD in the next 6 months?” (PD Surprise Question [PDSQ]).

Methods: This observational study included 1362 adults on PD receiving care at 35 centers in 3 states in the US, managed by a non-profit dialysis organization. A ‘no’ response to the PDSQ indicated high risk. Using multivariable logistic regression with backward elimination, we evaluated characteristics associated with being identified as high risk, including socio-demographic variables, BMI, primary kidney disease, vintage, comorbid conditions, renal and dialysate clearances, serum albumin, sodium, phosphorus, potassium, nPNA, last 3 months peritonitis and hospitalization, and insurance type. We used multiple imputations to handle missing data.

Results: Responses were obtained from 95/112 (85%) nurses for 1193/1362 (88%) patients. Mean age was 59 (SD: 16) years, 41% were female, median ESRD vintage 37 (IQR: 11 – 44) months and 46% had diabetes. 198 (17%) patients were identified as high risk. In the final model, patients were more likely to be identified as high risk if they were hospitalized in the last 3 months (odds ratio [OR]: 1.52, 95% confidence interval [CI] 1.30-1.74, p<0.0002). Having a higher serum sodium (for 1 meq/L: OR: 0.95, 95% CI 0.90-1.00, p=0.032), being married (OR: 0.76 95%CI 0.52-1.00, p=0.029), and longer PD vintage (for 1 month: OR: 0.99, 95%CI 0.98-1.00, p=0.013) were associated with lower odds of being identified as high risk.

Conclusions: The PD surprise question is a simple tool to assess the risk of transfer from PD to HD. Identified correlates of risk are consistent with high risk factors from the literature for transfer to HD. We are currently observing outcomes of included patients to examine the performance of the PDSQ to predict transfer to HD.

Machine Learning-Driven Prediction of Peritoneal Dialysis Technique Failure

Caitlin Monaghan,1 Joanna Willett,1 Hao Han,1 Michael A. Kraus,1,4 Dinesh K. Chatoth,1,4 Len A. Usvyat,2 Franklin W. Maddux,2 'Fresenius Medical Care, Global Medical Office, Waltham, MA; 'Fresenius Medical Care AG & Co. KGaA, Bad Homburg, Germany; 'Baxter Mexico, Ciudad de México, Mexico; 'Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; 'Harvard University T H Chan School of Public Health, Boston, MA.

Background: Despite increased focus on starting and keeping dialysis patients on home therapy, Peritoneal Dialysis (PD) and Home Hemodialysis (HHHD) rates are lower than desired. Two areas of opportunity are 1) keeping PD patients healthy so they can remain on PD longer and 2) transitioning PD patients to HHHD when appropriate. To identify patients at risk of leaving PD in the short-(1-3 month) and long-term (3-6 month) timeframes, two machine learning (ML) models were developed. Along with risk scores, these models identify the factors driving increased risk to aid in prolonging time on PD while also allowing adequate notice to prepare for permanent access placement and HHHD education.

Methods: Data were extracted for PD patients (n=53022) from 2016-2019; patients contributed one set of observations for each month they were on PD (n=823892 patient months). PD failure was defined as the first discharge from PD lasting over 30 days, and was coded as ‘1’ if the patient changed modality in the next 1-3 or 3-6 months for the short- and long-term models, respectively. All other observations were coded as ‘0’, including censored events such as transplantation, loss to follow-up, or death. Two XGBoost ML models were trained using 80% of the dataset, with 20% used for evaluating model performance using 237 variables, derived from laboratory measurements, infection and hospitalization history, and other relevant clinical parameters.

Results: Evaluation of model performance on withheld data showed an area under the curve of 0.75 and 0.67 for the short- and long-term models, respectively. Patients were classified as High, Medium, or Low risk for each of their short- and long-term predictions. In the short-term model, the risk category dropped in the next 3-6 months for patients at high risk, a rate almost 5 times higher than average and 12 times higher than low risk patients. For long-term predictions, 14% of high risk patients dropped in the next 3-6 months, 6% of medium risk, and 2% of low risk.

Conclusions: The two ML models showed good discrimination between patient risk categories for both short- and long-term timeframes. Further work is underway to gauge the clinical utility of these tools, these tools offer the potential to improve care of “failing” PD patients, reduce morbidity of transitions, and increase optimal starts with dialysis access.

Nurse-Based Educational Interventions in Patients with Peritoneal Dialysis: A Systematic Review and Meta-Analysis

Tanawin Nosponn,1,3 Piyawat Kantagowit,1,4 Chitsanucha Chumsiri,1 Krit Pongpirul1,2 Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee 'Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 'Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; 'Harvard University T H Chan School of Public Health, Boston, MA.

Background: Peritoneal dialysis (PD) is a major renal replacement therapy modality for patients with end-stage renal disease (ESRD) worldwide. As poor patient self-care could lead to serious complications, including peritonitis, exit-site infection, technique failure, and death, several nurse-based educational interventions have been introduced. However, these interventions have varied and been supported by small-scale studies so the effectiveness of nurse-based educational interventions on clinical outcomes of PD patients have been inconclusive.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL. Selection criteria included Randomized Controlled Trials (RCTs) relevant to nurse-based education interventions in ESRD patients with PD in the English language up to February 20, 2020. The meta-analyses were conducted using a random-effects model to evaluate the summary outcomes of peritonitis, PD-related infection, mortality, transfer to hemodialysis, and quality of life (QOL).

Results: Of 7,240 potential studies, 61 theme-related abstracts were selected for further full-text articles screening against eligibility criteria. Ten studies (1,404 PD patients in seven countries) were included in the systematic review. Eight studies (1,363 PD patients in five countries) were included in the meta-analysis. Sleep QOL in the intervention group was significantly higher than control (mean difference 12.76, 95% CI 5.26–20.27). There was no difference between intervention and control groups on peritonitis, PD-related infection, transfer to hemodialysis, and overall QOL.

Conclusions: The two ML models showed good discrimination between patient risk categories for both short- and long-term timeframes. While further work is underway to gauge the clinical utility of these tools, these tools offer the potential to improve care of “failing” PD patients, reduce morbidity of transitions, and increase optimal starts with dialysis access.

Technique Failure in the Dominican Republic National Peritoneal Dialysis Program

Erwin I. Campos,1,2 Miguel A. Cuevas Budhart,3 Elianny S. Polanco,3 Jhanna H. Collado,1 Mercedes Aquey,1 Janny Guzman Chavez,4 Alfonso Ramos,3 Macrotech ‘Macrotech, Santo Domingo, Dominican Republic; ‘Hospital Salvador B. Gautier, Santo Domingo, Dominican Republic; ‘Baxter Mexico, Ciudad de México, Mexico; ‘Baxter Colombia, Bogota, Colombia; ‘Instituto Mexicano del Seguro Social, Ciudad de México, Mexico.

Background: Technique failure is a critical concern in peritoneal dialysis (PD), and it’s associated with significant risk of patient lost. Technique failure is defined as transferral to HD 30 days after initiation of therapy or death within 30 days of transfer to HD.

Methods: This is a retrospective multicenter observational cohort study of incident Peritoneal Dialysis patients conducted between January 1st 2016 to December 31st 2020. Competing risk events were death and kidney transplantation, and patients were censored for recovery of kidney function, withdrawal or suspension of the therapy, and loss of a caregiver. Disease characteristics and baseline demographics were included. Data are expressed as mean ± standard deviation for continuous variables and as frequency counts and percentages for categorical variables. Incidence rates were performed for transfer to HD and finally, logistic regression analysis between the inferential type variables to determine the risk between having a history of diabetes mellitus and the variables of death and transfer to HD were calculated using an Odds Ratio analysis with 95% confidence intervals for comparing the 3 risk levels.

Results: A total of 2326 patients were included, 59% men; the mean age was 57 ± 16 years, 53% had a diagnosis of Diabetes Mellitus (DM) and 65% had a basic educational level. 151 patients were censored (11%). Risk events were 1096 of which death accounts for 108 (7%) and PD Peritonitis 13% and ultrafiltration failure 13%.

Conclusions: The technique failure rate is similar to the reported in RTS Colombian PD Program, but below the mean of Latin American countries reports. Still, improvement needs to be done in the catheter implant technique and mortality rates.

PD Peritonitis

Quality of Life (Sleep)
Conclusions: In this single center observational study, peritoneal catheters placed laparoscopically with careful abdominal rectus tunneling allowed for larger volume dialysis exchanges without concern for supine positioning or intermittent use. One leak was noted and no other complications for an acceptable leak rate of 4% in this small study. This study demonstrates that PD can be initiated sooner post dialysis and larger volumes are well tolerated.

PO0975
Converting ESKD Patients on Peritoneal Dialysis to Hemodialysis Post Cardiac Surgery: A Necessity or Comfort
Elisa Basili,1 Milad Matta,2 Aimen Liaqat,1 Adam Fawaz,1 Georges Nakhoul,2 Joanna J. Taliercio,2,1 Juan C. Calle,2,1 Serge C. Harb,1 Haytham Elgharably,1 Susana Arrigain,1 Jesse D. Schold,1 Remy Daou,1 Ali Mehdi,2,1 Cleveland Clinic, Cleveland, OH; 2Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH; 1Université Saint-Joseph, Beirut, Lebanon.

Background: End-stage kidney disease (ESKD) patients on peritoneal dialysis (PD) undergoing cardiac surgery are sometimes converted to hemodialysis (HD) post-surgery. The reasons for this conversion are not well defined in the literature. We sought to examine the reasons cited for converting PD patients to HD post operatively after undergoing major cardiac surgery.

Methods: We examined ESKD patients on PD undergoing cardiac surgery from 2009-2019 using an electronic health records (EHR)-based Cardio-Thoracic Surgery (CTS) registry at the Cleveland Clinic. We identified PD patients who were converted to HD postoperatively. We reviewed the EHR to identify the main causes for conversion.

Results: 62 ESKD patients on PD undergoing major cardiac surgery were identified. 16 patients, representing more than a quarter, were converted to HD post operatively. Out of those converted, 31.25% were converted for absolute indications (18.75% for PD catheter malfunction, 3.125% for gait abnormalities), 25% for gait abnormalities, 25% for concern of pericardio-peritoneal communication. 67.5% were converted for less clear and relative indications (25% based on clinician preference, 47.5% for hemodynamic instability or requiring vasopressors). Results are displayed in (Table 1).

Conclusions: A small percentage of PD patients are converted to HD for absolute indications. Most patients are converted based on relative indications including lack of familiarity with PD and hemodynamic instability. As the number of ESKD patients on PD is expected to increase, a better understanding of the outcomes of PD patients post cardiac surgery is needed. In addition, more education is urgently needed to increase the comfort of practitioners managing PD patients in special situations that might be amenable to prescription alterations without premature transition to hemodialysis.

Table 1

PO0976
Effect of Low-Dose PD in Elder Population on Protein Energy Wasting, Functionality, and Quality of Life
Gloria G. García Villalobos, L. M. Perez-Navarro, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Elder population currently involves 55% of those who initiate dialysis. Age-associated pathologies, functional status (FS), protein energy wasting (PEW) and quality of life (Qol) need to be considered. CAPD can cause PEW, loss of functionality and QoL decline, adjusting treatment to Intermittent Ambulatory PD (IAPD) (low-dose) has the intention to decrease disadvantages while maintaining the benefits. The aim of this study was to evaluate the effect of low-dose PD on PEW, functionality and Qol.

Methods: A retrospective cohort of patients 60 years and older was analyzed. IAPD was defined as less than 16hrs of treatment per day. Clinical, biochemical data were collected. Katz, Lawton-Brody scales and EQ-5D-5L questionnaire were applied.

Results: 90 patients were on IAPD. Prescription of hrs/day of dialysis did not correlate with residual ureas (r =-0.52, p=0.612). Questionnaires: QoL, EQ-5D-5L found the majority of patients were in the highest/positive scores for every category assessed. In the same way, 44% of the patients had 80 points or more in their perception of Qol. (fig.1). FS was found to be associated with albumin and phosphorus (r=0.306, p=0.015; r =0.312, p=0.027). Functionality, 67% of patients were classified as independent (figure 2) and FS was associated with albumin, uretras and VAS QoL. (r =0.462, p=0.000; r =0.416, p=0.000; r =0.407, p=0.000 respectively). A model to identify the predictors of functionality was made. It was found that female, age >75y, ureass<500m/d, albumin >3.5g/dl and hours of dialysis predict negatively scores. The interaction between hours of dialysis and age have the biggest effect size.

PO0977
A Uremic Pig Model for Peritoneal Dialysis Research
Jooet C. de Vries,1 Maaike K. van Gelder,1 Anneke S. Munninkhof,1 Sabbir Ahmed,2 Diënty Hazenbrink,1 Tri Q. Nguyen,1 Koen Vaessen,2 Jaap A. Joles,1 Marianne C. Verhaar,1 Karin G. Gerritsen,1 1University Medical Center Utrecht, Utrecht, Netherlands; 2Utrecht University, Utrecht, Netherlands.

Background: The renewed interest in home dialysis requires a translational uremic large animal model to evaluate innovations in peritoneal dialysis. Ideally, toxin plasma levels should be comparable to those in dialysis patients, without requiring maintenance dialysis for survival. To this end, we developed a pig model with stable moderate chronic kidney disease.

Methods: CKD was induced in five female pigs by bilateral subtotal renal artery embolization aiming for embolization of ~85-90% of total kidney tissue. Temporary aggravation of uremia was induced with gentamicin (10 mg/kg twice daily for 7 days). We hypothesized this approach would lead to stable CKD without the need for maintenance dialysis. Peritoneal transport was assessed with a standard peritoneal permeability assessment.

Results: After embolization, urea and creatinine levels increased from 1.6±0.2 to 7.5±1.0 mM and 103±12 to 338±60 µM, respectively, followed by stabilization within 2 weeks to 2.5±1.0 mM and 174±25 µM, respectively. GFR (iohexol clearance) decreased from 49 mL/min to 28 mL/min. Gentamicin induced temporary acute-on-chronic kidney injury with peak urea and creatinine concentrations of 17.0±6.1 mM and 932±504 µM, respectively (Figure 1), while potassium (range 4.1-4.7 mM) and phosphate (range 2.33±2.67 mM) remained stable. Peak indoxyl sulfate and hippuric acid levels were 10.5 ± 0.85 mg/L and 75.3 ± 81.5 mg/L, respectively. Peritoneal dialysis, although complicated by peritonitis, could be successfully applied. Peritoneal transport assessment showed a low transport status (D/P creatinine (4h): 0.45±0.12) with an MTAC of 9.6±3.0, 4.6±2.5, 3.4±2.2 mL/min for urea, creatinine, and phosphate respectively.

Conclusions: We have established a pig model with stable moderate CKD without the need for maintenance dialysis. Temporary-on-demand acute-on-chronic kidney injury, resulting in uremic solute levels representative for ESKD, allows evaluation of novel dialysis methods.

Figure 1. Urea (left) and creatinine (right) plasma levels after administration of gentamicin (day 0). Mean ± SD, n=10 administrations in n=5 pigs.

PO0978
Recurrent Abdominal Pain in a Patient on Peritoneal Dialysis
Sandipan Shringi, Sri Vibhavari Guntupalli, Kristin M. Corapi. Saint Vincent Hospital, Worcester, MA.

Introduction: Abdominal pain can have many differentials in patients on peritoneal dialysis (PD). Some of them, including fungal peritonitis, requires PD catheter removal and a change in dialysis modalities. Here we present a case of recurrent abdominal pain in a patient on peritoneal dialysis which highlights the importance of prompt diagnosis.
Case Description: 40-year-old female with end stage renal disease secondary to systemic hyperoxaluria (SH) presented for 3 year clinic appointment after her system was disconnected with leakage of PD fluid. PD effluent revealed white count of 300 with 2% neutrophils. She was treated empirically for peritonitis. 11 days later her fungal culture grew Candida famata and she was admitted with intermittent abdominal pain associated with nausea and weakness. She was hemodynamically stable, and her exam was significant for epigastric tenderness with normal looking PD catheter site. Her white count was elevated to 13,000 with unremarkable metabolic panel. CT abdomen was unremarkable. A repeat PD effluent had white count of 40. Her PD catheter was removed the next day and she was switched to hemodialysis. She was treated with 10 days of oral fluconazole. On review, she had been having intermittent abdominal pain with PD effluent sometimes showing high white count for which she got multiple antibiotic courses for either presumed or culture positive bacterial peritonitis. She had also grown positive fungal culture about 18 months ago with Candida albicans and Streptococcus viridans which went unnoticed.

Discussion: Fungal peritonitis can be catastrophic for patients on PD. Treatment involves prompt catheter removal and systemic antifungal treatment. Given its dire consequences, prevention is paramount. The ISPD recommends using anti-fungal prophylaxis when PD patients receive antibiotic courses. Risk factors include previous bacterial peritonitis and antibiotic use. This case demonstrates the need to follow cultures as fungal growth is slow and can take weeks. It is important to have a high index of suspicion for a fungal organism when cultures are negative. This patient received antibiotics on several occasions but only developed fungal peritonitis on 2 occasions which raises concern on antifungal prophylaxis. Further studies are indicated to determine number needed to treat to decide on need for antifungal prophylaxis.

PO0979
Micrococcus Peritonitis Complicating Peritoneal Dialysis
Martin L. Li,1 Ankur Shah,2,3 ‘Brown University Warren Alpert Medical School, Providence, RI; 2Rheode Island Hospital, Providence, RI.

Introduction: Peritonitis is one of the most common and consequential complications of peritoneal dialysis. Micrococcus sp are catalase-positive, coagulase-negative, gram-positive cocci that are increasingly recognized as opportunistic pathogens in patients with immunocompromised hosts or indwelling catheters. These bacteria have been rarely implicated as causative in peritonitis. We present a case of peritonitis due to Micrococcus sp and review the pertinent literature.

Case Description: A 55-year-old female with history of ESKD due to diabetic kidney disease, CAD s/p CABG, and hypertension presented with a 1 day history of cloudy effluent. She had no prior peritonitis episodes. Vital signs were stable and exam was notable for a soft non-tender abdomen and clean and dry exit site without discharge or granulation tissue. Effluent was hazy in appearance. Administration of empiric vancomycin and gentamicin was initiated, varying in duration of 24 to 48 hours. Effluent leukocyte count was 204 cells/µL with 58% neutrophils. Intraperitoneal vancomycin was continued for 3 weeks due to intermittent low troughs. Further history revealed intermittent mask use while performing exchanges. After completion of treatment, with complete resolution of symptoms and peritoneal cell count. Cell count and culture were repeated 1 month later during evaluation of abdominal pain eventually found to be due to constipation. Leukocyte count was 6 cells/µL but culture again grew Micrococcus sp. After culture was repeated once more and remained peritonitis negative, repeat treatment to eradicate was attempted with 2 more weeks IP vancomycin but culture remained positive. Eventually the catheter was removed due to a change in living situation. After 5 months of hemodialysis, peritoneal catheter was replaced and the patient was restarted on peritoneal dialysis, after which time she has not had a peritonitis episode.

Discussion: We present the 10th case of Micrococcus sp. Peritonitis in a peritoneal dialysis patient. Prior cases have been associated with breaks in technique and have shown a pattern of recurrence with resultant technique failure being very common. Attempted treatments have included vancomycin, cefazolin, cefazidime, and ticlopin. In the prior 9 published cases, 4 resulted in technique failure. This case and review of the pertinent literature. For dialysis patient. Prior cases have been associated with breaks in technique and have

PO0981
Chylous Peritoneal Fluid in a Patient on Peritoneal Dialysis Taking Nifedipine
Lauren E. Macaree, Dena E. Rifkin, Tyler Woodell, O. Alison Potok. University of California San Diego, La Jolla, CA.

Introduction: Chylous fluid in peritoneal dialysis (PD) patients may appear with lymphatic system disruption. This can be due to lymphatic obstruction, exudation through vessels, or via a lymphopertitoneal fistula.

Case Description: A 78-year-old man with ESKD due to diabetic nephropathy, transitioned five weeks prior from HD to PD, presented with newly cloudy PD fluid. His past medical history included hypertension, coronary artery disease, and monoclonal gammopathy of undetermined significance. He reported a newly cloudy white initial drain with lower abdominal pain, but denied fever, vomiting or diarrhea. He denied a breast in sterile technique. Medications included hydralazine, cinacalcet, furosemide, nifedipine, omeprazole, calcium acetate and darbepeotin. He was hemodynamically stable and had no abdominal tenderness. Laboratory results revealed a leukocytosis of 11.7 × 10^9/L. Peritoneal fluid was milky (figure 1a) with 101 white blood cells (4% neutrophils); gram stain and culture were negative. Triglycerides were 96 and 62 mg/dL in the PD fluid and serum, respectively. Etiologic work-up was negative for malignancy, pancreatitis, cirrhosis, trauma and tuberculosis. Chylous nature of the PD fluid resolved within a day of nifedipine discontinuation (figure 1b). The patient self-resumed nifedipine weeks later and the milky fluid recurrring the following day again before reinitiating after its repeat cessation.

Discussion: This patient had the onset of chylous PD fluid 5 weeks after initiating PD, which resolved with cessation and recurrence with reinstatement of his long-term nifedipine. The mechanism of calcium channel blockers (CCB) – related chylous ascites is not well established. Some have suggested it may be related to the lipophilic nature of CCB. Patients on PD with higher peritoneal membrane transport may be at higher risk. Genetic factors may predispose to this phenomenon. Nephrologists should be aware of this rare complication of CCB use in PD patients. More research is needed to better understand the underlying pathophysiology of this rare condition.
PO0982
Severe Bleeding and Deep Inferior Epigastric Pseudoaneurysm After PD Catheter Removal
Nicola Matthews,1 Tamara Glavinovic,2 Bourne L. Auguste.2 St. Michael’s Hospital, Toronto, ON, Canada; Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Introduction: In this case, the removal of a PD catheter with deep cuff calcification results in pseudoaneurysm formation with hemorrhage and hospitalization.

Case Description: A 56-year-old woman with end-stage kidney disease was switched from PD to HD due to worsening uremia and PD catheter removal was organized. At the time of catheter removal heavy calcification around the deep Dacron cuff was seen. Catheter removal should be done in settings equipped with interventional radiology support in the event of complication. We report a case of a 56 year old woman with end stage kidney disease previously on peritoneal dialysis (PD) with subsequent live donor kidney transplant on immunosuppression, who presented with right lower quadrant abdominal cellulitis and deep abscess around the catheter site. Post transplant, her PD catheter was removed, however, the catheter site never healed completely. Although she did have multiple superficial skin infections in the past, those resolved with antibiotics. But this specific cellulitis, did not improve despite multiple antibiotic regimens, and further imaging studies revealed she had developed an abscess. The abscess was managed by surgical incision and drainage with debridement of the skin, subcutaneous tissue, fascia, and muscles around the whole catheter tract. Aeromonas hydrophila was found as the causative organism.

Discussion: This is an important learning case in PD catheter removal and highlights the following: - Poorly controlled bone mineral disease may lead to excessive calcification of the deep Dacron cuff and DIEP vessels. - When heavy calcification of the PD cuff is seen, catheter removal should be done in settings equipped with interventional catheter removal.

PO0983
A Case of Abdominal Wall Abscess Caused by Aeromonas hydrophila in Prior Peritoneal Catheter Site in an Immunocompromised Patient Post Kidney Transplant
Angelica P. Trilleras Gomez,1 Maya Antony,2,3 Ahmed A. Waheed.2,3 Holy Cross Hospital, Ft Lauderdale, FL; University of Miami School of Medicine, Miami, FL; Holy Cross Hospital Department of Nephrology, Ft Lauderdale, FL.

Introduction: Aeromonas hydrophila is a gram-negative rod-shaped bacterium found in aquatic ecosystems; it has been identified as the causative organism of different opportunistic infections in the immunocompromised and there is growing evidence of infection in the immunocompetent. This pathogen has been implicated in acute gastroenteritis, soft tissue infections, meningitis, peritonitis and sepsis among others.

Case Description: We report a case of a 56-year-old woman with end-stage kidney disease previously on peritoneal dialysis (PD) with subsequent live donor kidney transplant on immunosuppression, who presented with right lower quadrant abdominal cellulitis and deep abscess around the catheter site. Post transplant, her PD catheter was removed; however, the catheter site never healed completely. Although she did have multiple superficial skin infections in the past, those resolved with antibiotics. But this specific cellulitis, did not improve despite multiple antibiotic regimens, and further imaging studies revealed she had developed an abscess. The abscess was managed by surgical incision and drainage with debridement of the skin, subcutaneous tissue, fascia, and muscles around the whole catheter tract. Aeromonas hydrophila was found as the causative organism.

Discussion: To our knowledge, this is the first case of an A. hydrophila abscess associated with peritoneal dialysis catheter. Firm association between aeromonads and the use of intravenous indwelling devices has already been demonstrated. We hypothesize that her deep seeded infection could be associated with the intrinsic ability of A. hydrophila to form biofilms upon detecting a suitable surface, making them more virulent. The formation of biofilm has been associated with exponential growth as the source of pathogenicity of this bacteria in pisciculture studies. This characteristic could be one of the factors contributing to reported cases of peritonitis and intravenous hemodialysis catheters by A. hydrophila. Further elucidation of A. hydrophila virulence factors in humans can provide insight on prevention of PD catheter associated infections by A. hydrophila.

PO0984
Mesenchymal Stem Cell Exosomes Protect Mouse Peritoneal Injury Induced by Human Peritonitis Dialysis Effluent
Fang Yu,1 Kehong Chen, Jia Chen, Yani He. Army Military Medical University, Daping Hospital, Department of Nephrology, Chongqing, China.

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but there are few effective therapies for it. The purpose of this study was to investigate the protective effect of exosomes secreted by mouse bone marrow mesenchymal stem cells (MSC) on peritoneal injury and to reveal the mechanism.

Methods: Forty-two male C57BL/6 mice were randomly divided into six groups: a control group (2.5% glucose dialysate), a peritonitis-effluent group (The overnight 2.5% glucose dialysate of patients with peritonitis), a high glucose (4.25%) dialysate group, a peritonitis-dialysate+exosome group, a high glucose dialysate+exosome group, and a control group (2.5% glucose dialysate). The mouse model of peritoneal injury was constructed by intraperitoneal injection of human peritonitis dialysis effluent continuously for 42 days. The mice in the exosome treatment group received intraperitoneal injection of MSC-exosomes twice. The level of peritoneal structural and functional damage was detected. The effect of MSC-exosomes was validated in vitro.

Results: Peritoneal transport and structure was significantly impaired in the peritonitis-effluent group and the high glucose dialysate group after 42 days, and was significantly higher than control group. The results suggested that human peritonitis dialysis effluent could be used to construct a mouse model of peritoneal injury. Masson staining showed that fibrosis degree of exosome treatment group was significantly less than peritonitis-effluent group. Immunohistochemical analysis showed that expressions of mesothelial markers E-cadherin and ZO-1, neutrophil granulocytes (MPO) and macrophages (F4/80), and fibrosis markers (collagen I, a-SMA) in exosome treatment group were significantly lower than peritonitis-effluent group. Peritoneal ultrafiltration function of exosome treatment group was significantly improved compared to peritonitis-effluent group. In vitro experiments showed that exosomes could down-regulate the secretion of IL-1β, IL-6 and TGF-β1 by peritoneal mesothelial cells stimulated by high glucose dialysate, maintain expression of mesothelial cell marker (E-cadherin), and inhibit mesenchymal marker (a-SMA), suggesting that exosomes could inhibit the transdifferentiation of peritoneal mesenchymal cells (MMT).

Conclusions: MSC-exosomes can alleviate peritoneal fibrosis by inhibiting peritoneal mesothelial cell-mesenchymal cell transdifferentiation.

**Dual Therapy with JAK1/2 Inhibitor and Losartan Attenuates Dialysate-Induced Angiogenesis in Polycystic Rats**

Pei Zhang,1,2 Kana N. Miyata,2 Madisyn Mahoney,3 Janine A. La page,4 Cynthia C. Nast,5 Sharon G. Adler,1 Tiane Dai,6 Department of Nephrology, the First Affiliated Hospital of Anhui Medical University, Hefei, China; 7The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA; 8 Cedars Sinai Medical Center, Los Angeles, CA.

**Background:** Long term peritoneal dialysis (PD) is limited by reduced efficacy over time. Early peritoneal membrane (PM) injury is characterized by inflammation which progresses to hyperviscosity and fibrosis. JAK-STAT signaling mediates inflammatory pathways, including angiogenesis signaling. Our previous study showed dual therapy with JAK1/2 inhibitor (JAK1/2i) and an ARB maintains PM structure and function in rats with polycystic kidneys (PKC) chronically infused with 4.25% Dianease x 16 wks. By using VEGF2R as an endothelial marker, we further investigated if this dual therapy can attenuate chronic dialysate infusion induced hyperviscosity in this rat model.

**Methods:** PCK rats were used. Dialysate infusions were performed BID via an implanted subcutaneous port in the neck tunneled to the intraperitoneal cavity. The following treatments were administered: (1) No surgery/infusions; (2) 4.25% Dianease; (3) 4.25% Dianease + JAK1/2i (5mg/kg BID); (4) 4.25% Dianease + Losartan (5mg/kg BID); and (5) 4.25% Dianease + Losartan + JAK1/2i (5mg/kg BID each). Parietal peritoneum was used for immunohistochemical staining of VEGF2R, which was digitally quantified by using Qu Path program. Data were analyzed by one-way-ANOVA followed by Tukey test. Results are mean ± SEM.

**Results:** VEGF2R staining was significantly elevated after 16 weeks IP infusion of 4.25% Dianease alone. JAK1/2i significantly reduced VEGF2R expression; losarant tended to reduce VEGF2R, but this did not reach significance. Dual therapy with JAK1/2i and losartan resulted in the greatest reduction of VEGF2R

**Conclusions:** Long-term JAK1/2i, or JAK1/2i plus losartan intraperitoneal treatment reduces angiogenesis. Angiogenesis inhibition is advocated to maintain residual renal function, by adding JAK1/2i, the combination also protects peritoneal structure/function by reducing angiogenesis.

**PO0986**

**The Effect of Far-Infrared Therapy on the Peritoneal Expression of Glucose Degradation Products in Diabetic Patients on Peritoneal Dialysis**

Chih-Ching Lin, Chih-Yuan Niu. Taipei Veterans General Hospital, Taipei, Taiwan.

**Background:** Peritoneal dialysis (PD) is a treatment modality for end-stage renal disease (ESRD) patients. Dextrose is a common osmotic agent used in PD solutions and its absorption may exacerbate diabetes mellitus. PD solutions also contain glucose degradation products (GDPs) that may lead to encapsulating peritoneal sclerosis (EPS). A previous study showed that far-infrared (FIR) therapy improved a patient’s gastrointestinal symptoms due to EPS. Due to limited literature, this study aims to investigate dialysate GDPs and peritoneal function in diabetic patients on PD.

**Methods:** A prospective analysis conducted in a single center. The participants were recruited from the peritoneal dialysis outpatient department from November 25, 2016 to September 5, 2018. We included the patients who met the following criteria: (1) ESRD patients aged 20-90 years without receiving FIR therapy within 12 months; (2) receiving continuous ambulatory peritoneal dialysis or automated peritoneal dialysis; (3) no history of peritonitis, cerebrovascular accident, myocardial infarction, or receiving any cardiovascular intervention in the past 3 months. Patients were allocated to two groups based on their underlying DM history. Both groups of PD patients received FIR therapy for 6 months. We collected the last daily bag of peritoneal dialysate and calculated the dialysate concentration of GDPs and clinical data in PD patients pre- and post-FIR therapy.

**Results:** Thirty-one PD patients were enrolled and underwent 40 min of FIR therapy twice daily for six months. We demonstrated the effect of FIR therapy on the following: (1) decrease of methylglyoxal (p = 0.02), furfural (p = 0.005), and 5-hydroxymethylfurfural (p = 0.03), (2) increase of D/D0 glucose ratio (p = 0.03), and (3) decrease of potassium levels (p = 0.008) in both DM and non-DM patients, as well as (4) maintenance and increase of peritoneal K+ in DM and non-DM patients, respectively (p = 0.03). FIR therapy is a non-invasive intervention that can decrease dialysate GDPs in PD patients by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

**Conclusions:** In conclusion, our study demonstrated that FIR therapy can decrease PD patients’dialysate GDPs by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

**PO0987**

**Cumulative Dialysate Glucose Exposure Is a Risk Factor for Peritoneal Sclerosis in Pediatric Peritoneal Dialysis Patients Using Neutral-pH Fluids**

Yoko Shirai,1 Kenichiro Miura,1 Taro Ando,1 Atsutoshi Shiratori,1 Naoto Kaneko,1 Kiyonobu Ishizuka,1 Sekiko Taneda,2 Daishi Hirano,1 Yoichiro Yamaguchi,1 Kazuhiro Honda,1 Motoishi Hatori,3 Department of Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan; 2Department of Pathology, Tokyo Women’s Medical University, Tokyo, Japan; 3Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; 4Yamaguchi Pathology Laboratory, Chiba, Japan; 5Department of Anatomy, Showa University School of Medicine, Tokyo, Japan.

**Background:** The benefits of neutral-pH fluids for preventing peritoneal dialysis (PD)-related peritoneal sclerosis have been established, however, advanced peritoneal sclerosis still has been described in pediatric PD patients using neutral-pH fluids (Kidney Int 2018). The factors associated with peritoneal pathological changes after long-term use of neutral-pH fluids have not been elucidated.

**Methods:** Pediatric PD patients using only conventional acidic fluids (conventional group) and those using only neutral-pH fluids (neutral-pH group, n=33) for more than one year were analyzed. Propensity score matching was performed to compare the peritoneal pathological changes between groups. Clinical risk factors including PD duration and cumulative dialysate glucose exposure for peritoneal pathological changes in the neutral-pH group were analyzed using generalized linear model. Furthermore, immunofluorescence studies were performed on vascular endothelial growth factor (VEGF-α), cytokertatin, and α-smooth muscle actin (α-SMA); a myofibroblastic marker of epithelial-mesenchymal transition (EMT).

**Results:** Age at biopsy was 1.3 (1-6) years (median [IQR]) and duration of dialysis was 3.2 (1.7-5.3) years. The neutral-pH group showed less peritoneal deterioration except for higher submesothelial microvesSEL density (P = 0.01) than conventional group. In the neutral-pH group, the cumulative dialysate glucose exposure was an independent risk factor for increased thickness of the submesothelial compact zone [OR, 1.004; 95%CI, 1.001-1.007] and submesothelial microvesSEL density [OR, 1.003; 95%CI, 1.000-1.005].

**Conclusions:** Cumulative dialysate glucose exposure correlated with the proportion of VEGF-α-positive areas (P<0.01, r=0.55). In immunofluorescence study, VEGF-α (+) cells comprised cytokertatin (+) cells and α-SMA (+) cells.

**PO0988**

**Predicting Patient and Technique Survival in a Cohort of Incident Peritoneal Dialysis (PD) Patients According to Peritoneal Small Solutes Transport Rate (PSTR)**

Rafael A. Gomez,1 Abdul Rashid T. Qureshi,2 Joanna Stachowska-Pietka,3 Malgorzata Debowska,4 Jacek Waniewski,5 Bengt Lindholm,2 Baxter Renal Care Services, Cali, Colombia; 2Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; 3Nalecz Institute of Biocybernetics and Biomedical Engineering Polish Academy of Sciences, Warsaw, Poland.

**Background:** The association between PSTR and clinical outcomes in patients undergoing chronic peritoneal dialysis (PD) is uncertain. We explored the association between PSTR with mortality and technique survival in a large cohort of incident patients undergoing PD in Colombia.

**Methods:** In a cross-sectional study, 8170 PD patients, treated with APD (2705, 33.1%) and with CAPD (5465, 66.9%), who underwent peritoneal equilibration test to determine dialysate/plasma glucose ratio (G/D) 4 hours were classified into low (16.0%), slow average (35.4%), fast average (32.9%) and fast (15.7%) PSTR categories. Demographic, clinical and laboratory variables were evaluated. During median follow-up of two years, 2633 (32.2%) patients died, 1079 (13.2%) patients transferred to hemodialysis, and 661 (8.1%) patients underwent renal transplantation. All-cause and cardiovascular disease (CVD) mortality risk and technique survival were analyzed with competing-risk regression with transplantation as competing risk.

**Results:** Patients with fast as compared to slow PSTR were older, more often male or diabetic (DM), and had lower Hb and serum albumin levels. In competing risk analysis, after adjusting for age, sex, body mass index, residual kidney function, presence of diabetes and hypertension and circulating albumin, Hb, and phosphate levels, higher PSTR associated with greater risk (subdistribution hazard ratio, sHR) for all-cause mortality (fast average: sHR 1.13, 95%CI 1.00-1.26; p=0.04) and fast: sHR 1.19, 95% CI 1.04-1.36; p=0.01), and CVD-related mortality (fast average: sHR 1.18, 95% CI 0.99-1.41; p=0.05) and fast: sHR 1.19, 95% CI 0.97-1.46; p=0.08), and reduced technique survival (fast average: sHR 1.15, 95% CI 0.95-1.38; p=0.13) and fast: sHR 1.24, 95% CI 1.02-1.52; p=0.05).

**Conclusions:** These results suggest that fast and fast average PSTR associates with increased mortality risk and tendency towards reduced technique survival when analyzed using adjusted competing-risk regression models.

Multifrequency Bioimpedance Is a Useful Adjunct to Control Fluid Overload in PD Patients
Szu-Yuan Li, Chiao-Lin Chuang, Jinn-Yang Chen. Taipei Veterans General Hospital PD team Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Fluid overload is a well recognized phenomenon in many peritoneal dialysis (PD) patients, but a balance between reduction of dry weight and preservation of residual renal function (RRF) is mandatory. We hypothesize that, to achieve an ideal dry weight, adjustment by multifrequency bioimpedance (MF-BIA) guide offers less adverse effect on residual renal function than that by clinical judgment alone.

Methods: The hydration status of various body compartments were measured using a MF-BIA device (Inbody 720, Biospace). The normalized hydration score was defined as extracellular water (ECW)/total body water (TBW). All patients were evaluated monthly for 6 months. The dry weight of study group was adjusted according to MF-BIA to avoid dehydration, and the dry weight of control group was determined clinically. Ambulatory blood pressure, anti-hypertension medication dosage, serum biochemical parameters, and RRF were recorded monthly. IL-6 and hs-CRP will be checked before and after the study.

Results: 93 stable PD patients (48 in study and 45 in control group) completed the study. ECW/TBW ratio was higher in PD patients than sex- and age-matched healthy subjects. (Figure 1). In PD patients, the ratio of ECW/TBW was positive correlated to age (r = 0.334), peritoneal D/P ratio (r = 0.518), systolic BP (r = 0.520) and negative correlated to urine volume (r = -0.526), serum albumin (r = -0.658). After 6 months intervention, study group decreased 1.2 kg and control group gained 0.2 kg. The study group had a better systolic and diastolic BP control and a higher serum albumin (3.75 ± 0.61 vs 3.48 ± 0.68 g/dl, p = 0.047). The RRF has no difference between two groups.

Conclusions: Our results showed that correction of fluid overload would improve blood pressure control. Being an objective tool to assess hydration status of various body compartments, MF-BIA is a useful adjunct to correct fluid overload without the loss of RRF in our short-term study.

PO0990

Associations Between Loop Diuretic Use and Outcomes Among Patients Treated with Peritoneal Dialysis
Jiacong Lu1, Dena E. Cohen,1 Carey Colson,1 Steven M. Brunelli,1 Francesca Tentori,1 Martin J. Schreiber,2 Davita Clinical Research, Minneapolis, MN; 3Davita Inc, Denver, CO.

Background: Among hemodialysis patients, an active loop diuretic prescription at the time of dialysis initiation is associated with a lower hospitalization rate and other favorable outcomes, compared to no prescription. Whether this finding extends to patients initiating peritoneal dialysis (PD) is not known.

Methods: Data used for this retrospective study comprised electronic health records and US Renal Data System claims data merged through direct linkage. Included patients initiated PD at a large dialysis organization between 01 Jan 2006 and 30 June 2014, were nonoliguric at dialysis start (24-hour urine collection >200 cc), and had Medicare insurance. Exposure was determined on the basis of an active, filled supply for a loop diuretic spanning day 90 of PD. Outcomes were considered from day 91 of PD through the first of death, loss to follow-up, or study end (31 Dec 2014) and were compared across exposure groups using appropriate statistical models adjusted for imbalanced patient characteristics.

Results: Among patients initiating PD with a loop diuretic prescription (N=792), the hospitalization rate during follow-up was 1.77 admissions/patient-year (pt-yr), compared to 1.75/pt-year for those without (N=1363), corresponding to an adjusted incidence rate ratio (aIRR) of 1.05 (95% confidence interval [CI] 0.97-1.15). Mortality was likewise comparable between groups, with crude rates of 0.21 and 0.18 deaths/pt-year, respectively (aIRR 1.05, 95% CI 0.82-1.35). No substantial differences were observed between exposure groups with respect to serum potassium, renal Kt/V, or time to transition to hemodialysis.

Conclusions: Among patients initiating PD, no beneficial associations were observed between loop diuretic use and any of the outcomes examined.
Identifying Peritoneal Dialysis (PD)-Associated Peritonitis Using Medicare Claims

Eric W. Young,1,3 Junhui Zhao,1 Ronald L. Pisoni,1 Keith McCullough,1 Beth M. Piraino,1 Jenny I. Shen,1 Neil Boadwine,1 Douglas E. Schaubel,2 Isaac Teitelbaum,3 Jeffrey Perl,61 Arbor Research Collaborative for Health, Ann Arbor, MI; 2University of Pennsylvania, Philadelphia, PA; 3University of Pittsburgh Medical Center, Pittsburgh, PA; 4University of Western Australia, CO; 6St. Michael’s, Toronto, ON, Canada; 7The Lundquist Institute, Torrance, CA; 1University of Michigan Health System, Ann Arbor, MI.

Background: Medicare fee-for-service (FFS) claims offer a population-based approach to PD-associated peritonitis that may offer valuable insights into predictors, trends and preferred practices.

Methods: We used United States Renal Data System (USRDS) standard analysis files for claims (inpatient, outpatient and physician-supplier), eligibility, modality and demographic information. The sample consisted of PD patient-months from 2013 through 2017 characterized by Medicare FFS coverage and paid claims for dialysis or hospital services. We identified ICD-9 and ICD-10 diagnosis codes for peritonitis, including those that do not clearly distinguish peritonitis from catheter infections/inflammation (“catheter codes”). A new peritonitis episode was defined as a peritonitis claim >30 days from any prior peritonitis claim or >30 days from the initial peritonitis claim for a prior episode.

Results: The sample included 88,396 adult patients (128,000 observed patient-years), yielding 510,000 peritonitis claims and 75,000 peritonitis episodes. Coding was heterogeneous with no single diagnosis code present on the majority of claims. Peritonitis episodes were inferred from aggregated claims (mean 6.3, median 2). Half of episodes were exclusively outpatient, 7% exclusively inpatient, and 16% exclusively comprised of catheter code claims. The overall peritonitis rate was 0.59 and 0.49 episodes per patient-year with and without inclusion of catheter codes respectively. Peritonitis rates declined 4%/year from 2013-2017, and varied by age, race (Black > White > Asian), and ESKD vintage.

Conclusions: Coding heterogeneity indicates a lack of standardization and need for clearer coding guidance. We found differences between races, ages, and patient vintages, and declining rates from 2013-2017. These rates are 2-fold higher than reported in US-PDOPPS by Perl et al (AJKD 2020) which is not restricted to Medicare. Claims are an important data source for peritonitis, but more work is needed to validate these rates.

Funding: Other NIH Support - Agency for Healthcare Research and Quality.

Protective Association Found Between Peritoneal Dialysis Patients Prescribed Home Antibiotics Kits and In-Center Hemodialysis Transition

Derek M. Blankenship,1 Michelle Carver,2 Dinesh K. Chathoth,1 Chance Myasynchon,1 Debu Ray,1 Patricia Mccarley,1 Len A. Usuy,1 Jeffrey L. Hymes,1 Franklin W. Maddux,1 Fresenius Medical Care, Global Medical Office, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA.

Background: Peritonitis is a complication of peritoneal dialysis (PD) and is likely associated with technique failure. To decrease time to peritonitis treatment, Fresenius Kidney Care (FKC) clinicians can prescribe broad-spectrum intraperitoneal and oral antibiotic kits. Kits are self-administered by home PD patients for suspected wet contamination or peritonitis per algorithm. The study purpose is to assess hemodialysis (HD) transition as well as peritonitis among PD patients receiving a home antibiotic kit.

Methods: This retrospective cohort study identified FKC PD patients prescribed home antibiotic kits between June 1, 2019 and June 30, 2020. Home FKC PD patients not receiving kit during same period composed the control pool. Patients are matched in a 1:4 ratio on clinical and demographic data using propensity scores. Patients were followed up to 6 months for transition to HD and first peritonitis event. Outcomes were analyzed with weighted competing risk Cox Proportional Hazards Models.

Results: 2,888 treatment and 10,613 controls were studied. Of the 2,888 treatment patients and weighted 1,921.2 matched controls, 11.9% and 13.5% transitioned to HD, respectively. A 0.88 hazard ratio (p=0.0448) determined treatment group is 12% less likely to transition to HD at any point during follow-up period. 10.4% treatment patients and 8.5% controls have at least one peritonitis event. The treatment group is 23% more likely to have a Peritonitis event (p=0.0019).

Critical care nurses prepped for patient autotransfusion

J Am Soc Nephrol 32: 2021 Peritoneal Dialysis Poster

Conclusions: The study identified a protective association in HD attrition for home PD patients receiving peritoneal kits vs. positive association between patients receiving the kits and peritonitis. These findings may reflect residual confounding factors such as clinicians prescribing kits for patients at higher risk of peritonitis for uncontrolled or unmeasurable factors since kits do not prevent peritonitis but increase uniformity of treatment. The findings justify need for further research including prospective randomized studies.

PO995
Assessing Physician Clinic Practices and Competencies in Performing Peritoneal Dialysis Catheter Flushing During the 10-Day Global Period

John H. Crabtree,
Marcus Pecora,
Mark H. Shapiro,
Eduardo Zanatta,
Martin J. Schreiber,
Harbor-UCLA Medical Center, Torrance, CA; DaVita Inc, Denver, CO; Balboa Nephrology Medical Group, San Diego, CA.

Background: Early flushing of peritoneal dialysis (PD) catheters theoretically reduces the incidence of catheter obstruction by decreasing formation of fibrin strands or blood clots. Early flushing also enables timely identification of catheter dysfunction, creating an opportunity to revise the catheter prior to scheduled training and initiation of therapy. It is unknown how frequently PD access providers perform flushes in their clinics, but Centers for Medicare & Medicaid Services (CMS) has indicated that services performed within 10 days following catheter placement (global period) are the responsibility of PD access providers. Therefore, under existing regulations, dialysis organizations generally defer to access providers to perform catheter flushes during this global period. The purpose of this study is to access current practices of PD access provider clinics (surgeon, interventional nephrologist or radiologist) in performing catheter flushes.

Methods: PD access providers placing catheters for a large dialysis organization in the southwestern United States during 2020 were surveyed. The 3-question survey asked: 1) PD access provider specialty, 2) if the clinic performed catheter flushes, and 3) the background of the staff person assisting the physician with clinic procedures. Responses were acquired by direct or telephone contact with the physician or clinic staff.

Results: Survey responses were obtained for all 201 providers who placed PD catheters during 2020 (Table). Significantly, none of the PD access provider clinics elected to provide these services during the global period for patient safety and optimal patient outcomes.

Peritoneal Dialysis Catheter Flushing Leading to Syncope from Vagal Nerve Stimulation

Sylvestor Barnes
Loyola University Health System, Maywood, IL; Edward Hines Junior VA Hospital, Hines, IL.

Introduction: Peritoneal dialysis is the most common form of home dialysis. Complications can arise however any time the peritoneum is invaded such as during surgery. The patient is a 57-year-old male on PD secondary to developing progressive IgA nephropathy. The patient suffered from an inguinal hernia which required open repair surgery. The patient is a 37-year-old male on PD secondary to developing progressive IgA nephropathy. The patient subsequently developed hypotension, diaphoresis and near syncope. This process continued every time the patient’s peritoneal catheter was flushed. 500 mL’s of 2.5% warm saline was used to fill the patient resulting in the same near syncopal episode. With repositioning of the patient’s catheter the symptoms completely resolved.

Background: It is unclear if the pharmacokinetics of vancomycin is the same during automated peritoneal dialysis (APD) where cycle exchanges may affect the systemic, peritoneal, and urinary disposition of drug.

Methods: This was a prospective pharmacokinetic study in peritonitis-negative patients on APD. A single dose of vancomycin (20 mg/kg) was administered through the peritoneum and allowed to dwell for at least 15 hours. Patients underwent four drug-free exchanges following the initial dwell period. Plasma, dialysate and urine were collected over the course of 7 days for pharmacokinetic analysis. A non-comparitional analysis was used to estimate vancomycin pharmacokinetic parameters.

Results: Four patients enrolled and completed the study with no adverse events. Three patients had residual renal function. Following a median (range) dwell of 14.6 (14.2 – 17.6 hours), the mean ± SD observed maximum plasma concentration was 28.7 ± 4.9 mg/L with a mean ± SD bioavailability of 98.5 ± 1.4% prior to starting the cycler. The overall mean plasma clearance estimated from study start to completion was 7.3 ± 1.2 mL/min. In patients with residual renal function, the mean ± SD vancomycin renal clearance was 3.1 ± 1.5 mL/min.

Conclusions: Despite the small sample size, this pilot study suggest that the dwell time has important implications for systemic vancomycin exposure, time to therapeutic plasma concentration, and dosing. Dose is driven by dwell time while the cycler determines the dosing interval. Rapid exchanges from APD will determine the frequency of dosing rather than the adequacy of absorption when vancomycin is given in the peritoneum.

Effect of Velphoro on Serum Phosphate and Albumin in Peritoneal Dialysis Patients

Luis M. Perez, Zhijing Yu, Jessica B. Kendrick, Isaac Teitelbaum. University of Colorado, Denver, CO.

Background: Hyperphosphatemia is common in patients on peritoneal dialysis (PD). Restricting phosphorus in the diet often leads to a decrease in protein intake, which may result in hypoalbuminemia. Hypoalbuminemia is associated with an increased risk of morbidity and mortality in PD patients. In observational studies, saccharin oxyhydroxide (SO), an iron-based phosphate binder, was associated with improved phosphate control and higher serum albumin in hemodialysis patients. Whether SO improves phosphate control and nutritional status in PD patients is unknown.

Methods: We performed a prospective, open-label, 6-month, pilot study of 17 adult PD patients from the Denver Metro Area. Patients had to use automated peritoneal dialysis for at least 3 months, have a serum albumin ≥ 3.8 g/dL, and have serum phosphate ≥ 5.5 mg/dL or ≥5.5 mg/dL on a binder other than SO. Patients currently on phosphate binders underwent a 2-week washout period. Participants were started on SO at a dose of 1 tablet daily with meals. Serum phosphate was checked monthly and the dose of SO was titrated to a goal serum phosphate of < 5.5 mg/dL. The primary outcome was change in serum phosphate and serum albumin over 6 months.

Results: The mean (SD) age and dialysis vintage was 55 ± 13 years and 3.8 ± 2.7 years, respectively. The majority of patients were male (65%), white (82%), and non-Hispanic (64.7%). 88% of patients were on a phosphate binder at baseline and the majority were on sevelamer (73%). Twelve patients completed the study. Two patients withdrew due to side effects (diarrhea), 1 patient changed to hemodialysis and 2 patients died (unrelated to the study). Mild diarrhea and change in stool color were the most frequently reported side effects. Results are shown in Table 1. Serum phosphate decreased significantly from baseline but there was no significant change in serum albumin. Phosphate binder pill burden significantly decreased.

Conclusions: Serum phosphate decreased significantly with fewer phosphate binder pills/day after switching to SO. There was no change in serum albumin.

Prognostic Significance of Plasma Vaspin and Adiponectin Levels in Peritoneal Dialysis Patients

Win H. Than,1,2 Cheuk-Chun Szeto.1,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Shatin, Hong Kong; 1Li Ka Shing Institute of Health Sciences (LISH), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Adiponectin and vaspin are key adipokines that play important roles in the physiology of adipose tissue and contribute to the pathogenesis of metabolic disturbances in chronic kidney disease (CKD). We explored the prognostic role of plasma adiponectin and vaspin levels in peritoneal dialysis (PD) patients – a population that may be at high risk of cardiovascular and renal events due to metabolic syndrome, obesity, and cachexia are common.

Methods: We measured plasma adiponectin and vaspin levels in a cohort of new PD patients and analyzed their relation with patient survival.

Results: We studied 152 patients. Their mean age was 58.38 ± 11.67 years; 102 (67.1%) were men, 92 (60.5%) were diabetic. The median plasma adiponectin level was 67.1% were men, 92 (60.5%) were diabetic. The median plasma adiponectin level was 31.98 ng/ml (Interquartile range [IQR]: 16.81-49.49 mg/ml; median vaspin level 0.18 (IQR: 0.01-0.32) ng/ml. There was no significant correlation between plasma adiponectin and vaspin levels. Plasma adiponectin level had modest correlations with Charlson’s comorbidity score (r = 0.174, p = 0.039), triceps skin fold (r = -0.269, p = 0.001), and vaspin levels. Plasma adiponectin level had modest correlations with Charlson’s comorbidity score (r = 0.174, p = 0.039), triceps skin fold (r = -0.269, p = 0.001), and vaspin levels. Plasma vaspin level correlated with carotid-to-femoral pulse wave velocity (r = -0.240, p = 0.005), triceps skin fold (r = 0.198, p = 0.018), and extracellular to Intracellular fluid volume ratio (r = -0.170, p = 0.047). After adjusting for clinical confounders, plasma adiponectin and vaspin levels were significantly predicted patient survival (adjusted hazard ratio [AHR] of adiponectin 1.018, 95% confidence interval [CI] 1.004-1.031, p = 0.010; AHR of vaspin 1.018, 95%CI 1.008-1.029, p=0.001).

Conclusions: Plasma adiponectin and vaspin levels were independent predictors of patient survival. Our results suggest that adiponectin and vaspin are involved in different pathways of metabolic disturbance in uremia.

The Impact of Peritoneal and Urine Protein Losses on Nutritional Status in Peritoneal Dialysis Patients

Background: The etiology of malnutrition in peritoneal dialysis (PD) patients is multifactorial, but the peritoneal protein losses (PLL) and proteinuria may be important contributing factors. We aimed to evaluate if the total protein losses (into urine and dialysate) in PD patients have an impact on their nutritional status.

Methods: A retrospective observational study of PD patients over the first year in PD. Demographic, clinical, and analytical data were collected at baseline (time of PD initiation), 6 and 12 months later. Nutritional status was assessed using normalized protein catabolic rate (nPCR), body mass index (BMI), lean body mass (LBMI), and body fat mass (BFM). The total amount of 24h urine and dialysate protein losses (ProtUrDial) and delta (Δ) values (difference between the end of follow-up period and baseline) of continuous variables were also calculated.

Results: Twenty patients were enrolled (55±8±10.8 years; 65% male). Except for serum albumin (sAlb), which changed significantly from the baseline to the end of the follow-up period (p=0.001), there were no differences in protein loss into dialysate (ProtDial), proteinuria (ProtUrine), nPCR, BMI, LBMI, and BFM over time. In the 3 time points there was a significant positive correlation between ProtUrine and nPCR (r=0.563, p=0.01; r=0.584, p=0.031; r=0.611, p=0.004, respectively). At the end of the follow-up period, we verified a negative correlation between sAlb and ProtUrDial (r = -0.512, p = 0.033). There was no correlation between ProtDial and nutritional parameters status, however, there was a positive correlation between ΔProtUrine and ΔBMI (r=0.492; p=0.028). Regarding ΔProtUrDial, we verified a negative correlation with ΔsAlb (r=-0.664; p=0.026) and, although not significant, a positive correlation with Δ%BFM (p=0.573; p=0.066).

Conclusions: The PLL has already been linked to malnutrition in PD patients. However, we found that the total amount of protein losses daily (into urine and dialysate), and not one each individually, seems to influence the nutritional status of PD patients. Besides, proteinuria appeared to have a greater impact on nutritional changes than peritoneal losses. However, more studies with larger samples are needed to clarify this association.

MMP-7 Affects Peritoneal Ultrafiltration Associated with Elevated Aquaporin-1 Expression via MAPK/ERK Pathway in Peritoneal Mesothelial Cells

Yue Yin,1 Fen Zhang,1 Zhwen Xiao,1 Daming Zuo,2 Jun Ai.1 Southern Medical University Nanfang Hospital, Guangzhou, China; 2Southern Medical University, Guangzhou, China.

Background: Peritoneal membrane dysfunction and the resulting ultrafiltration failure are the major disadvantages of long-term peritoneal dialysis (PD). It becomes increasingly clear that mesothelial cells play a vital role in the pathophysiological changes of the peritoneal membrane. Matrix metalloproteinases (MMPs) function in the extracellular environment of cells and mediate extracellular matrix turnover during peritoneal membrane homeostasis. Aquaporin-1 (AQP-1), one of the water-specific channel proteins distributed in the endothelium lining the peritoneal capillaries, facilitates the osmotic transport of water across the capillary endothelium, thereby playing an essential role in ultrafiltration during PD.

Methods: Human peritoneal mesothelial cell (HPMCs)/line (HMrSV5) strain was continuously cultured in vitro and stimulated with MMP-7. Western Blot, RNA isolation, real-time PCR and immunofluorescence assay were used to detect the expression of MMP-7, AQP-1 and mitogen-activated protein kinases (MAPKs) phosphorylation in HMrSV5 cells, to verify that MMP-7 affects peritoneal ultrafiltration associated with elevated aquaporin-1 expression via MAPK/ERK pathway in peritoneal mesothelial cells.

Results: We showed that dialyse MMP-7 levels markedly increased in the patients with PD, and the elevated MMP-7 level was negatively associated with peritoneal ultrafiltration volume. Interestingly, MMP-7 could regulate the cell osmotic pressure and volume of human peritoneal mesothelial cells. Moreover, we provided the evidence that MMP-7 activated mitogen-activated protein kinases (MAPKs) extracellular signal-regulated kinases 1/2 (ERK) pathway and subsequently promoted the expression of aquaporin-1 (AQP-1) resulting in the change of cell osmotic pressure. Using a specific inhibitor of ERK pathway abrogated the MMP-7-mediated AQP-1 upregulation and cellular homeostasis.

Conclusions: In summary, all the findings indicate that MMP-7 could modulate the activity of peritoneal cavity during PD, and dialyse MMP-7 might be a noninvasive biomarker and an alternative therapeutic target for PD patients with ultrafiltration failure.

Psychosocial Impact of COVID-19 Pandemic on Patients with ESKD on Peritoneal Dialysis
Jin Joo Cha, Booyeon Park, Sung Gi Yoon, Dae R. Cha, Young Sun Kang.
Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

Background: The mortality rate from COVID-19 is remarkably high in elderly patients and those with chronic conditions. Increases in physical and mental stress among patients with chronic conditions, especially end-stage kidney disease, were expected to have occurred in response to the COVID-19 pandemic. This study reports that the psychosocial impact of the COVID-19 pandemic on patients receiving peritoneal dialysis.

Methods: During the pandemic, we surveyed the mental health of patients with end-stage kidney disease on peritoneal dialysis at a single center. Depression using with BDI score was evaluated and then compared in peritoneal dialysis patients between before and the pandemic declaration. We also surveyed patient satisfaction with the self-care services associated with peritoneal dialysis under the pandemic period.

Results: One-third of the survey respondents (n=176) were moderately to extremely worried about their physical health being impacted by the pandemic, while 20% moderately to extremely worried about their mental and emotional health being impacted. About half of participant reported feeling that they were unable to handle their personal problems and that things were out of their control. However, most felt that they could retain control over the important things and overcome their difficulties. Despite COVID-19 pandemic, no significant changes in depression scores were apparent between before and during the pandemic. Most participants were satisfied with the in-home self-care services delivered by either telephone or remote monitoring.

Conclusions: Many participants reported that they were afraid of COVID-19, but most patients with PD felt that they could overcome the crisis. The COVID-19 pandemic did not affect the depression of patients receiving peritoneal dialysis.

Peritoneal-Mediastinal Communication Complication in Peritoneal Dialysis
Janina Paula T. Sy-Go, Lagu A. Androgra, Fawad Qureshi, Andrea G. Kattah.
Mayo Clinic Minnesota, Rochester, MN.

Introduction: Increased intra-abdominal pressure is a well-recognized non-infectious complication of peritoneal dialysis (PD) resulting from instillation of dialysate fluid into the peritoneal cavity. Peritoneal-pleural communication causing hydrothorax is well-described in the literature, but cases of peritoneal-mediastinal communication are scarce.

Case Description: A 36-year old Caucasian man with end-stage kidney disease secondary to calciuneurin inhibitor nephrotoxicity and BK virus nephropathy transitioned to continuous cyclic peritoneal dialysis (CCPD) after one year of intermittent hemodialysis (iHD). He presented to our institution nine months after starting CCPD primarily because of complications related to prior heart transplantation. He underwent cardiac surgery and did not have any problem with his CCPD in the immediate post-operative period and was discharged. One month later, however, he presented with increased serous drainage from his sternal incision site and reduced ultrafiltration. A chest CT scan revealed a partially loculated anterior chest wall subcutaneous fluid collection. He was taken to the operating room and was found to have a peritoneal-mediastinal communication. He was successfully managed with “low-pressure” PD by using reduced fill volumes for all his exchanges, which also allowed optimal healing of the muscle flap closing the communication. Transition to iHD was considered, but he had no vascular access options for all his exchanges, which also allowed optimal healing of his fill volumes. Unfortunately, one and a half months after his last hospitalization, he succumbed to septic shock secondary to trans-lumbar PICC-associated Candida glabrata fungemia.

Discussion: A peritoneal-mediastinal communication should be suspected in an otherwise asymptomatic patient on PD with reduced ultrafiltration who underwent any form of chest surgery. Clinical suspicion can be confirmed either through CT peritoneography or intraoperatively. Management with a trial of “low-pressure” PD is feasible and can be successful, particularly if iHD is not an option. A multi-disciplinary approach involving our surgical colleagues is also crucial to ensure appropriate patient care.

Sweet Pleural Effusion in a Peritoneal Dialysis Patient
Karla G. Carias Martinez,1 Nityasree Sriarlal,1 Jose M. Monroy-Trujillo.2
1Johns Hopkins Medicine, Baltimore, MD; 2Johns Hopkins University, Baltimore, MD.

Introduction: Pleural Effusions are frequently seen in dialysis patients with an incidence as high as 80%, with a variety of possible differential etiologies.

Case Description: A 62-year-old female with HHPEF, DM and ESRD due to biopsy proven diabetic nephropathy recently started on nightly continuous cyclic PD with a prescription of 4 exchanges of 2.5% Dextrose solution with 2 liters fill volumes with a dwell time of 1840 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining a dwell time of 1h40 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining dyspnea.

338
tubes, thus its accumulation reflects an impaired RKF. Our study aimed to evaluate if serum levels of β2MG could be used as a complementary tool for evaluating RKF in peritoneal dialysis (PD) patients.

Methods: For this retrospective cohort study, we evaluated 423 urine samples of 166 patients who were in the PD program of Hospital das Clinicas, HC FMUSP, Universidade de Sao Paulo, Brazil. To be included, patients needed to have been followed for at least 90 days prior to PD initiation. Urine samples were collected at the end of a 24-hour period and immediately sent to the laboratory. We measured serum β2MG levels using a fluorescence polarization immunoassay (FP-I), which was performed on a cobas 8000 analyzer. The median time from PD initiation to the last sample was 1.5 years (IQR: 1.0, 2.0).

Results: We found a correlation between renal Kt/V and β2 microglobulin (r = -0.656, p < 0.0001), serum creatinine and urinary volume (r = -0.682, p < 0.0001), and serum creatinine (r = -0.603, p < 0.0001), and urinary volume (r = -0.682, p < 0.0001). ROC curve revealed that β2 microglobulin had a high performance to predict renal Kt/V, with a sensitivity of 70% and 81.7% according to the best cutoff. The specificity varied from 71.5% to 84.2% for Kt/V cutoff 0.5, 1.0, 1.5 and 2.0.

Discussion: Based on the good correlation found, on serum β2MG and urea renal Kt/V, we suggest that β2MG can be a useful tool to estimate the RKF. This findings can be particularly useful in patients who have difficulties in storing or collecting a 24-hour urine sample.

PO1008

Unusual Cause of Recurrent Shortness of Breath in a Peritoneal Dialysis Patient

Sonali Gupta, Mecnaskshi Sambharma, Lama A. Noureddine. The University of Iowa Hospitals and Clinics, Iowa City, IA.

Introduction: Pleuroperitoneal leak (PPL) is an unusual cause of recurrent pleural effusion in patients on peritoneal dialysis (PD). It is a rare complication and occurs in less than 2% of cases. Diagnosis is challenging and requires high clinical suspicion and awareness of this life threatening complication. Pleural fluid to serum glucose ratio >30 mg/dl is highly specific for detecting leak of high glucose dialysate into pleural cavity, however this needs to be interpreted in relation with the last dialysis session.

Case Description: A 72-year-old-female with history of end stage renal disease due to biopsy proven focal segmental glomerular sclerosis thought to be secondary to obesity started on CCPD one-month prior presented with worsening shortness of breath of 1 week duration. Workup was unremarkable except for chest X-ray that showed right side pleural effusion. A non-contrast CT chest did not show a diaphragmatic defect. She continued to have worsening SOB prompting an emergent thoracentesis that drained 1.6 L transudate pleural fluid. Pleural fluid to serum glucose gradient was normal at 5 mg/dl but pleural fluid to serum glucose ratio was >1. However, last PD session was 2 days prior to thoracentesis, which could explain this lower ratio. Due to inconsiderable [NL] results, it was decided to instill 300 mL of saline in the chest and then do a sequential CT chest. It showed interval re-accumulation of high-density pleural effusion, suggesting trans-diaphragmatic communication. Cardiothoracic surgery was consulted for repair of diaphragmatic defect; however, patient opted for hemodialysis instead.

Discussion: It is important to maintain high clinical index of suspicion in PD patients presenting with hydrothorax. Although high pleural fluid to serum glucose gradient is specific for PPL, pleural to serum glucose ratio >1 is another index that should be considered in addition to post- gastrografin imaging or technetium 99 peritoneal scintigraphy, especially if the last dialysis session was not recent and could potentially alter the biochemical assay results as happened in our case. Most cases of PPL occur soon after PD initiation, common on right side. For those who wish to continue PD, surgical repair is often required while transitioning to HD temporarily or doing low volume recurrent PD. Some case series have noted the defect to close spontaneously after holding PD.

PO1009

The Association Between Lower Serum Potassium Level and Increased Cardiovascular Death Among Patients Undergoing Peritoneal Dialysis

Hiroaki Tsujikawa,1 Toshiaki Nakano,1 Shotao Ohnaka,2 Shunsuke Yamada,3 Kazuhiko Tsuuya,1 Kumiko Torisu,1 Hitotokoi Kanai,1 Takarani Kitazono,1 1Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, Fukuoka, Japan; 2Nara Kenritsu Iba Daigaku Yukarikagu Kyoushi, Kashihara, Japan; 3Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; 4Kokura Kinen Byoin, Kitakyushu, Japan; 5Tagawa Shiritu Byoin, Tagawa, Japan.

Background: In patients undergoing peritoneal dialysis (PD), lower serum potassium concentration has been related to low nutrition status and suggested as a risk factor for all-cause and cardiovascular mortality. However, the risk of lower serum potassium concentration for cardiovascular death in patients using renin-angiotensin system (RAS) inhibitors or β-blockers is not clear. This study investigated the relationship between lower serum potassium concentration and cardiovascular death among Japanese patients undergoing PD.

Methods: We retrospectively included the 549 patients from our previous multicenter cohort study (Fukuoka Peritoneal Dialysis Database Study). The participants who had undergone PD for at least 90 days were registered from 1 January 2006 to 31 December 2016 and followed until they were transferred to hemodialysis, received a kidney transplantation, died during PD, or were lost to follow-up, or until 31 December 2017. The patients were divided into three groups according to the baseline serum potassium concentration (T1 ≤ 4.0, 4.0 < T2 ≤ 4.5, T3 > 4.5 mEq/L). We estimated the relationship between serum potassium concentration and cardiovascular mortality using a Cox proportional hazards model.

Results: During the median observation period of 2.3 years, 111 patients died of any cause, and 38 died of cardiovascular. After multivariable adjustment in the Cox proportional hazard model, lower serum potassium concentration was shown to be an independent risk factor for cardiovascular death; (hazard ratio 95% confidence intervals) T2 and T1 vs. T3 were 2.21 (1.77-2.67) and 2.67 (1.01-7.07), respectively. Stratified-analysis according to the use of RAS inhibitors, β-blockers, or a combination of both drugs showed that this relation was not modified by the use of these drugs.

Conclusions: This study showed that lower serum potassium concentration was associated with increased cardiovascular mortality in PD patients. There was no difference in the risk of lower serum potassium concentration for cardiovascular death according to the use of the RAS inhibitors and/or β-blockers in PD patients.
PO1010

Higher Serum Total Cholesterol to High-Density Lipoprotein Cholesterol Ratio Was Associated with Increased Mortality Among Incident Peritoneal Dialysis Patients

Hae Won Noh, Soojeon Jeon, Jeong-Hoon Lim, Hye-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. Department of Internal Medicine, Kyungpook National University Hospital, Korea Kyungpook National University Hospital, Daegu, Republic of Korea.

Background: A few studies have shown that serum total cholesterol to high-density lipoprotein cholesterol ratio (TC/HDL-C) was a risk factor for cardiovascular mortality in the general population. This study was aimed to evaluate the association of TC/HDL-C with mortality in incident peritoneal dialysis patients.

Methods: We enrolled Total of 6,30 incident peritoneal dialysis patients from 2008 to 2015 in a multi-center, prospective cohort study of Korea. Participants were stratified into quintiles according to the baseline TC, HDL-C, or TC/HDL-C. The association between all-cause mortality and each lipid profile was evaluated using multivariate Cox regression analysis.

Results: During a median follow-up period of 70.3 ± 25.2 months, 185 deaths were recorded. The median TC/HDL-C was 4.54 ± 2.51. Highest TC/HDL-C group showed highest body mass index, percentage of diabetes, and serum albumin level. Multivariate analysis revealed that the highest quintile of the TC/HDL-C (>5.60) was associated with increased risk of all-cause mortality (hazard ratio 1.69, 95% confidence interval 1.04 to 2.76; P = 0.036), whereas neither of TC and HDL were associated with mortality. Increased serum TC/HDL-C was also independent risk factor for mortality in the patients with old age over 50 years, non-diabetes, and any cardiovascular disease.

Conclusions: The single lipid marker of TC or HDL-C could not predict mortality in PD patients. However, non-traditional lipid profile such as increased serum TC/HDL-C ratio was independently associated with an increased risk of all-cause mortality in PD patients.

PO1011

Peritoneal Dialysis Caregiver Scope and Functions: A Systematic Scoping Review

Tanawin Nopsoon,1,2 Chitsanucha Chumsri,1 Piyawat Kantagowit,1 Krit Pongpirul.3,5 Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 4Harvard University T H Chan School of Public Health, Boston, MA; 1Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: Caregivers play important roles in peritoneal dialysis (PD) care. Classifying PD self-care tasks is important for determining the PD caregiver roles. As the scope and functions of PD caregiver in published literature have been inconsistent, we aimed to systematically explore the variations of the term caregiver in high-quality PD studies.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL for randomized controlled trials and observational studies relevant to a caregiver in ESRD PD studies. We aimed to systematically explore the variations of the term caregiver in high-quality PD studies.

Results: Of 2,514 potential studies relevant to a caregiver in ESRD patients with PD, 299 theme-related abstracts were selected for further full-text articles screening according to eligibility criteria, and 111 were included in the systematic review (72,101 patients in 34 countries). In terms of word choice, “caregiver(s)” was used in 86.4%, “caretaker(s)” in 20.7%, and other words were used in 13.5% of included studies. Only 8.1% of studies gave the explicit definitions of those words. The most referred person is the parents (40.5%), followed by a spouse (37.8%), other family members (37.8%), children (34.2%), non-relative non-healthcare workers (25.2%), friends (20.7%), and healthcare workers (19.8%). The explanation of functions for each word comprises 41.4%, with the PD-specific functions by 32.4%, instrumental activities of daily living by 9.9%, and basic activities of daily living by 5.4%.

Conclusions: PD caregiver has been broadly defined and vary across studies. PD-specific functions should be used for making the definition of PD caregiver clearer.
Methods: An end-vein to side-artery AVF was surgically created in the femoral vessels of rats which had previously been subjected to uremia via subtotal nephrectomy. At 1 and 2 weeks after AVF formation the arterial and venous limbs of the AVF were harvested for the assessment of gene and protein expression and the assay of SA-B-Gal activity. Femoral veins and arteries from rats subjected to sham surgery were used as controls.

Results: At 1 week after AVF creation mRNA levels of senescence drivers p16 and p21 were markedly elevated in AVF veins compared to sham veins, as were p21 protein levels; the AVF artery also displayed elevated p21 protein levels at this time point. At 2 weeks, p21 protein was again upregulated in both the vein and artery of the AVF, and protein levels of an upstream mediator in the p21 senescence pathway, p53, were significantly increased in the AVF artery; p53 levels did not achieve significance (p=0.083) in the AVF vein at this time point. Upregulation of SASP factors was also observed in the AVF artery at 1 week: mRNAs expression of PAI-1, IL-6, TNF-α and MCP-1 was robustly increased as compared to sham veins at 1 week after AVF creation. Additionally, miR21, which has been associated with vascular senescence, was markedly elevated in the AVF vein at 1 week post AVF placement. Finally, SA-B-Gal activity, an established marker of senescence was significantly increased in both the artery and vein compared to their sham counterparts at both 1 and 2 weeks post AVF surgery.

Conclusions: Using established criteria, this study demonstrates that the rat femoral AVF in the setting of CKD has a senescence phenotype similar to the murine AVF-CKD model. These findings thus demonstrate the development of senescence in another species subjected to an AVF in the presence of uremia.

PO1014

The Adaptive Response of the Vein to CKD: A Transcriptomics Perspective

Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Miguel G. Rojas,1 Juan C. Duque,1 Loay H. Salman,1 Roberto I. Vazquez-Padron,2,3 University of Miami School of Medicine, Miami, FL;1 Albany Medical College, Albany, NY;1 VA Miami Healthcare System, Miami, FL.

Background: The impact of CKD on gene expression in the vascular wall remains unknown, particularly in veins, despite their fundamental role as conduits for hemodynamic stress.

Methods: In this study, we investigated the CKD fingerprint on the transcriptome of basilic veins by analyzing 48 pre-access veins from end-stage renal disease patients and 20 veins from non-CKD trauma donors by bulk RNA sequencing.

Results: We uncovered 16,893 differentially expressed genes (DEG) between CKD and control individuals (log(FoldChange)>1, FDR<0.05). The presence of kidney disease caused a noticeable decrease in transcriptional activity in veins, with the downregulation of >97% of DEG transcripts. These included 6,081 non-coding RNAs, 3,826 protein-coding genes, and other miscellaneous transcripts. In contrast, a unique set of 462 genes was upregulated in CKD veins vs. controls, 161 of which corresponded to non-coding RNAs, 201 to protein-coding genes, and the rest to minor RNA biotypes. Gene set enrichment analysis (GSEA) identified a suppression of pathways related to vascular maintenance, cell morphogenesis, cell metabolism, and microtubule-based cytoskeletal functions. Interestingly, the protein-coding genes upregulated in CKD veins belonged to processes related to gas transport and detoxification of oxidative stress byproducts.

Conclusions: In conclusion, we have uncovered a profound suppressive effect of CKD on the venous transcriptome, likely affecting basic cell functions such as metabolism, cell division, and migration. We also identified a transcriptional signature of upregulated genes in response to oxidative stress which may play a fundamental role in cell survival in the CKD environment.

Gender-Specific Risk Genes in Arteriovenous Fistula Failure

Roberto I. Vazquez-Padron,1 Marwan Tabbara,1 Miguel G. Rojas,1 Akshara Sree Challa,1 Juan C. Duque,1 Loay H. Salman,1 Laisel Martinez,1 University of Miami School of Medicine, Miami, FL;1 VA Miami Healthcare System, Miami, FL.

Background: Gender is known to play a role in arteriovenous fistula remodeling and risk of failure. However, the clinical and molecular mechanisms behind this phenomenon have not been elucidated.

Methods: To address this question, 48 pre-access veins obtained at the time of two-stage AVF creation (24 matured and 24 failed postoperatively) and 40 postoperative transposition samples (20 matured and 20 failed) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Females and males were equally represented in both outcome groups and were similar in demographics and baseline characteristics. We searched for common and sex-specific differentially expressed genes (DEG) in pre-access veins and postoperative samples in association with failure.

Results: In the pre-access vein, we found 28 DEG between veins that matured or failed postoperatively (log(FoldChange)>1, FDR<0.05) and in common between both sexes. In the veins, 115 DEG were differentially expressed between both outcomes, whereas no female-specific DEG were detected in the same number of individuals. Principal component analyses demonstrated more transcriptional variability in both outcome groups in females, decreasing our power to identify female-specific genes in the female cohort. In postoperative samples, we found 156 DEG between fistulas that matured or failed and in common between both sexes. In addition, 143 female-specific and 153 male-specific genes were differentially expressed between outcomes, indicating gender relevant processes of postoperative remodeling. Both sexes showed a downregulation of genes related to responses to external stimuli and stress. However, gene set enrichment analysis (GSEA) revealed a suppression of cell-surface receptor signaling and cell adhesion mechanisms in males but not in females, suggesting a sex-specific effect in cell migration.

Conclusions: In conclusions, these analyses uncover potential differences in postoperative remodeling between females and males in relation to AVF failure. They also indicate a more complex transcriptional landscape in female tissues which may affect our ability to predict remodeling in this group of patients. These data may open the door to personalized medicine in preventing or treating vascular access complications.

Inhibition of Phosphodiesterase Type 5A Prevents Pathological Cardiac Remodeling Following Arteriovenous Fistula Creation

Maheshika S. Somarathna,1 Taylor G. Lewis,2 Kevin A. Ingle,1 Tatyana Isayeva Waldrop,1 Jimmy C. Lee,1 'The University of Alabama at Birmingham, Birmingham, AL;2 Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.

Background: Cardiac events are the most common etiology of mortality in hemodialysis patients. The gold standard of vascular access, the arteriovenous fistula (AVF), may adversely affect cardiac structural and functional remodeling leading to heart failure. We hypothesize that inhibition of cGMP catalysis with a selective phosphodiesterase type 5A (PDE5A) inhibitor, sildenafil, may induce more favorable cardiac remodeling following AVF creation.

Methods: Sildenafil was administered to 12-16 weeks old Sprague-Dawley rats two weeks prior to AVF creation and continued until sacrifice at 28 days. Cardiac structural and functional changes were evaluated by 1) 2D-echocardiography 2) measurement of collagen volume and oxidative stress and 3) evaluation of cardiac contractility.

Results: Sildenafil treatment significantly improves the pathological collagen degradation, reduces HNE expression, reverses desmin demineralization and focal mitochondrial clustering following AVF creation, as compared to the control. We also observed a significant increase in cardiac output and stroke volume without reversing LV dilatation which may suggest improvement in cardiac contractility.

Conclusions: PDE5A inhibition may provide a new treatment strategy for pathological cardiac remodeling following AVF creation.

Pre-Access Vein Transcriptomics as a Predictor of Arteriovenous Fistula Failure: A Machine Learning Approach
Miguel G. Rojas,1 Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Juan C. Duque,2 Loay H. Salman,3 Roberto I. Vazquez-Padron,1,4 1University of Miami School of Medicine, Miami, FL; 2Albany Medical College, Albany, NY; 3VA Miami Healthcare System, Miami, FL.

Background: As the number of patients with end-stage renal disease continues to rise, the creation of a robust and efficient hemodialysis access is more important than ever. A mature arteriovenous fistula (AVF) is the preferred method for long-term hemodialysis. However, the nationwide maturation rate continues to be as low as 50-60%, and we currently lack an effective risk stratifying method to identify patients at higher risk of AVF failure.

Methods: To address this clinical need we developed a predictive model based on supervised machine learning from transcriptomics of the pre-access vein. Forty-eight pre-access veins obtained at the time of AVF creation (24 matured and 24 failed postoperatively) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Both outcome groups were matched by age, sex, demographics, and baseline clinical characteristics. The highest expressing genes (normalized gene expression counts >200) were used as input in KNN, SVM, XGBoost, and other machine learning algorithms. Area under the curve (AUC) and receiver-operating characteristic (ROC) plots were used to compare the performance of the models relative to each other. The best performing algorithm, XGBoost, was optimized with the following hyperparameters [gamma=0.25, learning_rate=0.001, max_depth=4, reg_lambda=10, scale_pos_weight=3]. The SHapley Additive exPlanations (SHAP) analysis was then used to evaluate the highest contributing features to the XGBoost model.

Results: Ten highly predictive and abundantly expressed genes were identified using this methodology (RICK1, CLIC3, DNLAL1, FOXO4, TIMMDC1, GALNT11, CDH13, KLHC10, ZNF8, and DBT). Using these transcripts, the AUC in the logistic regression model is 97.6%.

Conclusions: In conclusion, this study has identified 10 potential pre-access gene predictors of postoperative AVF failure, which could be used clinically as a stratifying or risk management tool in vascular access patients.

Arteriovenous Fistula Non-Maturation: Does the Immune System Play a Role?
Crystal A. Farrington,1 Gary R. Cutter,2 Michael Allon,3 1The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; 2The University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background: Arteriovenous fistula (AVF) non-maturation is a persistent problem, particularly among female and Black patients. The immune system promotes several well-studied. We evaluated the association of serum panel reactive antibodies (PRA), a measure of immune system reactivity assessed in patients undergoing kidney transplant, with the following hyperparameters {gamma=0.25, learning_rate=0.001, max_depth=4, reg_lambda=10, scale_pos_weight=3}. The SHapley Additive exPlanations (SHAP) analysis was then used to evaluate the highest contributing features to the XGBoost model.

Methods: To address this clinical need we developed a predictive model based on supervised machine learning from transcriptomics of the pre-access vein. Forty-eight pre-access veins obtained at the time of AVF creation (24 matured and 24 failed postoperatively) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. The Association of Transition-to-Dialysis Planning and Healthcare Resource Use and Mortality in Patients with ESRD

**Insyba B. Poonawalla,**1 Kanchan Barve,1 Meghan C. Cockrell,2 Amal Agarwal,2 Adrienne W. Casebeer,3 Yong Li,1 *Humana Healthcare Research, Inc., Louisville, KY; 2Humana Inc, Louisville, KY.*

**Background:** The onset of ESRD is associated with poor outcomes and high mortality, and the role of transition-to-dialysis planning is not well understood. We evaluated the association between dialysis transition planning factors such as nephrologist care, vascular access placement, and place of index dialysis, with inpatient (IP) stays, emergency department (ED) visits, and mortality.

**Methods:** This retrospective study used the Humana Research Database to identify 7,026 patients, 19-89 years of age, diagnosed with ESRD between 1/1/17 and 12/31/17, enrolled in a Medicare Advantage Prescription Drug plan, with ≥12 months of continuous enrollment pre- and post-index date (i.e., first evidence of ESRD). Patients with a kidney transplant indication, hospice election, or dialysis pre-index were excluded. Transition-to-dialysis planning was defined as optimal, partial, or unplanned (Table 1). IP stays, ED visits, and mortality were evaluated within 12 months post-index.

**Results:** The cohort was 41% female, 66% White, with an average age of 70 years. An optimally planned, partially planned, and unplanned transition to dialysis occurred for 15%, 34%, and 44% of the ESRD cohort, respectively. Among patients with pre-index CKD stages 3a and 3b, 64%, and 55%, respectively, had an unplanned dialysis transition. For patients with pre-index CKD stages 4 and 5, 68% and 84%, respectively, experienced planning prior to dialysis initiation. In adjusted models, patients with partially or optimally planned transition to dialysis were 57% to 72% less likely to die, 20% to 37% less likely to experience an IP stay, and 80% to 100% more likely to experience an ED visit than patients with an unplanned transition. Higher ED utilization with planned transition was attributed to longer time to mortality, allowing more time for healthcare utilization.

**Conclusions:** A planned transition to dialysis was associated with improved outcomes and lower mortality. Targeting care coordination for patients with CKD stages 3a/3b may help slow disease progression and ensure a planned, safer transition to dialysis.

Prediction of Stenosis in Arteriovenous Fistula Using Video Image Analysis

Fanfan Zhu,1 Lin-Chun Wang,1 Alhaji Cherifi,2 Ohmmar Thwin,1 Lela Tisdale,1 Xia Tao,1 Paulo Paneque Galuzio,1 Norbert Shatynberg,2 Dean C. Predicid,2 Peter Kotanko,1,3 Renal Research Institute, New York, NY; Azura Vascular Care, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** We developed a video image processing (VIP) technique with frequency domain analysis to predict stenosis in AVF. The study aimed to evaluate whether the degree of stenosis can be assessed using parameters from frequency domain signal analysis.

**Methods:** We employed VIP in 100 hemodialysis patients (age 63.3 ±14.1 years, 47 females) prior to endovascular arterio-venous fistula (AVF) interventions. A 1-minute video of the AVF area was recorded using a smartphone (Fig 1). We constructed time series based on pixel changes between two consecutive video frames (Fig 2-A) and used Fast Fourier Transform (FFT) to transform the time domain signals into the frequency domain (Fig 2-B). Parameters in the frequency domain included maximal (Max) and minimum (Min) amplitude, and frequency (F_min and F_max). AF was defined as F_max - F_min M2 was calculated by the squared ratio of the Max-to-median magnitude. The degree of AVF stenosis (%ST) was determined by angiography, the access flow (AF) by thermodilution.

**Results:** Data from 98 patients were analyzed. %ST was categorized into three groups: 60% stenosis (n=8), 70-80% (n=76), and 90% (n=14). AF correlated with %ST. Max, F_max, and AF were associated with %ST (Table 1). An algorithm was developed to predict degree of %ST based on patient characteristics and parameters of frequency domain analysis. In the respective three %ST groups the sensitivities to detect AVF stenoses were 88%, 86% and 100%, and the specificities 99%, 82% and 98% (Table 1).

**Conclusions:** VIP applied to videos taken with a smartphone may provide a contact-free method to estimate the degree of AVF stenosis. Validation studies in independent cohorts are needed to further assess the diagnostic capability of the proposed method.
Catheter-Related Bloodstream Infection Incidence and Associated Mortality Risk: Analysis of Merged USRDS-Medicare Claims

Aaron Kenneth 

Mortality Risk: Analysis of Merged USRDS-Medicare Claims

Vascular Access Arena: Challenges, Progress, and Prospects

J Am Soc Nephrol 32: 2021

of the 55,727 CVC-dependent HD patients (mean age 67.8, 45% female), nearly 29% (n=15,882) developed a CRBSI (median time, 69 days); 54% (n=8,393), 67% (n=10,327), and 80% (n=12,705) occurred within 90, 180 and 365 days of CVC insertion, respectively. After CRBSI occurrence, 40% and 50% died within 60 days and 180 days, respectively. CRBSI patients also had a significantly lower median survival (25.1 vs. 37.3 months) compared to non-CRBSI patients [hazard ratio: 0.74, 95% CI: 0.71-0.76].

Conclusions: CRBSI is a major complication that results in higher mortality risk and shorter survival. A CVC control group was identified by an assigned index date (i.e., CVC insertion date + median time to CRBSI). Patients with CRBSI had a higher risk of death compared to patients without CRBSI; with a 40% mortality within 60 days post-CRBSI.

Vascular Access in Kidney Transplant Patients with Allograft Failure Returning to Hemodialysis

Molly Fisher,1 Anirudh R. Gone,1 Linda Mathew,1 Crystal K. Johnson,1 Enver Akalin,1,2 Michele H. Mokrzycki,1,2 Tanya S. Johns,1,2 Montefiore Medical Center, Bronx, NY; 2Albert Einstein College of Medicine, Bronx, NY.

Background: Central vein catheters (CVC) are the predominant vascular access (VA) in incident hemodialysis (HD) patients and are associated with worse outcomes compared to arteriovenous (AV) access. Limited data exist on VA type and association with outcomes in kidney transplant recipients (KTR) with allograft failure. We aimed to determine factors associated with VA type among KTR with allograft failure who return to HD.

Methods: We performed a retrospective study of 147 KTR >18 years with allograft failure between 2010-2021 at an academic hospital in the Bronx, NY. KTR with immediate allograft failure or <1 month of HD following allograft failure were excluded. Data was collected on pre-transplant dialysis modality, vintage, and VA type. Data at allograft failure included sociodemographics, comorbidities, clinic visits, VA type. Descriptive analyses and logistic regression were performed to evaluate factors associated with VA among KTR who return to HD.

Results: At allograft failure, mean age was 53 years (SD 15), 62% were men and 46% were of Black race. Pre-transplant, 91.8% patients were on HD; 2.7% were on peritoneal dialysis (PD), and 5.5% were not on dialysis. Mean vintage was 4.6 years (SD 4.4). Pre-transplant VA included AV access in 87.7% and CVC in 4.1% of patients. At allograft failure, 82.3% and 17.7% KTR initiated HD with an AV access and CVC, respectively. Compared to pre-transplant HD patients, those on PD or who received a preemptive transplant were less likely to initiate HD with an AV access at time of allograft failure (80.6% vs 50% vs 12.5%, p<0.001). KTR were 19% less likely to initiate HD with an AV access for each year increase between the time of transplant and allograft failure (OR 0.81, 95% CI 0.69-0.94). Sociodemographics, comorbidities and number of clinic visits 1 year prior to allograft failure were not associated with VA. One year mortality was 10.7% in KTR initiating HD with a CVC vs 3.4% in those with an AV access (p=0.12).

Conclusions: The majority of KTR with allograft failure returned to HD with an AV. CVC use was higher in those with longer allograft survival, previously on PD or who received a preemptive transplant, highlighting a need for transition of care optimization. Larger studies are needed to determine if VA type is associated with mortality in this population.

Reusing Occluded Veins: Inside-Out Central Venous Access for Hemodialysis, Our Institutional Experience

Emaud A, Chishti, Sayee Sundar Alagusundaramorthy. University of Kentucky Medical Center, Lexington, KY.

Background: Central venous occlusion is a challenge in end-stage renal disease (ESRD) patients dependent on hemodialysis. The inside-out central venous access (IOCV) procedure is an established method of re-using occluded central veins.

Methods: Retrospective single-center study examining characteristics of patients with ESRD who underwent IOCVA between 01/01/2017 – 05/01/2021. All procedures were performed with moderate conscious sedation by an interventional cardiologist or nephrologist.

Results: 46 IOCVA procedures were performed in 39 ESRD patients. All procedures were performed to re-use the occluded right internal jugular vein (RIJ) for tunneled dialysis catheter placement. Mean patient age was 58 ± 14.6 years. 20 (51.3%) patients were male. Hypertension and diabetes were comorbid conditions in 29 (74.4%) and 20 (51.3%) patients, respectively. A total of 7 (17.9%) patients had prior kidney transplant.

Machine Learning for Prediction of Arteriovenous Fistula Failure
Suman K. Lana,1 Rishi Razdan,2 Murat Sor,2 Eyal Barzel,2 Caitlin Monaghan,1 Joanna Willetts,1 Sheetal Chaudhuri,1 Nancy Mclaughlin,1 Hanjie Zhang,2 Peter Kotanko,2 Jeffrey L. Hymes,1 John W. Larkin,1 Len A. Usvyat,1 Frank W. Maddux,1* Fresenius Medical Care, Waltham, MA; 1Akrora Vascular Care, Malvern, PA; 2Renal Research Institute, New York, NY; 3Fresenius Medical Care North America, Waltham, MA.

Background: Vascular access aneurysms are a frequent finding in hemodialysis patients with arterio-venous (AV) fistulas and grafts. Of great concern is aneurysm rupture that may result in fatal hemorrhage. To that end we used artificial intelligence (AI) to automatically evaluate vascular access aneurysms.

Methods: We collected images of a diverse range of AV vascular accesses using mobile devices. Vascular access experts adjudicated the images and diagnosed the severity of AV fistula and graft aneurysms. We then randomized the images for training (70%) and validation (30%). We trained a convolutional neural network (CNN) utilizing Amazon SageMaker platform. CNN performance was measured by the area under the receiver operating characteristics (ROC) curve in the validation images.

Results: We collected 1,341 AV access images in patients dialyzed in 20 Renal Research Institute clinics in six U.S. states. The adjudication of images identified 1,093 not advanced and 248 advanced aneurysms; examples are shown in Figure 1. With the validation images, we achieved an area under the ROC curve of 0.96. Considering different probability threshold for advanced aneurysm, if threshold is 0.37, we achieved sensitivity of 80%, specificity of 95%, false positive rate of 5%, precision of 79% if threshold is 0.7, specificity of 66%, specificity of 99%, false positive rate of 1%, precision of 92%.

Conclusions: Our solution of applying advanced AI technologies achieved very high sensitivity, specificity, precision, and a low false positive rate. The CNN could assist the clinician with actionable information and improve clinical outcomes.

Funding: Commercial Support - Fresenius Medical Care North America

PO1031
Evaluation of a Wearable Device for Continuous, Noninvasive Monitoring of Hematocrit Levels in Hemodialysis Patients

Background: Maintenance of euvelumia is a major challenge for hemodialysis patients, who account for a combined 6.5M annual hospital days. Clinical outcomes could be improved, and healthcare costs lowered, by enabling better management of fluid status and anemia, which is common among ESRD patients. This study presents a novel wearable device, SmartPatch, that uses multi-wavelength photoplethysmography (PPG) and other sensors to measure blood hematocrit (Hct), a key metric for monitoring fluid status and anemia. The SmartPatch is a component of a novel Remote Monitoring System (RMS) that facilitates secure data transmission and analysis and generates actionable alerts. Data demonstrating the feasibility of the RMS were previously presented at Kidney Week 2019 (Kuraguntla et al.). The aim of this study was to evaluate the system’s ability to accurately and precisely measure Hct in a real-world dialysis setting.

Methods: 14 ESRD patients with arteriovenous fistulae currently undergoing dialysis were recruited to participate in this study. Each of these patients had a SmartPatch device placed on the skin over their fistula at each of three dialysis sessions two weeks apart. Reference Hct measurements were taken immediately before and after the session, times to coincide with SmartPatch data recordings. A total of 83 sets of multi-channel PPG data were recorded and analyzed to determine the accuracy and precision of Hct measurement.

Results: The RMS measured Hct with root-mean-square error (RMSE) of 2.13 Hct compared to reference values obtained from a Sysmex XN-1000 blood analyzer. The standard deviations for each read on the same patient—with the same device—were computed and averaged, weighted by group size, as a measure of precision. The RMS measured Hct with a mean standard deviation of 1.15 Hct. These error and standard deviation values compare favorably to available point-of-care devices like the HemoCue Hb 201++, which has been reported to measure Hct with a mean of 4.32–4.81 Hct and standard deviation of 1.56–3.88 Hct.

Conclusions: The results of this study illustrate the ability of the wearable SmartPatch to non-invasively measure blood Hct in ESRD patients with AV fistulae, to a degree of accuracy and precision that may outperform available point-of-care methods. This study also demonstrated the efficacy of the end-to-end Remote Monitoring System.

Impact of a Change in Vascular Access Flow Volume After Percutaneous Transluminal Angioplasty on Cardiac Function
Koji Hashimoto, Makoto Harada, Yosuke Yamada, Yuji Kamijo. Shinshu Daigaku Ikgakubo Fuzoku Byoin, Matsumoto, Japan.

Background: Vascular access (VA) is necessary for patients on hemodialysis, and percutaneous transluminal angioplasty (PTA) is a useful treatment for maintaining VA function. PTA immediately increases the VA flow volume, which can affect cardiac function. We investigated the relationship between changes in VA flow volume and cardiac function in patients who underwent PTA.

Methods: This was a single-center retrospective observational study, including patients who underwent PTA between June 2016 and August 2016. VA flow volume and cardiac function were measured by sonography before and 1 hour after PTA.

Results: This study included 50 PTA procedures in 50 cases. PTA significantly increased the median VA flow volume from 445 (range, 150–1229) to 725 (350–1268) mL/min. Although the ejection fraction and diameter of the inferior vena cava were unchanged, the cardiac output (CO) and cardiac index increased significantly in most cases. Surprisingly, the CO was obviously decreased in 18% of cases despite the increased VA flow volume. In this atypical group, a high CO before PTA was found to be a significant factor for the decrease in CO by PTA.

Conclusions: In most cases, both VA flow volume and CO were increased by PTA, whereas in some cases, the CO was decreased despite increase in VA flow volume. This atypical phenomenon may be due to the insufficient adaptive response in the peripheral artery and heart and could predict risks for future cardiac events. Therefore, it is important that such patients are carefully followed up.

PO1033
Predicting Arteriovenous Graft Failure with Sound Signatures in Patients on Hemodialysis
Tiffany W. Shien,1,2 Juan-Wei Xu,1 Yu-Ren Yeh,1 Hugo Y. Lin,1,2 Kaohsiung Municipal United Hospital, Kaohsiung, Taiwan; 2Kaohsiung Medical University, Kaohsiung, Taiwan; National Kaohsiung Normal University - Yanchao Campus, Kaohsiung, Taiwan.

Background: The fast-growing prevalence of end stage renal disease leads to an increasing number of patients requiring dialysis worldwide. Specifically, patients on hemodialysis face the problem of maintaining their vascular accesses. Unfortunately, occurrence of stenosis and clots is not uncommon, especially in arteriovenous grafts (AVG). Graft longevity can be improved by effectively detecting and preventing these circumstances. The aim of this study is to develop a portable recording device that detects stenosis by extracting information from blood flow sounds.

Methods: Blood flow sounds were collected at four different locations on the arm, including venous and arterial ends of arteriovenous access. Measurements were conducted weekly, with four minute-recordings per patient. A logistic regression model is used to analyze sound data. Recordings obtained prior to percutaneous transluminal angioplasty (PTA) procedures were labeled abnormal and those after PTA were labeled normal. Extracted features from each labeled recording include energy, spectrum, mel-frequency cepstrum, and chroma, as shown in Figure 1.

Results: In total, we have 109 labels, 25 of which are abnormal cases. Note that each case contains 4 separate recordings. For evaluation purposes, we randomly chose 75% of the labels as training cases and used the rest as testing cases. Each random trial compares single-location detection models to one integrated model, which combines data from all four locations. The trial was repeated 100 times. Our results in Table 1 indicate that arterial sounds are more informative than venous sounds in detecting stenosis. Note that the integrated model also significantly outperforms the other single-location models.

Conclusions: Our proposed model shows excellent performance in screening for AVG failure. This algorithm has potential to provide reliable and reproducible detection of vascular access abnormalities, optimizing AVG outcome and management for clinicians and patients.

A Novel Method for Ligation of Accessory Veins: A Case Series of Eight Patients
Khaled Boubes,1 Nabil J. Haddad,1 Anil K. Agarwal1 1The Ohio State University, Columbus, OH; 2VA Central California Health Care System, Fresno, CA.

Introduction: Accessory veins are a common cause for decreased blood flow through the body of arteriovenous fistulae (AVF). A common practice is to have these ligated surgically through a cut-down procedure. Alternatively, these can be blocked by coiling, embolization, or by percutaneous ligation. We present a case series where accessory veins were ligated percutaneously under direct ultrasound (US) visualization.

Case Description: A total of 8 patients underwent percutaneous accessory vein ligation from Dec 2020 through May 2021. None had any immediate complications. Occlusion of blood flow through the accessory vein was confirmed by color doppler ultrasonography and by angiography. Technique description: After identifying the accessory vein on angiography and its impact on the flow through the AVF, the vein is then identified using the US. The location to ligate the vein is then chosen as close as possible to the vein “take-off”. Using a 4-0 absorbable suture and under direct US visualization, the needle is inserted from one side of the vein and passed underneath to come out from the other side. Then, the needle is flipped and inserted back subcutaneously, passing above the vein to come out eventually next to the initial insertion site. The suture is then tied firmly. Depending on the size and location of the vein, another suture can be done in a similar fashion a few millimeters away. Color doppler is then used to detect any flow through the vein. Confirmation of the cessation of flow can also be achieved by repeat angiography.

Discussion: Percutaneous ligation of the accessory veins is a technique that saves the patients from undergoing an open surgical intervention. Utilizing the US for direct visualization of the needle during the procedure enhances its safety and efficiency.
PO1035

Feasibility of Treating Stenotic Fistula Lesions with a Drug-Coated Balloon Prior to Using a Standard High Pressure Balloon
Sylvester Barnes,1,2 Edward Hines Junior VA Hospital, Hines, IL; Loyola University Chicago, Chicago, IL.

Background: Hemodialysis access maintenance is a major cost expenditure for dialysis care. Patients often require multiple procedures per year, often treating the same access lesion in a AVF / AVG. A large proportion of stenotic lesions develop secondary to neointimal hyperplasia. Standard treatment has been angioplasty using high pressure non-compliant balloons. Recently drug coated balloons (DCB), coated with the medication paclitaxel, to help decrease neointimal hyperplasia, have been used in dialysis access treatment. The safety profile and efficacy have been proven to decrease lesion reoccurrence at 6 months when compared to regular angioplasty. Traditionally the recommendation for use of DCB is to follow after the lesion has been primarily dilated with a high-pressure balloon (HPB).

Methods: For DCB use the manufacture recommends pretreatment of the lesion with a HPB followed by secondary DCB treatment. This Arthur decided to modify the technique and treat lesions needing angioplasty with DCB first (example in figure 1) and only secondary treatment with HPB if there was not sufficient resolution of the lesion / balloon inflation to achieve less than 50% residual stenosis. Observational data is being tracked for patients undergoing fistulograms to provide a single center observational prospective cohort to look into this issue.

Results: Currently 11 patients with 15 total lesions have undergone this modification of treatment in the past 9 months, with 3 of the 11 patients having repeat fistulograms post treatment. Nine of the 11 patients required no HPB follow up. One of the 11 patients suffered a cephalic arch rupture and required stent graft placement.

Conclusions: Early data from this observational study shows that treatment of a stenotic lesion using a DCB as the only treatment is effective in the majority of cases to achieve full lesion angioplasty. Preliminary results indicate no change in long term efficacy in the DCB lesion treatment.

PO1036

Predictors of Vascular Access Thrombosis in Maintenance Hemodialysis Patients: An Historic Cohort Study
Rita Verissimo,1,2 Luís Leite de sousa,1,3 Tiago J. Carvalho,1,4 Artur P. Mendes,1,2 1DaVita Vascular Access Center - Lisbon, Lisbon, Portugal; 2DaVita Sacavém Hemodialysis Unit, Lisbon, Portugal, 3DaVita Sintra Hemodialysis Unit, Lisbon, Portugal; 4DaVita Cascais Hemodialysis Unit, Lisbon, Portugal.

Background: Vascular access (VA) thrombosis is a known complication in patients with end-stage kidney disease on hemodialysis (HD), but its risk factors are not completely established. We performed a study with the aim of ascertaining risk factors for VA thrombosis.

Methods: A multicenter retrospective cohort study was performed in three HD units to determine VA thrombosis rate and associated risk factors in maintenance HD patients, from July 2019 to April 2021. Descriptive statistics were calculated and expressed as median (IQR) or count (%). Univariate and multivariate logistic regression was used to calculate the adjusted odds ratio (aOR) with 95% CI for the variables associated with VA thrombosis.

Results: From a total of 178 maintenance HD patients, there were 30 (16.9%) VA thrombosis during follow-up. Our cohort had a median of 71 years (61-80), 59.6% (n=106) were male, were on HD for a median of 63.52 months (37.58-98.87), 37.6% (n=67) had diabetes, 66.1% (n=107) cardiovascular disease and 35.6% were on anticoagulant or antiplatelet agents. As to the VA, 87.1% (n=155) had arteriovenous fistulas (AVFs) and 28.1% (n=50) had history of previous percutaneous or surgical interventions. When comparing cases that led to thrombosis to VAs that maintained patency, thrombosis was more likely in arteriovenous grafts (AVGs) versus AVFs (60.9% vs 19.3%, p< 0.001), in VAs that had previous percutaneous or surgical interventions (34% vs 10.2%, p<0.001), had a VA flow (Qa) slope ≥ 25% or Qa value < 500ml/min, excluding radiocephalic AVFs (30.4% vs 11.7%, <0.001) and those with spKt/V < 1.4 (40% vs 11.2%, p<0.001). Multivariate analysis risk factors independently associated with VA thrombosis were AVFs [aOR 13.35 (4.38-40.74), p<0.001], Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs [aOR 5.00 (1.76-14.18), p<0.003], and spKt/V <1.4 [aOR 8.23 (2.90- 23.35), p<0.001]. The model had a Nagelkerke R2 of 42.1%, Hosmer-Lemeshow goodness-of-fit test performed well (χ2= 0.215, df=3, p=0.975) and showed very good discrimination ability [AUROC 95% CI 0.85 (0.77-0.94)].

Conclusions: Our study showed AVGs, Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs, and spKt/V < 1.4 were independent predictors of VA thrombosis. Interestingly, patients’ demographic characteristics and comorbidities were not associated with VA thrombosis.

PO1037

Efficacy and Safety of Plastic Cannulae Compared with Metal Needles in the Initial Use of an Arteriovenous Fistulae in Incident Hemodialysis Patients: A Randomized Controlled Study
Sung Gyun Kim, Hoi Woul Lee, Jwa-kyung Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Successful cannulation of an arteriovenous fistula (AVF) is important in patients starting hemodialysis (HD). Metal needles have been used for decades, but the usefulness of plastic cannulae has recently been demonstrated as a new technique.

Methods: As a prospective, randomized study, eligible patients were randomized into two groups in a 1:1 ratio (n=45/group). Maturation of the AVF was confirmed using Doppler ultrasound. The primary endpoint was the initial cannulation failure rate, defined as the failure of successful completion of three consecutive dialysis sessions. The secondary endpoints were time for hemostasis at the end of HD, degree of patients’ pain, degree of cannulation difficulty felt by the nursing staffs, and achieving optimal HD adequacy.

Results: The mean time from AVF creation to the first cannulation was 48.1±16.7 days. A total of 17 cases of cannulation failure occurred, and the failure risk tended to be higher in the metal needle group than the plastic cannula group (HR 2.6, 95% CI 0.95-7.41) after adjusting for age, gender, comorbidities, and location. The overall incidence of vessel injury was higher and time for hemostasis was significantly longer in the metal group than the plastic group. The use of plastic cannula was associated with better HD adequacy compared to metal needle. However, the patients’ pain score (P=0.004) and nursing staff’s cannulation difficulty score (P=0.084) were higher in the plastic group, emphasizing the great importance of practice using plastic cannula.

Conclusions: The vascular outcomes of plastic cannulae were much favorable compared to metal needles in incident HD patients. The use of plastic cannulae could be a new and innovative way to improve the quality of dialysis.
Vascular Access Arena: Challenges, Progress, and Prospects

Conclusions: While patients and providers identified common perspectives related to the nature and timing of the vascular access decision, conflicting priorities and preferences may impact the decisional outcome. This study highlights opportunities to address decisional conflicts and enable shared decision making in vascular access selection.

Vascular Access Selection Among People Receiving Hemodialysis: A Qualitative Study of Shared Decision-Making
Meghan J. Elliott,1 Pietro Ravani,1 Robert R. Quinn,1 Jennifer M. MacRae,1 Shannon Love,2 Matthew J. Oliver,2 Swapnil Hiremath,2 Matthew T. James,1 Kathryn M. King–Shier,1 1University of Calgary, Calgary, AB, Canada; 2University of Ottawa, Ottawa, ON, Canada.

Background: Vascular access decision processes have been receiving increased attention; however, the extent to which these decisions are made is unclear. We aimed to explore how such decisions are made from the perspectives of patients, their caregivers, and their healthcare providers.

Methods: This qualitative descriptive study used purposively sampled patients receiving maintenance hemodialysis via an arteriovenous fistula or central venous catheter, their informal caregivers, and their healthcare providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, thematic analysis approach.

Results: Participants described a decisional hierarchy, whereby decisions regarding vascular access were predicated on upstream decisions (i.e., dialysis initiation, transplantation, home dialysis) that were preference sensitive and prioritized over vascular access type. Upon reaching a decision for hemodialysis, vascular access decision making was influenced by the following: 1) preferences for kidney replacement therapy, including anticipated timeline to transplantation or transition to home dialysis modalities; 2) urgency and timing of dialysis need, where urgent patients expressed preferences; 3) limitations of individualized decisions, as when preferences and practicalities diverged; 4) occasions to re-visit the vascular access selection; and 5) availability of support for vascular access decision making and the decisional outcome.

Conclusions: Although patients and caregivers prioritized upstream decisions, several influences on vascular access decision making were identified once the decision for hemodialysis was made. These findings can inform approaches to integrating shared decision making in dialysis and vascular access selection.
Feasibility of Creation of an Endovascular Arteriovenous Fistula in Patients Undergoing Preoperative Vascular Mapping

Alian, Albalas; Salam Madi, Anmar Almeihni, Michelle L. Robbin, Michael Alellan. The University of Alabama at Birmingham, Birmingham, AL.

Background: The endovascular arteriovenous fistula (endoAVF), a novel percutaneous technique of AVF creation, was approved by the Food and Drug Administration in 2018, and has been placed in a small number of U.S. hemodialysis patients. It is unknown how often patients with advanced chronic kidney disease have vascular anatomy suitable for endoAVF creation. The goal of the present study was to determine the proportion of patients with a vascular anatomy suitable for endoAVF creation, and to assess patient characteristics associated with such suitability.

Methods: All patients referred for vascular access placement at a large academic medical center underwent standardized preoperative sonographic vascular mapping to assess suitability for an AVF. During a two-year period (March 2019 to March 2021), we assessed the suitability of the vessels for creation of an endoAVF. We then compared the demographic characteristics, comorbidities, and vascular mapping measurements between patients who were or were not suitable for an endoAVF.

Results: During the study period, 233 patients had preoperative vascular mapping results suitable for creation of a surgical AVF. Of these, 140 (63%) were also suitable for an endoAVF. Patients with a vascular anatomy suitable for an endoAVF were younger (age 55 ± 15 vs 60 ± 14 years, p < 0.01), but similar in sex, race, diabetes, hypertension, coronary artery disease, and peripheral artery disease.

Conclusions: Among patients with chronic kidney disease with vascular anatomy suitable for a surgical AVF, 63% are also suitable for an endoAVF. Older patients are less frequently suitable for an endoAVF.

Endovascular Arteriovenous Fistula Closure with Covered Stent Placement

Introduction: WavelInQ™ endovascular arteriovenous fistula (EndoAVF) system is a new technique that uses radiofrequency energy to create AVF. It has been gaining popularity as it avoids major surgery, has less recovery time and better success rates than surgical AVF creation. Pseudoaneurysm, dissection of brachial artery, intra-procedure brachial artery thrombosis, device embolization, and steal syndrome are described complications of the procedure. We present a case of EndoAVF creation complicated with forearm swelling and its successful management.

Case Description: Patient is a 45 y/o male with End-Stage Renal Disease due to Hypertensive Nephrosclerosis and obstructive uropathy, now s/p failed kidney transplant, currently on Peritoneal Dialysis (PD). PD was failing and decision was made to transition patient to hemodialysis (HD). In preparation of HD, AVF using WavelInQ EndoAVF system was placed in right forearm between intramuscular artery and vein with coiling of the medial brachial vein. A week after fistula creation, patient developed right forearm swelling with numbness and tingling. Fistulogram demonstrated stenosis in the perforator vein with poorly developed cephalic vein and diversion of blood flow to multiple superficial collateral veins in the forearm causing swelling. Multiple attempts at balloon assisted maturation of the cephalic outflow were unsuccessful. Due to persistent forearm swelling with discomfort a decision was made to close the fistula. A 5 x 15 mm self-expanding Viabahn™ stent was deployed in interosseus vein across the anastomosis to close the fistula. Post fistula closure, arm swelling resolved completely.

Discussion: Covered stents have been used in the maintenance of hemodialysis AVF for various purposes including dialysis access stenosis, central vein stenosis, pseudoaneurysm exclusion and angioplasty associated vascular rupture that cannot be repaired using balloon catheter. This is the first reported case of successful use of covered stent graft to occlude anastomosis to close EndoAVF. As these fistulae are created more often, more novel complications will be encountered. It will be imperative for interventionalists to find creative solutions as well as actively report the successful management of complications.

Arteriovenous Access Creation and Re-Intervention Before Starting Hemodialysis

Epiphane E. Kolla, Raphael Coscias, Cécile Couchoud, Ziad Massy, Benedicte Stengeli, Marie Metzger, Natalia Alencar de Pinho. Paris-Saclay University, UVSQ, Inserm, Center for Research in Epidemiology and Population Health, Villejuif, France; Div. Nephrology, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France; Div. Vascular Surgery, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France; Biomedicine Agency, La Plaine Saint Denis, France.

Background: Patients with systemic lupus erythematosus (SLE) have a higher risk of vascular complications.

Methods: This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of interventional after vascular access creation. This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation.

Results: Totally, 1366 HD patients with SLE had higher incidence rates of AVF/AVG dysfunction than 4098 non-SLE HD patients in the following 4 periods, (1) after 1 year (incidence rates were 15.21% and 13.01% respectively; subdistribution hazard ratio (SHR) = 1.16; P = 0.007), (2) 1st-to-10th-year period (15.36% and 13.25%; SHR = 1.16; P = 0.007), (3) 5th-to-10th-year period (11.91% and 8.1%; SHR = 1.42; P = 0.003), and (4) overall period (23.53% and 21.66%; SHR = 1.13; P = 0.027). There were significantly higher incidence rates of AVF/AVG dysfunction in SLE patients during the long-term follow-up period.

Conclusions: In conclusion, regular surveillance of vascular access function by clinical examination after 1 year, especially during 5 to 10 years, is needed to improve vascular access patency and dialysis adequacy in SLE patients undergoing maintenance hemodialysis.
Results: Median age was 71 years, 64% were men, 43% had diabetes, and 33% started hemodialysis urgently. Half (51%) underwent a first arteriovenous access creation: a fistula in 21,240 patients, created a median of 5 months (IQR, 2-12), and a graft in 741 patients, 3 (1-8) months before hemodialysis initiation. Among patients with a first fistula attempt, 30% underwent at least one vascular access re-intervention before hemodialysis initiation, versus 21% among those with a first graft attempt (p<0.001). The types of intervention substantially differed according to vascular access (Figure). When dialysis start was urgent, catheter was used in 43% of patients from both access groups (p=0.06); when it was not, catheter was used in 12 and 14% of patients with a first fistula or graft attempt, respectively (p=0.15).

Conclusions: In incident hemodialysis patients in France, fistula is typically the first attempted arteriovenous access. Early arteriovenous access creation prevents from using catheter at dialysis initiation in a majority of patients, but requires close monitoring of potential complications.

Incidence of De Novo Central Vein Stenosis in Hemodialysis Patients Following Their First Tunneled Central Vein Catheter (CVC) Placement
Alian Albalas,1 Salam Madi, Ammar Almehmi, Michael Allon. The University of Alabama at Birmingham, Birmingham, AL.

Background: Central vein stenosis is a common complication in hemodialysis patients following tunneled CVC insertion. Little is known about its incidence, association with patient characteristics, or relationship with duration of CVC placement. We systematically evaluated central vein stenosis in hemodialysis patients receiving their first CVC at a large medical center.

Methods: All new hemodialysis patients underwent an ultrasound prior to their internal jugular tunneled CVC placement, to exclude venous stenosis or thrombosis. If they were subsequently referred for CVC exchange, a catheterogram/venogram was performed to assess for hemodynamically significant (≥50%) central vein stenosis. During a five-year period (January 2016 to January 2021), we quantified the incidence of central vein stenosis in patients undergoing CVC exchange. We also evaluated the association of central vein stenosis with patient demographics, comorbidities, and duration of CVC dependence prior to exchange.

Results: During the study period, 273 patients underwent exchange of a tunneled internal jugular vein CVC preceded by a catheterogram/venogram. Of these, hemodynamically significant central vein stenosis was observed in 36 patients (13%). Central vein stenosis was not associated with patient age, sex, race, diabetes, hypertension, coronary artery disease, peripheral artery disease or CVC laterality (Table 1). The frequency of central vein stenosis was progressively higher with greater duration of CVC dependence, being 10%, 12%, 24%, and 28% in patients with <3 months, 3 to 6 months, 6 to 9 months and >9 months of catheter dependence, respectively (p=0.025).

Conclusions: Among incident hemodialysis patients receiving their first tunneled internal jugular CVC, the overall incidence of hemodynamically significant central vein stenosis was 13%. The likelihood of central vein stenosis was directly associated with the duration of CVC dependence.

PO1046
Hospitalization Risk and Long-Term Complications Associated with Catheter-Related Bloodstream Infection Among Hemodialysis Patients
Krithika Rajagopalan,1 Kenneth Massey,2 Srirvivasan Rajagopalan,1 Stephen Imperiale-Hagerman,1 Paul Chew.1,2 Antilika Inc, Dover, MA; 2Cormedix, Berkeley Heights, MA.

Background: Central venous catheters (CVC) are frequently required for vascular access in hemodialysis (HD) and are commonly associated with catheter-related bloodstream infections (CRBSIs). CRBSIs may have devastating consequences leading to increased hospitalizations, and long-term complications such as stroke, myocardial infarction (MI), heart failure (HF), and endocarditis, among others. This analysis explores the risk of CRBSI-associated hospitalizations and long-term complications among HD patients.

Methods: A 1:1 propensity score matched case-control analysis was conducted using merged data from United States Renal Data System (USRDS), CROWNWeb (dialysis organizations), and Medicare claims database (2013-2017). All CVC-dependent HD patients from 2014-2016 with a 1-year pre- and ≥1-year post-index period were included. CRBSI was defined as a composite measure of its ICD codes or sepsis/bacteremia diagnosis with hospitalization or without occurring pneumonia, gangrene, or urinary tract infections and hospitalization. An assigned index date (i.e., CVC insertion date + median days to CRBSI reported in CRBSI-case group) was used to identify non-CRBSI patients. CRBSI/non-CRBSI group differences were described using frequency, mean, median, chi-square, and t-tests. At 1-year post CRBSI, adjusted differences in hospitalizations and hospital days and time to long-term complications were modeled using generalized linear models with proportional hazard models, respectively.

Results: CRBSIs result in higher 1-year incremental rates of: stroke (6.6%), MI (9.2%), HF (13.4%), PVD (13.6%), and endocarditis (9.4%). Mean number of hospitalizations and hospital days were 3.79 and 25.0 days for CRBSI, and 1.96 and 5.86 days for non-CRBSI patients, respectively. Mean hospitalizations and hospital days were significantly higher for CRBSI vs. non-CRBSI patients (p<0.05) at 1-year post-CRBSI. Hazard ratios for CRBSI patients were: stroke (1.64, 95% CI 1.53-1.75), MI (2.56, 95% CI 2.37-2.78), HF (2.01, 95% CI 1.88-2.14), and endocarditis (13.42, 95% CI 10.97-16.42).

Conclusions: Results show HD patients with CRBSIs incur a significant morbidity burden due to increased hospitalizations, hospital days, and long-term complications such as stroke, MI, HF, PVD, and endocarditis.

PO1047
Hemorrhagic Shock due to Cutting of the Tunneled Dialysis Catheter
Lucia Bogdan,1 Tushar S. Malavade.2,3 University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; 2Toronto General Hospital, Toronto, ON, Canada.

Introduction: Bleeding is a relatively rare complication of dialysis CVC overall. To our knowledge, this is the first report of a cut tunneled CVC proximal to the Y. This case demonstrates the risk of significant hemorrhage when a tunnelled CVC is damaged at this location and need for early recognition and control of bleeding. It also highlights important patient safety considerations given the risk of self-inflicted trauma in patients with dementia and language barrier for communication.

Discussion: Case Description: We describe the case of a 68-year-old non English speaking dementia patient with ESRD on HD. While in hospital, he had tried to cut the tape that was causing itching, but accidentally cut CVC. He was found in shock, bleeding from the exit site, which required aggressive resuscitation and compression to stop bleeding. After stabilisation examination revealed a palpable, well retracted catheter that was not visible (Fig 1). X ray showed the catheter in situ, but the Y along with the arterial and venous ports were absent (Fig 2). In retrospect, bleeding was particularly difficult to control because the cuff at this location is rigid and not compressible. This places the patient at increased risk for exanguination leading to hemorrhagic shock, air embolism and mortality.

Case Description: 81 year old male was admitted to hospital with ESRD on HD. While in hospital, he had tried to cut the tape that was causing itching, but accidentally cut CVC. He was found in shock, bleeding from the exit site, which required aggressive resuscitation and compression to stop bleeding. After stabilisation examination revealed a palpable, well retracted catheter that was not visible (Fig 1). X ray showed the catheter in situ, but the Y along with the arterial and venous ports were absent (Fig 2). In retrospect, bleeding was particularly difficult to control because the cuff at this location is rigid and not compressible. This places the patient at increased risk for exanguination leading to hemorrhagic shock, air embolism and mortality.

**Facial Swelling: Angioedema or Superior Vena Cava (SVC) Syndrome**

**Moarj A. Qazi,1 Huma Qazi,2 Anne M. Huml,1 Tushar J. Vachharajani.1**

1Cleveland Clinic, Cleveland, OH; 2Army Medical College, Rawalpindi, Pakistan.

**Introduction:** Central venous stenosis is a common complication of recurrent central venous catheters (CVCs). Diagnosis can be challenging given its versatile presentation. Facial, unilateral breast or upper extremity swelling and signs of congestion mimicking pulmonary edema can be subtle clues. We describe a case of SVC syndrome that eluded clinicians as angioedema.

**Case Description:** 55-year-old female with history of morbid obesity, CKD 4, recurrent bacteremia, endocarditis and anemia presented with 1-day history of facial and oropharyngeal swelling, requiring intubation for airway protection. She was unsuccessfully treated for presumed angioedema with steroids, H2 blocker and C1 esterase inhibitor. She deteriorated, requiring tracheostomy tube, dialysis and then transferred to our hospital. She had episodes of worsening facial swelling, drooling and dyspnea with dialysis. Her medical records revealed multiple infections of her more than 10 CVCs placed in the past 12 years for frequent IV draws, infusion infections and antibiotics. Six portacaths were on the right side including 3 in subclavian, 1 in internal jugular vein and 2 peripherally inserted central catheters. A CO2 angiogram revealed stenosis of the right internal jugular, subclavian and brachiocephalic veins. The left internal jugular had the dialysis catheter with some narrowing around it. Endovascular interventions were unsuccessful at recanalization. Surgical bypass was not an option given her comorbidities. She was being evaluated for sharp or radiofrequency recanalization and/or inside-out device intervention. Unfortunately, devastated with failures, she opted for hospice.

**Discussion:** A high index of suspicion is crucial in patients with prior CVC accesses and frequent access clotting, poor flows and facial or upper extremity swelling. The number, duration and infections of CVCs increase the risk of CV stenosis. Dialysis related dyspnea, drooling or treatment resistant angioedema should be evaluated with a venogram urgently. Prompt use of advanced treatments like endovascular recanalization can be lifesaving.

---
worsening sharp, non-radiating chest pain localized at the left hemithorax. Patient refused to move and vomiting for 2 days. Examination: a thick mucus possibly blood-streaked; however, no coffee-grounds. Stated he had never experienced this chest pain before. He reported not taking any medication at home for pain. On examination there was no cardiac murmurs, no lung abnormalities on auscultation and he had a patent arteriovenous fistula with good thrill and bruit and no signs of stenosis. Had 2 negative troponin levels with serial EKGs without ischemic changes. An echocardiogram that was negative for wall motion abnormalities or any changes in ejection fraction, ruling out an acute coronary syndrome. He had CXR showing curvilinear density projecting over the left hemithorax. He was referred to cardiology with a suspicion of metallic density adjacent to the ventricular apex. He was not on hemodialysis but before his transplant, he had multiple endovascular procedures including a stent placement to keep a patent AV access. A left upper extremity xray showed a left AV access stent fracture; findings were consistent with an embolized fragment from AVG stent. He underwent explant of the stent from AVG, but embolized fragment was not removed by CT surgery. Currently patient is chest pain free and asymptomatic.

Discussion: Stent fractures are commonly seen when they are in arteries, however this is an uncommon event in venous system specially in hemodialysis vascular access. Some of the complication associated with stent fracture are related to in-stent stenosis and central vein stenosis, but this is the first report of chest pain from stent fracture migrated to the left ventricle.

PO1052
Agitated Saline Bubble-Enhanced Ultrasonic to Visualize Appropriated Position of Hemodialysis Catheter: Does Catheter Venous Site Matter?
Gessica Sabrine Braga Barbosa, Rayra G. Ribeiro, Jorge L. Espinosa Armijos, Lucia Andrade, Igor Smolentzov, Camila E. Rodrigues. Universidade de Sao Paulo Hospital das Clínicas, Sao Paulo, Brazil.

Background: The hemodialysis non tunneled catheter (HDC) is the most common access of starting renal replacement therapy. Malposition of catheter is associated with delays in treatment. Agitated saline bubble-enhanced ultrasound (SBUS) has become a new method to visualize the HDC position. Delayed appearance of microbubbles (a 2-second) in the right atrium indicates malposition. Our objective is to analyze the accuracy of SBUS between right and left internal jugular vein (IJV) HDC insertion, comparing to chest radiography (standard method).

Methods: From December 2019 to May 2021, we evaluated 145 hospitalized patients submitted to HDC insertion in IJV. We compared SBUS with chest radiography (CR); the time spent to perform the CR, complications; patient characteristics; catheter blood flow and quality of dialysis.

Results: Total of 145 patients were analyzed, the median age was 62 years old [50.5-70], and there was no statistical difference between the site of insertion. In RIJV, 91% catheters were placed. AKI was more frequent than CKD (75% vs 25%), except when the site was LJV (46% vs 54%, p=0.05). AKI-related COVID-19 was the most common etiology (54%). The confirmation of catheter placement by SBUS was correlated with position by CR (All: r=0.6603, p<0.0001; R: r=0.7044, p<0.0001; L: r=0.6396, p=0.0769). SBUS was highly accurate in identifying adequate location of HDC, especially in R IJV (All: 97.9%; R IJV: 99.2%; L IJV: 84.6%, p<0.05). The time of the catheter insertion to perform radiography was 191 minutes [83.5-287]. Adequate syringe blood flow and an effective hemodialysis session was more frequent in R IJV catheter (99.2% vs 53.8%, p<0.05; 96.8% vs 72.7%, p<0.05, respectively). Complications occurred in 4.2%, without statistical differences between catheter sites.

Conclusions: Comparing with chest radiography, agitated saline bubble-enhanced ultrasound was more accurate in identifying adequate placement of R IJV than L IJV hemodialysis catheters.

PO1053
Using the Seraph® 100 Microbind®Affinity Blood Filter Under Slow Flow Conditions Through a Normal Central Line
Infant-Thises Seliger, Julius Schneider, Jan T. Kielsstein.1 Kielstein Lab, Academic Teaching Hospital Braunschweig, Braunschweig, Germany; 2Medizinische Hochschule Hannover, Hannover, Germany.

Background: The Seraph® 100 Microbind® Affinity blood filter has been in use since 2019 for the treatment of difficult to treat blood stream infections and since 2020 for the treatment of critically ill COVID-19 patients. It is operated under blood flow rates of 100 – 350 mL/min, which requires a large bore central line a dialysis catheter. The aim of our study was to evaluate the usability of the Seraph® 100 under slow flow conditions through a normal central line (in clinical practice).

Methods: A standard hemoperfusion blood tubing system as well as the Seraph® 100 (Exthera Medical, CA, USA) was used. Vascular access was a 20 cm trilumen central venous line (2 x 16 G and 1 x 16 G) that was inserted into a reservoir. The Multifiltrate (Fresenius Medical Care) was used to pump normal saline (n=5) or human plasma (n=5) through the Seraph® 100. Pressures were recorded at any given flows (Qb).

Results: Using saline or human plasma the Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of up to 100 mL/min even through a 16 & 18 G lumen at tolerable arterial and venous pressures. In men using either the 12 G or the 16 G lumen as "arterial line" blood a blood flow rate of 50 mL/min could be maintained for 24 hours without problems.

Conclusions: The Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of 50 mL/min even through 16 & 18 G catheters.

PO1054
Keeping the Vascular Access Alive During the COVID-19 Pandemic

Background: Delay in care of suspected stenosis or thrombosis can increase the chance of losing hemodialysis access. Many procedures were canceled or postponed at the start of the COVID-19 pandemic. We have done a study to determine if the COVID-19 pandemic affected dialysis access care.

Methods: We performed a retrospective chart review to evaluate the incidence of both fistula and graft thrombectomies between April 1, 2020, and March 31, 2021, designated as the COVID-19 group and compared it with an incidence between April 1, 2019, and March 31, 2020, designated as the pre-COVID-19 group. Unsuccessful thrombectomy was defined as subsequent tunneled hemodialysis catheter placement within 48 hours after thrombectomy due to clotted access.

Results: There was no significant difference in the total fistula and graft thrombectomies between the two time periods: 44 cases in the pre-COVID-19 era, the incidence rate of 0.12 per patient-year; 54 cases in the COVID-19 era, the incidence rate of 0.14 per patient-year (HR=1.23, 95% CI=0.81-1.89, p=0.31). However, there was a significant increase in the fistula thrombectomy in the COVID-19 era: 9 cases in the pre-COVID-19 era, the incidence rate of 0.024 per patient-year; 21 cases in the COVID-19 era, the incidence rate of 0.037 per patient-year (HR=2.38, 95% CI=1.03-5.88, p=0.02). In addition, the incidence of unsuccessful fistula thrombectomy also increased significantly: 2 cases in the pre-COVID-19 era, the incidence rate of 0.005 per patient-year; 9 cases in the COVID-19 era, the incidence rate of 0.024 per patient-year (HR=4.54, 95% CI=1.01-50, p=0.03). There was no significant difference in total as well as unsuccessful graft thrombectomy between the two eras.

Conclusions: We noticed a significant increase in fistula thrombosis and unsuccessful fistula thrombectomy in 1-year of the COVID-19 pandemic. This could be due to a delay in referring the patients for treatment of fistula stenosis. Even though the dialysis access procedures were considered essential, there might have been hesitancy on part of patients and referring dialysis center which led to this result. However, we did not notice this trend in AV graft. Timely referral for intervention is important to prevent vascular access thrombosis and loss.
PO1055
Virtual Interviewing in the COVID-19 Era: What Have We Learned?
Koval Jain, Gerald A. Hladik, Prabir Roy-Chaudhury, Pankaj Jawa. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Background: The COVID-19 pandemic forced institutions across the US to switch to virtual interviewing. While some institutions were already offering virtual interviews on a limited basis, this was the first time all interviews were conducted using a virtual platform. Herein, we describe the experience of the nephrology fellowship interviewees at the University of North Carolina (UNC).

Methods: We distributed an anonymous Qualtrics survey to all the nephrology fellowship interviewees (N=80) at UNC. The survey included questions on quality of virtual interviews and was completed after the match to avoid bias related to the matching process.

Results: Thirty-one candidates completed the survey (39%), although not all questions were answered by everyone. The total number of interviewees increased from 41 in 2019-20 to 80 in 2020-21. 95% were satisfied with their virtual experience. 82% indicated that the virtual interview process enabled an informed decision about the fellowship program. Everyone was satisfied with the organization of the interview day (N=22). 28% responders (5/18) identified as underrepresented minority (URM). In 2019-20, 641 interviewees identified as URM as compared to 14/80 in 2020-21. The most common reasons for not ranking our program amongst the top three included limited job opportunities for partners, inability to visit the area, and lack of family in the area. Candidates valued the people they met and were able to get a feel for the program despite virtual interviews. They were particularly satisfied with the opportunity to meet fellowship faculty and residents on one platform. Interviewees specified lower cost and time efficiency as advantages of virtual interviews.

Conclusions: This is the first report of the virtual interview experience for nephrology fellowship applicants. The virtual interview process increased the applications to our program although the number of URM applications were similar compared to previous years. There was uniform satisfaction with the virtual format and interviewees were able to appreciate the culture of the division. Most applicants found the virtual interview format favorable because of reduced cost and time expenditure, enabling them to interview at more programs. Our data suggest that serious consideration should be given to a virtual platform in future years to provide opportunity and flexibility to the applicant pool and improve geographical diversity.

PO1056
“Breaking Bad News” During the COVID-19 Epidemic: A Virtual Objective Structured Clinical Examination (OSCE) for Nephrology Fellows
Mauna A. Watson,1 Anna M. Howle,2 Oliver Lenz,2 Ross J. Scalese,3 Joshua D. King,4 Jonathan A. Bolanos,5 Christina M. Yuan,6 Nephrology Education & Development Consortium1 Walter Reed National Military Medical Center, Bethesda, MD; 2University of Maryland School of Medicine, Baltimore, MD; 3University of Miami School of Medicine, Miami, FL.

Background: The “Breaking Bad News” OSCE assesses fellow counseling/communication skills in 20-minute simulation scenarios: kidney replacement therapy (KRT) in ESKD, urgent KRT in AKI, and kidney biopsy. In-person simulation was impractical during the COVID-19 pandemic, so we adapted the OSCE to a virtual platform.

Methods: The AKI scenario was audio only. Fellows called a simulated patient (SP) surrogate for urgent KRT consent. The ESKD and kidney biopsy scenarios were video encounters between fellows and SPs. Faculty observed while muted/video off. After each scenario, fellows received feedback from SPs and faculty (unmutted/video on). Fellows from 2 programs at 2 centers completed the OSCE in May 2021. Post-OSCE, fellows were anonymously surveyed about each scenario, the OSCE overall, and their estimate of the percent of outpatient encounters and inpatient KRT counseling they had done virtually in the past year.

Results: 15 fellows did the OSCE; 14 completed the survey (93% response rate). 93% rated the OSCE overall as a good/very good approximation of a telemedicine experience. 100% were satisfied very satisfied with the AKI scenario, 79% with the ESKD, and 77% with the kidney biopsy scenarios. Several commented that the AKI scenario was the most realistic—they often counseled surrogates by telephone for urgent KRT. Fellows estimated that about 25% (median 27.5%; IQR 16-50%) of counseling for acute inpatient KRT was done virtually in the past year. They estimated about 50% (median 52.5%; IQR 36-70%) of outpatient encounters were done virtually in the past year, but several (dissatisfied with the ESKD and kidney biopsy scenarios) indicated they would not have counselled similar outpatients using telemedicine.

Conclusions: Overall, fellows felt the OSCE well-approximated virtual encounters. All were satisfied with the AKI scenario. The majority were satisfied with the ESKD and Kidney Biopsy scenarios, but some did not feel they were consistent with normal practice. The OSCE allows fellows to practice telemedicine communication skills that will remain relevant post-pandemic. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense or U.S. Government.

Figure 1: Association of Distress with Demographic Variables on Univariable and Multivariable Logistic Regression

PO1057
Well-Being of Nephrology Fellows: Evolution over the Course of a Pandemic Year
Hitesh H. Shah,1 Kurtis Pivert,2 Susan M. Halbach,1 Anna M. Burgner,4 Benjamin S. Ko,3 Lili Chan,4 Suzanne Boyle,3 Joshua S. Waitzman,2 Stephen M. Sozio,1 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 2American Society of Nephrology, Washington, DC; 3Seattle Children’s Hospital, Seattle, WA; 4Vanderbilt University Medical Center, Nashville, TN.

Background: We sought to assess changes in well-being of nephrology fellows over the first year of the COVID-19 pandemic in the U.S.

Methods: The Resident Well-Being Index (RWBI), a validated tool assessing physician distress, was distributed as part of ASN’s annual nephrology fellow survey to 920 current adult, pediatric, and adult/pediatric fellows. An RWBI > 5 (range 0–7) indicated distress. Demographic and fellowship factors associated with meeting the distress threshold were evaluated in univariable and multivariable logistic regression.

Results: A total of 511 fellows participated (56% response), of whom 463 completed the RWBI instrument. After 1 year of the COVID-19 pandemic, there were a higher proportion of nephrology fellows meeting the RWBI distress threshold—22% in 2021 versus 15% in 2020. Female nephrology fellows had higher RWBI scores (median 3 [IQR 3] versus their male colleagues (median 1 [IQR 3]). Higher proportions of 1st-year fellows (50% vs 42% for 2nd years, OR 0.91 [95% CI 0.76–1.09], p=0.024) and women (27% vs 18% of men, OR 1.71 [95%CI 1.06–2.76], p=0.028) met the distress threshold (Figure 1). There were no significant differences by race, ethnicity, medical school location, or adult vs pediatric fellowship. Despite the higher proportion of distress overall, 88% of respondents would recommend nephrology to medical students and residents.

Conclusions: Our follow-up assessment of nephrology fellows’ well-being after the first year of the COVID-19 pandemic indicate the continued need for supportive measures to ensure the health of the future nephrology workforce, especially among 1st year and women trainees.
Methods: Each of the 6 nephrology fellows filled out a daily survey between November 9, 2020 and January 31, 2021, which was the peak of the COVID-19 pandemic in Wisconsin to address: 1) the total amount of sleep hours 2) quality of sleep (restful or fragmented) and 3) whether on-call fellow reported to hospital from home. Responses were collected the following morning to decrease recall bias.

Results: Over the 3-month study period, 100% of the call night data was recorded. The average amount of sleep per night was 5.3 hours. When necessary to report, the average hours of sleep dropped to 4.3 hours. However, if not called in, sleep increased to 5.8 hours per night. The percentage of nights requiring patient evaluation by coming to the hospital overnight was 50% during the study period with a range of 48% of nights in December and 61% in January. Sleep during night call was described as 55% restful vs. 45% fragmented.

Conclusions: This survey has generated discussion amongst fellowship leadership and current fellows regarding novel ways to improve the night call experience to maximize education and clinical experience during training as well as improve fellow wellness. It was determined that the burden of call did not detract from the fellow education enough to warrant a change to a night float system. However, it did identify changes in management processes such as the timing of labs, implementation of dot phrases, and a sleep expert discussion to improve duration and quality of sleep.

Figure 1: Educational Tools Used by Nephrology Fellows in 2016 and 2021 (left) and Percentage 2021 Nephrology Fellows Ranking Tools as Very Effective (right).

PO1059
Shahid N. Muhammad1,2 1The University of the West of England (UWE), Bristol, United Kingdom; 2The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, retrospectively, whether there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Methods: Fourteen (14) topic tags were applied over 1-month (March and April 2020) between groups the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support (KDRAs) (est.2014) for Kids platforms. Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection.

Results: 2,560 threads were topic tagged between two groups. For adults, educational gaps surround Renal Replacement Therapy (166 tags, 12.66%) and Lab Tests and Biomarkers (153 tags, 10.29%). For paediatrics and young groups, educational gaps include Medication and Pharmacy (148 tags, 11.80%), Renal Replacement Therapy (133 tags, 10.65%), Peer Support (125 tags, 10.01%) and Nursing (115 tags, 9.20%).

Conclusions: Online educational modules should complement CKD pathways, and be championed by wider Allied Health Professionals. This is the first UK retrospective study that examines clinically relevant educational gaps between online paediatric and adult renal cohorts close to two decades. Education is where healthcare requires investment.

PO1060
Nephrology Education Needs Assessment: Five Years and a Pandemic Later
Benjamin S. Ko,1 Rob Roe,2 Kurtis Piver,1 Anna M. Burgner,3 Joshua S. Waitzman,4 Susan M. Halbach,5 Suzanne Boyle,6 Lili Chan,7 Hitesh Shah,8 Stephen M. Sozio,9 University of Chicago, Chicago, IL: 1American Society of Nephrology, Washington, DC; 2Oregon Health & Science University, Portland, OR; 3Beth Israel Deaconess Medical Center, Boston, MA; 4Vanderbilt University Medical Center, Nashville, TN; 5Seattle Children’s Hospital, Seattle, WA; 6Temple University, Philadelphia, PA; 7Icahn School of Medicine at Mount Sinai, New York, NY; 8Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 9Johns Hopkins Medicine, Baltimore, MD.

Background: We sought to identify how educational tools utilized in nephrology training had evolved in the past 5 years and through the COVID-19 pandemic.

Methods: Questions about educational tools were distributed as part of ASN’s annual nephrology fellow survey to 920 current adult pediatrics/fellows.

Results: 511 fellows participated in 2021 (56% response rate), compared with 377 fellows in 2016 (31% response rate). Fellows indicated that UpToDate was still the most used (82%) and most effective educational tool (66% rated it “Very Effective”); however, ASN KSAP increased in popularity (27% in 2016, 58% 2021) and was also highly rated (65% Very Effective). Use of online resource and social media increased, including both new opportunities and prior available ones such as NephIC (7% to 32%, with 46% rated Very Effective) (Figure 1). A majority of fellows (84%) rated their education as good or excellent in 2021, a percentage similar to 2016 (81%).

Conclusions: Our follow-up assessment of nephrology fellows’ educational tools found an increase in the adoption of online resources with similar effectiveness ratings as traditional resources.

PO1061
Curriculum-Based Online Education Improves Nephrologists’ Ability to Manage Hyperkalemia in Practice
Amy Larkin, Donald Blatherwick, George Boultaslis. Medscape Education, New York, NY.

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if series of online continuing medical education (CME) activities will improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 5 online activities housed on a dedicated collection page. All used repeated pairs pre-post-assessment study design was used and McNemar’s test (P<0.05 is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre CG) decisions using a McNemar’s test to determine P values. The activities launched between March and October, 2020 and data were collected for up to 12 weeks.

Results: The education reached over 15,000 physicians, including over 1,700 nephrologists. Overall, knowledge improved by 24% (P<0.001) and competence by 4% (P=NS) (all relative improvements) by nephrologists. Specific improvements: 40% relative increase in knowledge related to impact of hyperkalemia (P<0.001) 31% relative increase in knowledge related to clinical use of potassium binders (P=0.001) 24% relative increase in knowledge related to optimizing RAAS inhibitors in patients with hyperkalemia (P<0.05) 7% relative increase in competence related to clinical use of potassium binders (P=NS). Of the nephrologists who were included, 30% (P<0.001) had a measurable increase in confidence in hyperkalemia management.

Conclusions: This curriculum demonstrates that a curriculum is effective at moving learners on the continuum for knowledge improvements to competence improvements. Some gaps remain after education. Among these learners, 49% need knowledge improvements related to minimizing RAAS inhibitors in patients with hyperkalemia and 41% related to clinical use of potassium binders. As such, further education needed in these areas.

Funding: Commercial Support - Astrazeneca

PO1062
Level of Confidence, Knowledge, and Literacy in Genetics Among US Nephrologists

Background: Increased availability of genetic tests in nephrology and at reduced costs are promising for improved patient diagnostic and clinical care. Nephrologists’ confidence, knowledge and genetic literacy are likely to impact the utilization of genetic testing (GT). Identifying gaps in nephrologists’ knowledge and confidence and preferred methods of learning are needed to develop tailored approaches to improving it.
PO1063

Mind Map, an Educational Tool for Teaching Clinical Reasoning in Nephrology: A Mixed-Method Study

Aphile Hamroun,1 Éléonore Lepers,2 Aurélie Dupré,2 Patrick Truffert,1 François Glowacki,1  
1Centre Hospitalier Universitaire de Lille, Lille, France; 2Université de Lille Faculté de Médecine, Lille, France.

Background: Nephrology is commonly considered as one of the most complex disciplines for medical students, justifying the implementation of new educational tools. Although its relevance has been well-established, the mind map is still marginally used in medical education. The objective of this study is to assess the contribution of mind map for teaching clinical reasoning in nephrology.

Methods: Between November 2020 and April 2021, three groups of med students (4th to 6th year) were provided with a teaching program of 5 weekly sessions of 30-45 minutes focused on three topics (serum creatinine elevation/AKI, glomerular syndromes, dysnatremia), each developed through a specific mind map. The contribution of this program was evaluated by a mixed method: 1. quantitative assessment: comparison of three quiz scores respectively the day before, day after and two weeks after each learning session (paired Wilcoxon tests); 2. qualitative assessment: focus group interviews with each group at the end of the teaching program.

Results: In total, 12 med students took part in this educational experience (respectively four in 4th, 5th and 6th years). Quiz scores were significantly higher after each teaching session and overall (28.0 [26.0; 31.4], 33.0 [31.2; 36.1], 34.4 [32.4; 37.0] respectively at baseline, immediately after and after two weeks, p < 0.001) (Fig1). Moreover, focus group interviews highlighted several themes about the specific contribution of mind map (in addition to previous standard lessons): logical and intuitive tool, effective for quick knowledge transmission, promoting long-term memorization and providing a global/integrated vision of clinical reasoning in nephrology.

Conclusions: Mind map appears to be an interesting educational tool in teaching clinical nephrology reasoning to medical students.

PO1064

Improving the Management of Gout in Patients with CKD or Kidney Transplant: Effect of Online Education

Background: Gout is a chronic condition with a considerable effect on patient health and quality of life. Hyperuricemia and gout are associated with declining renal function. Recent studies have shown that renal dysfunction and kidney transplant are risk factors for gout. A study was conducted to determine if online, segmented education could improve knowledge, competence, and confidence of nephrologists regarding the management of gout in patients with chronic kidney disease (CKD) or kidney transplant (KT).

Methods: Educational design included a 45-minute video activity with slides, segmented into a series of 5 mini-lectures by different faculty covering various aspects of gout in patients with or without CKD and KT. Educational effectiveness was assessed with a repeated-pairs pre-/post-assessment study design with 3 knowledge questions and 1 confidence question, in which each individual served as his/her own control. A chi-squared test assessed statistical significance at the P < 0.05 level. The activity launched 9/25/2020, with data collected through 12/4/2020.

Results: The analysis set consisted of responses from nephrologists (n=89) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge; average correct responses increased from 52% pre to 76% post education. Specific areas of improvement included: Treat-to-target strategy with a target of serum UA level < 6 mg/dL in patients taking urate lowering therapy (20% relative improvement, P<0.05) Starting low-dose allopurinol in a patient previously diagnosed with gout and stage 3 CKD, presenting with painful subcutaneous tophi (25% relative improvement, P<0.01) Recommending pegloticase without dose adjustment for the management of refractory gout in patients with stage 4 or 5 CKD (222% relative improvement, P<0.001) Post-education, 48% of nephrologists had a measurable increase in confidence in their ability to manage patients with CKD who may develop gout.

Conclusions: This study demonstrated the success of online, segmented, mini-lectures on improving the evidence-based knowledge, competence, and confidence of nephrologists in appropriately managing gout in patients with CKD or kidney transplant.

Funding: Commercial Support - Horizon pharma

PO1065

Development and Implementation of an Immune Suppression Toolkit to Guide Nephrology Fellow Medication Prescribing and Monitoring

Lauren Lamie, Panduranga S. Rao, Laura H. Mariani, Andrea L. Oliverio, Julie A. Wright Nunes, Markus Bitzer. University of Michigan, Ann Arbor, MI.

Background: There are many important considerations when prescribing high risk medications like immune suppression (IS). Informed by surveys administered to nephrology faculty and fellows, we developed a training curriculum and a concise, clinically applicable guide for IS prescription and monitoring.

Methods: A cross sectional survey was administered to nephrology faculty and fellows in November 2017 to assess perceptions, self-efficacy, and knowledge about prescribing, monitoring, and adjusting IS (12 questions with item-responses from 1=strongly agree to 4=strongly disagree). Informed by this survey we developed and implemented a toolkit (one-time training curriculum and IS reference guide) for fellows and assessed their perceptions of the toolkit using pre-and post-surveys. Results are reported using mean (SD) or N (%). We also examined the correlation of toolkit usage with self-efficacy.

Results: Twenty-eight nephrology faculty and fellows completed the baseline survey; 19 (68%) were attending physicians and 9 (32%) fellows. Twenty (71%) were men, 16 (59%) Caucasian, 11 (41%) Asian. Collectively, 19 (77%) reported prescribing IS ranging from 1 to 40 times yearly. Attending physicians exhibited higher self-efficacy in prescribing IS (1.7 [0.6] compared to 3.3 [0.8]) and both attendings and fellows strongly agreed there was a need for IS guides 1.4 (0.8) and would use them if available 1.4 (0.6). In particular, fellows strongly disagreed they understood all steps needed to use
IS (3.3 (0.8) compared to 2.3 (0.7) for attending physicians). In May 2021, 5 nephrology fellows received the IS toolkit and completed the surveys. Self-efficacy improved post-intervention from mean (SD) 3.0 (1.2) to 2.2 (1.6). All 5 fellows (100%) strongly agreed that the toolkit added value to training, provided a guide they would use and recommended the toolkit for future fellows. 

Conclusions: Nephrology faculty and fellows strongly agreed that there is a need for guides and protocols for prescribing and monitoring IS medications. Our pilot IS toolkit incorporated into nephrology fellow training was well received and improved fellow self-efficacy.

PO1067

The Impact of Electronic Sign-Out Dot-Phrase and Simulation Exercises on Inpatient Nephrology Transitions of Care

James D. Alstott,1 Anand K. Ramadurai,2 Sayee Sundar Alagusundaramoorthy,2 Samantha J. Strennen,3 Laura J. Maursseter,1 Gauri Bhutani.1 1University of Wisconsin-Madison, Madison, WI; 2University of Kentucky, Lexington, KY.

Background: A fellow-led QI project was initiated in 2018 after division surveys indicated a need for change in the ongoing division transitions of care (TOC) practice. The current landscape and clinical use of POCUS in US nephrology training programs.

Methods: We developed a standardized “sign-out score” to objectively assess TOC on the EMR sign-out. We next developed and implemented a standardized electronic medical record (EMR) dot-phrase as our first QI intervention. Case-based simulation sessions highlighting TOC pearls were conducted as the second QI intervention. Pre- and Post-intervention data for sign-out score was evaluated.

Results: A total of 647 patient EMR sign outs were assessed between 2018-2021. Overall sign-out accuracy score (0-2) significantly improved with QI interventions (pre-intervention mean 0.9 [95% CI: 0.9-1.1; N=298] to 1.6 post-dot-phrase [1.5-1.6; N=220] to 1.7 post-simulation [1.6-1.8; N=129]; p<0.001). Table 1 provides details on the results of sign-out score. After adjustment for level of training, improvement in overall accuracy was independently associated with both dot-phrase (adjusted odds ratio (aOR) 7.6 [95% CI: 4.9-11.9]; p<0.001) and simulation (aOR 1.88 [1.3-2.1]; p=0.001). Although 2 sign-out score measures which were high performing pre-intervention worsened with dot-phrase implementation: anticipated changes and non-RRT management (aOR 0.15 [0.1-0.23]; p=0.001 and 0.07 [0.02-0.23]; p=0.001, respectively), improvement was seen following simulation (aOR 1.36 [0.84-2.2]; p=0.21 and 4.6 [1.74-14.5]; p=0.002).

Conclusions: A standardized EMR sign out dot-phrase and simulation exercises both improved the overall accuracy of TOC practiced in inpatient Nephrology consult service. The impact of dot-phrase alone on previously high performing TOC measures suggests the need for further optimization of dot-phrase and continuing simulation to enhance provider self-realization of important components of TOC.

Table 1: Frequency of best possible “sign-out score” before and after QI interventions

Point-of-Care Ultrasound Training for Nephrologists: A National Survey of Nephrology Fellows

Catherine A. Moore,1 Daniel W. Ross,2 W. Charles O’Neill.1 1University of Rochester Medical Center, Rochester, NY; 2Northwell Health, New Hyde Park, NY; 3Emory University, Atlanta, GA.

Background: Despite many potential applications of PoCUS in nephrology, nephrologists have been slow to adopt this technology. The past five years have seen an increase in ultrasound training within nephrology fellowship programs, although the scope of training is unknown. We conducted a national survey of nephrology fellows in United States-based training programs. The main objective of this survey was to identify the current landscape and clinical use of POCUS in US nephrology training programs.

Methods: We surveyed post-graduate year (PGY) 4-8 trainees in US nephrology fellowship programs. Survey items were included in a broader trainee survey disseminated to all programs by the American Society of Nephrology in April, 2021. The six-item survey instrument probed attitudes toward POCUS, current use, preferred instruction format, and perceived competence.

Results: Out of 822 US nephrology fellows surveyed, 631 (76.8 %) responded. A majority of respondents were 30-34 years of age with the majority of participants graduating from international medical schools. The majority of fellows (64.6%) indicated interest in PoCUS education, with highest interest in procedural ultrasound and diagnostic kidney imaging. Only 240 (38%) of fellows reported receiving PoCUS education during training. Of the fellows who received PoCUS training, 112 of 227 (49%) reported incorporation of PoCUS at a frequency of less than monthly, with only 62 of 227 (27%) of fellows incorporating PoCUS once per week or more. 83 of 226 (36%) fellows reported receiving adequate instruction to independently perform PoCUS, and 74 of 224 (33%) reported that they expect to be competent to independently perform PoCUS by the end of training. Hands-on training, particularly with an instructor, was highly valued as a teaching technique.

Conclusions: Despite high trainee interest in PoCUS, the majority of current nephrology fellows are not receiving training in this domain and do not feel competent to independently perform PoCUS procedures. Hands-on training guided by a skilled instructor is a highly valued PoCUS teaching technique. This survey identifies a need for the development of PoCUS programs within nephrology fellowships that incorporate hands-on teaching techniques.
POI1071
Patient Navigators and Study Coordinators: A Team Approach Towards Patient Support in Decentralized Clinical Trials
Cynthia J. D’Alessandri-Silva, Kimberley D. Cranston, Anna Klocokh.
Connecticut Children’s Medical Center, Hartford, CT; 2Advicenne Inc., Ardmore, PA; 3Children’s Hospital Colorado, Aurora, CO.

Background: COVID-19 related restrictions have accelerated adoption of decentralized clinical trials (DCT). DCTs offer increased patient flexibility via online study platforms, telemedicine and home-based nursing. DCTs reduce travel, hospitalization and in-person interactions, all problematic under COVID. Potential drawbacks exist for both patients and study coordinators, however. In DCTs, removal of study-site visits may leave patients feeling confused, unsafe, disempowered and disengaged, potentially increasing drop-out risk. While DCTs may mean increased enrollment for sites, management of novel patient pathways may prove more time-consuming for study coordinators. Crucial protocol driven events or patient concerns/questions may be missed due to complex patient tracking.

Methods: The role of the patient navigator (PN) was developed to support both patients and study coordinators in DCTs. PNs will provide culturally-appropriate psychosocial education to ensure patients feel safe, informed, and supported. PNs serve as conduits between the patient and the study site, ensuring bi-directional communication of patient progress. This unique approach is being trialed in ARENA2, a pediatric Phase III trial in primary distal renal tubular acidosis, a rare renal disease.

Results: A multi-lingual team with unique educational and counseling experience was recruited and trained on the protocol and disease. The team will provide weekly online consultations with patients to facilitate engagement as well as identify any concerns the patient may be having in home healthcare. This role will provide around-the-clock access to care and disease-related questions for both the patient and study site.

Conclusions: The concept of sponsor-driven PN team services in DCTs will offer both patients and study sites the added benefits of support.

POI1072
Do Undergraduates Know “Nephrology?” – A Single-Site Survey of College Students
Julia M. Hopkins, Juan Carlos Q. Velez, John M. Arthur, Michael G. Janecz.
1College of Charleston, Charleston, SC; 2Ochsner Medical Center - New Orleans, New Orleans, LA; 3University of Arkansas for Medical Sciences, Little Rock, AR.

Background: Over the past decade, Nephrology has experienced a 43% decline in fellowship applicants. A factor to choosing Nephrology could be a lack of early exposure. While studies have been conducted to explain why residents choose a specific fellowship, none have surveyed the undergraduate student population to inquire whether the name “Nephrology” was even a recognizable medical specialty compared to other medical specialties. To this end, we conducted a survey of undergraduate students at the College of Charleston (CoC) to test the hypothesis that Nephrology will rank amongst the least recognizable specialties.

Methods: 274 undergraduates at CoC responded to a survey where they were asked to select every medical specialty they recognized by name (15 real specialties/lifestyles). Demographic questions regarding sex, race, collegiate level, high school location, pre-med track, and household income were included. Differences were considered by comparing 95% confidence intervals or Chi-Square test. Spearman-Rank test was used to examine whether the number of applicants per specialty fellowship position was correlated with the proportion of responses.

Results: Out of 15 medical specialties, Nephrology ranked lowest (29%); whereas, Pediatrics (97%) and Surgery (97%) ranked highest. The fictitious specialty, “diasymptomology” was recognized least (4%). Sex, race, collegiate level, and household income were not different between those students that recognized the word Nephrology versus those that did not. Pre-med students were about twice as likely (p=0.001) to have recognized Nephrology versus non pre-med students (49% vs. 22%, respectively). There was no correlation between the proportion of undergraduate students who recognized a specific medical specialty and the number of applicants per fellowship position in 2019 (r=0.2, p=0.7).

Conclusions: Nephrology was the least recognized, non-fictional, specialty amongst undergraduates. Lack of correlation between student responses and fellowship applications, suggest that name recognition alone will not predict fellowship applicant number. The discrepancy between Nephrology and other specialties highlights a gap in name recognition at an early career stage, even amongst premedical students.

Teaching Application of Ultrasound in Nephrology Practice in Medical Schools Using Student Peer Teaching: A Prospective, Randomized Pediatric Trial
Rainer Bässcher, Philip Gelinger, Fiona Schmitt.
Universitätsklinikum Essen, Essen, Germany.

Background: Ultrasound has become the leading diagnostic technology in pediatrics due to its high sensitivity, easy applicability and lack of invasiveness and plays critical roles in many aspects of nephrology practice. However, it is associated with a higher examiner dependent variance. Teaching ultrasound in medical schools has grown in importance over the past years, while pediatric aspects are mainly reserved for postgraduate education. Student peer teachers take on the task of lecturers at many faculties with promising results in ultrasound education.

Methods: We designed a prospective, randomized trial in a pre-post-test design for 257 4th year medical students in our pediatric classes to investigate the effectiveness of peer teaching in pediatric ultrasound. Based on an examiner independent theory. Six students were split into smaller groups and received a standardized practical training by a multiple choice progress test was performed prior and after the course. Afterwards, participants received a supporting manual (group B). All students had to measure the right kidney volume of their partners in advance to test pre-existing practical skills and were randomized to one of the two groups. The discrepancy between Nephrology and other specialties highlights a gap in name recognition at an early career stage, even amongst premedical students.

The Information Dilemma

Tejas Desai, NOD Analytics, Harrsiburg, NC.

Background: The Internet has changed search. The amount of searchable information is growing as more bytes are added/modified than deleted and the criteria by which search results are obtained has also changed. Results are not exclusively obtained by their relevance to the query. Social media search uses predictive algorithms to display results with which the user is most likely to engage (weets, likes, replies, clicks). Results that promote engagement are valued more than those pertinent to the query. Known as customized search, this strategy is obvious when 2 individuals make an identical query and receive different search results and in a different order. Customized search protocols increase engagement but at the cost of creating an information dilemma. In this dilemma, each learner is exposed to a different set of facts upon which scientific discussions are started. In order to establish a common set of facts, I created a search engine based on a standard search protocol.

Methods: NephrTwitter.com is a non-commercial search engine that identifies search results for renal cohorts close to two decades. Education is where healthcare requires investment. This study examines clinically relevant educational gaps between online paediatric and adult health professional about blood tests and investigations (25.49%). Surrounding Healthcare, highest response included I have ability to communicate with a AHPs will increasingly work with GPs to provide laboratory screening, and POCT advice Males (42.86%). Relating CKD Patients, highest responses included Females (55.00%) P1074

Understanding Healthcare Education for Nephrology Best Practice – A Question of Which Health Professionals: A Quantitative Investigation

Tejas Desai, NOD Analytics, Harrsiburg, NC.

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, whether, retrospectively, there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Methods: Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection. Fourteen (14) topic tags were applied over 1-month (March and April 2020) between 1) To understand, whether, retrospectively, there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Results: 19 surveys completed from Health Professionals and 45 completed from community respondents (28 respondents at the time of reporting) and one directed to the community identified “Impact of renal disease and comorbidities on EV analysis” as key knowledge gaps.

Conclusions: In summary, the present survey identified key similarities and differences between current practices for the Urine Task Force and the urinary EV research community. Such information will be used to help guide future efforts to address key knowledge gaps.

A Potential Novel Variant of Slc4a4 Can Regulate the Functional Activity of the Electrogenic Na/HCO3 Cotransporter NBCe1-B

Seong-Ki Lee,1,2 Marie Michenkova,1 Michael F. Romero,1 Rossana Occhipinti,1 Bjarne G. Danielsen,1 Linda Eklund,1 Case Western Reserve University School of Medicine Department of Physiology and Biophysics, Cleveland, OH. 2Mayo Clinic Department of Physiology and Biomedical Engineering, Rochester, MN.

Background: The electrogenic Na/HCO3 cotransporter (NBCe1) regulates intracellular pH in many tissues and elicits vectorial HCO3− flow across many epithelia. Five variants of NBCe1 have been identified: Δα, mainly in kidneys; B, ubiquitous; -C, in brain; -D/E, in mouse reproductive organs. Because the A/D and B/C/E variants are transcribed from two distinct promoters, they have different NH2-termini (Nt). The Romero Lab developed an isoform-specific knockout (KO) mouse of NBCe1-A/D by causing a frameshifting mutation in the A/D variants’ unique Nt region (Chen et al, JASN 25:71A, 2014). Fang et al found that NBCe1-B (e1B) is expressed in kidneys of both WT and KO mice, and that e1B expression increases with metabolic acidosis in KOs (JAP Renal, 2018). They reached this conclusion by RT-PCR-amplification of B-variant– specific bands from KO kidneys. However, these amplifications generated several unidentified bands. Intrigued by these additional bands, we repeated the RT-PCR in an attempt to identify them.

Methods: Using TA cloning, we determined the sequences of two of the unidentified bands: (1) partial Slc4a4 product missing exon 4, which would lead to a frameshift, and (2) partial Slc4a4 product missing exons 4 & 5, but remaining in-frame. Five variants of NBCe1 have been identified: A, -mainly in kidneys; B, ubiquitous; Δα, in brain; -C, in brain; -D/E, in mouse reproductive organs. Because the A/D and B/C/E variants are transcribed from two distinct promoters, they have different NH2-termini (Nt). The Romero Lab developed an isoform-specific knockout (KO) mouse of NBCe1-A/D by causing a frameshifting mutation in the A/D variants’ unique Nt region (Chen et al, JASN 25:71A, 2014). Fang et al found that NBCe1-B (e1B) is expressed in kidneys of both WT and KO mice, and that e1B expression increases with metabolic acidosis in KOs (JAP Renal, 2018). They reached this conclusion by RT-PCR-amplification of B-variant– specific bands from KO kidneys. However, these amplifications generated several unidentified bands. Intrigued by these additional bands, we repeated the RT-PCR in an attempt to identify them.

Results: We found that neither mutant, alone, has activity even though Δα exon 4-5/e1B interacts with super-IRBIT. However, Δα 4-5/e1B has a dominant-negative (DN) effect on WT e1B. To test if these mutants are specific for KO mice, we inspected other WT tissues.

Conclusions: Contrary to our hypothesis, we found that e1B mutants (1) and (2) exist at least in kidneys, brain, and pancreas, leading us to conclude that cells could in principle regulate NBCe1-B activity by adjusting the amount of the novel DN variant Δα 4-5/e1B.

A Survey of Current Trends in Urinary Extracellular Vesicle Research

Uta Erdbrügger,1 Elena S. Martens-Uzunova,1 Alicia Llorente,1 Luca Musante,1 Charles J. Blijdorp,2 Dylan Burger.2 1University of Virginia, Charlottesville, VA; 2Ontario Hospital, Ottawa, ON, Canada; 3Erasmus MC, Rotterdam, Netherlands; 4Oslo University of Medicine, Oslo, Norway.

Background: The Urine Task Force of the International Society of Extracellular Vesicles (ISEV) was created to advocate for best practices in this emerging area of research. The purpose of this survey was to present an overview of various aspects of a survey, conducted using SurveyMonkey by the Urine Task Force, to better understand current research practices in the study of urinary extracellular vesicles (eVes).

PO1073
**Methods:** We investigated the functional properties of SNVs in NBCe1 using immunocytochemical, biochemical, and electrophysiological assays. From NCBI data base, we identified 13 SNVs that have not previously been characterized in highly conserved, transmembrane domains of NBCe1-A.

**Results:** Immunocytochemical analysis revealed that I551F variant was present predominantly in the cytoplasm in HEK293 cells, whereas all other SNVs did not show obvious changes in subcellular distribution. Western blot in HEK293 cells demonstrated that the I551F variant showed impaired glycosylation and a 69% reduction in cell surface levels. To determine the role of Ile551 in more detail, we examined the significance of various mutant variants both in non-polarized HEK293 cells and polarized MDCK cells, which indicated that only I551F substitution resulted in cytoplastic retention. Moreover, functional analysis using Xenopus oocytes demonstrated that the I551F variant had a significantly reduced activity corresponding to 39% of that of wild-type variants, whereas any other SNVs and artificial I551 mutants did not show significant changes in activity. Finally, immunofluorescence study in HEK293 cells indicated that the I551F variant retains wild-type NBCe1-A in the cytoplasm.

**Conclusions:** These data demonstrate that I551F-NBCe1-A shows impaired transport activity predominantly through cytoplasmic retention, and suggest that the variant can have a dominant-negative effect by forming complexes with wild-type NBCe1-A.

**Diacidic Motif Is Required for Efficient Transport of NKCC2 to the Plasma Membrane**

Dalal Bakhos Al Douaihy,1,3 Elie Seayafan,2 Sylvie Demarzé,1,3 Kamel Laghmami,1,3 Martin Köhmf,7 Inserm, CNRS-ERL8228 Sorbonne Université, Paris, France; 3Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; 4Centre de Recherche des Cordeliers, Paris, France.

**Background:** Mutations in the apical Na-K-2Cl cotransporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. We have previously demonstrated that BS1 nonsense mutation V990X, which interacts with the highly conserved diacidic like motifs of NKCC2 C-terminus, compromises NKCC2 surface delivery through ER retention mechanisms. However, whether these diacidic like motifs are sufficient for anterograde trafficking of NKCC2 remained to be determined. Consequently, the aim of the present study was to investigate whether additional motifs are required for NKCC2 efficient transport to the plasma membrane.

**Methods:** NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 surface expression was monitored by cell surface biotinylation assay. NKCC2 stability and maturation was monitored by cycloheximide chase assay.

**Results:** Among the motifs identified as ER export signals in ion channels are the diacidic D/E-X-D/E motifs, which have been shown to promote interaction of cargo with the coat complex II (COP II) budding machinery. Interestingly, sequence analysis of NKCC2 C-terminus revealed the presence of two di-acidic motifs, I551F-EED and I551F-HAD, located upstream and downstream of BS1 mutation V998X, respectively. Importantly, mutation of I551F-EED to I551F-AAA disrupted glycosylation and cell surface expression of NKCC2, whereas mutation of I551F-HAD had no effect. Cycloheximde chase analysis demonstrated that the absence of the terminally glycosylated form of I551F-AAA was not due to increased rates of degradation of mutant co-transporters, but was instead caused by defect in maturation. Accordingly, co-immunolocalization experiments showed that I551F-AAA was trapped in the ER. Finally, overexpression of dominant negative mutants of Sar1 GTPase completely abolished NKCC2 maturation, clearly indicating that NKCC2 exit from the ER is COP II dependent.

**Conclusions:** Our data indicate that in addition to highly conserved diacidic like motifs, the diacidic D/E-X-D/E motif in NKCC2 C-terminus is a transport signal that controls NKCC2 transport from the ER and targeting to the cell surface. Elucidating the molecular mechanisms of the motif-facilitated ER export may help to develop therapeutic strategies targeting NKCC2 transport from the ER to the cell surface.

**Furosemide Alleviates Hypercalciuria and Hypomagnesaemia in Claudiun 16-Deficient Mice**

Natalia Biebling,1 Tilman Breiderhoff, Dominik Müller, Dyugu E. Yilmaz, Sebastian Bachmann, Kerin Mutig, Charite Universitätsmedizin Berlin, Berlin, Germany.

**Background:** Loss-of-function mutations in the CLDN16 gene encoding for claudin-16 lead to Familial Hypomagnesaemia with Hypercalciuria and Nephrolcalcinosis (FHHNC) in human. Claudin-16 resides in tight junctions of the thick ascending limb (TAL) and mediates paracellular reabsorption of divalent cations. The ensuing distal convoluted tubule (DCT), connecting tubule (CNT) and cortical collecting duct (CCD) perform transcellular Ca2+ and Mg2+ reabsorption via the transient receptor potential (TRP) channels, TRPV5 and TRPM6. DCT, CNT, and CCD exhibit unique functional and structural plasticity enabling them to compensate for defects of proximal salt reabsorption. To determine whether diuretic treatment may alleviate symptoms of Cldn16-deficiency due to compensatory stimulation of electrolyte reabsorption in DCT, CNT, and CCD.

**PO1080**

**Cholesterol Efflux on Sodium-Sensitive Blood Pressure**

Karlin C. Oliveira,1,2 Robert L. Repetti,1,3 Rajeev Rohatgi,1,3 Stony Brook University Renaissance School of Medicine, Stony Brook, NY; 2Northport VA Medical Center, Northport, NY.

**Background:** Na sensitive BP is linked to greater mortality than Na resistant hypertension. Dyslipidemia and changes in plasma membrane (PM) lipid composition contribute to Na sensitivity. In addition, diets enriched in cholesterol (cholesterol) (1) raise cortical collecting duct (CCD) chol, (2) stimulate ENaC, and (3) repress natriuretic factors. Renal ABCA1, a cholest transport, increases in chol fed mice to mitigate cellular chool integration. Therefore, we hypothesize renal tubular ABCA1 ablation will lead to Na dependent changes in BP.

**Methods:** Transgenic mice (TGABCA1Rhoatgi) and WT control were housed in a 12h light/dark cycle and fed a standard diet (SM) (22 kcal% protein, 60 kcal% fat, 20 kcal% carbohydrate). The TG mice were treated with 1% cholesterol diet (FF) (27 kcal% protein, 70 kcal% fat, 13 kcal% carbohydrate). Enzyme-linked immunosorbent assay was used to measure cholesterol levels in serum and urine. Enzyme-linked immunosorbent assay was used to measure ABCA1 levels in kidney. Sodium sensitive BP was assessed by cell surface biotinylation assay. NKCC2 stability and maturation was monitored by cycloheximide chase assay. Western blot analysis in HEK293 cells predominantly in the cytoplasm in HEK293 cells, whereas all other SNVs and artificial I551 mutants did not show obvious changes in subcellular distribution.

**Results:** Immunoblotting of renal FF compared to WT kidney. FF vs FF mice post-dox feeding (Fig. 1; *, p<0.05 vs. FF post-dox). No difference in the ER exit from the ER is COP II dependent.

**Conclusions:** Tubular ABCA1 deficiency stimulates Na dependent SBP which we speculate is related to enhanced Na dependent ENaC and NKCC2 activity.

WNK4 is a Transducor of V2 Receptor Signaling in the Thick Ascending Limbs and Distal Convoluted Tubules

Hector Carbajal-Conteras,1,2 Adrian R. Murillo-de-Orozos,1,2 German R. Magaña,2 Norma H. Vázquez,2 Gerardo Gamba,2 Maria Castañeda-Bueno,2 Molecular Physiology Unit1Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico.

Background: Vasopressin (AVP) is essential for water and Na+ homeostasis. In the kidney, its actions are mediated by the V2 receptor (V2R), which signals through protein kinase A (PKA). The phosphorylation of the Na+-Cl- cotransporter (NCC) and the Na+-K+-Cl- cotransporter 2 (NKKC2) by the WNK4-SPAK signaling pathway upregulates their activity and increases in response to AVP. WNK4 can be regulated by PKA through the phosphorylation of its RRS motifs in vitro models. Thus, we hypothesized that WNK4 mediates the activation of NCC and NKKC2 in response to AVP.

Methods: We transfected HEK293 cells with NKKC2 or the V2R with SPAK and either WNK3, WNK4, WT WNK4 or WNK4 with Ala instead of Ser in its 5 RRS motifs. Cells were stimulated with 30 nM forskolin or 1 nM desmopressin (DDAVP). We cross-bred our WNK4- strain (a C57BL/6 background) with 129sv mice while selecting for the full-length allele of NKKC2 to evaluate the phosphorylation status of NKKC2. DDAVP (5 nM) was administered in minioosmotic pumps for 3 days. Protein extracts were subjected to immunoblot. qRT-PCR of WNK4, Slc12a3 and 18S was carried out with Taqman probes. 12 h urine collections were conducted and water intake between the groups was equalized using gelled diets.

Results: In HEK293 cells, we found that an increase in phosphorylation of SPAK and of NKKC2 at T109 and T105 (SPAK regulated sites) with forskolin requires WT WNK4. In contrast, phosphorylation of Sl130 of NKKC2 was WNK4-independent. Only cells with WT WNK4 and the V2R showed an increase in SPAK phosphorylation when stimulated by DDAVP. DDAVP also increased WNK4's phosphorylation at S1196, SPAK- phosphorylation levels were also increased in total and phosphorylated WNK4, NCC, and NKKC2, as well as phosphorylated SPAK and Slc12a3 mRNA levels. These effects were absent in WNK4-4 animals. In contrast, WNK4- mice did respond to DDAVP by increasing AQP2 protein levels. In addition, WNK4- mice had increased water consumption at baseline and increased urine output when water-restricted, with a tendency towards lower total kidney osmolality.

Conclusions: Our data suggest that WNK4 is a transducor of AVP signaling in the TAL and DCT, modulating NKCC2 and NCC. This might contribute to the antidiuretic response and an increased urine output when water-restricted, with a tendency towards lower total kidney osmolality.

Funding: Government Support - Non-U.S.

Upregulation of NCC by Hypokalemia Involves Additional Mechanisms to Direct Cl- Sensing by WNK4

Adrian R. Murillo-de-Orozos,1 Hector Carbajal-Conteras,1 German R. Magaña,2 Norma H. Vázquez,2 Eric J. Delpierre,3 Gerardo Gamba,2 Maria Castañeda-Bueno,21 Universidad Nacional Autonoma de Mexico, CDMX, Mexico; 2Humboldt University, Nashville, TN; 3Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMX, Mexico.

Background: Cl-sensitive WNK4 kinase plays an important role in the modulation of NaCl reabsorption in the distal convoluted tubule (DCT). WNK4 activates the NaCl transporters, NCC and NKCC2, by activating the CaSR-WNK4-SPAK-NCC pathway in vivo. Models of CaSR-WNK1-mediating NCC inhibition during hyperkalemia. Our work shows that low K+ mediated upregulation of NCC does not result in an increase in WNK4 activity. We have previously shown that hypokalemia and low plasma [K+] increase in WNK4 protein levels and its phosphorylation at Ser64 and Ser1196 in WNK4-/- mice. In addition, WNK4 -/- mice had increased water consumption at baseline with Taqman probes. 12 h urine collections were conducted and water intake between the groups was equalized using gelled diets.

Methods: In WT mice, we observed increased activity of the WNK4-SPAK-NCC pathway in the kidney after exposure to 20% fructose or administration of dapagliflozin (p<0.001). Thiazide administration in the renal artery.

Results: In WT mice, we observed increased activity of the WNK4-SPAK-NCC pathway in the kidney after exposure to 20% fructose or administration of dapagliflozin (p<0.001). Thiazide administration in the renal artery.

Conclusions: Our data suggest that WNK4 is a transducor of AVP signaling in the TAL and DCT, modulating NKCC2 and NCC. This might contribute to the anti-diuretic response and an increased urine output when water-restricted, with a tendency towards lower total kidney osmolality.

High Dietary Potassium Increases Blood Pressure in a Rat Model of CKD
Martin Gritter,1 Kuangyu Wei,1 Alexander H. Danser,1 Lifert Vogt,2 Martin H. De Borst,2 Eyout J. Hoorn,2 Josi L. Rotmans,4 Erasmus MC, Rotterdam, Netherlands; 3University of Amsterdam, Amsterdam, Netherlands; 4Leids Universitair Medisch Centrum, Leiden, Netherlands; 5Leids Universitair Medisch Centrum, Groningen, Netherlands; 6Leiden University Medical Center, Leiden, Netherlands.

Background: Potassium deficiency has been linked to increased incidence of cardiovascular disease (CVD). However, high dietary potassium (K+) intake is associated with lower blood pressure levels, and it has been shown that this regulation is intact in chronic kidney disease (CKD).

Methods: To address this, we induced CKD in rats that were fed a low KCl diet (0.03%), normal KCl diet (0.1%), modestly high KCl diet (0.8%), high KCl diet (2.5%) or high KCitrate diet (2.5%). The latter group was included to analyze if this response is intact in chronic kidney disease (CKD).

Results: Both the low and the high KCl diets increased blood pressure compared to the normal KCl diet, although the effect of the high KCl diets was more pronounced (Table). Higher dietary K intake caused higher plasma aldosterone levels, and high KCitrate further increased plasma aldosterone levels. nPCC was also increased in the high KCl diet compared to the low KCl diet. The effect of dietary KCl on nPCC, however, was lost with the high KCl diet. The high KCitrate diet attenuated the rise in blood pressure despite the highest plasma aldosterone and nPCC levels.

Conclusions: Although the inverse relationship between potassium and nPCC is intact in experimental CKD, high potassium diets cause hypertension possibly mediated by aldosterone. This rise in blood pressure is attenuated when potassium is given with citrate, despite high aldosterone and nPCC levels.

* P < 0.01 compared to normal KCl diet (ANOVA with post-hoc testing).
A.U., arbitrary units; BP, blood pressure; N.M., not measured.

Rescuing Low Blood Pressure in Amiloride-Treated Mice by Low-Potassium Diet Relies on NCC Activation
German R. Magaña,1,2 Hector Carbajal-Contreras,1,2 Adrian R. Murillo-de-Ozores,1,2 Norma H. Vázquez,1 Norma Bobadilla,1 Gerardo Gamba,1 María Castañeda-Bueno,1 Universidad Autónoma de Mexico, CDMX, Mexico; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMX, Mexico.

Background: NCC activity has been widely recognized to impact on blood pressure levels, as Gitelman syndrome, caused by inactivating mutations in the Slc12a3 gene, features arterial hypertension. In contrast, Familial Hyperkalemic Hypertension (FHHt) is a mendelian disease mainly driven by NCC overactivation. NCC activity is exquisitely regulated by changes in extracellular [K+], and it has been shown that this regulation might be at least in part responsible for the inverse relationship observed between dietary K+ consumption and blood pressure levels in animal models and in human populations. It has been shown that amiloride-induced hyperkalemia results in NCC inhibition, which can be prevented with administration of a low K+ diet. Thus, we decided to evaluate the role of NCC inhibition in the volume depletion and hypotension induced by amiloride treatment.

Methods: We treated 12-week-old C57Bl/6 male mice with amiloride at 25mg/K in the drinking water. During treatment, mice were kept on normal chow (0.4% NaCl, 0.8% K+) for 4 days, then switched to low K+ diet (0.1% K+), and at the 4th day of low K+ diet hydrochlorothiazide (HCTZ, 60 mg/kg/d, in the diet) treatment was started in a subset of mice.

Results: Amiloride-treated mice developed a PHA1-like syndrome (a severe hyperkalemic, salt losing nephropathy, with marked hypotension). Hyperkalemia and hypotension were prevented by low K+ diet. Basal blood pressure levels were re-established by day 4 on low K+ diet, while further treatment with HCTZ produced a steep increase in blood pressure of these animals. Immunoblot analysis of kidney lysates from amiloride-treated mice at various low K+ and repleted normal K+ levels were reversed by low K+ diet.

Conclusions: We show that the salt losing hyperkalemic phenotype induced by amiloride can be further mediated by low K+ diet and that this recovery is mediated by the increased activity of NCC.

SALL3 Is a Salt-Responsive Distal Convoluted Tubule-Specific Transcription Factor Induced in Distal Neprhon Remodeling
Hyun Jung,1 Eric J. Delprie,2 Paul A. Welling,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Vanderbilt University Medical Center, Nashville, TN.

Background: We engineered constitutively active the SPK kinase (CA-SPPK) in the distal convoluted tubule (DCT), causing constitutive NCC activation, and DCT hypertrophy and hyperplasia. SPK expression was found to be repressed by sodium chloride cotransporter (NCC) (N, Slc12a3) in the DCT is parallel by an increase in DCT mass as an adaptive response to intravascular volume depletion or hypokalemia. The downstream regulatory factors that induce structural expansion of DCT are unknown.

Methods: Mice were engineered to constitutively active the SPK kinase (CA-SPPK) in the DCT, causing constitutive NCC activation, and DCT hypertrophy and hyperplasia. Gene expression analysis was performed in renal cortical tissue. Differential gene expression analysis was performed to compare 1) CA-SPPK vs wild type (WT-CT) on control diet and 2) CA-SPPK on high salt diet (CS-HS) and WT on high salt diet (WT-HS). Bioinformatic approaches were applied to identify the DCT-specific transcription factors (TFs) that are dependent on the NCC activation. TF protein localization and expression was evaluated by immunofluorescence and confocal microscopy, and image analysis tools.

Results: Differential expression analysis and cell deconvolution of the bulk RNA-seq using single-cell genome-wide RNA-seq bioinformatic analysis was performed in renal cortical tissue. Differential gene expression analysis was performed to compare 1) CA-SPPK vs wild type (WT-CT) on control diet and 2) CA-SPPK on high salt diet (CS-HS) and WT on high salt diet (WT-HS). Bioinformatic approaches were applied to identify the DCT-specific transcription factors (TFs) that are dependent on the NCC activation. TF protein localization and expression was evaluated by immunofluorescence and confocal microscopy, and image analysis tools.

Conclusions: In summary, Sall3 is the predominant DCT-specific TF that is activated during DCT expansion, suggesting that it is a key component of the core transcriptional regulatory circuit maintaining DCT cell identity as the DCT expands.

Chemogenetic Activation of the Distal Convoluted Tubule Enhances Sodium Excretion Through Rapid Dephosphorylation of the Sodium-Chloride Cotransporter
Kevin Il. Martz,1 Xiao-Tong Su,1 Yujio Maeda,1 Avika Sharma,1 James A. McCormick,1 David H. Ellison,2 Jonathan W. Nelson.1 Oregon Health & Science University, Portland, OR; 2Veterans Affairs Portland Health Care System, Portland, OR.

Background: The distal convoluted tubule (DCT) plays a crucial role in the regulation of sodium and potassium balance, predominantly through its apical sodium chloride entry pathway, NCC, which is activated by N-terminal phosphorylation. This neprhin manages Gq-coupled GPCRs (GPCRs), including (proteinaseactivated F), ang2 (arginine vasopressin), and others. The role that these GPCRs play regulating DCT function has been a challenge to investigate as they are expressed within multiple cell types that alter kidney physiology. Design Receptors Exclusively Activated by Designer Drugs (DREADD) technology can be used to explore the physiological role of GPCR activation.

Methods: To explore the role of Gq-coupled GPCRs along the DCT, we bred DCT-specific inducible Cre Recombinase mice (NCC-creAKR) to Gq-coupled DREADD mice to create DCT-DREADD mice. We verified the localization of the Gq DREADD protein using immunohistochemistry. We then activated Gq signaling in DCT cells with i.p. injection of DREADD-specific agonist deschlorolarazocine (DCZ) and determined the abundance of phosphorylated NCC by Western blot. Lastly, we measured sodium excretion in metabolic cages for 4 hours following DCZ administration in WT compared to DCT-DREADD mice.

Results: We found that the Gq-DREADD protein was specifically expressed within the basolateral membrane of the DCT (Figure A). DCZ injection caused rapid dephosphorylation of NCC within 30 minutes to 15% of the abundance observed in DCT-

Mechanistic Importance of Reduced KLHL3 and CUL3 Expression in CUL3-A9-Mediated Familial Hyperkalemic Hypertension
Yujiro Maeoka, Mohammed Z. Ferdaus, Avika Sharma, Ryan J. Cornelius, Xiao-Tong Su, Joshua A. Robertson, Susan B. Gurley, David H. Ellison, James A. McCormick. Oregon Health & Science University, Portland, OR.

Background: Mutations in the ubiquitin ligase scaffold protein Cullin 3 (CUL3) cause the disease familial hyperkalemic hypertension (FHH). In the kidney, mutant CUL3 proteins localize with COP9 signalosome subunit JAB1 that negatively regulates CUL3 activity. This leads to CUL3-A9 autodegradation, and increased abundance of With-No-Lysine [K] Kinase 4 (WNK4), which inappropriately activates the downstream kinase SPAK, which then phosphorylates and hyperactivates the Na+-Cl- cotransporter (NCC). We showed lower that CUL3-alone does not increase WNK4, so the precise mechanism by which CUL3-A9 causes FHH is unclear. We hypothesized CUL3-A9 degrades Kelch-like 3 (KLHL3), the CUL3 substrate adaptor for WNK4; thus reduced abundance of KLHL3 combined with reduced CUL3 are mechanistically important in CUL3-A9-mediated FHH.

Methods: We studied Cal3 KO (Cul3+/−, mice, Cdl3 KO mice expressing CUL3-A9 (Cul3+/−Δ9), Cul3 heterozygotes expressing CUL3-A9 (Cul3+/−Δ9), compound Cul3 and Klhl3 heterozygotes (Cul3+/−Δ9, Klhl3+/−), and Jab1 KO (Jab1−/−) mice. All mouse lines were inducible and renal tubule-specific.

Results: CUL3-A9 did not promote degradation of CUL3 targets that accumulate in Cul3−/− kidney: WNK4, cykl, or NQO1 (a surrogate for the CUL3 substrate Nr2). In Cul3+/−Δ9 mice, CUL3-A9 prevented KLHL3 accumulation seen in Cul3−/− kidney and promoted KLHL3 degradation in Cul3+/−Δ9 mice. Higher NQO1 and lower cykl E abundances were observed in Cul3−/−Δ9 mice compared to control mice. Cul3−/−Δ9 mice displayed increased WNK4-SPAK activation and phospho-NCC abundance, and FHH-like phenotype with increased plasma [K+] and salt-sensitive blood pressure. Similarly, reduced CUL3 and KLHL3 abundances and increased abundances of WNK4 and phospho-NCC were observed in Jab1−/− mice.

Conclusions: Together, these data provide evidence for a mechanism of reduced KLHL3 and reduced CUL3 in CUL3-A9-mediated FHH. CUL3-A9 potently degrades KLHL3, but also exerts modest effects on other CUL3 targets, raising the possibility of undefined renal tubule phenotypes in human disease.

Non-Reabsorbable Anions Enhance Potassium Excretion by Multiple Mechanisms
Lama Al-Osairi,1 Paul R. Grimm,1 Tuyen D Pham,2 Ava Zapf,3 Delaney C. Abood,2 Susan M. Wall,2 Paul A. Welling,1,3 Johns Hopkins Medicine, Baltimore, MD; 2Emory University School of Medicine, Atlanta, GA; 3University of Maryland Baltimore, Baltimore, MD.

Background: Potassium (K+) secretion in the distal nephron (DN) is governed, in part, by the luminal-negative transepithelial potential (Vte), created by ENaC-mediated sodium reabsorption, and partially attenuated by paracellular chloride (Cl−) reabsorption. Part, by the lumen-negative transepithelial potential (Vte), created by ENaC-mediated sodium reabsorption, and partially attenuated by paracellular chloride (Cl−) reabsorption. Any intervention that reduces Vte increases K+ secretion.

Methods: To examine the effects of anions on K+ excretion, we performed perfusion experiments in the rat inner medulla on isolated DN segments. We exposed the DN segments to solutions containing 100 mmol/L KCl, 5% KHCO3, or 5% NaCl, which were isosmotic and isonitrogenous. KCl replaced NaCl in the solutions to investigate the effect of luminal Cl− on K+ secretion.

Results: When we replaced NaCl with KCl, K+ secretion increased by 5-fold compared to control. However, when we replaced NaCl with KHCO3, K+ secretion increased by 10-fold compared to control. When we replaced NaCl with NaCl, K+ secretion increased by 2-fold compared to control. These results suggest that luminal Cl− is a major determinant of K+ secretion.

Conclusions: These results suggest that luminal Cl− is a major determinant of K+ secretion.

Role of mTORC2/SKGl Signaling in Rapid Response to Acute K Load to Maintain K+ Homeostasis
Bidisha Saha,1 Waheed Shabbir,2 Enzo Takagi,3 John E. Demko,4 Mads V. Sorensen,1 Deise C. Leite-Dellola,5 David Pearce,6 1University of California San Francisco, San Francisco, CA; 2Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil; 3Aarhus Universitet, Aarhus, Denmark.

Background: The kinase mTORC2 phosphorylates SKG1 and is required for normal K+ secretion in the aldosterone-sensitive distal nephron. Aldosterone is known to play a role in mediating a sustained response through effects on SKG1 gene transcription, however, it is unknown how rapid responses are mediated. Here we have explored the role of mTORC2 and ENAC activity in the early response to an acute K+ load to regulate K+ secretion.

Methods: Inducible tubule-specific Rictor (a core component of mTORC2) knockout mice (TRKO) were generated (Pax8-rtTA/LC-1/Rictorflox/flox). Both WT and TRKO mice received control or 2% KCl via gavage following intraperitoneal vehicle or Bel-2 (an ENAC inhibitor) injection. Urea, K+, and Na+ in the urine was collected. ENAC and ROMK activity were measured in split open tubules by apical membrane patch clamp hz post gavage.

Results: Adult TRKO mice on normal diet displayed no abnormality except significantly elevated aldosterone. K+ administration by gavage triggered markedly greater net Na+ and lower K+ excretion in TRKO than WT mice, with differences detectable within 1 h of gavage. Benzamil induced a greater netureas in WT than in TRKO mice, and more strongly suppressed kaliuresis, consistent with greater ENAC activation in WT than in TRKO. The response of WT occurred rapidly, before significant change in aldosterone. In benzamil-treated mice, the kaliuresis and kaliuresis of WT and TRKO mice were comparable, strongly supporting the idea that KC1 induced
ENaC-dependent K+ secretion in WT, and that this response is defective in TRKO. Patch clamp analysis revealed decreased ENaC activity in WT but not in TRKO mice, and no change in ROMK activity in WT or TRKO by KCi1 gavage. Membrane expression of cleaved α- and γENaC were significantly increased in WT but not in TRKO mice receiving KCi1 gavage. No significant increase in membrane expression of ROMK was observed in WT or TRKO gavage. Finally, both SGK1 and Nedd2-2 phosphorylation were increased in WT but not TRKO mice receiving KCi1 gavage.

Conclusions: Overall, the data strongly suggest that an acute K+ load acts through mTORC2/SGLK1 to rapidly stimulate ENaC but not ROMK to promote K+ secretion. These effects are primarily due to local renal tubular K+ sensing.

Structural Determinants of mTORC2 Substrate Specificity and SGGK1 Phosphorylation Revealed by Cryogenic Electron Microscopy
Junliang Chen,1 Zanlin Yu,2 Feng Wang,2 Xi Liu,2 Enzo Takagi,1 Lydia-Marie Joubert,1 Mingliang Jin,2 Carlos Nowotny,2 David Agard,1 Yifan Cheng,2 David Pearce.2 SinoUnited Health, Shanghai, China; 1University of California San Francisco, San Francisco, CA; 2Stanford University, Stanford, CA

Background: mTORC2 is a multi-subunit kinase complex central to multiple essential signaling pathways. Notably, it responds to hormonal signals and local electrolyte concentrations to phosphorylate SGGK1 and regulate K+ secretion in the renal tubules. Two core subunits, Rictor and mSin1 distinguish mTORC2 from its much better characterized relative, mTORC1. Two other subunits, mTOR itself and a small scaffold, mLST8, complete the core complex. Previous mTORC2 reconstructions have lacked key regions of the >1 MDa complex, particularly determinants of specificity.

Methods: Core mTORC2 subunits were expressed in Exp293F cells and purified using new methods for on grid purification. cryo-EM was performed using Krios at SLAC for high energy electrons for density maps of human mTORC2. Structures were solved for apo-complex at overall 3.23 Å resolution, and for co-complexes with substrates, SGGK1 and its γγγ subunit, and 18 and 3.44 Å, respectively.

Results: The apo-complex reveals architectural features of functionally important domains, including specific side chain positions and interactions, which are visualized for the first time. In particular Rictor/Ser-1624 and Ser-1625 were observed to engage phosphorylation Revealed by Cryogenic Electron Microscopy, and explains mTORC2 resistance to the effects of this clinically important mTORC1 inhibitor. In addition, mSin1, the other defining subunit of mTORC2, is seen to form extensive contacts with Rictor, including an extended strand, which makes multiple weak contacts with a Rictor helical cluster. Most notably for the first time, mLST8 plays a central role in the interplay between the core-complex with mLST8—but not the Akt co-complex, we saw a marked change in the conformation of the mLST8 N-terminal extended strand in a manner consistent with previous functional data identifying this region as required for phosphorylation of SGGK1, but not Akt, thus providing a structural basis for differential regulation.

Conclusions: These findings provide new structural insight into mTORC2 specificity and context-dependent activities, and foundation for further mechanistic studies. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

PO1095
In Vivo Influence of a Protease-Resistant Epithelial Sodium Channel Gamma Subunit on Fluid Homeostasis

Background: Extracellular fluid depletion promotes proteolytic processing of ENaC's γ subunit. Removal of the subunit's inhibitory tract enhances channel open probability. Although several cleavage sites exist distal to the γ subunit's inhibitory tract, only one known site resides proximal to the inhibitory tract: a furin cleavage site (RRKK)12. We hypothesized that a mouse expressing a protease-resistant ENaC γ subunit would exhibit signals from A- and B-types of ICs. However, it is not possible to specifically change the driving force for Cl− at luminal or basolateral sides, which is used for transepithelial studies to identify Cl− types of certain cells on periphery. The technique of split-opening isolated CD allows unambiguous monitoring of alterations in function in multiple individual cells within the split-opened area. However, acid-secreting A- and base secreting B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether local renal tubular K+ sensing. These effects are primarily due to local renal tubular K+ sensing.

A Rare Case of Acquired 11-Beta-Hydroxysteroid Dehydrogenase Deficiency
Khairul Elhariffi,1,2 Nidal Alhousaini,2 Mica Alex,2 Petersen Greti,1 Hania Kassem.2 1Kern Medical Center, Bakersfield, CA; 2The University of Texas Medical Branch at Galveston, Galveston, TX

Introduction: 11-Beta Hydroxysteroid Dehydrogenase (HSD11B) is an enzyme that is involved in steroid hormone physiology. HSD11B enzyme exists in two isoforms, HSD11B-type 1 and type 2. Type 2 isomer is responsible for converting cortisol to inactive cortisone. Plasma concentration of cortisol is approximately 100-fold higher than aldosterone and activation of mineralocorticoid receptors by cortisol is normally limited due to its conversion to inactive cortisone at the sites of aldosterone action by the enzyme HSD11B-type 2. We are presenting a rare case of HSD11B deficiency in a patient taking herbal supplementation.

Case Description: A 73-year-old female with PMH of hypertension, hyperlipidemia and chronic pain was admitted to the hospital with fatigue and shortness of breath. She denied any history of diarrhea or recent use of diuretics or laxatives. She has a history of using some herbal supplements in large quantities for pain control. Initial blood pressure was 140/80 mmHg. EKG showed sinus bradycardia with PVCs and bigeminy. The lab results are summarized in table A. She received aggressive potassium supplementation and spironolactone with subsequent improvement of her condition.

Discussion: HSD11B deficiency is either congenital or acquired by ingestion of licensed or its derivatives (glycinebicyclic and glycinebicyclic acids). The deficiency results in a decreased conversion to cortisone and accumulation of cortisol. The effect of cortisol on the mineralocorticoid receptor results in hypokalemia, metabolic alkalosis, and low aldosterone and renin activity. The diagnosis requires careful history and identification of specific clinical features and biochemical abnormalities.

PO1097
New Method to Discriminate Function of A- and B Type of Intercalated Cells in Split-Opened Collecting Ducts
Naghneh Hassanzadeh Khayyat, Victor N. Tomilin, Kyrilo Pyrshev, Oleg L. Zaika, Oleh Pyrschynuk. The University of Texas Health Science Center at Houston, Houston, TX

Background: The collecting duct (CD) is a highly adaptive terminal part of the nephron and is essential for fluid and electrolyte homeostasis. Electrically uncoupled principal and intercalated cells (PCs and ICs) perform different physiological tasks and exhibit rather distinctive morphology. However, acid-secreting A- and base secreting B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether local renal tubular K+ sensing. These effects are primarily due to local renal tubular K+ sensing.

Methods: We used BCEF/C-sensitive intracellular pH (pH) measurements in split-opened CDs followed by immunofluorescent (IF) detection of AQP2 and pendrin from the collecting duct (CD) is a highly adaptive terminal part of the nephron and is essential for fluid and electrolyte homeostasis. Electrically uncoupled principal and intercalated cells (PCs and ICs) perform different physiological tasks and exhibit rather distinctive morphology. However, acid-secreting A- and base secreting B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether local renal tubular K+ sensing. These effects are primarily due to local renal tubular K+ sensing.

Results: Expression of the prostate specific antigen in oocytes, along with ENaC (N = 15), increased amiloride-sensitive currents, compared to oocytes with ENaC but no prostatic (N = 15; p < 0.0001). In oocytes expressing a Q4 gamma subunit (N = 15), prostatic no longer. Western blot of PgLase-digested tissue lysates revealed a full-length (60 kDa) γ subunit and two shorter proteins, consistent with subunits either cleaved at the furin site (~53 kDa) or at a more distal site. Tissues from Q4 mice lacked the 53 kDa band, suggesting impaired Furin site cleavage. Blood K+ was normal in Q4 mice (N ≥ 7 for each sex and genotype). On a LSD, Q4 male mice exhibited greater loss of body fluid in response to dietary Na depletion. Females did not show a impaired body fluid retention, suggesting additional compensatory mechanisms.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: We show that CIC-K2/C1-channel is exclusively expressed on the basolateral side of C2 cells in 3D cultures. However, it is likely that CIC-K2/C1-dependent H+/HCO₃⁻ transport. Indeed, CIC-K2 blocker, NPPB, had no effect on pHi in PCs, whereas it caused acidification or alkalization in different subpopulations of ICs in WT but not CIC-K2-/-. If assay of the same CDs revealed that NPPB decreased pHi in pendrin-positive B-type of ICs. Induction of metabolic acidosis markedly increased A/B cell ratio from 74% to 145%. Furthermore, dietary acidification also resulted in significantly increased H⁺ secretion (assessed as recovery after acidification) in A-type and decreased pH transport in B-type of ICs.

Discussion: Despite being extremely rare, metabolic acidosis induced by drug interactions such as between Paracetamol and Fluoxacinil is a severe and potentially life-threatening disorder. We recognize the relevance of this case since these drugs are commonly prescribed together.

PO1100
Dietary Ammonium Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux
Jeffrey M. Parkerson, George J. Schwartz. University of Rochester Medical Center; Rochester, NY.

Background: In a mouse model of urinary tract infection with Uropathogenic E. Coli (UPEC-UTI) dietary NH₄Cl (AC) induces metabolic acidosis and increases UPEC burden in reflux prone C3H-HeN but not Trit4 deficient, C3H-HeJ mice. We have confirmed and extended these studies by comparing the inflammatory response in C3H-HeN mice fed AC-diet vs. standard chow (SC), and by examining the effect of HC1-acidosis.

Methods: Female C3H-HeN mice were fed: standard chow (SC), NH₄Cl (2% w/w; AC), or 1g/ml 0.4 N HCl supplemented chow (HC-1). Acid-base state was assessed by blood /gas analysis using an iSTAT ® G3+ and urine pH. UPEC burden (cfu/g) was determined by quantitative culture. Statistics: Two-tailed T-test or Mann-Whitney U Test p<0.05.

Results: Consistent with higher UPEC burden in blander and kidney and increased chemokine/cytokine production, Ly6G⁻ kidney neutrophil infiltration, phagocytosis of UPEC-GFP (GFP mean fluorescence intensity, MFI, in Ly6G⁻ neutrophils) and oxidative burst (DHR123 fluorescence, MFI) were quantitated by flow cytometry. Statistics: Two-tailed T-test or Mann-Whitney U Test p<0.05. Ammonium exerts its effect on both UPEC burden and inflammatory response.

Conclusions: Dietary ammonium chloride impairs clearance of UPEC-UTI and exacerbates pyelonephritis. The effect of dietary ammonium is unrelated to acidosis and neutrophil function.

Piezo 1 in Intercalated Cells (ICs) Mediates Flow-Induced [Ca2+]i Transients in Mouse Cortical Collecting Duct (CCD)
Rolando Carrizosa-Gaytan,1 Stephanie Mutcher,2 Joanne Soong,3 Martinael G. Dalghi,3 Gerard Apodaca,3 Thomas R. Kleyman,3 Liu J (Peng).3 Icahn School of Medicine at Mount Sinai Department of Pediatrics, New York, NY; 2University of Pittsburgh Department of Medicine, Pittsburgh, PA; 3University of Pittsburgh Department of Cell Biology and Physiology, Pittsburgh, PA.

Background: Within the CCD, an acute increase in tubular fluid flow rate (TFFR) exposes principal cells (PCs) and ICs therein to hydrodynamic forces. In response, a biphasic increase in [Ca²⁺]i is observed, with an immediate high amplitude increase due to release of IP3-sensitive internal Ca²⁺ stores coupled to extracellular Ca²⁺ entry at the basolateral membrane. This is followed by a decrease to a plateau that is higher than baseline and sustained by luminal Ca²⁺ entry (Liu et al., 2003; 2005; 2007). This increase in [Ca²⁺]i is necessary for BK channel-mediated flow induced K⁺ secretion (FIKS) in the microperfused mammalian CCD. We have recently reported that PIEZO1, a mechanosensitive, Ca²⁺ permeable channel, is expressed on the basolateral membranes of PCs and ICs in the mouse CCD (Dalghi et al., 2019).

Methods: To examine whether IC Piezo 1 expression contributes to the increase in [Ca²⁺]i triggered by TFFR, we generated a mouse with targeted deletion of Piezo 1 in ICs (IC-Piezo1-KO).

Results: Immunofluorescence analyses of kidneys harvested from mice (C57BL/6) expressing PIEZO1-tdTomato revealed a significant increase of PIEZO1 expression in ICs from mice fed a high K (HK, 5% K, n=4) vs. standard K (SK, 1% K, n=4) diet for 10 days. Fluorescence intensity ratios (FIRs; ratio of the Ca²⁺ i in ICs (p≤0.001). However, ICs from HK-fed IC-Piezo1-KO mice exhibited a reduced or absent increase in [Ca²⁺]i in response to Yodalan vs. SK-fed control mice (p=0.001). Indeed, from HK-fed IC-Piezo1-KO mice exhibited a reduced or absent increase in [Ca²⁺]i in response to Yodalan vs. SK-fed control mice (p=0.001).

Conclusions: We find that Piezo is upregulated in the CCD by a HK diet and contributes to the TFFR-induced increase in [Ca²⁺]i in ICs necessary for FIKS.

PO1099
An Extremely Rare Interaction Between Two Commonly Used Drugs
Maria Teresa Furtado, Catarina A. Gonçalves, Patrícia Valério. Hospital de Sao Bernardino, Setubal, Portugal.

Introduction: The use of Paracetamol and Fluoxacinil can result in an elevated anion gap metabolic acidosis. Interaction between these drugs is a rare disorder that results from accumulation of pyroglutamic acid. Affected patients are usually women with chronic illness, sepsis, and malnutrition.

Methods: We present the case of a 79 year-old hypertensive and diabetic woman who had been treated with Paracetamol and Fluoxacinil in high doses as the leading cause of elevated anion gap metabolic acidosis. Despite these drugs were immediately stopped and sodium bicarbonate was started, the patient showed no clinical improvement and presented with respiratory failure. Hemodialysis was started to correct the acid-base disorder.

Discussion: Despite being extremely rare, metabolic acidosis induced by drug interactions such as between Paracetamol and Fluoxacinil is a severe and potentially life-threatening disorder. We recognize the relevance of this case since these drugs are commonly prescribed together.

PO1101
Molecular Insights into the Structural and Dynamical Changes of Calcium Channel TRPV6 Induced by Its Interaction with Phosphatidylinositol-4,5-Biphosphate
Xing-Zhen Chen1, Ji-Bin Peng1, 2 Ji-Bin Peng.1 1Division of Nephrology, Department of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL; 2Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada.

Background: Transient receptor potential vanilloid subfamily member 6 (TRPV6) is a Ca²⁺-selective channel that mediates Ca²⁺ entry into epithelial cells as the first step of the transcellular Ca²⁺-transport pathway. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol (PtdIns(4,5)P₂) and other phospholipids, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol-4,5-biphosphate (PIP₂); however, it is less clear how PIP, activates TRPV6 at the molecular level.

Methods: Recently, a structure of rabbit TRPV5 complex with dioctanoyl (diC8) PIP₂, a soluble form of PIP₂, was determined by cryo-electron microscopy. Based on this structure, the concept of human PIP₅Kα (a Ca²⁺ channel activator) is consistent with the structural data that residues R302 and K484 in TRPV5 are responsible for the binding of diC8 PIP₂. The binding of PIP₂ is expected to induce conformational changes in TRPV5, which is consistent with the structural data that residues R302 and K484 in TRPV5 are responsible for the binding of diC8 PIP₂. The binding of PIP₂ to TRPV6 increases the distance between the diagonally opposed residues D542 and E546 in the selectivity filter as well as the distance between the diagonally opposed residues M578 and D542 in the selectivity filter. Secondary structure and density analyses show that residue M578 in TRPV6 in the presence of PIP₂, a soluble form of PIP₂, was determined by cryo-electron microscopy. Based on this structure, the concept of human PIP₅Kα (a Ca²⁺ channel activator) is consistent with the structural data that residues R302 and K484 in TRPV5 are responsible for the binding of diC8 PIP₂. The binding of PIP₂ is expected to induce conformational changes in TRPV5, which is consistent with the structural data that residues R302 and K484 in TRPV5 are responsible for the binding of diC8 PIP₂.
Conclusions: Simulation results indicate that PIP, increases the fluctuation of the key residues in both the selectivity filter and the lower gate of TRPV6. In addition, PIP reduces the helix occupancy of a key residue in the lower gate. Furthermore, the diameters of both the selectivity filter and the lower gate are increased by PIP. These changes likely contribute to the opening of the TRPV6 channel.

Lithium Treatment Induces Changes in E-Cadherin, β-Catenin, and Na+/K+-ATPase β1 in Rat Inner Medullary Collecting Duct in a Time-Dependent Manner

Xabier Sarrivell, Jeppe Praetorius, Birgitte M. Christensen, Aarhus University Institut for Biomedicin, Aarhus, Denmark.

Background: Lithium (Li)-induced Nephrogenic Diabetes Insipidus (NDI) develops in around 40% of psychiatric patients receiving Li treatment. NDI is characterized by the inability of the kidney to concentrate urine due to insufficient water reabsorption in the kidney collecting duct (CD). Studies in rats have shown that Li induces a cellular compositional change of the CD with a fractional decrease in the ratio of principal-to-intercalated cells after 4 weeks of Li. This cellular remodeling is reversible in rats undergoing recovery for 19 days following 4 weeks of Li treatment. We aimed to investigate if regulation of the cell-contacts E-cadherin and β-catenin have a role in the cellular remodeling. The Na’/K’-ATPase was also investigated due to previously shown influences on cell polarity and cell-contact formation in kidney cells (Rajasekaran et al. Mol Biol Cell).

Methods: Immunohistochemistry (IHC) was performed on rat kidney sections used in previously published studies (Christensen et al, JPP, 2006; Treppiccione et al, JPP, 2011). Sections from rats treated with Li for 4, 10 and 15 days and 4 weeks were stained using antibodies against the cytoplasmatic domain of E-cadherin, β-catenin and Na’/K’-ATPase β1-subunit. Sections from rats that had undergone recovery for 6 and 12 days following 4 weeks of Li treatment were stained for β-catenin.

Results: E-cadherin and β-catenin labeled basal and lateral plasma membrane domains in the inner medullary CD (IMCD). In the proximal part of IMCD, the labeling was absent from the basal plasma membrane domains of multiple cells after 4 and 10 days of Li treatment and was present again after 4 weeks of Li. In addition, the basal labeling of E-cadherin was absent from some cells after 12 days of recovery. IHC of the Na’/K’-ATPase β1-subunit revealed a similar subcellular localization, and the protein was not present in the basal plasma membrane domains of multiple cells in the proximal part of the IMCD already after 4 days of Li.

Conclusions: The subcellular localization of the adhesions junction proteins E-cadherin, β-catenin and Na’, K’-ATPase β1 is affected by Li treatment in the proximal part of the IMCD. In addition, the absence of labeling from the basal plasma membrane domains appears to occur prior to the cellular remodeling.

Deletion of the EP3 Receptor in the Kidney Tubule of Adult Mice Has No Impact on the Major Channels and Transporters Involved in Kidney Water Handling

Cristina Esteva-Font,1 Frank Geurts,2 Ewout J. Hoorn,3 Robert A. Fenton.1 Aarhus University, Aarhus, Denmark; 2Erasmus MC, Rotterdam, Netherlands.

Background: Prostaglandin E2 (PGE2) is an important lipid mediator modulating various aspects of kidney function. PGE2 exerts its effects via four PGE2 receptors, EP1, EP4, but it is unclear which PGE2 effects are mediated through which receptor. The EP3 receptor is expressed in the thick ascending limb (TAL) and the collecting duct, where it is proposed to inhibit CAMP generation and NaCl and water reabsorption. However, EP3 is also expressed in endothelial cells of arteries and arterioles, that also play a role in kidney function.

Methods: To assess the tubular role of EP3 in adult mice we generated a mouse model based on the Pax8Cre system with doxycycline-dependent deletion of EP3 along the renal tubule and assessed their renal phenotype in respect to water handling. qPCR and RNAscope confirmed that EP3 was highly expressed in cortical and medullary TAL and connecting tubules, but it was not detected in proximal tubule and thin limbs. In addition, the expression of AQP1, AQP4, AQP11, Iba1 (microglial marker), Lamp2 (pro-autophagic factor), Bax (pro-apoptotic factor).

Results: Two weeks after treatment with doxycycline, EP3 mRNA expression was 365

PO1104
Bayesian Identification of Transcription Factors that Regulate Aqp2 Gene Expression

Hiroaki Ikikuchi,1 Hyun Jun Jung,2 Mark A. Knepper.1 National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and Aqp2 gene transcription is strongly regulated by vasopressin (V2 receptor). However, the precise transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes’ Rule to integrate several -omic datasets into a curated list of 1344 TFs present in the mouse genome with regard to probability of regulating Aqp2 gene transcription. To prioritize TFs, existing proteomic and transcriptomic data, ATAC-Seq, histone H3K27-acylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data are used. Beyond this, we use additional -omic datasets to prioritize TFs that are regulated by vasopressin. Finally, we carried out new RNA-Seq experiments mapping the time course of vasopressin induced changes in the transcriptome of mouse mpkCCD cells to further prioritize TFs that change in tandem with AQP2.

Results: The analysis identified 17 TFs out of 1344 in the mouse genome that are most likely to be involved in regulation of Aqp2 gene transcription. These TFs included eight that have been proposed in prior studies to play a role in Aqp2 regulation, viz. Cebpb, E2f1, E2f3, Ets1, Jun, Jnk, Nr4a1, and Sp1. The remaining nine represent new candidates for future studies (Aif1, Irf3, Klf5, Klf6, Mef2d, Nfly, Nr2f6, Stat3, Nr4a1).

Conclusions: The Bayesian analysis has identified the TFs most likely to bind to Aqp2 cis-regulatory elements and likely to be regulated by vasopressin stimulation, providing a roadmap for future studies to understand regulation of Aqp2 gene expression.

PO1105
The Enhanced Expression of AQP4 in Cerebral Ischemia Is Attenuated in AqP11 Heterologous Knockout Mice

Yasuko Tanaka, Kenichi Ishibashi, Meiji Iwakka Daigaiku, Kyiose, Japan.

Background: The role of aquaporins (AQP’s) in the brain edema needs to be clarified to advance its treatment. Since the importance of AQP4 for the formation of brain edema has been shown, expression of AQP11, expressed in the brain capillary, may also be important for the regulation of brain edema. In fact, we recently reported the associated expression of AQP4 and AQP11 in osmotically challenged AQP11 heterologous knockout mice (HKM) (Koike S et al. Biochimie. 2021).

Methods: Both common cervical arteries were ligated for 15 min or 60 min to produce an ischemic-reperfusion model of brain infarction. On one or two days after the reperfusion, total RNA in the brain between Bregma and Lambda was isolated from wild mice and HKM. A real-time RT-qPCR was employed to examine the expression levels of several genes including AQP1, AQP4, AQP11, Iba1 (microglial marker), GFAF (astrocyte marker), Lamp2 (pro-autophagic factor), Bax (pro-apoptotic factor).

Results: Gene expression profiles were similar between wild mice and HKM in Iba1 (increase), Lamp2 (increase) with more severity in 60 min ligation and in the second day. A similar profile was also observed with slightly decreased AQP1 by 5-22%. In contrast, the expression profiles of AQP4 and GFAF were outstanding in that both were more highly induced in wild mice than HKM, by 56% vs. 21% and by 750% vs. 335%, respectively, with further increases in 60 min ligation and in the second day. The results suggested the activation of astrocytes expressing AQP4 by the reperfusion, which might be attenuated in HKM. In agreement with this, the expression of Bax was increased in wild mice by 18% with 60-min ligation while it was decreased by 12% in HKM, suggesting a smaller brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased in HKM in 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing AQP4 expression after reperfusion.

Conclusions: The increased AQP11 expression in HKM attenuated the enhanced expression of AQP4 and Bax in a mouse ischemia-reperfusion model. Thus, the inhibition of AQP11 may alleviate the brain edema by attenuating the expression of detrimental AQP4 in brain infarction.

PO1106
Acute Hemoglobin Level Drop Based on Body Volume Gained

Phuong-Chi T Pham, Phuong-Thu T. Pham. UCLA Medical Center Olive View, Sylmar, CA.

Background: Hemoglobin (Hb) changes with blood transfusions have been widely studied, but to our knowledge, Hb drop associated with volume gain have not been studied. High fluid volume infusion in critically ill patients always result in Hb drop, but the exact extent of Hb change associated with fluid gain has not been studied. We aimed to assess Hb changes based on daily volume gained among anuric hemodialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: Chronic anuric hemodialysis (HD) patients without active bleed admitted to our institution for reasons other than dialysis were included. Strict input/output measurements and Hb levels peri-HD were obtained. Post-HD levels were measured at least 12 h post treatment to allow for equilibrated fluid compartmentalization. Changes in Hb per L of body volume gained were calculated.

Five HD individuals were included. Average age 60±7.2 years, 6 males, 4 females, estimated fat free mass (FFM) 49±3.5 Kg, pre-HD Hb 9.74±1.28, post-HD Hb 9.36±1.28 g/dL, positive fluid balance per patient 1187±775 mL. Average Hb drop was -0.19±0.38 g/dL per L of fluid gained, or 0.004±0.12 g/L/L of fluid gained/ Kg of body weight.

Conclusions: Hemoglobin drop with large fluid infusion may be studied in the anuric HD population. Our pilot study indicates thus far that Hb drop may be ~0.2 g/dL/L on an average or a maximum of ~0.8 g/dL per liter of positive fluid balance. Additional data are being collected. Our study may help clinicians gauge for possible blood loss during large fluid infusion required for hemodynamically unstable patients.

PO1107
A Salty Goodbye to Diuretic Resistance: Hypertonic Saline
Sean Barnett, Brooke Army Medical Center, Fort Sam Houston, TX.

Introduction: Understanding the complex interplay of Cardiorenal physiology and pathophysiology in diuretic resistance requires a deep understanding of RAAS, ADH, and virtually all segments of the nephron. To treat, requires not only understanding but also the ability to investigate and differentiate. However, a treatment that can inhibit RAAS (directly and indirectly), stimulate Cardiac Output, improve GFR, and increase natriuresis could be vital. The potential causes of diuretic resistance arise from the RAAS system and the individual nephron segments. The RAAS system however is the most universal target (when inhibited). While DCT, ASDN, CD and CCT are involved, regardless of which segment is primary, targeting the RAAS system would likely have significant benefits in all diuretic resistance. 3% Saline has the ability to improve Cardiac Output and decrease SVR, increase diuresis, inhibit RAAS (directly and indirectly), and stimulate ANP. Therefore, the answer to Diuretic Resistance is 3% Saline.

Case Description: A 55 y.o. AAF presented to the hospital for severe edema and shortness of breath. PMHx of HFpEF, DM, IHTN, CKD stage 5 (non-nephrotic). She presented with AKI III, severe hyponatremia, and anasarca. Echo revealed EF 40%, biatrial enlargement, RV overload and reduced RV function. She was initially treated with high dose furosemide but did not improve. She was given Metolazone which caused worsening hyponatremia which was treated with 100mL of 3% Saline. This caused an immediate increase in urine output and sodium. She was then changed to a bumex drip and high dose spironolactone (200mg) with some improvement (via objective urine electrolyte assessment) she was still inadequately diuresed. She was then treated with 3% + Loop pulse dosing and sustained a robust diuresis of ~3L of urine and maintained urinary sodium >50.

Discussion: The potential causes of diuretic resistance arise from the RAAS system and the individual nephron segments. The RAAS system however is the most universal target (when inhibited). While DCT, ASDN, CD and CCT are involved, regardless of which segment is primary, targeting the RAAS system would likely have significant benefits in all diuretic resistance. 3% Saline works as a potent IVF to improve Cardiac Output, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Using 100mL of 3% saline to augment diuresis (or alone) causes improvement in virtually all Cardiorenal parameters. The NaCl load directly inhibiting RAAS through distal NaCl delivery (salt load also increases salt wasting), this causes decreased arterial arteriolar constriction and thus further improving GFR. It also stimulates ANP in the RA to inhibit RAAS and ADH indirectly.

PO1108
Enhanced Diuresis with Sequential Nephron Blockade
Shawn Palomo,1,2 Raymond T. La,1,2 Chelay Valdes Sanchez,1,2 Gabriel A. Valle,1,2 University of Miami School of Medicine, Miami, FL; 1Holy Cross Hospital, Ft. Lauderdale, FL.

Introduction: Achieving volume control in patients with severe edema can be challenging, as diuretic resistance may occur. In such cases, sequential nephron blockade (SNB), a less invasive diuretic use strategy should be considered.

Case Description: A 60-year-old woman with HIV and Dilated Cardiomyopathy s/p CRT-D presented with dyspnea and anasarca despite conservative and losartan. In the ED she weighed 370 Lbs., had stable hemodynamic parameters, hypoxemia, diffuse lung infiltrates and low CD4 count. Oxygen, IV loop diuretics and Bactrim were initiated for concerns of PCP and HF. Despite an average UO of 3 L/day she had no meaningful weight loss, protracted lung congestion, hyponatremia and developed radiocontrast nephropathy after CTA. Fluid restriction and SNB with IV furosemide and loop agents were instituted. Tolvaptan was added to perform maximal diuresis of ~8-11 L/day, restored normonatremia and was hemodynamically and metabolically well tolerated. Within 12 days, weight loss of 154 Lbs. was achieved with major clinical improvement.

Discussion: Loop agents are a mainstay for diuresis in patients with volume overload, diuretic resistance can occur through various mechanisms, including the hypertrophy of the distal nephron and loss of function due to AKI. SNB provides a unique approach by strategically targeting ultrafiltrate dynamics in a stepwise manner and interfering with fluid reabsorption within various tubular segments. Central to this principle, the ability to maximize drug bioavailability and parenteral administration is initially necessary. Close hemodynamic and metabolic surveillance are mandatory as the mobilization of vast amounts of extracellular fluid may result in significant complications. Remarkably, in this case, while her eGFR was 25% she achieved 11 L diuresis (30% of UF) safely. This underscores the enormous capacity for fluid sequestration in the extracellular space and the crucial role of trans-compartmental fluid shifts in HF. SNB has been available for years and various diuretics combinations are plausible. This case exemplifies the effectiveness of a novel regimen with vaptans in promoting voluminous diuresis and aquaresis, improving outcomes and decreasing length of stay.

PO1109
Functional Sodium Magnetic Resonance Imaging of Human Kidney

Background: Maintenance of a cortico-medullary concentration gradient (CMG) is required for urine concentration. We explored the ability of 23NaMRI in measuring 1) the dynamics of CMG for the first time compared to urinary osmolality after a water load and 2) the CMG in kidney disease.

Methods: We conducted an exploratory pilot study for 10 healthy controls following water load then 5 cardiacorenal patients with kidney disease. 1) Fasting healthy controls provided urine samples to measure osmolality and baseline 23NaMRI scans were performed. They were instructed to ingest water (15 mL/kg) within 15 minutes. Four subsequent sodium images and urine samples were acquired at 15 min intervals starting one hour after water ingestion. 2) Cardiorenal patients underwent an MRI scan, provided a blood and urine sample, but no water loading.

Results: Mean age of the 10 healthy controls was 41.8 ± 15.3 years. In the morning fasting, medulla/cortex ratio was 1.55 ± 0.11 with concurrent urinary osmolality measured at 814 ± 121 mOsm/L. Mean a SD fasting urinary osmolality dropped significantly to 73 ± 14 mOsm/L, p=0.001. Mean medulla/cortex ratio dropped significantly to 1.31 ± 0.09 mOsm/L for maximal dilution, p=0.002. Figure 1 displays changes of 23NaMRI pictures before (A) then 1h (B), 1h15 (C), 1h30 (D) and 1h45 (E) after a water load. Urinary osmolality and medulla/cortex ratio are significantly correlated, r=0.54, p=0.0001. Mean age of the 5 cardiacorenal patients was 76.6 ± 12.2 years, eGFR was 54 ± 37 mL/min/1.73m2. Urinary osmolality was 498 ± 145 mOsm/L and medulla/cortex ratio was 1.35 ± 0.11. We measured corticomedullary osmolality and showed in cardiacorenal patient with different level of eGFR to show the ability and feasibility to measure this gradient in pathological settings.

Conclusions: We explored CMG dynamically every 15 min in healthy controls and demonstrated significant changes after a water load. We were also able to acquire 23NaMRI pictures in cardirenal patients with kidney disease with plans for future analyses.

PO1110
Validity of a Simple Equation to Estimate Urine Output in Outpatients with Suspected Nephrolithiasis
Luke Webster,1 Alexander Bullen,2 John R. Asplin,2 Michael Shlipak,2 Seth Bechis,2 Manoj Monga,1 Joachim H. Ix,3 1University of California San Diego, La Jolla, CA; 2Litholink Corp, Chicago, IL; 3University of California San Francisco, San Francisco, CA; 4VA San Diego Healthcare System, San Diego, CA.

Background: We previously developed and validated an equation to estimate urine volume from spot urine creatinine, demographic variables, and body weight in patients with or without nephrolithiasis. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

Methods: Among persons submitting specimens to Litholink Laboratories between May 2013 and January 2016, we identified 19,884 individuals who had two 24 hour urine collections on consecutive days, with creatinine excretion rates ±10%. We used Pearson correlations and Bland-Altman analysis to evaluate equation estimated daily urine volume from spot urine creatinine, demographic variables, and body weight in patients with or without nephrolithiasis. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

Results: Among persons submitting specimens to Litholink Laboratories between May 2013 and January 2016, we identified 19,884 individuals who had two 24 hour urine collections on consecutive days, with creatinine excretion rates ±10%. We used Pearson correlations and Bland-Altman analysis to evaluate equation estimated daily urine volume from spot urine creatinine, demographic variables, and body weight in patients with or without nephrolithiasis. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

Conclusions: A simple equation using urine creatinine, demographics and body weight in patients with or without nephrolithiasis could be used to estimate daily urine output and worthwhile studies in larger group of people with and without stone disease. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

**Attenuated Urinary Sodium and Volume in Response to Saline Load in Heart Failure with Preserved Ejection Fraction**

Adhish Agarwal,1 Srinivasan Beddhu,1 Robert E. Boucher,1 Nirupama Ramkumar,1 Aylin R. Rodan,1 Veena Rao,1 Habeeb Mohammad,1 Elizabeth Dranow,1 Guo Wei,1 Kevin S. Shah,1 James C. Fang,1 Alfred K. Cheung.1

1University of Utah Health, Salt Lake City, UT.

**Background:** Heart failure (HF) is characterized by fluid overload due to impaired sodium (Na) excretion. Impaired urinary Na excretion in response to intravenous Na load has been demonstrated in HF with reduced ejection fraction (HFrEF). We hypothesized that patients with HF with preserved ejection fraction (HFP EF) also have impaired urinary sodium excretion and volume in response to intravenous Na load.

**Methods:** All participants were instructed to follow a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

**Results:** Mean age and body mass index for the HFpEF participants were 62±12 years and 36.3±8.5 Kg/m², and for control participants were 47±18 years and 24.6±3.7 Kg/m² respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) (pmol/mg)/(pg/ml); p = 0.014) in cases as compared to controls.

**Conclusions:** In this rigorous, controlled human pilot study, patients with HFP EF had lower urinary volume and attenuated urinary sodium excretion compared to controls after intravenous sodium and volume load. Data and biospecimens collected in this study should inform the pathogenesis of sodium retention in HFP EF.

**Attenuated Renal Response to Endogenous Natriuretic Peptides in Heart Failure with Preserved Ejection Fraction**

Adhish Agarwal,1 Srinivasan Beddhu,1 Robert E. Boucher,1 Nirupama Ramkumar,1 Aylin R. Rodan,1 Veena Rao,1 Habeeb Mohammad,1 Elizabeth Dranow,1 Guo Wei,1 Kevin S. Shah,1 James C. Fang,1 Alfred K. Cheung.1

1University of Utah Health, Salt Lake City, UT; 2Yale University, New Haven, CT.

**Background:** The pathophysiology of sodium retention in heart failure with preserved ejection fraction (HFP EF) remains largely unknown. A potential mechanism is attenuated renal response to natriuretic peptides (NPs). Urinary cyclic guanosine monophosphate (ucGMP) is an intracellular messenger of NPs, and an attenuated ucGMP/B-type NP (BNP) ratio suggests decreased renal response to BNP. We hypothesized that patients with HFP EF have attenuated response to NPs.

**Methods:** We studied ucGMP/plasma BNP ratios in 9 HFP EF patients and 5 controls (no history of renal or heart disease). All participants were placed on a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

**Results:** Mean age and body mass index for the HFP EF participants were 62±12 years and 36.3±8.5 Kg/m², and for control participants were 47±18 years and 24.6±3.7 Kg/m² respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) (pmol/mg)/(pg/ml); p = 0.014) in cases as compared to controls.

**Conclusions:** Our pilot study shows that ucGMP/plasma BNP ratio, which reflects renal response to BNP, was attenuated in patients with HFP EF. These data suggest that impaired renal response to NPs may be implicated in the pathogenesis of fluid retention in HFP EF.

**Association of Urinary Potassium Excretion with Progression of CKD**

Daisuke Mori, Yuta Namiki, Ayaka Sugimachi, Manabu Kado, Shinjiro Tamai, Hiroki Nomi, Ryota Haga, Katsuyuki Nagatoya, Atsushi Yamauchi. Osaka Rosai Hospital, Osaka, Japan.

**Background:** Out of range serum potassium levels are associated with worsening renal function and increased occurrence of cardiovascular disease (CVD) events in...
chronic kidney disease (CKD). However, conflicting results have been reported regarding the protective value for adverse health outcomes of urinary potassium excretion. Therefore, we conducted a cohort study to determine whether urinary potassium excretion is an independent risk factor for renal function deterioration or increased CVD events.

Methods: We identified 650 patients with pre-dialysis CKD who were hospitalized for CKD educational program between 2010 and 2018. Study outcomes analyzed were CKD progression and incidence of CVD events. Baseline urinary potassium to creatinine ratio (UK/Cr, expressed as mmol/gCr) was ranked into quartiles as follows: Q1, <19.8; Q2, 19.9–27.7; Q3, 27.8–37.9; and Q4, >38.0.

Results: During follow-up (median 35 months), 509 CKD progression and 129 CVD events were identified. Further, 62 patients died during follow-up. Multivariate Cox models showed that an increased risk of CKD progression was observed in patients with low UK/Cr compared to those with high UK/Cr, after adjustment for demographic factors and laboratory data. In a fully adjusted model, adjusted hazard ratios (HRs) with the fourth (highest) quartile as reference category were 2.02 (95% CI, 1.50–2.71), 1.34 (95% CI, 1.02–1.77), and 1.14 (95% CI, 0.87–1.50), for Q1–3 respectively (trend: P < 0.001). Similarly, an inverse probability weighting analysis showed an increased risk of CKD progression in Q1 and Q2 compared with Q4. We did not observe any significant modification in subgroup analyses. Furthermore, consistent association was confirmed between lower fractional excretion of potassium and worsening renal function. However, UK/Cr had no association with the incidence of CVD events.

Conclusion: A low UK/Cr is independently associated with worsening renal function but not with an increased risk of a CVD event in patients with pre-dialysis CKD.

POI1114
Licorice-Induced Syndrome of Mineralocorticoid Excess
Nisarg Gandhi, Hassan N. Ibrahim. Houston Methodist Hospital, Houston, TX

Introduction: Edema and volume overload are common complaints. Here, we present a case of hypertension and potassium wasting due to licorice ingestion.

Case Description: A 34 y/o Caucasian woman with significant history for hypothyroidism and recurrent episodes of bronchitis presented for evaluation of recurrent cough, fever, and exacerbation of her chronic bronchitis. On examination, she was found to have a blood pressure of 139/72 mmHg. A urinary sodium test revealed a sodium level of 139 mmol/L. A 24-h urine study revealed a urine sodium level of 30 mmol/L. A urine sample was sent for a licorice level, which returned at 40 mg/mL. The patient denied licorice ingestion.

Discussion: Chronic ingestion of licorice is a rare but known cause of syndrome of mineralocorticoid excess (AME). Licorice contains a steroid, glycyrrhetinic acid, which inhibits the function of the enzyme 11-beta-HSD2. This same enzyme is deficient in mineralocorticoid excess (AME). Licorice contains a steroid, glycyrrhetinic acid, which inhibits the function of the enzyme 11-beta-HSD2. This same enzyme is deficient in mineralocorticoid excess (AME). This can occur at even low amounts of licorice ingestion. The patient was treated with cessation of licorice, and the sodium level returned to normal levels. The patient was discharged with no further licorice ingestion.

POI1115
Not Just Licorice: Abiraterone and Apparent Mineralocorticoid Excess
Natalie M. Beck, Katherine Rizzolo, Sophia L. Ambruso. University of Colorado, Denver, CO.; TA Eastern Colorado Health Care System, Aurora, CO.

Introduction: Abiraterone is a CYP17A1 inhibitor which blocks androgen synthesis and is used to treat castration-resistant prostate cancer. This drug also decreases cortisol synthesis, causing a compensatory increase in adrenocorticotropic hormone (ACTH) and accumulation of mineralocorticoids. The result is the syndrome of apparent mineralocorticoid excess (AME) which manifests clinically as hypokalemia, metabolic alkalosis and hypertension. Abiraterone is approved for use only with concurrent medical treatment to prevent or treat these effects. We present a case of refractory hypokalemia resulting from abiraterone use.

Case Description: A 74-year-old man with metastatic prostate cancer and neck cancer presented with urinary retention and acute kidney injury (AKI) as well as hypertension and metabolic alkalosis which were present a week prior. Home medications included abiraterone, ciplatin (given two weeks prior), prednisone 5 mg daily (recently decreased from 5 mg twice daily) and spironolactone. A urinary catheter was placed, the AKI improved rapidly and the patient remained with refractory hypokalemia. A urine potassium-to-creatinine ratio was high. Post-obstructive polyaury was considered as a reason for kaliuresis; however, hypokalemia and metabolic acidosis preceding this event made it unlikely to be the sole cause. Given abiraterone use, serum cortisol was checked and was low with no increase after giving cosyntropin. Serum aldosterone, renin and their ratios were normal. The patient was diagnosed with abiraterone-induced AME. Prednisone was increased to 5 mg twice daily and eplerenone was started in place of spironolactone.

Two months later, the serum potassium was normal without supplementation.

Discussion: Abiraterone-induced AME is characterized by low serum cortisol but unlike adrenal insufficiency, presents with hypokalemia, metabolic alkalosis and hypertension. In this case, AME resulted from inhibition of the 17α-hydroxylase activity of the CYP17A1 enzyme, leading to decreased cortisol, increased ACTH, and accumulation of the potent mineralocorticoid deoxycorticosterone. Glucocorticoid supplementation (prednisone 5 mg twice daily recommended) is needed to suppress ACTH and prevent these effects. Eplerenone is an adjunct and is preferred over spironolactone in patients with castrate-resistant prostate cancer as spironolactone interacts with the androgen receptor.

POI116
Jägermeister-Induced Pseudohyperaldosteronism
Joseph A. Gotesman, Jordan L. Rosenstock. Lenox Hill Hospital, New York, NY.

Introduction: Hypertension and hypokalemia is known to be caused by hyperaldosteronism. We report a case of hypertension, hypokalemia, and suppressed renin and aldosterone levels. Dietary work-up revealed copies ingestion of Jägermeister liquor which contains licorice, a known cause of pseudohyperaldosteronism.

Case Description: A 54-year-old man with a history of HIV on Genvoya and CAD, HTN on metoprolol and isosorbide monoate was referred to nephrology for evaluation of hypokalemia and accelerated hypertension. Prior to nephrology referral, he was started on oral potassium for 6 weeks and the repeat potassium was 3.5 mmol/L. On review of systems, he had no specific complaints except occasional diarrhea. On exam, his BP was 190/110, 1+ lower extremity edema; his exam was otherwise unremarkable. Initial workup revealed serum sodium 143 mmol/L, bicarb 24 mmol/L, potassium 3.5 mmol/L, creatinine 1.1 mg/dL, magnesium 1.5 mg/dL, calcium 1.0 mmol/L, uric acid 7.1 mg/dL, Fek 13.6%, TSH 2.95 uIU/mL, plasma renin activity 1.191 ng/mL/hr, and aldosterone <3.0 ng/dL, and plasma metanephrines <10 pg/mL. Repeat K was 3.1, bicarb 30, plasma renin activity 0.195 ng/mL/hr, and aldosterone <3.0 ng/dL; urine K 34, FeK 11%; renal dopplers without evidence of RAS. Given hypokalemia, metabolic alkalosis with evidence of potassium wasting, and suppressed renin and aldosterone levels, a thorough dietary review was conducted which revealed chronic Jägermeister ingestion of up to 500 mL per day. He stopped drinking Jägermeister and on subsequent follow-up, his BP was controlled on atenolol, carvedilol, and isosorbide mononitrate, and he no longer required potassium supplementation.

Discussion: Licorice contains glycyrrhizic acid which inhibits 11 beta-hydroxysteroid dehydrogenase, preventing inactivation of cortisol to cortisone, and resulting in excess mineralocorticoid activity manifested by suppressed renin and aldosterone levels, sodium retention, hypokalemia, hypertension, and edema. According to the manufacturer, Jägermeister liquor contains under 10 mg/L of licorice, however, the amount that can cause toxicity is not certain and literature suggests that the glycyrrhizic acid content of licorice is widely variable. Physicians ought to consider dietary, non-medication causes for electrolyte abnormalities in patients with initial negative workups.

POI117
Posaconazole-Related Mineralocorticoid Excess in a Patient with Acute Myeloid Leukemia
Sandeep K. Khosire, R. Muklu,1,2 Adnann S. Polani,1,2 Vishnuipriyadevi Parvathareddy,3,4 Sreedhar A. Mandayam.1, The University of Texas Medical Branch at Galveston, Galveston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Baylor College of Medicine, Houston, TX.

Introduction: Posaconazole is an antifungal used for treatment and prophylaxis of invasive fungal infections in cancer patients. We report a case of posaconazole related mineralocorticoid excess in a patient with acute myeloid leukemia (AML).

Case Description: A 58-year-old male with past medical history of relapsed AML status post stem cell transplant, was admitted on 08/16/2020 to UTMDACC for pain, nausea, vomiting, diarrhea, and fatigue. He developed multiple complications streptococcus viridans bacteremia, candidemia, Graft Versus Host Disease, disseminated intravascular coagulation, fungal pneumonia, tracheostomy, transplant-associated respiratory failure, and hepatitis B with HSV-1 on Foscarnet. Nephrology was consulted for hyponatremia, hypokalemia and alkalosis. No nausea, vomiting, diarrhea was reported. Due to a combination of hypertension, metabolic alkalosis, hypokalemia and being on Posaconazole, we suspected
Pseudo-hyperaldosteronism. Renin, aldosterone levels were checked which are low. CT scan of abdomen was not reported the same. Renal function test was negative and aldosterone was high. Hypokalemia and hyperkalemia was noted and aldosterone level was raised. CT scan revealed hyperplasia of the adrenal gland.

Discussion: Combination of hypokalemia, hypertension and metabolic alkalosis need to suspect mineralocorticoid excess. Posaconazole inhibits 11 beta-hydroxysteroid dehydrogenase type 2 which prevents conversion of cortisol to cortisone. Fracassos and aldosterone leads to amplification of mineralocorticoid receptor action causing increase in activity, number of epithelial sodium channels (ENaC), Na-K-ATPase channels. Excess uptake of sodium leads to hypertension and creates increased negativity causing K+ and HCO3- uptake. Hypokalemia leads to alkalosis and patient was hypertensive due to hyperkalemia. Patients with mineralocorticoid excess can be treated with aldosterone receptor antagonist or ENaC blockers or by stopping or decreasing the dose of Posaconazole. Patients on posaconazole need to be monitored for hypokalemia, hypertension and alkalosis. However, not every patient will develop these which may be likely due to genetic predisposition.

PO1118
Prednisolone-Related Mineralocorticoid Excess: Case of Hypokalemia and Metabolic Alkalosis
Lauren E. Macarag, Anna Astashchanka, Rakesh Malhotra, Cynthia Miracle. University of California San Diego, La Jolla, CA.

Introduction: We report a case of the mineralocorticoid effect of prednisolone resulting in hypokalemia and metabolic alkalosis. This is rare due to the lack of aldosterone deficiency in patients with prednisolone use.

Case Description: A 78 year-old male with past medical history of oropharyngeal squamous cell carcinoma presented with fatigue. One week prior, he was treated with pembrolizumab. Admission vital signs were significant for fever to 39.1°C and normotensive blood pressure 130/88. Laboratory results revealed serum potassium (K+) 4.1 mmol/L, bicarbonate (HCO3-) 26 mmol/L and newly elevated liver enzymes. He was diagnosed with immune checkpoint inhibitor hepatitis and treated with prednisolone 70 mg via nasogastric tube (NGT). Two days later, blood pressure increased to 170/80 and laboratory studies revealed hypokalemia and metabolic alkalosis. The triad of hypokalemia, metabolic alkalosis and hypertension lead us to suspect a hyper mineralocorticoid state. Workup revealed spot urinary aldosterone of 8 ng/mL and aldosterone 8 ng/dL. Patient was then started on aggressive intravenous and oral potassium repletion. He continued to require multiple doses of intravenous potassium to maintain potassium levels of 3.5 mEq/L. He was subsequently started on Eplerenone on Day 3 of admission with excellent response. He remained otherwise asymptomatic from COVID and as his infection improved, hypokalemia stabilized and he was ultimately discharged with a Potassium level of 3.6 mEq/L.

Discussion: The primary defect in BS is in sodium chloride reabsorption in the medullary thick ascending limb of the loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Rare cases of acquired BS are reported in association with tuberculosis, sarcoidosis, sjogrens, and certain drugs. All of these were ruled out in our patient and hence a diagnosis of idiopathic BS like phenotype was made. In our patient, we attribute the BS like phenotype to underlying COVID infection. As his infection improved, his hypokalemia also resolved. Hyperkalemia is a more common finding in COVID infection. However, in our patient, hypokalemia secondary to BS like phenotype was a unique presentation which was challenging to treat. In the absence of usual findings of acquired BS like phenotype, the patient with COVID infection should prompt suspicion for BS-like phenotype. Early and aggressive correction of electrolyte abnormalities is crucial.

PO1119
From Hypokalemia to Sjogren Syndrome: What a Twist!
Elisabeth Pabon-Vazquez, Jose Rivera Sepulveda. Mayaguez Medical Center, Mayaguez, Puerto Rico.

Introduction: Potassium disorders are one of the many serious conditions that could attempt against a patient’s life. Understanding the clinical presentation, diagnosis, management and the role of hypokalemia and treatments of hypokalemia are essential for the development of successful clinical physician. In addition, being aware of the associations between electrolyte disturbances and rheumatologic conditions increases the benefits of correctly treating and preventing underlying problems.

Case Description: This is the case of a 24 y/o female patient, G1P2A0, with a past medical history of hypoglycemia and hypokalemia since pregnancy with twins. Patient presented to emergency department with shortness of breath, general malaise, muscle weakness, and unable to ambulate. Physical examination was remarkable for proximal muscle weakness, decreased deep reflexes with intact sensation. Laboratory bloodwork revealed positive mycoplasma pneumonia infection, normal anion gap metabolic acidosis with severe bicarbonate and potassium deficiency with EKG changes as well hypertension.

Discussion: Pseudohypokalemia is associated with a variable degree of disease severity. The mutation types have been identified as large deletions, missense and nonsense mutations. This patient likely has type 3 BS but with a variable degree of disease will be used to suppress the high level of PGE2 associated with the disease.

PO1120
Idiopathic Bartter Syndrome-Like Phenotype Diagnosed in a Diabetic Patient with COVID-19 Infection
Abhinaya Sridhar,1 Aromapa Kapoor,2 Westchester Medical Center, Valhalla, NY; New York Medical College, Valhalla, NY.

Introduction: Bartter syndrome (BS) is a rare genetic tubulopathy affecting the loop of Henle leading to salt wasting. Acquired BS is very rare and is associated with underlying medical conditions or variants. We report a unique case of idiopathic BS-like phenotype that was diagnosed in the setting of COVID infection.

Case Description: A 71-year-old man with coronary artery disease, hypertension and diabetes presented after a mechanical fall. On admission, he was found to be hypotensive to 107/88 mmHg. Physical exam was within normal limits. Initial blood work was significant for Potassium 2.6 mEq/L, Bicarbonate 34 mEq/L, Calcium 8.0 mg/dL and Magnesium 1.7 mg/dL. Patient also tested positive for COVID-19. Upon further questioning, patient reported a remote history of hypokalemia but never needed any electrolyte supplementation. He denied diuretic use or surrepitious vomiting. Hypokalemia work up revealed increased urinary potassium of 85.4 mEq/L. Renin 15.72 ng/mL/hour and Aldosterone 8 ng/dL. Patient was then started on aggressive intravenous and oral potassium repletion. He continued to require multiple doses of intravenous potassium to maintain potassium levels of 3.5 mEq/L. He was subsequently started on Eplerenone on Day 3 of admission with excellent response. He remained otherwise asymptomatic from COVID and as his infection improved, hypokalemia stabilized and he was ultimately discharged with a Potassium level of 3.6 mEq/L.

Discussion: The primary defect in BS is in sodium chloride reabsorption in the medullary thick ascending limb of the loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Rare cases of acquired BS are reported in association with tuberculosis, sarcoidosis, sjogrens, and certain drugs. All of these were ruled out in our patient and hence a diagnosis of idiopathic BS like phenotype was made. In our patient, we attribute the BS like phenotype to underlying COVID infection. As his infection improved, his hypokalemia also resolved. Hyperkalemia is a more common finding in COVID infection. However, in our patient, hypokalemia secondary to BS like phenotype was a unique presentation which was challenging to treat. In the absence of usual findings of acquired BS like phenotype, the patient with COVID infection should prompt suspicion for BS-like phenotype. Early and aggressive correction of electrolyte abnormalities is crucial.

Colonial Pseudo-Obstruction and Hypokalemia
Akbar H. Hamid,1,2 Isha Puri,1,2 Mary C. Mallappallil,1,2 Man S. Oh,1,2 Moro O. Safiu,1,2
1 SUNY Downstate Health Sciences University Department of Medicine, New York, NY; 2 Kings County Hospital Center, Brooklyn, NY.

Introduction: Ogilvie’s syndrome, or colon pseudo-obstruction, is the pathologic dilation of the colon without underlying mechanical obstruction. It is caused by increased sympathetic activity or reduced parasympathetic activity. The common manifestation in constipation, but sometimes it may be associated with diarrhea when potassium secretion is greatly increased by stretch-activated maxi-K channel, also known as BK channel, resulting from dilatation of the colon. While exact mechanism is unclear, diagnosis is based on clinical and radiologic grounds.

Case Description: A 69 year old African American female with history of diabetes mellitus, hypertension, hyperlipidemia, and HIV infection presented with worsening lower back pain. Initial labs showed leukocytosis, anemia, mild renal impairment, and paraproteinemia. MRI of the spine showed extensive compression deformities and epidural extension, with lytic lesions on skeletal survey. Bone biopsy showed >80% blast cells with marked increase in circulating plasma cells, confirming plasma cell leukemia. Abdominal CT showed dilated ascending colon suggestive of obstruction, but she was having normal bowel movements. She successfully underwent induction therapy and was discharged. When she was readmitted for second cycle of chemotherapy, serum potassium of 1.8 mmol/L with U wave on ECG noted. She also complained of abdominal distension, diarrhea, and bilateral lower extremity edema. Despite aggressive potassium supplementation, her potassium level persistently remained below 3.5 mmol/L. Initial urine potassium was 23 mmol/L, which peaked at 45.8 mmol/L before becoming anuric. First stool potassium was >100 mmol/L with stool volume of 900 mL. Repeat stool study after a week showed stool potassium 59.5 mmol/L with stool sodium 42 mmol/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric.

Discussion: Colon pseudo-obstruction may result in, some patients, in dramatic upregulation of the maxi-K channel. When potassium secretion is greatly increased, diarrhea rather than constipation becomes predominant manifestation. Diarrhea is the result of high potassium content of the stool, unlike most other secretory diarrhea which contains sodium as the main cation.

PO1123

Prevalence and Recurrence of Hyperkalemia (HK) in Medicare Patients Admitted to Long-Term Care or Post-Acute Care (LTC/PAC) Settings
James F. Neumenschwander,1 Alison R. Silverstein,2 Christie Teigland,1 Dakota C. Powell,2 Shambhavi Kumar,3 Jill Dreyfus,2 Edric Y. Zeng,2 Abiy Agiro,3 William Potter,2 and William Peacock,1
1 Genesis HealthCare, Zanesville, OH; 2 Avalere Health, Washington, DC; 3 AstraZeneca Pharmaceuticals LP, Gaithersburg, MD.

Background: Hyperkalemia is a frequently encountered electrolyte disorder usually resulting from decreased dietary intake, gastrointestinal, and/or renal wasting. In distal tubule cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies. Tubule cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies. In distal tubule cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies.

Methods: This retrospective study used 100% Medicare Fee-For-Service data for patients age ≥65 with ≥1 LTC/PAC stay from 01/2017 to 11/2019; index date was admission date of first LTC/PAC stay. HK-related stay was defined as ≥1 HK diagnosis (ICD-10: E87.5) or evidence of potassium binder use during LTC/PAC stay or within 14 days pre-index. Baseline characteristics and prevalence of HK during 1 year of follow up among HK index stays were compared to non-HK index stays. HK index stays were stratified into 3 cohorts; CHF, CKD or end-stage renal disease (ESRD), and CHF+CKD/ESRD.

Results: Of 4,562,231 patients with ≥1 LTC/PAC stay, prevalence of HK during pre-index, index, or follow up periods was 14.7%. The final sample (4,081,103) excluded patients with an HK event only during follow up. Of the final cohort, 290,567 (7.1%) of index stays were HK-related. All-cause (HK-related) index stays consisted of 54.0% (46.5%) LTC/PAC stays, 27.8% (41.4%) skilled nursing facilities, 6.7% (8.8%) inpatient rehabilitation facilities, and 0.9% (3.1%) long term acute hospital settings. HK vs non-HK patients were more often male (43.0% vs 35.4%), Black (13.5% vs 8.0%), and dual eligible for Medicaid (34.2% vs 25%), with higher mean Charlson Comorbidity Index scores (6.19 vs 3.93). Mean annual HK event during follow up were highest in patients with CHF+CKD/ESRD (all patients=1.47; HK=6.98), followed by CKD (0.66; 5.53), and CHF (0.18; 3.00), with similar patterns across settings. In the HK cohort, 34.5% had HK recurrence during follow up; 2.7% filled a potassium binder prescription during index LTC/PAC stay, and 4.3% did not.

Conclusions: HK patients were more often non-White and low income, indicating possible disparities in care. Prevalence and recurrence of HK was high among patients with LTC/PAC stays, but few patients filled a potassium binder prescription, suggesting potential gaps in treatment during or after an LTC/PAC stay.

PO1124

Impact of Hyperkalemia and the Disruption of Emergencies and Surgical Care
Douglas P. Slakey,1 Marybeth Ingle,2 Abiy Agiro,3 Craig G. Schilling,2 William Potter,2 Rasha Khairat,1 William Pottorf,2 Christie Teigland,1,2 Baylor College of Medicine, Houston, TX; 3 Advocate Health Care Inc, Downers Grove, IL; AstraZeneca UK Ltd, Cambridge, United Kingdom.

Background: Due to the increasing prevalence of kidney disease, hyperkalemia (HK) may be diagnosed with greater frequency in Surgical and Emergency Departments (ED). Despite this, specific guidelines do not exist and patients with elevated potassium (K+) are typically managed on a case by case basis.

Methods: An anonymous structured survey was emailed to (~11,287) clinicians in the Advocate Aurora Health system regarding HK knowledge and treatment paradigms (n=237 responded). Survey was conducted from Feb to March 2021.

Results: Nearly half (47%) of respondents treat ≥ 10 HK patients annually, with most common diagnosis of HK occurring in the ED (43.8%) and OR (23%) setting. HK was considered a significant concern by 47% of respondents at a serum K+ level of 5.6-5.9 mEq/L and by 39% at K+ ≥ 6.0 mEq/L. Only 50% of respondents recognized RAASi medications as a potential risk factor for HK. IV fluids and keyesalate were the two most common treatments for HK. Limitations to pharmacological management included the need to monitor potassium, patient compliance, and time of onset. In the survey surgery, 66% felt that K+ more than 5.5 mEq/L on day of surgery will lead to cancellations and 52% believed pharmacologic agents having a shorter onset of action may reduce surgery cancellations and delays. Vascular (34%) and general (30%) surgeries were reported to be most impacted by HK. 82% stated urgent dialysis is difficult to arrange and admission is inevitable for dialysis.

Conclusions: The presence of HK creates challenges to ED or surgical clinical teams to manage and avoid cancellations. Standard treatment options for lowering serum K+ are limited due to time of onset and compliance considerations. Dialysis is difficult to arrange on short notice and almost always requires patient admission. In cases of emergent HK, newer K+ binding agents having a more rapid onset of action to lower serum K+, may reduce avoidable admission, surgical cancellation, and delay of surgery. More evidence-based care is needed in surgical settings to characterize patients at high risk for HK to prevent unnecessary surgical cancellation and limit health care costs.

Funding: Commercial Support - AstraZeneca
similar observation of transient hyperkalemia seen in a case published in 1953 of a young woman treated for chronic hypokalemia (Sciarrino, 1953). Critical hyperkalemia is an important consideration when treating patients with chronic hypokalemia.

POI1126

Potassium Hyperkalemia with Concurrent Hyperkalemia

Mohsen M Samii,1,2 Akbar H. Hamid,1,2 Yasmine N. Mahmoud,1,2 Mary C. Mallapallil,1,2 Man S. Oh,1,2 Sabu John,1,2 Moro O. Saifiu,1,2 SUNY Downstate Health Sciences University Department of Medicine, New York, NY; Kings County Hospital Center, Brooklyn, NY.

Introduction: In sickle cell patients, acute hematologic crisis and sickle cell nephropathy are relatively common. Risk of hyperkalemia increases with hemolysis and tubular dysfunction. Sepsis can also worsen the complication of hemorrhagic crisis with significant thrombocytopenia, a well-known cause of pseudohyperkalemia. We report a case of concurrent true hyperkalemia and pseudohyperkalemia in the setting of thrombocytosis due to acute sickle cell crisis.

Case Description: A 36 year old African American male with history of sickle cell disease, asthma and DVT presented with bilateral shoulder, knee, and back pain. In ED, he was hypertensive, and tachycardic. Labs were notable for leukocytosis, anemia, reticulocytosis, renal failure, and elevated lactate dehydrogenase. Chest x-ray showed left base atelectasis. He was admitted for acute sickle cell crisis and fluctuant right thigh abscess, which was surgically drained and managed with antibiotics. Platelet level was 585 K/ul, serum potassium was 4.7 mmol/L, and creatinine was 1.78 mg/dl. With normal urine output. Potassium level steadily rose and peaked at 6.5 mmol/L with sinus bradycardia but no other ECG changes. At the same time, platelet level peaked to 1105 K/ul.

Discussion: In our patient with significant thrombocytosis, pseudohyperkalemia was suspected. Degranulation of platelets during clotting releases about 50% of potassium inside platelets. For platelet count of 1000 K/ul, with normal MPV, serum potassium is expected to be higher than plasma potassium level by about 0.7 mEq/L. Serum-plasma potassium differences in our patient were within the expected range. In our patient, as shown below, mild concurrent true hyperkalemia is also noted likely due to sickle cell nephropathy, a known cause of hyperkalemia due to hyperreninemic hypoaldosteronism. Due to potassium release from platelets during clotting, serum potassium is always higher than plasma potassium in all normal persons by 0.2 to 0.3 mmol/L. With thrombocytosis, the difference becomes larger, and serum potassium is likely to reach hyperkalemic level if the baseline potassium is already higher than usual due to concomitant impairment of renal potassium excretion.

POI1127

Missing the Obvious? A Story of Salt, Water, and Unexplained Hyperkalemia

Aaron M. Spring,1 Mathieu Lemaire,1,2 1The Hospital for Sick Children Department of Paediatrics, Toronto, ON, Canada; 2SickKids Research Institute, Toronto, ON, Canada.

Introduction: Most clinicians are familiar with the differential diagnosis of hyperkalemia, from pseudohyperkalemia to rare tubulopathies. Herein, we describe three patients with years-long histories of unexplained hyperkalemia despite extensive investigations (details in Table 1). While all achieved normokalemia with various prescription regimens, the underlying etiology remained elusive. We suggest that all cases were likely due to chronic, mild hypovolemia in the context of self-imposed dietary salt restriction.

Case Description: Patient A: A 6-week-old girl with persistent hyperkalemia and very low urine Na+. Normokalemia was achieved with hydrochlorothiazide and dietary K+ restriction but maintained with optimized fluid and Na+ intake alone. Patient B: An 11-year-old boy with spastic cerebral palsy with persistent hyperkalemia after a mild AKI attributed to thalidomide. Serum K+ improved with sodium polystyrene (SPS) resins and dietary K+ restriction; it normalized after 5 days of intravenous infusion, while SPS. Patient C: A 5-month-old boy with Stüve-Wiedemann Syndrome and feeding difficulties with persistent hyperkalemia that normalized on SPS. After G-tube insertion at 2 years, K+ remained normal despite stopping the SPS due to improved fluid and Na+ intake.

Discussion: It has long been established that adequate Na+ and fluid delivery to distal nephrons is necessary for optimal K+ handling. It is therefore surprising to find almost no mention of Na+-responsive hyperkalemia in the literature for children beyond the neonatal period. Our patients all had hyperkalemia in the context of normotension, but very low fractional excretion of Na+ (FeNa) and low trans-tubular K+ gradient (TTKG). They all remained normokalemic when salt and water intake was optimized, despite stopping their hyperkalemic prescriptions. Careful, early consideration of low distal Na+ and water delivery as a cause for unexplained hyperkalemia could prevent extensive workups and unnecessary prescriptions.

POI1128

Machine Learning Models to Predict Cardiovascular and Renal Outcomes and Mortality in Hyperkalemic Patients

Fumihito Kanda,1 Suguru Okami,2 Shun Kohsaka,3 Xiaojun Ma,3 Masafumi Okada,1 Takeshi Kizuma,1 Toshikazu Yajima,2 Kawasaki Medical School, Kurashiki, Japan; 1AstraZeneca K.K., Osaka, Japan; 2IQVIA Solutions K.K., Tokyo, Japan; 3Real World Data, Co.Ltd., Kyoto, Japan; 4Keio University, Tokyo, Japan.

Background: Hyperkalemia is associated with increased risks of mortality and adverse clinical outcomes. To date, limited evidence is available for personalized risk evaluation in this heterogeneous and multifactorial pathophysiological conditions. Methods: We developed prediction models using extreme gradient boosting (XGB), logistic regression (LR), and neural network. Models were derived and cross-validated in a retrospective cohort of hyperkalemic patients with either heart failure or stage ≥3 chronic kidney disease and aged ≥18 years from a Japanese administrative hospital database (April 1, 2008–September 30, 2018). The outcomes of interest included all-cause death, introduction of renal replacement therapy (RRT), hospitalization for heart failure (HHF), and cardiovascular events within 3 years after first hyperkalemic episode. The best performing model was further validated using a separate hospital-based database. Results: 24,949 adult patients with hyperkalemia were selected for the model derivation and internal validation. The mean age was 75 years and 54% were male. Among machine learning algorithms tested, XGB outperformed other models, showing AUROC of XGB vs. LR for all-cause death, RRT, HHF, and cardiovascular events as 0.823 vs. 0.809, 0.957 vs. 0.947, 0.863 vs. 0.838, and 0.809 vs. 0.838, respectively. In the external validation set including 86,279 patients, AUROC of XGB for all-cause death, RRT, HHF, and cardiovascular events were 0.947, 0.988, 0.673, and 0.585, respectively. The Kaplan-Meier curves of high-risk predicted group showed a significant differentiation from that of low-risk predicted group for all outcomes (Figure).

Conclusions: These findings suggest the possible use of machine learning models for real-world risk assessment as a guide for treatment decision making that may lead to the improvement of cardiovascular and renal outcomes, and mortality in hyperkalemic patients.

Severe Hyperkalemia Secondary to Hypermagnesemia in a Patient with Preeclampsia

Aliyah Ibrahim, Alice Chedid. The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Introduction: Mg infusion remains the first-line treatment of preventing and controlling eclamptic seizures. While hypekalemia is a well-known side effect, hyperkalemia is not. We present a case of severe hyperkalemia secondary to magnesium infusion requiring hemodialysis.

Case Description: 36-year-old healthy female with no HTN or liver disease, pregnant at 25 weeks with twins, admitted for close monitoring given concern for intra-uterine growth restriction. Initial vitals on admission: BP 149/88 mm Hg, HR 89,
Changes in potassium and calcium concentrations in relation to hypermagnesemia (figure 1)

POI130
Severe Hypermagnesemia: A Potential Cause of Acute Hyperkalemia
Lusine Nahapetyan, Sindhuri Prakash-Polet, Raphael J. Rosen, Heedeok Han.
Columbia University Vagelos College of Physicians and Surgeons, New York, NY.

Introduction: Hypermagnesemia is not a well-established cause of hyperkalemia. In this case report we explore the association of acute hypermagnesemia and hyperkalemia.

Case Description: 30 year old female G1P0 with chronic HTN since age 26, CACUT was admitted for preeclampsia with severe features (new proteinuria 5.5 g/24h). Hypermagnesemia developed (peak 8), she simultaneously developed acute hyperkalemia (peak K 6.1, bicarb 19, lactate 85). Creatinine was normal at 0.7. Mg infusion was stopped. Other etiologies for hyperkalemia were ruled out including rhabdomyolysis or worsening hemolysis. The patient required one session of emergent hemodialysis which led to improvement in all electrolyte abnormalities.

Discussion: While the relationship between hypomagnesemia and hypokalemia is well understood, the relationship between hyperkalemia in the presence of hypermagnesemia remains not clear. Some of the mechanisms suggested (1) direct effect of magnesium on suppressing renin and aldosterone leading to impaired renal handling of K homeostasis (hyporeninemic hypoaldosteronism). (2) direct inhibition of the ROMK channel by Mg.

Conclusion: Severe hypermagnesemia can lead to acute hyperkalemia which can be life threatening. Close monitoring of serum electrolytes is advised.

POI131
When Sipping K Is Not OK
Anur Rajasekaran, Ammar Hasnic, Ashita J. Tolwani. The University of Alabama at Birmingham, Birmingham, AL.

Introduction: Hyperkalemia is one of the most common and potentially lethal electrolyte abnormalities that occurs in approximately 1% to 10% of hospitalized patients. It is associated with an increased risk of arrhythmias, poor cardiovascular outcomes, and increased morbidity and mortality. We highlight an unusual etiology of severe hyperkalemia in a patient with underlying CKD.

Case Description: A 74-year-old Black male with known arterial hypertension, coronary artery disease, CKD 3 [baseline serum creatinine (Cr) 1.7 mg/dl] presented with syncope secondary to severe bradycardia (heart rate 30/min) consequent to severe hyperkalemia, which necessitated a pacemaker placement, and non-oliguric AKI on CKD. Pertinent serum labs on presentation include Cr 2.8 mg/dl, potassium (K) 7.6 mmol/L, and bicarbonate 19 mmol/L. Serum osmolality, glucose, and creatinine kinase levels were within normal limits. Urine pH was 5. Renal imaging was unremarkable. He was not on any medication(s) commonly attributed with a propensity to elevate serum K, including renin angiotensin inhibitors, non-selective β blockers, or non-steroidal anti-inflammatory agents. Given that the hyperkalemia was out of proportion to his kidney injury, upon further questioning he attributed consuming a diet rich in K along with drinking multiple cups of Essiac tea daily for the last 2 months. Hyperkalemia was managed medically, including initial temporizing measures, bicarbonate supplementation, K binders, and intravenous crystalloids to enhance distal nephron K excretion. Placement was placed on consuming a K restricted diet along with discontinuing Essiac tea use. Serum K normalized in 3 days; however, Cr was 3 mg/dl on discharge.

Discussion: Essiac tea contains red clover, sheep sorrel, burdock root, and rhubarb which has extremely high potassium content. It is hepatotoxic and nephrotoxic when consumed in large amounts. We highlight the importance of obtaining a thorough dietary history, especially when the degree of hyperkalemia cannot be solely attributed to the extent of kidney injury. Dietary counselling is paramount in such cases.

POI132
Metabolic Acidosis That Exists with Hyperkalemia (HK) Among Patients That Initialize Binder Therapy: The MAXIMIZE Study
Seth P. Kurian,1 Ahby Agiro,2 Kaylen Brzozowski,1 William Pottorf,2 Pamela B. Landsman-Blumberg,1 Joachim H. Ix1,3TriNetX, LLC, Cambridge, MA; 4AstraZeneca, Global Medical Affairs, Wilmington, DE; 5University California San Diego, San Diego, CA.

Background: Approximately 25% of chronic kidney disease (CKD) patients with serum potassium (sK+) >5.0 mEq/L may also have metabolic acidosis (MA). However, successful management of comorbid HK and MA in CKD patients is unclear. This real-world evidence study examines the association between patient characteristics and binder treatment among CKD patients with HK and MA.

Methods: This was a retrospective study of stage 3-5 CKD patients with HK (sK+ >5.0 mmol/L) and MA (serum bicarbonate (sHCO3-)<20 mmol/L; OR=1.29 (1.03-1.61); OR=1.24 (1.04-1.47)) and liver disease (OR=1.61 (1.16-2.23); OR=1.47 (1.14-1.89)), respectively. Treatment with sHCO3-<20mmol/L in a US EMR network of 64 million patients. The index event was the first qualifying sK+ between 07/01/19 and 12/31/20. Baseline demographic and clinical characteristics were assessed among SZC, SPS, and NKB treated cohorts including age, sex, race, HK severity, sHCO3- level, visit type, and comorbidities. Logistic regression produced adjusted odds ratios (ORs) and 95% confidence intervals describing the association between baseline characteristics and treatment: sodium zirconium cyclosalicate (SZC) vs sodium polystyrene sulfonate (SPS) and SZC vs no potassium binder (NKB).

Results: Of the 32,113 patients who met study criteria 11.6% were treated with SZC (n=3,572). Age and sex were similar among SZC, SPS, and NKB cohorts and 81%, 77%, and 70% had moderate-to-severe acidosis (sHCO3- <20mmol/L), respectively. Baseline characteristics associated with increased odds of SZC vs SPS and SZC vs NKB treatment included sHCO3-<20mmol/L [OR=1.29 (1.03-1.61); OR=1.24 (1.04-1.47)] and liver disease [OR=1.61 (1.16-2.23); OR=1.47 (1.14-1.89)], respectively. Treatment with SZC vs NKB treatment was more likely in inpatient settings [OR=3.73 (3.06-4.55)] and in patients with comorbid congestive heart failure [OR=1.43 (1.12-1.84)].

Conclusions: Clinicians were more likely to treat HK with SZC than SPS or NKB in CKD patients with moderate-to-severe acidosis in a recent large, US, real-world sample. Secondary findings from prior clinical trials suggest that SZC may improve MA as well normalize sK+. Future clinical trials are needed to assess the impact of SZC on sHCO3- concentrations.

POII133
Real-world RAAS Inhibitor Use and Its Predictors Among Patients Initiating Sodium Zirconium Cyclosilicate
Abiy Agiro,1 Alpesh Amin,2 Fan Mu,3 Joshua A. Young,3 Erin Cook,3 Esteban J. Lemus Wirtz,4 Yasmin G. Brahmbhatt,5 Keith A. Betts,6 Charles V. Pollack,7 AstraZeneca, Wilmington, DE; University of California Irvine, Irvine, CA;8 Egham, UK;9 Analysis Group Inc., Boston, MA;10 University of Mississippi School of Medicine, Jackson, MS.

Background: Renin-angiotensin-aldosterone system inhibitors (RAASI) are associated with reduced risk of death and slower disease progression in patients with heart failure (HF) and chronic kidney disease (CKD). However, RAASI use increases the risk of hyperkalemia (HK), which may disrupt RAASI use and mitigate its benefits. There is limited real-world evidence characterizing RAASI use after sodium zirconium cyclosilicate (SZC) treatment.

Methods: Adult patients initiating SZC (index date) while on a RAASI in outpatient care were included from a large US claims database (January 2018-June 2020). Analyses were conducted among all patients, patients with CKD and patients with CKD + diabetes (DM). The percent of patients with a RAASI prescription at index was summarized. Characteristics among patients with and without a new RAASI fill were compared using descriptive statistics. A multivariable logistic regression model assessed predictors of a new RAASI fill.

Results: A total of 589 patients initiating SZC while on a RAASI were included (mean age 61 years, 65.2% male). Overall, 82.7% of patients had a new RAASI fill after index. The median time to discontinuation was not reached among patients with a new RAASI fill, of whom 88.1% at day 180 and 74.0% at 1 year remained on RAASI therapy. Compared to patients without a new RAASI fill, patients with a new fill had a higher burden of CKD (69.4% vs 58.8%) but a similar prevalence of DM (24.6% vs 28.4%). Results were similar in the CKD cohort (N=398; 84.9% had a new RAASI fill) and CKD and DM cohort (N=311; 85.2% had a new fill). Predictors of having a new RAASI fill included fewer prior hospitalizations (0.77 [0.60-0.98]; p=0.05) and emergency department (ED) visits (0.78 [0.63-0.97]; p=0.05).

Conclusions: In a real-world setting, 83% of patients had a new RAASI fill within 90 days after ending their RAASI. Results are consistent with clinical trial findings and similar among patients with CKD and patients with CKD + DM. Patients with hospital and ED visits will require follow up care to encourage RAASI continuation.

POII134
Compatibility Study of Patiromer with Juices/Liquids and Soft Foods
Martin Khoeiklang,1 Maria Wilhlim,1 Lingyun Li,2 Carol P. Moreno Quinn,3 Tamara Popov.1 Vifor International AG, Saint Gallen, Switzerland;2 Vifor Pharma Group, Redwood City, CA.

Background: Patiromer is a novel, once-daily, sodium-free K+- binder approved for treatment of hyperkalemia. The drug is a tasteless, odorless powder administered orally to mix patiromer with small amounts (per allowed dietary intake recommendations) of various liquids and foods may improve palatability and medication adherence. This study evaluated the compatibility of patiromer with juices/nectars, soft foods, and other liquids, the mean TKEC at low and high ratios was 8.5–8.7 mmol/g (reference: 9.2 mmol/g); exchange capacity for tested vehicles was within the prespecified range. For all mixtures, compatibility was assessed at two ratio levels: low (8.4 g patiromer in 40 mL of vehicle, ~1/6 cup); high (12.7 g patiromer in 20 mL of vehicle, ~1/4 cup).

Methods: For all mixtures, compatibility was assessed at two ratio levels: low (8.4 g patiromer in 40 mL of vehicle, ~1/6 cup); high (12.7 g patiromer in 20 mL of vehicle, ~1/4 cup; high (12.7 g patiromer in 20 mL of vehicle, ~1/4 cup).

Results: The drug–a tasteless, odorless powder–is administered orally and ED visits will require follow up care to encourage RAASi continuation.

Conclusions: Mixing of patiromer with small amounts of juices/nectars, soft foods, and other liquids, the mean TKEC at low and high ratios was 8.5–8.7 mmol/g (reference: 9.2 mmol/g); exchange capacity for tested vehicles was within the prespecified range. For all mixtures, compatibility was assessed at two ratio levels: low (8.4 g patiromer in 40 mL of vehicle, ~1/6 cup); high (12.7 g patiromer in 20 mL of vehicle, ~1/4 cup).

POII135
Risk of Heart Failure in Patients Who Initiated Sodium Zirconium Cyclosilicate vs. Patiromer
Min Zhuo,1,2 Seoyoung C. Kim,3 Elisabetta Patornò,3 Rishi J. Desai,3 Julie M. Park,1,2,7 Beth Israel Deaconess Medical Center, Boston, MA;3 Brigham and Women’s Hospital Department of Medicine, Boston, MA;1,4 V A New England Geriatric Research Education and Clinical Center, Boston, MA.

Background: Hyperkalemia is common in patients with chronic kidney disease (CKD), heart failure, and diabetes. Sodium zirconium cyclosilicate (SZC) and patiromer were recently approved for the treatment of hyperkalemia. Since SZC contains significant amounts of sodium, we assessed the risk of heart failure hospitalization (HHF) associated with the initiation of SZC versus patiromer in non-dialysis patients.

Methods: We used a U.S. commercial insurance claims database (Optum Clínifromatics® Data Mart) between May 2018 (after SZC approval) and September 2020. Participants were non-dialysis adults who had a 180 days of insurance enrollment and were newly prescribed SZC or patiromer. The primary outcome was a hospitalization with a discharge diagnosis of heart failure. The secondary outcome was a hospitalization or an emergency room visit with a diagnosis of any edema. Propensity score (PS) matching in a variable ratio up to 1:3 was used to adjust for more than 80 variables, including demographic characteristics, comorbidities, medication use, and health care utilization. Cox proportional hazards regression models were used to generate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Our cohort included 1,126 SZC initiators and 2,839 PS-matched patiromer initiators (total N=3,965). The mean age was 72 (±10) years, 30% had a history of heart failure and 85% had CKD stages 3-5. The risk of HHF was higher in the SZC initiators compared to patiromer initiators (HR 1.22, 95%CI 0.95-1.56), but the confidence interval included the null value (Table). Edema was more common in the SZC initiators (HR 1.89, 95%CI 1.05-3.39). In subgroup analyses, initiation of SZC was associated with an increased risk of HHF (HR 1.58, 95%CI 1.01-2.64) amongst patients without a history of heart failure.

Conclusions: Patients initiating SZC may need to monitor volume status and consider dietary salt restrictions and initiation or adjustment of diuretics. Larger studies are needed to more precisely evaluate the safety of SZC in routine practice.

POII136
RDX013, a Novel, Oral, Small Molecule Being Developed for Treatment of Hyperkalemia, Increases Colonic Secretion and Fecal Excretion of Potassium
Kenji Konuka,1 Matthias Siegel,2 Andrew J. King,3 Jill N. Kohler,3 Zhenghe Feng,1 Jingjing Jiang,1 Allison Quach,1 Cyra Fung,1 Bing He,1 Padmapriya Kumarawarminy,1 Limin He,1 Cathy M. Le,1 Catarina Tran,1 Jeremy Caldwell,2 David P. Rosenbaum,1 Jeffrey Jacobs.1 Ardelxy Inc, Fremont, CA;3 Awita Biosciences, San Carlos, CA;1 Chinuxx Therapeutics Inc, Vancouver, BC, Canada; Inception Therapeutics, San Diego, CA.

Background: Potassium (K+) homeostasis is maintained by the balance of dietary K+ intake, extra- and intracellular K+ distribution, and renal and intestinal excretion. Hyperkalemia (serum K+>5.0 mM) occurs frequently in CKD patients and can lead to cardiac arrhythmias and sudden death; controlling serum K+ may reduce mortality in this population. Current therapeutic options for the chronic treatment of hyperkalemia are limited to K+-binding agents. Here, we describe the discovery of RDX013, a novel, oral, small molecule K+ secretagogue in development for treatment of hyperkalemia.

Methods: Male Sprague Dawley rats (n=6/group) were orally administered vehicle or 6 mg/kg RDX013 twice daily for 6 days. 24-hour fecal samples collected from rats housed individually in metabolic cages on the final study day were homogenized, and K+ and sodium were analyzed by cation exchange chromatography.

Results: RDX013 significantly increased fecal K+ excretion compared to vehicle control animals (figure). Fecal sodium was also increased by RDX013 (figure), which was expected as luminal sodium retention in the intestine is key to the pharmacodynamic response. Fasting serum potassium was also increased by RDX013 (figure), which was expected as luminal sodium retention in the intestine is key to the pharmacodynamic response.

Conclusions: Based on its unique mechanism of action which involves pharmacologically enhancing K+ secretion through apical K+ channels in the colon, RDX013 is a potential first-in-class therapy which may provide a new approach to managing serum K+ in patients versus commonly prescribed K+ binders. A phase 2 clinical study with RDX013 (NCT04780841) is ongoing in non-dialysis CKD patients with hyperkalemia.

POI1137

Artificial Intelligence-Assisted Electrocardiography for Early Diagnosis of Thyrotoxic Periodic Paralysis

Shih-Hua P. Lin,1 Chih-Chien Sung,1 Min-hua Tseng,2 ‘Tri-Service General Hospital, Taipei, Taiwan; 2Chang Gung Memorial Hospital, Tao-yang, Taiwan.

Background: Thyrotoxic periodic paralysis (TPP) characterized by acute weakness, hypokalemia and hyperthyroidism is a medical emergency with a great challenge in early diagnosis since most TPP patients do not have overt symptoms. Since both hypokalemia and hyperthyroidism in TPP significantly affect the cardiovascular system, electrocardiography (ECG) as a prompt and non-invasive bedside tool universally used in the ED may detect these electrical changes. To assess artificial intelligence (AI)-assisted electrocardiography (ECG) combined with routine laboratory data in the early diagnosis of TPP.

Methods: A deep learning model (DLM) based on ECG12Net, an 82-layer convolutional neural network, was constructed to detect hypokalemia and hyperthyroidism. The development cohort consisted of 39 ECGs from patients with TPP and 502 ECGs of hypokalemic control; the validation cohort consisted of 11 ECGs of TPP and 36 ECGs of non-TPP with weakness. The AI-ECC based TPP diagnostic process was then consecutively evaluated in 22 male patients with TPP-like features.

Results: In the validation cohort, the DLM-based ECG system detected all cases of hypokalemia in TPP patients with a mean absolute error of 0.26 mEq/L and diagnosed TPP with an area under curve (AUC) of ~0.80%, surpassing the best standard ECG parameter (AUC=0.7285 for the QR interval). Combining the AI predictions with the estimated glomerular filtration rate (eGFR) and serum chloride (Cl) boosted the diagnostic accuracy of the algorithm to AUC 0.960. In the prospective study, our AI ECG system achieved perfect performance (F-measure 100%) on the task of hypokalemia detection in them and the integrated AI with routine laboratory had a PPV of 100% and F-measure 87.5% for TPP diagnosis.

Conclusions: An AI-ECC system reliably identifies hypokalemia in patients with paralysis and its integration with routine blood chemistries provides valuable decision support for the early diagnosis of TPP to avoid life-threatening complication.

POI1138

Will the Real Sodium Stand Up!

Nia Flemming, Michael Basir, Ro-Kaye A. Simmonds, Latoya N. Gayle, Zachary Banbury, Deborah A. Fein. Englewood Health, Englewood, NJ.

Introduction: Hyponatremia is a common finding as it could be precipitated by multiple factors ranging from medications to simple dehydration. Accurate approach to management depends on assessing serum osmolality in an effort to distinguish cases of true, factitious or pseudohyponatremia. We present a case of hyponatremia secondary to hypothyroidism.

Case Description: 36 year old Asian woman with HTN, Type 2 DM, HLD presented with 1 day of epigastric pain. On exam S1, S2 were heard with vesicular breath sounds throughout, epigastric tenderness and no focal neurological deficits. Initial labs: sodium 114 potassium 3.5 chloride 85 glucose 254, BHB 3.7. Sodium corrected for glucose 116 CO2, BUN, Cr and Ag were calculable. Urinalysis: pH 6.0, ketones < 160, glucose > 1000, protein > 1000. Total cholesterol 1020, HDL 25, Triglycerides >5600, LDL insatiable, serum osmolality 314, lipase 57. Venous blood gas: 7:37/30.194/8.17, sodiometry. VBG 132 Abdominal ultrasound revealed a normal pancreas with hepatic steatosis. She was treated in ICU with normal saline, insulin infusion, isocapent ethyl and gemfibrozil. Abdominal pain resolved and insulin was changed to Glargine. Over three days triglycerides trended down to 1744 and sodium to 132. She was discharged on isocapent ethyl, gemfibrozil, atorvastatin, glargine, metformin and lisinopril, with a sodium of 132.

Discussion: Sodium is most commonly measured by indirect potentiometry (ISE) measurement. By this method serum specimens are diluted based on estimated typical balance of serum to solid blood components. By this method factitious low sodium results are known to occur in patients with significantly elevated lipids and protein. As in this case, direct sodium measured by VBG/ABG are most accurate. Typically markedly elevated serum triglyceride with concentrations > 1500 mg/dl are thought to be responsible for factitious hyponatremia. In our patient the value of serum sodium on admission was unexpectedly low at 114 and severe hyperhypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides measured Na:

\[
\text{Measured Na} = \text{Corrected Na} \times \left(1 \frac{1}{	ext{mg/dL}} \times 1 \frac{1}{	ext{mmol/L}} \times \frac{7.8}{100} \right)
\]

Plasma triglycerides (g/L) x 0.002; measured serum sodium would have been expected to be 125 mEq/L. In cases of extremely high lipids, one must consider lab techniques for measuring serum sodium, as well as full lipid panel in the evaluation and treatment of factitious hyponatremia.

POI1139

Admission Sodium and Related Features to Predict Falls in Machine Learning Models

Alexander S. Leidner,1 Biruth Workeneh,2 Bing Ho.1 ‘Northwestern University Feinberg School of Medicine, Chicago, IL; 2The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Hyponatremia has been associated with an increased risk for falls, but evidence is primarily limited to outpatient events. Hyponatremia is a potential surrogate of conditions that may lead to falling including volume depletion, malignancy, pain, polypharmacy, and weakness. We hypothesized that a model could be developed to predict falls based upon accessible variables present on all hospital admissions. An accurate model could allow for measures to lower in-hospital falls.

Methods: Medical records from a single institution were collected over a period of 2011 to 2019. Subjects included admitted patients who suffered a recorded in-hospital fall and were admitted, and controls matched for admission on the same date. Variables collected included sodium, glucose, age and gender. There were 17,103 patients total of which 1,203 had unique falls. Data was split into an 80% training, 20% validation and 20% testing split. We computed an unadjusted odds ratio of falls for those with very low sodium (<126). We trained logistic regression, random forest, XGBoosted forest, and neural net classifiers. Classifier cutoff was calculated using Youden values.

Results: We did not see an increased incidence of falls in the population with a low sodium (N=377) with an unadjusted odds ratio of 0.62 (CI 0.38-1.01). Similarly, the model performances did not result in clinically useful predictions with a unanimously high false positive and false negative rates (Figure 1).

Conclusions: Despite reports of hyponatremia as an indicator of fall risk we did not observe this. The fall-prediction models did have the capacity for high performance on the training data, but this does not translate to validated performance. This discrepancy is termed ‘overfitting’ and is important to evaluate as machine learning models have a limited capacity than traditional models to incorporate previously seen examples. If a model cannot make predictions on new data it cannot be clinically useful. These models may be enhanced using other basic admission features and is the subject of future work.

POI1140

Association of Serum Sodium Levels with Bone Mineral Density, Fracture, and Mortality in Patients Undergoing Maintenance Hemodialysis

Ken'zuke Soeda,1 Hirotaka Komaba,1 Yosuke Nakagawa,2 Takehiko Wada,1 Takatoshi Kakuta,2 Masafumi Fukagawa,1 2Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan.

Background: Hyponatremia is implicated in pathological bone resorption and has been identified as a risk factor for bone fracture in the general population, but limited data exist in patients undergoing dialysis.

Methods: We analyzed a historical cohort of 2,292 patients undergoing maintenance hemodialysis in Japan. We first examined the association of baseline serum sodium levels with metacarpal bone mineral density (BMD) in a subcohort of 456 patients with available data. Next, we examined the association of baseline sodium serum levels with incident fracture and mortality in the overall cohort, using Cox regression models adjusted for potential confounders (age, sex, dialysis vintage, diabetes, prior cardiovascular disease, history of fracture, body mass index, hemoglobin, albumin, and creatinine) and competing risks regression models accounting for death as a competing endpoint.

Results: Baseline mean ± SD serum sodium level in the overall cohort was 139.7 ± 2.9 mEq/L, and among patients with available data, median metacarpal BMD T-score was -2.05 (IQR, -3.35 to -0.99). Serum sodium levels were not associated with metacarpal BMD T-score in unadjusted or adjusted models. During a median follow-up of 5.4 years (IQR, 2.5-7.0 years), 712 patients died; 113 experienced clinical fractures; and 64 experienced asymptomatic vertebral fractures as estimated by height loss. In adjusted Cox regression, serum sodium levels were associated with mortality (HR, 0.95 per 1 mEq/L higher; 95% CI, 0.92-0.98) but not incident clinical fracture (HR, 0.97 per 1 mEq/L higher; 95% CI, 0.90-1.04) or any fracture (a composite of clinical fracture and vertebral fracture). Similar results were obtained in competing risks regression models.

Conclusions: Serum sodium levels were associated with mortality but not BMD or incident fracture in maintenance hemodialysis patients.
PO1141

Hyponatremia, Inflammation, and Hospital Mortality in Hospitalized COVID-19 Patients

Juan Carlos Ayus,1 Michael L. Mortiz,2 Kyung Min Lee,3,4 Daniel Caputo,4 Maria E. Borda,2 Alan S. Go,2 Carlos Eghi.1 University of California Irvine School of Medicine, Irvine, CA; 2UPMC Children’s Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA; 3University of Pittsburgh School of Medicine, Pittsburgh, PA; 4Hospital Posadas, Buenos Aires, Argentina; 5Kaiser Permanente, Oakland, CA; 6University of California San Francisco, San Francisco, CA.

Background: Systemic inflammation has been associated with severe COVID-19 disease. Hyponatremia can result from inflammation due to non-ossimotic stimuli for vasopressin production. Hyponatremia is an independent risk factor for hospital mortality.

Methods: Hospitalized patients with COVID-19 were prospectively evaluated between March and November 2020 at Hospital Posadas in Buenos Aires, Argentina, in order to evaluate the association between hyponatremia and inflammation and its impact on clinical outcomes. Admission biochemistries, high-sensitivity C-reactive protein (hsCRP), ferretin, patient demographics, and outcome data were recorded. Outcomes (within 30 days after symptom) that were evaluated included admission to the ICU during hospitalization, mechanical ventilation, dialysis-requiring AKI, and in-hospital deaths. In-hospital mortality, length of hospital stay (in days), and hospital readmission for any cause within 30 days after discharge were evaluated using comprehensive data from the EHR.

Results: Among 799 hospitalized COVID-19 patients, hyponatremia was present on admission in 366 (45.8%). Hyponatremic patients had higher hsCRP levels than normonatremic patients (median 10.3 [IR 4.8-18.4] mg/dL vs 6.6 [IR 1.6 - 14.0] mg/dL, respectively, p< 0.01), and hsCRP level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient –0.23; p< 0.01). Hyponatremic patients had higher serum ferritin levels than normonatremic patients (median 649 [IQR 492-1168] mg/dL vs 393 [IQR 156-1440] mg/dL, respectively; p< 0.02), and serum ferritin level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient –0.26; p< 0.01). Hyponatremic patients had increased mortality on unadjusted (odds ratio 1.87, 95%CI:1.28-2.73) and adjusted (odds ratio 1.61, 95%CI:1.05-2,49) Cox proportional hazard models. Crude 30-day survival was lower for patients with hyponatremia at admission (mean [SD] survival 22.1 [0.70] days) compared with patients with normonatremia (mean [SD] survival 27.1 [0.40] days, p< 0.01).

Conclusions: This study demonstrates that hyponatremia on admission is common in patients with COVID-19 and is associated with inflammation and in-hospital mortality. Thus, hyponatremia could be a novel marker for identifying patients with COVID-19 at risk for hospital mortality.

PO1142

Trends of Overall Mortality by Severity of Hyponatremia: Five-Year Mortality Rates

Peter E. Umukoro1 Fahad A. Lodhi,2 Javad Najjar Mojarrad.1 Indiana University School of Medicine, Indianapolis, IN; 2Marshfield Clinic Health System, Marshfield, WI.

Background: We have previously reported increasing strengths of association between degree of hyponatremia on hospital admission and proportions of overall mortality at 1 year post-hospitalization. It is unclear if this association persists in the long term and if this association with overall mortality occurs in a linear manner. Here, we further explore this association over a longer mean follow up period. We hypothesized that a dose response relationship occurs between varying degrees of hyponatremia and overall mortality.

Methods: We obtained data from 46,783 patients, average age 62.2 years, 51.3% males, admitted from January 1, 2012 to December 31, 2016 at a tertiary referral hospital in Central Wisconsin. Of these, 7468 patients had admitting serum sodium <135 and 39315 controls with normal serum sodium (135-145). We parsed hyponatremia based in varying degrees of hyponatremia compared with controls. We obtained their vital status (alive or deceased) up to December 31, 2018 over a mean follow up period of 4.7 years. We used Cox proportional hazards model to estimate hazard ratios between varying degrees of hyponatremia compared with normonatremia group after adjusting for covariates.

Results: Hyponatremia occurred in 17.9% of total hospitalizations during the study period. Of 7468 patients with hyponatremia, there were 6,135 (82.2%), 995 (13.3%) and 338 (4.5%) with mild, moderate, and profound degrees of hyponatremia respectively. Hazard ratios for mild, moderate and severe hyponatremia when compared to controls were 1.35 (95%CI: 1.26 – 1.43), 1.81 (95% CI: 1.24 – 2.56) and 2.01 (95% CI: 1.24 – 3.27) respectively (all p<0.001) after adjusting for covariates.

Conclusions: All-cause mortality from CVD, stroke, cancer, liver cirrhosis deaths were occurring to a significant proportion even in patients with milder degrees of hyponatremia with a dose response relationship. Clinicians should incorporate hyponatremia in their assessment of critical patients as this is associated with mortality. These findings need to be explored further with research geared towards elucidating mechanisms that contribute to death in hyponatremia, and if correcting sodium levels early in hospitalizations may prevent mortality in the future.

PO1143

The Prognostic Importance of Serum Sodium for Mortality Among Critically Ill Patients Requiring Continuous Renal Replacement Therapy

Charat Thongprayoon,1 Wisth Cheungpasitporn,1 Khaled Shawwa,1,2 Kamboush Kashami.1 Mayo Clinic Minnesota, Rochester, MN; 2West Virginia University, Morgantown, WV.

Background: Serum sodium derangement is common in critically ill patients requiring continuous renal replacement therapy (CRRT). We aimed to assess the association between serum sodium (normal range 138-142 mmol/L) before and during CRRT with mortality.

Methods: This is a historical cohort study of 1,520 critically ill patients who received CRRT for at least 24 hours from December 2006 through November 2015 in a tertiary hospital in the United States. Using logistic regression analysis, we used serum sodium before CRRT, mean serum sodium, and serum sodium changes during CRRT to predict 90-day mortality after CRRT initiation.

Results: Compared with the normal serum sodium levels, the odds ratio (OR) of 90-day mortality in patients with serum sodium before CRRT of ≥134-147 and ≤148 mmol/L were 1.45 (95% CI 1.03-2.05), 2.24 (95% CI 1.33-3.87), respectively. There was no significant increase in 90-day mortality in serum sodium of ≤137 mmol/L. During CRRT, the mean serum sodium levels of ≤137 (OR 1.41; 95% CI 1.01-1.98) and ≤143 mmol/L (OR 1.52; 95% CI 1.14-2.03) were associated with higher 90-day mortality. The greater serum sodium changes during CRRT were associated with higher 90-mortality (OR 1.35; 95% CI 1.21-1.51 per 5 mmol/L increase).

Conclusions: Before CRRT initiation, hyponatremia and during CRRT, hypo- and hypernatremia were associated with increased mortality.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Restricted cubic spline of the association between serum sodium before CRRT and 90-day mortality

Restricted cubic spline of the association between mean serum sodium during CRRT and 90-day mortality

PO1144

Use of Tolvaptan to Maintain Eunatremia in Acute Brain Injury-Induced SIADH

Maria Christina Victoria M. Capistrano,1 Ankur Shah.2 ‘Kent Hospital, Warwick, RI; 2Brown University Warren Alpert Medical School, Providence, RI.

Introduction: Hyponatremia is a predictor of in-hospital mortality in intracerebral hemorrhage. In hyponatremia from SIADH, usual therapies may not be ideal in patients with stroke. We present a case of hyponatremia from acute brain injury induced SIADH being managed with Tolvaptan.

Case Description: Our patient is a 68 year old man with a history of hypertension who was admitted for an acute hemorrhagic stroke. He had a blood pressure of 204/127 mmHg over and an NIHSS of 110. His initial work up shows: glucose 199 mg/dL, creatinine 0.75 mg/dL, Na 137 mmol/L, potassium 3.8 mmol/L, HCO3 of 25 mmol/L, chloride 95 mmol/L. A head CT scan demonstrated a 10 cc right thalamic hemorrhage. He was then started on a nicardipine drip. On the next day, he was noted to have a Na of 129 mmol/L. His serum osmolality, urine osmolality, urine Na were 289 mOsm/kg, 6,783 mOsm/kg and 146 mmol/L respectively. He was given salt tablets with...
improvement of Na to 131. However, he developed headaches and became hypertensive at 180/94 mmHg. Instead, he was started on a high protein diet, 1 liter fluid restriction and lasix. The next Na level was 129. He was given Tolvaptan 15 mg, which increased the Na to 132, urine osm 645, and urine Na to 12. The dose was increased to 30 mg to achieve eunatremia with these values: Na 135-138, urine Na 12, urine osm 487. His BP improved, tolvaptan was discontinued and salt tablets were resumed. The patient maintained eunatremia throughout the hospital stay.

Discussion: Hyponatremia is a predictor of mortality due to cellular edema. Eunatremia with Na levels between 135-145 mmol/L is targeted in acute brain injury. SIADH induced by brain injury may be due to an increase in ADH from the overstimulation of the neurohumoral axis. ADH promotes water reabsorption at the cortical and medullary collecting tubules, and inappropriate levels lead to hyponatremia. Tolvaptan is a V2 receptor antagonist which combats this mechanism, thus increasing free water excretion. Additional therapies for hyponatremia from SIADH include fluid restriction, a high protein diet and salt tablets. However, salt tablets increase fluid retention; which increases blood pressure, and leads to recurrent hemorrhage and poor outcomes. The use of Tolvaptan increases free water excretion to achieve eunatremia, thereby decreasing the risk of brain edema and controls blood pressure, especially in this patient population.

PO1145
Acute Severe Symptomatic Hyponatremia in the Post-Partum Period: The Syndrome of Oxytocin-Induced Anti-Diuresis (SOIAD)
Muhammad A. Shahzad, William L. Whittier, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

Introduction: Oxytocin (OXT) is a neuropeptide used in pregnancy to induce uterine contraction. It is structurally related to vasopressin (AVP) by a difference of only 2 amino acids. While it does not have antidiuretic activity at physiologic levels, it can when administered at pharmacologic doses (>20 μL/min). We present a case of a severe symptomatic hyponatremia after receiving oxytocin in the post-partum period.

Case Description: A 31 y/o G1P0 woman was admitted with premature membrane rupture at week 38. An IV oxytocin infusion (2μL/min) was started to augment labor. Her serum sNa 6 hrs later was 132 mmol/L (baseline sNa 140). Her delivery was c/v with uterine atony and postpartum hemorrhage requiring a bolus of IV oxytocin (10 U over 30 min) followed by infusion at 8 μL/min. The sNa 18 hr later was 118 mmol/L. She reported nausea. Her sOsm was 252 mOsm/kg with UNa 95 mmol/L and Uosm 880 mosm/kg consistent with the syndrome of anti-diuresis (SIAD). OXT was suspected and was stopped. 2 hr later, a rapid water diuresis ensued (u vol 150-200 m/L, with UNa 92 mosmol/kg). The sNa and 8 hrs later increased to 124 and 127 respectively. Because of concern for over-correction, she was given DDAVP and D5W. This resulted in a gradual (6-8 mosmol/L/24 hr) sNa increase to 140 mmol/L over the next 48 hr (Fig 1).

Discussion: Therapeutic OXT can result in anti-diuresis with water retention. OXT half-life is only 1.6 min and is further reduced during pregnancy. Women are more likely to have severe neurologic sequelae of hyponatremia so it is fortuitous that the half-life of OXT is so short, and discontinuation alone should result in a rapid water diuresis. Still, although acute hyponatremia can usually be safely corrected rapidly, concern over what could have been an increase in sNa of 28 mmol/L over several hrs necessitated a DDAVP clamp to slow correction. She had a complete recovery. SOIAD can be a severe complication of OXT. Since it can occur rapidly and severely, sNa should be followed closely when patients are on OXT infusion.

PO1146
A Rare Cause of Hyponatremia: Renal Salt Wasting Syndrome of Unclear Etiology Post Autologous Hematopoietic Stem Cell Transplant
Adriam S. Polani,1 Vikas D. Reddy,2 Venkata Kishore R. Mukku,3 Vishnupriyadevi Parvathareddy,4 Sheldon Chen.5 Baylor College of Medicine, Houston, TX; The University of Texas Health Science Center at Houston John and Kathie Hone G McNair Medical School, Houston, TX; The University of Texas Medical Branch at Galveston School of Medicine, Galveston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Hyponatremia is common in cancer patients. We report a rare case of acute hyponatremia in a patient with multiple myeloma (MM) who developed renal salt wasting syndrome (RSWS) as a complication of autologous hematopoietic stem cell transplant (SCT).

Case Description: A 57-year-old female with history of Plasmacytoma treated with radiation therapy that subsequently relapsed as MM with POEMS syndrome and was treated with VRd regimen presented for autologous SCT. MM was in remission and patient underwent Melphalan pre-conditioning with last melphalan dose 48 hours prior to transplant. 36 hours post-transplant patient had a seizure. Labs revealed acute drop in serum sodium from 137 to 117 over 17 hours. CT head revealed mild generalized cerebral edema. Patient also had acute polyuria (> 4 L/day). Patient was treated emergently with hypertonic saline bolus and had resolution of neurological symptoms however, serum sodium continued to drop and she required around 2 L of hypertonic saline infusion over the next 24 hours to correct sodium at desired rate. Urine studies at the time of hyponatremia revealed urine osmolality of 477, sodium 161 and potassium 34. Initial working diagnosis was SIADH that was quickly revised to RSWS based on high urine sodium, hypovolemia and polyuria. The patient was able to be transitioned to salt tablets once polyuria resolved over the next 36 hours. Urine sodium remained elevated. A repeat CT head showed resolution of cerebral edema.

Discussion: RSWS post SCT is rarely reported. Among the few reported cases an underlying CNS complication or a post-transplant hyponatremia inducing medication exposure that predated acute hyponatremia was present. Moreover the reported cases appeared to be non autologous transplants. SIADH and RSWS (including CSWS) are similar in the sense that both present with similar urine studies. Volume status and urine output are the key factors to help differentiate between the two entities. Clinically differentiating between these two entities is important as fluid restriction is the key management in the one and solute plus volume replacement in the other. Based on our case we recommend that hyponatremia post SCT should be carefully evaluated and RSWS be considered in the differential even if there is no obvious underlying cause.

Explainable Prediction of Overcorrection in Severe Hyponatremia: A Post Hoc Analysis of the SALSA Trial
Huijin Yang,1 Seon Ha Baek,1 Sejoong Kim,2 'Hallym University Dongtan Sacred Heart Hospital, Gyeonggi-do, Republic of Korea; 'Seoul University Bundang Hospital, Gyeonggi-do, Republic of Korea.

Background: Overcorrection of hyponatremia can result in irreversible neurologic disability like osmotic demyelination syndrome. Few prospective studies have identified the individuals at high risk of overcorrection under controlled hypertonic saline treatment.

Methods: We performed a post hoc analysis of a multicenter, prospective randomized controlled study – the SALSA (Efficacy and Safety of Rapid Intermittent Correction Compared With Slow Continuous Correction With Hypertonic Saline In Patients With Moderately Severe or Severe Symptomatic Severe Hyponatremia) trial in 178 patients older than 18 years with symptomatic hyponatremia (mean age 73.1 years, mean serum sodium (sNa) concentrations 118.2 mmol/L). Overcorrection was defined as an increase in sNa by > 12/18 mmol/L within 24/48 hours at any time.

Results: Thirty-seven of 178 patients experienced overcorrection (20.7%). Overcorrection was independently associated with initial sNa level (≤ 110 mmol/L: 7 points; 110-115 mmol/L: 4 points; 115-120 mmol/L: 2 points; 120-125 mmol/L: 0 point), chronic alcoholism (7 points), severe symptoms of hyponatremia (3 points), and initial potassium level (< 3.0 mmol/L: 3 points). The NASK score was derived from these four risk factors for overcorrection (hyponatremia, Alcoholism, Severe symptoms, and hypokalemia) and was significantly associated with overcorrection (odds ratio 1.41, 95% CI 1.24 to 1.61; P < .001) with good discrimination (area under the receiver operating characteristic curve 0.76, 95% CI 0.66 to 0.85; P < .001). The AUROC value of the NASK score was statistically better comparing to those of each risk factor.

Conclusions: In treating patients with symptomatic hyponatremia, individuals at high risk of overcorrection were predictable using a novel risk score summarizing baseline information.

PO1148

Cerebral Salt Wasting in a Renal Transplant Patient
Prashanth Reddy, Sahityan Viswanathan. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Hyponatremia is a common occurrence in patients with cerebral injury and is usually thought to be secondary to SIADH. Though cerebral salt wasting is documented in literature it has been debated on if it is truly a phenomenon. Among patients with CNS disease, CSW is a much less diagnosed cause of hyponatremia and remains underdiagnosed owing to the challenge of proving its existence. Here we present a patient with a CNS injury who showed clear benefit from treatment not centered around SIADH, thus pushing us to diagnose him with CSW.

Case Description: A 63yo Male with a PMHx of DDKT presented with nausea/vomiting. A cerebellar abscess from a previous biopsy site was found and he underwent a debridement and washout. On POD#4 the patient had a drop in sodium to 131. Urine studies [urine osmolarity: 789; urine Na: 72]. With continued drop in sodium and orthostatic hypotension he was started on NS 75cc/hr. The sodium continued to drop to a low of 123. At that time the NS was increased to 125cc/hr. This resulted in an upswing in serum sodium to 130. A drop in NS rate was trialed with sodium dropping back to 127. The NS was eventually ramped up to 200cc/hr with good response. During the uptitration of fluids there was no significant drop in urine osmolality noted. The patient was eventually transitioned to a dose of salt tabs close to the equivalent to the amount of fluids he was receiving [5g Q4H]. He was also started on Fludrocortisone 0.1mg daily. This resulted in our ability to drop the Salt tabs to 4g Q6H with stability in serum sodium noted. He was discharged on this regimen and was noted to have stable serum sodium on follow up a few weeks later.

Discussion: CSW is difficult to diagnose due to the similarities in laboratory diagnostic markers with SIADH. One major difference is that in CSW patients are usually hypovolemic. Another aspect that differs from SIADH is the approach to treatment. In SIADH a combination of fluid restriction, lasix, and salt tabs are used. What makes our case unique is the successful use of NS to correct the patient’s sodium. If this was SIADH, continuous administration of NS would have dropped the sodium level. We believe we met the burden of proof to diagnose this patient with CSW. Though there may still be debate about the existence of CSW, we believe that with the difference in treatment approach it should always be considered in the differential in patients with CNS injury.
Case Description: A 58-year-old male with past medical history of hypertension on amiodpine and losartan presented with nausea, emesis and abdominal pain. The patient was recently discharged 2 weeks earlier s/p uncomplicated distal pancreatectomy with splenectomy for pancreatic adenocarcinoma. Post-operative course was stable with no complications and patient was discharged home on oxycodone/acetaminophen for pain.

At home, the patient noticed constipation with worsening abdominal distension with bilateral lower extremity swelling. He had been oliguric for the past week, performing manual suprapubic compression to void. On readmission patient was noted to be severely dehydrated with a large, distended abdomen. Vital signs were BP 102/53, HR 87, SpO2 97%. Notable labs include (mEq/L): Na 111, BUN 132, Cr 4.4, HCO3 18. Urine studies noted (mEq/L): Na 8, Cl -10, K 25, serum osmolality 366 mOsm/kg. Abdominal CT noted a large LUQ fluid collection, distal colonic distension with focal retention and mild bilateral hydronephrosis. Subsequent foley insertion immediately drained 2.5L. Repeat labs 12 hours later were (mEq/L): Na 118, BUN 118, Cr 2.89. Hypotonic fluids were started to prevent Na overcorrection. Over the next several days the patient’s Serum Na (135) and renal function improved (BUN 21, Cr 0.9) back to baseline.

Discussion: During the post-operative period urinary retention is commonly noted due to anesthesia, analgesics, pain and constipation. This can be exacerbated in elderly male patients due to the ubiquity of BPH. Therefore physicians must be aware of common post-operative complications of urinary retention like hyponatremia, especially given the higher prevalence and predisposition of geriatric populations to develop hyponatremia. The proposed mechanism of urinary retention induced hyponatremia involves bladder distension and/or pain-mediated ADH release.

PO1154
Point-of-Care Ultrasound-Assisted Management of Hyponatremia
Totini S, Chatterjee, Abhilash Koratala. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Point of care ultrasound (POCUS) is emerging as a valuable adjunct to conventional physical examination in patients with complex fluid and electrolyte disorders. Herein, we present a case of hyponatremia where nephrologist-performed focused cardiac ultrasound (FoCUS) aided in accurate diagnosis.

Case Description: A 73-year-old woman was admitted for the treatment of fractures after sustaining a fall. Nephrology was consulted for decrease in serum sodium level (to 123 mmol/L; baseline 130s). Laboratory data was significant for a urine sodium level of 46 mmol/L, urine osmolality 257 mOsm/kg, serum creatinine 0.5 mg/dL and BUN 9 mg/dL. As the patient had exertional dyspnea and crackles at lung bases, IV diuretic was administered by the rounding physician prior to urine studies. No active pain or thiazide use. X-ray showed a huge hiatal hernia with bowel contents in the chest, which was possibly mimicking crackles on auscultation and causing dyspnea. Systolic BP was in 140s. Urine sodium, though suggestive of euvolemic state, was confounded by diuretic. We performed a FoCUS exam. Left ventricular outflow tract velocity time integral (LVOT-VTI), which is a surrogate for stroke volume was lower than expected (~13 cm [normal 18-22]) suggestive of hypovolemia. Flow changes preceded drop in BP. We recommended to administer normal saline and the serum sodium improved to 130 mmol/L in 2 days; VTI normalized to ~22 cm [Fig. 1].Fig.2 illustrates stroke volume estimation using LVOT diameter and VTI. As the diameter is constant for a given person, VTI alone can be used to monitor response to therapy.

Discussion: POCUS is a valuable bedside diagnostic tool in day-to-day nephrology practice.

PO1156
Identifying Hypernatremia Subgroups with Differing Survival by Machine Learning Among Hospitalized Patients
Grace Y. Chong, Charat Thongprayoon, Michael A. Mao, Andrea G. Kattah, Miria T. Keddis, Stephen B. Erickson, John J. Dillon, Vesna D. Garovic, Wisit Cheungpasitporn. Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; Mayo Clinic Division of Nephrology and Hypertension, Jacksonville, FL; Mayo Clinic Division of Nephrology and Hypertension, Phoenix, AZ.

Background: The objective of this study was to characterize patients with hypernatremia on hospital admission into clusters using an unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

Methods: We performed consensus cluster analysis based on demographic information, principal diagnoses, comorbidities, and laboratory data among 6,297 hospitalized adult patients with hypernatremia present at admission. We calculated the standardized difference of each variable to identify each cluster’s key features. We assessed the association with each hypernatremia cluster with in-hospital and one-year mortality.

Results: There were three distinct clusters of hypernatremia: 1,570 patients (25%) in cluster 1; 2,648 (42%) in cluster 2; and 2,079 (33%) in cluster 3. Figure 1 is a plot of standardized mean differences to visualize key features for each cluster. Compared to cluster 2, the odds ratios for in-hospital mortality were 6.99 (95% CI 4.03-12.13) for cluster 1 and 5.73 (95% CI 3.31-9.90) for cluster 3, whereas hazard ratios for one-year mortality were 3.38 (95% CI 2.69-4.25) for cluster 1 and 4.71 (95% CI 3.82-5.80) for cluster 3.

Conclusions: The characteristics and outcomes of hospitalized patients admitted with hypernatremia were heterogeneous. Our cluster analysis identified three clinically distinct phenotypes with differing mortality risks. Identification of heterogeneity in hypernatremic patients using this approach may provide guidance for the management of hospitalized patients with hypernatremia at the time of hospital admission.

PO1155
Polyethylene Glycol-Induced Pseudohyponatremia
Sweeta Reddy, Sundararaman Swaminathan. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Pseudohyponatremia due to Polyethylene glycol (PEG) is poorly described and goes unrecognized. We describe a case of hyperosmolar pseudohyponatremia due to PEG absorption into the systemic circulation.

Case Description: An 84-year-old lady with hypertension and CKD stage 4 was admitted with an asymptomatic serum sodium of 121. Initially thought to be due to SIADH. She was started on 1-liter fluid restriction, sodium chloride tablet and torsemide. Nephrology was consulted on day 3 as her serum creatinine was 2.9 (baseline 2.3 mg/dl) and sodium improved to only 124. Patient complained of increased thirst and had dry mucus membrane on examination. Labs on admission revealed a serum sodium of 121 mEq/L, a serum osmolality of 286 mOsm/kg, urine osmolality of 230 mOsm/kg and urine sodium of 40. Serum creatinine was 2.3 mg/dL, BUN 50 mg/dL, glucose of 100mg/dL, uric acid 8.1 mg/dL. Thyroid function tests and cortisol were within normal range. An osmolar gap of 22 was noted. In the absence of hyperglycemia and other potential causes of an osmotic gap, such as mannitol or alcohol, a careful review of medication showed that she was on 3 weeks of PEG for constipation. PEG was held, fluid restriction and torsemide discontinued. Resolution of osmolar gap was confirmed in two weeks with return in sodium to 134 and creatinine to 2.3.

Discussion: The prevalence of hyponatremia is reported at 7% in bowel prep patients. Etiology in these cases was due to increased free water intake. Hyperosmolar hyponatremia is caused by the addition of an ‘effective solute’ (e.g. glucose, mannitol or sucrose) to the serum. Commonly used as an osmotic laxative, PEG is described as ‘a nonabsorbable, nonmetabolized polymers’ that when administered orally acts as a ‘pure osmotic agent’ in the gastrointestinal tract. Systemic absorption can occur in rare cases. When PEG absorption occurs, most of its clearance occurs via renal filtration, this process is likely impaired in a patient with CKD such as seen in our patient. When a patient presents with hyponatremia, the expectation of a low-serum osmolality needs to be confirmed with the actual measurement of serum osmolality. This case highlights the importance of detecting the etiology of hyponatremia without which treatment of the same can be impossible and expands the understanding of normal to high serum osmolality can go beyond the commonly known mannitol, paraproteinemia and lipidemia.
**PO1157**

A Rare Case of Acute Myeloid Leukemia Presenting as Central Diabetes Insipidus

Dharika P. Shah, Alka A. Tyagi, Mohankumar Doraissamy, Sethu M. Madhavan. The Ohio State University Wexner Medical Center, Columbus, OH.

**Introduction:** Central Diabetes Insipidus (CDI) is an uncommon condition, with an overall incidence of approximately 1:25,000 and is usually associated with neurosurgery, trauma, and vascular disease, infiltrative disorders, hypoxic brain injury, and head trauma. Patients with acute myeloid leukemia (AML) mostly present with symptoms of pancytopenia, not hematologic abnormalities and are subsequently diagnosed with AML after bone marrow biopsy. Here we describe a unique case of a patient who presented with symptoms of CDI and incidentally diagnosed with AML.

**Case Description:** A 64-year-old male with a history of coronary artery disease presented to his primary physician complaining of polyuria and polydipsia which affected his work as a truck driver. Labs were notable for mild anemia (Hgb 11 g/dL) with macrocytosis, anemia, and thrombocytopenia (platelet 667 K/uL), serum sodium was 146 mEq/L, Hgb Alc 5%, prostatic-specific-antigen 1.4 ng/mL, normal lipids panel, and normal thyroid function. No definitive diagnosis was made and he underwent evaluation by hematology. Peripheral smear showed increased (44%) blasts/promyelocytes, consistent with acute leukemia. Cytogenetic analysis showed an abnormal clone of cells with an inverted chromosome 3 and monosomy for chromosome 7. He was admitted for induction therapy and presenting symptoms worsened (~1 L urine output per day) along with hypernatremia which peaked at 160 mEq/L, serum osmolality 319 mOsm/kg and urine osmolality and serum osmolality and urine osmolality.

**Discussion:** The presentation of AML with concurrent CDI is associated with chromosome 3 or 7 abnormalities, not brain lesions, as in this case; the management of CDI involves continued DDAVP administration. Unfortunately this translocation has been associated with poorly differentiated acute myeloid leukemia. With this case, we suggest screening patients with CDI for who have an unclear reason of developing hypernatremia which peaked at 160 mmol/L, serum osmolality 319 mOsm/kg and urine osmolality.

**Conclusion:** This case reinforces the association between ketamine and central DI related to ketamine. We present a unique case of central DI associated with ketamine injection in a critically ill patient with acute respiratory failure.

**Case Description:** A 52-year-old African American man with a medical history of bipolar disorder, polysubstance abuse, chronic obstructive pulmonary disease, hypertension, and deep vein thrombosis was admitted to the medical intensive care unit with hemoptysis and acute respiratory failure. Due to agitation and refractory hypoxemia he required multiple sedating agents. Within hours of starting a ketamine infusion his urine output increased from a mean of 71 mL/hr to 305 mL/hr. Over 48 hours serum sodium (Na+) rose from 142 to 159 mM/L. Urine osmolality (Uosm) was 132 Osm/kg, 4 mcg intravenous (IV) desmopressin was administered. 90 minutes later Uosm had increased to 646 Osm/kg. Urine output fell to 49 mL/hr. About 28 hours after the initial dose of desmopressin polyuria recurred and Uosm fell to 272 Osm/kg. IV desmopressin was re-administered at 2 mcg with a similar response to the first dose. Sodium normalized with free water replacement. Ketamine was stopped. Urine output, Uosm, and Na+ remained stable without further intervention. Alternative etiologies for central DI such as hypoxic brain injury were considered but felt to be less likely due to the strong temporal relationship with ketamine. The Naranjo adverse drug reaction (ADR) likelihood score was 5 indicating a probable ADR.

**Discussion:** This case reinforces the association between ketamine and central DI which has been described in prior case reports. A hypothesized mechanism is ketamine’s antagonism of N-methyl-D-aspartate receptors in the posterior pituitary thus inhibiting arginine vasopressin production. Ketamine is being used with greater frequency in critical care. In these cases it is important to recognize this rare but potentially serious complication. Monitoring of Na+, Uosm, and urine output should be considered. When central DI related to ketamine is identified, withdrawal of the drug appears to be corrective.

**PO1158**

A Case of Ketamine-Induced Diabetes Insipidus

Karim T. Attia, Kara Kaplan, Alka A. Tyagi, Joshua Leisinger. The Ohio State University Wexner Medical Center, Columbus, OH.

**Introduction:** To our knowledge there have been six previously published case reports describing central diabetes insipidus (CDI) related to ketamine. We present a unique case of central DI associated with ketamine injection in a critically ill patient with acute respiratory failure.

**Case Description:** A 62-year-old female with no known past medical history with a history of smoking and 2+ gestations of her second pregnancy. Workup was significant for elevated creatinine with proteinuria and pyuria, normal anion gap metabolic acidosis, hypokalemia, and hyponatremia. Urine studies revealed an inappropriately alkaline urine with impaired renal reclamation of potassium and phosphorus. Serological workup was significant for positive ANA, SSA, and SSB antibodies. Kidney biopsy revealed acute tubulointerstitial nephritis. The patient was started on an IV steroid course with oral tapav and hydrochloroquine with improvement in Cr from 2.2 to 1.2 mg/dL with a potassium, phosphate and sodium bicarbonate supplementation regimen.

**Discussion:** Sjogren’s syndrome is typically associated with lymphocytic infiltration of exocrine glands. However, this can also affect the kidneys causing tubulointerstitial nephritis and defects in tubular function initiating a cascade of electrolyte abnormalities. Understanding the renal physiology behind the observed electrolyte abnormalities is important to optimize our treatment regimen. While the management of a distant ATA has been well described in Sjogren's syndrome typically involves judicious potassium and alkali supplementation, this case highlights the worsening potassium wasting and phosphorous wasting which also needs to be addressed with a concomitant proximal tubulopathy. We propose that this set of features can best be explained by dysfunctional acid-base axis, a cause of the extremely rare type III RTA. We use this case presentation to highlight the spectrum of renal manifestations of Sjogren’s syndrome and their treatment principles.

**PO1161**

Evidence for Abnormal Linkage Between Urine Oxalate and Citrate Excretion in Human Kidney Stone Formers

M.Z. Moe,1 Orson W. Moc,2 John R. Asplin,3 Fredric L. Coo,4 Elaine M. Worcester,1 ’University of Chicago Division of the Biological Sciences, Chicago, IL; ’The University of Texas Southwestern Medical Center, Dallas, TX; ’Litholink Corp, Chicago, IL.

**Background:** Animal models have demonstrated an interactive relationship between the epithelial anion exchanger SLC26A6 and carbonate, a cause of the extremely rare type Ia RTA. This relationship is a potential mechanism to protect against kidney stones as higher urine oxalate is accompanied by higher urine citrate but it has not been explored in humans.

**Methods:** We examined 24-hour urine data on 13,155 kidney stone forming patients (SF) from separate datasets at the University of Chicago and Litholith, a national laboratory, and 143 non-kidney stone forming participants (NSF) to examine this relationship in humans. We used autoregressive linear regression models to examine the association between oxalate and citrate in all study participants and separately in SF and NSF.

**Results:** Higher urinary oxalate was associated with higher urinary citrate in both SF and NSF. In NSF, the multivariate adjusted urinary citrate excretion was 3.0 (1.5 to 4.6) (mmol)/creatinine (mmol) per oxalate (mmol)/creatinine (mmol). In SF, the multivariate adjusted urinary citrate excretion was 0.3 (0.2 to 0.4) (mmol)/creatinine (mmol) per oxalate (mmol)/creatinine (mmol).

**Conclusion:** This case highlights the worsening potassium wasting and phosphorous wasting which also needs to be addressed with a concomitant proximal tubulopathy. We propose that this set of features can best be explained by dysfunctional acid-base axis, a cause of the extremely rare type III RTA. We use this case presentation to highlight the spectrum of renal manifestations of Sjogren’s syndrome and their treatment principles.

PO1162
Higher Risk of Incident Kidney Stones in Patients with Metabolic Acidosis and CKD
Nancy L. Reaven,1 Susan E. Funk,1 Vandana S. Mathur,2 Julie C. Lai,1 Navdeep Tangri,1 3Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.

Background: Epidemiological studies have shown an association between kidney stones and risk for CKD and its progression. Some types of stones are less likely to form at higher urine pH. Metabolic acidosis is a risk factor for CKD progression, but the association of serum bicarbonate with risk of incident kidney stones is not well understood.

Methods: Optum’s de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values of 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) with data a 3 years pre-index. The first qualifying serum bicarbonate test established the index date. Primary exposure variables were baseline serum bicarbonate and change in serum bicarbonate over time. Adjusted time-dependent Cox Proportional Hazards models were performed to evaluate time to first occurrence of kidney stones (by ICD-9 or ICD-10 diagnosis codes) during an average 3.6 year follow-up period. Other covariates included age, sex, race-ethnicity, and income status, history of kidney stones, pre-index comorbidities associated with kidney stones, bariatric surgery, obesity, smoking history, baseline eGFR.

Results: 142,904 patients qualified for the study cohort. Patients with metabolic acidosis at index experienced kidney stones at greater frequency than those with normal serum bicarbonate: 19% vs 9%, p<0.0001. Other significant factors associated with incident kidney stones included male sex, history of kidney stones, hyperoxaluria, and osteoporosis. Both higher serum bicarbonate at baseline (HR 0.956, 95% CI: 0.948-0.964) and higher serum bicarbonate over time (HR 0.968, 95% CI: 0.961-0.974) were associated with reduced risk of kidney stone development. The observed associations were unchanged in analyses examining death as a competing risk.

Conclusions: In patients with CKD, metabolic acidosis (vs. normal serum bicarbonate) was associated with a higher incidence of kidney stones and shorter time to incident stone formation. Future investigations should evaluate these associations by stone type.

PO1163
The Association of Body Mass Index with the Development of Metabolic Acidosis in Patients with CKD
Nancy L. Reaven,1 Susan E. Funk,1 Vandana S. Mathur,2 Thomas W. Ferguson,3 Navdeep Tangri,1 3Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.

Background: Bone is the largest body fluid and body mass index (BMI) is directly related to bone mass. We explored the relationship between BMI and incident metabolic acidosis in patients with CKD.

Methods: Optum’s de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values in the normal range (22 to <30 mEq/L) or metabolic acidosis (22 to <12 mEq/L normal serum bicarbonate) with data a 3 years pre-index. The first qualifying serum bicarbonate test established the index date. Primary exposure variables were baseline serum bicarbonate and change in serum bicarbonate over time. Adjusted Cox Proportional Hazards models were performed to evaluate the time to development of new-onset metabolic acidosis (serum bicarbonate 12 to <22 mEq/L) over a follow-up period of ≥11.5 years. Other covariates included age, sex, race, education and income status, diabetes or heart failure, eGFR, loguricemia to-calcium ratio, albuminuria, and serum creatinine. Multivariate Cox regression analysis was performed using independent variables (BMI, serum bicarbonate, change in serum bicarbonate, loguricemia to-calcium ratio, albuminuria, and serum creatinine).

Results: 97,294 patients qualified for this study. There was an inverse association between BMI category and the risk of developing metabolic acidosis. Compared to BMI category of 18.5-25, each incremental category of higher BMI was associated with a decreasing risk of developing metabolic acidosis: BMI 25 to <30, HR 0.866, 95% CI: 0.824-0.911; BMI 30 to <35, HR 0.770, 95% CI: 0.729-0.813; BMI 35 to <40, HR 0.664, 95% CI: 0.622-0.709; BMI 40+; HR 0.612, 95% CI: 0.571-0.655. Additionally, hypocalciuria and decreased HDL cholesterol and elevated triglycerides increased the risk of new-onset metabolic acidosis.

Conclusions: In this large cohort of patients with CKD, an incremental increase in BMI was inversely associated with the development metabolic acidosis. The mechanism of this association merits further study.

Effects of Pseudohyponatremia on the Diagnosis of Severe Metabolic Acidosis
Hafiz Muhammad Ali Raza,1 Barry M. Wall,1,2 The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 1VA Memphis Medical Center, Memphis, TN.

Introduction: Pseudohyponatremia is defined as falsely low sodium levels in plasma caused by severe hyperlipidemia or hyperproteinemia. We discuss a case of pseudohyponatremia due to hypertriglyceridemia in a patient admitted with severe metabolic acidosis and acetaminophen induced liver toxicity.

Case Description: 43-year-old male with hyperlipidemia, diabetes mellitus, and obesity presented with 4 day history of abdominal pain, nausea, vomiting, and polydipsia. He had decreased intake and was not taking his insulin for 4 days. Medications include glargine insulin, dulaglutide, empagliflozin, lisinopril, furosemide and losartan. BP:141/59 mmHg, HR:125 bpm, respirations 28/min, Temperature: 98.7, SpO2. 95% on room air. He appeared clinically volume depleted. Laboratory testing revealed severely lipemic serum, elevated acetaminophen level 44.1 ug/ml, severely elevated transaminases, arterial pH: 7.03, pCO2 11 mmHg, HCO3~ <5 mEq/L. Plasma sodium:109 mEq/L and chloride 81 mEq/L using indirect potentiometry and 131 and 111 mEq/L using direct potentiometry. Serum triglycerides 2951 mg/dl, blood glucose 204 mg/dl, plasma lactate 7.5 mmol/L, and creatinine 0.6 mg/dl. Plasma anion gap was 11 mEq/L using direct potentiometry and could not be calculated using indirect potentiometry, as bicarbonate concentration could not be determined due to lipemia. Based on severe metabolic acidosis, elevated lactate, and positive urinary ketones, a diagnosis of lactic acidosis and suspected euglycemic DKA was made. Patient was treated with DKA-protocol with insulin and fluid resuscitation, and N- acetylcysteine for acetaminophen induced liver toxicity. Metabolic acidosis markedly improved over the next 72 hours. Hypertriglyceridemia, transaminase elevations, and metabolic acidosis fully resolved during 6 week follow up visit.

Discussion: Severe hyperlipidemia reduces water content of plasma such that autoanalyzers utilizing indirect potentiometry requiring sample dilution, result in pseudohyponatremia. Direct potentiometry does not require sample dilution and measures true sodium concentration, however, plasma anion gap is reduced due to higher measured chloride concentrations with direct potentiometry. Therefore, physicians must be familiar with the laboratory methods to correctly interpret the plasma anion gap in management of metabolic acidosis when using direct potentiometry measurements.

PO1165
Anion Gap Metabolic Acidosis on Continuous Renal Replacement Therapy: Are You Missing Something?
Mustafa Dawood, Vandana D. Niyiary. Emory University School of Medicine, Atlanta, GA.

Introduction: Anion gap metabolic acidosis is a common metabolic abnormality seen in the clinical practice. Causes includes Lactic acidosis, Ketoacidosis, Renal failure, volatile acid toxicity and salicylate poisoning. Ketoacidosis is due to decreased glucose and insulin availability leading to starvation ketosis and diabetic ketoacidosis respectively. Ketoacidosis is uncommonly seen in patients on prolonged continuous renal replacement therapy. We present 2 cases at Grady Hospital admitted with Acute hypoxic Respiratory Failure due to COVID 19 pneumonia, developed euglycemic ketoacidosis on Continuous Renal Replacement Therapy.

Case Description: case 1: 73 male with the history of HTN, DM, CKD III admitted for acute hypoxic respiratory failure due to COVID 19 pneumonia. He was intubated on admission day 9. Course got complicated by hypotension during intubation leading to Acute Renal Failure on day 11. Patient was started on Renal Replacement Therapy on day 12 due to volume overload and acidosis. Day 19, Anion gap worsened and beta hydroxybutyrate was elevated. Patient was started on insulin drip with resolution of acidosis on day 20. Case 2: 48 yo male with the history of HTN, DM II, CKD stage III admitted for Altered mental status, hypotensive emergency and cough. He was diagnosed with COVID 19 Pneumonia. Patient had non obstructive acute kidney injury on admission. Hospital day 11, patient was oliguric, volume overloaded and hyperkalemia prompted Renal replacement therapy initiation. Day 14, Anion gap worsened and beta hydroxybutyrate was elevated. Tube feed were initiated and Dihydate prescription was continued leading to resolution of anion gap on day 12.

Discussion: Diabetic ketoacidosis is a medical emergency commonly in patients with Type 1 DM but also in Type II DM patients as well. It occurs due to decreased insulin concentration or increase insulin resistance with or without decreased glucose availability leading to release of counterregulatory hormone and fatty acid metabolism producing ketocids. Diagnostic criteria include pH<7.3, Serum HCO3<18, Serum glucose>250mg/dl and positive urine ketones. Euglycemic DKA is a subtype of DKA with serum glucose<200 mg/dl. Incidence of Euglycemic DKA varies from 2-6.3%. Continuous renal replacement therapy is an under-recognized cause of Euglycemic DKA in patients with Diabetes Mellitus.
PO1166
A Wide-Awake Patient with Severe Hypoglycemia and Lactic Acidosis
Sarah Abdelsamad, Madhumita J. Mohanty, Mili J. Shah. Wayne State University, Detroit, MI.
Introduction: Severe hypoglycemia is associated with altered mental status or loss of consciousness. We report an intriguing patient who had advanced liver disease and presented with severe hypoglycemia and lactic acidosis without any alteration in mental status.
Case Description: 57-year-old female with severe decompensated alcoholic liver cirrhosis, ascites and recurrent hepatic hydrothorax presented to the Emergency Room with worsening shortness of breath. She had poor oral intake except for actively consuming ethanol. Chest X ray revealed worsening right hydrothorax. Routine blood tests revealed severe hypoglycemia (serum glucose 28mg/dL, severe anion gap metabolic acidosis (arterial pH 7.11, serum bicarbonate 6mmol/L, anion gap 40 mmol/L) and acute kidney injury with elevation of serum creatinine to 2.2 mg/dL. Subsequent laboratory investigations revealed serum lactate level of 23mmol/L. Serum ethylene glycol, methanol, salicylate and acetaminophen levels were undetectable. She had no seizures, malignancy or hypoxia. The patient was alert and oriented. She was hemodynamically stable. There was no evidence of sepsis, tissue hypoperfusion or bowel ischemia. She was not taking any medications which may have led to hypoglycemia or lactic acidosis. The patient was administered intravenous glucose with rapid improvement of her serum glucose and lactate level.
Discussion: This patient had no alteration in mental status despite severe hypoglycemia. Under normal circumstances, the brain primarily depends on glucose as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactic acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hypoglycemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

PO1167
Sleeping Beauty: Hypersomnolence and Hyperammonemia in a Patient with Multifocal Myeloma
Stephen P. Regina,1 Roberto L. Collazo-Maldonado,2 Muhammad R. Qureshi.2
Methodist Health System, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.
Introduction: Metabolic encephalopathy in a patient with multiple myeloma is commonly reported in association with prevalent biochemical syndromes such as uremia, hypercalcemia, and or hyperviscosity due to immunoglobulin, but very rarely hyperammonemia has been described as another cause of encephalopathy.
Case Description: The patient is a 45 year old woman with a prior diagnosis of multiple myeloma in July 2020. A bone marrow biopsy confirmed plasma cell neoplasm with 90% plasma cells, and SPEP was positive for monoclonal IgA kappa. The patient was brought to the hospital again in August 2020, with the chief complaint of worsening confusion and hypersomnolence over two weeks. Labs included hemoglobin 7.3 g/dL, serum calcium 13.8 mg/dL, chloride 108 mEq/L, bicarbonate 16 mEq/L with anion gap of 19, lactate 1.4 mmol/L, albumin 3.2 g/dL, and a CT of the head showed numerous lytic skull lesions, including a 3.8 cm posterior skull lesion with extraosseous intracranial extension. The patient was transferred to Methodist Hospital, where a bone-marrow biopsy revealed 19% plasma cells, and SPEP was positive for monoclonal IgA kappa. The patient was administered intravenous glucose with rapid improvement of her serum glucose and lactate level.
Discussion: This patient had no alteration in mental status despite severe hypoglycemia. Under normal circumstances, the brain primarily depends on glucose as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactic acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hypoglycemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

Renal Outcomes and Safety Profile of Direct Peritoneal Resuscitation (DPR)
Kiranjit Shivani, Michael D. Klein, George N. Cortisidis. Westchester Medical Center, Valhalla, NY.
Background: DPR is a novel technique used after damage control surgery where peritoneal dialysis fluid is continuously irrigated and drained from the peritoneal cavity in a open abdomen. This has been shown to improve intestinal perfusion, leading to faster abdominal closure. We analyzed the safety profile in terms of changes in the electrolyte profile.

PO1169
Pyroglyutamic Acidosis: Gaps in the Gaps
Rov Rajan, Martin Sedlacek. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.
Introduction: Prolonged use of acetaminophen can lead to an acquired form of pyroglyutamic acidosis, a form of anion gap metabolic acidosis (AGMA) from increased production of 5- Oxopropionate (pyroglyutamic acid). 5- Oxopropionate accumulates in the body due to the failure its breakdown by 5- Oxopropionilase and is excreted in urine causing positive anion gap (AG).
Case Description: Case 1: First patient is a 59 y/o man with normal prior renal function with baseline creatinine (Cr) of 0.7mg/dL admitted with severe pancreatitis. At the time of presentation his serum calcium level 15mg/dL (8.5-10.5) and his serum Cr level was 2.21 mg/dL. His hospital course was complicated by sepsis due to multiple intra-abdominal infections and required iv pressor and ventilator support. He was later started on continuous veno-venous hemofiltration (CVVH) temporarily with recovery of renal function. Acetaminophen 1 gram three times daily was administered for pain control. On the 65th day of hospitalization, his bicarb was 15 with an AG of 14, but when corrected for low albumin of 1.8, it increased to 20. HE had a positive urine AG and his urine 5-Oxopropionate was 1583 mmol/mol Cr (range <62).
Results: Case 2: Second case is a 74-year-old man with a history of stage 4 CKD admitted with sepsis due to perforated viscus. He had long hospital course due to ischemic gut with continued bleeding and sepsis due to perforation. He was on Acetaminophen 1 gram four times daily for pain control. His serum bicarbonate started trending down to a nadir of 11 mmol/L on the 43rd day of admission. He had an anion gap of 12, but corrected anion gap was 18 and had a positive urine AG. His urine 5- Oxopropionate was 6316 mmol/mol creatinine (range <62).
Discussion: Both patients in our case series had critical illness, were malnourished, and was recovering from prolonged infection and sepsis which are risk factors for pyroglyutamic acidosis and low serum albumin levels. Their AG might appear to be within normal range if not corrected for albumin. Urine anion gap is an indirect method of measuring urine ammonia excretion is and is elevated in renal tubular acidosis and from excretion of organic anions like 5-Oxopropionate and ketone bodies. Correction for AG is proposed as measured AG + 2.5x (“normal” albumin –4.2 – measured albumin [g/dL]). This equation is called “normal AG” with a positive urine AG due to pyroglyutamic acidosis can mimic renal tubal acidosis and can be easily missed.
**PO1170**

**Diffuse Large B Cell Lymphoma and Synchronous Colon Adenocarcinoma Presenting with Type B Lactic Acidosis Secondary to the Warburg Effect in a Hispanic Man**

Daniel Varea,1,2 Leonardo Pozo Garcia,1,2 Daniela Hernandez,1,2 Mourad Alsabagh,3 John Manillo,1 Sergio A. Trevino Manillo.1,7 The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 1DVR Health, Edinburg, TX; 2South Texas kidney Specialists, McAllen, TX.

**Introduction:** Lactic acidosis is a major metabolic dysregulation characterized by hyperlactatemia and acidemia that is commonly associated with tissue hypoperfusion. In very rare circumstances, hematological malignancies have been associated with a paraneoplastic syndrome characterized by the modification of the metabolism of cancerous cells from aerobic to anaerobic glycolysis.

**Case Description:** A 61-year-old man presented to the hospital due to generalized body weakness. He was recently admitted to the hospital due to left knee pain; at that time incision, drainage, and tissue sample were done. The patient was discharged home with wound care and antibiotics. On presentation, patient was found to be tachypneic, hypotensive with Kussmaul breathing. A warm erythematous lesion was seen on left lower extremity. Laboratory results showed WBC 20,000/mm³, Hemoglobin 10 g/dL, Platelets 340 × 10³/mm³, creatinine 7.9 mg/dL, Bicarbonate 5 mmol/L, Lactate 6.21 mg/dL, and Ferritin 326 mg/dL, blood cultures positive for Enterobacter. Broad-spectrum antibiotics were administered. Nephrology consultation and dialysis started emergently. The pathology report showed Diffuse Large B-Cell Lymphoma. During the hospital stay, patient acidosis was persistent despite adequate renal replacement therapy and resolution of the septic process. ABG was done showing serum pH of 7.2, Bicarbonate 9 mmol/L, Lactic acid 17.5 mg/dL. Bowel ischemia was ruled out with CT angiogram however imaging showed neoplastic infiltration of peritoneal abdominal structures associated with multiple small nodules. Colonoscopy demonstrated synchronous colon adenocarcinoma. The decision was made to treat the patient with chemotherapy. One week after chemotherapy lactic acid trended down to 1.1 mg/L. The metabolic acidosis and renal function improved and RRT was stopped.

**Discussion:** Usually, lactic acidosis is a sign of hypoperfusion and septic shock. In this case, the source of lactic acidosis was not hypoperfusion but rather a rare paraneoplastic syndrome that leads to anaerobic metabolism of malignant cells, known as the Warburg effect. This condition can be fatal. Prompt initiation of chemotherapy is recommended.

**PO1171**

**Distal Renal Tubular Acidosis in Patients with Autoimmune Diseases**

Oana Ion,1 Ioana Alinici,1 Georgiana Fratila,1,2 Gener Ismail,2,3 Institutul Clinici Funedi, Bucharest, Romania; 2Universitatea de Medicina si Farmacie Carol Davila, Bucharest, Romania.

**Background:** Distal renal tubular acidosis (DRTA) is reported in association with autoimmune diseases. DRTA can evolve without symptoms and systemic acidosis, this form being defined as incomplete DRTA. The incomplete form necessitates the use of a urinary acidification test like the Furosemide and Fludrocortisone test for establishing the diagnosis.

**Methods:** We conducted a prospective observational study in a selected cohort of 48 patients diagnosed with autoimmune diseases (SLE,SJögren syndrome, ANCA vasculitis, cryoglobulinemic vasculitis), who presented in our clinic from December, 2020 until May, 2021. The patients were submitted to Furosemide and Fludrocortisone test for establishing the diagnosis.

**Results:** The study included 48 patients (36 females, mean age 41.92 ± 15.7 years), diagnosed with SLE (33 patients), pANCA vasculitis (7 patients), cANCA vasculitis (1 patient), SJögren syndrome (3 patients) and cryoglobulinemic vasculitis (4 patients). There was a significant difference regarding age (p=0.001) and eGFR (p=0.001) between the groups with vasculitis (mean age 60.75±23.3 years; eGFR 41.66 ± 16.71 ml/min/1.73 m²), SLE (mean age 35.18 ± 11.74 years; eGFR 73.24 ± 25.18 ml/min/1.73 m²) and SJögren syndrome (mean age 40.05 ± 20.03 years; eGFR 35.56 ± 17.24 ml/min/1.73 m²). The test was positive for 11 patients out of 48. There was not a significant change in inemia during the test (p=0.806). There was a significant increase in the level of serum bicarbonate (26.23 ± 3.5 mmol/l before the test vs 28.21 ± 1.3 mmol/l after the test, p=0.001) and also in the level of serum pH (7.36 ± 0.43 before the test vs 7.45 ± 0.43 after the test, p=0.001). None of the patients reported digestive or allergic side effects. There was not a significant difference regarding eGFR (p=0.665), proteinuria (p=0.372) and CRP (p=0.246) between the patients with or without a positive test. Regarding immunological activity, patients with a positive test had a higher ANA value at the meanement of the test (4.71 ± 3.04 U/ml vs 2.50 ± 2.55 U/ml, p=0.05) and a lower C4 value (12.66 ± 9.39 mg/dl vs 23.4 ± 11.54 mg/dl, p=0.016).

**Conclusions:** Incomplete DRTA was found in 11 out of 48 patients with autoimmune diseases. None of the patients developed severe hypokalemia or metabolic alkalosis or any other side effect after Furosemide and Fludrocortisone test.
A Patient with Combined Metformin-Induced Lactic Acidosis and Euglycemic Diabetic Ketoacidosis

Introduction: Metformin is a small, non-protein-bound molecule that can cause lactic acidosis in 6 out of 100,000 patients with a mortality rate of 30-50%. Concurrent euglycemic diabetic ketoacidosis (DKA) from sodium-glucose co-transporter-2 (SGLT2) inhibitor has been reported in one case. We report a unique case of a patient with acute kidney injury (AKI) in the setting of metformin-induced lactic acidosis and osmotic diuresis due to euglycemic DKA complicated by celexocib use.

Case Description: A 66-year-old female with a past medical history of type 2 diabetes mellitus for 21 years on metformin 1000 mg twice daily and empagliflozin 25 mg daily with baseline eGFR 51 mL/min/1.73m² 5 months prior, who was also on celexocib 200 mg daily for 40 days presented for elective cervical discectomy which was canceled due to AKI. On exam, blood pressure was 119/59 mmHg, pulse was 92 beats/min, and the temperature was 36.1°C. She was tachypneic at 24 breath/min. Labs showed sodium 136 mg/dL, potassium 8.4 mg/dL, bicarbonate 9 mg/dL, BUN 83 mg/dL, creatinine 8.78 mg/dL, and glucose 117 g/dL. Lactic acid was 3.8 mmol/L after 24 hours. Creatinine improved to 2.46 mg/dL on day 4 without further intervention. She was discharged off metformin, empagliflozin, and celexocib.

Discussion: Metformin is readily dialyzable but has a large volume of distribution. There is no specific antidote available to reverse the toxic effects of metformin or consensus on the modality of renal replacement therapy. Previously demonstrated biphasic elimination pattern of metformin intoxication suggests that a brief HD session is not sufficient to eliminate metformin due to a rebound phenomenon, but it is essential to correct severe acidosis and electrolyte derangements. Hyperkalemia required the use of HD which needed to be followed by CKRT as a more physiological way to maximize the correction of severe acidosis and electrolyte derangements.

Explaination of the high AG: The Figure describes the calculation of AG. In this patient, phosphate was a major contributor to the AG.

PO1176

Is an Increase in Anion Gap a Predictor of Hemodialysis Initiation in Patients with Advanced CKD?
Hikaru Kukimoto, Kazuhiito Fukuoka, Soko Ikigaya, Noriko Suto, Takahisa Kawakami, Mitsumasa Kishimoto, Yoshinori Komagata, Shinya Kaname. Kyorin Daigaku, Mitaka, Japan.

Background: Because uremic symptoms and manifestations vary among patients with advanced chronic kidney disease, it is sometimes difficult to decide on the timing of dialysis initiation only from uremic symptoms. We attempted to investigate whether anion gap (AG) that may reflect the accumulation of total organic acids in uremia can be a marker of uremia and may predict the timing of dialysis initiation.

Methods: This study included pre-dialysis patients who attended to our hospital for more than six months prior to the beginning of hemodialysis (HD), and retrospectively analyzed the relationship between their serological data, AG, and various uremic symptoms. The AG was calculated as the corrected AG (cAG) = Na-Cl-HCO3

(results).

Results: A total of 283 patients [diabetes mellitus: 136 (48.1%), nephrosclerosis: 66 (23.3%), glomerulonephritis: 36 (12.7%)] were included in this study. The most common clinical symptom before dialysis initiation was fluid overload, which was seen in 134 patients (47.3%), followed by anorexia 104 patients (36.7%) and general malaise 96 patients (33.9%). The cAG began to increase 3 months before the initiation of HD (14.2 mmol/L), which showed a rapid increase just before the initiation, and was correlated with uremia and fatigue, better than fluid retention. Of note is that cAG was most significantly associated with dialysis initiation among various factors. The ROC of cAG for dialysis initiation showed the highest value of AUC 0.797 (95% CI 0.72 to 0.85, p=0.05), with a cutoff value of adjusted cAG 15.975 (sensitivity 0.689, specificity 0.786). Patients with advanced CKD?

Conclusion: Uremic symptoms and some serological markers including azotemia, metabolic acids, and hyperphosphatemia have been usually used to predict the magnitude of uremia and the timing of dialysis initiation. In our study, it is suggested that a rapid increase in cAG over 16 mEq/L may also be a good predictor of dialysis initiation within the subsequent 3 months.

PO1177

Mysterious Case of Recurrent Life-Threatening Lactic Acidosis
Zakir Shaik, Waqas Ahmad Khan, Ajay D. Rao, Jean Lee. Temple University Hospital Temple University Health System Inc, Philadelphia, PA.

Introduction: Patients living with diabetes are prone to type-II lactic acidosis, often presenting with profound acid-base derangements. The reason for lactate production is not obvious hence management can be challenging. We present a case of life-threatening recurrent lactic acidosis in a diabetic patient.

Case Description: A 67-year-old man with type 2 diabetes, hypertension, presented to the hospital with malaise for 2 days. He had been on metformin in the past but had recently switched to insulin. There was no history of alcohol ingestion nor use of herbal supplements. The lactic acid level was 34 mM/kg. Her arterial blood gas showed: pH < 7, HCO3 7.5 mmol/L, pCO2 16 mmHg. Phosphorus level was unusually high, 21.3 mg/dL, with unknown etiology. There was no history of enema or laxative use. A significant contributor of AG was lactate at 14.5, given her history of metformin use. Urine drug screen was positive for amphetamines. The volatile alcohol panel was positive for acetone; methanol, ethanol, ethylene glycol and isopropanol alcohol were not detected. Continuous venous hemofiltration (CVVH) was initiated. After 3 days, renal function started recovering, lactate and phosphorus levels normalized and AG closed. The patient did not need CVVH thereafter. Two months later, the patient was discharged to a nursing facility in a stable condition.

Discussion: Extremely elevated AG of 52 in this patient can be explained by a rise in concentrations of organic acid anions, lactate, ketoacids, hyperphosphatemia, and retention anions.
and his lactate level was 14.8 mmol/L. This was treated with supportive care alone. Six months later, he returned again with lactate of 13.5 mmol/L, worsening to 18.6 mmol/L. He improved after treatment with CRRT and supportive care. Alcohol levels, liver function tests, pyruvate, glutamate, metformin levels were all negative or normal. The thiamine level was not checked during his first admission. During the second visit, the value was normal but this was drawn after thiamine had been given. During the third visit, the thiamine level was noted to be less than 6 mmol/L. The patient was started on thiamine and has not had further episodes of lactic acidosis.

**Discussion:** Patients with diabetes are prone to excess lactic acid generation due to the decreased mitochondrial oxidative phosphorylation with relative hypoxia at the microvascular level. In addition, it has been noted that many diabetics are thiamine deficient. In the absence of thiamine, pyruvate cannot enter the Krebs cycle and is converted to lactic acid predisposing diabetics to type-B lactic acidosis. Thiamine is filtered in the glomerulus and is reabsorbed in the proximal tubule through the thiamine H+ antiporter. Long term use of diuretics has been associated with thiamine deficiency. However our patient was not taking any nor did he have chronic kidney disease or any evidence of malnutrition.

**PO1178**  
**Serum Bicarbonate and Gait Abnormalities in Older Adults**  
Jim O. Ho, Joe Verghese, Matthew K. Abramowiz. Albert Einstein College of Medicine, Bronx, NY.

**Background:** Low serum bicarbonate levels are associated with slow gait speed in older adults. However, the association between serum bicarbonate and other quantitative gait markers is unknown.

**Methods:** Quantitative gait assessments were performed on 330 community-dwelling, nondisabled adults aged 65 years old. Serum bicarbonate was categorized into tertiles (≥24, 25-27, ≥28 mEq/L). The relationship between bicarbonate and gait markers was investigated with multivariable linear regression adjusting for demographics, comorbidities including COPD, medication use, smoking status, BUN, and eGFR (CKD-EPI). Factor analysis on eight gait markers was performed to synthesize individual gait characteristics into unifying domains. CKD was defined as eGFR<60 mL/min/1.73 m2.

**Results:** There were 116 (35%), 146 (44%), and 68 (21%) participants in the low (mean bicarbonate 22 mEq/L), middle (26 mEq/L), and high (29 mEq/L) bicarbonate tertiles, respectively. After multivariable adjustment, compared with participants in the middle tertile, those in the low tertile had significantly slower speed (8.4 cm/s [95% CI 3.1-13.8]), shorter stride length (7.7 cm [95% CI 3.4-12.1]), and longer time in the double support phase of the gait cycle (0.03 s [95% CI 0.002-0.05]). Within the lowest tertile, there was a graded association of lower bicarbonate with greater severity of gait deficits (Figure 1). Associations were similar when limited to participants with CKD. Associations remained significant after additional adjustment for muscle strength, cognitive function, sensory nerve function, and balance. No significant associations were found for the high tertile or for other gait markers (e.g., cadence). Factor analysis produced 3 independent gait domains: pace, rhythm, and variability. Compared with the middle tertile, the low tertile had significantly poorer performance in the pace domain (0.3 standard deviation [95% CI 0.1-0.6]).

**Conclusions:** Low serum bicarbonate is associated with gait abnormalities in older adults.

**PO1179**  
**Bicarbonate Target in Treating Renal Acidosis: Is Higher Better?**  
Ashraf Djalal. Ochsner Medical Center - New Orleans, New Orleans, LA.

**Background:** Metabolic acidosis is commonly seen in patients with CKD from a decrease in ammonium excretion which gets buffered by the extracellular bicarbonate, hence, low plasma carbon dioxide is a surrogate of acidosis. treatment of acidosis (usually sodium bicarbonate to decrease the progression of, maintain bone health, nutrition status, In clinical practice, we aim for plasma bicarbonate of ≥2.2 mmol/L, the upper limit target is unclear.

**Methods:** This was a single-center retrospective chart review of CKD patients with acidosis from 2010-2017. Inclusion criteria were adult patients receiving NaHco3 for CKD-associated acidosis with baseline estimated glomerular filtration rate (eGFR) ≥25 and < 60 mL/min/1.73 m2 when starting NaHco3. Patients with glomerulonephritis, kidney transplant, acute kidney injury (not back to at least 75% of eGFR baseline) were excluded. Four groups were identified for comparison based on mean serum Co2 (in mmol/L), from outpatient measures during 3 years follow-up, group A (< 22), group B (22 - < 24), group C (24 - <25), and Group D (≥ 25). Albumin, urine protein-creatinine ratio (UPCR), PTH, and eGFR were compared, p-values were calculated by a one-way ANOVA model with Bonferroni correction.

**Results:** There were 383 patients with CKD-associated acidosis receiving NaHco3, 93 patients qualified for the study. Group A (n=21), group B (n=41), group C (n=13), and Group D (n=18). Racial demographics: 35=black (38%), 57=white (61%), 1=Other. Females 49 (53%). Median age 69 years. Follow-up 3 years. At baseline mean eGFR, UPCR, and albumin, and diuretics use and osteoporosis diagnosis in the four groups were similar (p = 0.46, 0.32, 0.15, 0.39, 0.36 respectively). Mean hemoglobin A1C in each group did not exceed 8.2. At 3 years of follow-up, changes in eGFR, UPCR, and osteoporosis status between the four groups were similar (p = 0.14, 0.27, 0.19 respectively). Change of albumin was significantly worse in group A comparing to groups B, C, and D (p = 0.007, 0.049 respectively), and average PTH was significantly worse in group A comparing to group C (p = 0.045).

**Conclusions:** In our cohort, all groups of treated CKD-associated acidosis (B, C, and D) showed no statistical difference in CKD progression, the severity of parathyroidism, developing osteoporosis, or nutrition status assessed after 3 years follow-up. Hence, higher Co2 targets don’t carry worse outcomes.

**PO1180**  
**Acute Metabolic Alkalosis due to Citrate-Containing Oral Rehydration Solution**  
Megan Chalupska,1 Syndie Espiritu,1 Shubha Ananthakrishnan,2 Baback Roshanravan,2 Brian Y. Young,3 University of California Davis Department of Internal Medicine, Sacramento, CA; 2UC Davis Department of Nephrology, Sacramento, CA.

**Introduction:** Patients with ileostomies have high obligate gastrointestinal (GI) losses, predisposing to volume depletion and electrolyte derangements. Over-the-counter oral rehydration solutions (ORS) are advertised for dehydration. We present a case of acute metabolic alkalosis associated with an ORS containing citrate.

**Case Description:** 66 year old man with Crohn’s disease, status post small bowel excision, sigmoid colectomy with Hartman’s pouch, and ileostomy presented with weight loss of 35 pounds over 3 months. He was admitted for acute metabolic alkalosis associated with an ORS containing citrate.

**Conclusions:** In our cohort, all groups of treated CKD-associated acidosis (B, C, and D) showed no statistical difference in CKD progression, the severity of parathyroidism, developing osteoporosis, or nutrition status assessed after 3 years follow-up. Hence, higher Co2 targets don’t carry worse outcomes.

PO1181

Pseudo-Hypobicarbonatemia with Severe Hypertriglyceridemia Corrected by Insulin Infusion
Noah J. Poznanski, Howide Eldib, Ahlim Al sanani, Marshall University Joan C Edwards School of Medicine, Huntington, WV

Introduction: Anion gap metabolic acidosis (AGMA) is a condition characterized by low serum bicarbonate and unaccounted anions in the blood. Lactate or ketones are the most common anions causing AGMA. Severe hypertriglyceridemia and paraproteinaemia can result in Pseudo-hypobicarbonatemia due to interference by these components when the commonly used enzymatic assay is utilized for serum bicarbonate measurement. The calculated bicarbonate derived from blood gas machines show accurate bicarbonate level. It is very important to recognize Pseudo-hypobicarbonatemia to avoid expensive work-up.

Case Description: A 42-year-old male patient with a past medical history significant for diabetes mellitus type 2, obesity, and hyperlipidemia. The patient presented with nausea, vomiting and epigastric pain. Physical examination was significant for tenderness in the epigastrium and xanthelasma. The basic metabolic profile (BMP) was significant for Na+ 127 mEq/L, Cl- 94 mEq/L, HCO3- 9mEq/L, glucose 408mg/dL, BUN 160mg/dL, creatinine 0.87mg/dL and AGAP 24. A lipid panel showed a cholesterol 461mg/dL, and triglycerides 4061mg/dL. Lipase and amylase were 1183U/L and 202U/L respectively. Urinalysis revealed trace ketones. CT abdomen revealed peripancreatic stranding. The patient was diagnosed with AGMA due to diabetic ketoacidosis and pancreatitis secondary to hypertriglyceridemia. An arterial blood gas analysis (ABG) subsequently revealed a pH 7.39, pCO2 40, PaO2 73 and a HCO3- 24. A significant dissociation between the calculated and measured bicarbonate was noted. Following aggressive lowering of the triglycerides, with Insulin infusion there was an immediate resolution of the pseudo-hypobicarbonatemia and anion gap metabolic acidosis.

Discussion: This measurement error is due to the mechanism by which the analyzer interprets the bicarbonate level in the serum. Most analyzers utilize either anion-selective electrode (ISE) or function via an enzymatic/photometric method. High amounts of lipid particles may cause light scattering altering the photometric analysis. This likely caused the discrepancy between the enzymatic/photometric measured serum bicarbonate and the calculated bicarbonate of the aqueous phase ISE analyzer used by the ABG. Clinicians should be able to recognize that its essential to obtain a blood gas sample for determination of the acid-base status to avoid expensive work up.

PO1182

Pseudohypobicarbonatemia in a Patient with Paraproteinaemia
Marvi M. Bukhari,1 Cary R. Boyd-Shiwari,2 Blaise W. Abramovitz.1 UPMC Mercy, Pittsburgh, PA; 1University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA

Introduction: The first step in acid-base disorders’ diagnosis is obtaining measurement of blood bicarbonate (HCO3-), pH and partial pressure of carbon dioxide (pCO2) levels. Blood HCO3- levels are estimated via two methods: direct measurement of serum total carbon dioxide (TCO2), or via Henderson-Hasselbalch equation using arterial blood and directly measuring pH and pCO2 levels. With the enzymatic method, there have been reported cases of falsely low serum HCO3- due to interference by elevated triglyceride levels, but only two cases have been reported of spuriously low serum HCO3- due to interference by paraproteins.

Case Description: A 74-year-old male with a history of bladder carcinoma in situ and hypertension presented with complaints of malaise after a recent bladder irrigation. Basic metabolic panel (BMP) was unremarkable except for a HCO3- of 8 mmol/L measured using a Siemens Vista (SV) enzymatic chemistry analyzer. He was hospitalized for high anion gap metabolic acidosis with anion gap of 22. He was started on intravenous NaHCO3 (150 mEq/L) after nephrology was consulted. Repeat serum HCO3- was 11 mmol/L the next day with transition to oral NaHCO3 650 mg therapy thrice daily. On outpatient follow-up, he had low serum HCO3- ranging from 8-11 mmol/L (using SV analyzer) despite his reported compliance with NaHCO3. He was evaluated by another nephrologist with repeat BNP and an arterial blood gas (ABG). The results revealed a serum HCO3- of 8 mmol/L in contrast with ABG pH of 7.41 and HCO3- of 25 mmol/L. Due to the discrepancy, his serum HCO3- was analyzed at a different facility using a Beckman Coulter analyzer which revealed a normal serum HCO3- level of 21 mmol/L. He was hospitalized for near-total enterectomy and colectomy on total parenteral nutrition with a venting gastric tube. The patient was discharged home without diuretics and loop diuretics contributed to the development and maintenance of metabolic alkalosis. The loss of gastric acid in the G-J tube, but volume depletion, hypokalemia, AKI, high protein tube feeds, lack of respiratory compensation due to ventilator dependence and loop diuretics contributed to the development and maintenance of metabolic alkalosis.

Discussion: Paraproteins have been reported to cause interference with multiple laboratory test results. Paraproteins in our case may have resulted in artifactual error of serum HCO3- by direct interaction with assay reagents, binding of paraproteins to an assay reagent, or turbidity caused by the precipitation of the monoclonal proteins. Our case highlights the importance of being aware of this phenomenon of pseudohypobicarbonatemia that can occur with certain chemical analyzers.

PO1183

Proton Pump Inhibitor (PPI) for the Treatment of Metabolic Alkalosis due to Gastric Losses
Raphael J. Rosen, Heedekan Han, Sindhuri Prakash-Polet, Yonatan A. Peleg. Columbia University Irving Medical Center, New York, NY

Introduction: Gastric losses of hydrochloric acid can result in severe metabolic alkalosis (met alk). We describe two cases where patients with significant losses of gastric secretions presented with severe met alk and AKI. In both cases, PPI therapy was used to reduce the volume of the gastric secretions with excellent effect.

Case Description: Patient 1: A 44-year-old woman with Gardner Syndrome with near-total enterectomy and colectomy on total parenteral nutrition with a venting gastric tube (G-tube), presented with met alk (HCO3 30 meq/L and AKI (Scr 4 mg/dL). Met alk persisted despite normal saline (NS) administration and gastric tube losses ranged from 4-8 liters per day. Twice daily intravenous PPI was started with immediate decrease of gastric losses and normalization of HCO3. This patient was admitted one year later (off PPI therapy) with a similar derangements and resuming PPI therapy caused similar improvement. Patient 2: A 59 year-old man with gastric outlet obstruction and venting G-tube presented with met alk (HCO3 47 meq/L) and acute kidney injury (Scr 4.5 mg/dL from 1.3 mg/dL). Met alk persisted despite NS administration and his gastric tube losses ranged from 4-11 liters per day. Diurnal intravenous PPI was started with decrease of gastric losses and normalization of HCO3. This patient presented again to the hospital one month later with normal HCO3 on PPI therapy. Both patients’ bicarbonate and gastric fluid output trend relative to PPI therapy is detailed in figure 1.

Discussion: There are few reported cases of PPI therapy for metabolic alkalosis due to gastric losses. Generally, met alk that occurs due to gastric losses is readily rectified by increased renal bicarbonate excretion, but this compensatory mechanism is limited in the setting of AKI. We report two cases in which PPI therapy successfully decreased the quantity of gastric fluid losses and rapidly improved metabolic alkalosis.

Discussion: A 30-year-old male with Duchenne muscular dystrophy, chronic respiratory failure on mechanical ventilation via tracheostomy, gastrojejunoanostomy (G-J) tube dependent and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day. He was recently started on Lasix 20 mg daily. Initial labs showed blood pH of 7.81, bicarb 66 and PCO2 53. He had AKI with Creatinine (Cr) of 2.66, BUN 266 and Crystatin C 11. His baseline Cr was 0.9-1.1. UA showed 3+ protein and no sediment. Urine (Ur) sodium 87, Ur chloride <15, Ur Cr <10 and Ur Ph was 9. Chest Xray showed cardiomegaly with mild venous congestion and kidney ultrasound showed bilateral small echogenic kidneys. He was treated with normal saline (NS) IV q8h 100 cc/hr, acetazolamide IV, potassium IV, proton pump inhibitor to decrease gastric acid and minute ventilation was increased to allow for compensatory hypercapnia. AKI improved with adequate diuresis and PH normalized (Image 1) by day 5. He had hypernatremia after 24 hours of IV NS and fluid were changed to hypotonic + free water via G-J tube. High daily output of ~700cc was recorded from the G-J tube. He was discharged home without diuretics and tube feeds were changed to Suplena + increase free water but was re admitted in 1 week with hypernatremia and severe metabolic alkalosis. He underwent G-J tube exchange during 2nd admission followed by persistent normalization of blood PH.

Discussion: This is a unique case of extreme metabolic alkalosis primarily due to the loss of gastric acid in the G-J tube, but volume depletion, hypokalemia, AKI, high protein tube feeds, lack of respiratory compensation due to ventilator dependence and loop diuretics contributed to the development and maintenance of metabolic alkalosis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
We corrected his metabolic alkalosis and AKI with cautious use of IV fluids and furosemide. Chart review suggested that CSB implanted antibiotic spacers. CSBs are used for periprosthetic joint infections for new bone formation hydrophilic crystals used to deliver antibiotics locally, are one solution to prevent such complications. Hypercalcemia post-CSB placement is a rare complication that has only been presented in the literature a handful of times. We report on a such a patient, illustrating the importance of surgical history in investigating the cause of hypercalcemia.

Methods: From the MIMIC III v1.4 database, we paired chemistry panel iCa (mg/dL), Alb (g/dL), Na, and iCO2 values with panel iCa values (ref range: 1.12-1.32 mM) measured up to 20 min. apart. Limiting each pt. to the most closely-timed pair left 405 pairs (median:10 min apart). We calculated cCa (iCa +0.64×(4-Alb)) and ICaEST = 0.901×iCa -0.034×Alb -0.0042×Na -0.0073×Cl +0.0047×(iCO2) and compared their ROC curves (area(%)SE) for detecting iCa (CcA<1.10; rate=33.1%), and high iCa (1%Ca) (Ca<1.32; rate=3.8%).

Results: ICaEST was better than cCa by ROC analysis for both iCa (0.334±0.007 vs 0.752±0.008; p<10^-6) and 1%Ca (0.975±0.004 vs 0.963±0.006; p<0000). The table compares the sensitivity and specificity (SENS/SPEC) and positive and negative predictive values (PPV/NPV) of ICaEST and cCa at similar cutoffs. ICaEST overestimated iCa by 0.04 mM (1.17±0.002 vs 1.137±0.002; p<10^-6), a bias that was fairly consistent across the full prediction range.

Conclusions: The ICaEST model is superior to cCa in ranking critically ill pts for both iCa and 1%Ca. It can help clinicians decide when to directly measure iCa. ICaEST overestimated iCa but applying a local correction of -0.04 would make its absolute predictions accurate, and averaging, in the ICU setting.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Discussion: One of the rare and underappreciated causes of severe hypercalcemia is granulomatous hypercalcemia. Vigilant monitoring of calcium levels pre and post CSB placement is indicated, particularly in patients with a history of CKD. It has been hypothesized that there is a dose-dependent relationship between CSB volume and hypercalcemia, and limiting CSB to less than 40ml per operation may be beneficial. A 10ml pack of CSB contains 5.73 grams of elemental calcium which is released over a 30-60-day interval. There is limited information on the mechanism of hypercalcemia in CSB use, so further studies need to be implemented. It is crucial for physicians to have a high suspicion for CSB induced hypercalcemia post-arthroplasty as CSB use expands.

PO1189
Hypercalcemia in a Patient with Visceral Leishmaniasis (VL) and Immune Reconstitution Inflammatory Syndrome (IRIS)
Lubin Juarez, Jacob M. Winograd, Jie Tang, 1 Lifespan Health System, Providence, RI; 2 Brown University Warren Alpert Medical School, Providence, RI.

Introduction: Hypercalcemia is a relatively common clinical problem with a wide range of etiologies. We report an unusual case of hypercalcemia due to visceral leishmaniasis triggering immune reconstitution inflammatory syndrome in a patient with AIDS.

Case Description: A 45-year-old male with history of previously treated VL complicated by a relapse now on suppressive amphotericin presented with 2 weeks of poor appetite, weight loss, and malaise. Recent history was notable for AIDS restarted on Triumeq in the preceding 2 months with slow recovery of CD4 count to 18 but robust reduction in HIV viral load. He denied other infectious symptoms. Labs were notable for AKI, calcium of 13.1, and pancytopenia. Work up revealed low PTH, low calcidiol, elevated serum CRP levels and high-normal serum creatinine levels with bone marrow biopsy revealing non-necrotizing granulomas. Remainder of infectious work up including mycobacterium, histoplasma, and fungal cultures all remained negative. Of note, CD4 count rebounded to 354 during his month-long stay. He was ultimately diagnosed with IRIS secondary to VL leading to granulomatous hypercalcemia. Initial therapy consisted of fluids which resolved AKI and improved calcium. However, he proved to be fluid dependent as attempts at weaning would result in rise in calcium and creatinine. Definitive therapy consisted of steroids which resolved his hypercalcemia allowing him to come off fluids. Apoptosis improved and fatigue resolved over course of his stay with stabilization of calcium levels and creatinine returning to baseline. He was continued on suppressive Amphotericin B for VL.

Discussion: Granuloma formation is a known effect of leishmania infection to combat the invading parasites. Presumably, such inflammation could lead to hypercalcemia via increased conversion of calcidiol to calcitriol. To our knowledge, this is the first case of hypercalcemia caused by VL in humans. It was likely triggered by the reconstitution of his immune system given recent re-initiation of anti-retroviral therapy and rebound of CD4 cell count. Initial management consisted of fluids and bisphosphonates with definitive management consisting of steroids and amphotericin. We report this novel case of hypercalcemia in hopes of expanding the literature on the various potential manifestations of VL, particularly in the setting of IRIS and AIDS.

PO1190
Systemic Sarcoidosis Presenting with Hypercalcemia
Salman B. Mahnood, Milindy J. Junghare, Tetyana Mettler. University of Minnesota Twin Cities, Minneapolis, MN.

Introduction: Sarcoidosis is an idiopathic autoimmune illness that typically presents with pulmonary involvement but can affect virtually any organ. This often makes it challenging to diagnose as its manifestations can be quite varied. We report an interesting case of systemic sarcoidosis presenting with hypercalcemia of unclear mechanism.

Case Description: A 53-year-old Caucasian male presented to the clinic with polyuria, forgetfulness and weight loss. Medical history included hypercalcemia with recurrent nephrolithiasis, diabetes and positive ANA (titer 1:160) without any prior history of constitutional, respiratory or joint symptoms. Serum calcium returned 13 mg/dl. The patient also had an AKI and an elevated ALP. Further workup revealed a suppressed PTH, normal 25-OH and 1,25-OH vitamin D, but a borderline elevated PTHrp (2.5 pmol/L [0.2-3.0 pmol/L]). This prompted a CT CAP with contrast to rule out malignancy that instead showed mediatinal lymphadenopathy, heterogeneous liver enhancement suggestive of cirrhosis and an enlarged, nodular spleen. Transbronchial lymph node biopsies were normal and an extensive infectious and malignancy workup remained negative. The patient was given fluids followed by zoleodronate with resolution of hypercalcemia and AKI. A liver biopsy was ultimately pursued which showed non-caseating granulomas. The patient was prescribed steroids with improvement in symptoms and normalization of ALP.

Discussion: In patients with sarcoidosis, the development of hypercalcemia is thought to be mediated via aberrant activation of vitamin D leading to calcitriol excess. Our patient’s calcitriol level was normal and hypercalcemia may also occur in the absence of elevated levels. Possible described mechanisms include “inadequate normal” calcitriol concentration without elevation in systemic levels, elevated PTHrp and direct action of pro-inflammatory cytokines causing osteolysis.

CT with contrast showing heterogenous liver enhancement and a nodular spleen.

PO1191
Disseminated Histoplasmosis Presenting as Severe Hypercalcemia
Sushma Medikaval, Carla S. Mcwilliams, Shane A. Bobart, Silvia T. Bunting, Dianne T. Sandy, Mauro Braun, Surafel K. Gebreselassie. Cleveland Clinic Florida, Weston, FL.

Introduction: Hypercalcemia (HC) is a significant complication of Disseminated Histoplasmosis (DH). While there are case reports on DH causing HC in immunosuppressed patients including HIV and chemotherapy, there are very rare case reports on DH causing HC in Non-immunosuppressed hosts. The diagnosis of DH in HC may be delayed due to other differential diagnoses such a Sarcoisosis leading to prolonged and worsening hypercalcemia and subsequent renal failure. We report a case of HC in a patient who presented with generalized skin ulcers and bilateral adrenal masses. The initial manifestation of DH with HC, painful skin ulcers, bilateral large lobulated adrenal masses, prompted an initial concern for sarcoidosis. After presenting to our institution 5 months later, a diagnosis of DH was made as the cause of his Hypercalcemia.

Case Description: A 58-year-old male with new onset generalized skin rash was diagnosed with HC, empirically treated with prednisone for sarcoidosis due to elevated 1.25 di hydroxy Vitamin D, 5 months ago at an outside hospital. After starting prednisone, his skin lesions progressed to disseminated painful ulcers and was referred to our institution after developing AKI with a serum creatinine of 4.6mg/dl (Cr 1.6mg/dl, 5 months ago) calcium 14mg/dl, PTH 2pm/mL. CT abdomen revealed large lobulated bilateral adrenal masses. Bone marrow biopsy revealed non-necrotizing granulomas with yeast form fungal organisms on GMS stain. A Shave skin biopsy of an abdominal ulcer revealed fungal yeast forms consistent with histoplasmosis, associated with ulcers on GMS stain. Urine Histoplasma antigen positive. Adrenal mass biopsy revealed necrotic material and fibroconnective tissue. DH was initially treated with IV liposomal amphotericin and transitioned to oral Itraconazole. At the time of discharge, calcium was 9.8 mg/dl and serum creatinine was 2.9mg/dl.

Discussion: Hypercalcemia, in the setting of elevated 1.25 di hydroxy Vitamin D levels, prompts concern for granulomatous disease. Sarcoidosis is a common etiology, however, other causes must be entertained. The cluster of findings of adren al non-casing granulomas coupled with diffuse skin ulcers with hypercalcemia should prompt the provider to consider infectious etiologies such as disseminated histoplasmosis as early diagnosis and prompt treatment can result in improved outcomes.

PO1192
Electrolyte Disturbances Among Those with Malignancy on Anti-Neoplastic Agents
Mihoko Murashima, Atsuki Ide, Minamo Ono, Masashi Mizuno, Taiezu Suzuki, Takayuki Hamano. Nagoya Shiritsu Daigaku, Nagoya, Japan.

Background: The clinical characteristics of electrolyte disturbances among patients with malignancy in contemporary cohorts are lacking.

Methods: This is a retrospective cohort study on 2644 patients with malignancy on anti-neoplastic agents from 2019 to 2020. Anti-neoplastic agents associated with electrolyte disturbances were examined by multi-level mixed-effects logistic regression analyses. The data were adjusted for age, sex, serum albumin, eGFR, kinds of malignancy, and other medications which potentially affect electrolytes.

Results: Mean age was 64.8 (15.8) years, 55.5% were male, and median eGFR was 72.9 (58.1-88.1) mL/min/1.73m². The prevalences of hyponatremia (Na ≤130 mEq/L), hypomagnesemia (Mg ≤1.5 mg/dl), hypophosphatemia (P ≤2.0 mg/dl), and hypokalemia (K ≤3.0 mEq/L) were 2.1 (1.8-2.2), 2.0 (1.7-2.3), 1.7 (1.6-1.9), and 1.2 (1.1-1.4) events/100 patient-measurements, respectively. The use of bortezomib was associated with hypomagnesemia (OR: 3.04 [1.96-4.71]) and three immune checkpoint inhibitors were significantly associated with hyponatremia. The use of cetuximab and gemcitabine were strongly associated with hypomagnesemia (OR 11.79 [7.56-18.38] and 5.95 [3.36-10.55].

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
respectively). Other agents associated with electrolyte disturbances were shown in Table. Other than anti-neoplastic agents, lower albumin levels were consistently associated with development of electrolyte disturbances.

**Conclusions:** Electrolyte disturbances were common and associated with the use of novel anti-neoplastic agents among those with malignancy. Identifying the agents and patient population at high risk of developing electrolyte disturbances is important in taking appropriate preventive measures and monitoring for those undergoing treatments with anti-neoplastic agents.

**PO1193**

**Resistant Hyrophosphatemia with Vitamin D Deficiency**

Yasmin N. Mahmoud,1 Akbar H. Hamid,2 Anmar N. Mohamed,1 Mary C. Mallapallii,3 Man S. Oh,1 Moro O. Salifu,1 SUNY Downstate Health Sciences University Department of Medicine, New York, NY; 1 Kings County Hospital Center, Brooklyn, NY.

**Introduction:** The renal regulation of phosphate homeostasis is mediated mainly by reabsorption of P by NaPi-IIc in the proximal tubule, whereas intestinal absorption is mediated by NaPi-IIb. Normally, about 2/3 of dietary intake (1500 mg/day) is absorbed, but when given by mouth as Na or K phosphate, absorption is nearly 100% in a normal person. We report here a patient with severe hyrophosphatemia due to phosphate malabsorption caused by prior gastric bypass surgery along with vitamin D deficiency.

**Case Description:** A 34 year old African American female with past medical history of benign carcinoma of thyroid, pernicious anemia, Hashimoto thyroiditis, and gastric sleeve surgery for morbid obesity 3.5 years ago, was admitted for acute dizziness and lightheadedness at rest without vertigo. Initial labs were: BUN 4 mg/dL; creatinine 0.6 mg/dL; Ca 9.2 mg/dL; Mg 2.17 mg/dL; P 1.3 mg/dL; 25-OH vitamin D 10.88 ng/mL; 1,25(OH)2 vitamin D 15.35 pg/mL; PTH 7.77 pg/mL; urine P 77 mg/dL; urine creatinine 342.51 mg/dL. She was being given vitamin B12 injections for her pernicious anemia. She was treated with oral Na and K phosphate solution containing 560 mg of P, 320 mg of Na, and 500 mg of K in each dose for every 4 hours, and once daily dose of IV K phosphate containing 465 mg of phosphate for 14 days. She was also treated with 800 units daily of Vitamin D2 daily. Serum phosphate remained persistently low around 1.8 mg/dL despite the above treatment.

**Discussion:** Hyrophosphatemia in our patient was caused by impaired intestinal absorption of phosphate, and inappropriately increased urinary excretion due to secondary hyperparathyroidism due to vitamin D deficiency. The total daily amount of phosphate the patient received while in the hospital was 3825 mg per day. A 24 hour urine excretion of P estimated from urine creatinine concentration (342 mg/dL), assuming normal GFR (180 L/day), is very low (245 mg/day). Although P administered as Na or K salt is well absorbed in a normal person, she was unable to absorb P likely due to the gastric sleeve surgery causing rapid emptying of the gastric content, simulating the dumping syndrome, resulting in diarrhea by unabsorbed Na and K phosphate. Further impairment in intestinal P absorption may have been caused by vitamin D deficiency due to the inadequate dosing (800 units daily) and the inappropriate vitamin D type (Vitamin D2 instead of D3).

**PO1194**

**Severe Hyrophosphatemia Induced by Oncogenic Osteomalacia**

Abdullah Jalal, Ryan P. Brown. Overlook Medical Center, Summit, NJ.

**Introduction:** Oncogenic Osteomalacia (Oncom) is an uncommon paraneoplastic syndrome characterized by FGF-23 overexpression from benign mesenchymal tumors causing severe hyrophosphatemia. Very few cases of Oncom with concomitant paraneoplastic syndromes have been described. Herein we present a rare case of carboanin-associated hyponatremia in the setting of ScaADH-induced chronic hyponatremia unmasking an even rarer secondary paraneoplastic syndrome; oncogenic osteomalacia.

**Case Description:** A 52 year old male with past medical history of chronic hyponatremia on salt tablets secondary to recently diagnosed metastatic small cell lung cancer was admitted for initiation of chemotherapy with carboplatin/etopside. Two days after completing cycle 1 the patient developed acute hyponatremia; serum Na decreased from 141 to 129 mEq/L. Serum electrolytes were (mEq/L): K 3.9, Cl 94, HCO3 28, BUN 30, Cr 6.47. Cortisol (17.8 ug/dL) and TSH (2.28 uIU/mL) were within normal limits. Urine studies noted (mEq/L): Na 75, Cl 69, K 43.5, elevated osmolality 860 mOsm/kg. Endoscopy of acute hyponatremia was attributed to platinum chemotherapy in the setting of SCC-associated ScaADH and patient was treated with tolvaptan after several days of non-response to fluid restriction and urea. Patient’s hyponatremia subsequently corrected but was incidentally noted to have severe hyrophosphatemia (<1 mEq/L) refractory to aggressive IV and PO phosphate repletion. ALP was elevated 279 U/L, corrected Ca 10 mEq/L, low 25(OH) vitamin D 23.8 ng/mL, normal PTH 45.6 pg/mL and PTHrP <0.4 pmol/L. Urinary fractional excretion of phosphorus was increased at 24%. An FGF-23 level obtained 12 days after completing cycle 1 of carboplatin- etopside was considerably elevated at 219 pg/mL. Thus, the patient was diagnosed with oncogenic osteomalacia.

**Discussion:** This case highlights a unique and diagnostically challenging patient presentation of severe hyrophosphatemia in the setting of dual paraneoplastic syndromes. Oncom should be considered in the differential for severe refractory hyrophosphatemia. This occurs via FGF-23 mediated downregulation of PCT Na-Pi transporters and 1a-hydroxylase causing renal phosphate wasting and reduced 1,25-dihydroxyvitamin D levels. Over time chronic hyrophosphatemia impairs bone mineralization causing osteomalacia. Measurement of the fractional excretion of phosphorus is critical and FGF-23 levels should be obtained to confirm diagnosis.

**PO1195**

**Phenotypes of Patients with Abnormal Phosphate on Admission by Consensus Clustering and Associated Mortality Risks**

Carissa Y. Dumancas,1 Charat Thongprayoon,1 Andrea G. Kattah,1 Michael A. Mao,2 Stephen B. Erickson,1 John J. Dillon,1 Vesta D. Garovic,1 William H. Chunggartison.1 1 Mayo Clinic Jacksonville, Jacksonville, FL.

**Background:** Hospitalized patients with abnormal phosphate are heterogeneous and cluster approaches may identify specific homogeneous groups. This study aimed to cluster patients with abnormal phosphate on admission using unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

**Methods:** Consensus cluster analysis was performed on hospitalized adult patients with abnormal phosphate on admission, based on clinical and laboratory data. We determined each cluster’s key features using the standardized mean difference. We assessed the association of the clusters with hospital and one-year mortality.

**Results:** Cluster 2 patients with hyrophosphatemia had older age, higher comorbidity burden, hypertension, diabetes, coronary artery disease, lower eGFR, and more acute kidney injury (AKI) (Fig 1a). Cluster 2 patients with hyperphosphatemia had older age, more admission for kidney disease, hypertension, end-stage kidney disease, AKI, and higher admission K+, Mg2+, or PO2 levels (Fig 1b). Both cohorts in cluster 2 had higher one-year mortality while hyperphosphatemic cluster 2 patients had higher hospital mortality (Fig 2).

**Conclusions:** The cluster analysis identified clinically distinct phenotypes with differing mortality risk in hospitalized patients with abnormal phosphate on admission. The age, comorbidities, and kidney function were key features.
POI196

Anatto Leaf Tea Intoxication: An Unusual Cause of Green Urine
Eduardo Valle, Rayra G. Ribeiro, João Lucas M. Gorzoni, Guilherme P. Santa Catharina, Bernardo V. Reichert, Marcia Fernanda Arantes de Oliveira, Victor F. Seabra, Paulo R. Lins, Igor Smolentzov, Camila E. Rodrigues, Lucia Andrade. Hospital das Clínicas, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Introduction: The roots and leaves of the annatto (“urucu”) tree (Bixa Orellana) are used by the lay population in the treatment of many diseases. We describe a case of AKI with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use.

Case Description: A 59-year-old male without known comorbidities presented with a 2-week history of severe diarrhea. Three days prior to admission, he was diagnosed with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and urine cultures were negative and there was no history of drug use. He was discharged on day 14 with no remaining F+E imbalance or renal dysfunction.

Discussion: The diuretic effect of annatto leaf extracts has been shown in experimental models. To our knowledge, this is the first report of severe AKI and F+E imbalance due to annatto leaf tea use. In our patient, AKI was caused by the annatto leaf tea use. Patients frequently describe mass symptoms & reduced quality of life (QoL) that correlate with large (≥5cm diameter) organ cysts in ADPKD/ADPLD. Since 1/18/2017, we have studied the safety & impact of cyst drainage followed by sotradecol foam sclerotherapy (SFS) to treat symptomatic, large cysts.

Results: We performed 148 SFS procedures among 68 cases (mean age 55yr 77% Female, mean 2.2 procedures per pt): 53 (77.9%) with ADPKD/ADPLD, 5 (7.4%) with ADPLD, & 10 (14.7%) with cystic disease NOS. PLD-Q scores improved by 7.7 (IQR 0.1, 24.8) (p=0.012) at mo 12. A subgroup (13 patients) (mean age 54.7yr, 69% F) have undergone multiple sequential SFS procedures: 10 (77%) with ADPKD/ADPLD, 2 (15%) ADPLD, & 1 (8%) cystic disease NOS. Among 5 with multiple kidney procedures, median kidney volume decreased by 135mL/yr. Among 5 with multiple liver procedures, median liver volume decreased by 114mL/yr. SFS was well tolerated with low complication rates.

Conclusions: SFS directed at large, symptomatic liver and kidney cysts was well tolerated, improved QoL at 12 months, & decreased early satiety, SOB, pain & fullness. Furthermore, multiple sequential SFS procedures are feasible, efficacious, and have an acceptable safety profile.

Foam Sclerotherapy for Directed Treatment of Symptomatic Cysts in Autosomal Dominant Polycystic Kidney and Liver Disease
Marie C. Hogan,1 William P. Martin,2 Emily Bendel,1 Kristin C. Mara,1 Adriana Gregory,1 Grace Y. Chong,1 Vicente E. Torres,1 Newton Neidert,1 1Mayo Foundation for Medical Education and Research, Rochester, MN; 2University College Dublin, Dublin, Ireland.

Background: Patients frequently describe mass symptoms & reduced quality of life (QoL) that correlate with large (≥5cm diameter) organ cysts in ADPKD/ADPLD. Since 1/18/2017, we have studied the safety & impact of cyst drainage followed by sotradecol foam sclerotherapy (SFS) to treat symptomatic, large cysts.

Methods: In this single-center, single-arm, prospective observational study, ADPKD and ADPLD patients with compressive symptoms due to liver or kidney cysts are referred for SFS. Small volumes (20cc max) of 3% sotradecol sclerosant admixed with air are injected (fluoroscopy-guided under local anesthesia) to ablate the epithelial cyst lining. QoL measures using polycystic liver disease Qol tool (PLD-Q) & organ volumes (planimetry using CT/MR) are recorded at baseline & 12+ months post-SFS. Changes over time were tested using Wilcoxon tests and confirmed using repeated measures mixed models. Improvements >0.5 SD were considered clinically meaningful.

Results: We performed 148 SFS procedures among 68 cases (mean age 55yr 77% Female, mean 2.2 procedures per pt): 53 (77.9%) with ADPKD/ADPLD, 5 (7.4%) with ADPLD, & 10 (14.7%) with cystic disease NOS. PLD-Q scores improved by 7.7 (IQR 0.1, 24.8) (p=0.012) at mo 12. A subgroup (13 patients) (mean age 54.7yr, 69% F) have undergone multiple sequential SFS procedures: 10 (77%) with ADPKD/ADPLD, 2 (15%) ADPLD, & 1 (8%) cystic disease NOS. Among 5 with multiple kidney procedures, median kidney volume decreased by 135mL/yr. Among 5 with multiple liver procedures, median liver volume decreased by 114mL/yr. SFS was well tolerated with low complication rates.

Conclusions: SFS directed at large, symptomatic liver and kidney cysts was well tolerated, improved QoL at 12 months, & decreased early satiety, SOB, pain & fullness. Furthermore, multiple sequential SFS procedures are feasible, efficacious, and have an acceptable safety profile.

Development of AL01211, a Novel Glucosylceramide Synthase Inhibitor, to Treat Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Michael C. Babcock,1 Jianhong Zheng,1 Li Li,1 Changlin Mei,2 Marvin R. Garovoy,2 Yuqiao Shen,1 AceLink Therapeutics, Newark, CA; 1Shanghai Changzheng Hospital, Shanghai, China.

Background: AL01211 is a novel glucosylceramide synthase inhibitor (GCSi) that is undergoing clinical development as a potential disease modifying agent for ADPKD. The primary objective of this study was to determine the safety, pharmacokinetics (PK), and efficacy of AL01211 in healthy volunteers.

Methods: A 7-day, ascending dose study in healthy volunteers to evaluate AL01211 PK and safety. PK studies were conducted once daily, oral administration. AL01211 has low renal clearance in rats. AL01211 dose proportionally distributes to peripheral tissues and is not excreted in the urine. AL01211 is more potent with single digit nanomolar potency, has greater reduction of GSL (∼85%), is not subject to kidney clearance and does not enter the brain. Phase I clinical trials, consisting of Phase IA (single ascending dose study in healthy volunteers), Phase IB (14-day multiple ascending dose study in healthy volunteers), and Phase IC (28-day biomarker study in ADPKD patients) are underway.

The Tyrosine Kinase Inhibitor Nintedanib Ameliorates Autosomal Dominant Polycystic Kidney Disease

Abeda Jamadar, Reena Rao. University of Kansas Medical Center, Kansas City, KS.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and is characterized by progressive growth of fluid-filled cysts in the kidneys. ADPKD is generally diagnosed by imaging studies and may be delayed to P5 affecting mainly collecting tubules, causing death at P15, generating life expectancy. Mice Pkd1 f/f Pkhd1 Cre mice and in for 8 weeks starting at the age of 3 months in Pkd1 f/f mice. In vitro studies were performed using primary culture human ADPKD renal cystic epithelial cells and renal myofibroblasts.

Results: Nintedanib treatment significantly reduced kidney-to-body weight ratio, cyst renal index, cystic epithelial cell proliferation and blood urea nitrogen levels compared to vehicle treated Pkd1 f/f Pkhd1 Cre mice. Western blot data indicates reduction in the phosphorylation of ERK1/2, AKT, STAT3 and mTOR activation and pro-fibrotic factors, including Yes-associated protein (YAP), c-Myc and Cyclin D1 protein levels. Moreover, nintedanib treatment significantly reduced renal fibrosis in Pkd1 f/f mice, however, fibrosis in Pkd1 f/f Pkhd1 Cre mice remained unaffected. In vitro data suggests that nintedanib significantly reduced proliferation and cyst size of human ADPKD cystic epithelial cells as well as cell viability and migration of human ADPKD renal myofibroblasts.

Conclusions: The results suggest that Nintedanib is effective in reducing cyst growth and may be repurposed to treat ADPKD.

collecting tubular origin and survived until P12-15. While SBR reached Pkd1 therapeutic levels in the mild SBR/Pkd1-/-, the additional Tg copies suggest the presence of regulatory region within Pkd1 gene-body. Renal cysts in SBR/Pkd1-/- and SBR/Pkd1-/- co-detected by RNAscope and IF, arise likely from insufficient and chimeric Pkd1 re-expression. These analyses also shed light on Pkd1 spatio-temporal expression pattern with highest expression in collecting tubules during renal maturation that shifts to distal tubules following maturation.

Conclusions: Pkd1 is regulated by elements both upstream for spatio-temporal pattern and intragenic sequences for expression levels. The renal-specific SB minimal regulatory region is sufficient for therapeutic correction in one copy Tg. Our study demonstrates that Pcd re-expression can substantially delay cystogenesis and markedly extend lifespan.

Wheat-Gluten Diet Attenuates Ccl2-Mediated Immune Response and Slows Polycystic Kidney Disease
Jifeng Huang, Shinobu Yamaguchi, Jung-Shan Hsu, Takamitsu Saigusa. Department of Medicine, Division of Nephrology The University of Alabama at Birmingham, Birmingham, AL.

Background: Disease severity of autosomal-dominant polycystic kidney disease (ADPKD) is highly variable, even among families with the same gene mutation. A high protein diet is a well-recognized ADPKD progression-accelerating factor. Dietary protein composition is important, as pre-clinical studies have shown a soy protein-based diet slows kidney cyst formation in rodent PKD models. Recruitment of macrophages in the kidney is known to promote cystogenesis in PKD. We hypothesize that type of protein in the diet may serve as a potential environmental stimulant to immune response and cyst growth.

Methods: Using tamoxifen-inducible Pkd1-global knockout mice, we fed the mice with either a high casein-protein (animal-based protein: 60%), a low casein-protein (6%) or a high wheat-gluten (plant-based protein: 60%) for a total of 1 week or 6 weeks. Some mice fed a high casein protein diet were treated with liposomal clodronate or saline for a total of 5 weeks. Mice were euthanized and kidney cyst area, number of macrophages and chemokine/cytokine levels were measured.

Results: Pkd1-knockout mice fed a high casein diet increased the number of kidney macrophages, expression of macrophage-recruiting chemokine Ccl2 (but not chemokines Csf1 or Ccl5), pro-inflammatory cytokine (Il6, Tnf-a) and accelerated cyst growth compared to counterparts fed an iso-caloric high wheat-gluten (WG) diet or a low casein diet diet. We found that in very early stages during dietary casein load (1 week after diet modification), cyst expansion precedes macrophage recruitment in the kidney, indicating that diet per se triggers early cyst growth rather than as a consequence of macrophage recruitment and inflammation. High protein diet fed Pkd1-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine and fewer cysts.

Conclusions: Wheat-gluten diet fed Pkd1-knockout mice resulted in decreased the number of macrophages, suppressed levels of kidney Ccl2, but not Csf1 or Ccl5, and slowed cyst growth compared to counterparts fed an iso-caloric casein based diet. Dietary protein modification may suppress immune response and cyst growth in PKD.

High Prevalence of Kidney Cysts in Hereditary Hypophosphatemic Rickets with Hypercalcemia
Christian Hanna,1 Jennifer Arroyo,1 Peter Tebben,1 Vicente E. Torres,1 Peter C. Harris,1 David S. Goldfarb,2 David J. Sas,1 Dawn S. Milliner,2 John C. Lieske,1 Fouad T. Chebib,1 Theodora A. Potretzke.1 Mayo Clinic Minnesota, Rochester, MN; 2NYU Langone Health, New York, NY.

Background: Hereditary Hypophosphatemic Rickets with Hypercalcemia (IHRH) is a rare monogenic disorder caused by SLC34A3 pathogenic variants, characterized by renal phosphate wasting, hypophosphatemia, hypercalcuria (HC), elevated 1,25-dihydroxyvitamin D, nephrocalcinosis (NC), and urinary stone disease (USD). Previously we reported a high prevalence of kidney cysts in CYP24A1 deficiency. Thus, in the current study, we characterized cyst prevalence in HHRH, another monogenic cause of HC, NC, and USD.

Methods: Medical records from Mayo Clinic and Rare Kidney Stone Consortium research results were queried for all patients with genetically confirmed HHRH diagnosis. Clinical characteristics and imaging data are summarized in table 1. Results: Among 12 patients with SLC34A3 pathogenic variants (7 monoallelic, 5 biallelic), 42% (5/12) were males. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). None had a family history of cystic kidney disease. Kidney cysts (Figure 1) were present in 75% (9/12), among whom median age at first kidney imaging and first cyst detection was 41 yrs (range 9-64).

Conclusion: We found a strong association between IHRH and kidney cysts. Similarities in the biochemical profiles of IHRH and CYP24A1 deficiency suggest elevated active vitamin D, and/or HC may be potential factors in cyst formation. Further studies are needed to evaluate the role of the SLC34A3 gene in cyst formation.

Dysregulated Tryptophan Metabolism Promotes Polycystic Kidney Disease Progression
Dustin Nguyen, Emily K. Kleczko, Nidhi Dwivedi, Berenice Y. Gitomer, Michel Conchol, Raphael A. Nemenoff, Jelena Klawitter, Katharina Hopp. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Metabolic reprogramming is a feature and modifier of autosomal dominant polycystic kidney disease (ADPKD) progression. Moreover, immune cells regulate cyst growth. In cancer, a disease with parallels to PKD, the metabolic landscape created by tumors significantly impacts immune cell function and tumor growth. Yet, this link is unexplored in PKD. Here, we study tryptophan metabolism, a known immunosuppressive pathway, in cyst growth.

Methods: Metabolites were profiled in ADPKD patient plasma and kidneys of an orthologous ADPKD model (C57Bl/6J Pkd1^/-/-). We also crossed the ADPKD model to Ido1^/- mice, the enzyme metabolizing tryptophan to kynurenines, and inhibited Ido1 using the tryptophan analog 1-MT (400mg/kg, twice daily, orally). From these mice, kidney immune cells were profiled via flow cytometry.

Results: Tryptophan metabolites were significantly increased in Pkd1^/-/- mice at 3-, 6-, and 8-months compared to wild type and correlated with disease progression. Plasma levels of kynurenines significantly associated with HHTKV at baseline, and positively correlated with annual percent change of HHTKV in adult ADPKD patients. Ido1 levels were significantly increased in kidneys of PKD mice and patient cell lines. At 6-months of age, Pkd1^/-/Ido1^/- mice had significantly milder PKD compared to Pkd1^/-/Ido1^/- mice as measured by % KW/BW and cystic/iblritic index. Similarly, treatment of 1-month-old Pkd1^/-/Ido1^/- mice with 1-MT for 3 weeks slowed cyst growth; overall providing functional evidence of the pathway’s relevance to PKD. Kidney immune profiling of Pkd1^/-/-, Ido1^/- and 1-MT-treated mice revealed a significant reduction of resident macrophages, regulatory T cells, and immune checkpoint protein expression (PD-1/PD-L1), while the percentage of CD8^- T cells total T cells increased.

Conclusion: Our data highlight tryptophan metabolism as a novel dysregulated pathway in human and ADPKD and suggest that tryptophan metabolism are biomarkers of disease progression. Further, inhibition of the pathway presents a new treatment approach. Ido1 inhibitors are FDA approved for various cancers. Our data suggest a link between metabolic reprogramming, immune cell function, and disease progression, as Ido1 loss/inhibition impacted immune cell populations/pathways shown to regulate cyst growth.

Creatine Kinase Elevation in Patients with Autosomal Dominant Polycystic Kidney Disease on Tolvaptan Treatment
Diana Rodriguez-Espinosa, Elena C. Payán, Elena Guillen, Josep miquel Blasco pellico. Hospital Clinic de Barcelona, Barcelona, Spain.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease worldwide. Studies such as the TEMPO 3:4 and 4:4 have demonstrated tolvaptan's (vasopressin V2 receptor antagonist) effectiveness in slowing the progression of this disease. The best described adverse effect seen with this treatment is drug-induced liver injury, however, creatinine kinase (CK) elevation has also been described anecdotally in a couple of case reports.

Methods: This is a prospective observational study of adult patients with rapidly progressive ADPKD on tolvaptan treatment under follow-up at Hospital Clinic de Barcelona from October 2018 to March 2021. Quantitative variables are described as mean and standard deviation, while qualitative ones are reported as absolute and relative frequencies.

Results: A total of 37 patients started treatment with tolvaptan during this period. In 34 of them, serum CK levels were measured as part of the monthly biochemical follow-up. A total of 29.11% (10 of 34) of the patients elevated this parameter with a mean of 1368.2 ± 2807.28 U/L. Seven patients had a transient elevation with a mean of 446.43 ± 359.22 U/L, which reversed upon dose decrease or treatment pause. However, treatment had to be interrupted in the remaining three patients (mean 3519 ± 5016.36). In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was rarely related to exercise, although one patient reported a weekly intense cycling exercise with increased myalgia afterward) and was not significantly correlated with LDL levels, liver enzymes, calcium, potassium, urinary or plasma osmolarity.

Conclusions: By performing a general screening, we found that CK elevation is more frequently described previously in the literature, reaching significantly increased levels or producing symptomatology requiring definitive treatment interruption. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment’s follow-up, at the beginning of treatment and when increasing its dose, to promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.

PO1207

Protein 4.1O Links Polycystin 1 to the Actin Cytoskeleton and Modulates Hippo Signaling
Theresia Vienken, Eva Koenighausen, Lars C. Rump, Lorenz Sellin. Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.

Background: The majority of ADPKD patients have a PKD1 gene mutation. PKD1 codes for Polycystin-1 (PC-1). Cyst formation is caused by altered renal tubular cell proliferation. Protein 4.1 family members are actin adaptors, which link plasma membrane receptors to the actin cytoskeleton. Protein 4.1O (FRMD3) is a candidate gene for diabetic nephropathy. Furthermore, protein 4.1O has properties of a tumor suppressor. This study investigates the molecular and cellular properties of protein 4.1O as a potential ADPKD modifier and therapeutic target.

Methods: PC-1 full-length and truncation mutants were transiently expressed. PC-1 interaction with protein 4.1O and its truncation mutants were investigated. Truncation mutants cover the N- and C-terminal domains of protein 4.1O (Band 4.1, FERM, actin-binding domain and coiled coil domain). Communoprecipitations of protein 4.1O with PC-1 in IMCD cells were performed. Full-length protein 4.1O and F-actin were performed. The modulation of the PC-1 signaling properties by protein 4.1O were investigated in luciferase assays for c-myc and TEAD. FRMD3 core promoter regions were cloned into luciferase reporter. Results: Communoprecipitations show an interaction of protein 4.1O to PC-1 full-length. The C-terminus of PC-1 interacts with four isoforms of protein 4.1O (201, 202, 204, 207). The truncation mapping and isoform alignment identifies a potential leucine zipper domain in protein 4.1O as the C-terminal binding domain to PC-1. The N-terminal domain of protein 4.1O is also sufficient to mediate PC-1 interaction. Protein 4.1O C-terminus binds to F-actin and links the PC-1 C-terminus to the cytoskeleton. Protein 4.1O silences the PC-1 mediated transactivation of c-myc and hippo signaling (TEAD). Furthermore, F-actin desassociation influences the PC-1 induced hippo signaling. PC-1 activates the protein 4.1O prodeath activity.

Conclusions: Both, the FERM domain and leucine zipper containing coiled coil domain of protein 4.1O interact with the PC-1 C-terminus. The interaction of protein 4.1O links PC-1 to the actin cytoskeleton. The protein 4.1O interaction inhibits the PC-1 mediated propagation of c-myc and hippo signaling. Furthermore, protein 4.1O provides a F-actin based sensitivity to the PC-1 mediated hippo signaling. In summary, protein 4.1O shows features of an anti-cystogenic protein.

PO1208

Polycystin 2 Mediates Endoplasmic Reticulum K+–Ca2+ Exchange to Protect Against Polycystic Kidney Disease
Biswaajit Padhy, Jian Xie, Chou-Liang Huang. Huang Lab University of Iowa Carver College of Medicine, Iowa City, IA.

Background: Prevailing view is that PKD is a ciliopathy. Yet, PC2 is most abundantly expressed in ER. Early studies showed that PC2 is involved in agonist-induced ER Ca2+ release. Decrease in ER Ca2+ release in PC2-deficient cells is believed to contribute to CAMP overproduction and cystogenesis. Recent patch-clamp experiments reveal that PC2 channel is ~40X more selective to K+ than Ca2+, raising the question regarding how PC2 mediates ER Ca2+ release and role of ER-localized PC2 in PKD pathogenesis. To avoid potential polarization impeding ion fluxes, Ca2+ release from ER lumen to cystosol requires coupled counter cation exchange and/or parallel anion movement.

Methods: ER Ca2+ release is assayed by far2 fluorescently stimulated by ATP. PC2-deficient morphant zebrafish and doxycycline-inducible adult-onset PC2-deficient mice are used for in vivo PKD model.

Conclusions: A TP-stimulated ER Ca2+ release is blunted in PC2-null epithelial cells in which expression of WT, but not LOF, PC2 restores ER Ca2+ release. Tricb (trimeric intracellular cation-B) is an ER resident K+ channel mediates K+–Ca2+ exchange for IP3R-mediated Ca2+ release. Expressing WT, but not LOF mutant, Tricb rescues ER Ca2+ release in PC2-null cells. Vice versa, Tricb-null cells have defective ER Ca2+ release, which is rescued by expression of recombinant WT PC2. Zebrafish injected with PC2 antisense morpholin develops dorsal curvature. Co-injecting WT, but not LOF mutant, PC2 RNA rescues defects in PC2-deficient morphant fish. Co-injecting WT, but not LOF, Tricb RNA rescues defects in PC2-null fish. ER targeting of ROMK K+ channel normally expresses on the cell surface rescues Ca2+ release defect and PC2-morphant phenotypes. PC2L1, a PC2 related channel normally expressed on cell membrane and cilia, does not rescue PC2-deficient morphant fish. Transgenic expression of adult-onset kidney-specific Pkd2-inactivated mice ameliorates cystogenesis. Double deletion of Tricb and Pkd2 in mice reveal synergistic genetic interactions.

PO1209

Interactions Between TUL3P3 and ARHL13B in Lipidated Protein Transport to Cilia and Regulation of Renal Cystogenesis
Saikat Mukhopadhyay, Vivek R. Palcharla, Sun-hee Huang. The University of Texas Southwestern Medical Center, Dallas, TX.

Background: Signaling outputs from cilia maintain renal tubular homeostasis preventing cystogenesis; however, the ciliary proteins in this process are not well understood. The tubby family protein–TUL3P3 coordinates with the intraflagellar transport
Results: The transmembrane cargos have short motifs that are necessary and sufficient for TULP3-mediated trafficking. We now show that TULP3 is required for transport of the atypical GTPase ARL13B into cilia, and for cilary enrichment of ARL13B-dependent farnesylated and myristoylated proteins. ARL13B transport requires TULP3 binding to IFT-A core but not to phosphoinositides, unlike transmembrane cargo transport that requires binding to both by TULP3. A conserved lysine in TULP3’s tubby domain mediates direct ARL13B binding and trafficking of labelled and transmembrane cargo. We demonstrate that ARL13B helical motors in the palmitoylation site mediates binding to TULP3 and directs trafficking to cilia. TULP3 trafficked labelled cargos are depleted with distinctive temporal kinetics from kidney epithelial cilia during Tulp3 deletion-induced cystogenesis.

Conclusions: We conclude that TULP3 transports transmembrane proteins and ARL13B into cilia by capture of short sequences through a shared tubby domain site. Drugging this interaction domain could provide therapeutics in polycystic kidney disease. The depletion of lipitated cargos with distinct kinetics from kidney epithelial cilia following Tulp3 deletion suggests their differential roles in cilia in regulating renal cystogenesis.

POI1210
Augmented Renal TRPV4 Activity Attenuates Cystogenesis in ARPKD Rats
Kyrylo Pyrshiev, Victor N. Tomilin, Naghmeh Hassanzadeh Khayat, Oleg L. Zaika, Oleh Pochynyuk. The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: PKD is characterized by development of cysts in the kidney. Abundant evidence suggested that the impaired mechanosensitivity and disturbed [Ca++]i homeostasis are the major determinants of the rate of cystogenesis. ARPKD is caused by missense mutations in fibrocystin. ARL13B is characterized by the development of cysts almost exclusively in the collecting duct. We have previously demonstrated that mechanosensitive Ca++-permeable TRPV4 channel is preferentially expressed in the collecting duct where its activity is imperative for setting resting [Ca++]i levels and mediating flow-dependent [Ca++]i elevations. TRPV4 activity and expression is markedly augmented by high K+ intake, known to increase flow in the collecting duct. Thus, we hypothesized that dietary K+ supplementation would be beneficial in counteracting cystogenesis during ARPKD by stimulating TRPV4-dependent Ca++ influx.

Methods: We used dietary and pharmacological inputs to establish a correlation between the rate of cystogenesis and TRPV4 function in freshly isolated cyst monolayers in a homogenous ARPKD rodent model, PCK43 rats.

Results: We report that treatment of PCK43 rats with high KCI (10%) diet for 1 and 2 months significantly reduced kidney-to-body weight ratio, cystic index, and interstitial fibrosis. We also found a greatly increased total renal TRPV4 expression, channel activity and higher basal [Ca++] levels in native cyst cells compared with respective controls. Importantly, the beneficial effects of high KCI diet were abrogated when PCK43 rats were also treated with the selective TRPV4 inhibitor, GSK2193874. GSK2193874 treatment also exacerbated cystogenesis in control PCK43 rats by modestly increasing kidney-to-body weight ratio. Surprisingly, high K+ alkali diet (10% KClO4/Citrate) also aggravated the disease progression despite augmented renal TRPV4 expression. However, TRPV4-dependent Ca++ fluxes were dramatically suppressed in freshly isolated cyst cell monolayers from high K+ alkali fed rats, which is consistent with impaired TRPV4 activity.

Conclusions: Our experiments establish the direct link between TRPV4 function and cystogenesis during ARPKD. We propose that stimulation of TRPV4-dependent Ca++ influx.

POI1211
The Transcription Factor Tfap2a Maintains the Epithelial Integrity of Renal Collecting Ducts
Janna Leiz,1 Xiaoyan Hinze,1,2 Kai M. Schmidt-Orle,1,2 Charite Universitaetsmedizin Berlin, Berlin, Germany; 1Max-Delbruck-Centrum fur Molekularle Medizin in der Helmholtz-Gemeinschaft, Bch, Germany.

Background: The transcriptional regulator Tfap2a is a member of the AP-2 family of transcription factors. In humans, heterozygous mutations of Tfap2a result in branchio-oculo-facial syndrome (BOFS), which is associated with renal anomalies, including dysplastic, absent and multicystic kidneys. In this project, we aimed to elucidate the molecular functions of Tfap2a in the renal collecting duct.

Methods: We used direct in vivo binding, proximity biotinylation and mass spectrometry to map TULP3-cargo interactions. We generated knockouts of Tulp3 and cargoes in kidney epithelial cells stably co-expressing different variants of TULP3 or cargos, respectively. We generated conditional knockout of Tfap2a in mouse kidney nephric mesenchyme. We performed immunofluorescence for lipitated proteins with respect to kidney cystogenesis.

Results: The transmembrane cargos have short motifs that are necessary and sufficient for TULP3-mediated trafficking. We now show that TULP3 is required for transport of the atypical GTPase ARL13B into cilia, and for cilary enrichment of ARL13B-dependent farnesylated and myristoylated proteins. ARL13B transport requires TULP3 binding to IFT-A core but not to phosphoinositides, unlike transmembrane cargo transport that requires binding to both by TULP3. A conserved lysine in TULP3’s tubby domain mediates direct ARL13B binding and trafficking of labelled and transmembrane cargo. We demonstrate that ARL13B helical motors in the palmitoylation site mediates binding to TULP3 and directs trafficking to cilia. TULP3 trafficked labelled cargos are depleted with distinctive temporal kinetics from kidney epithelial cilia during Tulp3 deletion-induced cystogenesis.

Conclusions: We conclude that TULP3 transports transmembrane proteins and ARL13B into cilia by capture of short sequences through a shared tubby domain site. Drugging this interaction domain could provide therapeutics in polycystic kidney disease. The depletion of lipitated cargos with distinct kinetics from kidney epithelial cilia following Tulp3 deletion suggests their differential roles in cilia in regulating renal cystogenesis.

Comparative Multiple-Species Analysis of Renal Disease Mutations in HNF1B
Kelli Grand,1 Thomas Naert,1 Ludovica Rizzo,1 Maike Getyan,2 Roman Pichler,1 Soeren S. Lienkamp,1 Universitaet Zurich, Zurich, Switzerland; 2Albert-Ludwigs-Universitat Freiburg Medizinische Fakultat, Freiburg, Germany.

Background: Hepatocyte nuclear factor 1-beta (HNF1B) is a transcription factor involved in various stages of nephrogenesis and maintenance of renal tubular functions. Mutations in HNF1B are the most common monogenic cause for developmental renal disease, yet the underlying pathways affected are not fully understood. By comparative analysis in Xenopus and directly reprogrammed mammalian cells (iRECs) we investigated a patient-specific mutation (R295C) associated with cystic-dysplastic kidneys.

Methods: We used HNF1B to form renal-like organoids from Xenopus explants. In parallel, we analyzed how HNF1B R295C affects nephrogenesis in iRECs. Transcriptional changes were comparatively analyzed in two different species. We confirmed HNF1B target candidates in vivo using CRISPR/Cas9 editing of Xenopus embryos.

Results: We show that HNF1B is not only an essential component in direct reprogramming but can also induce ectopic pronephric tissue in Xenopus ectodermal explants. Changes in the transcriptomic profile demonstrated alterations in specific renal developmental modules and identified novel direct and indirect targets of the transcription factor HNF1B, which are linked to signaling pathways associated with renal morphogenesis, cilia and organic anion transport.

Conclusions: In conclusion, the combined use of directly reprogrammed mammalian cells and Xenopus renal organoid experiments allow us to gain a unique perspective into evolutionary conserved mechanisms of renal development and HNF1B associated kidney disease.

POI1213
Mosaic Inactivation of Pkd1 in Resistance Arteries Leads to Endothelial Dysfunction in Mice
Vivian C. Dourado, Patrizia Dardi, Luciana V. Rossoni, Luiz F. Onuchic. Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Cardiovascular problems are the leading cause of mortality in autosomal dominant polycystic kidney disease (ADPKD) and hypertension is observed in 50-70% of patients before significant reduction in renal function. The pathogenesis of ADPKD-associated vasculopathy, however, remains largely unclear.

Methods: Menseretic resistance arteries (MRA) of male normotensive non-cystic Pkd1+/- mice (HT) and their non-cystic Pkd1+/- controls (WT) as well as in hypertensive cystic Pkd1-/-Neater mice (CV) and their non-cystic Pkd1-/- controls (NC) were studied. HT and WT animals were analyzed at the ages of 8-12 and 55-60 weeks and had systolic blood pressure (SBP) recorded by tail plethysmography from 15 to 55 weeks of life, while CY and NC mice were analyzed at 8-12 weeks of life. The endothelium-dependent [acetylcholine (Ach) 10-6 M] and -independent relaxation [sodium nitroprusside (SNP) 10-6 M] and norepinephrine (NE, 10-6 M) and -MCI (120 mM)-mediated contraction were assessed in MRA rings by wire myograph. Structural and mechanical parameters (SMP) were evaluated at 55-60 weeks in HT and WT rings using pressure myograph.

Results: At 8-12 weeks, no significant difference in Ach-induced relaxation was observed in MRA between HT and WT mice. CV mice, on the other hand, displayed lower Ach-induced relaxation compared to NC animals (Maximal response: 44.5±7.7 vs 19.9±6.7%; P<0.05), although this parameter was impaired in NC compared to WT (P>0.001). SNP-induced relaxation was similar among groups. The contraction induced by NE did not differ between HT and WT or between the CV and NC mice. At 55-60 weeks, vascular reactivity and SMP did not differ in MRA between HT and WT mice. Interestingly, no difference in SBP was identified between these groups.

Conclusions: Mosaic inactivation of both copies of Pkd1 led to endothelial dysfunction in MRA, a phenotype not induced by Pkd1 haplosufficiency. Aging did not lead to development of hypertension or vascular dysfunction and remodeling in Pkd1-/-haplosufficient mice. While our data suggest that the endothelial abnormality observed in these cystic mice may be a primary dysfunction, current investigation is assessing a potential contribution of chronic hypertension.

Autophagy Inhibition Ameliorates Polycystic Disease

Parker Atwood, Deyopok Pokhrel, Nadhi Dvivedi, Katharina Hopp, Charles H. Edelstein. University of Colorado Denver School of Medicine, Aurora, CO.

Background: We published that there is a decrease in autophagy proteins in Pkd1-RC/RC mouse kidneys. Our study aimed to determine the mechanistic role of suppressed autophagy in causing cyst growth using pharmacological and genetic autophagy inhibition.

Methods: Male Pkd1-RC/RC (RC) mice were treated with 2-Deoxycoformycin (2DG) or Chloroquine (CHLQ) from 50-120 d of age. Kidney specific Pkd1 Atg7 double knockout mice were generated by Ksp1.3 Cre-lox recombination. Relative densitometry units (RDU) were determined on immunoblots. Autophagic flux was measured by the change in LC3-II (autophagosomes) +/− Bafilomycin (Baf).

Results: Autophagic flux was present in wild type (WT) and 120 d old RC but suppressed in 150 d old RC kidneys. LC3-II (RDU) +/− Baf was 0.1 vs 0.7 in WT (p<0.01), 0.6 vs 1.0 in 120 d old RC (p=0.05) and 2.4 vs 2.1 (NS) in 150 d old RC. 2DG resulted in a decrease in ATG12-5 complex and suppressed autophagic flux in RC kidneys. LC3-II (RDU) +/− Baf was 0.5 vs 0.8 in VEH (p=0.05), 0.7 vs 0.7 in 2DG (NS). 2DG significantly reduced cyst growth and improved kidney function. Cystic index (%), count +/− 2DG: 7.7 vs 3.7 (p=0.01), 211 vs 161 (p=0.05). BUN (mg/dL) +/− 2DG: 35 vs 27 (p=0.01). Next, RC mice were treated with CHLQ, a specific autophagy inhibitor. CHLQ resulted in suppressed autophagic flux, less PKD and improved kidney function in RC mice. LC3-II (RDU) +/− Baf was 1.2 vs 1.2 (NS) in CHLQ treated kidneys. Cyst index (%), Cyst no +/− CHLQ in RC mice was 15.5 vs 7 (p<0.007), 231 vs 105 (p=0.05). BUN and creatinine (by HPLC) (mg/dL) +/− CHLQ: 41 vs 26 (p<0.05), 2.9 vs 2.3 mg/dL (p<0.05). Next, autophagy was inhibited in PKD kidneys by generating double Pkd1 Atg7 KO mice. The 2 kidney/BW (%) was improved in Pkd1 Atg7 KO vs single Pkd1 KO mice (32 vs 39 p=0.05). Atg7 KO kidneys had a massive increase in p62 indicating a build-up of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 p<0.001. Interestingly Atg7 KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 p<0.001. Next, autophagy was inhibited in PKD kidneys by generating double Pkd1 Atg7 KO mice. The 2 kidney/BW (%) was improved in Pkd1 Atg7 KO vs single Pkd1 KO mice (32 vs 39 p=0.05). Atg7 KO kidneys had a massive increase in p62 indicating a build-up of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 p<0.001. Interestingly Atg7 KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of T and B cells. pAMPK+ was increased in Atg7 KO kidneys. AMPK activation is known to reduce PKD.

Conclusions: Both 2DG and CHLQ suppressed autophagic flux in RC kidneys and resulted in less PKD and improved kidney function. Double Pkd1 Atg7 KO mice had significantly lower kidney weight than single Pkd1 KO mice. Both pharmacological and genetic autophagy inhibition resulted in less PKD.

ARL13B Negatively Regulates Kidney Cysts from Within Cilia

Robert E. Van Sciver,1 Eduardo Caspary,2 Tamara Caspary.1 Emory University, Atlanta, GA; 2Georgia Institute of Technology, Atlanta, GA.

Background: Polycystic kidney disease (PKD) is intricately linked to the primary cilium. Polycystin proteins localize to cilia and loss of cilia leads to renal cysts. PKD mouse models often disrupt ciliary genes, removing both ciliary and cellular pools of the gene products; however, the molecular pathway(s) that drive cyst formation is unknown. ARL13B is a regulatory GTPase highly enriched in cilia due to a Vps4p motif near its C terminus. ARL13B is also localized to extraciliary sites within the cell. In most tissues, complete deletion of ARL13B leads to short cilia but in kidney ARL13B deletion leads to a loss of cilia and kidney cysts. As cilia loss leads to renal cysts, it was impossible to determine whether these cysts were due to the loss of cilia or the loss of ARL13B-dependent signaling in cilia. To determine the specific function of ARL13B within cilia, we needed a genetic tool that would allow us to isolate the cilial function of ARL13B.

Methods: We engineered mice in which we mutated the valine to alanine within ARL13B’s Vps4p cilia-localization motif so the mice express cilia-excluded ARL13B596A from the endogenous locus. ARL13B596A protein retains all known ARL13B biochemical functions, is stably expressed and is undetectable in cilia. We measured renal cysts and cilia phenotypes to functionally characterize the cistic phenotype of cilia-excluded ARL13B596A/+ mice.

Results: ARL13B596A/+ mice are viable and fertile with slowly progressing renal cysts. ARL13B596A/+ mice exhibit no cistic phenotypes and ARL13B596A+/− mice develop cysts at a more rapid rate than ARL13B596A/− mice. We detect cysts in all nephron segments of ARL13B596A/+ mice. Renal epithelia of ARL13B596A/+ mice retain cilia in normal nephrons as well as cistic regions. We cannot maintain these mice on a diet that restricts cyst growth.

Conclusions: Our findings indicate that ARL13B plays a critical role in the ciliary regulation of kidney cystogenesis. These results suggest that ARL13B functions as a negative regulator of renal cysts, specifically from within the cilium. Further studies are ongoing to dissect the mechanism(s) by which ciliary ARL13B regulates kidney cystogenesis.

Tsc Gene locus Disruption and Differences in Renal Epithelial Extracellular Vesicles

Prashant Kumar,1 Fahad Al-Zadjali,1 Ying Yao,1 John J. Bissler,2,1 ‘The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2St. Jude Children’s Research Hospital, Memphis, TN; 3Sultan Qaboos University, Muscat, Oman.

Background: In tuberous sclerosis complex (TSC), Tsc2 mutations are associated with more severe disease manifestations than Tsc1 mutations and the role of extracellular vesicles (EVs) in this context is not yet studied. We report a comparative analysis of EVs derived from isogenic renal cells except for Tsc1 or Tsc2 gene status and hypothesized that in spite of having similar physical characteristics, EVs modulate signaling pathways differently, thus leading to TSC heterogeneity.

Methods: We used mouse inner medullary collecting duct (mIMCD3) cells with the Tsc1 (TIG cells) or Tsc2 (T2J cells) gene disrupted by CRISPR/CAS9 methodology. EVs were isolated from the cell culture media by size-exclusion column chromatography followed by detailed physical and chemical characterization. Physical characterization of EVs was achieved by tunable resistive pulse sensing and dynamic light scattering, electron microscopy, and western blot analyses.

Results: Physical characterization of EVs revealing similar average sizes and zeta potentials (at pH 7.4) for EVs from mIMCD3 (123.5 ± 5.7 nm and –16.3 ± 2.1 mV), TIG cells (113.5 ± 8.3 nm and –19.2 ± 2.7 mV), and T2J cells (127.3 ± 4.9 nm and –20.2 ± 2.1 mV). EVs derived from parental mIMCD3 cells and both mutated cell lines were heterogeneous (90% of EVs < 150 nm) in nature. Immunoblotting detected cilial Hedgehog signaling protein Arl13b; intercellular proteins TSG101 and Alix; and transmembrane proteins CD63, CD9, and CD81. Compared to Tsc2 deletion, Tsc1 deletion cells had reduced EV production and release rates. EVs from Tsc1 mutant cells altered mTORC1, autophagy, and β-catenin pathways differently than EVs from Tsc2-mutated cells. Quantitative PCR analysis revealed the down regulation of miR-212a-3p and miR-99a-5p in EVs from Tsc2-mutated cells compared to EVs from Tsc1-mutant cells.

Conclusions: EV-derived miR-212-3p and miR-99a-5p axes may represent therapeutic targets or biomarkers for TSC disease.

Funding: Other U.S. Government Support
Background: ADPKD is characterized by epithelial proliferation and cyst growth. Metabolic abnormalities have been identified in renal models, but little is known about alterations in metabolic pathways in human ADPKD. We evaluated plasma metabolic profiles in ADPKD subjects prior to and after exposure to tolvaptan (T) as compared to healthy controls to better understand metabolic alterations in ADPKD and potential associations with disease progression and treatment response.

Methods: Plasma samples were collected and analyzed at baseline and month 12 in 100 ADPKD subjects (50 in T and 50 in placebo [P] arms) enrolled in TEMPO 3:4 (NCT010428948). The protein fraction was removed, and the remaining extract split into equal parts for analysis by tandem mass spectrometry and gas chromatography mass spectrometry platforms. Proprietary software (Metabolon, Inc., Durham, NC) matched ions to an in-house library of standards for metabolite identification and quantitation. Forty age- and sex-matched healthy subjects were analyzed as a control group. Linear mixed effect modeling identified associations of metabolites with ADPKD and treatment vs control, height-adjusted total kidney volume (htTKV), Mayo Imaging Classification (MIC), and T vs P.

Results: Baseline metabolic profiles differed between ADPKD and controls, with significant differences in lipid metabolism, TCA cycle, and amino acid metabolism. Baseline MIC 1C, 1D, 1E (vs 1B) were associated with accumulation of the uremic toxin pseudouridine, elevated fatty acid synthesis, and altered tryptophan metabolism, with similar findings when baseline hTKV was analyzed. Threonine, urea, and dimethylsulfone were decreased in T vs P at month 12, as well as other metabolites involved in lipid and amino acid metabolism.

Conclusions: We identified novel associations of amino acids and lipid metabolic pathways with ADPKD vs control and with measures of disease severity (MIC and hTKV). The metabolic profile was differentially affected in T vs P at month 12 of treatment, supporting a role for discovery metabolomics in evaluating response to therapy.

Sildenafil Inhibits ADPKD-Derived Cyst Growth in 3D Culture and Induces Apoptosis in the Han/SPRD Cyt+/Cy+ Rat Model of Renal Cyst Disease

Robert L. Bacalla,1,2 Weimin Xu,1 George Rhodes,3 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: In prior studies we found that human renal cyst cells express high levels of GMP phosphodiesterase 5, 6 and 9 as compared to normal human kidney cells. In breast cancer, inhibition of eGMP phosphodiesterases induces apoptosis. We tested the hypothesis that sildenafil blocks cell proliferation and/or induces apoptosis in cyst epithelia.

Methods: PKD Q0404X cells were grown in Matrigel and treated with vehicle or sildenafil for 7 days. Cyst size was assayed by light microscopy. Differences in cyst area were analyzed by two-way ANOVA. In separate experiments, male cy+/cy+ rats were given either vehicle or sildenafil in their water supply for 7 or 28 days. Kidneys were harvested and apoptosis was assayed by staining with anti-M30, a monoclonal antibody that binds to apoptosis-associated leakage of cytokeratin 18 in epithelial cells.

Results: 3D cultures of PKD Q0404X cells, cultures treated with sildenafil (1, 2 and 4 µg/ml) are significantly smaller than vehicle-treated cultures (p=0.05 for all doses). Further analysis showed that cysts larger than 150 µm3 were not observed in any sildenafil treated cultures. Figure 1 shows M30 staining in sildenafil (20 µg/kg/d) x 7 to 7 treated rats (panel B, red channel merged with the green autofluorescence channel) versus vehicle treated animals. M30 positive cells are found predominantly around cyst lumens. Apoptotic changes in cyst epithelia were also observed in rats treated with sildenafil for 40 days.

Conclusions: Sildenafil inhibits human kidney cyst growth in 3D culture. In male cy+ rats, sildenafil at a dose of 20 µg/kg/d for 7 or 40 days results in apoptosis of cyst epithelia.

Funding: Private Foundation Support

Seven days of sildenafil treatment induces apoptosis in cystic kidneys. Sections stained with anti-cytokeratin 8/18 (red channel). Nuclei are labeled with Hoechst 33342 Green channel is autofluorescence. A: Vehicle treated male rats. Note the absence of cytokeratin 8/18 in B: Vehicle + 20 µg/kg sildenafil treated for 7 days. Arrows point to cytokeratin 8/18 positive (red cytosolic stain) in cyst epithelia.

Mutation Position and Genetic Background Modulate Disease Expression in Pkhd1 Mouse Models

Maryanne Odinakachukwu1, Chaozhe Yang,1 Zsuzsanna M. Bebok,2 Lisa M. Guay-Woodford.2 1Children’s National Research Institute, Washington, DC; 2The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.

Background: Multiple Pkhd1 mutant mouse models have been generated by gene-targeting methods (del5-4, del57) or resulted from spontaneous mutations (cy5). When these mutations are homozygous on inbred backgrounds (DBA/2J (D2); C57BL/6 (B6)), there is either no renal cystic disease or very mild dilatation of the PCTs rather than CCDS. A recent ARegPKD report showed that the position of human Pkhd1 mutations correlates with ARPKD kidney and liver disease severity (Burgisser, KJ 2021). In the current study, we examined the impact of age, mutation position, and mixed genetic background on kidney, liver, and pancreatic disease in Pkhd1 mutants.

Methods: D2-Pkhd1Δ5,Δ7; B6-Pkhd1Δ5,Δ7 and B6-Pkhd1Δ10,Δ14 mouse lines. Intercross strategy to generate a suite of F2 mutants on mixed genetic backgrounds (D2.B6).

Results: D2.B6-Pkhd1Δ5,Δ7 mutants expressed both marked dilatation of the CCDS and liver ductal plate malformation (DPM); no pancreatic cysts were observed. Similarly, D2-B6-Pkhd1Δ10,Δ14 compound heterozygotes had occasional dilated DCTs, a marked DPM lesion, and diffuse cyst formation in the pancreatic ducts. The D2-B6-Pkhd1Δ5,Δ7 and D2-B6-Pkhd1Δ10,Δ14 mutants had occasional dilated DCTs, no DPM or pancreatic cysts.

Conclusions: Age, genetic background, and mutation position modulate organ-specific disease expression in Pkhd1 mutants. On the mixed D2.B6 background both cyli and del5-4 aged F2 mutants develop CCD cysts, similar to human Pkhd1 renal disease. Surprisingly, D2.B6-Pkhd1Δ5Δ7/+ mice had minimal kidney pathology and no pancreatic duct cysts, suggesting that genetic background differentially modulates kidney and pancreatic cystic phenotypes. Mice heterozygous or homozygous for the del5Δ7 mutation expressed minimal kidney, liver, or pancreatic cystic changes. Thus, defects at the 3’ end of Pkhd1 appear to have minimal pathobiological impact, that is not influenced by age or the mixed D2.B6 genetic background. These findings will inform our experimental strategies to identify organ-specific Pkhd1 genetic modifiers.

Rab GTase Regulation in Ciliogenesis and Polycystic Kidney Disease

Dominique J. McConnachie,1 Andrew J. Mallett,2 Jennifer L. Stow.1 Professor Jennifer Stow, Protein trafficking and inflammation group 1The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia; 2Townsville Hospital and Health Service, Townsville, QLD, Australia.

Background: Primary cilia are sensory organelles with widespread roles in development and epithelial functions. Mutations resulting in dysmorphic cilia and ciliary dysfunction are associated with renal ciliopathies such as polycystic kidney disease (PKD), yet primary cilia remain enigmatic in terms of their molecular and functional characterisation. Rab GTases are master regulators of vesicular trafficking that have been shown to regulate ciliogenesis and cilia composition, with downstream effects on ciliary function and signalling. Rab are therefore poised to vary or modify primary ciliary function, by working in conjunction with key cilia proteins, including those mutated in PKD and other ciliopathies. Hence, we are examining novel roles for Rab GTases in cilia formation and function and Rab13 has been the focus of recent studies.

Methods: Expression of fluorescently tagged, recombinant Rab13 and knockout of endogenous Rab13 were used to assess the roles of Rab13 GTase in ciliogenesis and cilia function in mouse renal epithelial cell lines grown as monolayers and spheroids. Ciliary morphogenesis, cell polarity and growth were assessed by confocal imaging in live and fixed cells, while biochemical approaches were used to test cilia-dependent signalling and associated molecular pathways, along with Rab13 expression, activation and effector functions.

Results: Our data show that Rab13 localises to the primary cilia of mouse kidney cells and Rab13 loss of function affects ciliogenesis in a variety of in vitro and in vivo models including zebrafish embryos. Characterisation of Rab13 knockout epithelial cell lines altered cilia, the perturbation of ciliopathy-associated protein localisation, and the formation of dysmorphic renal spheroids. Rab13 knockout zebrafish embryos display a range of cilia-associated developmental defects and Rab13 expression is diminished in mouse PKD kidneys.

Conclusions: Here we reveal a novel cilia-associated role for Rab13 GTase. Investigating how the genes and molecules that contribute to the cilial landscape is essential to improve knowledge, for potential translation and discovery of new therapeutic approaches for renal ciliopathies including PKD.

Efficacy and Adverse Effects of a Novel Mesoscale Nanoparticle-Guided Siroliimus Delivery Strategy in a Phkd1Pck-Rat Model 

PO1227

Majlak Murk,1 Daniel A. Heller,2 Chintan H. Kapadia,3 Ryan Williams,4 Phillip H. Chumley,1 Sean Mullen,1 Ronald E. Roye,1 Gabriel Rezonewicz,5 Juling Zhou,1 Edgar A. Jaimez,2 The University of Alabama at Birmingham, Birmingham, AL; 5Memorial Sloan Kettering Cancer Center, New York, NY; 7Goldaffex Therapeutics, New York, NY; 8The City College of New York, New York, NY.

Background: Preclinical studies have shown that mTOR inhibition attenuated renal cystic disease progression but it did not improve outcomes in patients with autosomal dominant polycystic kidney disease (ADPKD). This was attributed to the dose limitations in humans due to mTOR inhibitor toxicity. To increase the mTOR inhibition efficacy and reduce its toxicity in renal cystic diseases, we studied mesoscale nanoparticle (MNP)-guided delivery of an mTOR inhibitor, sirolimus (MNP-sirolimus), in Phkd1Pck-RCK rat. We used recently developed MNPs that selectively and with high affinity target the renal tubular epithelium.

Methods: We synthesized Empty-MNPs or MNP-sirolimus and used them in an experiment that resembles seminal pre-clinical studies of tolvaptan, the only FDA-approved ADPKD therapeutic. Newly outbred Phkd1Pck-RCK rats were divided into 3 groups (each N=8-9) and treated for 8 weeks (p22 to p77) with: Empty-MNP (50 mg/kg IV p06 hours), Pre- and post-treatment cyst volumes were assessed by MRI at p21 and p78.

Results: The MNP-sirolimus or Free-sirolimus both inhibited renal mTOR activity in Phkd1Pck-RCK rats. The mean pS6/total S6 ratios were: 7.9 for MNP-sirolimus vs 19.1 for Free-Rapa and 105.1 for Empty-MNP (p<0.001) while total S6 levels did not differ (p=0.806). Similarly, an 8-week mTOR inhibition reduced mean renal cyst volumes: 39.9 mm3 for MNP-sirolimus vs 59.3 mm3 for Free-sirolimus vs 148.4 mm3 for Empty-MNP (overall p=0.011). However, in pairwise comparison with Empty-MNP treatment, this difference was significant only for MNP-sirolimus (p=0.017) while for Free-sirolimus the significance was marginal (p=0.052). The pre-treatment renal cyst volumes at 3 weeks were not significantly different (p=0.720). Among side effects, mTOR inhibition reduced body weight and heart weight (p<0.004); in both cases, their averages were less severely reduced in MNP-sirolimus as compared to Free-sirolimus treated rats.

Conclusions: Together, our studies support the concept that a novel MNP-guided sirolimus delivery increases renal mTOR inhibition and therapeutic efficacy in renal cystic diseases, while reducing systemic toxicity.

PO1228

Biomarkers Reflecting Extracellular Matrix Turnover Are Prognostic for Kidney Function Decline in Patients with ADPKD

PO1229

Federica Genovese,1 Judith E. Heida,1 Nadja Spardin,1,2 Morten A. Karsdal,1 Ron T. Gansevoort,1 Daniel Guldager Kring Rasmussen,1 Nordic Bioscience, Herlev, Denmark; 3Biomedical Sciences, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; Dept. Nephrology, University Medical Center Groningen, Groningen, Netherlands.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common inherited disorders in humans and is caused by mutations in the PKD1 and PKD2 genes. The disease is characterized by development and growth of cysts leading to loss of kidney function. Early markers that reflect the progression of kidney disease in ADPKD and is characterized by an impaired turnover of extracellular matrix (ECM). Here, we investigated the association of ECM biomarkers with rate of kidney function decline in patients with ADPKD.

Methods: We measured four markers of ECM turnover in serum and urine from 305 patients with ADPKD from the DIPAK-1 study (NCT01616927): three markers of interstitial collagen turnover (C3M, PRO-C3 and PRO-C6) and one laminin degradation marker reflecting basement membrane turnover (LG1M). The association of the biomarkers with kidney function decline was investigated with a linear mixed model (change in eGFR/year) and logistic regression (decline in eGFR of >30%). Data was log-transformed if appropriate.

Results: All four markers of kidney fibrosis in serum were associated with eGFR at baseline when adjusting for sex, age, height adjusted total kidney volume (htTKV) and PKD mutation in serum (C3M, P<0.05; PRO-C3, P<0.001; PRO-C6, P<0.001; LG1M, P<0.001). In urine, only C3M and PRO-C6 (C3M, P=0.001; PRO-C6, P<0.001) and not PRO-C3 and LG1M (PRO-C3, P=0.07; LG1M, P=0.31) were independently associated with eGFR. Serum C3M (P=0.005) as well as urine PRO-C3 (P=0.001) and PRO-C6 (P=0.001) were associated with the rate of eGFR decline per year when adjusting for age, sex, baseline eGFR, htTKV and PKD mutation. A total of 60 patients had a decline in eGFR of >30% and when adjusting for sex, age, baseline eGFR htTKV and PKD mutation, only serum C3M (HR=1.48, P=0.02) was independently associated with a decline in eGFR of more than 30%.

Conclusions: Serum C3M as well as urinary PRO-C3 and PRO-C6 were associated with the rate of kidney function decline when adjusting for known determinants of disease severity. Also, serum C3M could identify fast progressors (decline in eGFR of >30%). These markers hold promise that components from the ECM may be used as prognostic markers in ADPKD, but should be validated first in an independent ADPKD cohort.

Magnetic Resonance Fingerprinting (MRF) Identifies Potential Imaging Biomarkers for Autosomal Recessive Polycystic Kidney Disease (ARPKD)

PO1229

Elise Keshock,1 Jacob R. Perino,1 Christina J. Macaskill,1 Ashlee Parsons,2 Jemma M. Hach,2 Susan Farr,3 Chris Flask,2 Katherine M. Dell.1,2 1Case Western Reserve University, Cleveland, OH; 2Cleveland Clinic Children’s Hospital, Cleveland, OH.

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is an important cause of morbidity and mortality in children with chronic kidney disease (CKD). Novel therapies have shown efficacy in ARPKD animal models, but clinical trials in ARPKD patients have not been possible due to the lack of sensitive measures of kidney disease progression. Non-invasive Magnetic Resonance Imaging (MRI) techniques, including novel MRF Fingerprinting (MRF), show promise in addressing this unmet need.

Methods: We used our recently developed MNPs that selectively and with high affinity target the renal tubular epithelium.

Results: Among side effects, mTOR inhibition reduced (overall p=0.011). However, in pairwise comparison with Empty-MNP treatment, this difference was significant only for MNP-sirolimus (p=0.017) while for Free-sirolimus the significance was marginal (p=0.052). The pre-treatment renal cyst volumes at 3 weeks were not significantly different (p=0.720). Among side effects, mTOR inhibition reduced body weight and heart weight (p<0.004); in both cases, their averages were less severely reduced in MNP-sirolimus as compared to Free-sirolimus treated rats.

Conclusions: Together, our studies support the concept that a novel MNP-guided sirolimus delivery increases renal mTOR inhibition and therapeutic efficacy in renal cystic diseases, while reducing systemic toxicity.

Interaction/Modulation of PKD2 by TACAN

PO1230

Xiong Liu,1 Mohammad Fatehi,2 Rui Zhang,3 Jingfeng Tang,7 Peter E. Light,2 King-Zhi Chen.1 Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; 7Department of Pharmacology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; 8National “111” Center for Cellular Regulation and Molecular Pharmaceutics, Hubei University of Technology, Wuhan, China.

Background: TACAN (also named TMEM128A), recently reported as a mechano- and pain-sensing ion channel, is distributed in diverse non-neuronal tissues such as heart, intestine and kidney, which indicates its potential role besides pain sensation. Previous experimental evidence suggests the presence of an interaction between PKD2 and TACAN. In this study, we investigated the physical and functional interaction between the two proteins.

Methods: We employed mutagenesis, molecular cloning, co-immunoprecipitation, immunoblotting, biotinylation, two-electrode voltage clamp in Xenopus oocytes to measure whole-cell currents and patch-clamp in Chinese hamster ovary (CHO) cells to measure single-channel currents.

Results: We found that TACAN is co-localized and in complex with PKD2 in primary cilia of different kidney cell lines and oocytes. Using oocyte expression, we found that TACAN inhibits the channel activity of PKD2 gain-of-function mutant F604P. Using CHO cell expression, we found that TACAN inhibits both wild-type PKD2 and mutant F604P through reducing their single-channel conductance and open probability. Co-expression of TACAN significantly enhanced the sensitivity of PKD2 to stretch. Further, our data showed that while the first and last transmembrane domains (Tm1 and Tm6) of TACAN are involved in interaction with transmembrane domains of PKD2 only the TACAN Tm6 is functionally relevant.

Conclusions: Our study revealed inhibition of PKD2 channel activity through physical TACAN-PKD2 complexing and that TACAN, but not PKD2, mediates mechanosensitivity of the channel complex. Whether and how TACAN participates in the pore formation remains to be determined.

Suppressed Autophagy Drives Increased Cellular Metabolic Activity in Human ADPKD Cells

Daniel Atwood, Deepak Pokhrel, Charles L. Edelstein. University of Colorado, Aurora, CO.

Background: We published that the autophagy phenotype in Pkd1<sup>h</sup>-<sup>h</sup> mouse kidneys is characterized by decreases in crucial autophagic proteins (Cell Signal 2020). We attempt to determine the mechanistic role of suppressed autophagy as it relates to cell metabolism, viability (viability and proliferation) in ADPKD cells.

Methods: Human primary immortalized cultured cells were used: normal renal cortical tubular epithelium (RCTE, Pkd1<sup>+/+</sup>) and ADPKD cyst lining epithelium (9-12, Pkd1<sup>−/−</sup>). To measure autophagic flux, cells were treated with lysosomal inhibitor chloroquine (C) and mCherry LC3 (fluorescence) was measured. MTX assay was used to measure cellular metabolic activity (cell viability and proliferation). Relative densitometry units (RDU) were measured on immunoblots.

Results: There was an increase in MTT and a decrease in AnnV in 9-12 vs RCTE cell types. MTT OD was 0.36 in RCTE vs 0.44 in 9-12 (p<0.001). AnnexinV (AnnV) (% gated) marker of apoptosis, was 67 in RCTE vs 18 in 9-12 (p<0.001). The increase in LC3-II in C was not seen in 9-12 indicating suppressed autophagy and decreased apoptosis. Autophagy inhibition increased with Veh vs. 0.2 with TAT (p<0.001). TAT did not affect AnnV.

Conclusions: In ADPKD cyst lining epithelial cells there is increased MTT, suppressed autophagy flux, and decreased apoptosis. Autophagy inhibition increased with TAT suggesting suppressed autophagy drives increased cellular metabolic activity in ADPKD cells. The effect of autophagy inhibition /induction on cyst growth in vivo merits further study.

Tsc2 Mutation Induces Renal Tubular Cell Nonafunctional Disease

Prashant C. Cystic Kidney Disease - I

Methods: To understand the diversity of kidney resident macrophages (KRM), we performed single cell RNA sequencing, parabiosis, and fate mapping on kidneys isolated from wild type and transgenic knock-in reporter mice.

Results: Using single cell RNA sequencing, we identified three subpopulations of KRM including one with enriched expression of Ccr2. Using Ccr2-RFP knock-in reporter mice, we confirmed that these resident macrophages were derived from monocyte precursors and preferentially localize to the renal cortex. Based on our single cell RNA sequencing data, we propose that monocytes undergo a series of differentiation steps upon entering the kidney in order to become Ccr2<sup>+</sup> KRM. Levels of single cell data from the main origin for systemic eKlotho suggest that monocytes require Cx3cr1 in order to differentiate into Ccr2<sup>+</sup> KRM. Loss of Cx3cr1 prevented the accumulation of Ccr2<sup>+</sup> KRM and resulted in a skewed macrophage profile that prevented cilia mutant mice from developing severe cystic disease.

Conclusions: Collectively, our data indicate that monocytes undergo a series of differentiation steps upon entering the kidney and require Cx3cr1 for differentiation into pathogenic Ccr2<sup>+</sup> KRM.

Species-Specific Differences in FPC-CTD Trafficking: Implications for Differential Activation of Intracellular Signaling Pathways

Chaozhe Yao,1 Naoya Harafuji,2 Maryanne Odinakachukwu,1 Lubjica Edelstein.1 The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.

Background: ARPKD (MIM 213600) is caused by mutations in PKHD1, which encodes FPC. But, orthologous mouse Pkd1 mutants either have no renal cystic disease or very mild PCT dilatation. We previously showed that MYC/Myc is overexpressed in human ARPKD and mouse Cys1<sup>del67</sup> (cypk) kidneys, but not in several Pkd1 mutants. We also showed that expression of the intracellular carboxy-terminus of mouse FPC (mFPC-CTD), but not human (hFPC-CTD), activates the Myc/Myc promoter (APN 2020). The current study focused on: 1) the intracellular trafficking of mFPC-CTD and hFPC-CTD, and 2) activation of the Src/STAT3 signaling pathway, linked to hFPC-CTD (Aurbil 2020), in a mouse Pkd1 mutant lacking FPC-CTD and in the cpl mouse model of ARPKD, with and without Cy-C rescue.

Methods: Comparative immunofluorescence analysis. Immunolabeled mouse ccd (mccd) and human (hccd) cell lines stably expressing mFPC-CTD and hFPC-CTD, respectively. Kidneys from cypk, Cys1-rescued cypk, and Pkd1<sup>h</sup>-<sup>h</sup>del67<sup>+</sup> mutant mice, western blot and immunofluorescence.

Results: FPC-CTD is the least conserved domain, with 55% identity between human-mouse ccdts, compared with 73% identity across the full-length FPC. The CTD is unique, with an AA-sequence not found in other terrestrial vertebrate proteins. In stable cell lines, mFPC-CTD localized to both nuclei and cilia, whereas hFPC-CTD primarily localized to the apical membrane. In non-cystic del67 kidneys (lacking FPC-CTD), pSTAT3<sup>735</sup> and c-Myc were similar to wild-type controls. In cypk kidneys, pSTAT3<sup>735</sup> and c-Myc were upregulated, but their levels in Cys1-rescued cypk kidneys (Liang 2021) were comparable to wild-type.

Conclusions: Differences in intracellular trafficking of mFPC-CTD and hFPC-CTD may explain the species-specific differences in Myc/Myc promoter activation. Distinct subcellular localizations may reflect divergence in the functional evolution of human and mouse FPC-CTD, with mFPC-CTD functioning as a transcriptional activator, whereas hFPC-CTD functions as a membrane-associated signaling regulator of Src-STAT3. Activation of Src-STAT3 signaling and Myc upregulation are signatures of cystic epithelia, suggesting that renoprotective mechanisms in FPC-deficient mouse kidneys may be more protective.

Reduction of Klotho Promotes Cyst Growth and Epigenetic Age Acceleration in ADPKD

Xiaoan Li,1 Xiaojing Zhang,2 Xia Zhou,1 James P. Calvert,2 Chou-Long Huang,2 Xiaogang Li.1 Mayo Clinic Department of Internal Medicine, Rochester, MN; 2University of Kansas Medical Center, Kansas City, KS; 3The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA.

Background: Symptoms of ADPKD vary in severity and age of onset and tend to accelerate quickly in older patients, eventually resulting in kidney failure. eKlotho has been identified as an anti-aging protein, and the kidney is the organ expressing the highest levels of Klotho protein and the main origin for systemic eKlotho. The soluble serum form of eKlotho (extracellular domain of klotho) was found to be decreased in ADPKD patients, however, the role of eKlotho in ADPKD remains unknown.

Methods: To investigate the role and mechanism of eKlotho in ADPKD, we introduced an eKlotho targeted murine model in lineage tracing and cellular induction experiments to understand TSC cystogenesis. For extracellular vesicle (EV) characterization experiments and a cell culture model in EV containment, we used a newly derived targeted murine model in lineage tracing and cellular induction experiments to understand TSC cystogenesis. For EV-producing cells.

Results: Using lineage tracing experiments, we found principal cells undergo clonal differentiation steps upon entering the kidney and require eKlotho for systemic eKlotho to be secreted. In stable cell lines, Myc/MYC (mFPC-CTD), but not human (hFPC-CTD), activates the Myc/Myc promoter (APN 2020). The current study focused on: 1) the intracellular trafficking of mFPC-CTD and hFPC-CTD, and 2) activation of the Src/STAT3 signaling pathway, linked to hFPC-CTD (Aurbil 2020), in a mouse Pkd1 mutant lacking FPC-CTD and in the cpl mouse model of ARPKD, with and without Cy-C rescue.

Conclusions: Differences in intracellular trafficking of mFPC-CTD and hFPC-CTD may explain the species-specific differences in Myc/Myc1 promoter activation. Distinct subcellular localizations may reflect divergence in the functional evolution of human and mouse FPC-CTD, with mFPC-CTD functioning as a transcriptional activator, whereas hFPC-CTD functions as a membrane-associated signaling regulator of Src-STAT3. Activation of Src-STAT3 signaling and Myc upregulation are signatures of cystic epithelia, suggesting that renoprotective mechanisms in FPC-deficient mouse kidneys may be more protective.

Exploring the Heterogeneity of Kidney Resident Macrophages Using Single-Cell RNA Sequencing

Alex Yashchenko,1 Sarah J. Bland,2 Zhang Li,1 Cheng Song,1 Kurt Zimmerman.1 1The University of Oklahoma Health Sciences Center, Oklahoma City, OK; 2The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL; 3University of Southern California, Los Angeles, CA.

Background: Tissue resident macrophages are highly diverse, even when located within the same organ. This heterogeneity is thought to be driven by localization, temporal origin, time in tissue, and niche specific cues. Importantly, these underlying factors likely influence resident macrophage phenotype and function during disease initiation and progression.

Results: We found that full length αKlotho was decreased in collecting duct cells, macrophages, fibroblasts and T/NK immune cells in Pkd1 homoygous kidneys. Transgenic αklotho delayed cyst growth in Pkd1 conditional knockout mice by normalizing the expression of genes associated with a number of diverse functions, including the genes associated with the transitions between collecting duct cell subtypes and genes involved in epithelial-mesenchymal transition. In addition, we found that the genes associated with the epigenetic clock (DNA methylation age) were dysregulated in those cells in cystic kidneys, and that they could be normalized by transgenic αklotho, suggesting that transgenic αklotho might slow down the process of epigenetic age acceleration in cystic kidneys. The dysregulation of the epigenetic age-acceleration genes, ApoE, Cldn4, Mge and Slc38a2, might contribute to PKD pathogenesis and might serve as potential biomarkers for ADPKD. Finally, transgenic αklotho affected a large number of genes associated with metabolic and oxidative signaling, suggesting that αklotho might act by modifying non-ciliated processes to extend the life span of mice.

Conclusions: Reduction of αklotho regulates cyst growth through diverse signaling pathways. Pkd1 mutation accelerates epigenetic age in ADPKD. Transgenic αklotho not only delayed cyst growth but also slowed down epigenetic age acceleration.

Mechanistic Interaction Between Cystin and Fibrocystin/Polyductin in Model Cell Lins and cpk/cpk Kidneys
Yiming J. Zhang,1 Chaohe Yang,2 Naee Harafuj,1 Wei Wang,1 Phillip D. Bell,1 Lisa M. Guay-Woodford,1 Zsuzsanna M. Mekb,1 The University of Alabama at Birmingham, Birmingham, AL; 2Massachusetts Institute of Technology, Cambridge, MA; 3Children’s National Research Institute, Washington, DC.

Background: Cystin/cpk (cpk) mice exhibit ARPKD-like renal phenotype due to a mutation in the Cys1 gene and loss of cystin. ARPKD (MIM 263200) is caused by mutations in PKHD1, encoding FPC. Both cystin and FPC are present in the primary kidney, but no physical interaction has been reported. Using mouse CCD cell lines, we have shown that FPC levels were reduced in cpk cells by 75% relative to wt. Cystin deficiency is specifically linked to FPC reduction and did not affect cilia development, but altered ciliary architecture (ASN 2020). The current study focuses on cellular mechanisms driving FPC reduction in cystin-deficient cells, and the consequences of FPC loss. We noted that FPC is necessary for proper E3 ubiquitin ligase function and consequently cellular proteome management (Kaimori 2017).

Methods: Immortalized wt and cpk mouse CCC cells. Wt and cpk mouse kidneys. siRNA silencing of Cys1, rQ-PCR, western blot, confocal microscopy, morphometry, patch clamp.

Results: Silencing Cystin in wt cells results in a siRNA dose-dependent reduction of both cystin and FPC. Correlative studies showed marked reduction of FPC in cpk kidneys. Similar Pkd1 mRNA levels in wt and cpk, and kidneys implicate FPC regulation at the protein level. Proteasome or lysosome inhibition did not recover FPC, but activation of autophagy further reduced FPC levels, suggesting a role for selective autophagy in FPC removal. Diminished FPC levels lead to E3 ubiquitin ligase defects and reduced polyubiquitination of proteins, necessary for proteome management. In cpk cells, we showed increased membrane retention of the epithelial sodium channel and increased sodium transport.

Conclusions: Our studies provide the first functional link between cystin and FPC in renal epithelial cells. We propose cystin as a gatekeeper for FPC at the base of the cilia and in the E3 ligase complex. In cystin-deficient cells, FPC is continuously degraded leading to dysregulated ubiquitination and altered proteome homeostasis. These data show a mechanistic connection between the renal phenotypes observed in human ARPKD and cpk mice. The recent identification of human CTSI-related ARPKD (Sci Report, in press) highlights the potential significance of the cystin-FPC mechanistic interaction in the complex pathobiology of ARPKD.

Tubular Flow Disruption During Cyst Development in Polycystic Kidney Disease
Isis Thomas, Hanan Chweih, Courtney J. Haycraft, Mandy J. Croyele, Zhang Li, Bradley K. Yoder. The University of Alabama at Birmingham, Birmingham, AL.

Background: Polycystic kidney disease is an inherited disorder in which clusters of cysts develop within the kidneys, causing the kidneys to enlarge and lose function. Cyst development can be due to functional changes caused by mutations in ciliary localized proteins Pkd1 and Pkd2 or changes in cilia formation/structure (e.g. i888 mutants). It is currently unknown how cysts impact tubule flow and cilia, or whether flow alterations occur prior to or after cyst formation is initiated.

Methods: We used inducible Cre conditional mutant mouse models with an optical imaging technique to visualize changes in tubular flow at multiple timepoints during cystogenesis in live kidneys. Additionally, we evaluated dextran absorption into proximal tubules as an indicator of tubule flow in mutant and control mice during cyst development. We determined the number of dextran+ proximal tubules in control and mutant kidneys at multiple timepoints during cyst development. This corresponds to a 56.8% of cells that are both dextran+ and LTA+ (proximal tubule) by flow cytometry and similar results were obtained by IF analysis. We also find an increase in resident and infiltrating macrophages around the forming cysts.

Conclusions: The use of intravital imaging approaches allows us to evaluate changes in tubule flow as cysts progress. With the addition of cilia markers, we will examine the responses of the cilium to the changes in flow. Preliminary data suggests that alterations in tubule flow occur at early time points during cyst initiation with larger cysts seldom containing epithelium that are dextran+. These data indicate that loss of tubule flow may be an early event associated with cystogenesis. Our data also suggests that disruption of tubule flow is progressive with fewer tubules with flow at later time points (4-6 months post induction). We are currently assessing whether there is an association between the disruption of flow in a tubule and localized immune responses.

FoxM1 Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease
Wenyao Yu, Guojuan Wang, Xiaoia Li, Xia Zhou, Xiaogang Li. Mayo Clinic Department of Internal Medicine, Rochester, MN.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is driven by mutations in PKD1 and PKD2 genes and is characterized by renal cyst formation, inflammation and fibrosis. Forkhead box protein M1 (FoxM1) is a transcription factor of the Forkhead box (Fox) protein super family which is defined by a conserved winged helix DNA-binding domain. FoxM1 has been reported to promote tumor formation, wound healing and fibrosis in many organs. However, the role and mechanism of FoxM1 in regulation of ADPKD progression is still poorly understood.

Methods: To evaluate the role and mechanisms of FoxM1 in cyst growth in vivo, we treated early stage and long lasting Pkd1 mutant mice with the FoxM1 specific inhibitor, FDL-6. To identify novel FoxM1 target genes involved in cystogenesis, we performed ChIP-sequencing analysis.

Results: We found that FoxM1 was upregulated in cyst-lining epithelial cells in polycystin-1-deficient murine kidneys and human ADPKD kidneys. Inhibition of FoxM1 with FDL-6 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in Pkd1 mutant mice (all p < 0.01). Targeting FoxM1 also decreased renal fibrosis in long last Pkd1 mutant kidneys. Upregulation of FoxM1 promotes cyst growth through: 1) regulation of the expression of Akt and Stat3 and activation of ERK and Rb signaling to increase cystic renal epithelial cell proliferation, 2) inhibition of p65-dependent cystic renal epithelial cell death, 3) facilitation of the recruitment and retention of renal macrophages, and 4) upregulation and activation of fibroblast markers to promote renal fibrosis. In addition, FoxM1-dependent macrophage recruitment was associated with upregulation of monocyte chemotactic protein 1 (MCP-1) and inflammatory cytokine TNFα. Further, we identified novel FoxM1 target genes by ChIP-seq analysis, which may connect FoxM1 signaling to the ciliopathy hypothesis in PKD.

Conclusions: FoxM1 promotes renal cyst growth and fibrosis in ADPKD through Akt, ERK, Rb and STAT3 signaling as well as NF-kB and ciliopathy associated signaling. Targeting FoxM1 in cystic renal epithelial cells may be a viable new therapy for ADPKD.

Allosteric Mechanism of PC1 Tethered Agonist-Mediated Signaling
Shristi Pawankar,1 Brenda S. Magenheimer,2 Ericka Nevarez Munoz,2 Robin L. Masar,1 Yinglong Miao,2 University of Kansas College of Liberal Arts and Sciences, Lawrence, KS; 3University of Kansas Medical Center, Kansas City, KS.

Background: Polycystin-1 (PC1) is the 11-transmembrane protein product of the human autosomal dominant polycystic kidney disease (ADPKD) gene PKD1. PC1 functions as an atypical GPCR and shares multiple features with the Adhesion GPCRs, including a GPCR autoproteolysis-inducing (GAIN) domain that catalyzes cis-cleavage of the receptors into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. We previously reported that CTF-mediated signaling to an NFAT promoter-luciferase reporter is dependent on the presence of the stalk, is reduced by ADPKD-associated missense mutations within the stalk, and can be rescued by synthetic, stalk-derived peptides, supporting a tethered ligand mechanism of PC1-G protein signaling (JASN 2018;29:671, JASN 2019;30:882).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

400
Methods: We have combined highly complementary experiments and computer simulations to investigate the mechanism of the tethered agonist-mediated signaling of PC1 CTF. A computer model of the human PC1 CTF was generated using the cryo-EM structure of the PC1-PC2 complex with important missing regions added through I-TASSER homology modeling. All-atom enhanced simulations (1000 ns) using a robust Gaussian accelerated molecular dynamics (GaMD) technique were performed, followed by calculations of residue correlation matrices and free energy profiles. GaMD simulation-predicted residue interactions important for WT stalk-mediated activation of PC1 CTF were validated with newly designed mutation experiments.

Conclusions: Complementary experiments and simulations studies support the function of the PC1 CTF stalk region as a tethered agonist and suggest a mechanism whereby it can induce TOP-pore loop interactions which can be further translated to the GaMD for G protein activation. This heightened knowledge is expected to facilitate future drug design efforts targeting this function of PC1 for more effective treatments of ADPKD.

PO1241

Analysis of Calcium Signaling in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Dorien Van Giel,1 Jean-Paul Decuyper,1 Djalila Mekahl,1,2 Rudi Vennekens.1

Background: ADPKD is an inheritable kidney disease characterized by the development of fluid-filled renal cysts, mainly caused by mutations in the PKD1 and PKD2 genes, leading to loss of renal function. Molecular mechanisms underlying cystogenesis are poorly characterized but it is postulated that disturbed calcium homeostasis is a primary event in cystogenesis. The precise molecular players that cause this disturbance are largely poorly explored especially in human cell types. We therefore aim to characterize the profile of calcium-coupled G-protein coupled receptors (GPCRs) in a human renal epithelial cell models, to identify which receptors are present, whether their function is affected in ADPKD and whether they can be used to modulate cyst formation and growth.

Methods: Urine-derived conditionally immortalized proximal tubule epithelial cells (ciPTCs) of ADPKD patients and healthy controls were screened for calcium-coupled GPCRs, using an agonist library on Fura-2 loaded cell populations seeded in a 96-well format. Validation of specific hits was done using single-cell measurements with a fluorescence microscope and built-in perfusion system in the ciPTCs as well as in tissue-derived conditionally immortalized cystic cells (ciCCs). Matrigel-based 3D cell culture was used to grow ciCCs to assess their ability to form cystic structures. Structures were stained with nuclear and cytosolic stains and imaged via confocal microscopy.

Results: From a library of 418 GPCR agonists a selective amount of calcium-coupled GPCRs was found functionally active in ciPTCs. ciPTCs from both healthy controls and ADPKD patients were found to functionally express purinergic -, histamine -, serotonin and dopamine receptors. In single-cell experiments, we did not find any significant differences in functionality between healthy controls and ADPKD patients, but observed that response characteristics are mainly donor-specific, suggesting patient-specific disease mechanisms. ciCCs grown in 3D cell culture were found to form hollow, cell-lined cyst-like structures.

Conclusions: We describe the first thorough characterization of calcium-coupled GPCRs in a human proximal tubule epithelial cell model. We established a 3D cyst growth assay using tissue-derived cystic cells to explore the possibility to use the identified GPCRs to modulate cyst formation and growth.

Loss of Polycystin Function in Lymphatic Cells Impair CPT1a Expression and Fatty Acid Uptake
Denis Basquin, Jinqing Liang, Terry J. Watnick, Patricia Outeda. University of Maryland School of Medicine, Baltimore, MD.

Background: Homozygous Pkdl or Pkd2 null mutant mice die at mid-gestation due to vascular abnormalities including edema and hemorrhage. We have previously shown that edema in Pkd1 and Pkd2 knock out mice is due to abnormal lymphatic morphogenesis, with grossly dilated, blood filled dermal lymphatic vessels. Because proper lymphatic development is supported by fatty acid β-oxidation (FAO), we probed fatty acid transport in Pkd1/Pkd2 lymphatic endothelial cells (LECs).

Methods: Pkd1- and Pkd2- mutant LECs were isolated from mouse E14.5 embryos or generated using lentiviral shRNAs against PKD1 or PKD2 in human dermal LECs (HDLECs). Protein levels of PC1, PC2 and CPT1a were determined by western blotting and CPT1a/CPT2 mRNA levels were analyzed by qRT-PCR. Fatty acid uptake was assessed by BODIPY® 585/596 C12, staining of control and Pkd mutant LECs pre-incubated with or without 50 µM palmitate, and counterstained with mitotracker. Cells were imaged by confocal microscopy and the relative abundance of lipid droplets were quantified using ImageJ software. Each experiment was repeated 3 times and pairs of means (mutant versus control) were compared using Student’s T-test.

Results: Embyronic Pkd1- and Pkd2- murine LECs exhibit a robust decrease of CPT1a protein levels. In addition, CPT1a protein levels were significantly reduced in PKD1 and PKD2 depleted HDLECs, suggesting a conserved role of Pkd1/2 in CPT1a regulation. PC1 and PC2 depletion in HDLECs results in an accumulation of cytoplasmic lipid droplets which often co-localized with mitochondria, indicative of impaired fatty acid utilization. The ability of PKD mutant cells to metabolize fatty acids is further challenged by pre-treatment with 50µM palmitate, which exacerbates the accumulation of lipid droplets.

Conclusions: Our results highly suggest that polycystin function is required to maintain normal levels of CPT1a expression and fatty acid transport to mitochondria in LECs. We thus speculate that a defect in FAO with consequent dysregulation of gene expression is the basis of impaired lymphangiogenesis in Pkd1/2 mutant embryos.

Pharmacological Activation of Long-Form PDE4 Enzymes Suppresses Disease Progression in PkdHRC/RC and Pkd1 Knockout (iKspCrePkd1/lox,lox) Mouse Models of ADPKD
David J. Henderson,1 Xiaofang Wang,2 Li Jiang,2 Miles D. Houslay,1 Peter C. Harris,2 Julia M. Adam,3 David R. Adams,3 Adele ROWLEY,3 Vicente E. Torres.1 1Miro Ltd, Glasgow, United Kingdom; 2Mayo Clinic Minnesota, Rochester, MN.

Background: Upregulation of cAMP signaling is thought to promote cystogenesis in ADPKD. Phosphodiesterase 4 (PDE4) enzymes degrade cAMP and contribute to its compartmentalized signaling. We have previously described novel small molecules that allosterically activate long isoforms of PDE4 and lower intracellular cAMP. Here we demonstrate significant efficacy with MR-L22, an advanced PDE4 activator compound, on suppressing cystic burden and preserving kidney health in orthologous models of ADPKD.

Methods: The effects of the long isoform PDE4 activator MR-L22 (administered or vagally) were assessed in rapidly (iKspCre (RC/RC mice) and more effective than vasopressin V2 receptor antagonists.

Results: Compared to vehicle treated controls, MR-L22 treated Pkd1/1 mice exhibited reduced kidney CAMP levels, cystic indices, kidney weight/body weight ratios (Kw/Bw) and MRI measured total kidney volumes (TKV) (Table and Figure). Long isoform PDE4 activation significantly protected kidney function and, when compared to tolvaptan, animals receiving MR-L22 produced significantly less urine volume. MR-L22 also suppressed the aggressive cystic disease exhibited by tamoxifen induced (P10) iKspCrePkd1/lox mice, where Kw/Bw and cystic indices were reduced in comparison to vehicle control (results not shown).

Conclusions: Small-molecule activators of long isoforms of PDE4 suppress cystic disease progression in key translational models of ADPKD and may be better tolerated and more effective than vasopressin V2 receptor antagonists.

RGLS4326 Increases Urinary PC1 and PC2 Levels in Individuals with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Edmund Lee,1 Tania M. Valencia,1 Tate Owen,1 Steven Neben,1 Karl F.Cremer,3 Rekha Garg,2 Denis Drygin,1 Christopher J. Ward,3 Alan S. Yu,2 Vishal Patel.3

1Regulus Therapeutics Inc, San Diego, CA; 2University of Kansas Medical Center, Kansas City, KS; 3The University of Texas Southwest Medical Center Department of Internal Medicine, Dallas, TX; 4PharmaDRS Consulting LLC, San Diego, CA.

Background: ADPKD is caused by mutations of either PKD1 or PKD2 genes, leading to reduced function of their respective protein products PC1 and PC2. Both proteins are secreted in exosomes, and their urinary levels inversely correlate with ADPKD severity. RGLS4326, a novel oligonucleotide inhibitor of miR-17, preferentially delivers to kidney tubules and cysts, derepresses miR-17 targets Pkd1 and Pkd2, increases PC1 and PC2, and attenuates cyst growth in multiple PKD mouse models. Whether RGLS4326 treatment would increase PC1 and PC2 in individuals with ADPKD was unknown.

Methods: An open-label, adaptive design, dose-ranging Phase 1b clinical study is ongoing to evaluate RGLS4326 safety, pharmacodynamics and pharmacokinetics in individuals with ADPKD. The study will enroll ~27 patients (9 per cohort) treated subcutaneously with one of three RGLS4326 doses (1, 0.3, and 0.1 or 0.5 mg/kg Q2W x 4 doses) and will be followed for 28 days after the last dose (Day 71). The major inclusion criteria are Mayo Imaging Classification of 1C, 1D, or 1E, and GFR between 30-90 mL/min/1.73 m2. The urinary biomarkers include PC1 and PC2 on exosomes, kidney injury marker 1 (KIM1), and neutrophil gelatinase-associated lipocalin (NGAL).

Results: Nine patients (mean GFR 49 mL/min/1.73 m2, mean age 50 yr) were enrolled in the first cohort; each patient received four doses of 1mg/kg of RGLS4326 Q2W. RGLS4326 was well tolerated with no serious adverse events. PK profiles were similar to healthy volunteers, with a plasma half-life of 9 hours and plasma AUC levels after the first cohort; each patient received four doses of 1mg/kg of RGLS4326 Q2W.

RGLS4326 was well tolerated with no serious adverse events. PK profiles were similar to healthy volunteers, with a plasma half-life of 9 hours and plasma AUC levels after the first cohort; each patient received four doses of 1mg/kg of RGLS4326 Q2W.

Beneficial Effects of Bempedoic Acid Treatment in ADPKD Mice
Kendra R. Hallow,1 Hui Li,1 Biagio Sartia,1 Saman Sepheh,1 Jessica Pham,1 Valeria Mancino,1 Stephen L. Pinkosky,2 Nuria M. Pastor-Soler,1 1University of Southern California Keck School of Medicine, Los Angeles, CA; 2Esperion Therapeutics Inc, Ann Arbor, MI.

Background: ADPKD has limited therapeutic options. Bempedoic acid (BA), an inhibitor of ATP citrate-lyase (ACLY), FDA-approved for hyperlipidemia, catalyzes a key step in cholesterol synthesis that is important for cell growth and proliferation. BA also activates AMPK in mice. We hypothesized that BA could be a novel ADPKD therapy by inhibiting cyst growth and proliferation and promoting oxidative metabolism via ACLY inhibition and AMPK activation.

Methods: Murine Pkd1-null kidney cell lines derived from either proximal tubule (PT) or collecting duct (IMCD) were grown in Matrigel cultures and treated with BA before cyst analysis by microscopy. In vivo, male and female Pkd1fl/fl, Pkd1fl/C125R, Tg-OR-Cre transgenic C57BL/6 mice were induced with IP doxycycline injection on P10 & 11. Mice were then treated with BA (30 mg/kg/d) ± tolvaptan (30-100 mg/kg/d) by oral gavage from P12-21. As measures of disease severity, total kidney weight to body weight (TKW/BW) and renal BUN were measured. Kidney homogenates were then treated immunoblotted for expression of key disease biomarkers and other relevant cell signaling markers.

Results: BA dramatically inhibited cystic growth in 3D cultures in PT and IMCD Pkd1fl/fl kidney cells. In ADPKD mice, BA reduced TKW/BW vs. vehicle at euthanasia (6.9 vs. 11.9%; P<0.05). Similarly, tolvanat (100 mg/kg/d) reduced TKW/BW to 7.8% vs. vehicle (P<0.05). Addition of BA to tolvanat caused a further reduction in TKW/BW (4.9%; P<0.05) vs. tolvanat alone. BA reduced BUN vs. vehicle (59 vs. 107 mg/dL; P<0.05). Tolvaptan also decreased BUN vs. vehicle at 30 mg/kg/d (68 vs. 86 mg/dL; P>0.05). Again, addition of BA to tolvanat at 30 mg/kg/d caused a further significant reduction in BUN (38; P<0.05). BA reduced ACLY and stimulated AMPK activity in kidneys vs. controls. BA also inhibited mTOR and ERK signaling, which are upregulated in ADPKD. BA also sharply reduced kidney injury markers KIM-1 and, to a lesser extent, NGAL. These BA effects occurred alone and in concert with tolvanat.

Conclusions: BA inhibited cyst growth in vitro and ADPKD severity in vivo. Combined BA and tolvaptan treatment further improved ADPKD outcomes in vivo. BA significantly reduced kidney injury markers and mTOR and ERK signaling. BA may be a promising new ADPKD therapy, having beneficial effects on disease severity when used alone with tolvanat in mice.

Unraveling Fundamental Mechanisms of UMOD Quality Control and Their Role in UMOD-Associated CKD
Silvana Bazus-Valenti,1,2 Eriene-Heidi Sidhom,1,2 Moran Dvola levit,1,2 Valeria Padovano,1 Julie Renigon,1 Keith H. Keller,1 Nina Himmerkus,1 Markus Bleich,3 Kerim Mutig,4 Sebastian Bachmann,4 Astrid Weins,4 Jillian Shaw,1 Jamie L. Marshall,3 Maria Alimova,1 Anna Greka,1 1Broad Institute of MIT and Harvard, Cambridge, MA; 2Department of Medicine, Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; 3Department of Physiology, Physiology of Membrane Transport, Christian-Albrechts-University, Kiel, Germany; 4Department of Functional Anatomy, Charité-Universitätsmedizin, Berlin, Germany.

Background: UMOD is a GPI-anchored protein expressed in the Thick Ascending Limb of Henle. When properly folded, it transits from the ER to the membrane via the Golgi. Little is known about UMOD’s specific trafficking partners and its quality control mechanisms in the early secretory pathway. Mutations in UMOD disrupt protein folding and promote ER retention, triggering ER-stress pathways and cell death that causes UMOD-associated dominant-tuberous-intestinal kidney disease. It was recently shown that mutant misfolded MUC1-cis is trapped in TME9-containing vesicles and that treatment with compound BRD4780, releases it to the lysosome. We hypothesize that a similar pathogenic quality control mechanism is active in ADTKD-UMOD.

Methods: Co-immunoprecipitation (co-IP) of UMOD and TMED cargo-receptors was assessed in HEK293 cells transfected with wild type (wt) or mutant (C126R) human UMOD. Next, we performed untargeted Affinity Purification Mass Spectrometry followed by tandem MS to generate a list of UMOD interactors. We also conducted in vivo studies in UMODfl/C125R mice.

Results: We identified distinct wt and mutant UMOD interactomes using an unbiased AP-MS proteomics approach. Several interactors, including members of the TMED family, were significantly enriched in the mutant UMOD interactome. Targeted co-IP in lysates of HEK293 cells transfected with UMOD and interacting protein candidates confirmed these results. Proteomics were further characterized, when pulling down TMEDs, we found abundant immature non-glycosylated UMOD, suggesting entrapment in early secretory compartments. In vivo, treatment with BRD4780 was suggestive of disrupted interactions between mutant UMOD and interacting partners responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTKD-UMOD.

Restricted Feeding Diet Overrides the Cyst Promoting Effect of Cisplatin-Induced Renal Injury in Both Ifh88 and Pkd2 Mutant Mouse Models
Zhang Li, Sreelakshmi Cherakara, Courtney J. Haycraft, Bradley K. Yoder. The University of Alabama at Birmingham, Birmingham, AL.

Background: Multiple renal cystic diseases, including PKD, are caused by dysfunction of the primary cilium. Links between cilia dysfunction, cyst formation, and renal injuries have been reported with evidence showing that injury exacerbated the rate of cyst formation in kidney. In addition, dietary restriction has been reported to ameliorate cyst growth in several PKD animal models. Here we evaluate the effects of both renal injury and dietary restriction on cyst formation in two different cilia-mutant mouse models.

Methods: To test the effect of renal injury on cyst formation, we established an alternative approach to induce chronic renal injury by utilizing a low-dose repeated cisplatin treatment (5.0mg/kg IP; once a week for 4 wks). To evaluate the impact of dietary restriction and renal injury on cyst formation, adult induced conditional Ifh88 and Pkd2 mutant mice were utilized. The study design including cisplatin treatment along with 85 % dietary intakes are shown in Figure 1. Mice were euthanized at 5 wks post last cisplatin injection for analysis. Multiple features including renal injury, proliferation, fibrosis, macrophage accumulation, and cystic index were analyzed.

Results: Low-dose repeated cisplatin treatment resulted in increased Kim1 expression in both Ifh88 and Pkd2 mutant mice compared to controls. Analysis of the cystic phenotype showed that there was a significant increase in cyst formation in mutant mice after cisplatin compared to saline-treated group and the location of cysts corresponded to the injured regions. Interestingly, the rapid cyst formation in cisplatin-treated kidneys was ameliorated when the mice were on the restricted diet (Figure 1). More importantly, kidneys from mice with restricted feeding displayed decreased levels of proliferation, fibrosis, macrophage accumulation, and cystic index were analyzed.

Conclusions: These data show that low-dose repeated cisplatin treatment could be used as an alternative approach to IRI to accelerate cyst formation in both ifh88 and pkd2 mutant models. More importantly, it suggests that cyst progression associated with injury to cystic kidney disease could be ameliorated through dietary interventions.

Peroxisomes Are Dispensable for Normal Renal Function
Yohan Bignon,1 Camille Ansermet,2 Gabriel Centeno,1 Andy Garcia,1 Sylvain Pradervand,3 Dmitri Firsov,3 1Université de Lausanne Faculté de biologie et médecine, Lausanne, Switzerland; 2Genomic Technologies Facility, University of Lausanne, Lausanne, Switzerland.

Background: Peroxisomes are single membrane-bound cellular organelles identified in the kidney in 1954. Peroxisomes are ubiquitously present in eucaryotic cells with highest abundance in renal proximal tubule cells and hepatocytes. The variety of metabolic and antioxidant functions in which peroxisomes are involved is highlighted by human mutations in PEX genes encoding peroxisomal proteins required for proper peroxisome biogenesis. Hence, the complete loss of peroxisomes causes Zellweger’s spectrum disorders (ZSD), devastating multiorgan failure which include renal impairment. However, the (patho)physiological role of peroxisomes in the kidney remains unknown.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author. 403
Methods: Here we addressed the role of peroxisomes in renal function in male and female adult rats with conditional ablation of Pex5-driven peroxisome biogenesis in the renal tubule (cKO mice).

Results: Functional and histological analyses of both infant and adult cKO mice did not reveal any overt kidney phenotype. However, male cKO mice exhibited substantial reduction in kidney weight and body weight ratio. Stereological analysis of electronic microscopy results showed a complete absence of peroxisomes accompanied by increase in the number and in the volume of mitochondria in proximal tubule cells of cKO mice. Integrated deep transcriptome-sequencing and metabolome analyses revealed profound reprogramming of a great number of metabolites, including upregulation of different classes of steroids, such as plasmalogens and sphingomyelins (two major classes of membrane lipids) and the metabolism of glutathione. Although this analysis suggested compensated oxidative stress, four weeks of high fat feeding challenging the ability of proximal tubule cells to metabolize lipids significantly increased mitochondrial dysfunction.

Conclusions: We demonstrate that renal tubular peroxisomes are dispensable for normal renal function. This indicates a large flexibility of proximal tubule cells both in terms of lipid membrane composition and metabolic/antioxidant functions. Our data also suggest that renal impairments in ZSD patients are of extrarenal origin.

PO1251
Weight Loss to Slow Cyst Growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Kristen J. Nowak,1 Victoria Catanecchi,1 Timothy L. Kline,1 Wei Wang,1 Zhiying You,1 Kristen Bing,1 Bhavya Poudyal,1 Cortney Steele,1 Michel Chonchol,1 Berenice Y. Gitomer,1* University of Colorado - Anschutz Medical Campus, Aurora, CO; 2Mayo Clinic College of Medicine and Science, Rochester, MN.

Background: Recent studies in animal models of ADPKD support that food restriction can profoundly slow cyst growth and maintain renal function. We have also reported that overweight and obesity are strong independent predictors of ADPKD progression. Thus, it is plausible that weight loss, caloric restriction, and/or periods of fasting may slow ADPKD progression in humans; however, the feasibility of these dietary interventions, and whether the driver of therapeutic efficacy is periods of fasting or reduction in body weight, is unknown.

Methods: We conducted a one-year study evaluating feasibility of delivery of a behavioral weight loss intervention based on either daily caloric restriction (DCR) or intermittent fasting (IFM) in adults with overweight/obesity, ADPKD, and eGFR ≥30 m/min/1.73m2 (targeted weekly energy deficit of ~34% in both groups). We also evaluated the safety, acceptability, and tolerability of each intervention, and obtained exploratory insight into changes height-corrected total kidney volume (htTKV).

Results: 28 participants (16F/12M; average age 40.9 yrs, average BMI 34.7 kg/m², eGFR of 69±23 m/min/1.73m²) were randomized to either DCR (n=15) or IFM (n=13).

- Clinical significance: (~5%) weight loss was achieved in both groups at month 3 (DCR: -7.1±4.2%; IFM: -5.5±3.3%). At 12 months DCR lost additional weight while weight loss in IFM plateaued (DCR: -9.1±6.0%; IFM: 4.9±5.6%; p<0.05 DCR vs. IFM).

- DCR had a more favorable safety, tolerability, and adherence profile than IFM. Annual htTKV %Δ was qualitatively low in both groups in comparison to histological data, despite comparable clinical characteristics (DCR: 1.5±3.4%; IFM: 1.7±6.1%). Annual htTKV %Δ was highly correlated with %Δ in weight (r = 0.68, p<0.001). Abdominal saturated adipose tissue (SAT), visceral adipose tissue (VAT) and total adipose tissue (TAT) quantified by MRI were all reduced at one year (p<0.05). Change in VAT (r = 0.49, p<0.05) and TAT (r = 0.46, p<0.05) also correlated with annual htTKV %Δ.

- Conclusions: DCR, and particularly DCR, were feasible interventions over a one-year period in adults with ADPKD and overweight/obesity and showed favorable effects on kidney weight as compared to historical controls, supporting conduction of a phase II randomized controlled trial.

PO1252
Social Determinants of Health (SDOH) and Healthcare Resource Utilization (HRU) in Autosomal Dominant Polycystic Kidney Disease (ADPKD) by CKD Stage
Karl M. Kilgore,1 Iman Mohammad,1 Hina Japés,2 Laura L. Frank,1 Tazin R. Aijaz,2 Christie Teigland,1 Kristin Pareja,1* Avalere Health, Washington, DC; 2Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ.

Background: SDOH contribute to health disparities in CKD. This study describes SDOH and HRU among ADPKD patients with commercial (COM) insurance compared to a lower income managed Medicaid (MM) population.

Methods: The study included 8,766 COM and 5,416 MM patients from a national claims database. Patients had ≥2 ADPKD diagnoses between 7/1/2016- 12/31/2018 and were continuously enrolled in the study period. Patients were linked to SDOH by 9-digit ZIP address providing a precise assignment compared to Census data. HRU included inpatient days and emergency room (ER) visits per 1000 patients per month (PPPM) over 1-year follow-up.

Results: COM patients were more likely to be female (60% vs 54% COM) and on average 8 years younger. MM patients had 1.3x higher Charlson Comorbidity Index (CCI) scores, 40% lower income, were 2x more likely to live below federal poverty level, 1.3x less likely to complete high school, 2.7x more likely to speak English not well or at all, 2.6x less likely to own a vehicle, 53% more likely to be unemployed, and lived in a poverty stricken census tract. Social determinants of health such as healthcare access area 6.8%-6.4% more often. The differences between payers were consistent across CKD stages, except CCI scores increased with higher CKD stage for both groups. Disparities in income, unemployment rates and provider shortages tended to increase with CKD stage. Mean bed days ranged from 34.6 (Stage 1) to 402 (Stage 5), and ER visits PPPM ranged from 38 to 114 for COM and 154 to 376 for MM. Hospital readmissions and use of post-acute care were high in both groups, with 15% of COM and 20% of MM readmitted within 30-days of inpatient admission. Median annual % increase in total charges was 25%-35% MM having at least one PAC stay during follow-up. HRU increased with CKD stage.

Conclusions: ADPKD patients have large variation in SDOH by type of insurance. Lower social status of MM patients may be associated with higher HRU, and these differences likely relate to increased healthcare and social service progresses. In the clinical care of this vulnerable population, consideration of SDOH such as language barriers, transportation insecurity, and poverty is recommended.

PO1254
Overweight and Obesity Predict Kidney Growth in Children and Young Adults with ADPKD
Cortney Steele, Zhiying You, Heather Farmer-Bailey, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: We have previously reported that overweight and obesity are independently associated with more rapid progression in adults with early-stage autosomal dominant polycystic kidney disease (ADPKD). We now evaluate whether overweight and obesity are also associated with faster kidney growth in children and young adults with ADPKD.

Methods: 54 non-diabetic children and young adults (6-25 years of age) with ADPKD and estimated glomerular filtration rate (eGFR) >80 ml/min/1.73m2 who participated in a 1-year controlled trial. Patients were categorized based on BMI (if <18 years; n=27) or BMI percent for age, sex, and height (if ≥18 years; n=27) as normal weight (n=40 [74%]) or overweight/obese (n=14 [26%]). The longitudinal (1-yr) association of overweight/obesity with change in height-corrected total kidney volume (htTKV) by magnetic resonance imaging was evaluated using multinomial logistic regression models.

Results: Mean±sd. age was 18±5 years, annual % change in htTKV was 6.1±9.0%, and eGFR (full-age spectrum equation) was 112±18 ml/min/1.73m2. The annual % change in htTKV was 5.5±9.1% in the normal weight participants and 7.9±8.6% in overweight/

Metabolomic Changes over 1 Year Following Drug or Lifestyle Interventions in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Kortney Steele, Jelena Klawitter, Wei Wang, Zhiying You, Victoria Catenacci, Taylor Struemph, Diana George, Berenice Y. Gitomer, Godela M. Brosnaham, Michael Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease. Studies have shown differences in metabolomic profiles in those with ADPKD; however few studies assess change over time.

Methods: We performed metabolomics to assess patterns of change across four groups of participants with ADPKD pooled from 2 randomized clinical trials: placebo control (CON), metformin (1,000 mg/day) (MET), intermittent fasting (IMF; 3 day/ wk of 80% energy restriction from baseline weight maintenance requirements), and daily caloric interventions. Further changes are depicted in Figure 1.

Results: Baseline characteristics for each trial included CON (n=22, 14 female (F), 49±7 yrs of age (means±s.d.), estimated glomerular filtration rate [eGFR] 73±13 ml/min/1.73m², body mass index (BMI) 29±3.4 kg/m²), MET (n=22, 14 F, 48±7 yrs of age, eGFR 69±14 ml/min/1.73m², BMI 29±7.7 kg/m²), IMF (n=10, 5 F, 47±6 yrs of age, eGFR 77±16 ml/min/1.73m², BMI 34±6.5 kg/m²), and DCR (n=9, 5 F, 46±13 yrs of age, eGFR 68±21 ml/min/1.73m², BMI 34±1.5 kg/m²). Age and eGFR did not differ between groups. BMI was higher in the IMF compared to CON (p=0.031). Metabolite changes are depicted in Figure 1.

Conclusions: There are changes at one year in metabolites in adults with ADPKD between control, metformin, intermittent fasting, and daily caloric interventions. Further research is needed to identify metabolomic profile shifts involving drug and dietary interventions.

POI1256

Identification of CLC-5, the Electrogenic 2Cl-/H+ Exchanger, as the Dominant Apical Chloride Secretory Transporter in Kidney Cyst Epithelium in Tuberous Sclerosis
Sharon L. Barone, Marybeth Brooks,1,2 John J. Bissler,3 Jane J. Yu,4 Kamyar A. Zadeh,1,3 Manoocher Soleimani,2,4 University of New Mexico Health Sciences Center, Albuquerque, NM; 2Raymond G. Murphy VA Medical Center, Albuquerque, NM; 3Le Bonheur Children’s Hospital and St. Jude Children’s Research Hospital, Memphis, TN; 4University of Cincinnati College of Medicine, Cincinnati, OH.

Background: Cyst expansion in Tuberous Sclerosis Complex (TSC) or PKD requires secretion of chloride into the cyst lumen as the driving mechanism for salt accumulation. In PKD, Cl secretion into the cyst lumen is mediated via the eAMP/PKA-stimulation of CFTR in principal cells consequent to the V2 receptor activation by AVP. Kidney cystogenesis in TSC differs from PKD in that cyst epithelia in TSC is comprised of genotypically normal A-intercalated cells, which do not exhibit noticeable expression of either CFTR or the V2 receptor. The identity of the Cl secreting molecule(s) in TSC cyst epithelia remains unknown. Based on RNA Seq analysis in kidneys of Tsc1 KO mice, we hypothesized that the chloride transporter CLC-5 is expressed on the apical membrane of A-intercalated cells in cyst epithelia of humans and animal models of TSC. CLC-5 is a 2Cl-/H+ exchanger that is located in collecting duct A-intercalated cells where it is predominantly localized to endosomes and plays a critical role in dissipating H+ secretion and membrane depolarization by H+-ATPase. This allows parallel movement of Cl and H+ into the endosomes.

Methods: Double immunofluorescence studies utilizing CLC-5 and H-ATPase antibodies were performed on kidney tissue from mice with principal cell inactivation of Tsc1 (Tsc1-Agon2 Cre), p-p.eptide inactivation of Tsc1 (Tsc/Remr Cre), principal cell inactivation of Tsc2 (Tsc2-Agon2 Cre), global heterozygous Tsc2(Tsc2+/−) and cysts from TSC patients.

Results: Double immunofluorescence labeling demonstrated remarkable colocalization of CLC-5 and H-ATPase on apical membranes of an overwhelming numbers of cyst epithelial cells in all models of TSC, including the human kidney cysts. In contrast, kidney cysts in Pkd1 mutant mice showed no apical CIC-5 expression and very few H-ATPase expressing cells.

Conclusions: These are the first reports on apical membrane localization of CLC-5 in A-intercalated cells in any disease state, and suggest that similar to late endosomes/lysosomes, CLC-5 and H-ATPase may function synergistically on cyst epithelia by secreting Cl and H+ into the cyst lumen. These results strongly point to enhanced translocation of CLC-5 and H-ATPase from late endosomes/lysosomes to the apical membrane of cyst epithelia in TSC.

Two Years In: The Development and Basic Characteristics of a National Patient-Powered Registry in ADPKD
Elise Hoover,1 Beverly A. Benson,1 Neera K. Dahl,2 Berenice Y. Gitomer,1 Amy Manelli,1 Michal Mrug,3 Meyeon Park,3 Chris Rusconi,1 Stephen L. Seliger,1 Ronald D. Perrone,1 Terry J. Watnick.2,4 PKD Foundation, Hyde Park, IL; 2Yale University, New Haven, CT; 3University of Colorado - Anschutz Medical Campus, Aurora, CO; 4The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 5UCSF Medical Center, San Francisco, CA; 6University of Maryland Baltimore, Baltimore, MD; 7Tufts Medical Center, Boston, MA.

Background: The therapeutic pipeline in autosomal dominant polycystic kidney disease (ADPKD) has grown, generating a need for more patient participation in clinical trials. To facilitate US ADPKD patient enrollment and to encourage the utilization of patient-reported outcomes in trial design, the PKD Foundation (PKDF) designed a national ADPKD Registry.

Methods: The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdeare). Participants are consented through the online system and complete a series of modules. The Core Questionnaire includes diagnosis, latest kidney function tests, and comorbidities. Family history, diet and lifestyle, quality of life, and complications of liver cysts, and vascular outcomes are queried.

Results: Between 9/4/19 and 5/1/21, 1,580 ADPKD patients have registered and completed the Core Questionnaire. Participants have a median age of 49 years, 73% have not reached ESKD, and 79% reported a family history of the disease. Currently, the cohort is 71% female, 93% Caucasian, 4.8% Hispanic/Latino and 2.5% African American. Strategic efforts are in development to increase diversity in the cohort. Nearly three quarters of participants had not previously participated in research, with only 27% indicating that they had been in another PKD study or clinical trial. All participants have consented to be contacted about future studies. Many will likely qualify for ongoing trials based on completed module data. Thus far, the Registry platform has made over 2,200 participant contacts regarding six clinical studies, with some individual overlap due to similar eligibility criteria.

Conclusions: The ADPKD Registry is a longitudinal research tool intended to capture ADPKD patient-reported data and is designed to impact research in multiple ways. It will allow for a range of outcomes in ADPKD from early disease through dialysis and post-transplant outcomes. Additionally, modules on health care access & utilization and COVID-19 impact will help the PKDF better understand the challenges of this community.

POI1258

Polycystic Kidney Disease and Race
Alexandra Hayward, Riia L. McGill, Milida R. Saunders, Arlene B. Chapman. University of Chicago Division of the Biological Sciences, Chicago, IL.

Background: Racial/ethnic differences in the development of kidney failure (ESKD) and transplant (TX) access are well-documented. ESKD is anticipated in familial autonomic polycystic adenomatous polycystic kidney disease (ADPKD), providing the opportunity for greater ESKD preparation. We sought to define the impact of race on ESKD/TX outcomes in ADPKD.
Methods: White (W), African-American (A), or Hispanic (H) ADPKD patients were identified in USRDS 1(2000-6/2018); demographic and laboratory data were obtained. Median income was derived from US Census. Models included: age at ESKD (linear), pre-emptive TX (logistic), and TX after dialysis initiation (Cox), adjusted for age, sex, albumin, hemoglobin, eGFR, insurance, income, ESKD Network, and employment, with W as referent.

Results: Among 41,485 patients, (77.3% W, 13.3% A, 9.4% H), characteristics/outcomes are shown in Table 1. AA and H had lower median income and less private insurance, pre-ESKD nephrology care, and employment. For AA and H, peritoneal dialysis and TX were less common than in W. Albumin, hemoglobin, and GFR were lowest in A. ESKD occurred 2.2 ± 0.2 and 4.8 ± 0.3 years earlier in A and H, compared to W. Adjusted odds of pre-emptive TX were 0.38(0.33, 0.42) and 0.47(0.40, 0.55) for A and H. Adjusted hazards for TX after dialysis initiation were 0.60(0.55, 0.65) for A and 0.78(0.72, 0.85) for H, P<0.001 for all TX rates for A vs W by network are shown in Figure 1.

Conclusions: Despite the hereditary nature of ADPKD, renal outcomes differed by race, attributed to in part, economic and geographic factors. Health inequity is a contributing factor to patient outcomes in ADPKD that needs to be addressed.

PO1260
Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Kristen L. Nowak,1 Heather Farmer-Bailey,1 Wei Wang,2 Zhijing You,1 Cortney Steele,1 Melissa A. Cadinaparrornchai,1 Jelena Klavitter,1 NicolePetel,1 Diana George,1 Anna Jovanovich,2 Danielle Sorensen,1 Berenice Y. Gitomer,1 Michel Choncho1
1Rocky Mountain Hospital for Children, Denver, CO; 2VA Eastern Colorado Health Care System, Aurora, CO; 1Children’s Hospital Colorado, Aurora, CO.

Background: Clinical manifestations of autosomal dominant polycystic kidney disease (ADPKD) can begin in childhood, including evidence of vascular dysfunction, an important predictor of cardiovascular events and mortality. Curcumin is a polyphenol found in turmeric that reduces vascular dysfunction in rodent models and humans free from ADPKD. It also slows kidney cystic progression in a murine model of ADPKD.

Methods: We hypothesized that curcumin supplementation would reduce vascular dysfunction (brachial arterial flow-mediated dilation [FMD]) and aortic pulse-wave velocity (PWV) in children and young adults with ADPKD. In a prospective, randomized, controlled, double-blind trial, n=68 participants 6-25 years of age with ADPKD and an estimated glomerular filtration rate >80 mL/min/1.73 m² were randomized to receive either curcumin supplementation (25 mg/kg body weight/day) or placebo administered in powder form for 12 months. We also assessed change in circulating and urine biomarkers of oxidative stress/inflammation and kidney function. Participants with baseline PWV ≥120 cm/sec were excluded from the aortic PWV analysis.

Results: Seven participants completed the trial. Participants were 18±5 (means±d.) years, 55% female, and 85% non-Hispanic White. The co-primary endpoint, FMD (%), did not change in the curcumin group (baseline: 9.4±4.1; 12-months: 10.6±3.9, compared to the placebo group (baseline: 8.9±4.0; 12-months: 9.3±4.5; p=0.01), and the other co-primary endpoint, APWV (cm/sec) was 51.7±12.0; 12-months: 51.7±8.1; placebo: baseline: 51.8±8.2 cm/sec; 12-months: 52.5±9.5 cm/sec; p=0.53). There was no curcumin specific reduction in vascular oxidative stress, nor any changes in mechanistic biomarkers. hTrkV also did not change over the 12-month study with curcumin administration as compared to placebo.

Conclusions: Curcumin supplementation does not reduce vascular dysfunction or slow kidney growth in children/young adults with ADPKD.

Funding: NIDDK Support, Commercial Support - Verdure Sciences (study drug), Private Foundation Support.

PO1261
Polycystic Kidney Disease Associates with Increased Myopia and Retinal Breaks

Background: Ophthalmologic manifestations in Polycystic Kidney Disease (PKD) are not well known.

Methods: We conducted a retrospective cohort study using EMR data extraction. All adult patients with polycystic kidney disease (“PKD”) and CKD from another cause (“non-PKD/CKD”), seen at our center between 1/1/2000-4/30/2020, and Eye disorders of interest in these 2 cohorts were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as “Index date”. The prevalence of Eye disorders at the index date was compared between “PKD” and “non-PKD CKD” cohorts.

Results: A total of 839 patients with “PKD” and 8309 patients with “non-PKD-CKD” were included. Majority of patients in both groups were male (58% [498] and 54% [4457]) and identified as White (88% [758] and 86% [7185]). At the index date, PKD patients were younger (mean age 55 vs 60 years in non-PKD/CKD; p=0.01) and had shorter follow up time (median 901 vs 1311 days; p=0.01). PKD patients had higher eGFR (52 [31-81]; N=795) vs 43 mL/min/1.73m² [29-59; N=3742; p<0.01] and lower prevalence of diabetes mellitus at the index date (23% [198] vs 39% [3270]; p=0.01). Hypertension prevalence was similar between the two groups (91% [778] and 90% [7444]). Myopia and all Retinal breaks (with or without detachment) were found to be more common in PKD as compared to non-PKD CKD after multivariable adjustment for age, gender, race, diabetes and follow up time (adjusted odds ratio 1.4 [95% CI: 1.1-1.7] and 1.7 [1.2-2.8]; respectively; p<0.01). Retinal breaks with detachments by themselves were also more frequent in PKD but did not reach statistical significance (Table). Peripheral retinal degeneration was similar between the two groups.
PO1264
The Impact of Salt Deficiency on Acid-Base Homeostasis in Autosomal Recessive Polycystic Kidney Disease
Jonathan Mallory,1 Morgan J. Spicer,1,2 Mark Domonondo,1 Ryan Schibalski,1,2 Denisha R. Spires,1,2 Mikhail Fomina,2 Thelma Amoah,1 Daria Ilatovskaya,1,2 1Medical University of South Carolina, Charleston, SC; 2Augusta University, Augusta, GA.

Background: In healthy subjects, dietary salt restriction exacerbales imbalances of acid-base homeostasis. The disease progression of autosomal dominant PKD is associated with decreasing serum bicarbonate levels and metabolic acidosis, however very little is known about acid-base imbalance in autosomal recessive (AR) PKD, particularly, in response to dietary restrictions. Here we hypothesized that a salt-deficient (SD) diet leads to electrolytic and acid-base imbalance in ARPKD.

Methods: Male and female PCK/CrlCrjPhd1pck/CRL (PCK) rats were fed a SD (0.01% NaCl, Deyts Inc) diet for 1, 3, 5, 7 and 9 weeks beginning at 4 weeks of age. Before each endpoint, urine was collected, and plasma and tissue samples were harvested. Plasma and urine creatinine, sodium and electrolytes, BUN, and plasma aldosterone levels were measured. Cystic index was defined using ImageJ. Statistical analysis was performed with 2-way ANOVA.

Results: Rats of both genders showed over the course of the SD diet in both sexes. Plasma Na+ and Cl− as well as creatinine increased; and BUN did not change. Plasma aldosterone increased from week 1 to week 5 (week 1: 2.6±1.5 mg/dL, week 5: 10.5±1.5 mg/dL) and 7.7±1.1 (F, p<0.001 (over time)), followed by a return to baseline by week 9 of the SD treatment. These results were significant in cystogenesis in female rats from week 1 to week 9 of the SD diet (week 1: 14.2±1.9%, week 9: 36.3±2.4%). Further, we observed an increase in plasma pH (week 1: 6.98±0.08 (M) and 6.83±0.03 (F), week 7: 7.16±0.08 (M) and 7.13±0.02 (F) (p<0.001 (over time)) and a decline in urine pH (week 1: 7.69±0.42 (M) and 8.75±0.06 (F), week 7: 5.80±0.07 (M) and 5.72±0.08 (F), p<0.001 (over time)) in both sexes throughout the dietary challenge.

Conclusions: PKC rats on a SD diet exhibit acidification of urine pH and an increase in plasma pH. We can speculate that acid base transporters such as NHE1, NBCe2, and pendrin are upregulated to conserve plasma sodium leading to a shift in acid-base homeostasis. Further studies aimed at elucidating the role of these transporters may add to the current knowledge regarding the pathogenesis and dietary management of ARPKD.

PO1265
A Combination Therapy with Two Dietary Supplements Acting on Different Mechanisms Ameliorates Disease Progression in a Rat Model of Polycystic Kidney Disease

Background: Recently, our lab reported that dietary interventions to induce ketosis ameliorate disease progression PKD animal models, and that this effect involves the natural ketone beta-hydroxybutyrate (BHB). Additionally, we have recently shown that renal microcrystals exacerbate disease progression in PKD models. We now show that a combination of citrate and BHB effectively inhibits PKD progression. These compounds act on separate mechanisms, synergistically preventing cyst formation and cyst growth in young rats. In adult rats, the combination treatment leads to a partial reversal of existing renal cystic disease.

Methods: Juvenile and adult male and female PCK rats were treated with BHB, citrate or in combination via drinking water for 5 or 4 weeks respectively, then sacrificed and analyzed for changes in cystic burden and markers of disease progression. Additionally, rats were placed in metabolic cages to assess changes in urine parameters.

Results: Administration of either BHB or citrate alone in the drinking water effectively ameliorates PKD progression in a rat model. Combining BHB and citrate produced a synergistic effect. Cystogenisis and cyst growth were inhibited in juvenile animals. In adult animals with pre-existing renal cystic disease, the treatment leads to TSC2 disease regression. We also found that administration of excess sodium and potassium alone, at doses that would be provided from the salts of citrate and BHB, lead to a worsening of PKD in our rat model.

Conclusions: The beneficial effects of ketosis are mimicked by administration of BHB in the drinking water and are consistent with a number of groups findings suggesting an underlying metabolic defect in PKD. Our other recent findings suggest excessive renal crystal burden leads to accelerated disease progression in PKD models. Renal cystal formation can be prevented by administration of citrate to both chelate calcium and raise urinary pH. These results are of high clinical significance because BHB and citrate
are widely available and classified as safe dietary supplements. These results suggest that a combination of widely available and generally safe dietary supplements, when appropriately formulated, demonstrate high promise for supporting kidney health in PKD.

**PO1266**

A Single-Center Experience of ARPKD in Adults

Mecnukuni Sambharia, Sonali Gupta, Christie P. Thomas. The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) is an inherited ciliopathy with 50% presenting with enlarged kidneys in utero or early infancy. ARPKD has an incidence of ~1:20,000 live births and arises from biallelic variants in \( PKHD1 \) encoding for fibrocystin, with variants in \( DZIP1L \) accounting for <1% cases. Imaging findings include large echogenic kidneys, poor cortico-medullary differentiation, renal cysts or "salt and pepper appearance". ARPKD-congenital hepatic fibrosis (ARPKD-CHF) complex consists of renal disease with biliary dilatation portal hypertension and splenomegaly. 50% develop ESRD in childhood with limited data on renal prognosis for those that present later.

**Methods:** A retrospective chart review of patients >16 yr of age with cystic kidney disease and/or congenital hepatic fibrosis to identify possible cases of ARPKD. Clinical phenotype (compatible hepato-biliary and renal involvement) and/or genetic testing were used to verify the diagnosis.

**Results:** We identified 29 patients with ARPKD-CHF, out of which 13 ≥16 yr (mean 32.4 yr). 38% were males, 15% identified as Hispanic and the rest as non-Hispanic whites. All had radiographic evidence of renal and/or hepato-biliary involvement and 5 of 13 patients had biallelic variants in \( PKHD1 \). On the most recent imaging study, 92% had renal cysts, 23% large echogenic kidneys, 23% poor renal corticomedullary differentiation, 15% medullary sponge kidney, 23% with salt and pepper pattern. Only 3 of 13 (23%) had reached ESRD or received a kidney transplant, while the remaining had a mean eGFR of 46ml/min/1.73m\(^2\). Of these, 50% had eGFR ≥60ml/min/1.73m\(^2\). Amongst those with hepato-biliary involvement, 40% had CHF, 53% portal hypertension, 40% splenomegaly, 26% liver cysts.

**Conclusions:** We describe a cohort of patients with ARPKD, the majority presenting as adults, with an eGFR ≥60ml/min/1.73m\(^2\). A significant number of these patients had multiple large renal cysts. Absence of obvious renal phenotype in patients with congenital kidney anomalies. Application of the SMV pipeline may increase diagnostic rate of the cohort to 22.5%.

**PO1267**

Analysis of Somatic Mosaic Mutations in Nephropathy-Associated Genes Reveal Candidate Disease-Causing Mutations in Previously Germ-line-Negative Cases

**Background:** Somatic mosaicism variant (SMV) arises due to postzygotic mutations that result in two genetically distinct populations of cells in the same person. SMVs may be missed by standard search for germline (or inherited) mutations, and the use of dedicated analytic pipelines for SMVs can potentially explain "exome negative" cases. Somatic mutations were identified through GATK Mutect2 software, and clinically annotated following the American College of Medical Genetics and Genomics (ACMG) guidelines. We focused on the analysis of 625 nephropathy-associated genes previously used for the germline analysis.

**Results:** Previous analyses germline variants had identified 52 diagnostic variants in this cohort (20.9% diagnostic rate). In addition, the SMV pipeline identified candidate disease-related SMVs in 4 "exome-negative" patients (1.6% of cases). The SMVs were detected in \( RET, EGF \) and \( COL4A5 \), and are reported in Table 1. This improved the diagnostic rate of the cohort to 22.5%.

**Conclusions:** Analyses of somatic mosaic variants can increase diagnostic yield in patients with congenital kidney anomalies. Application of the SMV pipeline may increase diagnostic in other forms of kidney disease.

**PO1268**

Comparison of Imaging Approaches for Quantifying Total Kidney Volume (TKV) and Fibrosis in a Mouse Model of Polycystic Kidney Disease (PKD)

Caroline R. Sussman, Heather L. Holmes, Ka Thao, Adriana Gregory, Ryan J. Meloche, Yaman G. Mkhaimeir, Harrison H. Wells, Slobodan Macura, Peter C. Harris, Timothy L. Kline, Michael F. Romero. Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** 3D imaging and histology are critical tools for assessing PKD in patients and animal models. Magnetic resonance (MR) imaging provides resolution, but is time consuming, expensive, and access to equipment and expertise is limiting. Robotic ultrasound (US) imaging is lower resolution but fast. Similarly, picrosirius red (PR) staining and standard light microscopy is used to assess fibrosis; however, alternative methods for quantifying PR staining have been shown in other tissues to allow greater sensitivity and more detailed characterization.

**Methods:** \( Pkd1^{+/+} \) mice were compared to \( Pkd1^{−/−} \) (WT). TKV was quantified from US and MRI (77 and 16T) at 1, 3, and 4 months old. US measurements of kidney and heart were made using the robotic Vevo770 system. Inter-observer variation (2 observers) was greater for US than MR, but able to detect differences between genotypes and time points. US allowed scanning in 2-5 minutes/mouse while MR required 20-30 minutes. Cylindrical light showed a greater percentage of the thickest collagen fibers in RC/RC mice, and a corresponding lower percentage of each of 3 categories of thinner collagen fibers. Preliminary data using fluorescence microscopy also showed a higher density of collagen fibers in RC/RC mice vs. WT. Analysis of collagen fiber angle, length, straightness, and width is ongoing. RC/RC had a lower GFR, higher BUN, and elevated cAMP vs WT. No differences were observed in cardiac function (ejection fraction, heart rate, or cardiac output).

**Conclusions:** These studies demonstrate the utility of US and alternative approaches of quantifying fibrosing using PR.

**Funding:** NIDDK Support

**PO1269**

Phenotypic Heterogeneity in Type IV Collagen-Associated Nephropathy: The Cystic Phenotype

Letizia Zeni,1,2 Cinzia Mazz,1 Diego Tos,1 Laura Econim,1 Roberta Cortinovis,1 Chiara Dordoni,1 Gianfranco Savoldi,1 Francesco Scolari,1,3 Claudia Izi,1,2 Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy; 1Universita degli Studi della Compagnia Luigi Vanvitelli, Caserta, Italy; 2Universita degli Studi di Brescia, Brescia, Italy.

**Background:** Exome sequencing (ES) revealed mutations (mut) in type IV collagen (COL4) genes in patients (pt) diagnosed with other forms of chronic kidney disease (CKD), supporting the concept of spectrum of phenotypes for COL4-Nephropathy. Unexpectedly, some pt with CKD presenting with cystic phenotype were identified with COL4-Nephropathy by ES.

**Materials and Methods:** The retrospective study included 130 pt referred to outpatient clinic of genetic kidney diseases of ASST Spedali Civili di Brescia from 2002 to 2021 and diagnosed with COL4-Nephropathy. Based on the presence of multiple and bilateral renal cysts on imaging (fig1), a group of pt with cystic phenotype was selected (27/130,21%).

**Results:** Among cystic group (CG), diagnosis was based on genetic test (g) and kidney biopsy in 10/27 pt, whereas it was "biopsy-proven only" in 7 pt, gt-based in 3 pt and clinically in 7 pt. Fifteen pt underwent gt (fig2): heterozygous mut in COL4A3 and COL4A4 were detected in 9 and 3 cases, respectively; 1 patient showed mut in COL4A5 and 2 pt had a digenic pattern. At baseline, comparison between CG and non-CG showed lower eGFR (70[IQ 35;91] vs 91[IQ 74;114] mL/min/1.73m\(^2\)) and proteinuria (1.1 vs 0.38 g/24 hrs), although the statistical significance was not reached for proteinuria (p=0.058). At last censoring, data confirmed a lower eGFR (26[IQ 7;55] vs 86[IQ 44;143]) and a tendency (p=0.045) of greater arteriolar thickening in CG. Prevalence of arterial hypertension, CKD (defined as eGFR < 60) and ESKD was higher in CG.

**Conclusions:** The study contributes to expand the emerging phenotypic heterogeneity of COL4-Nephropathy and suggests that cystic phenotype could predict progression of kidney disease.
POI1270

Rare Variants in Syndromic Ciliopathy Genes as Novel Causes of Isolated Renal Disease in Adults

Zachary T. Sennett,1,2 Lina Mougharbel,1 Sima Babayeva,1 Natascia Anastasio,2 Lee Lee Chu,1 Murielle M. Akpa,1 Paul R. Goodyer,1,3 Elena Torban,1,3 Thomas M. Kitzler,1,3 Research Institute of the McGill University Health Centre, Montreal, QC, Canada; 2McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.

Background: Renal ciliopathies are among the commonest genetic causes of end-stage renal disease (ESRD). Ciliopathies are caused by defects of the primary cilium, an antenna-like organelle with mechanochemical roles, crucial for organ development and maintenance. Disorders of the cilium present early with multi-organ involvement, but some individuals present as adults with organ-specific phenotypes, potentially due to milder mutations and organ-specific effects.

Methods: We identified rare variants in two ciliopathy genes in two unrelated adults presenting with ESRD. ACMG guidelines did not classify these variants as pathogenic, requiring functional validation to establish a causal genotype-phenotype relationship.

Results: Bi-allelic CC2D3 missense variants were identified in a patient, with ESRD, suggestive of an isolated renal ciliopathy. CC2D3 is essential for ciliogenesis, with complete loss of cilia in knockout mice (Development 135:4049 2008). Severe mutations were reported in patients with a syndromic ciliopathy (OPD X; OMIM# 615948), but no cases of isolated renal disease have been reported. We detected a moderate but consistent shortened cilia length in skin fibroblasts and renal epithelial cells from our proband, suggestive of a milder ciliary defect. Remarkably, the proportion of ciliated cells was significantly reduced in renal epithelial cells but not in fibroblasts, cells from our proband, suggesting a milder ciliary defect. Pathogenic variants in CC2D2A cause Joubert and Meckel syndrome, with no isolated renal presentations observed to date (Mol. Genet. Genom. e1603 2021). We identified a novel homozygous nonsense variant (Arg34*) in CC2D2A, classified as not pathogenic due to an alternate start-codon, in a previously healthy 37-year-old male with isolated ESRD of unknown etiology. Using public data (GTEx), we show that protein-coding transcripts harbouring this variant are the predominant transcripts in the kidney when compared to tissues relevant to CC2D2A-related phenotypes (e.g., cerebellum, liver).

Conclusions: Rare variants in known syndromic ciliopathy genes cause isolated renal disease in adults due to potential organ-specific effects. Using variant classification schemes without functional analysis may not accurately capture the genetic contribution to adult ESRD.

POI1271

Targeted Exome Sequencing Application for Genetic Diagnosis of Pediatric Patients with Cystic Kidney Disease

Jee-Su Min,1 Hyeonju Lee,1 Peong Gang Park,2 Yo Han Ahn,2 Hee Gyu Kang,1 Ji Hyun Kim,2 Euijin Park.2 1Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea; 3Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 4Hallym University Medical Center, Yeongdeungpo-gu, Seoul, Republic of Korea; 5Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea.

Background: Detection of a mono- genetic cause of chronic kidney disease accounts for almost 30% of cases in the pediatric cohort. Of these, the highest yield in the genetic diagnosis is currently seen in cystic kidney disease. Nearly 100 monogenic causes of renal cystic ciliopathies have been identified and the genetic diagnostic yield is reported to be approximately 50%. Here, we report the results of genetic testing in a cohort of Korean pediatric patients with cystic kidney disease.

Methods: From July 2019 to February 2021, children under the age of 18 with three or more cysts in both kidneys on imaging studies were recruited from three nephrology centers in Korea. Genetic identification was performed by targeted exome sequencing (TES) including 89 genes known as cystogenesis-related or causative-ciliopathy.

Results: A total of 46 pediatric patients with cystic kidney disease were recruited. The median age was 9.2 years (IQR, 5.49-14.53) and 60.9% were boys. Twelve patients (27.9%) had a family history of cystic kidney disease. The clinical diagnoses of the patients were 10 patients with autosomal dominant polycystic kidney disease, 5 patients with autosomal recessive polycystic kidney disease, 2 patients with multicystic dysplastic kidney, 1 patient with nephronophthisis, and the others were undiagnosed. The mutation detection rate was 52.2% (24 of 46). PKD1 was the most common causative gene (16 patients, 34.8%), followed by HNF1B (3 patients), PAZ2 (2 patients), PKD2 (1 patient), PKHD1 (1 patient) and NPHP3 (1 patient). Genetic mutations were identified in all patients (12 of 12) with a family history of cystic kidney disease. In patients without a family history, genetic mutations were found in 35.3 % (12 of 34).

Conclusions: The mutation detection rate in this cohort of Korean pediatric patients with cystic kidney disease was 52.2% by TES. Mutations in PKD1 were found most commonly, and the mutation detection rate was higher in patients with a family history of cystic kidney disease. For children with cystic kidney disease, molecular genetic testing is essential for an accurate diagnosis, personalized treatment, and prognosis prediction.

POI1272

The Prognostic Factors of Cyst Infection due to ADPKD

Hiroki Mizuno,1 Junichi Mizuno,1 Yoshifumi Ubara.1 Toranomon Byoin Buin, Kawasaki, Japan; 2Toranomon Byoin, Minato-ku, Japan.

Background: Renal or hepatic cyst infection is a complication of autosomal dominant polycystic kidney disease (ADPKD), which requires hospitalization and causes death. Cyst aspiration was the gold standard to diagnose this disease. Because of its invasiveness, several diagnostic criteria without using cyst aspiration have been proposed, but prognostic factors of cyst infection have not been analyzed in this setting.

Methods: Inclusion criteria of this retrospective cohort are ADPKD patients who were admitted in Toranomon hospital and Toranomon hospital Kaiyoga between 2016 April and 2021 March, and who were diagnosed as cyst infection based on MRI findings, which we previously published. Primary composite endpoint was defined combination of death, septic shock, or hospitalization for more than four weeks, and secondary outcomes were defined by each outcome mentioned above. Logistic analysis was planned to assess the predictors of the outcomes.

Results: One hundred ninety patients were eligible to this study. The average age was 65.0±9.2 years, 116 (61.1%) were female, and the average height-adjusted total liver volume (htTLV) was 332±2286 mL per meter, and 164 (86.3%) had hemorrhoidal therapy. Composite outcome occurred in 109 (57.4%): 25 death, 36 shock, and 98 longer-hospital-stay. Multivariable logistic regression model after adjusted related variables showed that older age (odds ratio(OR) 1.10 (95% confidence interval: 1.10-2.54), p-value=0.02), male (OR 2.49(1.16-5.33), p-value=0.02), higher htTLV (OR 2.29(1.39-3.77), p<0.01), lower mean blood pressure at admission (OR 0.735(0.579-0.9319), p<0.01), larger size of infectious cyst (OR 1.42(1.06-1.91), p<0.02) were significantly associated with the composite outcome. Although the culture-positive case or higher white blood cell count were not significantly associated with the primary outcome, they were associated with septic shock due to cyst infection.

Conclusions: Baseline characteristics at admission were associated with the prognosis of cyst infection diagnosed by MRI-based criteria, which was similar to cyst infection diagnosed by cyst aspiration. Culture-positive case or higher white cell count were reported as risk factors requiring more invasive therapies that could lead to septic shock and need longer hospitalization in our study’s cohort.

ExoGAG, A New Method for Extracellular Vesicle and Glycoprotein Isolation in Urine That Unmasks the Pathophysiology of the Kidney and Identifies New Biomarkers of Kidney Disease

Martà Vizoso,1 Nerea Lago,1 Tamara Camino,1 Olaya Lamas-González,1 Susana Bravo,1 Carmen Vazquez,1 Manuel Fidalgo Diaz,1 Cássia Rodríguez,1 María Pardo,1 Miguel A. García-González,1,2
1Nephrology Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; 2Proteomic Group, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; 3Nephrology Service, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain; 4Galician Public Foundation of Xenomic Medicine, Santiago de Compostela, Spain; 5Obesidomic Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain.

Background: Glycosaminoglycans (GAGs) are large polysaccharides that interact through glycosidic bonds with proteins and lipids, forming the extracellular matrix; or with secreted proteins, as uromodulin. Glycosylation is altered in pathologies, as cancer or kidney diseases. GAGs are present in extracellular vesicles (EVs), nanometric structures delimited by lipid bilayer that cells release and whose charge (RNA/miRNA, DNA and proteins) is essential in intercellular communication. Our group developed a method for GAG, glycoproteins and EVs isolation in any biological sample, called ExoGAG (commercialized by Nasas Biotech), which led us to identify and characterize new signalling mechanisms, and identify new prognostic/diagnostic biomarkers, for example, in polycystic kidney disease (PKD).

Methods: Urine samples have been collected from patients genetically diagnosed with type I and II PKD at different stages of disease. Using ExoGAG, GAG-glycoprotein-EVs complex has been isolated and characterized by different proteomic techniques (Western Blot, mass spectrometry), gene expression (RT-PCR), and image characterization (electron microscopy, immunofluorescence).

Results: ExoGAG has allowed us to identify a new biomarkers in urine (in protection) in PKD patients, which are altered in disease progression, even anticipating currently used kidney markers. The characterization of these complexes has led us to discover signalling mechanisms between the different segments of the nephrons, and whose function is altered in different pathologies. These findings have served other researchers deepen knowledge in different specialties such as Oncology and Endocrinology.

Conclusions: This new method for isolating the fraction associated with GAG in urine samples has allowed us to identify prognostic/diagnostic biomarkers of kidney diseases, based on glycoprotein and vesicular profile. Likewise, it has led us to identify new signalling mechanisms of the nephron, which opens a new field for a better understanding of renal pathophysiology. These results uncovered the potential to identify new signalling mechanisms between the different segments of the nephron, and whose function is altered in different pathologies. These findings have served other researchers deepen knowledge in different specialties such as Oncology and Endocrinology.

PO1274
Deposition of an Abnormal Extracellular Matrix as an Initiating Event in Cyst Formation

Valerie A. Schumacher,1,2 Mary E. Taglienti,1 Jordan A. Kreidberg,1,2 Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA.

Background: Extracellular matrix (ECM) refers to the proteins and other macromolecules outside of cells that provide a scaffolding to maintain tissue architecture. The distinct ECMs to which these cells are attached, epithelial cells to a laminin-rich basement membrane vs. interstitial cells to a collagen/fibronectin (FN) ECM, has profound implications for cell behavior and tissue architecture. These differences in cell behavior are mediated through a family of receptors known as integrins, used by cells to attach to the ECM. Here we provide evidence that cyst formation in ADPKD is a manifestation of abnormal cell behavior in response to an atypical extracellular matrix and changes in integrins.

Methods: To understand the pathological contribution of integrins and FN to ADPKD, we measured their expression and localization in vivo using a postnatal murine model of ADPKD and kidney samples from human ADPKD.

Results: We observed increased expression of FN in murine cystic kidneys and also in kidneys from humans with ADPKD. In mice, increased fibronectin expression preceded cyst formation. Moreover, laminin basement membrane underlying cyst lining cells was discontinuous and replaced in some sections by a FN-rich ECM. Some sections were conspicuous for expressing the FN receptor α5β1 integrin, and for cell morphology being cuboidal instead of flattened. In other areas of the FN rich ECM, αv-integrins, were present on flattened cyst lining cells. αvβ1 integrin was more abundant on cyst lining cells than on non-cystic tubules. Interestingly, in situ hybridization revealed that Fn1 was not expressed in all cyst lining cells but in the specific subset of cells that had a cuboidal appearance.

Conclusions: Our studies presented here identify a distinct subset of cuboidal cyst lining cells that express Fn1. They also demonstrate distinct integrin repertoires among subtypes of cyst lining cells. As FN deposition precedes cyst formation, these FN-expressing cuboidal cells may have a role in the initiation or early progression of cysts in ADPKD.

PO1275
Uncovering the Role of the Extracellular Matrix in ADPKD Progression

Elisa Pellegrino,1,2 Maria Elena Steidl,1,2 Marco Chiaravalli,1 Alessandra Boletta,2 Elisa Agnese Negro,1 Università Vita Salute San Raffaele, Milano, Italy; 2IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Polycystic Kidney Disease (PKD) is a genetic disorder due to mutation in either Pkd1 or Pkd2 genes and characterized by bilateral cysts formation. We recently uncovered a direct role of Pk1, the protein product of Pkd1 gene as a mechanosensor of extracellular stiffness. We found that Pk1-1 interactors mediate inhibition of actomyosin contraction that mediates the cellular response to the rigidity of the Extracellular Matrix (ECM). Based on these findings we speculated that Pkd1 cells fail to properly respond to the extracellular mechanical force of ECM leading to excessive matrix deposition and proliferation. In line with this, kidneys of end-stage PKD patients show enhanced fibrosis typical of cystic kidney disease and tumors. We then wondered whether PKD ECM is a part of an active Cyst Microenvironment (CME), exerting a key role in the evolution of the disease.

Methods: We characterized CME in the renal tissue of an aggressive Pkd1-/-/Cre- and a low progressive Pkd1-/-/Tam-Cre inducible mouse models. To study the composition and the mechanical properties of the cystic ECM we decellularized cystic kidneys obtaining ECM-derived kidney scaffolds. Furthermore, we isolated matrix from Pkd1 fibroblasts in vitro.

Results: We have characterized the renal tissue microenvironment of two Pkd1 inducible mouse models at a late stage of the disease confirming the presence of fibrosis, immune infiltrates and progressive accumulation of collagen I. In line with an active role for ECM in the progression of disease, we found that fibroblasts in the deposition and remodeling of the ECM, our data showed the presence of activated fibroblasts in cystic kidneys. We performed a proteomic analysis of cystic kidney scaffolds by Mass Spectrometry (MS). Cluster analysis of MS data showed a clear separation between cystic and control scaffolds. Finally we found that matrix isolated from Pkd1-/- cells was able to influence differently key cellular properties such as adhesion, polarization, proliferation and migration.

Conclusions: ECM plays an active role in the progression of ADPKD disease.

Abstract Withdrawn

PO1277
17q12 Deletion Syndrome Presenting as Congenital Diaphragmatic Hernia in a 2-Month-Old Infant

Introduction: 17q12 deletion syndrome results from the loss of as many as 15 genes on the long arm of chromosome 17 including the hepatocyte nuclear factor-I-gamma (HNF1B). Heterozygous pathogenic variants, whole gene deletion, or duplication in HNF1B are frequently linked to inherited kidney malformations including hyperechogenic kidneys, kidney cysts, solitary kidney, and hydrenephrosis as well as extrarenal phenotypic features. 17q12 deletion syndrome has also been linked to congenital diaphragmatic hernia (CDH). We present a case of an infant with hyperechogenic and cystic kidneys, diagnosed postnatally with CDH.

Case Description: A 2-month-old female with a history of hyperechogenic kidneys on prenatal ultrasound presented to the emergency department with increased work of breathing. A chest x-ray revealed left hemidiaphragm elevation, normal cardiac silhouette, and no focal pulmonary consolidation. Computed tomography of the chest confirmed the diagnosis of CDH. A repeat kidney ultrasound revealed diffuse hyperechogenic kidneys and a focal kidney cyst within the right upper pole (Image 1). Genetic workup revealed a 1.9 megabase deletion on the long arm of chromosome 17 consistent with the diagnosis of 17q12 deletion syndrome.

Discussion: Pathogenic variants in HNF1B or whole gene deletion as part of 17q12 deletion syndrome should be considered in infants with hyperechogenic kidneys with cysts, particularly in the context of extrarenal manifestations. Studies have examined the link between HNF1B and the development of a CDH. It is proposed that HNF1B is involved in the WNT signaling pathway that is critical to mesodermal differentiation and proper diaphragm formation. Only 4 other cases of HNF1B mutations associated with CDH are reported in the literature. Two cases describe HNF1B deletions, and 2 cases describe HNF1B duplications. It is possible that the high prenatal mortality of CDH could explain the paucity of this association.
POI1278

Recurrent Pneumothorax in a Marfanoid Adolescent with Autosomal Dominant Polycystic Kidney Disease

Allison Miller. Legacy Health System, Portland, OR.

Introduction: Pneumothorax may be a rare extra-renal manifestation of autosomal dominant polycystic kidney disease (ADPKD), and may indicate co-inheritance of other genetic diseases.

Case Description: A 21-year-old man with ADPKD and pneumothoraces presented to nephrology clinic. A screening ultrasound in late childhood was completed due to his family history and confirmed ADPKD. The patient was normotensive and had a tall, thin habitus. His musculoskeletal examination was pertinent for several marfanoid findings, including increased arm span ratios, pes planus, and positive thumb and wrist signs. His eGFR was normal and he did not have proteinuria. He was hospitalized several times between ages 13-20 for recurrent pneumothoraces requiring left apical wedge and lower bleb resections with pleurectomy, and right upper lobectomy and pleurectomy.

Discussion: The patient’s lung collapse was attributed to primary spontaneous pneumothorax due to his tall stature and intermittent tobacco use. However, this cannot account for his high rate of recurrence. The extent of pneumothorax burden in this patient should be considered in context of his underlying polycystic renal disease. Pulmonary manifestations of ADPKD are not well understood and have only been described in a handful of case reports. Bronchiectasis and cystic lung disease are thought to occur as a downstream consequence of impaired parenchymal healing. Mutated polycystin-1 in ADPKD prevents normal ciliary function, which is imperative for coordination of cellular repair in bronchial smooth muscle cells. Evolving cystic lung disease in the setting of underlying ADPKD could explain this patient’s recurrent pneumothoraces. The possibility of a co-inherited connective tissue disease should also be considered in patients with ADPKD and pneumothoraces. "Overlap" disorders between ADPKD, Marfan syndrome and Tuberous Sclerosis (TSC) have been examined in linkage studies, and have chromosomal proximity. Marfan syndrome and TSC are associated with pneumothorax. Though our patient did not manifest criteria for TSC, his examination is consistent with a Marfan’s variant phenotype. This patient may be an example of co-inherited disease, and raises the question of whether it is under this circumstance that rare pulmonary complications become apparent. Clinicians should be aware of these overlap disorders in relation to ADPKD.

POI1279

Ruptured Intracranial Aneurysm as the Initial Presentation of ADPKD in a Pediatric Patient

Marion Chedid, Fouad T. Chebib, Christian Hanna. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is associated with multiple extra-renal manifestations, most notably intracranial aneurysms (ICA). Approximately 10% of ADPKD patients develop ICA during their lifetime. Subarachnoid hemorrhage (SAH) is a major complication of ICA and usually occurs during the end of the 3rd decade. Aneurysm rupture in children <18 years of age is extremely rare. We report a case of a 9-year-old boy presenting with symptomatic ICA rupture as the initial presentation of ADPKD, despite a negative family history of ICA.

Case Description: A 9-year-old boy presented to the emergency department with an abrupt onset of severe headache and lethargy after a fall. His family history was remarkable for ADPKD in his father and grandfather. None of his affected family members developed ICA or intracranial hemorrhage. Initial non-contrast computed tomography scan of the head showed frontal lobe hemorrhage. Additional imaging studies revealed a ruptured anterior communicating artery with SAH. Urgent aneurysm coiling was performed, his bleeding was controlled, and the patient survived. Due to his strong family history for ADPKD, a kidney ultrasound was performed and showed enlarged kidneys with multiple renal cysts bilaterally confirming the diagnosis of ADPKD. The patient’s father underwent a screening MRI of the brain at the age of 48 years and was negative for ICA.

Discussion: Our case of SAH due to ICA rupture as the initial presentation of ADPKD, in the absence of a positive family history of ICA or hemorrhage, has not been reported in children. Rare cases of subarachnoid hemorrhage in pediatric patients with ADPKD and a positive family history of ICA or hemorrhage have been described. Based upon available data, it is unclear if either widespread or targeted screening for intracranial aneurysms is beneficial for pediatric patients with ADPKD. Screening is reserved for patients with a family history of hemorrhage, migraine, stroke, patients undergoing major surgery, or patients with high-risk jobs. However, we do not screen children <18 years of age because of the extreme rarity of aneurysmal rupture at that age. Though extremely rare, radiologists, care physicians and pediatricians should stay aware that ICA rupture occurs in children with ADPKD and may lead to devastating complications, even in the absence of positive family history.

POI1280

Congenital Solitary Kidney in ADPKD: A Genotype-Phenotype Correlation

Romina Bucci, Marta Vespa, Maria Teresa Sciarrone Alibrandi, Giancarlo Joli, Giulia Mancassola, Giuseppe Vezzoli, Paolo Manunita. IRCCS Ospedale San Raffaele, Milano, Italy.

Introduction: There are a very few cases of ADPKD associated with Unilateral Renal Agenesis (URA). The total amount is currently 9 cases known in the world and their renal function outcome is somewhat undefined.

Case Description: ZG is a pleasant 41-year-old man with a congenital solitary left kidney with multiple cysts and a genetic diagnosis of ADPKD. Familiarity is negative for ADPKD, but positive for URA (present in his sister and her son). Except for hypertension, there are no extrarenal ADPKD manifestations. Poster et al. analyzed 3 patients with a similar phenotype in a cohort of 182 ADPKD subjects, comparing how the volume of the single kidney increased (SKV) over time and how the GFR dropped, stratifying them for sex and age. A greater SKV in time has been recorded in these 3 patients, caused by both compensatory hypertrophy and cyst growth. Surprisingly though, their kidney function was better compared to controls. Late onset kidney failure is probably caused by hyperfiltration, and it is linked with a long-term worse outcome. In our case, ZG’s SKV increased less compared to another subject with same age and sex and with controls found in literature. Same goes for kidney function, which was better and more stable in a 10-year time-lapse compared to controls.

Discussion: The reason for this could be found in the PKD1 mutation: ZG has a missense mutation, while the aforementioned 3 cases had truncating ones. ZG’s increased SKV is probably more related to hypertrophy than cyst growth itself. Therefore, even in an unorthodox situation like this one, long-term outcome seems to depend on the genotype of the subject.

Note: Table shows values of SKV for patient ZG and patient with polycystic solitary kidney. For the matched 2-kidney ADPKD group is reported the SKV mean values with 95% CI. For this last group the volume given is that of the left kidney present in the other 2 cases. SKV is calculated from RMN scans. Creatinine clearance is estimated according to the Cockcroft-Gault formula. In the 2-kidney ADPKD group CCR is estimated by calculating both kidneys.

POI1281

Management of a Patient with ADPKD Who Needs Lithium

Katharine L Senter, Omar H. Maarouf, JingJing Zhang. Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.

Introduction: N/A

Case Description: A 35-year-old female with borderline personality disorder and schizoaffective disorder presented to nephrology for autosomal dominant polycystic kidney disease (ADPKD). Her biological father had ADPKD and was on dialysis at the time of death. The patient has taken lithium for 10 years, and only lithium allows her to work and live independently. She presented with polydipsia and polyuria, indicating possible nephrogenic diabetes insipidus (DID) from lithium, essential hypertension since age 30, and constant headache; brain MRI was negative for aneurysm. Labs showed a lithium level between 0.3-0.9 mmol/L, creatinine between 0.6-0.75 mg/dL, GFR of 85-90 ml/min, urine protein/creatinine ratio of 0.27-0.32 g/g, and urine osmolality <100 mOsmol/kg.

She was treated with 2.5 mg lisinopril, 10 mg amiloride, and 1350 mg lithium daily. Abdominal MRI without contrast showed scattered liver cysts and innumerable bilateral kidney cysts. Kidney volume indicated Mayo Class 1C PKD. Her father developed ESRD in his late 50s, suggesting rapidly progressive ADPKD class. Lithium nephropathy is usually characterized by 1-2 mm renal microcysts (Khan et al., Int J Psychiatr Med 50(3):290-298). The patient’s larger cysts, total kidney volume, and liver cysts suggest ADPKD. Genetic testing showed that the patient has a heterozygous mutation in c.12445+1G>T, expected to cause altered splicing and function of the PKD1 gene.
Discussion: Finding an appropriate agent to slow CKD progression is the current strategy to manage PKD. Her condition is complicated by likely lithium nephropathy. The TEMPO trial (Torres et al, N Engl J Med 367:2407–2418, 2012) showed that tolvaptan helps slow rapidly progressive ADPKD by inhibiting vasopressin’s effect, reducing cAMP production, further inhibiting cyst formation and growth (Wang X et al, J Am Soc Nephrol 19: 102–108, 2008; Aihara M et al, J Pharmacol Exp Ther 349: 258–267, 2014). Lithium can also inhibit vasopressin in the kidney, leading to nephrogenic DI (Bokenhauer et al, Nat Rev Nephrol11(10):576-88, 2015). In ADPKD, tolvaptan helps achieve a urine osmolality of less than 300 mOsmol/kg (Torres, Clin J Am Soc Nephrol. 13(11):1765-1776, 2018). Our patient already has polycystia and urine osmolality below 100 mOsmol/kg. Her condition requires agents targeting other pathways. For now, she is on lisinopril, with BP <110/75, and amiloride to limit polyuria.

PO1282
A Case of Mistaken Identity: Alport Syndrome Masquerading as Polycystic Kidney Disease
Kana R. Amari, Jennifer A. Tuazon. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Alport Syndrome (AS) is an inherited nephritis caused by a collagen-IV-related mutation leading to abnormalities in the glomerular basement membrane. Patients may present with unexplained hematuria, proteinuria, with or without renal insufficiency. Here, we describe two cases of patients presenting with multiple bilateral renal cysts, initially diagnosed with autosomal dominant polycystic kidney disease (ADPKD), who were later found to have Alport syndrome via genetic testing.

Case Description: We report two cases of patients followed in our nephrology clinic who were initially thought to have ADPKD. The first patient is a 75-year-old woman who was followed for long-standing hematuria, CKD3aA2, sensorineural hearing loss, retinal detachment, and a family history of cystic kidney disease. Due to normal kidney sizes, genetic testing was done which revealed a pathogenic COL4A3 mutation, c.1372G>C (p.Gly458Arg). Our second patient is a 64-year-old man with a history of hematuria, CKD3aA2, bilateral renal cysts, initially diagnosed with autosomal dominant polycystic kidney disease. The first patient is a 75-year-old woman who was initially thought to have ADPKD. The second patient is a 64-year-old man with a history of hematuria, proteinuria, with or without renal insufficiency. Here, we describe two cases of patients presenting with multiple bilateral renal cysts, initially diagnosed with autosomal dominant polycystic kidney disease (ADPKD), who were later found to have Alport syndrome via genetic testing.

Discussion: Very few cases have described an association with AS and cystic kidney disease. The causal mechanism for renal cyst formation and Alport syndrome is unknown. These cases illustrate the importance of considering alternate diagnosis when suspected ADPKD has atypical features such as normal kidney sizes or kidney dysfunction more than expected for the cyst burden.

PO1283
Heterozygous HSD11B2 Gene Mutations and Apparent Mineralocorticoid Excess (AME) in a Patient with Heterozygous ADPKD1
Celeste S. Chang,1,2 Hsiang C. Liu,1 Chinatown Kidney Care, New York, NY; Mount Sinai Beth Israel Hospital, New York, NY; Wei Gong Memorial Hospital, Taofen, Taiwan.

Introduction: HSD11B2 gene which locates at Chromosome 16q22.1 and encodes the Type 2 isoform of 11-beta-Hydroxysteroid Dehydrogenase that interconverts biologically active cortisol and inactive cortisone. Polycystin-1, encoded by the PKD1 gene, which locates at Chromosome 16p13.3. PKD1 gene forms a complex with polycystin-2 (PKD2) that regulates multiple signaling pathways to maintain normal renal tubular structure and function. We present a new finding of HSD11B2 gene in a patient with polycystic kidney disease.

Case Description: 58-year-old Chinese male presented with bilateral renal cysts and CKD Stage 3 A. PMHx is significant for early onset HTN at the age of 45, Left ICH without residual weakness at the age of 46 years and episode of hypokalemia. Denied Licorice ingestion. Family history is positive for HTN and polycystic kidney disease in his mother and all three siblings. His BP was 145/91 mmHg, not controlled well with daily dose of oral Lisinopril 40 mg and Amlodipine 10 mg. His Na 141, K 4.7, CO2 27, BUN 20, Cr: 1.6, GFR: 46, Hb 12.5 and Urine protein/ Cr ratio was 0.324. He was started with low dose of Spironolactone 12.5 mg daily for BP control and proteinuria. Renal ultrasound showed Right kidney was 19.5 cm, left kidney was 18.6 cm and presence of multiple bilateral renal cysts. Abdominal CT without contrast disclosed H1TKV: 1724 ml/m. Mayo clinic class was 1 C; estimated frequency of ESRD at 10 years was 37.8%. Kidney gene panels detected the gene of PKD1 (Autosomal Dominant) and HSD11B2 (Autosomal Recessive). BP stable at 125/78 mmHg, 24-hour urine protein was 125 mg per day, Serum cortisol 11 mcg/dl (normal: 8-19 mcg/dl), Serum cortisone: 0.74 mcg/dl (normal: 1.34-2.65 mcg/dl), Serum cortisol/cortisone ratio: 17.6 (normal: 3.3-9.1), 24 hours Urine free cortisol: 7 mcg/day (normal 5-64 mcg/day), 24 hours Urine free cortisone: 31 mcg/day (normal 16-128 mcg/day), 24 hours Urine free cortisol/cortisone ratio: 0.22 after spironolactone. However, it was discontinued upon repeated serum K was at the higher side of normal. He is currently treated with oral Tolvaptan. 

Discussion: This is an unique case which could be the first case report of HSD11B2 mutations with apparent mineralocorticoid excess associated with heterozygous ADPKD1.

PO1284
A Rare Presentation of Autosomal Recessive Polycystic Kidney Disease in Adulthood
Katerina Hysi, Saira Sajid, James Drakakis. NYU Winthrop Hospital, Mineola, NY.

Introduction: Autosomal recessive polycystic kidney disease (ARPKD) belongs to a group of congenital hepatoportal fibrocystic syndromes and causes significant renal and liver related morbidity and mortality in children. Renal cysts, congenital hepatic fibrosis, and recessive inheritance characterize ARPKD. The disorder usually manifests infancy, with a high mortality rate in the first year of life. For the patient who survives the neonatal period, the probability of being alive at age 15 ranges from 50-80%, with the majority requiring renal replacement therapy at that age. This diagnosis is rarely made in the adult years with the clinical course and prognosis much less well defined.
Case Description: 57-year-old male with PMHx of gout and long standing CKD with creatinine 1.9 mg/dl, daily back pain, bilaterally. His urine was sent to MOI in 2010 with little progression presented for evaluation. Urinalysis was without microscopic hematuria or proteinuria. Historic imaging showed small kidneys and medical renal disease. An updated MRA noted bilateral kidneys cysts with areas of atrophy and scarring, which along with an increase in his liver transaminases raised suspicion for ARPKD. The patient subsequently underwent whole exome sequencing, which confirmed two pathogenic variants (specifically S3018F and R1624W) in the PKHD1 gene, consistent with ARPKD. His brother was eventually tested as well and found to have the same two variants.

Discussion: The classic presentation for ARPKD is systemic hypertension with progression to ESRD by the age of 15. In a typical presentation, a small number of those with ARPKD live to adulthood with some compromise of kidney function; but with significant variability. ARPKD is a lethal disease. Due to its wide phenotypic variability, the diagnosis of ARPKD may be made during any stage of childhood; in rare cases, it does not present until adolescence or adulthood. A minority of affected individuals present as older children or young adults with evidence of hepatic dysfunction or otherwise unexplained renal cysts as the prominent presenting feature. This case exhibits the silent menace of ARPKD with a delay in recognition of clinical manifestations and thus an unusually older age at the time of diagnosis.

HDR: A Novel Mutation in GATA-3 with Variable Expressivity in an Affected Family

Meneukshi Sambaria, Jason Misurac, Christie P. Thomas. The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.

Introduction: Hypophosphatemic rickets, a disorder also known as Barakat syndrome, is a rare autosomal dominant disorder caused by a mutation in the GATA3 gene. Hypophosphatemic rickets is a multisystemic disease with manifestations involving bone, teeth, muscle, kidney, eye, and skin. The majority of affected patients have renal osteodystrophy, with or without sensorineural hearing loss. The missense variant described in our patient has not been previously reported, although an

Underline represents presenting author.

Assessing Genomic Needs

Jordan G. Nestor,1 Sumit Mohan,1 Ali G. Gharavi,1 Chunhua Weng,1 Jun C. Suh,1 Columbia University, New York, NY; 2Columbia University Mailman School of Public Health, New York, NY.

Background: Interventions must address nephrologists’ knowledge gaps, perceived needs and preferences for genomic data to guide personalized patient care. Previous studies have identified gaps in nephrologists’ knowledge of genomics and can inform the design of tailored interventions that address nephrologists’ needs, including education, workflow and clinical-decision support tools. Together, such tools can promote wider utilization of genomic resources and empower nephrologists to use genomic data.

Results: Between January-May 2021, 319 complete surveys were eligible for analysis by nephrologists across 47 U.S. States, (86% adult vs. 14% pediatric), with 34% community-based (vs. 66% academic) including 36% who perform transplant evaluations and 75% with prior experience ordering genetic testing; 77% responded that genetic test results have meaningful implications for a patient’s care; 91% were aware that a tailored lab report would be helpful; 53% identified important for disease diagnosis (92%), understanding (85%), prognosis (86%), treatment (88%); 86% indicated that a personalized lab report would be helpful. Most had referred > 20 patients for GT (61%). GT was considered clinically important for disease diagnosis (92%), understanding (85%), prognosis (88%), treatment planning (93%). 68% report they have reliable information for care of patient with genetic results. Top 3 challenges to GT included interpretation of results, selection of test, and ordering test. 86% felt patients could afford GT. Most indicated the importance of having clear guidelines for GT (84%). Majority (70%) would recommend GT for family members, especially in the presence of a tailored lab report (91%).

**PO1287**

Pediatric Nephrologists’ Perspectives on Genetic Testing and Return of Results to Children

Background: Pediatric (ped) nephrologists care for children with genetic causes of chronic kidney disease (CKD). While genetic testing (GT) is now more accessible in nephrology, little is known about the utility, clinical application, and relevance of GT in determining underlying CKD or other actionable secondary genetic findings for ped nephrology patients. We explored ped nephrologists’ views regarding GT in clinical and research settings.

Methods: An online 30-item survey was developed and distributed via professional listservs. Inclusion criteria required self-identification as a U.S. licensed nephrologist. Data collection was from 1/22/21-5/4/2021 and analyzed by STATA 15A. Descriptive statistics are reported.

Results: 85 ped nephrologists completed the survey. Respondents range in yrs in practice (35% 6-15 yrs, 21% 16-25 yrs, 28% > 25 yrs), and 75% practiced in a university hospital. Most had referred 20 patients for GT (61%). GT was considered clinically important for disease diagnosis (92%), understanding (85%), prognosis (88%), treatment (93%). 68% reported they have reliable information for care of patient with genetic results. Top 3 challenges to GT included interpretation of results, selection of test, and ordering test. 86% identified fitting GT into practice as a challenge, and 61% report offering counseling with a genetic expert after return of genetic results. 53% felt patients could not afford GT. Most indicated the importance of having clear guidelines for GT (84%). Majority (70%) would recommend GT for family members, especially in the presence of a tailored lab report (91%).
are involved in the return of results in their own practice (60%). Regarding the return of research-based results, most thought diagnostic (92%) and actionable secondary findings (75%) should be returned.

Conclusions: Ped nephrologists report on the importance of GT in CKD. They also report on their personal challenges with GT and structural barriers to the utilization of GT.

Funding: NIDDK Support

POI1288
Attitudes and Perceptions of APOL1 Genetic Testing in Black Patients with Hypertension: A Pilot Study
Krista L. Lentini,1 Anthony N. Muiru,2 Kathryn K. Lindsay,1 Amy Mosman,1 Yasar Caliskan,3 Barry J. Friedman,1 Amber Carrick,4 Chi-yanu Hsu,1 Kana N. Miyata,1 Thanh-Mai N. Vo,1 John C. Edwards,2 Marie D. Philipneri,3 Saint Louis University School of Medicine, Saint Louis, MO; 2University of Washington, Seattle, WA; 3Wake Forest University School of Medicine, Winston-Salem, NC; 4Mid-America Transplant Services, Saint Louis, MO.

Background: A portion of the chronic kidney disease risk in Black persons appears due to polymorphisms in the gene encoding apolipoprotein L1 (APOL1). While applications of APOL1 genotype testing for prognostication (e.g. in evaluation of organ donors) are emerging, the interest of Black patients in APOL1 genotyping and implications for individual kidney risk management are not well defined.

Methods: In this pilot study, we offered APOL1 genetic testing and assessed attitudes and concerns related to APOL1 testing and kidney risk management among Black persons seen in the Hypertension & Nephrology clinics at one urban, Midwestern center.

Results: Among 110 participants with genotyping results to date, 56% were women, mean age was 58 years, 72% were obese, and a mean of 3 antihypertensive agents were used (Table). 13% had 2 APOL1 renal risk variants (high-risk genotypes), and 42% had 1 risk variant. At baseline, most participants (86%) reported that they were concerned about kidney disease, 90% thought it was a good idea to be tested for genes that may impact kidney disease, 82% would want APOL1 testing for their children, and only 26% expected to feel upset if they were APOL1 high risk. Most participants reported that knowledge of a high-risk APOL1 genotype would lead to changes in health-related behaviors (Figure).

Conclusions: Black patients at a Midwestern medical center were receptive towards APOL1 genetic testing and believed that testing would motivate changes in health-related behaviors. Ongoing research is needed to determine optimal patient-centered use of this emerging risk assessment tool.

POI1289
Utility of Genetic Testing in Informing Management of Patients with Kidney Disease
Daniel W. Ross,1 Kenar D. Jhaveri,1 Laurel Kartchner,1 Dinah Clark,2 Kerry Gaj,2 Deepa A. Malieckal,1 1Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; 2Natera, Inc., San Carlos, CA.

Background: Early identification of monogenic causes of CKD through genetic testing can improve disease treatment, inform management and improve outcomes. Genetic testing can also be useful for families with a history of CKD to plan for the future, including appropriate identification of organ donors. Here we describe the use of genetic testing, with RenasightTM, an NGS-based >380 gene panel for kidney disease, to inform treatment for patients being treated for kidney abnormalities.

Methods: We performed a retrospective analysis of genetic test results using RenasightTM (NGS-based>380 broad kidney gene panel) at a large academic center over an 18-month period. After signed informed consent, broad genetic testing was performed on blood or saliva samples from 31 patients. Genetic testing results were then related to alterations in the management of treatment of these patients.

Results: In this cohort, 41.9% (13/31) were female with an average age 51 years. The most common demographic groups were African American and Caucasian (6 patients [19-4%] each). Nineteen patients (61.3%) underwent Renasight testing due to a CKD diagnosis, 5 (16.1%) due to nephritis/nephritic syndrome, 3 (9.7%) due to proteinuria/nephrotic syndrome, 1 (3.2%) due to thrombotic microangiopathy, 1 (3.2%) due to phosphorus metabolism disorder, and 1 (3.2%) due to hemochromatosis. Positive results were identified in 12.9% (4/31) of the patients in the COL4A3, COL4A4, and APOL1 genes. Genetic testing results led to changes in management for 35.4% (11/31) of patients, confirmed diagnoses for 22.6% (7/31), provided additional diagnoses for 41.9% (13/31), and prompted family testing for 22.6% (7/31). For 4 patients with positive findings, test results impacted treatment management: 1 had transplant management impacted, 1 underwent biopsy to confirm Alport Syndrome, 1 had FSGS diagnosis confirmed and 1 underwent biopsy to confirm FSGS and initiated dialysis. Additionally, negative results led to alterations in management for 48.4% (15/31) of patients.

Conclusions: In this cohort at an academic practice, genetic testing informed nephrologists' management of patients in multiple capacities. Negative results can rule out genetic causes of disease, and carriers and variants of uncertain significance (VUS) can inform family planning decisions and enable testing in family members.

POI1290
Early Experience with Broad-Panel Genetic Testing in Pre- and Post-Transplant Evaluation of Patients with Kidney Failure
Rupi K. Sodhi,1 Amishi S. Desai,2 Jongwon Yoo,3 Divya J. Arwindeker,4 Katya Brossart,2 Hossein Tabriziani,1 Sanjeev Akkina,1 Loyola University Medical Center, Maywood, IL; 2Natera, Inc., San Carlos, CA.

Background: Genetic testing plays an important role in kidney transplantation (KT). Genetic assessment during the pre-KT workup enables more accurate estimation of the risk of recurrent kidney disease and informs treatment of recurrence living-related kidney donor selection. Testing with a broad genetic panel may be beneficial for patients with advanced disease. Here we describe an academic transplant center’s early experience with a >380-gene kidney disease panel using NGS, with variant confirmation via orthogonal methods.

Methods: Twenty-six pre- and post-KT patients underwent genetic testing between June 2020 and April 2021. Patients ranged in age from 28 to 67 years, with a median age of 31 years. Genetic testing results were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 38.5% (10/26) of patients tested, in TTR, COL4A3, COL4A4, COL11A1, INF2, and PKD1. Two patients with a pathogenic variant in the TTR gene also had 2 APOL1 risk alleles (G1 and/or G2). Genetic findings confirmed clinical disease in 1 individual, identified a subcategory of clinical disease in 2 individuals, reclassified disease in 3 individuals, and established a molecular diagnosis in 4 individuals. In this cohort, 8 individuals received a KT, of which 6 had no pathogenic variant identified. Of those 6, two had biopsy proven glomerular disease that recurred after early KT, implicating a non-inherited cause of renal disease. Identification of positive pathogenic variants in 75% (3/4) of patients evaluated for a living related donor transplantation, prompted evaluation of the index donor.

Conclusions: Identification of patients awaiting KT who are at increased risk of a monogenic disease can result in a high yield via a broad-panel testing approach. The implications of a genetic diagnosis in this cohort are multifaceted, with potential to impact care and identify family members who may be at risk for kidney failure, and to enable early diagnosis and intervention.
Early Experience with Broad-Panel NGS Testing for Kidney Disease in a Community Nephrology Setting

Tarek Darwish,1 Katya Brossart,2 Hossein Tabriziani,2 "Kansas City Kidney Specialists, Overland Park, KS; 3Nätera, Inc., San Carlos, CA.

Background: Despite the increasing awareness of the value of incorporating genetic testing, its adoption in community nephrology settings is limited. Genetic testing can guide prognostication, targeted treatments, referral to specialists for extra-renal features, and identification of at-risk relatives. For individuals with kidney failure, additional testing can help assess the risk of recurrent kidney disease after transplant and evaluation of suitable living related kidney donors. Broad-panel testing can provide benefits over narrow panels based on clinical presentation.

Methods: Thirty-one patients with kidney disease completed genetic testing with the Nасenst¼±t (NGS-based >380-gene kidney disease panel) between October 2020 and April 2021. Median age of patients was 49 years (range: 28-78 years). Genetic testing results were correlated to clinical histories, demographic factors, family history (when available) and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 22.6% (7/31) of patients tested in the APOL1, PKD1, SLCO4A1, COL4A4, and PKD2 genes (Table 1). Testing resulted in an identification of a pathogenic variant in 85.7% (6/7) of patients and in changes in clinical management for 28.6% (2/7) of patients. Homozygosity or compound heterozygosity for the APOL1 high risk alleles G1 and G2 was identified in 9.7% (3/31) of patients and were found primarily in African American patients.

Conclusions: In the community nephrology setting, the utility of genetic testing as part of the diagnostic workup is multifaceted. As compared to selection of a narrow panel based on clinical features, use of a broad panel that includes reporting of the APOL1 high risk alleles has the additional benefit of identifying genetic causes of kidney disease with ambiguous or non-specific clinical findings.

Findings from Broad Panel Genetic Testing in Patients with Kidney Disease

The Emerging Role of Whole-Genome Investigation to Identify Undetected Nephropathies: The HIDDEN Study

Andrew J. Mallett,1 Amali Mallawarachchi,4 Zornitza Stark,6 Cas Simons,4 Catherine Quinlan,4 Ching Patel.4 The KidGen Collaborative ‘Toowoomba Hospital and Health Service, Toowoomba, QLD, Australia; 2James Cook University, Townsville, QLD, Australia; 3Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; 4Royal Prince Alfred Hospital, Camperdown, NSW, Australia; 5Murdoch Children Research Institute, Parkville, VIC, Australia; 6The Royal Children’s Hospital Melbourne, Parkville, VIC, Australia; 7Royal Brisbane and Women’s Hospital, Herston, QLD, Australia.

Background: 5% of Australian and New Zealand patients commencing kidney replacement therapy have an uncertain kidney disease aetiology. New approaches and tools are required to resolve such diagnostic odysseys. WGS is an emerging diagnostic technology whose role in this setting is unclear. We sought to determine the diagnostic yield of whole genome sequencing (WGS) in individuals with unexplained end stage kidney disease (ESKD).

Methods: Adult and paediatric patients reaching Chronic Kidney Disease Stage 5 before 51 years of age without an identified aetiology were prospectively recruited through an Australian national network of 18 clinics. Eligibility was determined by a national clinical committee based on pre-specified criteria. Clinically-accurated WGS analysis was undertaken with a curated “KidneyOme” virtual panel of genes associated with inherited kidney diseases. A genomic diagnosis constituted a KidneyOme result of pathogenic or likely pathogenic variant/s of appropriate zygoty.

Results: 168 individuals were referred (2018-2021) of whom 147 were approved and 104 consented. Of these, 40 (38.5%) were female and median age was 43yrs; 41 (39.8%) had an eGFR ≤ 90 mL/min/1.73m² and ESKD before 30yrs and 63 (60.6%) had undergone native kidney biopsy. Of 50 results returned to date, 7 (14%) were diagnostic, including both autosomal dominant (4/7) and recessive (3/7) inheritance patterns with 6/7 having a family history of CKD. A further 14/50 had variants of uncertain significance. One diagnosis was due to a copy number variation. The KidneyOme virtual panel curation of 384 genes is publicly available in PanelApp-Australia.

Conclusions: One in seven patients with ESKD of uncertain aetiology had an undetected underlying monogenic cause for their kidney disease. Application of KidneyOme with WGS has clinical utility and should be considered in younger patients with unexplained renal failure.

The Utility of an Inherited Kidney Disease Clinic Employing a Broad Range of Genomic Testing Platforms: Experience of the Irish Kidney Gene Project

Elhussein A. Elhassan,1,3 Katherine A. Benson,2 Susan L. Murray,1 Kane E. Collins,5 Edmund H. Gilbert,1 Dervla M. Connaughton,1,5 Claire Kennedy,1 Mark A. Little,6 Gianpietro Cavalleri,2 Peter J. Conlon,1,3 sailhamer Hospital, Dublin, Ireland; 2Royal College of Surgeons in Ireland Department of Molecular and Cellular Therapeutics, Dublin, Ireland; 3Royal College of Surgeons in Dublin, Ireland, Ireland; 4Western University Schulich School of Medicine & Dentistry, London, ON, Canada; 5Western University Division of Nephrology, London, ON, Canada; 6Saint James’ Hospital, Dublin, Ireland.

Background: Inherited kidney diseases (IKD) are increasingly identified in adult patients. Here we demonstrate the diagnostic and clinical impact of evaluating patients with IKD in a dedicated IKD clinic (IKDC) utilising various genomic testing technologies (whole-exome sequencing, comprehensive gene-panel, and dedicated MUC-1 sequencing) and immunostaining.

Methods: We undertook a prospective cohort study of adult patients referred to an academic medical centre with suspected monogenic cause as part of the Irish Kidney Gene Project (IKGP), between 2014 and 2020. Patients with chronic kidney disease (CKD) who had either a positive family history, extrarenal features, or had CKD of “unknown cause” (uCKD) were recruited from various centres across Ireland. We attempted to identify disease-causing variants and to assess the impact of the IKDC from diagnostic and clinical perspectives.

Results: During this period, genetic testing was performed for 677 adults (n= 501 families). The median age was 53 years (range, 18-93 years) and 73.9% participants had reported a family history of renal disease. We achieved a molecular diagnostic rate of 54% (n= 374/697). Among the identified disease-causing variants, PKD was the largest cohort (n= 183, 47.8% for PKD1 and PKD2), while mutations in three other causative genes were more prevalent among the remaining identified 42 genes encompassing several Mendelian disorders; MUC-1 (n= 43, 8.1%); COL4A5 (n= 36, 7.8%); UMOD (n= 35, 7%). In the remaining 5%, the diagnostic potential of the genetic diagnosis was confirmed in 60.5% and 18% of cases were reclassified. A molecular diagnosis was established in 27 (36.5%) patients with uCKD, implying the end of their diagnostic odyssey. Clinically, a diagnostic kidney biopsy was unnecessary in 13 (77.8%) patients based on the genomic testing. 80 (47.3%) had their treatment plan altered and further 76 (45%) patients had appropriate cascade testing.

Conclusions: The IKDC is a valuable resource and the implementation of a broad range of diagnostic platforms has a direct clinical and therapeutic impact on treatment of patients with CKD.
Characterization of Patients with Alport Syndrome in the United States: A Retrospective Analysis of Medical Claims

Baris Deniz,1 Aparna Singeetham,2 Ishan Goradia,3 Ashwaryaa Clarivite,2
1Reata Pharmaceuticals Inc, Irving, TX; 2Clarivate Analytics US LLC, Philadelphia, PA.

Background: Alport syndrome (AS) is a rare, hereditary genetic condition that often results in chronic kidney disease and may lead to early onset of end-stage kidney disease. The prevalence estimate in the literature is around 30,000–60,000 in the US. However, there are challenges with AS diagnosis (i.e. underdiagnosis and misdiagnosis), hence real-world patient population with AS diagnosis can be less than the prevalence estimates. This study is a retrospective analysis of medical insurance claims aimed to get a real-world estimate of the number of patients with a formal diagnosis of AS in the US, their disease characteristics, and treatment patterns.

Methods: A retrospective, observational cohort analysis was conducted, that leveraged DRG/Clarivate medical claims database, that integrates multi-payer and multi-plan data and covers >220 million annual patients in the US. Patients with at least one ICD-10 code (Q87.81) designated for AS in their medical history between October 2015 to September 2020 were considered diagnosed AS cases. Characteristics of patients and prescription data were analyzed descriptively. Patient interactions with health care professionals (HCP) within the last 24 months of the study window (i.e. October 2018 – September 2020) were used to determine the primary HCP responsible for patient management.

Results: The analysis identified total of 10,387 patients with at least one AS diagnosis code. Of the 42% of the population for whom chronic kidney disease (CKD) stage data were available, 44% had advanced CKD (IV & V). Adult or pediatric nephrologists were the primary HCPs for 59% of patients. Based on the prescription data, 21.6% (2,244 patients) were prescribed ACEs/ARBs, and 10.6% (1,101 patients) were prescribed CYP3A4 inhibitors.

Conclusions: The number of patients our study identified with AS diagnosis is lower than the commonly cited prevalence estimates in the US. The discrepancy can be explained by the fact that the database used covers a majority of but not the whole US population, and our study relies on real-world diagnoses.

PO1297

Utilization of Broad-Panel Genetic Testing for Collagen Disorders of the Basement Membrane Disorders in Patients Requiring Kidney Transplantation

Rupi K. Sodhi,1 Amishi S. Desai,1 Jongwon Yoo,1 Divya J. Arwindekar,2 Katya Brossart,3 Hossein Tabriziani,3 Sanjeev Akkina,1 Loyola University Medical Center, Maywood, IL; 2Natera, Inc., San Carlos, CA.

Background: Patients with advanced chronic kidney disease (CKD) are often misdiagnosed. Etiology of end-stage kidney disease (ESKD) significantly impacts the selection of candidates and donors for kidney transplant (KT), and post-KT management. Identification of a genetic etiology can reclassify disease and alter KT planning. Collagen disorders such as Alport syndrome present with heterogeneous phenotypes. However, a recently proposed classification system incorporates genetic variants into the diagnosis of this disease.

Methods: Twenty-two pre- and post-KT patients with a median age of 33 years (range: 26-67 years), completed genetic testing with RenasightSM (a NGS-based >380-gene kidney panel), between June 2020 and April 2021. Test results related to COL4A4 were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on renal diseases.

Results: Pathogenic or likely pathogenic variants in a type IV collagen gene were identified in 18.2% (4/22) of patients. All four patients had progressed to ESKD at the time of testing. One patient, with a variant in COL4A4, had a right nephrectomy and subsequently developed nephrotic range proteinuria. The second patient, with a variant in COL4A4, had genetic testing after a living related KT; the donor was subsequently referred for genetic counseling. The third and fourth individuals, brothers with a family history of CKD, for which the same familial COL4A4 variant was identified, were both carriers of the APOL1 G1 risk allele. One brother had biopsy-proven FSGS and did not respond to steroids.

Conclusions: Broad panel testing enables the identification of monogenic causes of CKD that can impact the selection of KT candidates and post-KT management.

Healthcare Resource Utilization by Patients with Alport Syndrome in the United States: A Retrospective Claims Analysis

Baris Deniz,1 Sureka Gattu,2 Mohit Mehra,2 Justin W. Li,2 Angela Yuan,2 Samina Khan,1,3 Reata Pharmaceuticals Inc, Plano, TX; 2Trinity Partners LLC, Waltham, MA.

Background: Alport syndrome (AS) is a rare and serious inherited form of chronic kidney disease (CKD) affecting as many as 60,000 persons in the US. In severe cases, patients develop end-stage kidney disease (ESKD) in their 20’s. The health and economic burden associated with AS has not been well-characterized in the literature. This study aims to address this evidence gap.

Methods: A retrospective claims analysis (IBMs MarketScan® Commercial Database) was conducted to assess the healthcare resource utilization (HCRT) by patients with AS in the US. Patients enrolled in a health plan for a minimum of six continuous months with at least 1 inpatient or 2 outpatient claims with the AS-specific ICD-10 code were considered to have a diagnosis of AS. Patients with AS were further segmented into CKD stages, where such information was available, to understand the impact of disease progression on HCRT. Patients with AS were age- and gender-matched to a comparator group without AS diagnosis in a 1:5 proportion. The analysis included commercial (medical and pharmacy) claims from 2015 to 2019.

Results: 851 patients with AS were identified, of which 518 also had a CKD diagnosis. The mean age was 33.3 years and 51% were males. 16.2% of patients were < 18 years old. Patients with AS required more healthcare services than the matched comparator group. 19.2% of patients with AS and CKD had at least 1 inpatient admission over the course of 6 months, versus 2.1% in the matched cohort; 100% had an outpatient or office visit, versus 66% in the matched cohort; 26.7% had at least one emergency department visit, versus 6.6% in the matched cohort. The rate of HCRU increased with the increasing CKD stage, the highest utilization being observed in patients with advanced CKD. Approximately 25% of patients with AS were prescribed RASi’s, which is a commonly used treatment in eligible patients with AS.

Conclusions: Patients with AS were observed to utilize inpatient, outpatient, and emergency department services at higher rates than the comparator group, with high utilization largely driven by late-stage CKD. Consequently, delaying or preventing kidney disease may substantially reduce healthcare expenditures among patients with AS, particularly among patients with ESKD.

Genotype-Phenotype Analyses in Korean X-Linked Alport Syndrome: A Multicenter Study

Hye Sun Kim,1 Hae Il Cheong,1 Hee Gyu Kang,2 Yu Han Ahn,2 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Hallym University Dongtan Sacred Heart Hospital, Hwasong, Gyeyeonggi, Republic of Korea.

Background: X-linked (XL) inheritance, caused by COL4A5 mutation, is most common in Alport syndrome (AS). Many clinical studies have elucidated the correlation between genotype and phenotype in male XLAS, whereas no association has been found in female XLAS. Here, we analyzed genotype-phenotype correlation in Korean XLAS.

Methods: This multicenter, retrospective study collected XLAS cases who has been diagnosed from 1985 to Jan 2021 in 13 tertiary centers of Korea. Sanger or next-generation sequencing were conducted in clinically suspected AS patients (male:female 96:42 from 121 Korean families) for genetic confirmation. We divided the cases into male (n=96) and female (n=4) cohorts according to the mutant types, and compared the clinical characteristics, and treatment patterns.

Results: 96 male patients (median age of presentation was 5.1 years) and 4 female patients (median age of presentation was 12 years) were analyzed. 196 patients according to mutant types, but kidney survival rate was worse for all variant types, especially for COL4A5 mutations (n=46); 2splicing mutations (n=12); 3frameshift or nonsense mutations (n=38). Kidney survival was compared between the groups using Kaplan-Meier method.

Conclusions: There were strong genotype-phenotype correlation in male Korean XLAS. Both male and female XLAS showed similar results consistent with previous papers according to mutant types, but kidney survival rate was worse for all variant types, despite the appropriate use of RASi. These data could potentially be helpful of counseling patients with XLAS.
PO1299

Sparsentan, the Dual Endothelin Angiotensin Receptor Antagonist (DEARA), Improves Kidney Function and Life Span and Protects Against Hearing Loss in Alport Mice with Developed Renal Structural Changes

Dominic E. Cosgrove,1 MichaelAnne Gratto,2 Daniel T. Meehan,1 Denise Vocisk,1 Jacob D. Madison,1 Duane C. Delmiento,1 Gina C. Samuelson,1 Diana Jarocki,1 Radko Komers,1 Celia P. Jenkinson,3 Boys Town National Research Hospital, Omaha, NE; 4Washington University, St. Louis, MO; 5Travere Therapeutics Inc, San Diego, CA.

Background: In Alport syndrome (AS), endothelin type A receptor activation is an important mediator of renal and inner ear pathologies. Sparsentan (SP) administered to COL4A3 -/- mice (AS mice) in prevention mode delayed increases in proteinuria, renal structural changes and hearing loss (HL). Whether these effects translate into preservation of glomerular filtration rate (GFR), increased lifespan (LS) and protection from HL in mice where renal pathology has initiated is unknown.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (WT-V or AS-V), 60 or 120 mg/kg SP (AS-SP60 or AS-SP120) starting at 4 weeks (W) of age or at 5, 6 or 7W. Baseline and 10W glomerulosclerosis (GS) were evaluated in kidney sections from WT and AS-V, AS-SP60 or AS-SP120 mice treated from 4W. The auditory brainstem response (ABR) was used to assess hearing. Evaluation of renal pathology in AS-SP120 11±3Travere Therapeutics Inc, San Diego, CA

Conclusions: Sp peripherally prevented the decline in GFR in AS mice, extends LS and prevents noise-induced HL even in mice with developed renal structural changes. If these results are translated successfully into the clinic, SP may offer a novel treatment approach for both renal injury and protecting hearing in AS.

Interim Analysis of the EAGLE Trial: An Open-Label Study to Assess the Long-Term Safety and Tolerability of Bardoxolone Methyl in Patients with Alport Syndrome

Pablo E. Persola,1 Gerald B. Appel,1 Melanie Chin,2 Bernard V. Fischbach,4 Bertrand Knebelmann,2 Kenneth V. Lieberman,1 Colin J. Meyer,2 Kandai Noku,4 David K. Packham,2 Bruce S. Spinnowitz,10 Stuart M. Sprague,11 Roser Torra,12 Philippe Zaoui,13 1Renal Associates PA, San Antonio, TX; 2Columbia University Irving Medical Center, New York, NY; 3Reata Pharmaceuticals Inc, Irving, TX; 4Kobe Daigaku, Kobe, Japan; 5Structure Federative de Recherche Necker, Paris, France; 6Hackensack Meridian School of Medicine, Nutley, NJ; 7The University of Melbourne Medicine at Royal Melbourne Hospital, Parkville, VIC, Australia; 8The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 9Boise Kidney and Hypertension Institute, Meridian, ID. 10New York Presbyterian Queens Hospital, Flushing, NY; 11NorthShore Medical Group, Evanston, IL; 12Universitat Autonoma de Barcelona, Barcelona, Spain; 13Centre Hospitalier Universitaire Grenoble Alpes, Grenoble, France; 14Dallas Nephrology Associates, Dallas, TX.

Background: Alport syndrome is a rare genetic disease affecting up to 60,000 persons in the US.

Methods: EAGLE (NCT03749447) is an ongoing, international, multi-center, open-label, extended access trial evaluating the longer-term safety and tolerability of bardoxolone methyl ( bardoxolone) in patients with Alport syndrome who completed a prior qualifying clinical trial (CARDINAL Phase 2 and 3; NCT03019185). At baseline, patients were 12 to 70 years old with eGFR 30 to 90 mL/min/1.73 m² and UACR ≥ 3500 mg/g. Patients receive bardoxolone daily and dose is escalated up to 20 mg or 30 mg (for patients with UACR > 300 mg/g).

Results: As of data cutoff (01/18/2021), 96 patients were enrolled in the EAGLE study, including 79 patients from CARDINAL Phase 3 (placebo: n=46, Bard: n=33), and 17 patients who received Bard in CARDINAL Phase 2. Mean age was 42 years, and 8 (8%) patients were <18. At baseline, mean eGFR was 58.2 ± 21.4 mL/min/1.73 m² and mean UACR was 183 ± 40 mg/g. Increases in eGFR were seen in patients who previously received placebo and initiated Bard treatment in EAGLE. Patients who previously received Bard for two years in CARDINAL also continued to experience mean eGFR increases in their third year of treatment. Bard has generally been well tolerated, with no deaths or drug-related severe adverse events (SAEs) reported in EAGLE to date. No drug-related SAEs were reported and no changes in blood pressure were observed. Nearly all (94%) adverse events were mild to moderate.

Conclusions: In EAGLE, Bard increased eGFR in patients with Alport syndrome, and increases observed in CARDINAL were sustained in the third year of treatment. To date, the longer-term safety profile of Bard is similar to that observed in the CARDINAL trial.

Integrated Analysis of the Efficacy and Safety of Bardoxolone Methyl in Patients with Alport Syndrome

Bradley A. Warady,1 Rajiv Agarwal,1 Sharon P. Andreoli,3 Sripal Bangalooru,4 Geoffrey A. Block,5 Arlene B. Chapman,6 Melanie Chin,7 Prasad Devajaran,8 Keisha L. Gibson,9 Angie Goldsberry,9 Laura H. Mariani,10 Colin J. Meyer,11 Megan O’Grady,12 Peter Stenvinkel,13 Glenn M. Chertow,14 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 2Indian University School of Medicine, Indianapolis, IN; 3Riley Hospital for Children at Indiana University Health, Indianapolis, IN; 4New York University Grossman School of Medicine, New York, NY; 5US Renal Care, Plano, TX; 6University of Chicago Division of the Biological Sciences, Chicago, IL; 7Reata Pharmaceuticals Inc, Irving, TX; 8Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 9University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 10University of Michigan Michigan Medicine, Ann Arbor, MI; 11Karolinska Institutet, Stockholm, Sweden; 12Stanford University School of Medicine, Stanford, CA.

Background: Alport syndrome is a rare and serious inherited form of CKD. An integrated analysis of efficacy and safety was conducted from the CARDINAL Phase 2/3 (NCT03019185) and EAGLE (NCT03749447) trials of bardoxolone methyl (Bard) in patients with Alport syndrome.

Methods: THE CARDINAL Phase 2 trial was open-label and enrolled 30 patients ages 12 to 60 years with Alport syndrome, baseline eGFR values 30 to 90 mL/min/1.73 m² and UACR ≥ 3500 mg/g. CARDINAL Phase 3 was an international, multi-center, double-blind, placebo-controlled trial with similar eligibility criteria and randomized 157 patients. EAGLE is an ongoing, open-label, extended access trial that is enrolling patients who completed CARDINAL Phase 2/3 trials.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: A total of 218 patients were included in the analysis (placebo: n=80, Bard: n=138). A majority (61%) of patients were female and receiving renin-angiotensin-aldosterone system inhibitor (83%). Mean age was 40 years, and 31 (14%) patients were <18 years old. Mean baseline eGFR was 60.4 and 62.3 mL/min/1.73 m² and the maximum duration of exposure was 3.2 and 1.9 years for Bard and placebo groups, respectively. The Bard group had significant increases in eGFR from baseline at the last on-treatment assessment (mean±SE: 3.37±1.21 mL/min/1.73 m²; p<0.006). Significant decreases in eGFR were seen in the placebo group (mean±SE: -8.30±1.58 mL/min/1.73 m²; p<0.0001), resulting in a significant difference between groups after treatment withdrawal (p<0.03 vs placebo). Consistent with prior studies, common adverse events (AE) included muscle spasms, aminotransferase increases, and hyperkalemia. Discontinuations due to AEs were uncommon (9% of Bard and 5% of placebo groups). Across all studies, no major cardiac events were observed and no changes in blood pressure were observed.

Conclusions: Consistent with individually reported prior trials, an integrated Alport syndrome analysis set showed that Bard preserved kidney function with significant on- and off-treatment eGFR benefits and was generally well tolerated by patients.

PO1302
Novel Keap-Nrf2 Protein-Protein Interaction Inhibitor UBE-1099 Ameliorates the Severity of Experimental Alport Syndrome
Shota Kasada,1,2 Mary Ann Suico,1 Sayaka Ogi,1 Hitoshi Fukuy1, Hiroki Nara,1 Tsuyoshi Shuto,1 Kazuhiro Onuma,1 Hirofumi Kaki.1,3 Department of Molecular Medicine, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto City, Japan; 2Pharmaceuticals Research Laboratory, UBE Industries, Ube city, Japan; 3Program for Leading Graduate Schools “HfGO (Health life science: Interdisciplinary and Gloal Oriented) Program”, Kumamoto University, Kumamoto, Japan.

Background: Bardoxolone methyl is an electrophilic agent that induces Nrf2 activation by irreversibly and covalently binding to the cysteine residue of Keap1. Bardoxolone methyl has been shown to improve glomerular filtration rate (GFR) in clinical trials, and is attracting attention as a novel agent for chronic kidney disease. However, there is concern about long-term efficacy due to the unknown mechanism of GFR improvement and transient increase in albuminuria. Moreover, irreversible Keap1 inhibitors such as Bardoxolone methyl may covalently bind to other proteins in a non-specific manner and induce side effects due to off-target activities.

Methods: We developed a reversible Keap1 inhibitor that inhibits Keap1-Nrf2 protein-protein interaction (PPI) and evaluated its efficacy using Alport syndrome mice model (Col4a5-G5X). Development of Keap1-Nrf2 PPI inhibitor was performed by fluorescence polarization and Nqo1 induction test. The obtained novel compound UBE-1099 (30 mg/kg/day) and CDDO-Im (3, 10 mg/kg/day; rodent tolerable Bardoxolone methyl analogue) were orally administrated to Alport mice and efficacy was evaluated.

Results: UBE-1099 showed higher Nqo1 induction efficiency compared with CDDO-Im in mouse renal tissue. While CDDO-Im only improved inflammation pathology in Alport mice, UBE-1099 uniformly improved renal function (GFR and Plasma creatinine, but not albuminuria), podocyte injury, glomerulosclerosis, inflammation and fibrosis. Moreover, UBE-1099 treatment significantly prolonged the lifespan of Alport mice.

Conclusions: This study firstly revealed the efficacy of Keap1-Nrf2 PPI inhibitor for glomerulosclerosis. We will elucidate next the mechanism of renal pathology improvement, which may provide useful information for Nrf2 activators including bardoxolone methyl for clinical application.

Silva,15 Peter Stenvinkel,18 Roser Torra,17 Bradley A. Warady,19 Stanford University School of Medicine, Stanford, CA; 2Renal Associates PA, San Antonio, TX; 3Indiana University School of Medicine, Indianapolis, IN; 4Riley Hospital for Children at Indiana University Health, Indianapolis, IN; 5Columbia University Irving Medical Center, New York, NY; 6NYU Langone Health, New York, NY; 7US Renal Care, Plan, TX; 8Reata Pharmaceuticals Inc., Irvine, TX; 9University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 10Kobe Daigaku Igakukai Kenkyuka Igakubu, Kobe, Japan; 11Tufs Medical Center, Boston, MA; 12University of Minnesota Health, Minneapolis, MN; 13Institut Necker-Enfants Malades, Paris, France; 14University of Michigan Medical School, Ann Arbor, MI; 15Boise Kidney and Hypertension Institute, Meridian, ID; 16Karolinska Institutet, Stockholm, Sweden; 17Universitat Autonoma de Barcelona, Barcelona, Spain; 18Children’s Mercy Hospitals and Clinics, Kansas City, MO.

Background: Alport syndrome is a rare and serious inherited disorder of the kidneys affecting as many as 60,000 persons in the US with no specific therapies approved for its treatment.

Methods: An international, multicenter, double-blind, placebo-controlled, randomized Phase 3 trial (CARDINAL; NCT03019185) evaluated the safety and efficacy of bardoxolone methyl (Bard) in patients with Alport syndrome 12 to 70 years of age with baseline eGFR 30-90 mL/min/1.73 m² and UACR ≥ 3500mg/g. As an exploratory endpoint, the trial assessed patient global impression of change (PGIC), a non-disease specific 7-point scale that asks patients to rate how much their illness has changed as very much/much/minimally improved (1, 2, and 3 points), no change (4 pts), or minimally/much very much worse (5, 6, and 7 pts) after 48 and 100 weeks of treatment.

Results: A total of 157 patients were randomized to Bard (n=77) or placebo (n=80). In addition to significant on-treatment and off-treatment increases in mean eGFR relative to placebo (between-group differences of 7.7 ± 2.1 [p=0.0005] at Week 100 and 4.3 ± 1.9 mL/min/1.73 m² [p=0.023] at Week 104, respectively), Bard improved PGIC scores relative to placebo (lower values) after 48 and 100 weeks. Categorical summaries also showed more patients randomized to bardoxolone (34%) reported their condition had improved compared to those on placebo (19%) after 100 weeks of treatment.

Conclusions: In CARDINAL, Bard significantly improved eGFR in patients with Alport syndrome and also resulted in improvements in how patients evaluated their wellbeing.

Funding: Commercial Support - Reata Pharmaceuticals

PO1304
Treatment with Antisense-Oligonucleotide or Splicing Regulating Proteins for X-Linked Alport Syndrome Cases with Deep Intronic Variant
Tomoko Horinouchi,1 Tomohiko Yamamura,1 Sadaayuki Nagai,1 Yuya Aoto,1 Nana Sakakibara,1 China Nagano,1 Kazumoto Iijima,2 Kandai Nozu,1 Kobe University Graduate School of Medicine, Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.

Background: X-linked Alport syndrome (XLAS) is a hereditary progressive renal disease caused by mutation in COL4A5. Some cases of XLAS are caused by deep intronic variants which cause aberrant splicing and produce cryptic exon inclusion. Preventing translation of such cryptic exon has the potential to be an effective therapy. We reported that exon skipping therapy with antisense-oligonucleotide (ASO) was very effective in the XLAS mice model with a truncating mutation. However, an ASO needs very high sequence specificity and few patients can be treated by the same ASO. Therefore, we attempted to modify the splicing pattern not only by ASO but also by proteins important for splicing regulation. U2A6F5 is one of the important splicing related proteins binding to polypyrimidine tracts promoting exonization. It has been reported that overexpression of the U2A6F5 promotes or suppresses exonization in some circumstances.

Methods: We identified four cases of XLAS caused by the presence of the same cryptic exon inclusion (c.384_385ins538-385-385(67)1) by different deep intronic variants: three cases (c.385-756C>G, c.385-749T>A and c.385-645T>A) were ours and 1 (c.385-719G>A) was a reported variant. For these cases, we introduced ASO that could skip cryptic exon. Moreover, using in vitro splicing evaluation system (minigene assay), we attempted to reduce the expression of cryptic exon by overexpression of U2A6F5.

Results: We succeeded in preventing the cryptic Exon insertion by introducing ASO treatment for patient’s urine derived cells. In addition, in all patients, overexpression of U2A6F5 in the minigene splicing analysis system successfully reduced the cryptic exon inclusion.

Small Molecule APOL1 Inhibitors Block APOL1 Pore Function and Reduce Proteinuria in an APOL1-Mediated Kidney Disease Mouse Model
Brandon Zimmerman, Leslie Dakin, Anne Fortier. Vertex Pharmaceuticals Inc, Boston, MA.

Background: Two genetic variants of APOL1 (G1 and G2) are associated with increased risk of kidney diseases. Current treatment options for APOL1-mediated kidney diseases are limited and do not address the underlying cause of disease. Here, we report the discovery of a series of novel small molecule APOL1 inhibitors, including the clinical candidate VX-147, that block APOL1-mediated cell death and ion flux. In addition, activity on APOL1 biological function was assessed using a trypanosome viability assay. Finally, changes in proteinuria following APOL1 inhibitor administration were assessed using a transgenic mouse model homozygous for the APOL1 G2 variant (G2ap50).

Results: Small molecule APOL1 inhibitors showed binding to all three forms of APOL1 (wild-type, G1 and G2 variants). In cellular assays, APOL1 inhibitors prevented APOL1-mediated HEK293 cell death and inhibited APOL1-mediated ion flux. Addition of APOL1 inhibitors to trypanosome cultures rescued the parasites from APOL1-induced killing. The potency of VX-147 was consistent across the in vitro functional assays described above (IC50 of approximately 2nM). Finally, administration of an APOL1-dependent proteinuria in an APOL1-mediated transgenic mouse model of kidney diseases. Taken together, our results strongly suggest small molecule APOL1 inhibitors, such as VX-147, target the underlying cause of disease, and have the potential to treat APOL1-mediated kidney diseases.

PO1306
Inhibition of Endoplasmic Reticulum Stress Signaling Rescues Cytotoxicity of Human APOL1 Risk Variants in Drosophila
Laura Rehnhöjd, Mengxing Chen, Lisa L. Kampf, Julian Milosavljevic, Konrad Lang, Martin Helmstädt, Tobias F. Hermle. Hermle lab Division of Nephrology, University Medical Center Freiburg, Freiburg, Germany.

Background: Renal risk variants of the APOL1 gene are associated with severe kidney disease, putting homogenous carriers at risk. APOL1 G1- and G2-alleles likely represent gain-of-function (GOF) mutations as human subjects with APOL1 null alleles have been found to be without renal anomalies. A wide range of mechanisms that are frequently in conflict have been described for APOL1-associated nephropathies.

Methods: The genetic tool-kit in Drosophila allows unique in vivo insights into disrupted cellular homeostasis. To perform a mechanistic analysis in this model, we expressed APOL1 control and the GOF renal risk variants in the podocyte-like Drosophila nephrocytes and a wing precursor tissue. Results: APOL1 risk variant expression entailed elevated endocrine function of garland cell nephrocytes while processing of endocytic cargo and slit diaphragm morphology remained unimpaired. All APOL1 variants located to the endoplasmic reticulum (ER) and electron microscopy revealed significantly elevated ER swelling upon expression of risk variant G2-APOL1, indicating stimulation of ER stress. We employed Drosophila wing precursor tissue since this epithelial model enables unique recording of relative changes side by side within the same animal to study ER stress. Overexpression of the renal risk variants G1 and G2 caused a markedly stronger upregulation of PDI and apoptosis, while expression of wildtype APOL1 resulted in milder upregulation. As a control, ER stress was absent upon deletion of 9 aa in the BH3 domain in the G2-APOL1 construct. We further confirmed APOL1-dependent ER stress by detection of chaperone induction and an Xbp1-reporter in the wing precursor. Both, genetic and pharmacological inhibition of ER stress abrogated apoptosis identifying ER stress as the essential factor of APOL1-induced cytotoxicity. This represents the first rescue of APOL1-associated cytotoxicity in vivo. Direct ER stress induction in nephrocytes phenocopied APOL1 risk variant expression, supporting that ER stress underlies the gain-of-function in nephrocytes.

Conclusions: Our data reveal ER stress as the essential consequence of APOL1 risk variant expression in vivo, indicating this pathway’s central role in the pathogenesis of APOL1-associated nephropathies.

PO1307
A Cohort Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) Started on SGLT2 Inhibitors
Anthony J. Bleyer,1,2 Kendrah O. Kidd,1,2 Hannah C. Ainsworth,1 Victoria C. Robins,1 Abbigail Taylor,1 Lauren Martin,1 Alice Kim,1 Venkata Sabbsieti,1 Carl D. Langefeld,1 Stanislav Knoech,1,2 Anthony J. Bleyer,1,2 Wake Forest University School of Medicine, Winston-Salem, NC; 3Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; 4Harvard Medical School, Boston, MA.

Background: Sodium-glucose co-transporter-2 inhibitors (SGLT2i) have been shown to slow estimated glomerular filtration rate (eGFR) decline in chronic kidney disease (CKD) but have not been tested in patients with ADTKD. We performed a prospective nested cohort observational study and analyzed changes in eGFR and kidney injury marker 1 (KIM-1) in patients who were prescribed SGLT2i by their physicians.

Methods: We obtained baseline and follow-up laboratory studies at 1 week, 1 month, and 4 months after starting an SGLT2i and compared eGFR with baseline function. We also obtained information about adverse events.

Results: 12 individuals were started on SGLT2i by their physicians, with 10 on empagliflozin, 2 dapagliflozin. Table 1 shows the changes in eGFR and KIM-1. For patients with eGFR > 30, mean eGFR increased at 1 month by 3 ml/min. At four months, eGFR was 3 ml/min below baseline (-18.5% due to low baseline eGFR). For eGFR > 30, eGFR decline was 12% from baseline at one month and 8% from baseline at 4 months. Plasma KIM-1 was unchanged, but urinary KIM-1 increased by 100%. One patient stopped empagliflozin at his request after 8 weeks due to decline in eGFR of 14% from baseline. No other adverse events noted. Two patients have been treated for 6 months with stable eGFR.

Conclusions: The change in eGFR after treatment with SGLT2i was consistent with prior studies of CKD. The plasma KIM-1 was unchanged, but the rise in urinary KIM-1 was very concerning. Further study is required to determine if these agents are beneficial in ADTKD. An additional 4 months of follow up will be presented at ASN.

Funding: NIDDK Support, Private Foundation Support

*Mean was computed as the average change in eGFR for each individual (at time point), compared to their baseline measurement.

PO1308
A Prospective Observational Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)
Kendrah O. Kidd,1,2 Adrienne H. Williams,1 Victoria C. Robins,1 Abbigail Taylor,1 Lauren Martin,1 Alice Kim,1 Martina Zivna,2 Carl D. Langefeld,1 Stanislav Knoech,1,2 Anthony J. Bleyer,1,2 Wake Forest University School of Medicine, Winston-Salem, NC; 3Univerzita Karlova 1 lekarska fakulta, Praha, Czechia.

Background: GFR decline in ADTKD due to UMOD or MUC1 mutations has not been well characterized. We have begun an international prospective cohort study to determine genetic and environmental factors associated with progression. We report here on early recruitment.

Methods: Patients with positive genetic testing for UMOD or MUC1 mutations prior to transplantation or starting dialysis are eligible. A baseline collection of health information, serum and urine biomarkers will be performed, with patients then followed longitudinally, with a serum creatinine measurement performed three times per year. There will be a nested cohort of study women who develop pregnancy during the study and patients started on ACE inhibition.

Results: Since March 2021, we have enrolled 57 patients in the prospective observational study, with 20 men, 35 women. The mean age of patients is 43.3 years, the mean baseline eGFR is 39.96 ml/min/1.73m2. Table 1 shows baseline characteristics of patients enrolled in the study. No patients with CKD Stage 1 or 2 suffered from HTN, and only 39% of patients with CKD Stage 3 had HTN. Only 18% of patients were receiving ACE/ARB inhibition.

Conclusions: Despite significant CKD, there was a relatively low prevalence of HTN. Only 18% of patients were receiving ACE inhibition, indicating a potential therapeutic intervention. Please contact us if you have a patient who may be interested in participating in this prospective study (tablever@wakehealth.edu).

Vasopressin Induces Urinary Uromodulin Secretion by Activating Protein Kinase A

Azuma Nanamatsu, Takayasu Mori, Fumiaki Ando, Taisuke Furusho, Shintaro Manda, Koichiro Sasa, Eisie Sohara, Tatetsu Ra, Shinichi Uchida.
Tokyo Medical and Dental University, Tokyo, Japan.

Background: Urinary uromodulin, secreted by renal tubular cells, protects against urinary tract infections (UTIs) and kidney stones. In contrast, the intracellular accumulation of uromodulin is associated with hypertension and chronic kidney disease (CKD). In addition, uromodulin gene mutations cause autosomal dominant tubulointerstitial kidney disease (ADTKD-UOMD) via abnormal intracellular accumulation of uromodulin. However, the physiological stimuli for urinary uromodulin secretion remain largely unknown.

Methods: We investigated the acute effect of vasopressin/cAMP signaling on urinary uromodulin secretion in mice and in kidney epithelial cells stably expressing uromodulin. Additionally, we assessed the effect of vasopressin/cAMP signaling in kidney epithelial cells stably expressing mutant uromodulin, which causes ADTKD-UOMD.

Results: Desmopressin, a vasopressin type 2 receptor agonist, dramatically increased short-term tubular uromodulin secretion in mice. Immunofluorescence studies and ultracentrifugation-based polymerization assay suggested that desmopressin induced intracellular polymorphic filaments of uromodulin, indicating physiologically functional secretion. As a result of increased excretion, uromodulin abundance in the murine kidney was clearly reduced by desmopressin. In the cellular model, apical uromodulin secretion was increased in response to vasopressin/cAMP signaling, consistent with in vivo experiments. We also demonstrated that the response was dependent on cyclic AMP-dependent protein kinase (PKA) signaling pathway. We further showed that cAMP signaling induced excretion of mutant uromodulin. cAMP signaling suppressed PERK phosphorylation, which was upregulated by mutant uromodulin. cAMP signaling induced cytoprotective effects.

Conclusions: Our work revealed vasopressin/cAMP/PKA signaling as a physiological stimulus of urinary uromodulin secretion. This finding may provide the basis for novel treatment strategies for UTIs, kidney stones, and potentially hypertension, nephrolithiasis, and nephrocalcinosis. This disease is caused by inactivating mutations in the CLOC5 gene, which encodes the voltage-gated CIC-5 chloride/proton antipporter. CIC-5 is expressed predominantly in the kidney and participates in the acidification of proximal tubule endosomes. Currently, the treatment of DD1 is only supportive and focused in delaying disease progression. Our group has generated a Clocn5 knock-in (KI) mouse that presents the main clinical manifestations of DD1 and carries the pathogenic mutation p.V232del, which causes partial CIC-5 retention in the endoplasmic reticulum. Here, we aimed to assess the ability of sodium tripolyphosphate (4-PBA), a small chemical chaperone, to ameliorate DD1 symptoms in this mouse model.

Methods: Twelve-weeks old male Clocn5 KI mice (n=50) and WT (n=33) littermates were divided into 2 groups, one was treated with 250 mg/kg/day of 4-PBA in drinking water for 30 days, whereas the other group was given water without the drug for the same amount of time. Mice were placed in metabolic cages before and after treatment for 24h. Urinary β2-microglobulin and serum and urinary creatinine were measured by ELISA. Calcium and phosphate concentrations in urine were estimated using colorimetric kits. Water intake and food intake and 24-h urinary excretion were also measured, and mouse body weights were monitored.

Results: We observed a significant reduction of β2-microglobulin urinary excretion in KI mice treated with 4-PBA compared to non-treated animals (p<0.0004). Glomerular filtration rate was also improved in treated mice (p=0.03). Urinary production, urinary calcium, and phosphate levels did not differ compared with non-treated mice.

Conclusions: 4-PBA reduces LMPB in Clocn5 KI mice, suggesting that this treatment could represent a promising therapeutic option for some DD1 patients.

Long-Term Efficacy of Migalastat on Renal Function and Outcomes in Patients with Fabry Disease (FD)

Daniel G. Bieche,1 Ulla Frist-Rasmussen,2 Roberto Giugliani,3 Derron Hughes,4 Eva Krasinska,2 Billiana O. Veleva-Rotse,6 Department of Medicine, Hôpital du Sacré-Cœur, University of Montréal, Montréal, QC, Canada; 2Department of Medical Endocrinology and Metabolism, Rigshospitalet, National University Hospital, Copenhagen University, Copenhagen, Denmark; 3Medical Genetics Service, HCPA, Department of Genetics, UFRGS, and INIAGEM, Porto Alegre, Brazil; 4Lysosomal Storage Disorders Unit, Royal Free London NHS Foundation Trust and University College, London, London, United Kingdom; 5Aimiere Therapeutics, Inc., Philadelphia, PA.

Background: FD, caused by pathogenic GLA variants leading to functional deficiency of α-galactosidase A (α-Gal A), can eventually result in key organ damage. Preserving renal function and preventing Fabry-associated clinical events (FACEs) are important treatment goals. Approved therapies include enzyme replacement therapy (ERT) and the pharmacological chaperone migalastat. Stabilized renal function and FACE occurrence up to 30 mo have been reported in migalastat-treated adults with amenable GLA variants; here, we extend these analyses up to 8.6 yrs.

Methods: Integrated data from phase 3 clinical trials (FACETS, NCT00925301; ATTRACT, NCT01218659) and open-label extension studies (NCT01458119; NCT00925185) were used to evaluate the eGFR slope using linear regression in pts treated with migalastat for 22 yrs (n=78). Incidences of FACEs (predefined renal, cardiac, and cerebrovascular events) were assessed in all pts (N=97). Analyses were stratified prior treatment and phenotype. Cox regression modeling was used to identify predictors of FACE occurrence.

Results: eGFR remained stable for both ERT-naive and ERT-experienced pts who received migalastat for 22 yrs (median [min-max] duration: 5.9 [2.0-8.6]); the mean (SD) annualized rates of change in eGFR (mL/min/1.73 m²) were -1.6 (3.1) and -1.6 (3.6), respectively. In male pts with the classic phenotype (classification based on multigorgan involvement and [ERT-naive only] α-Gal A level at baseline; n=25), mean (SD) rate of change in eGFR was -2.2 (4.4) mL/min/1.73 m², eGFR was also analyzed by baseline renal function and proteinuria levels. In all migalastat-treated pts (median duration: 5.1 yrs), the incidence of composite FACEs (per 1000 patient-years) was 48.3 (65.3 for...
classic males) and incidence of renal events was 4.4 (14.5 for classic males). Lower baseline eGFR and FACES in classic males vs all others; however, rate of renal events was too low to analyze predictors.

Conclusions: Results demonstrate long-term efficacy of migalastat in stabilizing eGFR in pts with FD, including male pts with the classic phenotype. FACES incidence in pts receiving migalastat compared favorably to historic reports of ERT. The inverse correlation of eGFR with FACES suggests the importance of early diagnosis and treatment to preserve renal function.

POI1313

Twenty-Year Renal Prognosis in Patients with Fabry Disease Who Underwent Enzyme Replacement Therapy

Akane Miura, Masahiro Okabe, Kotaro Harahara, Izumi Yamamoto, Nobuo Tsuboi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine Tokyo Jikeiiku Iku Daigaku, Minato-ku, Japan.

Background: The relationship between long-term renal prognosis and renal histopathology after enzyme replacement therapy (ERT) for Fabry disease (FD) has not been fully investigated.

Methods: Nine patients with FD from our hospital who had participated in a Japanese phase 2 study (August 2000–May 2001) on agalsidase β were eligible for this case-control study. They underwent repeated renal biopsy (before and six months after agalsidase β treatment), and the intra-renal amount of globotriaosylceramide (GL3) was measured at the same time points. Clinicopathological features were compared between the groups with or without developing end-stage kidney disease (ESKD).

Results: Seven patients were included in this study. Among them, two were lost to follow-up. All were males, with a median age at the start of treatment of 30 [quartile 24.5, 31.5] years, and median serum creatinine level (s-Cr) of 1.1 [1.0, 1.2] mg/dL. The podocyte score (International Study Group of Fabry Nephropathy score system) improved in all patients after ERT from that evaluated before ERT. Intersitial fibrosis/tubular atrophy (IF/TA) worsened in three patients. The proportion of foamed tubules improved in five patients. Intra-renal accumulation of GL3 decreased six months after ERT in all patients. All patients continued to receive agalsidase β or agalsidase α after the phase II study. While seven patients developed ESKD (median 6.7 years), three patients showed no exacerbation of renal function. The s-Cr level, age, and urinary protein excretion at the start of ERT were higher in the ESKD group. The decrease in the intra-renal accumulation of GL3 was not significantly different between the two groups, but the proportion of foamed tubules in the first biopsy and the degree of IF/TA in the second biopsy were higher in the non-ESKD group compared with the ESKD group. We found that the non-ESKD group had a lower baseline eGFR and a higher s-Cr level than the ESKD group. The difference in the expression of IF/TA was observed in all patients.

Conclusions: This study suggests that tubulointerstitial injury has a crucial role in the determination of renal prognosis and that earlier diagnosis and intervention in patients with FD may improve the renal prognosis. Further studies are needed on the relationship between tubulointerstitial injury and GL3 accumulation.

POI1314

Systems Analyses of Fabry Renal Transcriptome and Its Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Drugable ERT-Resistant Module

Emanuela Oystein, Peter Nowak, Andrea Rinaldi, Hans-Peter Marti,1,2 Department of Medicine, Hakioland University Hospital, Bergen, Norway; 3Department of Clinical Medicine, University of Bergen, Norway; 4Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 52cSysBioMed, Contra, Switzerland; 6Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland; 7Fundeni Clinical Institute, Bucharest, Romania; 8Department of Pathology, University of Zurich, Zurich, Switzerland; 9Department of Pathology, University of Zurich, Zurich, Switzerland; 10Department of Pathology, University of Zurich, Zurich, Switzerland; 11Institute of Pharmacology, Research Ocenol Institute of Southern Switzerland, Bellinzona, Switzerland.

Background: Fabry nephropathy (FN) is a rare disorder caused by mutations in the alpha-galactosidase A gene that can, to a certain degree, be managed with enzyme replacement therapy (ERT). Via understanding the molecular basis of FN and ERT's long-term impact, we aim at providing a framework allowing selection of biomarkers and drug targets.

Methods: Obtained from controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies taken prior and up to 10 years of ERT, were subjected to RNAseq. Combining pathway-centered analyses with network-science allowed to estimate their suitability as biomarkers and potential targets for adjunct treatment.

Results: Combining transcriptional landscapes comprehensively reflected differences in FN-cohort characteristics. With the exception of few key aspects, in particular concerning arteries, early ERT in classical Fabry patients could lastingly revert FN kidney-compartment's molecular state to closely match N. CTRs. Thus, we identified and cross-validated ERT-resistant modules that, when leveraged with external data, allowed estimating their suitability as biomarkers and potential targets for adjunct treatment.

POI1315

Resistant Focal Segmental Glomerulosclerosis (FSGS) due to Leci-thin-Colesterol Acyltransferase (LCAT) Deficiency: Is Early Gene Testing the Answer?

Moorj A. Qazi,1,2 Himu Qazi,1,2 Mary-Beth Roberts,1 Richard A. Fatica,1 Robert J. Heyka,1 Xiangling Wang,1 Cleveland Clinic, Cleveland, OH; 3Army Medical College, Rawalpindi, Pakistan.

Introduction: LCAT deficiency is a rare autosomal recessive disorder due to mutations in the LCAT gene presenting with corneal opacities, anemia, proteinuria, reduced HDL and CKD with progression to ESKD by the 4th–5th decade. Electron microscopy (EM) is characteristic for abundant partially electron-dense and lucent deposits in the mesangium and basement membrane. Late diagnosis is not uncommon due to its rarity and nonspecific presentations in the early stages. Here we report a case of therapy resistant FSGS later uncovered as LACT deficiency confirmed by gene tests.

Case Description: A 49-year-old male presented to genetic nephrology clinic in 2020 with a clinical diagnosis of LCAT deficiency. In 2007, he had presented with hematuria, proteinuria with a serum creatinine of 2.4mg/dL, Hb 11 g/dL, albumin 2.4g/dL, total cholesterol 416mg/dL, HDL 14mg/dL and urine protein of 8.9g/d. Urine microscopy showed fine granular casts and dysmorphic RBCs. Kidney biopsy revealed FSGS with moderate tubulointerstitial fibrosis. EM showed some unexplainable intramembranous podocyte lesions and subendothelial thickening, which were thought to be sequelae of prior immune mediated membranous glomerulonephritis. Patient failed treatment with months of steroids, oral cyclophosphamide and mycophenolate. Repeat biopsy in 2010 showed worsening of the prior findings. In 2011, corneal deposits led to a suspicion of LCAT deficiency. He progressed to ESKD in 2011 and kidney transplant in 2020. Genetic testing disclosed a homozygous nonsense variant c.321C>A (p.Tyr107*) in LCAT gene. A thorough genetic counseling included risk for his siblings and graft recurrence.

Discussion: LCAT deficiency can present with resistant or atypical appearing FSGS. This case emphasizes the need of early genetic assessment on suspicious biopsies or therapy resistant FSGS cases to timely diagnose and avoid unnecessary immunosuppression.

POI1316

ESKD due to Primary Hyperoxaluria Type I

Peter E. Thorpe, Julia Lewis. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Primary hyperoxaluria type I (PH1) is a rare autosomal recessive disease (less than 3 cases per million population). Nephrolithiasis and nephrocalcinosis lead to progressive renal impairment and subsequent oxalate deposition in various tissues. We present a case of PH1 diagnosed late in life and ultimately requiring definitive management with liver-kidney transplant due to rapid progression to end stage kidney disease.

Case Description: 55 year old male with history of renal calculi at birth, recurrent nephrolithiasis and PHT1 was hospitalized for acute kidney injury following 2 weeks of nausea and poor intake. His admission serum creatinine (Scr) was 11 from baseline of 3.5 four months before. He was diagnosed with PHT1 eight months prior via urinary oxalate measurement and genetic testing. He was started on low oxalate diet, calcium carbonate 1000mg with meals and pyridoxine 500mg daily. Ultrasound at admission notable for...

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
diffuse increased echogenicity and bilateral non-obstructing calculi. Initial serum oxalate level was 63.5micromol/L and 24 hour urine oxalate level was 116mg/24hrs. Ser failed to improve with intravenous fluid administration and renal replacement therapy was initiated with goal serum oxalate level of <30micromol/L. Hemodialysis was performed daily for four hours with high flux membrane. Serum oxalate levels improved to nadir of 40micromol/L. Definitive therapy with simultaneous liver-kidney transplant was ultimately pursued.

Discussion: Our patient required intensive hemodialysis while awaiting liver-kidney transplant following late diagnosis of PH1 and development of end stage kidney disease. Early diagnosis is key to reduce morbidity and mortality. Progressive kidney impairment leads to inability to excrete the increased oxalate produced by the liver and subsequent systemic deposition of oxalate including in the kidney causing multiorgan dysfunction. Hemodialysis removes oxalate but it is difficult to consistently reduce serum oxalate levels below goal given continued production of oxalate and rebound. Early treatment options include a trial of pyridoxine, hyperhydration, low oxalate diet and novel RNA inhibitors.

PO1319

Modeling the Risk of Progression to Kidney Failure in Patients with Primary Hyperoxaluria type 1 Treated with Lumasiran Relative to a Natural History Cohort Not Treated with Lumasiran

John C. Lieske,1 Kristin C. Mara,1 David S. Danese,2 Jiandong Liu,3 Dawn S. Milliner,1 Mayo Clinic Minnesota, Rochester, MN; 2Alnylam Pharmaceuticals Inc, Cambridge, MA.

Background: In primary hyperoxaluria type 1 (PH1), the risk of kidney failure (KF) is positively associated with urinary oxalate (UOx) excretion. Lumasiran is an RNAi therapeutic to lower UOx levels in patients with PH1. We estimated the risk of progression to KF in patients with PH1 treated with lumasiran, relative to patients not treated with lumasiran.

Methods: A skewed-normal distribution of 24hr UOx values for patients with PH1 was simulated based on reported UOx values from the Rare Kidney Stone Consortium (RKSC) PH Registry among patients who were not in KF at diagnosis and did not receive lumasiran. Data from the ILLUMINATE-A trial of lumasiran were used to build a log-linear model of post-lumasiran treatment steady-state UOx as a function of baseline UOx. The distribution of steady-state, on-treatment UOx values for RKSC patients was then predicted by applying this model to the simulated 24hr UOx values of the RKSC cohort.

Conclusions: A risk model of KF as a function of 24hr UOx excretion, based on Kaplan-Meier curves of renal survival reported from the RKSC, was used to estimate the number of KF events/100 patients in the RKSC PH1 cohort, had all received lumasiran.

Results: The mean (SD) 24hr UOx excretion for the RKSC PH1 cohort was 2.2 (1.1) mmol/24hr/1.73m2 in the absence of lumasiran treatment and was predicted to decrease to 0.62 (0.17) mmol/24hr/1.73m2 in a model that simulated the effect of lumasiran administration (Figure 1). The predicted number of KF events/100 patients (95% CI) using the model for patients not treated with lumasiran at 10, 20 and 30 years, is 10 (4, 23), 32 (19, 50), and 42 (27, 59), respectively. In the model of lumasiran treatment, the estimated cumulative number of KF events/100 patients (95% CI) was 4 (1, 12) at 10 years and remained unchanged at 20 and 30 years.

Conclusions: This analysis predicts a long-term reduction in KF risk among PH1 patients treated with lumasiran, associated with prompt treatment at diagnosis.

PO1318

Association Between Longitudinal Plasma and Urine Oxalate and Time-to-Kidney Failure in Primary Hyperoxaluria Using Joint Models

Lisa E. Vaughan, John C. Lieske, Phillip Schulte. Mayo Clinic Minnesota, Rochester, MN.

Background: The association between plasma oxalate (POX), urine oxalate (UOX) and time to kidney failure (KF) in patients with the rare disease primary hyperoxaluria (PH) is challenging to study due to small sample sizes and correlations among POX, UOX, and eGFR. To develop better KF models that simultaneously account for all 3 variables we used a novel statistical approach, joint models, modeling longitudinal biomarker processes (eGFR, POX, UOX) and survival process (time-to-KF) jointly, using retrospective data from the Rare Kidney Stone Consortium PH registry.

Discussion: To jointly model longitudinal biomarker processes and survival process, we employed the joint model framework. The joint model framework allows flexible estimation of the association, which may impact conclusions. These novel methods can be used to inform patient-specific decisions about future KF risk, and the risk-benefit of novel treatment approaches.

Methods: Repeated eGFR, UOX, and POX after PH diagnosis were obtained from the registry. Time-to-KF was defined as time between PH diagnosis until transplantation, dialysis or eGFR<15 mL/min/1.73m2. A multivariate joint model was fit with longitudinal sub-models for each biomarker and a survival sub-model for KF. Longitudinal sub-models employed linear mixed effects models with biomarkers on the log scale. Joint models shared information between longitudinal and survival sub-models such that eGFR, UOX, and POX were time-dependent variables in the survival sub-model, specifically using subject-specific mean biomarker values. Models were adjusted for age and sex at diagnosis. Results were compared to last observation carried forward (LOCF) analyses.

Results: A total 166 patients (mean 5 POX and 7 UOX per patient) with 60 KF events during follow up were included. With LOCF, POX positively associated with KF risk, both unadjusted and adjusted for other biomarkers (hazard ratio (HR) = 1.14 per mmol/L, 95%CI = 1.07, 1.22, p<0.001), while UOX was not associated with KF after adjustment. With joint modeling, POX and KF were not significantly associated after adjustment (HR = 1.12, 95%CI = 0.99, 1.30, p=0.08), while higher UOX was associated with lower KF risk (HR = 0.30 per mmol/1.73m2/24h, 95%CI = 0.07, 0.92, p=0.04).

Conclusions: When modeling unevenly spaced longitudinal biomarkers and their association with KF, the LOCF time-dependent model makes implausible assumptions about steady-state biomarkers between observations. Implementation of a joint modeling framework allows flexible estimation of the association, which may impact conclusions.

The Complex Landscape of Factor H and Factor I Rare Variants in Atypical Hemolytic Uremic Syndrome and C3 Glomerulopathy

Veronique Fremeaux-Bacchi,1,2 Marie-Sophie Meuleman,2 Paula Vieira-Martins,1 Sophie Chauvet,1 Fadi Fakhouri,1,2 Assistance Publique-Hôpitaux de Paris, Paris, France; INSERM U1138, Paris, France; Lausanne University Hospital, Lausanne, Switzerland.

Background: Complement genetics has been extensively studied to dissect the pathophysiology of atypical hemolytic uremic syndrome (aHUS) and C3 glomerulopathy (C3G) paving the way for highly tailored therapy. However, the assessment of each identified variant’s contribution to disease pathogenesis remains a challenge in particular for rare variants detected in patients as well as in healthy individuals in the genome Aggregation Database (gnomAD). In this study we aimed to describe the rare variants in Factor H (CHI) and Factor I (CFI) genes identified in the French cohort of patients with aHUS and C3G.

Methods: We analyzed the distribution of the allele frequency (AF) of rare variants identified in 397 and 398 adult patients with a diagnosis of aHUS without coexisting disease and with C3G/aggregated-mediated membranoproliferative glomerulonephritis (Ig-MPGN), respectively. We selected for this study variants with minor AF (MAF) below 0.1% in European healthy individuals.

Results: The frequency of patients with rare variants in CHI (108/398 vs 54/398) and CFI (33/397 vs 17/397) genes was higher in aHUS compared to C3G. A total of 148 variants were identified in CHI (n=98) and in CFI (n=50) genes. Among them, 9 were present in both diseases. We identified 43 (67%) and 20 (66%) novel variants in CHI and CFI in aHUS and C3G, respectively. Among them, 98% are pathogenic or likely pathogenic. The frequency of rare variants reported in gnomAD. The frequency of variants causing FH and FI deficiency is similarly in both diseases (70% of the variants). The frequency of CHI variants identified in more than 1 patient is increased in aHUS compared to C3G (11/64 vs 2/38). We identified 12 (12/38, 31%) and 2 (2/12, 16%) novel variants in CFI in aHUS and C3G, respectively. Reported variants in CHI are more frequent in C3G than in aHUS (10/12 vs 26/38). The frequency of variants reported in gnomAD is higher in CHI (80%) compared to CFI (14%).

Conclusions: Our study indicates that novel pathogenic rare variants in complement genes are more frequent in aHUS than in C3G. However, half of the variants reported in gnomAD have a potential impact on gene function. Our results suggest that CHI variants are more damaging than CFI variants, and may contribute more significantly to the pathogenesis of both diseases, as compared to CFI.

PO1321

Phenotypic-Genotypic Relationship of Focal and Segmental Glomerulosclerosis (FSGS)

Ana M. Tato,1 Noa Carrera cachaza,2 Maria Garcia-Murias,2 Amir Shabaka,1 Clara M. Cases Corana,1 Gema Fernandez Juarez,1 Miguel A. Garca-Gonzalez,2 Hospital Universitario Fundacion Alcorcon, Alcorcon, Spain; Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain.

Background: FSGS can be of primary, secondary or genetic origin. The objective of our work is to establish in which patients with a histological diagnosis of FSGS a genetic etiology should be suspected.

Methods: The study included adult patients with a histological diagnosis of FSGS and normal albumin less than 58%. We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases with normal albumin (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases with normal albumin (58%).

Results: Out of 108 samples received, 80 patients met the inclusion criteria. We detected FSGS-related pathogenic genetic variants in 31 (39%) patients, finding no difference between those whose indication was steroid resistance (32 %) or proteinuria with normal albumin (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases with normal albumin (58%).

Conclusions: Genetic testing should be considered in FSGS patients in which a secondary cause has been excluded, to determine the patient’s prognosis, treatment and perform familial screening.

Insight into the Pathophysiology of Hearing Loss and Renal Tubular Dysfunction Through Genetic Testing

Dylan H. West,1 Jones Samuel,1 2 Baton Rouge General Medical Center - Bluebonnet, Baton Rouge, LA; 2 Renal Associates of Baton Rouge, Baton Rouge, LA.

Introduction: In this case report, we present a case of Type 3b Bartter’s Syndrome associated with sensorineural hearing loss.

Case Description: A 69 year old caucasian female with a history of hypertension and osteoporosis presented to the emergency department with a worsening dry cough, altered mental status, and paresthesias. Physical examination was positive for Chvostek’s sign and hearing loss bilaterally. Laboratory analysis was significant hypokalemia, hypocalcemia, hypoparathyroidism, and nephrocalcinosis. EKG on presentation displayed significant QT prolongation (QTC of 482 ms). The patient was treated for symptomatic hypocalemia and initiated on calcium, potassium, and magnesium supplementation. 24 hour urine collection yielded: potassium and magnesium wasting and normal range calciuria. Parathyroid hormone was found to be inappropriately low in the setting of severe hypocalcemia but attributed to hypomagnesemia. Bartter’s vs. Gitelman’s was suspected, although profound hypomagnesemia suggested the latter. Renasight, a kidney gene panel employing next generation genome sequencing revealed a heterozygous variant in the basal chloride channel (CLCNKB), associated with Bartter’s Syndrome Type 3/4B. This channel is found in the stria vascularis and can lead to sensorineural deafness. Hypoparathyroidism persisted in spite of adequate Magnesium, Vit D levels suggestive of primary hypoparathyroidism of autoimmune etiology.

Discussion: The positivity of CLCNKB heterozygous mutation suggested Bartter’s Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 115 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes loss of type 1 (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidism for which no genetic basis was identified such as the calcium sensing receptor mutation.

Whole-Exome Sequencing as a First-Line Diagnostic Tool in Bartter and Gitelman Syndromes

Francesca Becherucci, Viviana Palazzo, Luigi Cirillo, Benedetta Mazzinghi, Valentina Raglianti, Samuela Landini, Paola Romagnani. Meyer Children's Hospital, Florence, Italy.

Background: The clinical diagnosis of Bartter (BS) and Gitelman syndrome (GS) can be challenging, as they are rare and phenotypically overlapping. Thus, genetic testing represents the gold standard for the diagnosis. Next-generation sequencing is increasingly utilized in diabetics and research of inherited tubulopathies. Sequencing of gene panels achieved high diagnostic yield and new insights into the phenotype spectrum of these rare disorders. Whole-exome (WES) is not routinely performed for the molecular diagnosis of BS and GS. The aim of our study was to assess the diagnostic performance of WES in BS and GS, to establish genotype-phenotype correlations and to assess cost-effectiveness of this approach.

Methods: We performed WES in all consecutive patients referred for genetic testing with a clinical suspicion of BS or GS. Variant prioritization was carried out according to ACMG guidelines. Clinical data were collected retrospectively.

Results: We enrolled 50 patients (22 males) with a clinical diagnosis of BS or GS. All the patients showed hypokalemic metabolic alkalosis at onset. The median age at clinical diagnosis was 7 years (range 0-67). WES showed pathogenic variants in 41/50 patients (82%). A dedicated analytic pipeline allowed us to identify copy number variations (CNVs) in 7/41 patients with a confirmed genetic diagnosis. In details, WES allowed us to confirm the clinical diagnosis in 33/50 patients and to change it 8 additional patients (6 patients from BS to GS, 2 patients outside the BS/GS spectrum). Nephrocalcinosis was detected in 38% vs 8% of patients with a genetic diagnosis of BS and GS, respectively. Hypoparathyroidism was similarly distributed among BS and GS patients (45% vs. 68%). Finally, patients with GS showed a median age at onset higher than patients with BS, but some overlap did exist, making differential diagnosis challenging at single-patient level.

Conclusions: The results of our study demonstrate that WES ensures a high diagnostic yield in patients with a clinical diagnosis of BS or GS, especially if coupled with analysis of CNVs. This approach showed to be useful in dealing with the phenotypic heterogeneity typical of these rare disorders, improving differential diagnosis by detecting phenocopies also outside the BS/GS spectrum.

Examination of the Predicted Prevalence of Gitelman Syndrome by Ethnicity Based on Genome Databases
Atsushi Kondo,1 Sadayuki Nagai,2 Yuya Aoto,1 Nana Sakakibara,1 China Nagano,1 Tomoko Horinouchi,1 Tomohiko Yamamura,1 Kazumoto Iijima,2 Kandai Noza,1 Kobe University Graduate School of Medicine, Department of Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: Gitelman syndrome is an autosomal recessive inherited salt-losing tubulopathy. It has a prevalence of around 1 in 40,000 people, and heterozygous carriers are estimated at approximately 1%, although the exact prevalence is unknown because most cases are thought to be asymptomatic or have nonspecific clinical findings. On the other hand, it has been reported that the non-specific symptoms can reduce the quality of life of patients, and in practice, we have often experienced cases where patients have suffered from these symptoms since childhood, but were not diagnosed and therefore not treated, and were diagnosed in adulthood. It could suggest that there are far more patients and carriers than expected.

Methods: We estimated the predicted prevalence of Gitelman syndrome based on multiple genome databases, HGVD and Jmorp for the Japanese population and gnomAD for other ethnicities, and included all 274 pathogenic missense or nonsense mutations registered in HGMD Professional. The frequencies of all these alleles were summed to calculate the total variant allele frequency in SLC12A3 which is the responsible gene for Gitelman syndrome. The carrier frequency and the disease prevalence were assumed to be twice and the square of the total allele frequency, respectively, according to the Hardy–Weinberg principle.

Results: In the Japanese population, the total carrier frequencies were 0.0048 (9.5%) and 0.0068 (8.7%) and the calculated prevalence was 0.00225 (2.1% in 1000 people) and 0.00188 (1.9 in 1000 people) in HGVD and Jmorp, respectively. Other ethnicities showed a prevalence varying from 0.000012 to 0.00083.

Conclusions: These findings indicate that the prevalence of Gitelman syndrome in the Japanese population is higher than expected and that some other ethnicities also have a higher prevalence than previously been considered.

PO1325
An Off-the-Shelf CRISPR Gene Therapy Approach in Human Kidney Organoids
Nicole Vo, Catherine A. Macnary, Benjamin S. Freedman. The Freedman lab University of Washington, Seattle, WA.

Background: Gene therapy offers many opportunities to treat kidney diseases. Targeted, off-the-shelf therapies are needed for both loss-of-function (e.g. nephronophthisis) and gain-of-function (e.g. Apol1) disease states. Kidney organoids are complex structures that resemble nephrons and can be used to develop gene therapy approaches. Commonly used gene transfer techniques, such as lentivirus and adenovirus, are size limited, transient, or introduce DNA non-specifically into the genome. While targeted CRISPR gene editing is routinely used in 2D cell cultures, it has not been challenging to use this powerful technique in intact organoids.

Methods: To achieve off-the-shelf gene transfer, organoids were transfected with Cas9 and gRNA ribonucleoprotein (RNP) complexes targeting the AATS1 safe harbor locus supplemented with knock-in cassettes encoding green fluorescent protein (GFP) or FLAG-tagged cystinosin (deficient in nephropathic cystinosis). Alternatively, to monitor gene knock-out, organoids expressing GFP from a genome. While targeted CRISPR gene editing is routinely used in 2D cell cultures, it has not been challenging to use this powerful technique in intact organoids.

Results: GFP and cystinosin knock-in events in organoids were detected using microscopy and PCR. Immunofluorescence analysis revealed knock-in in proximal tubule epithelial cells (LTL+). In knock-out experiments, live confocal microscopy indicated areas of GFP loss within kidney organoids treated with gRNA targeting GFP, but not with a scrambled guide. Mosaic patches of GFP knockout cells expanded over several days. Staining with nephron markers such as LTL and podocysin revealed knockout in both proximal tubule cells and podocytes. By next generation sequencing, the two-guide system produced larger deletions and was more efficient (20 % knockout), compared to single guide.

Conclusions: The strategy developed here is efficient for knocking in and knocking out genes in kidney epithelium. It uses commercially available reagents to perform CRISPR gene editing. sgRNA sequences or AATS1 knock-in templates can be customized to target or introduce any gene of interest at specific loci. This provides a platform for the development of off-the-shelf gene therapies for diverse kidney disease states.

PO1326
The Kidney Genome Atlas: A Resource to Understand APOL1 and Other Genetic Drivers of Adult Proteinuric Kidney Diseases
Eva Fast,1 Thomas Soare,2 Hari Sominemi,1 James Watkins,1 Adam Tebbe,1 Maria Lalotii,1 Liron Walsh,1 Matthias Kreitzler,1 Gisirah N. Nkarkiri,1 Rasheed A. Ghadegsim,1 Jamie L. Wenke,6 Daniel G. Macarthur,1 Peter J. Mundell,1,3 Thomas T. Tibbitts,1,3 Michelle Penny,1 Goldfinch Bio Inc, Cambridge, MA; 1Institro, South San Francisco, CA; 2University of Michigan, Ann Arbor; 3Mount Sinai Health System, New York, NY; 4Duke University School of Medicine, Durham, NC; 5Nashville Biosciences, Nashville, TN; 6Atlas Venture, Cambridge, MA; 2Dogadan Therapeutics, Westford, MA; 3Garvan Institute of Medical Research, Darlinghurst, NSW, Australia.

Background: Chronic kidney disease (CKD) affects more than 30 million people in the US with African Americans being particularly at risk. There is an unmet need for pharmaceutical therapies that extend or, ideally, restore kidney function.

Methods: To guide genetically-driven drug development, we have established the Kidney Genome Atlas (KGA), which contains whole-genome sequences (>30x) from adult patients with Focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD) and other, idiopathic, proteinuric disorders as well as public and technically matched controls. By implementing a rigorous quality control procedure, following the gnomAD pipeline, we obtained a high-confidence dataset for downstream analyses. Three genetically inferred ancestries (EUR, AFR, AMR) were included in association testing comparing 1400 cases, including 169 individuals with APOL1 G1/G1, G2/G2 or G1/G2 high risk haplotypes (APOL1-HRH), with 1468 controls (including 485 APOL1-HRH individuals).

Results: Overall, our common variant cross-ancestry meta-analysis showed minimal impact on potential confounders, such as ancestry or sequencing center differences (lambda=1.03). Using summary statistics from our EUR analysis, we estimated a SNP heritability of 0.15 (SE = 0.028) in proteinuric diseases. Comparison to a recent CKD GWAS (Wuttke et al., 2019) indicated a weak positive genetic correlation (rg) of 0.097 (SE = 0.053). We identified the previously reported significant disease association of APOL1-HRH (p=2x10^-10) in our study. Recent in vitro data suggests amino acid in position 150 (rs2239785) is critical for the pathogenicity of APOL1-HRH (PO1986, ASN 2020) which we confirmed in our cohort of AFR ancestry individuals.

Conclusions: We have built a high-quality, multiethnic cohort that enables understanding of genetic drivers of polygenic proteinuric kidney disease. Future analysis including genetic modifiers of APOL1 may provide opportunities for novel therapies and patient stratification.

PO1327
Effect of Apol1 Genotype on Kidney Failure and eGFR Decline in Patients with All-Cause CKD

Background: Apol1 risk variants G1 and G2 associate with an increased risk of kidney failure and a higher rate of eGFR loss. We assess the effect of Apol1 genotype in African American and Latino individuals with chronic kidney disease (CKD) in New York City.

Methods: Apol1 genotype determined by sequencing. CKD cases with high-risk Apol1 genotype (n= 242) were compared to CKD cases with a low-risk Apol1 genotype (n=885) and African ancestry per Admixture. Kaplan-Meier survival analyses assessed time to kidney failure followed by Adjusted Cox-proportional hazard model and competing risk regression against death both incorporating covariates. Linear mixed-effects modelling evaluated CKD-EPI eGFR_e decline rate using the same covariates.

Results: Cases with a high-risk Apol1 genotype reach kidney failure 10-15 years earlier than low-risk cases. G1/G1 reach kidney failure earliest, followed by G1/G2 and G2/G2 (Fig 1). These data are supported across multiple risk models (Table 1). Cases with a high-risk Apol1 genotype have a higher eGFR decline rate than low-risk cases with a similar trend per specific genotype (Fig 2). The addition of self-declared or genetically defined ancestry did not confer additional risk.

Conclusions: High-risk Apol1 genotypes increase the risk of kidney failure at an earlier age, likely due to a higher eGFR decline rate. G1/G1 genotypes appear most affected and G2/G2 least.

“APOL1-Plus Gene” Genotypes in Patients with CKD

Darby. Raible.1 Dinah Clark.1 Fang Fang.2 Jing Xie.1 ’Natera, Inc., San Carlos, CA;2Fulgent Genetics, Temple City, CA.

Background: Inheritance of homozygous or compound heterozygous APOL1 G1 G2 risk alleles is associated with an increased risk of chronic kidney disease (CKD) including focal segmental glomerulosclerosis (FSGS). The APOL1 high-risk genotype (HRG) is not completely penetrant; additional genetic and/or environmental factors are thought to be necessary for the development of CKD. While approximately 10% of individuals with CKD have causal variants when tested with exome-based next generation sequencing (NGS), few reports have examined co-occurrence of APOL1 HRG alongside these variants. Here we examine the co-occurrence of APOL1 HRG and additional genetic diagnoses ("APOL1-plus") using a broad NGS panel of >380 genes associated with isolated or syndromic CKD. Positive results had one pathogenic (P) or likely pathogenic (LP) variant in an autosomal dominant or X-linked gene, two P/LP variants in an autosomal recessive gene, or presence of two APOL1 risk alleles.

Results: Among 1691 cases with positive results, 25% (n=430) had positive findings in APOL1. Other positive findings included variants in PKD1/2 in 27% (456/1691) of cases, and in COL4A3/4/5 in 22% (379/1691) of cases. Among positive cases, 7% (119/1691) had 1 positive result, including both dual (n=115) and triple diagnoses (n=4). APOL1 HRG was present in 50% (59/119) of cases with multiple diagnoses, accounting for 3.5% of all positive cases and 14% of all APOL1 HRG cases. Among the APOL1-plus cases, second positive findings were observed in COL4A3/4/5 (29%; 17/59), TTR (29%; 17/59), and PKD1/2 (15%; 9/59).

Conclusions: Dual diagnoses comprised 7% of all positive genetic testing results, with APOL1 HRG present in half of these cases. Future studies are needed to understand how multiple genetic diagnoses, including those with APOL1 HRG, impact disease presentation and progression. Dual APOL1 and collagen IV-related diagnoses are of particular interest given the frequency of these glomerulopathies in the CKD population. Genetic testing via broad NGS panels can improve diagnosis and management of CKD and increased testing will contribute to an evolving understanding of genetic etiologies of CKD.

POI329

Uncovering Mechanisms of Risk-Variant APOL1-Modulated Inflammation Signaling in Macrophages

Esther Liu, Jennie Lin. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: In the United States, Black Americans face a higher risk to develop CKD and progress to end stage kidney disease (ESKD) even after accounting for clinical and socioeconomic factors. Variants in the gene encoding for innate immunity factor Apolipoprotein L1 (APOL1) have been identified as risk factors for focal segmental glomerulosclerosis (FSGS) and HIV-associated nephropathy (HIVAN) in individuals with recent African ancestry. However, the role of immune cells in APOL1 nephropathy is not well understood. In this study we seek to understand the effect of risk variant APOL1 on macrophage function and inflammation.

Methods: Isogenic induced pluripotent stem cell (iPSC) lines expressing the G0, G1, and G2 variants of APOL1 were generated through CRISPR/Cas9 gene editing. These iPSC lines were used to generate iPSC-derived macrophages (iPDSM). Pertussin and bone marrow-derived macrophages (BMMDMs) were collected from transgenic mice 4-18 weeks of age expressing G0, G1, and G2 variants of APOL1 in cultured iPDSM, peritoneal macrophages, and BMMDMs was induced with INFγ (5 ng/mL).

Results: We observed that risk-variant APOL1 expression results in higher TNF and IL1β gene expression by nine-fold and two-fold respectively, in G1 and G2 compared to G0 (P < 0.05). In APOL1 transgenic mouse peritoneal macrophages, oil red O staining revealed 2.83-fold increased neutral lipid accumulation (N = 3, P = 0.01) and 4.84-fold decreased efflorescence capacity measured with flow cytometry (N = 5, P = 0.05) in G1 and G2 mice as compared to G0. qRT-PCR analysis showed glycosylation genes to be increased in G1 iPDSM compared to G0. Additionally, G2 mouse BMMDS induced greater glycolytic rate compared to G0 both at baseline and under mitochondrial stress when APOL1 was induced with INFγ.

Conclusions: The findings in this study unveil some mechanisms by which risk-variant APOL1 modulates macrophage inflammatory phenotype and function, relevant to kidney disease progression.

POI330

A Multivariate Analysis of Genome-Wide Association (GWAS) Data to Identify Genes Associated with CKD

Amy J. Osborn, Agnieszka Bierzyńska, Gavin I. Welsh, Moin Saleem, Ian C. Campbell. University of Bristol, Bristol, United Kingdom.

Background: Chronic kidney disease (CKD), a major public health burden, is characterised by a progressive loss of nephron function which leads to an impaired ability to filter the blood. Genome-wide association studies (GWASs) have identified single nucleotide polymorphisms (SNPs) and loci associated with the kidney function biomarkers estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) by mostly univariate-based analyses. However, gene-based multivariate-SNP and multivariate-biomarker relationships have typically not been considered so far in this context. The purpose of this study was to highlight the additional insights gained from the statistical power of a multivariate-based approach to identify potential risk factor genes for CKD.

Methods: We used a multivariate statistical approach, canonical correlation analysis (CCA), to identify single nucleotide polymorphisms (SNPs) that showed significant correlation with estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) taken jointly. For the significant SNPs and genes we identified, their functions, signalling pathways and cellular expression were investigated using gene set enrichment analyses.

Results: For each of three published GWAS summary statistics datasets of both European and Japanese ancestry groups, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using genome set statistical enrichment analyses, these genes showed significant enrichment for kidney development processes, signalling pathways and kidney cell gene expression signatures. In addition, between all three datasets, we identified four significant genes (CBLB, MACROD2, MECOM and SHROOM3) that overlapped. Between two datasets, we identified a further four significant SNPs that overlapped.

Conclusions: By using a multivariate statistical approach, we have identified both previously reported and additional genes that contained SNPs statistically associated with FKSD function. Overall, these findings provide new insights into SNPs and genes potentially involved in kidney function and CKD risk.

PO1332
Genomic Disorders Are Associated with CKD Across the Life Span

Miguel Velezky,1 Sarah Babu Krishna Murthy,1 Maddalena Marasa,1 Junying Zhang,1 Atlas Khan,1 Craig S. Wong,1 Bradley A. Warady,3 Susan L. Furth,2 David R. Crosslin,1 Robert P. Igo,4 Sudha K. Iyengar,4 Simone Sanna-Cherchi,2 Krzysztof Kiriukl,1 Ashin Parsa,1 Harold I. Feldman,1 Ali G. Gharavi,1 Columbia University, New York, NY; 6The Children’s Hospital of Philadelphia, Philadelphia, PA; 3University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Turin University, Turin, Italy

Background: Genomic Disorders (GDs), caused by pathogenic deletions and duplications (copy number variants, CNV) of large genomic regions, are a major source of genetic susceptibility for multiple developmental traits and are enriched in pediatric chronic kidney disease (CKD) patients. In the Chronic Kidney Disease in Children Study (CKiD) cohort 1, 4.5% participants carried a GD.

Methods: We extended our previous study in CKiD to cohort 2 and also examined the prevalence of GDs in adults with all-cause CKD enrolled in the Chronic Renal Insufficiency (CRI, N = 3375), Columbia University CKD (CU-CKD, N=1146) and Family Investigation of Nephropathy and Diabetes (FIND, N=1318) cohorts, comparing them to 30746 controls. CNV calls were based on SNP microarrays and whole exome sequencing and annotated for known GDs. We also performed a phenome-wide association analysis of GDs in the Electronic Medical Records and Genomics (eMERGE, N=11971) cohort.

Results: We found 9,248 (3.6%) CKD 2 pediatric participants with mild childhood carried a GD, replicating prior findings in pediatric CKD. We next identified GDs in 74,467 1(1.1%) adult CKD patients in the CRIC, CU-CKD and FIND cohorts, compared to 165,30,246 (0.5%) GDs in controls (OR=1.6, p=5x10^-4). Recurrent known GDs in adult CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci. The 17q12 GD (renal cyst and diabetes syndrome) was most frequent, detected in 1:252 CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci.

Conclusions: GDs are significantly enriched in children and adults with CKD. Undiagnosed GDs can provide a molecular explanation for renal disease in both adults and children and represent hidden genetic links between CKD and other traits such as poorer neurocognitive performance. Systematic detection of GDs can enable a precise genetic diagnosis and inform prognosis and treatment.

PO1333
Genome-Wide Association Study in Mice Maps Susceptibility to HIV-Associated Nephropathy to the Ssbp2 Locus

Nicholas J. Steers,1 Yask Gupta,1 Vittore D. D’Agati,2 Tze Yin Lim,1 Anna Mo,1 Judy Liang,1 Kelsey O. Stevens,1 Natalia D. Demaria,1 Wan Yee Lam,1 Lalitha Nagarajan,1 Simone Sanna-Cherchi,1 Ali G. Gharavi,1 Columbia University Irving Medical Center, New York, NY; 2The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: To gain insight into the pathogenesis of collapsing glomerulopathy, a rare form of focal segmental glomerulosclerosis that often arises in the setting of viral infections, we performed a genome wide association study (GWAS) among inbred mouse strains using a murine model of HIV-1 associated nephropathy (HIVAN).

Methods: F1 hybrids were generated between HIV-1 transgenic mice on the FVB/NJ background and 20 inbred laboratory strains. Histology, BUN, proteinuria and urinary NGAL were assessed in the F1 hybrids. A GWAS in 366 transgenic F1 hybrids generated from these 20 inbred strains was performed.

Results: Six strains (A/J, C3H/HeJ, DBA/1J, KK/HJ, WSF/EiJ, and LP/J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 9 strains (129S1/SvImJ, Balb/CJ, C57BL/6J, C57BL/6NJ, C57BL/10J, C57BL/1J, C3H/J, CAST/EiJ and NZB/BNJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HILF and FVB/NJ) had intermediate glomerulosclerosis. Analysis of histology, BUN and urinary NGAL demonstrated a marked phenotypic variation among the transgenic F1 hybrids, providing strong evidence for host genetic factors in the predisposition to nephropathy. A GWAS identified a genome-wide significant locus on Chr. 13 and multiple additional suggestive loci. Cross annotation of the Chr. 13 locus, including single cell transcriptional analysis of wild type and HIV-1 transgenic mice kidneys, nominated Ssbp2 as the likely culprit gene. Ssbp2 is highly expressed in podocytes, encodes a transcriptional cofactor present in LDB1 containing complexes, and interacts with LMX1B, a known FSGS gene that requires LDL1 for optimal transcriptional activity. Consistent with these data, older Sshp2 null mice spontaneously develop glomerulosclerosis, tubular casts, interstitial fibrosis and inflammation, similar to the HIVAN mouse model.

Conclusions: These findings demonstrate the utility of GWAS in mice to uncover host genetic factors for rare kidney traits and suggest Ssbp2 as susceptibility gene for HIVAN, potentially acting via the LDL1-1MX1B transcriptional network. Future studies will evaluate the role of Sshp2 in vitro and in Sshp2 null mice.

**Primary AA Amyloidosis due to a chr11:18287683 T>C (hg19) Mutation in the SAA1 Promoter Linked to the Amyloidogenic SAA1.1 Haploype**

Jakub Sikorka,1 Dina Musalkova,1 Petr Prikyrl,1 Hana Hartmannova,1 Katerina Hodanova,1 Helena Treslova,1 Lenka Noskova,1 Viktor Stranecky,1 Milan Jirsa,2 Martina Zivna,2 Anthony J. Bleyer,2,1 Ivan Rychlík,1 Romana Rysava,1 Stanislav Knom,1 Chmielova,1 Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; 2Wake Forest University School of Medicine, Winston-Salem, NC, NC, Institutt klinike a experimentalul medicine Pravice laboratorium, metod, Praha, Czechia; 3Univerzita Karlova 3 lekarska fakulta, Praha, Czechia.

**Background:** AA amyloidosis results from deposition of amyloid A (AA), a product of the proteolytic cleavage of serum amyloid A (SAA) proteins. Previously described AA amyloidosis has been due to increased production and deposition of serum amyloid A (SAA) proteins secondary to inflammatory conditions arising from infectious or metabolic causes. We describe for the first time a family with primary AA amyloidosis due to an isolated increase in production of AA protein.

**Methods:** A family was identified with autosomal dominant transmission of amyloidosis affecting 12 family members and associated with progressive chronic kidney disease (CKD) as well as other systemic manifestations of amyloidosis. Family members underwent measurement of serum SAA and whole exome sequencing with targeted sequencing. The luciferase reporter assay was used to determine promoter activity.

**Results:** Affected individuals developed proteinuria, CKD and systemic deposition of amyloid composed specifically of the SAA1.1 isoform. Affected individuals had a doubling of the SAA1 promoter activity and sustained elevation of serum SAA levels that segregated in an autosomal dominant pattern in 12 genetically affected and in none of 6 genetically unaffected relatives with a LOD score of >5. Genetic evaluation revealed a chr11:18287683 T>C (hg19) mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype that segregated completely with affected individuals. Tocilizumab had a beneficial effect when prescribed early.

**Conclusions:** A mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype led to a doubling of production of SAA1, leading to characteristic findings of amyloidosis. This is the first investigation to show that manifestations of AA amyloidosis in humans are due solely to SAA overexpression. Idiopathic forms represent a significant and increasing proportion (15-20%) of all diagnosed cases of AA amyloidosis. Genetic screening of the SAA1 promoter should be pursued in individuals with AA amyloidosis without an obvious cause of systemic inflammation, especially if there is a positive family history. Contact apley@wakehealth.edu for genetic evaluation of familial amyloidosis.

**Genetic Testing in Focal Segmental Glomerulosclerosis (FSGS): Tale of Three Stories**

Gaurav Rajashekar, Ying M. Chen. Washington University in St. Louis Washington University in St. Louis, St. Louis, MO.

**Introduction:** Genetic testing in kidney disease has improved our understanding of various etiologies of glomerular diseases. FSGS is a histopathological diagnosis with diverse causes and patterns of inheritance. Genetic testing in FSGS has unlocked a treasure of pathogenic mutations that are either limited to the kidney or represent a broader extra-renal manifestation. Here we present 3 biopsy proven cases of FSGS with different genetic polymorphisms and varied presentations.

**Case Description:** Case 1: 29-year-old female with scoliosis, hearing loss, right optic nerve coloboma presented with 1.5 g/day of proteinuria and normal renal function when she was 16 years of age. Kidney biopsy revealed FSGS with 90% foot process effacement. 13 years later, her renal function worsened, with serum creatinine 1.4 mg/dl (baseline 0.9 mg/dl), and urine protein creatinine ratio of 4 g/l. Her mother had undergone a kidney transplant complicated by reflux nephropathy and genetic testing showed a truncating c.430>T in P.144* which can lead to FSGS, optic nerve coloboma and papilloneuritis syndrome. Case 2: 21-year-old male with biopsy proven FSGS when he was 8 years old mentioned that his maternal grandfather suffered from unknown renal disease requiring dialysis and died in his 40’s. Genetic testing revealed hemizygous, truncating p.W58* variant in the CLCN5 gene. Variants in CLCN5 gene can cause Dent’s Disease manifesting later in life as proteinuria, nephrocalcinosis, hypercalcuria and renal failure. In addition he had variant of unknown significance NPHS1 designated p.T233A, and APOL1G2 risk allele predisposing him to develop FSGS. Case 3: 21-year-old male born with genital ambiguity, perineal hypoplasia, 46 XY karyotype was noted to have 14 g of proteinuria, low albumin and hypertension. Kidney biopsy revealed FSGS, abnormal glomerular basement membrane. Genetic testing was positive for heterogeneous insertion of WT-1 and morphologically mosaic microdeletion variant of SMARCA1 p.R200H which are pathogenic variants that cause renal failure due to defective podocyte development and dysfunction respectively.

**Discussion:** Genetic analysis for FSGS has become an important diagnostic tool in nephrology. We currently have over 50 genes that are known to be involved in FSGS. Reporting of different genetic variants and their occurrence is crucial to yield insight into our current understanding of FSGS.

**Whole-Exome Sequencing Generates a Monogenic Cause of Disease in 26% of 335 Families with Steroid-Resistant Nephrotic Syndrome**

Ronen Schneider,1 Konstantin Deutsch,1 Ana C. Onuchic-Whitford,1,2 Kirolos Yousef,1 Muhammad Y. Zahoor,1 Camille H. Nicolas Frank,1 Florian Buerger,1 Shirlee Shril,1 Michael J. Somers,1 Friedrich Hildebrandt,1 1Boston Children’s Hospital, Boston, MA; 2Bingham and Women’s Hospital, Boston, MA.

**Background:** Steroid resistant nephrotic syndrome (SRNS) overwhelmingly progresses to end-stage renal disease. To date, more than 59 monogenic genes have been identified that cause SRNS. We previously detected causative mutations in 26% of whole exome sequencing (Warezek CJASN 13:53, 2018) and in 29.5% of patients with SRNS using targeted panel sequencing (Sadowski JASN 26:1279, 2015). However, whole exome sequencing (WES) has become more accessible, with the advantage of detecting not only monogenic causes of SRNS, but also novel candidate NS-causing genes.

**Methods:** We employed whole exome sequencing (WES) to detect monogenic causes of SRNS in a large international cohort of 335 families with SRNS presenting before the age of 25 years.

**Results:** Samples were recruited from April, 1998 to December, 2018 (21 years). WES was performed at the Yale Center of Mendelian Genomics. First, we examined the WES data for mutations in 59 known genes known to cause SRNS. In 87/335 families (26%), we identified mutations in 22 of the known genes. There were also 7 genes that were identified in phenotypes of SRNS e.g. COL4A3. In 58 families (17.3%), we have identified mutations in a potential novel candidate gene for SRNS. We found a 48.1% solve rate in individuals with high homozygosity by descent and 15.4% solve rate in non-homozygous individuals, recapitulating similar solve fractions to what has been previously published (Sadowski C.JASN 26:1279, 2015).

**Conclusions:** This study confirms that ~26% of families with NS in our cohort are due to monogenic causes, WES is a viable way to diagnose the underlying cause of NS in children and young adults, and to suggest novel monogenic candidate genes of NS.

**Discovery of Podocyte-Specific Interaction Partners of the Nephrotic Syndrome-Associated Protein NOS1AP**

David A. Ball, Florian Buerger, Friedrich Hildebrandt, Amar J. Majmundar. Boston Children’s Hospital Department of Pediatrics, Boston, MA.

**Background:** Recessiv NOS1AP mutations are a novel Mendelian cause of nephrotic syndrome (NS) in humans and mice (Majmundar Sci Adv 2021). The NS patient mutation p.C143Y destabilizes the predicted structure of the NOS1AP phosphotyrosine-binding domain, impairs NOS1AP-dependent actin remodeling in immortalized podocytes, and causes abnormal kidney organoid glomerulogenesis. Here, we aimed to discover podocyte-specific NOS1AP interaction partners, which may mediate NOS1AP functions in the podocyte and whose binding is abrogated by the patient mutation p.C143Y.

**Methods:** Protein interaction data from candidate immunoprecipitation, mass spectrometry, and yeast two-hybrid studies were queried from the literature and public databases (Oncomine NAR 2014; Oncoarray NAR 2019; Searlelab MX 2019). Gene expression was queried from kidney single cell mRNA sequencing (scRNAseq) datasets (Karaiskos JASN 2018; Menon Development 2018; Wang Cell Rep 2018; Wu JASN 2018). Protein interactions were validated by co-immunoprecipitation studies using patient and controls A constructs.

**Results:** 85 putative NOS1AP-interacting proteins were identified from candidate interaction and proteomics studies. Six interacting proteins (of 85) demonstrated co-expression with NOS1AP in podocyte clusters from at least three out of four kidney scRNAseq datasets (% cell expression z-score >1). Four of six candidates (FYN, GSN, SNTA1, HSPA12A) were cloned into expression vectors for interaction studies. SNTA1 and HSPA12A exhibited bi-directional co-immunoprecipitation with wildtype NOS1AP upon co-overexpression in a podocyte cell line. Co-immunoprecipitation was, similarly, observed with the NS patient mutant NOS1AP.

**Conclusions:** Our results suggest NOS1AP is co-expressed with and can physically interact with SNTA1 and HSPA12A in podocytes. These proteins may mediate NOS1AP functions in podocyte biology.

Synuclein Alpha Accumulation Drives Lysosomal Dysfunction in Fabry Podocytopathy

Fabian Braun,1 Ahmed Abed,2 Mathias Woidy,1 Oystein Ekrem,2 Nicola Wanner,1 Katharina M. von Cossel,3 Soeren W. Gersting,1 Ania C. Muntau,1 Behzad Najafian,1 Camilla Tondel,1 Michael Maurer,1 Florian Grahambumer,2 Thorsten Eierhoff,3 Hans-Peter Marti,1 Victor G. Puelles,3 Christoph Schell,2 Tobias B. Huber,1 University of Washington, Seattle, WA; 5University of Minnesota Medical School Twin Cities, Minneapolis, MN.

Background: Anderson-Fabry disease is an X-linked lysosomal disorder characterized by a multisystemic glycolipidosis, characterized by abnormal lysosomal glycosphingolipid accumulation due to reduced alpha-galactosidase activity (GLA). Podocyte injury is a major renal manifestation of Fabry disease. Recently, our data indicated Gb3 depletion to be insufficient in repairing podocyte damage seen in an in vitro model for Fabry disease. This project, therefore, focuses on the potential GL3 independent mechanisms in Fabry podocytopathy.

Methods: We employed CRISPR/Cas9 to generate GLA knock out lines of immortalized human podocytes in vitro. These cells were investigated by (ultra-) structural, transcriptome and proteome as well as functional analyses in the presence and absence of enzyme replacement therapy (ERT). The acquired data sets were integrated through network analysis and connectivity mapping. These data were complimented by the investigation of human biopsies taken sequentially before and after a period of ERT.

Results: We detected that enzyme replacement therapy (ERT) and Gb3 reduction failed to reduce Gb3 accumulation in patient biopsies. GLA knock out podocytes depicted high Gb3 levels that were fully reversed upon enzyme replacement. Still, lysosomal dysfunction was significantly but not completely reversible with enzyme substitution. Proteomics suggested alpha-synuclein (SNCA) accumulation as a potential driver for podocyte dysfunction. Transcription-based connectivity mapping revealed a potential anti-SNCA therapeutic effect of beta-adrenoceptor agonists. Indeed, genetic and pharmacological inhibition of this protein significantly improved lysosomal structure and function in Fabry podocytes beyond the effects of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmacological strategies to target Fabry podocytopathy.

Stable Genetic Deletion of Gapvd1 in Drosophila Results in a Nephrocyte-Restricted Phenotype

Konrad Lang, Julian Milosavljevic, Helena Heinkele, Lea Gerster, Tobias F. Hermle. Hermle Lab Universitätsklinikum Freiburg, Freiburg, Germany.

Background: Mutations in the gene GAPVD1 cause nephrotic syndrome in humans. GAPVD1 interacts with RAB5 and but the subcellular localization of GAPVD1 was unknown. Silencing of Gapvd1 in the podocyte-like Drosophila nephrocytes by RNA-interference resulted in mislocalization of fly nephrin.

Methods: We generated conditional knockdowns and a stable genetic deletion of Drosophila Gapvd1 by CRISPR/Cas9 and used microinjection-mediated end joiing to introduce a genomic HA-tag into the Gapvd1 c-termius. We performed a functional analysis of the novel fly models.

Results: We generated twin frameshift mutations at the second and third exons of the Drosophila Gapvd1 gene. Animals carrying these mutation were homozygous viable without any overt phenotype. However, the podocyte-like nephrocytes revealed a severely altered slit diaphragm morphology with mislocalization of fly nephrin and the orthologue of NEPH1 and partial loss of both proteins from the surface. This phenotype was similar but considerably stronger than the phenotype observed by RNA-mediated silencing. This suggests that the homozygous frameshift mutations result in a null allele. The phenotype was further confirmed by conditional CRISPR/Cas-mediated silencing using two different gRNAs. Deletion of Gapvd1 in the Drosophila model thus results in a phenotype that manifests exclusively in disturbed slit diaphragm formations. This recapitulates the nephrocyte-restricted phenotype.

Conclusions: We established suitable new Drosophila models to study the function of Gapvd1 in nephrocytes as an invertebrate podocyte model.

Pathogenicity Assessment of Non-Glycine Missense Variants in COL4A5 Collagenous Domain

Yuya Aoto,1 Tomoko Horinouchi,1 Tomohiko Yamamura,1,3 Chika Nagano,1 Atsushi Kondo,1 Sadayuki Nagai,1 Nana Sakakibara,1 Kazumoto Iijima,2 Kandai Nozu,3 Kobe Daigaku, Kobe, Japan; 2Hyogo Kenritsu Kodomoto Byoin, Kobe, Japan; 3Manchester Metropolitan University, Manchester, United Kingdom.

Background: COL4A5, which encodes type IV collagen α5 chain, is a causative gene of X-linked Alport Syndrome (XLAS). In triple-helical domain on collagen protein the phenotype observed in humans was limited to nephrotic syndrome, supporting the use of Drosophila model for this genetic disease. To study the subcellular localization of Drosophila Gapvd1, we introduced an HA-tag into the c-termius of the Gapvd1 locus. Immunofluorescence of nephrocytes derived from the knock-in lines showed that overexpression of ΔN117 led to mislocalization of fly nephrin. The glomerular localization of fly nephrin was altered in the Drosophila Gapvd1 gene. Animals carrying these mutantion were homozygous viable without any overt phenotype. However, analysis of the podocyte-like nephrocytes of these flies revealed a potential anti-SNCA therapeutic effect of beta-adrenoceptor agonists. Indeed, genetic and pharmacological inhibition of this protein significantly improved lysosomal structure and function in Fabry podocytes beyond the effects of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmacological strategies to target Fabry podocytopathy.

A Human Missense Integrin-Linked Kinase Variant Negatively Regulates Murine Renal Branching Morphogenesis via mTOR Signaling

Xiangye Hu,1,2 Dana Kablawi,1,2 Kirsten Y. Renkema,1 Nina V. Knoers,1 Norman D. Rosenstein,1,2 1Program in Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; 2Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada; 3Department of Genetics, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands.

Background: Branching morphogenesis is critical to kidney development and the pathogenesis of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT). Identification of gene variants via genomic sequencing aims to elucidate molecular mechanisms underlying CAKUT. The pathogenic contributions of such variants are largely unknown; functional analyses are required to identify pathogenic mechanisms. Here, we identify pathogenic effects of a CAKUT-associated human missense variant of Integrin-Linked Kinase (ILK), a key regulator of renal branching morphogenesis, on ureteric branching.

Methods: Targeted gene panel sequencing was performed to identify gene variants. ILK-T173I function was investigated in mouse inner medullary collecting duct (mIMCD3) cells and mouse embryonic kidney explants transduced with lentivirus expressing ILK-T173I. Gene expression was analyzed by RNA microarray and validated by qPCR and Western analysis. Mutant mice with a ILK c.518C>T point mutation were generated using CRISPR/Cas9. Morphological effects of ILK-T173I on ureteric branching were visualized using Hoxb7-driven fluorescent marker (MyrVenus) and quantitated by counts of ureteric bud tips and nephrons.

Results: An ILK missense variant, ILK-T173I, was identified in a CAKUT patient and her mother by targeted gene panel sequencing and verified by Sanger sequencing. mIMCD3 cells expressing ILK-T173I demonstrated dysregulated expression of AKT/mTOR target mRNAs, identified by RNA microarray and qPCR, and elevated levels of phospho-p70S6Kinase, a mTOR target (n=3, P<0.003). Overexpression of ILK-T173I in embryonic kidney explants increased phospho-p70S6Kinase expression (n=3, P=0.03) and decreased ureteric tip number by 50% (n=15, P=0.003), both of which were rescued by treatment with Rapamycin, an mTOR inhibitor (n=4, P=0.04). Knock-in mice in which ILK-T173I replaces the ILK-WT allele were characterized by low nephron number (n=6, P=0.04) and decreased ureteric branching (n=5, P=0.006), and increased expression of phospho-p70S6Kinase (n=3, P=0.014). Treatment of mutant cultured embryonic kidney explants with Rapamycin rescued ureteric branching to levels observed in ILK-WT mice.

Conclusions: Human ILK-T173I variant decreases branching morphogenesis in an mTOR-dependent manner. Increased mTOR signaling disrupts mouse kidney development.

Excess Burden of Rare Coding Variants in Mutation Intolerant Genes in Patients with Kidney Malformations
Hila Milo Rasouly,1 Sarath Babu Krishna Murthy,1 Gundula Poyvisil,1 Maddalena Marasa,2 Jeremiah Martino,1 Velibor Tasic,1 Enrico Fiaccadori,3 Gian Marco Ghiiggeri,3 Giuseppe Massana,4 Simone Sanna-Cerchii,5 Krzysztof Kuryluk,6 Ali G. Gharaiv,1 Columbia University Irving Medical Center, New York, NY; 2University Children’s Hospital, Skopje, Macedonia (the former Yugoslav Republic of); 3Istituto Giannina Gaslini, Genova, Italy; 4Azienda Ospedaliera Brotzu, Cagliari, Italy; 5Universita degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy.

Background: Renal hypoplasiasia (RHD) is one of the most common cause of pediatric kidney failure. Although multiple causative genes have been identified, they only account for 10-15% of cases. The contribution of rare variants has not been systematically examined.

Methods: To evaluate the contribution of rare variants to RHD, we analyzed exome sequencing (ES) data in 1,265 unrelated RHD cases and 13,303 unrelated controls. We used gene-level burden analysis, comparing the proportion of cases and controls carrying rare variants per gene across 20 statistical models.

Results: We observed a 1.63-fold case enrichment for rare variants (p=1.5x10^{-10}) in known genes associated with dominant forms of kidney diseases (165 cases versus 1,075 controls in 172 known genes), including PAX2 (7.6x10^{-10}) and HNF1B (5.6x10^{-10}). All other known genes did not reach statistical significance (p-value<10^{-10}). Applying a similar approach, we observed a 1.35-fold case enrichment for rare missense variants (p=5.8x10^{-10}) in genes constrained against missenses (misZ >3.09) and a 1.59-fold enrichment for rare protein truncating variants (PTV; p=2.4x10^{-10}) in genes constrained against PTV (pLift<0.9 and oe lof upper<0.35). We particularly identified a 2.38-fold enrichment for PTV in 421 genes constrained against PTV, expressed in the mouse developing kidney (E15.5), and not known to be associated with human kidney disease (p=1.4x10^{-6}).

Conclusions: We detected a significant excess of rare variants in mutation intolerant genes that are also expressed during early kidney development, suggesting the existence of many yet-to-be-identified causal genes. However, owing to the high genetic heterogeneity of RHD, larger-scale investigations will be required to establish causality for individual genes.

Reverse Phenytoin Facilitates Disease Allele Calling in Whole-Exome Sequencing of Patients with Congenital Anomalies of Kidney and Urinary Tract (CAKUT)
Steve Seltszam, Chunyan Wang, Bixia Zheng, Dervla M. Connaughton, Chen-Han W. Wu, Sophia Schneider, Luca M. Schierbaum, Shleree Shril, Friedhelm Hildebrandt, Boston Children’s Hospital, Boston, MA.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the leading cause of chronic kidney disease in children and young adults. To date, 174 genes are known to cause isolated or syndromic monogenic RHD. However, incomplete penetrance and broad phenotypic heterogeneity can impair disease allele identification, particularly in syndromic CAKUT. We hypothesized that the yield of a genetic diagnosis can be increased by combining whole exome sequencing (WES) with reverse phenotyping, in which the contributing physician is asked to examine a patient for signs/symptoms that may occur in the suspected clinical syndrome that results from the genetic variant detected by WES.

Methods: We conducted WES in an international cohort of 823 individuals with CAKUT from 732 unrelated families and evaluated WES data for variants in the 174 genes in which variants are known to cause isolated or syndromic CAKUT. In cases in whom the likely causative genotype suggested a syndromic phenotype that was not reported at enrollment, we conducted reverse phenotyping.

Results: In 84/732 (11.5%) families, we detected a likely causative variant consistent with an isolated or syndromic CAKUT phenotype. In 19 of the 84 families (22.6%) with detection of a likely CAKUT-causing variant, reverse phenotyping yielded syndromic findings, thereby strengthening the genotype-phenotype correlation.

Conclusions: We conclude that employing reverse phenotyping in the evaluation of (facultative) syndromic CAKUT genes by WES provides an important tool to establish a more valid and specific diagnosis mitigating the broad phenotypic and genotypic heterogeneity of CAKUT.

**Conclusions:** We have utilized CRISPR/Cas9-generated mice with mutant UMOD and by harnessing a newly invented ultrabright fluorescence nanoconstruct, termed “plasmonic fluor (PF)” (Nat Biomed Eng 2020).

**Results:** In the murine model and patients with ADTKD-UMOD, we find that immunoglobulin heavy chain-binding protein (BiP), an ER chaperone, was exclusively upregulated by mutant UMOD in TAL and easily detected by Western blot in the urine at an early stage of disease. However, even the most sensitive ELISA failed to detect urinary BiP in affected individuals. We therefore developed the ultra-sensitive, plasmon-enhanced fluorescence-linked immunosorbent assay (p-FLISA) to detect the urinary biomarker in ADTKD patients by harnessing a newly invented ultrabright fluorescent nanoconstruct, termed “plasmonic fluor (PF)” (Nat Biomed Eng 2020).

**Methods:** We have utilized CRISPR/Cas9-generated mice with Umod-C147W mutation, analogous to human UMOD-C148W mutation, and ADTKD-UMOD patients to discover a novel endoplasmic reticulum (ER) stress biomarker. In addition, we have developed an ultrasmall, plasmonic-enhanced fluorescence-linked immunosorbent assay (p-FLISA) to detect the urinary biomarker in ADTKD patients by harnessing a newly invented ultrabright fluorescent nanoconstruct, termed “plasmonic fluor (PF)” (Nat Biomed Eng 2020).

**Conclusions:** By developing the ultra-sensitive p-FLISA, we have identified secreted BiP as a novel urinary ER stress biomarker with potential utility in risk stratification, prediction of disease progression and guidance of ER-targeted therapies in ADTKD.

Genetic Analysis of a Brazilian Nephropathic Cystinosis Cohort Reveals Novel CTNS Variants Mostly of Non-European Origin

Maria H. Vaishich, Kelly Nunes, A. R. Santos, Juliana C. Ferreira, F. M. Nunes, Andreia Watanabe, Lutz F. Oumichi. Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Nephropathic Cystinosis (NC) is a severe autosomal recessive disease caused by intralysosomal cystine deposition. Most CTNS variants have been described in Europe and North America, where a specific 57kb deletion (del) is the most frequent one. In this study, we sought to characterize the CTNS variants and their genetic ancestry profiles in a NC Brazilian cohort, an admixed population.

**Methods:** 61 NC patients were studied, both sexes, ≥21 years old, followed at the University of Sao Paulo Medical Center. Mutation analysis was performed by gel electrophoresis and/or MLPA to assess the 57kb del, and NGS targeted sequencing. To characterize the genetic ancestry profiles, 48 patients were genotyped with a high-density SNP array. The average genomic ancestry was inferred using ADMIXTURE and the ancestry of the CTNS gene region using RFMix.

**Results:** Two disease-causing variants were identified in 58/61 patients, followed by segregation analysis whenever possible. The detected variants included 9 previously reported and 7 novel ones. Previously reported variants were observed in European genomic segments, except the African ancestry-linked variant c.62-2A>G. Among the novel variants, 4 are in genomic segments of African origin (del exons 2.4, c.227delT, c.557delC, c.412del-P.w133R and c.457T>p.K153X), 1 in Native American (c.16-19del-P.L66S), 1 in an European-ancestry segment (c.262-*26del6insCGGCAG), and 1 could not be determined (c.158delC-P.w535fs). The highest allele frequencies were 57kb del (55.7%), c.382T (14.0%), c.16-19del (7.4%) and c.611-613del (5.7%). Analyses of LD decay support that 57kb del, c.382T and c.611-613del originated in Europe at least 1,750 years ago (250-3,750 years ago) and 275 years ago (75-1,200 years ago), respectively, and suggest that c.16-19del likely originated in America 15,025 years ago (5,775-41,000). A new invention, c.62-2A>G, most likely originated in Europe at least 1,750 years ago.

**Conclusions:** We have utilized CRISPR/Cas9-generated mice with mutant CTNS and by harnessing a newly invented ultrabright fluorescent nanoconstruct, termed “plasmonic fluor (PF)” (Nat Biomed Eng 2020).

Adult Zebrfish as a Model to Study Renal and Extrarenal Manifestations of Cystinosis

Sante Principe Berlingerio,1 Junling He,2 Sara Cairoli,3 Bianca Maria Goffredo,1 L.F.W.J. Van Den Heuvel,1 Elena N. Levchenco,1 Pediatric Nephrology,1 Katholieke Universiteit Leuven,2 Groep Biomedische Wetenschappen, Leuven, Veurne; University Of Leiden, Leiden, Netherlands;2 Ospedale Pediatrico Bambino Gesu, Roma, Italy.

**Background:** Cystinosis is a rare autosomal recessive disease caused by mutations in the CTNS gene, which encodes for the cystine transporter cystinosin leading to lysosomal cystine accumulation in all cells of the body, with kidneys being the first affected organs. The current treatment with cysteamine decreases the lysosomal cystine accumulation, but does not reverse the renal Fanconi syndrome, glomerular injury or loss of renal function. We have developed a zebrfish larval model having truncating mutation in ctns, which recapitulates the kidney phenotype of cystinosis. However, long-term disease consequences in adult zebrfish have not been studied so far. In this study, we characterized the adult zebrfish model to evaluate the late effects of cystinosis on kidney and extra renal organs.

**Methods:** Cystinosis (ctns<sup>-/-</sup>) zebrfish of 18 months and wild type (WT) zebrfish were studied. Histologic examinations of kidneys and extra-renal organs were performed. Cleaved caspase-3 staining was used to evaluate apoptosis in the kidney. Cystine accumulation was evaluated via liquid chromatography-mass spectrometry and toluidine blue staining. For the fertility studies, the number of total eggs and fertile eggs produced by breeding female and male ctns<sup>-/-</sup> zebrfish compared to WT zebrfish was evaluated.

**Results:** ctns<sup>-/-</sup> zebrfish show increased cystine level, glomerular hypertrophy and proximal tubular accumulation of hyaline-like eosinophilic droplets and vacuolated cytoplasm. Moreover, the cystinotic zebrfish exhibit increased cleaved caspase-3, indicating enhanced apoptosis in the proximal tubules. In addition, instead of the typical striped pattern, ctns<sup>-/-</sup> zebrfish present an altered melanin skin pigmentation, resulting in spotted skin. Lastly, male ctns<sup>-/-</sup> zebrfish show spermatogenic cysts enriched in spermatozoa, while female display increased percentage of unfertilized eggs.

**Conclusions:** The adult ctns<sup>-/-</sup> zebrfish model reproduces several phenotypes of cystinosis, such as altered glomerular and proximal tubular morphology, whole body cystine accumulation, impaired skin pigmentation and decreased fertility. Therefore, this model may be useful for studying long-term effects of cystinosis and for the development of new therapeutic strategies for correcting cystinosis, which is - up to now - incurable.
Vascularized Kidney Organoids on Chip for Efficacy and Toxicity Testing of Somatic Genome Editing

Navin R. Gupta,1,2 Kayla J. Wolf,3 Krishna P. Maremada,3 Katharina T. Kroll,4 Chengchong Zhang,1 Venkata S. Sabbrisetti,1 Jennifer A. Lewis,1 Ryuji Morizane,1,2 Massachusetts General Hospital, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA; 4Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA.

Background: Somatic genome editing has therapeutic potential to cure inborn diseases. Clinical translation requires safety and efficacy analyses. DNA editing may be widely discrepant across species due to genomic differences, necessitating human tissue-based platforms. AAV-based delivery of DNA editing elements is under clinical investigation. If delivered systemically, the kidney may be particularly susceptible to genome editing owing to high blood flow. Kidney organoids have been generated from human stem cells through the co-induction of nephron, stromal, and endothelial progenitor cells that mature to form multipolar organoids. We matrarchitectured and organ-on-chip technologies to facilitate the maturation of nephron epithelia and the development of perfusable vascular networks to simulate systemic delivery of genome editing elements.

Methods: Using human reconstituted growth factors and defined small molecules, kidney organoids were generated and differentiated into the kidney organoids. We engineered epithelia from proximal & distal tubules and podocytes of kidney organoids by single cellular transcriptomics. Biomarker analysis demonstrated a statistically significant increase in tubular injury markers, KIM-1 and MCP-1, in epithelia after infection with AAV2/2 as compared to other AAVs. Following treatment with AAV6-mCherry-GFP, the majority of LTU- and CDH1- tubular epithelia were GFP+, while PODXL+ podocytes were infected. The optimal AAV serotype, MOI, and duration of infection under static conditions were applied to vascularized kidney organoids. Initial on-chip testing supports enhanced infectivity by single-cell monitoring and whole-mount immunostaining, including AAV infection in GFP PODXL+ podocytes.

Conclusions: We propose vascularized kidney organoids may simulate the systemic delivery of AAVs across kidney compartments, as a pre-clinical testing platform of the efficacy and safety of somatic cell genome editing.

Genotype and Phenotype Analysis in Patients with X-Linked Hypophosphatemia

Seon Hee Lim,1 Yo Han Ahn,2 Hee Gung Kang,3 Il-Joo Ha,3 Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 1Uijeongbu Saint Mary’s Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea.

Background: X-linked hypophosphatemia (XLH) is the most frequent form of hypophosphatemic rickets and is caused by mutations in the PHExE gene. We analyzed genotype-phenotype correlations in XLH patients with proven PHExE mutations.

Methods: PHExE mutations were detected in 57 out of 81 patients who clinically presented with hypophosphatemic rickets. The patients were grouped into non-truncating (n = 11) and truncating (n = 46) mutation groups; their initial presentation as well as long-term clinical findings were evaluated according to these groups.

Results: Initial findings, including presenting symptoms, onset age, height standard deviation scores (SDs), and laboratory tests, including serum phosphate level and tubular resorption of phosphate, were not significantly different between the two groups (onset age: non-truncating mutation group, 2.0 years, truncating mutation group, 2.1 years; height SD: non-truncating mutation group, -1.9, truncating mutation group, -1.8; serum phosphate: non-truncating mutation group, 2.5 mg/dL, truncating mutation group, 2.3 mg/dL). However, at their last follow-up, the serum phosphate level was significantly lower in patients with truncating mutations (non-truncating mutation group: 3.2 mg/dL, truncating mutation group: 2.3 mg/dL, P = 0.003). Additionally, 62.5% of patients with truncating mutations developed nephrocalcinosis within their first follow-up, while none of the patients with non-truncating mutations developed nephrocalcinosis (P = 0.008). Orthopedic surgery due to bony deformations was performed significantly more often in patients with truncating mutations (52.3% vs 10.0%, P = 0.008).

Conclusions: Although considerable inconsistency exists regarding the correlation of truncating mutations and their disease phenotype in several other studies, we cautiously suggest that there would be genotype-phenotype correlation in some aspects of disease manifestation after long-term follow-up. This information can be used when consulting patients with confirmed XLH regarding their disease progression.

Childhood-Onset Nephrocalcinosis in Twins Caused By Biallelic Mutations in CYP24A1 Gene: A Long Journey to a Genetic Diagnosis

Xi Yee Tan, Mary-Beth Roberts, Saul Nuru, Xiaolange Wang, Cleveland Clinic, Cleveland, OH.

Introduction: 24-hydroxylase deficiency is a rare autosomal recessive disorder caused by mutations in CYP24A1 gene, characterized by hypercalcemia, hyperparathyroidism and nephrolithiasis. Establishing a genetic diagnosis, while important to guide management and family counseling, can be challenging. We hereby report a case of twins with childhood-onset nephrocalcinosis and chronic hypercalcemia caused by biallelic mutations of CYP24A1, which took years to be diagnosed.

Case Description: A 26-year-old female presented for preconception evaluation for a history of childhood-onset nephrocalcinosis and chronic hypercalcemia. Patient reported similar history in identical twin sister. They had exome sequencing (ES) eight years ago after negative genes panel test which revealed a heterozygous variant of unknown significance (c.1186C>T) in CYP24A1. A reanalysis of ES was performed four years ago which demonstrated no changes. Work up revealed hypercalcemia, low 25(OH) vitamin D, elevated 1,25(OH) vitamin D and 24,25(OH) vitamin D, and suppressed PTH(fig.1). Ratio of 25(OH)D to 24,25(OH)D, a new biochemical test for 24-hydroxylase deficiency, suggested biallelic mutations in CYP24A1 gene. ES reanalysis at this time reclassified the c.1186C>T variant as pathogenic and disclosed a novel intronic variant (c.544-1G>A) which was predicted to cause splicing pattern change with multiple silico algorithms. Parental tests confirmed these two variants were in trans configuration consistent with autosomal recessive inheritance pattern. A thorough counselling included low recurrence risk for her children while high risk for her to develop severe hypercalcemia during pregnancy. She has been closely monitored with low calcium and vitamin D diet, sun avoidance and adequate hydration during current pregnancy with no complications to date.

Discussion: CYP24A1 gene related hypercalcemia is rare and challenging to diagnose even with ES. This case suggests the benefits of ES regular reanalysis for clinically suspected patients with inconclusive genetic findings. The novel intronic mutation identified in this case broadens the genetics spectrum of 24-hydroxylase deficiency.

TRPV4 Calcium Channel Activity Is Increased by With-No-Lysine
Kinase 1 in the Collecting Duct Cells

Vitor N. Tomilin, Kyrilko Pyrshev, Naghmeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochnyuk. The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: Kidneys play a central role in regulation of potassium homeostasis and maintaining plasma K+ levels within a narrow physiological range. Dietary K+ load increases circulating levels of the mineralocorticoid aldosterone leading to kalisuresis via stimulation calcium-activated large conductive maxi-K+ (BK) channel dependent K+ secretion in the collecting duct cells. WN1K and WN4K (With-no-lysine) kinases, have been recognized to regulate K+ balance, in part, by orchestrating BK-dependent K+ secretion in the ASDN (aldosterone sensitive renal nephron). Ca2+-permeable TRPV4 channel is essential for BK activation in the distal nephron, as we have recently demonstrated. Also of note, high K+ diet increases TRPV4 activity and expression largely in an aldosterone-dependent manner.

Methods: Patch-Clamp; [Ca2+]i imaging; Western blotting; Real-Time PCR.

Results: In the current study, we aimed to test whether WN1K/4 contribute to regulation of TRPV4 by aldosterone. First we investigated if TRPV4 is expressed in the kidney. The expression of TRPV4 was localized to the collecting duct cells. In WT mice, the expression of TRPV4 is upregulated under dietary potassium deficient conditions. However, in aldosterone dependent conditions, the expression of TRPV4 is downregulated.

Conclusions: Overall, we show that TRPV4 is essential in controlling aldosterone in collecting duct cells. We propose that the syncretism mechanism is likely contributing to regulation of urinary K+ levels to maintain systemic homeostasis.

Cyclin M2 (CNNM2) Is Essential for Development and Systemic Magnesium Homeostasis

Gijs A. Franken,1 Murat Seker,2 Femke Latta,3 Caro Bos,1 Joost Hoenderop,2 René J. Bindels,3 Tilman Breidtether,2 Karl P. Schlingmann,3 Dominik Müller,2 Jeroen H. De Baas,1 Radboudumc, Nijmegen, Netherlands; 4Charite, Universitätsmedizin Berlin, Berlin, Germany; 5Universitätessklinikum Munster, Munster, Germany.

Background: Patients with mutations in the Cyclin M2 (CNNM2) gene display hypomagnesemia and intellectual disability. CNNM2 is highly expressed in the distal convoluted tubule, where it is involved in renal magnesium (Mg2+) reabsorption. However, the complete phenotypical spectrum of the CNNM2-related disorder remains unknown. We characterized a large patient cohort with novel CNNM2 variants and used transgenic mouse models to investigate the role of CNNM2 in Mg2+ homeostasis.

Methods: The identified CNNM2 variants were found in a cohort of hypomagnesemic patients and characterized using [35S]Mg2+ transport assays in HEK293 cells. In addition, CNNM2-deficient mice were developed using CRISPR-Cas9 technology and exposed to deficient or saturated Mg2+ diets for two weeks. Using metabolic cages, the 24-hour urinary and faecal Mg excretion in WT and Cnnm2-/-, Cnnm2+/+ mice was determined.

Results: Eleven patients were identified with novel dominant variants in CNNM2. Using [35S]Mg2+ transport assays in HEK293 cells, seven variants showed decreased [35S]Mg2+ transport compared to wild type. These pathogenic mutations resulted in decreased membrane expression of CNNM2. The phenotype of these patients was compared with those previously published. Patients with pathogenic CNNM2 mutations had a more severe phenotype characterized by renal magnesium wasting, growth retardation, and neurological symptoms.

Conclusions: Overall, we show that CNNM2 is essential for normal development and Mg2+ homeostasis, although the clinical spectrum varies. Our mouse study suggests a putative role of CNNM2 in the intestine, which could have implications for the treatment of patients suffering from CNNM2 mutations.

Infantile Hypercalcemia Associated with a Novel Homozygous Mutation in SLC34A1 Gene Encoding Sodium-Dependent Phosphate Transporter 2A
Mohamed Hassanen, Jordana Yahr, Mary-Beth Roberts, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: Early-onset and familial hypercalcemia often suggest a genetic etiology which is rare. Infantile hypercalcemia (IH) is a rare, autosomal recessive disorder that occurs due to mutations in the SLC34A1 gene which encodes a sodium-dependent phosphate transporter 2A(NaPi-IIA) responsible for phosphate reabsorption in the kidney. We report an adult case who carried a clinical diagnosis of familial hypocalcicaturic hypercalcemia (FH) since infancy, which is usually a benign condition characterized by autosomal dominant inheritance caused by mutations in calcium-sensing receptor (CASR) gene, while recently uncovered as IH related to a novel homozygous mutation in the SLC34A1 gene.

Case Description: A 36-year-old Finnish male with a diagnosis of FHH presented to the genetics nephrology clinic for consultation regarding the recurrence risk for his children. He was diagnosed with FHH during infancy in Finland and has been treated with a low calcium diet. Family history was notable for a clinical diagnosis of FHH in his older sister. Physical exam was unremarkable. Labs showed mild hypophosphatemia and decreased glomerular filtration rate (69 mL/min/1.73m2), with normal serum ionized calcium and intact parathyroid hormone. Twenty-four hour urine analysis revealed hypercalciuria 363 mg/d (normal <250), hypernatremia 155 mmol/d (normal 50 – 150) and hypoproteinaemia 420 mg/d (normal >450). Kidney ultrasound showed bilateral medullary nephrocalcinosis. Genetic testing identified a novel homozygous variant in SLC34A1 gene (c.1483C>T) and was negative in his older sister. Physical exam was unremarkable. Labs showed mild hypophosphatemia and decreased glomerular filtration rate (69 mL/min/1.73m2), with normal serum ionized calcium and intact parathyroid hormone. Twenty-four hour urine analysis revealed hypercalciuria 363 mg/d (normal <250), hypernatremia 155 mmol/d (normal 50 – 150) and hypoproteinaemia 420 mg/d (normal >450). Kidney ultrasound showed bilateral medullary nephrocalcinosis. Genetic testing identified a novel homozygous variant in SLC34A1 gene (c.1483C>T) and was negative in CASR gene family. Family genetic studies revealed his affected sister is also homozygous for the same variant while his unaffected sister is only a carrier. With the new diagnosis, he was started on potassium citrate and chlorthalidone, and was reassured with the low recurrence risk for his children.

Discussion: Mutations in the SLC34A1 gene lead to altered NaPi-IIA expression and reduced phosphate reabsorption, leading to hypophosphatemia. Secondary vitamin D activation leads to hypercalcemia, hypercalciuria, and nephrocalcinosis. We identified a novel mutation in the SLC34A1 gene which broadens the genetic spectrum of IH. This case highlights the importance of early genetic testing for suspected hereditary hypercalcemia that may help improve its diagnosis and treatment.

Characteristics and Genetic Defects of Systemic Lupus Erythematosus-Associated Thrombotic Microangiopathy
Cui Queuan, Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Thrombotic microangiopathy (TMA) is a life-threatening complication of systemic lupus erythematosus (SLE). However, the etiology of a considerable number of patients is still unclear and the best treatment is unknown. Sporadic reports suggest that the activation of complement pathway may play a role in SLE-TMA.

Methods: We prospectively enrolled 40 SLE-TMA patients in Peking Union Medical College Hospital, 14 patients with lupus nephritis (LN) and 38 patients with other types of TMA. The clinical data were collected. Peripheral blood concentrations of CFH, cCFB, soluble C5b-9, relative activity of complement pathway, ICAM1, VCAM1 and E-Selectin were measured by ELISA in SLE-TMA patients and control groups. Whole exome sequencing (WES) was performed to analyze the genetic variants in SLE-TMA patients.

Results: SLE-TMA mediated by ADAMTS13 inhibitors had severe nervous system involvement, but less kidney involvement and good response to plasma exchange. Among SLE-TMA with unknown etiology, patients with TMA confined to kidney had lighter hematological manifestations and lower serum creatinine level than those in SLE-aHUS patients with MAHA (p = 0.016). There was no significant difference in genetic susceptibility among SLE-TMA with unknown etiology, patients with TMA confined to kidney had lighter hematological manifestations and lower serum creatinine level than SLE-aHUS patients with MAHA (p = 0.016). There was no significant difference in genetic susceptibility among SLE-aHUS patients. Peripheral blood concentrations of CFH, cCFB, soluble C5b-9, relative activity of complement pathway, ICAM1, VCAM1 and E-Selectin were measured by ELISA in SLE-TMA patients and control groups. Whole exome sequencing (WES) was performed to analyze the genetic variants in SLE-TMA patients.

Conclusions: SLE-TMA with unknown etiology can be divided into two subgroups with different severity according to the presence or absence of MAHA. The detection of complement factor and E-selectin may play a role in differentiating the two subgroups of SLE-TMA. The complement pathway is highly activated in patients with compound complement mutations, resulting in increased complement factors consumption.

Mapping Genomic Regulation of Kidney Diseases and Traits at a Cell Type and Variant Level of Specificity
Christopher Benway, Michelle McNulty, Seong Kyu Han, Dongwon Lee, Matt G. Sampson. Nephritic Syndrome Study Network (NEPTUNE) Consortium, Boston Children’s Hospital, Boston, MA.

Background: Although numerous genetically associated loci for kidney disease and disease have been identified by genome-wide association studies (GWAS), determining the causal genes and functional variants remains a major challenge. Integration of GWAS results with other data types (such as expression quantitative trait loci (eQTLs)) can help identify causal and functional variants in a tissue- or cell-type specific manner. Further, analysis of disease tissue may uncover context-specific associations that may otherwise not be detectable.

Methods: We integrated eQTL data from micro-dissected glomerular (n = 240) and tubulointerstitial (TI) (n = 311) transcripomes from individuals with nephrotic syndrome and summary statistics from two large trans-ethnic GWAS meta-analyses for estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). We used a Bayesian statistical framework for eQTL data integration and mapping (TORUS/DAP). eQTL signals from each renal compartment were integrated with summary statistics to perform a gene-level probabilistic transcriptome-wide association study (PTWAS) and SNP-level co-localization (fastENLOC).

Results: We identified 5,526 glomerular and 9,742 TI eQTLs at >5% FDR level. For eGFR, we identified 971 gene-trait pairs in the glomerulus and 1,816 gene-trait pairs in TI tissue that were significant (FDR < 5%). For UACR, we identified 194 and 340
significant gene–trait pairs in the glomerulus and T1 tissue, respectively. In the SNP-level co-localization analysis, we identified 46 T1 and 3 glomerular co-localization signals (regional co-localization probability [RCP] > 50%) for eGFR, including known associations with UMOD and FGFR5 expression, as well as novel associations to LARP4B and RABG5D which can be attributed to single variants. We identified 7 T1 and 16 glomerular co-localization signals (RCP > 50%) for UACR. In addition to replicating co-localization signals at PRKCI and TGFBI in glomerular tissue, we refined the co-localization signal at PTHFR to a single variant, rs6787229, which also co-localized with expression of MYL3.

Conclusions: Profiling and integrating renal compartment-specific eQTLs with kidney trait GWAS results in a probabilistic framework identified novel gene–trait associations and refined many known associations to a single variant.

PO1367
Factors Contributing to Decisional Conflict in Older Persons Facing Dialysis Decisions

Background: Dialysis and conservative kidney management are the two main treatment options for elderly persons with end-stage kidney disease who are ineligible for kidney transplantation. The high stakes of these decisions often force patients to choose between quality versus quantity of life. Thus, they face tremendous conflict while making dialysis decisions. This decisional conflict can adversely affect their mental health-related quality of life and leads to avoidable delays in decision making. Exploring factors contributing to dialysis decision conflict in older persons with chronic kidney disease is critical.

Methods: Using a qualitative descriptive approach, we purposefully sampled a cohort of 10 patients; 5 with high scores on decisional conflict scale, and 5 with low scores. Patients met with a palliative care physician to discuss dialysis and these visits were audio-recorded. Audio recordings were transcribed verbatim and entered into MAXQDA for data management. Following an iterative process, 2 independent reviewers analyzed the transcripts for common themes contributing to decisional conflict.

Results: The mean age of patients was 83 years. We observed 3 themes in the data of patients with low decisional conflict: (1) clarity in values, (2) good current quality of life, and (3) strong therapeutic alliance with their nephrologist. In the high decisional conflict group, we observed 5 themes: (1) fear of physical pain, complications from dialysis and its time commitment, loneliness, and losing independence, (2) concerns about being a burden to loved ones, (3) uncertainty about prognosis, (4) worries about transportation to and from dialysis, and (5) poor knowledge of treatment options.

Conclusions: Patients with high decisional conflict worried about their future quality of life, sense of burdensomeness, prognostic uncertainty, and issues related to transportation. They wished for detailed knowledge of treatment options. Future dialysis decision-making interventions should be tailored to identify each patient’s unique needs, and incorporate details about treatment options and information about logistics of dialysis. Nephrologists need to discuss the expected quality of life and prognosis. Last, family involvement in these discussions and buy-in for or against dialysis may be helpful in mitigating the patient’s sense of being a burden on their loved ones.

PO1368
Shared Decision-Making Among Older Adults with Advanced CKD
Rebecca Fraizer,1 Sarah Levine,2 Hocine Tighiouart,3 John B. Wong,3 Tamara M. Coch-Weser,1 Elisa J. Gordon,4 Daniel E. Weintraub,4 Keren Ladin,3 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Tufts Medical Center, Boston, MA; 3Tufts University, Medford, MA.

Background: Older adults with advanced chronic kidney disease (CKD) face difficult, preference-sensitive decisions about dialysis. Although shared decision-making (SDM) can help align treatment with patient preferences and values, the degree to which older CKD patients experience SDM and associated factors remain unknown.

Methods: Using data from the Decision Aid for Renal Therapy Trial, we examined SDM in adults ≥70 years with non-dialysis CKD stage 4–5 from 4 sites in the US using the validated SDMQ9 measure, with scores scaled from 0-100, and higher scores reflecting SDM in adults ≥70 years with advanced CKD and 10 of their clinicians. We also reviewed patients’ electronic health records and abstracted passages containing further information on treatment of their advanced CKD. We used thematic analysis to analyze interview transcripts and note passages and identify emergent themes reflecting their joint decision-making about treatment of their advanced CKD.

Results: Patients (age 73±6 years) were mostly men (60%) and Caucasian (59%). Of the patients (age 52±12 years, 30% male, 70% Caucasian) who participated in interviews, 4 (40%) were non-nephrologists. Four themes emerged from qualitative analysis: 1) Competing priorities: patients and their clinicians tended to differ on when to triage CKD and dialysis planning above other priorities; 2) Focusing on present or future: patients and their clinicians could be misaligned on their outlook on CKD, with patients being more focused on living well now; and clinicians, on preparing for dialysis and future adverse events; 3) Textbook approach to CKD: patients perceived their clinicians as taking a monolithic approach to CKD that was predicated on clinical practice guidelines and medical literature rather than their lived experience with illness, while clinicians were uncertain about how to incorporate patients’ personal values and goals into decision-making; and 4) Power dynamics: while patients described cautiously navigating a power differential between themselves and their clinicians, clinicians seemed less attuned to these power dynamics.

Conclusions: Improving shared decision-making for treatment of advanced CKD will likely require efforts that explicitly reconcile the differences in mindset between patients and their clinicians on decision-making about treatment of advanced CKD and that address the power imbalances in their therapeutic relationship.

PO1370
Effect of Estimated Glomerular Filtration Rate on Survival in Patients 75 Years of Age at Dialysis Initiation
Agnieszka Hamroun,1,2 Linh Bui,3 Sébastien Gomis,1 François Glowacki,1 1Centre Hospitalier Universitaire de Lille, Lille, France; 2Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; 3Paris Saclay University, Paris, France.

Background: Data regarding the prognostic impact of estimated glomerular filtration rate (eGFR) at dialysis start are discordant, and remain very scarce in elderly populations. The aim of this study is to explore whether the effect of eGFR on survival was similar in elderly incident dialysis patients compared with younger ones.

Methods: We included 4690 patients ≥75 years of age and 7045 patients 18-74 years of age starting dialysis between 2004 and 2018 from a French regional registry. Patients were followed until death or the end of 2019. Survival was assessed by Kaplan-Meier curves and the relative risk of death associated with eGFR (MDRD) was assessed by multivariate Cox regression analysis.

Results: The results showed an increasing trend of eGFR at dialysis start, which was also systematically higher in elderly patients (13.2 [10.1; 17.2] vs 11.2 [8.3; 14.9] ml/min/1.73m²; p < 0.001) (Figure). Overall, we found a significant dose-effect relationship between eGFR at dialysis initiation and mortality (HR = 1.33 [1.16; 1.51], 1.47 [1.29; 1.69], and 1.72 [1.49; 1.78] respectively for eGFR [5-10], [10-15], and > 15ml/min/1.73m²; p for trend < 0.001). The same results were found in subgroup analyses according to age category (Figure 2), with a significant interaction in favor of a stronger association in younger patients (p = 0.031).

Conclusions: In incident dialysis patients, our study shows a dose-effect relationship between higher eGFR at dialysis start and mortality, regardless of age category. This association seems to be even stronger in younger patients.

**Mortality Rates in a Nationally Representative Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis**

Amy S. You,1 Kamyar Kalantar-Zadeh,1 Yoko Narasaki,1 Csaba P. Kovesdy,2 Dana B. Mukamel,1 Susan T. Crowley,1,4 Alejandra Novoa-Vargas,1 Danh V. Nguyen,1 Connie Rhee,1 University of California Irvine, Irvine, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3Yale University School of Medicine, New Haven, CT; 4Veterans Health Administration, Washington, DC.

**Background:** While dialysis has been the prevailing treatment paradigm in CKD patients progressing to ESRD, this treatment approach may not offer survival benefit nor improved quality of life in certain subgroups (elderly, multi-morbid). Hence, there is growing interest in conservative management (CM) as an alternative treatment strategy in advanced CKD.

**Methods:** We compared mortality rates in advanced CKD patients (eGFRs <25 separated by a90 days) treated with CM vs. dialysis from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-2ys of the index eGFR (1st eGFR <25), with the former group parsed into late vs. early dialysis (eGFRs <15 vs. ≥15 at dialysis transition). Secondary analyses stratified the former group as late, intermediate, vs. early dialysis (eGFRs <5, 5-<10, vs. ≥10 at dialysis transition). Poisson regression was used to compare mortality rates across exposure groups.

**Results:** Among 309,188 advanced CKD patients, 60% vs. 40% of patients were treated with CM vs. dialysis, respectively. Patients who underwent CM vs. late dialysis had similar mortality, whereas those who underwent early dialysis had the highest mortality rates. In secondary analyses comparing CM and late vs. intermediate vs. early dialysis, a similar pattern was observed (140, 126, 141, vs. 158 deaths per 1000 person-yrs, respectively). In age-stratified analyses, compared to CM, all dialysis groups had higher mortality rates irrespective of timing of initiation in those <65 and ≥65 yrs old.

**Conclusions:** In a nationally representative cohort of advanced CKD patients, CM vs. late dialysis demonstrated similar mortality, whereas those who underwent early dialysis had the highest mortality rates.

**Hospitalization Risk Among Advanced CKD Patients Treated with Conservative Management vs. Dialysis**

Connie Rhee,1 Amy S. You,1 Yoko Narasaki,1 Csaba P. Kovesdy,2 Dana B. Mukamel,1 Susan T. Crowley,1,4 Alejandra Novoa-Vargas,1 Danh V. Nguyen,1 Kamyar Kalantar-Zadeh,1 University of California Irvine, Irvine, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3Yale University School of Medicine, New Haven, CT; 4Veterans Health Administration, Washington, DC.

**Background:** Regarded as the default treatment option for advanced CKD, dialysis has been associated with frequent hospitalizations, functional decline, and loss of independence, particularly in the elderly and comorbid. While there is rising interest in conservative management (CM) as an alternative treatment option, this strategy remains underutilized. We sought to quantify differences in healthcare utilization in advanced CKD patients transitioning to dialysis vs. CM.

**Methods:** We compared hospitalization risk in 309,188 advanced CKD patients (eGFRs <25 separated by a90 days) treated with dialysis vs. CM from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. We examined hospitalizations within 2yrs of the index eGFR to account for death as competing event for hospitalization.

**Results:** In the overall cohort, 55% and 20% of patients experienced ≥1 hospitalization(s) and death, respectively, within 2yrs of the index eGFR. Patients who transitioned to dialysis were more likely to be hospitalized vs. those treated with CM (77% and 47%), with a larger proportion of hospitalizations occurring pre- vs. post-dialysis transition in the former group (57% vs. 20%). While the proportion of deaths across dialysis vs. CM were similar (18% vs. 20%), the composite endpoint was more frequent in patients treated with dialysis vs. CM (79% and 55%).

**Conclusions:** In a national cohort of advanced CKD patients, while the proportion of death events was similar in those treated with dialysis vs. CM, patients who transitioned to dialysis had higher hospitalization risk. Further studies are needed to compare the components and effectiveness of CM vs. dialysis on CKD outcomes.

Continued Primary Care Use During the Transition to Kidney Failure (KFRT) Is Associated with Reduced Mortality Among Older Hemodialysis (HD) Patients

Raquel C. Greer, JD; Yoon B. Ahn, Laura Plantinga, John Spertei, Mara McAdams-DeMarco, Kelly H. Beers, Sandeep S. Soman, Michael J. Choi, Bernard G. Jaar.

Background: Primary care providers (PCPs) are responsible for addressing patients’ comprehensive health needs. However, the provision of primary care during the KFRT transition and its contribution to clinical outcomes among in-center HD patients have not been well explored.

Methods: We quantified the associations between PCP use, mortality, and hospitalization among older (age≥67) incident (2008-2014) in-center HD patients using data from the United States Renal Data System. We defined patients’ PCP use 1-year prior and 1-year post-KFRT as “continued” for PCP use pre- and post-KFRT; “initiated” for no PCP use pre-KFRT and PCP use post-KFRT; “discontinued” for PCP use pre-KFRT and no PCP use post-KFRT; or “never used” as no PCP use pre- or post KFRT. We used Cox proportional hazard models and adjusted for confounding by using inverse probability weighting method to estimate hazard ratios (HRs) for all-cause mortality and first all-cause hospitalization up to 2 years post-KFRT.

Results: Among 111,424 patients, 57% had continuity of PCP care, 10% initiated PCP use, 10% discontinued PCP use, and 23% never used PCP care during the KFRT transition. Compared to those who never used primary care during the KFRT transition, those with continued primary care use had a 14% lower risk of mortality. Continued and initiated PCP care post-KFRT transition was associated with a 5-12% higher risk of hospitalization, respectively.

Conclusions: Continued primary care use during the KFRT transition was associated with lower mortality, but a higher risk of hospitalization. Additional studies are needed to determine the aspects of primary care that may be beneficial and which patients are most likely to benefit from continued PCP use.

Predictors of Treatment Discussions in Geriatric Dialysis Patients Who Died

Laura Bywater, Hannah Douglass-Molloy, Matthew A. Roberts, Lawrence Mc Mahon, Kathryn Ducharlet, Eastern Health, Box Hill, VIC, Australia; Monash University Faculty of Medicine Nursing and Health Sciences, Melbourne, VIC, Australia.

Background: Geriatric patients on maintenance dialysis often have a high burden of symptoms and comorbidities with limited prognosis. Therefore, in the setting of declining clinical status, goals of treatment (GOT) discussions are important to inform illness expectations and balance the benefits and burdens of ongoing treatment. This study aimed to identify mortality risk factors that prompt nephrologists to have GOT discussions including dialysis withdrawal.

Methods: A cohort of 95 adult patients ≥65 years, cared for by Eastern Health (Victoria, Australia), who died between 1/1/2016-31/12/2019 was analysed using Fischer’s exact tests to identify psychosocial variables associated with functional decline and mortality.

Results: Mean age was 78 (SD 7.3), with mean dialysis vintage 5 years and average 3.7 admissions in the 12 months preceding death. Mean Charlson Comorbidity index (CCI) was 10 (SD 2.3), with hypertension 78%, T2DM (56%), IHD (56%), cardiac failure (51%), malignancy (34%), peripheral vascular disease (32%) and cognitive impairment (28%) major comorbidities. Almost one third (29%) of patients lived in a nursing facility, 74% used gait aids, and 55% needed assisted transport to dialysis. Median time between GOT discussion and death was 5 months [IQR 1, 11]. Discussions were more likely if patients had high comorbidity (CCI≥5, 57% vs CCI<5, 8%, p<0.05) with no association between GOT discussions and patient age, dialysis vintage, functional status, or specific comorbidities. Advance care plans were completed in 26% and were more likely if a GOT discussion had already transpired (23% vs 4%, p<0.05) or the patient lived in a nursing facility (16 v12%, p<0.05). Deaths occurred in hospital (50%), hospice (19%), or at home (7%). Dialysis was withdrawn median 8 days before death [IQR 6, 11].

Conclusions: Older patients died with significant comorbidities and functional dependency, though only the former prompted GOT discussions. Despite a long-term relationship, nephrologists could improve documentation of future treatment planning with patients to promote patient centered end of life experiences.

POI374

Vascular Access Type and Survival Outcomes in Elderly Hemodialysis Patients

Marisa Roldán, Cátia R. Figueredo, Raquel F. Escoli, Hernâni M. Gonzalves, Centro Hospitalar do Médio Tejo EPE, Unidade de Torres Novas, Torres Novas, Portugal.

Background: The ideal vascular access for elderly hemodialysis (HD) patients remains widely debated. Limited life expectancy and lower arteriovenous access (AVA) maturation rates increase the likelihood of starting HD with a central venous catheter (CVC). The aim of the study was to evaluate the influence of vascular access type in survival outcomes for elderly HD patients.

Methods: Single-center retrospective cohort study of incident HD patients aged > 80 years from January 2010 to May 2021. Patients who recovered renal function or switched to another renal replacement therapy were excluded. Patients were categorized according to their vascular access at the beginning of dialysis: CVC or AVA. Baseline clinical and demographic data were compared among groups. Survival outcomes by the end of follow-up (31st May 2021) were analyzed using Kaplan-Meier survival curves and Cox’s proportional hazards model. Statistical analysis was performed using SPSS (Version 23 for Mac OSX).

Results: The study included 99 patients: 48 (48.5%) were male, 44 (44.4%) diabetic, 60 (60.6%) had ischemic heart disease and 15 (15.2%) peripheral artery disease. Mean Charlson Comorbidity Index was 8.41±1.65 and mean age 85.14±3.98 years. Eleven patients (11.1%) were over 90 years old. Eighty patients (81%) started HD urgently as inpatients. The vascular access at dialysis start was a CVC in 75.8% (n=75) and an AVA in 24.2% (n=24). No statistical differences were found in age, gender, race, comorbidities among groups. During a mean follow-up of 2.3 years, there were 64 deaths, 27 due to infections (12 access-related infections). All-cause mortality (HR [95% CI]: 1.92 [1.05-3.49], p=0.033) and infection-related mortality (HR: 5.87 [3.18-24.94], p<0.017) were significantly higher among patients who initiate HD with a CVC as compared to an AVA.

Conclusions: The ideal vascular access in elderly patients remains controversial. Our results suggest that patients who start HD with a CVC presented higher all-cause and infection-related mortality when compared with patients who start with an AVA. Our study supports the initiative “fistula first” however more studies are needed to confirm the observations.

Nurse-Driven Advance Care Planning in a Hemodialysis Unit in a Veteran Population
Sam Tonthat,1,2 Rebecca Yamark,2 Jocell Fernandez,2 Jennifer Ballard-Hernandez,2 Marysol Cacciata,2 Pankaj Gupta,2 Jolene L. Chen.2,3 University of California Irvine, Orange, CA; Long Beach Veteran Affairs Healthcare System, Long Beach, CA.

Background: Patients with end-stage kidney disease (ESKD) face difficult choices near the end of life. Advance care planning (ACP) allows patients and their providers to plan for treatments that align with patients’ goals. In the US, only 6-35% of all ESKD patients have advance directives (AD). PREPARE is an interactive ACP website that helps patients complete AD and express their wishes regarding medical decisions. The goal of the study was to assess the feasibility and acceptability of using a nurse to facilitate ESKD patients to completing the PREPARE ACP during dialysis.

Methods: Inclusion criteria include patients without a documented AD within the past 3 years. Exclusion criteria are dementia/cognitive impairment, psychosis, deafness, or blindness. Pre and post engagement surveys were completed. Barriers related to navigating the PREPARE website were documented.

Results: Of 55 patients at the dialysis unit, 25 were eligible and 14 were enrolled. All participants are male with mean age of 69. All participants completed their AD within 1 dialysis treatment. In the pre-PREPARE questionnaire, using the Likert scale of 1 to 5 (1 for “not at all” to 5 for “extremely likely”), patients reported a mean score of 4.01 for readiness to talk about end-of-life care to a close family/friend, 4.23 for readiness to talk to a care provider, 4.46 for readiness to express wishes in writing, and 4.61 for readiness to sign official documentation. In the Post-PREPARE questionnaire, on a scale of 1 (very hard) to 10 (extremely easy), patients scored 7.61 for ease, 7.23 for comfortability, and 8.07 for helpfulness. Analysis of PREPARE AD showed that on a scale of 1 (AD goal mainly to extend life) to 5 (to focus on the quality of life), the mean score is 3.06 suggesting that patients value both “extend life” and “maintain quality of life”. Five patients expressed wishes for full care, 6 wanted a trial of resuscitation, and 3 requested DNR. Barriers to using PREPARE included patient difficulty navigating the website without help and using a laptop during dialysis when both hands are not always free.

Conclusions: Our study shows that PREPARE is a feasible method in facilitating ACP during dialysis; however, many patients needed assistance to complete the process. Future studies are needed to apply PREPARE and ACP wishes in the ESKD population.

POI1377
Dialysis Patients’ Preferences on Resuscitation: A Cross-Sectional Study Design
Husam Alzayer,1,2 Annette M. Geraghty,3 Kuruvilla K. Sebastian,1,4 Hardashar Panesar,4 Donal N. Reddan.1,2 Galway University Hospitals, Galway, Ireland; Mayo University Hospital, Castlebar, Ireland; National University of Ireland Galway; Galway, Ireland; Western University, London, ON, Canada; Royal College of Physicians of Ireland, Dublin, Ireland.

Background: End-stage kidney disease is associated with a 10-100-fold increase in cardiovascular mortality compared to age-, sex-, and race-matched population. Cardiopulmonary resuscitation (CPR) in this cohort has poor outcomes and is often followed by increased functional morbidity. Advance care planning (ACP) is an important aspect of patients’ care that is often missed in chronic kidney disease (CKD) and there is growing support for its use. Nephrologists are often involved in end-of-life care decisions as part of the program.

Methods: A 2-center cross-sectional study design. Adults > 18 years undergoing regular dialysis session or clinic visit. Demographic data were collected and baseline for their patients and frequent end-of-life care discussions can provide insight and help in using a laptop during dialysis when both hands are not always free.

Results: Of 55 patients at the dialysis unit, 25 were eligible and 14 were enrolled. All participants are male with mean age of 69. All participants completed their AD within 1 dialysis treatment. In the pre-PREPARE questionnaire, using the Likert scale of 1 to 5 (1 for “not at all” to 5 for “extremely likely”), patients reported a mean score of 4.01 for readiness to talk about end-of-life care to a close family/friend, 4.23 for readiness to talk to a care provider, 4.46 for readiness to express wishes in writing, and 4.61 for readiness to sign official documentation. In the Post-PREPARE questionnaire, on a scale of 1 (very hard) to 10 (extremely easy), patients scored 7.61 for ease, 7.23 for comfortability, and 8.07 for helpfulness. Analysis of PREPARE AD showed that on a scale of 1 (AD goal mainly to extend life) to 5 (to focus on the quality of life), the mean score is 3.06 suggesting that patients value both “extend life” and “maintain quality of life”. Five patients expressed wishes for full care, 6 wanted a trial of resuscitation, and 3 requested DNR. Barriers to using PREPARE included patient difficulty navigating the website without help and using a laptop during dialysis when both hands are not always free.

Conclusions: Our study shows that PREPARE is a feasible method in facilitating ACP during dialysis; however, many patients needed assistance to complete the process. Future studies are needed to apply PREPARE and ACP wishes in the ESKD population.

POI1378
Evaluation of a Concurrent Hospice-Dialysis Program for Patients with ESRD
Mayumi Robinson,1 Natalie C. Ernecoff,1 Erica M. Motter,1 Keith Lagnese,2,3 Robert Taylor,1 Jane O. Schell.1 University of Pittsburgh School of Medicine, Pittsburgh, PA; UPMC Family Hospice, Pittsburgh, PA; University of Pittsburgh Medical Center, Pittsburgh, PA; Dialysis Clinic Inc, Nashville, TN.

Background: Most dialysis patients are hospitalized in the last month of life, nearly half of whom receive intensive care. Hospice financing poses a major barrier to hospice delivery to dialysis patients, increasing inequities for high-quality end-of-life care. The Concurrent Hospice-Dialysis Program aims to promote timely hospice services for dialysis patients with limited prognosis by offering concurrent hospice and dialysis.

Methods: We conducted a mixed methods study comprised of chart reviews and semi-structured interviews with 10 bereaved caregivers of deceased patients who were enrolled in the Concurrent Hospice-Dialysis Program and 13 clinicians who provided care as part of the program.

Results: Four major themes were identified: 1) Decisional distress regarding stopping dialysis; 2) The option to continue dialysis served as a psychological bridge to hospice; 3) Clear referral process, formal patient education, and care coordination between hospice and dialysis teams facilitated successful implementation; 4) Providing hospice and dialysis promoted goal-consistent care at end-of-life.

Conclusions: Bereaved caregivers and clinicians involved with the Concurrent Hospice-Dialysis Program found the program broadly acceptable and recommended it for patients on dialysis interested in hospice services. They offered suggestions for systematizing and disseminating the program.

Table 1. Key Themes

POI1379
Concurrent Hospice Dialysis: Perspectives on Dissemination
Erica M. Motter,1 Mayumi Robinson,1 Natalie C. Ernecoff,1 Keith Lagnese,2,3 Robert Taylor,1 Jane O. Schell.1 University of Pittsburgh School of Medicine, Pittsburgh, PA; UPMC Family Hospice, Pittsburgh, PA; University of Pittsburgh Medical Center, Pittsburgh, PA; Dialysis Clinic Inc, Nashville, TN.

Background: In the United States, people receiving dialysis have traditionally been unable to enroll in hospice without ceasing dialysis treatments due to policy constraints. Therefore, these patients are often denied the full benefits of quality end-of-life care, either dying in hospitals or spending only a few days on hospice after dialysis is stopped. An alternative model would allow people living with end-stage renal disease (ESRD) to receive hospice services concurrently with dialysis treatments.

Methods: We implemented a concurrent hospice-dialysis program in one health system as a proof of concept. In this project, we sought to build evidence for feasibility and program requirements for extending such programs to other settings across the country. We conducted semi-structured interviews with people living with ESRD, family caregivers, hospice and dialysis clinicians, and health system administrators from the Pittsburgh area and other regions in the U.S. Interviews elicited perceptions of strengths and weaknesses of a scalable concurrent hospice and dialysis program, including barriers and facilitators of implementation across various settings.

Results: We conducted 25 interviews with 2 patients (8%), 3 caregivers (12%), 15 clinicians (60%), and 5 administrators (20%). Preliminary themes include important considerations: 1) Mechanisms and operational definitions for identification of eligible patients; 2) Procedures for decision-making conversations with patients and families; and 3) Protocols for communication between hospice and dialysis teams to coordinate care. Medicare policy and funding restrictions were also frequently discussed as barriers to the program.

Conclusions: Perspectives from patients, caregivers, clinicians and administrators describe critical implementation processes and resources for a successful concurrent hospice and dialysis program. These include the following: clear criteria for patient eligibility, consistent language to use when talking with patients and families, education for both hospice and dialysis teams, and a well-defined plan for care coordination between teams. Future evaluation of such programs may lead to policy change to make concurrent care broadly financially feasible.

Dialysis for the Hospice Patient: A Paradoxical Challenge for Palliative Medicine
Frank A. Portugal, Steve I. Khalil. Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, NJ.

Introduction: We present a case of a patient who developed anuric AKI who subsequently needed dialysis while patient and family were also simultaneously interested in hospice. Our case addresses the difficult conversation in prognosticating and hospice eligibility for patients requiring dialysis can be challenging.

Case Description: A 63-year-old woman with hypertension and recently diagnosed metastatic pancreatic adenocarcinoma initially presented for intractable right hip pain and was admitted for emergent palliative radiation. She experienced rapid deterioration including diaphoresis, hypotension and shock and was managed in the ICU until she was later stabilized off pressors and downgraded to the floors. Unfortunately, she had further complications and quickly experienced anuric AKI from ischemic ATN as her serum creatinine rose from 0.8 to 4.9 mg/dL and became significantly volume overloaded with worsening ascites. The decision was to start a trial of dialysis by family, but they also wanted hospice. Questions arose including prognosis and if patient could simultaneously be provided with dialysis during hospice. Given the current model of withdrawing from dialysis for hospice eligibility, the daughters agreed to transition their mother to hospice.

The patient passed prior to leaving the hospital.

Discussion: We present a difficult scenario for the nephrologist as serious illness conversations remain incredibly challenging. We may opt to not take part in these conversations either due to time commitment, not viewing it as a primary responsibility, or not wishing to upset the patient and their families. Also, so much uncertainty in predicting prognosis makes it intimidating. Here, what also needed to be addressed were hospice benefits for the dialysis patient, if any existed. Usually, one is required to withdraw from dialysis to receive hospice care. There have been suggestions in providing a trial or “as needed dialysis” to focus on a patient-centered type of care but unfortunately that could potentially impact quality metrics and Medicare reimbursement for dialysis centers. As such, these ongoing challenges not only require collaboration between Nephrology and Palliative medicine but also changes at the national broader level.

POI381

Kidney Palliative Care in Transplant Recipients with a Failing Allograft
Samantha L. Gelfand,1 Naoko Murakami,1 Joel T. Adler,1 Joshua R. Lakin.2 Brigham and Women’s Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA.

Background: Kidney transplantation provides longer survival and better quality of life than dialysis for patients with end-stage kidney disease. However, when allografts fail, navigating treatment options can be challenging as patients with allograft failure are older and sicker than when they were transplanted. Kidney palliative care, specialized interprofessional medical care working together with nephrology providers, providing communication, coordination, symptom management, and psychosocial support for seriously ill patients, has not yet been well-studied for those with kidney transplants.

Methods: We conducted a retrospecitive observational study comparing palliative care delivery, patient treatment choices, and clinical outcomes before and after creation of an inpatient kidney palliative care service (KidneyPal) at our institution. We included adult kidney transplant patients with an allograft failure who were ≥18 years of age and died within 2 years after starting KidneyPal. Allograft failure was defined as imminent indication or chronic need for dialysis for more than 3 months.

Results: Fifty-four and fifty-nine patients were included before and after KidneyPal implementation, respectively. For the patients who experienced death with a functioning graft, inpatient palliative consultation frequency was similar before and after the creation of KidneyPal (40% and 33%, respectively). However, for the patients with allograft failure, palliative care consultation increased from 5.9% to 24.1%. Death in the ICU was common (15% vs. 17%), but death in hospice was more frequent (7% vs. 15%) after KidneyPal was created. While palliative care clinicians addressed code status, symptom management, and psychosocial issues throughout the study period, KidneyPal clinicians held more discussions about treatment options for allograft failure (20% vs. 41%).

Conclusions: Our observational study suggests that kidney palliative care may be useful in the context of allograft failure, particularly with regard to ensuring goal-directed shared decision making. Discussing prognosis, goals of care, and care options after allograft failure are palliative skills that may be enhanced by collaboration with a specialty kidney palliative care team.

POI382

Patient Perspectives on Frailty Status Evaluation During Kidney Transplant Assessment
Henry H. Wu,1,2 Lyndsey Rushton,1 Fiona Biggins,1 Aimun K. Ahmed,1,2 Alexander Woywodt.1,2 Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 1University of Manchester Faculty of Biology Medicine and Health, Manchester; United Kingdom.

Background: The concept of frailty garnered attention within nephrology in recent years, given strong associations between frailty status and kidney disease outcomes. There is increased debate on formulating frailty status evaluation during the early stages of assessment for potential kidney transplant recipients. Studies investigating patient perspectives on frailty and frailty status evaluation during transplant assessment are lacking.

Methods: We conducted a qualitative study using cognitive interviews in English for 25 patients aged 65-85 yrs awaiting initial transplant clinic assessment. The interview explored patient understanding of frailty, perspectives on the impact of frailty on transplantation outcomes and whether formalized frailty status evaluation during transplant assessment should be established. An inductive thematic analysis of interviews to identify themes reflecting patients’ awareness, understanding and perspectives of frailty and frailty status evaluation during assessment was performed.

Results: There were 14 Male and 11 Female participants and mean age was 69.6 yrs ± 3.4. Participants were mainly white (n=18) and native English speakers (n=20). 3 prominent themes were identified. 1) Prerequisite awareness of the frailty syndrome and recognition of its strong associations with negative health outcomes. Most participants understood frailty as a composite of declining physical function, reduced ability to perform daily activities and increased comorbidity status. 2) Severe frailty status is associated with older transplant recipients. Many participants felt worse clinical frailty status is correlated with older age, and older transplant recipients generally do not perform as well. 3) Participants expressed the need for clear definitions and limits for frailty, as patients with end-stage kidney disease are likely to progress through several stages of frailty.

Conclusions: Patient education initiatives should continue to expand awareness of frailty and its implications in transplant care. Further work is required to determine an optimal approach to formally evaluate frailty status during transplant assessment.

Differences in Frailty by Sex in Kidney Transplant Candidates
Charlotte Worthworth,1 Amanda J. Vinson,1,2 Karine K. Tebeau1,2 Frailty Assessments in Canadians being Evaluated for Transplant Study (FACETS) 1Dalhousie University, Halifax, NS, Canada; 2Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Frailty prevalence is higher in women, despite the observed protective effect of female sex on mortality in the general population. Understanding whether there are differences in perceived frailty by sex and the differential impact of frailty on outcomes for males versus females is crucial to avoid a sex disparity within the transplant assessment process.

Methods: We analyzed initial frailty assessments for patients enrolled in a multicenter prospective cohort study across 6 kidney transplant referral centers. Frailty was assessed using the Frailty Phenotype (FP, 3 of slowness, weight loss, low activity, exhaustion, muscle weakness), a Frailty Index (FI, including 37 variables across the domains of social function/cognition, function, mobility, and comorbidity), and the Clinical Frailty Scale (CFS, based on clinical judgement). Assessments were performed prior to or shortly after waitlisting. Prevalence of frailty as measured by the FP, FI, and CFS was reported. An unadjusted Cox survival analysis (separately for males and females) was used to assess the effect of frailty on time to death or withdrawal from the waitlist among activated patients.

Results: A total of 767 unique patients had frailty assessments performed between 2016-2021. Patients were predominantly of male sex (64%), white race (82%) and had a mean age of 54±14. The prevalence of frailty for women was not significantly higher by the FP (16% vs 13%, p=0.15) or the FI (48% vs 46%, p=0.38), but was by the CFS (17% vs 12%, p=0.05). Among 325 activated patients, frailty by the CFS was significantly associated with death/withdrawal for men (HR 2.59; 95% CI 1.16-6.79) but not women (HR 1.1; 95% CI 0.48-4.18).

Conclusions: The prevalence of frailty was higher in females when measured by the CFS, but not by a transplant specific FI or the FP. Despite this, frailty was not significantly associated with mortality/withdrawal from the waitlist for female individuals, emphasizing the need to critically evaluate judgement based frailty assessments and their role in the transplant evaluation process.

Changes in Cognition After Kidney Transplantation
Aditi Gupta,1 Palash Sharma,1 Rebecca J. Lepping,1 Jonathan D. Mahnken,1 William M. Brooks,1 David K. Johnson,1 Jeffrey M. Burns.1 University of Kansas Medical Center; Kansas City, KS; 2University of California Davis, Davis, CA.

Background: Longitudinal studies examining changes in cognition pre- to post-kidney transplantation (KT) are small, of short duration and do not include comprehensive neuropsychological (NP) testing or comparison with normative data.

Methods: We analyzed pre- to post-KT cognition in 87 ESKD patients listed for KT and compared it to the National Alzheimer’s Coordination Center (NACC) data. We used linear mixed models for longitudinal, repeated NP test measurements, adjusted for for age, practice effect, sex, race, transplant status, and level of education, and assessed cognition pre- to post-KT for the following domains (Logical Memory I, II, and Digit Symbol tests) and secondary (Mini Mental State Exam (MMSE), Digit span, Category Fluency for animals & vegetables, Trail making A & B) outcomes.
Results: Data from 87 ESKD patients (age ≥ 55 years) and 6974 controls (age 64.9 ± 7.9 years) were analyzed. Pre-KT ESKD patients had lower Logit Memory I, II, Digit Symbol, MMSE, Digit Span Backward, and Category Fluency of vegetables test scores (Table 1). There was no difference in scores of Digit Span forward, Category Fluency of animals, and Trail Making A & B between pre-KT ESKD patients and controls. Post-KT, Logit Memory I and II, and Category Fluency animals & vegetables improved, while Digit Symbol, MMSE, and Digit Span backward scores remained lower than controls (Table 1).

Conclusions: Not all cognitive abilities are affected in ESKD. While some test scores improve with KT, others do not. Further studies are needed to understand the mechanisms underlying cognitive impairment in ESKD and to explore interventions to mitigate them.

Funding: Other NIH Support - NIA

Table 1: NP test comparisons in pre- and post-KT recipients and controls

PO1385
Patients Who Are Treated for Secondary Hyperparathyroidism Have a Lower Risk of Incident Dementia
JiYoon B. Ahn,1 Aarti Mathur,1 Dorry L. Segev,1,2 Mara McAdams-DeMarco,1,2 ERGOT 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: Almost all patients with end-stage kidney disease (ESKD) have secondary hyperparathyroidism (SHPT). Elevated parathyroid hormone has been reported as a potential risk factor of cognitive impairment. We aimed to study whether the risk of dementia is improved when patients on dialysis receive treatment for SHPT.

Methods: Using data from the United States Renal Data System and Medicare claims, we studied older (aged 66) ESKD patients without known pre-ESKD dementia claims, we studied older (aged 66) ESKD patients without known pre-ESKD dementia and the number of steps/d were -28, (95% CI -61 to 5 min/d), 13, (95% CI 1 to 24 min/d) in the age ≥ 70 group for sedentary and stepping durations ≥ 70 group for sedentary and stepping durations and the number of steps/day (-424, 95% CI -1669 to 820) in the age < 70 group.

Results: Of 189,433 ESRD patients, 65.1% received a treatment for SHPT during ≥ 70 (N =59) versus age < 70 (N=47).

PO1386
Kidney-Metabolic Risk Factors for Cognitive Impairment in Moderate CKD in the BRINK Study: Beyond eGFR and Albuminuria
Anne M. Murray,1,2 David Tupper,1,2 Cynthia S. Davey,1 Ryan Mello,1 Allyson Hart,1 Kirsten L. Johansen,2 The Berman Center for Outcomes and Clinical Research, Hennepin Healthcare Research Institute, Minneapolis, MN; Hennepin Healthcare, Minneapolis, MN; University of Minnesota Clinical and Translational Science Institute, Minneapolis, MN; 4University of Minnesota Twin Cities, Minneapolis, MN.

Background: Decreased kidney function is a risk factor for cognitive impairment (CI). We sought to identify kidney-metabolic biomarkers beyond eGFR and albuminuria associated with prevalent moderate to severe cognitive impairment (Mod/Sev CI) in a CKD cohort.

Methods: Community-dwelling non-dialysis participants aged ≥ 45 years with CKD (eGFR <60, in mL/min/1.73 m²) were recruited from four health systems. We examined biomarkers including phosphorus, TNFαR1, PTH, calcium, total cholesterol, hemoglobin A1c%, bicarbonate (CO₂), 2,3-DPG, vitamin D, triglycerides, albumin, hsCRP, and measured global and domain-specific cognitive performance. Logistic regression analyses estimated cross-sectional associations between kidney-metabolic measures and global and cognitive-domain-specific Mod/Sev CI at baseline, adjusted for eGFR, urinary albumin-creatinine ratio (UACR, in mg/g), demographics, and comorbid conditions.

Results: Among 436 participants age ≥ 70 years, 16% were Black, mean eGFR was 34 and median UACR. In adjusted models no kidney-metabolic biomarkers were significantly associated with global Mod/Sev CI. However, in cognitive-domain-specific analyses, low bicarbonate (CO₂, <20 mEq/L) was significantly associated with Mod/Sev impairment in memory [OR (95%CI): 3.04 (1.09, 8.47) P=0.03] and with language [3.82 (1.12, 13.0; P=0.03). In addition, lower total cholesterol was associated with impaired executive function [1.12 per -10mg/dL (1.02, 1.23; P=0.02).

Conclusions: Low bicarbonate (acidosis) and lower cholesterol levels in older patients with CKD may be modifiable kidney-metabolic risk factors for Mod/Sev domain-specific CI in CKD. Longitudinal analyses are needed to determine whether low bicarbonate and low cholesterol are associated with cognitive decline.

PO1387
Targeting Sedentary Behavior in Older Adults: Subgroup Analysis of a Randomized Clinical Trial
Nikita Abraham,1 Robert E. Boucher,1 Guo Wei,1 Jesse Christensen,1 Sydney E. Hartsell,1 Judy Carle,1 Victoria Gonce,1 Mark A. Supiano,2 Kate Lyden,2 Srinivasan Beddhu,1,2 The University of Utah School of Medicine, Salt Lake City, UT; University of Massachusetts Amherst, Amherst, MA; 3VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: Sedentary behavior (spending most of the awake hours in sitting/lying posture) is associated with increased mortality in CKD but few studies have examined the feasibility of interventions targeting sedentary behavior in older adults with CKD.

Methods: The Sit Less, Interact, Move More (SLIMM) Study was a 24-week RCT of an intervention to reduce sedenary duration with stepping duration in participants with CKD. Physical activity was measured using a mid-thigh accelerometer worn for 7 days before baseline and q8 weeks in standard of care (SOC) group (N=54) and baseline and q8 weeks in SLIMM group (N=54). Based on the accelerometer data, SLIMM group was provided instructions on reducing sedenary duration. In this post-hoc analyses, we used mixed model models to compare the effects of the SLIMM intervention in participants age ≥ 70 (N=59) versus age < 70 (N=47).

Results: Age ≥ 70 group compared to age < 70 group had a higher % of Whites and lower % of stage3b-5 CKD (Table 1). While sedentary duration was similar, the older group had lower stepping duration, gait speed and 6-min walk distance (Table 1). In mixed models, there were no significant differences between SLIMM and SOC groups for sedentary (1, 95% CI -0.36 to 0.35), walking (7, 95% CI -0.12 to 0.35), and number of steps/week (-28, 95% CI -61 to 5 min/d), 13, (95% CI 1 to 24 min/d) and 1330, (95% CI 322 to 2338 min/d), respectively.

Conclusions: It is feasible to decrease sedenary behavior In older adults with CKD.

Association of CKD Stages with Frailty Worsening or Death in Community-Dwelling Older Adults

Nina Mielke,1 Alice Schneider,1 Natalie Ebert,1 Markus van der Giet,1 Doerte Hüscher,1 Martin K. Kuhlmann,2 Elke Schaeffer,1 1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Vivantes Klinikum im Friedrichshain, Berlin, Germany.

Background: Albumin-creatinine-ratio (ACR) and glomerular filtration rate (GFR) have been associated with prevalent and incident frailty. We analyzed the association of the KDIGO CKD stages and frailty status worsening or death in data of the Berlin Initiative Study (BIS).

Methods: Prospective population-based cohort study interviewing participants biannually with a standardized questionnaire. Frailty assessment according to Fried took place at the 3rd and 4th follow-up. Frailty worsening was defined as the transition within a two-year period from robust to prefrail or frail, or from prefrail to frail. Partial proportional odds regression analysis was used to analyze the association between KDIGO CKD stages and the ordinal outcome of no worsening, frailty worsening, or death.

Results: Of 1076 participants with 46% male and mean age 84.3 years, initially 48% were prefrail and 32% frail. After 2.1 (2.0-2.3) years of follow-up 188 (17.5%) had worsened and 111 (10.3%) died. Participants who died were older (88 vs. 83 yrs), were less physically active, had less muscle mass (calve circumference <31: 10% vs. 5%), and were more likely to be cognitively impaired; 92% had a GFR <60 mL/min/1.73m² and 59% had an ACR ≥30 mg/g compared to 72% and 24% in participants who did not worsen, respectively. Baseline characteristics of participants who worsened were similar to participants who did not worsen. In the multivariable model participants in CKD stages G1/2/A2.3 and G3/A1 or higher had about 3-fold higher odds of frailty worsening than in CKD stages G1/2/A1. The odds for death increased remarkably with both higher CKD stage and increasing albuminuria. Wide confidence intervals are likely due to limited sample size/events. Additional adjustment for frailty baseline status did not alter the results.

Conclusions: In older adults, advanced CKD stages but also albuminuria independent of GFR were associated with 2-fold higher odds of frailty worsening independent of death.

PO1389

Role of Klotho in Aging, Relationship with Frailty, Renal Function, and Body Composition

Paolo Betti, Marta De Filippo, Marco Simonini, Simone Fontana, Lorenza Citterio, Elisabetta Messaggio, Patrizia Rovere Querini, Elena Brioni, Cristiano Magnaghi, Chiara Lanzani, Paolo Manunta. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Reduced expression of the Klotho protein has been associated with premature aging and increased mortality. Our aim is to evaluate the relationships between plasma Klotho levels and frailty, renal function and anthropomorphic parameters.

Methods: We enrolled a cohort of 1250 volunteers aged > 65 years (FRASNET Study) in recreation centers for the elderly, in hospital’s outpatient clinic and in nursing homes. All the volunteers have signed informed consent and subjects with severe cognitive impairment were excluded (MMSE >18). We measured eGFR (CKD-EPI formula) and body composition by impedancemetry. Plasma Klotho was assayed by an ELISA kit on 194 samples. Frailty was classified according to Fried’s criteria.

Results: A positive correlation between plasma Klotho and renal function (eGFR) has been observed (fig. 1). In agreement with what previously observed, in a younger population, we confirmed a reduction of klothemia in the sarcopenic patients (713 vs 791 pg/mL, p<0.0007 in patients with muscle mass <25% centile) and in patients with high visceral fat mass (fig.2). On the other hand, we did not observe different levels of plasma Klotho according to the frailty class or in relation to age.

Conclusions: In our elderly population, the plasma levels of Klotho do not correlate with age. Therefore, our results confirm the relevance of this biomarker in identifying pathological aging, in consideration of its association within the elderly population with CKD, abdominal obesity and sarcopenia (sarcopenic obesity). Klotho expression was demonstrated as an independent predictor of death in a follow up study and was related to many diseases (e.g: cognitive impairment, cardiovascular disease). The relation of plasma klotho levels and renal function is debated, and conflicting results have been published. Our findings evidenced a significative association of plasma Klotho with renal function and body composition.

PO1390

Shrunken Pore Syndrome: Prevalence and Association with Mortality in a Population-Based Cohort of Elderly Women

Lorena Malmgren,1,2 Fiona Mcguigan,1 Anders Christensson,1,2 Kristina Åkesson,1,2 1Lunds Universitet, Lund, Sweden; 2Skanes universitetssjukhus Malmo, Malmo, Sweden.

Background: Decreased kidney function results in lower clearance and increased plasma concentration of a GFR marker. So far creatinine has been the commonly used GFR marker but cystatin C becomes more common. Shrunken pore syndrome (SPS) is a recently identified kidney syndrome characterized by disturbed filtration of mid-sized molecules (5-30 kDa) compared to smaller ones (<9 kDa) (Fig1). Resulting in increased plasma levels of cystatin C (cysC) compared to creatinine. SPS is associated with increased risk of cardiovascular disease (CVD) and increased mortality risk. So far few data are available about SPS in population-based cohorts.

Methods: 75-yr old women (n=849) from the population-based Osteoporosis Prospective Risk Assessment (OPRA)-x cohort, with follow-up after 5yr and 10yr were studied. eGFR was calculated with the CKD-EPI equation. SPS was defined as eGFRcysC/eGFRratio <0.6 and mortality risk (HR [95% CI]) estimated. Women with sarcopenia or on glucocorticoids were excluded.

Results: Almost 1 in 10 women (9%) had SPS at age 75 but at age 80 the majority of these women had increased their eGFRcysC/eGFRratio >0.6 (range from 0.6-1.0). Women with SPS had higher 10-yr mortality risk compared to those with eGFRcysC/eGFRratio <0.6 (HRadj 1.7 [95% CI 1.1-2.6]). Table 1.

Conclusions: SPS defined as eGFRcysC/eGFRratio <0.6 is common in elderly women and associated with increased mortality. While longitudinal data indicate that the state may be reversible. Our results also confirm other studies and suggest that SPS may be a clinically applicable tool to assess mortality risk in the elderly.

PO1391

Women with SPS had higher 10-yr mortality risk compared with ratios >0.9 (HR
adj 1.7 [95% CI 1.1-2.6]). Table 1.

Conclusions:

1. Women with SPS had higher 10-yr mortality risk compared with ratios >0.9 (HRadj 1.7 [95% CI 1.1-2.6]). Table 1.
2. SPS defined as eGFRcysC/eGFRratio <0.6 is common in elderly women and associated with increased mortality.
3. Longitudinal data indicate that the state may be reversible. Our results also confirm other studies and suggest that SPS may be a clinically applicable tool to assess mortality risk in the elderly.

Molecular Changes Associated with Type IV Collagen Switching in 1-Day-Old Alport Murine Glomeruli

Akanehaya Rana,1,2 Sofia Farkona,1,2 James W. Scholey,1,2 Ana Konvalinka,1,2 Mounita Barua,1,2 A. University General Research Institute, Toronto, ON, Canada; 2Institute of Medical Science, University of Toronto, Toronto, ON, Canada.

Background: Alport syndrome (AS) is an inherited disorder caused by pathogenic variants in COL4A3, COL4A4 or COL4A5, which encodes proteins that comprise basement membranes of the ear, eye and kidney glomerulus. Type IV collagen chains assemble as heterotrimers and during glomerular development, α1α2(IV) within the developing glomerular basement membrane (GBM). This “switching” defines the starting point of disease in AS. We aimed to identify the molecular changes at the time of disease initiation in the developing glomeruli of Alport murine kidneys.

Methods: Immunofluorescence (IF) staining was done to identify the GBM distribution of type IV collagen chains in 1 day old COL4A3 knocko (KO) and wildtype (WT) mice. Urine albumin to creatinine ratio (uACR) was also measured. Subsequently, glomeruli from 1 day old (P1) COL4A3 KO and WT mice were isolated by cardiac injection of magnetic dynabeads that embolized to glomerular capillaries enabling their extraction from surrounding tissue. Protein was isolated and subjected to liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) analysis.

Results: IF localized type IV collagen α1 in the GBM, Bowman’s capsule and mesangial matrix in both P1 KO and WT mice. Type IV collagen α5 was present in short segments of some developing GBM in P1 WT but was absent in KO mice indicating switching. uACR was increased in P1 KO (423.61 ± 69.86 mg/mmol) with a p-value of 0.02. LC-MS/MS identified ~400 proteins from glomerular isolates. In males, 2 and 15 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. In females, 543 and 978 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. Pathway analysis revealed alteration in collagen metabolic process, collagen biosynthesis, collagen formation and extracellular matrix organization.

Conclusions: Increased uACR in P1 KO mice showed disease onset at the time of type IV collagen switching. LC-MS/MS analysis revealed dysregulation of matrix turnover pathways in P1 KO mice, identifying potential molecular targets.

PTEN-Induced Kinase 1 Has Association with Renal Aging in the Context of Inflammatory Response

Hyeyun Lee,1,2 Song Hee Lim,1 So-young Lee. CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.

Background: Among several changes of aging-related human organ system, functional and structural deterioration of kidney is the most dramatic phenomenon, and the role of mitophagy has recently considered important in pro-aging process in CKD patients. PTEN-induced kinase 1 (PINK1), known to be associated with age-related diseases regulates mitochondrial dysfunction. To enhance understanding the function of PINK1 on aging, we compared whole-kidney RNA sequencing between naturally aging mice and PINK1-overexpressing HKC8. We also investigated the function of PINK1 on aging, we used PINK1-deficient mice and PINK1-overexpressing HKC8.

Methods: Kyoto Encyclopedia of Genes and Genomes pathway analysis and gene ontology analysis were performed for gene expression analysis. To investigate the role of PINK1 on aging, we used PINK1-deficient mice and PINK1-overexpressing HKC8.

Results: Compared to naturally aging kidneys, PINK1 knock out aging mice showed prominent expression of the genes related to cytokines, immune system response, and inflammation (Fig 1). We also investigated the function of PINK1 in HKC8 and observed that PINK1 knock out aging mice showed more prominent expression of the genes related to cytokines, immune system response, and inflammation (Fig 2). The quantitative PCR analysis validated the expression of genes associated with aging, fibrosis, and inflammation increased in PINK1(-/-) mice compared to WT mice. Finally, on multivariate Cox-regression analysis, PINK1 expression correlated positively with segmental glomerulosclerosis (p=0.025) and creatinine level at diagnosis (p=0.002), while pSmad3 expression with interstitial inflammation (p=0.024). In glomerulus, concomitant expressions of high Smad7 and medium pSmad3 were observed to be correlated with renal inflammation, such as cellular crescent (p=0.011), intense interstitial inflammation (p=0.029) and lower serum complement 3 (p=0.028) and complement 4 (p=0.029). We also reported a significant association between pSmad3 expression in glomerular endothelial cells of proliferative GN (p=0.045) and in podocytes of non-proliferative GN (p=0.005). Finally, on multivariate Cox-regression analysis, TGF-β1 expression (HR = 6.078; 95% CI 1.168-31.627; p=0.032) was emerged as independent predictor for CKD.

Conclusions: In conclusion, our results suggest that PINK1 deficiency contributes to renal aging process via proinflammatory change in the kidney.

PO1393

TGF-β1/Smad Signaling in Glomerulonephritis and Its Association with Progression to CKD

Ahnaia Chalkia,1 Harikleia Gakiopoulou,2 Panagiotia E. Giannou,1 Zoe Alexakou,1 Athanasia Kapota,1 Dimitrios Koulostias,1 Dimitrios I. Petras,1 1Nephrology Department, Hippokration General Hospital, Athens, Greece; 21st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

Background: Transforming growth factor-β1 (TGF-β1) is a multifunctional cytokine, with diverse roles in fibrosis and inflammation, which acts through Smad signaling in renal pathology. We intended to investigate the expression of TGF-β1/Smad signaling in glomerulonephritis (GN) and to assess its role as risk factor for progression to chronic kidney disease (CKD).

Methods: We evaluated the immunohistochemical expression of TGF-β1, phosphorylated Smad3 (pSmad3) and Smad7 semi-quantitatively and quantitatively (computerized image analysis program has also been used) in different compartments of 50 renal biopsies with GN and the results were statistically analyzed with clinicopathological parameters. We also examined the associations among their expressions, the impact of their co-expression, and their role in progression to CKD.

Results: TGF-β1 expression correlated positively with segmental glomerulosclerosis (p=0.025) and creatinine level at diagnosis (p=0.002), while pSmad3 expression with interstitial inflammation (p=0.024). In glomerulus, concomitant expressions of high Smad7 and medium pSmad3 were observed to be correlated with renal inflammation, such as cellular crescent (p=0.011), intense interstitial inflammation (p=0.029) and lower serum complement 3 (p=0.028) and complement 4 (p=0.029). We also reported a significant association between pSmad3 expression in glomerular endothelial cells of proliferative GN (p=0.045) and in podocytes of non-proliferative GN (p=0.005). Finally, on multivariate Cox-regression analysis, TGF-β1 expression (HR = 6.078; 95% CI 1.168-31.627; p=0.032) was emerged as independent predictor for CKD.

Conclusions: TGF-β1/Smad signaling is upregulated with specific characteristics in different forms of GN. TGF-β1 expression is indicated as independent risk factor for progression to CKD, while specific co-expression pattern of pSmad3 and Smad7 in glomerulus is correlated with renal inflammation.

PO1394

ANCA Negative Medullary Angitis

Tarun Kapoor, Daniel Birchmore, Mark Lucso, Juan Pablo Arroyo Ornelas, Gautam B. Bhave. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Medullary angitis is a rare cause of renal failure. Most cases of medullary angitis are found to be ANCA positive. We present a rare case of ANCA negative medullary angitis with no identifiable secondary causes.
Steroids. Our patient had an initial improvement in his renal function with subsequent negative medullary angiitis not associated with IgA nephropathy and recent antibiotic use. This is one of the first case reports of ANCA positivity. ANCA negative medullary angiitis has been documented in the literature with recent reports showing IgA nephropathy and recent antibiotics use to be the most common etiologies. Given the rapid progression of the renal dysfunction, we decided to start our patient on high-dose steroids. Our patient had an initial improvement in his renal function with subsequent decline. However, treatment may have afforded time for AVF creation and patient education before the initiation of hemodialysis, which was the main goal of therapy.

PO1395

Calorie Restriction Ameliorates Obesity-Related Glomerulopathy in Adult Zebrafish

Evans Zeitler, J. Charles Jennette, Jennifer E. Flythe, Ronald J. Falk, John S. Poullon. UNC Kidney Center, Chapel Hill, NC.

Background: Obesity is a risk factor for chronic kidney disease. The mechanisms by which obesity results in kidney disease are understudied. Zebrafish are an attractive model animal for studying obesity due to their conserved biology and amenability to genetic screening. The effects of obesity on kidney function in zebrafish have not been reported.

Methods: Zebrafish were fed high-calorie and high-fat diets for 8 weeks. Kidneys were evaluated by light and electron microscopy, and the glomerular filtration barrier was assessed by fluorescent dextran permeability. We also tested the ability of calorie restriction to reverse obesity-related defects.

Results: Fish fed a high calorie diet developed glomerulomegaly, foot process effacement, GBM thickening, tubular enlargement (Figure 1) and ectopic lipid deposition after 8 weeks. High calorie feeding resulted in filtration barrier dysfunction. The observed effects resolved after 4 weeks of calorie restriction (Figure 2).

Conclusions: Our study reveals that obese zebrafish recapitulate key aspects of human pathology, and these defects can be reversed with calorie restriction. These findings establish zebrafish as a potential model for the study of obesity-related kidney disease.

PO1397

Automatic Artificial Intelligence-Assisted Glomerulosclerosis Analysis in Mice Models with Glomerulopathy

Thomas Secher, Casper G. Salinas, Michael Christensen, Niels Vrang, Mette V. Østergaard. Gubra, Harsholm, Denmark.

Background: Glomerulosclerosis (GS) is a hallmark pathological feature in glomerular diseases. In preclinical research, GS is recapitulated in a number of experimental mouse models with glomerulopathy, and a cross model characterization of GS would add to our understanding of their translatability to human disease. Here, we report GS quantification using an objective and newly developed automated AI assisted image analysis strategy in three mice models with glomerulopathy.

Methods: AI-assisted GS scoring was performed in three mice models with glomerulopathy and to assess drug treatment effects: 1) Diabetic nephropathy in remnAAV-induced hypertensive uninephrectomized db/db mice (DN/HT). Mice received treatment with vehicle, lisinopril, empagliflozin or combination. 2) T.I. injection of nephrotoxic anti-GBM serum (NTS) and 3) Adriamycin (ADR) in healthy mice. Automatic AI-assisted GS scoring was performed as a two-step process on PAS stained image analysis strategy in three mice models with glomerulopathy, and a cross model characterization of GS would add to our understanding of their translatability to human disease. Here, we report GS quantification using an objective and newly developed automated AI assisted image analysis strategy in three mice models with glomerulopathy.

Results: The automated AI-assisted scoring performed with high degree of accuracy and allowed for a large number of glomeruli to be evaluated pr. section (>100). We show that the mice models had very distinct GS profiles. The DN/HT model was most severely affected with highest average GS score (DN/HT: 2.5, NTS: 1.76, ADR: 0.68, control: 0.1) and the largest percentage of severely affect glomeruli, GS+GS4 (DN/HT: 54.1%, NTS: 37.2%, ADR: 16.8%, control: 1.1%). The ADR model was the least affected and

Increased Glomerular Parietal Epithelial Cell Expression of Cathepsins C and B in Anti-Thy1.1 Mouse Model of FSGS
Michael Merchant,1 Michelle T. Barati,1 Kenneth R. McLeish,1 Jon B. Klein,1,2 Bart Smeets,3 University of Louisville School of Medicine, Louisville, KY; 3VA Robley Rex Medical Center, Louisville, KY; 2Radboudumc, Nijmegen, Netherlands.
Background: Focal segmental glomerulosclerosis (FSGS) is characterized by replacement of glomerular capillaries by extracellular matrix (ECM). The collapsing FSGS (cFSGS) variant exhibits a poor prognosis and response to therapy. We recently reported that activated PECs migrate into glomerular tufts in human cFSGS and demonstrate increased cathepsins C and B expression. The absence of cathepsins B and C within normal glomerular tufts suggests these proteases may represent novel mediators of PEC-mediated glomerulosclerosis leading to collapse. We addressed the hypothesis that activated PECs expressing cathepsins C and B migrate into glomerular PECs in a mouse model of cFSGS.
Methods: Thy-1.1 transgenic mice were injected with either saline (vehicle control) or 250mg/kg anti-Thy1.1 (19XE5; 1mg/mouse) to induce FSGS. Mice were sacrificed 4, 7, and 21 days after injection. Kidney sections were subjected to immunofluorescence staining for claudin-1, a marker of PECs, and cathepsin C or cathepsin B. Images were acquired by confocal microscopy.
Results: Claudin-1, cathepsin C, and cathepsin B co-localized to glomerular parietal epithelial cells lining Bowman’s capsule in vehicle control mice. On day 4 after anti-Thy-1.1 administration, claudin-1 staining showed migration of PECs into glomerular tufts in more than half of the glomeruli. Both cathepsin B and C staining co-localized to activated PECs within glomeruli. PECs in the Bowman’s capsule with hypertrophied morphology, suggesting activation, demonstrated increased expression of cathepsins C and B. Claudin-1 and cathepsins B and C co-localized within glomeruli on days 7 and 21 after anti-Thy-1.1 administration, however, the number of stained cells per glomerulus and the percent glomeruli with positively stained cells in the glomerular tuft appeared decreased.
Conclusions: Glomerular PECs migrate into glomerular tufts and show increased expression of cathepsins C and B in the anti-thy1.1 model of cFSGS, recapitulating our findings in human cFSGS biopsies. The Thy-1.1 mouse model of cFSGS can be used to define the role of FSGS expression of cathepsins B and C in the pathogenesis of human cFSGS.

PO1399
Effects of Enzymatic Cross-Linking and Increased Stiffness on Glomerular Basement Membrane and Podocyte Function
Dan Wang,1 Nicholas J. Ferrell,1,2 Vanderbilt University Medical Center; Nashville, TN; 2Vanderbilt University; Nashville, TN.
Background: The Glomerular basement membrane (GBM) is a critical component of the glomerular filtration barrier. Stiffening of the extracellular matrix is an important regulator of cellular function. How GBM stiffening affects podocyte function is not fully understood. This work aims to investigate the effect of GBM stiffening on molecular permeability and the podocyte function using a biomimetic in vitro model directly derived from kidney glomeruli.
Methods: Decellularized glomeruli isolated from porcine kidneys were pressure crosslinked on a Transwell membrane. GBM stiffness was tuned by crosslinking with transglutaminase (TG). The stiffness of the TG-crosslinked decellularized glomeruli was evaluated using a custom cantilever-based compression system. Podocytes cultured on the TG crosslinked GBM were immunofluorescence stained with YAP, phalloidin and the nuclei counterstained with DAPI. The diffusional molecular permeability was evaluated on native and TG crosslinked GBM with and without podocytes using FITC-Ficoll and AF488-BSA. Effects of GBM stiffening on gene expression of markers of podocyte differentiation (NPEP1, WT1, Synaptopodin) were screened by qPCR.
Results: The stiffness of the decellularized glomeruli showed a dose-dependent increase after incubating with TG for 1 day and 4 days. On stiffer GBM, immunofluorescence imaging showed translocation of YAP to the podocyte nucleus. Passive molecular permeability of GBM was similar for native the TG crosslinked GBM. Podocytes cultured on both native and TG crosslinked GBM forms a stringent barrier to large molecules. qPCR results show an upregulation of differentiation markers as podocytes cultured on native and TG crosslinked GBM.
Conclusions: We developed a biomimetic in vitro model that fabricated directly from kidney tissue. nTG crosslinked glomeruli show a dose-dependent increase of stiffness. TG did not significantly effect the diffusive permeability of the GBM. GBM stiffness affects the YAP localization in the podocytes. The current in vitro model upregulates the gene expression of podocyte markers.

PO1400
Effect of ANG-3070 in the Unilateral Ureteral Obstruction Model of Renal Fibrosis
Bert Oehlen, Jingsong Li, Kai Jiang, Latsha Paka, Prakash Narayan, Izhak D. Goldberg, Angion Biomedica Corp, Uniondale, NY.
Background: Tubulointerstitial inflammation and fibrosis are strong predictors of progression in all kidney diseases regardless of etiology. Receptor tyrosine kinases such as platelet-derived growth factor receptor (PDGFR) and discoidin domain receptors (DDRs), contribute to renal inflammation and fibrosis. ANG-3070 is an inhibitor of multiple tyrosine kinases receptors including PDGFR and DDR. This study evaluated whether ANG-3070 can slow the progression of fibrosis in the unilateral ureteral obstruction (UUO) mouse model of renal fibrosis.
Methods: Male mice were subjected to UUO and randomized to daily oral treatment with vehicle (n=15) or 100 mg/kg of ANG-3070 (n=15) for 10 days after UUO and then sacrificed. Control male animals were age-matched and were not subjected to UUO (n=10). At sacrifice, obstructed and control kidneys were collected and processed for renal damage by hematotxylin-eosin (H&E) staining and scoring (0-8; 0 no damage and 8 damage to >80% of kidney) by blinded observers. Collagen deposition and myofibroblast transformation was determined by quantitative image analysis of picrosiris red (PSR)-stained slides and slides stained for α-smooth muscle cell actin (αSMA), respectively.
Results: Animals treated with ANG-3070 had a statistically significant reduction in histological damage as compared to vehicle (Vehicle, 6.4 vs ANG-3070, 4.3; p-value <0.001) and the histological markers of fibrosis, PSR (% control, vehicle, 1458% vs. ANG-3070, 503%; p-value <0.001), and αSMA (% control, vehicle, 511% vs. ANG-3070, 248%; p-value <0.001) as shown in Figure 1.
Conclusions: Daily oral administration of 100 mg/kg ANG-3070 reduces renal damage and renal fibrosis in a mouse model of renal fibrosis induced by UUO.
Funding: Commercial Support - Angion Biomedica, Inc.

Figure 1
chronicity index was still most powerful risk factor (P<0.05 for all) and they showed similar results to whole CKD stages. There was insufficient evidence to initiate IST according to chronicity index.

**Conclusions:** Among the known prognostic factors of IgAN, pathologic features were relatively abstract compared to other prognostic factors. But the chronicity index, presented as a simple integrated numeric scale, which is independently associated with renal outcome in IgAN, is more easily applicable in estimating renal outcome of IgAN patients.

Comparison of Glomerular Proteome Profiles of Healthy Human Kidney and Minimal Change Disease Identifies Distinct Targets and Pathways

Salem Almsaani, Sethu M. Madhavan, John P. Shapiro, Anjali A. Satoskar, Isabelle Ayoub, Brad H. Rovin, Samir V. Parikh. The Ohio State University, Columbus, OH.

**Background:** Minimal change disease (MCD) is a common cause of idiopathic nephrotic syndrome and is characterized by diffuse podocyte foot process effacement. The pathogenesis of MCD remains unclear. We hypothesized that proteomics analysis of glomeruli could identify molecular markers that reflect the pathogenesis of MCD.

**Methods:** We included formalin-fixed paraffin-embedded kidney biopsies from patients with steroid-sensitive MCD (n=9) and normal donor kidneys (n=4). Glomeruli were isolated using laser capture microdissection and HPLC MS/MS was done using Orbitrap eclipse mass spectrometer. After data normalization, groups were clustered using principal component analysis (PCA) and compared by paired t-tests.

**Results:** PCA showed separate clustering of healthy glomeruli and MCD samples (FDR<0.05). Out of the 6729 unique proteins identified in MCD glomeruli, 1088 proteins were significantly differentially expressed compared to controls. Pathway analysis showed upregulation of complement pathway components (C1R, C1S, C1Q&A, C2, C3, C4A, C4B, C5, C7, C8B, C9) and downregulation of carbohydrate and amino acid metabolic pathway enzymes (FBP1, FBP2, ALDOC, ALDOB, AKR1A1, ALDH1A1, ALDH5A1, ACAT1). MCD glomeruli showed a significant reduction in expression of ECM proteins FREM2, FRAS1, CDH12. Surprisingly, the expression of podocyte slit diaphragm-associated proteins (SYNO, NPHS2, CD2AP) was not significantly altered in MCD compared to controls. We did not observe differential expression of MCD associated proteins, KANK, CFL1, CMIP. No peptides from SMDP2L3 or ANGPTL4 were identified in MCD glomeruli.

**Conclusions:** Glomeruli from MCD showed differential proteomic signature compared to healthy human glomeruli. Activation of innate immune pathways including the complement system and loss of extracellular matrix and basement membrane-specific components in glomeruli of MCD are novel observations. The role of these markers in the pathogenesis of MCD needs to be investigated.

**Funding:** Clinical Revenue Support

**PO1403**

Effects of ANG-3070 in a Mouse Model of Alport Syndrome

**Background:** Alport syndrome (AS) is a hereditary kidney disease that presents in childhood and progresses to end stage kidney disease (ESKD) in adolescence. There are no approved therapies. AS is caused by mutations in type IV collagen genes Col4a3, a4 or a5; that result in reduced structural integrity of the glomerular basement membrane, triggering activation of fibrionic cytokines, including platelet derived growth factor (PDGF) and transforming growth factor beta (TGFB1) resulting in profibrotic disease and fibrosis. We hypothesized that an antifibrotic therapy may decrease proteinuria-induced fibrosis, and evaluated ANG-3070, a novel tyrosine kinase inhibitor, in a Col4a3 knockout mouse model of AS.

**Methods:** After confirming the Col4a3 mutation by genotyping, 4-week-old male and female AS mouse were randomized to Vehicle (oral, twice-daily) or ANG-3070 (oral, 25 mg/kg, twice-daily) for 5 weeks (n=12/group). Age-matched, wild-type mice were included (n=9) as a control. Animals were sacrificed after 5 weeks of treatment, after collecting spot urines to measure protein to creatinine ratio (PCR). Renal tissue was analyzed for hydroxyproline (HYP) content, by Western blot for tissue fibrotic markers, and for histopathology using hematoxylin-eosin (H&E) staining for renal damage score and picrosirius red (PSR) staining for fibrosis. All histological analyses were performed blinded by two independent observers using a 0-4 scale (0 being normal, 4 ≥75% injured or stained).

**Results:** ANG-3070 treatment reduced mortality (survivors; Vehicle: 8/12 vs ANG-3070: 12/12). In surviving mice, proteinuria was reduced (mg/ml; Vehicle 6.2 vs ANG-3070 3.1; p<0.05) along with PCR (mg/g; Vehicle 11.1 vs ANG-3070 5.5; p<0.05). There was a reduction in renal damage (Vehicle: 2.6 vs ANG-3070: 1.2; p= 0.002) along with renal fibrosis (Vehicle 2.4 vs ANG-3070 1.2; p<0.001). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.001). ANG-3070 along with fibrosis was related to collagen-I, TGFB1, and p-smooth muscle actin (5SMA) compared to Vehicle-treated Alport mice (p<0.05). Additionally, PDGF expression was reduced (p<0.05).

**Conclusions:** Treatment with a novel tyrosine kinase inhibitor, ANG-3070, was evident in AS mice compared to Vehicle. ANG-3070 may represent a novel therapeutic for AS.

Mesangial-Cell Activation by Circulating Immune Complexes Consisting of Galactose-Deficient IgA1 and IgG Autoantibodies from Patients with IgA Nephropathy

Zhi qiang Huang,1 Xianwen Zhang,2 Stacy D. Hall,3 Lin Wang,1 Yiping Chen,2 Bruce A. Julian,1 Jan Novak,1 The University of Alabama at Birmingham, Birmingham, AL; ’Long Hua Hospital, Shanghai, China.

**Background:** We and others have shown that immune complexes from the circulation of patients with IgA nephropathy (IgAN) that contain galactose-deficient IgA1 (Gd-IgA1) can induce proliferation of mesangial cells (MC) in culture. Here, we assessed cellular processes and signal transduction in MC after stimulation with CIC.

**Methods:** Quiescent primary MC were stimulated for 15 min at 37°C, with or without inhibitors, with circulating immune complexes (CIC) isolated from sera of 13 patients with IgAN. Cell lysates were analyzed directly, or after immunoprecipitation (IP) with antibodies specific for integrin β1 or PDGFR-β, by SDS-PAGE/immunoblotting for IgA, IgG, phospho-ERK1/2, phospho-PDGFR-β, talin, and Axl.

**Results:** Cell lysates from MC stimulated with CIC and the corresponding IP products of Gd-IgA1 (obtusted) and IgA1 (obtusted) contained IgA and IgG. Amounts of IgA and IgG were significantly reduced by an inhibitor of integrin αβ1 (obtustatin), but not by an inhibitor of integrin c5β1 (RGD), and partially inhibited by a tyrosine-kinase inhibitor (dasatinib). CIC induced phosphorylation of ERK1/2 that was inhibited by obtustatin, RGD, dasatinib, and a Chinese herbal medicine, ShenPeng decoction (SP) that has been used to treat IgAN patients in China. Dasatinib and SP inhibited CIC-induced phosphorylation of PDGF-β and Axl. In IP products of integrin β1 from CIC-activated MC, cytoktoskeleton-associated protein talin, known to activate ERK1/2, was associated with integrin β1. SP blocked binding of talin to integrin β1. In IP products of PDGFR-β, CIC induced association of integrin β1 with PDGFR-β, a process that may subsequently induce activation of MAP kinases. Dasatinib and SP inhibited this association.

**Conclusions:** Integrin αβ1 mediated activation of MC by IgA-IgG CIC; CIC activated multiple protein-tyrosine kinases in MC, leading to MAP kinase activation and cellular proliferation. Some of the inhibitors in this study may provide information about the mechanism of MC activation by the pathogenic CIC and, thus, inform development of future disease-specific therapeutic approaches.

Effect of Mycophenolate and Rapamycin on Pro-Inflammatory and Pro-Fibrotic Mediators in Human Mesangial Cells

Chenzhu Zhang, Susan Yung, Tak Mao D. Chan. Department of Medicine, The University of Hong Kong, Hong Kong, China.

**Background:** A significant proportion of lupus nephritis (LN) patients develop chronic kidney disease. TGF-β1 expression is increased in renal biopsies from LN patients and it plays an important role in kidney fibrosis. We previously reported that mycophenolate and rapamycin inhibited pro-fibrotic processes in resident kidney cells in murine LN. We proceeded to investigate the effect of mycophenolate and rapamycin on inflammatory and fibrotic processes in human mesangial cells.

**Methods:** Growth-factor arrested human mesangial cells (HMC) were incubated with or without exogenous TGF-β1 (10 ng/ml), in the presence or absence of mycophenolic acid (1 µg/ml) or rapamycin (3 ng/ml) for up to 72 h. The effect on inflammatory and fibrotic processes was examined.

**Results:** TGF-β1 increased IL-6 and MCP-1 secretion, and α-smooth muscle actin, collagen and fibronecin expression, in a time-dependent manner, accompanied by increased ERK, mTOR and PI3K phosphorylation (P<0.05, for all). Constitutive IL-6 and MCP-1 secretion was mediated through PI3K phosphorylation, whereas IL-6 and MCP-1 secretion induced by TGF-β1 was mediated through PI3K, mTOR and ERK phosphorylation. Cell activation was mediated through PI3K and mTOR activation, while increased collagen and fibronecin expression was mediated through ERK, PI3K and mTOR. Mycophenolic acid inhibited the secretion of pro-fibrotic and pro-inflammatory cytokines, cell activation, and collagen and fibronecin expression, through suppressing ERK activation. Rapamycin inhibited similar processes through suppression of mTOR and ERK activation. Overall, the inhibitory actions of mycophenolic acid were comparable to that of rapamycin.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.**
Conclusions: Mycophenolate and rapamycin both suppress pro-inflammatory and profibrotic processes in mesangial cells by targeting signaling pathways that overlap partially.

Collapsing FSGS Is Strongly Associated with Microvascular Injury
Nina A. Van de Lest, Kyra L. Dijkstra, Jamie S. Chua, Ron Wolterbeek, Jan A. Brujin, Marion Scharpfenecker, Ingeborg M. Bajema. Leids Universitair Medisch Centrum, Leiden, Netherlands.

Background: Recent studies have suggested that the collapsing variant of focal segmental glomerulosclerosis (FSGS) might be a common secondary feature in renal disease influenced by microvascular injury. Here, we investigated glomerular and arteriolar microvascular injury in patients with collapsing FSGS, including primary FSGS and HIV-associated FSGS, and compared these lesions to patients with other variants of FSGS.

Methods: Biopsies of patients with FSGS were collected, including primary FSGS in native biopsies or transplant biopsies, as well as HIV-associated FSGS. Cases of FSGS secondary to renal diseases known to be caused by microvascular injury were excluded. We assessed all glomeruli in a biopsy for the presence of lesions associated with FSGS or ischemic injury, assessed microvascular lesions in glomeruli and arterioles, and studied interstitial lesions.

Results: We included 53 cases of FSGS, of which 19 cases with collapsing FSGS, 18 cases with FSGS not otherwise specified (NOS), 11 cases with FSGS tip, 3 cases with perihilar FSGS and 2 cases with cellular FSGS. Compared to other variants of FSGS, glomerular endothelial swelling of the vascular pole was more common in patients with collapsing FSGS (11% vs 0.0%; p<0.05). Associations between thrombotic injury and FSGS variant were not found. Arteriolar abnormalities were seen in 58% of collapsing FSGS and 38% of other variants of FSGS (p=0.17). When evaluating the concomitant occurrence of FSGS lesions and microvascular injury in individual glomeruli, we found that collapsing lesions and FSGS NOS lesions were associated with endothelial swelling in the same glomerulus (OR=22; p<0.001 and OR=3.8; p<0.01, respectively). Endothelial swelling was more common in glomeruli with collapsing lesions than with glomeruli with FSGS NOS (OR=2.7; p<0.044). Collapsing FSGS was also associated with endocapillary hypercellularity (OR=4.3; p<0.001).

Conclusions: Here, we demonstrate that collapsing FSGS lesions are strongly associated with microvascular injury such as endothelial swelling and endocapillary hypercellularity, and often co-exist in the same glomerulus. In addition to collapsing FSGS occurrence, this secondary phenomenon in renal microangiopathies, these results indicate that endothelial injury could also be involved in the pathophysiology of collapsing FSGS due to primary podocyte injury.

POI1407
Danhong Injection (DHI) Inhibits Lipopolysaccharide-Enhanced Cell Proliferation of Rat Renal Mesangial Cells via NF-κB Signaling Pathway
Hua Liu. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

Background: To explore the mechanisms of DHI in the treatment of Mesangoproliferative glomerulonephritis (MsPGN), we investigated the effects of DHI on LPS-induced NF-κB activation and its downstream inflammatory mediators, such as ICAM-1, TGF-β1, iNOS and FN protein expression in rat MCs.

Methods: The rat MCs treated with different concentrations of DHI (0, 50, 100, 200, 500, 1000, and 2000 μL/L) for 12 h, then incubated with or without 100 ng/mL LPS for another 24 h. Then, cell proliferation was determined by CCK8. The MCs treated with low-dose DHI (250 μL/L), median-dose DHI (500 μL/L) and high-dose DHI (1000 μL/L) for 12 h or PDTC for 30 min before 24 h treatment of LPS. Then the activation of NF-κB was detected by Western blot and immunofluorescence. The protein levels of ICAM-1, TGF-β1, iNOS and FN in rat MCs were detected by Western blot.

Results: DHI significantly suppressed LPS-induced cell proliferation by CCK-8 results (Fig 1). LPS stimulation resulted in a significant increment of p65 contents in nucleus and a decrement of p65 contents in cytoplasm in rat MCs detected by Western blot. PDTC and DHI exerted potent inhibitory effect on increasing expression of p65 in nucleus and decreasing in cytoplasm compared with LPS-treatment group. The inhibitory effect on NF-κB nuclear translocation of DHI was in a dose-dependent manner (Fig 2). The protein level of kβ-β in cytoplasm treated by LPS decreased significantly compared with that in control (Fig 3) and this decrement was significantly reversed by PDTC and DHI. In addition, the protein expression of ICAM-1, TGF-β1, iNOS and FN was also inhibited by PDTC and DHI (Fig 4).

Conclusions: DHI significantly repressed LPS-induced cell proliferation and FN expression in rat MCs through inhibiting the activation of NF-κB signaling pathway also its downstream inflammatory mediators.
Case Description: A 50-year-old woman with a medical history of rheumatoid arthritis, hypertension, and diabetes was treated with a regimen that included hypoglycemic agents and antihypertensives at a treatment center. She was recently diagnosed with hypertension (174/82 mmHg) with elevated serum creatinine (Scr 3.2 mg/dL). She lost follow-up and returned to emergency department 5 months later complaining of worsening edema, fatigue, foamy urine, and joint pain for which she was taking NSAIDs daily. Further workup showed Scr of 8.1 mg/dL (glomerular filtration rate [GFR] 14 mL/min/1.73m²), hyperkalemia (5.5 mmol/L), and hypochloremic metabolic acidosis. A Congo red stain was negative for amyloidosis. She was treated with low dose prednisone (10mg/day) for her RA. Upon follow up it was noted her Scr decreased to 1.4mg/dL but nephrotic range proteinuria persisted.

Discussion: ITG is a rare cause of glomerulopathy. Determining the chronicity and the underlying etiology is essential for the management. This case is associated with RA and presents as a polycystic ITG. The exact treatment for this condition is unknown. Will continue following her closely as historically ITG carries a poor renal prognosis.

POI140
Fibrillary Glomerulonephritis: A Rare Entity, Responsive to Rituximab

Introduction: Fibrillary glomerulonephritis (FGN) is a rare proliferative type of glomerular disease with poor prognosis and limited therapeutic options. Literature review showed very few cases of FGN where Rituximab has been used.

Case Description: A 69-year-old Caucasian woman with a history of DM, HTN presented to the hospital with complaints of dyspepsia and leg swelling. Lab work revealed BUN/Scr of 3433.88 mg/dL (baseline Scr 1.4 mg/dL), proteinuria (7,902 mg/dL). Renal biopsy was performed which showed fibrillary deposits as shown in the picture. Histopathology was consistent with lupus nephritis.

Discussion: The diagnosis of FGN can only be established with kidney biopsy. Most of the patients present with renal insufficiency, nephrotic picture. Mostly idiopathic but can be associated with hepatitis C, dysproteinemia, autoimmune diseases and to lesser extent malignancies. The prognosis is very poor with very limited therapeutic options to date. Immunosuppressive therapy has been used in few cases in literature showing good clinical response. Our patient tolerated and responded very well to Rituximab with significant improvement in kidney function and hence we propose the use of Rituximab in FGN.

POI141
Renal-Limited Lupus Nephritis Misdiagnosed as Advanced CKD: Addressing the Need for Increasing Renal Biopsies in the Community Setting
Rajeev Chauhan, Megha Kalia, Katrina Hazim. Renal Associates LLC., Columbus, GA; Augusta University, Augusta, GA

Introduction: “Full-house” nephropathy is characteristic of lupus nephritis, but may be seen in patients without other evidence of SLE. Patient was presumed to have acute renal failure and was placed on dialysis for chronic management of ESRD. Despite no extraoral or clinical manifestations of SLE, renal biopsy revealed histopathology consistent with lupus nephritis.

Case Description: A 61-year old African American female presented to an outside hospital with complaints of mild abdominal pain, nausea, emesis, and diarrhea. Family history was positive for autoimmune disorders, including SLE and Sjogren’s Syndrome. Initial lab work revealed creatinine 8.1 mg/dL, eGFR 7 mL/min, BUN 117 mg/dL, proteinuria (7,902 mg/dL). Renal biopsy was performed which showed fibrillary deposits as shown in the picture. Hepatitis panel and work up of malignancy including bone marrow biopsy was negative. She was started on Rituximab 1gm every 14 days for 2 doses. Pt initially required HD but with lisinopril 20mg daily, levetiracetam 500mg twice daily and prednisone 10mg daily. Vital signs were remarkable for uncontrolled blood pressure. Home medications were discontinued unless medically indicated. Hematology was unremarkable. Renal function worsened. Complete blood count was noted to be within normal limits at the age of 24 months. Aging mice also had higher levels of urinary albumin, ACR, and proteinuria. Interestingly, both lysophosphatidic acid (LPA) and phosphatidylserine (PS) abundance were increased in aging glomeruli, suggesting the potential role of LPA signaling in the aging kidney.

Results: These findings suggest that reduced PLPP3 contributes to the accumulation of LPA in glomeruli of aging kidneys. Activation of LPA signaling in glomeruli may play an important role in the pathogenesis of aging-related kidney injury.

Focal Segmental Glomerulosclerosis: A Rare Cause of Nephrotic Syndrome in Graft vs. Host Disease

Introduction: Nephrotic syndrome (NS) is a very rare complication of allogeneic hematopoietic cell transplantation (HCT) and is usually associated with chronic graft versus host disease (GVHD). In such patients, membranous nephropathy and minimal change disease are the most frequently observed renal pathologies. However, focal segmental glomerulosclerosis (FSGS) is an extremely uncommon etiology in patients with HCT and GVHD. We herein describe a case of a patient with HCT and chronic GVHD who developed NS secondary to FSGS.

Case Description: A 24-year old man with medical history of Sickle Cell Disease status post splenectomy and HCT, epilepsy, arterial hypertension and chronic GVHD with cutaneous and esophageal manifestations who presented to the emergency department with a one month of evolution progressive lower extremity edema and intermittent hematuria. Vital signs were remarkable for uncontrolled blood pressure. Home medications were losinopril 20mg daily, levetiracetam 500mg twice daily and prednisone 10mg daily. Physical examination was remarkable for edema of the lower extremities, ascites, and cachexia. Laboratories revealed: BUN 35 mg/dL, serum creatinine 1.5 mg/dL, total protein 3.00 g/dL, serum albumin 1 g/dL, glucose 110mg/dL, total cholesterol 425 mg/dL, triglycerides 335 mg/dL, VLDL 67 mg/dL and LDL 316 mg/dL. Urine protein/creatinine ratio resulted in 30,000mg/g. Laboratory findings of hypoalbuminemia, hyperlipidemia, and nephrotic range proteinuria were consistent with NS. A renal biopsy was performed and it showed findings consistent with a diagnosis of FSGS, not otherwise specified. Partial remission of NS was achieved at 3 months of treatment with mycophenolate mofetil 500mg twice daily and prednisone 15mg twice daily.

Discussion: GVHD is a significant cause of morbidity and mortality in patients after HCT. Renal involvement can be a serious manifestation and prompt recognition is essential for adequate management and prevention of renal disease. FSGS is an extremely rare complication of HCT and very few cases have been reported in the literature linking FSGS to HCT. Further documentation of this phenomenon is important to further characterize the clinical and pathological features of this complication.

Catastrophic COVID-19-Associated Nephropathy (COVAN) in an Asymptomatic Patient

Samer Akrawi, Toni Sabbouh, Khaled Janom, Panduranga S. Rao, Cathryn J. Lapedis. University of Michigan Michigan Medicine, Ann Arbor, MI.

Introduction: Glomerular lesions were reported in a minority of patients with COVID-19, with collapsing focal segmental glomerulosclerosis (FSGS) also called COVID-associated nephropathy (COVAN). This typically occurs in the setting of prominent COVID symptoms. We describe a COVAN occurring in an asymptomatic patient.

Case Description: A 48-year-old, African American female patient who had CKD stage 3a secondary to hypertension, with serum creatinine of 1.2 mg/dl and absent proteinuria at baseline, presented to the hospital for evaluation of an asymptomatic elevation of her serum creatinine to 9.9 mg/dl, discovered during a routine evaluation by her PCP. Her urine Protein/ Creatinine was 6.15. Six weeks prior to her presentation, she endorsed 7 days of nausea and intermittent vomiting associated with non-bloody diarrhea without respiratory symptoms. Her GI symptoms has resolved on its own. She had multiple family members, including her husband and daughter, who had tested positive for COVID around the same time. Her nasal PCR for COVID was negative. She had not been vaccinated for SARS COVID. She has no family history of kidney disease; she denied IV drug use and had no risk factors for HIV. She was on Amlodipine for her hypertension. She had 1+ pedal edema with an unremarkable physical exam. A percutaneous kidney biopsy was performed to evaluate the cause of her renal dysfunction. This showed collapsing FSGS. HIV and ANA were negative. There was no evidence of glomerulonephritis. She was on Amlodipine for her hypertension. She had 1+ pedal edema with an unremarkable physical exam. A percutaneous kidney biopsy was performed to evaluate the cause of her renal dysfunction. This showed collapsing FSGS. HIV and ANA were negative. There was no evidence of glomerulonephritis.

Discussion: COVAN is increasing recognized as a serious complication of COVID. However, the typical presentation is in the setting of prominent respiratory involvement. Recognizing the minor fleeting symptoms of COVID preceding a catastrophic kidney disease and testing for it is an important in patients presenting with features of collapsing FSGS.

Siglec-9 Agonism Reduces ANCA-Mediated Neutrophil Responses In Vitro

Dana Kidder1, Kristine Nollany,1 Catriona Walls,1 NHS Grampian, Aberdeen, United Kingdom; 1University of Aberdeen School of Medicine Medical Sciences and Nutrition, Aberdeen, United Kingdom.

Background: Siglec family members, like sialic acid-binding Ig-like lectin 9 (Siglec-9) is constitutively expressed on neutrophils and monocytes. The expression and potential role of siglec-9 in ANCA-associated vasculitis (AAV) is yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on AAV.

Methods: Leukocytes and serum were isolated from peripheral venous blood of AAV patients and siglec-9 expression was measured by flow cytometry and ELISA, respectively. Immunohistochemistry was performed on kidney biopsies of AAV patients with AAGN and stained for siglec-9 and leukocyte markers. Functional studies were done using healthy donor neutrophils in the presence of ANCA and siglec-9 mAb to investigate its role in apoptosis and ROS production.

Results: We found increased serum siglec-9 expression in active AAV compared to remission AAV and a positive correlation with disease activity. Neutrophils and intermediate (CD14+CD16+) monocytes from PR3-ANCA patients displayed higher siglec-9 expression compared to MPO-ANCA patients. Siglec-9 expression in AAGN was restricted to areas of active inflammation. We observed increased siglec-9 shedding in neutrophils following AAGN stimulation. Siglec-9 agonism in these neutrophils was associated with increased apoptosis and reduced ROS production compared to isotype control and unstimulated neutrophils.

Conclusions: Our study suggests that siglec-9 expression correlates with disease activity in AAV. Our functional studies support a potential role for siglec-9 in modulating AAV

Proteinase 3-Alpha1-Antitrypsin Connection in PR3-ANCA Vasculitis

Maximilian Ebert1, Uwe Jerke,1 Claudia Eulenberg-Gustavus,1 Dieter E. Jenne,1 Markus Bieringer,1 Saban Elitok,2 Kai-Uwe Eckardt,2 Adrian Schreiber,3 Alan D. Salama,4 Ralph Ketritz,4 1Experimental and Clinical Research Center Charité - Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; 2Department of Nephrology, Helios Klinikum Berlin-Buch, Berlin, Germany; 3Department of Nephrology and Endocrinology, Ernst von Bergmann Klinikum, Potsdam, Potsdam, Germany; 4Institute of Lung Biology and Disease (ILBD), Comprehensive Pneumology Center (CPC), Helmholtz Zentrum, Munich, Germany.

Introduction: The Proteinase 3-Alpha1-Antitrypsin Connection in PR3-ANCA Vasculitis

Methods: We assessed PR3 and AAT in 100 AAV patients and 50 healthy controls (HC) and produced recombinant wt- and mut-AAT to study the effect on proteolytic PR3 activity, membrane PR3 (mPR3) by flow cytometry and surface plasmon resonance (SPR), and neutrophil activation.

Results: In active PR3- and MPO-AAV, plasma PR3 concentration increased approximately 5-fold and plasma AAT 1.8-fold shifting the PR3:AAT ratio significantly towards PR3. Both parameters normalized with remission. Notably, only one PR3-AAV remission patient showed strongly decreased plasma AAT. The PR3 neutrophil content was approximately 50% higher in active PR3- and MPO-AAV accompanied by increased PR3 translocation. The resulting total PR3 pool (plasma PR3 concentration + PR3 inside neutrophils) was increased by 2.5-fold in active PR3- and MPO-AAV.

Conclusions: We found a strongly increased PR3 pool in active PR3-AAV and decreased plasma AAT as the general underlying disease mechanism, as previously proposed. However, AAT controls mPR3 expression and subsequently PR3-ANCA induced neutrophil activation, suggesting adjunctive AAT administration may have beneficial effects in acute PR3-AAV.

Funding: Government Support - Non-U.S.

Serum Soluble CD206 Complements Urinary Soluble CD163 in Detecting Active ANCA-Associated Glomerulonephritis

Joop Aendrekker1, William F. Jiemy,2 Inge M. Strating,1 Gerjan J. Dekkema,2 Jan-Stephan Sanders,1 Coen A. Steegeman,1 Mark A. Little,4 Peter Heeringa,2 Pieter van Paassen,1 1Department of Nephrology and Clinical Immunology, Maastricht University Medical Center, Maastricht, The Netherlands; 2Department of Medical Biology and Pathology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; 3Department of Internal Medicine, Division of Nephrology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; 4Trinity Health Kidney Centre, Trinity Translational Medicine Institute, Dublin, Ireland, Dublin, Ireland.

Background: Early detection of active glomerulonephritis (GN) in anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV) is crucial to minimize renal damage, but accurate biomarkers are currently lacking. Urinary soluble CD163 (usCD163) has been shown as a potent biomarker for active ANCA GN. However, false negative rates can be as high as 29%. Here, we investigated whether serum soluble CD206 (ssCD206; macrophage mannose receptor), complements usCD163 in the detection of active AAV.

Methods: Three independent cohorts (C1-Maastricht University Medical Center, C2-University Medical Center Groningen & C3-Trinity College Dublin) with available serum, urine, and renal biopsy samples (C1 only) were included. usCD163/creatinine (ng/ml/mg) and ssCD206/creatinine (ng/ml/mg) were assessed by ELISA in urine and serum, respectively. The performance of usCD163 and ssCD206 to detect ANCA GN was assessed using receiver operating characteristics (ROC) curves. Biopsies from ANCA GN patients were immunohistochemically (IHC) stained for CD163 and CD206. Colocalization of CD163 and CD206 was assessed by immunofluorescence (IF).

Results: Patients C1/C2/C3 had active ANCA GN (n=42/17/47), active non-renal AAV (n=3/3/12) or were in remission (n=4/8/38). Healthy controls (HC; n=63/40) were included. usCD163 was significantly higher in active ANCA GN compared to active

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
non-renal AAV and remission in all cohorts, and healthy control urine in C1 (Kruskal-Wallis, P=0.001). ssCD206 was significantly higher in active ANCA GN compared to HCs in cohorts C1 & C2 (Kruskal-Wallis, P=0.01). ssCD163 had a specificity of 100% in all cohorts, whereas sensitivity was 71 (C1), 88% (C2) and 64% (C3). The addition of ssCD206 increased the sensitivity to detect active ANCA GN in all cohorts to 83% (C1), 100% (C2) and 81% (C3). IHC revealed CD163+ and CD206+ cells in the kidneys of active ANCA GN patients (n=8). IF showed glomerular presence of CD163+CD206- cells, whereas CD163+/CD206+ and CD163+/CD206+ cells were mainly found in the tubulointerstitium.

Conclusions: ssCD206 complements ssCD163 and reduces false negative rates in the detection of active ANCA GN. Histological assessment revealed distinct glomerular and tubulointerstitial populations of CD163+ and CD206+ cells.

POI1419
Alterations in Amino Acid and Lipid Metabolism in ANCA-Stimulated Monocytes
Emma Leacy,1 Hania Khouri,2 Gareth Brady,1 Mark A. Little,1 Trinity Translational Medicine Institute, Dublin, Ireland; 2Agilent Technologies UK Ltd, Cheadle, United Kingdom.

Background: Multiple metabolic pathways and intermediates are involved in inflammation. Altered immune cell metabolism is involved in the pathogenesis of autoimmune diseases such as anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). In particular, monocytes stimulated with ANCA show increased oxidative phosphorylation and glycolysis, with a more profound response to myeloperoxidase (MPO) ANCA than proteinase-3 (PR3). The aim of this work was to profile the metabolome of ANCA-stimulated primary monocytes.

Methods: Monocytes from healthy donors (n=24) were isolated and stimulated with mononclonal anti-MPO, anti-PR3 for 4 hours. Metabolites were extracted using an optimised extraction protocol and analysed by liquid chromatography–mass spectrometry (LC–MS). Targeted and untargeted analyses were carried out using Agilent MassHunter Profinder and Mass Profile Reporter. Cytokine production was measured by ELISA and flow cytometry was used to assess surface expression of MPO and PR3.

Results: Targeted metabolomic analysis showed increases in several amino acid and TCA cycle metabolites relative to unstimulated cells, notably phenylalanine, isomers leucine & isoleucine, and fumarate. Untargeted analysis confirmed alterations in amino acid and lipid metabolism in ANCA-stimulated monocytes (Figure 1). These metabolic differences did not correlate with the increased cytokine expression observed in anti-MPO-treated monocytes. Anti-PR3 stimulation did not induce major changes in metabolism or cytokine production. Monocytes expressed high levels of surface MPO and PR3, with MPO expression showing a significant inverse correlation with age.

Conclusions: Inflammatory and metabolic activation of primary human monocytes is greater with anti-MPO, but not anti-PR3 stimulation. Early increases in amino acid and lipid metabolism are evident in anti-MPO treated cells. Further work is needed to validate these findings and determine their physiological relevance in AAV.

POI1420
LFA-1 (CD11a/CD18) and Mac-1 (CD11b/CD18) Are Important for Mediating Myeloperoxidase-ANCA Glomerulonephritis in a Preclinical Mouse Model
Shen-Ju Gou, Peiqi Hu, Hong Xiao, Yanglin Hu, Marco A. Alba, Ronald J. Falk, J. Charles Jennette. The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Neutrophils play a critical role in the pathogenesis of necrotizing crescentic glomerulonephritis (NCGN) caused by anti-neutrophil cytoplasmic autoantibodies (ANCA). LFA-1 and Mac-1 are β2-integrins that have critical synergistic roles in neutrophil-mediated inflammation. In this study, we investigated the role of LFA-1 and Mac-1 in murine NCGN induced by mouse anti-mouse MPO, which is histopathologically indistinguishable from human ANCA NCGN.

Methods: Anti-MPO IgG was purified from sera of MPO knock out (KO) mice immunized with murine MPO. Mice with KO of LFA-1 or Mac-1, and normal wild-type C57BL/6j mice (WT B6) were injected i.v. with 50µg/g body weight anti-MPO IgG. Circulating anti-MPO IgG (MPO-ANCA) was monitored by ELISA. Proteinuria, hematuria, and leukocyturia were monitored, and mice were sacrificed at day 6 and kidney tissue obtained for pathologic examination. MPO-ANCA-induced neutrophil activation was assayed in vitro.

Results: At day 6, WT B6 (n=9), LFA-1 KO (n=8) and Mac-1 KO (n=9) mice that received anti-MPO IgG had similar levels of circulating MPO-ANCA. All WT B6 mice developed hematuria and NCGN with mean 13.9% glomeruli with crescents and 5.3% with necrosis. In contrast, LFA-1 KO mice and Mac-1 KO mice had normal urine and substantially reduced NCGN (Table). In vitro assays showed that anti-MPO IgG caused similar activation of neutrophils from LFA-1 KO, Mac-1 KO and WT mice.
Conclusions: Depletion of LFA-1 or Mac-1 blocks MPO-ANCA induced NCGN in mice, thus both of these β2-integrins are required for ANCA disease induction. Depletion of LFA-1 or Mac-1 does not block MPO-ANCA induced neutrophil activation. These observations indicate that blockade of either of these β2-integrins abrogates MPO-ANCA NGCN by inhibiting the recruitment of neutrophils that is required to induce inflammatory vascular injury in ANCA disease. These data suggest that pharmacologic blockade of β2-integrins may have a therapeutic role in ANCA disease.

Drilling into a Potential Correlation Between ANCA-Associated Vasculitis and Natural Gas Wells

Devan Makati, James L. Aker, Khaled Shawwa, Rebecca J. Schmidt, Dinesh Kannabhiran. West Virginia University Health Sciences Center, Morgantown, WV.

Background: ANCA-associated vasculitis (AAV), a systemic necrotizing disease affecting small and medium blood vessels, is caused by antineutrophil cytoplasmic autoantibodies which include anti-proteinase 3 (PR3) or myeloperoxidase (MPO). The incidences of PR3-AAV and MPO-AAV vary geographically with PR3-AAV most commonly reported in the United Kingdom and MPO-AAV the predominant type seen in Japan. Environmental exposure has been implicated in the pathophysiology of MPO-AAV. The aim of this study is to evaluate a potential relationship between AAV and environmental factors in north central West Virginia.

Methods: This is a retrospective cohort study of 212 patients diagnosed with AAV at West Virginia University and its affiliated hospitals from January 1, 1990 to December 31, 2019. Patients were mapped by zip code and prevalence of AAV assessed over time.

Results: The proportion of MPO-ANCA cases increased (37.5% before 2010 vs 71.7% after 2016 (p=0.008)) with a resultant increase in the prevalence of AAV overall after 2010 (Table). During this time, the production of natural gas through fracking increased with barreled production rising more than 5-fold after 2010. Regional heat mapping reveals that the increase in cases of AAV occurred in areas of increased fracking activity (Figure)

Conclusions: The increase in prevalence of MPO-ANCA AAV correlates temporally and geographically with escalations in fracking activity. These findings suggest that exposure to toxins from fracking could be operative in the pathophysiology of AAV and the increase in case numbers seen in north central West Virginia.
Immune Checkpoint Molecule BTLA Attenuates Inflammation and Glomerular Damage in Experimental Glomerulonephritis

Paul Diefenhardt,1,2 Marie Brand,1,3 Thomas Schömig,1,2 Bastian Trinch,1,2 Bernhard Schermer,1,2 Paul T. Brinkkoffer,1,2 Thomas Benzing,1,2 Sebastian Braehler.1,3 Uniklinik Koln, Koln, Germany; 1University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; 1Excellencecluster CECAD in der Universität zu Köln, Koln, Germany.

Background: An imbalance of pro- and anti-inflammatory signals in the kidney can result in irreversible damage and destruction of glomeruli leading to end stage kidney disease. Current treatment of the glomerulonephritis (GN) consists of unspecific, highly toxic immunosuppressive therapies with detrimental adverse effects. More specific therapies are therefore warranted. T Lymphocytes are not only key players in the nephrotic nephritis (NTN) model in rodents but also during GN in humans, representing potential targets for tailored therapies. As an immune checkpoint molecule, B and T lymphocyte attenuator (BTLA) is crucial in the regulation of T Lymphocyte activation and has been shown to mediate anti-inflammatory effects in other T cell-mediated disease models.

Methods: NTN was induced in BTLA knock out mice (BTLA-KO) and littermate controls. Regular urine analysis (ACR) was performed throughout the course of the disease. 14 days after NTN induction, blood, kidneys and spleens were harvested for further analysis. Histological assessment of the kidneys was used to evaluate the severity of NTN. Local immune response in the kidney and systemic immunity was analyzed via flow cytometry and qPCR.

Results: Wild type mice (WT) showed an increased BTLA expression on renal T cells and dendritic cells throughout the course of NTN. No immune-phenotype was observed in unstimulated BTLA-KO and WT mice. However, BTLA-KO resulted in aggravation of NTN compared to WT. Quantification and characterization of renal immune cells revealed an increase in proinflammatory cells. Interestingly, especially T Lymphocytes were significantly expanded in BTLA-KO mice.

Conclusions: BTLA attenuates inflammation in experimental GN through suppression of proinflammatory T Lymphocytes. These results build the foundation of a checkpoint inhibitor based therapy of inflammatory glomerular disease.

Collapsing FSGS or Crescentic GN or Both: A Diagnostic Challenge

Mahfuz Irshadjahan

Introduction: The finding of an ANCA associated necrotizing & crescentic GN with collapsing FSGS is a rarity with only few reported cases in literature.1,2

Case Description: A 53-yr-old AA female was admitted to hospital with difficulty in swallowing, poor oral intake, hemoptysis & AKI superimposed on CKD-III with hx of HTN & use of NSAIDs. Urine analysis showed hematuria, proteinuria & UPC ratio of 4.15. Blood analysis showed Hct 8.7mg/dl, BUN 60mg/dl, Albumin 2.4mg/dl, positive MPO ANCA & ANA titers. By light microscopy 36 glomeruli were present, 20% showed arterionephrosclerosis (ischemia) are the most likely etiologies for the collapsing FSGS.

POI426

CD11b Activation Suppresses Pro-Inflammatory IL-1β in Myeloid Cells and Protects Against Lupus Nephritis

Veronica Villanueva, Xiaobo Li, Viviana Jimenez, Vincent Gupta. Rush University Graduate College, Chicago, IL.

Background: Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Mutations in the ITGAM gene, encoding CD11b, are associated with LN and reduce integrin function. Interleukin-1β (IL-1β) is produced by myeloid cells as a propoerin and cleaved by caspase-1 where it mediates the inflammatory response. IL-1β is downstream of toll-like receptor and IL-1β receptor signaling. We previously showed that activation of CD11b suppresses TLR-dependent pro-inflammatory signaling. Here, we investigate if this mechanism includes control of IL-1β and/or if CD11b influences IL-1β by another mechanism, which may provide novel therapeutic options for proinflammatory diseases.

Methods: To investigate TLR-dependent signaling affected by CD11b activation, we utilized in vitro assays using primary macrophages. Cells were treated with TLR agonists, IL-1β protein, or IL-1β antibody and changes in protein expression was assessed by western blot and proinflammatory cytokine levels were assessed by ELISA.

For complementary in vivo studies, we utilized our newly generated mouse model, where we incorporated a constitutively active CD11b point mutation (I32G) globally in mice to generate a model for CD11b activation – CD11b knock-in model. CD3βL-β wild type mice, CD11b knock-out, and CD11b knock-in mice were used to determine the effect of CD11b activation on circulating IL-1β levels.

Results: TLR-stimulation increased IL-1β levels in vitro and in vivo. Importantly, CD11b activation resulted in significantly reduced IL-1β levels in both systems, suggesting a novel mechanism for controlling inflammation in glomerular diseases. Additional mechanistic studies are on-going to define the exact molecular mechanism of action. Murine models of SLE and LN display significant decreases in IL-1β when CD11b is activated, both genetically or pharmacologically, showing potential protection against LN.

Conclusions: Using these models, we have identified a possible link between CD11b activation and IL-1β secretion in myeloid cells. These studies will provide understanding of the influence CD11b has on signaling pathways and inflammation associated with inflammatory diseases such as LN.

Deletion of Smad3 Worsens Lupus Nephritis by Promoting B Cell Activation

Wenqian Xu,1,2 Jinhong Li,1 Xiaoyi Hu,3 Cheuk-Chun Szeto,2 Tak Mao D. Chan,1 Xuejing Yu,1 Zhihua Zheng,1 Hui Y. Lan,3 1Department of Nephrology, Center of Urology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2Department of Medicine & Therapeutics, Li Ka Shing Institute of Health Sciences, and Lui Che Woo Institute of Innovative Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; 3Department of Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; 4Guangdong-Hong Kong Joint Laboratory for Immunity and Genetics of Chronic Kidney Disease, Guangdong Academy of Medical Science, Guangdong Provincial People’s Hospital, Guangzhou, China; 5The Chinese University of Hong Kong-Guangdong Academy of Sciences/Guangdong Provincial People’s Hospital Joint Research Laboratory on Immunological and Genetic Kidney Diseases, The Chinese University of Hong Kong, Hong Kong, China.

Background: TGF-β signaling has been shown to play a critical role in many autoimmune diseases. However, its regulatory role in lupus nephritis remains unknown, which was investigated in the present study in a mouse model of lupus nephritis (LN) in which Smad3 gene was deficient.
**Methods:** To investigate the role of Smad3 in LN, we generated Smad3 knockout (KO) lupus mice by cross-breeding Smad3KO mice with B6.NZMSle1-3 lupus mice (C57BL/6J background) mouse. We then determined the regulatory role of Smad3 in the pathogenesis of LN and investigated the regulatory mechanisms of Smad3 in T cell and B cell activation and autoantibody production in Smad3 KO LN and Smad3 WT LN mice and B cells in vivo and in vitro.

**Results:** We successfully deleted the Smad3 gene from B6. NZMSle1-3 mice with unexpected findings that Smad3KO-LN mice developed much more severe LN with higher mortality rate (50%), higher circulating anti-dsDNA (60%), higher levels of serum creatinine (Cr), lower creatinine clearance rate (Ccr, 20%), more severe glomerular necrosis (50%), massive renal immune complex deposition and complement activation, and progressive renal inflammation and functional injury. Mechanistically, we observed that lupus mice lacking Smad3 largely promoted Th1, Th2 and Th17 populations which were directly associated with immune responses in the kidney. Unexpectedly, deletion of Smad3 largely increased macrophage inducible lectin-receptor (Mlec) expression by B220+ B cells (80%). Further studies showed that B cells lacking Smad3 were largely promoted Cytosine-phosphorothioate-guanine oligodeoxynucleotides (CpG ODN)-induced but failed to respond to the inhibitory effect of TGF-β1. Smad3KO-LN mice developed much more severe LN with higher mortality rate (50%), higher circulating anti-dsDNA (60%), higher levels of serum creatinine (Cr), lower creatinine clearance rate (Ccr, 20%) and more severe glomerular necrosis (50%) compared to WT LN mice.

In Conclusion: TGF-β1/Smad3 signaling plays a protective role in LN by maintaining the balance of T cell immunity and B cell function. Loss of Smad3 worsens LN by shifting Treg to Th1, Th2 and Th17 and promoting B cell activation and autoantibody production via the Mlec-Syk-NFκB-dependent mechanism. Thus, outcomes from this study will be of great significance both scientifically and clinically.

**Intrarenal B Cells in Systemic Lupus Erythematosus Upregulate Na+K+-ATPase to Facilitate Survival in a High-Sodium Environment**

Irene Chernova, Joseph Craft. Yale University, New Haven, CT.

**Background:** The kidney is a unique microenvironment characterized by high sodium concentrations, yet susceptible to infiltration by lymphocytes in autoimmune diseases, such as systemic lupus erythematosus. The effects of sodium-immune cell interactions on tissue injury in autoimmune disease and the mechanisms used by infiltrating lymphocytes to survive the high sodium environment of the kidney are not known.

**Methods:** We investigated the mechanisms utilized by B cells from lupus-prone mice to survive in a high Na+ environment in vitro and in vivo. We also utilized biopsies from lupus nephritis patients to confirm our key findings.

**Results:** Here we show that numbers of kidney infiltrating B cells in murine lupus are significantly decreased when exposed to elevated sodium concentrations [Na+] in vitro and that the expression of sodium potassium ATPase (Na+-K+-ATPase) correlates with the ability of infiltrating B cells to handle sodium stress. Pharmacological inhibition of Na+-K+-ATPase and a genetic knockout of the Na+-K+-ATPase gamma subunit, newly shown by us to be expressed in B cells, resulted in decreased kidney B cell infiltration and amelioration of proteinuria. Na+-K+-ATPase gamma subunit expression was also observed in renal B cells in human lupus nephritis.

**Conclusions:** These studies reveal that kidney-infiltrating B cells in lupus adapt to environmentally regulated sodium stress and identify Na+-K+-ATPase as a novel organ-specific therapeutic target in lupus nephritis.

**Environmental Factors Influence Site and Magnitude of Myeloperoxidase-dNA Autoimmunity in BXSB Murine Lupus**

Lanette Fee, Robert M. Tighe, Mary H. Foster. Duke University, Durham, NC, *DVAMC, Durham, NC.*

**Background:** SLE is a systemic autoimmune disease with devastating clinical manifestations and complex origins linked to gene-environment interactions. To better understand the role of environmental factors, we exposed lupus-prone female mice to crystalline silica (Si) or vehicle (V) by oropharyngeal aspiration (OPA), mimicking an inhalational exposure compellingly linked to human autoimmunity. Si but not V exposure compelled an autoimmune glomerulonephritis, uniquely demonstrated elevated anti-myeloperoxidase (anti-MPO) and anti-DNA Ig, are recruited to the lungs, where they can be activated by co-exposure to exogenous or endogenous TLR-L.

**Anti-SOD2 Antibodies in Lupus Nephritis as Second Wave Antibodies**

Andrea Angeletti, Maurizio Bruschi, Francesca Lugani, Gianluca Caridi, Enrico E. Verrina, Gian Marco Ghiglieri. ZEUS Study Istituto Giannina Gaslini, Genova, Italy.

**Background:** Superoxide dismutase-2 (SOD2) is an enzyme with antioxidant action. Anti-SOD2 antibodies (anti-SOD2 IgG2) were recently described in the serum of subjects with Membranous Nephropathy, as antigens of a possible second wave injury. The presence of anti-SOD2 IgG2 correlated with worse outcomes in terms of response to treatment [1]. The presence and role of anti-SOD2 IgG2 in Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN), a secondary autoimmune glomerulonephritis, are to be clarified.

**Methods:** We measured serum levels of anti-SOD2 IgG2 (Homemade designed ELISA), every six months, in 1,052 patients (459 LN and 573 SLE) enrolled at different times from the diagnosis (i.e., 0-1 month, 2-12 m, 13-24 m, 25-48 m, 49-96 m, and >96 m).

We also evaluated the main markers of the SLE activity, such as serum complement C3 and C4, ANA, ENA, anti-dsDNA and proteinuria. Of note, 91 LN and 130 SLE had a relevant follow-up of 36 months.

**Results:** As main characteristics, we report median age of 40 (IQR 28-54) years, the predominance of females (88%), disease activity (SLEDAI) of 4 (IQR 2-8). At the cross-sectional analysis, serum levels of anti-SOD2 IgG2 at T0 are significantly higher in LN than in SLE (Fig 1a). Considering LN, the serum levels of anti-SOD2 IgG2 at T0 were significantly higher than the other time points (Fig 1a).

**Conclusions:** Circulating anti-SOD2 IgG2 are elevated in active LN. Serum levels of Anti-SOD2 IgG2, also considering the concomitant negative serum levels of anti-dsDNAs in all phases of LN, support the hypothesis of direct involvement of anti-SOD2 antibodies in LN as second wave antibodies that actively contribute to the manifestations of autoimmune glomerulonephritides.

---

**Results:** Si but not V exposed BXSB mice developed chronic lung injury (scores 5.0±4.1 vs. 0.1±0.4) and lung TLS (counts 36±19 vs 6±10), n=13/group, p<0.0001. Levels of anti-DNA and anti-MPO IgM and IgG in BALF and anti-DNA IgG in serum were elevated in Si vs V exposed mice (p<0.05, for each). Spleenocytes produced little anti-MPO or anti-DNA Ig when cultured with medium and abundant anti-MPO IgM and anti-DNA IgG when cultured with TLR-L stimulation, regardless of Si vs V exposure (p=N.S; n=13/group).

Anti-DNA IgG levels were higher from stimulated splenocytes of Si-exposed mice (OD 0.08±0.05 Si vs 0.03±0.01 V, TLR4-L, p<0.0009). Lung cells from Si but not V exposed mice produced abundant autoAb after TLR-L stimulation (OD 1.23±1.100 Si vs 0.025±0.043 V, anti-MPO IgM; OD 0.012±0.010 Si vs 0.001±0.001 V, anti-DNA IgG, TLR7/9-L, p<0.05).

**Conclusions:** Inhaling Si exposure enhances local and systemic autoimmunity in lupus-prone BXSB mice. Autoreactive B cells with diverse disease-relevant specificities, including anti-MPO and anti-DNA Ig, are recruited to the lungs, where they can be activated by co-exposure to exogenous or endogenous TLR-L.

Altered Proaponeurotic Metabolism and gut Lachnospiraceae Composition in Lupus Nephritis Patients

Ji Eun Kim,1 Ji In Park,2 Hye Eun Kim,3 Jungwook Lee,4 Hyunjeong Cho,6 Dong Ki Kim,5,7 Yon Su Kim,5,7 Hajeong Lee,5,7 Korea University Guro Hospital, Seoul, Republic of Korea; 1Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; 2Seoul National University Hospital Department of Internal Medicine, Gwangju, Seoul, Republic of Korea; 5Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; 3Seoul National University, Gwanak-gu, Seoul, Republic of Korea; 4Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea.

Background: There are growing evidence for the role of gut microbiota in the pathogenesis systemic lupus erythematosus (SLE), especially lupus nephritis (LN). Recently, high abundance of Ruminococcus gravisus belonging to the family Lachnospiraceae has been noticed in fecal sample of LN patients. However, the functional role of gut microbiota and its metabolic pathway which affect host metabolism in LN are less understood.

Methods: Shotgun sequencing of fecal samples from biopsy-proven LN patients and matched controls was performed. We used Kraken2 for taxonomic analysis and humann2 with customized KEGG database for gene family analysis. Comparison of taxonomic abundance and gene families were assessed by Maaslin2.

Results: Control and LN group were included 24 and 20 patients, respectively. Both groups had similar age, sex, and eGFR. In the comparison of relative abundance of major species, Roseburia intestinalis, Butyrivibrio fagi, and Eubacterium eligs were significantly decreased while Ruminococcus gravisus was significantly elevated in LN group, respectively. Interestingly, 3 of these 4 species were included in the same Lachnospiraceae family showing a significantly different composition between the two groups (PERMANOVA p=0.042). Furthermore, we found 161 differentially expressed gene families including 65 metabolism-associated and 29 carbohydrate metabolism-associated genes. Considering Lachnospiraceae is known to play a role in proaponeurotic (esters of propionate) formation, we further assessed the proaponeurotic pathway (ko00064).

As a result, LN patients revealed more prone to proaponeurotic pathway rather than in succinate pathway in the proaponeurotic pathway. This tendency was more pronounce in the contribution to the p-value: gene by R. gravisus having well-known pathogenetic linkage with SLE.

Conclusions: LN patients showed altered proaponeurotic metabolism associated with the differential species composition of Lachnospiraceae including R. gravisus. Functional role of this alteration on the pathogenesis of LN should be clarified by further investigations.

PO1432

Gut Microbiome Changes in NZBWFI/J Murine Lupus Nephritis

Tak Mao D. Chan, Jing Yu, Chi pang Tai, Susan Yung. Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong.

Background: Lupus nephritis is an important cause of acute kidney injury and chronic kidney disease. There is preliminary data that gut dysbiosis may be involved in the pathogenesis of lupus nephritis. We investigated gut microbiota burden in murine lupus nephritis.

Methods: Eight-week old NZBWFI/J mice were randomized to receive drinking water alone or containing ampicillin (1.0 mg/ml) and neomycin (0.5 mg/ml) for 18 weeks. Mice with active nephritis showed increased gut permeability to LPS-FITC given orally, and decreased ZO-1 expression in the colonic epithelium. 16S rRNA sequencing data was compared with LN mice with dominant/co-dominant IgA (IgG-IgA-LN; pink) with overlapping features with LN (grey) and/or IgAN (blue).

Results: KM55 staining intensity >0.5 (trace) on a scale of 0-4 discriminates IgAN/IgAV from LN with a sensitivity of 1.00 [0.86-1.00] and specificity of 1.00 [0.82-1.00] (p<0.0001) (Fig 1). KM55 staining with mean 2+ intensity was detected in all SLE patients with LN and no features of LN. IgAN had no difference in KM55 intensity or distribution in non-SLE vs SLE patients. Mesangial KM55 staining was detected in cases with dual LN class V and IgAN. Of 19 IgG-IgA-LN biopsies, 9 (47%) showed positive KM55 staining in the same distribution as IgA.

Conclusions: Our results demonstrate that IF staining of KM55 is valuable in distinguishing IgAN from LN. In SLE patients, negative KM55 staining argues against the presence of IgAN while >0.5 (trace) KM55 staining with dominant/co-dominant IgA staining is suggestive of IgAN as the sole lesion or a co-occurring component of dual glomerulonephritis.

The Significance of Glomerular Galactose-Deficient IgA1 in Patients with Systemic Lupus Erythematosus (SLE)

Lihong Bu,1 Bayardo I. Garay,1 Youngki Kim,1 Fm Lai,2 Xin J. Zhou,2 Patrick H. Nachman,1 Cynthia C. Nast,2 1University of Minnesota Medical School Twin Cities, Minneapolis, MN; 2Cedars-Sinai Medical Center, Los Angeles, CA; 3Pathologists Bio-Medical Laboratories, Dallas, TX; 4The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, China.

Background: Approximately 0.3% of end stage kidney disease in SLE patients is due to non-lupus nephritis. IgA nephropathy (IgAN) is rarely reported in SLE patients. As galactose-deficient IgA1 (Gd-IgA1) plays a key role in the pathogenesis of IgAN but not SLE, the aim was to investigate whether KM55, a Gd-IgA1 specific monoclonal antibody, might identify IgAN in patients with SLE.

Methods: Immunofluorescence (IF) staining of KM55 was performed on 77 native kidney biopsies from 25 non-SLE (IgAN or IgA vasculitis (IgAV)) and 52 SLE patients, the latter including lupus nephritis (LN) with IgG dominant full house staining (LN; n=20), IgAN without features of LN (IgAN; n=11), concurrent LN class V and IgAN (n=2), and LN with dominant/co-dominant IgA (IgG/IgA-LN; n=19). In SLE patients, principal component analysis was carried out on LN, IgAN, and IgG-IgA-LN cases.

Results: KM55 staining intensity >0.5 (trace) on a scale of 0-4 discriminates IgAN/IgAV from LN with a sensitivity of 1.00 [0.86-1.00] and specificity of 1.00 [0.82-1.00] (p<0.0001) (Fig 1). KM55 staining with mean 2+ intensity was detected in all SLE patients with LN and no features of LN. IgAN had no difference in KM55 intensity or distribution in non-SLE vs SLE patients. Mesangial KM55 staining was detected in cases with dual LN class V and IgAN. Of 19 IgG-IgA-LN biopsies, 9 (47%) showed positive KM55 staining in the same distribution as IgA.

Conclusions: Our results demonstrate that IF staining of KM55 is valuable in distinguishing IgAN from LN. In SLE patients, negative KM55 staining argues against the presence of IgAN while >0.5 (trace) KM55 staining with dominant/co-dominant IgA staining is suggestive of IgAN as the sole lesion or a co-occurring component of dual glomerulonephritis.

Tertiary Lymphoid Tissue Development Is Associated with Impaired Renal Function in Lupus Nephritis

Yuki Sato,2,3 Makiko Kondo,2 Shingo Fukuma,2 Naoya Torii,2 Yoshifumi Ubara,2 Motoko Yanagita,2,3 Medical Innovation Center T VKP, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 3Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 4Department of Nephrology, Toranomon Hospital, Tokyo, Japan; 5Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University, Kyoto, Japan.

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE) and the pathophysiology is heterogeneous. Recently, the careful assessment of not only glomerular but tubulointerstitial lesions has been recognized for more precise evaluation of the disease activity, which leads to better management. Tertiary lymphoid tissues (TLTs) are inducible ectopic lymphoid tissues proposed for more precise evaluation of the disease activity, which leads to better management.

Methods: We examined the presence of TLTs in 205 kidney biopsy samples of patients with LN and investigated the clinical characteristics of patients with renal TLTs. TLTs were defined as organized T and B cell aggregates with sign of proliferation. Histological activity and damage at biopsy were calculated as the National Institute of Health (NIH) activity and chronicity indices (CI).

Conclusions: Murine lupus nephritis is associated with gut dysbiosis, which may contribute to the pathogenesis of nephritis progression. Funding: Government Support - Non-U.S.
Glomerular Diseases: Immunology and Inflammation in Vasculitis and Lupus Nephritis

PO1435

New Drugs and Evolving Treatment Patterns in Lupus Nephritis: How Nephrologists and Rheumatologists Are Responding Differently to New Treatment Options

Background: Existing uptake and experience with recently approved lupus nephritis (LN) drugs belimumab and voclosporin reveal different perceptions, comfort levels, and prescribing intentions between nephrologists and rheumatologists.

Methods: Data were collected over four waves of research between February and May 2021 via online surveys with 50 US nephrologists and 50 US rheumatologists who are actively treating LN patients followed-up with a subset of qualitative interviews.

Results: In a notable trend, rheumatologists deem more of their LN patients as candidates for belimumab, while nephrologists increasingly see their patients as better suited for voclosporin. Rheumatologists tend to rate belimumab higher overall than voclosporin particularly on safety and tolerability, thanks to long term history with the product in SLE patients. Both physician types generally use belimumab as a later-line therapy in mild-to-moderate LN, often to reduce steroid burden. It is generally used with at least one other advanced agent like an antimalarial, steroid, or MMF. Rheumatologists are more likely to use belimumab in moderate-to-severe LN patients given the drug’s perceived quicker onset of action, efficacy, and steroid-sparing effect. Voclosporin is nearly always used concomitantly with advanced drugs like antimalarials, steroids, or MMFs. Rheumatologists appear to be initiating voclosporin most often in CKD Stage 2, while nephrologists are initiating most often in CKD Stage 3. Rheumatologists are the leading prescribers of belimumab, and currently have a slight edge with voclosporin patient initiations as well. Nephrologists are tending to wait longer to initiate, due to cost- and risk-benefit uncertainty compared to other options like tacrolimus. Rheumatologists currently view both drugs as a greater treatment advance than nephrologists; nephrologists believe voclosporin is more of an advance in LN treatment than belimumab.

Conclusions: Physician understanding and comfort level with belimumab and voclosporin MOAs are driving early use and perceptions of the two new LN drugs.

PO1436

Treatment of Crescentic Lupus Nephritis with Voclosporin

Irshad Hussain,1 Syed H. Bukhari,1 Paul F. Shanley,2 Ramya Bhargava,1 1State University of New York Upstate Medical University Division of Nephrology, Syracuse, NY; 2State University of New York Upstate Medical University Department of Pathology, Syracuse, NY.

Introduction: Crescent glomerulonephritis (CGN) is a rare complication of Lupus nephritis (LN) and carries a worse prognosis. There is paucity of data regarding effective treatment options for CGN. We present a case of crescentic ANCA negative LN treated with voclosporin (VSN).

Case Description: 19-year-old African American female with 2-year history of Class II LN, treated with hydroxychloroquine 200 mg/day, prednisone 10 mg/day, mycophenolate mofetil 1 gm twice daily and Belimumab, presented with a 2-week history of anasarca and generalized bullous skin rash. On exam BP 126/78 mm Hg, HR 96/min, afebrile, RR 18/min, O2 saturation 97% on room air. Investigations revealed hemoglobin 9.2 g/dl, serum creatinine (SCR) 1.2 mg/dl (baseline 0.6), albumin 1.9 g/dl, hypocomplementemia, microscopic hematuria and proteinuria of 4.3 g. A kidney biopsy showed diffuse crescentic immune complex LN and membranous LN (Figure 1). The patient received IV methylprednisolone 1gm for 3 days, however, became anuric. SCR peaked at 3.5 mg/dl and was commenced on hemodialysis and 7 sessions of plasma exchange. She was started on VSN 15.8 mg BID and after 10 days of therapy, SCR improved and dialysis was discontinued. On discharge, SCR was 2.0 mg/dl and proteinuria 0.9 gm. C4 normalized and C3 improved.

Discussion: There has not been any published case report of Crescentic LN being treated successfully with VSN. Given poor prognostic of CGN, early diagnosis and treatment is imperative. Our patient had rapid recovery of renal function and resolution of proteinuria following treatment with VSN. VSN may be effective in combination with plasma exchange in ANCA negative Crescentic LN. Larger studies with longer follow up are needed to assess the efficacy of VSN in CGN.

Figure. Longitudinal HRU and costs among patients with a5 years of follow-up (N=335)

PO1437

Christopher F. Bell1, Benjamin Chastek2, Bernie Rubin,1 Shirley Huang,1 US Value, Evidence and Outcomes, GlaxoSmithKline, Research Triangle Park, NC; 2Optum, Eden Prairie, MN; 1GlaxoSmithKline, Philadelphia, PA.

Background: Lupus nephritis (LN) occurs in ~40% of adults with SLE. Despite the high burden of LN, current care management and utilization data are limited. This retrospective cohort study (GSK Study 214012) used data from the Optum Research Database. Index date was the first claim with a renal diagnosis code indicating LN during the identification period (Aug 1, 2011–Jul 31, 2018). Inclusion criteria: age ≥18 years; ≥2 renal diagnosis codes during the identification period; ≥1 outpatient or ≥2 outpatient SLE diagnosis codes in the 12 months pre index; and continuous enrollment of ≥2 months pre and post index. HRU and costs for the cohort with 5 years of continuous enrollment post index are reported.

Results: Overall, 2159 pts met the study criteria (mean [standard deviation, SD] age, 58.5 [14.9] years; 86.7% female) and 335 had ≥5 years of continuous enrollment post index. HRU and costs were highest in the first year post LN diagnosis (Figure). Mean healthcare costs were $44,205 in Year 1 and ~$30,000/year in Years 2 through 5. Approximately 50% of patients incurred an inpatient stay in Year 1, with ~25% of patients hospitalized in each subsequent year.

Conclusions: Patients with newly diagnosed LN incur substantial HRU and costs, which were highest in the year of diagnosis. These data highlight the need for interventions to prevent renal worsening in SLE.

Association of TNIP1 Variants with Disease Severity and Progression and IP-10 Chemokine Levels in Lupus Nephritis Patients

David W. Powell,1,2 Makayla Brady,1 Michelle T. Baratti,1 Dawn J.caster,1 University of Louisville School of Medicine, Division of Nephrology, Louisville, KY; 2Department of Biochemistry and Molecular Genetics, University of Louisville, Louisville, KY.

Background: African American SLE patients experience higher rates of LN, increased progression to ESKD, and higher mortality when compared with white patients, but etiology for this disparity is unclear. We reported that a TNIP1 polymorphism, rs4958881, is a risk variant for lupus nephritis (LN) in African American patients. TNIP1 encodes the protein ABIN1, which negatively regulates the transcription factor NF-κB. We generated mice with an Abin1 knockout (Abin1−/−) and C3aR−/− mice showed no glomerular basement membrane remodeling. D. Trichrome stain with moderate interstitial fibrosis and tubular atrophy (35%).

Increased tissue levels of IP-10 have been implicated in pathogenesis and as a diagnostic marker in LN, but the mechanism is unknown. The current project tested a hypothesis that LN severity and enhanced IP-10 levels are associated with the TNPI1 rs4958881 risk allele.

Methods: All endpoints were compared for LN patients w/wo TNPI1 variant rs4958881. Genotype classifications were compared for 125 African American and 133 White American LN patients. Urine and serum IP-10 levels were measured in 33 LN patients using ELISA. Progression of disease was assessed and compared from follow up (mean = 3 yrs) for 33 LN patients. Urine, plasma, and kidney levels of IP-10 were compared for AT1501 (KLH) challenge.

Results: A higher percent of African Americans with Class IV LN had the TNPI1 variant (68%) vs 42% for Whites with Class IV and 93% of African American with Class V LN had the variant versus 38% for Whites with Class V. 26.3% of patients with the variant reached the endpoint of doubling of creatinine or ESKD. Proteinuria at follow up was higher in (2800 mg/g) vs. non-variant (1175 mg/g) patients, suggesting refractory disease in variant patients. There were significantly higher levels of IP-10 in serum and urine from African American versus White LN patients and a trend for association in patients with the variant. Urine and plasma kidney levels of IP-10 were significantly enhanced in ABIN1/D45N versus wildtype mice.

Conclusions: Our findings suggest that TNPI1 variant genotyping and IP-10 measurement could provide precision diagnostics for African American LN patients and that inhibition of NF-κB or neutralization of IP-10 is a promising personalized therapeutic direction for these patients.

Inflammatory Dendritic Cell and Th17 Polarization in Mouse Model of Lupus Nephritis
Latha Prabha Ganesh1, Noushin Salajoughian1, James M. Turman1, Muratun Bin Rajjai1, and Samir V. Patel2,1,3
1Department of Pathology and Laboratory Medicine, 2Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH

Background: We have recently identified inflammatory dendritic cells (iDC) in human lupus kidneys. These cells are over expressed in LN patients compared to healthy controls. Knowledge on how the iDC interact with intra-renal T cells and their role in pathogenesis of LN kidney is crucially needed.

Methods: We examined iDC and T cells in the kidneys of NZM 2410 (NZM), from protein-primed NZM mice (protein-p 300mg/dl) and pre-proteinuric NZM (pre-protein-p NZM) mice by Immunofluorescence (IF). To quantitatively assess iDC and various T cells, we analyzed single cell suspensions obtained by enzymatic digestion followed by gentle MACS dissociation from prot-NZM kidneys and pre-protein-p kidneys by multi-color flow cytometry using specific markers for iDC, CD4+CD45R+ B cells, CD11b, CD11c, CD163, CD11b+, Ly6C+. Interestingly, 2 subtypes of iDCs were identified in NZM mice. FcγR1+/MHCII+CD11b+ and FcγR1+/MHCII-C11b+ and FcγR1-/MHCII+C11b+ and FcγR1-/MHCII-C11b- and differentiated by their presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotypes shows that Th17 expression, but not Th1 expression was significantly upregulated in prot-NZM compared to pre-protein-p NZM in parallel to iDC.

Results: The immunofluorescence studies recapitulated the human LN robust infiltration of the iDC marked by FcγRI in the periglomerular and tubulointerstitium in prot-NZM compared to pre-protein-p NZM. The iDC were also identified to be in close proximity to CD3+ T cells constant with an immunosuppressive analogue. Further characterization by IF revealed iDC in mice LN were FcγRI+, MHCII+, CD163+, CD11b+, Ly6C+. Interestingly, 2 subtypes of iDC were identified in NZM mice, FcγR1+/MHCII+CD11b+ and FcγR1-/MHCII-C11b- and differentiated by the presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotypes shows that Th17 expression, but not Th1 expression was significantly upregulated in prot-NZM compared to pre-protein-p NZM in parallel to iDC.

Conclusions: Similar to human LN, iDC are abundant in prot-NZM LN kidneys compared to pre-protein-p kidneys, and they are clearly seen in the renal interstitium. The presence of CD3+ T cells in LN kidneys; and 3) Th17 cells, but not Th1 cells, correlate with iDC’s expression in LN kidneys. These data suggest that iDC regulate the intra-renal Th17 cell response in LN and contribute to IL-17 mediated kidney injury. Ongoing studies will examine if these iDC are necessary or sufficient for LN pathogenesis.

SeqStain Is a Novel, Multiplex Imaging Method for Spatialomic Profiling of Human Kidney Tissues
Ishwarya Venkatesh, Anugraha R. Rajagopalan, Disha Varma, Vineet Gupta
Team SeqStain Rush University Medical Center, Chicago, IL.

Background: Chronic Kidney Disease (CKD) is the ninth leading cause of death in the United States, an emerging global health challenge affecting 10-15% of the population. Lack of reliable biomarkers precludes early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue changes. For instance in Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli, reduced podocyte number, inflammation in the renal tissue, influx of immune cells that ultimately lead to tissue damage. Understanding these tissue-centered events on a deeper level is important for effective intervention.

Methods: To understand molecular and cellular composition of tissues and their relative organization in three-dimensional space, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses fluorescently labeled DNA oligonucleotides (termed “SeqStain antibodies”) to stain while endolysosomes are used to achieve gentle de-staining after each round. This methodology can fluorescently label primary antibodies, secondary antibodies and Fabs of secondary antibodies to efficiently analyze multiple tissues. We use SeqStain multiplexed with antibodies that would probe different histological regions relevant to the kidney

Results: Normal kidney was stained with SeqStain antibodies and de-stained using endolysosomes. Using SeqStain methodology, we built 20x20-plex panel on kidney tissue and provided a gentle and rapid technique for multiplex imaging. Strikingly, de-staining using the SeqStain method was rapid and removed ~99% of the signal in <1min without affecting tissue integrity. The method was implemented using a simple perfusion setup with readily available components, allowing staining of tens of antigens on a single tissue section. Alignment of images and their analyses provided spatialomic data on multiple cell types in tissue

Conclusions: The SeqStain method offers a gentle, easy-to-use, and effective multiplex imaging technique that provides a unique platform for obtaining spatialomic insights. SeqStain method can profile the CKD kidney tissues and communicate the tissue-centered events that could play a role in disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments in comparison to healthy kidney to generate spatial maps

A Phase 1 Study to Evaluate the Safety, Tolerability, and Pharmacokinetics of AT1501
Steven Perrin, Eledon Pharmaceuticals, Irvine, CA.

Background: CD40L is a costimulatory receptor for CD40 found on T helper cells. Binding of CD40L on T cells to CD40 on antigen presenting cells induces downstream immune and inflammatory responses. Inhibition of CD40L signaling can abolish inflammatory responses and prevent the progression of disease, including transplant tolerance. AT-1501 is a humanized anti-CD40L antibody lacking Fc effector function and high affinity binding to CD40L. Purpose: Execute a phase 1 study of AT-1501 to assess safety, pharmacokinetics, and functional activity.

Methods: The study employed a placebo-controlled, sequential, dose-escalation design. 28 healthy subjects and 4 adults with ALS were enrolled. Five sequential ascending doses of AT1501 (0.5, 1, 2, 4, or 8 mg/kg) or placebo were administered by IV infusion. The primary endpoint was the safety and tolerability of AT1501. The secondary endpoint was to determine plasma pharmacokinetics (PK) and anti-drug antibody (ADA) responses to AT1501. An exploratory endpoint was to examine the ability of AT1501 to block an immune challenge in subjects who received a Keyhole Limpet Hemocyanin (KLH) challenge.

Results: Dose proportionality was achieved over the AT-1501 dose range of 0.5 to 8 mg/kg for Cmax and AUC0–∞. The mean AT-1501 t1/2 in healthy volunteers was 16 to 28 days. AT1501 had a safety profile comparable to placebo and was well tolerated in healthy subjects and subjects with ALS. 54% of subjects treated with AT1501 had at least 1 TEAE; 22% of subjects treated with placebo had at least 1 TEAE. The most commonly reported TEAEs overall were headache, somnolence, and upper respiratory tract infection. There were no meaningful laboratory abnormalities, vital sign assessments, ECG assessments, or physical examination findings. Positive ADA responses to AT-1501 were observed in 6 of 30 subjects in the study. There was no dose dependence with respect to the incidence of positive ADA titers. ADA did not appear to affect AT-1501 plasma PK profiles or parameters suggesting they were not neutralizing. 8 mg/kg AT1501 successfully blocked an immune response to KLH challenge in 2 of the 3 subjects tested.

Conclusions: Our results support further clinical development of AT-1501 for transplantation and autoimmune indications.

PO1442
High Expression of Mincle in Intermediate Monocytes of Patients with Autoimmune Diseases
Shuping Li,1 Lokyu Cheng,1 Tianjiao Cui,1 Lanuye Zhang,1,2 Xiuxun Tian,1 Zhihuang J. Zhao,2 Yen Chen,1 Zhihua Zheng,1 The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China; 2Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Mincle is a transmembrane C-type lectin receptor that is predominantly expressed on macrophages’ surface and regulates innate and adaptive immune and inflammatory responses. Inhibition of CD40L signaling can abolish inflammatory responses and prevent the progression of disease, including transplant tolerance. Thus, playing a pivotal role in tailoring immune response. Mincle’s function associates with its expression levels on immune cells’ surfaces. However, the differential expression of Mincle in various types of immune cells between patients with autoimmune disease and healthy controls (NCs) is yet to be examined, and its clinical relevance remains unclear. Therefore, this study aimed to investigate Mincle expression and distribution in different types of immune cells in patients with AD and NCs, and to explore the clinical relevance and potential mechanisms of Mincle expression levels in immune cells of peripheral blood in patients with systemic lupus erythematosus (SLE).

Methods: Mincle expression levels in leukocyte subtypes and monocyte subsets of peripheral blood from all participants were analyzed using flow cytometry and real time PCR, and the clinical characteristics of patients with SLE were collected for correlation analysis. The intermediate monocytes (IMs) from patients with SLE, healthy NCs, and patients with AD were isolated and stained using specific markers for IMs (CD14+CD11c−), CD16+ T cells, and the differentiations of naïve T cells were detected by flow cytometry.

Results: Mincle was expressed predominantly in myeloid cells, both in peripheral blood and cell lines. Moreover, monocytes expressed higher levels of Mincle than granulocytes in both patients with AD and NCs, and Mincle expression levels were higher in IMs of patients with AD, including patients with SLE, than in those of NCs;
PO1443
Development of Kidney Resident and Recruited Macrophages

Background: Macrophages are part of the phagocyte mononuclear system constantly replaced by the circulating blood monocytes. In the steady state, the myeloid cell compartment is highly heterogeneous, containing various subpopulations. These cells include macrophages and dendritic cells, and each play important roles in tissue maintenance, including development, homeostasis, immunity and repair following tissue injury. The composition of kidney macrophages is not well known.

Methods: A multi-parametric flow cytometry approach was used to identify the resident and recruited macrophage population in the kidneys of male and female C57BL/6J mice aged -7, -21 and -84 days in the steady state. Resident and recruited macrophage populations were characterized based on 33 cell surface and intracellular markers. Both resident and recruited macrophages were identified in the kidneys of male and female mice aged -7, -21 and -84 days in the steady state. We observed two distinct resident macrophage populations in young mice (7 and 21 days old) but by 84-days, male and female mice displayed 4 and 5 resident populations, respectively. The resident macrophage population in 7-day old mice displayed low surface expression of MHC class II and began to shift to an increased expression of MHC class II at 21 days, and high MHC class II expression at 84 days. We detected three recruited macrophage populations in 7- and 21-day-old mice, and two populations by 84-days of age. The recruited macrophage population displayed low MHC class II at all ages in both sexes. Analysis of the global macrophage populations at 84 days of age revealed female mice had twice as many recruited compared to resident macrophages, whereas male mice had an equal distribution.

Conclusions: The data indicate a dynamic change in the kidney macrophage populations with aging and resident macrophage phenotype. The composition of macrophage populations also differs by sex and age. These data suggest each population plays a role in kidney homeostasis. Future studies will be directed towards elucidating the functions of each of the identified macrophage populations.

Activation of the Integrated Stress Response Regulates the Production of IL-17 in Tissue Resident Memory T Cells

Background: CD4+ positive T cells produce cytokines and play a central role in immunity. Tissue-resident memory T (Trm) cells remain in organs after infection and contribute to efficient host defense by immediate production of cytokines, such as IL-17A. More recently, it was demonstrated that Trm cells also promote autoimmunity. Therefore, the regulation of cytokine production by Trm cells is of great importance to achieve efficient host defense without excessive inflammation. However, the control mechanisms of cytokine production by Trm cells are not well understood.

Methods: Human and mouse T cells including renal Trm cells were analyzed by single cell RNA sequencing (scRNAseq), polysome profiling combined with bulk RNA sequencing, RT-PCR, flow-cytometry, immunocytochemistry, and mRNA FISH. Mouse models for Staphylococcus aureus infection and crescentic glomerulonephritis were used to induce and study Trm cells in vivo.

Results: Conserved cytokine pathway, polysome profiling and tissue signature analysis of human and mouse tissue samples revealed that resting CD4+ Trm cells in the kidney express IL17A mRNA but do not produce or secrete the cytokine protein without re-stimulation. Mechanistically, we demonstrate that the phosphorylation of eIF2α, a key feature of the integrated stress response (ISR) activation, resulted in recruitment of IL17A mRNA into stress granules, which are organelle crucial for regulating mRNA translation during ISR, thereby inhibiting mRNA translation in resting Trm cells. Finally, we show that re-stimulation of human renal Trm cells through T cell receptor resulted in eIF2α dephosphorylation, leading to efficient translation of IL17A mRNA and subsequent IL17A secretion.

Conclusions: Tissue-resident memory CD4+ T cells in the kidney express high levels of IL-17A cytokine mRNA. Under homeostatic conditions the cytokine mRNA is stored in stress granules. In contrast, these Trm cells rapidly produce IL-17A upon re-stimulation. Our study identifies a novel mechanism of how “poised Trm cells” use the integrated stress response - stress granules pathway to regulate IL-17A cytokine mRNA translation. Dysregulation of this pathway might have a pathogenic role in organ repair and remodeling inflammatory diseases.

Differential Cell Cycle and Kinase Activation in IgA1-Producing Cells from IgAN Patients and Healthy Controls Mediated by Cytokine Stimulation
Colin Keily, Dana Rizk, Jan Novak. The University of Alabama at Birmingham, Birmingham, AL.

Background: Some cytokines increase production of galactose-deficient IgA1 (Gd-IgA1) in immortalized IgA1-producing cells derived from peripheral blood of patients with IgAN. Previous work has indicated dysregulated cytokine induced signaling may be responsible, but minimal work investigating the overlapping pathways has been performed. Using single-cell transcriptomics, we analyzed pathway responses in immortalized IgA1-secreting cells derived from IgAN patients and healthy controls (HC) before and after response to a mixture of cytokines.

Methods: A mixture of cytokines mimicking those produced by T-follicular helper (Thh) (IL-4, IL-6, IL-21, CD40L, 50 ng/mL) was used to stimulate immortalized IgA1-producing cells for 30 min before single-cell transcriptomic analysis. Gd-IgA1 level was determined by ELISA. Standard data processing using Seurat was performed along with Alteryx for IgA1 separation. Differential markers for genes in unstimulated and stimulated conditions were analyzed for pathway differences using the GSEA MSig database, and kinase-transcription factors were imputed using X2CK analysis.

Results: Thh cytokines mediated overproduction of Gd-IgA1 in IgAN cells but not HC. IgA1-secreting subpopulations were separated, and UMAP was used for unsupervised dimension reduction analysis. Within these UMAP groups, pathway analysis found multiple significant associations, including down-regulation of cell cycle processes (FDR<1X10^-25) in IgAN IgA1 cells compared to an increase in HC (FDR<4.7X10^-25) cells after Thh cytokine stimulation. Analysis of imputed kinases changed in IgAN stimulated IgA1 cells compared to HC identified MAPK14 (p=1X10^-28 and AKT1 (p<1X10^-28), which have been associated with controlling O-glycosylation expression. Conclusion: Significant changes in imputed kinases previously associated with O-glycosylation were found in IgA1-secreting cells in IgAN compared to HC in response to Thh cytokine stimulation. When stimulated with cytokines, there were significant decreases in cell cycle and proliferation pathway responses in the IgA1-secreting cells from IgAN vs. HC samples. Further investigation is needed to determine the role of cell cycle and MAPK14 pathways in driving Gd-IgA1 overproduction mediated by cytokine stimulation.

Serum and Glomerular Complement Component as Biomarkers in the First South Asian Prospective Longitudinal Observational IgA Nephropathy Cohort (GRACE-IgAN)
Succena Alexander,1 Santosh Varughese,2 Athul Thomas,3 Jeethu J. Eapen,4 Eliechen J. Eapen,1 Anna T. Valson,1 Vinoi G. David,1 John Feehally,1 Jonathan Barratt,2 George John,1,2 Marc M. Seelen,3 Mohamed R. Daha,3,1 Christian Medical College Vellore, Vellore, India; 2Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; 3Universitair Medisch Centrum Groningen, Groningen, Netherlands; 4University of Leicester College of Life Sciences, Leicester, United Kingdom; 5University of Leicester, Leicester, United Kingdom.

Background: The Glomerular Research And Clinical Experimental-IgA Nephropathy in Indians is a prospective longitudinal cohort. The study protocol has been published and is registered with WHO trial id: ISRCTN36831459. The role of serum and glomerular complement components in South Asian IgAN is unknown.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 192 (97%) patients completed 3 years. Serum complement C3 and C4 levels and glomerular C3d, C4d and C5b-9 by IHC were quantified at baseline in IgAN patients. Composite outcome (CO) was defined as a ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m^2 or RRT/death.

Results: 195 patients (97%) completed 3 year longitudinal follow-up. Lower serum C3 was significantly associated with S1, T1/T2 according to the Oxford MEST grading and with global glomerulosclerosis (GS-33%) whereas higher C4 levels were associated S1 scores. Increased mesangial C3d deposition correlated with increased mean arterial pressure, proteinuria, decreased serum albumin, decreased eGFR and with GS-33%. Increased C4d, increased mesangial C4d correlated with increased systemic blood pressure, decreased serum protein and decreased eGFR and with GS-33%. Mesangial deposition of C5b-9 did not have any clinical associations. Lower serum C3, higher serum C4 and increased mesangial C3d was significantly associated with CO over three years.

Conclusions: Serum and tissue complements could be potential biomarkers for severity and progression in the GRACE-IgAN cohort. This requires further validation.

Immune Complexes Containing Galactose-Deficient IgA1 Deposit on Mesangium Through Damage to Endothelial Cells

Yuko Makita,1 Hitoshi Suzuki,2 Daisuke Nakano,1 Toshiki Kano,1 Akira Nishiyama,1 Yusuke Suzuki,1 Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; 2Juntendo University Urayasu Hospital, Urayasu, Japan; 3Kagawa University, Kagawa, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). However, the pathogenic role of mesangial Gd-IgA1-containing immune complexes (ICs) remains unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is known to be involved in albuminuria. Here, we examined whether the deposition of Gd-IgA1-containing ICs in the mesangium may lead glomerular endothelial cell dysfunction in this disease.

Methods: Gd-IgA1 and recombinant anti-glycan IgG were used to form ICs to inject into nude mice. The renal microvascular endothelial glycocalyx removal of the injected nude mice was evaluated by real-time glycocalyx imaging. Human renal glomerular endothelial cells (HRGECs) were used to assess the potential capacity of Gd-IgA1-containing ICs to activate endothelial cells.

Results: After co-culture of Gd-IgA1-containing ICs with HRGECs, mRNA expression levels of endothelial adhesion molecules (ICAM-1, VCAM-1 and E-selectin) were significantly upregulated (P<0.01). Expression levels of proinflammatory mediators (TNFα and IL-6) that are able to induce the expression of the adhesion molecules on endothelial cells were also increased (P<0.001). Nude mice injected with Gd-IgA1-containing ICs showed podocyte and endothelial injuries with IgA, IgG, and C3 co-deposition along the glomerular capillaries and in the mesangium. Moreover, albuminuria and hematuria were also induced. Real-time glycocalyx imaging showed that renal microvascular glycocalyx was decreased immediately after the injection of Gd-IgA1-containing ICs and then mesangial IgA deposition was increased.

Conclusions: Present data suggest that Gd-IgA1-containing ICs may induce glomerular endothelial injuries resulting in mesangial deposits.

PO1448

Immune Complexes in the Peripheral Blood of Patients with IgA Nephropathy Contain Polymeric Galactose-Deficient IgA1 Associated with IgG and Complement C3

Stacy D. Hall,1 Sarah Coffee,1 Nicolas Maillard,1,2 Zina Moldoveanu,1 Ellenore P. Craine,1 Audra A. Hargett,1 Dana Rizk,1 Bruce A. Julian,1 Matthew B. Renfrow,2 Jan Novak,1 The University of Alabama at Birmingham, Birmingham, AL; 1Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein immune complexes (IC) consisting of IgA1 with some hinge-region O-glycans deficient in galactose (Gd-IgA1) and IgG autoantibodies deposit in the kidneys and induce injury. Although the glomerular immunodeposits are enriched for Gd-IgA1, not much is known about the distribution of different molecular forms of Gd-IgA1 in circulation.

Methods: Total serum IgA1 was isolated from 7 Caucasian and 10 African American patients with IgAN by jaccalin-affinity chromatography. Different molecular forms of IgA1 were then separated by size-exclusion chromatography (SEC). Gd-IgA1 was detected by lectin ELISA. IgA1-IC were isolated by SEC from sera of 4 IgAN patients. Biological activity of the isolated IC was assessed measuring the proliferation of cultured primary human mesangial cells (MC). IgA1, IgG, and complement C3 were analyzed by SDS-PAGE/immunoblotting.

Results: Total serum IgA1 included monomeric and polymeric forms and IgA1 bound in IC. Monomeric IgA1 represented ~88-92% of total IgA1, whereas polymeric IgA1 represented ~8-12%. IgA1 in IC was the least abundant form, representing <0.4% of total IgA1. Relative representation of Gd-IgA1 was highest in IC, followed by polymeric forms, and lowest in monomeric forms. Gd-IgA1 in IC had minimally sialylated O-glycans, whereas polymeric and monomeric forms were substantially sialylated. Caucasian patients had higher content of Gd-IgA1 in polymeric and monomeric forms of IgA1 compared to those of African American patients (P<0.03 and P<0.005, respectively). IgA1-IC in sera of IgAN patients had molecular mass ~700 kDa and stimulated proliferation of MC. These IC consisted of polymeric IgA1, IgG, and complement C3.

Conclusions: Biologically active IC in the circulation of IgAN patients contain polymeric, minimally sialylated Gd-IgA1 associated with IgG and C3. These findings support the pathogenic role of Gd-IgA1-IgG IC in IgAN.

PO1451

Histopathologic Association of Lambda Light Chain Predominance in IgA Nephropathy
Prasanth Raviрати,1, Virginie Royal,2 Lihong Bu,1 Rebecca L. Freese,1 Michelle N. Rheault,1 Patrick H. Nachman.1 CureGN Investigators1 University of Minnesota Twin Cities, Minneapolis, MN; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: A relative predominance of lambda (λ) over kappa (κ) light chain deposition has long been recognized in IgA Nephropathy (IgAN), which is not unique to any other glomerular disease. The reason for this predominance is unknown but may be related to a purported predominance of λ chain expression by gut associated lymphoid tissue B cells. There is limited information regarding the histopathologic findings, if any, associated with predominant λ light chain deposition. Utilizing the CureGN IgAN cohort, we evaluated if predominant λ chain deposition was associated with histologic markers of disease activity by examining MEST characteristics and other variables.

Methods: We divided the CureGN IgAN cohort into two groups based on the intensity of light chain deposition by immunofluorescence. The λ dominant group (LD) was defined by a difference in intensity score of staining of λ minus κ ≥ 1+, and the λ-κ codominant group (KL) by a difference of λ minus κ ≤ 1+. Fisher’s exact test was used to compare the histopathologic changes between the groups with respect to M, E, S, T, scores, total crescents, percent (% of globally sclerotic glomeruli, % of glomeruli with fibrinoid necrosis, degree of interstitial inflammation, and the intensity of IgG, C1q, and C3 staining.

Results: Among 695 IgAN patients, the kidney biopsy digital images of 269 patients were reviewed by CureGN pathologists and 234 patients had reported λ and κ staining intensity. Of these, 96 (41%) patients were classified as LD (including 7 patients (3%) with λ, monotypic staining) and 138 (59%) classified as KL. The two groups did not differ significantly in age, sex, or race. Compared to the KL group, the LD group had a greater frequency of endocapillary hypercellularity (E1, 51.1% vs 36.3%, p=0.04) and IgG staining intensity ≥ 1+ (37.3% vs 21.9% p=0.01). There were no significant differences between groups with respect to any other histologic finding.

Conclusions: In IgAN, patients with predominantly λ mesangial deposition are more likely to have increased endocapillary hypercellularity and IgG deposition, two findings previously linked with greater histologic disease activity and possibly worse prognosis. Further studies are needed to elucidate if the predominance of λ chains represents a unique pathogenesis in a subset of patients, or if it imparts a more severe disease course.

PO1450

Structural Characterization of Autoreactive IgG Antibodies in the Context of IgA Nephropathy
Jordan Lingo, Barbara Knoppova, Stacy D. Hall, Jan Novak, Todd J. Green. The University of Alabama at Birmingham, Birmingham, AL.

Background: IgA nephropathy (IgAN) is the most prevalent glomerulonephritis in the world. The pathology of IgAN is characterized by deposition of immune complexes in the kidneys. These complexes can trigger inflammation and mesangial cell proliferation in patients, where up to 40% of cases progress to renal failure. The pathogenic immunodeposits in kidneys of IgAN patients have been shown to contain IgA1, which has O-linked glycans in the hinge region of the heavy chain that are deficient in galactose (galactose-deficient IgA1; Gd-IgA1) and IgG autoantibodies to Gd-IgA1. Sequencing of IgG heavy chain variable regions from IgAN patients has identified a correlation between a serine residue, introduced by somatic hypermutation into the framework leading into the third hypervariable loop of the heavy chain, with an increased association of IgG autoantibodies with Gd-IgA1. We set out to understand how this single amino acid mutation affects the Ig Fab structure and antigen recognition with the aid of protein cryo-cryo-electron microscopy, reverse engineering, and binding studies.

Methods: Recombinant IgG constructs (rIgG) based on IgAN patient sample sequences and site-specific mutants were expressed in 293F cells and purified. Fab s were cleaved from IgG, purified, crystallized, and their protein structures determined. Binding differences between Gd-IgA1 and intact rIgGs were determined with ELISA-based experiments.

Results: Comparisons of rIgF Fab structures derived from a healthy control patient and an IgAN patient showed conformational differences that possibly influence the recognition of Gd-IgA1. Using this structural data and bioinformatics to guide antibody design, we reverse engineered the IgG from a healthy patient control to modulate binding to Gd-IgA1. Site-directed mutagenesis and binding studies indicated that residues in our designed, we reverse engineered the IgG from a healthy patient control to modulate binding to Gd-IgA1, and we have further identified residues in the Fabs that are important for Gd-IgA1-binding. This knowledge could inform future strategies to inhibit pathogenic immune complex formation.

Glomerular Diseases: Immunology and Inflammation in IgANP, C3GP, TMA, and Nephrotic Diseases

Methods: Plasma and urine levels of complement proteins (C4c, C3b and soluble C5b-9) were measured using in-house sandwich-ELISAs. Treatment differences between baseline, end of treatment and end of study were assessed by mixed-effects model analysis. The effect of the treatment correcting for the baseline was assessed by multiple linear regression. Significance: p < 0.05. Urinary protein excretion was adjusted for creatinine excretion.

Results: Circulating levels of MASP-3 were decreased in a dose-dependent manner after treatment (p = 0.013 Nefecon 8 mg/day, p = 0.0080 Nefecon 16 mg/day). MBL- creatinine was significantly reduced in the urine by both doses of Nefecon compared with placebo (p = 0.0001 Nefecon 8 mg and 16 mg/day). CL-11-creatinine levels were also significantly reduced in a dose-dependent manner after Nefecon administration (p = 0.0411 Nefecon 8 mg/day, p = 0.0095 Nefecon 16 mg/day). Complement activation markers and ficolin-3 levels were detectable in urine but levels remained unaltered.

Conclusions: Treatment with Nefecon modulates components of both the alternative (MASP-3) and lectin (MBL- and CL-11) pathways of complement, two pathways known to be important in mediating kidney damage in IgAN. These initial observations warrant further investigation.

Defining Cell Type Specificity of TNF Targets in Nephrotic Syndrome

Philip J McCagg, Scan Eddy, Fadil Alakwaa, Jennifer L. Harder, Janat El Saghri, Wenyuan Ju, Matthijs Kretzler, Laura H. Mariani. Nephrotic Syndrome Study Network (NEPTUNE) University of Michigan Michigan Medicine, Ann Arbor, MI.

Background: Mechanistic, targeted therapies are needed for patients with FSGS and MCD, as diverse biological processes produce similar histologic injury patterns. Bulk transcriptomic data from kidney biopsy tissue can be used to find subgroups with shared molecular features, but cellular signaling networks need to be defined.

Methods: Consensus clusters were enriched against bulk RNA sequencing data from the tubulointerstitial (TI) compartment of 220 participants from the NEPTUNE cohort, a study of children and adults with nephrotic syndrome enrolled at the time of kidney biopsy. Clusters were assessed for association with clinical outcome. Differential gene expression analysis was analyzed for enrichment of canonical pathways and functional groups between patient clusters. Nuclei were extracted from renal biopsies, processed, and quality control analyzed to remove low quality nuclei. Nuclei identity were assigned by comparisons of enriched genes in a cluster to previously identified cell-type specific genes.

Results: One cluster of 59 patients was associated with a greater risk of loss of kidney function over time and observed TNF activation. To test the cellular source of the TNF pathway biomarker candidates, we performed mRNA-seq on 10 NEPTUNE biopsies, 5 with high TNF activity scores and 5 with moderate to low TNF activity scores in TI gene expression profiles. We pooled 45,175 nuclei into 15 clusters, which included all major kidney cell types. TNF expression was found in nuclei from immune clusters and in a proximal tubule and loop of Henle clusters. TNFRSF1A was universally expressed across all clusters, while TNFRSF1B was universally expressed across cell clusters, while TNFRSF1B showed more restrictive expression. TNF targets CCL2 and TNF superfamily - higher levels in all patients with activated TNF scores with maximal increase in epithelial cells (proximal and podocytes). Kidney organoids confirmed MCP1 (encoded by CCL2) and TIMP1 upregulation by TNF treatment.

Conclusions: TNF, TNF receptors, and TNF-responsive biomarkers reflect alterations in inflammatory and intrinsic kidney cell populations in patients with TNF-associated signaling profile and are currently assessed as TNF target engagement biomarkers in a clinical trial of FSGS patients (NCT04009668).

POI457
Dysregulated T Cell Metabolomic Profile in Patients with Steroid-Resistant Nephrotic Syndrome

Chang-Yien Chan,1,2 Liangjian Lu,1 Sharon Teo,1 Yaochun Zhang,1 Kong Peng Lam,1 Kar Hui Ng,1 Hui Kim Yap,1National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; 2Khoo Teck Puat - National Children's Medical Institute, Singapore, Singapore; Agency for Science Technology and Research, Singapore, Singapore.

**Background:** We have recently reported early relapse following rituximab in patients with minimal change disease was associated with baseline reduction in regulatory T-cells and T-cell hyporesponsiveness to activation, suggesting chronic T-cell activation. This study aimed to compare T-cell activation and characterise the metabolic alterations associated with T-cell hyporesponsiveness in patients with steroid-dependent (SDNS) and steroid-resistant nephrotic syndrome (SRNS) in relapse.

**Methods:** A total of 48 patients with childhood-onset SDNS (n=31) and SRNS (n=17) were recruited during relapse. T-cell activation assay was performed on whole blood while metabolomic profiling was performed on purified stimulated CD4 T-cell culture supernatants (n=23) using GC-MS/MS and analysed using Shimadzu Smart Metabolites Database. Differences in the metabolomic profile between SDNS and SRNS were identified using PLS-DA (SIMCA), and pathway analysis was performed using MetaboAnalyst 4.0. Metabolomic validation assay was performed using Glucose 6 Phosphate Dehydrogenase (G6PD) assay kit.

**Results:** SRNS patients had significantly lower T-cell expression of CD69 (88a.3% vs 91a.3%, P=0.024) and IFNγ (1.19a.73% vs 6.6a.133%, P=0.016) compared to SDNS patients. PLS-DA modeling of the 93 metabolites identified in CD4 culture supernatants yielded one fitted component, in which 24% of the variability in metabolites measured (R²X) could explain 58% of the variation in steroid-response (R²Y). Of note, 85% of the metabolites tended to be lower in SRNS compared to SDNS patients. Pathway analysis of the 38 metabolites with VIP>1 implicated the biosynthetic pathways glyoxylate and dicarboxylate metabolism, ascorbate and aldarate metabolism as well as galactose metabolism (Benjamini-Hochberg P<0.05). Interestingly, the 2 metabolites with the highest VIP score have been implicated as downstream products in the pentose phosphate shunt and were reduced in SRNS compared to SDNS patients (P<0.001). G6PD activities in SDNS patients in relapse negatively correlated with T-cell expression of CD69 (r=-0.58, P=0.047).

**Conclusions:** We demonstrated that muted T-cells response to in vitro stimulation in SRNS patients was associated with metabolic quiescence, with dysregulated biosynthetic pathways including the pentose phosphate shunt.

**Funding:** Government Support - Non-U.S.

POI458
Blocking the IL-1β/IL-1Ra Signaling as a Potential Therapy for Multidrug-Resistant Nephrotic Syndrome

Andrea Angeletti,1 Francesca Lugani,1 Gianluca Cardi,1 Enrico E. Verrina,1 Paolo Cravero,1 Gian Marco Ghiggeri,1 Istituto Giannina Gaslini, Genova, Italy; 2Icahn School of Medicine at Mount Sinai, New York, NY.

**Introduction:** Idiopathic nephrotic syndrome (NS), Steroid-resistant patients with complete or partial resistance to the combination of prednisone and steroid sparing-agents are at high risk to progress to end-stage kidney disease. Considering the toxicities associated with chronic use of these drugs, alternative interventions are urgently needed. IL-1β/IL-1Ra has been recently suggested as a possible mechanism of complement-mediated progression of Focal Segmental Glomerulosclerosis.

**Case Description:** A 26-year-old white woman had FSGS (kidney biopsy) presenting with NS and kidney failure. Serum creatinine level was 1.6 mg/dL, urinoma protein excretion 20.4 g/d and serum albumin 0.9 g/dL. She received methylprednisolone, 1g rituximab, and CNI with partial remission. Three months later, she presented relapse of NS and kidney failure requiring 5 HD: CNI was switched to MMF. Immunoglobulins rituximab, and CNI with partial remission. Three months later, she presented relapse of NS and kidney failure requiring 5 HD: CNI was switched to MMF. Immunoglobulins rituximab, and CNI with partial remission. Three months later, she presented relapse of NS and kidney failure requiring 5 HD: CNI was switched to MMF. We hypothesized that the pathogenesis of minimal change disease (MCD) may be associated with mitochondrial injury and that the degree of mitochondrial injury at the time of diagnosis may serve as a prognostic marker in MCD.

**Methods:** We retrospectively enrolled patients with MCD who were followed up for more than 5 years and IgA nephropathy (IgAN) patients as controls (n = 20 each). Focusing on the stimulator of interferon genes (STING) pathway activated by mitochondrial injury, immunohistochemical (IHC) staining for STING was performed on kidney tissue at the time of diagnosis. The IHC stain site and signal intensity for STING were analyzed. Time-averaged proteinuria (TA-proteinuria) was calculated as the average of the mean of proteinuria measurements were obtained by 24-hour urine collection every 6 months for each patient. A relapse after treatment was defined as proteinuria >3.5 g per 24 hours or complete or partial remission.

**Results:** In patients with IgAN and MCD, kidney tissue from 13 patients each showed positive IHC staining for STING. While various kidney structures including glomeruli and tubulointerstitium were stained in IgAN patients, the glomerulus was exclusively stained in MCD patients (Figure). MCD patients were divided into the high (n = 6) and low (n = 14) intensity subgroups according to the signal intensity based on 2+ and more or less, respectively. TA-proteinuria and frequency of relapses during the follow-up period were higher in the high intensity group than in the low intensity group (1.18 ± 0.54 vs. 0.57 ± 0.45 g/d, p = 0.022; and 0.72 ± 0.60 vs. 0.09 ± 0.22 episodes/year, p = 0.022, respectively).

**Conclusions:** These findings suggest that more severe mitochondrial injury, as represented by a high signal intensity of IHC stain for STING at the time of diagnosis, could be used as a prognostic marker to predict poor prognosis in MCD.

POI460
Maturation of Decay Accelerating Activity Response Across the Natural History of C3 Glomerulopathy

Christopher Culek,1 Richard J. Smith,1,2 Carla M. Nester,1 1University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; 2The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA.

**Background:** C3 glomerulopathy (C3G) is an ultra-rare complement-mediated renal disease characterized by dysregulation of the alternative pathway (AP) of complement. Dysregulation is often driven by a nephritic factor (C3NeF), an autoantibody to the C3 convertase (C3BbBb) of the AP. We hypothesized that the properties of Nef change
over time and that changes will be associated with changes in underlying complement dysregulation.

**Methods:** IgG was purified from normal human serum and from sera collected across six time points of a well characterized C3G patient. Using SPR (Biacore), the C3 convertase (C3bBb) was formed on a CM5 sensor chip. Purified test or control IgG was injected to form the Neu-C3NfBb complex. The ability of native complement regulators to decay the Neu-C3NfBb complex was assessed by injecting Decay Accelerating Factor (DAF), Complement Receptor 1 (CR1), Factor H (FH), or control reagent. Residual C3bBb was determined by the ratio of post- to pre-regulated convertase. Data were compared to time-matched complement biomarker results.

**Results:** The presence of Neu conferred resistance to the normal decay accelerating activity (DAA) by DAF, CR1, and FH. Resistance to DAA was highest in the earliest sample (S1, p = 0.0001), with a reduction in subsequent samples. This change was independent of Neu titer and coincident with reduced complement activity. Low DAF resistance was maintained in later samples, whereas CR1 and FH resistance gradually increased.

**Conclusions:** Neu-stabilized C3bBb resistance to native DAA proteins matures over time and is independent of Neu titer. Changes in response to regulators is accompanied by a relative change in underlying complement dysregulation as reflected by complement biomarkers. How this variance (in time and across regulators) impacts disease course and outcome in patients with C3G or whether the phenomenon represents a novel treatment target warrants further study.

**POI146**

C3 Glomerulonephritis with Nephritic Factor Treated with Rituximab

**Case Description:** Patient is a 64-year-old male diagnosed with biopsy proven C3GN after being found with decreased kidney function with a peak creatinine of 1.97 mg/dL and nephrotic range proteinuria with a maximal urinary protein excretion of 4.3 g/dL. Evaluation revealed low C3 and C4 at 60 mg/dL and 5 mg/dL respectively, negative monoclonal testing, and a C3NeF of 21 unit/mL (reference range 0). Patient was initiated on prednisone 60 mg/day with taper, MMF with a maximal dose 3 grams/day, and valacyclovir for 2 years with little improvement in clinical parameters. Therapy was switched to rituximab 1 gram on weeks 0, 2, 6. Within 3 months patient had; normalization of complements, negative C3NeF, 0.7 urine protein-to-creatinine ratio (UPCR), and serum creatinine 1.5 mg/dL. Since his initial rituximab regimen 2 years ago, he remains off maintenance therapy, with negative C3NeF, normal complements, 0.1 UPCR, and serum creatinine 1.04 mg/dL.

**Discussion:** C3GN was successfully treated with rituximab based on the disappearance of C3NeF and improvement in clinical parameters. Rituximab was chosen to target CD20 cells to halt the production of the C3NeF autoantibody. Laboratory response (complements and C3NeF) was seen within 3 months of initial rituximab dosing, and UPCR and serum creatinine required a longer follow up for a nadir. Recurrence of relapse is being monitored using serial C3NeF measurements. We believe that targeted B cell therapy should be considered in the treatment of C3GN cases which are C3NeF antibody mediated.

**POI1462**

Complement-Activated Polymorphonuclear Neutrophils Contribute to C3G Pathogenesis

**Background:** C3G is caused by dysregulation of the complement alternative pathway, but there is a gap in the pathogenetic cascade from complement activation (intravascular space) to inflammation and complement deposition in the glomeruli (extravascular space). Recently, biopsies have shown the presence of (activated) polymorphonuclear neutrophils (PMNs) in C3G glomeruli indicating an underappreciated role for PMNs in C3G pathogenesis.

**Methods:** PMNs were investigated in a transwell chamber allowing for different environments. Conditions were chosen to resemble the intravascular space (top well; serum containing) versus extravascular space (bottom well; serum-free conditions). PMNs were stimulated in the top well via various agonists, including complement, and allowed to transmigrate to the bottom well where they were monitored for the formation of Neutrophil Extracellular Traps (NETs) via immunofluorescence and SYTOX assay. Circulating C3G patient PMNs were examined for priming via flow cytometry.

**Results:** Upon complement stimulation, PMNs showed evidence for priming in serum conditions (top well). PMNs travelled to the bottom well following chemotractant fMLP where they then completed the process of NET formation (NETosis) in serum-free conditions (bottom well). Results were validated ex vivo using C3G patient PMNs and autologous serum (Figure). In addition, incubation of control PMNs in C3G patient serum revealed a correlation between serum-albumin levels and the degree of NET formation. C3G patient PMNs showed upregulation of CD11b compared to controls.

**Conclusions:** Assigning a pathogenetic role to PMNs in C3G identifies a new treatment and monitoring strategy with the potential for improved long-term outcomes and quality of life.

PMNs were seeded in the top well of a transwell system and allowed to transmigrate for 12 h. PMNs from both wells were stained for IF with DAPI (blue), Citrullinated histone 3 (Ch3H3; green) and Myeloperoxidase (MPO; red). Scale bar 20 um. 63x magnification.

**POI1463**

Differential Expression of Complement and Non-Complement Proteins in C3 Glomerulonephritis and Dense Deposit Disease

**Background:** C3 glomerulopathy comprising dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) results from overactivation of the alternative pathway of complement. Mass spectrometry (MS) studies have previously shown accumulation of complement proteins in C3GN and DDD. However, complete MS analysis of non-complement proteins and comparison of complement proteins in C3GN and DDD has not been done.

**Methods:** We performed laser microdissection of glomeruli followed by MS in 12 cases each of biopsy-proven C3GN and DDD, and 6 control cases of time 0 transplant biopsies.

**Results:** Compared to the controls, C3GN showed increased intensity based absolute quantification (iBAQ) values of C3 (20-fold), C5 (52-fold), C7 (90-fold), C8 (66-fold), C9 (30-fold), C1r/C1s (146-fold) and CFR3 (65-fold). Similarly, DDD showed also increased iBAQ values compared to controls of C3 (26-fold), C5 (365-fold), C6 (473-fold), C7 (261-fold), C8 (353-fold), C9 (159-fold), and CFHR1 (73-fold). When DDD was compared to C3GN, there was a 2-5 fold increase in iBAQ values in C5, C7, C8, C9 and C9 (p<0.001), although there was no significant difference in C3. Among the non-complement proteins Apolipoprotein E (APOE) and A-II and V (APOA-II and V), Serine protease HTRA1, Rykandine receptor 1 (RVR1), and Translational activator GCN1 were expressed 3-7 fold higher in DDD compared to C3GN (p<0.001). On the other hand, proteoglycan 2 and 3 (PRG2 and 3), angiostatin (AGT) and properdin (CFP) were expressed 2-5 fold higher in C3GN compared to DDD (p<0.001).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: MS of C3GN and DDD show high iBAQ values of complement proteins. DDD shows a higher iBAQ values in terminal complement proteins compared to C3GN. In addition, proteins such as APOE and APOA I/FV are increased in DDD compared to C3GN, while PRG2/3 and properdin are increased in C3GN compared to DDD suggesting a role for the proteins in the pathophysiology of C3GN and DDD.

PO1464
Clinical and Histological Features of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: A Single-Center Retrospective Study from China
Yifeng Wang, Xiaoye Zhu, Shaojun Liu, Jun Xue, Chuang-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: PGNMID is a new entity of monoclonal gammopathy affecting the kidney characterized by intact monoclonal immunoglobulins (mlg) deposits that result in membranoproliferative pattern of glomerular injury. In this study, clinical and histological of PGNMID cases were evaluated.

Methods: A total of 23 patients with biopsy-confirmed PGNMID in native kidney diagnosed between December 2015 to April 2021 were enrolled in this study. Clinical, histological, hematologic, and follow-up data were abstracted from the medical record.

Results: Of 23 cases, majority were male (65.2%), and the mean age was 49.5 years with 8 cases (34.8%) under 40 years old. At the time of biopsy, 19 cases had proteinuria with a mean 24h urine protein of 3.99g (0.28 to 8.96), 11 of 22 cases had nephrotic syndrome, and 18 of 22 cases had hematuria. The mean serum creatinine was 1.52mg/dl (0.6 to 7.8), 15 cases (65.2%) had eGFR<90 mL/min (CKD-EPI), and 4 cases had eGFR <60 mL/min. Eleven of 23 cases (47.8%) showed MPGA, 6 cases showed EPGN, 2 cases showed MesPGN, and 2 cases showed MN. By IF, 21 cases (91.3%) showed mIgG deposits (12 IgG3, 5 IgG1, 1 IgG1A, 1 IgG3, and 2 IgGk without determined subclass) and 2 cases (8.7%) showed mIgA deposits. All cases showed C3 co-deposits, and 6 of 18 cases (33.3%) had a low serum C3 level. EM revealed unorganized and granular deposits in the mesangial area (17 of 17), subendothelial area (15 of 17), and subepithelial area (12 of 17). Three of 4 cases whose eGFR<60 mL/min showed EPGN. SIFE showed mlg that matched the renal deposits in 2 of 13 cases (15.3%). After mean follow up of 3 months in 3 cases, 1 patient treated with bortezomib+CTX+DXM and another patient treated with rituximab both achieved partial renal remission. But the third patient treated with rituximab had a persistent renal dysfunction. Of note, previous or concurrent infections by fungi, HIV, HBV, HPV or other undetermined pathogen, were observed in 5 cases (21.7%). We also found 1 patient with autoimmunity and another with malignancy.

Conclusions: Compared with previous reports, our PGNMID cases showed similar clinical and histological features. EPGN pattern seems to be associated with more severe renal function damage. Previous or concurrent infections, autoimmunity and malignancy were observed in 21.7% of cases.

PO1465
Diagnostic and Risk Factors for Deregulated Complement in Thrombotic Microangiopathy
Sjoerd Timmermans, Pieter van Paasen. Limburg Renal Registry Maastricht Universitair Medisch Centrum, Maastricht, Netherlands.

Background: The syndromes of thrombotic microangiopathy (TMA) are diverse and represent severe endothelial damage caused by various etiologies. The early recognition of complement-mediated (C-TMA) is of utmost importance to select patients for complement inhibition. Whether or not clinicopathologic features at presentation can distinguish C-TMA from secondary TMA and/or predict the response to complement inhibition remains unknown.

Methods: Fifty-seven patients with TMA on kidney biopsy and a normal activity of von Willebrand factor cleaving protease were screened for deregulated complement using ex vivo C5b9 formation on the endothelium and genotyping. Massive ex vivo C5b9 formation and/or rare complement gene variants defined C-TMA. Clinicopathologic features that may distinguish C-TMA from secondary TMA were studied. Regression models were used to assess the prognostic value of chronic damage on kidney biopsy.

Results: C-TMA was diagnosed in 30 patients (coexisting conditions, n=26 [87%]), including 16 (53%) cases with rare complement gene variants; 27 patients had secondary TMA related to autoimmunity (n=13), hypertension (n=10), and other etiologies (n=4). Patients presented with acute kidney injury, while systemic hemolysis was uncommon in both groups (n=14/30 vs. n=6/27; P>0.05). C-TMA was linked to younger age (37 [14] vs. 46 [15] years; P=0.04), low plasma C3 (n=16/29 vs. n=3/22; P=0.01), and glomerular thrombosis (n=19/30 vs. n=8/27; P=0.02) as compared to secondary TMA; glomerular thrombosis, however, was common in patients with autoimmunity (n=6/13; P=0.05 vs. C-TMA). These characteristics, when combined, had a specificity and sensitivity for C-TMA of 100% and 33%, respectively. Eculizumab treatment was associated with clinical remission in C-TMA (n=12/14; P<0.01 vs. n=3/16 untreated patients). Morphologic features of chronic damage, i.e., glomerulosclerosis, interstitial fibrosis/tubular atrophy, and arteriosclerosis, did not predict prognosis; 5 out of 6 patients with C-TMA and moderate-to-severe chronicity scores treated with eculizumab recovered and/or improved kidney function.

Conclusions: Patients with TMA, low plasma C3, and glomerular thrombosis who present at younger age (i.e., <45 years) are at high risk for C-TMA. Although a kidney biopsy is often needed to detect the TMA, morphologic features of chronic damage cannot predict prognosis.
Hematopoietic Stem Cell Transplant Membranous Nephropathy Is Associated with Protocaderhin FAT1
Sanjeev Sethi,1 Benjamin J. Madden,1 Samih H. Nasr,1 Fernando C. Fervenza,1 Mark Haas,2 Mayo Clinic Minnesota, Rochester, MN; 2Cedars-Sinai Medical Center, Los Angeles, CA.

Background: Membranous nephropathy (MN) is a common cause of proteinuria in patients with a hematopoietic stem cell transplant (HSCT). The antigen(s) responsible for MN in HSCT-associated MN is unknown.

Methods: We performed laser microdissection and mass spectrometry (MS/MS) of glomeruli of 230 cases of PLA2R-negative MN to detect novel proteins/antigens in MN. These included PLA2R-negative MN developing in the setting of HSCT and de-novo MN in the kidney transplant.

Results: We detected a novel protein Protocaderhin FAT1 (FAT1) in 9 cases of PLA2R-negative MN. Of the 9 FAT1-associated MN cases, 7 patients followed HSCT and 2 followed kidney transplant (de-novo MN). HSCT was done for treatment of AML (5 cases), MDS (1 case) and essential thrombocytopenia (1 case). All 9 cases were negative for known antigens of MN including PLA2R, THSD7A, NELL1, PCDH7, NCAM1, SEMA3B and HTRA1. Baseline PLA2R spectral counts were detected in 7 of the 9 cases. The FAT1 total spectral counts ranged from 27 to 70 (mean 44 ± 13.1). FAT1 was not detected by MS/MS in 115 control cases that included time 0 transplant, minimal change disease, FSGS, diabetes and IgA nephropathy. FAT1 was also not detected in 28 cases of PLA2R-positive MN. No case of FAT1-associated MN was detected in a non-transplant setting. The mean age of patients with FAT1-associated MN was 56 ± 9.7 years, 7 patients were females and 2 were males. MN occurred 2.5 ± 0.8 years and 7.5 ± 1.2 years after HSCT and kidney transplant, respectively. The mean serum creatinine and proteinuria at kidney biopsy was 1.9 ± 1.2 mg/dL and 7.4 ± 5.4 gms/L, respectively. Kidney biopsy showed IgG (2-3+), and minimal C3 (0-1+) along glomerular capillary walls; electron microscopy showed stage II MN in 8 out of 9 cases.

Conclusions: FAT1 appears to be a unique protein found in MN developing in the setting of HSCT and de-novo MN following kidney transplant. Further studies to localize FAT1 on the glomerular basement membranes and detect circulating antibodies are ongoing.

POI1468
Netrin G1 Is a Novel Target Antigen in Membranous Nephropathy

Background: PLA-R is the main target antigen in membranous nephropathy (MN) representing 70-80% of cases. In the past years a number of confirmed, or potential target antigens, such as THSD7A, NELL1, HTRA1, SEMA3B and PCDH7 have been reported, showing that the pathophysiology of PLA2R-antibody (ab) negative MN represents a diverse repertoire of antigens with low frequency.

Methods: Western blot (WB) analysis was used to identify sera of MN patients with IgG4 specific signals binding to antigens in the membrane fraction of human glomerular extracts (HGE). Only sera which were negative for PLA-R- and THSD7A- were used. IgG4-Ab from the serum of an index patient was purified and used to immunoprecipitate the corresponding target antigen from the membrane fraction of HGE. The purified antigen in the eluate was identified by mass spectrometry. Recombinant protein was used to confirm the reactivity of patient sera by WB and identify other patients in a large cohort of MN patients. The deposition of the target antigen in the glomerular immune deposits was confirmed by immunohistochemistry (IHC).

Results: Using this approach, we identified Netrin G1 (NTNG1) as a novel target antigen in MN. NTNG1 is a 50 kDa secreted glycoprotein, which is attached to the cell surface by a GPI anchor (Fig. A, B). We identified NTNG1-ab in two out of 110 PLA-R- and THSD7A-ab negative MN patients. A follow-up of 5 years was available for the index patient. During this time, both proteinuria and NTNG1-ab persisted while renal function (eGFR 73 ml/min) and hypoalbuminemia (2.89 g/dl); 24h proteinuria was 3.6 g/24h. Autoantibodies (ANA, ENA, DNA, LAC, anti-cardiolipin, ANCA) were undetectable, serum immunoglobulins and C3 and C4 complement components were normal. A kidney biopsy (KB) demonstrated a picture of MN. Anti-PLA2R antibody was negative in the serum and PLA2R and THSD7A antigens were not detected in the KB. Three CIDP-associated autoantibodies (anti-contactin 1 (CNTN1), anti-contactin associated protein 1 and anti-neurofascin) were tested by ELISA which revealed the presence of anti-CNTN1 at 1:100 serum dilution. CNTN1 antibody was revealed by immunohistochemistry in the subepithelial immune deposits in the patient’s paraffin biopsy sections but not in control PLA2R-positive KB (figure 1).

Discussion: CNTN1 should be added to the armamentarium of antigens involved in MN and tested in PLA2R negative MN associated with CIDP. Further studies are needed to determine the prevalence of CNTN1-associated MN among patients with CIDP, and in those without CIDP and as yet unidentified antigen.
PO1470

Epitho Epitope Spreading and Immune Complex Rearrangement in Membranous Nephropathy
Olusola Sogbein, Marjan Afzouzian, Tina Kochar. The University of Texas Medical Branch at Galveston, Galveston, TX.

Introduction: We present a rare case of ANA and anti-dsDNA negative, anti-GBM positive lupus nephritis (LN) patient with two biopsies demonstrating LN Class III-V with possible immune complex (IC) rearrangement and/or epitope spreading (ES).

Case Description: A 62-year-old white male who presented with a year-long history of purpuric rash and hematuria. His hospital admission laboratory data is detailed in Table 1. The first renal biopsy showed crescents in 2/4 glomeruli with mild (+++) granular and segmentally linear deposits by immunofluorescence (IF). The patient received cyclophosphamide, corticosteroids and one session of thrombopelagic plasma exchange due to rapidly worsening renal function and an initial presumptive diagnosis of anti-GBM disease. The second biopsy demonstrated no crescents but features of combined class III + V LN with IF findings suggestive of a fail-house pattern with a change in the deposits from segmentally linear to pure granular. He began therapy with mycophenolate mofetil and prednisone resulting in a decrease in his UPCR from 2.3 to 0.3 mg/ml (complete remission) over the next four months and significant improvement in renal function.

Discussion: A link has been reported between anti-GBM histopathology and membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-dominant epitopes leading to propagation of autoimmune. Circulating anti-GBM antibodies may continually stimulate the upregulation and alteration of anti-GBM epitopes leading to the development of granular deposits and membranous nephropathy. We believe our case suggests this possible pathogenic mechanism. More research is needed to improve understanding of the sequential change observed on immunofluorescence microscopy.

Laboratory Data

PO1471

Generation of Anti-THSD7A Antibodies Using a Human Antibody Phage Display Library
Sarah Köllner,1 Larissa Seifert,1 Philip A. Heine,2 Michael Hue,3 Nicola M. Toms,1 Universitas klinikum Hamburg-Eppendorf, Hamburg, Germany; 2Technische Universität Braunschweig, Braunschweig, Germany.

Background: Membranous nephropathy (MN) is an antibody-mediated autoimmune renal disease. In the majority of cases, autoantibodies target podocyte membrane proteins such as PLAr21 and THSD7A. We could previously demonstrate that autoantibodies in THSD7A-associated MN cause disease and recognize several extracellular domains of the target antigen. However, the mechanisms underlie this antibody polyclonality relates to disease pathogenicity. The aim of this study was the generation of anti-THSD7A antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Methods: In the antibody phage display technology, antibody fragments are displayed on the phage particle and the corresponding gene fragment encoding the antibody is packaged in the phage particle. A selection process called panning enables the selection of antibody fragments against virtually any target structure. However, it remains unclear how this antibody polyreactivity relates towards the clinical outcome, which could be investigated by further studies.

Results: Four binders (SAK79-B1, SAK78-C12, SAK78-E6, SAK78-F8) could be obtained. While SAK78-F8 exclusively bound human THSD7A, the other binders reacted with both human and murine THSD7A in Western blot, ELISA and IFT. A domain-specific ELISA revealed binding of SAK78-B1, SAK78-C12 and SAK78-F8 to the regions d9, d11-d2 and d6-d7, respectively. SAK78-B1 did not react with any domain combination, but showed strong binding to murine and human d11-d21. We suspect a conformational epitope that was not conserved in the coated domain fragments. SAK78-C12 and SAK78-E6 were successfully cloned into human IgG subclass backbones IgG1-4.

Conclusions: Antibody phage display represents a powerful method to generate recombinant antibodies. The antibodies selected show different binding characteristics in vitro. In vivo binding characteristics, pathogenicity and potential as a diagnostic tool, e.g. to stain THSD7A in patient biopsies, need to be determined.

PO1472

A Comparison of aPLa2Rab Assays on Treatment with Cyclophophamide and Steroids
Coralien Vink- van Setten,1 Anne-Elis van de Logt,1 Alexander Kühnl,2 Jack F. Wetzel3.1 Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany.

Background: Anti-PLa2R antibodies (aPLa2R) are present in ~75% of patients with primary membranous nephropathy (MN). A qualitative immunofluorescence test (IFT) allows accurate detection of aPLa2R, additionally ELISA and ChLIA provide quantitative analysis. Sensitivity of the two latter methods after start of immunosuppressive therapy is not well studied.

Methods: We retrieved stored samples of patients with aPLa2R associated MN, who were treated with cyclophosphamide and steroids (CP), collected at baseline and 8 weeks after start of therapy. Assays were performed by the EUROIMMUN researchlab, Lubeck, Germany. All samples were analysed by IIFT, ELISA and ChLIA. We categorized ELISA results to cut-off values used in literature: 2, 14, and 20 RU/ml resp.

Results: We included baseline samples of 50, and 8 week samples of 51 patients. At baseline, all patients tested IIFT positive; ELISA test was positive in 94% or 98% of samples using cut-off values of 20 RU/ml or 14 RU/ml resp., indicating high sensitivity. Agreement between IIFT and ChLIA was 100%. After 8 weeks on CP, 37/51 patients had immunological remission by IIFT. ELISA test results are given in Table 1.

In the IIFT positive samples collected after 8 weeks, ELISA titers were < 20RU/ml or < 14 RU/ml in 9/14 and 5/14 patients respectively, suggesting lower sensitivity. All IIFT negative samples had ELISA titers < 14 RU/ml. When analysing IIFT negative patients with ELISA titer <2 UL/ml (N=23) vs. 2-14 UL/ml (N=18), persistent immunological and clinical remission was better in the first group (74% vs 58%), however not statistically different. With ChLIA only 4/51 (8%) had different results (2 IIFT+/ChLIA+, 2 IIFT-/ChLIA+); resulting in a sensitivity of 86% and a specificity of 95%, when compared to IIFT.

Conclusions: Using immunological remission as treatment target, as described here after 8 weeks of CP, requires evaluation of the applied assay for this purpose. Of the examined quantitative methods, ChLIA demonstrated the highest agreement with IIFT. ELISA titers below the recommended cut-off for initial diagnosis still show a tendency towards the clinical outcome, which could be investigated by further studies.

PO1473

The Classical Pathway Triggers Pathogenic Complement Activation in Membranous Nephropathy
Larissa Seifert,1 Gunther Zahner,1 Naomi C. Hickstein,1 Sarah Köllner,1 Catherine Meyer-Schwesinger,1 Dominik Kylies,1 Anna Borodovsky,2 Peter F. Zipfel,1 Victor G. Puuelles,1 UL Fanzer,1 Tobias B. Huber,1 Thomas Weich,1 Nicola M. Toms,1 Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2Aylum Pharmaceuticals Inc, Cambridge, MA; 3Leibniz-Institut für Naturstoff-Forschung und Infektionsbiologie eV, Jena, Germany.

Background: Membranous nephropathy (MN) is characterized by severe proteinuria, circulating autoantibodies against podocyte antigens such as PLAr21 and THSD7A, and glomerular deposition of IgG and complement components (CCs). However, the pathways triggering the complement cascade (classical, alternative or lectin) and the significance of local glomerular complement action for podocyte damage and proteinuria are poorly understood.

Methods: Complement activation was investigated in 20 biopsies from patients with PLAr21- and THSD7A-associated MN using immunofluorescence and proximity ligations to visualize the assembly of CCs/convertases. Experimental autoimmune MN (EAMN) in C3-/- mice. The efficacy of complement-targeted treatment was evaluated by weekly injection of a C3-silencing siRNA after the onset of proteinuria.

Results: The assembly of the classical/lectin convertase was identified in 19/20 MN biopsies, which was accompanied by detection of IgG and C1q in the majority of cases. The alternative convertase and MBL deposits were detected in fewer cases. Upon immunization, mice developed clinical and histopathological features of MN. Proteinuria ranged from mild to severe nephrotic syndrome and histopathological features included granular glomerular deposition of IgG and CCs including C1q and C3 as well as loss of the podocyte cytoplasmic networks nephrin and nephrin. Strikingly, severe disease with ascites was prevented in C3-/- mice and overall proteinuria was reduced in comparison to WT littermates. Finally, treatment with C3-silencing siRNA after the onset of proteinuria attenuated disease.
Conclusions: The complement system is dominantly activated via the classical pathway in MN patients. Experimental data in the first author’s murine model demonstrate that an antigen that is pathologically relevant in patients suggests complement-targeted treatment as a promising strategy for MN patients with severe disease, but also hint at a role of complement-independent mechanisms in the pathogenesis of MN.

POI1474

Positive PLA2R Detection by Mass Spectrometry but Negative PLA2R Staining on Immunofluorescence Microscopy

Sanjeev Sethi, Benjamin J. Madden, Ladan Zand, Fernando C. Fervenza. Mayo Clinic Minnesota, Rochester, MN.

Background: Detection of PLA2R along the glomerular basement membranes by immunofluorescence (IF) studies using antibodies directed against PLA2R is considered the gold standard for diagnosis of PLA2R-positive MN on the kidney biopsy. Microdissection of glomeruli followed by mass spectrometry (MS) of PLA2R-positive MN also detects high total spectral counts of PLA2R confirming the IF studies. However, correlation of PLA2R-negative MN cases by IF and MS has not been done.

Methods: We performed laser microdissection and mass spectrometry in 230 cases PLA2R-negative MN in search of novel proteins that may represent new target antigens in PLA2R-negative MN. All 230 cases were negative for PLA2R by IF staining.

Results: We detected high total spectral counts of PLA2R in 8 (3.5%) of the 230 PLA2R-negative MN cases by IF. The mean total spectral count of PLA2R in the 8 cases was 57 (range 24 to 83, SD ± 25.0) (Figure 1). This is comparable to the mean total spectral counts in PLA2R-positive MN (57.7 ± 23.7). The baseline mean total spectral count of PLA2R in 6 time zero transplant biopsies (control cases) was 6. Interestingly, all subtypes of IgG1 were present in the 8 cases that were positive for PLA2R by MS with IgG1 being the dominant (total spectral count 57 ± 16.9) followed by IgG3 (50.0 ± 11.5), IgG4 (46.3 ± 18.1) and IgG2 (39.3 ± 11.4). On kidney biopsy, 3 of the 8 cases showed findings for secondary autoimmune MN such as C1q positivity or full house Ig staining. Electron microscopy showed stage I MN in 2 cases, stage II MN in 5 cases and stage III in 1 case. Clinical details at presentation were as follows: 3 females and 5 males, mean age 53.6 years (± 20.7), mean serum creatinine 1.38 mg/dL (± 0.6), and mean proteinuria 6.8 g/mo/24 hours (± 2).

Conclusions: IF is negative for PLA2R staining in a small (3.5%) number of PLA2R-negative MN. These cases can be detected by IF. Thus, MS is an alternative to IF staining and the new gold standard to detect PLA2R on the kidney biopsy.

POI1475

Can the Use of the Serum Anti-PLA2R Antibody Negate the Need for a Renal Biopsy in Primary Membranous Nephropathy?

Omar S. Ragy, Vimal Rautemaa, Durga Anil K. Kanigicherla, Patrick Hamilton. Manchester Metropolitan University, Manchester, United Kingdom.

Background: Since the emergence of the anti-PLA2R antibody test, nephrology practice has not changed dramatically, and most nephrologists are still relying on performing a kidney biopsy in diagnosing membranous nephropathy. In this study, we sought to examine how anti-PLA2R antibody tests using ELISA can be utilized in clinical practice.

Methods: We have conducted a retrospective analysis for 187 patients between 2003 and 2020 correlating their renal biopsy findings with their anti-PLA2R antibody test when performed. We have recorded all patient’s demographics, urine protein creatinine ratios, serum albumin, anti-PLA2R antibody test, among other antibodies using ELISA or immunosuppression treatment. Using a statistical analysis model, we have calculated the positive and negative predictive values of the anti-PLA2R at test carried out during that period.

Results: The mean levels of anti-PLA2R antibody titer in primary membranous nephropathy were 217 RU/ml, whereas the mean level was only 3 RU/ml for both secondary membranous nephropathy and other diagnoses. The majority of our cohort who had a positive anti-PLA2R antibody test had a confirmed renal biopsy diagnosis of primary membranous nephropathy with a PPV of 97.3%. Also, we found that the test sensitivity was 75.5%. On the other hand, we found that the NPV was 98.6% and the specificity was 97.8% at a level of ≥20 RU/ml

Conclusions: The anti-PLA2R antibody test is a highly specific test for diagnosing membranous nephropathy. Experience from our center supported by some evidence from the literature suggests that we can rely solely on a positive test without the need to perform a renal biopsy. More prospective trials are required to further validate that notion.

POI1476

Complement Activation and Suppression Profile Reveals Distinct Subtypes in C3 Glomerulonephritis

Background: The complement pathway is an innate immune defense mechanism, and uncontrolled activation can cause damage to host tissues including the kidney. C3GN is characterized by deposits in the glomerulus made up entirely of complement C3 protein without the presence of immunoglobulins.

Methods: The activity of the alternative complement pathway (ACP) was determined in serum derived from C3GN patients, IgA Nephropathy (IgAN) and Polycystic Kidney Disease (PKD) and healthy controls (HC) by measuring the lysis of rabbit red blood cells (rRBC). Complement factor H (CFH) was added to the serum of C3GN patients to determine if CFH is capable of inhibiting the ACP in C3GN patients.

Results: Analysis of the ACP using the serum of C3GN, IgAN, PKD patients and healthy controls can be calculated by the lysis of rRBC. The percent lysis at specified time points (5, 10 and 15 minutes) was calculated using the maximal lysis for each sample. Serum from C3GN patients result in more significant lysis (one way ANOVA, P = 0.01) at 5 and 10 minutes (22.9% ± 11% and 42.7% ± 12%, respectively) compared to HC (7.1% ± 3% and 21.7% ± 6%, respectively), IgAN (10.9% ± 7% and 27.3% ± 15%, respectively) and PKD (8.6% ± 6% and 24.4% ± 12%, respectively). However, all 3 groups had similar lysis rates in the 15 minutes, suggesting that the ACP is more rapidly activated in C3GN patients, leading to faster depletion of C3. Addition of CFH to the serum of C3GN patients reduced the ACP activity to control levels in 6 out of 14 patients. We did not detect CFH specific antibodies in the serum of patients who did not respond to CFH, indicating additional mechanisms are involved with the rapid activation of the ACP in C3GN.

Conclusions: The ACP is rapidly activated by the serum of C3GN patients compared to other kidney diseases and HC. Although the addition of CFH to the serum reduced the lysis this activation comparison does not extend to all C3GN patients, not all the serum samples responded to CFH. Future work may elucidate additional mechanisms of the continued ACP activation in C3GN patients and have implications for therapy of these patients.

POI1477

Preexisting Autoimmune Dysregulation Unmasks a Role for Silica Dust Exposure in Nephrotropic Autoantibody Production

Lanette Feg1, Robert M. Tighe,2 Mary H. Foster.1,2 Duke University, Durham, NC; 1DVAMC, Durham, NC.

Background: Pathogenic autoantibodies (autoAb) promote severe glomerulonephritis in ANCA vasculitis and lupus. Genetic susceptibility and environmental exposures, particularly inhalation of silica (Si) dust, are implicated in dysregulated autoimmunity and are targets for therapeutic intervention. Using a mouse reporter system expressing a regulated nephrotropic autoAb transgene (Tg) targeting basement membrane (BM) and instilling Si by oropharyngeal aspiration (OPA), we demonstrated that central B cell tolerance and anergy to BM are preserved in multiple lupus strains despite induction of lung inflammation and ectopic lymphoid tissue. Nonetheless, Si exposure increased local and systemic anti-DNA Ig levels in wildtype (WT) B6 and lupus mice, suggesting subversion of alternative regulatory checkpoints. Herein we leverage the aberrant M7 anti-BM Tg lineage that demonstrates partial escape from tolerance and evidence of glomerular Ig deposition to study the interaction of Si exposure with preexisting defects in autoreactive cell regulation.

Methods: M7 Tg mice (WT at Ig light chain, or LC, locus) were exposed to Si or vehicle (V) by OPA, organs harvested at 5-6 weeks, and cells cultured with or without CD3/CD28 beads (TLR-L). To restrict Ig specificity, a subset of mice (TgKi) was bred to heterozygosity for the V6/8.9.5 V8R Ig LC knock-in. Tg autoAb were measured by ELISA; mean OD±SD.

Results: Presence of serum Tg autoAb and induction of high levels of autoAb by TLR-L stimulation upregulated splenocytes (OD 2.61±2.49; TLR7/9, v 0.06±0.03; medium, p<0.0001) confirmed Tg phenotype, and bronchoalveolar lavage fluid cell counts confirmed exposure (237±130 ± 18.1±7, x1000, Si vs V, p<0.05). Among Tg WT mice, more autoAb were produced by TLR7/9-stimulated lung cells from Si-exposed mice (OD 0.13±0.15, Si, vs 0.03±0.01, V, p<0.05), indicating that Tg B cells recruited by Si exposure contribute to local autoAb production. Among Si-exposed mice, Tg autoAb levels were higher in Tg WT vs TgKi mice: OD 1.239±0.47 for TLR4-L stimulated splenocytes, Tg, vs 0.51±0.63 TgKi, p<0.05.

Conclusion: An autoAb reporter system reveals that anti-BM autoreactive lymphocytes that escape tolerance can be recruited to the lung after exposure to inhaled silica dust. Anti-BM cell activation by superimposed stimuli, such as TLR-L, can lead to secretion of nephrotropic autoAb.

Characteristics of Membranous Nephropathy Patients with IgG and IgA Co-Deposits on Capillary Wall

Guang Yu, Qionghong Xie, Ruining Chen, Shaojun Liu, Lingyun Lai. Huashan Hospital Fudan University, Shanghai, China.

Background: Membranous nephropathy (MN) is characterized by immune deposits on glomerular capillary wall, predominantly IgG. There have been several reports of MN combined with IgA nephropathy with features of IgA immunofluorescence staining in the glomerular mesangium. However, we found that IgA can also be deposited on the capillary wall with IgG. This study aimed to investigate the prognostic, clinical and renal histopathological characteristics of adult MN patients with IgA and IgG co-deposits on capillary wall.

Methods: A retrospective study was conducted in biopsy-proven MN patients of our renal department during January, 2007 to May, 2020. Clinical data were collected at time of biopsy and the latest follow-up. Pathological parameters included immunofluorescence staining, plaq2r staining, membranous Chang’s stages, sclerosis, crescent, focal segmental sclerosis lesion, chronic tubulointerstitial injury and et al. Indirect immunofluorescence experiment was conducted in 293T cells transfected with plaq2r plasmid.

Results: Out of 531 cases diagnosed with MN, 53 patients have moderate IgA deposit on capillary walls with IgG. 19 cases were determined to be secondary MN, which were 10 cases of autoimmune disease, 4 cases of Hepatitis B, 3 cases of kidney transplantation. 1 case of chemical exposure and 1 case of AL amyloidosis-associated secondary MN. 31 Idiopathic MN patients with both IgA and IgG depositing along capillary wall were followed up for a median interval of 42months (interquartile-range, 17-82) and 3 with IgA only (6.5%) patients progressed to ESKD or death, 2 (6.5%) patients had their eGFR declined by half, 11 (35.5%) patients had no remission and 15 (53.6%) patients were followed up for a median interval of 49months (interquartile-range, 17-82) and 3.

Conclusions: IgA and IgG could be co-depositing on glomerular capillary wall in MN patients, secondary causes should be screened with cation. IgA and IgG type of autoantibodies linked to MN co-existed in serum of idiopathic MN patients, whose prognosis might be poor.

Mystery Cryoglobulinemic Glomerulonephritis Treated with Rituximab

Mohamed Hassanein, Hanny Sawaf, Leal C. Herlitzi, Michael Lioudis. Cleveland Clinic, Cleveland, OH.

Introduction: Cryoglobulinemic Glomerulonephritis (GN) is characterized by the deposition of immunoglobulins (IG), also known as cryoglobulins (CG), in the kidney. We report a case of idiopathic mixed cryoglobulinic GN treated with rituximab and prednisone.

Case Description: A 42-year-old triathlete with a history of pediatric meningitis with hydrocephalus requiring placement of a ventriculoperitoneal shunt presented with lower extremity swelling limiting his ability to exercise. He denied non-steroidal anti-inflammatory drug and illicit drug use, and was not on any prescribed medications. Laboratory workup showed serum creatinine: 1.2 mg/dL (normal 0.7 – 1.2), serum albumin: 2.1 mg/dL (normal 3.9 – 4.9), CG: 140 mg/mL (normal 0 – 50), C3: 39 mg/dL (normal 86 – 166), C4: 7 (normal 13 - 46), and a urine protein to creatinine ratio (UPCR) 5.9 g/g. Kidney biopsy showed diffuse proliferative GN with polyclonal IG deposits consistent with mixed cryoglobulinic GN (figure 1). An infectious workup, including human immunodeficiency virus (HIV), viral hepatitis, blood and urine culture, and a lumbar puncture were unremarkable. Computed tomography of the chest, abdomen, and pelvis revealed splenomegaly. Echocardiogram and bone marrow biopsy were non-diagnostic. He was treated with rituximab and prednisone with normalization of CG, C3, and C4, a reduction in UPCR to 0.5 g/g and return to full exercise capacity five months later.

Discussion: Mixed cryoglobulinic GN is a rare disorder caused by polyclonal deposition of IG in the kidney. Autoimmune disease, hematological malignancies, and infectious etiologies such as endocarditis, HIV, and viral hepatitis should be ruled out prior to immunosuppressive therapy. Our patient elected to proceed with treatment due to his poor quality of life and evidence of end-organ involvement. Although workup for hematological malignancies was unremarkable, it is unclear if his splenomegaly could be reflective of an underlying indolent lymphoma, which could have simultaneously responded to rituximab treatment.
Case Description: 28-year-old African American man with ESKD secondary to biopsy-proven PLA2R-positive membranous nephropathy undergoing a 2/2 mismatch ABO incompatible living-unrelated kidney transplantation. Induction immunosuppression included methylprednisolone and Thymogobulin. Post-op course was complicated by bleeding and he was taken back to the OR on POD 1. Labs showed anemia (Hgb 7.5 g/dl), thrombocytopenia (PLT 25 k/µl), low haptoglobin (< 10 mg/L), high LDH (580 Units/L), low C3 and normal C4. ADAMTS-13 activity and coagulation profile were normal. Graft function was delayed. This raised concern for a TMA. Tacrolimus was not initiated. Allograft biopsy performed on POD 4 confirmed the diagnosis. Eculizumab was administered, resulting in resolution of anuria and hemolysis, and gradual renal recovery. Genetic testing for complement revealed a ‘variant of uncertain significance’ in CFI (Iso357Met). This variant is located in the serum protease domain of Factor 1 which contains the catalytic site. Functional analysis of the variant using recombinant proteins revealed that it had defective complement regulatory activity. This work established that the CFI variant was deleterious and thus defined the etiopathogenesis of TMA in the patient.

Discussion: This is a case of de novo post-transplant aHUS due to a pathogenic complement mutation, likely triggered by transplant surgery. Our strategy of recombinant protein production followed by detailed functional assessment defined the functional repertoire of the variant protein and provided critical guidance relative to the underlying pathophysiology and appropriate therapeutic regimen.

PO1483

Post-Transplant Thrombotic Microangiopathy due to a Pathogenic Mutation in Complement Factor I

Sanaa J. Shaikh, Maryam Saleem, Anuja Java. Washington University in St. Louis Washington University in St. Louis, St. Louis, MO.

Introduction: Thrombotic microangiopathies (TMA) are life-threatening conditions characterized by hemolytic anemia, thrombocytopenia and AKI. Drug-induced TMA (DITMA) is a diagnostic challenge because specific tests to identify a drug etiology are not available.

Case Description: A 40 yr-old female with history of neurofibromatosis type 2 underwent resection of a T10-11 schwannoma. The surgery was complicated by wound dehiscence which was treated with incision and drainage followed by intravenous vancomycin and cefazolin. The next day, she developed fever, altered mental status and a diffuse purpuric rash (Fig 1). Labs showed anemia (Hgb, 6.2 g/dl), thrombocytopenia (PLT, 15k/µl), elevated LDH and anuric AKI requiring dialysis. C3 and C4 were low. Coombs test was negative. She subsequently developed disseminated intravascular coagulation and elevated liver enzymes. Skin biopsy revealed a leukocytoclastic vasculitis with IgG and complement deposition within vessel walls. Given the concern for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Treatment with prednisone and plasmapheresis was initiated which led to improvement of renal function, mental status and hematoctitic parameters within 48 hrs. Renal biopsy confirmed TMA. ADAMTS-13 activity and complement genetic testing came back not available.

Discussion: This is a rare case of vancomycin-induced TMA. We speculate the mechanism is immune-mediated given the presence of low complement levels (although we did not test for vancomycin-dependent antibodies). Patients with immune-mediated DITMA present with sudden onset of severe systemic symptoms after a short exposure to the implicated drug. Greater awareness with improved methodology for diagnosis of DITMA is critical for clinicians evaluating such patients. Recognition of DITMA and documentation of the drug etiology are essential for patient safety.

PO1482

Vancomycin-Induced Thrombotic Microangiopathy: A Rare Association

Gaurav Rajashekar, Anuja Java. Washington University in St. Louis, St. Louis, MO.

Introduction: Thrombotic microangiopathies (TMA) are life-threatening conditions characterized by hemolytic anemia, thrombocytopenia and AKI. Drug-induced TMA (DITMA) is a diagnostic challenge because specific tests to identify a drug etiology are not available.

Case Description: A 40 yr-old female with history of neurofibromatosis type 2 underwent resection of a T10-11 schwannoma. The surgery was complicated by wound dehiscence which was treated with incision and drainage followed by intravenous vancomycin and cefazolin. The next day, she developed fever, altered mental status and a diffuse purpuric rash (Fig 1). Labs showed anemia (Hgb, 6.2 g/dl), thrombocytopenia (PLT, 15k/µl), elevated LDH and anuric AKI requiring dialysis. C3 and C4 were low. Coombs test was negative. She subsequently developed disseminated intravascular coagulation and elevated liver enzymes. Skin biopsy revealed a leukocytoclastic vasculitis with IgG and complement deposition within vessel walls. Given the concern for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Treatment with prednisone and plasmapheresis was initiated which led to improvement of renal function, mental status and hematoctitic parameters within 48 hrs. Renal biopsy confirmed TMA. ADAMTS-13 activity and complement genetic testing came back not available.

Discussion: This is a rare case of vancomycin-induced TMA. We speculate the mechanism is immune-mediated given the presence of low complement levels (although we did not test for vancomycin-dependent antibodies). Patients with immune-mediated DITMA present with sudden onset of severe systemic symptoms after a short exposure to the implicated drug. Greater awareness with improved methodology for diagnosis of DITMA is critical for clinicians evaluating such patients. Recognition of DITMA and documentation of the drug etiology are essential for patient safety.
PO1485

Minimal Change Disease as a Novel Manifestation of Cytomegalovirus
Andrew Lee, Hsiao L. Lai, Abdullah Thayyil, Reginald I. Obi. ECU Nephrology and Hypertension East Carolina University Division of Health Sciences, Greenville, NC.

Introduction: Cytomegalovirus (CMV) infection is typically asymptomatic among the immunocompetent or can cause a mononucleosis. Among immunosuppressed patients common presentations are colitis, hepatitis, encephalitis, retinitis and even Guillain-Barre syndrome. This case is a rare dissemination of CMV manifesting as acute glomerulopathy.

Case Description: A 67 year-old female with past medical history of lupus, rheumatoid arthritis, and Sjogrens syndrome on maintenance steroids presented with a prolonged cough, joint swelling, shortness of breath and rash consistent with livedo reticularis. She developed worsening weakness in the arms and legs. High dose IV steroids were initiated for presumed rheumatoid vasculitis. Nephrology was consulted for worsening renal function with urine protein to creatinine ratio of 42 g, later requiring hemodialysis for volume management. Work up for nephritic range proteinuria including hepatitis B/C, HIV, SPEP, UPEP, and complement screen was unrevealing. Renal ultrasound demonstrated an 11.7 cm right kidney and 14 cm left kidney. Renal biopsy demonstrated diffuse podocyte effacement and large atypical mononuclear cells within the glomerulus. No immune deposits seen on electron microscopy. Immunohistochemical staining confirmed glomerular CMV. Six weeks after starting treatment with ganciclovir the glomerulus. No immune deposits seen on electron microscopy. Immunohistochemical staining confirmed glomerular CMV. Six weeks after starting treatment with ganciclovir, CMV viral load was undetectable and renal function recovered to baseline.

Discussion: CMV involvement of the kidney is unusual aside from tubulointerstitial nephritis. Rare cases of collapsing glomerulopathy and focal segmental glomerular sclerosis are found in literature. We report a novel presentation of CMV glomerulopathy with minimal change disease and renal failure. To prevent tissue invasive CMV in a chronically immune suppressed patient one needs to maintain clinical suspicion for infectious pathogens and perform tissue biopsy.

Minimal Change Disease Following the mRNA-1273 Vaccine in a Kidney Transplant Recipient
Juanly N. Rodriguez, Shobana Sivan, Mariella O. Thayyil, Reginald I. Obi. University of Miami School of Medicine, Miami, FL.

Introduction: Kidney transplant recipients (KTR) are susceptible to post-transplant glomerulopathies. Minimal change disease (MCD) is seen rarely. Few cases have been reported post-immunization, recently with the Pfizer-BioNTech vaccine against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report a case of de novo MCD after mRNA-1273 vaccine in a deceased donor KTR with sudden onset nephritic syndrome (NS) and acute kidney injury (AKI) a week after the first dose.

Case Description: 45-yo woman with history of ESKD from lupus nephritis, underwent DDKT on 09/2019 from a 20-y Caucasian male, kidney donor profile index 16%, calculated panel reactive antibody 0%. Complicated by delayed graft function. On day 27 post-transplantation serum creatinine (Scr) improved to 0.8 mg/dl. Maintenance immunosuppression tacrolimus and mycophenolic acid. 11 months post-KT contracted COVID-19 pneumonia, managed conservatively. 6 months later developed anasarca 4 days post mRNA-1273 vaccine in a deceased donor KTR, with sudden onset nephritic syndrome (NS) and acute kidney injury (AKI) a week after the first dose.

Discussion: This is a seropositive SARS-CoV-2 KTR from previous COVID-19 pneumonia developed NS. Contrasting mRNA vaccine mRNA vaccines contain mRNA that does not enter the cell nucleus and directs the cell to produce a protein that elicits an immune response. The cell is not infected or damaged. mRNA vaccines transcribed into mRNA, synthesized by the ribosome, translated into protein, and the immune system recognizes and mounts a response. This case may represent a rare association between SAPHO and IgA nephropathy.
Kidney biopsy for IgA case depicting membranoproliferative pattern of glomerular injury in patient with SAPHO syndrome

PO1489
Crescentic Pauci-Immune Glomerulonephritis in a Patient with Sickle Cell Anemia and Cocaine Abuse
Marimar Contreras Nieves, Stanford Medicine, Stanford, CA.

Introduction: Levamisole is an anthelmintic agent and a common contaminant found in cocaine. It has been linked to ANCA-associated vasculitis with cutaneous, and more rarely, renal and pulmonary manifestations. This is the case of a patient with sickle cell anemia and cocaine abuse presenting with acute kidney injury (AKI) and nephrotic-range proteinuria.

Case Description: A 58-year-old male with history of sickle cell anemia, CKD Stage 3, hypertension, and cocaine abuse, was admitted for epidermidis and found to have AKI. He presented with testicular pain, as well as right knee and back pain. Initial workup revealed a creatinine of 2.45 mg/dL, from baseline of 1.8 mg/dL. Urine toxicology was positive for cocaine. His urine studies were consistent with intrinsic renal disease.

He received red blood cell exchange transfusion, but he continued with worsening renal function following the procedure. His 24-hr urine collection revealed 6.2 g proteinuria. Extensive workup included normal C3 and C4, positive rheumatoid factor, negative UPEP, free kappa/lambda light chain ratio 1.8, negative HIV and anti-HCV, hepatitis B immunity, negative c-ANCA, but positive p-ANCA and anti-MPO. Patient chronically smoked cocaine, sometimes cut with levamisole, which is associated with vasculitis.

A kidney biopsy! performed, with pathology showing a pauci-immune glomerulonephritis, necrotizing crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy. He was treated with pulse dose steroids and rituximab, followed by maintenance prednisone and additional doses of rituximab after discharge. His renal function improved, but did not return to baseline, which could have been due to his degree of kidney injury and ongoing cocaine use after discharge.

Discussion: This case demonstrates the importance of keeping a broad differential diagnosis in the evaluation of AKI and nephrotic-range proteinuria in sickle cell anemia, particularly in the setting of cocaine use and its known association with levamisole.

Although sickle cell nephropathy could have explained this patient’s presentation, a broader workup was key to arrive to the correct diagnosis, and therefore prompt treatment.

PO1490
A Case of Rapid Progressive Glomerulonephritis Associated with Disseminated Gonococcal Infection
Safa Osman, Nihal M. Ali, Pradeep Varita, Franco H. Cabeza Rivera. The University of Mississippi Medical Center, Jackson, MS.

Introduction: Disseminated gonococcal infection (DGI) results from bacteremic spread of the sexually transmitted pathogen, Neisseria gonorrhoeae. Direct and immunological damage of multiple organs can be seen. We are reporting a case of sterile DGI with RPGN as part of the initial presentation.

Case Description: A 60-years old male with a 5-year history of seronegative spondyloarthropathy, hypertension, heart failure, poor dentition who presented to the hospital with shortness of breathing, diarrhea, joint pain, and palpable purpura ongoing for several weeks. Work-up revealed severe anemia and rapidly progressive acute renal failure (Baseline creatinine unknown, peaked at 7.2 mg/dL on admission), urine showed 9.3 g of proteinuria, hematuria, and pyuria. Serological w/up showed low C3 with normal C4, ASO, ANA, ANCA and anti GBM. Negative HIV, hepatitis B, C, syphilis serologies, monoclonals, and cryoglobulins. Skin biopsy showed leukocytoclastic vasculitis which improved with steroids. Kidney biopsy showed crescentic glomerulonephritis (GN) with 10% IFTA likely due to infectious GN (RPGN). Patient completed 3-day course of ceftriaxone but left before ceftriaxone could be initiated. A week later he presented with persistent hematuria and oliguria. Echocardiogram showed tricuspid endocarditis and leaflet perforation. Blood cultures were negative. Patient started on vancomycin and Rocephin for culture negative endocarditis. Extensive infectious disease workup, metagenomics test showed Neisseria gonorrhoeae as the cause of endocarditis. Kidney function improved. Due to disseminated GC and concern for complement deficiency, he was referred to Adult Immunology clinic.

Discussion: DGI is estimated to occur in up to 3 percent of patients infected with N. gonorrhoeae. The probability that a localized gonococcal infection will spread to joints and other tissues depends upon specific host, microbial, and possibly immune factors.

RPNG is unusual presentation, the immunopathogenesis is uncertain but immunological and hypersensitivity damage is postulated based on the frequent lack of N. gonorrhoeae growth from blood, skin, and synovial fluid cultures during disseminated infection. Congenital or acquired complement deficiencies (C5, C6, C7, or C8) predispose to DGI as a result of decreased complement-mediated killing of N. gonorrhoeae.

PO1491
Proliferative Glomerulonephritis with Monoclonal IgM Deposits in ANCA Vasculitis
Rama Kethineni, Marc Barry, Monica P. Revelo Penafiel, Janane J. Kotkey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNMID) is a rare entity of unclear etiology that can be occasionally associated with an underlying hemato logical malignancy. We report a case of PGNMID in a patient with ANCA vasculitis.

Case Description: A 78 yr old female with hypertension presented with a history of recurrent sinusitis over 6 months that was treated with steroids and antibiotics. She had progressive weight loss, fatigue, cough, and dyspnea. Chest X-ray was normal prompting a CT chest, which showed bilateral pulmonary nodules. Her creatinine was 0.96mg/dL. Urine analysis was notable for hematuria. Antineutrophil cytoplasmic antibodies were positive at 1: 640 with myeloperoxidase Abs IgG of 199. Serum protein electrophoresis showed a normal pattern with no monoclonal spike on immunofixation electrophoresis. Her Kappa/Lambda light chain ratio was normal at 1.04, infections were ruled out, and cryoglobulin was not detected. She was started on prednisone 60 mg and had a renal biopsy. Renal biopsy showed focal segmental necrotizing glomerulonephritis, mesangial hypercellularity with deposition of IgM with lambda light chains restriction on immunofluorescence and occasional mesangial and subendothelial granular electron densities on electron microscopy. She was referred to hematology for concern with monoclonal gammopathy of renal significance and had a negative evaluation on serological tests, bone marrow biopsy and PET CT scan. She was treated with Rituximab. Her creatinine had remained stable with resolution of hematuria and respiratory symptoms.

Discussion: PGNMID is an immune complex glomerulonephritis that is occasionally associated with a hemoglobinopathy malignancy. The pathophysiology remains elusive and treatment can be challenging. We present a case of PGNMID with monoclonal IgM with light lambda chain restriction with an unusual association with ANCA vasculitis.
severe interstitial fibrosis and tubular atrophy indicating MPA. Patient was treated with pulse steroid and plasma pheresis initially, later received Rituximab. Patient improved clinically with therapy. Later, serum creatinine plateaued around 3.6 with eGFR 15.6 indicating patient’s CKD had progressed to advanced CKD stage 4/5.

**Discussion:** Though the presence of AAV is not common in MCTD, this case illustrates the importance of considering AAV for worsening pulmonary and renal function in overlap syndrome. Microscopic polyangiitis is one of the most common causes of pulmonary-renal syndrome. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis.

**Case Description:** The patient is a 32-year old woman with diffuse systemic sclerosis complicated by pulmonary fibrosis who had been treated with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antineutrophil antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL).

Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

**Discussion:** Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

**PO1493**

Nephrotic Range Proteinuria due to ANCA-Associated Vasculitis in a Diffuse Systemic Sclerosis Patient: A Rare Presentation

Pranav Sharma, Steve I. Khalil, Jonathan Lebowitz. Rutgers University New Brunswick, New Brunswick, NJ.

**Introduction:** Scleroderma renal crisis (SRC) is a severe complication of SSc and typically presents with new-onset hypertension and a reduction in renal functioning. Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a rare co-occurrence with SSc. We present a rare case of diffuse systemic sclerosis who presented with features of SRC and AAV with nephrotic range proteinuria without significant renal failure.

**Case Description:** The patient is a 32-year old woman with diffuse systemic sclerosis complicated by pulmonary fibrosis who had been treated with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antineutrophil antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL).

Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

**Discussion:** Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

**PO1494**

Filgrastim-Induced ANCA-Associated Glomerulonephritis in the Presence of Membranous “Full House Nephropathy"

Ayial Angel-Korman, Adi Leiba. Ashdod Ashdod Hospital, Ashdod, Israel; Harvard Medical School, Boston, MA.

**Introduction:** G-CSF is commonly used to stimulate progenitor cell collection for bone marrow transplantation. We present a seemingly healthy altruistic bone marrow donor who developed glomerulonephritis secondary to G-CSF treatment.

**Case Description:** A 34-year old man presented after altruistic bone marrow donation. During G-CSF treatment he developed headache, epistaxis, painless macrohematuria and AKI (creatinine- 2.91 mg/dl). Seven years and one year prior to this event he had similar episodes of macrohematuria, AKI and proteinuria. In between episodes he had persistent microhematuria. All other serologies were unremarkable. A kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed pulmonary hemorrhages. Ivermectin was discontinued. He received prednisone 1mg/kg, 3 biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antineutrophil antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL). Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

**Discussion:** Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

**PO1495**

Ivermectin-Induced ANCA Vasculitis

Shuchi Pandey,1 Hemant Magoo,1 Ashish Verma,1 Sudhir Perincheri,2 Saint Vincent Hospital, Worcester, MA; 2Yale-New Haven Hospital, New Haven, CT.

**Introduction:** Ivermectin is an antiparasitic agent that has demonstrated antiviral potential against HIV-1, Dengue, Zika viruses and most recently, COVID-19. The rampant self-medication and off-label use for COVID prophylaxis in some countries is cause for concern. Here, we present what may be the first reported case of ANCA-associated vasculitis (AAV) from Ivermectin use.

**Case Description:** A 56-year male with no significant past medical history presented with dark urine, epistaxis, conjunctival redness, arthralgias, and malaise. His mother was on dialysis for the past few years for ESRD of unknown etiology. For several months, he had been taking Ivermectin imported from Peru for COVID prophylaxis per family advice. He was on no other medications. His creatinine, normal at baseline, was now 4.5mg/dl. He had hematuria, 3g/d proteinuria, dysmorphic RBCs and RBC casts. Serum C3, C4, ANA, anti-dsDNA, anti-GBM, hepatitisB&C screen, SPEP&UPEP were negative. Atypical and p-ANCA were negative, but c-ANCA was 1:640. Kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed pulmonary hemorrhages. Ivermectin was discontinued. He received prednisone 1mg/kg, 3 biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was initiated on dialysis. Four weeks later, he has no epistaxis or pulmonary hemorrhages and is off oxygen. He does remain dialysis-dependent.

**Discussion:** Drug exposure can trigger ANCA formation against myeloperoxidase (MPO) and, less commonly, proteinase 3 (PR3). Drug-associated AAV can’t be discerned from primary AAV based on clinical and pathological findings. Clues suggesting drug-associated AAV include a temporal relationship of symptom onset with suspected drug, a high ANCA titer, and positive autoantibodies like elastase and myeloperoxidase. Drug-associated AAV has a better prognosis than its primary counterpart, with symptoms often resolving with drug withdrawal. Though this may not suffice in cases with pulmonary and renal involvement, outcomes in drug-associated AAV remain comparable even with shorter induction and often no maintenance regimens. Commonly implicated drugs are hydralazine, levamisole-contaminated cocaine, propylthiouracil, allopurinol.
Although no case of Ivermectin-induced AAV has been reported, we recommend a high
index of suspicion as prompt cessation of the offending drug can significantly improve
prognosis in drug-associated AAV.

PO1496
Myeloperoxidase-ANCA and Takayasu Arteritis Overlap Syndrome
Presenting as Rapidly Progressive Glomerulonephritis

Introduction: The spectrum of vasculitides is classified according to the size of
the vessels involved and the clinical and histopathological findings. The simultaneous
involvement of Takayasu arteritis and myeloperoxidase-ANCA vasculitis is extremely rare
Case Description: A 12-year-old female with no previous medical history. In the last
two years she has developed lower limb claudication and unexplained intermittent
fever. In recent weeks she developed edema and oliguria, she was admitted in another
hospital where she was started on renal replacement therapy. Large vessel involvement
was suspected so a contrast enhanced CT was ordered and was compatible with Takayasu
arteritis. The patient was referred to our hospital for evaluation. During nephrology
assessment she was found to have acute kidney disease with massive proteinuria (16 g/dl),
so work up was directed towards rapidly progressive kidney disease. Percutaneous kidney
biopsy was performed, and it revealed pauci-immune crescentic glomerulonephritis.
ANCAs and glomerular basement membrane antibodies were ordered, with a positive
MPO-ANCA result. She was then started on IV methylprednisolone pulses and 5 cycles of
plasma exchange therapy. After this, rituximab was started on a weekly basis. The
patient has not recovered kidney function and is still dependent on hemodialysis therapy,
pending to finish the final two rituximab doses.

Discussion: This an extremely rare case which highlights the diagnostic and therapeutic
difficulties in patients presenting with overlap clinical and serological features
of different forms of systemic vasculitis.

PO1497
Granulocyte Colony Stimulating Factor-Associated Vasculitis: Adding Fuel to the Fire
Nilem Patel, Ahmed Siddiqui, Pravir V. Baxi. Rush University Medical Center, Chicago, IL.

Introduction: Granulocyte colony-stimulating factor (G-CSF) is commonly used
with chemotherapy to stimulate bone marrow production and prevent neutropenia.
Although usually well tolerated, G-CSF can exacerbate underlying autoimmune
diseases with the development or progression of glomerulonephritis (GN). We present a case
of pauci-immune necrotizing GN that developed in a patient with rheumatoid arthritis (RA)
after receiving G-CSF therapy.

Case Description: A 61 y/o man with ampullary adenocarcinoma and RA without
prior renal involvement presented with AKI. One week prior to admission he had received
5th cycle of FOLFOX and a first dose of G-CSF. His creatinine (Cr) was 4.8 mg/dL
from a baseline of 0.9 mg/dL. His urinalysis was notable for hematuria and urine protein-
creatinine ratio (UPC) of 5.2 g/g. Workup showed: +p-ANCA (1:320), -anti-histone Ab,
+SSA and +ANA (1:1280 speckled pattern). A renal biopsy revealed necrotizing GN with
necrosis or crescents in 75% of the glomeruli. There was no evidence of immune
deposits/c-PAuci-immune GN. He received steroids and rituximab for induction. His
Cr peaked at 6.0 mg/dL but improved down to 1.1 and UPC improved to 0.6 g/g after
3 months.

Discussion: G-CSF is used to prevent neutropenia and reduce infection risk by
activating mature neutrophils and preventing neutrophil apoptosis. G-CSF can also have
inflammatory effects including the release of proinflammatory cytokines and tissue
infiltration by activated neutrophils with the potential of end-organ damage. In patients with
preexisting GN or an autoimmune disease (eg, RA, SLE), G-CSF administration can
exacerbate or even initiate a de-novo GN. Pauci-immune GN is a rare but well established
complication of RA. In our case, the almost immediate temporal relationship between
the development of the GN and the G-CSF administration supports G-CSF as etiologic.
This case demonstrates the importance of considering the possible renal complications
and need for close monitoring while giving G-CSF in patients with autoimmune diseases.

PO1498
Spontaneously Resolved Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits
Salma Shaikhouni, Alexandria M. Peirce, Andrea L. Oliverio, Laura H. Mariani. University of Michigan, Ann Arbor, MI.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is thought to be a progressive disease, with early studies showing
38% of patients with persistent renal dysfunction and 22% progressing to ESKD within a
30 month follow up period. We present two cases of PGNMID who achieved spontaneous
remission without directed therapy.

Case Description: Case 1: A 53 yo woman with hypertension and diabetes presented
for evaluation of proteinuria with UPCR 3.86 g/g and normal creatinine. She was
asymptomatic, but had an upper respiratory infection 1 month prior. Serologic evaluation
for nephrotic range proteinuria was unrevealing. Renal biopsy showed PGNMID with
IgG A light chain deposits. Serum paraprotein was not detected. Bone marrow biopsy
showed no concern for malignancy. UPCR decreased to 0.63 within 4 months with no
therapy but an ACEi. Case 2: A 53 yo man with primary biliary cholangitis presented
with edema and new hypertension. He was found to have AKI with SCR 1.85 mg/dL,
UPCR of 12.9 g/g, and microscopic hematuria. While serum autoimmune markers were
notable for mildly elevated anti-dsDNA (75 IU/mL), normal C3 and low C4 (8 mg/dL),
renal biopsy revealed PGNMID with IgG A light chain deposits. A low titer IgM k was
detected in the serum. The patient had diffuse lymphadenopathy on imaging, and two
exocytotic biopsies showed reactive follicular hyperplasia. Bone marrow biopsy was
normal. UPCR decreased to 1.23 g/g within 2.5 months of presentation and SCR down to
1.22 without any therapy.

Discussion: These unique cases demonstrate that PGNMID is likely a heterogeneous
disease whose pathogenesis and natural history is poorly understood. We hypothesize
that an infectious antigen or autoantigen may induce clonal proliferation of B-cells and
the formation of transient monoclonal antibodies leading to complement activation
and proliferative glomerulonephritis. When the stimulus is controlled, the associated
immune response is resolved. Our patients did not require any immunomodulatory
therapy, contrary to most recent case series. Recognition of the potential for spontaneous
remission in PGNMID has important implications on treatment paradigms for this
emerging diagnosis.
PO1500

**Pemphigus vulgaris and PLA2R-associated Membranous Nephropathy:**

*Two IgG4-related Diseases in the Same Patient*

Camila L. Costa,1 Matheus R. Correia,2 Luis H. Sette,2 Denise M. Costa,2 Camila B. Oliveira,3 Maria Alina G. Cavalcante,3 Lucila Maria Valente,1 Gisele Vajgel.1 1Hospital dos Servidores do Estado de Pernambuco, Recife, Brazil; 2Hospital Getulio Vargas, Recife, Brazil; 3Universidade Federal de Pernambuco, Recife, Brazil.

**Introduction:** The relationship between bullous skin diseases and glomerulopathies has been increasingly recognised. Other bullous diseases were previously reported in association with membranous nephropathy (MN), but the association between pemphigus vulgaris (PV) and pemphigus vulgaris (PV) has not been reported in the letter between MN.

**Case Description:** A 39-years-old smoker woman presented with trunk blisters and worsened mouth ulcers after stopping the treatment for MN. One year before she had nephrotic syndrome and the kidney biopsy was positive for anti-PLA2R and IgG4 (and negative for THSD7A) in the immunohistochemistry (IHQ). Serum anti-PLA2R was negative. Four months earlier she was started on cyclosporine, but stopped it due to mouth ulcers. She had nephrotic range proteinuria, no edema, when the painful blisters spread out on the trunk, back, limbs, scalp as well as ulcers of the oral cavity and esophagus. The diagnosis of PV was confirmed by skin and esophagus biopsy and IHQ showed the presence of IgG4 subclass antibody in the epithelial tissue. She received pulse and oral steroids along with azathioprine for the PV. The skin lesions were slowly healing and no more new blisters have appeared.

**Discussion:** The humoral auto-immune response in pemphigus produces anti-desmoglein 1 and 3, both IgG4. Desmogleins are responsible for adhesion in stratified squamous epithelia, when damaged produces to the blistering eruptions. There is a genetic predisposition between PV and MN, with HALA-DQA1, HALA-DRB1 and the thrombospondin gene (THSD7A). Environmental factors such as smoking and air pollution could act as a second trigger for the development of auto-immune diseases. PLA2R can be expressed in the bronchiolar tissue and in macrophages of the lung, however there is no evidence of histological damage in the pulmonary tissue. Although we found no description on the expression of PLA2R in the skin, in an attempt to find a common antigen for both diseases, we did search for anti-PLA2R in the skin, but it was negative. In conclusion, this is the first described case of association of pemphigus vulgaris and PLA2R-associated MN, both IgG4-related conditions that involve the production of different autoantibodies directed to skin and kidney antigens.

**PO1501**

A Case of an Elderly Woman with Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits Whose Renal Biopsy Revealed Renal Cell Carcinoma

**Introduction:** Membranous-like glomerulopathy with masked monoclonal IgG deposits (MGIMID) is a recently described form of glomerulopathy with a unique histopathology reported by Larsen et al. The pattern is characterized by subepithelial and/or subendothelial immune deposits that are “masked”, to immunoglobulin staining by routine immunofluorescence but strongly stained for IgG and kappa light chain after protease digestion. Patients with MGIMID are commonly young females and have a vague history of autoimmune diseases such as low titer antinuclear antibodies.

**Case Description:** A 65-year-old woman was referred to our hospital with urinary protein (0.80 g/gCr) and microscopic hematuria. Serum antinuclear antibody, rheumatoid factor, and M-protein were negative and serum C3 and C4 were normal. Plain CT showed no neoplastic lesions in the kidney, and a renal biopsy was performed. Part of kidney biopsy tissue contained clear cell renal carcinoma (RCC). Light microscopy revealed increased mesangial matrix and partial thickening and double contour of the basement membrane. Immunofluorescence examination of the frozen sections was negative for IgG and C3. Electron microscopy revealed electron dense deposits in both the subepithelium and mesangium (Churg classification stage II). After protease digestion, paraffin-embedded sections were stained again, and IgG and kappa light chain were strongly positive in granular pattern along the basement membrane (IgG subclass: IgG1/IgG4). Staining for anti-PLA2R/THSD7A antibody was negative, and staining for anti-serum amyloid P antibody was positive. Based on the above, this patient was diagnosed as MGIMID. Subsequently, she underwent a partial nephrectomy for RCC, and her urinary protein decreased significantly.

**Discussion:** Although most patients with MGIMID are young women (<40 years), this patient was an elderly woman with RCC. IgA nephropathy and membranous nephropathy have been reported as glomerular lesions associated with RCC. In this case, the proteinuria decreased after RCC resection, suggesting that RCC may be related to the development of MGIMID in elderly patients, although the details are unknown. This is the first case of MGIMID in Japan.
polyclonal increase in gamma globulins. It is likely that in some patients with lupus, B cell regulation becomes impaired in a way that allows a clonal, but not necessarily neoplastic, an expansion that results in increased production of paraproteins, leading to MGUS. This case adds to the literature showing that there indeed may be an association between MGUS and lupus.

PO1504

Bartonella Henselae Infective Endocarditis (BHIE): A Rare Cause of Pauci-Immune Necrotizing GN (PINGN)

Muhammad A. Shahzad, Ami Purohit, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Introduction: Bartonella is the commonest cause of culture negative endocarditis. While, Infection Related GN (IRGN) can mimic pauci-immune vasculitis, the majority of cases of BHIE have been immune complex (IC) mediated. We present a rare case of BHIE related PINGN. Timely recognition of this atypical presentation led to appropriate medical therapy.

Case Description: A 33 yo M with HIV on HAART and recent tooth extraction was admitted with a severe headache due to a sub arachnoid hemorrhage from a ruptured right anterior cerebral artery aneurysm. TEE showed a vegetation on the aortic valve (AV). Blood cultures were negative. Initial SCR was 3.3 mg/dl and urinalysis had 2+ protein, 3+ blood with 29 RBC/hpf and a UPro/Cr ratio was 1.7 g/l. The C4 was low (10.2 mg/dL) and PR3-ANCA elevated-4.0 (NL <3.5 U/mL). The Bartonella henselae IgG titer was elevated-1.5 (NL <1.320). Renal biopsy revealed pauci-immune necrotizing GN (Figure) with no evidence of IC deposition. BHIE associated PINGN was diagnosed and treatment with doxycycline, ceftriaxone and gentamicin initiated. The AV was replaced and was positive for BH by PCR. After a prolonged course of antibiotics the SCR improved to 2.5 mg/dl.

Discussion: B henselae associated GN is a rare cause of PR3-ANCA positive GN with only 6 cases previously reported. By immunofluorescence, 4 cases were immune complex (IC) mediated. We present a rare case of BHIE related PINGN. Timely recognition of this atypical presentation led to appropriate medical therapy.

PO1505

Atypical Hemolytic Uremic Syndrome and Systemic Lupus Erythematosus-Dermatomyositis Overlap: A Challenging Scenario

Yelena R. Drexler, Juanly N. Rodriguez. University of Miami School of Medicine, Miami, FL.

Introduction: Overlap syndromes are rare disorders wherein at least two systemic autoimmune diseases meet diagnostic criteria. We present a case of atypical hemolytic uremic syndrome (aHUS) in a patient with systemic lupus erythematosus (SLE) and anti-melanoma differentiation-associated gene 5 antibody (anti-MDA5) dermatomyositis (DM) overlap.

Case Description: A 45-year-old woman with SLE diagnosed 8mo prior, treated with belimumab and prednisone, developed proximal muscle weakness, violaceous erythema of eyelids, neck, hands and feet with ulcers. Three weeks later, she presented with abdominal pain, shock and respiratory failure. Testing showed WBC 19,200/uL, lipase >600 and ionized calcium 0.47 mmol/L, acute kidney injury (BUN 64 mg/dL, SCR 2.4 mg/dL); anemia (Hb 7.1 g/dL); and thrombocytopenia (PLT 24,000). CT showed pancreatitis and biliary ductal dilatation. Given oliguria and hypocalcemia despite high-dose calcium infusion, she initiated renal replacement therapy. Further workup showed low C3 level 42, C4 level 7, elevated anti-dsDNA Ab 237 IU/ml and UPCR 2.2 g/g; haptoglobin <10, LDH 1,371 U/L. Positive direct Coombs, schistocytes on smear and ADAMTS13 activity 18%. Due to autoimmun vs microangiopathic hemolytic anemia, received pulse therapy with IVIG and IV methylprednisolone and IV cyclophosphamide. She then started eculizumab. Within 7d, LDH decreased to 772, haptoglobin increased to 79 and platelets normalized. Further workup revealed elevated creatinine kinase 1,271 U/L, aldolase 17 U/L, AST 566 U/L with normal ALT and positive anti-MDA5 and transcription intermediary factor 1-gamma (TIF-1γ) Abs, meeting criteria for DM. Patient continued eculizumab and prednisone. Eventually developed invasive aspergillosis and expired.

Discussion: We report a case of SLE-DM overlap with anti-MDA5 and TIF-1γ Abs complicated by aHUS and severe hypocalcemia in the setting of pancreatitis. The cutaneous manifestations are typical of MDA5-associated DM. Our patient did not develop intestinal lung disease, exemplifying range of variation from case to case. The presence of anti-TIF-1γ confers a 6-fold increased malignancy risk; finding of omental nodularity in this case would warrant further investigation. aHUS as a complication of SLE-DM overlap is rare, with mortality risk up to 52%. AKI, infection and low C3 are associated with highest mortality. Prompt diagnosis, high clinical suspicion and early initiation of eculizumab resulted in a rapid response.

PO1506

Anti-LRP2 Nephropathy in a Patient with Chronic Lymphocytic Leukemia

Derek Tran, Chien-Wen Yang, Avantika Israni, Allahbuddin Garea, Al J. Lee, St Mary Medical Center, Langhorne, PA; Penn Medicine, Philadelphia, PA.

Introduction: Anti-LRP2-anti-Brush Border Border nephropathy is a newly identified autoantibodies tubulointerstitial nephritis triggered by circulating antibodies to low-density lipoprotein receptor-related lipoprotein 2 (LRP2). We present a case of anti-LRP2 nephropathy in a patient with chronic lymphocytic leukemia (CLL).

Case Description: A 74-year-old Caucasian male patient known to have CLL presented following a fall with a forearm laceration. At presentation, he had acute renal failure (SCR of 5.04 mg/dl) and severe thrombocytopenia (platelets of 11,000/uL).

Additional evaluation showed positive ANA and p-ANCA. The patient had proteinuria of 1754 mg/g of creatinine. The kidney biopsy showed moderate interstitial fibrosis and tubular atrophy involving 30-40% of the renal cortex. The tubular epithelium showed reactive-appearing nuclei as well as cytoplasmic thinning with loss of the proximal tubular brush border. Immunofluorescence showed IgG(3+) and C3 (3+) for the glomerular capillary and the TBM. There was focal staining of the brush border by IgG with positive LRP2 stain in the TBM. Electron microscopy revealed numerous subepithelial electron-dense deposits. The serum anti-LRP2 antibody titer was 1:100. The patient was started on dexamethasone and rituximab with improvement of the thrombocytopenia. Plasmapheresis was prescribed for 5 sessions, the creatinine continued to worsen (sCr of 7.73 mg/dL), and the anti-LRP2 titer did not improve. The patient is being transitioned to renal replacement therapy.

Discussion: The mechanism that links the ABBA disease with lymphoproliferative disease is still unknown. The current reported cases suggest an association between direct lymphoma renal infiltration, progression of the lymphoproliferative disease and the presence of the ABBA disease. However, in our reported case, the patient’s underlying CLL was stable without evidence of renal infiltration. The poor response to treatment in this case is consistent with the poor outcomes of many anti-LRP2 reported cases. The renal biopsy on this patient also showed membranous glomerulonephritis. We presented a case with anti-LRP2 nephropathy/ABBA disease with concurrent CLL without evidence of LRP2 infiltration which is rare. In our opinion, prompt diagnosis and timely initiation of appropriate therapy the prognosis of ABBA associated paraneoplastic syndrome with underlying CLL warrants future investigation.

PO1507

Black Tar Heroin and AA Amyloidosis

Rama Kethineni, Monique E. Cho, Monica P. Revelo Penafiel, Olesya Ilkun, Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: AA amyloidosis due to deposition of serum amyloid A protein occurs as a secondary reaction to chronic inflammatory disease, chronic infections, and familial period fever syndromes. We present a case of AA amyloidosis secondary to chronic black tar heroin use in the Intermountain West.

Case Description: A 61 yr. old Caucasian female with a history of Hepatitis C, IV Heroin use presented with bilateral leg pain, swelling, and abdominal distension. Examination was significant for ulceration in lower extremities with purulent discharges. Notable lab data include Hemoglobin of 8.2 g/dL, potassium of 6 meq/L, calcium of 10.6 mg/dl, BUN of 90 mg/dl, creatinine of 2.9 mg/dl, serum albumin of 2.1 g/dl, and ESR of 129 mm/hour. She had a urine protein to creatinine ratio of 12.3 g/g. Abdominal US revealed enlarged liver and normal renal echogenicity. The quantification of HCV RNA by polymerase chain reaction was negative, and her complement levels were within normal range. Cryoglobulin was also negative with a kappa/lambda light chain ratio of 1.33. Serum protein electrophoresis showed decreased albumin and immunofixation electrophoresis showed a faint band in IgG kappa suggestive of a specific immune response. An early morning bone marrow biopsy showed non-AL amyloid deposition involving glomeruli, and arteries. Mass spectrometry performed at Mayo Clinic Laboratories confirmed renal involvement by Amyloidosis, AA (serum amyloid A)-type.

Discussion: “Black tar heroin” has increasingly been identified as a risk factor for AA Amyloidosis. Impurities in heroin promote vascular sclerosis and lead to the use of injection into muscle and skin. The suppurative infections that follow stimulate

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

473
the production of serum amyloid A protein with subsequent deposition in the kidney leading to nephrotic syndrome and end stage kidney disease. Greater awareness of this complication may help prevention in areas with increased black tar heroin use.

**Discussion:** Proteinuria is one of the lesser known side effects of statin therapy. It was reviewed in the clinical development programme for Rosuvastatin, where it was found that the 80 mg dose caused proteinuria in 12% of patients. Furthermore, a comprehensive review of the renal effects of rosuvastatin, found that 1.2% of patients taking 40 mg of rosuvastatin developed 2+ proteinuria, and 0.3% developed 2+ proteinuria and 1+ hematuria. Our case highlights a rare manifestation of Rosuvastatin induced urinary abnormalities, which improve after stopping the drug. This should be kept in mind for patients on Rosuvastatin with negative workup for proteinuria and hematuria, before a renal biopsy is pursued.

**Rituximab for Membranous Nephropathy in a Patient with Sjögren Syndrome and Mixed-Connective Tissue Disease**

*Joshua D. Pollock, Maurice I. Khayat, Madigan Army Medical Center, Tacoma, WA.*

**Introduction:** Membranous nephropathy (MN), a cause of nephrotic syndrome, is characterized by the deposition of immune complexes in the glomerular basement membrane with resultant subepithelial “spikes” visualized under light microscopy. Although often a primary disease process, several secondary etiologies exist, including Sjögren’s syndrome (SS) and mixed-connective tissue disease (MCTD). Treatment typically targets the underlying condition. Despite rituximab’s demonstrated efficacy in MN, MCTD and SS, case reports for specific treatment of MN secondary to these conditions have primarily described regimens of systemic corticosteroids with or without cyclophosphamide.

**Case Description:** A 54-year-old male was diagnosed with MN on renal biopsy in 2001. Several features suggested secondary etiology (tubulo-interstitial, mild to moderate proteinuria and tubular interstitial chronic injury likely secondary to arteriosclerosis). There was no right hydronephrosis or renal vein thrombosis seen on imaging. Serological testing including ANCA, HBsAg, Hep C ab, HIV, RVP, COVID-19 PCR, Parvovirus B19 PCR, and CMV PCR were all negative. Patient initially received diuretic therapy for LE edema. Kidney biopsy performed during hospital stay showed CG and acute tubular injury. Electrolyte microscopy examination of kidney biopsy specimen was significant for extensive effacement of podocyte foot processes and rare tubuloreticular inclusions in endothelial cell cytoplasm. Scr rapidly worsened to 7.98 and HD treatment was initiated. Our patient was also initiated on daily high dose oral corticosteroid therapy.

**Discussion:** Guselkumab, an IL-23 blocker is FDA approved for the treatment of plaque psoriasis and active psoriatic arthritis. A case of Ustekinumab (IL-12/23 inhibitor) associated FSGS (after 2 years of treatment) has been reported in the literature. Our patient while on chronic Guselkumab treatment developed rapidly worsening AKI and CG, a week following the last dose of Guselkumab. We believe that in absence of any additional known risk factors, Guselkumab was responsible for AKI and CG in our patient. Our patient currently remains dialysis dependent. Clinicians should be aware of this very rare but potential association.

**PO1508**

**Guselkumab-Associated Severe AKI from Collapsing Glomerulopathy**

*Varun Madireddy, Deepa A. Malieckal, Boonyanuth N. Maturotrakul, Philip S. Yune, Vanesa Bijol, Hitesh H. Shah, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

**Introduction:** Collapsing glomerulopathy (CG) has been commonly associated with viral infections, mainly HIV. Several medications have also been associated with CG. We present the first case of Guselkumab-associated rapidly progressive AKI from CG and acute tubular injury.

**Case Description:** 86-year-old African American female with history of HTN, RCC with left nephrectomy, CKD, CHF, and psoriasis (on Guselkumab treatment since 2018) presented to our hospital for worsening bilateral LE edema and AKI. On presentation, Scr was elevated at 3.75 and serum albumin was WNL (3.5). Three weeks prior to presentation, Scr was elevated but stable at 1.77 on outpatient labs. Of significance, pt. received Guselkumab injection one week prior to presentation. During hospital stay, UA was significant for proteinuria and hematuria. Spot urine total protein-to-creatinine ratio (TPCR) was significantly elevated at 13.7. Of note, spot urine TPCR was 1.6, four months prior to presentation. There was no right hydronephrosis or renal vein thrombosis seen on imaging. Serological testing including ANCA, HBsAg, Hep C ab, HIV, RVP, COVID-19 PCR, Parvovirus B19 PCR, and CMV PCR were all negative. Patient initially received diuretic therapy for LE edema. Kidney biopsy performed during hospital stay showed CG and acute tubular injury. Electrolyte microscopy examination of kidney biopsy specimen was significant for extensive effacement of podocyte foot processes and rare tubuloreticular inclusions in endothelial cell cytoplasm. Scr rapidly worsened to 7.98 and HD treatment was initiated. Our patient was also initiated on daily high dose oral corticosteroid therapy.

**Discussion:** Guselkumab, an IL-23 blocker is FDA approved for the treatment of plaque psoriasis and active psoriatic arthritis. A case of Ustekinumab (IL-12/23 inhibitor) associated FSGS (after 2 years of treatment) has been reported in the literature. Our patient while on chronic Guselkumab treatment developed rapidly worsening AKI and CG, a week following the last dose of Guselkumab. We believe that in absence of any additional known risk factors, Guselkumab was responsible for AKI and CG in our patient. Our patient currently remains dialysis dependent. Clinicians should be aware of this very rare but potential association.

**PO1509**

**Proteinuria and Hematuria, an Unfamiliar Side Effect of Statin Therapy**

*Marco B. Thierry, 1, 2 Daniel Varela, 2 Mourad Alsabbagh, 2 Sergio A. Trevino Manillo, 2 Salil Mangi. 1 The University of Texas Rio Grande Valley, Edinburg, TX; 2DHR Health, Edinburg, TX.*

**Introduction:** Statins are among the most commonly prescribed medications worldwide, and have a relatively mild side effect profile. We describe a rare manifestation of statin therapy, with proteinuria and microscopic hematuria.

**Case Description:** A 53-year old Hispanic lady with a history of proteinuria and hematuria for 1 year with negative Urologic workup was referred to nephrology for further evaluation. Patient complained of foamy urine. Her only medication was rosuvastatin 40 mg. Initial UA showed 2+ protein and 5-10 RBC/HFP. Lab work - BUN 16, creatinine 1.0 mg/dL, albumin 4.8 mg/dL. Urine Protein Creatinine Ratio 2.1 g/g creatinine. Serologies were negative and complement levels were normal. Patient was started on ARB and a low sodium diet for proteinuria. Proteinuria persisted and renal biopsy was recommended with suspicion of IgA nephropathy. Biopsy showed mild glomerular and tubular interstitial chronic injury likely secondary to arteriosclerosis. There was no immune complex deposition and no evidence of this basement membrane disease. Genetic workup was negative for Alport’s syndrome. Because of the rare association of Rosuvastatin with urinary abnormalities, we decided to hold patient’s Rosuvastatin. Only three days later the patient reported that foamy urine had resolved. Repeat UPCR showed 99 mg protein/g creatinine. Hematuria also decreased to 0-2 RBC/HFP.
PO1512
C2 Deficiency Associated with Severe Recurrent ANA-Negative Lupus and Necrotizing Glomerulonephritis
Maria Llanos, Daniel Marino, Sanjay K. Menon, Kotresha Neelakantappa, Michael Malekan. New York-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.

Introduction: Deficiencies in the classical complement pathway have been associated with the development of systemic lupus erythematosus (SLE) and lupus-like disease in 10-20% of affected patients. In fact, SLE patients deficient in classical complement present at an earlier age, with severe manifestations and a worse prognosis. Several mechanisms have been described to explain these immune phenomena including impaired clearance of immune complexes, impaired handling of apoptotic cells, or changes in regulation of cytokines. Here, we present a case of a young female with ANA-negative lupus presenting with dyspnea and acute renal failure responsive to immunosuppressive therapy found to have C2 Complement deficiency.

Case Description: 44-year-old female with sickle cell trait, ANA-negative SLE, ESRD due to biopsy-proven class IV lupus nephritis briefly requiring HD, pulmonary HTN, presented with signs of fluid overload, acute on chronic renal failure in the setting of malignant hypertension. Labs revealed thrombocytopenia of 52 with a creatinine of 2.66 (prior 1.61), hypocomplementemia and undetectable CH50 levels concerning for acute flare of SLE and an underlying functional complement deficiency. Low haptoglobin and peripheral smear with schistocytes raised concerns for microangiopathy. Hospital course was complicated by encephalopathy and possible CNS involvement of lupus. Renal biopsy confirmed chronic sclerosing immune complex glomerulonephritis with minimal activity. The patient responded well to high dose corticosteroids, plasma exchange and mycophenolate mofetil. Final serology confirmed persistent C2 complement deficiency.

Discussion: There is a well-documented link between immune complex disease and complement deficiency. Of these, C2 deficiency is the most common. In our case, a C2 deficiency was found in the setting of ANA-negative SLE with severe clinical manifestations. Our case raises the question of whether testing to exclude underlying complement deficiency is particularly indicated in patients with ANA-negative SLE. It also remains to be seen whether clinical manifestations of microangiopathy are prevalent in these patients, and whether therapeutics targeting complement may be effective in their treatment.

PO1513
De Novo IgA Vasculitis Following Exposure to SARS-CoV-2 Immunization
Terrance Wickman, Muner Mohamed, Agnes B. Fogo, Juan Carlos Q. Velez. Ochsner Medical Center - New Orleans, New Orleans, LA; Vanderbilt University Medical Center, Nashville, TN; The University of Queensland, Saint Lucia, QLD, Australia.

Introduction: Immunizations have been previously described as potential triggering events for development of certain glomerular diseases. However, there is paucity of reports of occurrence of glomerular diseases following exposure to a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine.

Case Description: A 50-year-old man presented to a nephrology clinic for evaluation of persistent proteinuria. Six weeks prior to evaluation, the patient had reported developing a new rash approximately 2 weeks after receiving the first dose of a SARS-CoV-2 vaccine (Pfizer®). The rash was treated by his primary care provider with topical and oral corticosteroids, leading to partial improvement of the skin lesions. Three weeks after the first vaccine injection, the patient received his scheduled second vaccine injection. Within 2 days, the rash reappeared. This time, the lesions were more severe in nature, with a violaceous papular rash involving his lower legs and with some areas progressing to blisters. He also reported myalgias and arthralgias. A skin biopsy was performed and revealed IgA dominant leukocytoclastic vasculitis. After completion of 2 weeks of oral corticosteroids, a urinalysis revealed proteinuria and a consultation to nephrology was requested. On examination, healing papules were noted on his legs but otherwise exam was normal. Serum creatinine was 0.9 mg/dL. Microscopic examination of the urinary sediment revealed acanthocytes. An urine protein-to-creatinine ratio (UPCR) was 1.1 g/g. Serum complements were normal and all pertinent serology was negative. A kidney biopsy was performed and light and immunofluorescence microscopy findings showed an IgA nephropathy. UPCR decreased to 0.7 g/g and rash completely subsided.

Conclusion: The clinical presentation and pathological findings in this case strongly suggest that SARS-CoV-2 Vaccine (Pfizer®) can trigger a clinical syndrome compatible with Henoch-Schönlein purpura. The recurrence of the rash following re-exposure to the vaccine injection (second dose) argues for a definite causal association by Naranjo criteria.
Discussion: Hydralazine has been known to cause DI-GN since the 1950s, and it can manifest with features of pauci-immune glomerulonephritis and lupus nephritis. Drug-induced vasculitis has a high incidence of renal involvement compared to drug-induced systemic lupus erythematosus, however both entities have multiple auto-antibodies and ANCA positivity. The use of hydralazine has increased over the years due to trials demonstrating mortality benefit in heart failure. There is no consensus on the treatment, but discontinuing the offending agent, early diagnosis, and immunosuppressant therapy may result in favorable prognosis.

Chicken or the Egg Causality Dilemma: Primary ANCA Vasculitis Complicated by Infective Endocarditis (IE) vs. IE Leading to ANCA Vasculitis
Benjamin P. Catanese, Ayesha Anwar, Shuchi Anand. Stanford Health Care, Stanford, CA.

Introduction: As the cases of infective endocarditis increase in the United States it is important to recognize the associated complications. Glomerulonephritis is a well-recognized but not fully understood consequence. Immune complex deposition is the most common etiology but ANCA-mediated kidney injury is increasingly described and even less understood.

Case Description: A 65 year old male presented with acute onset dysarthria, left facial droop, left sided weakness, and dizziness. 5 months prior he was diagnosed with PR3+ ANCA vasculitis after presenting with 18 lbs weight loss, purpura, anemia, hematuria and sub nephrotic proteinuria. He was treated with methotrexate and a steroid taper, which finished one week prior to the current presentation. Admission vitals were: 145/74 mmHg, heart rate of 90 bpm, and 100% oxygen saturation on room air. Lab work revealed: hemoglobin of 10.7 K/uL, creatinine of 1.17 mg/dl (baseline 0.9), low C3: 81 mg/dl, positive PR3 (>8.0), positive c-ANCA (1:128), negative MPO and p-ANCA, and U/A: 3+ blood, negative protein, and 11-20 WBC. MIRIs of the brain and heart revealed numerous acute and subacute infarcts and severe mitral regurgitation respectively, concerning for small vessel vasculitis, and he was started on high dose steroids. Discovery of streptococcus mutans bacteraemia was a surprise. Suspicion was raised that the ANCA vasculitis may have been a consequence of underlying sub-acute endocarditis rather than a primary disease hence a kidney biopsy was planned and he was discharged on steroids and IV antibiotics. Kidney biopsy confirmed the diagnosis of ANCA-mediated endocarditis-associated glomerulonephritis with the presence of glomerulosclerosis with fibrocellular/fibrous crescents, segmental fibrinoid necrosis but no obvious immune deposits on light microscopy. Granular deposits in the mesangial and capillary wall stained for C3, IgM, IgA, kappa and lambda. He underwent 6 weeks of ceftriaxone and mitral valve replacement. His renal function is mildly impaired; he is recovering neurologically.

Discussion: Endocarditis-associated GN typically requires treatment of the underlying infection without immunosuppression, but when the injury is primarily ANCA-mediated, this presents a unique challenge in that end-organ damage from vasculitis may not improve without immunosuppression.

PO1517

Crescentic Glomerulonephritis in Sjögren Syndrome
Jake N. Cho,1,2 Danielle Janisson,3 Grant Oakley,1,2 Gary DiPerna. 1 Maine Medical Center, Portland, ME; 2 Tufts University School of Medicine, Boston, MA; 3 Maine Nephrology Associates PA, Portland, ME.

Introduction: Sjögren’s syndrome (SS) is an infiltrative autoimmune disorder involving the parotid, lacrimal and salivary glands causing sicca syndrome. Kidney involvement is variable and most often results in tubulointerstitial nephritis. Glomerular disease is infrequent with MPGN and membranous nephropathy being most prevalent pathologically.

Case Description: Patient is a 21 year old female with SS, hypothyroidism and asthma who was being evaluated for fever and fatigue. Lab evaluation revealed acute kidney injury (AKI) with creatinine rising from 1.0 to 1.8 mg/dl over several weeks. Echocardiogram was concerning for mobile echodensity at the tricuspid valve, but transesophageal echo showed no abnormalities and evaluation for infection was negative. CT showed extensive prominent lymph nodes in the chest, abdomen, and pelvis but lymph node biopsy showed benign reactive hyperplasia without neoplasm. Renal ultrasound showed normal sized kidneys. Urinalysis was positive for trace proteinuria and sediment revealed dysmorphic RBCs. She was started on high dose prednisone and hydroxychloroquine for possible lupus nephritis but due to diagnostic uncertainty and unresolved AKI, kidney biopsy was performed.

Discussion: Kidney biopsy demonstrated plasma rich interstitial nephritis with severe tubulitis consistent with SS. Interestingly, the biopsy showed 3 active cellular crescents out of 21 glomeruli with focal crescentic GN. Tubulointerstitial nephritis is the most common renal pathology in primary SS leading to renal tubular acidosis, impaired concentrating ability and proximal tubule defects. GN in SS is rare but has been associated with membranoproliferative GN, membranous nephropathy and cryoglobulinemic GN. Crescentic GN was unexpected and the treatment plan was adapted to taper the prednisone, start on Mycophenolate Mofetil and trial on Rituximab.

Light microscopy for renal biopsy of Sjögren’s case depicting interstitial nephritis and crescentic glomeruli

PO1518

Crescentic Glomerulonephritis and Membranous Nephropathy: A Case Report of a Rare Overlap
Mohamedanwar M. Ghandour, Zeenat Y. Bhat. Wayne State University, Detroit, MI.

Introduction: Membranous nephropathy (MN) is a disease that affects the basement membrane of the glomeruli of the kidney resulting in proteinuria. The concurrent incidence of vasculitic glomerulonephritis and MN in the same patient is unusual. Herein, we report a case with this unusual combination.

Case Description: Our patient is a 53-year-old Hispanic male with a past medical history of tobacco use, type 2 diabetes mellitus, and hypertension who presented with hematuria and was found to have nephrotic range proteinuria and renal impairment. Blood workup revealed positive ANCA serology, which led to a renal biopsy that showed crescentic vasculitis in addition to membranous nephropathy. The patient was started on intermittent hemodialysis (HD) and treated initially with intravenous (IV) pulse steroids; subsequently, oral prednisolone and IV cyclophosphamide was initiated. The patient remained HD dependent at the time of discharge with the resolution of hematuria. A follow-up with an outpatient nephrology clinic was arranged.

Discussion: Membranous nephropathy complicated by crescentic glomerulonephritis has a more aggressive clinical course and decline in renal function compared to MN alone which can lead to initiating renal replacement therapy. However, immunosuppressive drugs can result in significant improvement of renal function if started early enough.
PO1519

Unmasking a Case of Membranous-Like Glomerulopathy with Masked IgG-κ Deposits
Alissa Ice, Darren W. Barefield. Louisiana State University Health Sciences Center, Baton Rouge, LA.

Introduction: Membranous-like glomerulopathy with masked IgG-κ deposits (MGMID) is a recently described, exceedingly uncommon entity of glomerular immune-complex deposition requiring antigen retrieval on formalin-fixed paraffin-embedded tissue. We report a rare case of MGMID in a young female with newly diagnosed APLA.

Case Description: An 18 year old female with no medical history presented with left leg swelling. Vital signs were normal and an enlarged, discolored left lower extremity was appreciated on exam. Initial laboratory results were remarkable for Cr 0.78 mg/dL, albumin 2.3 g/dL, platelets 128,000/µL, PTT 87.1 s, INR 1.02, and hematuria and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PLA2r, complements, hepatitis serologies, ANA, ANCA, A1C, SPEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

Discussion: Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.

PO1520

A Case of Secondary Renal Amyloidosis Associated with HIV

Introduction: Secondary amyloidosis is known to be associated with multiple chronic infections and inflammatory conditions including rheumatoid arthritis, inflammatory bowel disease, systemic lupus erythematosus, and tuberculosis. HIV has not yet been established as a known association. We present a case of secondary amyloidosis associated with well-controlled HIV with no history of other potential etiologies.

Case Description: A 71-year-old man with hypertension and well-controlled HIV for 40 years (viral load undetectable and last CD4 917) was referred to the renal clinic for acute kidney injury and heavy proteinuria. He had complained of leg swelling and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8.

Serologic work-up was unrevealing; PLA2r, complements, hepatitis serologies, ANA, ANCA, A1C, SPEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

Discussion: Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.
**PO1521**

Renal Cell Carcinoma Presenting as Henoch-Schönlein Purpura with AKI and Leukocytoclastic Vasculitis in Adults

Ashton N, Breithaupt, Neelharika Mettupalli, Stacy A. Johnson, Alice Chedid.
The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

**Introduction:** Henoch-Schönlein purpura (HSP) is a small vessel vasculitis characterized by IgA tissue deposition. HSP presenting in adults is often the result of an underlying malignancy.

**Case Description:** A 60-year-old man with history of HTN, CVA, DMII, recent COVID-19 infection, presented for 2 week history of petechiae on bilateral upper and lower extremities. Skin biopsy findings were compatible with leukocytoclastic vasculitis (LCV). Patient on admission was also found to have AKI with creatinine 2.1 mg/dl, microscopic hematuria, and sub-nephrotic range proteinuria with urine protein/creatinine ratio of 2.66 g/g. Kidney biopsy findings were consistent with IgA dominant glomerulonephritis. Given multi-system involvement, patient was diagnosed with Henoch-Schönlein Purpura. Given unusual presentation with extreme of age, there was concern for malignancy. CT scan chest abdomen pelvis was performed which revealed a solid and septated 8.3 cm exophytic mass on the superior pole of left kidney. A partial left nephrectomy was performed with pathology report consistent with clear cell renal carcinoma. Patient’s hematuria, proteinuria and skin rash resolved with surgical intervention. Creatinine remained stable in the 1.6-1.8 mg/dl range on discharge.

**Discussion:** Henoch-Schönlein purpura (HSP) is generally seen in the first decade of life. There have been a few cases of HSP presenting in adults due to underlying solid organ malignancies including renal cell carcinoma (RCC). Our case illustrates the importance of evaluating adults presenting with clinical findings of HSP for underlying malignancy. Treatment of underlying malignancy will improve vasculitis symptoms including renal parameters.

Exophytic and sepatated mass within superior pole of left kidney (Figure 1).

**PO1522**

A Case of Necrotizing Crescentic Glomerulonephritis due to ANCA Vasculitis and Fibrillary Glomerulonephritis

Munahal Nasim, Faizan Babar. Nishat Medical College and Hospital, Multan, Pakistan; Nephrology Associates Lexington, Lexington, KY.

**Introduction:** Fibrillary Glomerulonephritis is a rare disorder thought to be idiopathic in nature. Cases of fibrillary GN have been associated with malignancy, monoclonal gammopathy, autoimmune disease, or infection. We present a unique case of fibrillary GN with pauc-immune crescentic GN due to Myeloperoxidase antibody (MPO) vasculitis.

**Case Description:** A 77 year old lady with history of well controlled diabetes, hypertension, congenital deafness, presented with weakness, fatigue & weight loss for four weeks. She was noted to have severe anemia with Hemoglobin of 6.6 g/dl, and presumed acute kidney injury. Her labs on admission were remarkable for creatinine 2.5mg/dl (unclear baseline creatinine), eGFR 25ml/min, potassium 5.3, Bicarbonate 16, Sodium 128. Urinalysis showed large blood and + protein. The serological workup was positive for P ANCA 1:640, C ANCA 1:640, MPO ab and negative for PR-3 ANA, SREP. Free light chain ratio, HIV, Hepatitis panel. Endoscopy and Colonoscopy was negative for any obvious bleeding. Patient underwent renal biopsy which showed 7 out of 15 glomeruli with early fibrocellular crescents with fibrinoid necrosis, along with healing phase of necrotizing arteritis. Immunofluorescence didn’t show any preferential staining for immunoglobulins, kappa or lambda. Electron microscopy showed mesangial mild non-branched randomly arrayed thick fibrils with no immune complex type deposits. EM findings were confirmed by positive DNAJ9B9 stain. Patient received treatment with pulse dose steroids, two doses of rituximab 1 gm 14 days apart and continued on prednisone for slow taper with good renal response. Due to the findings of Fibrillary GN addition workup for lymphoproliferative disorder was done Whole body CT scan was negative but flow cytometry testing still pending.

**Discussion:** We present a unique case of fibrillary GN and pauci-immune crescentic GN with positive MPO antibodies. The significance of fibrillary deposits in this setting is unclear and usually not seen with pauci-immune crescentic GN. Fibrillary GN is a very rare diagnosis mostly thought to be idiopathic in nature. This unique presentation of fibrillary GN with ANCA vasculitis questions the current pathogenesis fibrillary GN and overall renal prognosis in association with glomerular pathologies like ANCA vasculitis.

---

**PO1523**

An Unexpected Clue in the Urinary Space: The Overlap Between IgA Predominant Staphylococcus aureus-Associated Glomerulonephritis and IgA Nephropathy: A Case Report

Luis J. Froessl, Luan D. Truong, Justin Merszei. Baylor College of Medicine, Houston, TX; Houston Methodist Hospital, Houston, TX.

**Introduction:** There is significant histological overlap between IgA nephropathy (IgANP) and IgA predominant Staphylococcus-aureus associated glomerulonephritis (IgASAAGN). [1] [1] Satoskar et al., “Staphylococcus Infection-Associated Glomerulonephritis Mimicking IgA Nephropathy,” November 2006.

**Case Description:** Kidney biopsy was performed in a 60 yo male for an unexpected decline in kidney function. IgASAAGN was diagnosed on histology and foreign particles that were consistent with staphylococci were noted in the urinary space on electron microscopy. The patient was found to have methicillin-sensitive staphylococcus aureus (MSSA) pneumonia. Two months later, after a second decline in kidney function, IgANP was diagnosed on repeat kidney biopsy.

**Discussion:** This patient was diagnosed with two distinct conditions on pathology samples that show very similar histological findings. The presence of SA in the urinary space is a previously unreported finding. SA infection is known as the initiating factor for the development of IgASAAGN. Recent studies have also suggested SA cell envelope antigens as a new candidate for the induction of IgANP and antigens have been colocalized with IgA deposits in the glomeruli of affected patients. [2] SA infection and IgA deposition seem to play an essential role in the pathogenesis of both conditions, and the consideration that they may be two extremes of a disease spectrum could be considered. If the role of SA in the development of IgA nephropathy is confirmed, it may be of interest to explore the role of anti-staphylococcal antibodies in the treatment regimen of IgANP. [2] Koyama et al., “Staphylococcus Aureus Cell Envelope Antigen Is A New Candidate for the Induction of IgA Nephropathy.”
PO1525
Diagnostic Dilemma: Glomerular IgG Deposit with Negative Anti-GBM Antibody
Sonali Gupta,1 Meenakshi Sambarharia,1 Daniele G. Holanda,1 Elyas Safar,2 Y-Chen Huang,1 1The University of Iowa Hospitals and Clinics, Iowa City, IA; 2Blessing Hospital, Quincy, IL.

Introduction: Linear deposition of IgG along glomerular basement membrane (GBM) is hallmark of anti GBM glomerulonephritis. Subclass IgG3 deposition is seen predominantly in these cases. Rare atypical anti-GBM cases have been described in literature as rare, indolent, no pulmonary involvement and undetectable antibodies. We describe a case of atypical anti GBM, four days after mRNA COVID vaccine.

Case Description: A 77-year-old male with history of hypertension presented with hypertensive emergency and acute kidney injury 4 days after first COVID vaccine (mRNA). Workup revealed sCr 2.6 mg/dl (1.5 mg/dl 1 month back), 3+ blood and 3+ protein by UA, normal C3, C4, ANA 1: 160, spot urine protein: creatinine- 2.2, serum albumin- 4g/dl, anti ds-DNA, ANCA and anti-GBM antibody was negative so was Hepatitis panel and HIV. Serum electrophoresis was negative for monoclonal protein. He did not have any pulmonary symptoms and CXR was negative for acute pathology. Renal biopsy was performed. LM: mild to moderate nodular mesangial expansion, mildly increased mesangial cellularity and focal segmental nodular mesangial sclerosis. IF showed positive linear global capillary loop staining with IgG (2+), with kappa (1+) and lambda (2+) co-staining. Trace mesangial IgM and granular C3 (trace1+) are also noted in the peripheral capillary loops. EM showed diffuse foot process effacement. Few subepithelial, intramembranous and mesangial electron dense deposits were seen. Additional IgG subclasses IF showed positive linear glomerular staining for IgG1 (3+), IgG2 (1+), IgG4 (1+), negative for IgG3.

Discussion: Although no definitive active glomerular crescents or necrotizing lesions were seen, positive linear IgG staining in the glomerular capillary loops was concerning for atypical anti-GBM disease in setting of negative antibody and negative IgG3A. A study looking at 20 atypical anti-GBM patients found that 1 year patient and renal survival was 93% and 85% respectively. A few patients in this study had biopsy findings of DFPE and sub-epithelial deposits like ours. There have been few reports of COVID vaccine unmasking glomerulonephritis. However, it needs further investigation.

PO1526
Rapidly Progressive Glomerulonephritis due to Crescentic IgA Nephropathy in the Setting of HIV

Introduction: In patients with HIV-related kidney diseases, the most widely recognized histological abnormality is focal segmental glomerulosclerosis (FSGS). Less commonly found is IgA nephropathy in HIV patients, which tends to have a chronic stable course. We report a case of crescentic IgA nephropathy and FSGS in a patient with rapidly progressive glomerulonephritis and newly diagnosed HIV.

Case Description: A 34-year-old transgender woman with a history of alcohol use disorder presented with a petechial rash and lower extremity edema for 1 week, and was found to have a new diagnosis of HIV with an elevated creatinine. CD4 count was 143 and viral load was 103,774, and she was started on renally-dosed dolutegravir, abacavir and emtricitabine. Creatinine on admission was 1.27 mg/dl (baseline 0.7), and increased over the next several days to 5.3. Urine microscopy revealed dysmorphic RBCs and granular casts, with spot urine protein:creatinine 2.3. Renal biopsy demonstrated crescentic IgA nephropathy (Oslo classification M1 E1 S1 T1 C2) with concomitant FSGS (NOS subtype). Cellular crescents were seen in 4/7 glomeruli (figure 1), mesangial and endocapillary hypercellularity in all non-sclerotic glomeruli, and FSGS in 2/7 glomeruli. Immunofluorescence showed strong granular segmental mesangial staining for IgA (3+) and C3 (3+), and was otherwise negative. She was started on pulse-dose steroids (methylprednisolone 500mg x 3 days followed by 1 mg/kg x 2 weeks), as well as plasmapheresis every other day for 5 sessions. Her renal function had not improved by the time of discharge.

Discussion: To our knowledge this is the first reported case of IgA-induced RPGN in the setting of newly diagnosed HIV. A few prior case reports describe stabile IgA nephropathy in individuals with HIV, suggesting that there may be some unifying pathogenesis. This case highlights the need for investigation of this potential mechanism, which may help determine the optimal therapy for IgA nephropathy and IgA-induced RPGN in the setting of HIV.

Features and Outcomes of Patients with C1q Nephropathy in the NEPTUNE and CureGN Cohorts: Comparisons to Minimal Change Disease and Focal Segmental Glomerulosclerosis
Scott E. Wenderter,1,2 Maria Larkina,1,3 Mir Reza Barisoni,1,3 Clarissa A. Cassol,4 Carmen Avila-Cassado,1 Laura Barisoni,3 William E. Smoyer,3 Laura H. Mariani,1 Baylor College of Medicine, Houston, TX; 4Texas Children’s Hospital, Houston, TX; 5University of Michigan, Ann Arbor, MI; 6Arkana Laboratories, Little Rock, AR; 7University Health Network, Toronto, ON, Canada; 8University of Michigan, Detroit, MI; 9University of Pennsylvania, Philadelphia, PA; 10JAMCO Pharma Consulting, Stockholm, Sweden; 11KLC Private Foundation Support

Background: Predominant immunostaining for C1q distinguishes a subset of patients with primary glomerular disease. C1q nephropathy (C1qN) has been proposed but not universally accepted as a distinct glomerular disease. This study describes clinical characteristics and short-term outcomes of patients meeting the provisional CureGN definition of C1qN, including comparisons to patients with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) without C1qN.

Methods: MCD and FSGS patients with C1qN were identified from the Cure Glomerulonephropathy Network (CureGN) and NEPTUNE cohorts. Comparisons were made to MCD and FSGS patients without C1qN, based on age, disease, and time since kidney biopsy, using 5-to-1 matching. We performed cross-sectional analyses of clinical and treatment data at enrollment and a longitudinal analysis of disease course.

Results: A total of 42 patients met the provisional CureGN definition for C1qN (16 adults >18yo, 11 teens 12-18yo, and 15 children <12yo), including 15 with MCD and 27 with FSGS. Those with C1qN were more commonly female (60 vs 49%, p=0.2) and black (34 vs 27%, p=0.4). At enrollment, those with and without C1qN had comparable kidney function (eGFR 90 vs 88 mL/min/1.73m², p=0.8). Individuals with C1qN were equally likely to have been treated with steroids or other immunosuppressive therapy (76 vs 81%, p=0.4) and to have ever achieved complete remission of proteinuria (defined as uPCR <0.3) (54 vs 65%, p=0.2). Median time to last follow-up was 3.1 yrs (IQR 1.9, 4.4) from enrollment and 4.8 yrs (IQR 3.3, 6.5) from biopsy date. While proportions with kidney failure were higher for FSGS compared to MCD (14 vs 1%, p=0.01), they were similar between patients with and without C1qN (7 vs 10%, p=0.6). There was a trend towards steeper GFR slope in C1qN patients (4.8 vs -0.2 mL/min/yr, p=0.06).

Conclusions: FSGS and MCD patients with and without C1qN have comparable demographics and short-term outcomes in CureGN and NEPTUNE. Outcomes do not appear to be biased by differences in immunosuppressive therapies. Further interrogation of genetic and molecular profiles between patients with and without C1q immunostaining on biopsy may be more informative.

Morphologic Descriptors Most Predictive of Clinical Outcomes in Minimal Change Disease and FSGS
Jacee Zee,1 Qian Liu,4 Abigail R. Smith,5 Laura H. Mariani,3 Jeffrey B. Hodgkin,3 Brenda W. Gillespie,3 Laura Barisoni,3 Lawrence B. Holzman,1 University of Pennsylvania, Philadelphia, PA; 2University of Michigan, Ann Arbor, MI; 3Royal Free Hospital, London, United Kingdom; 4Leicester General Hospital, Leicester, United Kingdom; 5UK Renal Registry, Bristol, United Kingdom; 6Royal Free Hospital, London, United Kingdom; 7University College London, London, United Kingdom; 8Traveur Therapeutics Inc, San Diego, CA; 9University of Edinburgh, Edinburgh, United Kingdom; 10JAMCO Pharma Consulting, Stockholm, Sweden; 11KCL Statistics Ltd, Cheshire, United Kingdom; 12The Renal Association, Bristol, United Kingdom

Background: Previous studies applying the NEPTUNE Digital Pathology Scoring System (NDPSS) uncovered the value of kidney tissue features for clinically relevant patient subcategorization. This study aims to identify ultrastructural descriptors most predictive of clinical outcomes in NEPTUNE patients.

Methods: 39 glomerular, 9 tubulointerstitial, 2 vascular, and 20 ultrastructural descriptors were quantified using the NDPSS on 39 MCD, 61 MCD-like, and 124 FSGS NEPTUNE digital kidney biopsies. Outcomes included time from biopsy to disease progression (kidney failure or a 40% eGFR decline with eGFR <90) and first complete remission (CR) of proteinuria (UPCR <0.3). Relative importance of descriptors for prediction of outcomes was obtained from random forest models, without adjusting for clinical features.

Results: The mean age, eGFR and UPCR at biopsy for the total 224 participants was 28.8, 85.2, and 5.4, respectively. Model performance was excellent (predictive discrimination 0.902 for disease progression and 0.853 for CR). Most predictive descriptors included conventional (e.g., global sclerosis or segmental sclerosis, and interstitial fibrosis/tubular atrophy) and unconventional features [Fig]. Top 10 predictors included inflammation, podocyte abnormalities, and acute tubular injury for both outcomes; deflation, interstitial foam cells, and collapse for disease progression; and endothelial cell abnormalities, hyalinosis, and periglomerular fibrosis for CR.

Conclusions: Most predictive descriptors of proteinuric glomerulopathies reflected structural changes in various renal compartments. Reporting these descriptors should be standardized to guide the subcategorization of proteinuric glomerular diseases and improve targeted clinical care.

Proteinuria End Points and Associations with Renal Survival in FSGS:
Analysis of the UK National RaDaR Idiopathic Nephrotic Syndrome Cohort

Main Saleem,1,2 Jonathan Barratt,1,3 Fiona E. Braddock,1,3 Kevin Carroll,1,3
Ulysses A. Diva,3 Bruce M. Hendry,4 Alex Mercer,2 David Pitcher,1,2
Retha D. Steenkamp,1,2 A. Neil Turner,1 Daniel P. Gale,3,4 University of Bristol, Bristol, United Kingdom; 3Bristol Royal Hospital for Children, Bristol, United Kingdom; 4UK Renal Registry, Bristol, United Kingdom; 5Royal Free Hospital, London, United Kingdom; 6University College London, London, United Kingdom; 7Travere Therapeutics Inc, San Diego, CA; 8JAMCO Pharma Kingdom; 9University of Leicester, Leicester, United Kingdom; 10Leicester General Hospital, Leicester, United Kingdom; 11KLC Statistics Ltd, Cheshire, United Kingdom; 12The Renal Association, Bristol, United Kingdom.

Background: In patients with FSGS, severity of proteinuria (PU) at onset and during follow up is associated with renal failure. In this study, we tested for associations between defined PU endpoints and renal survival in patients with FSGS from the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort.

Methods: A total of 225 biopsy-proven or monogenic FSGS pts met study eligibility criteria, including a nephrotic PU value (≥3.5 g/g), a follow-up PU within 6-12 mo. and no ESKD (eGFR <15 mL/min/1.73m²) or death prior to first PU follow-up. Baseline pertains to first nephrotic PU value (T0 for survival analyses). Applied PU responder/non-responder definitions are described (Table 1). Time to ESKD/ death was analysed using accelerated failure time modelling of the Weibull distribution.

Results: Within 6-12 mo. from baseline, 63% of patients achieved complete or partial remission (CR/PR), while 37% were non-responders (NR). Applying the FSGS partial remission of PU endpoint (FPRE) and including CR patients, 49% met this definition (CR/PR), while 37% were non-responders (NR). A higher probability for survival was observed among patients achieving remission definitions (Figure 1), extending median time to ESKD/death by ≈8 years for CR/PR vs NR, and ≈17 years for CR/FPRE-R vs NR (Table 1) independent of initial PU level. Further analyses are ongoing.

Conclusions: Achieving partial or complete remission of PU is associated with clinically meaningful increases in time FSGS patients are alive and free from ESKD.

Clinicopathological Characteristics of Adult Patients in the United States with Focal Segmental Glomerulosclerosis (FSGS)

Katherine R. Tuttle,1 Clint Abner,1 Kerime Ararat,2 Patrick D. Walker,2 Amin Yakuju,2 Martin C. Bunke,2 University of Washington, Spokane, WA; 2Arkana Laboratories, Little Rock, AR; 3Genesis Research, LLC, Hoboken, NJ; 4Travere Therapeutics Inc. San Diego, CA.

Background: Focal segmental glomerulosclerosis (FSGS) is a common histopathologic lesion of glomerular injury in patients with nephrotic syndrome. These analyses characterize clinical and histological features of FSGS in adults at time of kidney biopsy.

Methods: A retrospective study was performed using data from the Arkana Biopsy Database (January 1, 2016 to May 31, 2020) in patients that met study criteria, which included: a18 yrs, aFSGS positive kidney biopsy, and no prior kidney transplant, and available data on race/ethnicity. Outcomes included clinical and histologic characteristics. eGFR was calculated using CKD-EPI-creatinine equation without race modifier.

Results: Of 64,105 adult kidney biopsies performed during the study period, 2,065 (3.2%) FSGS positive cases were identified and 1,482 pts (71.8%) evaluated met study criteria. Demographic characteristics included: 56.2% male, 55.1% White, 32.1% African American (AA), 7.7% Hispanic and 3.4% Asian. Overall mean (SD) age at biopsy was 49.0 (17.2) with older ages in Whites (52.8 (17.3) yrs) and younger ages in Hispanics (39.4 (15.8) yrs). Mean urine protein to creatinine ratio was similar by race/ethnicity (range 5.1-6.0 g/g). Asians were more frequently biopsied at eGFR Stage 4 (32.7%) compared to other race/ethnicity groups: AAs (29.0%), Whites (23.1%), and Hispanics (18.7%). The highest rates of ≥50% global glomerular sclerosis (GCS) were observed in AAs (31.1%) and lowest in Whites (14.6%). Whites (51.9%) and AAs (39.7%) exhibited the highest rates of severe foot process effacement (≥80%), while interstitial fibrosis and tubular atrophy ≥50% was more common in AAs (34.6%) compared to Hispanics (27.2%), Asians (17.7%) or Whites (14.6%). Of all FSGS types, “not otherwise specified” was most common across all race/ethnicity groups (range 64.2-75.4%). Among other FSGS types, tip lesion was most frequent in Whites (21.5%) and collapsing was most frequent in AA patients (12.4%).

Conclusions: Non-White patients are more frequently diagnosed with FSGS at later CKD stages with advanced GS. Strategies to improve earlier awareness and detection of FSGS are needed to allow effective intervention before severe kidney damage has occurred.

PO1532

Long-Term Outcomes of Patients with Focal and Segmental Glomerulosclerosis Treated with Tacrolimus

Mukunthan Srikumarrajah,1 Thomas M. Connor,1 Jeremy B. Levy,1 Stephen P. McDaid,2 Megan Griffith,1 Imperial College Healthcare NHS Trust, London, United Kingdom; 2Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.

Background: Tacrolimus (TAC) is used to treat Focal and Segmental Glomerulosclerosis (FSGS). Prolonged treatment is often required and there is little data on long-term outcomes.

Methods: This is a retrospective study of 29 patients who received TAC as first line immunosuppression for nephrotic syndrome (NS) secondary to FSGS from December 2007- January 2020 at our institution.

Results: Mean follow up was 59.6 months (12-144). The mean age at diagnosis was 42 years (range 18-85). 52% were Male. 59% were White, 10% Black, 21% Asian, 3% Chinese, 7% Other. Baseline mean eGFR was 64 mL/min (18-90). 23/29 (79%) obtained complete (CR) or partial remission (PR) of NS, at a mean time of 5.09 months (range 1-31 months). 6/29 (21%) did not enter remission with TAC. 2/6 subsequently achieved
remission with CyP and prednisolone/rituximab. 7/23 (30%) patients who achieved remission with TAC had at least one relapse, 4/7 after stopping TAC, 1/7 during TAC wean and 2/7 with therapeutic TAC levels. 4/7 were treated by restarting or increasing TAC, 1/7 also had steroids added, 1/7 received rituximab (achieving remission) and 1/7 was not further treated with immunosuppression. 4/4 restarted with TAC monotheraphy reached remission. 16/23 (70%) patients did not relapse and 7 of these remain off TAC and in remission (mean follow up of 92.6 months). At 1 year, the mean eGFR was 67.4 ml/minute (21-90). 1/29 patient developed end-stage kidney disease (ESKD) at 2 months. This patient had not responded to TAC, 16 patients have 5-year-follow up. The mean eGFR was 66.5 ml/minute (11-90). 1 further patient developed ESKD (this patient had not responded to TAC nor subsequent immunosuppression). 4 patients have 10-year follow-up. The mean eGFR was 80.8 ml/minute (67-90). 3 further patients developed ESKD. 1/3 had achieved PR, 1/3 had achieved CR but had multiple relapses despite re-treatment and 1/3 had CR but defaulted from follow up, presenting with ESKD 6 years later.

Conclusions: The long-term data from this study suggests tacrolimus can be effective in both achieving and maintaining remission of NS in FSGS. CR is associated with good long-term outcomes in most patients although relapse can occur and long term careful follow up is required. Non-responders have a worse outcome, although some patients do respond to alternative immunosuppression.

PO1533

Collapsing FSGS in a Patient with Acute Myeloid Leukemia and Prior COVID-19 Infection

Surya Maniyanman, Stephanie S. Pavlovich, Irshadjahe Malek, Koyal Jain

University of North Carolina System, Chapel Hill, NC.

Introduction: Collapsing focal segmental glomerulosclerosis (c-FSGS) has been independently associated with COVID-19 infection, acute myeloid leukemia (AML), and apolipoprotein L1 (APOL1) risk variants. We describe a patient with homozygous APOL1 G1 risk allele and AML who developed renal failure due to c-FSGS and acute tubular injury.

Case Description: A 25-year-old male with a history of mild asthma and COVID-19 infection 1 month prior presented with a 3-week history of severe fatigue, weight loss, persistent dyspnea, and fevers. He was found to have leukopenia, thrombocytopenia, an acute kidney injury, and nephrotic range proteinuria. The patient was diagnosed with AML by bone marrow biopsy (BMMBs). At presentation, his serum creatine was 2.8 mg/dL, which rapidly increased to 6.9 mg/dL over 2 weeks. Urine protein:creatinine ratio (UPCR) was 3.4g/L on admission. Renal biopsy demonstrated c-FSGS (Figure) and diffuse acute tubular injury. He was treated with standard remission induction therapy for AML with 7+3 therapy (7-day continuous infusion of cytarabine, daunorubicin on days 1-3, and an inhibitor, associated with MCD exist. TNF-α inhibitors are increasingly utilized for the treatment of several autoimmune conditions. They have been associated, in rare cases, with renal complications. We report a patient who developed minimal change disease (MCD) and interstitial nephritis while being treated with infliximab (IFX) for ulcerative colitis (UC).

Case Description: A 48-year-old male with a history of primary sclerosing cholangitis, liver transplant 8 years prior, psoriasis, and UC well-controlled on monthly IFX presented with a one-week history of lower extremity swelling, dyspnea, and weight gain. He was found to have rapidly progressive renal failure and nephrotic syndrome. Laboratory data showed a serum creatinine of 11mg/dL up from 1mg/dL 3-weeks prior and urine protein:creatinine ratio (UPCR) of 11g/L. Renal biopsy demonstrated acute interstitial nephritis (AIN) on light microscopy. Electron microscopy revealed global podocyte activation and foot process effacement, consistent with MCD (Figure). He continued to become progressively oliguric despite escalating doses of diuretics and received two days of hemodialysis due to volume overload. After a total of 7 days of high dose steroids, his urine output increased and hemodialysis was stopped. IFX was discontinued due to the association of TNF-α inhibitors with MCD and AIN. After a month of prednison, his creatine improved to 1.6 mg/dL and UPC improved to 0.33g/L.

Discussion: This is the first report of IFX associated MCD. Although IFX has been associated with IgA nephropathy, crescentic glomerulonephritis, renal artery occlusion, membranous glomerulopathy, and AIN in patients with spondylarthritus spectrum diseases, no reports exist in the literature regarding MCD. However, several case reports of Etanercept, another TNF-α inhibitor, associated with MCD exist. TNF-α inhibitors are implicated in immunoregulatory effects in the kidney, which are not well understood.

PO1534

Role of LDL-Apheresis in Management of Glucocorticoid-ResistantMinimal Change Disease

Dharia P. Shah, Alka A. Tyagi, Jason Prosek, Eshtetu L. Obote. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Minimal Change Disease (MCD) is described as diffuse podocyte foot process effacement on kidney biopsy, resulting in nephrotic proteinuria, >3 grams/day. Glucocorticoids (GC) are the mainstay of therapy and most patients achieve complete remission in a few months. 7-12% patients, however, have GC-resistance and thus limited treatment options. Often, they are suspected of having focal segmental glomerulosclerosis (FSGS) due to biopsy sampling error. We present a challenging case of GC-resistant MCD, managed with immunosuppression, and ultimately lipid (LDL) apheresis.

Case Description: An otherwise healthy 20-year-old male presented for sudden onset lower extremity swelling and 10-pound weight gain. Work up including ANA, C3, C4, p-ANCA, c-ANCA, serum and urine immunofixation and renal ultrasound were unremarkable. Notably, LDL was 390 mg/dL and proteinuria of 9 grams/day and serum creatinine (Scr) of 0.96 mg/dL. Kidney biopsy revealed diffuse podocyte effacement, consistent with MCD. He was treated with oral prednisone 1 mg/kg/day and diuretics for several weeks with minimal symptomatic improvement and had worsening kidney function, Scr 1.5 mg/dL and proteinuria of 36 grams/day. Unfortunately, he also contracted COVID-19 disease prior to second kidney biopsy. Repeat kidney biopsy revealed acute tubular necrosis along with widespread podocyte effacement, without sclerotic lesions, ~10% interstitial fibrosis and tubular atrophy. He was empirically treated with tacrolimus for FSGS. However, proteinuria continued to worsen and peaked at 83 grams/day. Ultimately diagnosed as GC-resistant MCD, he was weaned off steroids, he was referred for LDL-apheresis therapy. He is maintained on tacrolimus and LDL apheresis with symptomatic improvement, still has significant proteinuria of 67 grams/day and advanced chronic kidney disease (CKD).

Discussion: The exact pathophysiology of nephrotic syndromes is unclear, mechanisms of T-cell dysfunction causing production of glomerular permeability factor and nephrotic hyperlipidemia have been described. In cases of GC-resistant diseases, immunosuppression has only been partially successful. LDL-apheresis has a role in the management of such nephrotic syndromes, thought to reduce circulating lipid induced disruption of podocyte integrity, and help prevent decline of kidney function and decrease proteinuria as seen in this patient.
PO1536
Anti-Phospholipase A2 Receptor Antibody Levels in Asian Patients with Primary Membranous Nephropathy: A Territory-Wide Study
Desmond Y. Yap, Irene Yam, Michelle Lam, Hemlata Binsuauthsing, Tak Mao D. Chan. University of Hong Kong, Hong Kong, Hong Kong.

Background: Different cut-off values of anti-phospholipase A2 receptor (anti-PLA2R) antibody for differentiating between primary membranous nephropathy (PMN) and secondary membranous nephropathy have been reported. The optimal anti-PLA2R levels to reflect disease activity states in Asian patients with PMN remain undefined.

Methods: We conducted a territory-wide study in Hong Kong to investigate the serum anti-PLA2R levels in Chinese patients with PMN during 2017-2020. Anti-PLA2R levels were measured by commercial ELISA kits (Euroimmun, Germany) in serum samples collected from biopsy-confirmed PMN patients during active disease or remission, and their predictive values for active PMN were evaluated.

Results: Forty and six serum samples from 320 PMN patients were analysed. 319 samples were obtained during active disease and 87 during disease remission. Anti-PLA2R titres during active diseases were significantly higher than that during remission (95.1±235.0 RU/mL vs. 19.3±9.3 RU/mL respectively, p<0.001). Using 20 RU/mL as cut-off, the sensitivity (SN) and specificity (SP) for predicting active disease were 39% and 98% respectively [AUC 0.68, p<0.001; positive predictive value (PPV) and negative predictive value (NPV) were 98% and 30% respectively]. Using 10 RU/mL as cut-off, the SN and SP for diagnosing active PMN were 46% and 95% respectively [AUC<0.71, p<0.001; PPV and NPV were 97% and 32% respectively]. Anti-PLA2R titres correlated with urine protein-to-creatinine ratio and 24-hr urine protein levels (r=0.32 and 0.37 respectively, p<0.001).

Conclusions: Anti-PLA2R showed good SP and PPV prediction for active PMN in Chinese patients, and correlated with severity of proteinuria. A lower threshold (10 RU/mL) may show improved SN for predicting active PMN in Asian patients.

PO1537
Qualitative and Quantitative Dosage of the Anti M-Type Phospholipase A2 Receptor Autoantibody: One-Year Experience in Quebec’s Reference Center
Simon Leclerc,1,2 Karim Benkiran,1,2 Caroline Lamarque,1,2 Jean-Pierre Lagrange,1,2 Annie-Claire Nadeau-Fredette,1 Virginie Royal,1,2 Vincent Picotte,1,2 Louis-Philippe Laurin,1,2 Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 1Université de Montréal, Montreal, QC, Canada.

Background: Dosage of the M-type phospholipase A2 receptor antibodies (anti-PLA2R) in serum is an essential tool for diagnosis and management of primary membranous nephropathy (MN). Since October 2018, Hôpital Maisonneuve-Rosemont (HMR) has been designated as Quebec’s reference center for serum anti-PLA2R antibody testing by the Institut National d’Excellence en Santé et Services Sociaux (INESSS), the regulatory body on drugs and tests usage in Quebec.

Methods: All patients who had serum anti-PLA2R antibody testing performed at HMR from October 1st, 2018 to October 1st, 2019 were included in the study. Serum anti-PLA2R antibodies were screened by a qualitative test, followed by a quantitative test if the results were undetermined or positive. We calculated sensitivity, specificity, predictive value, and likelihood ratio for both tests, using kidney biopsy findings as the gold standard.

Results: In the province of Quebec, a total of 1690 tests were performed among 1025 patients during the study year. A small proportion of these patients (8%) were followed at HMR from October 1st

PO1538
Clinical Relevance of NELL1 Antibodies in Patients with Membranous Nephropathy
Linda Reinhard, Benedict Krümpelmann, Thorsten Wiech, Rolf A. Stahl, Elion Hoxha. 1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany; 3Medizinisches Versorgungszentrum Hamburg-Sinstorf der MVZ gGmbH der PHV, Hamburg, Germany.

Background: PLA2R and THSD7A antibodies (ab) are considered to be specific for the diagnosis of membranous nephropathy (MN). There is a controversial discussion whether the detection of circulating PLA2R- or THSD7A-ab is sufficient to diagnose MN, without the need of a kidney biopsy. We conducted a territory-wide study in Hong Kong to investigate the serum anti-PLA2R levels in Chinese patients with PMN during 2017-2020. Anti-PLA2R levels were measured by commercial ELISA kits (Euroimmun, Germany) in serum samples collected from biopsy-confirmed PMN patients during active disease or remission, and their predictive values for active PMN were evaluated.

Results: Forty and six serum samples from 320 PMN patients were analysed. 319 samples were obtained during active disease and 87 during disease remission. Anti-PLA2R titres during active diseases were significantly higher than that during remission (95.1±235.0 RU/mL vs. 19.3±9.3 RU/mL respectively, p<0.001). Using 20 RU/mL as cut-off, the sensitivity (SN) and specificity (SP) for predicting active disease were 39% and 98% respectively [AUC 0.68, p<0.001; positive predictive value (PPV) and negative predictive value (NPV) were 98% and 30% respectively]. Using 10 RU/mL as cut-off, the SN and SP for diagnosing active PMN were 46% and 95% respectively [AUC<0.71, p<0.001; PPV and NPV were 97% and 32% respectively]. Anti-PLA2R titres correlated with urine protein-to-creatinine ratio and 24-hr urine protein levels (r=0.32 and 0.37 respectively, p<0.001).

Conclusions: Anti-PLA2R showed good SP and PPV prediction for active PMN in Chinese patients, and correlated with severity of proteinuria. A lower threshold (10 RU/mL) may show improved SN for predicting active PMN in Asian patients.

Urinary NPHS2-mRNA in Relation to Glomerular and Tubular Damage Markers in Patients with Membranous Nephropathy
Bartholomeus T. van der Berge,1,2 Anne-Elis van de Logt,1 Jitske Jansen,1,2 Bart Smeeurs,1 Johan Van der vlag,1 Jack F. Wetzels,1 Rutger J. Maas,1,2

1Radboudumc Afdeling Nierziekten, Nijmegen, Netherlands; 2Radboudumc Afdeling Pathologie, Nijmegen, Netherlands; 3Radboudumc Afdeling Kindergeneeskunde, Nijmegen, Netherlands.

Background: Measurement of podocyte-specific mRNA in patients’ urine samples has been proposed as a novel tool to monitor podocyte loss in glomerular disease, and may have prognostic value. In our hospital, we routinely measure timed urinary excretion of high- and low-molecular weight proteins as prognostic markers in patients with membranous nephropathy (MN). Here, we investigated the relationship between NPHS2-mRNA and high- and low-molecular weight proteins in patients with MN.

Urine Biomarkers Predict Treatment Response in the MENTOR Study
Pratha Patipramponpit,1 Sarah M. Moran,1 Gary Bader,1 Chiangjiang Xu,1 Paul C. Boutros,1 Fernando C. Fervenza,1 Sean Barbour,1 Daniel C. Cattran,1 Heather N. Reich1,5 for the MENTOR investigators1 University Health Network, Toronto, ON, Canada;2 Bhumirajangarvinda Kidney Institute, Bangkok, Thailand;3 The University of British Columbia, Vancouver, BC, Canada;4 Queen’s University, Kingston, ON, Canada;5 University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada;6 University of California Los Angeles, Los Angeles, CA;7 Mayo Clinic Minnesota, Rochester, MN;8 Mayo Clinic Florida, Weston, FL.

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. The outcome of patients with MN is highly variable and clinical parameters do not reliably identify which patients will respond to immunosuppressive therapy (IS). In the MENTOR trial >40% of subjects did not achieve complete or partial remission (CR/PR) of proteinuria by 12 months despite IS with rituximab or cyclosporine, exposing them to unnecessary IS and portending potentially poor prognosis. We evaluated whether a panel of urinary molecular markers of kidney inflammation and fibrosis improves the ability to identify treatment responders in the MENTOR trial beyond clinical data alone.

Methods: We measured the abundance of 55 urinary cytokines, metalloproteases and their inhibitors at the randomization in 104 subjects using a Luminex-based multiplex assay. The primary outcome of interest was achievement of CR/PR at 12 months.

Results: Patients achieving CR/PR had significantly higher CrCl (94.25 ± 31.42 vs 75.17 ± 28.52 mL/min/1.73m2, p<0.002) and lower anti-PLA2R titre (168.5 IQR 20.5,341 vs 549 IQR 115.5,1345 U/mL, p = 0.0002) at baseline. Stepwise selection identified 3 clinical variables (CrCl, PL2AR, treatment) and 8 urinary proteins (IL9, IL10, GM-CSF, VEGF-A, TGFB, MMP2, MMP3, MMP10) associated with CR/PR. A model including the clinical and molecular variables improved discrimination of patients who are predicted to achieve CR/PR compared to a model containing clinical variables alone (ANOVA test p-value = 1.30x10^-3, AUC 0.81 ± 0.096 vs. 0.70 ± 0.109).

Conclusions: In summary, measurement of a panel urinary molecular markers improves the ability to predict remission at 12 months in patients with MN. Improved prediction of patients resistant to standard therapy using non-invasive markers has potential to offer more individualized treatment, to spare unnecessary treatment toxicity and to identify patients who may benefit from trials of novel therapeutic agents.

POI542
Use of Urinary Proteins as Predictors of Response to Immunosuppressive Treatment in Membranous Nephropathy
Lauren Androga1, Jason K. Viehman,1 Shane A. Bobart,1 Lisa E. Vaughn,1 John C. Lieske,1 Ladan Zand,1 Eddie L. Greene,1 Sanjeev Sethi,1 Daniel C. Cattran,1 Fernando C. Fervenza,1 Mayo Clinic Minnesota, Rochester, MN;2 Toronto General Hospital, Toronto, ON, Canada;3 Cleveland Clinic Florida, Weston, FL.

Background: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in adults. Progression is defined by remission in proteinuria. Response to immunosuppression agents such as calcineurin inhibitors and rituximab vary. While the presence of anti-PLA2R antibodies may help to guide prognosis and treatment strategies, further identifying biomarkers that could refine treatment decision would be useful. Using data from the MENTOR trial (NEJM 2019), we evaluated whether 24-hour total urinary protein, urinary albumin, immunoglobulin M (ulgM), immunoglobulin G (ulgG), and urinary alpha 1 microglobulin (u1m) at baseline could be used to predict response to immunosuppressive therapy at 12 months in patients with MN.

Methods: Logistic regression models were used to study the relationship between baseline urinary proteins with patients’ treatment outcomes by treatment drug (rituximab or cyclosporine). The treatment outcome was defined as patients achieving either complete (CR; <0.3g/24 hours) or partial remission (PR; 0.3–<3.5g/24 hours) of proteinuria at 12 months.

Results: In both cyclosporine and rituximab arm, all urinary proteins exhibited a decline from baseline to 12 months post treatment. However, none of the baseline urinary proteins were found to be significantly associated with treatment response at 12 months (p>0.05 for all). Results were similar when restricted to patients with positive anti-PLA2R at baseline.

Conclusions: Baseline measures of the urinary albumin, ulgM, ulgG, and u1m are not predictors of patients going into CR or PR at 12 months after treatment with rituximab or cyclosporine.

Table 1: Odds ratio of urinary protein predicting CR or PR at 12 months in patients treated with Rituximab or Cyclosporine (Fully Adjusted model)

*Adjusted for adjust for age, sex, eGFR, and creatinine clearance

POI543
APOL1 High-Risk Genotype Is Associated with Worse Renal Outcomes in Black Patients with Membranous Nephropathy

Background: Black patients have a higher propensity for progression to end-stage kidney disease (ESKD) and this disparity persists in glomerular diseases studied thus far. Genetic variants in the Apolipoprotein L1 (APOL1) gene contribute to kidney disease burden in those with African ancestry. To date, there are no data on the role of APOL1 risk alleles in outcomes among black patients with membranous nephropathy (MN).

Methods: Sanger sequencing for APOL1 risk allele genotyping was completed on patients of African-American ancestry (self or clinician reported) with diagnosis of MN enrolled in the Glomerular Disease Collaborative Network (GDCN) or Cure Glomerulonephropathy Network (CureGN) with DNA samples available were included.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
patient with MN and metastatic breast cancer who developed nephrotic syndrome after receiving her second mRNA-1273 COVID-19 vaccine with positive PLA2R Ab by ELISA suggesting MN flare.

Case Description: A 62 year old female with history of Stage IIIIB T3N3M1 ER/PR positive HER-2 negative metastatic left breast invasive ductal carcinoma, hypertension, and hyperlipidemia presented with bilateral leg edema and proteinuria 2 weeks after COVID-19 vaccination. She had previous proteinuria of 7029 mg/24hr in August 2018 with PLA2R Ab 128 RU/mL in October 2018. She underwent modified radical mastectomy in September 2018 followed by adjuvant chemotherapy in November 2018, after which PLA2R Ab decreased to <2 RU/mL. In February 2019 and urine protein/Cr ratio (UPCR) decreased to 1094 mg/g Cr in April 2019. She was diagnosed with metastatic breast cancer and started anastrozole transiently. She received mRNA-1273 COVID-19 vaccines in late January and February 2021. In March 2021, she presented with bilateral leg edema, dyspnea, and bilateral pleural effusion. Urinalysis had >1000 protein, 24hr urine protein 11.2 g, Cr 1.6 mg/dL, and PLA2R Ab 787 RU/mL. Renal biopsy showed immune complex-mediated glomerulopathy with positive PLA2R, consistent with primary MN stage II-III. Glomerular basement membrane deposits were strongly positive for IgG. Electron microscopy showed numerous subepithelial and occasional intramembranous electron-dense immune-type deposits. She was treated with lisinopril and furosemide followed by rituximab in May 2021. Prior to rituximab PLA2R Ab was 342 RU/mL and UPCR was 8671 mg/g Cr.

Discussion: There is insufficient data on the risk of flare after COVID-19 vaccine in glomerular diseases. There have been a few case reports of primary MN and minimal change disease after COVID-19 vaccine as well as MN after influenza vaccine. Our case of primary MN flare after COVID-19 vaccine adds support to a potential association between SARS-CoV-2 antigens and loss of tolerance to the PLA2R antigen. Close follow-up of patients with primary MN and other glomerular diseases after COVID-19 vaccination is warranted.

PO1546
Primary Membranous Nephropathy Concurrent with ANCA-Positive Crescentic Glomerulopathy in a Hispanic Man
Leonardo Pozo Garcia,1,2 Daniel Varela,1,2 Steffi Sathyaraj,1,2 Mourad Alsbagh,2 Sergio A. Trevino Manlio,2 John Manlio,3 The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 2DHR Health, Edinburg, TX; 3South Texas Kidney Specialists, McAllen, TX

Introduction: Primary membranous nephropathy (MN) is a common cause of glomerular disease in adults usually presenting with nephrotic syndrome. Crescents are an unusual finding in MN; its presence suggests a concomitant disease process, such as pauci-immune anti-neutrophil cytoplasmic antibody-related (ANCA) glomerulonephritis (GN).

Case Description: A 36-year-old Hispanic man presented with a 1-week history of malaise and lethargy. Examination revealed an obese Hispanic man with rules on lung auscultation and lower-extremity edema. Laboratory results showed a serum creatinine (sCr) 8.8 mg/dL, BUN of 34 mg/dL. Urinalysis revealed 4+ protein, 25-50 red blood cells per hpf. Spot urine protein creatinine ratio (UPCR) was 19 g/g, p-ANCA titer 1:640. Urine toxicology screen was positive for cocaine. Other serologies and imaging were unremarkable. Renal biopsy showed MN with PLA2R positive staining as well as necrotizing and crescentic glomerulonephritis. Interstitial fibrosis and tubular atrophy were seen only in 10% of the sample. Management was initiated with a pulse of steroids followed by a taper, and renally dosed oral cyclophosphamide. The patient was initiated on hemodialysis due to uremic symptoms and volume overload. Three months after initiation of therapy, urine output significantly improved. Laboratory data showed: a 24 hours urine creatinine clearance of 31 ml/min, sCr 2.9 mg/dL, and UPCR 5.3 g/g. Patient was euolemic. Hemodialysis was discontinued.

Discussion: MN and ANCA GN are distinct manifestations of renal injury with different clinical, laboratory, and pathology findings. Our case highlights an individual with both entities. We hypothesize that the patient’s renal findings of p-ANCA and crescentic GN were likely associated with levamisole adulterated cocaine in the background of primary MN. The patient discontinued cocaine use after our discussions. We decided to treat the patient’s MN with immunosuppressive therapy. Fortunately, the patient has responded favorably to our management with significant improvement in renal function.

PO1547
Clinical-Pathological Features of Podocyte Infolding Glomerulopathy
Ling Hong,1,2 Lin Wang,2 Zhihua Zheng,1 Wenfang Chen,2 Department of Nephrology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3Department of Renal Pathology, Guangzhou Kingmed Diagnostic Laboratory Ltd, Guangzhou, China

Background: Podocyte infolding glomerulopathy (PIG) is characterized by presence of microstructural aggregates originated from cytoplasmic infoldings of podocytes in the glomerular basement membrane (GBM). Few PIG cases have been reported and the significance of this morphology is still unclear. This study aims to elucidate the incidence, clinical-pathological features and prognosis of PIG.

Methods: Renal biopsies with PIG features from January 2018 to December 2020 in Kingmed Diagnostic Laboratory were reviewed. Patients were divided into three groups according to their clinical and pathological findings.
Results: Among 87452 biopsies, 116 (1.37%) cases were found to have features of PIG and 61 patients among them had complete clinical data and follow-up information. Most PIG cases were accompanied with other glomerular diseases, among which were 39 cases (63.9%) with lupus nephritis (Group PIG-LN), 14 cases (23%) with other glomerulonephritis such as membranous nephropathy, focal segmental glomerulosclerosis (FSGS), and minimal change (Group PIG-MCN). Only 8 cases (13.1%) were presented with pure PIG with absence of immunoglobulins and complement deposits. In the PIG-LN group, most patients revealed presence of immunoglobulin deposits, with IgG in 84.6% of the patients, C3 in 74.4% and C4 in 69.2%. Similarly, electron dense deposits were seen in PIG-N (65.9%) and PIG-GN (57.1%) in accordance with immunofluorescence, but there is no significant difference in levels of proteinuria, hematuria and creatinine among the three groups. Most patients in PIG-LN group showed increased ANA tier (100) and decreased C3 level (84.6%). The patients in the pure PIG group showed more sensitivity to glucocorticoid therapy and got a significantly higher complete remission rate (75%) than those in group PIG-LN (53.8%) and group PIG-GN (14.3%).

Conclusions: PIG is a special type of podocyte injury, which is either a separate disease entity or concomitant with other GN, among which LN is the most frequent one. Patients with pure PIG tend to be more sensitive to glucocorticoid therapy compared with those coincide with other GN.

Different degree of PIG.

PO1549
Kidney Outcomes in Biopsy-Proven Thrombotic Microangiopathy with Eculizumab Therapy
Mohammad A. Sohail,1 John R. Sedor,2 Susana Arriguín,3 Jesse D. Schold,2 Leaf C. Herlitz,2 Ali Mehdi.2 Cleveland Clinic, Cleveland, OH; ‘Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: There are limited long-term data on kidney outcomes in eculizumab-treated patients with biopsy-proven thrombotic microangiopathy (TMA). We report our experience of using eculizumab in patients with primary (genetic/antibody mediated) TMA, secondary TMA syndromes associated with antiphospholipid syndrome (APS) or systemic lupus erythematosus (SLE), as well as TMA of undetermined etiology.

Methods: We reviewed adult patients with kidney biopsy-proven TMA treated with eculizumab between 2014-2019. Transplant recipients, pregnant patients and those with scleroderma, shiga-toxin related hemolytic uremic syndrome or thrombotic thrombocytopenic purpura were excluded. Kidney response to eculizumab at 26 weeks for patients not on kidney replacement therapy (KRT) and for those requiring KRT at the time of or within 1 week of an episode of initiation of eculizumab, was defined as an increase in eGFR of 15 mL/min/1.73m² and liberation from KRT respectively. Death within 26 weeks was considered lack of response.

Results: We collected data on 16 patients (primary TMA [n=3]; secondary TMA including SLE [n=3] and APS [n=4]; TMA of undetermined etiology [n=6]). The median time from biopsy diagnosis to treatment initiation was 3.0 days (IQR: 1.0, 10.0) and the median duration of therapy was 303 days (IQR: 160, 604). 13 patients (81%) required KRT at the time of initiation of eculizumab. 4 patients died during follow up, 2 of whom died within 6 (37.5%) weeks of initiating eculizumab. Kidney response, defined as a patient required KRT when therapy was started. 2 of 3 patients who did not need KRT initially eventually progressed to end-stage kidney disease after 1 and 5.5 years from treatment initiation. 3/6 patients (50%) and 3/8 patients (37.5%) with mild and moderate interstitial fibrosis and tubular atrophy (IFTA) (IFTA) on biopsy respectively responded to therapy, whilst those with severe IFTA (n=2) showed no response.

Conclusions: Although eculizumab use has been expanding rapidly for primary and secondary TMA syndromes, our data depicts a suboptimal kidney response, which appears independent of the need for KRT at treatment initiation. Severity of IFTA may be a predictor of kidney response to eculizumab. We suggest that more data is needed on long-term kidney outcomes with eculizumab across TMA syndromes before universally adopting this expensive therapeutic strategy.

PO1550
Recurrence of Atypical Hemolytic Uremic Syndrome After Kidney Transplantation: A Prospective Cohort Study
Caroline Duineveld, Romy N. Bouwmeester, Khoa L. Wijnmsa, Nicolas Van De Kar, Jack F. Wétzels. CUREiHUS study group Radboudumc, Nijmegen, Netherlands.

Background: Since 2016, aHUS patients in the Netherlands are treated with a restrictive treatment protocol. Withdrawal of eculizumab is considered after a treatment period of three months. Furthermore, kidney transplantations in aHUS patients are performed without eculizumab prophylaxis, with initiation of eculizumab in case of post-transplant recurrence. This restrictive treatment protocol is monitored in the CUREiHUS study. Here, we present the CUREiHUS study results for kidney transplant patients.

Methods: All kidney transplant patients who received eculizumab therapy for a suspected aHUS recurrence, and who were included in the CUREiHUS study (after informed consent), were evaluated.

Results: In the period from January 2016 until October 2020 we included 15 (F 12, M 3; median age 42y, range 24-66) patients with suspected aHUS recurrence after kidney transplantation. Patients were classified as high (N=8) or moderate (N=7) recurrence risk. The time-interval to recurrence showed a bimodal distribution. Seven patients presented early after transplantation (median 3 m, range 0.3-8.8), with typical aHUS features: rapid GFR loss and laboratory signs of TMA. Eight patients presented late (median 46m, range 18-69) after transplantation. Of these, 3 patients showed typical aHUS features, while in 5 patients no laboratory evidence of TMA was seen, and only a gradual eGFR loss. Treatment with eculizumab resulted in disappearance of TMA and improvement/stabilization of eGFR in 14 patients. Withdrawal of eculizumab was thus far proposed in 10 patients, and successful in only 5. Median follow-up after recurrence was 29 months (range 3-53 months). At last follow-up median eGFR was 32.0 mL/min/1.73m² (range 7-80), considerably less than eGFR before recurrence (54.3 mL/min/1.73m², range 22-103).

Conclusions: Patients with aHUS who develop recurrence after kidney transplantation do not fully recover kidney function. The major cause is treatment delay due to late recognition of disease recurrence in patients who present with a “creeping creatinine”. Discontinuation of eculizumab is often unsuccessful.

PO1551
A Case of Thrombotic Microangiopathy from an Intra-Abdominal Abscess

Introduction: Infection mediated thrombotic microangiopathy (TMA) has a high mortality with many patients requiring kidney replacement therapy. Recognition of TMA secondary to infection in the setting of an intra-abdominal abscess is uncommon. We report a case of TMA from complicated diverticulitis and polymicrobial intra-abdominal abscess.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 25 year old non-vegetarian man presented with generalized abdominal pain, fatigue, chills and intermittent epistaxis. He was found to have severe acute renal failure with Coombs positive hemolytic anemia, thrombocytopenia, high fibrinogen, high PT/PTT, low ADAMTS13 activity (15%) and ADAMTS13 inhibitor. Further workup showed sigmoid diverticulitis with a large intra-abdominal and small intracranial mass culture positive for Streptococcus anginosus (an oral microbe with proclivity to abscess formation) and Escherichia coli. Shiga toxin was not tested. Kidney biopsy revealed acute TMA. Drainage of the abscess and treatment with antibiotics resolved the systemic features of TMA. Renal recovery was protracted and the patient required dialysis for three months, with a last sCr of ~2mg/dl.

Discussion: Infection mediated TMA is an important third subgroup of thrombotic microangiopathy. The mechanism of injury is likely due to the concerted effort of both bacteria. Escherichia coli produced shiga toxin causes direct damage to the endothelial cells, whereas the incorporation of non-human sialic acid from dairy and meat increased toxin affinity to endothelial cells and injury. S. anginosus produces an exotoxin that can lyse erythrocytes and platelets allowing IgM binding to the exposed Tn antigen, leading to the coombs positivity observed. There is decreased hepatic synthesis of ADAMTS13 in sepsis, and ADAMTS13 autoantibodies are reported in E. coli mediated TMA. Given high fatality rate, prompt recognition and treatment of the underlying infection is pivotal as ongoing infection propagates microangiopathy. Severe features of TMA can develop during the clinical course necessitating intensive treatments such as plasmapheresis. As infection can be a frequent trigger of TMA among patients with complement abnormalities, patients should undergo genetic testing of the regulatory genes involved in the complement system.

PO1552
Characteristics and Outcomes of Immune-Complex Membranoproliferative Glomerulonephritis and C3 Glomerulonephritis in Japan: A Retrospective Analysis of Data from the Japan Renal Biopsy Registry
Naoki Nakagawa,1 Sawako Kato,2 Shoichi Maruyama,3 Ichiei Narita,3 Yoshiataka Isaka,3 Committee for Renal Biopsy and Disease Registry of the Japanese Society of Nephrology,1 Asahikawa Ika Daigaku, Asahikawa, Japan; 2Niigata Daigaku Igakubu Ikaigakuka Daigakuin Ishigaku Sogo Kenkyuka,2 Niigata, Japan; 3Osaka Daigaku Igakubu Ikaigakuka Daigakuin Ishigaku Sogo Kenkyuka, Osaka, Japan.

Background: The reclassification of membranoproliferative glomerulonephritis (MPGN) into immune-complex mediated MPGN (IC-MPGN) and C3 glomerulopathy (C3G) based on immunofluorescence findings in kidney biopsies has provided insights into two distinct diseases. C3G is further classified into dense deposit disease and C3 glomerulonephritis based on electron microscopic findings. Although these diseases have poor outcomes, limited Japanese literature confined to small, single-center cohorts exist on these diseases.

Methods: We retrospectively analyzed 81 patients with MPGN type I and III from 15 hospitals in the Japan Renal Biopsy Registry (J-RBR) to compare demographic, clinical characteristics and treatment outcomes of patients with IC-MPGN to those with C3G.

Results: Of the 81 patients reviewed by immunofluorescence findings in kidney biopsies, 67 patients had IC-MPGN and 14 patients had C3G. Age at diagnosis, systolic and diastolic pressures, proteinuria, impaired renal function, and hypoalbuminemia were significantly higher in patients with IC-MPGN than in those with C3G. About 80% of the patients in both groups were treated with immunosuppressive therapy. At last follow-up (median 4.8 years), complete remission rate of proteinuria was significantly higher in patients with IC-MPGN (64.3%) than in those with C3G (29.9%; P = 0.015). The renal survival rate was lower in patients with IC-MPGN when compared to C3G (73.1% vs. 100%; log-rank, P = 0.031). Systolic blood pressure and renal function at baseline were independent predictors of progression to end-stage kidney disease.

Conclusions: The overall prognosis of patients with C3G is more favorable than for patients with IC-MPGN.

Funding: Government Support - Non-U.S.

PO1553
Early Recurrence of C3 Glomerulopathy (C3G) in the Allograft

Background: C3G encompasses both C3 glomerulonephritis (C3GN) and Dense Deposit Disease (DDD), a rare group of kidney diseases associated with alternative complement pathway dysregulation that commonly recurs in the allograft. How early recurrence occurs is underexplored.

Methods: We reviewed cases of recurrent C3G in the allograft at CUIMC. Protocol biopsies were encouraged for transplanted C3G patients (PTS) at 6 months if a for-cause biopsy (bx) had not already been performed. Median (range) reported.

Results: 9 pts (13 F; 6 C3GN, 3 DDD) were included (Table 1). 6 PTS (46%) had previous allografts fail due to C3G recurrence. Age at transplant was 32 years (18-71). Time from transplant to histologic recurrence was 54 days (5-472). 4 PTS (31%) had bland urine at first recurrence. 7 PTS (54%) had histologic recurrence at first allograft bx, 15-18 months after transplant. After 2.3 years (0.33-10.1), 11 PTS (85%) remained with functioning allografts; 5 PTS (46%) had creatinine > 2 mg/dl. 2 DDD PTS had allograft failure. 6 PTS (43%) had acute T cell mediated rejection. 2 PTS received eculizumab-both were without clinical recurrence.

Conclusions: This series highlights earlier histologic recurrence of C3G in the allograft than previously reported, partly due to protocol bx. Many PTS were without urinary abnormalities. At last follow up, majority of PTS had significant transplant CKD, severe hypertension, proteinuria, and complement abnormality. Future study is needed to better understand if early detection of recurrence, coupled with anti-complement therapies, improves outcomes.

Summary of Clinicopathologic Course After Histologic Recurrence

PO1554
C3 Glomerulopathy in Children and Adolescents
Yael Borovitz,1 Hadas Affandary,1,2 Amit Dagan,1,2 Orly Haskin,1,2 Daniel Landau,1,2 Miriam Davidovits,1,2 Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; 1Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: C3 glomerulopathy (C3G) has been classified as a glomerular complement mediated disease with predominant C3 deposits since a decade ago. Data regarding clinical course, treatment options and long term prognosis in children and adolescents is still scarce. The aim of the study was to retrospectively describe a single tertiary center’s experience with C3G in the pediatric population, and correlate presentation, pathology, complement findings, response to treatment and disease progression.

Methods: A retrospective cohort study. Patients presented with C3G by the age of 18 years compromised the study group. All cases underwent kidney biopsy at presentation. Repeated kidney biopsy was performed on a need basis, in native or transplanted kidneys.

Definition of C3G was based on the 2013 consensus guidelines. Patients underwent complement workup and genetic tests. Treatment regimen was not uniform.

Results: 17 patients were diagnosed with C3 glomerulopathy. Features of Dense deposit disease (DDD) were found in 8 patients, C3 glomerulonephritis in 6 patients. For 1 patient EM was not available. Mean age at diagnosis was 12.7 years (range 1.9 – 17.3). 6 girls and 11 boys. Median follow up 4.4 years (range 1.1-20.9). Treatment modalities ranged from ACE inhibitors and Angiotensin receptor blockers to corticosteroids, Mycophenolate Mofetil, Plasmapheresis, Rituximab and Eculizumab. Only 2 (12%) patients achieved complete remission. 4 (23%) patients reached end stage renal failure and had kidney transplantation. All of them had disease recurrence in the transplanted kidney. Complement workup was positive for C3 in 6 patients, C4NeF in 2 patients, C3NeF in 2 patients, factor H antibodies in 2 patients. Genetic testing was positive in one patient. Elevated creatinine at presentation, severe proteinuria, DDD in kidney biopsy–were correlated with worse prognosis.

Conclusions: Understanding the pathophysiology of C3G as a complement mediated disease has progressed during the past years. Still no guidelines exist regarding treatment and prognosis in the pediatric population. Our cohort presented a wide variability in disease course and presentation. Further understanding of the correlation between exact complement abnormality and C3G prognosis is warranted, especially now when new complement system blockers may become available.
Utilizing Pharmacokinetic Studies to Optimize Therapy in a Child with C3 Glomerulonephritis and Nephrotic Syndrome: A Precision Medicine Approach

Magdalena Riedl Khursigara, Damien G. Noone, Seetha Radhakrishnan, James A. Tjon, Rose Chami, Rulan S. Parekh, Valerie Langlois, Christoph Licht, Chia Wei Teoh. The Hospital for Sick Children, Toronto, ON, Canada.

Introduction: C3 glomerulonephritis (C3GN) is caused by complement alternative pathway dysregulation, has no definitive treatment and is characterized by progression to ESRD. Terminal complement blockade has successfully been used especially in patients with elevated C5b-9 levels.

Case Description: We describe a 6 year old boy with C3GN, who presented with nephrotic syndrome, severe hypertension (4 anti-hypertensive medications) and acute kidney injury. Complement C3 level was 0.12 g/L (normal 0.8-1.5) with pos C3NeF and elevated C5b-9 levels (2135, normal <239ng/ml) with a urine protein to creatinine ratio of 7, and complement C3 level of 76 mg/dL. He was re-dosed with eculizumab (600 mg every 2 weeks) and azathioprine, and over the course of 6 months, his serum creatinine, proteinuria, and complement C3 levels returned to normal. After weaning the frequency of his eculizumab infusions, he experienced a flare of DDD 15 months later. We confirmed sub-therapeutic plasma concentrations of eculizumab as free eculizumab levels were low on day 7 (9, normal >99 ug/ml) and undetectable on days 10 and 14 post-infusion. Eculizumab frequency was subsequently increased to weekly with MPA-AUC guided adjustment of MMF dosing.

Discussion: Use of pharmacokinetic studies can aid in individualized eculizumab treatment in C3GN patients with ongoing proteinuria and who failed to respond to standard dosing.

Remission of C3 Glomerulonephritis with Rituximab

Aklilanadavaky Angamuthu, Fatima Batool, Neethu Gopisetti, Imara Dissanayake, Ji Young Shin. Albert Einstein Medical Center, Philadelphia, PA.

Introduction: C3 glomerulonephritis (C3GN) is a rare form of glomerulonephritis. It is diagnosed primarily by kidney biopsy with immunofluorescence showing deposits of C3 along the basement membranes. It differs from dense deposit disease with absence of the pathognomonic deposits on electron microscopy (1). There are no randomized trials to guide therapeutic decisions. Spontaneous and treatment-associated complete remissions are rare.

Case Description: 69-year-old female with history of well controlled hypertension on amloidine was sent to hospital with elevated creatinine of 2.52 (unknown baseline) with positive ANA - 1:320 titer. Patient was asymptomatic with negative family history of kidney disease. She denied taking NSAIDS. Serum creatinine on admission was 3.05 mg/dL. Urinalysis showed numerous RBCs with 2 g of proteinuria in the 24-hour urine collection. P-ANCA was positive. All other pertinent serologies were negative including complement levels. C-ANCA, MPO, PR3. Renal ultrasound revealed medical renal disease. Renal biopsy was performed and preliminary reports showed crescentic glomerulonephritis. Pulse dose steroids was started followed by oral prednisone. In addition, Rituximab was started weekly. Final biopsy confirmed C3GN. Patient did not require dialysis and renal function significantly improved after 4 doses of rituximab to serum creatinine of 1.5 mg/dL.

Discussion: In C3GN with rapidly progressive glomerulonephritis (crescents on biopsy), treatment is not well established. Most patients are treated with steroids in combination with either cyclophosphamide or Mycophenolate mofetil (2). Rituximab was used in some case reports (3). In our patient, since P-ANCA was positive and preliminary biopsy showed crescents, Rituximab was started immediately after pulse dose steroids. Patient did not require dialysis, due to good response and remission. Rituximab is a promising treatment option for C3GN. Mycophenolate Mofetil in C3 Glomerulopathy, and Pathogenic Drivers of the Disease. Clin J Am Soc Nephrol. September 2020, 15 (9) 1287-1298. Giaine P et al. Remission of C3 glomerulopathy with rituximab as only immunosuppressive therapy. Clin Nephrol. 2015 Jan;83(1):57-60.

Myeloperoxidase Immunohistochemical Staining and Response to Eculizumab in a Pediatric Patient with Dense Deposit Disease

Introduction: Previous studies have demonstrated residual complement mediated deposits in repeat renal biopsies of patients with C3 glomerulonephropathies (Dense deposit disease (DDD) and C3 glomerulonephritis) following eculizumab treatment despite clinical improvement. With the residual complement deposition, it is often difficult to determine whether there is a reduced complement mediated endothelial cell injury. Herein, we report the use of myeloperoxidase (MPO) immunohistochemical staining to show decreased glomerular endothelial cell injury in a pediatric patient with DDD on chronic eculizumab therapy.

Case Description: Our patient was diagnosed with DDD by renal biopsy when he was 5 years old after presenting with a serum creatinine of 5.2 mg/dL, a urine protein to creatinine ratio of 2.5, and a complement C3 level of 50 mg/dL. Functional complement testing showed the presence of C3 and C5 nephritic factors. He was treated with eculizumab (600 mg every 2 weeks) and azathioprine, and over the course of 6 months, his serum creatinine, proteinuria, and complement C3 levels returned to normal. After weaning the frequency of his eculizumab infusions, he experienced a flare of DDD 15 months after initial presentation with a serum creatinine of 3.6 mg/dL, urine protein to creatinine ratio of 7, and complement C3 level of 76 mg/dL. He was re-dosed with eculizumab (600 mg every 2 weeks) with a rapid response to treatment. He had normalization of his serum creatinine to pre-flare levels within 6 months. Since then he has been maintained on eculizumab infusions (600 mg every 4 weeks) along with mycophenolate mofetil. A second kidney biopsy was performed after 3 years of treatment with eculizumab to evaluate response to treatment. The biopsy showed some residual features of dense deposit disease including C3 complement deposition. To evaluate if eculizumab blocked complement mediated injury on glomerular endothelial cells, MPO staining of his initial and repeat biopsy was performed: his initial biopsy revealed diffuse endothelial staining for MPO along glomerular endothelium and the repeat biopsy showed either no MPO staining or weak MPO staining in the glomerular endothelium.

Discussion: In this case, we find that MPO immunohistochemical staining may be useful for monitoring the response to complement blockade in patients with DDD.

Pregnancy-Associated Membranoproliferative Glomerulonephritis (MPGN)

Pamela C. Vasquez Buitron,1 Saedel K. Shaffi,1 Zhi Xu,1 Michael B. Kuperman,2 J Pedro Teixeira.1 1University of New Mexico School of Medicine, Albuquerque, NM; 2Arkana Laboratories, Little Rock, AR.

Introduction: Nephrotic syndrome (NS) in pregnancy is rarely due to MPGN. We present a case of MPGN in pregnancy for which no other cause was found.

Case Description: A 33-year-old G1P0 woman develops hypertension and proteinuria at 12 weeks gestation followed at 21 weeks by NS (75 g/24h proteinuria, albumin 1.1 g/dL), AKI with creatinine (Cr) 1.1 mg/dL (up from 0.6), hematuria, and mildly elevated AST and ALT. C4 is low (5.9 mg/dL). SPEP and UPEP detect monoclonal IgG kappa with serum light chain ratio 5.1. ANA, anti-dDNA, cryoglobulins, C3 nephritic factor, and serologies for hepatitis B and C, T. pallidum, and HIV are negative. Renal failure (B) reveals MPGN. After counseling, she opts to end the pregnancy. Cr, AST, ALT, and hematuria rapidly normalize, but the proteinuria at first persists. Immunosuppression is offered, but she declines. The proteinuria slowly falls to <0.7 g Cr with supportive care and telmisartan over a year. Apart from low C4, an atypical hemolytic uremic syndrome (aHUS) panel is negative. Genetic testing for aHUS is also negative (heterozygous mutation in DFGK and heterozygous deletion in CFH R1-CFH R3). HLA analysis shows B35 and B51 alleles. C4d staining later performed on the biopsy is strongly positive.

Discussion: As in this case, NS in pregnancy is associated with an increased risk of complications such as superimposed preeclampsia. The etiology of this MPGN case is unknown, with no clear infectious or autoimmune cause. The C4d deposition and negative aHUS testing suggest a defect in the classic complement pathway. This paraprotein may or may not be involved as, though the immune complex deposition was polyclonal, monoclonal IgG-kappa has been rarely reported to activate complement in other autoimmune disorders. Regardless of mechanism, we speculate this MPGN case was triggered by pregnancy as it improved after the pregnancy with supportive care alone.

PO1559

Comparing and Contrasting Glomerular Disease Patients: A Real-World Analysis Showing Demographic, Clinical, and Treatment Differences Across More Than 1,000 Patients

Tucker B. Hurtado, Ryan Rex, Jennifer Robinson. SphereX Advanced Analytics Group SphereX Global Insights, Exton, PA.

Background: One-half of nephrologists selected glomerular diseases as their leading area of interest in nephrology in 2020. These rare and often-idiopathic disorders are seen as particularly challenging to manage, but an influx of promising pipeline drugs may offer new treatment options in the not-so-distant future.

Methods: 1,112 glomerular disease patient records were collected in collaboration with 290 US nephrologists via HIPAA-compliant, online chart review tool between December 20, 2020 – February 16, 2021.

Results: Chart audits reveal ~8% of nephrologists’ patient populations have a glomerular disorder. Of that group, 26% have IgAN, 26% have FSGS, and 3% have Alport’s Syndrome, among other conditions. IgAN patients are typically middle-aged, white males, in the middle-to-upper class and often present with hypertension, hyperlipidemia, and/or obesity. FSGS patients are mostly middle-aged, black males, in the lower-to-middle class and often present with hypertension, hyperlipidemia, obesity, and/or edema. Alport Syndrome patients tend to be younger (18-49), white males, in the lower-to-middle class and present with hypertension, hearing loss, and sometimes ocular abnormalities. Of the three conditions, FSGS patients most heavily prescribed steroids and advanced therapies like MMF, cyclophosphamide, and Achar Gel and are least likely to be deemed “optimally managed” by their nephrologist. Alport patients are much less likely to receive steroids and are most likely to be seen as optimally managed. Interestingly, despite the value of ACEI/ARB therapy, 42% of IgAN patients were not on therapy at referral, with FSGS and Alport close behind. Nephrologists are trialing SOLITZis across conditions, with up to one-in-ten patients currently on the drug. A diagnosis for Alport Syndrome may take several months or even years after referral to determine (unlike IgAN and FSGS where it usually takes under four months). Alport is also the least likely of the three diseases to be diagnosed via kidney biopsy. Patient referrals are often deemed “late” by nephrologists, but particularly with the faster-progressing FSGS and IgAN.

Conclusions: Deeper understanding of key comparative differences among rare glomerular diseases may aid physicians in developing strategies for diagnosis and treatment.

PO1560

Glomerular Diseases in Flanders: Overview of the FCWG Biopsy Registry

Dries Deleersnie,1 Wim Laurens,2 Johan M. De Meester,2 Amelie Dendooven,2 Ben Sprangers.3 Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium, 1AZ Nikolaas, Sint-Niklaas, Belgium; 2Universitair Ziekenhuis Gent, Gent, Belgium.

Background: High-quality population-based registries on glomerular diseases are required for epidemiological study and new trial design. The FCWG (Flemish Collaborative Glomerulonephritis Group) database is a population-based registry that has been including data on all native kidney biopsies performed in Flanders since 2017 (Northern part of Belgium) covering a population of approximately 6.5 million inhabitants.

Methods: Clinical data and pathological diagnosis according to the ERA-EDTA Coding system for Primary Renal Disease are collected together with pathological data including primary and secondary pathological diagnoses according to the Mayo Clinic/Renal Pathology Society Consensus Guideline 2016. Here, we describe the main results of the first three years of the registry.

Results: From 2017 until 2019, 2178 biopsies were included, of which 5.7% were performed in the pediatric population. Median age (IQR) was 59 years (42-71). Biopsy incidence proportion was 1.30 biopsies p.m.p. per year in the adult population. Glomerular disease was present in 54% of the adult biopsies (Fig. 1A). IgA-nephropathy (IgAN) was the most frequently diagnosed disease in adults (17.3% of total, 30.2% of glomerular subcategory). The etiologies of the nephrotic syndrome differed across age categories, with membranous nephropathy (MN) being most frequently diagnosed in the total group of adult nephrotic patients (Fig. 1B). IgAN and pauci-immune glomerulonephritis (AAS) were the two most important causes of the nephritic syndrome in adults. A crescentic pattern of injury was most frequently diagnosed in adults with AAV, lupus nephritis (LN) and IgAN (Fig. 1C, crescents in 82%, 31% and 24% of biopsies, respectively).

Conclusions: The FCWG database is a valuable population-based registry that characterizes the epidemiology of glomerular disease in Flanders. These results are relevant to the clinician, will enable disease subgroup analyses and are useful to set up observational or interventional trials in patients with glomerular disease.
PO1562
The Thromboembolism Among Hospitalized Patients with Different Types of Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital
Xiaohong Fan, Jie Ma, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Chronic kidney disease is associated with hypercoagulability and platelet dysfunction. However, data on thromboembolism associating different types of chronic glomerulonephritis (CGN) are less.

Methods: We conducted a retrospective analysis using the database of hospitalization with CGN in Peking Union Medical College Hospital (PUMCH), China from 2000 through 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify types of thromboembolism and glomerulonephritis including lupus nephritis (LN), systemic vasculitis (AAV), Henoch-Schönlein purpura nephritis (HSPN), IgA nephritis (IgAN), idiopathic membranous nephropathy (IMN), minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS). Cochran-Armitage trend and Logistic regression were used in the analysis.

Results: Between 2000 and 2017, there were 15,714 hospitalizations with the aforementioned CGN. Their mean age was 51.7±19.8 years and 39.4% were males. The annual prevalence of overall thromboembolism increased steadily from 1.6% in 2000 to 6.6% in 2017 in a dose-response manner (p for trend <0.001). Among all thromboembolism cases, 49.8% had venous thromboembolism and 31.7% had a pulmonary embolism. The prevalence of thromboembolism in IgAN, FSGS, MCD, IMN, HSPN, LN, and AAV were 0.6%, 2.4%, 2.6%, 5.89%, 2.2%, 4.4%, and 5.3%, respectively. The patients with thromboembolism had a 2.30-fold increased risk of death (95%CI 1.53-3.40) after adjustment for age and gender. In multivariate analyses adjusted for multiple confounders such as gender, hypertension, diabetes, cardiovascular disease, cerebrovascular disease, heart failure, chronic obstructive pulmonary disease, infection, LN (OR 8.15; 95% CI 5.25-12.65), IMN (OR 6.93; 95% CI 4.39-10.92), AAV (OR 4.53; 95% CI 2.66-7.61), MCD (OR 4.42; 95% CI 2.56-7.61), HSPN (OR 4.05; 95% CI 2.33-7.03), and FSGS (OR 3.18; 95% CI 1.56-6.49) were significantly associated with the increased risk of thromboembolism compared with IgAN.

Conclusions: In the present study, chronic glomerulonephritis, particularly lupus nephritis, idiopathic membranous nephropathy, and systemic vasculitis were independently associated with an increased risk of thromboembolism.

PO1563
Identification and Validation of Infection-Related Acute Care Events in Patients with Glomerular Disease
Dorey A. Glenn,1 Jaryc Zec,2 Anisha R. Hegde,3 Candace D. Henderson,3 Michelle M. O’Shaughnessy,4 Andrew S. Bomback,5 Keisha L. Gibson,5 Larry A. Greenbaum,5,6 Sarah Mansfield,7 Yichun Hu,7 Laura H. Mariani,8 Ronald J. Falk,1 Susan L. Hogan,9 Michelle Denburg,4 Amy K. Mottl.10 University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC;1 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA;9 Columbia University, New York, NY;4 University of Michigan, Ann Arbor, MI;1 Children’s Healthcare of Atlanta Inc, Atlanta, GA;2 Emory University School of Medicine, Atlanta, GA;4 University College Cork, Cork, Ireland;5 Arbor Research Collaborative for Health, Ann Arbor, MI;6 The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Infections are an important contributor to morbidity and mortality in glomerular disease (GD). Accurate identification of infections using real world clinical data would support the conduct of observational studies examining infection risk, but standard approaches are labor-intensive. We sought to derive and test the validity of diagnosis-code based algorithms to identify infection-related acute care events (ACEs) within a large cohort of children and adults with GD.

Methods: CureGN is a prospective multi-center cohort study of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, or IgA Nephropathy. We describe the sensitivity, specificity, and positive and negative predictive values (PPV/NPV) of four infection diagnosis code lists using manually curated infectious and non-infectious ACEs (hospitalization or emergency department visit) as the gold standard. We then validate the best performing code list within a more contemporary CureGN cohort, using multi-site adjudication of medical records.

Results: In the development phase, the optimal performing combination of diagnosis code lists were used by CureGN coordinators combined with those described by Sahil et al. (PPV 78%, 95% CI 73-83%) (Table 1). Using this code list, 265 infections and 1231 non-infectious ACEs were identified among 2599 CureGN participants in the validation phase, of which 124 were randomly selected and adjudicated. The PPV and NPV for the final code set were 87% (95% CI: 75-99%) and 83% (95% CI: 72-93%) respectively.

Conclusions: Diagnosis codes can be used to accurately identify infection-related ACEs among patients with GD. Future studies should validate our findings in other GD cohorts and for specific infection types of high-severity or burden.

PO1564
Patients with Glomerular Disease Are at Very High Risk of TB Infection Compared to the General Population
Canney,1,2 Jonathan Greenbaum,3 Yuyan Zheng,1 Jonathan Hogan,2 Sean Barbour,1,4 BC Provincial Renal Agency, Vancouver, BC, Canada; 2Department of Medicine, University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, ON, Canada; 3Division of Nephrology, University of Pennsylvania, Philadelphia, PA; 4Division of Nephrology, University of British Columbia, Vancouver, BC, Canada.

Background: Advanced kidney disease is a known risk factor for active TB disease; however this risk has not been studied in patients with glomerular disease (GN). We sought to determine the incidence of TB disease in patients with GN and to explore the risk of TB disease associated with immunosuppression in patients with GN.

Methods: A population-level cohort was created using a centralized kidney registry (2000-2012) of all GN cases in British Columbia, Canada: IgA nephropathy (IgAN) n=857, focal segmental glomerulosclerosis (FSGS) n=564, ANCA-GN n=404, lupus nephritis (LN) n=360, membranous nephropathy (MN) n=398, minimal change disease (MCD) n=191, and other GN (n=305). TB disease was ascertained by linkage to administrative databases. High TB incidence was defined as >30 per 100,000 person years (PY) consistent with the definition used in first-world countries. Incidence rates were standardized to the general population to generate standardized incidence ratios (SIR, 95% CI). Hazard ratios were calculated using Cox proportional hazards regression.

Results: During a median follow-up 6.2 years, there were 41 cases of TB disease. TB incidence rate was 197.4/100,000PY, and was higher in patients with LN vs. other types of GN (403.0/100,000PY, p<0.05). TB incidence in patients with GN was 23-fold higher than the general population (SIR 23.4, 16.8-31.7), and was high in both Canadian and foreign-born patients (range 124.1-579.6/100,000PY). TB incidence was higher during periods of IS use (282.4 vs. 147.8 per 100,000PY, p<0.05), and most cases (80.5%) had IS exposure prior to TB diagnosis. Time from IS to TB disease was highly variable, with median 3.9 years but 24% of TB cases occurred within 1 year. Reduced kidney function and higher proteinuria were also associated with increased TB risk (Table).

Conclusions: Patients with GN have a high risk of TB disease, irrespective of GN type or country of origin. TB disease can occur within months of starting IS, suggesting that all GN patients should be screened for latent TB early in their disease course.
PO1565
The Impact of Obesity on Glomerulonephritis: A Multicenter Cohort Study of Kidney Biopsy over 40 Years
Tae-bum Kim,1 Hyeon-Jin Min,2 Young-Bin Son,1 Jonghyun Lee,1 Myung-Gyu Kim,1 Sang-Kyung Jo,3 Won-Yong Cho,1 Eun Hui Bae,1 Jeun Oh,1 Shin-Young Ahn,1 Sewon Oh.1 Korea University Medical Center, Seoul, Republic of Korea;2Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea;3Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea.

Background: Worldwide obesity has increased by almost three times between 1975 and 2020. Many studies reported that obesity related kidney disease was also increasing, and most of them were focal segmental glomerulosclerosis (FSGS). However, little was known about the prevalence and outcome of other type of glomerulonephritis (GN) in obese patients.

Methods: A total of 14,833 adult patients who underwent kidney biopsy and had body mass index (BMI) were identified in 18 tertiary hospitals during 1979-2018. Obesity was defined as BMI ≥ 30 kg/m². We analyzed the prevalence of specific forms of glomerulonephritis in obese patients and effect of obesity on mortality and end stage kidney disease (ESKD).

Results: Obese patients in glomerular disease have increased about 12.8-fold over 40 years between 1979-1988 (0.6%) and 2009-2018 (7.7%). In GN patients with obesity, prevalence of IgA nephropathy (IgAN) is the most common (33.7%) followed by FSGS (13.3%), minimal change disease (MCD) (10.8%), membranoproliferative (MPGN) (10.6%), diabetic nephropathy (DMN) (6.0%), lupus nephritis (LN) (2.7%), and hypertensive nephropathy (HT-N) (2.6%). The prevalence of FSGS (HR 1.60, 95% CI 1.24-2.06), DMN (HR 1.46, 95% CI 1.01-2.12) and HT-N (HR 2.14, 95% CI 1.29-3.54) were significant higher in obese patients compared than non-obese patients. Obesity had a 1.39-fold increased risk for ESKD progression during 93.8 ± 13.3% months follow up in total patients (95% CI 1.11-1.73). Obesity had higher risks for progression of ESKD in MCD (HR 2.48, 95% CI 1.02-6.04) and LN (HR, 3.28, 95% CI 1.30-8.31). In patients with FSGS, DMN, and HT-N, obesity was not associated with ESKD. Obesity was not associated with mortality in GN patients although obesity was related to mortality only in MCD patients (HR 2.48, 95% CI 1.02-6.04).

Conclusions: Obesity rates are increasing in GN patients. The prevalence of FSGS, DMN, and HT-N are significantly higher in obese patients although IgAN is the most common form of GN. Obesity had significant risks for progression of ESKD in patients with GN, especially MCD and LN patients.

PO1566
Obesity at Time of Diagnosis Is Associated with Proteinuria in Glomerular Disease
Evan Zeijler, Yichun Hu, Caroline J. Poulton, Lauren N. Blazek, Amy K. Mottl, Jennifer E. Flythe, Susan L. Hogan. UNC Kidney Center, Chapel Hill, NC.

Background: Obesity is an established risk factor for chronic kidney disease (CKD). The relationship between obesity and glomerular disease outcomes is not well studied.

Methods: We evaluated a cohort of adult patients with biopsy-proven IgA nephropathy, focal segmental glomerulosclerosis (FSGS), ANCA-associated vasculitis (ANCA), or membranoproliferative (MPN) between January 2014 and June 2020, and follow up through April 2021. We categorized body mass index (BMI) at time of biopsy as BMI<25 kg/m², 25 kg/m²≤BMI<30 kg/m² or ≥30 kg/m². We used Fisher's exact and Kruskal-Wallis tests to compare baseline characteristics between groups and a proportional hazards model to evaluate factors associated with CKD progression to kidney replacement therapy (KRT).

Results: The cohort included 153 patients: 77 (50%) male with median age 50 (IQR 38-65) years and median BMI 28 (IQR 24-34) kg/m². Compared to patients with lower BMIs, patients with BMI ≥25 kg/m² had higher median urine protein to creatinine ratios (uPCR) (p=0.02, Table 1). In univariate analyses, factors associated with progression to KRT were: blood pressure (p = 0.01), uPCR (p <0.01), and lower eGFR (p=0.001). BMI at biopsy was not associated with CKD progression, adjusted HRs (95% CIs): BMI 25-29.9 kg/m² ≤ 1.09 (0.42-2.83); BMI ≥ 30 kg/m² ≤ 1.54 (0.68-3.52). Logrank PC-value for KM curves was 0.004, with paired uPCR values imparting the greatest distinction between curves (data not shown).

Conclusions: Among glomerular disease patients, BMI was associated with proteinuria, but not with progression to KRT.

PO1567
When to Biopsy Type 2 Diabetes Mellitus (DM2)
Haridjan Sosa Barrios,1,2 Victor Burguera,1,2 Maria Garcia,1,2 Ana Saiz,1,2 Javier Villacortaperez,1,2,3 Guillermo F. Conde,1,2 Milagros Fernández-Lucas,1,2 Maite Rivera Gorria,1,2 1Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Instituto Ramon y Cajal de Investigacion Sanitaria, Madrid, Spain; 3Universidad de Alcala de Henares Facultad de Medicina y Ciencias de la Salud, Alcala de Henares, Spain.

Background: DM2 patients may have diabetic (DN) or non-diabetic renal disease (NDRD) and a histological diagnosis is needed. There is no clear consensus on when to biopsy, but a predictive model was recently published (1).

Methods: Aim: Assess NDRD prevalence, histology and apply the predictive score in our cohort. Methods: Retrospective analysis of native kidney (NK) biopsies performed in our center from 2016 to 2020. Data collected included DM history, retinopathy, peripheral vascular disease (PVD), insulin prescription, proteinuria, BMI and hematuria >10 cells/HPF. A score ≥3 was highly suggestive of DN and would preclude renal biopsy (RB). Results: 62 of 274 NK RB’s had DM, 66.1% males with a mean age of 64±13.7 (range 23-83). Mean estimated glomerular filtration rate (MDRD4) was 41±26.5 ml/min/1.73m² (range 6-98) with mean BMI 27.9 (range 18-41). Mean proteinuria was 4453 mg/g (range 4.56249) and 51.6% had microhematuria. 51.6% had a DM history >10 and 28.3% < 5 years since diagnosis. 82.3% did not have retinopathy, 11.3% had neuropathy and 48.4% were on insulin. 27.4% had PVD, 6.5 % ischaemic cardiomyopathy (ICD) and 3 had a previous stroke. RB indications: 21 nephrotic syndrome, 2 nephritic syndrome, 6 proteinuria-hematuria, 18 non-nephrotic proteinuria, 7 renal impairment and 8 AKI. Histology: 22 had DN (38.6%), 35 NDRD (61.4%) and insufficient in 5. NDRD included crescentic glomerulonephritis, membranous, FSGS, chronic tubulointerstitial nephritis, ATN, IgA GN, minimal change, amyloid, hiperfiltration, glomerular sclerosis and chronic inespecific lesions. Longstanding DM (>10 y), retinopathy, neuropathy and PVD were independent predictors of DN (p value 0.02, 0.01, 0.001 and 0.001). Neither hematuria, nephrotic range proteinuria nor ICD were significant. Score: Patients with a score>3 had DN except 2 (oxalate crystals and cast nephropathy). 70.2% with a score>3 had NDRD and 64% of those with <1 did not have DN.

Conclusions: Excellent correlation with DN and could be efficient on RB decision making process in these patients. Validation in multicentric studies is desirable. 1.García-Martín F. et al. When to perform renal biopsy in patients with type 2 diabetes mellitus? Predictive model of non-diabetic renal disease. 10.1016/j nefro.2019.07.005

PO1568
Year of Life Lost due to Premature Death from Glomerulonephritis in Thailand
Chitnamorn Janphrang, Suchin Worawichwong, Sarinya Boongird, Umaporn Udomsubpayakul, Montira Assanatham, Chagriya Kitiyakara. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: The contribution of Glomerulonephritis (GN) on mortality is not fully known. The impact of each GN subtype on premature mortality can be measured by calculating the year of life lost (YLL), which takes into account the age at which deaths occur. Therefore, this study aimed to estimate premature mortality in GN using the average YLL.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: A total of 1,022 kidney biopsies was performed. The median follow-up time was 67 (IQR 45, 92) months. Age for GN patients was 43.9 ± 16.7 years and 44.8% males. The total and average YLL of all GN were 4741.9 years and 4.6 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 vs 2.23 years (p < 0.05). DN (n = 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 1.57.

Conclusions: GN causes premature mortality with secondary GN being associated with higher premature death than primary GN. DN and LN nephritis have the highest YLL. This study provides useful information on the impact of GN for prioritization of public health policies intervention.

PO1569
The Significance of Hematuria in Primary Proteinuric Glomerular Disease Outcomes
Dorota Marchel,1 Maria Larkina,1 Damien Ferman,1 Jennifer Lai Yee,1 Debbie S. Gipson,1 Andrew S. Bomback,2 Pietro A. Canetta,2 Amy K. Mottl,2 Rulan S. Parekh,3 Manish K. Saha,3 Matt G. Sampson,3 Howard Trachman,3 Richard A. Lafayette,4 Laura H. Mariani,1 University of Michigan, Ann Arbor, MI; Columbia University, New York, NY; University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; Boston Children’s Hospital, Boston, MA; NYU Langone Health, New York, NY; The Hospital for Sick Children, Toronto, ON, Canada; Stanford University, Stanford, CA.

Background: Hematuria is associated with the incidence and progression of CKD. The study aims were to assess the prevalence of hematuria in a large cohort of proteinuric glomerular disease and assess the association between hematuria and kidney-related outcomes.

Methods: Hematuria was assessed at first reported study urinalysis in patients with MN, MCD, and FSGS in NEPTUNE and CureGN cohorts with >24 months of follow-up. Hematuria was defined as small, moderate, or large blood on urinary dipstick and no hematuria was negative or trace blood. Multivariable Cox proportional hazards models were fit for time to composite outcome (ESKD or 40% decline in GFR and eGFR <60) and proteinuria remission (UPCR <0.3 mg/g).

Results: 1,108 adults and children were included. 412 (37%) patients had FSGS, 389 (36%) had MCD, and 307 (28%) had MN. 745 (67%) participants were positive for hematuria at first urinalysis. Those who had hematuria vs. those without at first urinalysis were more likely to have an underlying diagnosis of MN (37% vs 23%), be older (34 vs 25 years), have shorter time since biopsy (128 vs 315 days) and higher UPCR (3.6 vs 8.0). Patients with hematuria had higher rates of the composite outcome and lower rates of complete remission (Figure 1). After adjusting for diagnosis, age, sex, UPCR, eGFR, time since biopsy, and cohort, hematuria was associated with a higher hazard of reaching the composite outcome (HR 1.39 [1.05, 1.84], p-value 0.02) and lower hazard of reaching proteinuria remission (HR 0.71 [0.55-0.91], p-value 0.006).

Conclusions: Hematuria is prevalent among patients with podocytopathic disease not classically considered nephritic. There was an independent association between hematuria and worse kidney related outcomes. The underlying mechanisms warrants further investigation and include genetic predisposition, structural alterations in the glomerular basement membrane, and tubular toxicity from heme pigment.

PO1570
Vacularised Denatured Casts Are a Distinct Type of Urinary Cysts Associated with Severe Nephrotic Glomerulopathy
Akanaskh Ramandan,1,2 José A. Poloni,3 Abhirup Sarkar,3 Ana P. Giolo Franz,4 Juan Carlos Q. Veloz,1 3 Ochsner Medical Center - New Orleans, New Orleans, LA, 4Universidade do Vale do Rio dos Sinos, Sao Leopoldo, Brazil, 5Suraksha Diagnostics, Kolkata, India; *Hospital de Clinicas de Passo Fundo, Passo Fundo, Brazil.

Background: Urinary casts identified through microscopic examination of the urinary sediment (MicrExUrSed) constitute clinically useful elements for the diagnosis of acute and chronic kidney pathologies. Granular, waxy and cellular casts are well characterized. However, a unique type of casts containing non-polarizable lipid-like granules immersed within a lightly granular cast matrix is occasionally found. These casts have been labeled as vacuolated denatured casts (VDC).

Methods: We utilized an educational social media platform (Twitter) to probe for individual cases of VDC. We surveyed known educators who frequently post microphotographs of MicrExUrSed asking for filed cases of identification of VDC. Demographic and clinical characteristics were extracted and representative images were compiled for correct identification of VDC.

Results: Four urine microscopists (2 from South America, 1 from India, 1 from USA) contributed to the case series. A total of 12 cases were identified. Images were carefully reviewed to confirm identity of VDC. Median age 53 (27-78), 80% men, 50% had type 2 diabetes mellitus. Median serum creatinine at the time of MicrExUrSed was 3.6 (1.7-5.5) mg/dl. All (100%) patients had >3 protein by urine dipstick. Urine protein-creatinine ratio was in the nephrotic range in all 5 cases with available value (median 10.2 [3.3-11.8] g/g). Concomitant findings included hematuria (58%), waxy casts (67%), granular casts (80%), fatty casts (42%) and renal tubular epithelial cells (58%). Histopathological diagnosis was available in 10 cases: 3 diabetic glomerulopathy, 3 focal segmental glomerulosclerosis, 2 transplant glomerulopathy, 1 membranous nephropathy and 1 advanced arterio nephrosclerosis. Greater than 25% interstitial fibrosis was present in 6/10 (60%) cases.

Conclusions: VDC are a distinct type of casts that can be found in specimens of patients with advanced proteinic glomerulopathy. The specific origin and composition of these casts remains unknown and requires further study.

PO1571
Detection of Urinary Acanthocytes for the Diagnosis of Glomerulonephritis
Akanaskh Ramandan,1,2 Sweeta Rani Kanduri,1 Vinip Varghese,1 Sarah P. Rosenbloom,1 Juan Carlos Q. Veloz,1,3 Ochsner Medical Center - New Orleans, New Orleans, LA; The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.

Background: Acanthocyturia is a specific indicator of glomerulonephritis (GN). However, it is reported that the sensitivity of acanthocyturia for the diagnosis of GN is merely around 50%. Examiner expertise is expected to affect the ability to identify urinary acanthocytes. Thus, we hypothesized that in a well-equipped laboratory with proficient observers, the sensitivity of acanthocyturia for the diagnosis of GN can be improved.

Methods: In our institution, we have established a prospective data collection of individuals seen in nephrology consultation who had urine specimen subjected to microscopic examination (MicrExUrSed) as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed within 2 weeks of the MicrExUrSed. We assessed the performance of acanthocyturia in the diagnosis of biopsy-proven GN. Acanthocyturia reflects glomerular hematuria caused by forms of glomerular disease characterized by injury to the endothelium, mesangium, glomerular basement membrane or blood vessel, but not injury to the podocyte that classically presents with proteinuria. Therefore, podocytocytic casts were grouped with other diagnoses (tubular, interstitial, etc.) as non-GN.

Results: Among 390 patients with MicrExUrSed, 70 underwent kidney biopsy and were included. Mean age was 55 years, 50% were women. White race accounted for 52% (median 16.7 years and 44.8% males). The total and average YLL of all GN were 4741.9 years and 4.6 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 vs 2.23 years (p < 0.05). DN (n = 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 1.57.

Conclusions: GN causes premature mortality with secondary GN being associated with higher premature death than primary GN. DN and LN nephritis have the highest YLL. This study provides useful information on the impact of GN for prioritization of public health policies intervention.

PO1572
Feasibility and Acceptability of Home Urinalysis Monitoring Using a Smartphone Application
Daniella Levy Erez, Hannah C. Derwick, Susan L. Furth, Lance S. Ballester, Jonah Mint, Stephanie Onuemu, Michelle Denburg, The Children's Hospital of Philadelphia, Philadelphia, PA; Schneider Children's Medical Center of Israel, Petah Tikva, Israel; Hebrew IO, Tel Aviv, Israel; Ben Gurion University Faculty of Health Sciences, Beer Sheva, Israel.

Background: Monitoring proteinuria in patients with kidney disease is of crucial importance given its implications for long term disease progression and clinical management. As part of efforts to encourage test adherence, leveraging technology to provide a clinical grade urine analysis result from a home test can greatly enhance the clinical experience for patients, caregivers and providers.

Methods: Children and young adults (5-21 yrs old) at a single pediatric center participated. Caregivers or patients (>12yrs) completed a brief survey and then received a home urinalysis kit by mail. The Healthy.io smartphone app uses advanced computer vision to assess the urinalysis dipstick using the smartphone camera. Families downloaded the app through a text message link and performed a home urine test followed by a survey about their experience. Urine results immediately appeared in the app for patients and accessed by the study team through a secure portal. Patient satisfaction was compared between the new app and current practice (home albustix or a urine sample brought to clinic) using Wilcoxon rank test with a p value <0.05. Free text responses were analyzed to identify themes related to the app experience.

Results: 103 children, 63 (61%) male, median age 10.9 yrs. (IQR 7.8-14.2) were enrolled. Primary diagnosis included: 47(46%) glomerular disease, 48 (47%) non-glomerular disease and 8 (8%) kidney transplant recipients. 101(98%) patients were satisfied with the smartphone app compared to 41(40%) patients who were satisfied with the current practice (p=0.0001. (Table 1) Patients’ free text comments were divided into themes in table 2.

Conclusions: The Healthy.io home testing app received very high rates of satisfaction among patients and caregivers compared to current practice and holds great potential to enhance patient-centered care.

Proliferative Glomerulonephritis in a Patient with NK Cell Lymphocytosis
Hannah Angle, Jia Yi, Koyal Jain. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Introduction: Monoclonal gammapathy of renal significance (MGRS) occurs in patients with non-malignant lymphoproliferative disorders who present with kidney injury secondary to monoclonal immunoglobulin deposition. 1 We present a rare case of proliferative glomerulonephritis (PGN) likely due to NK cell lymphocytosis.

Case Description: A 57-year-old male with NK lymphocytosis and IHTN presented with progressively worsening oliguric renal failure (creatinine 1.1 to 6.2 mg/dL over 3 months) and elevated lambda free light chains (FLC) with a k/λ ratio of 0.06 (k=3.14, λ=52.58). Urine sediment showed numerous dysmorphic RBCs and granular casts. Renal biopsy (limited specimen) revealed PGN with polyclonal-IgG-dominant deposition and background of moderate interstitial fibrosis and tubular atrophy. Although obvious monoclonal lesions were absent and the PGN may have been coincidental, there was concern for a potential paraneoplastic GN induced by NK lymphocytosis or, less likely, MGRS. Thus, patient was treated with Cyclophosphamide-Bortezomib-Dexamethasone (CyBorD). However, due to worsening kidney function patient was started on hemodialysis, hoping for potential renal recovery. Despite significant hematologic response (plasma cell burden <1%), chemotherapy was discontinued after 7 months due to lack of renal improvement and worsening medication side effects.

Discussion: This case suggests a potential rare cause of PGN with polyclonal-IgG-dominant deposition due to NK cell lymphocytosis. This is the first case to describe a potential association between them. Additionally, while the patient did have a hematologic response to the CyBorD, there was no renal recovery. Although the PGN may have been coincidental, CyBorD therapy should have had some effect while treating PGN. A potential of the disease resulting in end-stage kidney disease within 3 months in our patient. It also brings up the question of whether it was the presence of NK cell lymphocytosis that worsened the renal prognosis. Such cases are extremely difficult to treat and likely have a poor prognosis. PO1574
A Sporadic Case of Fibronectin Glomerulopathy in Which Mass Spectrometry Was Indispensable for the Diagnosis
Takahisa Kunitomo, Takahisa Kawakami, Kiyotaka Nagahama, Satoru Hibino, Kazuhiro Fukuoka, Yosinori Komagata, Shinya Kaname. Kyorin University, Tokyo, Japan.

Introduction: Fibronectin glomerulopathy (FG) is an autosomal-dominant hereditary disease, which is caused by deposition of mutated fibronectin (FN). The immunostaining of FN is decisive for the diagnosis. We present a case of FG, in which FN was not detected with immunostaining and the detection of FN with mass spectrometry determined the diagnosis.

Case Description: A 60-year-old female with non-functional right kidney with calculi, 5-year history of proteinuria and 2-year history of hypertension presented with proteinuria and nephrotic edema. There was no family history of kidney diseases. Physical examination was significant for blood pressure of 176/98 mmHg and the edema. Laboratory test showed serum creatinine of 2.53 mg/dL, serum albumin of 2.3 g/L, urinary protein 5.8 g/day, and slight urinary glomerular RBCs. Anti-nuclear antibody, monoclonal protein, cryoglobulin, HCV, or hypocomplementemia was not detected. Open biopsy was performed. Light microscopy showed lobular glomeruli with mesangial expansion with PAS-positive material. Immunoglobulins, including k and λ, light chains, and complements were not detected. Electron microscopy showed massive mesangial deposits with fibrillar structure. However, Congo red staining and immunostaining of DNAJPB and fibronectin (IST-4 and IST-9) were all negative. Finally, the analysis of microdissected glomeruli with liquid chromatography/mass spectrometry (LC/MS) revealed abundance of FN, demonstrating the diagnosis of solitary FG.

Discussion: FG is caused by deposition of the soluble form of FN from serum, rather than the insoluble form produced by resident cells. Therefore, immunostaining with the monoclonal antibody IST-4, which can detect soluble FN, is usually positive in FG, while that with IST-9, which binds only to cellular FN, is negative. Although IST-9 staining was negative in the reported case, FN was detected with LC/MS. This might be due to a structural change of FN in the deposits, which hindered the binding of IST-4 antibody to FN. Furthermore, it was also confirmed that LC/MS is a powerful method to identify characteristics of unexplained glomerular deposits.

PO1575
To Treat or Not to Treat? Therapeutic Challenges in a Case of Advanced Renal Sarcoma
Catherine Larned, John S. Thurlow, Maura A. Watson. Walter Reed National Military Medical Center, Bethesda, MD.

Introduction: Use of potentially toxic therapy in patients with low chance of renal recovery is clinically challenging. Kidney biopsy with significant interstitial fibrosis and tubular atrophy (IFTA) and reduced estimated glomerular filtration rate (eGFR) suggests unlikely recovery. We describe a patient with advanced IFTA who recovered substantial kidney function with treatment.

Case Description: A 55-year-old man was diagnosed with pulmonary and renal sarcomas. Renal biopsy at diagnosis showed granulomatous interstitial nephritis with non-caseating granulomas and 20% IFTA. Prednisone was started but was discontinued by the patient for onerous side effects. Serum creatinine (Scr) stabilized at 1.5-1.8 mg/dL. He returned two years later with Scr=5.8 mg/dL (eGFR 12 mL/min/1.73m2). Urinalysis was within normal limits with 10 mg/dL phosphorus 4.0 mg/dL and intact PTH 200 pg/mL. He lacked pulmonary or systemic symptoms to merit empiric treatment, and he was hesitant to receive steroids due to prior side effects. Given new concurrent diagnosis of a granulomatous and sclerotic lesions, repeat renal biopsy was performed revealing moderate interstitial fibrosis and nonspecific chronic interstitial nephritis with 50% IFTA consistent with sarcomatoid sarcoma. Despite concern for lack of recoverable kidney function due to high chronicity and reduced eGFR, treatment with high-dose prednisone was started based on the unknown time course of recurrence in a relatively young active patient. Scr improved to 3.0-3.2 mg/dL (eGFR 25 mL/min/1.73m2). The patient continued to receive prednisone until full renal recovery was achieved. Despite resolution of IFTA, prednisone was tapered over 12 months. Prednisone was stopped 9 months after initiation due to lack of clinical improvement and prednisone side effects.

Clinicopathological Characteristics of Adult IgA Nephropathy: A Retrospective Cohort Study

Dawn J. Caster,¹ Clint Abner,² Kerime Ararat,³ Patrick D. Walker,² Amin Yakubu,⁴ Martin C. Bunke,⁴ ¹University of Louisville, Louisville, KY; ²Arkana Laboratories, Little Rock, AR; ³Genesis Research, LLC, Hoboken, NJ; ⁴Traverse Therapeutics Inc, San Diego, CA.

Background: IgA nephropathy (IgAN) is the most common form of primary glomerular nephropathy and a leading cause of chronic kidney disease (CKD). These analyses characterize clinical and histological features of IgAN in adults at time of kidney biopsy.

Methods: A retrospective study of clinical and histologic characteristics was performed in patients (pts) ≥18 yrs of age with ≥1 IgAN-positive kidney biopsy without prior kidney transplant reported from Arkana Laboratories (Jan 1, 2016-May 30, 2020). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-Epi equation without race modifier. All results are at the time of biopsy.

Results: Of 67,262 kidney biopsies performed during the study period, 4,384 (6.5%) IgAN positive cases met the study criteria and were included, of which, 62.7% were male, 49.6% White, 5.1% African American, 5.3% Hispanic, 5.6% Asian and 34.4% Unknown/Other race/ethnicity. Mean (SD) age at biopsy was 47.7 (16.6) yrs. Urine protein to creatinine ratio/24-hour urine protein data were available for 52.4% of pts and the median (Q1-Q3) was 3.0 (1.0 – 5.0) g/g. Additionally, 65.2% of pts had hypertension, 63.1% had known hematuria, 25.7% had severe arteriosclerosis, 15.8% had severe arteriolosclerosis, and 49.6% had ESKD/death occurred in 53% of patients (<1% death). Kaplan-Meier survival curves of those without ESKD at baseline with renal diagnosis or symptom presentation. Patients were grouped into those with ESKD or negative notion. Patients without a record of renal biopsy, valid eGFR and proteinuria or negative notion. Patients without a record of renal biopsy, valid eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Conclusions: The large proportion of pts diagnosed at CKD stage 3 and high MEST-C scores for S and T suggest significant disease duration at the time of biopsy. Earlier intervention may be of value to prevent ESKD.

Natural History of IgA Nephropathy: A Retrospective Cohort Study

Jonathan Barratt,¹ ² Moin Saleem,¹ Fiona E. Braddon,¹ Kevin Carroll,¹ Ping He,² Bruce M. Hendry,³ Alex Mercer,⁴ David Pitcher,⁴ Retha D. Steenkamp,¹ A. Neil Turner,¹ Daniel P. Gale,⁴ ¹University of Leicester, Leicester; United Kingdom; ²Leicester General Hospital, Leicester; United Kingdom; ³University of Bristol, Bristol, United Kingdom; ⁴Bristol Royal Hospital for Children, Bristol, United Kingdom; ⁵UK Renal Registry, Bristol, United Kingdom; ⁶The Renal Association, Bristol, United Kingdom; ⁷Royal Free Hospital, London, United Kingdom; ⁸University College London, London, United Kingdom; ⁹Traverse Therapeutics Inc, San Diego, CA; ¹¹JAMCO Pharma Consulting, Stockholm, Sweden; ¹²KJC Statistics Ltd, Cheshire, United Kingdom.

Background: Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis and a major cause of renal failure. Here we describe the natural history of IgAN using the UK National Registry of Rare Kidney Diseases (RaDaR). Since 2013, patients with biopsy-proven IgAN and eGFR <60 mL/min/1.73m² or proteinuria >1 g/24h have been enrolled into RaDaR from 107 adult and paediatric kidney units across the UK, including retrospective and prospective data. Patients with systemic vasculitis or pre-existing liver disease were excluded.

Methods: Baseline date was defined as first occurrence of renal biopsy, primary renal diagnosis or symptom presentation. Patients were grouped into those with ESKD (ESKD), or those without ESKD at baseline with a ≥12 months follow-up (CKD group). For survival analyses, ESKD or death was applied with survival time calculated from baseline to last follow-up.

Results: In the ESKD group (n=326), median age at first dialysis (56% of patients) and kidney transplant (7%) was 38 yrs (IQR 29-50). In the CKD group (n=1838), median baseline age was 39 yrs (IQR 28-50) with paediatric onset of disease comprising 6%. Baseline median urine PCR was 1.5 g/g (IQR 0.6-3.2; n=356) and mean eGFR was 58 mL/min/1.73m² (SD 32; n=440). Median follow-up was 9.2 years (IQR 5.1-16.3) and ESKD/death occurred in 53% of patients (~1% death). Kaplan-Meier survival curves of paediatric and adult patients show 50% survival probability of 24 & 10 years, respectively (Figure 1).

Conclusions: RaDaR contains a large cohort with long follow up enabling detailed investigation of the natural history of IgAN. These results indicate associations between rapid disease progression and poor outcomes, highlighting a need for effective treatments for patients with IgAN with renal impairment or >1g/24h proteinuria.

PO1578

Symptom Burden Among Immunoglobulin A Nephropathy (IgAN) Patients in a US Real-World Setting

Robert M. Perkins,¹ Carolina A. Aldworth,² Raymond Przybylsz,¹ Jim P. Doherty,² Stephen W. Olson,¹ Aneshe T. George,² Jaydeep Das,² Rachel Studer,² Novartis Pharmaceuticals Corporation, East Hanover, NJ; ²Novartis Pharmaceuticals Corporation, East Hanover, NJ; ³Novartis Pharma AG, Basel, Switzerland; ⁴Novartis Healthcare Pvt. Ltd., Hyderabad, India.

Background: Immunoglobulin A nephropathy (IgAN) is the most prevalent chronic glomerulonephritis and 15-40% of patients will progress to end stage kidney disease (ESKD) within 20-20 years of diagnosis. The symptom burden by eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Methods: This is a descriptive, retrospective study of adult (≥18 years) patients in de-identified Optum® Electronic Health Records (2007-2019). Pre-processed physician notes were used to select patients with at least two IgAN records without any secondary or negative notion. Patients without a record of renal biopsy, valid eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

494
levels, or with a history of ESKD/kidney transplant were excluded. The demographic and clinical characteristics, including symptoms up to 12 months before and up to the 1st record of IgAN are presented here; these symptoms were stratified by eGFR and proteinuria levels.

**Results:** The final cohort consisted of 846 patients with a mean age of 48.5 years; 57% were male and 7.0% Asian. Proteinuria levels of ≥ 1 g/day were found in 35.7% of patients. The median eGFR was 39.0 ml/min/1.73m², median creatinine was 1.8 mg/dL, and 20.8% of patients had severe deterioration of kidney function (eGFR <15). Overall, more patients in higher chronic kidney disease (CKD) stages experienced any given symptom but this trend was not consistent for higher proteinuria levels.

**Conclusions:** Our study found that a considerable proportion of patients experienced pain, fatigue and edema. Except in a few instances, all symptoms increased with lower eGFR levels but this trend was less apparent for proteinuria. Our overall findings suggest that a relatively large proportion of IgAN patients, even those with preserved kidney functions could be experiencing substantial symptomatic burden and this warrants further investigation.

**Clinical Outcomes of Kidney Diseases Diagnosed in Active Duty Service Members**

**Trevor W. Tobin,** John S. Thurlow, Robert Nee, Christina M. Yuan. **Walter Reed National Military Medical Center, Bethesda, MD.**

**Background:** There are no studies that have reported glomerulonephritis prevalence and looked at the overall healthcare outcomes following renal biopsies in active duty soldiers. We aimed to determine the prevalence of renal diseases amongst the soldiers biopsied at our institution and determine the outcomes for these individuals as a result of their diagnoses.

**Methods:** In this retrospective study, we evaluated the results of all native renal biopsies performed at Walter Reed National Military Medical Center from 2005 to 2020. We used this data to determine the prevalence of patients who progressed to have ESKD (End Stage Kidney Disease), renal transplantation, creatinine doubling, proteinuria greater than 3.5 g/dL/day, medical evaluation board (MEB), and death. The AHLTA and JLV EMR systems were used to collect data on the patients who met our inclusion criteria. After the data was collected, chi-squared tests were performed and Kaplan-Meier Curves were created for analysis.

**Results:** Among 169 patients (mean age =32 years old; 79% male; 48% white; 37% black; 7% Hispanic; 4% Asian; 3% Pacific islander; 2% other), the most common indication for renal biopsy was for concomitant hematuria and proteinuria (31%) and the most common histologic diagnosis was IgA Nephropathy (23%). The mean time of follow up was 7.3 years. 11% progressed to ESKD, of whom 87% received a kidney transplant (10% overall). Approximately one third progressed to proteinuria greater than 3.5 grams per day and 55% died.

**Conclusions:** We identified IgA Nephropathy as the dominant histologic diagnosis in our patients undergoing renal biopsy between 2005 and 2020. Despite our patients being largely young and healthy individuals, renal biopsy identified severe disease with over 10% of patients progressing to ESKD and 5% mortality.

**Clinicopathological Features, Risk Factors, and Outcomes of Immuno- globulin A Nephropathy Associated with Hepatitis B Virus Infection**

**Juchuan Xiong, XinQiao Hospital, Chongqing, China.**

**Background:** Hepatitis B virus (HBV) infections are associated with an increased risk of kidney diseases. However, the effects of HBV infection on the progression of idiopathic A nephropathy (IgAN) are unclear.

**Methods:** A total of 838 patients with biopsy-confirmed IgAN were enrolled in this retrospective cohort study. The patients were categorized into either affected by IgAN and HBV infection (HBsAg-IgAN) or by primary IgAN with no sign of HBV infection (P-IgAN). A 1:1 propensity-score matching was performed between the two groups, followed by a Kaplan-Meier survival analysis, to compare the prognoses, and a Cox regression analysis, to identify factors influencing the HBsAg-IgAN outcomes.

**Results:** A total of 176 pairs of patients were successfully matched. A significant difference in the systolic blood pressure and urea, serum creatinine, uric acid, and 24-h urine protein levels was observed between the groups. A renal pathological analysis also revealed a significant difference in the mesangial hypercellularity between the groups. During a median follow-up period of 2.4 years, Kaplan-Meier analysis also revealed a significant difference in the renal survival between the groups. Furthermore, multivariate Cox analysis confirmed that HBV infection is an independent risk factor for IgAN progression (hazard ratio [HR] 2.996; 95% confidence interval [CI] 1.091–4.026). Finally, the HBsAg-IgAN patients who received treatment with renin-angiotensin-aldosterone system inhibitors had a better overall prognosis than those who received immunosuppressive therapy and antiviral treatment.

**Factors Associated with ESKD in Mexican Patients with IgA Nephropathy: A Single-Centre Retrospective Cohort Study**

**Daniela Xavier,** Guadalupe Ramos De Jesus, Octavio R. Garcia-Flores, Bernardo Moguel. **Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.**

**Background:** IgA nephropathy (IgAN) is the most common primary glomerulonephritis in the world among patients undergoing renal biopsy. To standardize the histological findings, the Oxford Classification (OC) has allowed clarifying kidney lesions that confer potential risk of progression. The aims are describe the factors associated with ESKD and treatment implemented in Mexican patients with IgAN.

**Methods:** We conducted a single-center, retrospective cohort study in a tertiary hospital in Mexico City, patients with biopsy-proven IgAN and followed up for at least 2 years and examined the relationship between clinical parameters and OC to predict the risk of ESKD after biopsy. We used age and sex adjusted Cox proportional hazards models to study the association of the predictor variables (MEST-C, global glomerulosclerosis and proteinuria >1 g/day) with the incidence of ESKD. The HRs were expressed with 95% confidence intervals (95% CI).

**Results:** 35 patients were included, mean age 37.2±15.2 years, 60% were female, mean eGFR and proteinuria at biopsy were 60.8±34.6 ml/min/1.73m² and 3.4±4.0 g/dL/day respectively. ESKD or eGFR decline by ≥50% as compared to baseline occurred in 10 patients (28.6%) in of follow-up of 2 years. The eGFR at 24 months post-biopsy 39.1±39.6 ml/min/1.73m². 18 patients received immunosuppressive treatment and 24 received prednisone. The distribution of MEST-C lesions were: M1=35(100%), E1=20(57.1%), S1=33(94.3%), T1=15(42.9%) and T2=7(20.6%), C1=11(31.4%) and podocytopathic features in 3(8.5%). Of the MEST-C components, only T2 was significantly associated with ESKD (HR 4.66, 95% CI 0.8 to 27.1). After adjusting for confounding variables global glomerulosclerosis >50% (HR 1.92 [1.02-3.58], p=0.001) and New oxford classification system (O-grade) grade III (HR 2.79 [0.89-8.58], p=0.001) were independently associated with ESKD.

**Conclusions:** There are no reports in Mexico of clinical characteristics and outcomes of IgA nephropathy. This study demonstrates that IgA nephropathy was more common in young adults and women and that the progression to ESKD or the global glomerulosclerosis >50% is similar to the reported in the literature. IFTA >50%, and O-grade III were associated with the development of ESKD in Mexican population.

**PO1582**

**External Validation of Two New IgA Risk-Prediction Tools in a Norwegian Cohort**

**Nynvar Lunde Haaska,1 Njalur Lura,1 Rune Bjorneklett,1,2 Lars S. Bostad,1,2 Thomas Knop,1,2 Haukeland Universitetssjukehus, Bergen, Norway; 1Universitetet i Bergen, Bergen, Norway.**

**Background:** Recently two prediction tools for IgA nephropathy (IgAN) have been developed combining clinical and histopathological parameters. Barbour and colleagues developed the International IgAN Prediction Tool, to predict the risk for 50% decline in estimated glomerular filtration rate (eGFR) or end stage renal disease (ESRD) up to 80 months after diagnosis. Schena and colleagues developed the IgA Nephropathy Clinical Decision Support System (CDSS), using artificial neural networks (ANN) to estimate the risk for ESRD. In the present study we aim to externally validate both prediction tools using a Norwegian cohort with long-term follow-up.
POI1583

International IgA Nephropathy Network (IIgANN) Risk Prediction and Longitudinal Outcomes in the First South-Asian Prospective IgA Nephropathy Cohort (GRACE-IgANI)

Suceena Alexander,1 Santosh Varughese,1 Atlul Thomas,1 Jeethu J. Eappen,1 Elenjickal E. John,1 Anna T. Valson,1 Vinici G. David,1 Mohamed R. Daha,2 George John,1,3 John Fechely,3 Jonathan Barratt,4 Christian Medical College Vellore, Vellore, India; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; 4University of Leicester College of Life Sciences, Leicester, United Kingdom; 5University of Leicester, Leicester, United Kingdom.

Background: The Glomerular Research And Clinical Experiments- IgA Nephropathy in Indians is a prospective longitudinal cohort registered with WHO trial id: ISRCTN36834159. The performance of the IIgANN risk prediction score (Barbour et al.) has not been assessed in South Asian IgAN.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 195 patients (97%) completed 3 year longitudinal follow-up. Of these, 180 patients had complete Oxford MEST-C score at baseline. Composite outcome (CO) was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m2 or RRT/death.

Results: The median predicted 3-year risk of a ≥50% decline in eGFR or ESKD using the IIgANN risk prediction tool was 18.1% (IQR 7.4–31.2) at baseline. The minimum score was 0.64% and the maximum was 55%. Short course IS was used in 146/201 (73%) of patients. 72 patients (36.9%) experienced CO over 3 years. The median risk in patients with favourable outcome was 13.15% (IQR 4.2–21.7) and in those with CO was 32.2% of patients. 72 patients (36.9%) experienced CO over 3 years. The median risk in patients the IIGANN risk prediction tool was 18.1% (IQR 7.4–31.2) at baseline. The minimum RRT/death.

180 patients had complete Oxford MEST-C score at baseline. Composite outcome (CO) kidney biopsy. 195 patients (97%) completed 3 year longitudinal follow-up. Of these, has not been assessed in South Asian IgAN.

Conclusions: Both prediction tools perform well and could become helpful tools for clinicians to identify patients at risk. Barbour’s tool seems to lose prognostic discriminative value at a faster rate than Schena’s over time.

POI1584

IgA Nephropathy Histopathology and Long-Term Renal Prognosis

Nora C. Maddy, Robert Nee, Sarah M. Gordon, Stephen W. Olson. Walter Reed National Military Medical Center, Bethesda, MD.

Background: The Oxford Classification established the mesangial hypercellularity (M), Endocapillary hypercellularity (E), segmental sclerosis (S), Tubulointerstitial fibrosis (T), and crescents (C) score as an important prognostic tool for IgA nephropathy (IgAN). However, these studies did not investigate the impact of complement 3 (C3) immunofluorescence (IF) staining or interstitial inflammation (iI) on long term renal outcomes, nor evaluate an ethnically diverse population which included African Americans.

Methods: We queried the military health system (MHS) by ICD-9/10 codes to identify potential IgA nephropathy cases. We then reviewed the electronic medical record to find those with biopsy-proven IgA nephropathy. Prespecified clinical data was collected to include MEST-C scores, iI, and C3 IF. Primary outcomes included >50% decline in estimated glomerular filtration rates (eGFR), chronic kidney disease (CKD) with eGFR <60ml/min/1.73m2, and end-stage kidney disease (ESKD).

Results: 172 patients were identified with a mean follow-up of 11 years. Mean age was 32 years; 77.9% male; 64.5% White, 9.9% Black, and 12.2% Asian/Pacific Islanders. C3 IF≥2+ was significantly associated with ESKD (p=0.03) and >50% decline in eGFR (p=0.02). If ≥15% was significant for ESKD (p=0.003), CKD (p=0.01), and >50% decline in GFR (p=0.01). T and C scores were significant for ESKD, CKD, and >50% decline in GFR (all p<0.001). S score was significant for ESKD (p=0.02) and CKD (p=0.009). E score was significant for CKD (p=0.003). M score was not significant for any of the primary outcomes.

Conclusions: We present histopathology associated long term renal outcome data for the most ethnically diverse IgAN cohort with the longest follow up to date in such a population. Our data suggests that degree of C3 staining on IF and amount of interstitial inflammation could augment the prognostic accuracy of the MEST-C score. In addition, it supports the theory that IgA immune complexes activate the alternative complement pathway which drives significant interstitial inflammation ultimately resulting in tubular atrophy and interstitial fibrosis. PO1585
Severity of Arterial and Arteriolar Sclerosis in IgA Nephropathy and Effects of Renin-Angiotensin System Inhibitors on Its Prognosis
Naoko Sugiuara, Takahito Moriyama, Yoci Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: IgA nephropathy (IgAN) patients often suffer from renal arterial intimal thickening (AIT) and arteriolar hyaline (AH) however, it is unclear whether these features are associated with a poor prognosis. This study aimed to analyze whether treatment with renin-angiotensin system inhibitors (RASI) improves those patient’s survival.

Methods: This retrospective cohort analysis included total 871 patients with IgAN, grouped according to the absence or presence of AIT (Study 1; AIT0: n=415, AIT1: n=268) or AH (Study 2; AH0: n=405, AH1: n=354). The clinical, laboratory, and histological backgrounds of the patients were analyzed along with their 20-year renal prognosis. In the AIT1 and AH1 groups, the effect of renin-angiotensin system inhibitors (RASI) on renal prognosis after making adjustments for the background was analyzed and risk factors for progression were also analyzed.

Results: IgAN patients with AIT1 or AH1 had significantly higher age, blood pressure, body mass index, total cholesterol, uric acid levels, and proteinuria than patients with AIT0 or AH0. They also had more marked histologic findings, decreased renal function, and lower survival rates (AIT: 62.2% vs. 83.4%, P=0.0001; AH: 63.5% vs. 85.4%, P=0.0001). Multivariate Cox regression analysis considering with clinical and histological findings and treatments revealed AIT and AH as an independent factor for disease progression (AIT1: hazard ratio [HR], 1.98, 95% confidence interval [CI], 1.01-3.97; AH1: HR, 2.12, P=0.014). The renal survival rate was significantly higher in IgAN patients with AIT0 or AH0 who were treated with RASI than in those who were not treated with RASI after background adjustments (AIT: 71.1% vs. 50.4%, P=0.023; AH: 76.4% vs. 39.5%, P=0.006). RASI was found to be an independent factor in the prevention of progression, by multivariate Cox regression analysis (AIT1: HR, 0.40, 95% CI, 0.14-1.16; AH1, 0.42, P=0.07).

Conclusions: AIT and AH are associated with serious clinical, laboratory and histological findings and a poor prognosis. RASI was found to improve renal prognosis of those patients.

PO1586
Intensity of Glomerular Galactose-Deficient IgA1 Deposition Can Be a Marker of Disease Activity in IgA Nephropathy
Maiko Nakayama,1 Hitoshi Suzuki,2 Yusuke Fukao,3 Mingfeng Lee,1 Toshiki Makita,1 Yuyuko Matsumoto,1 1Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; 3Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the development of IgA nephropathy (IgAN). Recently, it was reported that Gd-IgA1 specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association between the intensity of Gd-IgA1 deposition and clinical course and histological severity is not clarified.

Methods: We performed immunostaining with KM55 mAb on paraffin sections of IgAN tissues. We divided patients into tertiles according to the amount of Gd-IgA1 deposition intensity of glomerular Gd-IgA1 by Image-J software, and analyzed its association with specific histological findings and treatments revealed AIT and AH as an independent factor for disease progression. In the AIT1 and AH1 groups, the effect of renin-angiotensin system inhibitors (RASI) on renal prognosis after making adjustments for the background was analyzed and risk factors for progression were also analyzed.

Results: Patients with M1, E1, S1, and C1 scores according to the Oxford classification (M, mesangial hypercellularity; E, endocapillary hypercellularity; S, segmental sclerosis; T, tubular atrophy/intertubular fibrosis; and C, crescents) were examined using Kaplan-Meier analysis and Cox regression analysis. The steroid responder score (SRS) and steroid non-responder score (SNRS) were determined using the obtained results. The effects of steroid therapy on renal prognosis according to the combination of the total SRS and SNRS for IgAN were analyzed using Cox regression analysis.

Conclusions: Steroid therapy improved the 20-year renal survival rates in all IgAN patients (steroid (+): 75.5% vs. steroid (-): 61.7%, P=0.025) and patients with M1, E1, S1, C1, and T0 scores. We recognized the total score of M1, E1, S1, and C1 scores (0–4 points) as the SRS and that of T1 and T2 scores (0–2 points) as the SNRS. Multivariate Cox regression analysis revealed that steroid therapy improved the long-term renal prognosis in IgAN patients with higher SRS and lower SNRS (SRS4/SNRS0: hazard ratio [HR], 0.08 and P=0.008; SRS3/SNRS5: HR, 0.05 and P=0.025; SRS4/SNRS1: HR, 0.11 and P=0.007), but not in IgAN patients with lower SRS (0–3) SNRS1 and any SRS/SNRS2.

PO1587
Segmental Necrotizing/Crescentic Glomerulonephritis (SGN) in IgA Nephropathy (IgAN): A Single-Center Experience
Niral B. Ramani, William L. Whittier, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Background: The presence of SNGN on renal biopsy generally portends a poor prognosis, and is typically treated with immunosuppressive agents. The association of pts with IgAN to determine if the presence of SNGN portends a poorer prognosis in this pt population.

Methods: Biopsies done at Rush University Medical Center from 1992-2019, found SNGN in 35 pts (21 males). Of these 35 pts, 1 of which had M0 (0%) and 24 of which had M1 (69%) SNGN was seen in 21 (60%). Clinical, laboratory, histologic features at biopsy, treatment and outcome data (doubled of SCr and ESKD) were collected retrospectively. Pts with and without SNGN were compared. Data is presented a meansSD and a P value of <0.05 was significant.

PO1588
Novel Scoring System Based on the Oxford Classification Indicating Steroid Therapy Use for IgA Nephropathy
Takahito Moriyama, Eri Kasama, Yoci Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: The Oxford classification identifies predictors of the renal prognosis for IgA nephropathy (IgAN); however, it has been unclear about usefulness for deciding the management approach. We analyzed the clinical utility of this classification for indicating steroid therapy.

Methods: The effects of steroid therapy on the long-term prognosis for all 858 IgAN patients and patients divided with M0, M1, E1, S1, T0, T1, T2, C1, and C2 scores according to the Oxford classification (M, mesangial hypercellularity; E, endocapillary hypercellularity; S, segmental sclerosis; T, tubular atrophy/intertubular fibrosis; and C, crescents) were examined using Kaplan-Meier analysis and Cox regression analysis. The steroid responder score (SRS) and steroid non-responder score (SNRS) were determined using the obtained results. The effects of steroid therapy on renal prognosis according to the combination of the total SRS and SNRS for IgAN were analyzed using Cox regression analysis.

Results: Steroid therapy improved the 20-year renal survival rates in all IgAN patients (steroid (+): 75.5% vs. steroid (-): 61.7%, P=0.025) and patients with M1, E1, S1, C1, and T0 scores. We recognized the total score of M1, E1, S1, and C1 scores (0–4 points) as the SRS and that of T1 and T2 scores (0–2 points) as the SNRS. Multivariate Cox regression analysis revealed that steroid therapy improved the long-term renal prognosis in IgAN patients with higher SRS and lower SNRS (SRS4/SNRS0: hazard ratio [HR], 0.08 and P=0.008; SRS3/SNRS5: HR, 0.05 and P=0.025; SRS4/SNRS1: HR, 0.11 and P=0.007), but not in IgAN patients with lower SRS (0–3) SNRS1 and any SRS/SNRS2.

Conclusions: Patients who responded to steroid treatment; contrarily, those with T1 and T2 scores did not. A higher SRS was a useful indicator for steroid therapy. Nevertheless, prevention of progression in IgAN patients with SRSN was difficult with steroid therapy.
Remission of Hematuria Is Associated with Favorable Prognosis in IgA Nephropathy

Kyung Ho Lee, Young seung Oh, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang, Byung chul Yu. Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: Recent studies have shown that remission of hematuria is associated with favorable clinical outcomes in patients with immunoglobulin A nephropathy (IgAN). The current study was conducted to compare the long-term clinical outcomes between patients with remission of hematuria and those with persistent hematuria using the stricter but intuitive definition of “remission of hematuria” than that used in previous studies.

Methods: This retrospective, multicenter, observational study was conducted using a cohort of patients diagnosed with IgAN through kidney biopsy at three tertiary hospitals. A total of 403 patients who had been followed up for more than 3 years and who underwent regular check-ups at intervals of at least 6 months were enrolled. Hematuria remission was defined as the presence of hematuria for at least 3 months after biopsy for diagnosis but with no RBC per high-power field observed in the urine under the microscope for at least 2 years thereafter.

Results: The mean annual rate of eGFR decline was lower in the remission of hematuria group than in the persistent hematuria group (-1.51 ± 2.86 vs. -2.60 ± 3.18 mL/min/1.73 m²/year, p = 0.002). In the remission of hematuria group, the mean annual rate of eGFR decline decreased after hematuria disappearance (from -1.28 ± 7.06 to 0.09 ± 0.29 mL/min/1.73 m²/year, p = 0.016). Multivariable analysis revealed remission of hematuria as an independent predictor of a 50% reduction in kidney function (hazard ratio, 0.55; 95% CI, 0.33 to 0.99). Renal survival, defined as a 50% reduction in kidney function, was better in the remission of hematuria group than in the persistent hematuria group (p = 0.030). However, free of ESRD was not significantly different between the two groups (p = 0.079).

Conclusions: In this study, which used a more rigorous but intuitive definition of hematuria remission than that used in previous studies, patients with remission of hematuria showed favorable kidney prognosis. This new definition for remission of hematuria could be used as a prognostic marker in actual clinical practice.

Comparison of renal outcomes between the two groups

Reduction of Urinary Levels of Lectin Pathway Complement Components in an IgA Vasculitis Patient After MASP-2 Inhibition with Narsoplimab

Laura Pérez Alós, Katrin Sciorti, Karen Molyneux, Jonathan Barratt, Peter Gurr. Rigshospitalet, Copenhagen, Denmark; 2 University of Leicester, Leicester, United Kingdom; 3 Leicester General Hospital, Leicester; United Kingdom.

Background: A young female suffering from IgA vasculitis was treated with 4 mg/kg weekly infusions of narsoplimab (a MASP-2 inhibitor) for 12 weeks. MASP-2 is considered the key activator of the lectin pathway (LP) by cleaving C4 and C2, after the binding of LP pattern recognition molecules to its ligands. Inhibition of MASP-2 is predicted to decrease complement activation in complement-mediated kidney diseases. In this exploratory study, we measured the levels of different LP complement components to evaluate the influence of narsoplimab on complement activation.

Methods: Urine levels of complement activation markers (C4c, C3bc and soluble C5b-9) and urine levels of ficolin-1, 2 and 3, MBL, CL-11, MASP-3, MASP-1 and PTX-3 were measured using sandwich-ELISAs. Urine samples were subjected to LC/MS-MS. Correlations between LC/MS-MS and sandwich-ELISAs were conducted using simple linear regression and Spearman's rank correlation coefficient. Significance: p value < 0.05. Urine proteins were adjusted for creatinine excretion and expressed as specific protein/creatinine ratio.

Results: C4c:creatinine ratio, ficolin-3:creatinine ratio and C3bc/creatinine ratio levels were decreased 75%, 58% and 29%, respectively, from baseline to the end of the treatment; while levels of MBL and CL-11 remained stable during the treatment. C4c/creatinine ratio levels were significantly correlated to LC/MS-MS C4 data (R²: 0.5059; Spearman: r = 0.5824, p = 0.0402). Circulating levels of complement components in serum were unaltered during treatment. Soluble C5b-9, ficolin-1, -2, MASP-3 and MASP-1 were undetectable in urine and PTX-3 was undetectable in both urine and serum.

Conclusions: This is the first report describing the effect of narsoplimab on urinary complement levels in a complement-mediated kidney disease. Our data suggest a decrease in local complement activation with narsoplimab treatment. Further studies are ongoing to evaluate the use of urine as a non-invasive, inexpensive and readily accessible resource to monitor responses to complement-directed treatments.

GWAS methods. The results were tested for Hardy-Weinberg equilibrium (control group; 136-unmatched healthy controls (mean age 48.7
±2.9 patients (mean age 42.9
±2.2Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Michał Pac,1 Natalia Krata,1 Beata Kaléta,2 Barbara Moszczyk,1,2 Aleksandra Wyczalkowska-Tomasik,1 Julia Prystupa,1 Krzysztof Krylik,1 Krzysztof Mucha,1,4 Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; Department of Medicine, Columbia University, College of Physicians and Surgeons, New York, NY; Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland.

Background: In other diseases (ex. asthma and pemphigus vulgaris) NR3C1 single nucleotide polymorphisms (SNPs) were associated with glucocorticoid (GC) treatment outcomes. The aim of the study was evaluation of the frequency of NR3C1 (SNPs) in adult membranous (MN) and IgA (IgAN) nephropathies biopsy proven patients.

Methods: We used two approaches to establish a transcriptional signature of ET-activation. First, using a targeted approach, an ET-activation network was generated using three publicly available datasets, produced a gene list of 60 transcripts to create an activity score which was assessed in kidney biopsy profiles in patients with IgAN (n = 25) from the European Renal DNA Bank (ERCB). In addition, an ET-activation signature was also generated using RNAseq profiling of human MCs isolated with ET1 (4nM) /- the selective ET receptor antagonist (1nM, 25nM, n=3/group). Pairwise differential gene expression and gene set enrichment analysis (GSEA) was performed.

Results: The targeted analysis showed that the ET-activity score correlated with increased proteinuria (r=0.42, p=0.05) and decreased eGFR (r=0.47, p=0.02) in patients with IgAN. The transcript network showed enrichment in endothelial and mesangial cell clusters in renal single cell RNASeq profiles. Differential expression analysis identified the ET gene network was reversed by atorvastatin in MCs (25nM, n=7–8 genes, q<0.05). GSEA in MCs revealed up-regulation of cell proliferation, inflammatory and fibrotic clusters, with ET1 treatment, which were blocked by atorvastatin.

Conclusions: We generated an ET-activation score using a systems biology approach to identify patients with IgAN. ET-receptor antagonists were associated with progression, providing additional support for the therapeutic potential of ETA receptor blockade in IgAN patients at high risk of progression. Ongoing work is focused on optimizing the signature, extending findings to additional cohorts and identifying mechanistic biomarkers.

NR3C1 Polymorphisms in Membranous and IgA Nephropathies
Michał Pac,1 Natalia Krata,1 Beata Kaléta,2 Barbara Moszczyk,1,2 Aleksandra Wyczalkowska-Tomasik,1 Julia Prystupa,1 Krzysztof Krylik,1 Krzysztof Mucha,1,4 Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; Department of Medicine, Columbia University, College of Physicians and Surgeons, New York, NY; Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland.

Background: In other diseases (ex. asthma and pemphigus vulgaris) NR3C1 single nucleotide polymorphisms (SNPs) were associated with glucocorticoid (GC) treatment outcomes. The aim of the study was evaluation of the frequency of NR3C1 (SNPs) in adult membranous (MN) and IgA (IgAN) nephropathies biopsy proven patients.

Methods: We analyzed SNPs: rs6198, rs14123247 and rs17209237 in 39 MN patients (mean age 42.9±14.2, y; 34 ½, 39 sex- and age-matched and 35-unmatched IgAN patients (mean age 33.5±12.3, y; 34 ½ and 39 sex- and age-matched and 136-unmatched healthy controls (mean age 48.7±17.9, y; 89 ½) using RT-PCR and GWAS methods. The results were tested for Hardy-Weinberg equilibrium (control group; p<0.05) and compared between MN, IgAN and controls and within MN and IgAN between GC-resistant and -sensitive and GC-dependent and -independent groups using the γ2 with Yates’s correction test.

Results: The frequency of the minor C allele of rs6198 SNP was significantly increased in MN (p=0.05) and IgAN (p=0.05) compared to controls; and in GC-resistant MN (p=0.05), GC-resistant (p=0.05) and GC-dependent (p=0.05) IgAN. The rs6198 SNP genotypes were unequally distributed among GC-resistant patients (p=0.05) and GC-dependent (p=0.05) IgAN. The frequency of the major A allele of rs17209237 was significantly increased in GC-sensitive (p=0.05) and -independent (p=0.05) IgAN. There was a disequilibrium in rs17209237 SNP distribution among GC-sensitive and GC-resistant patients (p=0.05). The minor C allele was significantly more frequent among MN (p=0.05) and IgAN (p=0.05) relapse patients and there was rs6198 genotypes distribution inequality for these both groups (p<0.05).

Conclusions: Rs6198 and rs17209237 alleles and genotypes have different distribution between MN and IgAN and -GCs and controls; and between patients differently responding to the GC treatment. Results indicate that they predict GC treatment outcomes and therefore should be further investigated for their potential prognostic value.

PO1595
A Rare Case of Paraneoplastic IgA Nephropathy in the Setting of Renal Cell Carcinoma
Alka A. Tyagi, Mohankumar Doraswimy, Sethu M. Madhavan. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Paraneoplastic nephropathy can present in patients with malignancy. Renal cell carcinoma (RCC) is the most common urologic malignancy; there is a paucity of reported paraneoplastic nephropathies associated with this condition. As such, we present an intriguingly unique case of nephrotic range proteinuria in the setting of recurrent, metastatic renal cell carcinoma.

Case Description: An 81-year-old male with history of recurrent metastatic RCC, solitary kidney after a nephrectomy, with stage III chronic kidney disease (CKD) presents with newly worsening renal function. In a 3-month span, his creatinine (C) rose from 3.5 mg/dL to 4.6 mg/dL, which prompted further workup. He had a history of prostate cancer and his most recent biopsy showed adenocarcinoma. His chart was notable for recurrent, metastatic renal cell carcinoma.

Discussion: Acutely worsening renal function and nephrotic range proteinuria in the setting of malignancy prompts investigation into a paraneoplastic nephropathy. As in this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is rare and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.

PO1596
Circulating and Depositing Glomerular Antibodies: A Concurrence or Coexistence
Deepti Avanavelli, Dhanalakshmi Vurum, ESIC Medical College and Hospital Hyderabad, Hyderabad, India.

Introduction: Anti-GBM disease is a systemic autoimmune disorder characterized by circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune crescentic/necrotizing/cyclosporin-responsive chronic interstitial nephritis, and membranous glomerulopathy. The concurrent or sequential presentation of anti-GBM disease with IgA nephropathy has been rarely described.

Case Description: We herein report a case of 51-year-old female who had presented with sudden onset of breathlessness, pedal oedema for 15 days and oliguria for 5 days with 1 episode of haematuria. There were no arthralgias, oral ulcers, alopecia, skin rash, sore throat and diarrhoea. Her marital life was of five years with no history of conception and pregnancy. She had undergone tonsillectomy for chronic tonsillitis and adenoids. Her medical history was otherwise unremarkable. She had a past history of hypertension for 4 years and recently undergone a nephrectomy for stage III chronic kidney disease (CKD) presented.

Discussion: In the setting of malignancy, paraneoplastic nephropathy has been rarely described. The concurrent or sequential presentation of anti-GBM disease with IgA nephropathy has been rarely described.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: Presentation of IgAN along with anti GBM without linear deposition on renal biopsy but with positive anti GBM titers makes this case interesting. The association of anti GBM disease with IgAN nephropathy could be a coexistence as IgAN is most common glomerular disease or these IgA mesangial deposits might have role in the pathogenesis of triggering GBM antigens and formation of antibodies in this case.

POI1597
Early Predictors of Stable Kidney Function in Lupus Nephritis
Juan M. Mejia-Vilet, Megan Ashley N. Gerrard, Roque A. Comunidad Bonilla, Luis E. Morales-Buenrostro. National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico.

Background: Early prediction of outcomes in LN is essential to adjust LN treatment. The aim of this study was to evaluate the early course of laboratory parameters and their association with long-term stability of kidney function.

Methods: We studied 433 patients from our local LN cohort recruited between 2008 and 2017. All patients had >36 months follow-up and complete evaluation at LN flare, 3-, 6-, and 12-months of follow up with hemoglobin, creatinine, 24h-proteinuria, albumin, anti-dsDNA-Ab, complement C3 and C4 fragments. The main outcome was stable kidney function defined as eGFR within 25% of the best eGFR attained in the first 12 months of treatment. Each variable was evaluated individually by ROC curves and in association with other variables. The change in area under the curve (AUC) was analyzed with De Long's test.

Results: Median follow up was 73 months (IQR 51-101). Kidney survival was 90% and 81% at 3- and 5-years, respectively. Stability of kidney function was 77% and 65% at 3- and 5-years, respectively. The predictive performance of each parameter varied with the timepoint where evaluated (Table). Serum albumin and hemoglobin AUCs improved from baseline to the 3- and 6-month timepoint. Proteinuria and eGFR AUCs improved at each timepoint up to the 12-month timepoint. C3, C4, and anti-dsDNA-Ab level did not improve at any timepoint vs. baseline. The best predictor of 36-month eGFR stability was proteinuria <1g/d by 12 months. The sum of proteinuria plus eGFR provided the best combined AUC at each timepoint (Figure 1).

Conclusions: Early course of albumin, hemoglobin, and serological parameters does not improve prediction for stable kidney function in LN. The predictive performance of each biomarker improves over time. The combination of proteinuria and eGFR remains the best predictor of kidney outcomes.

POI1598
Long-Term Outcomes of Lupus Nephritis in a Single Tertiary Care Center in South India
SriniVasa N. Kinjarapu, Swamalatha Geduti, Siddharth Herur. Nizam’s Institute of Medical Sciences, Hyderabad, India.

Background: Lupus nephritis (LN) is a frequent and severe manifestation of SLE. It is a risk factor for chronic kidney injury and end-stage renal disease in SLE we evaluated the clinical presentation and outcome with various treatment regimens in patients with lupus nephritis.

Methods: A retrospective study in 50 patients with biopsy proven LN [class III (12), class IV (11), class V (4), class III+IV (10), class III+V (7), class IV+V (6)] treated with NMP for 3 days followed by monthly CYC for 6 months and oral corticosteroids 0.5-1mg/kg with tapering to 10mg/day at the end of 6th month as induction protocol. AZA or MMF as maintenance regimen based on clinician discretion. Clinical presentation, histopathological (LM+IF) features, treatment regimen, treatment response and renal relapse and outcome were evaluated.

Results: Patients had a mean follow up of 3.6 years, clinical presentation nephrotic syndrome were seen in 42 (84%) patients. Most frequent IGs were present in 29 (58%) patients, of which 24 (48%) patients were female (87.5%) and black (87.5%). Mean serum creatinine (Sr Cr) was 3.1mg/dL and proteinuria by 24-hour urine collection or spot urine protein:creatinine ratio was 7.12g. Excluding 2 patients with limited follow-up, 11 of 14 (78.6%) patients had poor renal outcomes. These patients were similar in age (mean 33 years) and were also majority female (90.1%) and black (90.1%). In this group, mean Sr Cr was 5.35mg/dL and proteinuria was 3.69g. This group had significant interstitial fibrosis and tubular atrophy compared to patients with 71% moderate and 28% severe IFTA. Therefore the requirement for renal replacement therapy at end of 5 years (average). Of 3 patients who did not have a renal end point, mean Sr Cr was 1.83 mg/dL with less IFTA noted on biopsy. Treatment options varied with most receiving mycophenolate or cyclophosphamide.

Conclusions: This descriptive project confirmed that CG was associated with poor renal prognosis in LN; the majority of the patients required dialysis, proceeded to transplantation, or had doubling of serum creatinine during follow up. Despite treatment with standard of care agents, outcomes remained poor. Patients who had worse Sr Cr at presentation or severe IFTA had worse outcomes.

POI1600
Collapsing Glomerulopathy Can Worsen Prognosis in Lupus Nephritis

Background: Collapsing glomerulopathy (CG) conveys a poor renal prognosis and is characterized by podocytopathy with segmental or global collapse of the capillary walls. While it can be idiopathic, it is often seen in association with other viral, drug, and autoimmune conditions including lupus nephritis (LN). This retrospective study describes features and clinical outcomes of 16 patients with SLE and biopsy proven CG.

Methods: Using our Glomerular Disease Collaborative Network registry, we performed retrospective chart review on patients with systemic lupus erythematosus and CG on kidney biopsy with or without an LN lesion from 2000 - 2021. Patients with multiple biopsies, the first biopsy with GC was identified as the incident biopsy. We defined poor renal outcome as reaching a renal endpoint of serum creatinine doubling, chronic dialysis initiation, or renal transplantation. Patients were characterized by baseline demographics, laboratory results, CG on kidney biopsy with or without LN lesion, treatment received, and the number and type of previous appointments (dichotomized into ≤5 vs. >5).

Results: We identified 16 patients with mean age of 33 years at incident biopsy. Most were female (87.5%) and black (87.5%). Mean serum creatinine (Sr Cr) was 3.1mg/dL and mean proteinuria by 24-hour urine collection or spot urine protein:creatinine ratio was 7.12g. Excluding 2 patients with limited follow-up, 11 of 14 (78.6%) patients had poor renal outcomes. These patients were similar in age (mean 33 years) and were also majority female (90.1%) and black (90.1%). In this group, mean Sr Cr was 5.35mg/dL and proteinuria was 3.69g. This group had significant interstitial fibrosis and tubular atrophy compared to patients with 71% moderate and 28% severe IFTA. Therefore the requirement for renal replacement therapy at end of 5 years (average). Of 3 patients who did not have a renal end point, mean Sr Cr was 1.83 mg/dL with less IFTA noted on biopsy. Treatment options varied with most receiving mycophenolate or cyclophosphamide.

Conclusions: This descriptive project confirmed that CG was associated with poor renal prognosis in LN; the majority of the patients required dialysis, proceeded to transplantation, or had doubling of serum creatinine during follow up. Despite treatment with standard of care agents, outcomes remained poor. Patients who had worse Sr Cr at presentation or severe IFTA had worse outcomes.
PO1601

Serological Activity in Pure Membranous Lupus Nephritis in a Predominantly Black Population
Levard G. Roberts, Aakriti Arora, Hilton Mozee, Jason Cobb. Emory University, Atlanta, GA.

Background: Clinically significant kidney disease is estimated to occur in nearly 60% of patients with systemic lupus erythematosus (SLE). A majority of these patients develop proliferative disease, however 10-15% develop a non-proliferative form of disease known as membranous lupus nephritis (LN) (Class V lupus nephritis). These patients typically present with significant proteinuria. Austin et al. reported 7% of patients with low complements levels and 21% with elevated anti-dsDNA levels. In this study we assess serological activity (C3, C4, anti-dsDNA) of pure membranous LN in a predominantly black patient population.

Methods: Kidney biopsy log from 2010 – 2017, and a retrospective chart review was completed. We excluded any patients with proliferative disease (active or chronic). We analyzed serological activity (C3 level, C4 level & anti-dsDNA) at time of renal biopsy and again at 24 weeks.

Results: Of the total 101 patients with pure membranous LN, we had 54 patients with sufficient follow-up data. 52 of the 54 patients were female with an average age of 35.5; 92.5% (50 of 54) were black. At time of kidney biopsy, low C3 and low C4 was found in 54% and 41% of patients respectively. Whereas an elevated anti-dsDNA was identified in 39% with 20% having the classic triad of low C3, low C4 and elevated anti-dsDNA. When compared to 24 weeks (roughly end of induction therapy) low C3 and low C4 was found in 37% and 24% of patients respectively. Whereas an elevated anti-dsDNA was identified in 31% with 13% have the combination of low C3, low C4 and elevated anti-dsDNA.

Conclusions: In this predominantly black population of pure membranous LN the majority of patients did not have the classic triad of low complements and elevated dsDNA (20% at time of diagnosis/biopsy). Compared to others looking at pure membranous we did find higher rates of low complements and elevated anti-dsDNA at time of diagnosis (54% with low C3 initially). Possibly due to our unique urban patient population which is >90 percent black, i.e. more severe SLE. Despite the majority of patients not having the classic triad of low C3, low C4, and elevated anti-dsDNA, clinical providers must be diligent in assessing the need for kidney biopsy in SLE: and non-SLE patients as serological activity does not correlate with biopsy findings. Earlier treatment correlates with improved prognosis.

PO1602

Role of Kidney Biopsies in Lupus Erythematosus Patients: Clinicopathologic Correlation
Lorenz Leuprecht, James M. Chevalier, Thangamani Muthukumar, Surya V. Seshan. Weill Cornell Medicine, New York, NY.

Background: Lupus nephritis (LN) affects >50% of the patients with systemic lupus erythematosus (SLE) and is a major cause for morbidity and mortality. The diagnosis of LN as well as the extent and severity of renal involvement are assessed via kidney biopsy. However, appropriate clinical indications for a kidney biopsy are not well defined in adults, nor is the predictability of the clinical presentation. Therefore, a clinicopathologic correlation of patients with SLE and presumed SLE who underwent a kidney biopsy is conducted.

Methods: We evaluated a total of 134 biopsy samples from 123 patients with either SLE or presumed SLE at the time of biopsy that were obtained during a 10-year period at a large medical center in New York City. 11 patients underwent a biopsy twice during that period. Laboratory, and clinical data were also collected retrospectively via chart review.

Results: 86% of the patients were female, 31% African American, 21% White, and 11% Asian. The mean age at the time of the biopsy was 36.2±12.6 years, the mean serum-creatinine 1.45±1.28 mg/dl, and the mean urinary protein excretion 3.86±3.43 g/d. 97% of the biopsy samples had evidence of LN, with the majority showing either Class IV-V (29%) or Class V (33%). About 13% had findings other than LN, such as TMA, focal collapsing features of the glomeruli, diabetic nephropathy, or possible ANCA vasculitis, with or without evidence of LN. Additionally, in patients of 65% of the biopsy samples, eGFR was <60 ml/min/1.73 m², and 29% (38/132) had a negative urine dipstick for blood. Complement levels were low in 88/128 instances, and anti-dsDNA was positive in 57% of patients.

Conclusions: We conclude that normal serum-creatinine values may not preclude significant kidney pathology in SLE patients and those with proliferative forms of LN may have a negative urine test for blood (14%), normal complement levels (14%), and/or a negative anti-dsDNA test (29%) around the time of the biopsy. Furthermore, patients with SLE may have other morphologic findings correlating with clinical renal presentation, instead of LN.

PO1603

Rituximab for Severe Recurrent Proliferative Lupus Nephritis After Kidney Transplantation: Pondering a Rare Case
Rui Song, Mingyue He, Ilay Rahaman, Serban Constantinescu, Iris J. Lee. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Severe histologic recurrence of lupus nephritis (LN) post-kidney transplantation (KTX) is extremely rare on standard transplant immunosuppression. Severe recurrence shortens allograft survival, yet treatment guidelines post-KTX are lacking.

Case Description: A 52-year-old African American (AA) man with ESRD secondary to LN underwent a second KTX from a deceased donor. He had a prior living-unrelated KTX with graft failure due to mixed rejection without LN recurrence. For the second KTX, he received Thymoglobulin induction and maintenance immunosuppressive regimens including antithymocyte globulin sodium (ATG), Tacrolimus, Prednisone, with immediate graft function (nadir creatinine 1.4 mg/dL). He developed leukopenia requiring a reduction of EC-MPS to 360mg twice daily. He developed nephrotic range proteinuria 6 months post-KTX but had stable allograft function, bland urine sediment, normal complements, and negative anti-dsDNA antibodies. Despite inactive serologies, allograft biopsy revealed diffuse proliferative sclerosing and crescentic LN (ISN/RPS class IV). Due to persistent leukopenia, Rituximab was chosen over commonly-used Cyclophosphamide (CYC) for therapy. He received intravenous Methylprednisolone (3000 mg) and Rituximab 800mg (375 mg/m²) for 4 doses. Complete B-cell depletion was maintained for 3 months. His proteinuria decreased from 6.9 g/d to 1.2 g/d, and renal allograft function remained stable.

Discussion: Severe recurrent LN post-kidney transplantation is rare and can present atypical serologic markers, bland urine sediment and lack of LN recurrence on the first KTX did not rule out LN recurrence on the second kidney allograft. In our case, only the presence of persistent progressive proteinuria warranted allograft biopsy. AA ethnicity and reduction of EC-MPS were risk factors, which highlights the significance of KTX pathogenesis. Rituximab targets CD20+ B cells and has been successfully utilized for refractory LN. It has a more favorable toxicity profile compared to CYC which has been the conventional treatment for clinically significant LN post-KTX. We propose Rituximab as a better treatment option for severe recurrence of LN post-KTX.

PO1604

Influenza Vaccination in Systemic Lupus Erythematosus (SLE): Effectiveness, Efficacy, Safety, Utilization, and Barriers
Loo Lin Sing,1 Cybele S. da Cunha,1 Monica M. Seshan.1 1Singapore General Hospital Singapore Yong Loo Lin School of Medicine, Singapore, Singapore, 2Singapore General Hospital, Singapore, Singapore.

Background: Influenza infections increase morbidity and mortality among immunocompromised individuals with SLE and lupus nephritis. Yet, they are highly preventable through vaccination. We aimed to describe the effectiveness, efficacy, safety, utilization and barriers to influenza vaccination in SLE so that targeted strategies can be implemented to improve vaccination rates.

Methods: We conducted a systematic review and meta-analysis of all published and unpublished studies up to 19 May 2021 via PubMed, Embase, Cochrane, WHO Clinical Trials, and ClinicalTrials.gov, which reported on our desired outcomes relating to influenza vaccination in SLE and lupus nephritis.

Results: Of 726 articles screened, 44 studies (14779 patients) were included. 9 studies reported on effectiveness, 20 studies on efficacy, 24 studies on safety, 12 studies on utilization, and 4 studies on barriers to influenza vaccination. Involvement or lupus nephritis was present in 20.5%. The majority were female (90.8%). The mean age was 41.3 years (95% CI 36.8-45.7), mean disease duration was 10.91 years (95% CI 7.10-14.72), and mean SLEDAI score was 4.15 (95% CI 3.18-5.12). Individuals who received influenza vaccination were less likely to develop pneumonia (relative risk, RR 0.38, 95% CI 0.08-1.86, p=0.23), acute bronchitis (RR 0.21, 95% CI 0.09-0.48, p=0.0002), and viral respiratory infections (RR 0.36, 95% CI 0.21-0.64, p<0.0005). Pooled seroconversion and seroprotection rates were 56.6% and 68.2% for H1N1, 56.7% and 73.7% for H3N2, and 46.8% and 69.9% for B influenza strains. Mean SLEDAI scores did not change significantly after vaccination. Flares occurred in 20.3%, while local and systemic adverse events occurred in 20.5% and 26.6%, respectively. Only 39.1% of SLE patients were currently vaccinated against influenza. Meta-regression showed that vaccination rates were significantly associated with increasing GDP of the country (p=0.002) and increasing events occurred in 20.5% and 26.6%, respectively. Only 39.1% of SLE patients were currently vaccinated against influenza. Meta-regression showed that vaccination rates were significantly associated with increasing GDP of the country (p=0.002) and increasing

Conclusions: Influenza vaccination is effective and safe in SLE and lupus nephritis. Targeted strategies are required to overcome barriers to improve influenza vaccination uptake.

PO1605

Lupus Nephritis in a Patient with Autoimmune Hepatitis: A Case Report
Soo H. Kang, Erin Lawler, Sankar N. Niranjana.1 UConn Health, Farmington, CT, 2Greater Hartford Nephrology, Bloomfield, CT.

Introduction: Overlapping of autoimmune hepatitis (AIH) and lupus nephritis (LN) is a rare entity, only occurring in 1-2.6% of AIH cases, and is difficult to diagnose due to the overlap of clinical symptoms. Overlapping reports have been revisited in the literature.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Delayed Clinical Manifestation of Biopsy-Proven Thrombotic Microangiopathy in a Patient with Lupus Nephritis: A Case Report

Najia Idrice,1 Madeline A. Dilorenzo,1 Joshua S. Hundert,2 Jean M. Francis,1 Hann Menn-Josephy.1 1Boston Medical Center, Boston, MA; 2South Shore Hospital, Weymouth, MA.

**Introduction:** Complement-mediated thrombotic microangiopathy (c-TMA) involves unregulated complement activation due to inherited or acquired mutations in complement regulatory proteins. Immune complex formation, an important component of lupus nephritis (LN) pathogenesis, can over activate the complement system leading to c-TMA in the kidneys. Findings of c-TMA in LN patients have been associated with end-stage kidney disease (ESKD) or death in up to 50% of patients.

**Case Description:** 32-year-old female, with a history of lupus and ISN/RPS class III LN since 2017 and recent stroke, was evaluated at our lupus clinic for LN flare with worsening kidney function, increased proteinuria and low complements. A repeat kidney biopsy showed focal proliferative and membranous LN (ISN/RPS class III and V) and c-TMA. She received standard of care treatment for LN with methylprednisolone and cyclophosphamide, due to past mycophenolate therapy failure. Kidney function and proteinuria improved and complement levels normalized. Three weeks later, she was admitted with hemorrhagic shock secondary to renal subcapsular hematoma stabilized with PRBC transfusions. After one week, she again developed worsening anemia, worsening thrombocytopenia and oliguric acute kidney injury with diuretic resistant anasarca prompting intubation and initiation of hemodialysis. Hemolysis panel revealed a low haptoglobin, high LDH and schistocytes on peripheral smear. Serum complements were low. Due to high suspicion of c-TMA, she received weekly eculizumab followed by eculizumab every 2 weeks. Three weeks later, her hemoglobin and platelets improved and LDH decreased. Her urine output improved and she was able to come off of hemodialysis. She remained with stage 3b CKD.

**Discussion:** In patients with LN, severe renally-limited TMA can present without systemic manifestations. In our patient, hematologic signs of TMA appeared only 4 weeks after her initial biopsy-proven TMA, and after clinical improvement of her LN. This highlights the importance of monitoring LN patients with asymptomatic renally-limited TMA. We hypothesize that they may present with clinical features of active TMA. Anti-complement therapy with eculizumab is shown to be effective in these patients.

**Conclusions:** Despite the majority of patients receiving treatment, a significant proportion (44%) still reached the primary outcome of death or ESKD. Novel and efficacious treatment options are therefore needed to improve the outcomes and prognosis of patients with such a debilitating condition.

**PO1608**

Clinical Characteristics and Outcomes of Severe ANCA-Associated Renal Disease in a Multiethnic Urban Population

Allison J. Leonard,1 Shilpa Arora,2 Ambirath Avathale.1 1John H Stroger Hospital of Cook County, Chicago, IL; 2 Rush University Medical Center, Chicago, IL.

**Background:** To study the clinical characteristics, treatment and outcomes of ANCA vasculitides patients in an inner-city county hospital.

**Methods:** Retrospective study of 60 patients with biopsy-proven ANCA glomerulonephritis and a minimum follow-up of 6 months (median, IQR 23, 29 months) were included. Demographic and clinical information including pathology data, treatment and outcomes were collected. Multivariate regression analyses were done to study predictors of outcomes of estimated Glomerular Filtration Rate (eGFR) at 6 months and End Stage kidney Disease (ESKD).

**Results:** Patients represented an ethnically diverse population (Figure 1) with baseline characteristics as shown in Table 1. Mean age (SD) at diagnosis was 57.4 (13.7). Almost all patients (59/60, 98.3%) presented with hematuria and 17/60 (28.3%) had nephrotic-range proteinuria. Extra renal involvement most commonly pulmonary was seen in 35/60 (58.3%) patients. 44/60 (73.0%) had crescents and nearly all had interstitial fibrosis and tubular atrophy (IFTA) (median, IQR 30%, 56%). Most patients were induced with cyclophosphamide (49/60, 81.7%) and 16/60 (26.7%) received plasma exchange. eGFR (meanSD) at baseline and 6 months follow up were 20.8±19.4 and 43.5±23.0 respectively. 15/60 (25%) patients progressed to ESKD. On multivariate linear regression analysis, age (B -0.5), IFTA (B -27.7) and baseline eGFR (B 0.3) predicted eGFR at 6 months and IFTA (OR, 95% CI, 11.5, 1.1-11907.7) and eGFR at 6 months (OR 0.9, 95% CI 0.8-1.0) were associated with ESKD (P >0.05) on multivariate logistic regression analysis. Ethnicity, ANCA type or titer, crescents on biopsy and treatment received did not predict ESKD at 6 months or ESKD.

**Conclusions:** In this cohort of patients with severe ANCA glomerulonephritis IFTA and baseline eGFR were the most significant predictors of eGFR at 6 months follow up which in turn was associated with progression to ESKD.

Long-Term Outcome in Patients with ANCA-Associated Vasculitis (AAV): The Monocentric Experience of Brescia

Chiara Salvianti,1 Giana A. Gregorini,2 Gianluca Tedolli,3 Federico Alberici,1,2 Francesco Scolari,1,2 Nephrology Unit, ASST Spedali Civili di Brescia, Brescia, Italy; Universita degli Studi di Brescia, Brescia, Italy.

Background: Renal involvement in AAV is common, ranging between 80 and 90%; of note, up to 40% of patients (pts) with renal involvement will develop End-Stage Renal Disease (ESRD). We explored prognostic factors of renal and overall long-term survival in AAV pts with renal involvement.

Methods: Monocentric, retrospective study, including all pts with clinical or histological diagnosis of AAV with renal involvement followed at our Unit from 1990 to 2019, with follow-up (fu) ≥12 months.

Results: We identified 281 patients. Median fu was 75 months (IQR 33.1-141). Most pts were classified as MPA (71%), followed by GPA (26%) and eosinophilic granulomatosis with polyangiitis (3%). ANCA were positive in 97% (anti-MPO in 66%, anti-PR3 in 31%). At onset, median creatinine was 3.5 mg/dL (IQR 1.9-6.7) and proteinuria 1.1 g/24h (IQR 0.5-2.3). 20% of pts required haemodialysis (HD), with subsequent recovery of renal function in 55% of them. Induction therapy consisted of oral corticosteroids for all pts, along with CYC or RTX. The MCCS stratified renal outcomes for each MCCS grade and can be used as a means for treatment strategy adjustments.

Conclusions: Despite several therapeutic advances, AAV with renal involvement are still characterized by poor prognosis, especially in pts requiring HD at onset and of older age; infection, CV diseases and malignancies were the main causes of death.

PO1610

Predicting Outcomes in ANCA-Associated Vasculitis Using a Complete National Cohort

Dominic P. McGovern, Jennifer S. Lees, Colin C. Geddes, Emily Mcquarrie, Kate I. Stevens. The Scottish Renal Biopsy Registry The Glasgow Renal and Transplant Unit, Glasgow, United Kingdom.

Background: Outcomes in ANCA vasculitis remain difficult to predict & therapeutic decision-making can be challenging. We aimed to establish if a renal risk score (RRS) could predict outcomes.

Methods: The Scottish Renal Biopsy Registry is a complete national dataset of all biopsies performed in Scotland. Those who had a first renal biopsy between 2014 & 2017 with evidence of ANCA vasculitis were included. Demographic data & outcomes were recorded. RRS was calculated. Each patient was categorised according to % of normal glomeruli, % of tubular atrophy/intestinal fibrosis & eGFR (CKD-EPI) at time of biopsy. Individual scores were summed & patients defined as low, medium or high risk. Cox proportional hazard models were created for survival to ESRD, relapse & death, stratified by risk group.

Results: Two-hundred & forty-six patients with biopsy proven ANCA vasculitis were identified. Fifty percent (n=123), 46% (n=112) & 8% (n=11) were stratified as low, medium, or high risk, respectively. Most deaths were due to infections (33%), followed by cardiovascular (CV) diseases (20%) and malignancies (13%). At multivariate Cox regression analysis, age; infection, CV diseases and malignancies were the main causes of death.

PO1611

ANCA-Associated Crescentic Glomerulonephritis (AAV-GN) in Patients with Chronic Lymphocytic Leukemia (CLL): A Case Series

Background: Previous case reports have identified an association between CLL and AAV-GN. However, information on the clinical and pathologic characteristics and long-term outcomes of AAV in these patients is rare.

Methods: We queried medical records and research databases of CLL and AAV subjects seen at our institution to identify patients with diagnoses of CLL and AAV-GN from 1990-2020. We analyzed patient demographics, AAV-GN, CLL specific characteristics, treatments, and outcomes. Kidney biopsies were also reviewed.

Results: We identified 12 patients with AAV-GN and CLL. The mean age at diagnosis was 65 years (48, 80) for CLl and 67 years (37, 90) for AAV-GN. 7 patients were diagnosed with CLL prior to AAV-GN, 4 the same month, and 1 developed AAV-GN >3 years after CLL. At the time of AAV-GN diagnosis, all had acute kidney injury, with a median serum creatinine (Scr) of 1.9 mg/dL (SD 3.2). Other organs involved included lungs (n=3), skin (n=1), and eyes/encephalitis (n=1). 9 patients p-ANCA-MPO and 2 had c-ANCA-PR3 and one with an indeterminate ANCA but had PR3. On light microscopy, all had crescents, no vasculitis of the arteries, but 9 patients had focal lymphoid infiltrates without a formal diagnosis of CLL in the kidneys. On immunofluorescence 6/12 had trace to 1+ of IgA, 5/12 with IgG and 4/12 with C3. 5/12 of the biopsies had mesangial deposits and majority (1 with diffuse and 7 with mild–moderate) had foot process effacement. All patients received treatment for AAV (9 with rituximab, and 3 with cytotoxic drugs). Renal outcomes were favorable with 11 patients showing an improvement or stabilization in Scr. One patient (p-ANCA MPO) had high Scr and was managed with HD. All patients lived with both conditions for at least 1 year. We identified 5 patients with both AAV-GN and CLL, the vast majority had p-ANCA MPO, suggesting that the two conditions have either a common underlying lymphocyte dysfunction or that AAV-GN is a predisposing factor to the development of AAV. Anti-CD20 monoclonal antibody therapy was most commonly used, and it led to remission of AAV-GN.

PO1612

Kidney Biopsy Chronicity Grading in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

Marta I. Casal Moura, Fernando C. Fervenza, Ulrich Specks, Sanjeev Sethi. Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: Kidney biopsy is valuable for prognostic assessment of renal outcomes in antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with glomerulonephritis (AAV-GN) but the impact of chronic changes is not determined.

Methods: A retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV and active renal disease. We applied the Mayo Clinic Chronicity Score (MCCS), validated and evaluated its implications on outcome prediction in AAV-GN.

Results: We analyzed 329 patients with kidney biopsies available to score. The extent of chronicity was graded by MCCS as (i) minimal ~ 10% (31.0%), (ii) mild ~ 106 (32.2%), (iii) moderate ~ 86 (26.1%), and (iv) severe ~ 35 (10.6%). The MCCS grades correlated with the degree of renal function impairment at presentation (mean eGFR 48.3 vs. 29.2 vs. 23.7 vs. 18.5 mg/L/1.73 m², p<0.0001). Higher degrees of the individual components of the MCCS (glomerulosclerosis, interstitial fibrosis, tubular atrophy and arteriosclerosis) were associated with lower median eGFR (p<0.0001) and decreased event free (kidney failure (KF) and death) survival (p=0.002, p<0.0001 and p<0.0001, respectively). Patients AAV-GN with MCCS grades 1 and 2 had a lower renal function recovery than patients with grades 3 and 4 (p<0.0001). Increasing MCCS grades were associated with decreased renal recovery (p<0.001), more frequent events and shorter time to KF (p<0.0001), KF and death (p<0.0001), and death (p<0.0001) from non-renal events. The MCCS stratified renal outcomes for each MCCS grade and can be used in clinical practice as a risk factor for KF prediction (MCCSa4).

Conclusions: Chronic changes on kidney histology independently predict renal function, outcomes and response to treatment in AAV-GN.

PO1613

The Effect of Cumulative UVB Dose on ANCA-Associated Vasculitis

Jennifer Scott.1 Enoch Havyarimana,2 Albert Navarro-Galinat,2 Jason Wyse,1 Jos van Geffen,1 Antonia Buettener,1 Tamara Wanigasekara,1 Louis J. Aslett,4 Norman Basu,1 Lisa Zgaga,1 Martin A. Leung,2 Andrea G. Kattah.1 Trinity Health Kidney Centre, Trinity College Dublin, Ireland; 2The University of Dublin Trinity College, Dublin, Ireland; 3Institute of infection, immunity and inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; 4Royal Netherlands Meteorological Institute (KNMI), De Bilt, Netherlands; 5Department of Mathematical Science, University of Durham, Durham, United Kingdom.

Background: ANCA-associated vasculitis (AAV) has a relapsing-remitting course but the precise triggers of onset and relapse are unknown. The potential effect of cumulative ultraviolet B (UVB) radiation on disease phenotype and activity, mediated by vitamin D (vitD), has been proposed, given the marked incidence variation of AAV phenotypes and serotypes with latitude. Using a well-validated vitD proxy (cumulative-weighted UVB) as a marker of cumulative vitD exposure, we hypothesized that cumulative vitD exposure may influence AAV disease phenotype and activity.

Methods: 114 patients with biopsy proven AAV were treated with long-term corticosteroids and immunosuppressants. A cumulative vitD proxy (cumulative-weighted UVB) was calculated. The primary endpoint was the cumulative number of relapses over a given period of time. Secondary endpoints included total renal, extrarenal, and extracranial relapse rates. Mann-Whitney ranksum test and Wilcoxon rank sum test were used to compare AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively. The primary endpoint was compared between AAV phenotypes and disease activity, respectively.
UVB dose (CW-D-UVB) at wavelengths that induce vitD synthesis we hypothesized that prolonged periods of low ambient UVB are associated with an increased risk of GPA phenotype and AAV relapse in this subgroup.

**Methods:** The UKIVAS (n=1994) and Irish Rare Kidney Disease (RKD) (n=439) registries were used (total n=2433). Inclusion criteria: i) definite AAV diagnosis, ii) positive proteinase-3 (PR3) or myeloperoxidase (MPO) serology and/or positive histopathology. Logistic regression was used to investigate the relationship between latitude, CW-D-UVB and AAV phenotype/serotype in the entire cohort. A multi-level model was then applied to examine their effect on AAV relapse risk in the RKD subgroup.

**Results:** CW-D-UVB varied across seasons and latitudes. There was no relationship between latitude/CW-D-UVB at disease onset and AAV phenotype/serotype. MPA, MPO-ANCA, older age and rituximab maintenance were protective against relapse. There was no association between CW-D-UVB and relapse risk, even when examining phenotype specific risk (table 1).

**Conclusions:** We found no association between cumulative UVB, a validated vitD proxy, and AAV phenotype, ANCA serotype nor AAV disease activity in a genetically homogeneous cohort. These findings cast doubt on the role of vitD in AAV disease activity.

**Random effects:**

**N = 689, 284 observations. OR refers to the probability of having an AAV relapse (relative to remission).**

**Cumulative weighted UV index (CW-D-UVB), Standard deviation (SD), Microscope pathologist (MPH), Myeloperoxidase (MPO), Odds ratio (OR), 95% Confidence interval (DS/CI), Athlete profile (AAP).**

**Results:**

- **Acute Kidney Injury (AKI):**
  - Present in 30% of cases
  - Median serum creatinine increased from 1.2 to 2 mg/dL
  - Recovery observed in 70% of cases

**Discussion:**

- UVB exposure is significantly lower in areas with higher latitude, which may contribute to increased AAV relapse risk.
- Further studies are needed to confirm these findings and explore potential interventions to reduce relapse risk.

PO1615

Pauci-Immune Crescentic Glomerulonephritis Associated with Pulmonary Coccidioidomycosis
Elvira González, Erika R. Bracamonte, Amy Yau. Banner University Medical Center Tucson, Tucson, AZ.

**Introduction:** Coccidioidomycosis is an endemic fungal infection in the southwestern United States. There are around 150,000-300,000 cases annually, of which 60% occur in the state of Arizona. Most patients are asymptomatic. 40% have primary pulmonary involvement and present with dyspnea and fatigue. A minority (around 1%) have extrapulmonary dissemination with unknown incidence of renal involvement.

**Case Description:** We report a 70-year-old immunocompetent patient with CKD (baseline creatinine of 1.2 mg/dL) with a recent diagnosis of pulmonary coccidioidomycosis presenting with AKI due to ANCA negative pauci-immune crescentic GN. Our patient was referred to nephrology for worsened renal function, creatinine of 1.7 mg/dL. He was diagnosed with pulmonary coccidioidomycosis 3 months prior and started on fluconazole 400 mg daily. Due to concern for disseminated coccidioidomycosis, underwent a renal biopsy showing minimally active pauci-immune crescentic GN (Fig 1). Complement levels were normal, ANCA immunofluorescence, anti-MPO and anti-PR3 titers were negative.

**Discussion:** This is the third known reported case of pauci-immune crescentic GN associated with coccidioidomycosis, and one of a handful of case reports describing pauci-immune crescentic GN in patients with chronic fungal infections. Our case highlights the importance in understanding the pathogenesis and prognosis of chronic fungal infections and GN.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
and diffuse ATN. As creatinine worsened (peak 2.66mg/dL), mycophenolate (MMF) was added after resolution of bacteremia following iv antibiotics. 1 week after stopping antibiotics, he was readmitted with AKI, nephritic syndrome, and recurrent E. faecalis bacteremia. MMF was stopped and antibiotics restarted with improvement in creatinine (1.40mg/dL) and urine sediment.

Discussion: This is a rare case of PR3-ANCA vasculitis due to E. faecalis endocarditis. A kidney biopsy and high index of suspicion is crucial in diagnosing pauci-immune GN in patients with preexisting vasculitis. Absence of hypocomplementemia raised suspicion for a superimposed process. This case highlights the importance of a careful evaluation in patients presenting with vasculitis despite appropriate treatment of a preexisting vasculitic syndrome.

PO1617

A Rare Case of Crescentic Glomerulonephritis, Diffuse Proliferative Class IV Lupus Nephritis, and Collapsing Glomerulopathy in a COVID, P-ANCA, and Myeloperoxidase-Positive Patient

Introduction: An unusual case of Diffuse Class 4 Lupus nephritis, along with collapsing Glomerulopathy from asymptomatic COVID infection

Case Description: A 42 year old Asian female presented with painless hematuria, anasarca, reduced hearing, and eye redness over a month. She had empiric antibiotics and steroids prior to admission. On admission, she was hypotensive with anasarca. Labs revealed AKI creatinine of 2.5 mg/dl, proteinuria of 11 grams, and serum albumin 1.9 gm/dL. Urine analysis showed dysmorphic RBCs, RBC casts. Ultrasound showed 12 cm kidneys bilaterally. She had normal complements and DS DNA, antinuclear antibodies, lupus anticoagulant, anti-DNAase B, anti-histone, and anticardiolipin antibodies. Chest CT showed bilateral patchy infiltrates. Sputum and blood cultures for bacterial, fungal, and mycobacterial were negative.

Discussion: This is a rare case of diffuse class IV lupus nephritis with normal complements, DS DNA, and full house pattern on IF. She tested positive for COVID. Her labs showed Hgb: 10.4g/dl, WBC: 6780/mm3, MCV: 80fl, MCH: 28pg, MCHC: 33%, platelets: 357,000, Eosinophils 25%, Cr: 0.7mg/dl, H. Pylori: Positive. Guaic negative. Stool negative for ova/parasites. Endoscopy showed non-blooding erosive gastropathy with scattered punctate ulcerations in the duodenum. On biopsy diffuse acute and chronic inflammation, focal cryptitis, erosion of mucosa, Schistosoma Mansoni ova in glands of stomach, duodenum and jejunum were noted. CT brain negative for cysticercosis. CT chest showed calcified granulomas in right middle lobe and right lower lobe. On reevaluation she admitted to consuming snails. Rituximab maintenance therapy was not continued because of schistosomiasis. She was admitted for a multidisciplinary approach. Renal function remained stable protein/creatinine ratio 0.8, Myeloperoxidase positive . Patient was started on Praziquantel 1.2 g tid and prednisone 60 mg for 5 days which was followed by another cycle after 4 weeks to treat any remaining adult schistosomes. Repeat EGD and colonoscopy with multiple biopsies to ensure eradication of schistosomiasis before resuming rituximab is planned.

Discussion: Our case emphasizes the need to consider parasitic infections when starting patients from endemic areas on immunosuppressive therapy. Schistosomiasis can involve multi-organ systems and can lead to potentially debilitating and fatal complications such as liver fibrosis, portal hypertension, hypersplenism, esophageal variceal bleeding, GN and nephrotic syndrome. Detailed history for dietary habits and lifestyle is important. Serology, antigen detection or other diagnostic tools can be used when the suspicion is high.

PO1618

Schistosomiasis in a Patient on Rituximab for ANCA-Associated Glomerulonephritis

Mihica Jovanovic,1,2 Muhammad U. Aameish,1,2 Donald I. Baumstein,1,2 Ashok P. Chaudhari.1,2 1Metropolitan Hospital Center, New York, NY; 2New York Medical College, Valhalla, NY.

Introduction: Rituximab and glucocorticoids induce remission in ANCA associated vasculitis with renal involvement. Rituximab induces B-cell depletion and influences T-cell immunity, which predisposes patients to serious infectious complications. We present a case of schistosomiasis in a patient on rituximab for Pauzi Immune Glomerulonephritis (GN) associated with ANCA vasculitis.

Case Description: A 39 years old female from Honduras with history of sero-negative arthritis, acute kidney injury with pauci immune, focal necrotizing and diffuse crescentic GN on kidney biopsy and P-ANCA positive, was treated on rituximab and glucocorticoids. Ten months later, while in remission she presented with nausea, vomiting, obstipation and abdominal pain. Her labs showed, Hgb: 10.4g/dl, WBC: 6780/ mm3, Eosinophils 25%, Cr: 0.7mg/dl, H. Pylori: Positive. Guaic negative. Stool negative for ova/parasites. Endoscopy showed non-blooding erosive gastropathy with scattered punctate ulcerations in the duodenum. On biopsy diffuse acute and chronic inflammation, focal cryptitis, erosion of mucosa, Schistosoma Mansoni ova in glands of stomach, duodenum and jejunum were noted. CT brain negative for cysticercosis. CT chest showed calcified granulomas in right middle lobe and right lower lobe. On reevaluation she admitted to consuming snails. Rituximab maintenance therapy was not continued because of schistosomiasis. She was admitted for a multidisciplinary approach. Renal function remained stable protein/creatinine ratio 0.8, Myeloperoxidase positive . Patient was started on Praziquantel 1.2 g tid and prednisone 60 mg for 5 days which was followed by another cycle after 4 weeks to treat any remaining adult schistosomes. Repeat EGD and colonoscopy with multiple biopsies to ensure eradication of schistosomiasis before resuming rituximab is planned.

Discussion: Our case emphasizes the need to consider parasitic infections when starting patients from endemic areas on immunosuppressive therapy. Schistosomiasis can involve multi-organ systems and can lead to potentially debilitating and fatal complications such as liver fibrosis, portal hypertension, hypersplenism, esophageal variceal bleeding, GN and nephrotic syndrome. Detailed history for dietary habits and lifestyle is important. Serology, antigen detection or other diagnostic tools can be used when the suspicion is high.
protocol and Rituximab therapy per the RAVE trial protocol. Cr improved (1.6 mg/dL) after induction therapy with persistent mild proteinuria at <500 mg/g at 6 months. Dual MPO and PR3 positivity persisted until Rituximab completion, after which only MPO positivity continued.

**Discussion:** It is well known that anti-thyroid medications can cause drug-induced AA V. However, this renal limited AA V case with desiccated thyroid supplementation suggests clinicians should also be aware of AA V as a possible adverse consequence of thyroid supplementation. Management should include discontinuation of the offending agent and consideration of immunosuppression with standard induction regimens based on disease severity.

**Renal Survival in Anti-Glomerular Basement Membrane Disease**

Lauren Floyd,1 Anna S. Li,2,3 Nina Brown,2 Helen Alderson,3 Silke R. Brix,4 Jay P. Dhaygude,1,4 Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 2The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 3Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4Salford Royal NHS Foundation Trust, Salford, United Kingdom.

**Background:** Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD).

Reliable predictors of kidney survival are needed.

**Methods:** Retrospective analysis of patients with anti-GBM disease from the North West of England.

**Results:** Seventy patients with GBM nephritis were identified, 20 patients presented double positive for anti-neutrophil cytoplasmic antibodies (ANCA) and GBM antibodies (28.57%). Median age was 64 years (Interquartile range 43 – 76 years). 39 patients were female (55.7%). Median kidney function at presentation was an estimated glomerular filtration rate of 93 ml/min (eGFR, IQR 41.95 – 83.55 ml/min). Sixty patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw RRT (25.5%). Median follow up was 41 months (IQR 11 – 77.5), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2.1 ml/min recovered function.

**Conclusions:** Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

**PO1621**

**Validation of the Renal Risk Score in Anti-GBM Disease**

Anna S. Li,1,4 Lauren Floyd,1 Nina Brown,2 Helen Alderson,3 Jay P. Dhaygude,1,4 Graeme T. Reid,4 Silke R. Brix,1,4 The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 3Salford Royal NHS Foundation Trust, Salford, United Kingdom; 1Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 4Manchester University NHS Foundation Trust, Manchester, United Kingdom.

**Background:** Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD). Clinical and histological variables predicting outcome are needed to identify individual therapy and improve outcome.

**Methods:** We performed a retrospective multicentre analysis and investigated the Renal Risk Score (RRS) proposed in anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis for its prognostic value in anti-GBM disease. We used the published cut-offs for percentage of normal glomeruli (N0 > 25%, N1 10 - 25%, N2 < 10%), estimated glomerular filtration rate (eGFR, G0 > 15 ml/min/1.73 m2, G1 15 ml/min/1.73 m2) and a simplified cut off for tubular atrophy and interstitial fibrosis (TA ≤ mild, T1 ≥ moderate, T2 ≥ severe) according to the published RRS. We identified 70 patients with ANCA and GBM antibodies (28.57%). Median age was 64 years (Interquartile range, IQR 43 – 76 years). 39 patients were female (55.7%). Median eGFR at presentation was 93 ml/min (IQR 41.95 – 83.55 ml/min). Median follow up was 41 months (IQR 11 – 77.5), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was 2.1 ml/min.

**Results:** Seventy patients with GBM nephritis were identified, 20 patients presented double positive for ANCA and GBM antibodies (28.57%). Median age was 64 years (Interquartile range 43 – 76 years). 39 patients were female (55.7%). Median kidney function at presentation was an estimated glomerular filtration rate of 93 ml/min (eGFR, IQR 41.95 – 83.55 ml/min). Sixty patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw RRT (25.5%). Median follow up was 41 months (IQR 11 – 77.5), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2.1 ml/min recovered function.

**Conclusions:** Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

Adding Low-Dose CYC to RTX Combined with a Tailored RTX Maintenance Regimen Seems to Favor Stable Remission in Severe ANCA Vasculitis

Renee Yeomans, Matthias H. Busch, Joop Aendekerk, Pieter van Paasen, Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands

Background: Rituximab (RTX) and cyclophosphamide (CYC) are effective remission-induction therapies in ANCA-associated vasculitis (AAV). High dose CYC is however considered toxic, whereas RTX monotherapy may increase the risk of relapse, depending on the choice of maintenance therapy and baseline disease severity. Particularly with renal involvement, stable remission will favor prognosis. In this respect, adding low dose CYC to RTX could be superior to RTX alone. We checked this premise by retrospectively analyzing our data derived from a pragmatic, clinical approach in patients with severe AAV.

Methods: Between 2007 and January 2019, 246 patients with severe active AAV, needing remission-induction therapy, were screened and 62 patients were included. Remission-induction consisted of either RTX only (n=7) or RTX-CYC (n=55). Secondary endpoint was major relapse rate and adverse events at 2 and 5 years, compared with the log-rank test.

Results: 28 patients received RTX only and 34 patients received RTX-CYC. Disease presentation, severity of disease (BVAS), and laboratory parameters (serum creatinine, CRP, and IgG) at 20 the UCPR were similar. Baseline UCPCR was more prevalent in the RTX-CYC patients (85.3%) as compared to RTX only (60.7%) (P = 0.028). Relapse rates within 2 years were significantly higher in the RTX only group (n=7 in RTX only, n=1 in RTX-CYC, P = 0.015), however the number of patients receiving RTX maintenance and the number of infusions did not differ. After 5 years, however, relapse rates did not differ (n=9 in RTX only and n=7 in RTX-CYC). The rate of infections, hypogammaglobulinemia, end stage renal disease, malignancies, and mortality did not differ after 2 and 5 years.

Conclusions: Adding low dose CYC to RTX is safe and may favor the prevention of major relapses in patients with severe AAV, predominantly with renal involvement. Future prospective studies are needed to examine the role of reconstituted B cells and ANCA features to better define tailor-made treatment decisions.

POI1626

Preferencias Regarding Treatment with Plasma Exchange for ANCA-Associated Vasculitis (AVE) are uncertain. We sought to elicit patient preferences regarding the use of PLEX in AAV.

Methods: An online survey was circulated via national vasculitis and kidney patient networks. Respondent characteristics were collected and information regarding PLEX in AAV was provided including its minimal effect on mortality. One year incidence of end stage kidney disease (ESKD) and serious infections with and without PLEX in AAV were presented across 5 serum creatinine categories: 150, 250, 350, 450 and 600µmol/L. For each scenario, participants were asked: "If they were a patient with a new diagnosis of ANCA vasculitis, they would choose PLEX (yes or no) given its absolute risk reduction in ESKD, but absolute risk increase in serious infections?" Multilevel multivariable logistic regression was performed to identify independent predictors of choosing treatment with PLEX.

Results: There were 549 responses. The mean age of respondents was 57.4 (SD 14.5) years, 72.3% were female, and respondents were from the United States (58.1%), United Kingdom (23.7%), Canada (14.0%), and other countries (4.2%). The majority had AAV (86.7%). 190/549 (34.6%) would always choose PLEX and 87/549 (15.8%) would always decline PLEX across the baseline risks of ESKD or serious infections presented. Independent predictors for choosing PLEX included age (OR 0.98, 95% CI 0.96-0.99 per 1 year increase), country (United Kingdom OR 2.73, 95% CI 1.20-6.21), diagnosis (individuals with vasculitis other than AAV were more likely), previous dialysis (OR 3.34, 95% CI 1.37-8.16), preference for maintenance strategy (OR 2.50, 95% CI 2.50-10.49), and increased baseline risk of ESKD (Cr 350 and 450µmol/L only).

Conclusions: One third of participants would always choose treatment with PLEX across the 5 scenarios presented. The decision to choose PLEX is influenced by age, country, previous dialysis, and the baseline risk of ESKD and serious infections. Patient values and preferences are needed to inform shared decision-making regarding PLEX in AAV.

POI1627

Maintenance of Remission and Risk for Relapse in Myeloperoxidase Positive Antineutrophil Cytoplasmic Antibody-Associated Vasculitis with Kidney Involvement

Marta I. Casal Morua, Shahrazad Tehranian, Shane A. Bobart, Ladan Zand, Eddie L. Greene, Sanjeev Sethi, Ulrich Specks, Fernando C. Fervenza, Mayo Foundation for Medical Education and Research, Rochester, MN; 2Cleveland Clinic, Cleveland, FL.

Background: Optimal time of remission-maintenance therapy in patients with MPO-ANCA associated vasculitis (MPO-AAV) is not established. Defining clinical and laboratory parameters to guide safe withdrawal of maintenance immunosuppression is required in order to mitigate the risk of relapse.

Methods: A retrospective cohort study of all patients followed at the Mayo Clinic with MPO-AAV (MPA and GPA) and their remission strategy was characterized.

Results: We analyzed 159 MPO-ANCA positive patients with active kidney involvement. A total of 66 (41.5%) patients had at least 1 relapse. MPO-ANCA patients who became and remained seromorfolgic did not relapse (HR 0.03, [95%CI, 0.001-0.970], p=0.048). MPO-ANCA reappearance after seronegative conversion was associated with increased relapse rate at 24 months (HR 3.651, [95%CI, 1.14-11.966]; p=0.012). Immunosuppression was withdrawn in 80 (50.3%) and this was predicted by persistent MPO-ANCA seronegative conversion (OR 3.028, [95%CI, 1.262-7.268]; p=0.031). In patients who withdrew remission-maintenance therapy, 32 (40.0%) relapsed (in comparison with 34 relapses [43.0%] in those who maintained immunosuppression, p=0.097). ENT involvement (OR 6.095 [95%CI, 1.280-29.010], p=0.023) and MPO-ANCA reappearance (OR 9.248, [95%CI, 2.743-27.361], p<0.0001), were independent predictive factors for relapse after withdrawal.

Conclusions: Our results suggest that patients who seroconverted and remain MPO-ANCA negative are at lower risk of relapse: remission-maintenance treatment might be withdrawn without an additional risk of relapse. MPO-ANCA reappearance after seronegative conversion is not a risk factor for relapse at 24 months. Serial MPO-ANCA determinations are useful to guide clinical decisions on remission-maintenance treatment strategies.
PO1628
Renal Histological Biomarkers and Response to Different Induction Regimens in ANCA-Associated Glomerulonephritis: The REASSESS Study
Martina Uzzo, Jennifer Scott, Alice A. Guerini, Stefania Afflato, Rosanna Lacetera, Andreas Kronbichler, Iva Gunnarsson, Marco Allinovi, Gaetano La Manna, Mario Cuzzolin, Annette Bruchfeld, Federica Mescia, Federico Pieruzzi, Stephen P. McAdoo, Renato A. Sinico, Mattia Cmorgone, Francesco Scolari, Mark A. Little, David R. Jayne, Federico Alberici.

Background: The role of kidney biopsy on ANCA-associated vasculitis (AAV) is still debated: despite its significant prognostic value, whether it has an impact on the induction regimen choice has not been explored yet.

Methods: 323 AAV patients with biopsy-proven renal involvement were collected retrospectively from eleven centers and stratified according to the histopathological characteristics at the kidney biopsy and the induction regimen employed.

Results: The median follow-up time was 36 months; the eGFR was 19 ml/min/1.73m². 53% were MPO-ANCA and 41% PR3-ANCA; 58% were treated with Cyclophosphamide (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the K-M classification, 24% biopsies were classified as Focal, 31% as Crescentic, 33% as Mixed (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the response analysis with the K-M curve, patients in the Crescentic group treated with RTX had a shorter ESRD-free survival compared to the CYC group (p=0.033) and the RTX-CYC one (p=0.044). This was confirmed with a Cox regression analysis adjusted for sex, age, ANCA type, AAV diagnosis, creatinine and proteinuria when comparing the RTX group with the CYC one.

Conclusions: Response rates and relapse rate were comparable in the overall cohort and in each histopathological subgroup. The ESRD-free survival in the Crescentic class was shorter in the RTX group compared to the CYC one.

PO1629
ANCA Vasculitis Induction Management in the COVID-19 Pandemic: Results of an International Retrospective Cohort Study
Antonio Salas, Duvuru Geetha, ANCAITCOV Johns Hopkins University School of Medicine, Baltimore, MD; Johns Hopkins University Department of Medicine, Baltimore, MD.

Background: Induction therapy for severe ANCA-associated vasculitis (AAV) combines glucocorticoids (GC) with either rituximab (RTX) or cyclophosphamide (CYC). The coronavirus 2019 disease (COVID-19) pandemic has increased concern around using aggressive immunosuppression; whether this concern has impacted AAV management is unknown. Here, we report treatment regimens and outcomes of patients with active AAV receiving induction immunosuppression during the first wave of the pandemic.

Methods: We retrospectively studied AAV patients with new or relapsing disease receiving remission induction therapy during the first wave of the COVID-19 pandemic across sites in the US, UK and Europe. Primary outcome was achievement of complete remission at 6 months.

Results: Of 191 patients with a mean age of 65 years old, 52% were female and a majority (89%) were Caucasian. Standard induction was deployed across all sites. Out of the US, UK, and European patient populations, the US used higher GC pulses leading to a higher average cumulative GC dose for remission induction (4153 mg, 2174 mg, 3400 mg respectively, p<0.001) and had the highest proportion of patients given RTX induction therapy (64%; p=0.005). Complete remission was achieved in 90% of patients. Improvement in kidney function at 6 months was similar with all treatment regimens (6 ml/min² increase, p=0.68). Sixteen patients were diagnosed with COVID-19 and had similar exposures to CYC and RTX. There were no differences in remission rates, ESKD or death when stratified by induction therapy type.

Conclusions: Induction immunotherapy practices differ across the world, but specialists continued their standard management during the COVID-19 pandemic. AAV outcomes or rates of COVID-19 infection were not influenced by different induction regimens.

PO1630
Non-Sucrose Containing IV Immunoglobulin in ANCA Vasculitis Has No Adverse Effects on Renal Function
Renee Ysermans, Matthias H. Buseh, Joop Aedekerck, Pieter van Paassen, Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.

Background: Intravenous immunoglobulin (IVIG) has proven to be effective as an immunomodulator in several autoimmune and inflammatory diseases, including antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Moreover, in the era of B cell-depleting therapies, secondary immunodeficiencies are common, urging supplementation by IVIG. Reported adverse effects are generally mild in nature. However, concerns have been raised about the safety profile of IVIG in relation to renal function. IVIG associated kidney injury is proposed to be mainly related to sucrose stabilized products. Non-sucrose containing alternatives are available and increasingly used. We therefore aimed to analyze the safety of non-sucrose containing IVIG with regard to renal function in patients with AAV.

Methods: AAV patients of the Maastricht University Medical Center were retrospectively analyzed for dynamics of serum creatinine levels before and after IVIG using the Wilcoxon signed rank-test. Subanalyses were performed with regard to the presence of ANCA-associated renal disease and IVIG indication. In addition, correlation analysis was conducted to evaluate the relation between serum creatinine change and cumulative IVIG dose during a 1-year follow-up.

Results: 36 with 49 courses of IVIG were included in the short-term and 54 patients with 70 courses of IVIG were included in the long-term analysis. No significant differences were found between serum creatinine levels before and after IVIG in the short-term (median [IQR], 32 [28-39] and 32 [28-39] mmol/L, P=0.60), with a median follow-up of 16 days after the initial IVIG infusion, and the long-term (median [IQR], 110 [90-135] and 110 [90-152] mmol/L, P=0.077), after a year. One patient with active AAV and renal involvement had a reversible serum creatinine increase >30% 6 days after IVIG. Subanalyses showed no significant changes in serum creatinine levels with regard to renal involvement and IVIG indication. There was no association between serum creatinine change and cumulative IVIG dose 1 year after the initial IVIG infusion (P=0.667).

Conclusions: This study shows no short-term and long-term deleterious effects on renal function in response to treatment with non-sucrose containing IVIG in patients with AAV.

Efficacy and Safety of a Combination Treatment of Mycophenolate Mofetil and Corticosteroid in Advanced IgA Nephropathy: A Multi-center, Prospective Study
Cha-June Jung,1 Sang Youb Han,2 Beom seok Kim.1 1Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea; 2Inje University Ilsan Paik Hospital, Goyang, Republic of Korea.

Background: It remains unclear whether immunosuppressive agents are effective in patients with IgA nephropathy (IgAN). We sought to determine the efficacy of mycophenolate mofetil (MMF) and corticosteroid combination therapy in patients with advanced IgAN.

Methods: We conducted a multicenter, randomized, placebo-controlled, parallel group study of a 48-week administration of MMF and corticosteroids in biopsy-proven advanced IgAN patients with an estimated glomerular filtration rate (eGFR) between 20-50 mL/min/1.73m² and a urine protein-to-creatinine ratio (UPCR) greater than 0.75g/day. The primary outcome was complete (UPCR<0.3g/day) or partial remission (reduction of UPCR >50%) compared to baseline at 48 weeks.

Results: Of the 48 randomized patients, complete and partial remission rates were higher in the MMF and corticosteroid combination therapy group (29.1% vs. 5.0%, P<0.05). In contrast to the combination therapy group, eGFR in the control group significantly decreased from 36 weeks onwards, resulting in a final adjusted mean change of -4.39 ± 1.22 mL/min/1.73m² (P<0.002). The adjusted mean changes at 48 weeks were 0.62 ± 1.30 and -5.11 ± 1.30 mL/min/1.73m² (P=0.005) in the treatment and control groups, respectively. The amount of UPCR was also significantly different between the two groups, where the adjusted mean change was -0.47 ± 0.17 mg/mgCr in the treatment group and 0.07 ± 0.17 mg/mgCr in the control group (P=0.04). Overall adverse events did not differ between the groups.

Conclusions: In patients with advanced IgAN with a high risk for disease progression, combination therapy of MMF and corticosteroid appears to be beneficial in reducing proteinuria and preserving renal function.

Pharmacodynamic and Clinical Responses to BION-1301 in Patients with IgA Nephropathy: Initial Results of a Ph1/2 Trial
Jonathan Barratt,1 Billy T. Hour,2 Brian S. Schwartz,2 Bess Sorensen,3 Suzanne E. Roy,2 Colleen L. Stromat,4 Margaret MacDonald,4 Aaron M. Endesley,4 Jeanette Lo,5 Alan Glicklich,6 Andrew J. King.7 1University of Leicester, Leicester, United Kingdom; 2Chinook Therapeutics Inc, Seattle, WA; 3Certa Pharma, London, United Kingdom; 4Chinook Therapeutics Inc, Seattle, WA; 5Certa Pharma, London, United Kingdom; 6Certa LP, Princeton, NJ; 7Amicus Research Center, Northbridge, CA.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis globally, with up to 45% of patients at risk of progressing to ESKD. The initiating step in IgAN pathogenesis is the excessive production of galactose-deficient IgA1 (Gd-IgA1), resulting in the formation of immune complexes that cause kidney inflammation and damage. A Proliferation-Inducing Ligand (APRIL) is elevated in IgAN patients and correlated with higher levels of Gd-IgA1 and proteinuria, and lower eGFR.

BION-1301 is a novel monoclonal antibody targeting APRIL. Here we present interim results from Part 3 of a Phase 1/2 study that characterizes the safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary activity of BION-1301 delivered by IV administration in patients with IgAN.

Methods: Part 3 of this Phase 1/2 study (NCT03945318) is an ongoing multicenter, multicohort, open-label study in up to 40 IgAN patients. In Cohort 1, BION-1301 is dosed at 450mg IV every 2 weeks for up to 12 months. Key objectives of the study include safety and the characterization of PK, PD, immunogenicity and changes in proteinuria. Key eligibility criteria include: (1) urine protein ≥0.5 g/24h or baseline UPCR ≥0.5 g/g, (2) stable/optimized dose of ACE-I/ARB or ACE-I/ARB intolerant and (3) biopsy-verified diagnosis of IgAN within the past 10 years.

Results: Preliminary results from the first 5 patients show BION-1301 is well tolerated with no serious adverse events and no adverse events leading to discontinuation to date. BION-1301 drives durable reductions in serum free APRIL, Gd-IgA1, IgA and IgG with a lesser reduction in IgM. A clinically meaningful reduction of UPCR was observed within 3 months. Updated data in all 46 treated patients, along with mechanistic response kinetics, will be presented at the meeting.

Conclusions: BION-1301 is a novel anti-APRIL monoclonal antibody being developed for potential therapy for patients with IgAN. BION-1301 treatment was modifying potential by directly targeting the pathogenesis of IgAN. Promising early biomarker and clinical activity support the continued development of BION-1301 in IgAN.

Atrasentan Exhibits a Consistent, Predictable Pharmacokinetic Profile Among Healthy Asian Adults
Anil Rastogi,1 Jiecheng Liu,2 David A. Catanzaro,3 Vince Tong,3 Jonathan Stromat,1 University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 2Peking University First Hospital, Beijing, China; 3Chinook Therapeutics Inc, Seattle, WA; 4Juntendo Daigaku Igakubu Daigaku Kenkyu-ku, Bunkyo-ku, Japan.

Background: Atrasentan, a potent and selective endothelin-A receptor antagonist, is under investigation for reducing proteinuria and preserving kidney function in IgA nephropathy and other glomerular diseases. Two phase 1 studies evaluated the pharmacokinetics (PK) and safety of atrasentan in healthy adults of Chinese (Study M11-521) and Japanese (Study M11-522) parentage.

Methods: Study M11-521 was an open-label, randomized (for single-dose regimens), single-center study of single and multiple doses of atrasentan in 36 healthy Chinese adults. Single doses of atrasentan tablets (0.5, 1, or 1.5 mg) were administered in Part I, and multiple dose studies of atrasentan 1.5 mg were administered in Part II. Study M11-522 was a double-blind, randomized, placebo-controlled, single-center study of single doses of atrasentan (0.5, 0.75, or 1.25 mg) in 36 healthy Japanese adults. Blood samples were collected for analysis of plasma PK parameters, including the area under the plasma concentration-time curve (AUC) and the maximum observed plasma concentration (Cmax).

Results: In Study M11-521, atrasentan AUC increased proportionally with dose in the 0.5 mg to 1.5 mg dose range, and Cmax increased proportionally with dose in the 1 mg to 1.5 mg dose range. No statistically significant differences were observed in either the dose-normalized AUC or for the comparison of the 1.5 mg and 0.5 mg dose groups (P = 0.260) or the dose-normalized Cmax, for the comparison of the 1.5 mg and the 1 mg dose groups (P = 0.279). In Study M11-522, a linear increase in atrasentan mean AUC, was observed across the 0.5 to 1.25 mg dose range; dose-normalized mean Cmax did not show a statistically significantly different across the doses (P = 0.735). Atrasentan was generally well tolerated. No clinically significant vital signs, electrocardiogram activity, or laboratory measurements were observed, and no apparent significant differences among the dose regimens were found with respect to safety.

Conclusions: Dose-proportional increases in AUC were observed across the studied range, which includes the 0.75 mg dose being studied in ongoing clinical trials. These data support the safety and tolerability of atrasentan and suggest a consistent and predictable PK profile among patients of Asian descent.

Randomized Clinical Study to Evaluate the Effect of Personalized Therapy on Patients with Immunoglobulin A Nephropathy (IgAN)
Franco Scuderi1, Sara Ronca,2 Giovanni Trippe,2 Daniela L. Abbrescia,2 M. Rossini,4 Carlo Manno,5 Hildo J. L Heerspink.1 1Universita degli Studi di Bari Aldo Moro, Bari, Italy; 2Fondazione Scena, Bari, Italy; 3CNR-IFC, Reggio Calabria, Italy; 4Ospedale Consorziale Policlinico, Bari, Italy; 5Dept Clinical Pharmacy and Pharmacology, Groningen, Netherlands.

Background: IgA nephropathy is known to be a highly heterogeneous disease, with patients having different disease severities, treatment responses, and outcomes. Personalized therapy is critical to optimize clinical outcomes and reduce treatment-related complications.

Methods: Our clinical study of IgAN (CLIgAN) is a multicentre, prospective, controlled and open-label randomized clinical trial based on patient’s stratification at the time of their kidney biopsy. The trial has been registered in ClinicalTrials.gov (NCT 04662723). We will consider, first, the type of renal lesions followed by serum creatinine values, GFR and proteinuria. Primary and secondary end points have been established. Second, we will determine whether personalized therapy can slow the decline of the renal function and delay the ESKD.

Results: We will enroll 132 IgAN patients with active renal lesions (66 patients per arm) in the first RCT (ACLigAN). They will receive corticosteroids combined with renin-angiotensin system blocker (RASB) or RASB alone. Two hundred ninety-four IgAN patients with chronic renal lesions at high or very high risk of chronic kidney disease (147 patients per arm) will be enrolled in the second RCT (CHRONIgAN) in which they will receive sodium-glucose cotransporter -2 inhibitor (SGLT2-i) combined with RASB or RASB alone.
Conclusions: Using this approach we hypothesize that patients could receive personalized therapy based on renal lesions to ensure that the right drug gets to the right patient at the right time.

PO1635
Enhanced Efficacy of Corticosteroid Therapy by Tonsillectomy in IgA Nephropathy
Keita Hirano,1,2 Tetsuya Kawamura,1 Kentaro Koike,2 Nobuo Tsuboi,2 Takashi Yokoo,3 Yusuke Suzuki,3,4 Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 1The Jikei University School of Medicine, Minato-ku, Japan; 2Juntendo University Faculty of Medicine, Bunkyo-ku, Japan.

Background: Efficacy of corticosteroid therapy in IgA nephropathy may vary among countries or races. Nowadays, the strategy to enhance efficacy of corticosteroid therapy is desired. In 2014, our randomized controlled trial demonstrated that corticosteroid therapy combined with tonsillectomy had superior anti-proteinuric effect than that of corticosteroid therapy alone (Nephrol Dial Transplant. 2014). However, the benefit of combining corticosteroid therapy with tonsillectomy for long-term renal survival was uncertain. Therefore, in a Japanese nationwide prospective cohort dataset, we aimed to evaluate whether the benefit of corticosteroid therapy may increase when it was combined with tonsillectomy, or not.

Methods: Patients were registered between April 1, 2005 and August 31, 2015 at 44 facilities throughout Japan. The primary outcome was a 50% increase in serum creatinine from baseline or dialysis initiation. Two interventions were focused in the present study: corticosteroid with or without tonsillectomy. Survival analysis was adjusted with baseline clinicopathological parameters including eGFR, proteinuria, hematuria, RAS inhibitor use and MEST-C score in Oxford classification.

Results: Enrolled 991 patients showed 75.4 ml/min as mean eGFR and 0.58 g/day as median level of proteinuria. Among them, 634 (64.0%) and 425 (42.9%) patients received corticosteroid therapy and tonsillectomy, respectively. During the median follow up of 5.5 years, 87 patients (8.8%) reached primary outcome. Adjusted hazard ratio (HR) of corticosteroid therapy for primary outcome in patients with tonsillectomy was 3-fold favorable than that in those without tonsillectomy (HR 0.18, 95% confidence interval [CI] 0.06-0.65, versus HR 0.59, 95%CI 0.34-1.01; P value for interaction between corticosteroid therapy and tonsillectomy 0.060).

Conclusions: Enhanced efficacy of corticosteroid therapy by tonsillectomy in IgA nephropathy was confirmed in a Japanese nationwide prospective cohort.

PO1636
The Potential Role of Monthly Corticosteroid Pulse in IgA Nephropathy
Arisa Kobavashi,1,2 Keita Hirano,1,2 Nobuo Tsuboi,2 Takashi Yokoo,3 Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 1The Jikei University School of Medicine, Minato-ku, Japan.

Background: The risk of corticosteroid therapy may be underestimated in IgA nephropathy (IgAN). Previous studies provided that a fifth part of patients was older than 60 years and the rate of diabetes mellitus (DM) was increased in IgAN. The novel corticosteroid therapies with not losing benefit and reduced risk of corticosteroid are desired. Here, we aimed to determine whether monthly corticosteroid pulse is inferior in proteinuria remission and superior in blood glucose control to standard corticosteroid therapy or not.

Methods: Design: Retrospective, non-inferiority study. Participants: Adult patients with IgAN received intervention described below between 2013 and 2020. Intervention: Monthly corticosteroid pulse alone for 6 months versus standard corticosteroid therapy having oral corticosteroid for 6 months and three times of pulse corticosteroid in the same 6 months (Lancet 1999). Outcomes: The primary outcome was proteinuria remission (<0.3g/day) at 1 year and we prespecified 0.67 in odds ratio (OR) as non-inferiority margin. The secondary outcome was safety of blood glucose care, which was defined by glucose level by 1 quartile, atacicept 25 mg stably reduced Gd-IgA1 levels by 1 quartile in 2/6 group had significant reductions. PBO pts transiently increased or decreased Gd-IgA1 levels by 1 quartile all 3 of 3 in the PBO group did not reach the statistical requirements for a proven non-inferiority on proteinuria remission, but significantly exhibited safety outcome in the control of blood glucose. Prospective larger studies are needed to determine the role of monthly corticosteroid pulse in IgAN.

PO1637
The Beneficial Effects of Renin-Angiotensin System Inhibitors on IgA Nephropathy with Global Sclerosis
Eri Kasama, Takahito Moriyama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: In IgA nephropathy (IgAN), global sclerosis has been recognized as one of the risk factors for progression, because it induces glomerular hypertension and hyperfiltration in the remained glomeruli. The reno-protective effects of renin-angiotensin system inhibitors (RASI) are considered to decrease glomerular hypertension and hyperfiltration, but their effectiveness in IgAN with global sclerosis has been unknown.

Methods: Of the 871 IgAN patients diagnosed at our institution, we classified them into three grades by the ratio of global sclerosis (G) against whole glomeruli (G0 (n=225): none, G1 (n=445): at least one but <25%, G2 (n=191): ≥25%). We compared each clinical background and 20-year prognosis. Then, we examined the effect of RASI initiated during follow-up period on the long-term prognosis in patients with G1+G2 and in patients with G2 by Kaplan-Meier analysis and Cox regression analysis. To adjust the background characteristics between patients treated with or without RASI, propensity matching score was performed.

Results: The age, blood pressure, proteinuria, renal function, and histological findings were significantly severer with increasing grade in G0, G1, and G2, and 20-year renal survival rate was 83.5%, 75.0% and 54.4% in patients with G0, G1, and G2, respectively (p<0.001). After propensity matching between patients treated with or without RASI, 366 patients in G1+G2 and 90 patients in G2 were eligible for the evaluation. The 20-year renal survival rate was significantly higher in the patients with RASI than in the patients without RASI (G1+G2: 84.5% vs. 59.0%, p<0.001, G2: 63.8% vs. 33.5%, p=0.037). In multivariate Cox regression analysis considering clinical and histological findings and treatment, RASI was an independent factor to prevent progression in patients with G1+G2 and G2 (G1+G2, hazard ratio: 0.39, 95% confidence interval: 0.25-0.62, p<0.001; G2, hazard ratio: 0.35, 95% confidence interval: 0.19-0.66, p<0.001).

Conclusions: In this study, global sclerosis was associated with severer clinical and histological findings, and poor prognosis. However, RASI initiated during follow up period was found to improve renal prognosis in IgAN with at least one global sclerosis.
PO1639

Remission of IgA Nephropathy with Hydroxychloroquine

Hafsa Tariq,1 Jagmeet S. Dhingra,2 1University Hospitals, Cleveland, OH; 2MetroHealth Medical Center, Cleveland, OH.

Introduction: IgA nephropathy is the most common form of glomerulonephritis in the world. Treatment options include blockade of renin-angiotensin-system (RAS) as the first line of therapy. Steroids may be beneficial in refractory cases, however, can result in several adverse effects. Data regarding use of immunosuppression is inconclusive. Combination of RAS inhibition and hydroxychloroquine has shown to reduce proteinuria in recent studies, though, complete remission with long term use has not been described. We report the case of a 46-year-old Asian female with IgA nephropathy, who was treated with maximally tolerated RAS inhibition and hydroxychloroquine for about 24-months resulting in complete remission of proteinuria and hematuria.

Case Description: The patient was referred to nephrology for evaluation of hematuria and proteinuria (1.5 g/g, Serum creatinine 0.9 mg/dl). Serological work-up was negative. She was initiated on angiotensin receptor blocker (ARB) and underwent kidney biopsy which confirmed IgA Nephropathy. There were 8 glomeruli with 20-25% sclerosis, mild to moderate chronic tubulointerstitial nephritis and fibrosis, no crescents, mild mesangial proliferation and hypercellularity with IgA staining 3+. She did not have any significant improvement in proteinuria despite maximally tolerated ARB (losartan 100 mg daily) therapy for three months. Her kidney function also declined, creatinine 1.2 mg/dl. Hydroxychloroquine 200 mg daily was then initiated along with regular eye exams and hepatic function tests. Repeat workup in three months showed improvement in proteinuria to 0.2 g/g and creatinine 1.1 mg/dl. She was continued on the same regimen for about 24-months with recent work-up showing complete resolution of proteinuria and hematuria.

Discussion: As per our literature review, this is the first reported case of IgA nephropathy treated with RAS inhibition and hydroxychloroquine over a span of almost two years resulting in complete remission. Hydroxychloroquine can be considered, in select cases, as an alternative to steroid therapy in refractory proteinuria.

Trend of serum creatinine and spot proteinuria measurement

An International Delphi Survey on IgA Nephropathy: Results from the DEFINE Physicians Study

Marina Vivarelli,1 Jürgen Floege,2 Jonathan Barratt,3 Rosanna Coppo,4 Richard A. Lafayette,2 Jai Radhakrishnan,1 Brad H. Rovin,1 David T. Slezewski,4 Vladimir Tesar,5 Marcello Tonelli,6 Heather N. Reich.7 1Bambino Gesù Pediatric Hospital Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS), Rome, Italy; 2Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany; 3University of Leicester, Leicester, United Kingdom; 4Regina Margherita Hospital, Turin, Italy; 5Stanford University, Stanford, CA; 6Columbia University Medical Center, New York, NY; 7The Ohio State University Wexner Medical Center, Columbus, OH; 8Medical University of South Carolina, Charleston, SC; 9Charles University, Prague, Czechia; 10Cumming School of Medicine, University of Calgary, Calgary, AB, Canada; 11University Health Network and University of Toronto, Toronto, ON, Canada.

Background: It is unclear whether treatment guidelines for patients with IgA nephropathy (IgAN) are uniformly applied in clinical practice. The DEFINE: Physicians initiative sought to describe the opinions of nephrologists about the pathophysiology, diagnosis, and optimal management of adult and pediatric patients with IgAN.

Methods: A 2-round Delphi survey was distributed to nephrologists in Canada, France, Germany, Italy, Spain, the UK, and the US. A 1-9 Likert scale (9=strongly agree) was used to score statements. Consensus was defined as median and mean score ≥75% of participants scoring agreement (ie, score 7-9). Feedback collected in Round 1 was used to revise statements not achieving high consensus (≤80% agreement) for retesting in Round 2. Moderate consensus was defined as 75-89% agreement.

Results: In Round 1, 207 participants with a median clinical experience of 18 years (range, 5-49) rated 19 statements about IgAN. Half (50%) of participants worked in nonacademic settings. All statements met criteria for moderate or high consensus after the second round. Notably, a statement on corticosteroid therapy in adult patients reached moderate consensus after Round 1 and was divided into 2 parts in Round 2 (Figure 1). Both revised statements reached levels of agreement similar to the original statement. In contrast, a statement on corticosteroid and cyclophosphamide use in adults with rapidly progressive glomerulonephritis and 2 statements on corticosteroid therapy in pediatric patients reached high consensus in Round 1 (Figure 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: High consensus regarding clinical decisions and the importance of controlling proteinuria in IgAN was observed in this Delphi survey. Although the level of consensus related to corticosteroid use was lower for adult patients vs pediatric patients, the level of consensus was relatively high for both groups.

Funding: Commercial Support - Traverse Therapeutics, Inc.

Methods: DEFINE: Physicians was a 2-round Delphi survey that recruited nephrologists from North America and Europe. A total of 22 FSGS/INS statements were scored using a 1-9 Likert scale (9=strongly agree). Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score 7-9). Statements not achieving high consensus (≥80% agreement) in Round 1 were revised and restated in Round 2.

Results: This study involved 207 adult and pediatric nephrologists. Median clinical experience was 18 (range 5-49) years; 103 participants (50%) worked in nonacademic settings. In Round 1, 21 statements met consensus criteria and 7 statements not achieving high consensus were revised or divided into multiple parts, creating 11 revised statements for testing in Round 2. In Round 2, 9 of 11 statements met at least moderate consensus. Round 1 statements with high consensus described prognostic significance of proteinuria and disease management (Figure 1). Controversial statements restated in Round 2 pertained to distinction between primary and secondary FSGS in adults, and to management of frequently relapsing INS in children (Figure 2).

Conclusions: The level of consensus in this Delphi survey was high for statements on treatment decisions and the importance of proteinuria control. The main area where high consensus was not reached pertained to differentiation between primary and secondary FSGS and managing frequently relapsing INS in children, suggesting that these areas require further research.

PO1642

Long-Term Effectiveness of Low-Dose Prednisone Treatment in Relapses of Steroid-Sensitive Minimal Change Disease

Irene Martin Capon,1 Elizabeth R. Viera,1 Eduardo Gutierrez-martinez,2 Milagros Fernandez-Lucas,1 Javier Villacorta Perez.1 1Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Madrid, Spain.

Background: Treatment of relapses of steroid-sensitive minimal change disease (SMCD) involves administration of high doses of prednisone for several weeks, implying significant pharmacological toxicity. In a previous pilot study, the efficacy of treatment with low doses of prednisone for the treatment of relapses in these patients was demonstrated.

Methods: Retrospective analysis of SMCD relapses treated with low doses of prednisone in two centers, was performed, and the response to treatment, the time to reach remission and the free-time of relapse was studied, comparing it with previous relapses of the same patients treated with standard doses of steroids.

Results: 85 relapses in 21 patients with SMCD were analyzed. The median age of patients was 35 years (IQR 18-53), with 62% being male. The mean proteinuria at relapse debut was 5.37 ± 4.11 g/g, serum albumin 2.47 ± 0.94 gr/dL and creatinine 0.86 ± 0.35 mg/dL. Thirty-six relapses (42.3%) were treated with low doses of prednisone (LDP) and compared with 49 previous relapses (57.6%) of the same patients, treated with high doses of prednisone (HDP). The mean initial prednisone dose in relapses treated with LDP and HDP was 0.45 ± 0.1 mg/kg and 1.00 ± 0.3 mg/kg, respectively (p<0.001). The mean cumulative dose of prednisone in relapses treated with LDP and HDP was 1771 ± 1303 mg and 3894 ± 2134 mg respectively (p < 0.001). There were no differences in treatment duration between relapses treated with low and high corticosteroids doses (124 days vs 153 respectively; p=0.2). All patients achieved complete remission after steroid treatment. Mean time to remission was 18.4 days for relapses with LDP and 17.1 days for HDP (p = 0.6). The mean free time to relapse after treatment with low doses was 12.6 months vs 10.9 months for those treated with high doses (p = 0.6).

Conclusions: Among SMCD patients, treatment of relapses with low doses of prednisone (0.5 mg/kg) is effective and safe, allowing to minimize cumulative steroid doses and derived toxicity.

PO1643

DEFINE Physicians: An International Delphi Survey to Identify Consensus in the Care of Patients with FSGS or Idiopathic Nephrotic Syndrome

Marina Vivarelli,1 Keisha L. Gibson,2 Debbie S. Gipsen,2 Manuel Praga,4 Heather N. Reich,3 Michiel F. Schreuder,1 Vladimir Tesar,5 Marcello Tonelli,6 Jack F. Wetzels,7 Jai Radhakrishnan,8 Shirshak Aslam,2 John F. Neylan,2 Dana Rizk,3 Howard Trachtman,4 1Columbia University Irving Medical Center, New York, NY; 2Angion Biomedica Corp, Uniondale, NY; 3University of Alabama at Birmingham, Birmingham, AL; 4NYU Grossman School of Medicine, New York, NY.

Background: Primary nephritic syndrome (PPKDs) are among the leading causes of End-Stage Kidney Disease (ESKD). Receptor tyrosine kinases like PDGFR, DDR1, DDR2 are thought to play a role in the progression of PPKDs to ESKD. ANG-3070, a selective oral tyrosine kinase inhibitor, has demonstrated beneficial effects in chronic kidney disease animal models. Objective: Describe the design of a proof-of-concept study of ANG-3070 in the treatment of PPKD patients with persistent proteinuria while on standard of care (SOC).

Methods: A 12-week, randomized, double-blind, placebo-controlled study enrolling 100 patients with biopsy-proven PPKD and persistent proteinuria, ≥ 1 g/day, while on the SOC including maximum tolerated RAAS inhibitors. Patients will be randomized 1:1:1:1 to 200 mg or 400 mg once-daily or 300 mg twice-daily of ANG-3070 or placebo (Fig. 1). Results: The primary endpoint is the percentage change in 24-hr urinary protein at Week 12. Key secondary endpoints evaluated at week 12 include percentage change in 24-hr urinary albumin, number of patients with complete remission in proteinuria (24-hr urinary protein < 300 mg), number of patients with partial remissions in proteinuria (24-hr urinary protein reduction of ≥ 50% from the baseline and a 24-hr urinary protein < 3.5 g/day if the baseline 24-hr urinary protein > 3.5 g), number of patients with ≥ 50% reduction in 24-hr urinary protein from the baseline, and number of patients with a ≥ 50% reduction in 24-hr urinary albumin from baseline. An independent data monitoring committee will review safety throughout the study.

Conclusions: This Phase 2 study will provide data about the safety and efficacy of ANG-3070 in PPKD patients that will inform the design of a Phase 3 study.

Funding: Commercial Support - Angion Biomedica, Inc.

PO1645
Transcutaneous Auricular Vagus Nerve Stimulation (taVNS) for the Treatment of Pediatric Nephrotic Syndrome (NS)
Christine B. Sethna,1,2 Kumail Merchant,1 Stavros Zanos,2 Timir Datta-Chaudhuri,1 Pamela Singer,1 Laura J. Castellanos,3 Rachel Frank,1 Steven and Alexandra Cohen Children’s Medical Center, New Hyde Park, NY; 2Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

Background: Children with NS, especially those with frequent relapses (FRNS) or steroid resistance (SRNS), are exposed to prolonged courses of immunosuppressant medications with side effects and variable efficacy. There is an urgent need to identify novel and safe therapies to treat pediatric NS. taVNS modulates the immune system via the cholinergic anti-inflammatory pathway and has become a therapy of interest for treating immune-mediated illnesses. The objective was to conduct an open-label early feasibility study of taVNS therapy for pediatric NS.

Methods: Children with FRNS (≥2 relapses in previous 6 months) or SRNS (no remission after 4 weeks of steroids) were enrolled. Participants with FRNS were in remission and off immunosuppression (off steroids >14 days and other immunosuppression >3 months). SRNS patients were on a stable regimen of medications for 6 months prior to enrollment. Participants performed taVNS therapy 5 minutes daily for 6 months with a TENs 7000 unit. taVNS was delivered to the auricular branch of the vagus nerve via the left cymba concha. Cytokine levels were compared using the Wilcoxon test.

Results: Seven participants (3 FRNS, 3 SRNS, 1 genetic congenital nephrotic syndrome [CNS]) had a median age of 7 years (range 3-17) and 63% were male. FRNS participants remained relapse-free during the study period (two continued taVNS at 9 and 13 months and remained in remission). SRNS participants had a 25-76% reduction in urine protein to creatinine ratio (upc) compared to baseline (Figure). Upe decreased (13.7%) in the participant with CNS but remained in nephrotic range. All but one participant (non-compliant) had a reduction in TNF-α (7.33pg/mL vs. 5.46pg/mL, p=0.03). No adverse effects were reported.

Conclusions: taVNS prevented NS relapses in FRNS, reduced proteinuria in SRNS, and reduced TNF-α levels without any adverse effects, suggesting taVNS as a promising therapy for pediatric NS. A larger, randomized clinical trial is needed to confirm these findings.

PO1646
A Study Comparing Rituximab and Modified Ponticelli (MP) Regimen in Primary Membranous Nephropathy (PMN)
Abhishek Kumar, Arpita Ray Chaudhury, Saugat D. Gupta, Sriranjan Mukherjee, Moumita Sengupta. IPGIMER Nephrology Institute of Postgraduate Medical Education and Research, Kolkata, India.

Background: The study was designed in December 2018 when the Gemritux trial had established Rituximab as an alternative to MP regimen in the treatment of PMN. So we designed a study comparing Rituximab and MP Regimen.

Methods: We allocated 35 adults with PMN and proteinuria >3.5 gm/day in a 3:2 ratio to MP regimen or Rituximab 375mg/m² on days 1,8,15 and 22. The primary outcome was complete or partial remission (CR+PR) at 6 and 12 months in the 2 groups. The other findings included trends of 24 hr urine protein, albumin, creatine and serious adverse events at 6 and 12 months in both groups.

Results: At 6 months, 12 of 21 patients (57.14%) allocated to MP Regimen and 5 of 14 patients (35.71%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 2.4; 95% CI, 0.596−9.670, p value 0.10). At 12 months, 14 of 21 patients (66.66%) allocated to MP Regimen and 10 of 14 patients (71.43%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 0.8; 95% CI, 0.184−3.487, p value 0.383). Serious adverse events occurred in 15% of patients receiving Rituximab and in 24% receiving the MP Regimen.

Conclusions: We found No Statistically Significant difference between Rituximab and the Modified Ponticelli Regimen in the treatment of membranous nephropathy. A head-to-head, longer follow up study comparing MP Regimen versus Rituximab is required in terms of duration of remission and side effect profile between the two treatment groups.

Methods: M-PLACE (NCT04145440) is an open-label, multi-national Phase Ib/II study of adults with anti-PLA2R+ MN requiring immunosuppressive therapy (IST). Cohort 1 includes de novo and IST-relapsed pts (n=20) and Cohort 2 IST-refractory pts (n=10). Participants receive nine felzartamab infusions (16 mg/kg) over six 28-day cycles (weekly in Cycle 1; monthly thereafter), followed by a 26-week observational follow-up. Concomitant IST use is prohibited. The primary endpoint is the incidence and severity of treatment-emergent adverse events. The key secondary endpoint is the immunologic response rate, as determined by anti-PLA2R Ab reductions. Exploratory endpoints include evaluations of proteinuria and kidney function.

Results: As of April 2021, 12/30 planned pts were enrolled (Cohort 1, n=8; Cohort 2, n=4). Median age was 62.5 years (range 43 to 77 years), 83% were male, and median baseline anti-PLA2R Ab titer was 178 U/mL (18 to 1027 U/mL). Seven pts had received ≥4 weeks of felzartamab therapy. At Week 4, 5/7 pts had a ≥50% reduction from baseline in anti-PLA2R Ab (Cohort 1, n=3; Cohort 2, n=2); the other 2/7 pts had reductions from baseline of −16.8% to −5.0% (both Cohort 1). Mean % decline in anti-PLA2R Ab from baseline to Week 4 was −53.0% (−92.0% to −5.0%). B-cell counts were not markedly changed from baseline. Felzartamab was well tolerated.

Conclusions: The M-PLACE proof-of-concept study has so far shown that felzartamab rapidly and substantially reduces anti-PLA2R Ab titers in pts with anti-PLA2R+ MN. Longer follow-up is required to assess felzartamab safety and efficacy in this population.

Evaluating the Efficacy of Rituximab in Primary Membranous Nephropathy: An Observational Study from Southern India
Megha Saigal, Swarnalatha Guditi. Nizam’s Institute of Medical Sciences, Hyderabad, India.

Background: Membranous nephropathy, is an immunological disease. It can occur secondary to infection, malignancy, or SLE. In 70% of patients M-type phospholipase A2 receptor (PLA2R) was positive, and these patients are considered to suffer from secondary immunosuppressive agent in primary MN has not been evaluated among Indian population.

Methods: Single centre observational pilot study 20 subjects with histological/serum PLA2R positive progressive primary membranous nephropathy were recruited. They were then either started on conventional immunosuppressive therapy (modified ponticelli regimen) and if no or partial response were initiated on rituximab as a second line agent or in some cases as a primary immunosuppressive agent. Rituximab was started at 375mg/m2 weekly doses. Data regarding urine protein creatinine, serum albumin, serum creatinine, CD 19 count, time to achieve to remission and side-effects were noted.

Results: In our study, males were 65% (13), females contribute to 35% (7). After 8 weeks, 71% of patients were in immunological remission. As of April 2021, 12/30 planned pts were enrolled (Cohort 1, n=8; Cohort 2, n=4). Median age was 62.5 years (range 43 to 77 years), 83% were male, and median baseline anti-PLA2R Ab titer was 178 U/mL (18 to 1027 U/mL). Seven pts had received ≥4 weeks of felzartamab therapy. At Week 4, 5/7 pts had a ≥50% reduction from baseline in anti-PLA2R Ab (Cohort 1, n=3; Cohort 2, n=2); the other 2/7 pts had reductions from baseline of −16.8% to −5.0% (both Cohort 1). Mean % decline in anti-PLA2R Ab from baseline to Week 4 was −53.0% (−92.0% to −5.0%). B-cell counts were not markedly changed from baseline. Felzartamab was well tolerated.

Conclusions: The M-PLACE proof-of-concept study has so far shown that felzartamab rapidly and substantially reduces anti-PLA2R Ab titers in pts with anti-PLA2R+ MN. Longer follow-up is required to assess felzartamab safety and efficacy in this population.

Intravenous Cyclophosphamide vs. Calcineurin Inhibitors as Treatment in High-Risk Idiopathic Membranous Nephropathy: The Benefit in MAKE Is Preserved in the Presentation IV
Angela M. Cordoba Hurtado,1 L. M. Perez-Navarro,1 Jesus D. Lima-Lucero,1 Virgilia Soto,2 Rafael Valdez-Ortiz.1 Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: The use of intravenous cyclophosphamide (IV CYC) in high-risk idiopathic membranous nephropathy (IMN) has not been fully evaluated in the make primary endpoints (serum Cr doubling, ERSD, mortality). In our center, the treatment of high-risk IMN is performed with IV CYC or with calcineurin inhibitors (CNI) according to criteria of accessibility and availability of the drug. Our aim was to compare the immunosuppressive treatment scheme with IV CYC vs CNI in primary MAKE events in patients with high-risk IMN.

Methods: Retrospective cohort study. Patients with a diagnosis of IMN diagnosed between January 2012 and January 2020 were included. The patients were treated with IV CYC or CNI. With a minimum follow-up of 12 months and MAKE primary events were recorded in addition to complete, partial, composite response and adverse events at the end of the study.

Results: Thirty-seven patients of which 14 (37.8%) were treated with IV CYC and 23 (62.2%) with CNI. The mean age was 46 ± 15.3 years, 54% male, and 27% hypertensive. Average Pts/ Cr/ CrTU 10.43 ± 4.4 gr/g; mean serum albumin 1.8 ± 0.68 g/dL; and GFR by CKD EPI of 75min/mL/1.73m2. With a follow-up of 45.91 ± 23.9 months, no baseline differences were observed between the groups. Table 1 shows the comparison between IV CYC vs CNI for high-risk IMN shows similar outcomes focused on MAKE. However, the comparison in composite and partial response shows a result in favor of the use of CNI. This perspective provides clinical evidence about the use of IV CYC, which is why it is suggested that there are possible differences between our findings and those reported so far with oral CYC. Prospective clinical trials are required to have conclusive results.

An 8-Week Course of Cyclophosphamide and Steroids Is Effective Therapy in Patients with Membranous Nephropathy (MN) and Low PLA2R Levels
Coralin Vink- van Setten,1 Anne-Elis van de Logt,1 Alexander Kühnl,2 Jack F. Wetzel,3 1Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lübeck, Germany.

Background: We introduced individualized therapy in patients with MN and positive anti PLA2R antibodies (aPLA2R) by IFIst test. Treatment (cyclophosphamide combined with steroids) was stopped when the IFT test (measured at 8, 16, or 24 weeks) became negative. After 8 weeks, 71% of patients were in immunological remission. Unfortunately, 30% of these latter patients needed renewed therapy within 12 months because of immunological and/or clinical relapse. We questioned if quantitative aPLA2R measurement would predict response.

Methods: Available, stored serum samples were retrieved, and aPLA2R levels were measured by ELISA (EUROIMMUN Lübeck, Germany). Good outcome was defined as immunological remission at 8 weeks, followed by clinical remission without clinical relapse or the need for additional immunosuppressive therapy within 12 months.

Results: Serum samples of 60 patients were available for analysis. Patients were grouped according tertiles of aPLA2R (Table). Higher aPLA2R levels were associated with more severe proteinuria. Patients in the lowest tertile were more likely to develop immunological remission at 8 weeks (95% vs 65% and 50% in the middle and highest tertiles). Moreover, in the subgroup of patients who were treated for 8 weeks only, fewer patients in the lowest tertile of aPLA2R needed renewed immunosuppressive therapy, although not statistically significant (16% vs 43%, p = 0.05).

Conclusions: Individualized treatment of MN patients with cyclophosphamide and steroids has been recently introduced. In this study we show that baseline aPLA2R levels predict immunological remission at 8 weeks. Furthermore, patients with low aPLA2R at baseline seem to be more likely to have a good overall outcome.

Prospective Cohort Study of Antibody-Guided Therapy in Patients with Membranous Nephropathy

Background: Guidelines advise a standard course of 6 months of cyclophosphamide (CP) and steroids in patients with membranous nephropathy (MN). We hypothesized that monitoring of aPLA2R-antibodies (aPLA2R) may enable individualized (and shorter duration of) therapy.

Methods: Patients with MN, with positive aPLA2R and high risk of progression were included. Treatment consisted of CP (1.5 mg/kg/day combined with steroids). aPLA2R were monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If the IFT test was negative, CP was stopped and prednisone tapered. If the IFT test remained positive at 24 weeks, CP was switched to MMF and therapy continued.

Results: Sixty-five patients (48 males) were included; mean age 61 ± 12 yrs, median serum creatinine 156 [IQR 100-161] µmol/l, serum albumin 21 [IQR 16-26] g/l and UPCR 7.7 [IQR 5.4-11.1] g/10 mmol. Follow-up was 37 [IQR 27-58] months. aPLA2R test was negative in 46 patients after 8 weeks (group A), in 10 patients after 16 weeks (group B1), in 1 patient after 24 weeks (group B2) and in 8 patients aPLA2R remained positive after more than 24 weeks (group B3). In group A no clinical remission (PCR <3.0 g/10 mmol) was observed in 26 % (12 patients) compared to 21 % (4 patients) in group B1-B3 (Log rank p=0.579). Overall 22 patients (34 %) received additional immunosuppressive (IS) therapy because of persistent proteinuria (after aPLA2R disappearance) or clinical relapse. IS free survival was lower in group A compared to group B1-B3. (Figure 1).

Conclusions: Approximately 50% of patients developed long-term clinical remission after 8 weeks of therapy. Our data support aPLA2R-guided therapy. However, in approximately 25% of patients immunological remission was not followed by clinical remission, underlining the need for better biomarkers.

PO1652
Economic Evaluation of the MENTOR Trial Comparing Rituximab and Cyclosporine for the Treatment of Membranous Nephropathy (MN)
Matthew J. Kadatz,1,2 Scott Klarenbach,1 Helen So,1 Fernando C. Fervenza,3 Daniel C. Cattran,1 Sean Barbour.1 On behalf of the MENTOR trial investigators 1The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; 2Vancouver Coastal Health Research Institute, Vancouver, BC, Canada; 3University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; 4Mayo Clinic Minnesota, Rochester, MN; 5University of Toronto, Toronto, ON, Canada.

Background: The MENTOR trial (Membranous Nephropathy Trial Of Rituximab) showed that rituximab (RTX) was noninferior to cyclosporine (CSA) in inducing complete or partial remission of proteinuria and was superior in maintaining proteinuria remission. However, the cost of RTX is high and it’s cost-effectiveness has not been determined.

Methods: A Markov model (Fig 1) was used to determine the incremental cost-effectiveness ratio (ICER) of RTX compared with CSA for the treatment MN from the perspective of a health care payer with a life-time time horizon ($2020 USD). The model outcomes were informed by data from the MENTOR trial and previously published literature. Cost and utility inputs were obtained from the literature.

Results: Based on 1,000 simulations, the mean additional cost of RTX therapy for MN compared with CSA was $168,064 with an improvement in utility of 6.70 QALYs (Fig 2). RTX was cost-effective (assuming a willingness-to-pay threshold of $50,000 / QALY) compared with cyclosporine, with an ICER of $25,071 per additional quality adjusted life year (QALY) over a lifetime time horizon (45 years).

Conclusions: While the initial cost of RTX is high, RTX is a cost-effective option (assuming willingness to pay thresholds of $50,000 or greater) for the treatment of MN when compared with the alternative of CSA. The cost-effectiveness will be further improved with the use of less expensive biosimilars.

A Multicenter, Prospective, Open-Labeled Study of Acthar Gel Alone or with Tacrolimus to Reduce Urinary Proteinuria in Patients with Idiopathic DNA-JB9-Positive Fibrillary Glomerulopathy
James A. Tumlin,1 Richard A. Lafayette,2 Andrew S. Bomback,2 Amber S. Podoll,4 FACT Trial Group 1Emory University, Atlanta, GA; 2Columbia University, New York, NY; 3Stanford University, Stanford, CA; 4University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Fibrillary Glomerulopathy (FGN) is a rare primary glomerular disease characterized by glomerular accumulation of nonbranching, randomly arranged 10-30 nm in diameter fibrils. The resulting podocyte dysfunction and progressive proteinuria leads to ESRD rates of 50% within 4 years. Herein we present data on 15 patients treated with ACTH or ACTH + Tacrolimus completing 12 months of therapy.

Methods: Study Design: Randomized prospective open labeled study of 12 months of SQ ACTH alone or with Tacrolimus completing 12 months of therapy.

Results: Of the 15 patients completing 12 months of treatment, 14.3% achieved complete remission (UP/Cr ratio < 300 mg/gm); 26.0% achieved a ≥ 75% reduction from baseline, while 60.7% achieved a ≥ 50% reduction in UP/Cr at 12 months. A total...
of 86.6% achieved a minimum 30% reduction in U/P Cr. The addition of Tacrolimus to ACTH tended to further lower U/P Cr at 12 months (1654.7±317 vs. 4449.5±1665) respectively, but did not reach statistical significance.

**Conclusions:** In summary, de-ropository ACTH induced a complete or partial remission in 75% of patients with DNA-JH9 + Fibrillary GN. The addition of Tacrolimus in this population tended to improve complete-partial response rates.

**Early Eculizumab Withdrawal in Atypical Hemolytic Uremic Syndrome Is Safe and Cost-Effective**

**Background:** The introduction of eculizumab has improved outcome in patients with atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy is debated. It is unknown if unbiased withdrawal of eculizumab is a safe strategy. Here we report the results of the CUREiHUS study, a national observational study monitoring eculizumab discontinuation in Dutch aHUS patients after three months of therapy.

**Methods:** All pediatric and adult aHUS patients with native kidneys and first-time eculizumab treatment (n=21) were evaluated. At last follow-up, there were no chronic sequelae, i.e. no clinically relevant increase in serum creatinine, proteinuria and/or hypertension, in the relapsing patients. No clinically relevant predictors of relapse (including the presence of a pathogenic mutation) could be determined. The total medical expenses, including costs of among others others hospital admission and disease recurrence, of our population were only 33% of the fictive expenses made when patients would have received eculizumab every fortnight.

**Conclusions:** It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.

**PO1656**

**Outcome of Kidney Transplantation in Atypical Hemolytic Uremic Syndrome Without Eculizumab Prophylaxis: A Single-Center Experience**

Caroline Duineveld, Romy N. Bouwmeester, Kiao L. Wijnmsa, Nicole Van De Kar, Jack F. Wetzels. Radboudumc, Nijmegen, Netherlands.

**Background:** A high risk of aHUS recurrence (60-80%) is reported after kidney transplantation. Therefore, it is suggested to perform kidney transplantation in aHUS patients with eculizumab prophylaxis. In 2017 we reported a favorable outcome after kidney transplantation in aHUS patients without eculizumab prophylaxis, using kidneys from living donors and a transplantation protocol aimed at reduction of endothelial injury. It is unknown if unbiased withdrawal of eculizumab is a safe strategy. Here we report the results of our treatment protocol with prolonged follow-up.

**Methods:** All patients with a previous history of aHUS who received a living or deceased donor kidney transplantation in the Radboud University medical center between 2011 and 2020 were evaluated.

**Results:** We included 26 aHUS patients (M 9; F 17, median age at transplantation 47y, range 22-69). In 22 patients (85%) 24 genetic variants were found: C3 (N=14), CFH (N=8), CFB (N=2). Recurrence risk was considered high in 18 patients and moderate in 8 patients. Nineteen patients received a graft from a living donor (LD) and 7 patients a graft from a brain-death deceased donor (DBD). All patients were treated with low-dose tacrolimus. Six patients (23%) developed aHUS recurrence (4/19 LD, 2/7 DBD) and were treated with eculizumab. Of note, recurrence occurred >12 months after transplantation in two patients. No patient lost the graft due to aHUS recurrence. One patient lost the graft due to rejection and BK nephropathy, one patient died with a functioning graft due to infections. After a median follow-up of 63.6 months (range 12-116) median eGFR was 53.5 ml/min/1.73m2, and proteinuria was negligible (median urine protein-creatinine ratio 0.12 g/100mmol, range 0.04-0.6).

**Conclusions:** It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.
PO1657
Podocytes Soften in Proteinuric CKD: A Potential New Mechanism for Proteinuria?

Luisa Ulloa severtón,1 Xiaolin He,2 Franziska Lausecker,2 Rachel Lennon,2 Mira Kendzé,2 Darren A. Yuen,2 Yuen Lab ’St Michael’s Hospital, Toronto, ON; 2Department of the University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 1State University of New York Upstate Medical University, Syracuse, NY.

Background: Proteinuria is one of the most common manifestations of glomerular injury, and an important predictor of disease progression. Podocytes are a critical component of the glomerular filtration barrier, and as such podocyte injury is a major cause of proteinuria. Historically, investigators have focused on biochemical changes in podocytes that occur following podocyte injury. In contrast, little is known about the changes in the physical properties of these high-scaled epithelial cells.

Methods: 3 different models of proteinuric glomerular disease were studied: (1) Akita-/- Ren-/- mice (a murine model of diabetes and renin-mediated hypertension that we have recently shown develops progressive glomerulocarcinosis that mimics human diabetic kidney disease, n = 7); (2) Myo1e-/- mice (a mouse model of genetic FSGS characterized by deficiency of a non-muscle myosin involved in actomyosin contraction, n = 6); and (3) Col4a5-/- mice, a mouse model of Alport’s syndrome (n = 12). The stiffness of glomeruli, glomerular basement membrane (GBM), and podocytes was measured using atomic force microscopy (AFM) and associated histology (picrosirius red, silver, and WT1 staining). Similar stiffness measurements were performed in human FSGS and healthy kidney donor biopsies.

Results: AFM measurements revealed that glomerular stiffness increased in Akita-/- Ren-/- and Col4a5-/- mice, a finding that correlated with the degree of glomerulosclerosis. Glomerular stiffness was not increased in Myo1e-/- mice. GBM stiffness was increased in Akita-/- Ren-/- and Myo1e-/- mice, but not in Col4a5-/- Alport’s mice. In all 3 mouse models, as well as in human FSGS biopsies, podocytes were softer than in healthy control kidneys.

Conclusions: Taken together, these are the first data demonstrating that podocytes soften in proteinuric glomerular disease. Given the major rearrangements in the actomyosin network that occur in podocytes of proteinuric kidneys, our data suggest that podocyte injury, and an important predictor of disease progression, Podocytes are a critical component of the glomerular filtration barrier, and as such podocyte injury is a major cause of proteinuria. Historically, investigators have focused on biochemical changes in podocytes that occur following podocyte injury. In contrast, little is known about the changes in the physical properties of these high-scaled epithelial cells.

Novel Small Molecule Compounds Protect Podocytes from Injury In Vitro and In Vivo

Richard Helmut1, Manuel Noben,1 Ha Won Lee,1 Jean-Michel Safrin,2 Jochen Reiser,1 Susanne Heynen-Genel,1 Vinette Gupta,1 Gupta lab ’Rush University Medical Center, Chicago, IL; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocyte dysfunction and loss is a key determinant of proteinuria and glomerular injury. Thus, maintaining healthy podocytes is a therapeutic strategy against kidney disease. We previously developed a high-content imaging-based assay and used it to screen a number of small molecule compounds that show protection of podocytes from injury, suggesting it to be a viable strategy for the discovery and development of novel podocyte-protective agents.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates as previously described (Lee et al. JASN, 2015). Cells were exposed to puromycin aminonucleoside (PAN, podocyte injury inducing agent), with compounds from the screening libraries, or DMSO as control, for 48 hours. Cells were fixed and stained which allowed detection using the Opera High-Content Screening (HCS) System. Columbus software was used to quantify morphology properties such as rounding, as well as the overall F-actin signal. Drosophila based screening assays were used to determine efficacy of selected hits in vivo.

Results: PAN damage resulted in quantitative reduction in F-actin fiber numbers and intensity, and increased rounding in podocytes in the ultra-miniaturized assay system. Screening of a library of chemical compounds identified >28 hits that dose-dependently reduced podocyte damage. A set of 9 compounds showed significant protection in a drosophila model of kidney injury, supporting the findings from the high-throughput screening assay.

Conclusions: Our 1536-well plate-based assay system identified a number of small molecule compounds that dose dependently protected podocytes from damage in vitro. A drosophila model of kidney injury validated most of the in vitro data from the podocyte screening assay in vitro and in vivo mechanistic studies are underway to elucidate new insights into podocyte pathways that are therapeutically targeted by the selected hits. These agents hold promise as novel therapeutics for kidney disease patients with podocyte pathologies.

PO1659
Characterization of the Direct Effect of Mycophenolic Acid on Murine Podocytes

Seif El Din Abo Zed,1 Agnes Hackl,2 Katrin Bohl,2 Gregor Fink,1 Eva Nüskén,3 Kai D. Nüskén,1 Bernhard Schermner,2 Lutz T. Weber,2 Nephrologisches Forschungslabor ’Children’s and Adolescents’ Hospital, Faculty of Medicine and University Hospital of Cologne, Cologne, Germany; 2Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 3Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany.

Background: Mycophenolic Acid (MPA) is the active component of Mycophenolate Mofetil, a selective, noncompetitive inhibitor of the inosine monophosphate dehydrogenase. Blockade of the de novo purine synthesis depletes the pool of deoxyguanosine triphosphate, leading to a specific suppression of proliferation of B- and T-Lymphocytes. MFA has an established role as a therapeutic agent in childhood nephrotic syndrome, where it currently serves as a second line option for frequent relapsing and steroid dependent cases. Although its immunological functions are well studied, direct effects of MPA on podocytes remain largely unknown. With first preliminary results showing a protective effect in vivo, the present study aims to examine the direct effect of MPA on murine podocytes and its abilities to alter albumin-induced podocyte injury.

Methods: Cultured murine podocytes were exposed to albumin for 48 hours, with one group receiving treatment with MPA for the second 24 hours. Cells were stained with a Synaptopodin antibody and additional markers to visualize components of the cytoskeleton. Currently, we are analyzing apoptosis through a TUNEL assay as well as alterations in intracellular Calcium content with Fluo-4 and fura red. In addition, we study podocyte stiffness under injury with MPA intervention and use real-time fluorescence. We will also study small GTPases content and activity through a pull-down assay for RhoA and Rac1. In an unbiased approach, podocytes were exposed to either 2 hours of 10 mg/1 MP A or an additional 22 hours of 4 mg/1 MPA. Total RNA was isolated and subjected to RNAseq analyses.

Results: Synaptopodin immunofluorescence shows significant alterations of the actin cytoskeleton through albumin exposure. MPA treated cells reveal a restorative ability of the drug, with a recovery of stress fiber formation and a reduction of albumin-induced vacuoles. mRNA expression data from the RNAseq analysis will provide an objective and detailed picture of the direct effects of MPA on podocytes.

Integration of Plasma Proteomics and Metabolomics Revealed Multiple Protein-Metabolite Networks in Steroid-Resistant Nephrotic Pediatric Patients

Sagar Bhagyani,1 Yue Zhao,2 Michael Merchant,2 Timothy Cummins,2 Wimnal Pathmasiri,1 Susan Mcrtrich,1 Susan J. Summer,1 Jon B. Klein,2 William E. Smoyer,1 ’Nationwide Children’s Hospital, Columbus, OH; 2University of Louisville, Louisville, KY; 1University of North Carolina System, Chapel Hill, NC; 4The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Nephrotic Syndrome (NS) is a common glomerular disease in children. Childhood NS (NSC) and steroid-dependent NS (SSNS) are the mainstays, whereas the NS with steroid-resistant NS (SRNS) develops in 5-20% of children, dramatically increasing risk for progressive CKD vs. children with steroid sensitive NS (SSNS). There are no validated biomarkers able to predict which children will have SRNS. Here, we used previously published plasma proteomic and metabolomic profiles from children with SSNS and SRNS to test the hypothesis that integrating proteomic + metabolomic data could identify biomarkers and/or targets to define SRNS pathways that were not identified in the individual datasets.

Methods: Proteomic data from 15 paired NS plasma samples (n=7 SSNS; n=8 SRNS) and metabolomic data from the same subjects underwent joint pathway analyses using Metabo Analyst 5.0 software. Fold change (FC) was calculated as the ratio of pre-treatment to post-treatment for each protein and metabolite, and then log2 transformed. Proteins with LogFC>10 or LogFC<-10 and metabolites with Log FC<1 or Log FC>1 were included in the analyses.

Results: Pathway analyses of proteomic data identified “ECM receptor interaction” and “focal adhesion” as the most significantly up- and down-regulated pathways in SRNS vs. SSNS, whereas “Valine, Leucine & Isoleucine biosynthesis”, and “Glycosaminoglycan biosynthesis” were the most up- and down-regulated metabolic pathways in SRNS, respectively. The integrated proteomic + metabolomic pathway map identified 3 metabolic pathways that were perturbed in SRNS but not in SSNS: 1) “Nicotinate & Nicotinamide” pathway was perturbed in 50% of SRNS subjects (4 SRNS vs. 0 SSNS), 2) “Butanoate” pathway was perturbed in 37.5% of SRNS subjects (3 vs. 0), and 3) “Glycine, Serine & Threonine” metabolism was perturbed in 25% of SRNS subjects (2 vs. 0).

Conclusions: Integrating proteomic + metabolomic data from children with SRNS vs. SSNS have identified multiple pathways and protein-metabolite linkages with potential to become future candidate biomarkers or drug targets of SRNS.

Spatially Resolved Analysis of Glomerular Structures in Alport Syndrome and FSGS

Laura Perin,1 Hasim Soloyan,2 Paolo Cravedi,2 Fadi E. Salem,2 Andrea Angeletti,1 Sargis Sedrakyan.1
1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Mount Sinai Health System, New York, NY; Università di Bologna, Bologna, Italy.

Background: Many transcriptomics studies highlighted the molecular mechanism underlying glomerular disease, but very little is known about interglomerular heterogeneity and how each glomerulus is affected during progressive CKD. Using Spatial transcriptomics, which allows the characterization of the gene expression based on morphological context, we showed important differences between glomeruli of Alport Syndrome (AS) and FSGS patients and defined the interactive gene networks involved in glomerulus damage using healthy glomeruli as reference.

Methods: Using the Nanostring GeoMX Spatial Differential Profiling (DSP, Whole Transcriptomic Atlas) we generated spatial maps of gene expression of human AS (COL4A5 and COL4A6) and FSGS glomeruli (both males and females) and compared them to age-matched healthy controls. A total of 90 regions of interest were selected. After data QC and normalization, data were analyzed using different platforms and integrated with histopathology assessment.

Results: Data distinguished genes associated with podocyte, glomerular endothelial and mesangial cell phenotype. Unsupervised clustering and dimensionality reduction analysis showed clear differences between not only diseased and normal glomeruli (which presented homogenous gene expression profile), but also between glomeruli of AS vs FSGS. Though glomeruli of AS and FSGS were histologically similar within each sample, they presented different transcriptomic profiles (for instance, while oxidative phosphorylation, focal adhesions were common to all gloms in AS, Apelin, PI3K-Akt and Hippo signaling were unique to only a few glomeruli). Marked differences between males and females were observed in both AS and FSGS glomeruli (sheer stress and leukocyte transendothelial migration was more typical in AS male than female, while insulin signaling was only present in AS female). Similar heterogeneity patterns were observed in FSGSs. In contrast to FSGS, AS were more enriched for genes associated with TCA cycle, protein processing in the ER, and neurotrophin signaling.

Conclusions: DSP revealed significant interglomerular heterogeneity in AS and FSGS regardless of age and gender leading to the discovery of pathways defining disease phenotypes at single glomerulus level. These preliminary data using DSP may allow the discovery of potential new therapeutic targets for CKD patients.

EGR1 Is an Injury Marker in Podocytes

Masahiro Okabe,1 Nobuo Tsutori,2 Taiji Matsuasa,2 Takashi Yokoo.1 Jikei University School of Medicine, Tokyo, Japan; Tokai University School of Medicine, Isehara, Japan.

Background: There is no good marker that depicts injured podocytes in human histology samples as well as desmin staining in rodent samples. EGR1 (Early Growth Response 1) is an injury marker in podocytes in human glomeruli. This study aimed to explore an association between EGR1 staining in podocytes and podocyte injury in human glomerular diseases.

Methods: Patients who underwent kidney biopsy at Jikei University Hospital, Tokyo, from June 2018 to March 2020 were recruited. Exclusion criteria included age ≤20 years, glomeruli < 8 tubulointerstitial diseases, and kidney transplant patients. Blood and urine were collected during the kidney biopsy, and estimated glomerular filtration rate (eGFR), urinary protein to creatinine ratio (UPCR), urinary nephrin mRNA, and urinary podocin mRNA were analyzed. For the kidney biopsy specimen, the percentage of glomeruli with podocytes expressing EGR1 (%EGR1), the percentage of sclerotic glomeruli (%GS), and the glomerular podocin expression scores were measured. The %EGR1 was compared with these parameters using Spearman’s rank correlation coefficient.

Results: Ninety-eight patients were included in this study (male, 58%; median age, 49 [interquartile range, 36–60] years; eGFR, 65 [44–79] mL/min/1.73 m², UPCR, 0.90 [0.43–2.46] g/g; %EGR1, 26.1 [14.6–41.4%]; IgA nephropathy, n=35; hypertensive nephrosclerosis, n=10; membranous nephropathy, n=6; lupus nephropathy, n=5; minimal change disease (MCD), n=2; focal segmental glomerulosclerosis (FSGS), n=9; %GS was correlated with UPCR, urinary nephrin mRNA, urinary podocin mRNA, and glomerular podocin expression scores (r=0.303, 0.378, 0.369, and -0.286; and P=0.0024, <0.001, 0.001, and 0.0043, respectively) but not with eGFR and %GS. In the absence of nephropathy, %EGR1 was also correlated with UPCR and urinary podocin mRNA (r=0.413 and 0.378; and P=0.014 and 0.025, respectively). Interestingly, the %EGR1 was low in MCD (8.33 [0.0–15.4%]), and high in FSGS (40.0 [36.8–46.3%]).

Conclusions: EGR1 expression in podocytes is associated with podocyte injury. EGR1 could be a podocyte injury marker in human glomeruli.

The CLVS1 H310Y Variant Associated with Steroid-Responsive Nephrotic Syndrome Affects Podocyte Function and Glomerular Filtration Barrier Integrity

Brandon M. Lane,1,2 Megan Chryst-Stangl,2,3 Mohmed A. Shalaby,2 Sherif M. El desoky2,3, Guanghong Wu,2,3 Riccardo Vancini,1 David N. Howell,4 Gentzoun Iliou,5 Januela A. Kari,1 Rashid A. Gbadegesin.1,2 Duke University Department of Pediatrics, Durham, NC; 3Duke Molecular Physiology Institute, Duke University, Durham, NC; 4Duke University School of Medicine, Durham, NC; 1Duke University Department of Pathology, Durham, NC; King Abdulaziz University Hospital, Jeddah, Saudi Arabia; 2Duke University Hospital, Durham, NC.

Background: We identified a rare homozygous variant, p.H310Y, in the gene encoding clavesin1 (CLVS1) as a novel cause of steroid sensitive nephrotic syndrome (SSNS) in a backcross-down of the c.1579G>A (p.H526R) mutation detected in edema phenotypes that could be rescued with WT CLVS1 mRNA but not the H310Y variant. CLVS1 knockout in cultured human podocytes decreased endocytosis, increased reactive oxygen species (ROS) accumulation, and increased apoptosis. These aberrant phenotypes were rescued in the presence of glucocorticoids, mimicking the steroid responsive phenotype of CLVS1 H510Y patients.

Methods: To better understand the effects of the CLVS1 H510Y variant on podocyte homeostasis, we created human podocyte cell lines with CRISPR-Cas9 mediated heterozygous and homozygous CLVS1 H310Y knock-in (KI) mutations. We evaluated the KO and KI podocytes through automated live-cell imaging. Additionally, we further evaluated the effects of reduced CLVS1 function on podocyte function in vivo in zebrafish. Wild-type and mutant clavesin1 is expressed ubiquitously in zebrafish larval kidneys. CLVS1 knockout in cultured human podocytes. Additionally, transgenic H310Y KI KO displayed similar corticosteroid responsive phenotypes to CLVS1 KO lines, including increased apoptosis that could be rescued with ROS inhibition, while heterozygous KI lines were unaffected. Furthermore, we confirmed that the H310Y variant reduces binding to a critical antioxidant transporter, alpha tocopherol transfer protein (p=0.006), likely contributing to the ROS phenotypes. Electron microscopy analysis and quantification of excreted proteins revealed podocyte effacement and decreased glomerular filtration barrier integrity in zebrafish with knockdown of orthologous CLVS1 when compared to controls (p<0.0001).

Conclusions: Our data further demonstrates the importance of clavesin1 in the maintenance of podocyte viability and GFB integrity. It also suggests that oxidative stress regulation may be compromised in patients carrying pathogenic CLVS1 variants and highlights the potential for alternative therapies for NS patients that target ROS accumulation in podocytes.

Rare Variants in RCAN1-3 Genes Are Enriched in Patients with CKD

Brandan M. Lane,1,2 Katherine A. Benson,1 Susan L. Murray,1 Megan Chryst-Stangl,2,3 Guanghong Wu,2,3 Liming Wang,2 Elhussein A. Elhassan,3 David N. Howell,2 Peter J. Conlon,2 Robert F. Spurney,2 Rashid A. Gbadegesin.1,2 Duke University Department of Pediatrics, Durham, NC; 1Duke Molecular Physiology Institute, Duke University, Durham, NC; 2Beaumont Hospital, Dublin, Ireland; 3Royal College of Surgeons in Ireland, Dublin, Ireland; 4Duke University Hospital, Durham, NC; 5King Abdulaziz University Hospital, Jeddah, Saudi Arabia; 2Duke University Department of Pathology, Durham, NC; King Abdulaziz University Hospital, Jeddah, Saudi Arabia; 2Duke University Hospital, Durham, NC.

Background: We recently identified rare variants in the gene encoding Regulator of Calcineurin Type 1 (RCAN1) as a novel cause of FSGS/SRNS. Cells expressing mutant RCAN1 and human podocytes with reduced RCAN1 displayed increased CN activity (p=0.4946, 0.3980 and 0.0912 respectively) and reduced viability (p>0.05) in the presence of glucocorticoids, mimicking the steroid responsive phenotype of CLVS1 H510Y patients. Treatment with ROS inhibitors also rescued the reduced viability phenotype in CLVS1 KO podocytes.

Methods: To better understand the effects of the CLVS1 H510Y variant on podocyte homeostasis, we created human podocyte cell lines with CRISPR-Cas9 mediated heterozygous and homozygous CLVS1 H310Y knock-in (KI) mutations. We evaluated the KO and KI podocytes through automated live-cell imaging. Additionally, we further evaluated the effects of reduced CLVS1 function on podocyte function in vivo in zebrafish. Wild-type and mutant clavesin1 is expressed ubiquitously in zebrafish larval kidneys. CLVS1 knockout in cultured human podocytes. Additionally, transgenic H310Y KI KO displayed similar corticosteroid responsive phenotypes to CLVS1 KO lines, including increased apoptosis that could be rescued with ROS inhibition, while heterozygous KI lines were unaffected. Furthermore, we confirmed that the H310Y variant reduces binding to a critical antioxidant transporter, alpha tocopherol transfer protein (p=0.006), likely contributing to the ROS phenotypes. Electron microscopy analysis and quantification of excreted proteins revealed podocyte effacement and decreased glomerular filtration barrier integrity in zebrafish with knockdown of orthologous CLVS1 when compared to controls (p<0.0001).

Conclusions: Our data further demonstrates the importance of clavesin1 in the maintenance of podocyte viability and GFB integrity. It also suggests that oxidative stress regulation may be compromised in patients carrying pathogenic CLVS1 variants and highlights the potential for alternative therapies for NS patients that target ROS accumulation in podocytes.

Spatial Transcriptomic Profiling of Collapsing Glomerulopathy
Shreeram Akilesh,1 Kammi J. Henriksen,2 Roberto F. Nicosia,3 Charles E. Alpers,1 Kelly D. Smith.1 1University of Washington, Seattle, WA; 2University of Chicago Pritzker School of Medicine, Chicago, IL.

Background: Collapsing glomerulopathy is a histologically distinct variant of focal and segmental glomerulosclerosis that presents with heavy proteinuria and portends a poor prognosis. Collapsing glomerulopathy can be triggered by viral infections such as HIV and SARS-CoV-2. However, it is not known if distinct molecular mechanisms drive histologically indistinguishable lesions of collapsing glomerulopathy in different clinical contexts.

Methods: Transcriptional profiling of collapsing glomerulopathy lesions is difficult since only a few glomeruli may exhibit this histology within a kidney biopsy. Therefore, we used recently developed spatial transcriptional profiling to quantify 1,852 transcripts in individual glomeruli from HIV and SARS-CoV-2 infected patients with biopsy confirmed collapsing glomerulopathy.

Results: We compared transcriptional signatures on the basis of disease or histology and identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy and thrombotic microangiopathy (Figure). Focused validation using RNA in situ hybridization showed good concordance with spatial transcriptional profiling results.

Conclusions: Spatial transcriptional profiling represents a powerful new method to dissect transcriptional programs of pathologically discernible kidney lesions.

Protein Kinase R Inhibition Ameliorates Mitochondrial Dysfunction in the Tg26 HIV-Associated Nephropathy Mouse Model
Teruhiko Yoshida,1 Khan Zaw Latt,1 Ali V. Rosenberg,2 Shashi Shrivastav,1 Jurgen Heymann,1 Moshe Levi,2,7 Cheryl A. Winkler,4 Jeffrey B. Kopp.1
1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 2Johns Hopkins University, Baltimore, MD; 3Georgetown University, Washington, DC; 4Frederick National Laboratory for Cancer Research, Frederick, MD.

Background: Double-stranded RNA (dsRNA)-activated protein kinase (PKR) is a sensor for dsRNA in response to viral infections, including HIV-1. We previously reported that APOL1 risk alleles damage podocytes through double-stranded RNA-activated protein kinase (PKR) activation (Okamoto, Comm Biol, 2018). Here, we hypothesized that PKR activation could be a mechanistic pathway shared by HIV- and APOL1-mediated nephropathies. Hence, we investigated the effects of PKR inhibition on HIVAN in the well-characterized Tg26 mouse model, which expresses HIV regulatory and accessory genes.

Methods: We evaluated the kidney phenotype of Tg26 mice and wild-type mice treated with the PKR inhibitor (C16) from 6 to 12 weeks of age. We profiled kidney gene expression by RNA-seq and mitochondrial function by the extracellular flux assay using ex vivo glomerular tissues.

Results: Kidney disease manifestations, including albuminuria (mean [IQR]) (668 mg/g Cr [60, 1064] vs 2564 [1785, 5646], p=0.03) and global glomerulosclerosis (0.0% [0.0-0.0] vs 8.1 [2.3, 15.8], p<0.008), were reduced in the C16 treated group compared to the vehicle control group. C16 treatment increased mitochondrial gene expression and restored spare respiratory capacity as measured by extracellular flux assay (Fig. B).

Conclusions: PKR inhibition ameliorated mitochondrial dysfunction associated with the HIVAN phenotype observed in Tg26 mice, suggesting that PKR activation contributes to the development of mitochondrial dysfunction in HIVAN.

PO1667
Recurrent Nephrotic Plasma Activates Pro-Fibrotic Signalling Pathways Downstream of Protease-Activated Receptor 1
Musleeda Chesaot,1,2 Jack P. Tuffin,1 Carl J. May,1 Irene Gobrial,1,3 Melissa H. Little,1,4 Moin Saleem,1 Gavin L. Welsh,1 1University of Bristol, Bristol, United Kingdom; 2Princess of Naradhiwas University, Narathiwat, Thailand; 3Mardoch Childens Research Institute, Parkville, VIC, Australia; 4University of Melbourne, Melbourne, VIC, Australia.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous work suggests a signaling role for protease-activated receptor-1 (PAR-1), leading to impaired podocyte function. The signaling pathways downstream of PAR-1 in podocytes are unknown and could reveal novel mechanistic insights into the disease.

Methods: Conditionally immortalized human podocytes (ciPods), glomerular-like structure spheroids, and human kidney organoids were treated with PAR-1 agonist peptide or nephrotic plasma (NP), in the absence or presence of four different PAR-1 antagonists.

Results: PAR-1 agonist and patient relapse NP, but not paired remission plasma, induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by PAR-1 inhibitors, but not by TGF-β1 inhibition. Four PAR-1 inhibitors demonstrated specific antagonistic properties. The phosphorylation of VASP and JNK in a 3D spheroid model and from stem-cell derived kidney organoids corroborated the finding from the 2D model. Functionally, relapse NP induced podocyte motility and podocyte loss from spheroids both of which were also selectively rescued by PAR-1 inhibitors. Treatment of kidney organoids with relapse NP induced the same VASP and pro-fibrotic phosphorylation in podocytes and the loss of podocyte-specific markers.

Conclusions: We propose that the circulating factor acts as a pro-fibrotic effector by activating PAR-1. A greater understanding of these signaling pathways will lead to the identification of novel therapeutic targets for this disease.

Molecular and Functional Characterization of Human Urinary APOL1 G2/G2 High-Risk Genotype Podocyte

Oyindamola C. Adebayo,1,2 Pepe M. Eku,2,3 Jean-Paul Decuyper,2 Mohamed A. Elmomen,2,3 Agathe B. Nkoy,1,3 Djaliha Mekahli,2 Benedetta Bussolari,1 L.P.W.J. Van Den Heuvel,1 Fanny O. Arcolino,2 Elena N. Levchenko.3 Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; 1Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; 2Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; 3Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); 4Department of Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; 5Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy; 6Department of Pediatric Nephrology, Radboud University Medical Center, Nijmegen, Netherlands.

Background: Apolipoprotein L1 (APOL1) risk variants, G1 and G2, increase the risk of various non-diabetic kidney diseases in the African population. To date, the precise mechanisms by which APOL1 risk variants induce injury on podocytes and other kidney cells remain unclear. Trying to unravel these mechanisms, most studies used animal or cell models created by gene editing.

Methods: Conditionally immortalized human podocyte cell lines from urine of a donor carrying APOL1 high risk genotype, G2/G2 was developed. The APOL1 G2/G2 cell lines were characterized for podocyte markers at both the mRNA and the protein levels, using real-time quantitative PCR, Western blot and immunofluorescence staining. Following induction of APOL1 expression by 50 µg/mL polyinosinic-polycytidylic acid (poly(C)), we assessed the functional features of APOL1-induced podocyte dysfunction such as cell detachment, cell viability, cell death, autophagy, cytoskeleton organization and podocyte permeability. As control, APOL1 wild type (G0/G0) podocytes previously generated from a Caucasian donor were used.

Results: We successfully generated human APOL1 G2/G2 urinary podocyte cell lines. Upon exposure to poly(C), G2/G2 and G0/G0 podocytes upregulated APOL1 expression resulting in podocytes detachment, decreased cells viability and increased apoptosis rate in a genotype-independent manner. G2/G2 podocyte cell lines exhibited altered features, including upregulation of CD2AP, alteration of cytoskeleton, reduction of autophagic flux and increased permeability in an in vitro model under continuous perfusion.

Conclusions: The human APOL1 G2/G2 podocyte cell model is a useful tool for unraveling the mechanisms of APOL1-induced podocyte injury and the cellular functions of APOL1.

PO1669

Topology Mapping of Membrane-Inserted ApoL1

John C. Edwards, Jonathan M. Bruno. Saint Louis University, Saint Louis, MO.

Background: ApoL1 inserts into membranes at pH 6 where it has anion permease activity. Titration of the cis compartment to pH 7.5 suppresses the anion permease and activates a cation channel. How ApoL1 is arranged in the membrane-inserted form at various pH values is unclear.

Methods: Cys was substituted for Ser or Thr at positions throughout ApoL1 and resulting mutants expressed in E. coli. Purified mutants were allowed to insert into phospholipid vesicles at pH 6.0, held at pH 6.0 or titrated to pH 7.5, and reacted with extravesicular membrane-impermeant fluorescent Cys modifying reagent, Alexafluor-568-maleimide. Unreacted reagent was quenched. Non-membrane-inserted protein was removed by chaotropic extraction and Sepharose 4B chromatography. Membrane-associated protein was separated on SDS-PAGE along with ApoL1 standards for quantification. Ratio of fluorescence intensity to mass of ApoL1 protein was normalized to that of protein modified after detergent denaturation to determine relative accessibility of each Cys to the modifying reagent.

Results: Cys substitutions were generated at amino acid positions 40, 80, 149, 173, 186, 200, 204, 226, 247, and 365. We found three patterns of reactivity after membrane insertion. Cys at positions 40, 149, and 365 showed reactivity that was roughly comparable to that in detergent solution with little difference between pH 6.0 and 7.5, consistent with exposure to the aqueous solution on the cis face of the membrane under all conditions. In contrast, Cys at positions 186, 226 and 247 showed decreased reactivity after membrane insertion that was similar at both pH 6.0 and pH 7.5; these positions are not fully accessible from the external solution. Finally, Cys at positions 80, 173, 200, and 204 had decreased reactivity at pH 6.0 with increase in reactivity at pH 7.5, suggesting these positions may be initially buried in the membrane upon insertion at low pH, but titration to neutral pH induces a structural transition that exposes them to the external solution.

Conclusions: Mapping accessibility of individual amino acid positions in ApoL1 support a model in which a substantial structural transition accompanies the pH shift-induced activation of the cation channel.

Podometrics in Different Cortical Zones and Associations with the Number of Non-Sclerotic Glomeruli

Kotaro Haruhara,1,2 Go Kanazaki,1 Takaya Sasaki,1 Saeko Hatanaka,2 Yuuuke Okabayashi,1 Akira Shimizu,1 Luise A. Cullen-McEwen,1 Nobuo Tsuboi,1 Takashi Yokoo,1 John F. Bertram,1 Monash University, Clayton, VIC, Australia; 2Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; 3Nihon Ika Daigaku, Bunkyo-ku, Japan.

Background: Reduced nephron and podocyte number are common features in CKD. While it is well known that glomerular volume and glomerular density (glomerular number per cortical area) differ between cortical zones, zonal differences in podometrics and correlations with nephron number have not previously been explored.

Methods: Non-sclerotic glomerular number per kidney was estimated using the physical disector/fractionator combination. Podocyte density, podocyte number, podocyte volume and volumetric density of podocyte to glomerulus in each cortical zone were estimated using model-based stereology on a single histological section immunostained with two podocyte markers and imaged by confocal microscopy.

Results: Fifty autopsy kidneys were studied. The median age was 68 years ranging from 28 to 85 years. Median eGFR was 74 mL/min/1.73m². The median number of non-sclerotic glomeruli per kidney was 421,547 (IQR, 289,095−638,233). Non-sclerotic glomerular number was directly correlated with podocyte number per tuft, podocyte density and volumetric density of podocytes in each cortical zone (Fig). Glomeruli in the superficial cortex were smaller than glomeruli in other zones and had the highest podocyte density and volumetric density of podocytes (Fig). Glomerulosclerotic index (GSI).

Conclusions: These results demonstrate for the first time that a higher number of non-sclerotic glomeruli is directly associated with three beneficial indices of podocyte and glomerular health. Podocyte number and volumetric density of podocytes were more reliable indicators of non-sclerotic nephron number, independent of cortical zones.

Can Podocyte Number and Density Predict the Response to Therapy in Patients with Primary FSGS?

Natascha de Zoya,1 Jonathan E. Ling,2 Kotaro Haruhara,1,3 Peter G. Kerr,2 David J. Nikolic-Paterson,1 John F. Bertram,1 Luise A. Cullen-McEwen,1 Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; 2Monash Medical Centre Clayton, Clayton, VIC, Australia; 3Tokyo Jikeikai Ika Igakubu Igakuka, Minato-ku, Japan.

Background: Podocyte loss is a key event in primary focal segmental glomerulosclerosis (FSGS). Common first-line therapy for patients with primary FSGS involves steroid therapy with or without blood pressure control; however 40-70% of patients achieve no remission. Animal studies have shown that treatment efficacy is achieved partly through preservation of podocyte number, as well as podocyte protective effects. Animal studies have also determined that podocyte number and density are predictive of FSGS severity. Therefore, this study aimed to determine if podocyte number and density can predict the response to therapy in patients with primary FSGS.

Methods: A retrospective cohort study of renal biopsies was conducted from 2009-2020 in Melbourne, Australia at a tertiary hospital (Monash Medical Centre). Patients diagnosed with primary FSGS were screened (n=84). Patients were excluded for lack of consent for samples to be used for research purposes (n=38), risks of other forms of FSGS (n=13), insufficient clinical data available (n=2), no biopsy tissue available (n=7) or <6 glomerular profiles available in the biopsy (n=5). Included patients were allocated into groups of treatment responders (n=11) or non-responders (n=8) based on urinary/serum data 6 months following initial diagnosis and commencement of treatment. Biopsies were immunofluorescently stained for podocyte-specific markers. Model-based stereology was used to estimate podometrics. Sections were re-stained with PAS to measure the glomerulosclerotic index (GSI).

Results: Podocyte number per glomerulus in responders (347 (215-606); median (IQR)) was 45% higher than in non-responders (190; 143-263) (P=0.03). Podocyte density in responders (76; 58-142 per 10⁶ of glomerular volume) was similar to non-responders (66; 44-88 per 10⁶ of glomerular volume) (P=0.38). GSI was significantly higher in non-responder patients (1.1; 0.6-2.3) than responders (0.6; 0.2-0.9) (P=0.04), and was significantly and negatively correlated with podocyte number (r = -0.64; P=0.003) and podocyte density (r = -0.48; P=0.04).

Conclusions: Podocyte number per glomerulus in diagnostic renal biopsies could be used as a predictor of treatment response for patients with primary FSGS.

Nephrotic Syndrome in a Patient with Systemic Lupus Erythematosus: Is it Lupus Podocytopathy?

Nora H. Hernandez Garciaiza,1,2 Mohamed Hassanein,2 Christopher C. Garces,3 Si Yuan Khor,1 Becnu Kaw,2 Michigan State University, East Lansing, MI; 2Cleveland Clinic, Cleveland, OH; 3Sparrow Health System, Lansing, MI.

Introduction: Lupus podocytopathy (LP) is a rare form of lupus nephritis (LN) that clinically mimics minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS). We present a case of LP in a patient with systemic lupus erythematosus (SLE). Case Description: A 73-year-old female with a history of SLE (on Hydroxychloroquine), and nephrolithiasis presented with left flank pain for 2 weeks. Physical exam was notable for peripheral edema and left costovertebral angle tenderness. Labs showed a creatinine 1.02 mg/dL (baseline 0.7), serum albumin 2.6 mg/dL, and urine microalbumin/creatinine (MA/Cr) ratio of 7.5 g/g. Further workup revealed a positive ANA, negative anti-dsDNA antibodies, and normal complements. Kidney biopsy showed FSGS, tip variant, and 100% podocyte foot process effacement (FPE). She was started on high-dose prednisone, simvastatin, ACE inhibitor, and furosemide with potassium supplementation for significant pedal edema. Two months later, her MA/Cr ratio improved to 3 g/g. Prednisone was slowly tapered off over a 7-month period during which symptoms were well-controlled and MA/Cr ratio continued to improve.

Discussion: Nephrotic syndrome in patients with SLE raises suspicion for LP, which represents 1% of LN biopsies. Biopsy findings include diffuse FPE (>70%) on electron microscopy, and absence of immune deposits on light, immunofluorescence, and electron microscopy. LP is divided into MCD or FSGS, with the latter having higher rates of hypertension, acute kidney injury on presentation, and overall worse outcomes. Treatment consists of a short course of high-dose glucocorticoids; however high rates of relapse are observed and tend to coincide with SLE activity.
PO1674

Minimal Change Disease as a Sequela of Psoriasis in an Adult
Priya Debnath, Chibuzo C. Okeye, Arham Zia, Samiran Roy Chaudhury, Elena Frolova. New York City Health and Hospitals Coney Island, Brooklyn, NY.

Introduction: Minimal change disease (MCD) is usually found in children but can be an uncommon presentation in adults. Relation to psoriasis has not been significantly established even though the latter has been associated with kidney disease such as IgA nephropathy, focal segmental glomerulosclerosis leading to kidney failure. This is an interesting case given that this is a young patient with psoriasis presenting with a flare in the setting of newly diagnosed MCD.

Case Description: A 34-year-old male with history of psoriasis presented with severe body edema after psoriatic flare two weeks prior admission. He was found to have exceptionally low serum albumin of 1.4g/dL, massive proteinuria with spot urine protein creatinine ratio of 7.6 and significant hyperlipidemia. Protein electrophoresis did not show glomerular pathology or spikes in proteins and extensive serological workup was normal. Kidney biopsy reported MCD. Patient improved quickly with steroids of 1mg/kg/day, IV furosemide and albumin infusion. Six months later, the patient was readmitted with new psoriasis flare and again nephrotic syndrome with 7.2g of proteinuria. His symptoms resolved quickly with same treatment used on the first admission. Follow up in clinic one-month post discharge showed normal renal function with proteinuria now at 100mg/day.

Discussion: While there has been evidence of link between psoriasis and kidney disease, finding of MCD is a unique development. The idea can be postulated that since psoriasis is a disease due to dysfunction of T-cells among other causes, a flare can be the initiating event leading to dysregulation of an otherwise stable immune system. This T-cell dysregulation has also been noted in MCD. The underlying cause of MCD is not clear. However, a lot of studies suggest that T-cell dysfunction is one of the implicated agents, known for cell destruction, causing damage to the glomerular membrane leading to the loss of proteins. The rarity of this case belies the complexity of the immunological process leading to the presentation and further research needs to be done to document and establish this as the pathologic process linking the two diseases.

Collapsing FSGS from Acquired Nephrin Antibody
Hsiao L. Lai1 Abdullah Thayil,1 Astrid Weins,2 Keith H. Keller.1,2 East Carolina University, Greenville, NC; 1Brigham and Women’s Hospital, Boston, MA.

Introduction: Deficits in nephrin and other podocyte components are known to result in congenital nephrotic and familial FSGS syndromes. Weins et al. recently described acquired anti-nephrin antibody localizing in glomerular podocytes of patients with minimal change disease.

Case Description: A 16 year old male referred for new onset nephrotic syndrome progressive over 2 weeks was found to have serum albumin 1.2 gm/dL, UPCR 3.1, and elevated lipids with BP 160/100 mm Hg. Hepatitis B/C, HIV, SLE screens were negative. Renal biopsy demonstrated focal collapsing lesions with diffuse podocyte effacement. Immunofluorescence showed punctate IgG, kappa and lambda light chain staining in podocytes, but no albumin. Anti-human IgG colocalized with nephrin in the granular staining. ParvoB19 and COVID-19 titers were negative. Creatinine rose from 0.65 to 1.65 and UPCR to 10.3 but improved rapidly with high dose prednisone and ACEI. Serology for circulating anti-nephrin 2 weeks into treatment was negative, consistent with previous finding that circulating antibody levels quickly drop to low or undetectable with partial clinical remission.

Discussion: This case strengthens evidence that anti-nephrin antibodies cause disruption of the slit pore diaphragm which appears to be readily responsive to immune therapy. Anti-nephrin mediated podocytopathy may present with a spectrum of glomerular histopathology, which on the background of other susceptibility factors, can lead to more severe presentations such as collapsing FSGS.

PO1676

Anti-Nephrin Autoimmunity in Early Primary FSGS
Astrid Weins,1,2 Walter P. Mutter,3 Keith H. Keller,1,2 Sujal I. Shah,1,2 Helmut G. Renneke,1,2 Brigham and Women’s Hospital, Boston, MA; 1Harvard Medical School, Boston, MA; 3Newton Wellesley Hospital, Newton, MA; 2Broad Institute, Cambridge, MA.

Introduction: Minimal change disease (MCD) and primary FSGS are important diagnoses in adults and children with acute nephrotic syndrome (NS). We have reported anti-nephrin-mediated autoimmunity in NS with MCD on kidney biopsy (KBx). Here, we describe a patient with KBx-proven diagnosis of early primary FSGS and persistent anti-nephrin IgG in glomeruli and serum.

Case Description: A 69yo Caucasian man with history of type 2 DM presents with acute kidney injury (6Cr 3.49g/dl), anasarca, hyperlipidemia, s Alb 3.8g/dL, UPCR 18g/gCr. Serologies including ANA, HIV, anti-PLA2r are negative; FLC ratio is 2.91. A kidney biopsy is ordered; the differential diagnosis includes MCD, membranous nephropathy, FSGS and paraprotein-related diseases. The biopsy contains 52 glomeruli with 12% global sclerosis, and 2 glomeruli with early segmental sclerosis with capillary collapse, epithelial hyperplasia and protein reabsorption granules (PRGs). Diabetic glomerular changes are not seen. Tubular atrophy and interstitial fibrosis are mild, and vascular sclerosis is moderate to severe. Immunofluorescence microscopy (IF) shows trace mesangial IgM and fine granular podocyte IgG with equal kappa/lambda. Electron microscopy reveals diffuse podocyte foot process effacement without deposits and loss of

Nephrotic Syndrome Secondary to Minimal Change Disease Following Moderna COVID-19 Vaccine

Shaefiq B. Thappy, Sherin R. Thalappil, Shahem Abbarh, Mohammed Akhtar, Mohammad M. Alkadi. Hamad Medical Corporation, Doha, Qatar.

Introduction: Minimal Change Disease (MCD) has been reported following vaccines against hepatitis, pneumococcus, influenza and measles. In the COVID-19 era, 3 cases of new-onset MCD and one case of MCD relapse have been reported following the Pfizer-BioNTech COVID-19 vaccine. We herein report a case of MCD after receiving the first dose of Moderna COVID-19 vaccine.

Case Description: A 43-year-old Ethiopian man with no significant past medical history presented with progressive bilateral lower limb edema for two weeks. His symptoms started 7 days after receiving the first dose of COVID-19 vaccine. He then developed dyspnea and scrotal swelling over the following 10-14 days. On physical examination, his blood pressure was 150/92 mm Hg. There was decreased air entry at lung bases, significant bilateral lower limb pitting edema extending to above the knees and scrotal swelling. Lab investigations revealed hypoalbuminemia, hyperlipidemia and proteinuria of 15 grams. There was no hematuria and his immunologic and serologic work up was negative. Renal biopsy showed minimal change disease with underlying IgA nephropathy. There was no global or segmental glomerulosclerosis, mesangial or endocapillary proliferation. Patient was started on oral prednisolone and furosemide. His edema resolved, serum albumin doubled and proteinuria decreased within the first week of treatment.

Discussion: Symptoms of MCD have been reported 4 days to 16 weeks after vaccination. Although the pathogenesis of MCD is not fully understood, studies suggest that T-cell dysfunction might play a role. More studies are needed to determine the incidence and pathophysiology of this adverse event post COVID-19 vaccine. It is not clear in this case if or when the second dose of the COVID-19 vaccine should be administered.

Antiproteinuric and Podocytoprotective Effects of Direct Oral Anticoagulant Therapy in Glomerular Disease

Amanda P. Waller,1 Katelyn Wolfgang,1 Eman Abdelghani,1 Bryce A. Kerlin.1,2

1Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2The Ohio State University College of Medicine, Columbus, OH

Background: Podocyte injury is a key determinant of chronic kidney disease (CKD) progression toward end stage kidney disease. We and others have recently uncovered a putative podocytopathic role for intraglomerular thrombin during proteinuric glomerular disease. Direct oral anticoagulant (DOAC) therapies limit thrombin activity but their ability to improve podocyte health and potentially slow CKD progression remains unknown. Thus, the aim of this study is to determine if DOACs reduce thrombin-mediated podocytopathy during glomerular proteinuria. We hypothesized that DOACs would preserve podocyte health and function in a podocyte-specific model of proteinuric glomerular disease.

Methods: Diphtheria Toxin was used to induce proteinuria in transgenic rats expressing human diphtheria toxin receptor (DTR) in a podocyte-specific manner and was subsequently treated with 1) Dabigatran (20 mg/kg; Dabi), 2) Rivaroxaban (3 mg/kg; Riva), or 3) Sham (saline) and compared to healthy controls (n=7-9/group). Morning spot urine was collected on day 0 and 10 post-DT. Glomeruli were isolated from the kidney, dissociated into single-cell suspensions, and analyzed by flow cytometry after immunofluorescent synaptopodin antibody and TUNEL staining.

Results: Both Dabi and Riva significantly reduced proteinuria (Fig A) and terminal podocyte injury (TUNEL positive podocyte fraction; Fig B). In addition, there was a trend toward in situ podocyte preservation with both DOACs with a significant overall effect of DOAC therapy on podocyte survival (Fig C).

Conclusions: Both Dabi (a direct thrombin inhibitor) and Riva (a direct factor Xa inhibitor) reduce proteinuria and enhance podocyte health in a podocyte-specific model of proteinuric glomerular disease. These data suggest that DOACs may be repurposed as a novel approach to slow or halt proteinuric glomerular disease progression. Because thrombotic disease is a life-threatening co-morbidity of both glomerular disease and CKD, this approach may enable simultaneous thromboprophylaxis and glomerular disease therapy.

A Highly Efficient and Reproducible Differentiation Protocol for Induced Pluripotent Stem Cell-Derived Podocytes

Sergei Kryuchenko, Justin A. Gallagher, Timothy A. Norman, Alyssa Fanelli, Xiang Pan, Eva Fast, Rachel Gallagher, Thomas A. Gustafson, Maria Lalioti. Goldflinch Bio Inc., Cambridge, MA.

Background: Podocyte processes intertwine to create a slit diaphragm, which, when imbalanced, leads to proteinuria, dysfiltration, and, eventually, to renal failure. It is critical to be able to study the disease and test therapeutic interventions in patient-derived cells, and assess genetic and environmental aspects. Current protocols for differentiation of iPSCs into podocytes (iPods) suffer from a lack of podocyte maturity or low reproducibility. Our goal was to test and optimize multiple protocols to establish a more translatable, physiologically relevant, and reproducible method.

Methods: We compared two distinct published protocols [Ciampi 2016; Mulsat 2018]. Additional conditions were tested, including varying the extracellular matrices, media, and length of differentiation. Podocyte signature was evaluated by IF, flow cytometry, and Nanostring analysis. For models of injury, we utilized proline transamine (PS) or purinergic annomusinoicid (PAN) treatment. A mouse podocyte cell line was used as a control.

Results: Both protocols generated iPods with similar efficiency, as measured by synaptopodin, nephrin and podocin staining. iPods generated from protocol-1 could be maintained in culture up to 14 days but remained relatively immature, based on the expression of collagen α1(IV) and lack of collagen α3(IV). Response to PS and PAN treatment was variable compared to mouse podocytes. Altering the matrix from collagen to laminin did not improve reproducibility. iPods from protocol-2 developed more filopodia and complex cell-cell junctions and appeared more homogenous, with extended survival up to 4 weeks post-differentiation. PS treatment induced a significant and reproducible dose- and time-dependent decrease in synaptopodin expression, and a more robust accumulation of phalloidin aggregation. Both effects were effectively prevented by cyclosporin A, a calcineurin inhibitor, in a similar manner as in mouse podocytes. iPods from protocol-2 also showed a more consistent dose-dependent response to PAN injury.

Conclusions: We achieved a more robust and translatable iPod platform utilizing human iPSCs. Patient-derived iPodos will be an invaluable tool for both research and clinical applications.

PO1680

Novel Ex Vivo Culture System Reveals Mechanosensitive “Sarcocere-Mike Structures” During Early Podocyte Spreading

Shumeng Jiang, Jeffrey H. Miner, Guy M. Genin, Hani Suleiman. Washington University in St. Louis, Missouri, MO; Washington University in St. Louis School of Medicine, St. Louis, MO.

Background: Chronic kidney disease and ESKD are widespread health problems with no cure, in part because the biophysics underlying them are still not clear. A recently discovered feature of injured podocytes includes the de novo assembly of sarcocere-like stress fibers, identified by their alternating myosin and synaptopodin-a-actin-4. It is not known whether these indicate a transient healing phenotype or are a feature of the cascade leading to foot process effacement.

Methods: To model the early events of podocyte injury, we developed a novel in vitro system that enables the study of podocytes outside of their native microenvironment, but with in vivo-like mechanobiological and extracellular matrix (ECM) features. This system includes controllable stiffness, micro-patterned substrates for spreading, and the use of primary podocytes as they migrate from freshly isolated glomeruli.

Results: When cultured on micropatterns of physiologically relevant extracellular matrix proteins and appropriate stiffness, myosin- and synaptopodin-positive stress fibers develop. Two days of culture, then disappeared after six days, and the appearance of these stress fibers was sensitive to substrate stiffness and could be disrupted by inhibiting actomyosin contraction (blebbistatin), culturing cells with stiffness outside of the physiologic range, or presenting cells with substrates associated with pathology.

Conclusions: These results reveal the role of mechanobiological factors in podocytes represented by the mechanoresponsive sarcocere-like structure and establish a novel system for characterizing this mechanobiology in vitro.

Primary Cilia in Podocyte Health and Disease

Linsey A. FitzSimons,1,2 Kara M. Button,1 Jake N. Cho,1 Michael C. Akom,3,4 Kerry L. Tucker,1,2 Ron Korstanje.1,1 University of Maine at Orono, Graduate School of Biomedical Science & Engineering, Orono, ME; 2University of New England College of Osteopathic Medicine, Biddeford, ME; 3Maine Medical Center, Portland, ME; 4Tufts University School of Medicine, Boston, MA; 5The Jackson Laboratory, Bar Harbor, ME.

Background: Primary cilia are highly specialized elaborations of the plasma membrane that direct many of the signaling cascades critical for pre- and post-natal development and disease. While renal primary cilia are recognized as key genetic and cellular targets in polycystic kidney disease, the presence and function of primary cilia within the renal corpuscle and glomerulus have yet to be fully characterized. The purpose of our study was to perform a focused and quantifiable characterization of primary cilium of glomerular cell populations in health and disease.

Methods: Renal biopsy samples were obtained from patients with Minimal Change Disease (MCD; N=6), Focal Segmental Glomerular Sclerosis (FSGS; N=5), and control renal tissue (CON; N=4). Immunofluorescence analyses (IF) were used to quantify primary cilia number and length, as well as the expression of Sonic Hedgehog (SHH) protein, the ligand component of the Hedgehog signaling pathway and one measure of primary cilia function.

Results: Mean percent ciliation was significantly increased in MCD and FSGS when compared to CON. Analysis of individual glomerular primary cilia revealed increased ciliary length (µm) in both MCD and FSGS when compared to CON. Further analysis comparing primary cilia length in WT-1-positive nuclei (WT-1+; podocytes) also revealed a pronounced increase in cilia length in MCD and FSGS podocyte primary cilia versus CON. Despite increased length of primary cilia, glomerular SHH expression was significantly decreased in both MCD and FSGS when compared to CON. Glomerular diseases MCD and FSGS are therefore associated with an overall increase in podocyte primary cilia length and ciliation, an effect which corresponded to a decrease in SHH expression.

Conclusions: These data provide evidence in support of a role for primary cilia in glomerular disease pathogenesis. Ongoing and future research is needed to establish a mechanistic explanation for these changes observed in glomerular and podocyte cilia number and length. A more thorough understanding of the role(s) of primary cilia in glomerular cells, and specifically in podocytes, remains critical for both our understanding of disease pathogenesis as well as for the pharmacologic treatment of glomerular chronic kidney disease.

524
of cytotoxic sheep anti-glomerular antibodies (or media alone as control) for 2 hours. The two groups were kept at room temperature to allow immunoprecipitation for 1 to 4 days. Diffusion calculations suggested moderate sized (10 kDa) signaling molecules take approximately 2 days to reach the other chamber. Immunocytochemistry characterized podocyte injury and PEC activation and epithelial-mesenchymal transition (EMT).

Results: Podocyte foot processes, accompanied by a dose-dependent increase in the de novo expression of the injury marker desmin. In contrast to F-actin staining of the control group exhibiting thick bundles of actin, podocytes with Fc-CLEC-2 showed a round morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rho1-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tarantula toxin. Intriguingly, treatment with tarantula toxin reversed the elevated Rho1-GTP levels observed upon Piezo overexpression.

Conclusions: Taken together, our data confirms the functional expression of Piezo in nephropathy, its role in regulating GTPases and the beneficial effect of tarantula toxin to reverse the pathological effects caused by increased Piezo levels.

PO1685

The Mechanosensitive Ion Channel Piezo Activates Rh1 in Drosophila Nephrocytes

Sybille Koehler, Barry Denholm. Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Podocytes constantly face biomechanical forces such as shear stress and hydrostatic pressure. Increasing forces result in morphological changes, detachment from the glomerular basement membrane and loss into the primary urine. This highlights a requirement for podocytes to sense changes in their physical environment and induce a response to react to increased biomechanical force.

Methods: Here, we investigated the functional role of the mechanosensitive ion channel Piezo in Drosophila nephrocytes.

Results: First, we confirmed Piezo expression and localisation at the nephrocyte diaphragm. Additionally, we investigated the role of Piezo in nephrocytes and delineating the putative Piezo mechanosensitive pathway. For further analysis, we used knockout flies and observed a filtration phenotype, while morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rho1-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tarantula toxin. Intriguingly, treatment with tarantula toxin reversed the elevated Rho1-GTP levels observed upon Piezo overexpression.

Conclusions: Taken together, our data confirms the functional expression of Piezo in nephropathy, its role in regulating GTPases and the beneficial effect of tarantula toxin to reverse the pathological effects caused by increased Piezo levels.

PO1686

Drosophila Filamin Exhibits a Mechanoprotective Role During Nephrocyte Injury via Hypertrophy

Sybille Koehler, Barry Denholm. Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Podocytes are constantly exposed to biomechanical forces such as shear stress and hydrostatic pressure. These forces increase during disease like diabetes and hypertension, resulting in adaptive mechanisms such as podocyte hypertrophy. But how do podocytes sense changes in biomechanical forces and how does the molecular response look like?

Methods: To investigate this, we utilized Drosophila nephrocytes and studied the functional role of the mechanosensor Cheerio (dFilamin). FilaminB is upregulated in podocyte injury models and upon increased biomechanical stress, therefore serving as an ideal candidate for mediating mechanoprotection in response to injury.

Results: Expression of an over-active mechanosensor region variant of Cheerio resulted in a significant hypertrophy phenotype, while morphology and filtration function were only mildly affected. Interestingly, the expression of over-active Cheerio caused a rescue of filtration function after depletion of the nephrocyte diaphragm proteins Duf (dNEPH) and Sns (dNeph). Additional analysis with human FilaminB confirmed this mechano-protective role and the involvement of the mechanosensor region in the hypertrophy phenotype. To delineate the mechanoprotective pathway acting downstream of FilaminB, we studied the candidates: TOR, WNT and YAP. Activation of these pathways result in nephrocyte hypertrophy. Interestingly, TOR repression reversed the hypertrophy in over-active Cheerio expressing cells, suggesting TOR to be a novel downstream target of Cheerio and to be responsible for the hypertrophy phenotype.

Conclusions: Although Cheerio and FilaminB mediate a mechanoprotective role in the face of injury, their excessive expression resulted in a severe morphological and functional phenotype, emphasizing the need of a tight control of expression levels.

Membrane Localization and CLIC5A-Stimulated Rac1 Activation in Podocytes

Keiko Tanaka, Taiji Matsuaka. 2Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan.

PO1684

A Direct CLIC5A/Ezrin Interaction Accounts for CLIC5A Plasma Membrane Localization and CLIC5A-Stimulated Rac1 Activation in Renal Glomeruli

Background: CLIC5A is a part of the Podocalyxin/Ezrin complex at the apical domain of podocyte foot processes. Ezrin binds membrane phosphatidylinositol-4,5-bisphosphate (PI(4,5)P2) inducing its activation and C-terminal (T567) phosphorylation. Activated Ezrin bridges membrane-spanning proteins to cortical actin, shaping the cellular architecture. We reported that CLIC5A stimulates Rac1-GTP-dependent PI(4,5)P2 generation and Ezrin activation and that CLIC5A deleteriously affects the pERM and podocalyxin confirming dephosphorylation of ERM in podocytes. CLEC-2, the endogenous ligand of podoplanin, is highly expressed in platelets and also exists in the plasma as a soluble form. Normally, podocytes are sequestered from CLEC-2, but when the glomerular barrier is injured, podocytes can have access to CLEC-2. We studied potential actions of CLEC-2 on podocytes.

Methods: First, we confirmed Piezo expression and localisation at the nephrocyte diaphragm. Additionally, we investigated the role of Piezo in nephrocytes and delineating the putative Piezo mechanosensitive pathway. For further analysis, we used knockout flies and observed a filtration phenotype, while morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rho1-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tarantula toxin. Intriguingly, treatment with tarantula toxin reversed the elevated Rho1-GTP levels observed upon Piezo overexpression.

Conclusions: Taken together, our data confirms the functional expression of Piezo in nephropathy, its role in regulating GTPases and the beneficial effect of tarantula toxin to reverse the pathological effects caused by increased Piezo levels.

Characterization of a Novel FSGS-Associated ACTN4 Mutation in Drosophila melanogaster

Background: Decisive for podocyte morphology and homeostasis during health and disease is a specialized and highly regulated organization of the actin cytoskeleton. In this context, the actin cross-linking protein Alpha-actinin4 (ACTN4) has been shown to play a crucial role in podocyte architecture and function. Mutations in the ACTN4 gene are associated with focal segmental glomerulosclerosis (FSGS). Here, performing gene panel sequencing in a pediatric patient presenting with steroid resistant nephrotic syndrome and FSGS, a de novo, potentially disease causing variant of ACTN4 was identified, which was previously undescribed and not found in available genome or exome databases. Our aim is to elucidate the pathogenic potential of this variant for podocytes and FSGS progression.

Methods: To elucidate pathogenic effects of the newly identified ACTN4 variant, we employed the genetic toolbox of Drosophila. The fly holds podocyte-equivalent cells called nephrocytes, which are responsible for filtration and detoxification of the hemolymph. Cell-specific genetic manipulation enabled us to analyze RNAI-mediated knockdown of Actinin, the single fly homolog, in nephrocytes and its impact on cell morphology and function. Rescue experiments with the novel human ACTN4 variant will now reveal whether or not possible pathogenic consequences of the mutation when compared to wildtype as well as previously described disease-associated variants of ACTN4.

Results: Knockdown of Drosophila Actinin in nephrocytes leads to severe functional impairment, reduced cell-cell contact and up to 50% mislocalization of the ZO-1 homolog Polychoactid as observed well as overall reduction of nephrocyte diaphragms. First rescue experiments with wildtype human ACTN4 led to partial rescue of functional and morphological phenotypes observed upon Actinin knockdowns.

Conclusions: Our results underline the importance of Actinin for nephrocyte biology. Capacity of wildtype human ACTN4 in rescuing the knockdown associated phenotypes indicates the model’s suitability. Further experiments will be performed to elucidate the pathogenic potential of the novel ACTN4 variant also in comparison to previously described pathogenic mutations.

Selective PPARγ Modulator with Reduced Adipogenic Potential Ameliorates Experimental Nephrotic Syndrome

Claire Burton,1 Galen Rask,1 Amanda P. Waller,2 Amy Webb,2 Marina G. da Rocha Pita,1 Angélica A. Amato,1 Rachel Cianciolo,1 Brian Becknell,2 Bryce A. Kerlin,2 Francisco R. Neves,1 Alessia Fornoni,1 Shripa Agrawal,2 Ulrika Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 3The Ohio State University, Columbus, OH; 4Universidade de Brasilia, Brasilia, Brazil; 5University of Miami School of Medicine, Miami, FL; 6Universidade Federal de Pernambuco, Recife, Brazil.

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, can be refractory to standard treatment and is typically associated with hypoalbuminemia, hyperchloremia, and hypercoagulopathy. We hypothesized that the nuclear receptor PPARγ can be selectively modulated using a novel partial agonist, PQ-16, to gain therapeutic advantage over traditional PPARγ agonists for NS treatment.

Methods: Pio and PQ-16 were administered daily to male Wistar rats with puromycin amine-nucleoside (PAN)-induced nephropathy. Serum and urine chemistries were performed and kidneys, glomeruli, liver, and white adipose tissue (WAT) were harvested for RNA and protein extraction. Blood was collected for determination of thrombin generation parameters.

Results: PAN induced robust proteinuria, which was significantly reduced with Pio to 64% of PAN-value, and robustly with PQ-16 to 81% of PAN, which was comparable to controls. Podocyte hypertrophy also returned to normal with Pio and PQ-16. While both Pio and PQ-16 lowered 38.1 vs 85.9 ± 7.8 CaSR positive

PO1690

Simultaneous Loss of Podocyte Insulin Receptor (IR) and Insulin-Like Growth Factor 1 Receptor (IGF1R) Is Detrimental and Associated with Spliceosome Dysfunction

Jenny Hurcombe,1 Luzyan Dayalan,1 Fern Barrington,1 Lan Ni,2 Paul T. Brinkkoeetter,3 Martin Holzenberger,4 Gavin I. Welsh,5 Richard Coward,1 University of Bristol, Bristol, United Kingdom; 2Uniklinik Köln, Köln, Germany; 3INSERM, Paris, France.

Background: Insulin signalling to the podocyte via the insulin receptor (IR) is crucial to podocyte function. Insulin-like growth factor 1 (IGF1) signalling through the structurally related insulin-like growth factor 1 receptor (IGF1R) is also known to directly affect the podocyte. Since the IR and IGF1R may act redundantly in some contexts, this study sought to elucidate the compound role of the insulin/IGF1 axis in podocyte function using mouse and cell culture models deficient in both receptors.

Methods: To examine the effects of combined receptor loss in vivo, a transgenic mouse model with conditional inactivation of podocyte IR and IGF1R was generated. In vitro, conditionally immortalised genetic IR knockout, IGF1R knockout and IR/IGF1R dual knockout podocytes were characterised using global proteomic and transcriptomic analysis.

Results: Podocyte specific IR/IGF1R knockout mice developed significant albuminuria and a severe renal phenotype with global sclerosis, renal failure and death occurring between 4 and 24 weeks. -90% loss of IR/IGF1R in cultured mouse podocytes was also detrimental resulting in >50% cell death 7 days after gene knockdown. Enrichment analysis of total proteomic data revealed a striking downregulation of gene ontology terms associated with splicing and RNA processing activity in IR/IGF1R knockout cells. Western blot analysis was used to validate the reduced expression of proteins responsible for spliceosome synthesis and regulation in dual knockout podocytes, including polyypyrimidine tract-binding protein 2 (PTBP2), eukaryotic initiation factor 4A (EIF4A) and splicing factor 3B subunit 4 (SF3B4).

Conclusions: This work underlines the critical importance of podocyte insulin/IGF signalling and reveals a novel role for this signalling axis in RNA processing by regulating spliceosome activity.

PO1691
Regression of Severe Preexisting Glomerular Pathology in a Mouse FSGS Model in Response to Treatment with Macula Densa-Derived Biologicals
Georgina Gvaramatı, Urvi Nikhil Shroff, Audrey Izhara, Janos Peteteri, University of Southern California Keck School of Medicine, Los Angeles, CA.

Background: Macula densa (MD) cells localized at the glomerular vascular pole synthesize and release numerous vasoactive autacoids and newly identified angiogenic (e.g. CCN1) and glomulotrophic factors that act in a paracrine fashion to maintain high renal/glomerular blood flow and endogenous tissue remodeling. The present study aimed to test the tissue regenerative therapeutic potential of MD-derived biologicals in vivo in a mouse model of focal segmental glomerulosclerosis (FSGS).

Methods: BalbC mice with Adriamycin-induced stable, severe FSGS and albuminuria (albumin/creatinine ratio ACR>10,000/gm) were randomized into 3 groups and started daily ip injections (150µl each) of either saline (S), human recombinant (hr) CCN1 in low-dose (0.3 ng/mouse), L, hrCCN1 high-dose (2µg/mouse), H, and dextrane(F12 control, D), and conditioned culture media of the new MD cell line mMDR+ (MD) for 4 weeks. Transcutaneous GFR (MediBeacon) and ACR were measured weekly. Terminal histological analysis was performed using PAS and Trichrome staining.

Results: Kidney injury was severe at the onset (GFR 1160±51 mL/min/100 g BW, ACR 1322±159, and was sustained throughout the 4 weeks of treatment in control S and D groups (GFR 1080±143, 992±164, ACR: 1022±75, 369, 358±163, respectively).

In contrast, a progressive and significant improvement in kidney function was observed against doxorubicin-induced cell death whilst wild-type podocytes treated with PPP proteins involved in cell death and those that directly interact with CaMK4 in FSGS.

Selecting target molecules that improve outcomes in the presence of adriamycin and glomerulosclerosis (FSGS), but the involved mechanisms remain poorly understood. Calcium/calmodulin kinase 4 (CaMK4), a serine threonine kinase, is increased in podocytes of people with FSGS and in mice models of FSGS. Result: we found that lack of CaMK4 in podocytes suppressed the development of kidney pathology including the presence of hyaline deposits in glomeruli, podocytopenia and tubulointerstitial damage with intratubular casts in mice injected with adriamycin. Proteinuria in mice lacking CaMK4 in podocytes exposed to adriamycin, was reduced at 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that CaMK4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CaMK4 inhibits autophagy, a process needed for the renewal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

Conclusions: We demonstrate that mice lacking CaMK4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocytopenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

Funding: NIDDK Support.

PO1692
Insulin-Like Growth Factor 1 Receptor (IGF1R) Suppression in the Glomerular Podocyte Has Beneficial and Detrimental Consequences Dependent on the Level of Inhibition
Jenny Hurcombe,1 Fern Barrington,2 Virginie M. Betin,1 Abigail C. Lay,1 Luyun Dayalan,1 Lan Ni,1 Paul T. Brinkkötter,2 Martin Holzenberger,3 Gavin I. Welsh,1 Richard Coward,1 1University of Bristol, Bristol, United Kingdom; 2Uniklinik Köln, Köln, Germany; 3INSERM, Paris, France.

Background: Insulin signaling to the glomerular podocyte via the insulin receptor (IR) is known to be critical for normal kidney function. This study aimed to define the physiological importance of the closely related insulin-like growth factor 1 receptor (IGFIR) in podocytes.

Methods: Transgenic mice with conditional inactivation of podocyte IGFIR were generated to determine the effects of IGFIR suppression in vivo. In vitro, conditionally immortalised genetic IGFIR knockout and wild-type podocytes treated with the IGFIR inhibitor pircopodophilppin (PPP) were characterised using global proteomic analysis.

Results: Transgenic mice with partial podocyte-specific IGFIR knockout, generated using conventional Cre recombinase, had no apparent basal renal phenotype but unexpectedly, were protected from doxorubicin-induced nephropathy. An additional mouse model using an epigenetically resistant podocyte Cre driver designed to increase CaMK4 inhibits autophagy, a process needed for the renewal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

Conclusions: We demonstrate that mice lacking CaMK4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocytopenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

Calcium/Calmodulin Kinase 4 Induces FSGS by Promoting Apoptosis While Inhibiting Autophagy in Podocytes
Rhea Bhargava, Kayaho Maeda, Abhigyan Satyan, Isaac E. Stillman, George C. Tsokos. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Podocyte injury and death precede the development of focal segmental glomerulosclerosis(FSGS), but the involved mechanisms remain poorly understood. Calcium/calmodulin kinase 4 (CaMK4), a serine threonine kinase, is increased in podocytes of people with FSGS and in mice models of FSGS.

Methods: B6, B6 CDMK4fl/fl.podocite-ir or CDMK4fl/fl.podocite-ir mice were created and injected with i.v. adriamycin. Urine was collected on days 0, 3, 7, or 14, and kidney samples were collected on day 7 or 14 after adriamycin injection. Cultured human podocytes in the presence and absence of CAMK4 inhibitor (KN93) were exposed to adriamycin after which immunofluorescence and western blot was performed. Pull down mass-spectrometry and co-immunoprecipitation analysis was performed to identify proteins involved in cell death and those that directly interact with CaMK4 in FSGS.

Results: We found that lack of CaMK4 in podocytes suppressed the development of kidney pathology including the presence of hyaline deposits in glomeruli, podocytopenia and tubulointerstitial damage with intratubular casts in mice injected with adriamycin. Proteinuria in mice lacking CaMK4 in podocytes exposed to adriamycin, was reduced at 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that CaMK4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CaMK4 inhibits autophagy, a process needed for the renewal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

Conclusions: We demonstrate that mice lacking CaMK4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocytopenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

A Noncanonical Role for IRE1α in Podocyte Endoplasmic Reticulum (ER)-Phagy
José R. Navarro-Betancourt,1 Joan Papillon,1 Julie Guillermet,1 Takao Iwawaki,2 Andrey V. Cybulsky.1 1McGill University, Montreal, QC, Canada; 2Kanazawa Medical University, Kanazawa, Japan.

Background: Glomerular diseases involving podocyte (glomerular epithelial cell; GEC) injury feature endoplasmic reticulum (ER) stress and activation of the unfolded protein response (UPR). Inositol requiring enzyme-1α (IRE1α), a UPR transducer, mediates chaperone production and autophagy in podocytes during ER stress. Selective autophagy of the ER (ERphagy) is dependent on ER-resident adaptors (e.g. RTN3L) and is stimulated by ER stress. ER-derived coat protein complex II (COP II) vesicles may participate in the delivery of ER cargo to autophagosomes; however, regulation and importance of ERphagy in glomerular disease are not understood.

Methods: We employed mice with podocyte-specific deletion of IRE1α and littermate controls. IRE1α knockout (KO) and control GECs were produced from these mice. GECs were incubated with tunicamycin (TM) to induce ER stress.

Results: Mass spectrometry analysis of TM-stimulated control and IRE1α KO GECs showed that in addition to ER chaperones, proteins in the secretory pathway, including the COP II component Sec23B, were increased in an IRE1α-dependent manner. By immunoblotting, TM enhanced Sec23B and RTN3L expression in control, but not IRE1α KO GECs. By immunofluorescence microscopy, in control GECs, TM increased the biogenesis of LC3 and Sec23B particles, as well as colocalization of Sec23B with LC3 and RTN3L with LC3; increases were attenuated in IRE1α KO GECs. Thus, deletion of IRE1α impaired delivery of COP II vesicles and RTN3L-coated ER fragments to autophagosomes. Knockdown of Sec23B with siRNAAs reduced autophagosome formation in TM-stimulated control GECs. After blocking protein synthesis with cycloheximide, TM stimulated degradation of RTN3L in control GECs, consistent with ERphagy flux, but RTN3L degradation was impaired in IRE1α KO cells. Similarly, TM induced degradation of e3,4,5 collagen IV in control, but not IRE1α KO GECs, suggesting that collagen IV is an IRE1α-dependent ERphagy target. In adriamycin nephrosis, where IRE1α activates an adaptive UPR and autophagy, expression of Sec23B and RTN3L was increased in glomerular control, but not IRE1α KO mice.

Conclusions: During ER stress, IRE1α redirects a subset of Sec23B-positive COP II vesicles to deliver RTN3L-coated ER fragments to autophagosomes. ERphagy is a novel outcome of the IRE1α pathway in podocytes and may play a cytoprotective role in glomerular diseases.

PO1695
ACE Inhibition Modulates Insulin-Like Growth Factor I (IGF-1) Filtration to Regulate Compensatory Kidney and Glomerular Hypertrophy

Background: Modeling suggests that preventing glomerular volume (GV) increase could serve as a therapeutic target to mitigate hypertrophy-associated progressive glomerulosclerosis (GS). We, therefore, evaluated how GV is regulated, and how Angiotensin-Converting Enzyme inhibition (ACEi) could reduce compensatory GV increase.

Methods: Uni-nephrectomized (Uni-Nx) wild-type Fischer344 rats were used to model progressive GV triggered by the single kidney state, and the effect of ACEi started either before or after Uni-Nx. Urine IGF ELISA assay, computer-assisted morphometry, single-cell, bulk transcriptomics, immunofluorescence, and human databases were analyzed.

Results: ACEi started before, but not after Uni-Nx, reduced short (Panel A) and long-term (Panel B) compensatory GV increase, and the associated 8-fold peak of urine IGF-1 post-nephrectomy (Panel C). An IGF-IR inhibitor (pirprofopophyllin) also reduced compensatory kidney hypertrophy (Panel D). Post-Uni-Nx, a decrease in both serum IGF-1 and glomerular kidney-IGF-1 transcript were noted, and IGFBP3 (the major blood IGFBP) was present in podocyte cytoplasm in the absence of detectable podocyte IGFBP3 transcript, suggesting that IGF-1 and IGF-IGFBP complexes had come from blood. A model was developed to predict how IGF-1, IGF-2, and IGF-IGFBP protein complexes would interact with the glomerular filter, and its predictions were confirmed in ERCB database. The importance of hyperfiltered IGF-1 as a driver of glomerular failure in single kidney states was further supported by human kidney allograft half-life analysis.

Conclusions: Hyperfiltered IGF-1 drives compensatory GV increase leading to long-term proteinuria and GS. Timing of ACEi in relation to Uni-Nx can reduce both IGF-1-hyperfiltration and GV increase, thereby prolonging single kidney lifespan.

Angiotensin II Induces Oxidative Podocyte Injury via the Upregulation of Nox4
Tae-Sun Ha, Chungbuk National University, Cheongju, Chungcheongbuk-do, Republic of Korea.

Background: Angiotensin II (Ang II) induces glomerular and podocyte injury via systemic and local vasoconstrictive or non-hemodynamic effects including oxidative stress. The release of free radicals from podocytes may participate in the development of glomerular injury and proteinuria. We studied the pathophysiologic roles of oxidative stress in Ang II-induced podocyte apoptosis.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times and transfected by Nox4 or AT1R siRNAs or negative control scrambled siRNA for 24 h. The changes of podocyte oxidative stress and apoptosis were observed by confocal imaging, western blotting, real-time PCR, FACS and TUNEL assay according to the presence of Ang II.

Results: Ang II increased the generation of superoxide anions and intracellular reactive oxygen species (ROS) levels but suppressed superoxide dismutase activity that was reversed by an antioxidant, probucol. Ang II also increased Nox4 protein and expression in podocytes, measured using western blotting and real-time PCR analysis that was also reversed by probucol. Nox4 suppression by small interference RNA (siRNA) reduced the oxidative stress induced by Ang II. These results suggest that Ang II induced oxidative stress via the upregulation of Nox4 protein in a transcriptional mechanism. Ang II promoted podocyte apoptosis that was reduced significantly by probucol and Nox4 siRNA. Ang II-induced podocyte apoptosis were also recovered by Ang II type 1 receptor (AT1R) siRNA.

Conclusions: Our findings suggest that Ang II induced podocyte oxidative stress and apoptosis through AT1R and Nox4. These findings suggest that Ang II promoted podocyte oxidative stress and apoptosis through AT1R and via the upregulation of Nox4, which could be reversible by Nox4 inhibition and/or antagonizing AT1R as well as antioxidants.

Anillin Serves a Protective Function in a Mouse Model of HIV-Associated Nephropathy
Brandon M. Lane,1,2 Alexis Musick,1 Guanghong Wu,1,2 Megan Christ-Stangl,1,2 Gentzon Hall,1,2 David N. Howell,3 Rasheed A. Gbadegesin,1,2 Duke University Department of Pediatrics, Durham, NC; 3Duke Molecular Physiology Institute, Duke University, Durham, NC; 1Duke University School of Medicine, Durham, NC; 2Duke University Department of Pathology, Durham, NC; 3Duke University Hospital, Durham, NC.

Background: HIV associated nephropathy (HIVAN) is characterized by a rapid progression to end stage kidney disease with limited treatment options. We previously demonstrated that mutations in the gene encoding anillin (ANLN) can cause FSGS and showed that ANLN is upregulated in the glomerulus of HIVAN patients as well as the HIVAN Tg26 mouse model. ANLN is an F-actin binding protein that affects cell proliferation and survival, two cell processes that are predicted to play a key role in the phenotype associated with HIVAN. We hypothesized that ANLN upregulation is one of the drivers of glomerular failure in HIVAN mice, therefore modulating ANLN expression may present an alternative therapeutic strategy for HIVAN.

Methods: To evaluate the therapeutic potential of reduced functional ANLN in a HIVAN mouse model, we created a mouse line using CRISPR Cas9 mediated gene editing that contains an early stop codon in the Anln gene (ANLNx). We then bred heterozygous ANLNx mice with Tg26 HIVAN mice and evaluated proteinuria and mortality over 16 weeks for each genotype. Sclerotic glomeruli from 3 mice in each group were evaluated and quantified at 16 weeks of age by pathologists blinded to genotype.

Results: There was no improvement in glomerular disease phenotype associated with the reduction of functional ANLN in the Tg26 HIVAN model. Urine albumin to creatinine ratio at 8, 12, and 16 weeks were similar between ANLNx and Tg26 heterozygotes compared to Tg26 HIVAN mice (p=0.838, 0.8063, 0.8071 for each time point). Mice heterozygous for both the ANLNx and Tg26 alleles also did not display any increase in survival compared to mice carrying only the Tg26 allele (p=0.361). Evaluation and scoring of PAS stained kidney sections by independent pathologists revealed similar levels of sclerosis between Tg26 HIVAN mice and mice heterozygous for both the ANLNx and Tg26 alleles.

Conclusions: Genetic ablation of ANLN does not improve kidney disease phenotypes in Tg26 HIVAN mice. ANLN upregulation likely represents a survival mechanism in Tg26 HIVAN mice and not a cause of injury.

Dach1 Is Essential for Maintaining Normal Podocytes
Keiko Tanaka,1 Taiji Matsuoka,2  Okayama Daigaku Daigakuin Ishiyakugaku Sogo Kenkyusha, Okayama, Japan; 1Tokai Daigaku Igakubu Daigakuin Igakusha Kenkyuka, Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We aimed to elucidate the function of Dach1 in podocytes in vivo.

Methods: Because Dach1 null mice die shortly after birth, kidneys were harvested at P0 and histologically examined. To study the role of Dach1 in mature podocytes, podocyte-specific Dach1 deleted mice were generated by mating Dach1fl/fl mice with Nphs1-Cre or Nphs2-CreERTT2 mice. Eleven Nphs1-Cre/Dach1fl/fl mice were analyzed at 8-35 weeks of age. 14 Nphs2-CreERTT2/Dach1fl/fl mice were treated with tamoxifen (0.1mg/g BW/day, p.o. 5 days courses) and analyzed 7 days later.

Results: In neonatal wild-type mice, Dach1 is faintly expressed in the cap mesenchyme and increased in the renal vesicles/shaped bodies and further intensified and concentrated in mature podocytes. Dach1 is also intensely expressed in the ureteric bud. In Dach1 null mice, negative Dach1 staining was confirmed. Kidsneys of Dach1 null mice were 14.2 % smaller than those of control mice but showed normal structure. Podocytes in Dach1 null mice showed normal phenotypes in SEM and TEM with normal slit membrane, and no abnormal leakage of albumin. Immunostaining for WT1, nephrin, podocin, synaptopodin and nestin was normal. Only a small number of podocytes lacked Dach1 staining in Nphs1-Cre/Dach1fl/fl and Nphs2-CreERTT2/Dach1fl/fl mice, indicating inefficient Cre-mediated recombination. Nevertheless, all Nphs1-Cre/Dach1fl/fl exhibited abnormal albuminuria (UACR 4.7x10^6 mg/mg vs 0.06x10^6), which increased with age, and seven (63%) mice showed FSGS. Seven (50%) Nphs2-CreERTT2/Dach1fl/fl mice exhibited abnormal albuminuria, and three (21%) mice showed early sclerotic lesions. Immunostaining showed that sclerotic lesions lacked Dach1 as well as WT1, synaptopodin and nephrin. Most of Dach1 negative podocytes in non-sclerotic glomeruli had normal staining for podocyte marker proteins.

Conclusions: These results indicate that Dach1 does not determine the fate of differentiation into podocytes but is indispensable for maintaining normal integrity of mature podocytes.

TAZ Is Important for Structural and Functional Integrity of Podocytes
Jianchun Chen, Raymond C. Harris. Vanderbilt University Medical Center; Nashville, TN.

Background: Podocyte is an important component of glomerular filtration barrier (GFB). Maintenance of integrity of slit-diaphragm(SD) structure is critical for normal kidney function. Podocytes lost most epithelial cell tight junction components except for Zonula occludens-1 and -2 (ZO-1 and ZO-2). In podocytes, ZO-1 is an important binding partner of Nephrin, and mice with podocyte-specific ZO-1 deletion showed significant growth retardation and severe proteinuria starting at 2 weeks of age, but the regulation of ZO-1 expression in podocytes are not clear. TAZ (transcriptional coactivator with PDZ-binding motif) and its paralog Yes-associated protein (YAP) are two crucial effectors of Hippo signaling pathway. Recent study has shown that podocyte-specific YAP deletion causes FSGS and progressive renal failure, but the potential role of TAZ in podocytes and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We aimed to elucidate the function of Dach1 in podocytes in vivo.

Methods: Because Dach1 null mice die shortly after birth, kidneys were harvested at P0 and histologically examined. To study the role of Dach1 in mature podocytes, podocyte-specific Dach1 deleted mice were generated by mating Dach1fl/fl mice with Nphs1-Cre or Nphs2-CreERTT2 mice. Eleven Nphs1-Cre/Dach1fl/fl mice were analyzed at 8-35 weeks of age. 14 Nphs2-CreERTT2/Dach1fl/fl mice were treated with tamoxifen (0.1mg/g BW/day, p.o. 5 days courses) and analyzed 7 days later.

Results: In neonatal wild-type mice, Dach1 is faintly expressed in the cap mesenchyme and increased in the renal vesicles/shaped bodies and further intensified and concentrated in mature podocytes. Dach1 is also intensely expressed in the ureteric bud. In Dach1 null mice, negative Dach1 staining was confirmed. Kidsneys of Dach1 null mice were 14.2 % smaller than those of control mice but showed normal structure. Podocytes in Dach1 null mice showed normal phenotypes in SEM and TEM with normal slit membrane, and no abnormal leakage of albumin. Immunostaining for WT1, nephrin, podocin, synaptopodin and nestin was normal. Only a small number of podocytes lacked Dach1 staining in Nphs1-Cre/Dach1fl/fl and Nphs2-CreERTT2/Dach1fl/fl mice, indicating inefficient Cre-mediated recombination. Nevertheless, all Nphs1-Cre/Dach1fl/fl exhibited abnormal albuminuria (UACR 4.7x10^6 mg/mg vs 0.06x10^6), which increased with age, and seven (63%) mice showed FSGS. Seven (50%) Nphs2-CreERTT2/Dach1fl/fl mice exhibited abnormal albuminuria, and three (21%) mice showed early sclerotic lesions. Immunostaining showed that sclerotic lesions lacked Dach1 as well as WT1, synaptopodin and nephrin. Most of Dach1 negative podocytes in non-sclerotic glomeruli had normal staining for podocyte marker proteins.

Conclusions: These results indicate that Dach1 does not determine the fate of differentiation into podocytes but is indispensable for maintaining normal integrity of mature podocytes.

Neurexin1α Containing Splice Site 4 Interacts with Nephrin and Contributes to Maintenance of the Integrity of Podocyte Slit Diaphragm
Yoshiyasu Fukusumi, Hidenori Yasuda, Ying Zhang, Hiroshi Kawachi. Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background: Neurexins (NRXNs) are synaptic cell adhesion molecules having essential roles in the assembly and maturation of synapses. It is known that NRXN1α contains 6 splicing sites (SSs), and multiple splicing variants were diffusely expressed in neuronal tissues. We have previously reported that NRXN1α is expressed at slit diaphragm (SD), a cell-cell junction of podocyte, and is downregulated in injured podocytes. The report also showed that NRXN1α expressed in podocytes is a unique variant containing SS1, 3, 4, and 5, which is a rare variant in neural tissues (Am J Physiol, 300:R340, 2011). However, the role of NRXN1α at SD is not well understood yet.

Methods: The interaction of NRXN1α with SD-associated molecules was analyzed by the immunoprecipitation (IP) assay. The function and structure of SD of NRXN1α KO mice were precisely analyzed.

Results: The interaction of NRXN1α with SD molecules such as nephrin and ephrin-B1 was detected by the IP assay with rat glomerular lysates. IP assay with the HEK cell expression systems showed NRXN1α containing SS4 interacted with nephrin, but NRXN1α lacking SS4 did not. The interaction between NRXN1α and nephrin was dissociated, if nephrin was phosphorylated. The interaction of NRXN1α with ephrin-B1 was not detected in the HEK system, suggesting NRXN1α interacts with ephrin-B1 via nephrin. Abnormal proteinuria (92.1 mg/day vs 23.8 mg/day, p=0.05) and clear proteinuria components (bDNA) were detected in NRXN1α KO mice at the age of 20 weeks of NRXN1α KO mice (IF score; nephrin, 2.68 vs 3.83, p=0.05; ephrin-B1, 2.68 vs 3.84, p=0.05; podocin, 2.78 vs 3.58, p=0.05), although these alterations were not detected at the age of 10 weeks. The phenotypes of the KO mice suggest NRXN1α does not play a major role for formation of SD but contributes to the maintenance of the integrity of SD at an elderly age.

Conclusions: Neurexin1α containing SS4 interacts with nephrin, and is a novel SD component. NRXN1α contributes to maintenance of the function and the molecular integrity of SD. It is conceivable that downregulation of NRXN1α participates in the development of podocyte injury onset at an elderly age.

Possible Role of the Cytosolic RNase Inhibitor in Maintaining the Integrity of the Glomerular Filtration Barrier
Patricia Bolanos-Palmieri, Franz Tiefenböck, Mario Schiffer. Universitätssklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.

Background: The ribonuclease inhibitor (RI) is a cytoplasmic protein encoded by the RNHI1 gene. The RI forms a tight non-covalent bond with members of the RNaseA superfamily and therefore it’s considered that its main function is to act as a sentinel for dysregulated RNases. The ratio of RI to substrate has also been shown to vary according to the proliferative and metabolic status of the cell suggesting that the balance in the protein-protein interactions between the RI and its substrates plays a role in maintaining cell homeostasis by impacting processes such as protein synthesis and various signaling pathways. However, the entirety of the biological roles fulfilled by the RI are yet to be described.

Methods: Immunofluorescence staining of human kidney tissue and protein detection by western blot from samples of immortalized podocytes were carried out to confirm the presence of the RI in glomerular cells. As an initial injury model, podocytes were treated with PAN to determine if changes in RI expression occur as a response. RNHI1 inhibition was performed in a transgenic zebrafish line that allows for the detection of proteinuria via a GFP-tagged protein in the circulation. At 90hpf the severity of the edema phenotype and the fluorescence levels were recorded.

Results: Our preliminary data shows that the RI is present in human podocytes both in vitro and in vivo, as its expression domain coincides with glomerular cells labelled with synaptopodin. Additionally, the RI is present in cultured podocytes both before and after the temperature shift used to induce quiescence, and it appears to increase after differentiation. There is also expression modulation of RNHI1 in response to PAN treatment of podocytes. In our zebrafish model, RNHI1 knockdown resulted in up to a 40% increase in mild to severe edema and over 30% decrease in fluorescence suggesting that a reduction in RI might compromise the filtration barrier enough to lead to proteinuria.

Conclusions: Taken together our initial data show a promising avenue for research where the balance between members of the RNaseA superfamily and their cytoplasmic inhibitor may represent a powerful mechanism that allows the cells to modulate the proliferative response to stimuli. An imbalance in this relationship might ultimately affect the integrity of the cells in the kidney.

Atypical Caspase 3-Dependent Death in Podocytes
Kazuyoshi Yamamoto,1,2 Masahiro Okabe,1,2 Taiji Matsumasa,1 Takashi Yokoo,1 Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; 2Tokai Daigaku, Hiratsuka, Japan.

Background: Apoptosis of podocytes has been widely reported in many in vitro studies, but definitive apoptosis has never been documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo.

Methods: Primary mouse podocytes were transiently transfected with ICD25 and EGFP expression plasmids and treated with a ICD25-targeting immunotoxin, LMB2 (1nM), and observed 1 day later. In some experiments, the cultured podocytes were transfected with Bak1 or Bax siRNA before treatment with LMB2. In in vivo experiments, podocyte injury was induced by injecting LMB2 (1.25ng/gBW) into NEP25 mice, which express ICD25 in podocytes, and analyzed 7 days later.

Results: In in vitro studies, administration of LMB2 caused loss of co-introduced EGFP in 56.8±13.6%, incorporation of propidium iodide in 15.6±2.5%, activation of caspase 3 (Casp3) in 19.6±2.6% and TUNEL staining in 4.5±1.3% without significant increase in LDH activity in the culture medium. These phenomena were not observed in cells without ICD25 or without LMB2. Ac-DEVD-CHO (10uM), a Casp3 inhibitor, attenuated the loss of EGFP by 38.2%. Inhibition of Bak1 and Bax using siRNAs attenuated EGFP loss by 77.6% and 28.4%, respectively. These indicate that LMB2 induced the typical Casp3 dependent intrinsic apoptosis in podocytes in vitro. In in vivo studies, kidneys of NEP25 mice contained podocytes positive for cleaved (c) Casp3 and those for ClaminA, a product of Casp3, but no TUNEL+ podocytes. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. The urinary sediments contained podocalyxin-positive podocytes (2.5±0.3%). Among these, 39.1±3.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to UUO 1 day before sacrifice. The obstructed kidney contained significantly more cLaminA+ podocytes than the contralateral kidney. In addition, detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: Thus, due to physical force of glomerular filtration, podocytes doomed to Casp3 dependent death are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. This accounts for the absence of podocyte apoptosis in vivo.

PO1705

Glomerular Endothelial Cell-Derived MicroRNA-192 Regulates Podocyte Nephrinectin in Membranous Glomerulonephritis

Background: Autoantibodies binding to podocyte antigens cause idiopathic membranous glomerulonephritis (mGN). It remains elusive how autoantibodies reach the subepithelial space because the glomerular filtration barrier (GBF) is normally size-selective and impermeable for antibodies.

Methods: Kidney biopsies from patients with mGN, cell culture, zebrafish and mice models were used to investigate the role of nephrinectin (NPNT) regulating microRNAs (miRs) for the GBF.

Results: Glomerular endothelial cell (GEC)-derived miR-192-5p and podocyte-derived miR-378a-3p are upregulated in glomeruli of patients with mGN whereas NPNT expression is reduced. Overexpression miR-192-5p as well as morpholino-mediated mnt knockdown induced edema, proteinuria and podocyte effacement similar to podocyte-derived miR-378a-3p in zebrafish. Moreover, structural changes of the glomerular basement membrane (GBM) with increased lucidity, slicing and lamellation especially of the lamina rara interna similar to ultrastructural findings seen in advanced stages of iMGN were found (Fig. 1). IgG size nanoparticles accumulated in lucidity areas of the lamina rara interna and lamina densa of the GBM in mnt knockdown zebrafish models. Loss of slit diaphragm proteins and severe structural impairment of the GBM were further confirmed in podocyte-specific Npnt knockout mice. GECs downregulate podocyte Nptnt by secretion of miR-192-5p containing exosomes in a paracrine manner.

Conclusions: Podocyte Nptnt is important for proper GBF function and GBM structure and is regulated by GEC-derived miR-192-5p and podocyte-derived miR-378a-3p. We hypothesize that loss of Nptnt in the GBM is part of the pathophysiology of mGN and enables subepithelial immune complex deposition in iMGN.

Mice Deficient in Aminopeptidase A Have Worse Glomerular Injury in Response to Chronic Renal Mass Reduction
Wayne R. Fitzgibbon,1 Ehtesham Arif,1 Peifeng Deng,1 Joshua H. Lipschutz,1,2 Yasuke Okabayashi,1,2 Victor G. Puelles,1 Jan Wysocki,1 Daniel Batlle,1 Juan Carlos Q. Velez,1 1Medical University of South Carolina, Charleston, SC; 2VA Medical Center Ralph H Johnson, Charleston, SC; 3Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 4Northwestern University, Evanston, IL; 5The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.

Background: Aminopeptidase A (APA) is a membrane-bound metalloprotease expressed in podocytes and tubular epithelia. It is a key enzyme in metabolizing angiotensin (Ang) II and diverting Ang I from the formation of Ang II. A recent finding suggests that APA also plays a role in the maintenance of glomerular structure. We have shown in vivo experiments, kidneys of NEP25 mice contained podocytes positive for cleaved (c) Casp3 and those for ClaminA, a product of Casp3, but no TUNEL+ podocytes. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. The urinary sediments contained podocalyxin-positive podocytes (2.5±0.3%). Among these, 39.1±3.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to UUO 1 day before sacrifice. The obstructed kidney contained significantly more cLaminA+ podocytes than the contralateral kidney. In addition, detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: Thus, due to physical force of glomerular filtration, podocytes doomed to Casp3 dependent death are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. This accounts for the absence of podocyte apoptosis in vivo.

Identification of the Mechanism Underlying the Toxicity of Systemically Administered miR-145-5p on Podocytes Based on Podocyte Essential Genes

Zhang Xian, Jannan Wu, Xiaoqiang Zhu, Hui Song, Lu Ren, Qiaoli Tang, Xu Xiaodong, Jiong Zhang, Weixin Hu, Zhizhong Liu, Shaolin Shi. Jinling Hospital National Clinical Research Center for Kidney Diseases, Nanjing, China.

Background: MicroRNAs are emerging as effective therapeutic agents. MiR-145-5p dysregulation has been shown to be involved in kidney injury. To determine whether supplement of miR-145-5p would alleviate kidney injury in mouse models, we first tested the miR-145-5p enriched extracellular vesicles (miR-145-5p EVs) sample for toxicity or side effects on healthy control mice.

Methods: miR-145-5p EVs were injected to mice intravenously every day for a total of 6 days. A group of mice were simultaneously injected with miR-145-5p inhibitor using TransIT®-EE Delivery Solution. Cultured cells were transfected with RNAiMAX or Fugene.

Results: miR-145-5p EVs resulted in proteinuria and podocyte foot process effacement in normal control mice, and this effect was abolished by miR-145-5p inhibitor. We demonstrated that systemically administered miRNA can enter podocytes. miR-145-5p EVs could enter cultured podocytes and cause F-actin loss. miR-145-5p mimic caused a similar reduction of F-actin in the cells. We speculated that miR-145-5p is toxic to podocytes because it is not normally expressed in podocytes and exogenous miR-145-5p can effectively target genes essential for podocytes. By using the concept that genes commonly expressed in all individual podocytes are likely podocyte essential genes, we predicted podocyte essential genes when expression cutoff was set to > 0.1 RPMK. We found that 32 of them are predicted to be targeted by miR-145-5p. Functional annotation of the 32 genes revealed small GTPase mediated signal transduction as the top function. Among genes associated with the small GTPases pathway, Arhgap24 is known to control the Rac1 GTPase activity. We performed APATrap and JunctionSeq bioinformatics analyses software, and we found miR-145-5p significantly repressed Arhgap24 expression in podocytes in vivo and in vitro. miR-145-5p increased activity of both Rac1 and Cdc42.

Conclusions: MiR-145-5p induced podocyte injury through targeting podocyte essential genes associated with small GTPase mediated pathway. Our study provides a novel approach to investigate how a miRNA affects a given cell type, allowing not only identification of the molecular mechanism underlying an observed side effect of a miRNA drug but also prediction of miRNA drug toxicity on various cell types.

Glomerular miRNAs Are Alternatively Spliced and Polyadenylated During Podocyte Injury in Animal Models of Nephrotic Syndrome

Claire Barton, Amy Webb, Rachel Cianciolo, Claire L. Moore, Shipra Agraval, Abigail Wexor Research Institute at Nationwide Children's Hospital, Columbus, OH; The Ohio State University, Columbus, OH; Tufts University School of Medicine, Boston, MA.

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, is characterized by podocyte loss and injury. Furthermore, alternative miRNA processing, such as alternative splicing (AS) and alternative polyadenylation (APA) play important roles in physiology, development, and disease; however, there is very limited knowledge on their roles in glomerular disease. We hypothesized that AS and APA events of glomerular RNAs is associated with podocyte injury and proteinuria in NS.

Methods: Glomerular damage characterized by proteinuria was induced by purmorphamin aminonucleoside (PAN) or adriamycin (ADR) to mimic human minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS), respectively. Urine and serum chemistries, kidney histology and glomerular RNA-seq analyses were performed. APATrap and JunctionSeq bioinformatics analyses software were used to detect APA and AS glomerular events. Correlation of differentially expressed genes (DEGs) was performed with known glomerular disease genes and polyadenylation and splicing factors.

Results: Robust proteinuria was induced in both PAN-MCD and ADR-FSGS models, accompanied by hyperaluminaemia, hypercholesterolaemia and histological alterations in the kidneys (protein casts and podocyte hypertrophy). Out of 13,265 genes, MCD model resulted in 1033 and FSGS model in 1308 glomerular DEGs with abs(log2FC)>1 and p<.05. Of 80 analyzed genes with established roles in glomerular disease, 30 were altered in both MCD and FSGS. Significant APA was identified in 71 and 746 genes in MCD and FSGS, respectively. Similarly, 21 were altered in MCD and 24 in FSGS. Significant AS was identified in 136 and 1875 genes in MCD and FSGS models, respectively. In accordance, of 50 splicing factors analyzed, 3 were altered in MCD and 5 in FSGS. Specifically, the identified APA and AS events affected genes of the slit diaphragm complex such as Neph1, Neph2, and Tjp1, which are critical determinants of podocyte structure and function.

Conclusions: Association of global glomerular miRNA alteration due to AS and APA with podocyte and glomerular injury is a newly recognized phenomenon, with potential implications for therapy and molecular understanding of the disease.

Continuous Non-Mutagenic DNA Damage in Podocytes Activates Inflammatory Response and May Accelerate Kidney Aging

Ran Nakamichi, Akihito Hishikawa, Kaori Hayashi, Hiroshi Itoh. Keio University School of Medicine Department of Internal Medicine, Tokyo, Japan.

Background: Podocytes are suggested to contribute to kidney aging because of their terminally differentiated features. We have previously reported the association of KAT5-mediated DNA damage repair with altered DNA methylation in podocytes (Cell Rep 2019). However, the role of podocyte DNA damage itself on DNA methylation changes and kidney aging has remained to be adequately elucidated.

Methods: To investigate the significance of DNA double-strand breaks (DSBs) in podocytes, we generated podocyte-specific I-Ppol knockout mice (podocin-Cre ROSA26-STOP- I-Ppol) . I-Ppol is a homing endonuclease which causes non-mutagenic DSBs. RNA-seq and MeDIP-seq analysis were performed using isolated podocytes in I-Ppol mice and wildtype controls.

Results: I-Ppol mice showed severe albuminuria (WT 43±3.4 mg/gCr, I-Ppol 2224±7.3 mg/gCr, p<0.01) with diffuse foot process effacement in podocytes but glomerulosclerosis and interstitial fibrosis were not observed at 12 weeks of age. Interestingly, infiltration of CD11b-positive cells was shown in I-Ppol podocytes, which is a similar finding in 2-year-old aged mice. The aged mice showed increased DNA damage and DNA methylation. In I-Ppol mice, rapid deterioration of renal function with glomerulosclerosis and tubulointerstitial fibrosis developed around the age of 20 weeks. RNA-seq analysis revealed that inflammatory-related genes were upregulated in podocytes of I-Ppol mice. Senescence-associated secretory phenotype (SASP)-related gene expression was also increased. MeDIP-seq analysis revealed that 5219 differentially methylated regions (DMRs) were identified in I-Ppol mice compared with controls. Interestingly, there was no significant correlation between the distance from the I-Ppol cutting site and DMRs. DNA methylation was increased in genes containing I-Ppol cutting sites or podocyte epithelial genes such as neprhin and podocin, whereas it was decreased in inflammatory related genes, suggesting gene-specific DNA methylation changes following DNA damage.

Conclusions: The phenotype of the I-Ppol mice may reflect one aspect of accelerated kidney aging. Repeated DNA damage repair in podocytes may cause altered DNA methylation independent of primary DNA damaged sites with promoted inflammation and podocyte morphological changes.

PO1709

Deletion of MCP-1 in Podocytes Does Not Protect Against Glomerular Injury

Corry D. Bondi, Britney M. Rush, Roderick J. Tan. University of Pittsburgh Department of Medicine, Pittsburgh, PA.

Background: Over the past three decades, the global burden of chronic kidney disease (CKD) has nearly doubled straining healthcare budgets. Understanding the role of podocytes in the pathophysiology of proteinuric disease is important for development of novel treatments. Prior studies implicate monocyte chemotractant protein-1 (MCP-1) in podocyte injury, but the source of MCP-1 has not been definitely identified. Both MCP-1 and its cognate receptor, CCR2, are expressed in podocytes. Therefore, using podocyte-specific MCP-1 knockout mice (PODO-MCP-1-/-), we evaluated whether autocrine MCP-1 signaling by podocytes contributes to proteinuric CKD.

Methods: PODO-MCP-1-/- mice were generated by crossing MCP-1 flexed mice with mice harboring Cre recombinase under the control of the podocin promotor. Knockout mice and wild-type littermates were subjected to angiotensin II by osmotic minipumps (Ang II; 1.5mg/kg/day) for 28 days. Weekly spot urines were collected, assessed with ELISA for albuminuria, and results normalized to urinary creatinine. After 28 days, kidneys were harvested and histologic, immunofluorescent, immunoblot, and quantitative PCR analyses were performed. Results are reported as mean ± S.E.M. Threshold for significance was P<.05.

Results: There were no baseline differences in bodyweight, histology, and urinary albumin levels between the two groups. Following 28 days of Ang II infusion, histologic analysis revealed renal pathology particularly glomerulosclerosis. There were no differences in bodyweight, albuminuria, renal function, expression of nephrin and WT1, and number of podocytes. Ccr2 gene expression also revealed no significant difference.

Conclusions: Our results demonstrate that podocyte-specific MCP-1 production is not a major contributor to Ang II-induced glomerular injury as demonstrated by lack of protection in the podocyte-specific MCP-1 knockout mice. Future studies will evaluate other sources of MCP-1 that may impact disease.

Delayed Treatment with a Novel Highly Selective Small-Molecule Agonist of MC5R Attenuates Podocyte Injury and Proteinuria in Puromycin Aminonucleoside Nephrosis

Bohan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. University of Toledo College of Medicine and Life Sciences, Toledo, OH.

Background: Clinical studies indicate that the melanocortin peptide ACTH is effective in inducing remission of nephrotic glomerulopathies like MCD and FSGS, even those resistant to steroids, suggesting that a steroid-independent melanocortinergic mechanism might contribute. However, the type of melanocortin receptor (MCR) that conveys this beneficial effect as well as the underlying mechanisms remains controversial. Recently, burgeoning evidence suggests that MC5R is likely involved in glomerular pathobiology. This study aims to test the effectiveness of a novel highly selective MC5R agonist (MC5RA) in puromycin aminonucleoside (PAN) nephrosis.

Methods: MC5RA was generated by N-terminal modification of the melanocortin core tetrapeptide His-D-β-Arg-Trp-NH₂ with an aromatic group, resulting in a triphenylpropionyl melanocortin analog with a 100-fold selective agonistic activity on MC5R. Rats were injured with a tail vein injection of PAN, and 5 days later, were randomized to daily MC5R or vehicle treatment.

Results: Upon PAN injury, rats developed heavy proteinuria on day 5, entailing an established nphrotic glomerulopathy. Following vehicle treatment, proteinuria continued to progress on day 14 and was sustained till day 21, accompanied by evident histologic signs of podocyteopathy, marked by ultrastructural lesions of glomeruli, including extensive effacement of podocyte foot processes and podocyte microvillus transformation, and concomitant with loss of podocyte homeostatic markers, such as synaptopodin and nephrin, and de novo expression of podocyte injury marker desmin. Rescue treatment with MC5SA significantly attenuated urine albumin excretion and mitigated the loss of podocyte markers proteins, resulting in improved podocyte ultrastructural changes. In vitro in cultured podocytes, MC5RA prevented the PAN-induced disruption of actin cytoskeleton integrity and apoptosis. Mechanistically, MC5RA treatment reinstated inhibitory pharmacology and thus averted hyperactivity of GSK3β, a critical point of multiple podotypathic pathways, in PAN-injured podocytes in vitro and in vivo.

Conclusions: Pharmacologic targeting of MC5R by using the highly selective small-molecule agonist is likely a promising and feasible therapeutic strategy to improve proteinuria and podocyte injury in glomerular disease.

Tadalafil, a PDE5 inhibitor, Exhibits Renoprotective Effects Preventing Podocyte Damage in an Adriamycin-Induced Nephrotic Syndrome Model

Natsumi Tomita,1 Yuji Hotta,1 Aya Naiki-Ito,2 Tomoya Kataoka,3 Satoru Takahashi,4 Kazumori Kimura.1 1Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; 2Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; 3Department of Clinical Pharmacaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

Background: Phosphodiesterase (PDE)-5 inhibitor is reportedly a renoprotective compound. Although PDE5 expression is confirmed in the glomeruli, its relationship with renal dysfunction remains elusive. We have previously investigated the renoprotective effects of tadalafil in a CKD model (Tomita N, et al. Physiol Rep. 2020), suggesting that such an effect would be related to podocyte damage attenuation. In this study, we investigated how tadalafil, a PDE5 inhibitor, could affect a rat nephrotic syndrome model.

Methods: Wistar ST rats were established as nephrotic syndrome models by administrating adriamycin (ADR) injection. The animals were divided into 3 groups: control (n = 6), ADR (n = 5), and ADR + tadalafil (n = 5). Tadalafil was administered 10 mg/kg daily. After 2 weeks of treatment, the urinary protein and serum albumin levels were evaluated, and the kidney tissue was harvested. WT1-positive cells were identified as podocytes by WT1 immunostaining. Moreover, human renal glomerular epithelial cell damage was induced in vitro by ADR supplementation. After 24 h of ADR treatment with or without tadalafil, cell viability was determined using CCK-8.

Results: The ADR injection induced high urinary protein and low serum albumin levels. Two weeks of tadalafil treatment attenuated proteinuria compared to the ADR group (P < 0.01). ADR reduced the WT1-positive cell number and the tadalafil treatment prevented the reduction (P < 0.05). Moreover, the ADR treatment resulted in reduced cell viability in vitro. The tadalafil treatment improved cell viability compared to the ADR treatment only (P < 0.05).

Conclusions: This study suggests that the treatment with tadalafil, a PDE5 inhibitor, could effectively prevent podocyte damage in the case of nephrotic syndrome.

Targeting mTOR Signaling Improved Kidney Function in APOL1 Risk Variant Mice with Chronic Exposure to Inflammatory Stimuli

Shrijal Shah, Calum Tattersfield, David Demeritt, Olivia Donovan, Lena B. Schaller, Gizelle Mccarthy, Martin R. Pollak, David J. Friedman. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Inheriting two copies of APOL1 risk variants significantly increases the likelihood of developing chronic kidney disease in African Americans. Many different types of disease have been proposed using cell-based model systems. Here we try to understand risk variant pathophysiolog by using a transgenic mouse model.

Methods: Transgenic mice with a single copy of human APOL1 G0 and G2 were generated using bacterial artificial chromosome (BAC) on a FVB background. Mice were injected with interferon gamma (IFN-γ) plasmid via hydrodynamic tail vein injections to induce APOL1 expression. Since mTOR activation has been frequently observed in podocytes during FSGS, we blocked the pathway using rapamycin to see if it could improve disease outcomes. Mice were injected with 2mg/kg of rapamycin every other day (3 days/week, intraperitoneally) for a total of 2 weeks. Paraffin embedded tissue sections were used for immunohistochemistry and Periodic acid–Schiff (PAS) staining. Glomerular isolations were performed using Dynabeads. APOL1 oligomerization was assessed using blue native PAGE.

Results: 7 Days after IFN-γ plasmid injection, the podocytes of G2 mice stained positive for phospo-S6 ribosomal protein indicating mTOR activation accompanied by proteinuria. Blocking mTOR activation using rapamycin reversed ribosomal protein S6 phosphorylation, reduced proteinuria, and improved tissue histology as seen by PAS staining. We hypothesized that rapamycin might be activating autophagy and clearing APOL1 oligomers, but found no evidence for this mechanism of rescue. Instead, we were able to replicate the rescue we had observed with rapamycin using a cell cycle inhibitor, suggesting that rapamycin might be rescuing G2 phenotype by inhibiting podocyte cell entry downstream of risk variant mediated injury.

Conclusions: Persistent expression of APOL1 risk variants pushes podocytes into cell cycle entry. Inhibiting mTOR signaling and subsequent cell cycle entry alleviated injury.

Plin5 Deficiency in Podocyte Negatively Affects the Communication Between Lipid Droplets and Mitochondria in Alport Syndrome

Jin Ju Kim,1 Sydney S. Wilbon,2 Judith T. Molina David,3 Hazel H. Soto,2 Jeffrey H. Miner,2 Flavia Fontanesi,1 Sandra M. Merscher,1 Alessia Fortoni,1 1University of Miami School of Medicine, Miami, FL; 2Washington University in St Louis, St Louis, MO; 3Social Profit Network, Melno Park, CA; 4The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid droplets (LD) and triglyceride (TG) accumulation in experimental AS (Col4a3K/O mice). Excessive FA accumulation resulting from increased expression of TG is a major contributor to cell lipotoxicity. Perilipin 5 (PLIN5) is an LD-related protein that plays a critical role in regulating TG lipase activity and the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FA. Here we test the hypothesis that PLIN5 deficiency, when expressed in podocytes and that PLIN5 deficiency in AS causes extracellular TG breakdown and the loss of LD-mitochondrial contact, thus contributing to kidney failure.

Methods: In vitro, Immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3K/O mice (Jackson Laboratory) to H-2kb-tsA58 transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in AS podocytes and kidney cortex in AS mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM analysis.

Results: PLIN5 deficiency was observed in the kidney cortex of Col4a3K/O mice when compared to controls (p < 0.001). We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes (p < 0.001). AS podocytes also showed significantly increased rates of TG lipolysis (p < 0.05), intracellular free fatty acids (p < 0.05) and apoptosis (p < 0.01) when compared to WT podocytes. AS podocytes had reduced number of LD-mitochondrial contacts (p < 0.05), implying that and apoptosis. Moreover, Ezetimibe, which restored LD-Mitochondrial contact in vitro (p < 0.05) and improved kidney function in vivo, was found to restore PLIN5 expression in vitro and in vivo (p < 0.05).

Conclusions: Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria, leading to mitochondrial dysfunction and contributing to disease progression.
POI1714

UCP2 Regulates Mitochondrial Dynamics and Podocyte Injury by OMA1-Dependent Proteolytic Processing of OPA1
Qianqian Yang, Lingling Xu, Yang Zhou, Lei Jiang, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Podocyte injury and loss are pivotal events in the progression of glomerular diseases, such as diabetic kidney disease (DKD) and focal segmental glomerulosclerosis (FSGS). Disordered mitochondrial dynamics leads to mitochondrial dysfunction, which is extensively involved in podocyte injury. The mitochondrial inner membrane uncoupling protein, UCP2, is involved in the regulation of mitochondrial dynamics, but the specific mechanism is unknown.

Methods: The function and structure of podocyte were detected by electron microscopy, immunofluorescence, and primary urinary albinosis. A Seahorse Bioscience XF24 Extracellular Flux Analyzer was used to measure dissolved oxygen in culture medium around adherent cells. Mitochondrial membrane potential was detected using TMRM dye. The content of ATP in cells of each well was determined with an ATP Assay Kit.

Results: We reported that the mitochondrial inner membrane UCP2 expression in podocyte was correlated with proteinuria level in patients. Mice with podocyte-specific Ucp2 deficiency developed podocytopathy with proteinuria with aging. Furthermore, those mice exhibited increased proteinuria in experimental models evoked by diabetes or adriamycin. Our findings suggest that UCP2 mediates mitochondrial dysfunction by regulating mitochondrial dynamic balance. Ucp2 deleted podocyte exhibited increased mitochondrial fission and deficient in ATP production. Mechanistically, opacity protein 1 (OPA1), a key protein in fusion of mitochondrial inner membrane, was regulated by UCP2. Ucp2 deficiency promoted proteolysis of OPA1 by activation OMA1 which belongs to mitochondrial inner membrane zinc metalloproteinase. These findings demonstrate the role of UCP2 in mitochondrial dynamics in podocyte and provide new insights into pathogenesis associated with podocyte injury and proteinuria.

Conclusions: Our findings suggest that UCP2 protects mitochondrial dynamics balance by OMA1-dependent proteolytic processing of OPA1.

L-WNK1 Inhibition Protects from Glomerular Injury in Mice
Cyril Mousseaux,1,2 Tiffany Migeon,1,2 Perrine Frère,1,2 Liliane Louedec,1,2 Pierre Galichon,1 Juliette Hadchouel,1,3 CoRaKID - Inserm UMR_S1155, Paris, France; Sorbonne Université, Paris, France.

Background: The With no lysine (K) kinase L-WNK1 plays a key role in the maintenance of cellular homeostasis in response to variations in osmolarity, intracellular chloride concentration or cell volume. We have shown that L-WNK1 activation in the glomerulus, its predominant site of expression within the kidney.

Methods: The function and structure of podocyte were detected by electron microscopy, immunofluorescence, and primary urinary albinosis. A Seahorse Bioscience XF24 Extracellular Flux Analyzer was used to measure dissolved oxygen in culture medium around adherent cells. Mitochondrial membrane potential was detected using TMRM dye. The content of ATP in cells of each well was determined with an ATP Assay Kit.

Results: We reported that the mitochondrial inner membrane UCP2 expression in podocyte was correlated with proteinuria level in patients. Mice with podocyte-specific Ucp2 deficiency developed podocytopathy with proteinuria with aging. Furthermore, those mice exhibited increased proteinuria in experimental models evoked by diabetes or adriamycin. Our findings suggest that UCP2 mediates mitochondrial dysfunction by regulating mitochondrial dynamic balance. Ucp2 deleted podocyte exhibited increased mitochondrial fission and deficient in ATP production. Mechanistically, opacity protein 1 (OPA1), a key protein in fusion of mitochondrial inner membrane, was regulated by UCP2. Ucp2 deficiency promoted proteolysis of OPA1 by activation OMA1 which belongs to mitochondrial inner membrane zinc metalloproteinase. These findings demonstrate the role of UCP2 in mitochondrial dynamics in podocyte and provide new insights into pathogenesis associated with podocyte injury and proteinuria.

Conclusions: Our findings suggest that UCP2 protects mitochondrial dynamics balance by OMA1-dependent proteolytic processing of OPA1.

Protective Role of the Epithelial STAT5 Pathway in Kidney Injury
Aissata Niassè,1 Kevin Louis,2 Laurent Mesnard,3 Juliette Hadchouel,1 Yous Luque,3 Inserm UMR_S1155 team, Paris, France; INSERM, Paris, France; Assistance Publique - Hôpitaux de Paris, Paris, France; Sorbonne Université, Paris, France.

Background: During kidney diseases, diverse tissue-specific pathways can regulate kidney injury and prognosis. Thus, therapeutic targeting of these pathways could improve the management and prognosis of chronic kidney diseases. The Janus Kinase/ Signal Transducer and Activator of Transcription (JAK/STAT) pathway, classically described in immune cells, has been recently described in intrinsic kidney cells.

Methods: We 1) analyzed STAT5 activation in kidney biopsies from patients with focal segmental glomerulosclerosis (FSGS) and acute tubular injury (ATI), 2) used experimental models of glomerular and tubular injury in mice with podocyte- or tubular-specific STAT5 deficiency, 3) studied transcriptional modifications related to STAT5 deletion in human kidney epithelial cells, 4) explored interleukin-15 mediated STAT5 activation in podocytes and glomerular injury.

Results: Here, we show, for the first time, that STAT5 is activated in both human podocytes (Figure 1A) and tubular cells in FSGS and ATI, respectively. Additionally, STAT5 deficiency in either glomerular or tubular epithelium aggravates the functional and structural alterations in a range of experimental models of glomerular (Figure 1B) or tubular disease. STAT5 deficiency in kidney epithelial cells resulted in dysregulation of multiple metabolic pathways, including glycolysis and oxidative phosphorylation (Figure 1C). Interleukin 15 (IL-15), a classical activator of STAT5 in immune cells, increases STAT5 phosphorylation in human podocytes and alleviates glomerular injury in vivo (Figure 1D) by activating anti-apoptotic pathways.

Conclusions: In conclusion, activating renal epithelial STAT5 represents a new therapeutic avenue with the potential for a range of beneficial effects in kidney diseases.

Shiga Toxin Targets the Podocyte in Haemolytic Uraemic Syndrome (HUS) Resulting in Glomerular Endothelial Cell Complement Dysregulation
Emily E. Bowen, Jenny Hurcombe, Lindsay S. Keir, Fern Barrington, Louise K. Farmer, Abigail C. Lay, Gavin I. Welsh, Eva Larkai, Moin Saleem, Richard Coward. Bristol Renal University of Bristol Faculty of Health Sciences, Bristol, United Kingdom.

Background: Haemolytic uraemic syndrome (HUS) is a thrombotic microangiopathy (TMA) that has a predilection to present in the kidney. It is a triad of microangiopathic haemolytic anaemia, thrombocytopenia, and acute kidney injury. In 90% of cases, HUS follows gastroenteritis secondary to enterohemorrhagic infection with Shiga toxin (Stx) producing bacteria such as Escherichia coli. Stx HUS is the leading cause of acute kidney injury in children with a mortality of 5%. However, the precise pathophysiological mechanisms following Stx infection leading to TMA remain poorly understood. Here we show that the podocyte is a key initiator in Shiga toxin HUS, which could explain why the glomerulus is the prime target of systemic Shiga toxin driven infection.

Methods: To demonstrate that the podocyte Shiga toxin receptor (Gb3) is sufficient to trigger the development of HUS, we used conditional gene targeting to engineer human Gb3 expression specifically in the podocytes of adult mice.

Results: Following intraperitoneal Shiga toxin challenge, these mice developed thrombocytopenia, haemolytic anaemia and uremia (Figure 1) with evidence of glomerular TMA on histology. Interrogation of this model revealed evidence of glomerular endothelial cell complement activation, with loss of local complement factor H protection. Furthermore, C5 inhibition was found to rescue the Shiga toxin HUS phenotype.

Conclusions: Together, these observations provide compelling evidence for the importance of podocyte-glomerular endothelial cell cross-talk within the kidney in the development of Shiga toxin associated HUS and suggest a possible therapeutic role for complement inhibition in patients with this devastating disease.

Nephronectin Expression Is Controlled by the Non-Canonical TGF-β Pathway in Podocytes

Nina Sopel, Alexandre Ohs, Mario Schiffer, Janina Müller-Deile. Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.

Background: Within the glomerulus, podocytes, glomerular endothelial cells (GEC) and the glomerular basement membrane (GBM) build the glomerular filtration barrier. Extracellular matrix (ECM) of the GBM is mainly composed of proteins synthesized by GECs and podocytes. Our interest focuses on nphronectin (NPNT), an ECM protein mainly produced by podocytes. Recently, it has been described that NPNT expression patterns vary in different glomerular diseases. For example, in focal segmental glomerulosclerosis (FSGS) and membranous glomerulonephropy (MGN) NPNT expression was decreased compared to healthy controls, while it was increased in diabetic nephropathy (DN). In addition, transforming growth factor beta (TGFβ) is able to down-regulate NPNT on both mRNA and protein level. Our aim is to further analyze this TGFβ-mediated regulation of NPNT in human podocytes.

Methods: Immunolized human podocytes were differentiated for 10 to 12 days at 37°C and pre-incubated with inhibitors for components of the canonical and the non-canonical TGFβ signaling pathway with subsequent culture in the presence or absence of TGFβ. We used cell culture supernatants for ELISA, as well as cell lysates for qPCR and western blot analyses.

Results: While treating differentiated immortalized human podocytes with TGFβ decreased NPNT on both mRNA and protein level, we observed that inhibition of single components of the TGFβ pathway did not alter NPNT mRNA expression and exontr. On protein level, we noted no change after blockade of either Smad2 or Smad3 under baseline conditions. However, TGFβ was still able to decrease NPNT expression when canonical pathway components were inhibited, suggesting a minor role for this pathway in NPNT regulation via TGFβ. If single components of the non-canonical pathway were blocked, we observed an increase in NPNT protein expression, which was not further altered by TGFβ addition.

Conclusions: Taken together, our data suggest that in podocytes NPNT expression is fine-tuned via the non-canonical TGFβ pathway with additional regulation on the post-translational level.

Podocyte Damage in Chimeric Kidney Organoids

Taiji Matsusaka,1 Tomohiro Udagawa,2 Kenji Osafune,3 Yoshikazu Araoka.3 1Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan; 2Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; 3Kyoto Daigaku, Kyoto, Japan.

Background: We previously found that when a portion of podocytes are injured, other podocytes are secondarily injured in a mouse model, which may underlie the relentless progression of chronic renal failure. In the present study, we tested whether this phenomenon is observed in kidney organoids.

Methods: Nephrin organoid cells (NPCs) were established by culture-dependent purification (CDP) method from 12.5-dpc NEP25 and RiboTag mouse kidneys (Cell Stem Cell, 2016, 19, 516-29). Podocytes of NEP25 mice express hCD25 and can be injured by hCD25-targeted immunotoxin, LMB2. Podocytes of RiboTag mice express hemagglutinin (HA)-tagged ribosomal protein. Kidney organoids were generated by transient stimulation with FGFI and CHIR99021 of NPC aggregates and subsequent 8-day culture. On day 8, LMB2 (20 nM) was added to induce injury in hCD25+ podocytes.

Results: We confirmed that podocytes in both organoids are stained for nephrin, podocin and WT1. Podocytes derived from NEP25 NPC expressed hCD25 and were injured by LMB2, and those from RiboTag NPC expressed HA and were resistant to LMB2. When two types of NPCs were mixed at 1:1 ratio, organoids showed a chimeric pattern containing hCD25+ and HA+ podocytes (Fig). 2 days after LMB2 treatment, hCD25 staining completely disappeared accompanied by cleaved (c)- lamin A staining, a cell death marker. HA staining was retained, but WT1 was diminished and podocin disappeared (Fig 2). Occasionally, c-lamin A was positive in HA+ cells. RNA of Ribotec podocytes can be obtained by immunoprecipitation with anti-hemagglutinin (HA) antibody. Q-PCR revealed that Nphs1 (0.31), Nphs2 (0.04), Wt1 (0.37) were decreased to the indicated fold by LMB2 and that Gadd45β was increased to 4.82-fold.

Conclusions: Thus, podocyte damage damages podocytes in kidney organoids that lack glomerular filtration.

Podocyte-Derived RARRES1 Aggravates Kidney Disease Progression by Inducing Both Glomerular and Tubular Injury

Ye Feng, 1 Bi-Cheng Liu, 1 Kyung Lee, 1 John C. He. 1 Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; 2Southeast University Zhongda Hospital, Nanjing, China.

Background: Our previous study demonstrated that the expression of retinoic acid receptor responder protein 1 (RARRES1) increases in glomeruli of patients with diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS). The glomerular expression of RARRES1 also correlates with eGFR slope and predicts glomerular disease progression. Single-cell RNA-sequencing of the kidney showed that RARRES1 was expressed mostly in podocytes within the kidney. Mechanistically, WT-RARRES1 is cleaved into a soluble form which subsequently induces podocyte apoptosis whereas mutant RARRES1 with cleavage defect failed to induce podocyte apoptosis in vitro. Here, we further determined whether increased expression of WT-RARRES1 in the podocytes aggravated progression of glomerular disease.

Methods: Mice with podocyte-specific overexpression of human WT-RARRES1 or mutant RARRES1 with cleavage defect were generated and then subjected to aging, adriamycin (ADR) administration or streptozotocin (STZ) injection. To identify the role of podocyte-derived soluble RARRES1 in tubular cells, HK2 cells were treated with soluble RARRES1 obtained from podocyte supernatants.

Results: In vivo, podocyte-specific overexpression of WT-RARRES1 resulted in severe proteinuria and marked glomerular cell injury in mice with aging, adriamycin-induced nephropathy, or STZ-induced diabetic nephropathy as compared to the control mice with overexpression of mutant RARRES1. Interestingly, tubular vacuolation and interstitial injury were also observed in these mice with podocyte-specific overexpression of RARRES1. In addition, we showed that soluble RARRES1 collected from podocyte supernatants was endocytosed in HK2 cells to induce cellular injury. Similarly, cleaved form of human RARRES1 in the mice with podocyte-specific human RARRES1 overexpression was found in the tubular compartments, indicating that soluble RARRES1 generated from podocytes may act on tubular cells through glomerulotubule crosstalk.

Conclusions: Our study suggests that RARRES1 is a risk gene for glomerular disease progression through its direct effects in podocytes as well as indirect effects in tubular cells probably via glomerulotubule crosstalk.

PO1722

Podocyte-Specific Extracellular Vesicles Yield Novel Insight into Intercellular Signaling in the Glomerulus

Background: Extracellular vesicles (EVs) have been identified to play an essential role in basic pathological processes such as priming of the metastatic niche, autoimmunity and propagation of insulin resistance. Nevertheless, knowledge about their role in kidney health and disease remains scarce. A new group of EVs, shed upon apoptosis with the ability to induce a proliferative effect in neighboring cells, was recently identified in health and disease. Ongoing analyses aim to characterize their proteomic content and effect other renal epithelial cells. As these vesicles can be separated without advanced equipment such as ultracentrifuges, we believe they could also be a valuable source for biomarker research in various nephropathies.

Methods: Using differential centrifugation and filtration we established a protocol to separate medium-sized EVs from cell culture supernatants, kidney tissue and urine samples. We quantified the number of various podocyte-derived extracellular vesicles or podocyte-specific EVs exerted different effects on the proliferative and migratory behavior of primary parietal epithelial cells.

Results: Podocyte-specific medium-sized EVs were detected in baseline podocyte culture supernatant, untreated murine kidney tissue as well as the urine of healthy human volunteers. Vessel quantification revealed a drastic increase of vesicle release upon podocyte damage both in vitro and in vivo. Interestingly, podocyte-specific EVs exerted different effects on the proliferative and migratory behavior of primary parietal epithelial cells.

Conclusions: Our study represents the first investigation of podocyte-specific medium-sized vesicles, their release dynamics and functional implications in health and disease. Ongoing analyses aim to characterize their proteomic content and effect other renal epithelial cells. As these vesicles can be separated without advanced equipment such as ultracentrifuges, we believe they could also be a valuable source for biomarker research in various nephropathies.

PO1723

Effects of Varying Mild Tubular Injury on Subsequent Glomerular Injury

Janka Babickova, 1,2 Haichun Lee, 1 John C. He. 1 Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; 2Southeast University Zhongda Hospital, Nanjing, China.

Background: Tubular injury predisposes to CKD, including glomerular injury. We analyzed effects of mild tubular injury on subsequent glomerular injury.

Methods: Double transgenic, Nep25/DTR + male and female mice (with human CD25 receptor on podocytes and Diphtheria toxin (DT) receptor on proximal tubules) received DT (25, 50, or 100ng/kg; 2x one week apart, n=5/group) to induce tubular injury, or vehicle (VEH). Uninephrectomy was done 4 wks later; 5 wks later glomerular injury was induced by LMB2 toxin (CD25 ligand) and mice were sacrificed 10 days later.

Results: In males, urinary KIM-1 was significantly higher vs VEH with all DT doses on d3 after DT injections, lowest in DT50 and similar to DT50 and DT100. KIM-1 levels overexpressed additionally in males numerically in DT50 and DT100 vs VEH by wk 6. Urinary NGAL was significantly increased at d3 only in DT100 vs VEH. NGAL levels normalized in all DT groups by week 6. In females, KIM-1 levels were increased by d3 with highest level with DT100. KIM-1 levels were only numerically higher vs VEH in a dose-dependent manner in males. Urinary NGAL was increased at sacrifice after additional podocyte injury showed numerically higher levels by 67% in DT100 vs VEH. In females, albuminuria gradually increased, with levels lower than in males in all groups. Ultrastructural analysis after podocyte injury showed similar significant foot process effacement, glomerular capillary fenestration loss and increased GBM thickness in all groups.

Conclusions: Sex differences in response to tubular injury and albuminuria were observed. Even very mild tubular injury, recovered by assessment of KIM-1 and NGAL-1 led to numerical increase in albuminuria after second hit glomerular injury in both sexes. The sex-dependent differences in KIM-1 and NGAL-1 further support differential susceptibility of nephron segments to injury in females vs males, which may play a role in glomerular sensitization to injury.

Effect of Glomerular Disease on the Podocyte Cell Cycle

Laura Perin, 1 Camille H. Nicolas Frank, 2 Xiaogang Hou, 1 Geremy Clair, 1 Fadi E. Salem, 4 Roger E. De Filippo, 1 Paolo Cravedi, 1 Kevin V. Lemley, 1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Harvard Medical School, Boston, MA; 3Pacific Northwest National Laboratory Biological Sciences Division, Richland, WA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Progression of glomerulosclerosis is associated with loss of podocytes and subsequent glomerular tuft instability. A decreased number of podocytes may be able to preserve tuft stability through cell hypertrophy associated with cell cycle re-entry. At the same time, re-entry into the cell cycle can lead to podocyte detachment from the glomerular basement membrane, if podocytes cross the G1/S checkpoint and undergo apoptosis.

Methods: To study cell cycle dynamics during CKD development, we used a Fucci mouse model (fluorescence ubiquitination-based cell cycle indicator) affected by X-linked Alport Syndrome (AS). This model has progressive CKD and expresses cell cycle fluorescent reporters exclusively in podocytes. We quantified podocytes cell cycle distribution in WT and AS mice at different ages and collected podocytes in G0 and G1 for proteomics studies.

Results: We showed that with the development of CKD, an increasing fraction of podocytes in vivo are in G1 or later cell cycle stages. G1 and G2 podocytes are hypertrophic. Heterozygous female mice, with milder manifestations of CKD, show G1 fraction numbers intermediate between WT and male AS mice. Proteomic analysis showed differences in cytoskeleton re-organization and metabolic processes between podocytes in G0 and G1 in different WT and WT/AS groups. WT and indicate alteration of specific proteins also identified in human AS podocytes.

Conclusions: Our data showed that, during progressive CKD, the podocyte cell cycle distribution changes dramatically, suggesting that cell cycle manipulation may have a role in the prevention and treatment of progressive glomerular diseases characterized by podocyteopathy.

Glucocorticoid- and Pigioglitazone-Induced Proteinuria Reduction Correlates with Glomerular Extracellular Matrix Remodeling in Experimental Nephritic Syndrome

Sagar Bhayana, Shipra Agrawal, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Peter White, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephritic Syndrome (NS) is a common glomerular disease in children. While glucocorticoids (GC) are the mainstay of childhood NS treatment, pioglitazone (Pio; an FDA-approved PPARg agonist to treat type 2 diabetes) has been reported to reduce proteinuria in experimental NS and to directly protect podocytes from injury. Since both GC and Pio activate nuclear receptors (NR3C1 and PPARg, respectively) we hypothesized that their proteinuria-reducing effects result from overlapping glomerular gene transcriptional patterns.

Methods: We performed transcriptome analyses on glomeruli isolated from GC (immunosuppressive)- and Pio (non-immunosuppressive)-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Unsupervised clustering revealed partial reversibility of PAN-associated mRNAs; treatments with either GC or Pio IPA analyses + web-based bioinformatic platforms identified 29 genes-of-interest common to GC- and Pio-induced proteinuria reduction, which included ECM remodeling, lipid metabolism, DNA-binding and cytoskeletal organization. Based on expression differences using real-time PCR, gene expression downstream of Pio upregulated genes included those involved in extracellular matrix remodeling.

Conclusions: The expression of ECM remodeling genes is associated with Pio treatment in PAN-induced NS, suggesting that Pio may act through ECM remodeling to reduce proteinuria.

Alteration of Intestinal Microbiota in Patients with ESRD Undergoing Hemodialysis
Takoe Koshida,1 Tomohito Gohda,1 Takuya Sugimoto,2 Takashi Asahara,2 Masanori Ishizaka,1 Maki Murakoshi,1 Yusuke Suzuki,1 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Yakult Central Institute, Yakult Honsha Co. Ltd, Tokyo, Japan.

Background: The alteration in the intestinal microbiota is reported to be associated with various diseases, indicating that the development and progression of end-stage kidney disease also might be associated with dysbiosis.

Methods: The stool samples were collected from patients with hemodialysis (n = 41, HD group) and those with normal renal function (n = 40, NRF group). Both groups are comprised of patients with (HD_DM, n = 20; NRF_DM, n = 19) and without diabetes (HD_non-DM, n = 21; NRF_non-DM, n = 21). We conducted 16S rRNA gene amplicon sequencing using stool samples to analyze the intestinal microbiota.

Results: The reduced abundance of the genera Megamonas and Fusosphaeribacter, and the enriched abundance of the genera Family_XIII_AD3011_group (Aeromonaraceae family), UBA_1819 (Ruminococcaceae family), and Pseudomonas in the stool samples of HD patients were observed significantly compared with those of NRF patients. Compared with patients with NRF DM, the relative abundance of the genera Megamonas was decreased and that of Family_XIII_AD3011_group was increased significantly in patients with HD DM, although those relative abundance did not alter between NRF_non-DM and HD_non-DM. The relative abundance of the genus Sutterella in HD_non-DM was significantly decreased than that in NRF_non-DM, although that relative abundance did not differ between NRF_DM and HD_DM. In the microbial beta diversity, there was no difference between NRF_DM and NRF_non-DM by weighted and unweighted Unifrac analysis, however, there was significant difference between HD_DM and HD_non-DM by unweighted Unifrac analysis (p = 0.007). These results suggest that the gut microbiota alters with renal function decline, and varies depending on the presence or absence of diabetes.

Conclusions: The intestinal microbiota might be varied substantially depending on renal function and the presence or absence of diabetes.

PO1727
Nutritional Intervention in Intensive Care Unit Patients Undergoing CRRT
Jihyun Yang, Tae-bum Kim, Hyeon-Jin Min, Young-Bin Son, Jonghyun Lee, Sewon Oh, Myung-Gyu Kim, Won-Yong Cho, Sang-Kyung Jo. Korea University Anam Hospital, Seoul, Republic of Korea.

Background: Providing adequate calories and protein constitutes an important part of critical care, and inadequate nutrition for critically ill patients is associated with poor prognosis. Therefore, increased loss of amino acids, electrolytes, and water-soluble vitamins during continuous renal replacement therapy (CRRT) could be a therapeutic target. We evaluated whether enforcing protein, trace elements and vitamin supply could improve the prognosis of CRRT patients.

Methods: A nutritional intervention (100 mg/day of Thiamine, 25–30 kcal/kg of energy, 1.8 g/kg of protein, and 50–100 mcg/day of microelement with selenium) was provided in patients subject to CRRT from May 2020 to December 2020. The primary outcomes were 28-day mortality, CRRT day, ICU stay, and ventilator-free day, and the outcomes before and after the intervention were compared.

Results: Total 88 patients were included during the study period and compared with 88 patients in the previous year. The average age was 68.05 years old, 56 (63.5%) patients were male. At day 1 APACHE-II score was 35.45±11.9, SAPS3 88.1±16.8, SOFA 10.4±4.2. There were 9 (10.2%) patients with ECMO, 78 (88.6%) using ventilator. There were 19 (21.6%) pneumonia with ARDS patient, 18 (20.5%) cardiac disease, 9 (10.2%) UTE sepsis, 11 (12.5%) gastrointestinal bleeding and sepsis, 6 (6.8%) cerebral hemorrhage, and others. The main reason for CRRT was hemodynamic instability. Baseline characteristics including APACHE-II score, SAPS 3, and SOFA were not significantly different between the nutritional intervention and the non-intervention patients. Nutritional intervention did not induce any significant changes in 28-day mortality (36 versus 37, p = 0.56) and CRRT days (7.3 ± 6.9 versus 6.3 ± 5.2, p = 0.29). However, nutritional intervention showed minimal improvement in ICU stay (22.1 ± 23.9 versus 20.7 ± 22.1, p = 0.05) and ventilator-free days (17.8 ± 22.3 versus 12.4 ± 14.4, p = 0.05).

Conclusions: This study suggests that support for protein, trace elements, and vitamins may have a positive effect in CRRT patients. Therefore, the nutritional requirements of patients with CRRT should be carefully assessed, individualized, and considered as an important axis of CRRT treatment.

PO1728
Nutritional Phenotypes and Variation in Nutritional Parameter Trajectories Among Non-Dialysis CKD (CKD-ND) Patients Prescribed Oral Nutritional Supplementation
Michelle M. Wong,1,2 Yuyan Zheng,3 Dani Renouf,1 Adeera Levin,1,3 1The University of British Columbia, Vancouver, BC, Canada; 2BC Provincial Renal Agency, Vancouver, BC, Canada; 3Provider Health Care, Vancouver, BC, Canada.

Background: Among CKD-ND patients at risk of undernutrition/protein-energy wasting, the definition of patient subgroups most likely to benefit from ONS treatment is not known. Therefore, our aims were to identify phenotypes of non-dialysis CKD patients prescribed ONS, and to assess nutritional parameter slopes before and after ONS use, by phenotype.

Methods: This longitudinal cohort study included 2543 adult CKD-ND patients who entered multidisciplinary CKD clinics across British Columbia during 2010–2019, met weight and/or dietary intake criteria for ONS prescription based on dietitian assessment, received ≥21 ONS prescription. Hierarchical cluster analysis was used to identify phenotypes using baseline nutritional parameters. Using linear mixed models, slopes for body mass index (BMI), serum albumin, bicarbonate, phosphate, and neutrophil-to-lymphocyte ratio (NLR), an inflammation marker, were assessed in the 2-year periods before and after the first ONS prescription.

Results: Cluster analysis identified five nutritional phenotypes. Changes in parameter slopes (Aslope = post-ONS slope - pre-ONS slope) varied by cluster (Figure). Cluster 1 (characterized by the highest mean NLR and the lowest mean BMI among clusters) demonstrated statistically significant positive Aslopes for BMI, albumin and bicarbonate, and a negative Aslope for NLR. Cluster 2 (hypoalbuninemia) demonstrated positive Aslopes for BMI, albumin, and phosphate. Cluster 3 (low mean BMI) demonstrated a positive Aslope for BMI, accompanied by negative Aslopes for albumin and bicarbonate, and a positive Aslope for NLR. Cluster 4 (acidosis) demonstrated positive Aslopes for BMI and bicarbonate. In Cluster 5 (highest BMI), a negative Aslope for albumin and a positive Aslope for NLR were observed (no improvement with ONS).

Conclusions: The variation in response to ONS by cluster subgroup lends support to an individualized approach to nutritional management of patients at risk of undernutrition/protein-energy wasting.

The Beneficial Effects of Intradialytic Parenteral Nutrition in Malnourished Hemodialysis Patients: A Randomized Controlled Trial
Athiphat Banjongjit, Kamonchonak Metta, Yingyos Avihingsanon, Somchai Eiam-Ong, Piyawan Kittiakulnan. Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

Background: Intradialytic parenteral nutrition (IPDN) is an intermittently supplemental nutrition support administered during hemodialysis (HD). IPDN has been suggested as a trial option after a failure response to oral nutritional supplement (ONS). However, the extent to which IPDN contributes to improve protein-energy status remains unclear.

Methods: Maintenance HD patients having spontaneous energy and protein intake of ≥ 29 kcal/kg/day and ≥ 0.8 g/kg/day, respectively, and intolerance to ONS were randomly assigned 1:1 to receive IPDN or intensive dietary counselling. In group 3, 1-3 anti-inflammatory omega 3-rich parenteral nutrition was infused during HD for 3 months followed by a treatment-free period of 3 months. The control group received an individualized dietary counselling once a week for 3 months to target the required nutrient intake. The outcomes were changes in serum albumin, muscle parameters and nutritional biomarkers. Serious adverse events were also monitored.

Results: A total of 38 patients were completed the study (age 67±11). Baseline characteristics were not different between groups. After 3 months, serum albumin was significantly higher in the IPDN (18) compared with control group (from 3.5±0.3 to 3.8±0.2 g/dL, p<0.01) and muscle mass was also significantly increased in IPDN (0.5±0.03% vs 0.01%, p<0.05). Among non-diabetic patients, IPDN significantly reduced serum IL-6 as an inflammatory marker (p<0.03) but unaltered serum acylated ghrelin as an orexigenic hormone (p=0.31). Muscle mass, strength, and serum prealbumin were not different between both groups. Participants in IPDN group reverted to baseline albumin levels after 3-month post-intervention follow-up. Neither volume overload nor uncontrolled hyperglycemia was found throughout the study.

Conclusions: A short-term IPDN supplementation significantly increased serum albumin level, a survival surrogate among HD patients. The impact of IPDN therapy on clinical outcomes may require larger scale with longer period of study.

PO1731
An Itch to Scratch: The Problem with Pruritus

Background: Dialysis patients often suffer from some level of associated pruritus and nephrologists generally recognize the condition’s impact on patient lives, rating pruritus as a high unmet need for new therapeutic options. However, official diagnosis of CKD-associated pruritus and physician-reported estimates may be highly underestimated.

Methods: Using a HIPAA-compliant, online chart review tool, 177 nephrologists submitted de-identified clinical and non-clinical demographic information for 1,008 dialysis patients in Fall 2020. These data were then merged with physician demographic profiles and attitudinal responses; the full data set was analyzed in SPSS.

Results: When thinking generally, nephrologists estimate that nearly one-half of end-stage renal disease (ESRD) patients on dialysis have some level of pruritus, making it extremely prevalent in this population. However, chart reviews reveal that only 3.2% of dialysis patients are diagnosed with uraemic pruritus (3.4% of HD patients and 1.4% of PD patients). On their last visit with their dialysis patients, nephrologists noted that only 4% of patients were treated (or they were told about pruritus, rash, itch, or pruritus) (3.7% of HD patients and 5.6% of PD patients). Interestingly, only approximately one-third of those patients were diagnosed with uraemic pruritus, indicating there are more patients presenting with a rash or itch who are not actually being diagnosed. Despite the impact on patient lives, nephrologists report that only 25% of HD patients diagnosed with uraemic pruritus are pharmacologically treated; this drops to 17% of PD patients with uraemic pruritus. Treatments vary wildly and have varying levels of reported success among physicians. Nephrologists do recognize the impact pruritus can have on a patient’s quality of life, making it a high rate of underdiagnosis especially troubling. On a 1-10 scale rating unmet need for a new therapeutic agent, 62% of nephrologists rated a high unmet need (8-10) for pruritis in dialysis patients.

Conclusions: While many recognize that itching impacts many dialysis patients, actual diagnoses and treatment are rare, driven by a lack of effective treatment options. Elevating awareness among nephrologists will help with patient identification and treatment, especially as new treatment options are available on the market to help patients.

PO1732
Long-Term Safety of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Serum Electrolytes and Albumin
Pablo E. Pergola,1 Jeannene Fogli,2 Yang Yang,3 David M. Spiegel.2 Renal Associates PA, San Antonio, TX;1 Ardelxy Inc, Fremont, CA.

Background: Tenapanor, an investigational first-in-class phosphate absorption inhibitor (PAI), blocks the paracellular absorption of phosphate in the gastrointestinal tract by local inhibition of the sodium-hydrogen exchanger (NHE3). Tenapanor is being studied as a non-binder approach for the management of hyperphosphatemia in patients on dialysis and it is dosed as one pill (10, 20, or 30 mg) twice daily. Due to its novel mechanism of action, it is important to understand its safety profile, including any potential effects on serum electrolytes and albumin.

Methods: This report evaluates the effects of tenapanor on serum electrolyte and albumin concentrations using data from 3 pivotal trials in which tenapanor met its primary phosphorus-lowering endpoint. Trials included a 12-week monotherapy study (BLOCK), a 52-week monotherapy study (PIREDDOM), and a 4-week tenapanor + phosphate binder combination study (AMPLIFY). Serum electrolytes and albumin were measured per study protocol in central research laboratories.

Results: Tenapanor was generally well tolerated, with diarrhea being the only adverse event reported by ≥5% of patients. Diarrhea was typically mild to moderate in severity, was transient, and resolved with continued treatment. Data from all 3 trials showed that tenapanor treatment, either alone or in combination with phosphate binders, resulted in no clinically meaningful changes in measured serum electrolytes or albumin at any time point. Data from patients treated with tenapanor continuously for 52 weeks in the longest trial, PIREDDOM, are shown in the table.

Conclusions: In these clinical trials, tenapanor inhibited paracellular absorption of phosphate and decreased serum phosphorus with an acceptable safety profile, with no observed effect on serum electrolytes or albumin in patients on maintenance dialysis with hyperphosphataemia.

Funding: Commercial Support - Ardelxy, Inc.

PO1733
Patient-Reported Experience with Tenapanor in the OPTIMIZE Trial
Susan A. Edelstein, Yang Yang, Brett Stephenson, Suling Zhao, Lynae Pagliaro, Jeannene Fogli. Ardelxy Inc, Fremont, CA.

Background: Tenapanor (TEN), a first-in-class phosphate absorption inhibitor (PAI) that works via the paracellular pathway, provides a novel approach for hyperphosphatemia management. The primary goal of this study is to evaluate how to optimize the treatment of hyperphosphatemia in patients with chronic kidney disease (CKD) on dialysis with the use of TEN and its novel mechanism of action.

Methods: Patients with serum phosphorus (P) ≥5.5 and ≤10.0 mg/dL during stable phosphate binder (PB) treatment were randomized 1:1 to 2 different treatment cohorts: Cohort 1 (straight switch; n=151) – discontinued current PB and began TEN 30 mg twice daily (BID); or Cohort 2 (50% PB reduction; n=152) – decreased current PB dose by 50% (or more if taking an odd number of PB tablets) and began TEN 30 mg BID. After week 2 investigators could increase PB doses to achieve sP ≤5.5 mg/dL with TEN as the core therapy. Additionally, patients on TEN with sP ≥5.5 mg/dL could add low dose PB, and patients on TEN and PBs with sP ≥5.0 mg/dL could reduce PB dose. Participants were monitored for safety and efficacy at weeks 0, 1, 2, 3, 4, 6, 8, and 10. At week 10 or the early termination visit, patients were asked about their experience with their sP management routine during OPTIMIZE compared to before the study. Here we report findings from a selection of questions from the patient experience questionnaires completed by a total of 179 patients in Cohort 1 and 179 in Cohort 2.

Results: When interviewed, 85.1% of patients in Cohort 1 and 83.5% of patients in Cohort 2 reported an improved perception of their sP management routine. Overall,
Decline in Glomerular Filtration Rate in CKD Stages 1 and 2

Apparently Paradoxical Relations of Serum Phosphate and Albumin Variability with Outcomes Are Explained by the Directional Change

Xiaoling Ye,1 Karlien J. ter Meulen,2 Len A. Usyvan,2 Jeroen Kooiman,3 Peter Kotanko,3,4 Franklin W. Maddux,5 Renal Research Institute, New York, NY; 1 Fresenius Medical Care North America, Waltham, MA; 3 Mount Sinai Hospital Mount Sinai Heart, New York, NY; 4 Maastricht Universiteit Medisch Centrum,5 Maastricht, Netherlands.

Background: Evidence indicates that variability of serum phosphate (P) and albumin (Alb) is associated with higher risk of mortality. We aimed to study the variability of P and Alb with all-cause mortality taking into account the interaction with the averaged levels.

Methods: All adult incident HD patients (pts) treated in Fresenius Medical Care NA clinics between 2010 & 2018 were included. Serum P and Alb levels were averaged from month(1) to 6 after HD initiation. Variability of P and Alb were described by standard deviation(SD) and directional changes(DR). All-cause mortality was recorded between mo 7 and 18. Cox proportional hazards models with spline terms were applied to explore the association between variability of P & Alb and all-cause mortality. Additionally, tensor product smoothing splines were computed to study the effect of interactions between averaged values of parameters and their variability with outcomes.

Results: We enrolled 353,142 pts. Averaged P was 4.98 mg/dL, median SD and DR were 0.92 and 1.10. Baseline Alb was 3.61 g/dL, median SD and DR were 0.21 and 0.40. Across different levels of P, higher SD of P were associated with higher risk of mortality, especially in those pts with lower averaged P. Contrasting, in pts with low Alb, higher SD was associated with reduced mortality. Regression analysis showed an unidirectional relation between DR and outcome was observed, whereas the relation between DR with outcomes was bidirectional for P (Fig1&2).

Conclusions: The relationship between P variability and mortality was apparent at all levels of P. In well-nourished pts, higher P variability are associated with increased risk of mortality, which is related to the adverse effects of both an increase and a decline of this parameter. In pts with low Alb, the apparently paradoxical association between higher levels Alb variability and better survival due to an improvement of nutritional and inflammatory status, related to a positive DR. Due to possible nonlinear relations between risk factors and outcomes in patients on HD, variability should ideally be explored by various metrics.

Restrict Dietary Phosphorus to Decrease Proteinuria and Prevent Decline in Glomerular Filtration Rate in CKD Stages 1 and 2

Anita Saxena. Renal Nutrition Group Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: Though dietary phosphorus restriction is therapeutic for disordered phosphorus homeostasis, restriction of dietary phosphorus is not advised in CKD.

Aim: Does early control of dietary phosphorus ameliorates proteinuria, prevent decline in glomerular filtration rate and prevent rise in FGF-23.

Methods: One year longitudinal study on 79 CKD stages 1 and 2 patients. eGFR, serum creatinine, phosphorus, calcium, FGF-23, soluble o-Klotho iPTH FGF 23, blood pressure, were evaluated and compared with 35 controls. 3 days dietary intake was taken using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake: Group 1 (n=42): normal phosphorous intake (<1000mg/day) and Group 2 (n=37): high phosphorous intake (>1000mg/d).

Patients in Group 2 were educated on high and low phosphorus foods and counselled to adopt a plant-based diet, for low phosphorus absorption with directed diet plan. Data were analysed using SPSS.

Results: At baseline there was no significant difference in the GFR (group 1 85.00 vs 91.64 SD 13.22 vs 14.30) and serum creatinine between groups. In group 2; GFR, sKlotho, serum phosphorus and FGF23 correlated significantly with dietary phosphorus intake. In group 2, FGF-23, serum phosphorus, dietary protein and phosphorus intake were significantly higher and sKlotho was significantly lower than group 1. There was significant difference in serum phosphorus (p 0.000), iPTH (p 0.004), FGF23 (p 0.000), Klotho (p 0.000), urinary protein (p 0.000), dietary protein (Group 1 37.57±3.40; Group 248.79±8.66 p 0.000) and phosphorus (Group 1868.96±69.99 mg/d and Group 2 1312.26±137.57 mg/d p 0.000) intake and dietary phosphorus to protein ratio (p 0.000) between groups 1 and 2. On dietary intervention in group 2 FGF increased p 0.012 from 80.93±15.34 to 84.11±15.38, and to 87.43±18.27 ml/min at 6 and 12 months respectively, Urinary protein declined to 220.1±3.39 mg/L. FGF 23 declined from 60.67±6.26 to 58.00±7.07 to 53.29±9.48 pg/mL at 12 months. Dietary phosphorus: protein ratio reduced significantly from 27.16±4.33 to 24.75±4.34 p 0.000 at 12 months (p<0.000). Urinary phosphorus excretion increased from 574.37±214.22 to 624.64±137.67 at 12 months.

Conclusions: Restricting dietary phosphorus in stages 1 and 2 can prevent progression of CKD and for control proteinuria.

Understanding Obesity Management in CKD Patients

Background: Obesity is a global epidemic that is directly and indirectly linked to progression of chronic kidney disease (CKD). Nephrologists’ attitude towards obesity management is not understood.

Methods: We surveyed 14 nephrologists practicing in an academic centre in London, Ontario, Canada to investigate their perception and management of obesity. Then we performed a retrospective chart review of patients in a CKD clinic with obesity (BMI >30kg/m2). Ten follow-up visits were randomly selected for each nephrologist between Jan-Dec 2019. Each chart was assessed for documentation of obesity and a management plan such as lifestyle counselling, pharmacologic intervention, or specialist referral.

Results: There were 13 responses (93%). Responses from a 5-point Likert scale, agree and strongly agree, have been combined. All nephrologists agreed that obesity negatively impacts CKD patients. 92% reported that discussing obesity evokes a negative response and 39% thought patients want to discuss obesity. Interestingly, 0% of nephrologists thought patients know that obesity has effective treatments. 85% of nephrologists talked to their patients about obesity, but 0% felt that they had time to treat it. With regards to management, 54% of nephrologists were comfortable with non-pharmacologic treatment, but only one was comfortable with pharmacologic treatments. 85% of respondents felt that patients should be referred to a specialist. A total of 140 charts were reviewed with a mean age 66 years, weight 105 kg, and BMI 37 kg/m2. Only one chart had obesity as a clinical issue and documented a weight loss discussion using non-pharmacologic strategies.

Conclusions: Our results suggest that obesity is rarely managed despite nephrologists’ desire to treat it. This care gap can be addressed using robust Quality Improvement principles. Our centre will improve obesity management by developing a clinical handbook for nephrologists on how to efficiently address obesity with patients as well as a partnership and streamlined referral process to an obesity specialist.

Changes over Time in DASH Diet Accordance by Racial/Ethnic Groups Among Us Adults

Tasneem Banerjee,1 Charles E. McCulloch,3 Deidra C. Crews,2 Nilka Rios Burrows,2 Alain Koyama,3 Hal Morgenstern,2 Rajiv Saran,2 Neil R. Powe.1 1 University of California San Francisco, San Francisco, CA; 2 Johns Hopkins University, Baltimore, MD; 3 Centers for Disease Control and Prevention, Atlanta, GA; 4 University of Michigan, Ann Arbor, MI.

Background: Recommendations for healthy dietary patterns may vary for individuals with and without CKD. Racial/ethnic disparities in dietary quality exist, yet there is limited understanding of how dietary patterns have changed over years in different racial/ethnic groups. We examined trends in accordance to a Dietary Approaches to Stop Hypertension (DASH) diet by different racial/ethnic groups in adults with and without CKD.
POI1738

Experiences of Participants of a Dietary Intervention Trial for African Americans with Hypertension and CKD

**Background:** African Americans are disproportionately affected by hypertension (HTN) and CKD and evidence suggests dietary modifications towards a more Dietary Approaches to Stop Hypertension (DASH) diet could improve outcomes for this population. We aimed to explicate barriers and facilitators of healthy eating, and the perceived benefits of the intervention among completed participants of a dietary intervention trial for African Americans with HTN and CKD. Participants were randomized to one of two groups: 1) Self-Shopping DASH (S-DASH) diet group with $30/week grocery allowance for 4 mo. but no specific guidance on purchases, followed by no food allowance for 8 mo.; or 2) Coaching DASH (C-DASH) diet advice group with a $30/week food allowance and assistance in purchasing foods for 4 mo., followed by intermittent coaching without food allowance for 8 mo.

**Methods:** We performed a content analysis of transcripts from semi-structured interviews with participants who completed the trial (13 C-DASH; 12 S-DASH were randomly selected). Thematic analyses followed 5 stages: 1) reading and rereading all transcripts and utilizing audio recordings as needed for clarity; 2) three coders reading two of the same transcripts, coding them, and comparing codes which were then used to create the initial coding framework; 3) defining codes, coding additional transcripts, discussing/ revising the coding framework; 4) formulating initial themes and 5) diagramming relationships among initial themes to merge overlapping themes.

**Results:** Participants were a mean age of 62 ± 9.3 years, 36% were male. Key themes included healthy diet facilitators (food tracking, motivation, social support, and perception of healthy foods); barriers (transportation, past eating habits, stress and COVID mitigation); and impacts of the intervention on knowledge and behavior.

**Conclusions:** Participants of a dietary intervention trial for African Americans with HTN and CKD identified several facilitators and barriers to healthy eating that could inform future efforts to address disease burden in this population.

POI1740

Barriers and Facilitators to DASH Diet Adherence Among Black Adults with CKD: A Qualitative Study

Crystal C. Tyson,1 Laura P. Svetkey,1 Isa Granados,1 Danielle L. Kennedy,1 Travia K. Dunbar,1 Pao-Hwa Lin,2 Gary Bennett,3 Cynthia H. Redd,1 L. Ebony Boulware,1 Laura J. Fish,3 Duke University School of Medicine, Durham, NC; 2Duke University, Durham, NC; 3Duke Cancer Institute, Durham, NC.

**Background:** Black individuals are disproportionately burdened by hypertension and chronic kidney disease (CKD). The Dietary Approaches to Stop Hypertension diet (DASH) improves hypertension in Black individuals and is associated with improved CKD outcomes. Yet, adherence to DASH among Black individuals is low. We conducted a qualitative study to assess barriers and facilitators to DASH adherence in Black adults with CKD.

**Methods:** We conducted focus groups and individual interviews with Black adults with CKD stages 3 or 4 (n=22). Questions included perceptions of DASH and DASH, the cultural-centeredness of DASH, and barriers and facilitators to adopting DASH. Qualitative content analysis was used to analyze interview transcripts.

**Results:** Among 22 participants (2 focus groups, 8 individual interviews), 13 (59%) had CKD stage 3, 13 (59%) were female, the median age was 61 years, and 19 (90%) had hypertension. Some participants reported having previously heard of DASH, which they perceived as a healthy diet. Participants perceived DASH as culturally-compatible and the perceived benefits of the intervention among completed participants of a dietary intervention trial for African Americans with HTN and CKD. Participants were randomized to one of two groups: 1) Self-Shopping DASH (S-DASH) diet group with $30/week grocery allowance for 4 mo. but no specific guidance on purchases, followed by no food allowance for 8 mo.; or 2) Coaching DASH (C-DASH) diet advice group with a $30/week food allowance and assistance in purchasing foods for 4 mo., followed by intermittent coaching without food allowance for 8 mo.

**Methods:** We performed a content analysis of transcripts from semi-structured interviews with participants who completed the trial (13 C-DASH; 12 S-DASH were randomly selected). Thematic analyses followed 5 stages: 1) reading and rereading all transcripts and utilizing audio recordings as needed for clarity; 2) three coders reading two of the same transcripts, coding them, and comparing codes which were then used to create the initial coding framework; 3) defining codes, coding additional transcripts, discussing/ revising the coding framework; 4) formulating initial themes and 5) diagramming relationships among initial themes to merge overlapping themes.

**Results:** Participants were a mean age of 62 ± 9.3 years, 36% were male. Key themes included healthy diet facilitators (food tracking, motivation, social support, and perception of healthy foods); barriers (transportation, past eating habits, stress and COVID mitigation); and impacts of the intervention on knowledge and behavior.

**Conclusions:** Participants of a dietary intervention trial for African Americans with HTN and CKD identified several facilitators and barriers to healthy eating that could inform future efforts to address disease burden in this population.

**Funding:** Other NIH Support - NHLBI; NIMHD
purchase healthy food after paying monthly bills. Facilitators included having local access to healthy food, living alone or with supportive household members, and having will power and internal/external motivation for change.

Conclusions: Black adults with CKD were interested in adopting DASH and viewed it as a healthy, culturally-compatible diet. Recognizing that diet in Black adults is not uniform, interventions should emphasize person-centered, rather than culture-centered, approaches that minimize barriers and enhance facilitators to adherence.

PO1741
Priorities for Person-Centered Obesity Management in ESKD

Background: Although obesity is a pervasive kidney transplant barrier, little is known about the social, dietary, and process-of-care challenges to addressing obesity among individuals with ESKD.

Methods: Using purposive sampling we recruited adults with ESKD and obesity (N=40) and ESKD health care professionals (HCPs, N=20) in the United States for semi-structured interviews to elicit perspectives about obesity and barriers and strategies for healthy weight loss. Recorded phone interviews lasting 1.5 hours were transcribed verbatim and analyzed using inductive and deductive thematic analysis.

Results: Median patient age was 55 (interquartile range [IQR] 47.63) years, median dialysis exposure was 5 (IQR 3.10) years, 51% were female, 27% were Black, and median BMI was 37.8 (IQR 33.5, 40.8) kg/m2. HCPs were renal dietitians, nephrologists, and transplant surgeons. Five themes emerged from patient interviews: 1) obesity-related counseling typically limited to immediate goal (transplant BMI requirements); 2) obesity as a life-long disease or linked to trauma; 3) food choices driven by fatigue and poor sleep quality; 4) existing nutrition programs not transferable to ESKD; 5) absence of culturally-effective nutrition counseling. HCP interviews revealed uncertainty about provider roles and responsibilities for addressing obesity and underscored that poverty and low health literacy are barriers to healthy weight loss.

Conclusions: Obesity-related care for people with ESKD is often limited to addressing BMI limits for transplant. Weight loss interventions for people with ESKD and obesity should be tailored with knowledge of social and financial context and a shift in focus from short-term goals to long-term health.

Funding: NIDDK Support

PO1742
Association of Nutritional Data and Glycemic Variability in CKD Patients

Background: Insulin resistance is highly prevalent in chronic kidney disease (CKD) and strongly associated with adverse clinical outcomes. Glycemic variability measured by continuous glucose monitoring (CGM) is a clinical measure of insulin resistance. The association of dietary recalls and healthy eating measures with CGM readings in CKD is unknown.

Methods: We recruited diabetic (n=7) and non-diabetic (n=8) participants with eGFR<60ml/min/1.73m2 and BMI 32.4±6.4kg/m2. Greater dietary added sugar, total carbohydrate, and carbohydrate to fiber ratio was associated with higher average daily blood sugar (P=0.001, P=0.001, and P=0.006, respectively). One-point greater HbA1c score (healthier eating) was inversely associated with average daily blood sugar for fatty acid (-1.09 mg/dL; 95% CI -2.11,-0.07), added sugar (-1.76 mg/dL; CI -3.11,-0.4), vegetable (-2.85 mg/dL; CI -5.5,-0.2), and fruit (-2.63 mg/dL; CI -5.03,-0.22). HEI total score did not show significant association with the CGM readings.

Conclusions: Greater added sugar, saturated fats, and dietary carbohydrate to fiber ratio are strongly associated with greater average daily blood sugar. Sugar, carbohydrates, and saturated fats contribute to glycemic variability. Healthy eating centered on low sugar, low fat, and high vegetable and fruit intake may improve glycemic control in both diabetic and non-diabetic CKD patients.

PO1743
Late Stage 3 CKD Is an Independent Risk Factor for Sarcopenia, but Not Proteinuria
Yong Seon Choi, Jung Nam An, Jwa-kyung Kim, Sung gyun Kim, Young rim Song. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Most epidemiologic studies assessing the relationship between chronic kidney disease (CKD) and sarcopenia have been performed in dialysis patients. This study aimed to evaluate the relationship between estimated glomerular filtration rate (eGFR), proteinuria, and sarcopenia in patients with non-dialysis-dependent CKD.

Methods: A total of 892 outpatients who did not show any rapid changes in renal function were enrolled in this observational cohort study. We measured the muscle mass using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was found in 28.1% of the patients and its prevalence decreased as body mass index (BMI) increased; however, in patients with BMI ≥ 23 kg/m2, the prevalence did not increase with BMI. As eGFR decreased, the lean tissue index and HGS significantly decreased. However, the eGFR did not affect the fat tissue index. The risk of sarcopenia increased approximately 1.6 times in patients with eGFR < 45 mL/min/1.73 m2. However, proteinuria was not associated with sarcopenia. With a decrease in eGFR, the lean muscle mass and muscle strength decreased, and the prevalence of sarcopenia increased.

Conclusions: In patients with late stage 3 CKD, further assessment of body composition and screening for sarcopenia may be needed.

PO1744
Association of Serum Selenium Levels with the Response to Erythropoiesis-Stimulating Agents in Maintenance Hemodialysis Patients

Background: Reduced response to erythropoiesis-stimulating agent (ESA) has been shown to be associated with poor outcomes in maintenance hemodialysis (MHD) patients. Selenium is a trace element that modulates diverse physiological processes, such as immune responses and cardiovascular function. Previous studies also indicate that selenium and selenoproteins are involved in erythropoiesis. However, its role in the control of anemia in chronic kidney disease patients remains unclear. In this study, we determined serum selenium levels in MHD patients and analyzed their association with hemoglobin levels and the doses of ESA.

Results: Participants had a mean age 59±11years, eGFR 35.5±4.6ml/min/1.73m2 and BMI 32.4±6.4kg/m2. Greater dietary added sugar, total carbohydrate, and carbohydrate to fiber ratio was associated with higher average daily blood sugar (P=0.001, P=0.001, and P=0.006, respectively). Each 1-point greater HEI score (healthier eating) was inversely associated with average daily blood sugar for fatty acid (-1.09 mg/dL; 95% CI -2.11,-0.07), added sugar (-1.76 mg/dL; CI -3.11,-0.4), vegetable (-2.85 mg/dL; CI -5.5,-0.2), and fruit (-2.63 mg/dL; CI -5.03,-0.22). HEI total score did not show significant association with the CGM readings.

Conclusions: Greater added sugar, saturated fats, and dietary carbohydrate to fiber ratio are strongly associated with greater average daily blood sugar. Sugar, carbohydrates, and saturated fats contribute to glycemic variability. Healthy eating centered on low sugar, low fat, and high vegetable and fruit intake may improve glycemic control in both diabetic and non-diabetic CKD patients.

Underline represents presenting author.
Methods: The study included 174 patients who received MHD from four dialysis facilities. We obtained data on demographics, laboratory, comorbidities, hemodialysis prescription and medication by medical record abstraction. Concentration of selenium was measured in serum using ICP-MS.

Results: The mean age was 67.2 years, 77% were male, and 44% of patients received dialysis at least for five years. The average serum selenium concentrations in our cohort were 10.7 ± 2.9 µg/dL, and 88 patients (51%) had a selenium levels of less than 10.5 µg/dL (a lower limit of normal serum selenium levels for adult Japanese population). Patient characteristics, including age, sex, BMI, dialysis vintage, and comorbidities were not significantly different between the low selenium (Low) group and normal selenium (Normal) group. However, the percentage of patients receiving ESA tended to be higher in Low group than in Normal group, whereas hemoglobin levels as well as percentage of patients receiving iron therapy were similar between the groups. In a subgroup analysis involving 146 patients who received ESA, we found a significant negative correlation between serum selenium levels and ESA-resistance index (ERI) (r = -0.25, p = 0.002).

Conclusions: Our study indicates that low levels of serum selenium are associated with poor response to ESA. The relationship between selenium and response to ESA in MHD patients merits further evaluation in larger populations.

PO1745
Serum Irisin and Prediction of Cardiovascular Events in Elderly Patients with CKD Stage 3-5
Teresa Del Mastro, Teresa Arcidiacono, Monica Avino, Arianna Bologna, Nadia Edvige Foligno, Federico Persico, Giuseppe Vezzoli. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Irisin is a circulating myokine released from skeletal muscles after physical exercise. Irisin production decreases during the course of chronic kidney disease (CKD) as a potential consequence of sarcopenia and physical inactivity.

Methods: This observational study explored the relationship of serum irisin with cardiovascular outcome in 79 patients with stage 3-5 CKD.

Results: Serum irisin was significantly higher in healthy subjects (n=20) than CKD patients (7.2 vs 3.1±0.9 µg/ml; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/ml) compared with patients at stage 4 and 5 taken together (n=36, 2.8±0.7 µg/ml; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)2D levels (21 ±0.7 pg/ml, p=0.05). Patients in the highest tertile had lower Kaupilla score (10.6±6.9) than patients in the middle (11.8±5.5; p=0.007) and the lowest tertile (6.9±6.8; p=0.043). Twenty patients suffered from cardiovascular events during a 3-year follow-up. A Cox regression model using age, body weight, presence of diabetes mellitus, gender, Kaupilla calcification score, serum values of FGF23 (as logarithm), phosphate, sclerostin, albumin and cholesterol, eGFR and serum irisin tertiles as covariates showed that patients in the highest tertile of serum irisin had a lower cardiovascular risk than patients in the middle tertile (B=2.38, OR 10.8, 95%CI 1.65-58.13; p=0.013) or in the lowest tertile (B=1.61, OR 5, 95%CI 1.09-22.83; p=0.038).

Conclusions: These findings suggest that serum irisin may be a marker of cardiovascular outcome in CKD patients.
Conclusions: High dietary sodium intake is an independent risk factor for albuminuria and this association was highlighted in high Ucot/Ucrea group. The synergistic effects of cigarette smoking and high salt intake might increase the risk of albuminuria.

PO1748
Interplay Between Serum Thyrotropin, Free Thyroxine, and Thyroid Autoantibody Levels and Survival in a Prospective Hemodialysis Cohort
Amy S. You,1 Gregory Brent,2 John J. Sim,3 Yaltizzi Guerrero,4 Sara S. Kalantar,4,5 Rebecca Ahhdoot,6 Yoko Narasaki,6 Matthew D. Nguyen,6 Caspa P. Kovedsy,6 Danh V. Nguyen,6 Kamyar Kalantar-Zadeh,6 Connie Rhee,1 University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 2University of California Los Angeles Los Angeles Biomedical Research Institute, Anyang, Gyeonggi-do, Republic of Korea; 3S.invoke, Inc, Jackson, MS; 4University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 5Kaiser Permanente Southern California, Pasadena, CA; 6University of California Berkeley, Berkeley, CA; 7The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: CKD patients have a high prevalence of hyperthyroidism (elevated serum thyrotropin [TSH]) which has been associated with worse outcome. In patients with altered protein-hormone binding states (uremia, low/high circulating proteins) among whom routine “indirect” free thyroxine (FT4) assays are not as accurate, little is known about the impact of subclinical (high TSH-normal FT4) and overt (high TSH-low FT4) hyperthyroidism and thyroid autoimmune status on hemodialysis (HD) survival.

Methods: In a multicenter prospective cohort of 1117 HD patients from the “Hyperthyroidism, Cardiovascular Health, and Survival (HYCARDHS)” Study, we conducted protocolized TSH, “direct” FT4 by equilibrium dialysis/tandem mass spectrometry (robust FT4 assessment method in altered protein-hormone binding), and anti-thyroid peroxidase antibody (anti-TPO Ab) assays every 6 months from 2011-19. We examined associations of severity of thyroid dysfunction ascertained by TSH gradations (subclinical vs. overt hyperthyroid-range TSH levels) and pairings of TSH+FT4 (subclinical vs. overt hypothyroidism), as well as presence of elevated anti-TPO Abs with mortality using time-varying Cox models.

Results: TSH distributions were higher in those with elevated anti-TPO Abs. In analyses of TSH gradations, elevated TSH was associated with higher mortality (ref. 0.5-<3.0: HRs [95%CI] 1.30 [0.96-1.77] and 1.88 [1.31-2.68] for TSH 3.0-5.0 and >5.0. In analyses of paired TSH+FT4, overt hyperthyroidism was associated with higher mortality (aHR [95%CI] 5.11 [1.23-20.8], while subclinical hypothyroidism trended towards higher mortality (aHR [95%CI] 1.63 [0.98-2.72]). Elevated anti-TPO Abs were not associated with death.

Conclusions: In a prospective cohort of HD patients who underwent rigorous thyroid function assessment, both mild (subclinical) and severe (overt) hypothyroidism were associated with risk of death. Further studies are needed to determine if correction of thyroid status with thyroid hormone replacement therapy improves survival in this population.

Effect of Water Intake and Water Balance on All-Cause and Cardiovascular Mortality Based on a Nationwide Population Study
Seonmi Hwang,1 Yaerim Kim,1 Jeonghwan Lee,2 Jae Yoon Park,3 Kyung Don Yoo,1 Yong Chul Kim,1 Dong Ki Kim,1 Yun So Kim,1 Chun Soo Lim,1 Jung Pyo Lee.1 1Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Seoul National University Seoul Metropolitan Government Borumae Medical Center, Dongjak-gu, Seoul, Republic of Korea; 3Keimyung University, Seoul, South Korea.

Background: We aimed to investigate the relationship between daily water intake and mortality in patients with chronic kidney disease (CKD).

Methods: We conducted a prospective cohort study using data from the Korea National Health and Nutrition Examination Survey (KNHANES). A total of 117,484 participants aged over 19 years with no history of dialysis were included. The study population was categorized into quartiles based on water intake.

Results: The water balance consists of loss of water and intake of water. Healthy people maintain a good physiological water balance in their daily lives. The aim of this study was to investigate whether fluid intake is independently correlated with all-cause mortality among the general US adult population. In addition, we evaluated the relationship between daily water intake and mortality in patients with CKD.

Conclusions: In patients with CKD, higher water intake was associated with reduced mortality. Further research is needed to confirm these findings.

PO1750
Serum Cystatin C-to-Creatinine Ratio Is a Potential Biomarker for Sarcopenia in Patients with Non-Dialysis-Dependent CKD
Illeen Cho,1 Yong Seon Choi,2 Jung Nam An,3 Sung guny Kim,2 Young rim Song,2 Hallym University Sacred Heart Hospital, Anyang, Gyeyonggi-do, Republic of Korea.

Background: Sarcopenia is a prevalent complication in patients with chronic kidney disease (CKD) and linked with quality of life, morbidity and mortality. Sarcopenia is defined as clinical, functional and body compositional parameters, although several candidate biomarkers for this condition have been evaluated. This study aimed to evaluate serum cystatin C to creatinine (C(r)) ratio as a potential biomarker for sarcopenia in patients with non-dialysis-dependent CKD.

Methods: A total of 517 outpatients were enrolled in this observational cohort study. We measured the muscle mass ( lean tissue index, LTI) using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was observed in 25.5% patients. The serum cystatin C(r) ratio was significantly higher in patients with sarcopenia regardless of age, sex, eGFR, and BMI; and showed a positive correlation with age and pulse pressure, but LTI, HGS, hemoglobin, and serum albumin level showed a negative correlation with serum cystatin C(r) ratio. Especially in patients with eGFR > 45 mL/min/1.73 m2, serum cystatin C(r) ratio showed high negative predictive value in predicting sarcopenia (90.5%) and low LTI (90.4%). As the serum cystatin C(r) ratio increased by 1, the prevalence rate of sarcopenia and low LTI increased by about 5.8 times and about 9.9 times ever after adjusting for sex, age, BMI, undergoing dialysis, albumin, Hb, and eGFR. The association between serum cystatin C(r) ratio and sarcopenia was maximized in patients with eGFR less than 30, resulting in an increased prevalence risk of about 22.7 times, and in the case of low LTI, an independent association was found in patients with eGFR less than 45, and among them, a 43.9-fold increase in risk was identified. However, there was also no significant result for low HGS.

Conclusions: Serum cystatin C(r) ratio is inexpensive and easily, quickly, and repeatedly measured; therefore, quick screening and management of sarcopenia will be possible, which will be of great help in the treatment of CKD patients.

PO1751
Prevalence of Inflammation and Associated Healthcare Resource Utilization in Patients with CKD
Rachel Lai,1 Lynda Szczecz,2 Sarah Clayton,1 Lewis Harrison,1 Molly Lowe,1 James Jackson.2 FibroGen Inc, San Francisco, CA; 2Adelphi Group Ltd, Bollington, United Kingdom.

Background: Many patients with chronic kidney disease (CKD) suffer from inflammation, which often increases as CKD progresses. Inflammation is a risk factor for comorbidities and complications, as well as treatments for anemia. Increased inflammation has been associated with reduced red blood cell and erythropoietin production, as well as increased hepcidin levels, which can lead to functional iron deficiency. Because data on the impact of inflammation on healthcare utilization (HCRU) in patients with CKD are limited, we aimed to assess HCRU in these patients.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a point-in-time survey of physicians and their patients with CKD (stage 3-5D) collected in the United States in 2018. Physician and patient reported HCRU-related information, such as the number of healthcare visits, hospitalizations, and tests conducted to diagnose and monitor patients. Inflammation was defined as C-reactive protein ≥4.9 mg/L, ferritin ≥700 ng/mL, or albumin ≤3.6 g/L. Fisher’s exact and t-tests were conducted to assess differences in HCRU between patients with and without inflammation.

Results: There were 22,787 patients with eGFR < 60 mL/min/1.73 m2. The prevalence of inflammation was present in 136/491 (28%) non-dialysis-dependent, and 91/212 (43%) dialysis-dependent patients. HCRU, including the mean number of healthcare visits, tests conducted, and hospitalizations in the last 12 months, number of pills and injections taken per day, and days off work of requiring a carer were greater in patients with inflammation vs those without (all p<0.05; Table 1).

Effects of Home BP-Based Behavioral Guidance on Urinary Albumin Excretion in School Workers with Microalbuminuria—Miyagi Karoshi Prevention Study

Masanori Yumakaka,1 Tomomi Hattori,1 Fumie Kubota-Nakayama,1 Sachiho Konno,1 Nobutaka Inoue,1 Tomohiro Nakamura,2 Atsushi Hozawa,3 Tohoku Rosai Byoin, Sendai, Japan; 2Kobe Rosai Byoin, Kobe, Japan; 3Tohoku Medical Megabank Organization, Sendai, Japan.

Background: Prevention of work-related cardiovascular events, or Karoshi is an important social issue in Japan. This study aimed to examine if home-BP based behavioral guidance is effective to reduce CV event risk in school staffs associated with microalbuminuria, a marker of endothelial damage.

Methods: Subjects were 3868 Miyagi prefectural school workers. Urinary albumin excretion adjusted for creatinine (UAE) and daily sodium intake based on Tanaka method were examined together with usual annual health check-up in 2019. Among them, 169 were diagnosed as having microalbuminuria (30-299.9mg/gCr). Ninety-one subjects agreed to receive the home-BP based health guidance. Guidance was given according to 5 days mean BP levels. UAE was examined at baseline in 2019, and one year after the guidance was given.

Results: Final analysis number was 48 and 43 for guided and non-guided groups. Subjects with menstruation were excluded from analysis. Reduction in UAE did not differ between groups with or without home-BP based behavioral guidance. Our data suggest that notification of microalbuminuria per se have considerable degree of favorable behavioral effects in school workers with microalbuminuria.

Weight Changes Following Diabetes Medication: A Population-Based Study

Bojin Lyu,1 Morgan Grams,2 Lesley A. Inker,3 Alex R. Chang,4 Jung-Jin Shim,3 1University of Wisconsin-Madison, Madison, WI; 2Johns Hopkins Medicine, Baltimore, MD; 3Tifs Medical Center, Boston, MA; 4Geisinger Medicine, Danville, PA; 5Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: The majority of patients with type 2 diabetes are obese, with greater percentages in those with concomitant CKD. Clinical trials suggest that the newer glucose-lowering medications, including sodium-glucose cotransporter-2 inhibitors (SGLT2i) and glucagon-like-peptide-1 receptor antagonists (DPP4i), provide an added benefit of weight loss in people with type 2 diabetes. We evaluated the magnitude of weight change associated with diabetes medication prescription in real-world practice in persons with and without CKD (eGFR <60 vs. ≥60 ml/kg/1.73 m²).

Methods: We identified patients with diabetes who initiated SGLT2i (n=925), GLP1RA (n=1571), and DPP4i (n=2206) between 2015 and 2018 in Geisinger Health System. Outcomes were percent weight change per year among all patients within 1 year after medication initiation and time to first achieving 5% weight loss among patients with obesity/obesity at medication initiation. Inverse probability of treatment weighting (IPTW) based on multinomial propensity scores was used to account for differences in baseline patient characteristics by medication class.

Results: The mean (SD) age of the 6919 patients was 58 (14) years and 3381 (49%) were female. Comparisons with SU, SGLT2i, GLP1RA, and DPP4i were associated with significant weight loss, with stronger associations for SGLT2i and GLP1RA (Table). Similarly, SGLT2i, GLP1RA, and DPP4i users were more likely to achieve 5% weight loss compared with SU (HR [95% CI]: 1.47 [1.28, 1.69] for SGLT2i; HR: 1.55 [1.32,1.82] for GLP1; HR: 1.31 [1.19,1.44] for DPP4i). The associations were consistent across CKD stages.

Conclusions: In patients with and without CKD, SGLT2i and GLP1RA were associated with significant weight loss compared with SU. These results may further motivate uptake of SGLT2i and GLP1RA, two classes of medications with proven renal benefits among patients with overweight or obesity.

Effects of Caloric Restriction and Aerobic Exercise on Circulating Cell-Free Mitochondrial DNA in Patients with Moderate-to-Severe CKD

Javier Jaramillo Morales,1 Berfu Korucu,2 Mindy Pike,1 Sam A. Headley,2 BethAnn Micaronamara,3 Judit St. L. C. R. Tuggle,2 Jonathan Meade,2 Cassianne Robinson-Cohen,2 Talat Alp Ikizler,1 Jorge Gamboa.1 1Vanderbilt University Medical Center, Nashville, TN; 2University of Washington, Seattle, WA; 3University of California Davis, Davis, CA; 4Springfield College, Springfield, MA.

Background: Understanding mechanisms for increased oxidative stress and inflammation in patients with chronic kidney disease (CKD) is vital due to their role in the pathophysiology of this population. Circulating cell-free mitochondrial DNA (ccf-mtDNA) is released to the plasma and believed to promote inflammation by acting as a damaged-associated molecular pattern. Previous studies suggested that in patients with kidney disease, ccf-mtDNA increases and may induce inflammation. Past investigations in patients with CKD have found that aerobic exercise decreases inflammation. We hypothesized that in patients with moderate to severe CKD, aerobic exercise would reduce plasma levels of ccf-mtDNA.

Methods: We performed a post hoc analysis of a multi-center pilot randomized trial of aerobic exercise and caloric restriction (NCT01150851). We measured ccf-mtDNA in plasma at baseline and four months after four interventions (aerobic exercise (EX), caloric restriction (CR), EX + CR, usual activity and usual diet). A multivariable model adjusted for age, race, sex, systolic BP, BMI, diabetes, and eGFR was done.

Results: Of a cohort of 111 participants who were randomized, 99 had baseline ccf-mtDNA levels, and 92 completed the study. The median age was 57 years old, 44% were female, and 92% had diabetes. Plasma ccf-mtDNA median concentrations at baseline, two, and four months were 3.62, 3.08, 2.78 pM for the usual activity group and 2.01, 2.20, 2.67 pM for the aerobic exercise group. There was a 16.1% increase per month in ccf-mtDNA in the aerobic exercise group compared to the usual activity group (p < 0.024), especially with the combination of aerobic exercise and caloric restriction (29.5% increase per month). After four months of intervention, ccf-mtDNA increased in the aerobic exercise group by 81.6% (95% confidence intervals [CI] 8.2-208.4; p = 0.024) compared to the usual activity group, but it was only observed in the aerobic exercise and caloric restriction group (181.7% increase, 95% CI 41.1-462.2; p = 0.003).

Conclusions: Our data suggest that aerobic exercise increases plasma ccf-mtDNA levels in patients with CKD stages 3-4, more profoundly in ones with a combination of caloric restriction.

Physical Activity in Patients Undergoing Dialysis: A Pilot Study

Denghui Guo, William F. Fadel, Alissa A. Cranor, Sharon M. Moe, Keith G. Avant, Ranjan S. Doshi, University School of Medicine, Indianapolis, IN.

Background: Patients on chronic dialysis have impaired physical function and poor quality of life. Slow gait speed and handgrip strength are indicators of increased all-cause mortality and cardiovascular events in dialysis patients. The relationship between physical activity and gait speed is inconsistent in prior studies. "Cadence", a gait characteristic measured as steps/minute by accelerometer is strongly associated with walking speed and physical activity. We hypothesized that cadence will be lower in dialysis patients compared to healthy adults and that cadence will be correlated with their gait speed.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Poster 543
Methods: Physical activity was measured in N=20 subjects incident to dialysis over 7 days using a validated wrist worn tri-axial accelerometer (ActiGraph). The 7 days included dialysis and non-dialysis days. Average daily cadence (steps/sec) was extrapolated from accelerometer data utilizing a published algorithm. Subject demographics were recorded by self-report or from medical records. Gait speed (meter/sec) was measured over 4 meters. Data on cadence from healthy subjects (N=32) were obtained from a prior study.

Results: Of twenty subjects (4 peritoneal dialysis, 16 hemodialysis), no one recorded any vigorous activity in the entire period, while most (59.4%) of their time was spent in sedentary behavior. Median average daily cadence across subjects was 1.38 [IQR = (1.31 – 1.48)] steps/second. Dialysis subjects had lower average daily cadence than healthy subjects (1.38 vs 1.66 steps/second, p = 0.001). When adjusted for age and sex, being “on dialysis” was associated with a 0.24 (95% CI -0.34, -0.14) steps/second lower cadence compared to healthy subjects. For patients on hemodialysis, average daily cadence was not significantly different between HD days and non-HD days, with no significant correlation between 4m speed and cadence (r=−0.28).

Conclusions: In this prospective study, we show that cadence is low in dialysis patients, that dialysis patients are sedentary and cadence does not correlate with gait speed. Thus gait speed alone may not be an accurate representation of intensity of daily physical activity. This pilot study supports the need for detailed studies of gait characteristics in dialysis patients, which will help in the development of personalized exercise and activity programs in patients undergoing dialysis.

PO1756

Physical Activity Scores in Hemodialysis Patients with Thyroid Dysfunction: A Substudy of the NIH THYROID-HD Trial

Yuhei Otoe,1,2 Richard Casaburi,1,3 Harry B. Rossiter,1 Shlomit Radom-Aizik,1 Joel D. Kopple,1,2 Matthew J. Budoff,3 Rachelle Bross,2 Mackenzie K. Cervantes,3 Gregory Brent,1,3 Csaba P. Kovesity,1 Yalitzi Guerrero,1 Yoko Narasaki,1 Amy S. You,1 Danh V. Nguyen,1 Kamyar Kalantar-Zadeh,1 Connie Rhee.3 1University of California Irvine, Irvine, CA; 2The Lundquist Institute, Torrance, CA; 3Harbor-UCLA Medical Center, Torrance, CA; 4University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 5VA Greater Los Angeles Healthcare System, Los Angeles, CA; 6The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: Low physical activity is common in hemodialysis (HD) patients and is associated with adverse outcomes in this population (poor health-related quality of life, cardiovascular [CV] disease, death). Prior studies show that hypothyroidism is highly prevalent in HD patients, and is associated with worse self-reported physical function.

Methods: In a substudy of the ongoing multi-center NIH THYROID-HD Trial, we examined baseline physical activity scores determined by the Human Activity Profile (HAP), a validated 94-item instrument assessing daily activities across a wide range of energy expenditures, in HD patients with TSH levels in the high-normal (TSH >3.5 mIU/L) and subclinical hypothyroid range (TSH >5-10 mIU/L). The HAP was used to derive the Maximum Activity Score (MAS) and Adjusted Activity Score (AAS), representing greatest and mean estimated energy expenditures, respectively (range 0-94, segmented to low [<52], moderate [54-73], and high [>74] scores).

Results: Among 57 HD patients who underwent baseline HAP assessment, the mean±SD MAS and AAS scores were 52±21 and 26±27, respectively; median (IQR) MAS and AAS scores were 52 (40, 68) and 22 (6, 49), respectively. In the overall cohort, 79% had low, 14% moderate, and 7% high AAS scores. MAS scores were lower in patients who were older (≥65 yrs), female, White, Hispanic, of longer (>1 yr) vintage, diabetic, or with underlying CV disease. A similar trend was observed for AAS scores.

Conclusions: In this substudy of the NIH THYROID-HD Trial, HAP scores in HD patients with high-normal and subclinical hypothyroid range TSH levels were lower than observed in prior historical dialysis cohorts that did not have underlying thyroid dysfunction. Further research is needed to determine the impact of thyroid hormone replacement on improving physical activity and function in this population.

**Comparisons of In-Clinic and Free-Living Measures of Physical Function in Predicting Hospitalization in Patients with CKD**

Nikita Abraham,1 Robert E. Boucher,1 Guo Wei,2 Jesse Christensen,2 Sydney E. Hartsell,1 Judy Carle,1 Victoria Gonce,3 Srinivas Beddu,1,2 Kate Lyden.1  
1The University of Utah School of Medicine, Salt Lake City, UT; 2Yale Salt Lake City Health Care System, Salt Lake City, UT; 3University of Massachusetts Amherst, Amherst, MA.

**Background:** Physical function is associated with risk of hospitalization; however, comparisons of in-clinic and free-living measures of physical function and their associations with risk of hospitalization has not been well established.

**Methods:** In this secondary analysis of the Sit Less, Interact, Move More (SLIMM) pilot study, we compared in clinic and free-living measures using accelerometry data. Participants with CKD were randomized to the SLIMM intervention or standard of care and asked to wear a thigh worn accelerometer 7 days before a visit to capture their physical activity. In clinic measures of physical function like 6-minute walk distance were performed during visits. Free-living measures were determined from accelerometry. Free-living 6-minute steps were defined as the number of steps taken during the most active 6-minute period. Free-living measures of physical function were compared to in clinic measures using Cox proportional hazards models adjusted for age, sex, smoking, alcohol use, BMI, diabetes, CKD, hypertension, heart failure, and peripheral vascular disease.

**Results:** 106 participants were randomized, the mean age was 69 ± 12 and 69 ± 14, baseline eGFR was 44 ± 12 and 45 ± 14, and 48% and 37% were female for the standard of care and SLIMM groups respectively. When adjusted for covariates, both in clinic and free-living 6-minute walk distance and steps respectively were associated with hospitalizations (table). In comparisons between in clinic and free-living measures, in clinic measures were not significantly associated with hospitalizations while free-living measures were (table).

**Conclusions:** Both in clinic and free-living measures of physical function were predictors of hospitalization in patients with CKD.

**Blood Pressure Trends in a Cohort of 9- and 10-Year-Old Children in Iceland: A 10-Year Follow-Up Study**

Asdis H. Sigurdardottir,1,2 Olafur S. Indridason,3 Sigurdur S. Stephenson,3 Thordis J. Hrafnkleidsson,1 Vidar O. Edvardsson.1,4 1Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland; 2Children’s Medical Center, Landspitali – The National University Hospital of Iceland, Reykjavik, Iceland; 3Division of Nephrology, Landspitali – The National University Hospital of Iceland, Reykjavik, Iceland; 4Division of Cardiology, Landspitali-The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** Although there is significant evidence for an association between childhood and adult office blood pressure (BP), data on the correlation of childhood BP and ambulatory BP (ABP) in young adults is missing. The aim of this study was to examine the association between childhood office BP and both ABP and office BP indices in a cohort of young adults born preterm and follow-up BP.

**Methods:** Subjects were recruited from a cohort of 970 young adults aged 20-21 years who participated in a population-based study of BP in 9-10-year-old Icelandic school children. All participants underwent a minimum of 4 resting BP measurements at the childhood BP screening. A total of 121 individuals have completed their participation in the follow-up study, which included office and ambulatory BP measurements. Pearson correlation and linear regression analysis were used to examine the relationship between childhood and follow-up BP.

**Results:** A significant positive correlation was observed between childhood mean systolic BP (SBP) and systolic and office BP at follow-up (r=0.386, p<0.001 and r=0.370, p=0.001, respectively). The correlation between childhood mean systolic office BP and follow-up mean systolic office BP was stronger for males (r=0.50, p<0.001 than for females (r=0.298, p=0.012), and the same applied for mean systolic ABP (r=0.491, p<0.001 and r=0.323, p=0.006, respectively). The correlation of mean childhood diastolic office BP and follow-up mean DBP indices at follow-up was insignificant for males (office DBP: r=0.05, p=0.78) and remained significant for females (office DBP: r=0.55, p=0.0026; ABP: r=0.449, p<0.001). In adjusted analysis, childhood mean office SBP significantly associated with mean office SBP at follow-up in both males (beta=0.69, p<0.001) and females (beta=0.26, p=0.001). Each mmHg increment in childhood office SBP predicted an increase of mean ambulatory SBP by 0.52 mmHg (p<0.001), unaffected by sex. Childhood DBP did not significantly predict office or ambulatory BP at follow-up in adjusted analysis.

**Conclusions:** These preliminary results indicate that childhood SBP significantly predicts both systolic office and ambulatory SBP in young adults and these associations are stronger in males.

**Preterm Birth and Its Association with Altered Renal Sodium Handling in Response to Mental Stress in Young Adults**

Nicholas W. Tully, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

**Background:** Early-life programming events such as preterm birth and very low birth weight (VLBW; <1500 g) contribute to later hypertension development, but the underlying mechanisms are unknown. Experimental data suggest that altered pressure natriuresis and renal sodium handling may be important contributing mechanisms. Adults with primary hypertension exhibit blunted pressure natriuresis in response to sympathetic arousal, but this has not been described in adults born preterm. We investigated renal sodium excretion relative to the change in blood pressure (BP) in response to stress in a cohort of young adults born preterm with VLBW. We hypothesized that young adults born preterm will have a blunted pressure natriuresis response to mental stress compared to those born term with normal birth weight.

**Methods:** In this long-term prospective cohort of 161 individuals, 129 (80%) born preterm with VLBW and 32 (20%) term-born controls, we measured spot urine sodium/creatinine before and after a 30-min mental stress test and non-invasive continuous BP every 2 min during the stress test. We defined our outcome, pressure natriuresis, as the change in sodium excretion relative to the change in mean arterial pressure (MAP) and defined our exposure variable as the stress test with a blunted response being < 0 mg/dl per mmHg. We used generalized linear models to estimate the association between prematurity and the outcome.

**Results:** The mean age of study participants was 19.8 (SD 0.9) of whom 56% were females. The absolute change in sodium excretion relative to change in MAP was 0.022 mg/dl per mmHg [90. -0.021, 0.121], while the change in term-born counterparts was 0.04 mg/dl per mmHg [0.005, 0.184]. On unadjusted analyses, the preterm/term difference in pressure natriuresis was 0.068 mg/dl per mmHg [-0.092 to 0.239] and the relative risk of a blunted pressure natriuresis was 1.3 (0.71 to 2.36).

**Conclusions:** We observed no statistically significant difference in pressure natriuresis response in adults born preterm with VLBW when compared to those born term. Ongoing analyses include investigating other measures of pressure natriuresis in adjusted multivariable models.

**The Cardiovascular Risk Analysis According to Different Pediatric Hypertension Guidelines: Data from the Korea National Health and Nutrition Examination Survey, 2016-2018**

Jeong Yeon Kim, Sangshin Park,2 Hyecheon Cho,3 Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; 2University of Seoul, Dongdaemun-gu, Seoul, Republic of Korea.

**Background:** Worldwide pediatric hypertension (HTN) prevalence is increasing. Pediatric HTN predicts adulthood HTN, the modifiable leading factor of cardiovascular disease (CVD). Therefore, pediatric HTN is important for CVD risk prevention. There are two well-known pediatric HTN guidelines, the 2017 American Academy of Pediatrics (AAP) and the 2016 European Society for Hypertension (ESH). Also, Korea Center for Disease Control established the blood pressure (BP) classification in 2008 (K-CDC). There is discordance of HTN prevalence in each BP classification. However, no study evaluated the CVD risk according to each BP criteria in the Korean pediatric population. This study evaluated the difference in prevalence and pediatric CVD risk factors according to each BP criteria.

**Methods:** The data of 2060 children and adolescents aged 10-18 years from the Korea National Health and Nutrition Examination Survey 2016-2018 was reviewed. The BP was classified by AAP, ESH, K-CDC and modified AAP (K-AAP, applying the normal weight Korean children BP reference table in AAP definition). The high BP was defined when BP was above normotension. To analyze the difference in CVD risk, AAP and ESH, K-CDC and K-AAP and K-CDC were compared. In each comparison, those newly defined as high BP are compared to those with consistent normotensive - age, sex, height matched. Finally, the BP criteria reflecting more CVD risk was used to analyze data from Korea School Health Examination Survey 2018.

**Results:** The prevalence of high BP in Korean children and adolescents was generally high in AAP than ESH (19.5% vs 10.6%, p<0.001). However, there were some differences in prevalence according to age, sex and obesity. AAP reflected more CVD risk factors, including obesity and metabolic risk, than ESH. K-AAP well-screened non-obese children with metabolic risk than AAP and children with obesity and metabolic risks than K-CDC. The prevalence of high BP and HTN in Korean school students with K-AAP was 13.7% and 5.1%, respectively.

**Conclusions:** The K-AAP classifies Korean children and adolescent with more CVD risk factors as high BP. Therefore, for early CVD risk control, K-AAP could be used to define pediatric HTN in Korea. Further study is warranted for actual CVD association.
PO1762
Clinical Event Reductions in Hypertension Patients with and Without CKD Treated with Renal Denervation: A Model-Based Estimate Based on Data from the Global SYMPLICITY Registry

Edward Schmieder,1 Felix Mahfoud,2 Bryan Williams,3 Giuseppe Mancia,4 Krzysztof Narkiewicz,5 Luis M. Ruilope,6 Markus Schlaich,7 Michael Böhm,8 Jan B. Pietzch,1 1Universitätsklinikum Erlangen, Erlangen, Germany; 2Universidad de La República, Montevideo, Uruguay; 3Kidney Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; 4Eulji University Hospital in Uijeongbu, Republic of Korea; 5Gdanski Uniwersytet Medyczny, Gdansk, Poland; 6Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina; 7Universität College London, London, United Kingdom; 8Università degli Studi di Milano-Bicocca, Milan, Italy; 9Gdansk University of Technology, Gdansk, Poland; 10Facultad de Ciencias Medicas 10 de Octubre, La Habana, Cuba; 11The University of Western Australia, Perth, WA, Australia; 12Wing Tech, Inc., Menlo Park, CA, USA.

Background: Estimates of clinical event reductions following renal denervation (RDN) were modelled for patients with and without chronic kidney disease (CKD) based on data from the Global SYMPLICITY Registry (GSR). 2) standard well-C (SBP 120-130 and DBP <80 mmHg), 2) standard well-C (SBP <120 and DBP <70), 3) standard well-C (SBP 120-130 and DBP 80-90), and 4) standard well-C (SBP 120-130 and DBP 90-100). The overall incidence rate (IR) for the well-C standard group. The study outcomes were investigated using multivariate Cox-regression analysis after adjusting for clinical variables.

Methods: 1. The study cohort consisted of male, non-smoking individuals, aged 27 ± 11 years. We analysed the renal hemodynamic using steady state input clearance method. Results: Among the 502 participants, the following parameters: RPF (p = 0.006), GFR (p = 0.017), RBF (p = 0.006), RVR (p = 0.02), and APWV (p = 0.005).

Conclusions: Uncontrolled hypertension increased risk for MACCE and all-cause mortality in patients with or without MetS, whereas intensive control of BP also increased risk. Therefore, properly targeting the blood pressure is important to reduce the risk of major clinical outcomes irrespective of the presence of MetS.

PO1764
Vascular Function Indices Are Strong Predictors of the Severity and Characteristics of Carotid Atherosclerosis

Ashutosh M. Shukla,1 Lisa Ly,2 Malca Joyce,1,2 Tatiana Orozco,1 Albania Thara Chung,2 Sudhii M. Shah,3 Mark S. Segal,4 1VA North Florida South Georgia Veterans Health System, Gainesville, FL; 2University of Florida, Gainesville, FL; 3University of Utah Health, Salt Lake City, UT; 4University of Arkansas for Medical Sciences, Little Rock, AR.

Background: Vascular functional indices strongly predict adverse cardiac outcomes in CKD. However, few have examined the link between vascular function and the severity and characteristics of carotid atherosclerosis in CKD. Management of Cardiovascular disease in CKD(McK, NCT03563152) is a randomized controlled study aimed to evaluate the effects of hydroxychloroquine on inflammation, vascular dysfunction and carotid atherosclerosis in Veterans with high-CV risk CKD. Analyzing the baseline parameters of enrollees, we aim to evaluate the predictors of carotid atherosclerosis in CKD patients.

Methods: All randomized participants of Mcck study underwent detailed clinical and laboratory evaluations, including evaluation of carotid atherosclerosis (main atherosclerotic burden and carotid intima-media thickness), vascular function (central aortic pressure (CAP), augmentation index (AI), and aortic pulse wave velocity (APWV) by sphygmocore™ XCEL) and detailed evaluation of carotid atherosclerosis 15 mm above bifurcation (total plaque volume (TPV), lipid-rich necrosis, calcification, fibrous cap, and intraplaque hemorrhage by 3T MRI analyzed with Plaqueview™ software).

Results: Initial 17 randomized participants(age 73±4years, all males, 41% with pre-existing CKD and 88% on statins, with eGFR 40±6ml/min/m², microalbuminuria/creatinine ratio (MCR) 1912±7270mg/gm, hsCRP 10.6±20.6ng/mL, total cholesterol 168±40mg/dL, and LDL/ HDL ratio 2.1±0.7) with full analyzable MRI were included in the analysis. Significant vascular stiffness was evident at baseline with CAP 98.3±12.6 mmHg, Augmentation Index:15.5±7.6 and APWV:9.3±2.4 m/s. Atherosclerotic burden was high, carotid TPV:3.7±1.0cm³ and Normalized Wall Index:71.7±9.4, with necrotic core, calcification, fibrous cap, and intraplaque hemorrhage volumes of 357.6±289, 556.2±478, 153.8±122 and 49.6±78 mm³ respectively. Univariate analysis showed that detailed baseline clinical and laboratory parameters had no significant correlations with TPV or its individual components whereas, vascular functional indices had strong positive correlations with TPV and individual plaque components(p<0.01, especially the CAP), which had among the strongest correlations with lipid-rich necrotic core (p<0.000).

Conclusions: Non-invasively measured central aortic pressure and aortic pulse wave velocity are strong predictors of carotid atherosclerosis and unstable plaques.

PO1765
Relation Between Waist Circumference and Renal Hemodynamics in Healthy Individuals

Agnes Bosch,1 Dennis Kannerkerl,1 Christian Ott,1,2 Robert Pietschker,1 Kristina Stiere,1 Mario Schiffer,1 Roland E. Schmieder,1 1Department of Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Erlangen, Germany; 2Paracelsus Medical School Nuremberg, Nuremberg, Germany.

Background: Abdominal adiposity, measured by waist circumference (WC), is associated with increased mortality in individuals with chronic kidney disease. Little is known about the impact of abdominal obesity on the renal perfusion and function in humans. We analyzed whether abdominal adiposity changes renal hemodynamics in 80 healthy, young, male individuals without cardiovascular (CV) disease.

Methods: We analysed the renal hemodynamic using steady state input clearance method. Results: Among the 502 participants, the following parameters: RPF (p = 0.006), GFR (p = 0.017), RBF (p = 0.006), RVR (p = 0.006), and APWV (p = 0.005).

Conclusions: Non-invasively measured central aortic pressure and aortic pulse wave velocity are strong predictors of carotid atherosclerosis and unstable plaques.

Funding: Veterans Affairs Support
Patients with CKD and Multiple Chronic Conditions Are at Increased Risk of Cardiovascular Events

Background: Major adverse cardiovascular events (MACE) are the leading cause of mortality in chronic kidney disease (CKD). We studied the relationship between the number and type of multiple chronic conditions (MCCs) and the risk of MACE in patients with CKD.

Methods: We retrospectively examined the SAIL database: a cohort consisting of the population of Scotland, UK (2011-2018). Patients were categorised by the number of MCCs additional to CKD: the primary analysis included all MCCs (e.g. asthma, depression), and a secondary analysis excluded cardiometabolic conditions (hypertension, ischaemic heart disease, cerebrovascular disease, heart failure, atrial fibrillation, peripheral vascular disease, diabetes). The outcome was MACE: myocardial infarction, stroke, heart failure hospitalisation. The risk of MACE associated with number of MCCs was calculated using Cox proportional hazards models. Adjustments were made for age, sex, smoking, deprivation, eGFR and cholesterol.

Results: Of the 173,388 patients with CKD, median age was 78 years, 57% were female, 98% were of white ethnicity and median eGFR was 51.8 ± 17.3 mL/min/1.73m². There was a graded rise in the risk of MACE by MCC count (Table 1): 1 condition adjusted hazard ratio (aHR) 1.15 (1.02-1.29), 2 MCCs aHR 1.37 (1.22-1.53), 3 MCCs 1.68 (1.50-1.88), 4+ MCCs 2.61 (2.34-2.92). For non-cardiometabolic conditions, MACE risk was lessened, but the trend persisted: 1 condition aHR 1.16 (1.12-1.20), 2 MCCs aHR 1.30 (1.25-1.35), 3 MCCs 1.43 (1.38-1.49), 4+ MCCs aHR 1.65 (1.59-1.71).

Conclusions: Patients with CKD and MCCs are at high risk of MACE, even when cardiometabolic conditions are excluded. Cardiovascular risk stratification and preventative strategies in patients with CKD should take into account the number and type of other chronic conditions.

POI1776

Framingham Risk Score and ACC/AHA Pooled Cohort Equation for Prediction of Atherosclerotic Cardiovascular Events in CKD

Benjamin Lidgard,1 Leiia R. Zelnick,1 Alan S. Go,2 Kevin D. O'brien,1 Nisha Bansal.1 University of Washington, Seattle, WA; 2Kaiser Permanente Southern California, Pasadena, CA.

Background: The Framingham Risk Score and the ACC/AHA Pooled Cohort Equation are used clinically to identify patients at high risk for atherosclerotic cardiovascular disease (ASCVD). The performance of these equations (alone or with clinically available cardiac biomarkers) is unclear in patients with chronic kidney disease (CKD), particularly at more advanced stages. We tested the discrimination of these risk scores and cardiac biomarkers to predict ASCVD in CKD.

Methods: We studied 1027 participants in the Chronic Renal Insufficiency Cohort without ASCVD who were not taking aspirin or statins. Framingham Risk Score, Pooled Cohort Equation, N-terminal pro-brain type natriuretic peptide (NT-proBNP), and high-sensitivity troponin T (hsTnT) were measured at baseline. Outcomes were the composite of fatal and non-fatal myocardial infarction (MI) and cardiac death, with or without stroke, over 10 years. We estimated internally valid C-indices using a Wald cross validation for each risk score and cardiac risk marker overall, and across categories of eGFR.

Results: Among 1027 participants, the mean age was 52 years, and the mean eGFR was 48 mL/min/1.73 m². The C-index (95% CI) was 0.74 (0.69, 0.79) for the Framingham Risk Score, and 0.72 (0.67, 0.78) for the Pooled Cohort Equation. Both risk scores had better discrimination for predicting ASCVD at eGFR >60 mL/min/1.73 m² compared with lower eGFR. HsTnT had comparable discrimination to both risk scores overall. HsTnT alone had comparable discrimination across the spectrum of CKD severity (difference in C-index for lowest vs highest eGFR category for ASCVD 0.04-0.05, 95% CI -0.21, 0.14) (Table).

Conclusions: The Framingham Risk Score and Pooled Cohort Equation had moderate discrimination for prediction of ASCVD in CKD and performed better at eGFRs >60 versus <60 mL/min/1.73 m². HsTnT alone had discrimination comparable to each risk score overall, and comparable discrimination across the spectrum of CKD severity.

Further work is needed to develop novel risk scores including cardiac biomarkers specifically for use in CKD.

Funding: NIDDK Support

POI1768

Nondipping Heart Rate in Patients with CKD

Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.

Background: A decrease in the nocturnal heart rate (HR) decline, nondipping HR (NHR), was reported to be 14% in the general population and related to cardiovascular events and all-cause mortality; however, the clinicopathologic features of chronic kidney disease (CKD) patients with NHR is still unclear. Previous studies have reported that interstitial and/or tubular atrophy (IT/A) was significantly associated with both daytime and nighttime hypertension observed with ambulatory blood pressure monitoring (ABPM). We aimed to investigate the clinicopathologic findings associated with NHR status in patients with CKD.

Methods: We retrospectively identified 135 subjects who underwent ABPM and kidney biopsy simultaneously at our institution, from 2016 to 2019. We excluded patients with age <20 years, end-stage kidney disease, less than 5 glomeruli in the kidney biopsy, and patients taking β-blockers. NHR status was defined as (daytime HR − nighttime HR) / daytime HR > 0.1. The percentage of global glomerulosclerosis (GS%), IT/A, and the severity of arteriosclerosis were scored semi-quantitatively according to the Mayo Clinic/Renal Pathology Society Chronicity Score (CS).

Background: Decrease in the nocturnal heart rate (HR) decline, nondipping HR (NHR), was reported to be 14% in the general population and related to cardiovascular events and all-cause mortality; however, the clinicopathologic features of chronic kidney disease (CKD) patients with NHR is still unclear. Previous studies have reported that interstitial and/or tubular atrophy (IT/A) was significantly associated with both daytime and nighttime hypertension observed with ambulatory blood pressure monitoring (ABPM). We aimed to investigate the clinicopathologic findings associated with NHR status in patients with CKD.

Results: The median age was 51 years [interquartile range: 35–63], 54.0% of which were male, and the median eGFR was 53.0 [30.0–75.0] mL/min/1.73m². NHR status was found in 39 out of 135 patients (28.9%). Patients with NHR were older and had worse renal function, higher blood pressure, lower hemoglobin level, and a larger amount of urinary protein excretion than patients with dipping HR. In terms of histopathological parameters, patients with NHR had more severe GS%, IT/A, and arteriosclerosis, and a secondary analysis excluded cardiometabolic conditions (hypertension, ischaemic heart disease, cerebrovascular disease, heart failure, atrial fibrillation, peripheral vascular disease, diabetes). The outcome was MACE: myocardial infarction, stroke, heart failure hospitalisation. The risk of MACE associated with number of MCCs was calculated using Cox proportional hazards models. Adjustments were made for age, sex, smoking, deprivation, eGFR and cholesterol.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Results: Of the 173,388 patients with CKD, median age was 78 years, 57% were female, 98% were of white ethnicity and median eGFR was 51.8 ± 17.3 mL/min/1.73m². There was a graded rise in the risk of MACE by MCC count (Figure 1): 1 condition adjusted hazard ratio (aHR) 1.15 (1.02-1.29), 2 MCCs aHR 1.37 (1.22-1.53), 3 MCCs 1.68 (1.50-1.88), 4+ MCCs 2.61 (2.34-2.92). For non-cardiometabolic conditions, MACE risk was lessened, but the trend persisted: 1 condition aHR 1.16 (1.12-1.20), 2 MCCs aHR 1.30 (1.25-1.35), 3 MCCs 1.43 (1.38-1.49), 4+ MCCs aHR 1.65 (1.59-1.71).

Conclusions: Patients with CKD and MCCs are at high risk of MACE, even when cardiometabolic conditions are excluded. Cardiovascular risk stratification and preventative strategies in patients with CKD should take into account the number and type of other chronic conditions.

Turning the Page on Page Kidney with Dual RAAS Blockade
William J. AssantZA,1 Jennifer GriffithsA,1 Aromma KapoorA,1 1Westchester Medical Center Health Network, Valhalla, NY; 2New York Medical College, Valhalla, NY.

Introduction: Page kidney is a rare form of secondary hypertension from activation of the renin-angiotensin-aldosterone (RAAS) axis by compression of renal parenchyma. It can occur with blunt abdominal trauma/procedures, but it can occur spontaneously. Initial treatment is an ACE inhibitor (ACE) or angiotensin receptor blocker (ARB). Surgical intervention is necessary if more conservative measures fail. Procedures carry their own inherent risk for morbidity and mortality, particularly in the setting of uncontrolled hypertension. This report details the case of a patient with Page kidney responsive to an unconventional conservative management approach: dual RAAS blockade with ACE + ARB for a lack of response to other agents.

Case Description: The patient is a 55M with a history of end stage renal disease (ESRD) on hemodialysis (HD), atrial fibrillation, and type 2 diabetes mellitus admitted for anemia. The patient was dyspneic and weak with right flank pain. He denied hematemesis, melena, or hematuria. Hemoglobin on admission was 4.7 g/dL with INR of 4.8 (on Coumadin for atrial fibrillation). Vitals were normal except a fever to 38.4°C. A CT scan of the abdomen showed a 16.5cm right retroperitoneal hematoma adjacent to the right kidney with anterior dislocation of the kidney. A CT angiogram showed active extravasation within the hematoma. Coumadin was held and a dose of Vitamin K and two units of blood were given. The patient underwent arterial embolization. Hemoglobin was stable thereafter. The patient soon developed hypertensive urgency with blood pressure reaching 190/100 mmHg. The patient’s only home medication for blood pressure was Carvedilol. Lisinopril 20mg PO daily was added and increased to maximum dosage, only partially relieving the hypertension. Losartan was added and uptitrated to 100mg PO daily. The patient’s blood pressure normalized with average in 120s systolic by discharge. The patient was continued on this regimen as an outpatient. No hyperkalemia or hematemesis, melena, or hematuria. Hemoglobin on admission was 4.7 g/dL with INR of 4.8 (on Coumadin for atrial fibrillation). Vitals were normal except a fever to 38.4°C. A CT scan of the abdomen showed a 16.5cm right retroperitoneal hematoma adjacent to the right kidney with anterior dislocation of the kidney. A CT angiogram showed active extravasation within the hematoma. Coumadin was held and a dose of Vitamin K and two units of blood were given. The patient underwent arterial embolization. Hemoglobin was stable thereafter. The patient soon developed hypertensive urgency with blood pressure reaching 190/100 mmHg. The patient’s only home medication for blood pressure was Carvedilol. Lisinopril 20mg PO daily was added and increased to maximum dosage, only partially relieving the hypertension. Losartan was added and uptitrated to 100mg PO daily. The patient’s blood pressure normalized with average in 120s systolic by discharge. The patient was continued on this regimen as an outpatient. No hyperkalemia was observed.

Discussion: Page kidney is a rare but serious form of secondary hypertension from RAAS activation from renal parenchymal compression. Historically, a trial of either an ACE or ARB is indicated, with refractory cases being managed surgically. In this case, dual RAAS blockade was required for blood pressure control, which allowed surgical interventions, and their associated risk of morbidity and mortality, to be avoided.

ESRD Risk Predicting Using Cumulative Hypertension Burden
Chang Seoon Kim A,1 Hong sang Choi A,1 Eun Hui Bae A,1 Seong Kwon Ma A,1 Soo Wan Kang A,1,2 1Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea; 2Chonnam National University Medical School, Gwangju, Republic of Korea.

Background: Hypertension is the leading risk factor for end-stage renal disease (ESRD). However, the association between sustained exposure of increased blood pressure (BP) and ESRD is not well-established. This study investigated whether the hypertension burden over a certain period for predicting the risk of ESRD from a large population-based cohort.

Methods: We retrospectively analyzed data from VHA including Veterans with ≥1 office BP measurements between January 2016 and December 2017. If more than one BP value was available, we used the lowest of the day. Prevalent hypertension was defined as diagnostic codes related to hypertension, prescribed anti-hypertensive drugs, or based on office BP values. We then evaluated the clinical variables associated with uncontrolled BP (mean BP ≥130/90 mmHg) via multivariable logistic regression with risk estimates expressed as relative risk.

Results: Of the 1,959,337 Veterans eligible for inclusion in the analysis, we found that 1,394,230 (71%) and 1,594,093 (81%) met the hypertension diagnosis criteria including ≥140/90 and ≥130/90 mmHg, respectively. Among those who met the diagnosis hypertension criteria including BP ≥140/90 mmHg (n=1,394,230), 34% (n=538,947) had controlled BP (mean BP <130/90 mmHg) and 66% (n=1,054,993) had uncontrolled BP (mean BP ≥130/90 mmHg). Older age, Black race, obesity, kidney disease, and prior cardiovascular disease (CVD) were associated with increased risk of uncontrolled hypertension (Table 1).

Conclusions: Applying the new 130/90 cut-off to the definition of hypertension increased the prevalence of hypertension by 10% in VHA. Among those with hypertension, 66% of Veterans did not meet the new BP goal of <130/90 mmHg. In addition, our findings indicate the need for targeted interventions in high-risk individuals such as Veterans with obesity, kidney disease, CVD, or of Black race.

Additional information: This study underlines the usefulness of a new assessment of the hypertension burden over a certain period for predicting the risk of ESRD from a large population-based cohort.
Disparities in hypertension control persist among older adults. The proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group. Interaction term of sex*age group (<65 years, >65 years) was significant (P < 0.001) so adjusted odds of uncontrolled hypertension were calculated by sex and by age group. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects. Results: Mean age of patients with hypertension was 64.8 ± 12.7 years; 56.3% were female, 66.6% were White, 21.4% were Black and 11.0% were of Hispanic ethnicity. Among the 5973 (27.3%) with uncontrolled hypertension, 54.7% were female; mean age was 56.2 ± 12.9 years. Adjusted odds of uncontrolled hypertension was significantly higher among women vs. men age 66-75 years (OR 1.33; 95% CI 1.30, 2.28) and age 76+ years (OR 1.73; 95% CI 1.31, 2.28) vs. age 65 years. Figure 1 shows the adjusted proportion of patients with uncontrolled hypertension by sex and by age group. Conclusions: Despite implementation of a hypertension improvement program, sex disparities in hypertension control persist among older adults.

Background: Age-dependent sex differences in hypertension control have been demonstrated in multiple populations. Four large primary care (PC) practices at Loyola adopted the Target:BP hypertension improvement program in 2018; hypertension control rates increased after adoption. Our study evaluated the impact of the Target:BP program on hypertension control by sex and by age group. Methods: Analysis used data from 21,864 patients age ≥ 18 years with a hypertension diagnosis and ≥ one outpatient visit in 2019 to a PC clinic enrolled in Target:BP program. Uncontrolled hypertension was defined as blood pressure ≥140/90 mmHg based on last visit. Mixed effects models were used to calculate adjusted odds of uncontrolled hypertension after adjustment for demographics and co-morbidities. Interaction term of sex*age group (<65 years, >65 years) was significant (P < 0.001) so adjusted odds of uncontrolled hypertension were calculated by sex and by age group. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects. Results: Mean age of patients with hypertension was 64.8 ± 12.7 years; 56.3% were female, 66.6% were White, 21.4% were Black and 11.0% were of Hispanic ethnicity. Among the 5973 (27.3%) with uncontrolled hypertension, 54.7% were female; mean age was 56.2 ± 12.9 years. Adjusted odds of uncontrolled hypertension was significantly higher among women vs. men age 66-75 years (OR 1.33; 95% CI 1.30, 2.28) and age 76+ years (OR 1.73; 95% CI 1.31, 2.28) vs. age 65 years. Figure 1 shows the adjusted proportion of patients with uncontrolled hypertension by sex and by age group. Conclusions: Despite implementation of a hypertension improvement program, sex disparities in hypertension control persist among older adults.

Background: High potassium intake is associated with lower blood pressure and lower risk of cardiovascular disease. Whether these associations differ between men and women and whether they depend on daily sodium intake is unknown. Methods: We performed an analysis in 11,267 men and 13,696 women from the Epic-Norfolk cohort. Daily sodium and potassium consumption was estimated from sodium and potassium concentration in spot urine samples by using the Kawasaki formula. Linear and Cox regression were used to explore the association between potassium intake, systolic blood pressure and cardiovascular events (defined as hospitalization or death due to cardiovascular disease). Results: After adjustment for confounders, interaction between potassium intake and sex was significantly associated with systolic blood pressure (p = 0.001) and cardiovascular events (p = 0.035). In women, but not in men, the inverse slope between potassium intake and systolic blood pressure was steeper in those within the highest quintile compared to the lowest quintile of sodium intake (p = 0.001 for interaction). In women within the highest quintile of sodium intake, every 1-gram increase in potassium intake was associated with a 2.9 mmHg lower systolic blood pressure. These associations were paralleled with lower hazards of cardiovascular disease (highest vs. lowest potassium intake quintile: HR 0.89, 95% CI 0.83-0.95). Conversely, in men, the inverse association between potassium intake and cardiovascular disease was not statistically significant (highest vs. lowest potassium intake quintile: HR 0.94, 95% CI 0.88-1.01). Conclusions: We demonstrate that the association between potassium intake and both systolic blood pressure and cardiovascular disease is sex-specific. Our data suggests that particularly women may benefit most from a high potassium intake.

Tryptophan Metabolites Associate with Subclinical and Incident Cardiovascular Disease in CKD
Trista M. Benitez, Elizabeth Vanderwoude, Yun Han, Jaeman Byun, Vetalise K. Cheofor, Brenda W. Gillespie, Rajiv Saran, Anna V. Mathew. University of Michigan, Ann Arbor, MI.

Background: Inflammation and oxidative stress contribute to the increased cardiovascular disease (CVD) burden in CKD patients. Altered tryptophan catabolism via the kynurenine pathway associates with CVD, but the ability of these specific metabolites to act as biomarkers of CVD risk in CKD warrants further research.

Methods: We measured tryptophan metabolites using targeted mass spectrometry in moderate to severe CKD patients (n=325; median follow-up 3 years). Vascular calcification at the coronary artery and aorta was measured using a 4-slice LightSpeed QXI and reported as Agatston scores. Incident CVD events included myocardial infarction, coronary revascularization procedures, stroke, transient ischemic attack, new-onset heart failure, sudden cardiac death, and peripheral vascular disease requiring revascularization or amputation. Multiple linear regression and Cox proportional hazard analyses assessed the relationship of tryptophan metabolites to subclinical markers of CVD and CVD events.

Results: We found that lower baseline tryptophan levels predicted increased aortic calcification in a fully adjusted model controlling for demographics, CVD history, traditional risk factors, renal function, CRP, and serum albumin (p=0.006). Higher baseline levels of anthranilic acid and hydroxyanthranilic acid predicted increased coronary calcification and higher total Agatston score, respectively, in the fully adjusted model (p=1.56, p=0.02 respectively). One unit decrease in serum tryptophan at baseline is associated with 70% decrease in time to incident CVD event when adjusting for demographics, CVD history, risk factors, and renal function (HR: 0.31, p = 0.04). Increased anthranilic acid and quinolinic acid independently reduced time to incident CVD event (HR: 1.88, p=0.02; HR: 1.31, p=0.02 respectively), but were not significant in the fully adjusted model.

Conclusions: Lower tryptophan levels are associated with increased aortic calcification and decreased time to incident CVD events. Higher levels of anthranilic acid, hydroxyanthranilic acid, and quinolinic acid are associated with subclinical CVD. Together, these data demonstrate that catalysis of kynurenine pathway via the kynurenine pathway is associated with subclinical CVD and predicts cardiovascular events in CKD.

High Level of Uromodulin Increases the Risk of Hypertension: A Mendelian Randomization Study
Ruilian You,1 Lanlan Chen,2 Lubin Xu,3 Haitao Li,4 Xiaoxiao Shi,1 Yali Zheng,1 Limeng Chen.1 1Peking Union Medical College Hospital, Dongcheng-qu, China; 2Jilin University, Changchun, China; 3Ningxia Medical University, Yinchuan, China.

Background: The association of uromodulin and hypertension was clinically observed, but not proved as a causal relationship. We conducted a two-sample Mendelian randomization (MR) analysis to investigate the causal relationship between uromodulin and blood pressure based on the public datasets.

Methods: We selected two SNPs for the uUMOD exposure from the Genome-Wide Association Studies (GWAS) meta-analysis study(N=10884) and sixteen SNPs for uUMOD based on the open studies in Pubmed(N=4147). Six summary level studies based on the UKBiobank and ICBP served as outcomes with the sample of hypertension is 46188, a total sample size of SBP is 1194020, and the DBP is 1194025. We used the inverse variance weighted (IVW) method to combine each SNP’s effect. Three methods (IVW, MR-Egger, and Weighted median) were used to access the causal effect of serum uromodulin(uUMOD) on blood pressure. We also adopted Cochran’s Q statistic to test the heterogeneity and MR-PRESSO to confirm the horizontal pleiotropy.

Results: MR analysis of the IVW method shows uromodulin could elevate blood pressure and enhance the risk of hypertension. Odds Ratios(OR) of the uUMOD to hypertension (ukb-b-14057 and ukb-b-14117) is 1.0495% (95% Confidence Interval (CI), 1.03-1.04), while in sUMOD is 1.0195% (95% CI 1.01-1.02). Both sUMOD and uUMOD can predict the elevation of the SBP and DBP. The effect sizes of the UMOD to SBP are 1.100 and 0.028 in ieu-b-39 and ukb-b-20175 respectively. The causal relationship between uUMOD and DBP of the ieu-b-39 is 0.88g(p-value=4.3E-06) and 0.05 of the ukb-b-79292 (p-value=2.13E-10). The β coefficient of sUMOD IVW in ieu-b-38 is 0.371 and 0.011 in ukb-b-20175. For DBP in ieu-b-39 are β=0.315 (SE=0.050) and β=0.018 (SE=0.035) in ukb-b-7992.

Conclusions: Our results solidly indicated that high urinary and serum uromodulin level is a causal risk factor for hypertension.

Follistatin Is a Potential Novel Therapeutic Agent for Essential Hypertension
Ann Kuganathan, Marcos S. Leal, Chao Lu, Bo Gao, Jeffrey G. Dickhout, Joan C. Krepsinsky. McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.

Background: Follistatin (FST) is an inhibitor of several members of the profibrotic TGFβ superfamily. It is highly effective at neutralizing activins, without activity against TGFβ itself. Activins are known to induce inflammation, oxidative stress and fibrosis, all of which contribute to the vascular dysfunction characteristic of hypertension (HTN). We previously showed that FST inhibits kidney fibrosis, improves kidney function and lowers blood pressure (BP) in a hypertension chronic kidney disease mouse model. While this is a model of secondary HTN, here we seek to analyze the efficacy of FST in improving BP and vascular structure and function in a model of essential HTN.

Methods: Telemeters were implanted in the abdominal aorta of spontaneously hypertensive rats (SHR), a model of essential HTN, and normotensive control Wistar Kyoto (WKY) rats for wireless BP monitoring. Rats were treated with 0.075mg/kg FST or vehicle IP every other day from 12-20 weeks of age (8 weeks). BP was recorded weekly. First branch mesenteric arteries were harvested for analysis of vascular function using myography, assessed for oxidative stress by DHE, or formalin fixed for IHC.

Results: By the end of the study, FST significantly lowered both systolic and diastolic BP in SHRs (200 ±9.9 over 132 ±4.3 mmHg in control and 189 ±2.2 over 123 ±2.2 mmHg in FST-treated SHRs, P < 0.04 and P < 0.03 respectively). SHR vessels showed increased contractility with the a1 adrenergic agonist phenylephrine, which was attenuated by FST. Post-hoc analyses demonstrated a decrease in myogenic-dependent relaxation in SHR vessels was also improved by FST. Structurally, FST-treated vessels had less collagen deposition, assessed by Trichrome, which was accompanied by a reduction in medial thickness. Increased oxidative stress seen in SHR vessels was inhibited by FST.

Conclusions: FST lowers BP in SHR with established HTN, at least in part by reducing vascular oxidative stress and medial thickening. This manifests as improved vascular function, with decreased hypersensitivity to contractile agents and improved endothelial function. Future work will identify the effects of FST on inflammation, and the role of specific activins in essential HTN.

Age and Sex Disparities in Hypertension Treatment Inertia After Implementation of Target: BP
Olivea Myers,1 Talar Markossian,1 Beatrice D. Probst,2 Katherine Habich,2 Holly J. Kramer.1 Loyola University Chicago, Chicago, IL; 2Loyola University Health System, Maywood, IL.

Background: Blood pressure (BP) control decreases with advancing age among women but not men, but reasons for sex disparities remain uncertain. Our institution enrolled four large outpatient primary care clinics in the Target:BP hypertension improvement program in 2018. This hypertension improvement program included audit and feedback of physician prescribing practices of BP lowering medications. We examined the adjusted association of medication escalation, a measure of treatment inertia, with age group among adults with uncontrolled hypertension and determined whether this association is modified by sex. We hypothesized that medication escalation for BP control differs by age group and by sex.

Methods: Adults age 18 years with uncontrolled hypertension (BP ≥ 140/90 mmHg at last visit) receiving primary care at a clinic enrolled in Target:BP and a 1 primary care visit during 2019 were included. Medication escalation was defined as a change in BP lowering medication class or dose during a visit when hypertension was uncontrolled. Mixed effects models were used to calculate adjusted odds of medication escalation by age group (≤ 65, 66-75, ≥ 76 years) after adjustment for demographics and co-morbidities. Interaction term of sex by age group was then fitted in fully adjusted mixed effects models and was significant (P < 0.001). Adjusted odds of medication escalation were then calculated by sex and by age group and adjusted prevalence of medication escalation by age group and by sex was calculated using marginal effects.

Results: Mean age of 5973 adults with uncontrolled hypertension was 65.2 (SD 5.2) years; 54.7% were women; 64.7% were White, 24.0% were Black and 9.9% were Hispanic ethnicity. Figure (left panel) shows that adjusted prevalence of medication escalation declined with advancing age group among men and women combined. Right panel shows the decline in medication escalation with advancing age group differed by sex until age 76+ years.

Conclusions: Medication escalation for uncontrolled hypertension declines with advancing age and this age associated treatment inertia differs by sex.

Oscillometric vs. Auscultatory Blood Pressure Measurements and the Impact of Atrial Fibrillation
Ahmed Abrahama, Christopher B. McFadden. Cooper University Health Care, Camden, NJ.

Background: The Hypertension literature recognizes a difference in Oscillometric Blood pressures compared to Auscultatory Blood pressure measurements. These differences are small but increased in patients with Atrial fibrillation. This difference varies in previous studies. Again this Difference is larger in subjects with atrial fibrillation. Current Blood pressure measurement guidelines emphasize the use of an Auscultatory method or repeated oscillometric measures to measure blood pressure in patient with arrhythmias including atrial fibrillation. This recommendation is not consistently implemented in clinical medicine. We aim to quantify the differences in blood pressure readings between oscillometric and auscultatory method and correlate that to presence or absence of atrial fibrillation.

Methods: This is a retrospective study that involved adult patients seen in the outpatient nephrology clinic by one of the investigators (CM) between January 2016 and January 2020. Data collection included age, sex, BMI, atrial fibrillation (AF), CKD stage, diabetes mellitus, blood pressure readings (by both methods, which were done by the investigator (CM) in all antihypertensive patients) and number of blood pressure medications. Information on a total of 200 patients were collected. 100 of those had hypertension with AF while the other 100 had hypertension but no AF to achieve a power of 80% and P value of 0.05.

Results: After using Unpaired t test, the average difference between two methods in hypertensive patients with atrial fibrillation was 0.9±1.29 mmHg in systolic blood pressure (P value of 0.9 and 95% CI from -5.5 to 6.12) and 5.39 mmHg in diastolic blood pressure (P value of 0.0068 and 95% CI from 1.5 to 9.24). On the other hand, the average difference between two methods in hypertensive patients with atrial fibrillation were 6.8 mmHg in systolic blood pressure (P value of 0.018 and 95% CI from 1.18 to 12.5) and 5.04 mmHg in diastolic blood pressure (P value of 0.002 and 95% CI from 1.87 to 8.21).

Conclusions: This study showed a statistical difference between the two methods in measuring the blood pressure of hypertensive patients with atrial fibrillation. A larger study is needed to show no difference between the two methods. For now we need to encourage the use of auscultatory method in measuring the Blood pressure in this group of patients.

PO1781
Single-Nephron Salt Excretion and Nighttime Hypertension: A Cross-Sectional Study in Patients with IgA Nephropathy
Nobu Tsuibo, Hirokazu Marumoto, Kotaro Harahara, Takaya Sasaki, Yusuke Okabayashi, Go Kanzaki, Kentaro Koike, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan, Tokyo, Japan.

Background: Abnormalities in diurnal blood pressure variability and renal salt handling may contribute to poor disease outcomes in patients with IgA nephropathy (IgAN). This study examined the relationships between diurnal blood pressure variability and single-nephron urinary salt excretion (SNUSE) in IgAN patients.

Methods: The subjects were IgAN patients who underwent ambulatory blood pressure (ABP) monitoring and 24-h urine collection during hospitalization for a diagnostic biopsy. In all patients, dietary salt intake was restricted to 6 g/day during hospitalization. Daytime and nighttime hypertension were defined as daytime ABP ≥ 135/85 mmHg and nighttime ABP ≥120/70 mmHg, respectively. The total nephron number per kidney was estimated by a combined cortical volume assessment of unenhanced computed tomography images and stereology-based measurements of non-sclerotic glomerular density in a biopsy. SNUSE was calculated by dividing urinary salt excretion per day by the total nephron number of both kidneys.

Results: Among the 112 patients (42 years old, 63.4% male, estimated glomerular filtration rate [GFR] 62.4 mL/min/1.73 m²) included, daytime and nighttime hypertension were noted in 33.0% and 50.9%, respectively. There was no marked difference in the total nephron number or SNUSE in relation to the daytime hypertension. In patients with nighttime hypertension, the total nephron number per kidney was lower (490,000 vs. 796,000/kidney, p = 0.01) and SNUSE was higher (6.53 vs. 4.22 µg/day, p =0.003) than in normotensive patients during nighttime. An increase in SNUSE in patients with nighttime hypertension was associated with advanced tubulointerstitial injury, defined as a T score in the Oxford histopathological classification of IgAN. The single-nephron GFR was comparable among groups with and without hypertension both during the daytime and nighttime and was not associated with a T score.

Conclusions: These results provide evidence that salt excretion per nephron is increased in IgAN patients presenting with nighttime hypertension. The difference in SNUSE was identified in relation to the tubulointerstitial injury without producing a difference in single-nephron GFR values among ABP categories, indicating compensatory changes in tubular salt handling at the single-nephron level.

PO1782
Small Changes in eGFR Are Associated with Different Patterns of 24-Hour Ambulatory Blood Pressure Monitoring in the General Population
Sang Youn Han, Sanggyoon Yoon, Seung Ku Lee, Chol Shin. Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

Background: Alteration of circadian blood pressure (BP) rhythm such as non-dipper and reverse dipper pattern is associated with cardiovascular diseases and chronic kidney disease (CKD). However, most studies did not control for kidney function even though kidney function is an important risk factor. In this study, we tried to show 24-h ambulatory blood pressure monitoring (ABPM) patterns based on an eGFR in patients without CKD.

Methods: This study was a cross-sectional study from the data of the Korean Genome and Epidemiology Study, which is ongoing prospective cohort study. A total of 1733 participants (60.0±7.0 years, 938 women) who had an eGFR > 60 ml/min/1.73m² were included. Dipping status was stratified as reverse dipper (≥40%), non-dipper (0% to <40%), and dipper (≥10%) based on the night to day ratio of mean BP. They were divided into 4 groups based on quartile of an eGFR (Q4, 128.6-101.6; Q3, 101.5-95.7; Q2, 95.6-87.4; Q1, 87.3-60.5).

Results: The proportion of dipper was progressively decreased from the highest to the lowest eGFR whereas that of reverse dipper and non-dipper significantly increased. (P<0.001). We analyzed the data using logistic regression model in relation to dipper, non- dipper, reverse dipper, and non-dipper plus reverse dipper according to the quartiles of an eGFR. The highest quartile group (Q4) was fixed as the reference. In univariate analyses, Q1 and Q2 groups were significantly associated with increasing odds ratio (OR) with increased reverse dipper, non-dipper plus reverse dipper. After full-adjustment with age, sex, hypertension, diabetes, body mass index, smoking status, exercise, and alcohol consumption, the lowest eGFR group was significantly associated with reverse dippers and non-dipper plus reverse dippers compared to the highest eGFR group (OR=1.689, 95% CI, 1.005-2.840; OR=1.427, 95% CI, 1.027-1.895, respectively). The significant linear trend of non-dipper plus reverse dipper with a decrease in eGFR was confirmed with the test for trend (P=0.024).

Conclusions: Small changes in eGFR are associated with different pattern of 24-h Ambulatory blood pressure in general population. ABPM could be useful tool to detect patients with non- dipper in this population.

Crit-Line Monitoring Effect on Blood Pressure Control in ESRD Patients Undergoing In-Center Hemodialysis
Maggie Meier, Hassan Ifikhar, Alexandra Y. Li, Frank J. O Brien. Washington University in St Louis, St Louis, MO.

Background: Patients with end stage renal disease (ESRD) are admitted to the hospital about twice per year, with a 35% readmission rate. Cardiovascular disease (CVD) makes up 28% of admissions, 38% of patients with CVD admissions have pneumonia edema. Fluid overload in ESRD increases morbidity and mortality. Fluid management improvements have potential to positively impact clinic outcomes in dialysis patients.

Methods: This was a prospective cohort study with adult patients at two outpatient dialysis facilities on the Washington University in St Louis Campus. Our inclusion criteria were patients with consistent 3x weekly in center hemodialysis defined as 80% attendance in the 30 days prior to the study. A critline protocol was implemented by the treatment team (Figure 1).

Results: Among 58 qualified patients, average age was 59. 77% were African American with male predominance (57%). Average BMI was 29. In the Critline cohort, systolic blood pressure trended down (Figure 2). In the initial 25 weeks, average number of antihypertensive medications per patient decreased from 2.6 to 1.8. The number of admissions for fluid overload stayed at stable, however readmissions decreased from 4 to 1.

Conclusions: Implementing a Critline protocol trended towards improvements in blood pressure and reduced number of antihypertensives medications. Our findings suggest that a protocolized approach to fluid management using critline will improve our patients outcomes.

PO1785

Cardiovascular Functional Changes in Transplant Waitlist Dialysis Patients
Peter E. Umuoku,1 Tzongshi Lu,2 Sharon M. Moe,1 Ranjani N. Moorthi,1 Gordon Megregor,2 Thomas F. Hienstra,1 Kenneth Lim.1 Indiana University School of Medicine, Indianapolis, IN; 2Brigham and Women’s Hospital, Boston, MA; 3University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; 4University of Warwick Warwick Medical School, Coventry, United Kingdom.

Background: The transition to dialysis is a crucial time in patients with advanced chronic kidney disease (CKD), conferring an increased risk for cardiovascular death. We recently showed that VO,Pek, an index of cardiovascular functional capacity (CFC) significantly declined in advanced CKD patients following 1-year follow-up in the absence of changes in left ventricular mass index (LVMI). Herein, we hypothesized that initiating dialysis and continuing dialysis could worsen an individual’s CFC over time.

Methods: We conducted a cross-sectional study of 241 CKD stage 5 patients from the Cardiopulmonary Exercise Testing in Renal Failure (CAPER) cohort. VO,Pek (primary endpoint) was assessed by cardiopulmonary exercise testing (CPET) in parallel with transthoracic echocardiography.

Results: Of the 241 patients (mean age [SD] age, 48.9 [14.9] years; 154 [65.9%] male), 77% were predialysis (mean eGFR [SD], 14 [3.4] ml/min/1.73m²). Major 78% were in tertile 1 of dialysis vintage (0-17 months), n=69 in tertile 2 (18-50 months) and n=64 in tertile 3 (≥51 months). Predialysis patients had an impaired VO,Pek of 22.7 [5.2] ml/min/kg, and this significantly declined to 18.5 [5.5] ml/min/kg in tertile 1 dialysis patients compared to the pre-dialysis group, tertile 1 dialysis patients exhibited reduced maximal workload (p=0.003), impaired maximal heart rate (p=0.02), increased LVM (p=0.001) and markedly elevated FGF23 levels (p=0.01). On assessment of the effects of dialysis vintage, we found an incremental downward trend in VO,Pek across the groups (22.7 [5.2] tertile 1, 18.4 [4.7] tertile 2, 16.9 [4.2] ml/min/kg) following exclusion of patients who had prior kidney transplants, however this did not reach statistical significance (p=0.2).

Conclusions: Initiating dialysis in advanced CKD patients is associated with impaired CFC comparable to declines seen in new onset heart failure, making this a critical time for these patients.

PO1786

Major Adverse Limb Events and Mortality After Peripheral Artery Revascularization in Hemodialysis Patients
Ting-yan Lin, Shu-Chun Hung. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Revascularization is important for symptom relief and limb salvage in peripheral artery disease, yet limited information exists on the prognosis of hemodialysis patients who receive the procedure. This study sought to determine the incidence and associated factors of major adverse limb events (MALE) after peripheral artery revascularization among hemodialysis patients.

Methods: Hemodialysis patients undergoing peripheral artery revascularization between July 1, 2005, and December 31, 2019, in the Taipei Tzu Chi Hospital were examined for the primary outcome of MALE, defined as severe limb ischemia leading to an intervention or amputation. The secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality. Multivariable-adjusted Cox proportional hazards models were used to explore risk factors associated with development of MALE.

Results: A total of 402 hemodialysis patients were included in the final analysis. Overall, the mean age was 68 years, 56.5% (n = 227) were male, 83.3% (n = 335) had diabetes, and 58.0% (n = 213) had coronary artery disease. During a median follow-up of 2.2 years, 54.0% (n = 217) experienced a subsequent MALE, 33.6% (n = 136) had a MACE, and 54.5% (n = 219) died. Diabetes, coronary artery disease, current smoking, lower body mass index, and higher platelet count or total cholesterol were significantly associated with increased risk of post-procedure MALE.

Conclusions: A significant proportion of hemodialysis patients undergoing peripheral artery revascularization developed a subsequent MALE and MACE or died. Strategies that address risk factors for MALE should be evaluated to improve the outcomes of revascularized hemodialysis patients.

PO1787

Central Blood Pressure Calibration Method and Cardiovascular Risk Prediction According to Sex
Florence Lamarche1, Mohsen Agharazi3, Annie-Claire Nadeau-Fredette,7 Francois Madore1, Remi Goupil.1 Hôpital du Sacre-Coeur de Montreal, Montreal, QC, Canada; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 3CHU de Quebec-Universite Laval, Quebec, QC, Canada.

Background: The accuracy of central BP is improved when calibrated on the mean BP and diastolic BP (C2SBP) compared to calibration on the systolic BP and diastolic BP (C1SBP). Furthermore, preliminary data suggest C2SBP may have the best accuracy in females. We aim to assess whether this enhanced accuracy translates into improved cardiovascular (CV) risk prediction when compared to brachial SBP (bSBP) and C1SBP in the general population and stratified by sex.

Methods: 12,927 participants exempt of known CV disease, with prospective follow-up from administrative databases and central BP measurements, were included. The SphygmoCor Px device was used to estimate C1SBP. C2SBP was derived from unprocessed radial pressure waveforms extracted from SphygmoCor output data, which was recalibrated with diastolic BP and 40% form factor derived mean BP. Participants with heart rate <60 were excluded due to incomplete waveforms. Major adverse CV events (MACE) comprised myocardial infarction, stroke, heart failure with hospitalization and CV death. Multivariable Cox regressions, differences in area under the curve, net reclassification index and integrated discrimination index were calculated comparing C2SBP to C1SBP and to bSBP.

Results: Over a median follow-up of 10.1 years (IQR 9.9-10.3), there were 2125 MACE (723/7013 females and 860/5934 males). All BP parameters were significantly associated with MACE, regardless of sex. In the overall cohort, risk prediction metrics marginally favored C2SBP compared to bSBP, but were similar to C1SBP. No significant improvement of CV risk prediction was found in sex-stratified analyses (see Table).

Conclusions: C2SBP marginally improved CV risk prediction when compared to bSBP but not C1SBP in the overall cohort only. All three BP parameters were similarly predictive in both sex, although this analysis possibly lacked power. This may be related to the FP-derived MAP (rather than oscillometric MAP), which is highly dependent on the brachial SBP.

PO1788
Suppressed Renin Activity in CKD: Are We Missing Primary Hyperaldosteronism?

Methods:
We reviewed patients in the Cleveland Clinic CKD registry with documented PRA and absolute plasma aldosterone concentration (PAC). Patients in the lowest PRA quartile were identified and stratified by PAC/PRA ratio. A cutoff ratio of ≥20 was considered suggestive of PA regardless of the PAC. Characteristics and outcomes of these two subgroups were compared using t-tests, chi-square tests, Kaplan-Meier analyses and Cox models.

Results:
276 patients were identified for this analysis. Median PRA and PAC were 0.5 µg/L/hr and 8.7 ng/dl, respectively. 141 (51%) patients had a PAC/PRA ratio of ≥20 with a median PAC of 14.6 ng/dl in this subgroup. Patients with PAC/PRA of ≥20 had significantly lower eGFR than patients with PAC/PRA of <20 (mean: 50.7 vs. 55.4, p<0.001), more resistant hypertension (63.1% vs. 48.9%, p=0.044), lower serum potassium values (mean: 3.9 vs. 4.2 mmol/L; p<0.001), and higher serum bicarbonate levels (mean: 26.4 vs. 25.3 mmol/L; p=0.001). With median follow up of 4.2 years, there was no difference in mortality between the two subgroups on adjusted cox model analysis (HR for ≥20 vs.<20: 1.03, 95% CI: 0.61-1.74). There was no difference in ESKD-free survival at 5 years was noted but the event rate was low (92.6 vs. 91.9 for ≥20 vs.<20; p=0.77).

Conclusions: We hypothesized that some of these patients with suppressed PRA may have undiagnosed PA. More than half of our suppressed PRA cohort had elevated PAC/PRA ratio suggestive of PA. The biochemical profile and severe hypertension further support the diagnosis. We hypothesize that the diagnosis of PA was possibly ruled out because of the “not very high” PAC. Given the limitations of the spot PAC/PRA screen owing to diurnal PAC variations, a suppressed PRA should merit an in-depth evaluation for undiagnosed PA regardless of the PAC. Making this diagnosis is critical since it has significant therapeutic implications.

PO1790
Cardiovascular and Renal Outcomes of the New Intensive Blood Pressure Target in a CKD Population in Korea

Methods:
The data of 166,397 adults whose baseline estimated glomerular filtration rate (eGFR) <60 ml/min per 1.73 m² were extracted from the Korean National Health Insurance Service database between 2009 and 2011. The data were adjusted for multiple factors such as age, sex, smoking, eGFR, and anti-hypertensive medications in multivariate Cox proportional hazards regression models. All participants were divided into four SBP categories (<120 mmHg, 120-129 mmHg, 130-139 mmHg, ≥140 mmHg). The primary outcome was CVD risk, and the secondary outcome was the risk of progression to end-stage renal disease (ESRD), especially in need of intermittent hemodialysis (HD).

Results:
The mean ages of the each group of CKD patients were 45.1±15.7 years in SBP <120 mmHg group and 52.1±16.0 years in SBP 120-129 mmHg group. 11.1% in SBP <120 mmHg group and 24.6% in SBP 120-129 mmHg group of the participants were already taking anti-hypertensive medications. 112,012 patients (67.3%) had SBP ≥120 mmHg, and 78,119 patients (46.9%) had SBP ≥130 mmHg. Participants with SBP ≥120-129 mmHg exhibited a significantly high risk for HD (hazard ratio (HR), 1.29; 95% confidence interval (CI), 1.03-1.61; P<0.05) and stroke (HR, 1.57; 95% CI, 1.13-2.18; P<0.01) compared with the participants with SBP <120 mmHg. Also, the risk of progression to ESRD was also higher (HR, 1.67; 95% CI, 1.46-1.91; P<0.001).

Conclusions: Therefore, the new intensive BP target can be applied to the real clinical practice in CKD population with proper BP monitoring in Korea and it may eventually reduce the risk of CVD and progression to ESRD in a number of CKD outpatients.

PO1791
Intensive Blood Pressure Control, Age, and All-Cause Mortality in the US Veterans Health Administration

Methods:
We retrospectively analyzed a Veterans Health Administration (VHA) database included Veterans with ≥2 systolic blood pressure (SBP) readings between January 2016 and December 2017 excluding those with mean SBP <100 mmHg to minimize reverse causation. Pevlant hypertension was defined as diagnostic codes related to hypertension, prescribed antihypertensive drugs, or ≥2 office BP of ≥130 mmHg. Of the 1,959,003 Veterans, 18% had SBP <120 mmHg (n=352,684), 26% had SBP 120-129 mmHg (n=507,907), and 56% had SBP >130 mmHg (n=1,091,412)

Results:
The estimated effect of SBP control on all-cause mortality and evaluated the potential interaction with age using a random-effect Cox regression model.

Conclusions: Intensive blood pressure (BP) control has been shown to improve survival in large clinical trials. It is unknown if intensive BP control is associated with improved outcomes amongst older adults in the real-world setting. We examined the association of intensive BP control with all-cause mortality in U.S. Veterans.

Markers of Kidney Tubular Secretion and Risk of Cardiovascular Disease and Mortality in Persons with CKD in SPRINT
Simon Ascher,1,2 Ronit Katz,3 Rebecca Scherzer,1 Alexander Bullen,4,*
Stein I. Hallan,5 Vasantha Jotwani,1 Rakesh Malhotra,1 Michelle M. Estrella,1
Jesse C. Seegmiller,1 Joachim H. Ix,6 Michael Shlipak,1 Pranav S. Garimella,1
Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; 2University of California Davis, Davis, CA; 3University of Washington, Seattle, WA; 4University of California San Diego, La Jolla, CA, US, academic, La Jolla, CA; 5University of California San Diego, San Diego, CA; 6University of Minnesota Academic Health Center, Minneapolis, MN; 7Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion of organic solutes is essential to the clearance of many drugs, metabolites, and toxins. Whether novel measures of tubular secretion have prognostic value for cardiovascular and mortality risk among hypertensive, non-diabetic persons with CKD is uncertain.

Methods: In 2089 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. We used multivariable Cox proportional hazards models to evaluate associations between secretion scores and risk of cardiovascular disease (CVD) and all-cause mortality.

Results: Mean age at baseline was 73 ± 9 years and mean eGFR was 46 ± 11 ml/min/1.73m2. There were 272 CVD events and 144 deaths during a median follow-up of 3.2 years. In unadjusted analyses, a 1-SD higher secretion score was associated with a lower risk of CVD (hazard ratio [HR] per 1-SD higher secretion score: 0.87; 95% CI: 0.76, 0.99), but not all-cause mortality (HR: 0.95, 95% CI: 0.80, 1.13) (Table). After additionally adjusting for baseline eGFR and albuminuria, the association attenuated and was no longer significant (HR: 1.01, 95% CI: 0.67, 1.50). In multivariable analyses of the individual AEs, higher secretion was independently associated with higher risk of syncope or hypotension (HR per 1-SD higher secretion score: 1.30, 95% CI: 1.10, 1.54) and lower risk of ambulatory hypokalemia (HR: 0.71, 95% CI: 0.54, 0.95).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was not significantly associated with risk of CVD or mortality after adjustment for eGFR and albuminuria.

POI1796

Associations of CKD with Dementia Before and After Transient Ischemic Attack and Stroke in a Population-Based Cohort Study

Background: Individuals with chronic kidney disease (CKD) appear to have a greater risk of developing cognitive disorders than the general population. Both vascular and neurodegenerative hypotheses have been proposed to underlie this cognitive burden.

To explore the vascular hypothesis further, we investigated the association between CKD and dementia before and after transient ischaemic attack (TIA) and stroke.

Methods: In a prospective, population-based cohort study of TIA and stroke (Oxford Vascular Study; 2002-2012), pre-event and new post-event dementia were ascertained through direct patient assessment and follow-up for 5 years, supplemented by review of hospital/primary care records. Associations between pre-dementia and CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73 m²) were examined using logistic regression, and between post-event dementia and CKD using both Cox and competing risk regression models, adjusted for age, sex, education, cerebrovascular burden (stroke severity, prior stroke, white matter disease), diabetes mellitus, and dyslipidaemia.

Results: Among 2305 TIA/stroke patients (median [IQR] age, 77 [67-84] years, 1174 [51%] male, 688 [30%] TIA), 1174 (50.9%) had CKD. CKD initially appeared to be associated with both pre-event (odds ratio [OR], 2.04 [95% CI, 1.52-2.72]; P<0.001) and post-event dementia (hazard ratio [HR], 2.01 [95% CI, 1.65-2.44]; P=0.001); however, these associations attenuated and became non-significant after adjustment for the above covariates (OR=0.92 [0.65-1.31]; P=0.65 and HR=1.09 [0.85-1.39]; P=0.50). The results were similar when a competing risk model was used (subdistribution HR [SHR] =1.74 [1.43-2.12]; P<0.001, attenuating to 1.01 [0.78-1.33]; P=0.92 with complete adjustment).

CKD was more strongly associated with late (>1 year) post-event dementia (SHR=2.32, 1.70-3.17; P<0.001), particularly in the minor events subgroup (SHR=3.08, 2.05-4.64; P=0.001), but not significantly so after complete adjustment (SHR=1.53, 0.90-2.60; P=0.12).

Conclusions: In patients with TIA and stroke, CKD was not independently associated with either pre- or post-event dementia, suggesting that age, sex, education, and cerebrovascular burden may play a more important role in the relationship than renal-specific neurodegenerative mechanisms.

POI1795

Carotid Plaque Characteristics and Incident Cognitive Impairment in Hypertensive Adults

L Parker Gregg,1-2 Srinivasan Beddhu,4-5 Robert E. Boucher,3-4 Manjula Kurella Tamura,a Chun Yuen,a Je Sun,a Niranjan Balu,a Nicholas M. Pajewski,7 Jeff D. Williamson,7 Sankar D. Navaneethan.2,2 Baylor College of Medicine, Houston, TX; 3Michael E DeBakey VA Medical Center, Houston, TX; 4University of Utah Health, Salt Lake City, UT; 5VA Salt Lake City Health Care System, Salt Lake City, UT; 6Stanford Medicine, Stanford, CA; 7University of Washington, Seattle, WA; Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Carotid atherosclerosis is associated with cognitive impairment. We investigated associations of plaque characteristics on carotid magnetic resonance imaging (MRI) with the development of mild cognitive impairment (MCI) or probable dementia.

Methods: In an ancillary study to the Systolic Blood Pressure Intervention Trial (SPRINT), carotid plaque was identified by MRI and characterized as having a lipid-rich necrotic core (NC) or calcification. In the parent study, adjudicated MCI and probable dementia were adjudicated on the basis of neuropsychological testing and proxy reports of cognitive-related decline in functional status. We related baseline plaque presence and characteristics of NC or calcification with the incidence of MCI/probable dementia at 3 years of follow-up.

Results: Of 465 participants, 137 (29.5%) had NC plaque. Those with NC plaque were older and more likely to have cardiovascular disease than those without NC plaque. There were 38 MCI/probable dementia outcomes in the entire cohort over 2220 person-years of follow-up. The incidence (95% CI) of a composite outcome of MCI or probable dementia at 3 years was 12.0% (7.5, 18.9) in the NC group and 7.0% (4.6, 10.4) in the no NC group with an absolute risk difference of 5.1% (95% CI -1.2, 11.3, P=0.11). With further adjustment, the absolute risk difference attenuated but the point estimate remained significant (Figure). Results for the presence of any plaque or calcified plaque with MCI/probable dementia are also summarized in the Figure.

Conclusions: We observed large differences in risk for MCI/probable dementia associated with the presence vs. absence of NC plaques, but the significance of this finding is uncertain due to the small number of incident cases of cognitive impairment. Nonetheless, our observations indicate the need to study NC plaque as a novel and potentially more relevant marker of vascular health in future studies of cognitive impairment in hypertensive adults.

PO1798
Platelet Activity Mediates Enhanced Cardiovascular Risk in Patients with CKD and Peripheral Artery Disease

Background: Chronic kidney disease (CKD) is common in patients with peripheral artery disease (PAD), and both are associated with poor cardiovascular (CV) outcomes. Platelets drive PAD pathogenesis and mediate atherosclerosis. Platelet function in CKD and the related CV risk is unclear. We investigated relationships between CKD, platelet activity, and incident CV events in a cohort of patients with PAD.

Methods: The Platelet Activity and Cardiovascular Events (PACE) study enrolled 289 patients with PAD undergoing lower extremity revascularization (LER). CKD was defined as eGFR<60 mL/min/1.73m² by the CKD-EPI equation. We measured platelet activity via light transmission aggregometry (LTA) in response to submaximal ADP, serotonin, epinephrine, and arachidonic acid (AA) prior to LER, and followed patients for a median of 18 months. The primary clinical endpoints were myocardial infarction (MI) and a composite of major adverse CV events (MACE; MI, stroke, death).

Results: There were 113 (40%) patients with and 172 (60%) without CKD. Patients with CKD (vs. non-CKD) were older and more likely to be female, Hispanic, have diabetes, heart failure, and critical limb ischemia (P<0.05 for each). There were no significant differences in prevalent coronary artery disease or use of antithrombolytic therapy between groups. Platelet aggregation in response to submaximal ADP, serotonin, epinephrine, and AA was elevated in the CKD group (Figure). After multivariable adjustment, patients with CKD were at greater risk of MI (aHR 2.2 [95% CI: 1.02–4.9]; P=0.045) and MACE (aHR 1.9 [1.2–3.3]; P=0.01). Patients with CKD were also associated with an increased risk of incident CV events and cardiac events in HD patients. Our results indicate that VAP-1 helps clinicians identify those at high risk of CV events.

Conclusions: Plasma VAP-1 levels had the positive relationship with circulating levels of neprilysin and RAS activity and LV diastolic dysfunction. Higher VAP-1 levels were also associated with an increased risk of incident CV events and cardiac events in HD patients. We investigated relationships between CKD and the risk of incident CV events in a cohort of patients with PAD. Our results indicate that VAP-1 helps clinicians identify those at high risk of CV events.

Kidney Function Trajectory Following Left Ventricular Assist Device Implantation

Carl P. Walther,1 Julia Benoit,2 Harveen Lamba,1 Sankar D. Navaneethan.1
1Baylor College of Medicine, Houston, TX; 2University of Houston, Houston, TX.

Background: LVADs have variable effects on kidney function. Identification of distinctive eGFR trajectory groups after LVAD placement, by applying unsupervised techniques to longitudinal eGFR measures, may enable insights into diverse pathophysiology.

Methods: From a national cohort, we identified persons who underwent isolated, primary continuous flow LVAD implantation in the US, 2016-17. eGFR values from pre-LVAD implantation to 12 months post were used. Latent class mixed models using cubic splines were applied to derivation and validation subsets, and models with 2-9 distinct groups were evaluated to find the optimal number.

Results: In the cohort (3,461 in derivation subset, 1,154 in validation), we identified 5 distinct trajectory groups. The 2 largest groups (1,2) are similar to previously reported cohort averages, with early eGFR increase followed by decline, but differed by baseline eGFR. Three smaller groups (3-5, ~15% of the cohort) demonstrated novel trajectories: group 3 had early worsening with sustained low kidney function; 4 had early and sustained eGFR improvement, and 5 had substantial eGFR variation. These groups differed in baseline factors (groups 3 and 4 had the most pre-LVAD acute dialysis, 4 and 5 the most cardiogenic shock) and outcomes (groups 2 and 4 had the highest survival, 3 and 5 had the lowest).

Conclusions: Novel eGFR trajectories after LVAD implantation were identified in a national cohort. Group 4, with early and sustained increase in eGFR, may reflect type 1 cardiorenal syndrome. Group 3 may reflect chronic kidney disease with early complications, and group 5 may reflect intact kidney parenchyma but post-LVAD right ventricular failure. These results demonstrate the feasibility of identifying previously unobserved heterogeneity in kidney outcomes. The novel trajectory groups may reveal potential for tailored care, in addition to pathophysiologic insights.

Diuretic Resistance in Acute Decompensated Heart Failure with Preserved vs. Reduced Ejection Fraction

Akash Sharma, Rahul Patel, Chakradhar Velagapudi, Shweta Bansal. The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Background: Loop diuretics are one of the common causes of inadequate decongestion in patients hospitalized with acute decompensated heart failure (ADHF). However, DR has not been characterized in patients with HF with preserved ejection fraction (HFpEF).

Methods: In a post hoc analysis of a pilot study which evaluated the role of high-dose spironolactone in hospitalized ADHF patients with DR, we analyzed the prevalence and potential pathophysiologic factors of DR in HFpEF (n=20), and compared those with HF with reduced EF (HFrEF) (n=27). DR was defined as weight loss<1lb/day despite intravenous furosemide>160mg/day (at least one dose of 80mg/day) or no change in urine sodium/potassium ratio, plasma renin activity and aldosterone were lower in DR-HFpEF as compared to DR-HFrEF, though still higher than diuretic responsive-HFpEF patients (Table 1). Weight loss in response to high-dose spironolactone was similar in DR-HFpEF and HFpEF (14±8.6 vs.14±13 lb).

Results: DR was observed in 10 (50%) of HFpEF subjects as compared to 10 (37%) of HFrEF subjects (p=ns). In general, patients with HFpEF were older, more female and obese, had more diabetes, higher systolic blood pressure and lower brain natriuretic peptide compared to HFrEF (Table 1). There was no difference in clinical presentation, eGFR and pulmonary arterial systolic pressure in DR-HFpEF vs. DR-HFrEF. However, urine sodium/potassium ratio, plasma renin activity and aldosterone were lower in DR-HFpEF as compared to DR-HFrEF, though still higher than diuretic responsive-HFpEF patients (Table 1).

Funding: NIDDK Support
Conclusions: Although the comparisons were not statistically significant due to small sample size; the results suggest that DR is more prevalent in HfPEF. Despite similar clinical features of congestion and response to high-dose spironolactone, a state of reduced neurohormonal activation points that additional factors might be contributing to DR in HfPEF compared to HFrEF patients.

Renal Outcomes and Safety of Angiotensin Receptor Neprilysin Inhibitors in Patients with Heart Failure: A Meta-Analysis

Rima N. Abou arkoub, Thomas Mavarakas, Amy Bergeron, Abhinav Sharma, Alsan Alam. McGill University Health Centre, Montreal, QC, Canada; McGill University Health Centre Glen Site McConnell Resource Centre Medical Library, Montreal, QC, Canada.

Background: Angiotensin receptor neprilysin inhibitors (ARNIs) are an effective treatment for heart failure. However, their safety profile compared with angiotensin converting enzyme-inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) with respect to renal outcomes has not been clearly established.

Methods: We conducted a literature search of MEDLINE, Cochrane library, Embase, and clinical trials registries using relevant search terms (last search date May 7, 2021). The primary renal outcome was kidney function decline and the safety outcome was hyperkalemia. Only studies with at least 12 weeks of follow up were included in the renal outcome analysis to better capture CKD.

Results: Ten randomized controlled trials were eligible for inclusion (n=22,174 participants). ARNIs were associated with a lower risk of kidney function decline compared with ACEIs or ARBs: RR 0.65 (95%CI 0.53-0.81). The risk of hyperkalemia was similar in both treatment groups: RR 0.96 (95%CI 0.81-1.13).

Conclusions: ARNI use in patients with heart failure is associated with a lower risk of kidney function decline and a similar risk of hyperkalemia compared to ACEIs or ARBs.
Hydralazine-Isosorbide Dinitrate Associated with Reduced All-Cause and Cardiovascular Mortality in Patients on Dialysis with Heart Failure

Qandeel Soomro,1 Thomas Mavrakanas,2,3 David M. Charytan,1,4 NYU Langone Health, New York, NY; 1McGill University, Montreal, QC, Canada; 2Bingham and Women’s Hospital, Boston, MA.

Background: Heart failure (HF) is an important contributor to the increased cardiovascular (CV) mortality incidence in ESKD. Therapies targeting HF’s unique pathophysiology in ESKD are lacking. Hydralazine-isosorbide dinitrate (H-ISDN) targets reduced nitric oxide bioavailability and could improve CV mortality in ESKD.

Methods: Adult patients with HF on maintenance dialysis between January 2011 and December 31, 2016 were identified using the United States Renal Data System. There were 6306 patients with at least one prescription for H-ISDN and 75,851 non-users. The primary outcome was death from any cause. Secondary outcomes included cardiovascular death and sudden death. Treatment effects were estimated using stabilized inverse probability weights in Cox proportional hazards regression. Because H-ISDN has been shown to improve outcomes in Black HF patients, we investigated effect modification by race.

Results: Age was similar in H-ISDN users (66 ± 13 years) and non-users (69 ± 13 years) with 50% and 51% men, respectively. H-ISDN (51%) users were more likely to be of Black race than non-users (27%). Dialysis vintage was longer in H-ISDN (25 months) vs non-users (15 months). All characteristics were well balanced in weighted models. Risks of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared to non-users (Table). We did not identify significant effect modification by race.

Conclusions: To our knowledge, this is the first analysis of the impact of H-ISDN on mortality in ESKD. Our results suggest that combination H-ISDN improves survival in dialysis patients with HF.

Long-Term Outcomes After Renal Revascularization for Atherosclerotic Renovascular Disease in the ASTRAL Trial

Philip A. Kalra,1,2 Darren Green,1,2 Natalie Ives.1 The ASTRAL trial investigators Salford Royal Hospital, Salford, United Kingdom; 2The University of Manchester, Manchester, United Kingdom; 3University of Birmingham, Birmingham, United Kingdom.

Background: The Angioplasty and Stenting for Renal Artery Lesions (ASTRAL) trial randomized 806 patients with atherothrombotic renal artery stenosis (RAS) between 2000-2007, randomised 1:1 to medical therapy with or without renal artery stenting. The initial results were presented in 2009 at median follow-up 34.6 months when no benefit of revascularization to renal functional outcomes or cardiovascular events (CVE) were evident. Surviving patients remained under follow up until 2014.

Methods: All available data were analysed to assess whether there was a later impact of revascularization on renal function, CVE and survival, including a composite outcome of renal and CVE outcomes and death (as used in the CORAL trial). Pre-specified sub-group analyses of different categories of renal function, renal length, prior rapid deterioration in kidney function, and severity of RAS. Further post-hoc analysis of patients with severe RAS (defined as bilateral 70% or > 70% RAS in a solitary kidney – global renal ischemia), those with/without proteinuria and a per protocol analysis were performed.

Results: The mean age of the entry population was 70.5 years, mean eGFR 40 ml/min/1.73m², with mean RAS 76% and blood pressure 150/76 mmHg; 83% of the revascularization group underwent attempted stenting. Median follow-up was 56.4 months with 108 patients lost to follow up or withdrawn; 50% of the evaluable population had died, 14% had received RRT and 40% had suffered a 1° CVE. No benefit of revascularization was observed for any outcome in the intention to treat and per protocol analyses, either in the whole population or the pre-specified sub-groups. In the severe RAS sub-group (163 patients) revascularization was associated with a hazard ratio (HR) of 0.74 (0.54-1.01; p=0.062) for the composite renal and CVE outcome and an HR of 0.70 (0.49-1.0) for death (p=0.051).

Conclusions: The long-term follow-up of the ASTRAL trial population showed no overall benefit of renal revascularization to renal and CVE outcomes. It has been highlighted that a proportion of the population had lower risk mild-moderate RAS. The long-term outcomes in patients with severe RAS (global renal ischemia) point to a potential benefit of stenting that may be worthy of further study in a more selected population.

Revascularization in Atherosclerotic Bilateral Renal Artery Stenosis

Sana J. Shaikh, Bilal Al-Khalil, Ling Chen, Anitha Vijayan. Washington University in St Louis, St Louis, MO.

Background: Patients with B/L RAS, if found to have worsening renal failure, refractory HTN or recurrent CHF, are often referred for revascularization despite limited evidence. We hypothesized that revascularization plus medical management prevents adverse outcomes in patients with B/L RAS.

Methods: This was a retrospective single-center cohort study in patients with B/L RAS, B/L RAS in a solitary kidney, U/L RAS with an atrophic or >1cm smaller contralateral kidney or, RAS in a U/L functioning kidney. We excluded patients with non-atherothrombotic RAS, renal artery dissection, atheroembolism and renal transplantation. The primary outcome was Major Adverse Kidney Events (MAKE) at 3 mo. Secondary outcomes were renal events, changes in BP, hospital admissions and all-cause mortality at 1 yr. We used the Chi-square test for the primary outcome and the Chi-square test or two-sample t-tests for the secondary outcomes.

Results: 153 patients were included in the study. There were no differences in the baseline characteristics of the intervention and control groups, except for higher number of smokers in the control cohort (Table 1). There was no difference in MAKE between the 2 groups at 3 mo. At 1 yr, there were fewer admissions for CHF in the intervention group (Table 2). There were no other major differences in secondary outcome measures.

Conclusions: Revascularization for B/L RAS does not improve renal outcomes, BP control or mortality, but may prevent admissions for CHF.

Hypertension in a Young Female: A Common but an Intriguing Anecdote
Batool Butt,1 Sohail Sabit,2 1Foundation University Medical College, Rawalpindi, Pakistan; 2National University of Medical Sciences, Rawalpindi, Pakistan

Introduction: Renal artery stenosis accounts for about 1-10% of the 50 million people worldwide with hypertension. All major trials conducted so far on RAS found no benefit with renal artery stenting. Here we report a case of resistant hypertension in a young female who subsequently found to have bilateral renal artery stenosis and ultimately benefited from unilateral stenting.

Case Description: A 35 yrs female, married, with no comorbidities, presented with 03 months history of intermittent episodes of throbbing headache along with dizziness, without any anti hypertensive medicine. Hepatitis B and C serology were negative) USG abdomen showed right shrunken kidney with no renal artery flows on Doppler ultrasound. She was put on four different groups of anti hypertensives including a beta blocker, a calcium channel blocker, thiazide diuretic and an angiotensin receptor blocker but her blood pressure did not settle. Further investigations revealed raised ESR but other tests including autoimmune screening, proteinuria (>300mg/g) was found in 24,4% (n=10) of the patients. A significant reduction of proteinuria was found in the patients who received RDN (p < 0.05).

Results: Currently there are 641 patients treated with the Symplicity Spyral catheter (baseline office BP 168±25 mmHg, 4.6±1.5 prescribed anti-hypertensive medication classes, mean age 60.5 ± 12.5 years, 56.9% male, 42.5% history of cardiac disease, 37.2% type II diabetes mellitus, and 19.1% renal insufficiency with eGFR < 60 ml/min/1.73m²). At 3 years, there were no cases of new renal artery stenosis >70% or renal artery re-intervention. Rates of other adverse events at 3 years included new onset end stage renal disease (2.4%), cardiovascular death (1.6%) and myocardial infarction (0.8%). Mean change in eGFR from baseline to 3 years was -6.5±15.7 mL/min/1.73m². Changes in mean 24-hour and office BP from baseline to 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years. In this analysis, we present safety and efficacy data for patients who received RDN with the multi-electrode Symplicity Spyral catheter in GSR.

PO1810
Long-Term Safety and Efficacy of Renal Denervation with the Symplicity Spyral Catheter in the Global SYMPLICITY Registry
Markus P. Schlaich,1 Felix Mahfoud,2 Bryan Williams,3 Luis M. Ruilope,4 Krzysztof Narkiewicz,4 Martin Faly,4 Giuseppe Mancia,4 Michael Böhm,2 1The University of Western Australia, Perth, WA, Australia; 2Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany; 3University College London, London, United Kingdom; 4Hospital Universitario 12 de Octubre, Madrid, Spain; 5Gdański Uniwersytet Medyczny, Gdańsk, Poland; 6Università degli Studi di Milano-Bicocca, Milano, Italy; 7Medtronic Inc, Minneapolis, MN.

Background: Catheter-based renal denervation (RDN) therapy targets upregulation of the sympathetic nervous system to treat hypertension. Results from recent randomized sham-controlled clinical trials have demonstrated the safety and efficacy of RDN, but long-term safety and durability of the procedure in real-world patients is also important.

Methods: The Global SYMPLICITY Registry (GSR) is a prospective, international registry of patients who receive radiofrequency RDN treatment due to uncontrolled hypertension or conditions associated with excessive sympathetic nervous system activation. Office and ambulatory blood pressure (BP) levels were measured at baseline, 3, 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years. In this analysis, we present safety and efficacy data for patients who received RDN with the multi-electrode Symplicity Spyral catheter.

Results: Currently there are 641 patients treated with the Symplicity Spyral catheter (baseline office BP 168±25 mmHg, 4.6±1.5 prescribed anti-hypertensive medication classes, mean age 60.5 ± 12.5 years, 56.9% male, 42.5% history of cardiac disease, 37.2% type II diabetes mellitus, and 19.1% renal insufficiency with eGFR < 60 ml/min/1.73m²). At 3 years, there were no cases of new renal artery stenosis >70% or renal artery re-intervention. Rates of other adverse events at 3 years included new onset end stage renal disease (2.4%), cardiovascular death (1.6%) and myocardial infarction (0.8%). Mean change in eGFR from baseline to 3 years was -6.5±15.7 mL/min/1.73m². Changes in mean 24-hour and office BP from baseline to 6, 12, 24, and 36 months are shown in the Figure.

Conclusions: Office and 24-hour BP were significantly reduced from baseline at all follow up time-points after RDN with the Symplicity Spyral catheter, with no instances of renal artery re-intervention.

PO1811
Endovascular Renal Denervation Efficacy in a Five-Year Follow-Up
João Carvalho,1 Patricia Q. Branco,2 Catarina Mateus,2 Pedro Gonçalves,2 Manuel D. Almeida,3 Maria augusta C. Gaspar,1 1Servico de Saude da Regiao Autonoma da Madeira, Funchal, Portugal; 2Centro Hospitalar de Lisboa Ocidental EPE Hospital de Santa Cruz, Carnaxide, Portugal.

Background: Endovascular renal denervation (ERD) is a minimally invasive procedure that uses radiofrequency ablation to burn the nerves in the renal arteries. Renal sympathetic nerves can modulate sympathetic activity at the whole body level, playing an important role in essential hypertension. This study aims to evaluate ERD efficacy in the treatment of essential hypertension in a five-year follow-up.

Methods: We conducted a prospective study including 41 patients with essential hypertension. ERD was performed using Simplicity Probe or Spyral. Blood pressure (BP) was evaluated using 24-hour ambulatory BP monitoring. Echocardiography was performed using HDI 5000. Clinical and biochemical variables were explored.

Results: A total of 41 patients were included. Overall, 53.7% (n=22) were females with a mean age of 63.6 ± 7.5 years, BMI 30.8 ± 5.2 Kg/m², 17.1% (n=7) had an estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m² and 68.3% (n=29) had diabetes. Proteinuria (>300mg/g) was found in 24.4% (n=10) of the patients. A significant reduction in the number of antihypertensive drugs being taken was found after 5 years' follow-up (p<0.001). Despite this reduction, a significant increase in diastolic blood pressure

Potential Benefits of Asymptomatic Hyperuricemia Treatment: A Systematic Review and Meta-analysis of Randomized Controlled Trials

Dhir N. Gala,1 Kireillos S. Said,2 Nuala A. El-Shafat,3 Allison Parrill,4 Hadir S. Mohamed,5 Nada Abdellahim,5 Mostafa A. Amin,5 Hassan S. AbdalLaham,5 Majd Alahmar,4 Nguyen Tien Huy,5 Mohammed Abdel Gawad.6 1American University of the Caribbean School of Medicine BV, Curacao, Sint Maarten (Dutch part); 2Alexandria University Faculty of Medicine, Alexandria, Egypt; 3Al-Azhar University Faculty of Medicine, Cairo, Egypt; 4University of Istanbul, Istanbul, Turkey; 5Cairo University Kastr Alainy Faculty of Medicine, Cairo, Egypt; 6Mansoura University Faculty of Medicine, Mansoura, Egypt; 7Gawad Nephrology Clinic, Alexandria, Egypt; 8School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan.

Background: Asymptomatic hyperuricemia is strongly associated with an increased risk for chronic kidney disease and cardiovascular conditions. However, many current guidelines suggest no medical treatment for patients with asymptomatic hyperuricemia. We aim to systematically analyze randomized controlled trials with serum uric acid-lowering medication in the treatment of patients with asymptomatic hyperuricemia.

Methods: A literature review of seven medical databases (Scopus, Clinical Gov, Pubmed, Web of Science, Google Scholar, VHL, and GHL) for randomized controlled trials related to the treatment of asymptomatic hyperuricemia was conducted. Bias was evaluated using the Cochrane Risk of Bias 2 tool. Standard differences of means of variables of interest were combined across studies to compare the effects of uric acid lowering treatment versus control. Using the Comprehensive Meta-analysis program, fixed-effects and random heterogeneity model, forest plots were created for each variable of interest.

Results: Analysis of eleven studies showed significant decreases in creatinine [−0.302 (95% CI: −0.599, −0.005)], systolic blood pressure [−0.277 (95% CI: −0.5, −0.055)], and serum uric acid [−1.972 (95% CI: −2.145, −1.800)] in the treatment versus control group. Furthermore, significant increases in estimated glomerular filtration rate (eGFR) with sensitivity analysis [0.228 (95% CI: 0.027, 0.428)], and high sensitivity-C-reactive protein [0.588 (95% CI: 0.205, 0.971)] were observed in the treatment versus control group. Lastly, non-significant decreases in creatinine clearance in an animal test [−0.113 (95% CI: −0.269, 0.042)], and diastolic blood pressure [−0.312 (95% CI: −0.638, 0.013)] while non-significant increases in hemoglobin A1C [0.394 (95% CI: −0.026, 0.813)] and fasting glucose level [0.117 (95% CI: −0.145, 0.380)] were found in the treatment versus control group.

Conclusions: This study showed that uric acid lowering treatment of patients with asymptomatic hyperuricemia may be beneficial in those with elevated creatinine and blood pressure, and decreased eGFR.

POI183

Urinary Glycogen Synthase Kinase β3 Level Predicts the Progression of Hypertensive Nephrosclerosis

LinFeng Zheng, Cheuk-Chun Szeto. Department of Medicine & Therapeutics and Li Ka Shing Institute of Health Sciences (LiHSI), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Hypertensive nephrosclerosis (HTN) is a serious consequence of prolonged hypertension. In the United States, HTN is the second most common cause of end-stage kidney disease. Recently, emerging evidence suggests that glycogen synthase kinase (GSK) β3 is a key factor in the progression of diabetic kidney disease (DKD). However, it remains uncertain whether the role of GSKβ3 is specific for DKD or a generic mediator of renal damage irrespective to the underlying cause.

Methods: We performed correlation analysis with the frozen and fixed HTN patients. Their GSKβ3 level in urinary supernatant was measured by conventional ELISA, and GSKβ3 mRNA level in urinary sediment was measured by quantitative polymerase chain reaction. The results were compared to the baseline kidney function and the subsequent risk of renal function deterioration.

Results: The average urinary GSKβ3 level was 212.67±47.74 ng/mL by conventional ELISA, and GSKβ3 mRNA level in urinary sediment (r=0.821, P<0.0001). Urinary GSKβ3 level significantly correlated with baseline glomerular filtration rate (GFR) (r=−0.751, P=0.010) and the slope of GFR decline (r=−0.397, P=0.033). Patients with a high urinary GSKβ3 level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSKβ3 level (P<0.022 and P=0.044, respectively). Similarly, urinary GSKβ3 mrRNA level also significantly correlated with baseline GFR (r=−0.582, P=0.0001) and the slope of GFR decline (r=−0.402, P=0.022). Patients with a high urinary GSKβ3 mrRNA level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSKβ3 mrRNA level (P<0.022 and P=0.044, respectively).

Conclusions: These results demonstrated that urinary GSKβ3 level correlates with the rate of kidney function loss in patients with biopsy-proved HTN, and urinary sediment GSKβ3 mRNA level appears to be a good prognostic marker than urinary GSKβ3 level by ELISA. Our results suggest that GSKβ3 is a generic mediator for the progression of chronic kidney disease and is not specific for DKD.

POI184

Deletion of the Dopamine D2 Receptor in the Renal Proximal Tubule Increases Blood Pressure on Low-Salt Diet and Decreases Blood Pressure on High-Salt Diet: A Case of Inverse Salt Sensitivity

Laurenzo D. Asico, Shaun C. Moore, Pedro A. Jose, Ines Armando. The George Washington University School of Medicine and Health Sciences, Washington, DC.

Background: The dopamine D2 receptor (D2R) in the kidney is important in maintaining renal blood pressure (BP) and preventing inflammation and tissue injury. Global D2R gene (Drd2) knockdown or 1 renal-selective D2R downregulation in the mouse increases BP and results in renal inflammation, tubular injury, and fibrosis. To study the D2R deletion in the renal proximal tubule, we generated Dnd2-fl/fl; Pgc1α-Cre mice (D2R−/−) that lack D2R only in the renal proximal tubule and Dnd2-fl/fl; Pgc1α-Cre-Drd2−/− mice that do not have the deletion.

Methods: Mice were genotyped for Dnd2−/− and a smaller amplicon representing the Cre deletion mutant. We studied male mice on normal salt (NS; 0.4% NaCl), high (HS; 1% NaCl), and low (LS; <0.08% NaCl), and low (LS; <0.08% NaCl).

Results: On NS diet, male D2R−/− had slightly higher BP, measured under anesthesia, than male D2R−/− mice (106±1 vs 101±2 mmHg, n=15/group; P<0.05). On HS diet D2R−/− mice had lower BP than D2R+/+ mice (100±3 vs 107±2 mmHg; P=0.04; n=12) but on LS diet D2R−/− had higher BP than D2R+/+ mice (125±5 vs 103±4 mmHg; P=0.01; n=7). Both the decrease in BP on HS diet and the increase in BP on LS diet, relative to BP on NS diet, were confirmed by telemetry in conscious mice. These data indicated that D2R deletion only in the renal proximal tubule impairs the normal responses to changes in salt intake. On the diet the renal mRNA mrRNA expression of Na/K ATPase, NCC, and D2R were similar in both groups. On HS diet NHE3 and NCC mrRNA were lower in D2R−/− than D2R+/+ mice (NHE3: 0.7±0.02 vs 1.0±0.03 fold-change; P<0.05; n=4-5/group; NCC: 0.5±0.01 vs 1.0±0.09 fold-change; P<0.05) while Na/K ATPase was similar in both groups. On LS diet NHE3, Na/K ATPase, and NCC expression were higher (P<0.05) in D2R−/− than in D2R+/+ mice.

Conclusions: There are marked differences in the response to changes in dietary salt intake on BP and renal expression of sodium exchanger/transporter/pump in mice lacking D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis.

Renal Proximal Tubule-Specific Expression of the NKA/Src Receptor Complex in the Mouse: Evidence for Sexual Dimorphism

Background: The Na+/K’-ATPase (NKA) expressed on the basolateral membrane of renal proximal tubule (RPT) cells serves an anti-natriuretic enzymatic function through its classically recognized ion-pumping properties. There is also pharmacological evidence that, through a Src-mediated mechanism, Na/K-ATPase α1 serves a counteracting natriuretic receptor function that reduces NKA- and NHE3-mediated transport, leading to decreased transepithelial Na+ flux. No studies have been performed to confirm the role of NKA/Src signaling in renal proximal tubule (RPT) cell signaling.

Methods: To test this genetically, we generated RPT cells and mice lacking D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis.

Results: In male mice, expression of NKA/Src receptor complexes is significantly lower in females by 62% (n=6-8, P<0.05, n=2-3/group). In contrast, the NKA/Src receptor complexes are significantly higher in females by 42% (n=6-8, P<0.05, n=2-3/group). The NKA/Src receptor complexes were significantly higher in females by 42% (n=6-8, P<0.05, n=2-3/group).

Conclusions: There are marked sex differences in the expression of NKA/Src receptor complexes in the RPT. These results may have important implications for renal proximal tubule physiology. The presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. However, the presence of D2R variants, D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis.

Sex-Dependent Regulation of the WNK-NCC Pathway via Ubiquitination in Response to Dietary High Salt Intake in Young Sprague-Dawley Rats

Kyoung Kim, Mohammed Z. Ferdaus, Richard D. Wainford. Boston University School of Medicine, Boston, MA.

**Background:** The thiazide-sensitive Na\(^+\)-Cl\(^-\) cotransporter (NCC), located in the apical membrane of distal convoluted tubule, fine-tunes sodium reabsorption and regulates blood pressure. The NCC is downregulated by high salt intake in normotensive salt resistant rats. These studies investigated the potential mechanistic pathways by which NCC is degraded in response to high salt intake in male and female Sprague-Dawley (SD) rats.

**Methods:** 3-month-old normotensive male and female SD rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days. On day 21, the kidneys were collected and ~200 mg of the renal cortex was used to measure the expression of total NCC, WNK1, WNK4, Nedd4-2, Sortilin, KLHL3, and calcineurin using immunoblotting (N=5–6/group).

**Results:** A 21-day HS diet evokes the suppression of total NCC protein expression in young normotensive male and female SD rats. A HS diet downregulated WNK1 in male but not female SD rats. A HS diet suppresses the expression of the full-length and short WNK4 variants in female SD rats only. There was a trend for HS to increase Nedd4-2 expression in male SD rats (P=0.06), in contrast female rats downregulated Nedd4-2 in response to HS. The expression of sortilin, KLHL3, and calcineurin was suppressed by a HS diet in female rats only.

**Conclusions:** These data suggest that response to a HS diet young female SD rats exhibit greater ubiquitin-dependent proteolytic and lysosomal degradation of the NCC than young male SD rats to regulate sodium homeostasis and blood pressure via a WNK-dependent signaling pathway.

**Table 1**: NS, 0.6% NaCl; HS, 4% NaCl. *P<0.05 vs. respective NS Group.

**Background:** Afferent renal nerve pathways likely play a role in salt sensitive hypertension. We recently reported that high salt diet (HS) impairs these afferent renal pathways in rats. Now we tested the hypothesis that during HS a decrease in sensitivity of renal afferent neurons is prevented by the SGLT2 inhibitor empagliflozin.

**Methods:** Respectively of groups of rats were put on HS containing 8% NaCl or a normal diet. Two groups (HS, controls) received empagiflozin 20 mg/kg BW/day orally. Renal denervation (DNX) was performed retrogradely labeled with DiI. In culture, isolated dorsal root ganglion neurons (DRG Th1-L2) with HS afferent renal afferent axons were investigated electrophysiologically using current clamp mode to assess action potential generation during current injection (neurons were characterized as tonic highly active (>5 action potentials, AP) and phasic less active neurons (≤5 AP upon stimulation).

**Results:** In neurons from rats on HS, the relation of tonic highly active neurons to less active phasic neurons shifted consistently towards phasic units (63.8% tonic neurons in controls vs. 42%* on HS, *P<0.05, t-test). However, continuous treatment with empagliflozin preserved the proportion of tonic neurons as in controls (67.9% on HS with concomitant administration of empagliflozin). In controls, empagliflozin did not affect the proportion of tonic to phasic neurons (63.8% tonic neurons in controls vs. 67.9% on HS & empagliflozin, p=0.7, t-test). Blood pressure and heart rate were not altered by HS and/or treatment with any chosen dose of empagliflozin.

**Conclusions:** These data suggest that response to a HS diet young female SD rats exhibit greater ubiquitin-dependent proteolytic and lysosomal degradation of the NCC than young male SD rats to regulate sodium homeostasis and blood pressure via a WNK-dependent signaling pathway.
