Results: Of the 390 patients who met eligibility criteria (mean age 59 years, 45% females, 15% Black, and 32% American Indian/Alaska Native, 29% Hispanic), 303 (78%) displayed at least one clinically significant symptom - pain, fatigue, or depression. Of those experiencing symptoms, 39% reported experiencing 1 clinically significant symptom, 35% reported 2, and 26% reported 3. There were no statistically significant differences by age, race, ethnicity, or gender in those reporting symptoms versus those who were not. Of those ready to seek treatment (80%) versus those not ready to seek treatment (20%). Of those who were experiencing symptoms, the percentage of patients willing to receive treatment increased as the number of symptoms increased (71%, 86% and 90% willing to receive treatment with 1, 2 or 3 symptoms respectively, p<.01).

Conclusions: The majority of HD patients report experiencing at least one clinically significant symptom and experiencing more of these symptoms increased readiness to seek treatment. Demographic difference in symptom burden and readiness for treatment were not evident in this sample and should continue to be the focus of additional research.

PO0833 Health-Related Quality of Life During Dialysis Modality Transitions: A Mixed-Methods Study
Chance S. Dumaing,1 Danielle E. Fox,2 Pietro Ravani,3 Maria Jose Santanta, Jennifer M. MacRae.1 1University of Saskatchewan, Saskatoon, SK, Canada; 2University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: Dialysis transitions may have an impact on health related quality of life (HRQOL), a patient defined priority for research and clinical care. We measured HRQOL and explored perceptions of adults who were initiating dialysis for the first time or transitioning to a new dialysis modality in a large urban centre in Canada.

Methods: In this prospective convergent parallel mixed-methods study we recruited eligible patients who were transitioning to dialysis from pre-care (n=9, incident) or undertaking a dialysis modality change (n=10, prevalent) between July and September 2017. Patients completed the five domains of the Kidney Disease Quality of Life (KDQOL-36) survey on their first day of dialysis treatment or first day of home dialysis training and underwent a semi-structured interview and follow up KDQOL-36 survey at 3 months.

Results: Of those experiencing symptoms, 39% reported experiencing 1 clinically significant symptom, 35% reported 2, and 26% reported 3. There were no statistically significant differences by age, race, ethnicity, or gender in those reporting symptoms versus those who were not. Of those ready to seek treatment (80%) versus those not ready to seek treatment (20%). Of those who were experiencing symptoms, the percentage of patients willing to receive treatment increased as the number of symptoms increased (71%, 86% and 90% willing to receive treatment with 1, 2 or 3 symptoms respectively, p<.01).

Conclusions: The majority of HD patients report experiencing at least one clinically significant symptom and experiencing more of these symptoms increased readiness to seek treatment. Demographic difference in symptom burden and readiness for treatment were not evident in this sample and should continue to be the focus of additional research.

PO0834 Prevalence and Demographic Correlates of Pain, Depression, Fatigue, and Readiness to Seek Treatment for These Symptoms in Hemodialysis Patients
Susan M. Devanar.,1 Jonathan Yabes,2 Maria-Eleni Roumelioti, Jennifer L. Steel,1 Sarah J. Erickson,2 Mark L. Urnul,3 Manisha Jambh,3 1University of Pittsburgh Department of Medicine, Pittsburgh, PA; 2University of New Mexico School of Medicine, Albuquerque, NM.

Background: Patients with End Stage Renal Disease on hemodialysis (HD) experience a high burden of pain, fatigue and depressive symptoms. This study aims to better understand demographic differences in symptom burden and readiness to seek treatment among HD patients being recruited for an ongoing multi-center randomized controlled trial (TACare).

Methods: Patients on in-center HD were screened for clinical levels of pain (Likert scale ≥4), fatigue (Likert scale ≥3), and depression (Patient Health Questionnaire-9 score ≥10) within the last 2 weeks. Patients with at least one clinical symptom were then screened to assess readiness for seeking treatment for symptoms, and eligible to enroll if they were at least in the contemplation stage of Readiness for Behavior Change. Demographic differences in symptom screening and readiness to change (yes/no) were assessed using chi-square tests (age) and Chi-Square or Fisher's Exact tests (race, ethnicity, gender). Symptom burden by readiness to change status was assessed using Chi-Square tests.

Results: Of the 390 patients who met eligibility criteria (mean age 59 years, 45% females, 15% Black, and 32% American Indian/Alaska Native, 29% Hispanic), 303 (78%) displayed at least one clinically significant symptom - pain, fatigue, or depression. Of those experiencing symptoms, 39% reported experiencing 1 clinically significant symptom, 35% reported 2, and 26% reported 3. There were no statistically significant differences by age, race, ethnicity, or gender in those reporting symptoms versus those who were not. Of those ready to seek treatment (80%) versus those not ready to seek treatment (20%). Of those who were experiencing symptoms, the percentage of patients willing to receive treatment increased as the number of symptoms increased (71%, 86% and 90% willing to receive treatment with 1, 2 or 3 symptoms respectively, p<.01).

Conclusions: The majority of HD patients report experiencing at least one clinically significant symptom and experiencing more of these symptoms increased readiness to seek treatment. Demographic difference in symptom burden and readiness for treatment were not evident in this sample and should continue to be the focus of additional research.

PO0835 Latino Patients’ Perspectives on Their Kidney Disease Education and Recommendations for Improvement: A Qualitative Study
Teena K. Novick,1 Santiago Diaz,2 Kayvaa D. Choudhary,3 Doris A. Cubas,4 Francesco A. Barrios,5 Lilia Cervantes,6 Elizabeth A. Jacobs,7 1The University of Texas at Austin Dell Medical School, Austin, TX; 2University of Colorado, Denver, CO; 3Maine Medical Center - Scarborough Campus, Scarborough, ME.

Background: In most states, Latinx immigrants with kidney failure receive dialysis in acute care settings on an emergency-only basis. What and how much kidney disease education they receive, and how to improve kidney disease education and outreach among Latinx populations is unknown. The objective of this study was to understand the kidney disease education and informational gaps of Latinx individuals who need but lack access to scheduled outpatient dialysis.

Methods: We conducted a qualitative, semi-structured interview study in a Texas hospital system from March 2020 to January 2021 with 15 individuals who received emergency-only dialysis when they were first diagnosed with kidney failure. We collected demographic information, and performed thematic analysis using the constant comparative method on interviews after they were audio-recorded, translated and transcribed verbatim.

Results: All 15 persons interviewed (60% male; mean age 51 years) identified as Hispanic (63%), Mexican, and described having limited knowledge of kidney disease more than 6 months before starting dialysis. The themes were: 1) lack of kidney disease awareness; 2) education provided was incomplete and poor quality; 3) lack of culturally concordant communication and care; 4) elements Latinx patients receiving emergency-only dialysis want in their education; 5) facilitators of patient activation and coping; and 6) Latinx patient recommendations to improve community outreach.
**PO0836**

**Improving Education and Satisfaction of Hemodialysis Patients Through Anonymous Feedback**

Arun Rajasekaran, Anand Prakash, Spencer Hatch, Yan Lu, Abolfazl Zarjou. The University of Alabama at Birmingham, Birmingham, AL.

**Background:** Patients on outpatient hemodialysis (HD) are a particularly vulnerable population who may not feel comfortable sharing their experience given the complex and frequent nature of their care. This could lead to conceivable gaps in knowledge pertaining to improving their satisfaction and education. To account for this potential limiting factor and to build on previous surveys performed on HD patients we conducted a study in nine of our university affiliated HD units.

**Methods:** The study had 3 major objectives: 1) apprehend the level of satisfaction of patients with varying aspects of HD-related care, 2) evaluate level of understanding and education of patients regarding issues that pertain to their health and wellbeing, and 3) identify potential avenues for improvement based on patients’ input. The survey was in English, paper based, with individual answer choices graded using a 1-5 rating scale [1: very poor, 2: poor, 3: neutral, 4: good, 5: excellent]. To ensure anonymity, the completed surveys were folded and dropped into a box.

**Results:** Among 516 screened patients 228 did not participate. Additional 35 patients were excluded for ≥ 1 reasons: legally blind, unable to read/write/speak English, advanced dementia, too frail. 253 eligible patients completed the survey. While the overall results were reassuring with 18 out of 24 questions yielding an average of ≥ 4.2 per question, we found specific areas for improving care and education. These included providing additional resources and information regarding palliative care, mental health, cardiovascular diseases, transplant process, addressing discomfort during HD, improving privacy, and improving the time that the nephrologist spends with patients.

**Conclusions:** The US centers for Medicare and Medicaid services ESRD prospective payment system and quality incentive program requires that dialysis centers meet predefined criteria for quality of patient care to ensure future funding. We took advantage of an anonymous survey to further reflect on the potential needs of this patient population to enhance their quality of life and education. Despite specific limitations, our survey demonstrated patients undergoing HD were overall satisfied and had a good understanding about their overall health. However, we identified several aspects to improve upon as requested by our respondents.

**PO0837**

**Provider Recognition of Patient-Reported Symptoms in Patients on Maintenance Hemodialysis**

Huei Hsu, Weng, Kinuk Cauhan, Steven G. Coca, Girish N. Nadkarni, Lili Chan. Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Patients with ESKD on maintenance HD (HD) experience more symptoms than the general population. In order to enable better symptomatic management, it is critical that providers recognize and document these symptoms; however, recognition by nurses and physicians is unclear.

**Methods:** We surveyed patients that were receiving in-center HD for ≥30 days, and attended HD three times a week at the Mount Sinai Kidney Center. Patients were surveyed on if they experienced 21 symptoms over the past 24 hours at the end of their treatments for 12 sessions. The treating nurses were surveyed at the end of each HD treatment to identify if the patient had any of the 21 symptoms. We considered a positive response on any of the 12 surveys as a positive during the study period. Physicians were asked during week three of the study period if the patient had experienced any of the 21 symptoms during the past 4 weeks.

**Results:** Of the 166 eligible patients, 101 consented to the study, and 97 completed all 12 surveys. The mean age was 56±14 years, 52% were female, and 52% were Black. The most common symptoms reported by the patients were fatigue (61%), cramping (59%), and dry skin (53%) (Figure 1). Nurses under-recognized 17/21 symptoms, mean relative difference of 23±36%. Physicians under recognized 16/21 symptoms, by a mean difference of 23±33%. Symptoms with the largest degree of under-recognition by nurses were dry skin (difference of 51 percentage points) and fatigue (difference of 42 percentage points). Physicians struggled most with recognition of cramping (difference of 39 percentage points) and fatigue (difference of 34 percentage points).

**Conclusions:** Patient symptoms were generally under-recognized by both dialysis nurses and physicians. While several symptoms such as shortness of breath, nausea, and vomiting were well recognized by nurses and physicians, nurses under-recognized dry skin and fatigue and physicians under-recognized cramping and fatigue.

**Funding:** NIDDK Support, Commercial Support - Renal Research Institute

**PO0838**

**Improving Food Insecurity in Patients with ESKD on Hemodialysis: Partnership with Local Food Bank**

Elaine T. McCall, Emaad M. Abdel-Rahman. University of Virginia, Charlottesville, VA.

**Background:** Nutrition plays an important role in the management of ESKD on HD. Barriers to appropriate nutrition include medical, behavioral and socio-economic factors. Socio-economic factors may include poor purchase power and problems with transportation. Poverty rate at the area of University of Virginia (UVA) is 12.9%, which is 1.3 times the state average.

**Methods:** UVA partnered with the local food bank to meet the basic nutritional needs of our patients by delivering renal appropriate diet to patients at the dialysis unit, with an aim of reducing individual food insecurity.

**Results:** The current UVA food bank collaboration program distributes more than 50 bags each month and roughly 80% of the entire dialysis program has received at least one bag since the inception of the program. Presently 34 patients consistently received bags each month (bi-monthly or greater distribution of bags). There was no significant changes in weight, serum albumin, calcium, phosphorous or potassium between baseline and 6 months of consistently receiving food bags. 28/34 (82.4%) patients responded to a survey. Patients were 64.3% African American with 57.1% females with average age of 61.3 years. Average household of these patients were 2.2, receiving 2.3 bags/week with an average of 3.3 meals/week. While 50% of patients reported satisfaction with the program, 10% of patients very satisfied, 32.1% neutral and 3.6% were unsatisfied. 57.1% viewed the food as healthy, with 21.4% perceived food to be very healthy, 17.8% were neutral and 3.6% viewed the food to be unhealthy. The majority of the patients reported improved nutrition with these food items (82.1%). While only 10.7% of the patients reported they had to skip a meal because of being short on food, 85.7% reported that these bags helped them eat more meals on a regular basis.

**Conclusions:** Partnership with local food banks helps decrease food insecurity and improved satisfaction in patients on hemodialysis. Nutritional parameters did not improve, which may be due to consumption of supplemental food outside of the program. Expanding such programs to other dialysis units and in other areas of the country may improve patients’ outcomes.

**PO0839**

**Medication Burden and Prescribing Patterns Among ESKD Patients on Hemodialysis in the United States, 2013-2017**

Julie M. Park, Min Zhao, Seoyoung C. Kim, Rishi J. Desai. Brigham and Women’s Hospital, Boston, MA.

**Background:** The medication burden of patients with ESKD on HD is amongst the highest of any of the chronic diseases. This study describes the medication burden and prescribing patterns in a contemporary cohort of patients with ESKD on HD in the U.S.

**Methods:** We used the United States Renal Data System database from January 1, 2013 and December 31, 2017 to quantify the medication burden of patients on HD aged ≥18 years. We included patients who had continuous Medicare parts A, B, and D coverage
for at least 3 months prior to January 1 of the respective year and excluded patients with a history of peritoneal dialysis or kidney transplantation during the study period. Patients could contribute data to multiple yearly cohorts. We calculated the average number of prescription medications per patient during each respective year, number of medications within classes, including potentially harmful medications, and trends in the number of medications and classes over the study period.

Results: We included 163,228 to 176,133 patients from 2013 to 2017. In 2013, the mean age was 63.5 years and increased to 65.1 years by 2017. The percentage in the age 18-64 years category decreased (51.3% in 2013 compared with 45.0% in 2017) and the percentage in the older age categories all increased. In 2013, 51.8% were male and 48.2% were female, compared with 53.6% male and 46.4% female in 2017. The overall burden of medications decreased prescribed, from a mean of 7.4 (SD 3.8) in 2013 to 6.8 (SD 3.6) in 2017. Prescribing of potentially harmful medications decreased over time (74.0% with at least one harmful medication class in 2013 to 68.5% in 2017). In particular, the prescribing of non-benzodiazepine hypnotics, benzodiazepines, and opioids decreased from 2013 to 2017 (12.2% to 6.3%, 23.4% to 19.3%, and 60.0% to 53.4%, respectively). This trend was consistent across subgroups of age, sex, race, and low-income subsidy status.

Conclusions: Patients with ESKD on HD continued to have a high overall medication burden, with a slight reduction over time accompanied by a decrease in prescribing of several classes of harmful medications. Continued emphasis on assessment of appropriateness of high medication burden in patients with ESKD is needed to avoid exposure to potentially harmful or futile medications in this vulnerable patient population.

PO0840 The Impact of Late Initiation of Chronic Dialysis on Mortality: A National Retrospective Cohort Study

George L. Worthen,1,2 David Clark,1,2 Keigam More,1,2 Amanda J. Vinson,1,2 Artikith K. Tennankore,1,2 Dalhousie University, Halifax, NS, Canada; ‘Nova Scotia Health Authority; Halifax, NS, Canada.

Background: Current Canadian guidelines recommend deferring dialysis initiation in asymptomatic patients until the glomerular filtration rate (GFR) reaches 6 mL/min/1.73m², an ‘intend-to-defer’ strategy. However, little is known about how dialysis initiation and post-dialysis outcomes are impacted when patients start at or below this threshold.

Methods: We sought to characterize the impact of starting dialysis at or below 6 mL/min/1.73m² in a national retrospective cohort study of incident dialysis patients from 2004-2019. Dialysis data (excluding Manitoba and Quebec) was acquired from the Canadian Organ Replacement Register (CORR) and linked to hospitalization data using the well-established discharge abstract database (DAD). The cohort was restricted to only those who initiated dialysis as an outpatient and with previous nephrology follow-up of three months or more. Time to death was compared for those starting at or below 6 mL/min/1.73m² (using the CKD-EPI formula) to those initiating between an eGFR of 6-15 mL/min/1.73m² and analyzed using an adjusted cox proportional hazard model.

Results: A total of 63327 unique patients started dialysis from 2004-2019, of whom 39696 patients started dialysis as an outpatient after at least three months of nephrology follow-up. The mean age was 63.1±14.68% were white, and 61% were male. 24% of the population started dialysis at an eGFR by CKD-EPI at or below 6 mL/min/1.73m². Patients starting at or below 6 mL/min/1.73m² were more likely to start dialysis with a CVC (59% vs 50%, p<0.001). During the study period 18979 patients died (48%). Starting dialysis at or below 6 mL/min/1.73m² was associated with a longer time to death (HR 0.87; 95% CI 0.84-0.90) after adjusting for sex, race, age, access type, diabetic kidney disease, and other comorbidities.

Conclusions: In this cohort of incident dialysis patients, those with an eGFR at or below 6 mL/min/1.73m² had a lower risk for mortality compared with those starting with a higher eGFR. These findings support deferral of dialysis initiation beyond the threshold of 6 mL/min/1.73m² in the absence of traditional indications.

PO0841 Hurricane Harvey Increased Need for Emergency Care in Patients with ESKD

Frederick L. Lemaistre,1 Caroline M. Schaefer,2 Donald A. Molony,1 Johns Hopkins Medicine, Baltimore, MD; ‘The University of Texas Health Science Center at Houston School of Public Health, Houston, TX; ‘The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: During natural disasters, end-stage kidney disease (ESKD) patients may represent a particularly vulnerable population due to interruption in care. These patients have increased morbidity due to cardiovascular events, other hospitalizations, and emergency department visits. After Hurricane Harvey (HH), the cohort of patients with ESKD in an urban area may have experienced an increase in emergency care utilization.

Methods: Of the 920 hemodialysis patients assessed for eligibility, 446 were enrolled in a regional program designed to evaluate functional status in all patients as a result of the disruptions in care related to Hurricane Harvey (HH).

Results: Of the 920 hemodialysis patients assessed for eligibility, 446 were enrolled in three groups on the basis of SPPB scores: high SPPB (n=167, EFR 6-15 mL/min/1.73m²) compared with lower SPPB (n=279, EFR 16 mL/min/1.73m²) and normal SPPB scores (n=100, EFR ≥16 mL/min/1.73m²). The median GCS score at admission was 13 (IQR, 6–14). Mortality, inpatient admissions, emergency department (ED) visits, and diagnosis of complications were compared between the three SPPB scorers and adjusted for age, sex, race, and history of peritoneal dialysis or kidney transplant at any time prior to the year of interest. The eGFR by CKD-EPI at or below 6 mL/min/1.73m² to those initiating between an eGFR of 6-15 mL/min/1.73m² (using the CKD-EPI formula) to those initiating between an eGFR of 6-15 mL/min/1.73m² and analyzed using an adjusted cox proportional hazard model.

Results: A total of 63327 unique patients started dialysis from 2004-2019, of whom 39696 patients started dialysis as an outpatient after at least three months of nephrology follow-up. The mean age was 63.1±14.68% were white, and 61% were male. 24% of the population started dialysis at an eGFR by CKD-EPI at or below 6 mL/min/1.73m². Patients starting at or below 6 mL/min/1.73m² were more likely to start dialysis with a CVC (59% vs 50%, p<0.001). During the study period 18979 patients died (48%). Starting dialysis at or below 6 mL/min/1.73m² was associated with a longer time to death (HR 0.87; 95% CI 0.84-0.90) after adjusting for sex, race, age, access type, diabetic kidney disease, and other comorbidities.

Conclusions: In this cohort of incident dialysis patients, those with an eGFR at or below 6 mL/min/1.73m² had a lower risk for mortality compared with those starting with a higher eGFR. These findings support deferral of dialysis initiation beyond the threshold of 6 mL/min/1.73m² in the absence of traditional indications.

PO0843 Functional Prognosis Following Cerebral Hemorrhage in Patients on Hemodialysis

Background: It has been reported that patients on hemodialysis have a higher morbidity and mortality for hypertensive cerebral hemorrhage. However, little is known about the functional outcomes in the surviving patients.

Methods: We retrospectively analyzed 62 consecutive patients on hemodialysis who developed hypertensive cerebral hemorrhage between 2016 and 2020. Patient background data, data on the clinical presentation of cerebral hemorrhage, and details of the lifesaving brain surgery (cereanotomy for removal of hematoma and ventricular drainage) were reviewed. The outcomes examined were in-hospital mortality and Glasgow Coma Scale (GCS), modified Rankin Scale (mRS), and Functional Independence Measure (FIM) scores at discharge.

Results: The median age of the patients was 66.5 years (interquartile range [IQR] 61.7–72.5). The median GCS score at admission was 13 (IQR, 6–14). Ventricular perforation was observed in 46.8% of patients. The median estimated hematoma volume

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
was 26.9 mL (IQR, 7.7–69.6). The in-hospital mortality rate was 29.0%. Palliative care policy was selected by 16.1% of patients at admission, and 27.4% of patients underwent the lifesaving brain surgery. Compared with survivors, the non-survivors had a lower level of consciousness at admission (GCS score, median [IQR]: 4.5 [3–8] vs. 14 [11–14], respectively, p < 0.001), higher rate of ventriculal perforation (88.9% vs. 29.5%, p < 0.001), and larger estimated hemorhema volume (55.5 [29.6–124.5] vs. 16.3 [5.5–43.6] mL, respectively, p = 0.003). After excluding patients with palliative care policy at admission, the ventricular perforation rate and estimated hemorhema volume were higher in patients who underwent surgery than those who did not undergo surgery. Patients who underwent brain surgery had a lower level of consciousness, median [IQR]: 4.0 [3.0–5.0] vs. 5.0 [5.0–6.0], respectively p < 0.001, and FIM score (18 [18–53.8] vs. 59 [20–84.5], respectively, p < 0.009) at discharge than patients who did not undergo surgery.

Conclusions: In our single-center experience, a lower level of consciousness at admission, larger estimated hemorhema volume, and ventricular perforation were associated with high mortality in patients on hemodialysis with cerebellar hemorrhage. Survivors who underwent the lifesaving brain surgery had very poor functional outcomes at discharge.

P00844

Hyperammonemia in an ESRD Patient
Roy Rajan, Kimberly J. Manzella, Charles W. Hopley. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.

Introduction: Carnitine is an important co-factor in long-chain fatty acid metabolism, and is involved in transport of long chain fatty acids into the mitochondria. Carnitine deficiency can present with hyperammonemia. We present a patient with ESRD with hyperammonemia and encephalopathy.

Case Description: This is a 48-year-old man with End Stage Renal disease due to neprolcalcinosis secondary to treatment complications due to X-Linked Hypophosphatemic rickets, presented to emergency room with nausea vomiting and severe confusion. He had severe delirium driven by encephalopathy and was not on valproate or any other psychotropic medications. His liver enzymes were normal, ALT, albumin levels but he had persistently elevated alkaline phosphate of 313 unit / L (40–130). PCO2 levels were normal. L. His ammonia level of 578 micro mol/L. There was no intracranial abnormalities in imaging. Free carnitine (FC) levels came back as 26 nmol/ml (25-54). Acyl Carnitine (AC) 13 nmol/ml (5-30) AC/FC ratio of 0.5. Even though he had low normal FC levels, his AC/FC ratio was elevated and it has been proposed that car/acyl car ratio greater than 0.4 represents carnitine deficiency. Patient initiated on IV L carnitine 20 mg/kg twice daily for 10 days without repeat renal ammonium screening. It was also noted that patient no longer experienced intracranial hypertrophy.

Discussion: Carnitine deficiency causes accumulation of non-oxidized fatty acyl-coenzyme A in the mitochondria, which inhibits degradation of ammonia. This typically responds to supplementation. An inverse correlation between plasma carnitine levels and ammonia has been observed in patients treated with valproic acid, and L. Carnitine has been used as treatment reduce the ammonia levels in valproate induced hyperammonemia. Carnitine deficiency can present with hyperammonemia, and clinicians should have high index of suspicion for this entity in malnourished dialysis patients without significant liver disease. Treatment is directed at replacement with intravenous Carnitine. Oral preparation containing mixture of D and L- carnitine is available but D- Carnitine is toxic. L- carnitine has limited oral absorption and has a limited bioavailability of 15%. The unabsorbed carnitine is degraded by intestinal bacteria to metabolites that are potentially toxic and have been shown to cause cognitive impairment. These limits use of oral supplementation of Carnitine.

P00845

Neurocognitive Function with Conventional Hemodialysis vs. Post-Dilution Hemodialfiltration as Initial Treatment: A Randomized Controlled Trial (The DA-VINCI Study)
Enzo C. Vasquez Jiménez,1 María Guadalupe C. Núñez,1 Salvador L. Gil,1 Abel V. Lema Talamanes,2 Claudia V. Lema Gonzalez,3 Aloha V. Meave Gonzalez,4 Magdalena Madero,5 Instituto Nacional de Cardiología Ignacio Chavez, México, Mexico; Instituto de Seguridad Social del Estado de Mexico y Municipios, Toluca, Mexico; Universidad Autónoma del Estado de Hidalgo Instituto de Ciencias de la Salud, Pachuca, Mexico.

Background: The ideal modality-choice and dialysis prescription during the first renal replacement therapy (RRT) session remains controversial. We conducted a pilot study to determine the safety risk for hemodialysis versus hemofiltration and its relationship with neurocognitive assessment on incident RRT patients.

Methods: Twenty-four incident RRT patients were included. Patients were randomized to the conventional HD group or the post-dilution HF group. MMSE and MOCA tests were applied in all patients before and after RRT and brain MRI was performed in 7 patients from each group before and after the intervention.

Results: Baseline characteristics were similar between groups. Compared to conventional HD, post-dilution HF had longer treatment time and blood volume. There were no significant changes in blood pressure after RRT in both groups. The MMSE test showed no significant differences between groups or within groups. The MOCA test showed an increase in the total score for the post dilution HF group with no significant changes between groups. The magnetic resonance image (MRI) evaluation showed no differences between or within groups.

Conclusions: Post-dilution hemofiltration is a safe alternative for the first hemodialysis session in incident RRT; it allows longer treatment time if ultrafiltration is required has a similar neurological risk than conventional HD.

Hemodialysis and hemodynamic variables.

Data are shown as mean ± standard deviation, median (percentile 25, percentile 75) or absolute frequency (percentage).

* p ≤ 0.05 compared to before dialysis (within same group)

P00846

Intradialytic Yoga-Based Breathing and Relaxation to Improve Anxiety, Depression, and Quality of Life: A Pilot Feasibility Study
Frans Conway,1 Martha N. Desta,2 Young sun Jung,2 Daniel M. Levine,2 Andrew Bohnart,1 1Well Cornell Medicine, New York, NY; 2Rogosin Institute, New York, NY.

Background: In-center hemodialysis patients have high rates of depression and anxiety. Pharmacologic interventions to ameliorate psychological burdens have proven to be limited in efficacy. Alternative therapies are increasingly used for those with chronic disease. A small number of studies have looked at the impact of meditation and yoga to improve symptoms of anxiety and depression and to promote a better quality of life. The aim of this study was to test the feasibility of implementing a chairside intradialytic yoga-based breathing and relaxation technique. A secondary goal was assessing the efficacy of such an intervention.

Methods: Eligible subjects were patients with a below average score on the Mental Component Summary (MCS) of a previously completed Kidney Disease Quality of Life (KDQOL™-36) survey. For inclusion consent, each subject was provided with an MP3 player, pre-loaded with a 12-minute recording of a specific yogaic breathing and relaxation exercise, the Three-Part Breath. The intervention consisted of listening to the recording at each dialysis treatment over a 12-treatment period. Subjects completed a KDQOL™-36 survey both at the start and the end of the study. A Likert scale to measure anxiety was completed at each dialysis treatment both pre- and post-intervention.

Results: 11 subjects were enrolled over a 10-month period in 2020; 10 completed the study. As measured by the Likert scale, anxiety was significantly reduced after listening to the recording. Notably, there was a larger reduction in anxiety on a post-treatment basis in the period after the start of the Covid-19 pandemic compared to the pre-pandemic period. Over the study period, there was a significant improvement in the scores of the Effects of Kidney Disease on Quality of Life component of the KDQOL™-36, and a trend toward significant improvement in the Mental Component Summary score.

Conclusions: A chairside, intradialytic breathing and relaxation program can be integrated into a dialysis treatment session. The study demonstrates an improvement in scores related to anxiety, depression, and measures of quality of life. Larger and randomized trials using this intervention are needed to better understand its benefits and adverse effects, as well as the obstacles to large scale implementation.

P00847

Quality of Life and Symptom Burden Before and After Start of Dialysis in Older Patients
Esther N. de Rooy,1 Yvette Meuleman,1 Johan W. De Fijter,1 Kitty J. Jager,2 Nicholas C. Chernyayev,3 Christoph Wanner,4 Friedo W. Dekker,5 Ellen K. Hoogenveen,1,3 The EQUAL Study investigators 1Leids Universitair Medisch Centrum, Leiden, Netherlands; 2Amsterdam UMC Locate AMC, Amsterdam, Netherlands; 3Jeroen Bosch Ziekenhuis, 4Hertogenbosch, Netherlands; 5Universitätsklinikum Würzburg, Würzburg, Germany.

Background: The number of ESKD patients ≥65 years starting chronic dialysis increases. Many of these patients have low quality of life (QoL) and high symptom burden. Little is known about the effect of dialysis initiation on QoL and symptoms. Therefore, we studied QoL and symptoms before and after start of dialysis in older patients.

Methods: The European Quality (EQUAL) study is an ongoing prospective multicenter cohort study in late stage 4/5 CKD patients ≥65 years. For this analysis, we included all patients who started dialysis. QoL was assessed every 3-6 months using the SF-36, resulting in a physical (PCS) and mental (MCS) component score, with higher scores meaning better QoL. Symptom number and severity were assessed every 3-6 months using the symptom index (DIS), with higher scores meaning higher burden. With linear mixed models we examined the effect of physical QoL, symptom number and severity in the year before and after dialysis start.

Dialysis Care: Epidemiology and the Patient Experience
Poster
Results: We included 571 older patients at dialysis start. Mean (SD) age was 77 (6) years, 74% were men, 45% had diabetes or cardiovascular disease and mean eGFR was 8.2 (3.7) ml/min/1.73m². In the year before dialysis MCS decreased by -15.7 (95% CI: -19.5 to -11.8), PCS by -12.0 (-15.7 to -8.2), symptom number increased by +3.5 (+2.5 to +4.6) and severity by +1.48 (+1.09 to +1.85). In the year after, MCS increased by +1.9 (-2.7 to +6.4), PCS decreased by -2.1 (-6.9 to +2.7), symptom number by -0.9 (-2.1 to -0.3) and severity by -6.0 (-10.4 to -1.7).

Conclusions: Mental and physical QoL, symptom number and severity, worsened considerably in the year before dialysis, but stabilized after dialysis initiation. These results could inform older ESKD patients who consider starting dialysis.

Objective Evaluation of Quality-of-Life Assessment as Predictors of Overall Health in Hemodialysis Patients in KSA
Afef Dridi, Laila Halawani, Ayman Sabri. DUVAita KSA, Riyadh, Saudi Arabia.

Background: Dialysis effect on a patient’s quality of life (QoL) is associated with death in regular hemodialysis (HD) patients and is a marker of wellbeing. In addition to clinical outcome measures QoL is influenced by socioeconomic status and education. Our aim was to explore the QoL in HD patients in population of prevalent HD patients in KSA.

Methods: The study consisted of 1032 patients undergoing HD in 17 centers. Data were collected by the completion of a specially designed questionnaire The Kidney Disease Quality of Life-Short Form (KDQOL-SF®) Arabic version 1.3 for assessing QoL.

Results: The study included 1032 patients (527 [51%] males and 505 [49%] females) with mean age 54.1 (±16.6) years and undergoing HD for 57.9 (±63.3) months. Multiple logistic regression analysis was done to identify parameters that independently associated with QoL. Lowest score was for the “burden of kidney disease” 33.1 (±23.4). Both “Physical Health Composite” (PHC) and “Mental health composite” (MHC) scores were poor as well, 36.5 (±8.7) and 42.0 (±8.7) respectively. “Patient satisfaction” and “Dialysis staff encouragement” scores were relatively higher 71.5 (±22.7) and 84.4 (±18.8) respectively. Age, duration of HD, cardiac comorbidity and abnormal phosphorus level were significant negative predictors for “overall health” scores while education and home medications’ count were significant negative predictors for that domain. Abnormal phosphorus level and longer durations on HD treatment were significant negative predictors for “overall health”, “MHC”, “Burden of kidney disease” and perceived “Dialysis staff encouragement” scores. Age, female gender and hypoalbuminemia were significant negative predictors of “PHC” scores. Controlling serum phosphorus level and albumin might predict better QoL.

Conclusions: Misconceptions about QoL still represent a substantial barrier among HD patients. Most are educated about fundamental clinical outcomes after initiation of dialysis. In our study, Patients on hemodialysis have a poor QoL score. Different sociodemographic and clinical characteristics affect scores. Initiatives to promote and improve onboarding dialysis education and knowledge about QoL are needed to improve the low QoL in Saudi Arabia. Such patients may benefit from efforts on the part of the health care provider to support patient QoL as part of the monthly care plan.

PO0849
Fetal and Non-Fatal Gastrointestinal Events with Sodium Polystyrene Sulfonate Use in Hemodialysis: DOPPS
Ana C. Farfan Ruiz, Greg A. Knoll, Emily Rhodes, Manish M. Sood. University of Ottawa Faculty of Medicine, Ottawa, ON, Canada.

Background: There are increasing concerns regarding the gastrointestinal (GI) safety of sodium polystyrene sulfonate (SPS), a medication commonly used in the management of hyperkalemia. The objective is to compare the risk for fatal, non-fatal and their composite GI events following initiation of SPS in patients on hemodialysis compared to non-use.

Methods: An international registry of adults (≥18) on chronic intermittent hemodialysis (Dialysis Outcomes and Practice Patterns Study, DOPPS, Phases 2-6 from 2002 to 2018, 17 countries, n=229,295) who were prescribed SPS (n=24,668, 10.76%) were compared with non-users of SPS. Individual patient and facility-level analysis of fatal and non-fatal GI events were examined using weighted models.

Results: Country-level variation in SPS use ranged from 0.74% (UK) to 47.42% (France). 934 fatal and, 837 non-fatal events occurred [3-year cumulative incidence for fatal GI events: SPS 9.0% vs. no SPS 7.6%; non-fatal: SPS 0.4% vs. non-use 0.5%]. The weighted risk of fatal and composite GI events was elevated with SPS use compared to non-use (fatal HR 1.18 95%CI 1.05-1.32, non-fatal HR 0.73 95%CI 0.64-0.84, composite HR 1.02 95%CI 1.082-1.26). Younger age (<65), men, country (France, Belgium, Japan), dialysis vintage (>4 years), shorter HD treatment time (<3.5 hours) and a higher K gradient (serum potassium – dialysate potassium) were associated with a higher risk of a fatal GI event with SPS. The findings were consistent when limited to individuals with known vascular access (n=135, 628) and in an analysis examining the fraction of SPS use by facility.

Conclusions: SPS use in patients on hemodialysis is associated with a higher risk of fatal GI events.

Improved One-Year Survival and Decreased Hospitalization Rate in Incident Hemodialysis Patients with Incremental as Compared to Standard Hemodialysis Regimen: A Single-Centre Experience

Background: Preservation of residual kidney function (RFK) in maintenance hemodialysis (HD) patients is associated with better survival and quality of life. RFK may be better preserved with an incremental HD regimen in patients starting HD. Since 2013, incremental HD (frequency < 3x/week) has been used in our center.

Methods: Incremental HD is implemented in incident HD patients who have a daily residual diuresis > 600 ml, a urea clearance ≥ 2 ml/min and an interdialytic weight gain < 2.5 kgs. Patients are clinically assessed every week and a 24 hr urine sample is collected every other month in order to measure RFK.

Results: From January 2013 to March 2020, 295 patients started chronic dialysis in our center, of whom 221 were on hemodialysis. Among them, 63 patients started maintenance HD with an incremental regimen. These patients did not differ significantly from those with a thrice-weekly HD regimen in terms of age, gender and comorbidity score. Residual diuresis, eGFR and urea clearance at incremental HD initiation were respectively 1842 ± 749 ml/day, 6.7± 3.1 ml/min and 4.0 ± 1.8 ml/min. Among these 63 patients, four could retrieve a sufficient RFK to become dialysis-independent after a mean 6-month duration of incremental HD and 2 were transplanted while on incremental dialysis. Among the remaining 57 patients, mean duration of incremental HD until transition to a thrice-weekly HD regimen or death was 12 ± 12 months (median, IQR: 10, 6-20). Within the first dialysis year, survival and hospital-free days (median, IQR) were higher in patients starting with incremental HD than in patients with a thrice-weekly HD regimen (91 vs 77%; p=0.02 and 344 (318-360) vs 338 (295-354) days; p=0.03).

Conclusions: These preliminary results show that incremental HD can be implemented in incident HD patients as long as regular clinical and RFK assessments are found adequate. However, randomised clinical trials assessing long-term survival and quality of life in incremental HD are necessary prior to its large-scale implementation.

PO0851
Association Between Systolic Blood Pressure Changes and Residual Kidney Function Decline Among Hemodialysis Patients After 1 Year
Miguel A. Morillo,1 Jui-Ting Hsiung,1 Csaba P. Kovovsky,2 Kamyar Kalantar-Zadeh,3 Elani Streja.1 University of California Irvine, Irvine, CA; 2VA Memphis Medical Center, Memphis, TN; 3The University of Tennessee Health Science Center, Memphis, TN.

Background: For patients undergoing hemodialysis, large changes in systolic blood pressure (SBP) from before to after the dialysis has been associated with worse survival. Declines in residual kidney function has also been associated with worse survival. However, the association between SBP changes and residual kidney function decline has not yet been examined.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We constructed a retrospective cohort of 6659 hemodialysis patients who started hemodialysis between 2007-2011 with baseline changes in SBP and renal urea clearance (KRU) at the 1st and 5th patient quarter (91 day interval from dialysis start). KRU difference was measured as KRU difference between 5th minus 1st patient quarter. The association between baseline average changes in SBP and KRU difference was examined using linear regression analyses. Covariates included age, sex, race, BMI, dialysis modality type, and comorbidities.

Results: Linear regression analysis indicated a linear relationship between change in SBP and KRU decline even after adjusting for covariates. Trends across all models showed hemodialysis patients with increased systolic blood pressure showed increased residual kidney function compared to the reference (-10 to -0 mmHg). After adjusting for covariates, hemodialysis patients with SBP levels that increased by 10mmHg or more had the greatest increase of KRU (0.12, 95% CI (-0.39, -0.62)), while patients with a decrease of SBP by 10-20mmHg had the greatest decline (-0.31, 95% CI (-0.60, 0.02)). Models adjusting for SBP measures showed similar trends, while the model without low-SBP and post-SBP showed an increased in KRU when SBP decreased by 10-20mmHg (0.23, 95% CI (0.01, 0.05)).

Conclusions: Increase in SBP was associated with a greater KRU decline in hemodialysis patients. Further studies should examine the underlying causes of this association and determine if modifications to dialysis treatments can improve preserving KRU and patient survival.

PO0853
Variability of Plasma Refill Rate and Risk of Intradialytic Hypotension During Maintenance Hemodialysis

Hao Wang,1 Dan Negoiu,1 Hanjie Zhang,2 Sabrina Rogg,3 Jesse Y. Hsu,4 Peter Kotanko,2,3 Jochen G. Raimann,2 Laura M. Dembert.1
1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Renal Research Institute, New York, NY; 3Leona School of Medicine at Mount Sinai, New York, NY; 4Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Continuous hemotocrit data can be combined with time-updated ultrafiltration data to non-invasively estimate a semi-instantaneous plasma refill rate (PRR) throughout hemodialysis. The PRR is a dynamic metric that varies throughout hemodialysis, even during periods of constant rates of ultrafiltration, and is influenced by oncotic and hydrostatic forces. We aimed to determine whether variability in PRR is associated with intradialytic hypotension (IDH).

Methods: We used data from continuous hemotocrit monitoring performed at 17 dialysis units from January 2017-October 2019 to calculate intradialytic plasma refill rates standardized to weight and height. PRR variability was defined as the coefficient of variance in PRR (PRRcov) every 15 minutes and categorized into three groups: low (PRRcov < 1.0), moderate (PRRcov 1.0-2.0) and high (PRRcov > 2.0). IDH was defined in three ways: (1) nadir systolic blood pressure (SBP) < 90 mmHg, (2) SBP < 90 mmHg or associated symptoms, and (3) either drop in SBP of 20 mmHg or mean arterial blood pressure of 10 mmHg with associated symptoms. Cox proportional hazard regression was used to assess the impact of starting PRR variability on time to first IDH. Marginal structural modeling was used to assess the impact of time-updated plasma refill rate variability on the risk of IDH.

Results: Among 2350 patients and 184,453 hemodialysis sessions, mean session time was 220 ± 26 min and ultrafiltration rate was 9.0 ± 3.3 ml/kg/hr. Median PRRcov was 1.20 (IQR 0.68, 2.18) across all sessions. Compared to hemodialysis sessions with low PRRcov sessions with high PRRcov in the first 15 minutes of treatment were associated with a 1.14 hazard of intradialytic hypotension (95% CI 1.05, 1.24). Accounting for repeated measures and changes in systolic blood pressure and ultrafiltration, sessions with high PRRcov throughout the duration of hemodialysis were associated with an increased risk of IDH based on adjusted definitions: definition 1 (OR 1.29, 95% CI 1.16, 1.43), definition 2 (OR 1.85, 95% CI 1.77, 1.94), and definition 3 (OR 1.87, 95% CI 1.78, 1.98).

Conclusions: PRR variability was associated with higher risk of IDH, independent of time-varying confounding from SBP and UFR. PRR variability could be a promising bedside metric for hemodynamic instability during hemodialysis.

Systemic Parameters of the Renin-Angiotensin-Aldosterone System Remain Unaffected by Changes in Fibroblast Growth Factor 23 Levels in Hemodialysis Patients

Katharina Dörr,1 Michael Kammer,1 Roman Reinidl-Schwaghofer,1 Matthias Lorenz,2 Rodrigo Marculescu,1 Marko Poglitsch,3 Rainer Oberbauer.1
1Medizinische Universität Wien, Wien, Austria; 2Attoucan, Vienna, Austria.

Background: Fibroblast growth factor 23 (FGF23) is elevated in patients with chronic kidney disease and promotes the development of left ventricular hypertrophy (LVH). Decreasing the levels of FGF23 with the calcimimetic drug etelcalcetide can abate these changes, but hemodialysis patients with the prohypertrophic effect of FGF23 is modified by the renin-angiotensin-aldosterone system (RAAS). The aim of the analysis was to determine whether changes in FGF23 levels are associated with differences in RAAS-parameters in hemodialysis patients, possibly explaining its influence on LVH.

Methods: Serum samples were obtained at baseline and one year from participants in the randomized EIECAR-HD trial. In this study 62 hemodialysis patients were treated with either calcimimetic or vitamin D treatment, which have opposite effects on FGF23. We analyzed PRA-S as the angiotensin-based marker for renin activity, angiotensin II (AngII), angiotensin-converting enzyme-2 (ACE2) and aldosterone using a high throughput mass spectrometry assay.

Results: The median levels of FGF23 were 2386 pg/ml (1st to 3rd quartile 819–5166) and 1386 pg/ml (288–4068) at baseline and end of study, respectively. The association of changes between baseline and end of study in FGF23 with the levels of the RAAS-components (i.e. PRA-S, AngII, ACE2, aldosterone) estimated by linear regression models was weak, with effect sizes for log2-fold-change in FGF23 close to zero. The amount of explained variation by FGF23 fold-change was generally small (drop-in-R2 values all below 0.03). The median overall levels of PRA-S were 130 pg/ml (1st to 3rd quartile 79–2669), of AngII 70 pg/ml (28–157), of aldosterone 130 pg/ml (54–218) and of ACE2 1.4 ng/ml (1.1-1.8), as compared with healthy controls (PRA-S 196 pg/ml [98–238], AngII 137 pg/ml [76-201], aldosterone 335 pg/ml [139-454], ACE2 1.38 ng/ml [1.17-1.65]).

Conclusions: In the present study we were able to show that systemic RAAS activity was grossly unaffected by the treatment induced changes in FGF23 levels in this cohort. Overall, the levels of PRA-S, AngII and aldosterone were well below the ranges measured in healthy controls suggesting that the RAAS is not systemically activated in hemodialysis patients.

Prediction of Left Ventricular Function Using Electrocardiogram Data in Patients on Hemodialysis

Akhil Vaid,1 David M. Charytan,2 Lili Chan,3 Girish N. Nadkarni,1 1Icahn School of Medicine at Mount Sinai, New York, NY; 2NYU Langone Health, New York, NY.

Background: Left ventricular (LV) systolic dysfunction is common in patients on maintenance hemodialysis (HD). Early identification of patients with depressed left ventricular ejection fraction (LVEF) can facilitate disease modifying treatment. Electrocardiograms (ECGs) are routinely performed in patients on HD, however, they have not been used for estimating LVEF in this population.

Methods: We analyzed data from five Mount Sinai facilities. Patients on HD with a transthoracic echocardiogram within 7 days of an ECG were identified using diagnostic and procedure codes. ECG data were preprocessed to remove recording artifacts, plotted to an image, and along with patient demographics were analyzed using a model comprised of a Multi-Layer Perceptron and a Convolutional Neural Network. We developed three models: 1) trained from scratch in only HD patients, 2) pre-trained on natural images (Imagenet), and 3) pre-trained on all LVEF-ECG pairs (n=699,890) excluding those for ESRD patients. Models 2 and 3 leverage transfer learning, which reuses knowledge gained from a task to perform a similar task. All models were trained/tested on LVEF-ECG pairs for ESRD patients within a Group Stratified K Fold (K=5) Cross Validation design and performance was compared per Area Under Receiver Operating Characteristic curve (AUROC) for each category of LVEF, ≤40%, 40% to ≤50%, and >50%.

Results: We extracted 18,626 LVEF-ECG pairs for 2,168 ESRD patients. For detection of LVEF ≤40%, models trained from scratch and pre-trained on Imagenet had AUROCs of 0.74 (95% CI: 0.67-0.80) and 0.71 (95% CI: 0.65-0.77) respectively. These were outperformed by the model pre-trained on ECG data [AUROC of 0.91 (95% CI: 0.88-0.93)]. Similar results were seen at detection of LVEF ≥40% with the AUROC being 0.85 (95% CI: 0.84-0.87) for both the model trained from scratch and the Imagenet model, while the model pre-trained on ECG data achieved an AUROC of 0.82 (95% CI: 0.78-0.87).

Conclusions: A model pre-trained on non-HD LVEF-ECG pairs using transfer learning and LeNet-15 outperformed models trained from scratch or pre-trained on Imagenet. This model facilitates identification of LV systolic dysfunction in patients on HD.

PO0856

Clinical Outcomes of Bioimpedance Analysis-Guided Hemodialysis: A Meta-Analysis of Randomized Controlled Trials

Panupong Hansrivijit,1 Chennchen Qian,1 Sumit Mohan,2 1UPMC Pinnacle, Harrisburg, PA; 2Columbia University Irving Medical Center, New York, NY.

Background: Determination of fluid status in hemodialysis patients could be a great challenge for providers. Body composition monitoring using bioimpedance analysis (BIA) is an emerging tool in guiding fluid removal in hemodialysis population. However, although there are some randomized controlled trials (RCT), the reported outcomes remain heterogenous and inconclusive across studies.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched for eligible articles through May 2021. Inclusion criteria were: 1) RCT comparing BIA against clinical assessment, 2) sample size > 50, 3) adults > 18 years on hemodialysis (HD), 4) clinical outcomes were reported. No publication bias detected by Egger’s regression intercept analysis.

Results: A total of seven RCTs (n = 1029 total; 519 BIA, 510 control), dated from 2010 to 2019, with a mean follow-up duration of 15.0±10.6 months were identified. There was no difference in mortality between BIA and clinical group (odds ratio [OR] 0.79; 95% CI 0.55-1.15; I2 47.8%) compared to BIA group. There was no difference in post-HD body weight compared to BIA group (SMD 0.157; 95% CI 0.034, 0.280; I2 2.3%) with a mean follow-up duration of 15.0±10.6 months and order for 2 or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e’, portal vein (PV) pulsatility and IVS size. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fischer’s and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

PO0857

Point-of-Care Ultrasound Measurements to Predict Intradialytic Hypotension: A Cross-Sectional Pilot Study

Chrysted Pawls,1 Wiel Azzam,2 Christy Costanian,1 Gonzalo Matzumura Umemoto,1 Enyo Ablordey,2 Fadi Tohme.1 1Lebanese American University, Beirut, Lebanon; 2University of Southern California, Los Angeles, CA; 1Washington University in St Louis, St Louis, MO.

Background: Intradialytic hypotension (IDH) results from excessive ultrafiltration in patients on chronic hemodialysis (HD) and has been linked to increased mortality. Prescribing the right amount of ultrafiltration can be challenging, partly due to the poor sensitivity of physical examination for detection of volume overload in HD patients. POCUS is emerging as a valuable tool in the assessment of volume status. The goal of this study is to determine whether pre-dialysis POCUS measurements are associated with development of IDH.

Methods: Patients >18 years old on HD for at least 6 months and ordered for 2 or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e’, portal vein (PV) pulsatility and IVS size. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fischer’s and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

Conclusions: In this pilot study, an elevated lateral E/e’ was associated with lower rates of IDH events or post HD orthostasis. The role of POCUS in guiding fluid removal during HD warrants further exploration.

PO0858

A Clinical Approach of Intradialytic Creatine Supplementation in Dialysis-Dependent CKD Patients: A Rationale and Study Design

Vanjone van der Ven,1 Adrain Post,1 Daan Kremer,2 Ralf Westerhuis,2 Casper F. Fransson,1 Theo Wallimann,3 Stephan J. Bakker.1 1Universitair Medisch Centrum Groningen, Groningen, Netherlands; 2Dialyse Centrum Groningen, Groningen, Netherlands; 3Idéogenossische Technische Hochschule Zurich, Zurich, Switzerland.

Background: There is great need for identification of new, potentially modifiable risk factors for the poor HRQoL and excess risk of mortality in dialysis-dependent chronic kidney disease patients. Creatine is an essential contributor to cellular energy homeostasis, yet on a daily basis 1.6-1.7% of the total creatine pool is non-enzymatically degraded to creatinine and subsequently lost via urinary excretion, thus necessitating a continuous supply of new creatine to remain in steady-state. Due to an insufficient ability to synthesize creatine, unopposed losses to the dialysis fluid, and insufficient intake, hemodialysis patients are prone to create deficiency, and may benefit from creatine supplementation. To avoid problems with compliance, fluid balance and, furthermore, to prevent intradialytic losses of creatine to the dialysate, we aim to investigate the potential of intradialytic creatine supplementation in improving outcomes.

Methods: Here, we describe the rationale and design for a block-randomized, double-blind, placebo-controlled pilot study. A total of 16 hemodialysis patients will be included, divided into four groups receiving intradialytic creatine supplementation (0.5mM, 1.0mM, 1.5mM, 2.0mM), or a placebo for six weeks. The aim of the pilot study is to explore the creatine uptake in the circulation and tissues following different creatine supplementation dosages.

Results: The main parameters for the pilot study are the plasma creatine concentration and intra-erythrocytic creatine concentration of both pre- and post-hemodialysis samples. Secondary study parameters are handgrip strength as a measure of muscle strength, combined intradialytic urinary and intradialytic dialysate excretion of creatinine as a measure of muscle mass, and body composition measured with bioelectrical impedance analysis (BIA).

Conclusions: Intradialytic creatine supplementation may help to maintain creatine homeostasis among dialysis-dependent chronic kidney disease patients, and consequently improve important causes for impaired HRQoL, including protein energy wasting (PEW), fatigue, muscle weakness, depression, and cognitive impairment. The results from the pilot study will serve as a basis for a larger double-blind, placebo-controlled supplementation trial.
PO0859

Relationship Between Fluid Overload and Hemoglobin Concentration in Hemodialysis Patients: A Longitudinal Analysis

Lemuel Rivera Fuentes,1 Arielle E. Mermelstein,1 George A. Kayser,2 Jochen G. Raimann,1 Ulfrich Moissl1, Stephan Thijssen,1 Peter Kotanko,1 Renal Research Institute,2 Renal Research Institute, New York, NY; University of California Davis, Davis, CA; 3 Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Quantification of fluid status by bioimpedance spectroscopy (BIS) has become routine outside United States (US). We performed the first assessment of fluid status in US hemodialysis (HD) clinics using a BIS device. We studied the longitudinal association between fluid overload (FO) and hemoglobin (Hgb) concentration adjusting for inflammation and erythropoiesis-stimulating agents (ESA).

Methods: Measurement of FO [Body Composition Monitor (BCM); Fresenius Medical Care] was conducted cross-sectionally in chronic HD patients in 4 HD clinics in New York. We built linear mixed effects models with Hgb as the dependent variable and calculated FO longitudinally to include as a fixed effect. We tested the robustness of the association to account for the influence of inflammation by including the neutrophil-lymphocyte ratio (NLR) as an additional fixed effect. As a subset analysis 2 separate models were built in subjects with or without ESAs. To corroborate the dilutional effect of FO we exchanged Hgb for albumin as a fixed effect.

Results: We studied 169 patients (Figure 1). FO was inversely associated with Hgb [Estimate -0.06 (-0.20 to -0.12) g/dl per 1L of FO], a significant fixed effect that remained unchanged in magnitude even after inclusion of NLR [Estimate 0.04 (-0.05 to 0.06) g/dl per 1 unit of NLR]. The effect was larger in patients without ESA prescription [Estimate -0.02 (-0.32 to 0.12) g/dl per 1L of FO]. FO was a significant determinant of albumin [Estimate -0.02 (-0.03 to 0.01) g/dl per 1L of FO] with NLR being a significant fixed effect [Estimate -0.03 (-0.04 to -0.01) g/dl per 1 unit of NLR].

Conclusions: Hgb is inversely affected by FO, a significant effect independent of inflammation (NLR). The impact of FO on Hgb concentration is larger in those with no ESA treatment emphasizing that fluid status has to be considered in anemia management. The effect of FO on albumin supports hemodilution as the principal cause for the changes seen on Hgb.

Interpreting Home Blood Pressure Measurements in Haemodialysis: A Post Hoc Analysis of a Randomized Cross-Over Study

Vicki K. Sandys,1 Lavleen Bhat,1 Emer C. O’Hare,1 Conall M. O’Seaghdha,1 Donal J. Sexton,2 Royal College of Surgeons in Ireland, Dublin, Ireland; The University of Dublin Trinity College, Dublin, Ireland.

Background: Home BP correlates better with ambulatory BP, target organ damage and mortality in dialysis patients. We aimed to determine the agreement of in-centre BP with home BP.

Methods: A post-hoc analysis of a pilot-scale, randomised two-period cross-over study comparing self-monitoring of BP over 4 weeks with usual care in 41 haemodialysis patients. www.clinicaltrials.gov. NCT0340349. Dialysis clinic BP and home BP (using average real variability (ARV). Mixed effects models for repeated measures with a moving average window of 2 weeks were used to examine associations with BP and ARV.

Results: 33 out of 41 participants had sufficient home BP measurements for inclusion (mean age: 52 +/- 13 years, 65% male). Post-dialysis SBP had moderate agreement with home SBP measurements (K = 0.6) compared with pre-dialysis SBP measurements (K = 0.4). The mean bias between home SBP and post SBP measurements was -4.15 mmHg (95% CI 23.5 to -31.8 mmHg) (Figure 1). Home SBP ARV (16 +/- 6) was as high as pre SBP ARV (14 +/- 5) and post SBP ARV (13 +/- 5). In univariate analysis only calcium channel blockers were consistently associated with pre-dialysis (P = 0.02), post-dialysis and home SBP (both P < 0.001).

Conclusions: Post-dialysis SBP demonstrates moderate agreement with home BP when two week BP averages are used. Home BP measurements are as variable as clinic BP measurements and isolated measurements may lack interpretability. Averaging the home BP over two weeks may improve the utility of home BP monitoring.

Funding: Commercial Support - patientMpower

Figure 1: An illustrative BP profile for one study participant a) All home BP raw data compared to in-centre data b) Averaged home BP data on non-dialysis days c) Bland Altman plot of all patients comparing home and post-dialysis BP using 2 week averaged values.

Increased Tricuspid Regurgitation Jet Velocity as a Predictor of Acute Decompensated Heart Failure in ESRD Patients on Maintenance Hemodialysis

Youngchan Park,1 Ye na Kim,1,2 Ho Sik Shin,1,2 Yeonsoo Jung,1,2 Hark Rim,1,2 Kosin University Gospel Hospital, Busan, Busan, Republic of Korea; 2 Transplantation Research Institute, Kosin University College of Medicine, Busan, South Korea, Republic of Korea.

Background: Many patients with end-stage renal disease (ESRD) on hemodialysis (HD) experience left ventricular hypertrophy and reduced vascular compliance and are likely to develop heart failure (HF). We aimed to determine the hemodynamic factors associated with acute decompensated events among ESRD patients undergoing HD.

Methods: We retrospectively investigated ESRD patients on HD through a medical record review. We excluded patients with significant ischemic heart disease (IHD), percutaneous coronary intervention or coronary artery bypass graft, significant valvular heart disease (VHD), or malignancy. We divided patients into those who experienced any admission due to acute decompensated HF (ADHF) and those who did not.

Results: Of the 188 ESRD patients on HD, 87 were excluded, and 101 were enrolled (mean age: 63.7 years, 52.1% male). The ADHF group demonstrated significantly higher tricuspid regurgitation (TR) jet velocity (2.9 ± 0.6 vs. 2.5 ± 0.4 m/s, respectively; p=0.004) than the non-ADHF group. Multivariate logistic regression analysis demonstrated that TR jet velocity (odds ratio: 8.356, 95% confidence interval: 1.806–38.658; p=0.007) was an independent predictor of ADHF after adjusting for age and sex, while LVEF and E/E’ were not. Per receiver operating characteristic curve analysis, TR jet velocity > 2.8 m/s was associated with ADHF with 47.7% sensitivity and 76.4% specificity (area under the curve: 0.656).

Conclusions: Our data showed that increased TR jet velocity was an independent predictor of ADHF events in ESRD patients on HD, but LVEF and E/E’ were not.

Benefit of More Frequent Dialysis on Dialysis Recovery Time in Nursing Home Patients with ESRD

Alice Hellebrand,1 Eran Y. Bellin,1,2 Steven M. Kaplan,1 Jordan Ledvina,1 William Marks,2 Nathan W. Levin,1 Allen Kaufman,1 Dialyze Direct Brooklyn 1Dialyze Direct Brooklyn, Brooklyn, NY; 2Albert Einstein College of Medicine, Bronx, NY.

Background: Dialysis patients admitted to a skilled nursing facility (SNF) are characterized by advanced age; frailty, and multiple comorbidities. Based on prior studies which demonstrated shortened dialysis recovery time (DRT) with more frequent dialysis (MFD) in populations aged ~50s living at home (FREEDOM Study 2010, FHN trial 2006), it was postulated that dialysis patients in a SNF would benefit from MFD.

Methods: Patients studied were admitted to SNFs in OH, TX, FL, NY, and PA from November-December 2019 (pre-COVID) and could reliably answer questions about DRT. 80% were undergoing subacute rehabilitation and 20% were permanent residents of the SNF. Patients received NxStage on-site staff assisted MFD 5x (80%) or 4x (20%) per week. StdKt/V was ≥ 2.1. At every dialysis, patients were asked by their RN caregiver “How long did it take you to recover from your last HD session?” Responses were deemed unreliable if a patient had cognitive impairment. Reliable responses were used for outcome analysis. In the present study, DRT data was collected by a caregiver nurse, differing from the methodology of the FREEDOM/FHN studies which collected DRT data via KDQOL form or phone interview. The implications of these differences in data collection methods are currently unknown.

Results: 485 unique patients were included in the study. Demographics included 53% males, mean age 67.5 +/- 13 years, African American 19%, Caucasian 25%, Hispanic 5%, Asian 0.4%, unknown or other 51%. Mean DRT was 1.5 +/- 2.6 hours. Mean DRT was calculated using the midpoint recovery time for intervals, or 18 hours when DRT was the next morning or beyond. In 69%, DRT was < 2 hours.

Conclusions: In the FREEDOM and FHN conventional HD 3x per week study arms, DRT averaged 6-8 hours. MFD reduced DRT to ~1.0 hour in those relatively young patients living at home. In our study, HD patients residing in a SNF and receiving MFD experienced DRT of 1.5 hours. Age, frailty and comorbid conditions therefore do not prevent DRT benefits of MFD. DRT benefits could stem from more effective, gentler fluid management by MFD. Further studies are needed to fully explore the impact of shortened DRT on rehabilitation scores, hospitalizations and deaths in elderly patients residing in SNFs.

PO0863

The Combination of Arterial Stiffness and Peripheral Vascular Disease Aggravates Survival Among Hemodialysis Patient Using Competing Risk Analysis

Adisorn Pathumarak, Kanin Thammanvaranucut, Chagriya Kityakara, Arkorn Nongnuch. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: The survival in end state renal disease (ESRD) patient is unacceptable high. The Skin autofluorescence (SAF) for advance glycated end products (AGEs), peripheral vascular disease (PVD) (ankle-brachial index, ABI ≤0.9) and arterial stiffness (carotid ankle vascular index, CAVI>9) were reports as predictors of mortality. However, kidney transplantation (KT) competes the mortality outcome. We aim to explore these markers for precisely prediction of mortality using competing risk method.

Methods: Retrospective chart review in chronic hemodialysis patients was done in 3 hemodialysis centers in North Bangkok during November 2015 and March 2016. Arterial stiffness, SAF, IMAR and PVD were collected as a clinical predictor: Cumulative incidence of mortality was used as was a primary outcome. Logistic regression with competing risk model was used to analyze the factor affecting mortality.

Results: A Total of 176 patients were eligible and classified into 4 groups according to PVD and stiffness status. During follow up 44.5±14.8 months, the overall mortality rate was 27% which is 13.2, 28.6, 31.5 and 61.9% in no PVD and stiffness, exclusively PVD, exclusively stiffness, and combine group respectively. The PVD (HR 2.93, CI 1.2 to 7.14, P=0.018) and stiffness (HR 2.57, CI 1.1 to 5.73, P=0.021) were independent predictors of mortality. In competing risk method, the combination of PVD and stiffness associate with highest mortality (P=0.0002139), while the patients who no PVD and stiffness had the highest rate for KT (P=0.0050275).

Conclusions: The PVD and stiffness were an independent risk of mortality among hemodialysis patients. The combination of PVD and stiffness may stratify risk of mortality in hemodialysis patient using competing risk method.

PO0864

Body: Fat Mass Plays an Important Role in Over- or Underestimation of Bioimpedance Spectroscopy-Based Dry Weight for Patients with Hemodialysis

Dae Eun Choi,1 Hae Ri Kim,2 Jae wan Jeon,2 Jin Ah Shin,1 Soo hyun Han,1 Haet Bih Hwang,1 Eu Jin Lee,1 Kiryang Na,1 Kang Wook Lee.1 Chungnam National University School of Medicine, Daejeon, Daejeon, Republic of Korea; 2Chungnam National University Sejong Hospital, Sejong, Republic of Korea.

Background: Accurate dry weight (DW) estimation is important for hemodialysis patients. Although bioimpedance spectroscopy (BIS) is commonly used to measure DW, the BIS-based DW frequently differs from the clinical DW.

Methods: We analyzed the characteristics of patients whose BIS-based DWs were over- and underestimated. In this retrospective cohort study, we evaluated 1,555 patients undergoing maintenance hemodialysis in Chungnam National University Hospital. The gap (DW_{BIS} - DW_{clinical}) was calculated by comparing the BIS and clinical DWs.

Results: We analyzed the clinical characteristics of patients with positive (n = 835) and negative (n = 720) gaps. Compared with other patients, the DW_{BIS} positive group was taller, had higher extracellular water (ECW) level and extracellular/intracellular water index (E/I). and had lower weight, body mass index (BMI), lean tissue index (LTI), fat tissue index (FTI), fat mass (FAT), and adipose tissue mass (ATM), as well as lower levels of hemoglobin, total protein, albumin, and phosphorous. The DW_{BIS} negative group exhibited higher levels of hemoglobin, total protein, albumin, and phosphorous, as well as elevated BMI, FTI, FAT, and ATM, however, it had lower height, ECW, and E/I. Linear regression analysis revealed that FAT significantly predicted DW_{BIS} accuracy.

Conclusions: The clinical DW of patients with malnutrition and a low fat mass tended to be underestimated, while the clinical DW of patients with comparatively large fat reserves tended to be overestimated. These characteristics of dialysis patients will aid in the correction of BIS-associated DW errors.

PO0865

Consistency of the Dry Weight of Hemodialysis Patients Predicted Using Bioelectrical Impedance Analysis Between Standing and Lying-Down Positions

Hyunsuk Kim. Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-do, Republic of Korea.

Background: Although the InBody S10 is widely used for hemodialysis patients in the lying position, clinicians must make the measurements in person. In contrast, patients can use the InBody 770 to obtain measurements by themselves in the standing position according to instructions provided by the machine, which may be more convenient. Therefore, this study compared the measurements of hemodialysis patients' dry weight obtained lying down using the S10 to those obtained in the standing position using the 770.

Methods: Measurements from 56 patients before and after hemodialysis were obtained. Dry weight was calculated using the ratio of extracellular water to total body water, taking into consideration diabetes status and albumin levels, and comparing the results according to body position (lying vs. standing).

Results: The patients' median age was 64 years old, and 51% were men. Their mean dry weight before hemodialysis was 60.9±12.5 kg using the S10 device and 60.1±12.5 kg using the 770 device (paired t-test; t=-6.472, P<0.001). The correlation between these
measurements was high (R²=1.0000). Patients’ mean dry weight after hemodialysis was 58.4±12.2 kg using the S10 device and 58.5±12.0 kg using the 770 device (paired t-test; t<1.560, P=0.124). The correlation between these measurements was also very close (R²=1.0000). The Bland-Altman test yielded similar results.

**Conclusions:** This study showed that patients’ predicted dry weights in the lying position using the InBody S10 device and in the standing position using the InBody 770 device were consistent in both pre- and post-hemodialysis states. It can be concluded that the dry weight of a patient in the standing position can be measured with more convenience and autonomy using the InBody 770 device.

Use of Crit-Line to Reduce Intradialytic Hypotension in Hospitalized Patients Receiving Dialysis

**Background:** Intradialytic hypotension (IDH) is a frequent complication of hemodialysis in hospitalized patients with acute kidney injury (AKI) and end stage kidney disease (ESKD). Crit-Line is a device that monitors absolute hematocrit and oxygen saturation during dialysis and reads out the percent blood volume change. Whether the use of Crit-Line during HD in hospitalized patients results in less IDH is unknown.

**Methods:** We performed a time series study in all hospitalized adult AKI/ESKD patients undergoing acute HD at the University of Colorado. During the control period baseline data was collected. During the intervention period, Crit-Line was used on all hospitalized patients undergoing HD including those receiving portable HD treatments in the ICU. During both time periods, nurses recorded number of hypotensive events, patient symptoms and modifications that were made to the dialysis prescription. The primary outcome was number of IDH events defined by the NKF KDOQI Guidelines. Baseline data was collected. During the intervention period, Crit-Line was used on all hospitalized patients undergoing HD including those receiving portable HD treatments in the ICU. During both time periods, nurses recorded number of hypotensive events, patient symptoms and modifications that were made to the dialysis prescription. The primary outcome was number of IDH events defined by the NKF KDOQI Guidelines.

**Results:** 328 patients were included, 161 from the control period and 167 from the intervention period. Patient characteristics were similar in both time periods and are shown in Table 1. IDH occurred in 23.5% of treatments during the control period and 18.7% during the intervention period. Patient characteristics were similar in both time periods and are shown in Table 1. IDH occurred in 23.5% of treatments during the control period and 18.7% during the intervention period.

**Conclusions:** Use of Crit-Line in hospitalized patients undergoing dialysis in the ICU resulted in less IDH.

Dry Weight Adjustments for Hemodialysis Patients Using Machine Learning

Hae Ri Kim,1 Jae wan Jeon,1 Youngrok Ham,1 Kiyang Na,2 Kang Wook Lee,2 Yoon-Kyung Chang,1 Dae Eun Choi.1 Chungnam National University Sejong Hospital, Sejong, Republic of Korea; 2Chungnam National University, Daejeon, Daejeon, Republic of Korea; 1Daejeon Saint Mary’s Hospital, Daejeon, Daejeon, Republic of Korea.

**Background:** Knowledge of the proper dry weight plays a critical role in the efficiency of dialysis and the survival of hemodialysis patients. Recently, bioimpedance spectroscopy (BIS) has been widely used for set dry weight in hemodialysis patients. However, BIS is often misrepresented in clinical healthy weight. In this study, we tried to predict the clinically proper dry weight (DWCP) using machine learning for patient’s clinical information including BIS. We then analyze the factors that influence the prediction of the clinical dry weight.

**Methods:** As a retrospective, single center study, data of 1672 hemodialysis patients were reviewed. DWCP data were collected when the dry weight was measured using the BIS (DWCP). The gap between the two (GapCP = DWCP - measured) was calculated and then grouped and analyzed based on gaps of 1 kg and 2 kg.

**Results:** Based on the gap between DWCP and DWmin, 972, 303, and 384 patients were placed in groups with gaps of <1 kg, ≥1kg and <2 kg, and ≥2 kg, respectively. For less than 1 kg and 2 kg of GapCP, it can be seen that the average accuracies for the two groups are 83% and 72%, respectively, in using XGBoost machine learning. As GapCP increases, it is more difficult to predict the target property. As GapCP increases, the mean values of hemoglobin, total protein, serum albumin, creatinine, phosphorus, potassium, and the fat tissue index tended to decrease. However, the height, total body water, extracellular water (ECW), and ECW to intracellular water ratio tended to increase.

**Conclusions:** Machine learning made it slightly easier to predict DWCP based on DWmin under limited conditions and gave better insights into predicting DWCP. Malnutrition-related factors and ECW were important in reflecting the differences between DWmin and DWCP.

**PO0868**

Interdialytic Weight Gain in Long Intervals and Mortality Among Maintenance Hemodialysis Patients

Yoshikazu Miyasato,1,2 Tsuyoshi Miyagi,1 Yoko Narasaki,1 Hiroshi Kimura,1 Elani Streja,1 Kamyar Kalantar-Zadeh.1,2 University of California Irvine, Irvine, CA, 1Kumamoto Daigaku, Kumamoto, Japan.

**Background:** Interdialytic weight gain (IDWG) is an important factor for sudden death on the first dialysis day right after long interdialytic intervals (i.e. 2-day breaks between dialysis treatments) in hemodialysis patients. We defined IDWG in long intervals (IDWG L) as the IDWG during 2-day breaks. In this study we examined the association between IDWG L and medium-term mortality.

**Methods:** This retrospective cohort study included patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWG L and all-cause mortality using Cox regression model. Seven categories of IDWG L were as follows: 0,<1%, ±1%,-2%,-3%, ±3%,-4%, ±4%,-5%, ±5%,-6%, ±6%, and ±6%. We also examined continuous associations between IDWG L and mortality using restricted cubic spline analysis.

**Results:** We examined mortality in 35225 patients. The mean age (and standard deviation) was 62±15 years, and 8112 died during the median follow-up period of 14 years. Higher categories of IDWG L were associated with increased risk of mortality. The hazard ratios (95% confidence intervals) of all-cause mortality for 3-<4%, 4-<5%, 5-<6%, and ±6% were 1.09 (1.03-1.16), 1.14 (1.06-1.23), 1.17 (1.06-1.29), and 1.25 (1.14-1.38) (Reference: 2-<3%) (Figure a). The restricted cubic spline analysis showed that risk of mortality increased when IDWG L exceeded 2% (Figure b). However, BIS is often misrepresented in clinical healthy weight. In this study, we tried to predict the clinically proper dry weight (DWCP) using machine learning for patient’s clinical information including BIS. We then analyze the factors that influence the prediction of the clinical dry weight.

**Conclusions:** IDWG L exceeded 2% was associated with higher risk of mortality. Our results suggest IDWG L can be a risk parameter for medium-term mortality.
PO0869
Coronary Artery Calcification is a Risk Factor for Intradialytic Hypotension in Hemodialysis Patients
Sono Mizuiri,1 Yoshiko Nishizawa,1 Toshiki Doi,1,2 Kazuomi Yamashita,1 Kenichiro Shigemoto,1 Koji Usui,2 Michiko Arita,2 Takayuki Takei,4 Shigehiro Doi,2 Takao Masaki,4 1Iryo Hoin Ichiyokai Harada Byoin, Hiroshima, Japan; 2Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; 4Ichiyokai East Clinic, Hiroshima, Japan; 1Ichiyokai Yokogawa Clinic, Hiroshima, Japan; 1Hiroshima Daigaku Byoin, Hiroshima, Japan.

Background: Vascular calcification and intradialytic hypotension (IDH) share common risk factors in hemodialysis (HD) patients, but there are few reports about the association. We investigated the associations between IDH and coronary artery calcification (CAC) and their effects on mortality in HD patients.

Methods: Subjects were consecutive maintenance HD patients. IDH was defined as nadir systolic blood pressure <100 mmHg, or the requirement for bolus infusion of saline and vasopressor (dopamine hydrochloride) during at least two of 10 HD sessions. Laboratory data and Agatston coronary artery calcium score (CAC) were obtained at baseline. Logistic regression analyses for CACs and Cox analyses for mortality were conducted.

Results: In all subjects (n=173), age and dialysis vintage were 66±12 years and 10±29 months, respectively. IDH occurred in 37 patients (21.4%), and CACs was higher in the IDH group than in the non-IDH group [1,845 (243–3,774) vs. 884 (161–2,465), p<0.001]. IDH was significantly (P=0.05) associated with CACS odds ratio (OR): 1.01, diabetes (OR: 2.90), mean predialysis systolic blood pressure (OR: 0.93), mean ultrafiltration (OR: 1.92), KiVuraz (OR: 11.27) and erythropoietin responsiveness index (ERI) (OR: 0.91), but not with serum albumin or use of calcium channel blockers. For 3-year all-cause mortality, the cut-off value of CACs, determined by receiver operating characteristics curve analysis, was 1,829 with sensitivity of 69% and specificity of 77%. Of the 173 patients, 45 all-cause cardiovascular events (19 cardiac arrests occurred for 3 years). Patients with both IDH and CACs ≥1,829 had the highest 3-year cumulative CV death rate (33.5%, P=0.01) compared with 19.7%, 11.5%, and 4.5% in those with CACS ≥1,829 only, IDH only, and neither, respectively. In Cox models including age, sex, diabetes, albumin, phosphate, CRP, ERI and FGF23, hazard ratios (HRs) for 3-year all-cause mortality of IDH, CACs ≥1,829, or IDH with CACS ≥1,829 were similar, but HR for 3-year CV mortality was the highest in CACs ≥1,829 (9.68, P=0.001) compared with 7.29 (P=0.01) and 6.77 (P=0.01), in those with CACS ≥1,829 only, and IDH only.

Conclusions: Independent risk factor for IDH, and CACs provide additional risk-discrimination over IDH for CV mortality in HD patients.

PO0870
Cardiac Arrests During Hemodialysis Among Maintenance Hemodialysis Patients in a Large Dialysis Network in India

Background: Cardiac arrest (CA) during a HD session carries a high mortality and is reported associations include age, comorbidity, dialysis characteristics. Since much is unknown in India, we aimed to study Incidence of CA, predispoding factors and outcome of CPR following intra HD cardiac arrests

Methods: Consecutive CA in a dialysis network from July 2019 to March 2020 were reviewed for age, gender, HD frequency, adequacy, vascular access, HD facility location, size, nephrologist coverage, b/o DM and IHD, HD session timing, delivered HD frequency & hospitalization in recent past & ultrafiltration rate. Surivors vs non-surivors of CPR were compared with t-test, Chi-square test or Fisher’s exact statistic and risk ratio (RR) for significance of associated factors were analyzed using STATA, v 14.2. Two-sided tests with a P-value <0.05 was considered significant

Results: 122 CA occurred among 2,981,759 sessions; rate of 1/24441. 71 survived CPR and 51 died. μ age: 55.5 ± 1.2 yrs, M:F =77%:23%. Tier 1/2/3 cities: 11.4%,37.7% 50.8%, daily Nephrologist visits: 67.2%, Facilities monthly sessions: 250 ± 10.6%, 250-749: 42.6%, >750 :46.7% μ Hb: 8.7 ± 2 g %. Temp access: 43.4%, HD freq 1/2/3 per wk: 36.9/28.7/34.3%, DM: 44.8% IHD: 26.2%, Morn afternoon, eve session(%): 39.3/5.6/39.3%, hospitalized <2mon: 40%, <2HD/week in recent past: 27%, μ UFR: 10.4± 5 ml/kg/hr. RR for significant factors are shown in Table 1.

Conclusions: Incidence of CA in India is much developed countries experience; larger facilities & smaller cities form a high proportion of events. Age > 80 tr risk of death. Female, μ Hb adequacy, UFR >10ml/kg/hour, low HD freq in 2 months prior to CA show tendency to higher risk for non survival. Limitation includes lack of analysis of CPR and post CPR hospitalization course

Relative risk of major factors associated with non-surival following CPR for CA

PO0871
Clinical Significance of Plasma Matrix Metalloproteinase-2 and Matrix Metalloproteinase-9 Levels to Assess the Cardiovascular Risk in Hemodialysis Patients
Yu ho Lee,1 So-young Lee,2 Hye-uen Jeong,1 Young gyun Kim,2 Ju young Moon,2 Sangho Lee,2 Jin sug Kim,2 Kyung iwan Jeong,1 Shin-Young Ahn,4 Dong-Young Lee,5 Hyeon Seok Hwang,1 1CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; 2Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea; 3Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; 4Korea University, Seongbuk-gu, Seoul, Republic of Korea; 5Seoul Veterans Hospital, Gangdong-gu, Seoul, Republic of Korea.

Background: Matrix metalloproteinases (MMPs) are endopeptidases that control extracellular matrix synthesis and degradation. Two MMP subtypes, MMP-2 and MMP-9, are known to play important roles in the development and progression of cardiovascular (CV) disease, but its clinical relevance as predictors of cardiovascular events is unclear in hemodialysis patients.

Methods: We prospectively enrolled 435 patients undergoing maintenance hemodialysis from K-cohort between June 2016 and April 2019. Plasma MMP-2 and MMP-9 levels, and several biomarkers were measured at the time of study data entry. Primary endpoint was defined as a composite of cardiovascular events.

Results: Plasma MMP-2 level were increased in patients with incident CV events than those without CV events, whereas plasma MMP-9 levels were not different between groups. MMP-2 levels were positively correlated with circulating cardiac markers including brain natriuretic peptides (BNP), N-terminal proBNP, and heart-type fatty acid binding protein. The cumulative event rate of the composite of CV events was significantly greater in patients with higher MMP-2 tertile 3 than in those with other MMP-2 tertile 1 (p = 0.015). MMP-2 tertile 3 was associated with a 2.77-fold higher risk of the composite of CV events (95% CI, 1.40–5.45) and 4.67-fold higher risk of cardiac events (95% CI, 2.06–10.56) after multivariable adjustments. However, plasma MMP-9 levels were not positively correlated with circulating cardiac markers, and not associated with risk of incident CV events.

Conclusions: Higher plasma MMP-2 levels, but not MMP-9 levels, had the positive relationship with circulating levels of cardiac pathology markers, and were associated with increased risks of incident CV events and cardiac events among hemodialysis patients.

PO0872
Utility of CHA2DS2-VASc Score to Predict Mid-Term Clinical Outcomes in Hemodialysis Patients
Aiko Okubo,1 Toshiki Doi,1,2 Yoshiko Nishizawa,1 Kenichiro Shigemoto,1 Sono Mizuiri,1 Takao Masaki,4 1Iryo Hoin Ichiyokai Harada Byoin, Hiroshima, Japan; 2Ichiyokai Yokogawa Clinic, Hiroshima, Japan.

Background: The CHA2DS2-VASc score has been widely used as a predictive score for stroke in patients with atrial fibrillation (AF). Recently, it was reported that the CHA2DS2-VASc score is useful for predicting cardiovascular disease (CVD) or all-cause mortality in patients with or without AF. However, few reports have examined the association between this score and mortality in hemodialysis patients.

Methods: We analyzed 525 consecutive patients who started hemodialysis at our facilities from March 2006 to October 2017. CHA2DS2-VASc score was calculated at time of initiation of hemodialysis. Multivariate Cox proportional hazards analysis was used to assess independent risk factors for 3-year all-cause mortality.

Results: During the 3-year follow-up period, 153 (29.1%) patients died (cardiovascular death, n=88). According to multivariate analysis, serum albumin [hazard ratio (HR) 0.62, 95% confidence interval (CI) 0.43–0.89, P=0.01], creatinine (HR 0.81, 95% CI 0.71–0.99, P=0.03), and CHA2DS2-VASc score (HR 1.31, 95% CI 1.21–1.46, P<0.001) were associated with 3-year all-cause mortality. Patients with CHA2DS2-VASc score ≥4 had higher risk of all-cause and CVD mortality than those with CHA2DS2-VASc score <4 (all-cause mortality: HR 2.20, 95% CI 1.42–3.71, P<0.001; CVD mortality: HR 2.83, 95% CI 1.37–5.44, P<0.001).

Conclusions: The CHA2DS2-VASc score is a useful predictor of 3-year all-cause and CVD mortality in incident hemodialysis patients.
PO0873
Fibrosis-4 Index May Predict Mortality and Non-Fatal Cardiovascular Events in ESKD Patients Starting Dialysis
Yeonhee Lee, Da won Kim, Seok Joon Shin, Hye Eun Yoon, Joo Eun Lee. The Catholic University of Korea Incheon St. Mary’s Hospital, Incheon, Republic of Korea.

Background: CKD and ESKD are known risk factors of heart failure (HF). And liver dysfunction as congestive hepatopathy due to HF is also common. Recent studies report that Fibrosis-4 (FIB4) index (age×ALT(IU/L)/platelet count(10^9/mL)×squared root of ALT(IU/L)), which was known to be useful tool for evaluating liver stiffness, can be prognostic factor of HF. Therefore, this study investigated whether FIB4 index may predict mortality and cardiovascular events (CVE) in patients with ESKD starting dialysis.

Methods: This was a retrospective cohort study including 388 patients who started dialysis at a single center. FIB4 index at dialysis initiation was calculated. Patients were stratified into three groups according to FIB4 index(<1.45:low, 1.45~3.25:intermediate, >3.25: high). The association between FIB4 index and event free survival rates for all-cause mortality and non-fatal CVE in ESKD patients starting dialysis was analyzed. In addition, the association between FIB4 index and echocardiographic findings was analyzed.

Results: During a median follow-up duration of 40.0(0.03-142.3) months, 84 deaths(21.6%) and 83 non-fatal CVE(21.4%) occurred. Event free survival rates were lower in high-FIB4 group, compared with those in low-FIB4 group(p<0.001) and intermediate-FIB4 group(p=0.005), respectively. In Cox proportional hazard model, the high FIB4 index was independently associated with event free survival rates of all-cause mortality and non-fatal CVE was added. In analysis, the association between FIB4 index and echocardiographic findings was analyzed.

Conclusions: In conclusion, FIB4 index is associated with event free survival rates for all cause mortality and non-fatal CVE in ESKD patients starting dialysis.

PO0874
NT-ProBNP for Heart Function and Volume Status in Hemodialysis Patients
Kyung Ho Lee, Young seung Oh, Byung chul Yu, Moo Yong Park, Jinkuk Kim, Seung D. Hwang, Soo Jeong Choi. Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: N-terminal pro brain natriuretic peptide (NT-proBNP) is a biomarker that predicts heart failure and evaluates volume status in Hemodialysis (HD) patients. However, it is difficult to determine the cutoff value of NT-proBNP in HD patients. In this study, we analyzed whether NT-proBNP helps with predicting heart function and volume status in HD patients.

Methods: Retrospective study was conducted on 96 end-stage renal disease patients with HD. All patients underwent echocardiography and Bioelectrical Impedance Analysis (BIA) after a post HD session. Overhydration (OH) was measured by BIA. Laboratory data were obtained on preHD during the mid-week HD sessions. Serum NT-proBNP was measured after HD.

Results: There was an inverse correlation between NT-proBNP and ejection fraction (EF) (β=-0.34, P=0.001). Overhydration (OH) (β=-0.33, P=0.001) and presence of diastolic dysfunction (β=-0.226, P=0.027) had positive correlations with NT-proBNP. In the subgroup analysis with diastolic dysfunction grade, NT-proBNP increased as the dysfunction grade increased. (diastolic dysfunction grade 0; 4177(2637-10391), grade 1; 9736 (5471-21110), grade 2, 3, 24627(16975-44988)) Elevation of NT-proBNP above 4058 pg/ml was associated with the presence of diastolic dysfunction (p=0.001) and Left ventricular hypertrophy (LVH) (p=0.004). Elevation of NT-proBNP above 1157 pg/ml was associated with the presence of diastolic dysfunction (P<0.001), LVH (p=0.001) as well as EF<55% (P=0.07). The group with lower dry weight followed up NT-proBNP one month later, compared to the group with no change in dry weight, NT-proBNP showed a tendency to decrease, and the group with no change in dry weight showed a relatively low level of NT-proBNP variability. (-210 (-12899 - 3142) vs 330(-1090 - 3858); interquartile range, p=0.104)

Conclusions: We confirmed that NT-proBNP is associated with volume status as well as heart functions such as diastolic dysfunction, LVH and EF in HD patients.

Heart function according to NT-proBNP level

PO0875
Dysregulation of Fatty Acid Binding Protein and Their Relationship with Inflammatory Biomarkers in ESRD
Emily Bontekoe, Vinod K. Bansal, Fakhi Siddiqui, Omer M. Iqbal, Jawed Fareed. Loyola University Health System, Maywood, IL.

Background: End stage renal disease (ESRD) patients are at high risk of cardiovascular disorders and hemostatic complications. Fatty acid binding proteins (FABPs) regulate the transport of fatty acids and other lipophilic mediators such as eicosanoids and retinoids by both intracellular and extracellular mechanisms. While upregulation of FABPs have been reported in ESRD, their relationship with inflammatory biomarkers is not fully understood. Liver fatty acid binding protein (L-FABP) also known as FABP-1 is a 14kDa protein expressed in the liver. This protein is also expressed in tubular kidney cells. Kidney damage and other pathologic conditions result in the marked increase of LFABP in ESRD patients. Simultaneous measurement of LFABP with inflammatory response biomarkers and kidney damage may be helpful in the risk stratification and prediction of the adverse outcome in ESRD patients.

Methods: Citrated blood samples from 95 ESRD patients undergoing maintenance hemodialysis were collected prior to hemodialysis. For comparison purposes normal human plasma collected from 50 normal healthy male and female individuals were used. Plasma prepared from these patients and normal individuals was analyzed for FABP-1 and such inflammatory biomarkers as IL-6, TNFa and inflammasomes as using commercially available ELISA methods. All results were compiled and correlation analysis between FABP-1 levels and biomarkers of inflammation was carried out using GraphPad prism software.

Results: The ESRD patients showed a marked increase in FABP-1 levels (106 ng/ml ± 18ng/ml SEM) with a broad range (8 – 974 ng/ml) in comparison to normal (5.1 ± 0.2ng/ml SEM) with a range of (3.4 – 9.2 ng/ml). Marked increases in IL-6, TNFa and inflammation were also noted (2 – 4 fold). FABP-1 showed varying degrees of positive correlation with inflammatory biomarkers.

Conclusions: These studies suggest that plasma levels of FABP-1 is markedly increased (upto 10 fold) in ESRD patients undergoing maintenance hemodialysis. Other biomarkers of inflammation are also upregulated and demonstrate varying degrees of correlation suggesting inter-relationship between FABP-1 and inflammatory processes. These results also suggest that impaired renal function and tubular damage contribute to the marked increase of LFABP in ESRD patients. Simultaneous measurement of LFABP with biomarkers of inflammatory responses and kidney damage may be helpful in the risk stratification and prediction of the adverse outcome in ESRD patients.

PO0876
Transcapillary Refilling Rate Profile in Hemodiafiltration
Juan P. Rivas de Noriega, Gerardo Medina, Salvador L. Gil. Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Reaching dry weight in end-stage kidney disease (ESKD) patients is subject to high ultrafiltration rates (UFR) during their hemodiafiltration (HDF) sessions. We seek to profile the transcapillary refilling rate (TRR) during HDF, which we infer to be an important protective factor against intradiastolic hypotension (IDH).

Methods: We studied 30 patients in HDF scheduled 3 times a week. Absolute blood volume was measured with the dilutional method and plasma volume was calculated based on the patient’s hematocrit. Each session was divided in 18 intervals of 10 minutes each. Overhydration (UFR defined as the one-hour UFR delta) was used to calculate the expected plasma volume. Real plasma volume at the end of each interval was calculated on the basis of the relative blood volume. The difference between the real and the expected plasma volume was the plasma refill volume, which divided by the time of each interval gave us the TRR. The HDF session prescription was determined by the nephrologist in charge of the HDF clinic.

Results: 84 HDF sessions were recorded. Mean age was 44 years (±18.8), 66% were female. TRR/UFR ratio difference between patients with and without IDH was statistically significant (p <0.001, CI 95%), as well as the UFR-TRR delta (p <0.001, CI 95%). This ratio achieved stability after 30 minutes. Eight patients (27%) presented an IDH episode during HDF, during a total of 9 sessions (10.7%); 8 (89%) occurred in the first 10 minutes and corresponded to a patient who presented fever and bacteremia.

Conclusions: Both the TRR/UFR ratio and UFR-TRR delta were statistically significant for predicting IDH. Understanding each patient’s TRR will help us plan interventions in order to try and optimize it and reduce the risk of IDH.

Figure 1. UFR (solid lines) and TRR (dashed lines) profiles.

PO0877
Impact of Hydration Status Measurement by Bioimpedence Analysis (BIA) on Haemodialysis Patients
Nasreen Samad,1 Franel Ave,1 Sara Z. Khan,2,3 Jerilyn Lalu.1 1Barts Health NHS Trust, London, United Kingdom; 2American University of Antigua College of Medicine, Saint Johns, Antigua and Barbuda; 3Northwell Health, New Hyde Park, NY.

Background: Volume status in haemodialysis patients is an important prognostic factor. Overhydration is associated with a higher frequency of mortality while diuresis-induced volume depletion is also an independent mortality risk factor. Clinical indices do not always accurately reflect volume status. Bioimpedence analysis (BIA) is used as a simple, noninvasive method which can measure normovolemic status in haemodialysis patients by measurement of height, weight, and body composition. Fluid overload is calculated by subtracting the normovolemic status from the overhydration status.

Methods: All patients at Queens satellite dialysis unit, Romford, United Kingdom, which has a prevalent population of 106 patients had BIA based assessment of fluid status every 3 months from July 2020 to May 2021 and dry weight adjusted accordingly. Outcomes were noted for blood pressure, overhydration, Interdialytic weight gains, intrinsic hypertensions, hospitalisation and mortality.

Results: 121 haemodialysis patients were followed with male to female ratio of 55:66, mean age of 62 (25-87) of whom 46 were diabetics. By end of assessment period, 46 patients (38%) had combined CABG and VS. Baseline characteristics and comorbidities were similar between the PD and HD groups. In patients undergoing CABG only, PD patients (26.3%) had combined CABG and VS. Baseline characteristics and comorbidities were similar between the PD and HD groups. In patients undergoing CABG only, PD patients were statistically significant (p <0.001, CI 95%).

Conclusions: Bioimpedence analysis (BIA) is a simple, non invasive tool helpful in assessing fluid status in haemodialysis patients. It is easy to convince a patient about their volume status by providing a machine assessed figure rather than clinical parameters. There was significant improvement in overhydration without increasing the number of dehydration patients. The high mortality in prevalent patients during COVID pandemic highlights the need for continued body composition measurements in a larger population once COVID cases subside to come to a significant conclusion about the impact of BIA in improving patient outcomes including effect on residual renal function.

PO0878
Association of Different Definitions of Intradiastolic Hypertension with Long-Term Mortality in Hemodialysis
Anuka T. Singh,1,2 Sushrut S. Waikar,1,2 Finnian R. McCausland.1,2 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 1Boston Medical Center, Boston, MA; 2Boston University Renal Section, Boston, MA.

Background: Hypertension is common in patients receiving maintenance hemodialysis (HDF). A subset of patients experience increases in systolic blood pressure (SBP) from pre- to post-HDF (intradiastolic hypertension). This phenomenon is known to be associated with adverse short and long-term outcomes, but there is little consensus on an evidence-based definition.

Methods: In a retrospective cohort of 3,198 HD patients, unadjusted and adjusted Cox proportional hazards models were fit to examine the association of various definitions of intradiastolic hypertension (≥30% of baseline sessions with an increase in pre- to post-HDF SBP of 1) ≥0 mmHg [Hyper1]; 2) ≥10 mmHg [Hyper10]; or 3) ≥20 mmHg increase [Hyper20]) with all-cause mortality. Interaction terms were used to assess for effect modification according to pre-specified demographic (age, sex), HD-related (pre-HDF, ultrafiltration rate), and comorbidity disease variables (diabetes, heart failure, and peripheral vascular disease [PVD]).

Results: At baseline, mean age was 62 ±15 years, 57% were male, and 14% were Black. Average change in BP from pre to post-HDF was 13 ±16 mmHg (median 12 [3 to 22] mmHg). During the baseline period, 47% of individuals met the Hyper0 definition and were at a 29% (HR 1.29; 95%CI 1.03 to 1.62) higher adjusted risk of death, compared with participants with no SBP increase. Hyper10 was present in 21.2% and associated with a 21% higher adjusted risk of death (HR 1.21; 95%CI 0.96 to 1.51). Hyper20 was present in 6.8% and associated with a 5% higher risk of death (HR 1.05; 95%CI 0.76 to 1.46). There was evidence for effect modification by age and PVD (P-interaction=0.02 for both), with a higher risk of death in those aged 45-70 years and those without PVD. This study shows that individuals with any increase in SBP from pre to post-HDF experienced the highest adjusted risk of mortality, compared with other threshold-based definitions with effect modification by age and PVD.

Funding: NIDDK Support

Figure 1. Adjusted association of change in pre- to post-HDF systolic BP with mortality.

PO0879
Outcomes of ESKD Patients on Hemodialysis vs. Peritoneal Dialysis Post Open Heart Surgery
Elias Bassil,1 Milad Matta,1 Aimen Liaqt,3 Adam Fawaz,1 Ali Mehdi,3 Juan C. Calle,2,3 Jonathan J. Taliercio,1 Haytham Elgharably,1 Serge C. Harb,1 Remy Daou,1 Susana Arriagin,1 Jese D. Schold,1 Georges Nakhoul,3 1Cleveland Clinic, Cleveland, OH; 2University Saint-Joseph, Beirut, Lebanon; 3Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: ESKD patients on dialysis suffer from poor outcomes following cardiac surgery compared to the non-dialysis populations. However, the impact of the dialysis modality and the type of cardiac surgery are not well studied.

Methods: We identified 590 patients with ESKD on HD or PD who underwent Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery using our Electronic Health Records-based Cardio-Thoracic Surgery (CTS) registry from 2009-2020, the demographics and comorbidities of PD and HD were compared using Chi-square, and t-tests for categorical and continuous variables, respectively. In hospital death, hospital length of stay (LOS), intensive care unit LOS, red blood cell transfusions required, and the incidence of post-operative complications including (pericardial effusions requiring intervention, gastro-intestinal bleed (GIB), and sternal wound infections) were compared using Kruskal-Wallis test, Chi-square and Fisher’s exact tests.

Results: Out of 590 patients, 62 (11%) were on PD, and 528 (89%) were on IHD. 277 (47%) underwent Valvular Surgery (VS) only, 158 (26.7%) CABG only, and 155 (26%) combined CABG and VS. Baseline characteristics and comorbidities were similar between the PD and HD groups. In patients undergoing CABG only, PD patients were statistically significant (p <0.001, CI 95%).

Conclusions: Bioimpedence analysis (BIA) on Haemodialysis Patients

had more pericardial effusions (12.5% vs 2.3% p = 0.048) and more GIB (12.5% vs 2.2% p = 0.046) (Table 1). There were no differences in in-hospital mortality, hospital length of stay (LOS), ICU LOS, and sternal wound infections between groups across the different surgeries. 16 PD patients were converted to HD post-surgery, intent to treat analysis was applied for these patients.

**Conclusions:** In patients on maintenance dialysis, patients who underwent CABG, VS, and combined surgery had similar outcomes. PD patients appeared to experience more GIB and pericardial effusions requiring intervention in the CABG group.

**Prevalence and Risk Factors for Development of Cardiac Arrhythmias and Electrocardiographic Abnormalities in Hemodialysis Patients: A Single-Center Experience in Mexico.**

Andrea San-German Morales,1 Pedro A. Escamilla Galindo,2 Armando Castillo García,1 Paulina Paniagua,1 Juan M. Ardavin Ituarte,2 Mario Jimenez Hernandez1,2 Universidad de las Americas Puebla, Cholula, Mexico; 3Medica Santa Carmen, Puebla, Mexico.

**Background:** Mexico is among the countries with the highest number of patients on kidney replacement therapy (RRT). Despite this, the incidence and prevalence of CKD in Mexico is unknown, due to the lack of a national registry as a result we do not know risk factors associated to this population. Electrocardiographic abnormalities or arrhythmias are among the most frequent cardiovascular pathologies, being the first cause of death during the first month in RRT. That is why the present study aims to identify the prevalence of arrhythmias in a group of Mexican patients on hemodialysis as well as their associated risk factors.

**Methods:** A non-experimental, observational, descriptive, and cross-sectional study was carried out in the period from March to July 2020 with Mexican patients older than 18 years in maintained hemodialysis. The electrocardiograms and blood test analysis were taken on the day of hemodialysis therapy.

**Results:** The mean age of the population was 42.37 years, 57% were male. Arrhythmias were found in 50 patients (41.67%), the prevalence of arrhythmias found was bundle branch block (17.50%), sinus tachycardia (12.50%), sinus bradycardia (7.50%), atrial fibrillation (2.50%), extrasystoles (1.67%). A significant difference in mean ages was found between patients with (47.14) and without arrhythmia (38.97) (P = 0.041). A history of heart disease (OR 7.54 95% CI 1.05-184.7), and the diagnosis of chronic renal failure secondary to diabetic nephropathy (OR 2.549 95% CI 1.1026-5.8785) were identified as risk factors. The diagnosis of chronic renal failure secondary to arterial hypertension was not related as risk factor (p=0.86). No laboratory study was identified as a risk or protective factor for the development of arrhythmia either the vascular access type.

**Conclusions:** The studied population presented similar characteristics to the described previously, a high prevalence of electrocardiographic abnormalities was identified, laboratory studies were not related to the presence of arrhythmias. History of heart disease and kidney disease secondary to diabetic nephropathy were associated as a risk factors, while the presence of arterial hypertension was not identified as risk factor.

**PO0882**

**Evaluation of Venous Congestion in Chronic Hemodialysis Patients During Ultrafiltration: A Prospective Cohort Study.**

Pedro Gudiño Bravo, Mariana M. Cano Nieto, Nikie D. Ibarra Marquez, Gabriela Leal, Magdalena Madero, Edith L. Posada-Martinez, Salvador L. Gil Instituto Nacional de Cardiología Ignacio Chavez, Mexico City, Mexico.

**Background:** Fluid overload is deleterious in chronic hemodialysis patients. The combination of multiple POCUS markers can identify significant venous congestion. These markers have not been prospectively studied in this population.

**Methods:** We measured inferior vena cava (IVC) diameter, portal vein pulsatility fraction (PVPF), jugular vein at rest (YVR) and hepatic vein flow (HVF) at five points: pre-dialysis, three times during dialysis and post-dialysis. All measurements were done three times and averaged. All patients had at least 5% weight gain based on their estimated dry weight. We recorded ultrafiltration volume at each point.

**Results:** We performed measurements during 30 on-line post dilution hemodialfiltration sessions in 20 patients (13 were female, mean age 38.6 years old). The average total ultrafiltration (UF) volume was 250.5 cc (1250-4250 cc). There was a significant reduction in PVPF, IVC diameter, YVR, HVF during sessions. See Figure 1. Likewise, UF volume correlated with IVC diameter: R -0.38 p<0.001; PVPF: R -0.31 p<0.001; and HVF: R -0.19 p=0.035.

**Conclusions:** In chronic hemodialysis patients, even in the absence of a dilated IVC, markers of venous congestion tracked ultrafiltration volume. This study warrants further research with regards to clinical decision to continue fluid removal in chronic hemodialysis patients.
PO0883

Knowledge and Practice of Incremental Dialysis: A Survey of Canadian Nephrologists

Background: Incremental hemodialysis, a strategy to individualize dialysis prescriptions at initiation, is being linked to enhanced quality of life and acceptability by patients and decreased health care costs. We aimed to explore knowledge and practice patterns regarding facility-based incremental hemodialysis in Canada.

Methods: A web-based survey of nephrologists, elicited current incremental hemodialysis (HD) prescribing practices, clinical and patient factors used to determine suitability for treatment, and potential barriers to implementation. The survey was circulated over a period of six weeks (September 21, 2020 and October 30, 2020).

Results: The overall response rates 35% (243/691 nephrologists surveyed). Majority (66/111, 59%) of respondents prescribed incremental HD using an individualized approach at the discretion of the nephrologist. Most centers (200/203, 98%) did not report policy or guidance for implementation. Residual urine output was identified as the most important factor for eligibility (112/172, 65%), electrolyte stability (76/172,44%) and existing patient goals of care (69/117, 40%). The majority of nephrologists agreed that dialysis prescriptions are dynamic and should take residual kidney function into consideration; however, 74% of nephrologists did not think there was strong evidence supporting incremental dialysis. Potential barriers identified were patient safety, logistics of scheduling, limited evidence, and acceptance of dose escalation. Despite these barriers, 82% of participants felt that facility-based incremental dialysis is feasible with their current resources and 78% agreed that with specific exclusion and inclusion criteria, incremental dialysis is a safe option.

Conclusions: Incremental hemodialysis is commonly practiced amongst Canadian nephrologists despite a lack of formal criteria for initiation and treatment escalation. This highlights a need for research to guide policy and practice for incremental hemodialysis in Canada.

PO0884

Thrice vs. Twice Weekly Hemodialysis in a Rural Community Center Paavan Bonagiri,1 Namrata Singhania,1 Girish Singhania,2 Abutaleb A. Eajaz.4
1University of Virginia, Charlottesville, VA; 2University of Utah Health, Salt Lake City, UT; 3Mount Carmel East Hospital, Columbus, OH; 4University of Florida, Gainesville, FL.

Background: Converting stable ESRD patients from thrice to twice weekly HD sessions.

Methods: ESRD patients on 3xWkly HD sessions for at least 3 months duration were screened for eligibility for conversion to 2xWkly HD session in a university-affiliated community dialysis program. Eligibility criteria were: residual renal function > 3ml/min; urine output >500ml/day; intradialytic weight gain <2.5kg; hemoglobin >12gm/dL; manageable phosphorus and potassium levels. Clinical parameters on 3xwkly vs. 2xwkly HD sessions were then performed in the eligible patients. Patients were followed for 6 months post conversion.

Results: 9.8% of total HD pts were eligible. Baseline characteristics: age 65±16.5yrs, P 57.1%, HTN 71.4%, DM 14.2%, MM 14.2%. Major indication for HD initiation was symptomatic progression of disease. Less than 50% of patients had a functioning arteriovenous fistula at initiation of HD. In the current cohort, residual renal function > 3ml/min was maintained for > 200 days after initiation of HD. There were no significant changes in electrolytes, hemoglobin, nutrition status or adequacy of dialysis. PTH levels were not significantly different: 3xwkly, 625.7±346.2pg/mL vs. 2xwkly, 399.3±344.2pg/mL; p=0.374. Karnofsky Performance Status Scale improved post conversion but did not achieve statistical significance (3xwkly, 57.1 vs. 2xwkly, 70; p=0.316). There were no hospital admissions since conversion to 2xwkly schedule during the study period.

Conclusions: 10% of total HD patients qualified for conversion from 3xWkly to 2xWkly maintenance HD without significant changes to laboratory or clinical performance measures. These observations stimulate discussion regarding increased application of incremental dialysis initiation strategies to preserve residual renal function, increase dialysis-free days and alleviate transportation and care provider-related burden to patients and families, especially in underserved areas.

PO0885

Impact of the Ratio of Monocyte to High-Density Lipoprotein Cholesterol on Cardiovascular Outcome in Incident Dialysis Patients Min Gyo Jeong, Hye Eun Yoon, Seok Joon Shin, Yeonhee Lee, Da won Kim. Catholic University of Korea, Incheon, Republic of Korea.

Background: Monocyte count to high-density lipoprotein ratio (MHR) is a well known risk factor of cardiovascular disease and atherosclerosis. We evaluated the impact of the MHR value on the CV outcomes in end-stage kidney disease (ESKD) patients. The primary outcome was comparison of cardiovascular event-free survival rate between the low MHR group and the high MHR group. The secondary outcome included all-cause mortality, overall CV mortality and possibility of MHR as an independent risk factor for CV complication.

Methods: The medical records of 719 ESKD patients who started maintenance dialysis between January 2006 and July 2017 were reviewed. Patients were divided into low MHR and high MHR groups based on the median MHR value.

Results: Overall CV event was 130 cases, 55 in the low MHR group and 75 in the high MHR group, respectively. The CV event-free survival rate was significantly lower in the high MHR group compared to the low MHR group (47.6% vs. 57.5%, P = 0.017). Of the 577 enrolled patients, there was no statistical difference in all-cause mortality between the two groups during a mean follow-up of 3.2 years (P = 0.371). Overall CV mortality rate was also comparable between the two groups (P= 0.615). In multivariate Cox regression analysis, high MHR was an independent predictor for CV events (HR 1.463, 95% CI, 1.019 – 2.102, P = 0.039) even after adjustment for age, smoking, diabetes, body mass index, C-reactive protein, and previous CV disease.

Conclusions: In conclusion, high MHR at the time of dialysis initiation in the incident ESKD patients may be a simple and useful method for predicting development of CV complication.

PO0886

Differences in Clinical Characteristics and Outcomes Between Hemodialysis-Dependent and Non-Hemodialysis-Dependent Patients with Gram-Negative Bacteremia Matthew B. Sinclair,1,2 Joshua T. Thaden,1 Felicia Ruffin,1 Lawrence Park,1,4 Michael M. Dagher,1 Christina M. Wyatt,1,2 Vance G. Fowler,1,2 ‘1 Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3Duke University Hospital, Durham, NC; 4Duke Global Health Institute, Durham, NC.

Background: Gram-negative bacteremia (GNB) is a common and potentially lethal infection among hemodialysis (HD)-dependent patients. The determinants of clinical outcomes in HD-dependent patients with GNB are incompletely understood. We compared clinical characteristics and outcomes between HD- and non-HD-dependent patients with GNB in a large cohort of hospitalized patients and subsequently examined associations between specific characteristics and all-cause mortality among HD-dependent patients.

Methods: Hospitalized, non-neutropenic adults with GNB were prospectively enrolled from Jan 1, 2002 to July 1, 2015. Clinical characteristics and outcome data were collected. Differences between HD- and non-HD-dependent patients were estimated using means/standard deviations or counts/percentages with statistical significance evaluated with independent sample T-tests or Pearson’s chi-squared test. Associations between clinical characteristics and outcomes were estimated using logistic regression. 

Results: Among 1,827 unique participants, 180 were HD-dependent (9.9%). Compared to non-HD-dependent patients, HD-dependent patients were younger (58.6 vs 61.0 years, p=0.05) and more likely to be Black (55.6% vs 26.4%, p<0.001), to have diabetes (56.1% vs 32.1%, p<0.001), and to die prior to hospital discharge (28.9% vs
19.9%, p=0.01). Among HD-dependent patients, having a higher total APACHE II score (OR: 1.15, 95% CI 1.08-1.23) was inversely associated with mortality. Among HD-dependent patients, being >4.5 mmol/L was associated with the greatest difference in KRU in both the case-model (0.28, 95% CI 0.44-0.11) and in the case-model + MICS model (0.20, 95% CI 0.50, -0.06) [Figure 1A]. Similar results were seen for KRU slope [Figure 1B]. It was also observed that KRU slope mediated the relationship between potassium and mortality by 1.78%.

Conclusions: Hyperkalemia shows associations with renal decline over the first year on HD. Future studies should be conducted to investigate the pathways underlying these associations.

Predictors of Hyperkalemia Among Chronic Hemodialysis Patients Transported to the ED

Karthik T. Tennankore,1,2 David Clark,1,2 Patrick T. Fok,1 Judah Goldstein,1,2 Keigan More,1,2 Megi Nallbani,2 Amanda J. Vinson,1,2 Hana Wiemer,1 Wayel Zanjir,1,2 Dalhousie University, Halifax, NS, Canada; 3Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Chronic hemodialysis (HD) patients often present to the emergency department (ED) with hyperkalemia, which in turn, is associated with morbidity and mortality. In this study we sought to identify pre-hospital predictors of hyperkalemia in patients transported to the ED via ambulance (ambulance-ED).

Methods: We analyzed all ambulance-ED transports in a cohort of chronic hemodialysis patients from 2014-2018 (using a province-wide emergency medical services database). The outcome was severe hyperkalemia using the first blood draw after ambulance-ED transport defined as ≥6.0 mmol/L. Characteristics of interest included vital signs prior to transport, days from last dialysis and prehospital electrocardiograms (ECGs) interpreted by paramedics prior to transport. The association between prehospital factors and hyperkalemia was analyzed using adjusted logistic regression.

Results: A total of 750 ambulance-ED transports participated (571 HD patients). The median (IQR) of one year difference in KRU was -1.24 (-2.91, 0.12) while the median KRU slope was -1.64 (-2.53, -0.95). Compared to the reference, potassium >4.5 mmol/L was associated with the greatest difference in KRU in both the case-model (0.28, 95% CI 0.44-0.11) and in the case-model + MICS model (0.20, 95% CI 0.50, -0.06) [Figure 1A]. Similar results were seen for KRU slope [Figure 1B]. It was also observed that KRU slope mediated the relationship between potassium and mortality by 1.78%.

Conclusions: Hyperkalemia shows associations with renal decline over the first year on HD. Future studies should be conducted to investigate the pathways underlying these associations.

PO0888

Association of Potassium with Decline in Residual Kidney Function in Incident Dialysis Patients

Jessica A. Edward,1 Cachet Wenziger,1 Jui-Ting Hsiung,1 Fridjofj Thomas,2 Csaba P. Kovesdy,1 Kannyar Kalantar-Zadeh,1 Elani Streja,2 1University of California Irvine, Irvine, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3VA Memphis Medical Center, Memphis, TN

Background: Hyperkalemia has been associated with higher risks for renal decline in non-dialysis kidney disease patients. However, it is unclear whether this relationship exists in hemodialysis (HD) patients.

Methods: A retrospective cohort study was conducted on 6,655 incident HD patients who received treatments from January 2007 to December 2011 and had renal urea clearance (KRU) data in the first and fifth patient quarter (91 day interval) post dialysis initiation. Renal decline was estimated by both KRU difference in the fifth minus first patient quarter as well as by a mixed-effect linear regression to estimate KRU slope over the first year. Baseline potassium levels were stratified into four groups: (≤4.0, > 4.0 to ≤4.5, > 4.5 to ≤5.0, >5.0 mmol/L) and linear regression models were used to analyze the relationship between potassium and KRU renal decline across models adjusted for demographics (case-mix), malnutrition-inflammation (MICS), and baseline KRU. Mediation analysis was also conducted to analyze if renal decline is a mediator in the association between potassium and mortality.

Results: The median (IQR) of one year difference in KRU was -1.24 (-2.91, 0.12) while the median KRU slope was -1.64 (-2.53, -0.95). Compared to the reference, potassium >4.5 mmol/L was associated with the greatest difference in KRU in both the case-model (0.28, 95% CI 0.44-0.11) and in the case-model + MICS model (0.20, 95% CI 0.50, -0.06) [Figure 1A]. Similar results were seen for KRU slope [Figure 1B]. It was also observed that KRU slope mediated the relationship between potassium and mortality by 1.78%.

Conclusions: Hyperkalemia shows associations with renal decline over the first year on HD. Future studies should be conducted to investigate the pathways underlying these associations.

304
Results: We studied 15,190 persons on HD without prior AF diagnosis; average age was 76 yrs, 49% were male; 69% were white, 26% black, and 8% Hispanic. At baseline, 7183 persons had a S-K+ ≥4.5 and 6988 <4.5 mEq/L. With the exception of race and ethnicity, all other characteristics, including D-K+, which was 2 mEq/L in 52% and 3 mEq/L in 34%, were balanced between groups. During a mean follow-up of 527 days the overall incidence of AF was 13/100 person-years. S-K+ quartiles were strongly associated with the risk of developing AF. After multivariable adjustment, AF was associated with lower, but not with higher S-K+ concentrations unless extreme values >6.5 mEq/L were reached. D-K+ of 3 mEq/L vs. 2 mEq/L, was associated with 14% (95% CI: 5-24%) lower adjusted rates of AF. No interaction between S-K+ and D-K+ was found.

Conclusions: Hypokalemia was strongly and independently associated with incident AF whereas hyperkalemia was not. However, choice of D-K+ of 2 mEq/L vs. 3 mEq/L did associate with higher AF rates, independent of S-K+ and other measured characteristics.

Serum Potassium Changes in US Veterans Receiving Patiromer with Dialysis-Dependent ESKD and Hyperkalemia

Casha P. Kovesdy,1 Elvira O. Grosmannova,2 Steven D. Woods,3 Christopher G. Rowan,4 Jared Hansen,5 Brian C. Sauer,6 The University of Tennessee Health Science Center, Memphis, TN; 2Albany Medical College, Albany, NY; 3Vifor Pharma, Inc., Redwood City, CA; 4COHRDATA, San Clemente, CA; 5Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT.

Background: Patiromer is a sodium-free, non-absorbed, potassium (K)-binding polymer approved for the treatment of hyperkalemia (HK). This retrospective cohort study aimed to describe serum K+ changes in Veterans with HK and end-stage kidney disease (ESKD) receiving dialysis who initiated patiromer.

Methods: Serum K+ concentrations were evaluated pre- and post-patiromer initiation using the National VA Corporate Data Warehouse (1/1/16–8/31/18). Changes in mean serum K+ concentration were compared at 1, 3, and 6 months following first patiromer dispensing (index date) using the paired t-test (pre K+ versus post K+). All patients had a baseline K+ ≥5.1 mEq/L and ESKD. Patients with continuous exposure to patiromer were identified. Follow-up began on the index date and ended at first censoring event (discontinuation or switch of index K+ binder, death, end of follow-up, or 6 months post-index).

Results: 98 patients with ESKD requiring dialysis and HK initiated patiromer. Patient characteristics at baseline were median age 66 years, African-American race 39%, diabetes 71%, heart failure 40%, and mean K+ value of 6.1 mEq/L (standard deviation = 0.7). The initial dose of patiromer was 8.4 g in 96% of patients with few observed increases in unit dose during the follow-up period. Following patiromer initiation, statistically significant reductions in serum K+ concentration were observed at 1 month (~1.24 mEq/L), 3 months (~1.15 mEq/L), and 6 months (~1.36 mEq/L; Figure). Reductions in dependent years. Means with HK, patiromer was associated with clinically relevant reductions in serum K+ concentrations at all study time points. These findings warrant additional investigation in a larger dialysis cohort with HK.

PO0892

Hyperkalemia: Medical Management vs. Hemodialysis

Joseph A. Gotesman, Maria V. DeVita. Lenox Hill Hospital, New York, NY.

Background: Hyperkalemia is a life-threatening electrolyte disorder for which there exists a paucity of data regarding benefit of urgent hemodialysis over medical management. We hypothesized there would be no difference in potassium levels among hyperkalemic patients who received only medical management compared to those who received hemodialysis, with or without hemodialysis.

Methods: This was a retrospective study of patients 18+ years old with hyperkalemia (K+ ≥5.1 mEq/L). One group (medical management, or MM) had medication(s)—including insulin/dextrose, sodium zirconium cyclosilicate, sodium polystyrene sulfonate, calcium gluconate, albuterol, or furosemide—ordered within 3h of initial elevated potassium. The other group (hemodialysis, or HD), had hemodialysis ordered—with or without medical management—within 3h of elevated potassium. The initial potassium level was considered “time-zero” and subsequent timepoints were followed up to 100h. T1 readings were established between 0-3 hours; T6: 3–8h; T12: 8–16h; T24: 20-28h; T48: 40–56h; T72: 60–100h.

Conclusions: Among patients presenting with hyperkalemia, we found no difference in potassium levels between those who received only medical management and those who received hemodialysis, with or without medical management. Further studies are necessary to confirm these findings. Nationally standardized treatment algorithms ought to be developed; a randomized trial would be conducive to that end.

PO0893

Metabolic Alkalosis in Hemodialysis Patients

Sitarama Arvind Mudunuru, Jose E. Navarrete, W. Charles O’Neill. Emory University School of Medicine, Atlanta, GA.

Background: Hemodialysis (HD) typically employs a high dialysate alkali concentration to counteract interdialytic acid production. Since acid production varies due to the amount and type of protein consumed, some patients may remain alkalotic throughout the interdialytic period and be more alkalotic during HD. This could have adverse effects including arrhythmias, hypotension, hypoventilation, and vascular calcification but dialysate alkali is rarely adjusted. Pre-HD alkalosis is usually ascribed to chronic illness and poor nutrition, but this has not been carefully examined.

Methods: We conducted a retrospective case-control study of all in-center HD patients from 2010 - 2020 at 4 outpatient HD units using citrate-containing dialysate (34.6 mEq/L HC03, 0.4 mEq/L acetate, 2.4 mEq/L citrate; citrasate, Fresenius). Interdialytic alkalosis was defined as pre-HD serum [HC03] ≥26 in ≥ 7 months of any 12-month period. Persistent alkalosis was defined as interdialytic alkalosis in every subsequent 12-month period. Patients with serum [HC03] 19-23 ≥ 7.6 months of every 12-month period constituted the control cohort.

Results: Of 1271 patients with at least 12 months of HD, 444 met the alkalosis criteria for at least one 12-month period and 73 had persistent alkalosis. 189 patients met the control criteria for every 12-month period. Patients with persistent alkalosis were older (66 vs 55 years, p<0.001) and weighed less (69 vs 82 kg, p<0.003), but the prevalence of comorbidities including cardiovascular disease, neoplasia, and diabetes was not increased. HD dose (kT/V) was greater (1.47 vs 1.37, p<0.001), protein catabolic rate was lower (0.85 vs 0.96 g/kg/day, p<0.001), and interdialytic weight gain was less (1.62 ± 2.28 kg, p<0.001). Despite significant weight loss over time (7 ± 13 vs > 0 ± 9 kg, p<0.001), mortality was not increased when adjusted for age, serum albumin was only slightly higher (3.71 vs 3.68 g/dL, p=0.05), and a marked p<0.001 decrease in mean body mass index to 23.51±3.17 mEq/L. There was no difference between serum bicarbonate and body mass index (r=0.22, p<0.006), lean tissue index (r=0.35, p<0.001), hemoglobin (<0.19, p=0.016), albumin (p=0.30, p<0.001), phosphate (p=0.33, p<0.001) and nPCR.

Conclusions: Transient interdialytic alkalosis was common in this HD population and persistent alkalosis was not rare (>5%). Alkalosis appeared to result from a greater dialysis dose and lower protein intake but not chronic illness. Further studies are needed to determine whether this alkalosis is detrimental and adjustment of dialysate [HC03] is indicated.
The relationship between kidney disease and PRES is not fully understood. Reported cases of PRES have been linked with hypertension, autoimmune diseases, and immunosuppressive states, common diseases in ESKD. The pathophysiology of PRES appears to be related to cerebral blood flow dysregulation and endothelial cell dysfunction. The proinflammatory response in COVID-19 produces dysfunction and disease, and immunosuppressive states, common diseases in ESKD. The pathophysiology of PRES is better represented by the following text:

**The Use of Caffeine to Treat Intradialytic Hypotension**

Indrani G. Das, 1,2 Shab E Gul Rahman, 1,3 Sri Lekha TummalaPalap. 1,3 Weill Cornell Medicine, New York, NY; 2NewYork-Presbyterian Healthcare System Inc, New York, NY.

**Introduction:** Intradialytic hypotension (IDH) affects over 10% of individuals on hemodialysis (HD) and can cause long-term multisystemic ischemic damage. One proposed mechanism for IDH is the accumulation of local adenosine causing vasodilation. Agents such as midodrine and caffeine counter these vasodilatory effects. Herein we present a case of IDH where the ingestion of caffeine prior to HD sessions significantly reduced the severity of IDH.

**Case Description:**

A 77-year-old female with CKD-5, longstanding hypertension, and type 2 diabetes mellitus was admitted for initiation of HD. During her 1st HD session, she experienced IDH with a sudden drop in her systolic blood pressure (SBP) from the 193 to 113, accompanied by loss of consciousness and convulsions of the bilateral upper extremities. She recovered consciousness without a postictal state and no significant changes were noted on ECG. Echocardiography ruled out pericardial effusion. On subsequent HD sessions, the patient continued to experience IDH with average decreases of over 100 mmHg in her SBP. Initial management by lowering blood flow rate, lowering dialysate temperature, and holding the patient’s pre-dialysis antihypertensive regimen had only a mild effect in preventing IDH. Given previous studies showing the efficacy of 250 mg caffeine capsules in preventing IDH, we tested the effect of caffeine on this patient’s IDH. 30 minutes prior to her next inpatient HD session, we administered 10 oz of coffee (150 mg of caffeine). Her drop in SBP during that session was markedly reduced from 187 to 149.

**Discussion:** Non-pharmacological measures to prevent IDH have previously been implemented but lack well-powered clinical trial evidence. Using coffee as a vehicle for caffeine administration was an effective preventive measure for IDH in our patient. We hypothesize that this effect is adenosine inhibition mediated. Adenosine is released by cells undergoing localized ischemia during HD, causing vasodilation. Studies show an increase in serum adenosine during IDH. Caffeine is a non-selective adenosine receptor antagonist, and can prevent sudden vasodilation during dialysis. Thus, coffee may be an effective alternative to midodrine for the prevention of IDH. In conclusion, coffee provided a readily available, inexpensive, patient-centered, non-pharmacological measure to reduce IDH while also decreasing the risk of polypharmacy.

**A Case of Posterior Reversible Encephalopathy Syndrome (PRES) in an ESKD Patient with COVID-19**

Viktor J. Martinez, Darance Chewapruong. Albert Einstein Medical Center, Philadelphia, PA.

**Introduction:** Posterior reversible encephalopathy syndrome (PRES) is a clinicoradiological syndrome first reported in 1996 which describes the presence of a wide range of neurological symptoms, and posterior brain white matter edema on imaging studies which may be reversible. The clinical presentation is characterized by headache, altered consciousness, visual disturbances and seizures; hypertension is frequent, although not invariant.

**Case Description:** A 37-year-old male with past medical history of hypertension and diabetes was admitted to the hospital with shortness of breath, occipital headache, and bilateral acute vision loss. On admission, he was afebrile with a blood pressure of 274/147 mmHg, RR of 16, HR 98 bpm and oxygen saturation of 89% on room air. Due to acute vision loss, a stroke alert was initiated. A head CT scan showed subcortical hypodensities in the bilateral occipital lobes consistent with PRES. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure to 166/105 mmHg. His vision restored fully without further episodes of vision loss. Patient was found to be positive for COVID-19 and did not receive treatment for it as his shortness of breath and hypertension were resolved with initiation of HD. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure to 166/105 mmHg. His vision restored fully without further episodes of vision loss.

**Discussion:** The relationship between kidney disease and PRES is not fully understood. Reported cases of PRES have been linked with hypertension, autoimmune diseases, and immunosuppressive states, common diseases in ESKD. The pathophysiology of PRES appears to be related to cerebral blood flow dysregulation and endothelial cell dysfunction. The proinflammatory response in COVID-19 produces dysfunction and death of endothelial cells which may increase vascular permeability, promoting the cerebral edema seen in PRES. The estimated prevalence of PRES in COVID-19 patients is between 1-4%. Reports of PRES in ESKD are rare. PRES may not be readily recognized given the heterogeneity of presentation. Therefore, high index of suspicion is needed in the ESKD population.

**Eye Pain During Hemodialysis: Ocular Dialysis Disequilibrium?**

Sarah Abdell Massah, 1 Monika Aggarwal (Gupta). 2 Virginia Commonwealth University Health System, Richmond, VA; 2VA Richmond Medical Center, Richmond, VA.

**Introduction:** Changes in Intraocular pressure (IOP) during hemodialysis (HD) are underrecognized. We report a case of increased IOP during HD, successfully treated with adjustments to dialysis prescription.

**Case Description:** 59-year-old African American man with End Stage Renal Disease (ESRD) secondary to diabetic nephropathy on HD since 2017, presented with exsiccating right eye pain during HD for 2 weeks. He described increasing right eye pain during HD, requiring early termination of dialysis after 3 hours. He has known right eye glaucoma with no vision. He was on atropine sulfate, predisolone acetate, latanoprost, dorzolamide/timol, and brimonidine tartrate eye drops. IOP in right eye were 63 and 80 mm of Hg, before and after hemodialysis, respectively. Left eye IOP were < 20 mm of Hg and did not change significantly with dialysis. Due to concerns for ocular dialysis disequilibrium; blood flow rate, dialysate flow rate, dialysate temperature, and dialysate sodium were changed to 400 ml/minute from 450 minute/500 minute/500 ml/minute from 800 ml/minute, 35.6°C from 37°C, and 145 mmHg from 140 mmHg, respectively. Subsequent to changes to dialysis prescription, patient was able to complete dialysis with no worsening of right eye pain and IOP (62 and 64 mm of Hg before and after dialysis, respectively).

**Discussion:** Increase in IOP during HD is thought be due to rapid decline in plasma osmolality relative to aqueous humor, creating an osmotic gradient that causes movement of water into the eye. Patients with normal eye outflow have minimal rise in IOP as aqueous humor is drained simultaneously. However, patients with glaucoma are not able to drain excess water, causing increase in IOP and eye pain. Older age, diabetes mellitus, and African-American race are risk factors for ESRD and Glaucoma. Early recognition of ocular dialysis syndrome can allow for safe delivery of dialysis in patients with glaucoma. While acetazolamide is an effective treatment for raised IOP, it’s efficacy and safety in ESRD remains unknown. Similarly role of Mannitol in mitigation of ocular dialysis disequilibrium is unclear. Our patient had resolution of ocular dialysis disequilibrium with decrease in blood and dialysate flow rates, increase in dialysate sodium, and decrease in dialysate temperature. Increase in ultrafiltration may also reduce risk of ocular dialysis disequilibrium by raising extracellular oncotic pressure.

**The Association of Interdialytic Weight Gain in Long Intervals with Residual Renal Function Decline**

Yoshikazu Mivansato, 1,2 Tsuyoshi Miyagi, 1,3 Yoko Narasaki, 1,3 Hiroshi Kimura, 1,3 Kamyar Kalantar-Zadeh, 1 Elani Sreja. 1University of California Irvine, Irvine, CA; 2Kumamoto Daigaku, Kumamoto, Japan.

**Background:** Preservation of residual renal function (RRF) in dialysis patients is important for better prognosis. The effect of interdialytic weight gain (IDWGL) on change of RRF has not been investigated well. We examined the association of IDWGL in long intervals (i.e. 2-day breaks between dialysis treatments) with rapid decline of RRF.

**Methods:** This retrospective cohort study included 6425 patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWGL in long intervals (IDWGGL) and rapid decline of RRF using logistic regression model. Rapid decline of RRF was defined as the percent decline in renal urea clearance (KRU) greater than the median value of the cohort in the first year after dialysis initiation. Seven categories of IDWGGL were as follows: 0-1%, 1-2%, 2-3%, 3-4%, 4-5%, 5-6%, and ≥6%. We also examined continuous associations between IDWGGL and rapid decline of RRF using restricted cubic spline analysis.

**Results:** Higher categories of IDWGGL were associated with increased risk of rapid decline of RRF. The odds ratios (95% confidence intervals) of rapid decline of RRF for 3-4%, 4-5%, 5-6%, and ≥6% were 1.04 (0.90-1.20), 1.31 (1.09-1.56), 1.19 (0.94-1.51), and 1.30 (1.14-1.97) (Reference: 2-3%) (Figure a). The restricted cubic spline analysis showed that risk of rapid decline of RRF increased when IDWGGL exceeded 2% (Figure b).

**Conclusions:** Our results showed higher IDWGGL was associated with higher risk of rapid decline of RRF. IDWGGL exceeded 2%, especially ≥6%, seems to be thresholds for higher risk of RRF decline.
Prevalence of Anti-Erythropoietin Antibodies in Patients with ESRD on Regular Hemodialysis: A Single-Centre Experience

Kevin T John Keeppallil, Manikantan Shekar, Ramprasad Elumalai. Sri Ramachandra Institute of Higher Education and Research, Chennai, India.

Background: Recombinant human erythropoietin (rHuEPO) is a glycoprotein that acts as a biological substitute for the endogenous substance used to treat anemia in individuals with end-stage renal failure. Patients with rHuEPO resistance have been described, requiring higher and higher dosages of the drug to maintain an appropriate haemoglobin level. These antibodies probably cross react with the patient’s endogenous EPO and lead to anemia that can be more severe than even before the onset of EPO therapy. The prevalence of anti-erythropoietin antibodies in renal patients who respond poorly to erythropoietin is unknown.

Methods: We screened 262 patients who were on maintenance haemodialysis and excluded patients who were malnourished and had chronic liver disease, hypothyroidism, ongoing active autoimmune disease, active infection, on steroid therapy, with bleeding or hemolysis and elderly. 96 ISRD patients who were on recombinant human erythropoietin > 6 months and haemoglobin < 10 g /dL were included. Serum anti-EPO antibodies were detected by enzyme-linked immunosorbant assay technique. All patients were subjected to full history taking and clinical examination. Complete blood count, reticulocytes count, serum creatinine, blood urea, serum albumin, serum ferritin, and hematocrit markers were performed for all patients.

Results: Results showed that 26 patients (27.08%) had the anti-EPO antibodies in their blood, while 70 patients (72.91%) did not have the circulating antibodies. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.4 g/dl ± 1.52) than in the antibody negative group (9.68 g/dl ± 1.14) (P = 0.000).

The dose of EPO administered in both studied groups were significantly different. Logistic regression analysis also revealed that gender or age were not associated with any significant variation of serum antibody level. High levels of serum antibodies to EPO are a risk factor for EPO resistance.

Conclusions: Many anaemic ESRD patients treated with recombinant human erythropoietin have a low-affinity immune response to the recombinant protein that is readily detectable. Antibodies to rHuEPO were shown to be greater in patients who received high EPO weekly dose. More research into anaemia management protocols in HD patients with positive anti-EPO antibodies is needed.

PO0901

Ocular Dysequilibrium with Eye Pain During Hemodialysis

Introduction: Eye complications may occur in ESRD patients with glaucoma. Hemodialysis (HD) may lower plasma osmolality at a faster rate than changes in ocular osmolality can adapt. Here we are presenting two cases of ESRD patients who repeatedly developed eye pain only during HD.

Case Description: A 54 y/o Hispanic male with ESRD, right eye blindness & glaucoma who developed right eye pain only during dialysis treatments. The maintenance HD prescription was with duration of 4.5 hr, blood flow rate (BFR) 450mL/min, dialysate flow 800mL/min. Sodium (Na) 138 meq/L, Calcium 2.5 meq/L, Potassium 2meq/L, Calcium 17 mEq/L, O2 30mL/kg, & an average 2L fluid removal per HD. His BP was 130-140mmHg/ 80-90 mmHg. In response to the eye symptoms, the BFR was reduced to 350 mL/min & time was increased to 4.5 hr. This change gave the patient initial relief from intradialytic eye symptoms. Initially Ophthalmologist was hesitant to perform these HD treatments to eliminate the intradialytic eye pain. The 2nd case was a 64 y/o AA female with ESRD and glaucoma developed recurrent left eye pain with headaches only during HD. She went to her Ophthalmologist who renewed her glaucoma medications. This relieved her eye symptoms, and normalized her intradialytic pressure off of dialysis. By taking her eye medications, she no longer developed eye pain or headaches during HD.

Discussion: Glaucoma is an ocular disorder where there is an increased IOP most commonly >22mmHg, this elevated pressure can cause blinding optic neuropathy. The current hypothesis for the rise of IOP during HD is related to an osmotic disequilibrium between the plasma & IO fluid, where the IO fluid is slightly hypertonic compared to plasma. Several medical therapies have been reported to mitigate the IOP increase during HD, such as the use of daily acetazolamide, manitol infusion or 20% hyperosmolar glucose solution, or modified dialysis parameters with colloid infusion to raise plasma tonicity and decrease fluid shift during HD. However, these maneuvers have not been proven to relieve ocular symptoms. In general, use of higher dialysate Na conc. at hemodialysis are not considered a long term solution to intradialytic ocular hypertension, due to the tendency for increased fluid intake between HDs. Lower BFR with longer duration of hemodialysis treatments has been beneficial in some cases.

PO0902

Transient, Severe, Unilateral Eye Pain and Vision Loss Associated with Hemodialysis

Anas Diab. WVU Nephrology, Morgantown, WV.

Introduction: Acute on chronic angle-closure glaucoma with elevated intraocular pressure and well-established etiology of severe eye pain and profound vision loss, if not treated emergently. This case is a recurrent and episodic eye pain with transient visual loss during HD.

Case Description: 64 year-old Caucasian female with comorbidities including poorly-controlled insulin dependent type 2 diabetes, uncontrolled hypertension, obesity. She is on intermittent hemodialysis three times weekly the last 5 years. She was previously followed by a retina specialist for proliferative diabetic retinopathy with subsequent neovascular glaucoma. Initial onset approximately 1 year prior, with episodic hyperopic vision with severe eye pain and complete unilateral vision loss start at initiating dialysis, symptoms resolved with cessation of treatment. Due to worsening pain symptoms, patient compliance becomes an issue, leading to frequent missing Dialysis and Pule edema required hospitalization. A glaucoma specialist, diagnosed neovascular glaucoma of the right eye. Maximal topical and oral tolerated medical therapy was started, but her disease was refractory to conservative management. Surgical intervention was pursued, Valved Drainage Device (New World Medical) was placed under topical anesthesia. Post-operatively, the patient was able to undergo dialysis sessions without ocular symptoms and compliance has improved.

Discussion: The effect of hemodialysis (HD) on intraocular pressure (IOP) is variable and the exact mechanisms are still not clear. Previous reports in the literature suggest both increased and decreased intraocular pressure during fluid shifts associated with hemodialysis. Argon Laser trabeculoplasty is used in the treatment of open-angle glaucoma. Its advantage is that it lowers IOP by inducing a thermic effect in the tissue, which results in the destruction of the trabecular meshwork. In this case, no laser was performed because of the patient’s history of open-angle glaucoma.

Caffeine Overdose Requiring Extracorporeal Mechanical Oxidation (ECMO) and Hemodialysis

Luuke C. Lee, Connie J. Wang, Hennepin Healthcare, Minneapolis, MN.

Introduction: Caffeine (1,3,7-trimethylxanthine) is the most widely consumed psychostimulant in the world. It is considered safe if consumed in moderate amounts and is said to lead to cardiovascular collapse if the dose exceeds 150-200mg/kg. Extracorporeal removal of caffeine with intermittent hemodialysis (CHD) has been reported to improve outcomes. However, continuous veno-venous hemodiafiltration (CVVHDF), which is a routinely used extracorporeal therapy in patients with severe caffeine toxicity, is, traditionally less favored for caffeine overdose because of inadequate rate of clearance. We present a case of combination therapy using both HHD and CVVHDF in the treatment of life-threatening caffeine overdose.
Case Description: A 33-year-old female weighing 63kg presented after ingestion of approximately 100g of guarma powder (22g of caffeine). She presented with tachycardia (140-170 BPM) and severe hypotension (blood pressure 50/40 mmHg) resistant to 4 vasopressors at maximal dose. She required extracorporeal membrane oxygenation (ECMO). Baseline renal function was normal. IHD was initiated with blood flow rate (BFR) 200ml/min and dialysate flow rate (DFR) 500ml/min, which was gradually increased over 4 hours to a BFR of 400ml/min and DFR of 800ml/min; IHD continued for an additional 4 hours at this rate. During this 8-hour IHD treatment, her initial 4 pressor doses were halved, and she was transitioned to CVVHDF; the caffeine level was not available. However, after 12 hours of CVVHDF, the patient did not experience continued hemodynamic improvement, so IHD was reinitiated for 12 hours. Following this second prolonged session of IHD, she was weaned down to moderate doses of just two pressors. She was then transitioned back to CVVHDF for an additional 36 hours. At that time she was able to come off ECMO and all pressors. She had a full neurologic recovery. We later received a serum caffeine level of 425mg/L (drawn soon after arrival at the hospital), which is the second-highest level ever reported; the established lethal concentration is 80mg/L.

Discussion: Despite continuous dialytic therapies being generally favored in patients with hemodynamic instability, a combination of IHD and CVVHDF may be used for hemodynamically unstable patients who ingest extremely high dose of caffeine. However, in such patients, continuous therapies are unlikely to supplant prolonged and repeated IHD treatment sessions.

Discussion: Patients with advanced CKD often have a variety of gastrointestinal symptoms. However, severe uremic colitis mimicking pseudomembranous pattern is extremely rare in ESKD. Extensive literature review revealed only single case report of uremic panceolitis in a patient with severe kidney injury related to IgA nephropathy. With the improvement of care of patients with kidney disease, uremic colitis is rarely seen in the routine nephrology practice. However, it should be included in the differential diagnosis and evaluation of patient with ESKD, particularly if other more frequent etiologies of colitis have been excluded.

PO0904
Anaphylaxis Secondary to Citric Acid Allergy in ESKD Patients
Hassaan Hiktha, George Jarad. Washington University in St Louis, St Louis, MO.

Introduction: Dialysis reactions are common in ESKD patients undergoing hemodialysis (HD). We report first case of anaphylaxis related to citric acid solution used for dialysis disinfection & descaling.

Case Description: 61-year-old male with history of ESKD on HD for 7 years, presented after missing dialysis. Patient underwent urgent HD upon presentation and developed signs of angioedema within first 30 minutes, requiring nasal intubation & treatment with epinephrine, steroids & antihistamine. While intubated and hypotensive patient had uneventful Slow Low Efficiency Dialysis. Angioedema was presumed secondary to antiemetics, which patient required due to severe nausea shortly after starting HD. Post extubation, patient developed similar reaction with milder symptoms with HD that responded to stopping HD and medical therapy. He had normal complement and mildly elevated tryptase. He was presumed to have a dialyzer reaction therefore, the dialyzer was changed from Revaclear to REXEED & it was tolerated well. He had similar severe reaction a week later while using the REXEED dialyzer. Investigations showed elevated anti-ethylene oxide antibodies (ETO) but clinical significance was questionable given the reaction only developed in inpatient setting. Later we discovered that dialysis machines are disinfected/descaled differently between inpatient & outpatient dialysis, even though both utilize citric acid, which might have led to more exposure to citric acid solution in inpatient setting. For next 2 weeks, patient was dialyzed using different combinations of dialysis machines, dialyzer & dialysis circuits including ones sterilized with ETO, however, all machines were disinfected/descaled using a combination of bleach & heat. After elimination of citric acid, patient had no further anaphylactic reaction.

Discussion: Dialyzer membrane reactions have been commonly described as Type A reactions mediated by dialyzer membrane (IgG mediated) and Type B membrane reactions mediated by complement activation. In our case clinical significance of ETO antibody was not clear, & angioedema was eliminated after removing citric acid from the machine disinfection protocols. Citric acid mediated angioedema has not been reported before, & it might be an important mediator of allergy in ESRD, & careful review of the dialysis machine preparation should be reviewed in every case of severe allergic reaction.

PO0905
An Unexpected Cause of Colitis
Alon Bnaya, Ofer Benjominov, Eyal Itzkowitz, Jawad Atrash, Omar Abu Lybdeh, Mhosen Abu Afieiat, Linda Shavit. Shaare Zedek Medical Center; Jerusalem, Israel.

Introduction: Gastrointenstinal manifestations are common among patients with advanced kidney disease. However, uremia associated colitis is rarely described in patients with ESKD. We present a unique case of uremic panceolitis in a patient with ESKD of unknown cause.

Case Description: An 18-year-old male with a history of asthma was admitted with nausea, vomiting and diffuse abdominal pain. He had no fever, arthralgias, rash, respiratory symptoms, or diarrhea. Mild peripheral edema and flapping tremors were noted on physical examination. Laboratory blood tests revealed severe kidney injury (creatinine 10.2 mg/dL, BUN 129 mg/dL). Urinalysis was positive for blood and protein. Immunologic and infectious serologies were unremarkable. An abdominal CT scan detected two small atrophic kidneys and diffuse severe bowel wall thickening of the colon with thumb printing noted (Figure 1), mimicking a pseudomembranous colitis pattern. Abdominal ultrasound revealed severe edema along with high vascularization of the colon wall. Uremia associated colitis was suspected due to the patient’s extreme urerrmic state and hemodialysis was initiated. Following three weeks of hemodialysis, an abdominal ultrasound showed a significant improvement in edema and vascularization of the colon wall.
PO0907

Prediction of Severe Gastrointestinal Bleeding Events in Hemodialysis: Collaborative Development of Machine Learning Model Within INSPIRE

Suman K. Lama,1 Sheetal Chaudhuri,1 Joanna Willetts,1 John W. Larkin,1 Anke Winter,2 Manuela Stauss-Grabo,2 Len A. Ussyvat,2 Jeffrey L. Hymes,1 Franklin W. Maddux,3 David C. Wheeler,2 Peter Stenvinkel,4 Jürgen Floege,3

On behalf of the INSPIRE Core Group 1Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; 3University College London, London, United Kingdom; 4Karolinska Institutet, Stockholm, Sweden; 5RWTH Aachen University Hospital, Aachen, Germany; 6Fresenius Medical Care AG and Co KGaA, Bad Homburg, Germany.

Background: INSPIRE is an academia and industry collaboration set forth to identify critical patient’s outcomes in Renal disease. As an inaugural effort, INSPIRE group aims to develop a machine learning (ML) model that can identify a hemodialysis (HD) patient’s 30-day risk for hospitalization due to gastrointestinal (GI) bleeding.

Methods: We used data from adult (age ≥18 years) HD patients (Jan 2017-Dec 2020) in the United States to build a XGBoost model considering 2,292 variables for classification of 30-day GI bleed hospitalization risk. Data were randomly split in 50%:20%:30% ratio for model training, validation, and testing. Unseen data by model (testing) was used for assessing performance via area under the curve (AUC) and feature importance of predictors via Shapley (SHAP) values.

Results: Among 58,187 HD patients included in the testing dataset, 1150 had a GI bleed hospitalization event. The model showed AUC=0.67 and top predictors of a GI bleed hospitalization in 30 days were the minimum hemoglobin level in prior 180 days, time since prior GI bleed hospitalization, and higher vitamin D levels (Figure 1). Unseen data by model (testing) achieved an accuracy of 93.9%, 95.8% of category (a), 91.2% of category (b) and 82.8% of category (c) pattern were classified correctly by our 1D-CNN.

Conclusions: Our 1D-CNN algorithm accurately classifies saw-tooth pattern in SaO2 time series recorded in HD patients. The SaO2 pattern classification could be performed in real time during an ongoing HD treatment and provide timely alert in the event of respiratory instability.

Artificial Intelligence-Driven System to Automatically Identify Arterial Oxygen Saturation Saw-Tooth Pattern in Hemodialysis

Hanjie Zhang,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Sleep apnea (SA) is a condition where normal respiration is disrupted by episodes of apnea because of disturbed respiratory control (central SA) or upper airway obstruction (obstructive SA). Arterial oxygen saturation (SaO2) saw-tooth pattern indicate respiratory instability. We aimed to automatically identify patients with repetitive episodes of intermittent SaO2 saw-tooth pattern.

Methods: The analysis was based on SaO2 recordings taken at a frequency of 0.1 by the Crit-Line® device (Fresenius Medical Care, Waltham, MA). Segments of 30 consecutive SaO2 recordings (i.e., 5 minutes of SaO2 time series) were adjudicated and categorized as (a) no saw-tooth pattern; (b) mild saw-tooth pattern; and (c) severe saw-tooth pattern (examples shown in Figure 1). We used one-dimensional convolutional neural networks (1D-CNN) for time series classification. We randomly assigned SaO2 time series segments to training (80%) and validation (20%) sets, respectively.

Results: We analyzed 89 hemodialysis (HD) treatments with 4,075 adjudicated SaO2 time series segments. Their distribution across the 3 categories was 78% (a), 11% (b), and 11% (c), respectively. In the validation data set of 815 SaO2 time series segments, we achieved an accuracy of 93.9%, 95.8% of category (a), 91.2% of category (b) and 82.8% of category (c) pattern were classified correctly by our 1D-CNN.

Conclusions: Our 1D-CNN algorithm accurately classifies saw-tooth pattern in SaO2 time series recorded in HD patients. The SaO2 pattern classification could be performed in real time during an ongoing HD treatment and provide timely alert in the event of respiratory instability.

Methods: We used EHR data on pts new to HD between 2003-2016 from a national provider (n=54,148) linked with USRDS. We abstracted 86 predictor variables organized into person-mth and divided into training (n=32,488) and testing sets (n=21,660). The dynamic training set contained > 800k person months. The static training set contained the first pt-month for those who initiated HD within 90-days (n=24,026). We fit LASSO logistic regression to predict mortality in the next 6-months and assessed both models on a time-varying test dataset. We report overall predictive performance metrics as well as visualization of time varying patient risk in the 24 mths before a pt dies.

Results: Pt median age at initiation was 64 yrs; 43% female, 63% Caucasian; 7% died w/in 6 mths of initiation and 53% w/in 5 yrs. Top predictor variables were similar between the two models: age, serum chloride and serum albumin. The table shows performance metrics for the two models on the test data with the dynamic model performing significantly better. The plot shows the predicted risk for pts in the 24 mths prior to mortality. The dynamic model more quickly responds to pts changing risk, producing a higher predicted probability leading up to mortality.

Conclusions: A risk model built using time-varying data performs better than one using baseline data. Incorporation of dynamic models in dialysis-EHR could be used to direct appropriate population health interventions to the highest risk pts. Examination of dynamic risk models can elucidate pt-risk trajectories.

PO0910
Machine Learning Classification of Tweets for Patient Dialysis Experience
Alexander S. Leidner, Hawkins Gay, Bing Ho. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Popular microblog (e.g. Twitter, Facebook) services provide a continuous stream of public health information. This data has been used to monitor viral spread, medication adherence, and false health information. There are thousands of posts on Twitter daily regarding personal dialysis experience, access, and side effects. While these posts include valuable public health information, evaluating these posts to meaningfully assist dialysis patients is difficult as there are even more tweets mentioning dialysis in a professional context. We aimed to modify a state of the art natural language model to classify posts about dialysis as personal or professional.

Methods: We filtered posts containing the word dialysis. Posts were manually labeled as personal or professional by a nephrologist depending on the context dialysis was mentioned. The data was randomized and split for 60% training, 20% validation, and 20% testing. The text was preprocessed to remove extraneous characters and input into a Bidirectional Encoder Representations from Transformers (BERT) model for fine tuning, and a term frequency inverse document frequency vectorized Multinomial Naïve Bayes Classifier.

Results: We collected 6011 tweets from May 3, 2021 to May 14, 2021. 1000 tweets were randomized and labeled. 57% were categorized as professional. BERT and Naive Bayes models attained 88% and 82% accuracy, respectively, on the testing data. The BERT model classified far less false negatives with a small increase in false positives (Figure 1).

Conclusions: BERT’s semantically rich word embeddings can enhance social media mining algorithms on dialysis content. We show superiority of a BERT model over a traditional count-based language model. This method can be easily applied as a pre-processing step to remove noisy posts to better study dialysis and other health trends in social media. This novel processing task and pipeline have broad clinical and public health implications for reducing the amount of data and time required for accurate, real-time monitoring of patient level posts.

PO0911
Automating Dialysis Machine Alarms During Sustained Low-Efficiency Dialysis (SLED)
Gerard Zasuwa, Jerry Yee, Stanley Frnak. Henry Ford Health System, Detroit, MI.

Background: Sustained-low efficiency dialysis (SLED) with regional citrate anticoagulation (RCA) is frequently employed at our institution. RCA requires constant monitoring because a dialysis machines alarm that stops the blood pump (BP) or bypasses dialysate leads to an increased rate of citrate infusion into the patient, with consequence of ionized hypocalcemia. To enhance safety and surveillance efficiency, we developed an innovative computer/phone system that identifies SLED machine alarms and notifies clinical care staff directly via pripropriate phone network.

Methods: In 2017, we linked onboard SLED computer Wi-Fi systems to the hospital’s internal phone network (ASCOM). An alarm recorded by the SLED machine’s computer delivers an email to a dedicated email account that is subsequently transmitted to the ASCOM MailGate System. Mailgate produced and relayed text message alarms to dedicated ASCOM phones of dialysis technicians or nurses. Importantly, no additional training or changes in workflow are required for adoption of this method.

Results: This innovation has increased safety and efficiency. Response times for machine alarms improved and downtimes on dialysis were reduced, increasing dialysis dose of dialysis. To ascertain end-user satisfaction of the automated alarming system, we conducted a survey that demonstrates high-level satisfaction with the system (Table 1.)

Conclusions: Currently, no medical alert companies connect dialysis machine information to a medical alert phone system. ASCOM provides wireless messaging systems for dedicated hospital applications. Notably, ASCOM does not directly connect to dialysis machines. In addition, Email Alerts can be browsed by managers for archival retrieval, quality and safety report generation, and investigation of unanticipated events.

Funding: Clinical Revenue Support
Staff Satisfaction Survey
Results: While physicians comprised most of the potential users, APPs and dialysis nurses were also included (Table). Activity was most distributed among users: e.g., one hospital-based APP recorded most of the admissions (n=225, 89%) and discharges (n=226, 93%) among patients treated at the dialysis clinics included in the pilot.

Conclusions: We found that physicians were unlikely to use DiaylsisConnect. Our user statistics suggest that APPs and nurses may be the most likely to engage with a care coordination system, which informs future pragmatic research in this area.

PO0913
Family-Friendly, Work-Friendly, Home-Hemodialysis and In-Center Hemodialysis Hybrid: The First of Its Kind
Adam Locke, Macaulay A. Onuigbo. University of Vermont College of Medicine, Burlington, VT.

Introduction: Hybrid dialysis is traditionally defined as the combination of peritoneal and hemodialysis (HD) in patients with end-stage renal disease. Its reported use is quite limited outside of Japan. We recently encountered major family-related and employment-related constraints that prevented a 39- yo male with ESRD on home HD from completing the four-times weekly HD treatments with HD inadequacy and worsening of patient’s physiology. We successfully switched him to a new hybrid of twice-weekly HD + twice weekly In-Center HD. This is the first such report.

Case Description: A 41- yo male with ESRD secondary to SLE and hypertension on home HD, 4 x weekly, for some years experienced family-related constraints including non-availability of day-care for two young children due to COVID-19 pandemic, spousal illness and work-related challenges with missed work and was missing his HD sessions. The result was inadequate HD delivery and worsening laboratory indices.

He now receives 2 in-center HD treatments on Tuesdays and Thursdays, and 2 home HD treatments, one during the weekend and one during the week. This was started in February 2021. Each HD session lasts for 3.5 hours, 2000 units Heparin bolus, and his left brachiocephalic AVF is accessed by the button-hole method. The Home Dialysis Staff coordinates his dialysis care. Standardized Kv for May 2021 was 2.6.

Discussion: Hybrid dialysis is traditionally defined as the combination of peritoneal and hemodialysis in patients with ESRD. A 2020 Italian report described another type of hybrid dialysis that consisted of once-weekly in-hospital HD and home peritoneal dialysis to limit patient exposure to the hospital environment during the COVID-19 pandemic. We have described the successful application of a new Hybrid HD system that combined Home HD + In-center HD. To our knowledge, our report is the first of its kind and was designed and implemented primarily for the purpose of overcoming increasing family and employment demands on the patient. This new hybrid dialysis option was designed to facilitate a family-friendly work-friendly HD on a long-term continuous basis. The patient and family worry that the young children have no one to look after them and visitor hours are 4-6 pm. The patient indicated that the young children and his wife are happy and very satisfied. Simultaneously, the patient has continued to do well with adequate dialysis and meeting all the required goals of management in the past 3 months.

PO0914
Triple I Study: Hubs of Care Survey
Melanie D. Talson, Marcello Tonelli, Clara Bohm. Can-SOLVE CKD Triple I Study Team. University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: The Can-SOLVE CKD Triple I Study identified continuity of care; access to a primary care provider (PCP) in the hemodialysis (HD) unit; and access to care for other medical conditions as key challenges to in-centre HD care (www.betterkidneycare.ca). The Hubs of Care project aims to address these challenges by incorporating health care providers (HCPs) from other settings in the HD unit; firstly, we identify current practice, potential interest and need and desire for different HCPs in HD.

Methods: A cross-sectional self-reported survey administered Feb-May 2021 with HD patients and staff at four academic sites across Canada. Eligible participants included adults fluent in English or French who could complete the survey independently. The survey asked which HCPs are currently in HD units, which additional HCPs would be most useful to add and whether patients are in favor of other HCPs visiting them either virtually or in-person. Additional data were solicited by free text. Preliminary analyses using descriptive, median (IQR) and proportion and summative content analysis, are presented.

PO0915
Utilization of the Tablo Hemodialysis System’s Data Platform: An Analysis of 100,000 Acute Dialysis Treatments
Josh Schumacher, Brittany Lim, Michael A. Aragon. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission capable of providing therapy up to 24 hours in a hospital setting. Limited connectivity of traditional hemodialysis systems constrains the ability to drive improvement in quality and efficiency of dialysis care. Tablo’s cloud-based data platform expedites care delivery in real time and informs on dialysis program metrics to facilitate quality improvement. The objective was to demonstrate Tablo’s automated wireless data capabilities through analysis of 100,000 Tablo acute treatments.

Methods: Tablo data were collected through real-time transmission via a cloud-based, HIPAA compliant platform. Analysis was performed by combining prescribed and achieved data on consecutive treatments. Treatments were divided into groups based on treatment time of less than 6 hours (conventional therapy) or greater than 6 hours (extended therapy).

Results: A total of 100,000 treatments between April 2020 and May 2021 were analyzed. Treatments ranged from 2-24 hours. Treatment time success, defined as achieved within 10% of prescribed time, was 90.7% across the population. The most common reason for early termination was “User ended” (8.6%), with 0.7% due to “Device Directed”. Mean total number of alarms per treatment was 2.5 across the population with no difference in alarm frequency (0.7 alarms per hour) between treatment groups. The most frequent clinically significant alarms were high and low venous pressures. Mean time to alarm resolution was 14 seconds with shorter alarm resolution time demonstrated in the IHD group (13 vs 22 secs).

Conclusions: With high utilization across a wide range of treatment times in the acute setting, Tablo successfully achieved treatment goals. The few observed alarms were quickly resolved by clinical users. Tablo’s robust data reporting capability enables the identification of treatment trends that can be used to drive quality improvement.

PO0916
Impact of Medication Reconciliation by a Dialysis Pharmacist
Summer Dyer, Linda Awdishu, Sally Rafie, Victoria T. Nguyen. University of California San Diego, La Jolla, CA.

Background: Medication reconciliation (MR) improves patient outcomes, reduces cost, and is a reporting measure for the CMS End-Stage Renal Disease Quality Incentive Program. Most dialysis facilities do not have a clinical pharmacist to perform MR. The purpose of this study is to evaluate the impact of a pharmacist performing MR and medication management for patients receiving outpatient chronic hemodialysis at an academic institution.

Methods: We conducted a retrospective study from 10/1/18 to 11/2/20 to determine if MR by a pharmacist reduced medication discrepancies (MDs) and medication related problems (MRPs) over time. Secondary outcomes were to describe the type of MDs, type and severity of MRp, impact of a pharmacy delivery service, and number of emergency department (ED) visits and hospitalizations pre- and post-pharmacist integration.

Results: A total of 135 patients with 479 unique pharmacist encounters were included. The mean (SD) age was 61.7 (14) years, 58% were male, 63% caucasian, mean (SD) time on dialysis was 6.4 (6.4) years and most common comorbidities were diabetes and hypertension. The pharmacist conducted 3.5 MR/patient with a mean time spent of 39.7 (16) minutes and 16% required an interpreter. Unintentional discrepancies were noted in 53% encounters, undocumented intentional discrepancies in 71%, MRP in 59% but decreased significantly from the first to the second encounter (1.9 vs 0.9, 1.9 vs 1.2, and 1.1 vs 0.5 per patient, respectively, p<0.05). Most common MRP types included non-adherence, prescription renewals, and excessive drug doses. Over half (54%) were enrolled in a pharmacy delivery service and had significantly fewer undocumented intentional discrepancies compared to non-enrollees (p<0.05). ED visits and admissions pre- and post-pharmacist integration were not statistically different.

Conclusions: Integrating a pharmacist into a hemodialysis unit enabled effective medication reconciliation and management to significantly reduce medication discrepancies and problems, and improve safety.

PO0917
Interim Analysis of the Extension of Tablo Treatment Duration (XTEND) Study
Yaadveer Chahal, Josh Schumacher, Michael A. Aragon. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission and is approved for use in the acute, chronic and home settings. Prior reports have demonstrated Tablo’s ability to achieve clinical goals, seamlessly integrate into hospitals and reduce cost across a wide range of treatment times. The XTEND study (NCT04912050) is shown in Figure 2. Age, gender, race, living status, and education were not associated with a small portion of patients were continuously non-compliant with treatment success was defined as either ending within 10% of prescribed time or site investigator assessment that all patient treatment goals were met.

Results: Fifty (50) Tablo XT treatments had a median prescribed treatment time of 24 hours and a median achieved treatment time of 23.5 hours. Median cartridge use was 1.0 per treatment. Clinical treatment success was 84%. Treatments ended due to clotting/clogging were 4% (2 of 50). Median total ultrafiltration (UF) rate was 1.7 mL/kg/hr. Clinically significant alarms occurred at a median rate of 7 per treatment with a resolution time of 14 seconds. Most frequent alarms experienced were arterial and venous pressure discrepancies and problems, and improve safety.

Conclusions: Tablo’s XT successfully achieves prescribed treatment time and favorable ultrafiltration rates with minimal therapy interruptions from alarms or cartridge changes. This data demonstrates the effectiveness of Tablo’s newly expanded versatility in achieving personalization of treatments necessary for unstable patients and enabling successful delivery of extended therapy with minimal clotting. Tablo’s 24-hour therapy meets the needs of critically ill patients that require renal replacement therapy for greater than 12 hours.

Funding: Commercial Support - Outset Medical, Inc.
Glycemic Status Ascertained by Continuous Glucose Monitoring in a Prospective Hemodialysis Cohort

Background: Hemodialysis (HD) patients with diabetes are at heightened risk of hypo- and hyperglycemia due to multiple pathways. While self-monitored blood glucose is the standard approach for glucose assessment in HD patients, it may not adequately capture glycemic status given its infrequent nature. We thus sought to measure glucose levels using continuous glucose monitoring (CGM) as a more frequent (every 5-minutes), convenient, and automated method of glycemic status in a prospective HD cohort with diabetes.

Methods: Among 18 HD patients with diabetes hospitalized during 10/2020-5/2021, we conducted simultaneous protocollized glucose measurements using 1) CGM measured by Dexcom G6 devices vs. 2) blood glucose levels using capillary fingerstick or venous blood glucose, with the latter measured 4-8 times per day (before each meal and at night), plus every 30 minutes during HD (total of 6-8 measures during HD). Using American Diabetes Association (ADA)-defined CGM targets, we examined the prevalence of patients achieving the recommended percentage (%) of CGM levels in the ranges of <54, <70, 70-180, >180, and >250mg/dl (ADA target % of glucose levels <1%, <4%, >70%, <25%, and >5%, respectively).

Results: Whereas 64% of CGM measurements (N=9444) were within target glucose range (time in range [TIR] 70-180mg/dl), 80% of blood glucose levels (N=100) were within TIR. The proportion of patients achieving the recommended % of CGM measurements within ADA-defined glycemic ranges of >250, >180, 70-180 (target range), and >70, and >54mg/dl were 67%, 44%, 44%, 89%, and 78, respectively.

Conclusions: In a cohort of hospitalized diabetic HD patients who underwent concurrent CGM and blood glucose measurements using the Dexcom G6 remote access system, blood glucose testing overestimated the % of time patients were in target glycemic range as compared with CGM. CGM showed that less than half of patients achieved the recommended % of CGM measurements within target range. Further studies are needed to determine whether CGM can improve the glycemic management of HD patients compared to conventional approaches.

Funding: Commercial Support - Dexcom, Inc.

Validation of Automated Sodium Control in a Novel Dialysis System

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To test an automated feedback program designed to regulate the infusion of an alkali needed to maintain proper sodium concentration in a dialysate solution.

Methods: A 125L volume of simulated dialysate was circulated at ~400 mL/min and ~37°C through a sorbent cartridge which removed the ursol from the solution. The fluid exiting the cartridge had no Ca, Mg or K. These chemicals were reinflushed through a pump in a solution containing Ca, Mg and salts. A conductivity sensor (cond) was used in a feedback control of the alkali infusion pump. The feedback control adjusted the pump flow rate to maintain the conductivity of the infusate at 14.0 mS/cm. The sensor was programmed from a curve model of the alkali over time from previous experiments. Occasional spikes of Na+ were added to test the feedback control. The experiment ran until a Na+ level reached 10ppm which defined filter breakthrough.

Results: The results are depicted in table 1. TP1, the mean sodium concentration [Na+] in the dialysate at pump 1, after mixing in a 125L tank was in the range 139.8 ~ 141.7 mEq/L. TP2, the mean dialysate [Na+] at pump 2 after leaving the sorbent filter was 124.2 (~2.4) mEq/L. This correlates with cond1 and was 12.8 (~0.4) mS/cm. TP3, the mean dialysate [Na+] after being replenished with the alkali solution immediately prior entering the tank for remixing was 139.5 (~1.9) mEq/L and correlated with cond2 of 14.1 mS/cm.

Conclusions: The results validate the accuracy of the conductivity sensor in correctly regulating the alkali infusate.

HIF-PH inhibitors, Depending on the Blood Type in Hemodialysis (HD) Patients

Satoshi Funakoshi,1 Takashi Harada,1 Jyunichiro Hashiguchi,1 Kenji Sawase,1 Akihiro Mackawa,2 Tayo Kawazu,1 Asami Nakamura,1 Tomoya Nishino.2
1Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki University Graduate School of Medicine, Nagasaki, Japan.

Background: Human blood group antigens are glycoproteins and glycolipids expressed on the surface of red blood cells and a variety of human tissues. This study aimed to determine if there is an association between ABO blood type and the efficacy of HIF-PH inhibitors. Roxadustat and daprodustat are potent inhibitors of HIF-PH and capable of stimulating erythropoiesis in patients on impaired renal function. These two compounds are reported to act mechanistically similar but display differences in their effects on cells, and the differences may affect their efficacy in the treatment of renal anemia in HD patients. In this study we compared the response rate by blood type type between roxadustat and daprodustat, respectively.

Methods: Sixty-eight HD patients treated with roxadustat (20-100mg, 3/week) and ninety-five treated with daprodustat (1-12mg, daily) were recruited in our observational study. We defined >1.5g/dl increase in hemoglobin as effective, and <1.5g/dl decrease as ineffective.

Results: As shown in the figure, type A had the highest response rate at 47% in HD patients treated with roxadustat. On the other hand, type O had the highest response rate at 55% in those who were treated with daprodustat.

Conclusions: We found the association in the effectiveness of roxadustat on the treatment for anemia in HD patients in type A, while the effectiveness was higher in type O treated with daprodustat. The results suggest that the therapeutic effect of HIF-PH inhibitors may differ depending on the blood type.

Nanostructured Capillary Membranes for Size-Selective Hemofiltration
Peifu Cheng,1 Francesco Fornasier,1 Nicholas J. Ferrell,1 Shuvo Roy,2 William H. Fissell,1 Piran Kidambi,1 1Vanderbilt University, Nashville, TN; 2University of California San Francisco, San Francisco, CA; 3Lawrence Livermore National Laboratory, Livermore, CA.

Background: Size-selective separations offer potentially transformative advances for hemofiltration. In the context of hemodialysis, the tradeoff between selectivity and permeability often results in large package sizes and high driving pressures that limit wearable and implantable options of therapy. Here, we report on composite membranes with vertically aligned precise nanoscale capillaries with improved permeability.

Methods: Arrays of carbon nanotubes (CNTs) were synthesized via chemical vapor deposition and the catalyst composition was carefully selected to achieve a uniform distribution of diameters. The area between the CNTs were filled with a polymer to form a membrane. The CNT membranes were backed with microporous silicon supports and mounted into a filtration cell. Hydraulic permeability was calculated from gravimetric flow rates at stepped transmembrane pressures. Size-selectivity was measured by filtering fluorescently-labeled polydisperse Ficoll in phosphate-buffered saline. Size-specific Ficoll concentrations in feed and filtrate were measured by size-exclusion chromatography.

Results: CNT membranes membrane exhibited a cut-off ~6nm and the measured hydraulic permeability was 102.3 ml h⁻¹ m⁻² mmhg⁻¹ compared to published data of 30 ml h⁻¹ m⁻² mmhg⁻¹ for conventional high flux dialyzers. CNT membranes retained large molecules while passing small and medium-sized molecules. Sieving coefficient at 2 nm, approximately the size of b₂ microglobulin, was unity (Figure).

Conclusions: The CNT membranes provide excellent middle molecule clearance and hydraulic permeability multiples of conventional membranes. Further research is necessary to move to clinically implement this technology.

PO0923
Delivered Dialysate Potassium Is Higher Than What Is Prescribed When High Sodium and Low Bicarbonate Are Prescribed
Saiyed W. Ali, Andrew I. Chin. University of California Davis Department of Internal Medicine, Sacramento, CA.

Background: Most hemodialysis machines utilize the 3-stream method of making dialysate. In hospital settings, dialysate prescriptions are customized to the clinical setting. We determined the differences between delivered and prescribed dialysate K⁺ in unusual prescriptions.

Methods: Dialysate samples drawn 15 minutes into HD were analyzed via indirect ion-specific electrodes for Na⁺, K⁺, and HCO₃⁻. 5200 HDs with extremes of ordere Na⁺ and HCO₃⁻ were analyzed. Outcome was measured versus ordered K⁺. Analysis used ANOVA using SPSS.

Results: Means of the difference between measured and ordered K⁺ and Na⁺ are shown in figure 1. For K⁺ there was significant difference amongst the groups (p<0.001). There were no differences amongst the groups for Na⁺.

Conclusions: When a very high Na⁺ is prescribed along with a low HCO₃⁻ the the delivered Na⁺ remains close to prescribed Na⁺. As the acid concentrate contains both Na⁺ and K⁺, a high Na⁺ and low HCO₃⁻ prescription will use a relatively more of the acid concentrate and less of the bicarbonate concentrate. Dialysate prescriptions with a high Na⁺ and low HCO₃⁻ increase delivered dialysate K⁺ by an average of 0.5 mEq/L; we observed some HDs where delivered K⁺ was 1 mEq/L higher than prescribed.

PO0924
Urea Clearance Performance in a Modified Batch Dialysis System

Background: Urea clearance is the key measure of dialysis adequacy. The Diality Hemodialysis Machine will provide good clearance performance to ensure an adequate dose of dialysis. Specific Aims: To assess clearance performance during simulated dialysis utilizing a novel modified batch process. In this setup, dialysis was conducted by alternating dialysate delivery from subsequent two-liter reservoirs.

Methods: Simulated dialysis sessions were conducted utilizing blood flowrates of 300 ml/min, dialysate flowrates of 350 ml/min and no ultrafiltration. Dialysis occurs off of a two-liter batch of dialysate. Once two liters of dialysate has been circulated through the dialyzer, the spent dialysate is discarded and dialysis switches to a separate two-liter reservoir of dialysate while the first reservoir is drained and filled with fresh dialysate. A single compartment simulated patient was created by combining 50 L of DI water with a 20mM concentration of urea. Simulated blood samples were collected at the dialyzer inlet and outlet and dialysate samples collected at the dialyzer outlet to determine urea concentrations over the course of the simulated treatment.

Results: The results are provided in Figure 1. The urea concentrations in the blood decreased over the course of treatment as expected given the stated clearance values of the dialyzer used in the simulated treatment.

Conclusions: The initial experiments using a modified batch system show promising urea clearance. Future tests will better characterize performance compared with conventional devices that do not use a modified batch configuration.

PO0925
Increasing the Clearance of Protein-Bound Uremic Solutes by Introducing an Activated Carbon Block into the Dialysate Stream
Seolhyun Lee,1,2 Tammy L. Sirich,1,2 Timothy W. Meyer,1,2 Stanford University School of Medicine, Stanford, CA; VA Palo Alto Health Care System, Palo Alto, CA.

Background: The hemodialytic clearance of protein-bound solutes is limited because only the free solute concentration drives diffusion across the membrane. This study tested whether an activated carbon block could reduce accumulation of these solutes in the dialysate and thereby increase their clearance.

Methods: In vitro dialysis of artificial plasma containing urea and the protein-bound solutes p-cresol sulfate (PCS) and indoxyl sulfate (IS) was performed using two dialyzers in series with and without an activated carbon block at the midpoint of the dialysate stream (Figure). Six dialysis experiments were performed each with plasma flow 240 mL/min and dialysate flows of 200 mL/min and 600 mL/min. Nine additional experiments tested the capacity of the carbon block to take up solutes by measuring solute removal from spent dialysate collected at patient treatments. Spent dialysate was passed through the carbon block at 600 mL/min and fractional removal of solutes was assessed after more than 180 liters had passed through the block.

Results: Use of the carbon block increased the clearances of the tightly bound solutes PCS and IS by 70 ± 3 and 64 ± 19%, respectively, when the dialysate flow was 200 mL/min. Lesser increases occurred when the dialysate flow was 600 mL/min (PCS 38 ± 5%, IS 33 ± 8%). Urea clearance was unchanged by the carbon block. The carbon blocks removed 97 ± 2% of PCS and 96 ± 2% of IS but only 2 ± 5% of urea from spent dialysate flowing at 600 mL/min.

Conclusions: Use of a carbon block can increase the clearance of protein-bound solutes particularly at the low dialysate flows often used for home hemodialysis.

PO0926
Comparative Effectiveness Between Novel Medium Cut-Off Membrane Hemodialysis and Mixed-Dilution Online Hemodiafiltration on Middle Molecule Uremic Toxins Reduction: A Prospective Cross-Over Study
Jirarat Eiamcharoenying, Pajaree Charityavilaskul, Kulaya Takkvatarkarn, Paweena Susantitaphong, Yingyos Avihingsanon, Somchait Eiam-ong, Khajiron Tiranathanagul, King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

Background: Mixed-dilution online hemodiafiltration (mixed HDF), one of the best hemodialysis (HD) modes, provides superior removal of middle molecule uremic toxins to standard HD using high flux dialyzer. Due to the limited availabilities and high cost of HDF, we performed standard HD utilizing a novel medium cut-off membrane with a larger pore size and compared the effectiveness in removal of middle molecule uremic toxins with mixed HDF.

Methods: A prospective cross-over randomized controlled trial was conducted in 14 prevalent HDF patients who were randomly allocated into group (n=7): mixed-dilution online HDF with high flux dialyzer ELJSI021H and group (n=7): standard HD with MCO membrane, Theranova 500. In this 8-week study, the primary outcome was a reduction ratio (RR) of B2M, microglobulin (B,M). Other small to middle molecules and protein-bound uremic toxins reduction ratio, dialysate albumin loss, and nutritional parameters were also compared.

Results: In this 8-week study, B,M RR from both modalities was higher than the survival benefit cut-point of 80%. In comparison, B,M RR was slightly lower but significant in MCO HD than mixed HDF (82.57±5.34% vs 85.12±3.87%, respectively) with the mean difference of 2.59 (95% confidence interval [CI], -4.07 to -1.03; P=0.001). The upk/Varea and URR, a small uremic toxin removal marker, were comparable. kFCL and Indoxyl sulfate RR also were similar in mixed HDF and MCO HD. Whereas RR of the larger middle molecule uremic toxin, Alpha M and JFLC was lower with mixed HDF compare to MCO HD (30.13±15.90 vs 41.49±11.46 and 40.85±13.92 vs 50.81±13.18, respectively; P<0.001). Dialysate albumin loss was 3.5±0.0g/session with MCO HD and 0.58 g/session with mixed HDF (P<0.005). Regarding, nutritional parameter, serum albumin levels were not different.

Conclusions: Mixed HDF and MCO HD provided the RR values of B,M and small uraemic toxins above the recommended cut-point. Despite mixed HDF provided higher B,M RR, MCO HD also provided more performance in the clearance of the larger middle molecules, particularly aM and JFCL. However, mixed HDF loss lower albumin than MCO HD. Therefore, both techniques can be used as alternative options.

PO0927
Clearance of Protein-Bound Uremic Toxins on the Tablo Hemodialysis System
Logan Rivas, Dean Hu, Michael A. Aragon. Outset Medical, San Jose, CA.

Background: The Tablo Hemodialysis system (Tablo) is an all-in one, easy-to-learn device. While clearance of small and middle molecules has been documented in modern dialysis, the clearance of Protein Bound Uremic Toxins (PBUTs) merits further exploration. Clearance of albumin bound toxins such as indoxyl sulfate (IS) and p-cresol sulfone (PCS) can be limited in dialysis where removal is based on molecular size. Although a clear association has yet to be demonstrated, PBUTs have been considered to be a possible cause of adverse outcomes in patients requiring renal replacement therapy.

Methods: A simulated hemodialysis treatment using Tablo was performed with solution of bovine serum albumin and urea. PCS and IS were added to the solution to maintain a constant concentration. A screening design of experiment was performed utilizing the factors of dialysis flow rate (Qd), blood flow rate (Qb), and ultrafiltration (UF). After each factor was changed and allowed to equilibrate, samples were collected from the venous, arterial and spent dialysate lines. Samples of Urea, PCS and IS were analyzed and compared to predicted values from previously published models.

Results: The Tablo system cleared PCS and IS as predicted or better at all conditions. See table and images for details.

Dialysis Disequilibrium Syndrome (DDS) in Hemodialysis Patients: Systematic Review
Rupesh Rama,1,2 Siddhartha S. Singh,1,2 Ronith Chakraborty,1,2 Cleveland Clinic, Akron, OH; 3Akron Children’s Hospital, Akron, OH.

Background: Dialysis disequilibrium syndrome (DDS) affects patients who have missed multiple dialysis treatments, especially new initiates of hemodialysis (HD), and presents as a rare neurological complication. The conceptual pathogenesis of DDS is likely a result of multiple physiological abnormalities which we explore in this systematic review alongside preventive measures with focus on effective management strategies.

Methods: A literature search was conducted on PubMed/Medline and Embase and included studies if the patient developed DDS irrespective of age and gender. Two independent reviewers conducted the process of article selection with a third reviewer present to resolve any conflicts. The data was analyzed and a summary table was extracted with the following variables: study type, population group, age, patient characteristics, blood and dialysate flow rate, and study outcome. A descriptive analysis was performed analyzing the population size and frequency of symptoms and treatments utilizing the R software.

Results: A total of 49 studies (321 samples) were identified and analyzed. There were 72.4% of patients (based on 48 studies) who reported having DDS with most common symptoms of headache (39.4%), nausea (40.4%), vomiting (39.1%), confusion (66.7%) and seizure (78.6%). Within this sample, 12 studies switched from HD to alternative dialysis modalities including continuous venovenous hemofiltration/hemodiafiltration (CVVH/CVVHDF) or peritoneal dialysis (PD) with no further reported DDS symptoms.

Conclusions: We have provided a comprehensive clinical practice points for both the pediatric and adolescent and young adult population; interestingly, DDS was reported more often in the early dialysis era prior to recent advances and improvement of resource allocation. Existing literature shows it is crucial to recognize symptoms of DDS and implement timely prevention to improve outcomes.

PO0929

Protein Loss with Medium Cut-Off and High Flux Dialyzer: A Proteomic Analysis
Xiaoling Wang,1 Xia Tao,1 Leticia M. Tapia Silva,1 Amrish U. Patel,1 Mohammad I. Hakim,1 Nadja Grobe,1 Stephan Thijsse,1 Peter Kotanko,1,2 1Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Hemodialysis (HD) patients frequently suffer from low serum albumin levels, making dialytic albumin and protein loss a concern. Medium cut-off (MCO) dialysis membranes report a greater albumin loss compared to high-flux (HF) membranes. To better understand the spectrum of proteins cleared with MCO membranes, we set up an ex vivo dialysis system and perform proteomic analysis of the dialysate.

Methods: Eight liters of human plasma (EDTA added) were split into two 4-liter batches and dialyzed for 4 hrs in single-pass, either with an MCO (Theranova 400) or HiFlux dialyzer (Optiflux F810NR) using a Fresenius 2008RT machine. Blood flow was 400 ml/min. Dialysate flow was 600 ml/min for the first 3 hrs and zero for the 4th hr. Ultrafiltration rate was zero for the first 2 hrs and switched to 1 L/hr thereafter. This design allowed us to study three HD modes: diffusion only (2 hrs); diffusion with convection (1 hr); convection only (1 hr). Dialysates were sampled at multiple time points (Fig 1B).

Results: Three µg of initial plasma and 23 µl dialysate were loaded on an SDS-page gel and silver stained (Fig 1A). Initial lanes 3 and 4 were from MCO, lanes 4 and 6 from HiFlux. Lanes 3 and 4 were collected 15 mins into dialysis, lanes 5 and 6 at 240 mins. Results show that dialysates contain less high molecular weight proteins compared to plasma, and MCO dialysates contain much more proteins compared to HiFlux dialysates. The strong band at ~62 kD is most likely albumin. Using mass spectroscopy, we can identify 56 different protein species in MCO dialysate. Dialysate protein levels (measured by Bradford assay) with the 3 dialytic modalities are shown in Fig 1C. The total protein losses are listed in Fig 1C. The ratio of protein loss between MCO and HiFlux dialyzers is 17-fold in the convection only mode.

Conclusions: Our results show a higher diffuse and convective protein loss with MCO compared to HiFlux membranes. Further characterization and quantitation of proteins cleared in vivo during HD are necessary to better understand the clinical impact of our ex vivo observations.

Intradialytic and Interdialytic Urea Dynamics in Blood and Cerebrospinal Fluid in Hemodialysis Patients
Xia Tao,1 Lin-Chun Wang,1 Xin Wang,1 Ohnmar Thwin,1 Nadja Grobe,1 Amrish U. Patel,1 Stephan Thijsse,1 Joshua E. Chao,1 Ludovic Debure,2 Thomas Wisniewski,2 Peter Kotanko,1,2 1Renal Research Institute, New York, NY; 2NYU School of Medicine, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Modern, highly efficient hemodialysis (HD) results in rapid decline of blood urea. Urea gradients across the blood-brain barrier (BBB) can drive water movements. A positive urea gradient, i.e. brain urea to plasma urea, can result in brain swelling and impair brain function. We explored the dialytic changes of urea in blood and cerebrospinal fluid (CSF) to better understand intradialytic osmotic gradients across the BBB and provide insights that support the development of brain-protective HD.

Methods: Two HD patients (39 and 26 years old) with ventriculo-peritoneal (VP) shunts were enrolled into this one-week IRB-approved study with a Monday/Wednesday/ Friday dialysis schedule. CSF was collected via VP shunt tap 2 hrs before and 2 hrs after HD (Wednesday and Friday), and Tuesday and Thursday. Plasma samples were collected concurrently with CSF and during HD. In addition, the patients underwent test of executive function (Trail Making Test Part B, TMT B) and global cognitive function (Montreal Cognitive Assessment; MoCA) on Monday.

Results: Urea was removed efficiently from patients’ blood by HD. While patient A showed a small post-HD plasma-to-CSF urea gradient, it was highly positive (~60 mg/dL) in patient B (Fig 1). TMT B and MoCA score were normal for patient A but not patient B (TMT B 415 sec; TMT B error count: 2; MoCA score: 11).

Conclusions: Our patients showed very different post-HD plasma-to-CSF gradients. Theoretically, the positive gradient in patient B would favor intradialytic brain swelling. Patient B showed impaired neurological testing results which are not related to patient’s pre-existing neurological conditions. We can only speculate if and to what extent trans-BBB water movements driven by dialytic urea dynamics may have impacted the patient’s cognitive functions. We believe that patient-specific levels of osmotic stress need to be considered when developing neuro-protective HD technologies.

Figure 1: Urea concentrations in plasma (black line) and CSF (red line; left panel: patient A; right panel: patient B).

Can Plasma Filters Be Reused for Plasmapheresis in Resource-Poor Settings? Experience from a Tertiary Care Hospital
Priti Meena, Sandip Panda, Rishita Mondal, Swati Das. All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India.

Background: Therapeutic plasma exchange (TPE) is used in the management of various life-threatening illnesses. It is widely performed by nephrologists, intensivists, pathologists, or experts of transfusion medicine worldwide. However, the costs of TPE sessions are exceedingly high and it has a huge impact on patients’ financial burden. Most of the patients cannot afford such a high-cost treatment. Herein, we investigated the outcomes of reuse of plasma filters in TPE for several occasions

Methods: This was an ambidirectional study that included retrospective analysis of patients receiving TPE from January 1, 2021, to December 31, 2020, whereas the patients receiving TPE from January 1, 2021, to April 30, 2021, were prospectively analysed. The procedure was performed in our hospital’s dialysis unit. Formulation of 4% peracetic acid and 24% hydrogen peroxide acid with RO water was used for reprocessing. Freesius Plasma Flux P2 (0.6 m2) was used in the study. Clinical outcomes, risks, and cost-benefit were evaluated and compared between the plasma filter reusing group (GP-1) and no reusing group (GP-2).

Results: 46 patients were included in the study. 26 patients were in the Plasma filter reuse group. 122 and 119 TPE sessions were performed in GP-1 and GP-2 respectively. A total of 58 plasma filters were used in GP-1. In six patients single plasma filter was used on 3 occasions whereas, it was used for 2 occasions in other patients. The most common indication for TPE in both groups was Guillain barre syndrome. The rates of clinical improvement in disorders for which the TPE were performed were similar in both GP-1 and GP-2 (88% vs 90%, p=0.4). None of the patients in either group had clotting of plasma filter, any allergic reaction, or increased bleeding risk. No higher chances of sepsis were noticed in GP-1 (P<0.08). No difference in patient survival was noticed between the two groups (97% vs 96%, p=0.5). The cost of overall treatment was 2.5 times higher in GP-2, (P=0.003).

Conclusions: Reuse of plasma-filter is a safe and effective method for cost minimization in patients requiring TPE. This method can effectively be utilized in resource-poor settings without any increased risk of adverse effects

A Forgotten Technique of RRT for Correction of Severe Hyponatremia in CKD: Case Report
Rodolfo A. Moreno,1,2 Alexandra M. Trochez,1,2 Pedro Gonzales,1,2 Antonio J. Palma,1,2 Lidia B. Sánchez,1,2 Rafael J. Hernández,1,2 Jorge A. Hernández,1 Centro Médico Militar, Guatemala, Guatemala; 2Universidad Mariano Galván Facultad de Ciencias Médicas y de la Salud, Guatemala, Guatemala.

Introduction: Patients with chronic kidney disease (CKD) present electrolyte disorders. This represents a challenge when hyponatremia is below 125 mmol/L, associated with any criteria for urgent renal replacement therapy (RRT) with conventional hemodialysis because of higher risk of over correction above the security threshold of 10 mmol/L/day and osmotic demyelination syndrome.

Case Description: A 49-year-old Guatemalan female with a history of 15 days of edema and slurred speech. Only history of T2DM. Was brought to the ER with BP 100/80 mmHg and anasarca. Initial laboratory: negative COVID-19Ag, Cr 5.12 mg/dL, (previous 2mg/dL) BUN 105 mg/dL, glucose 156 mg/dL, Na 108 mmol/L, K 5.2 mmol/L, Cl 70 mmol/L, SO4 224 mmol/L, UOsm 289 mmol/L. Because of neurologic symptoms, received a 150 mL bolus of 3% saline twice with a rise to 112 mmol/L. After the bolus, we initiated a 24-hour infusion with 3% hypertonic solution reaching a rise of Na up to 119 mmol/L in 48 hours, but because of persistence of neurologic symptoms plus fluid overload >10% of body weight and hyperkalemia, we initiated RRT. In the absence of CRRT or CVVH we planned a conventional HD with blood flow of 100 mL/min, dialysate flow 600 mL/min, dialysate Na 130 mmol/L (the lowest Na possible) and 3 hours duration. After the first session had neurological and edema improvement. After two sessions with an interdialytic period of 48 hours, Na control of 122 mmol/L and 132 mmol/L respectively with resolution of uremic syndrome. Later was diagnosed with hospital-acquired pneumonia receiving antibiotic treatment for 14 days and was discharged home with ambulatory HD.

Discussion: In underdeveloped countries where the access to CRRT or CVVH is unavailable, conventional modalities can be used with low blood flows and modification of the dialysate Na to a minimum (130 mmol/L) offering a safe option to Na correction for patients with severe hyponatremia and any other HD criteria.

PO0935

Single-Bolus Tinzaparin Anticoagulation in Extended Hemodialysis Sessions: A Feasibility Study
Benoit Harvey,1 Simon Laporte,2 Naoul Elfouh,1 Michel Vallée,1 Louis-Philippe Laurin,2 Annie-Claire Nadeau-Fredette,3 Université de Montréal, Montreal, QC, Canada; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Few studies have assessed the use of low-molecular weight heparins for anticoagulation during extended hemodialysis (HD) sessions. This study aimed to evaluate the safety and efficacy of tinzaparin for anticoagulation of the extracorporeal circuit and dialyzer in extended, 8-hour, sessions.

Methods: This single-center study included all patients who underwent a single in-centre 8-hour session as part of their nocturnal home HD training between 2019 and 2020. Tinzaparin was delivered as a single bolus injection at time 0 with dosing based on the patient’s weight and doubling of standard 4-hour session dose. Tinzaparin safety was assessed as anti-Xa levels measured at 15-, 30-, 60-, 120- and 180-min post-dose. Efficacy was examined via visual observations (score 1-4) of the dialyzer and venous bubble trap at the end of dialysis. Predictors of clotting levels were assessed in exploratory logistic regressions.

Results: Forty-seven patients were included: age 45±14 yrs, 28% women, 9% on warfarin, 42% on antiplatelets, BMI 29±7 kg/m², hemoglobin 114±15 g/L and platelet 203±61 *10^10/L. Mean tinzaparin dose was 107±20 IU/kg. Anti-Xa levels peaked at 15-min with 1.3±0.4 IU/mL and progressively declined reaching 0.9±0.3 IU/mL at 1-hour, 0.2±0.1 IU/mL at 4-hour, and 0.15±0.15 IU/mL after 8-hour. Figure 1 After the 8-hour session, none of the patients had severe clotting of their dialyzer or venous chamber. Moderate blood clotting was observed in the dialyzer of 6 (20%) patients and in the venous chamber of 22 (61%) patients. Tinzaparin dose was increased for 27 (81%) patients with a mean maintenance dose of 123±28 IU/kg. None of the main baseline characteristics (including tinzaparin dose per kg) were associated with clotting scores.

Conclusions: This study shows that anti-Xa levels stabilize rapidly after administration on tinzaparin for 8-hour HD. Administration of a single bolus tinzaparin at the start of an eight-hour dialysis session appeared safe and effective, although dose adjustment may be required.

PO0936

Green Hemodialysis: Is It Really Possible to Save Water and Plastic Without Affecting the Quality of the Treatment? Ismael A. Gómez Ruiz, Geovana Martin-Alemaydy, Juan M. Ardavin Izuarte, Rossana Olmedo Ocampo, Santa Carmen Médica Santa Carmen, Ciudad de México, Mexico.

Background: Hemodialysis (HD) is essential for the preservation of life in many patients but represents a complex issue in ecology producing a large waste load that affects the environment. Sustainable waste management policies are scarce. The aim of the present study was to show the particular water and plastic savings in a Mexican HD center that practices the reuse of dialyzers and reject water (RW) without affecting the quality of care provided for patients.

Methods: Prospective cohort study performed between January and May in 2021 in a HD center with 90 patients (AK 98 Baxter®). HD center has 15 employees, 5 bathrooms and 12 sinks. Volumes of produced and reused RW were measured by flow meters. A detailed analysis of the residual biochemical content of RW was performed. The weight of plastic waste was compared between patients with reused membranes and patients with non-reused membranes. Finally, to evaluate the quality of the HD treatment in reused dialyzers (1-12 reuses), the difference between 5 monthly measurements of the spKt/V was determined using a repeated measure ANOVA considering a p<0.05 for no difference.

Results: During the study period 4158 HD sessions were provided, 394 m3 of RW were produced, 312 m3 (79%) were reused for all center sanitation purposes. Analysis of the residual biochemical content of RW is shown in Table 1. A total of 1902 HD sessions were performed with reused dialyzers. With each dialyzer reuse (Revaclear Baxter®) 0.88 lbs of plastic waste was spared. This translates into 1.53 tons less waste. No adverse effects were observed. No statistical significance difference was observed in single pool Kt/V between treatments with reused filters.

Conclusions: These results suggest that reuse of RW in the sanitation of the centers and dialyzer reuse resulted in significant savings in water and plastic without affecting the quality of treatment received by patients.

Table 1: Analysis results for RW compared with US Environmental Protection Agency (EPA) and the Association for the Advancement of Medical Instrumentation (AAMI) standards.

Targeted Alteplase Administration to Improve Hemodialysis Catheter Patency: A Quality Improvement Pilot Study

Jason T. Bau,1 Tyrone Harrison,1,3 Kokak Younis,2 Nathen Gallagher,2 Juliya Hemmett,2 Elena Qrijaz,1 1University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2Alberta Health Services, Calgary, AB, Canada; 3University of Calgary Department of Community Health Sciences, Calgary, AB, Canada.

Background: Catheter dysfunction (CD) is a frequent complication during the provision of hemodialysis. Thromboembolic agents (i.e. alteplase) are the mainstay for resolving CD, however, alteplase usage has increased 16% ($440,000CAD) annually in the Alberta Kidney Care South program without improved patient or dialysis outcomes. We assessed the implementation of a protocoded algorithm to reduce alteplase usage.

Methods: In this pilot quality improvement study, we designed an algorithm where CD was treated with high-dose (2mg) alteplase therapy to the problematic lumen only, after meeting pre-specified criteria (Fig 1). This protocol was implemented in a satellite hemodialysis unit (~110 patients) from Jan 2021 to Mar 2021. The baseline comparison period was Jan 2020 to Dec 2020 when CD was treated with low-dose 1mg/lumen alteplase. Outcome measures included total alteplase usage, changes in Kt/V, recirculation, clearance, line interventions and hospitalization rates. Statistical analysis was completed using Mann-Whitney and Z-score calculations.

Results: Sixty-nine alteplase administrations occurred over the two-month period, versus 438 in the baseline period. Patients in the 2mg group were more likely to achieve an increase in Kt/V of at least 10% in the next dialysis session (34.7% vs 28.9% p=0.04). Otherwise the 2mg alteplase with our protocol was not inferior to baseline with respect to blood volume processed (26.1% vs 20.1% p=0.13) and average clearance (37.7% vs 28.5% p=0.37). A 12% decrease (88 vs 100mg/mo p=0.05) in alteplase use was observed with no differences in frequency of hospitalizations (8% vs 5.9% p=0.39) or line interventions (12.3% vs 7.3% p=0.20).

Conclusions: Our protocol with 2mg alteplase therapy to the problematic lumen was not inferior with respect to patient outcomes compared to baseline practices and resulted in lower alteplase use. An expanded multi-center prospective study is underway to further assess the broader applicability of these findings.
PO0942
Validation of Urea Removal in Novel Sorbent Dialysis System

Background: The Duality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aim: To assess urea mass removal during a simulated dialysis utilizing a novel sorbent filter.

Methods: Nine simulated dialysis sessions were conducted utilizing between 50L and 125L volumes of dialysate circulated at approx. 400 mL / min & 37 C through a sorbent cartridge with a standard dialysate. (Table 1) It is expected that with each pass through the filter the dialysate urea mass will decline. The experiment is continued until breakthrough occurs or the infused outlet reaches 10 ppm of NH₃. A solution containing K, Ca and Mg salts were constantly infused to replenish electrolytes lost in each pass. Another solution was infused at a variable rate as determined by conductivity to maintain Na Balance.

Results: The results are provided in table 1. The average URR was 63.8 % ranging from 53.3 to 87.0 %. The average starting HUN was 48.2 mg/dL and the average ending HUN was 16.8 mg/dL.

Conclusions: The initial experiments using a sorbent filter demonstrate a URR of near 65 is feasible. Future design changes will be scaled to handle larger amounts of urea and provide acceptable clearances.

Effect of Hemodialysis on Amyloid-β in Cerebrospinal Fluid and Plasma
Lin-Chun Wang,1 Ohnmar Thwin,1 Joshua E. Chao,1 Amritsh U. Patel,1 Ludovic Debre,2 Nadja Grobe,1 Xia Yao,1 Hanjie Zhang,1 Stephan Thijsen,1 Thomas Wisniewski,2 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY; 2NYU Langone Health, New York, NY.

Background: Hemodialysis (HD) can reduce amyloid-beta (Aβ) species in whole-body circulation by 30 to 50%. Due to the dynamic exchange of Aβ between the brain and the blood, we hypothesized that HD might lower Aβ levels in the cerebrospinal fluid (CSF).

Methods: In a dialysis network with over 160,000 patients, we identified three maintenance HD patients (age 36±9 years) with ventriculo-peritoneal (VP) shunts who were subsequently recruited for this IRB-approved research study. Study subjects were dialyzed on Monday, Wednesday, and Friday. Plasma samples were collected at 6 timepoints during the 3 HD sessions. One subject was withdrawn over safety concern related to the VP shunt tap procedure. Two subjects further underwent VP shunt taps for CSF sample collection before and after the Wednesday and Friday HD sessions, and once on interdialytic days (Tuesday, Thursday).

Results: HD effectively reduced plasma Aβ1-40 by 41% and Aβ1-42 by 34% (Fig 1a and 1b, p < 0.01). In CSF, levels of Aβ1-40 increased after Wednesday HD sessions in subject 1 (Aβ1-40: +4.2-fold, Aβ1-40: +5.5-fold) and subject 2 (Aβ1-40: +1.06-fold), while Aβ1-42 decreased after Friday HD sessions in both subject 1 (Aβ1-42: -0.1-fold, Aβ1-40: -0.1-fold) and 2 (Aβ1-42: -0.7-fold, Aβ1-40: -0.7-fold) shown in Figure 1c-e.

Conclusions: This is the first report of Aβ dynamics in the CSF and plasma of HD patients. While plasma levels were in similar ranges, we found high inter-individual variations of CSF levels. Different plasma-to-CSF ratios after HD may reflect individual brain Aβ pools that are accessed by HD. We corroborate previous reports demonstrating the removal of Aβ from the blood compartment by HD.
Circulating Microbiome and Cardiovascular Death in Patients with ESRD

Keichi Sumida,1 Joseph F. Pierre,1 Zhongji Han,1 Tahliyah S. Mims,1 Praveen Kumar Potukuchi,1 Susmita Datta,1 Csaba P. Kovacs.1 The University of Tennessee Health Science Center, Memphis, TN; 1University of Florida, Gainesville, FL.

Background: Patients with end-stage renal disease (ESRD) suffer from disproportionately high cardiovascular (CV) mortality. Accumulating evidence suggests a role for the circulating microbiome (CM) in the pathogenesis of CV disease; however, little is known about its association with premature CV mortality in ESRD.

Methods: In a pilot case-control study of 17 hemodialysis (HD) patients who died of a CV event and 17 matched HD controls who remained alive during a median follow-up period of 2.0 years, we compared the levels and composition of CM, including Bacteria, Archaea, and Fungi in serum samples by quantitative PCR and 16S or Internal Transcribed Spacer (ITS) ribosomal RNA (rRNA) sequencing, respectively. Association of the CM with CV death were examined using multivariable conditional logistic regression.

Results: 16S and ITS rRNA was detectable in all (except 3 for ITS) examined patients’ serum samples. Despite no significant difference in 16S rRNA levels and diversity between cases and controls, taxonomic analysis demonstrated differential community membership between groups, with significantly greater Actinobacteria and less Proteobacteria observed in cases than controls at the phylum level. At the genus level, Staphylococcus was numerically higher in cases than in controls, albeit not reaching statistical significance. Proportions of Actinobacteria and Proteobacteria phyla were marginally associated with risk of cardiovascular death (adjusted ORs [95% CI], 1.12 [0.98-1.29] and 0.88 [0.76-1.02] for 1% increase, respectively; Table). Although circulating fungal community diversity was significantly elevated in cases than controls, no significant association was observed with CV death.

Conclusions: Alterations of the CM may be associated with a higher risk of premature CV mortality in ESRD patients.

Association of circulating microbiome with cardiovascular death in hemodialysis patients

PO0945

Dysregulation of Fibrinolytic Process Contributes to the Thrombotic and Bleeding Complications in ESRD Patients

Fakha Siddiqui, Vinod K. Bansal, Omer M. Iqbal, Emily Bontoeke, Jawed Fareed. Loyola University Health System, Maywood, IL.

Background: End stage renal disease (ESRD) is a complex syndrome involving both cellular and humoral mechanisms. Both thrombotic and bleeding complications are observed which may result in cardiovascular and cerebrovascular adverse outcomes. Fibrinolytic system placed an important role in the regulation of hemostatic process. A comprehensive profiling of the components of fibrinolytic process may provide additional understanding of the bleeding and thrombotic complications in ESRD.

Methods: Citrated whole blood samples were collected from a cohort of ESRD patients (n=95). Normal citrated plasmas were obtained from healthy male and female individuals. These samples were analyzed for prothrombin time (PT), activated partial thromboplastin time (aPTT), prothrombinase-induced clotting time (PicT) and thrombin time (TT) using clot based technique. Fibrinolytic parameters such as urokinase type plasminogen activator (uPA), plasminogen activator inhibitor-1 (PAI-1), and D-Dimer were measured by using ELISA method. Functional PAI-1 was measured by using an amylofix method. All results were compiled as group means ± SEM and respective ratios were calculated.

Results: All of the clotting resulted showed varying levels of elevated values in comparison to normal plasma. uPA levels showed wide variations and were increased (1.6 fold). D-Dimer was markedly increased in the ESRD patients (11.53 fold). Both functional (1.2 fold) and antigenic (3.07 fold) levels of PAI-1 were increased. Interestingly, the PAI-1 antigen levels was much higher in contrast to the functional levels suggesting a progressive consumption of this mediator.

Conclusions: These results suggest that the overall hemostatic system in ESRD patients is dysregulated due to the imbalance of the inhibitors such as PAI-1. The persistent activation of fibrinolysis is due to the increase production of uPA which facilitates endogenous fibrinolysis resulting in the elevation of D-Dimer. The generation of fibrinolytic enzymes results in increased fibrin/fibrinogen degradation products which may contribute to the observed intrinsic and extrinsic coagulation defects as measured by the prolongation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting test may be helpful in the risk stratification and prediction of adverse outcomes in ESRD patients.

PO0946

Successful Treatment of Systemic Calcinosis in a Teenager on Hemodialysis

Naile Tufan pekkuksen, 1 Mohammed Al-Humiari,1 Sai Sudha Mannemuddu,1 Lawrence R. Shoemaker,1 University of Florida, Gainesville, FL; 1East Tennessee Children's Hospital, Knoxville, TN.

Introduction: Systemic calcinosis is rare in pediatric ESKD patients compared to adults. The subcutaneous tissues are most frequently involved. We present teenager in whom calcinosis was detected incidentally on chest radiograph, and review its successful treatment.

Case Description: A 15 yo anuric female who had received hemodialysis(HD) for 18 months after renal transplant failure, was treated for progressive respiratory distress in the ICU. Significant history included osteoporosis, hypertensive cardiomyopathy, and renal failure since age 1. Chest-XR revealed bilateral pulmonary infiltrates and calcified lesions. Thoracic CT scan demonstrated calcified tracheal and bronchial cartilage rings. Flexible bronchoscopy revealed diffuse white/grey nodules throughout the wall of tracheobronchial tree. All cultures were negative. When notified of the finding of calcifications on CT scan, patient’s mother also asked about the firm nodules in the space between patient’s fingers. Dialytic phosphate (P) clearance, and non-calcium(Ca), non-aluminum(Al) based binder use were maximized, using sevelamer and lanthanum carbonate. Sodium thiosulfate and etalcalcetide were given iv post each dialysis. Dialysate Ca varied between 2.5-3 meq/L, to avoid hypocalcemic stimulation of PTH and high CaXP. Lanthanum was discontinued after 3 months, once P levels declined. Other therapies were continued for 10 months; with monthly dose adjustment. PTH level decreased and P levels normalized. Etelcalcitide was reduced to maintain normal Ca level. After 10 months, is punisoderat was tried to prevent further demineralization. This led to transient marked elevation in PTH. Combined therapies led to resolution of calcinosis. However, tracheobronchial calcifications have not been reassessed, since neither chest imaging nor bronchoscopy have been clinically indicated.

Discussion: Calcinosi is uncommon, yet treatable condition in pediatric dialysis patients. Combined use of old and new therapies was successful. Advantge side effects of therapies affect dosing. Etelcalcitide often causes hypocalcemia. Thiosulfate use is associated with nausea. Lanthanum is an effective metal Ca binder, but prolonged use may lead to accumulation and systemic deposition. The emergence of new P binders: ferric citrate, sucrorrtic oxyhydroxide, and bisalomer will offer exciting new treatment options.
Severe Thrombocytopenia due to Electron-Beam Sterilized Polysulfone Dialyzer Membrane Reaction

Zachary Chandler, Iritza Hasan, Vishal Jaikaransingh. University of Florida Health Science Center Jacksonville, Jacksonville, FL.

Introduction: We describe a case of severe thrombocytopenia due to reaction with an electron-beam sterilized polysulfone (PS) membrane. This phenomenon has been previously described but is rarely reported. E-beam sterilized PS membranes are commonly not biocompatible with cellulose-based membranes but adverse reactions may occur as demonstrated in our case.

Case Description: A 74 y.o. woman with CKD Stage 4 and secondary hyperparathyroidism presented for evaluation of generalized weakness, anorexia, and weight loss. Her past medical history included gout, short bowel syndrome following weight loss. Her past medical history included gout, short bowel syndrome following weight loss. She was started on hemodialysis (HD) for suspected progression to ESRD. She developed progressive thrombocytopenia (Figure 1) that was noted, following HD, with improvement on non-HD days. Evaluation of usual culprits of thrombocytopenia was unrevealing. Reaction to the polysulfone filter was suspected and she was switched to a cellulose-based filter with resolution of her thrombocytopenia. She was dialyzed with a PS membrane on HD20 as proof of concept with recurrent thrombocytopenia following HD. She was dialyzed with cellulose-based filter thereafter with no further thrombocytopenia.

Discussion: We describe a case of PS-membrane induced thrombocytopenia. It is hypothesized that e-beam radiation may affect membrane integrity or structure, or produce intermediary products which may cause platelet activation, aggregation, and adsorption, and therefore thrombocytopenia. This entity should be considered in the differential diagnosis of patients undergoing HD who develop thrombocytopenia. Early recognition may reduce incidence of bleeding and need for blood products in these patients.

The frequency of treatments reported on a Saturday was only 92% of that on a Tuesday. The frequency of bypass (on duty) was not related to the day of week.

Conclusions: The variation in frequency of treatment by the day of week suggests “social” causes — i.e. a “night off” is more frequent on the weekend. Either some form of treatment event or alert is present in a substantial minority of APD sessions. The relationship of these events with technique survival is important, but not yet known. In this time linked data will allow examination of events recorded during treatment with patient outcomes.

Leveraging Technology and Innovation to Predict Events and Improve Dialysis Delivery

Matthew B. Rivara,1 David K. Prince,1 Kerstin Leuthner,2 Wael F. Hussein,2 Brigitte Schiller,7 Rajnish Mehrotra,1 Todd C. Edwards,1 Donald Patrick,1 University of Washington, Seattle, WA; 2Satellite Healthcare, San Jose, CA.

Background: There are no validated patient-reported experience measures (PREMs) for use among patients undergoing home dialysis in the United States. We sought to test the home dialysis care experience (Home-DCE) survey, a newly developed multi-item PREM, in a sample of patients from 30 dialysis facilities operated by a single dialysis organization in the United States.

Methods: Using mail and phone survey modalities, we approached 1372 patients treated with peritoneal dialysis (PD) or home hemodialysis (HD) for participation. Using results from completed Home-DCE surveys, we hypothesized multi-item scales and used factor analysis to assess model fit. We assessed scale internal consistency reliability, and assessed floor and ceiling effects for scales and individual items. We evaluated test-retest reliability using intra-class correlation coefficients (ICCs) in a subset of patients who completed the Home-DCE twice. Finally, we evaluated patient demographic and home dialysis facility characteristics (nurse-to-patient ratio, hospitalization rate, star rating, and census) associated with Home-DCE scores.

Results: Overall, 495 eligible patients completed at least one survey (response rate 36%), including 399 treated with PD and 88 treated with home HD; 7 did not indicate their modality. Of these, 49 completed the Home-DCE in Spanish and 61 completed a second survey within 30 days. Analyses supported one 12-item composite scale with high internal consistency reliability (Cronbach alpha = 0.85). This scale was strongly correlated with overall staff rating (r = 0.73) and overall center rating (r = 0.70). ICCs in the test-retest population were 0.73 for the Quality scale, 0.88 for the overall staff rating, and 0.9 for the overall center rating. Patient demographic and dialysis facility characteristics were not consistently associated with Quality scale scores or overall staff or center ratings.

Conclusions: The Home-DCE includes one statistically robust multi-item scale and two global rating scales, and is an informative tool to evaluate patient-reported experience of care for home dialysis. Additional studies are needed to further evaluate the Home-DCE among different dialysis care providers, and to assess the feasibility of electronic administration.

Feasibility of a Staff-Assisted Peritoneal Dialysis Program in the United States: Results of a Pilot Study

Wael F. Hussein,1,3 Graham E. Abra,1,2 Paul N. Bennett,1,3 Jugjeet Atwal,1 Veronica Legg,1 Brigitte Schiller,7 Satellite Healthcare, San Jose, CA; 1University of Washington, Seattle, WA; 2Stanford University School of Medicine, Stanford, CA; 3University of South Australia, Adelaide, SA, Australia.

Background: Staff-assistance can support patients to utilize peritoneal dialysis (PD) and is available in many countries but not in the US. We report on the initial experience from a feasibility study for staff-assisted PD in the US.

Methods: An assisted PD program was initiated at one home dialysis center in Aug 2020, and expanded to a total of 6 centers by Feb 2021. Home assistance by non-registered nurse staff was offered to patients with barriers to self-care with the aim to support patients and families to become independent from staff assistance.

Results: Participating centers referred 33 patients (range: 0 – 16 referrals/center). 16 referrals were cancelled [admission from HD to the program cancelled (3 referrals), transfer to HD prior to referral (4), staff assistance cancellation (1), and death (1)]. 3 referrals are pending, and 14 patients received staff assistance at home. Of those who received assistance, median age was 72 years (range 43-87 years), and 8 were new to PD. Indications included: physical weakness (10 patients), cognition (8), and psychosocial issues (7). One prevalent PD patient required assistance following a PD peritonitis episode. Anxiety and lack of confidence were common among referred patients. Staff member attending the patient’s home assisted with removal and replacement of PD bags (5 patients), machine setup (9), dressing of exit site (7), checking the blood pressure (2), and other requests (8) such as documentation. Assisting staff worked with patients to build problem-solving skills, gain self-confidence, and arrange a safer home environment. Median length of time on the service was 17 (IQR: 6 – 23, range: 2 – 49 days), and median number of visits was 15 (range: 4 – 38, IQR: 5 – 26 visits/patient). Median visit duration was 46 minutes (IQR: 55 – 90 minutes). Seven of the patients who finished are more than 90 days after starting assistance. Six of them remain on PD and one patient transferred to HD.

Conclusions: Staff-assistance can support patient transition to, and maintenance on, PD. Staff-assist programs are operationally feasible with non-RN staff in the US and should be supported by Medicare and regulatory agencies.

Methods: Using a HIPAA-compliant, online chart review tool, nephrologists submitted de-identified clinical and non-clinical demographic information beginning at the time of patient referral and concluding with details from the most recent visit. These data, from 2017 through 2020, were then merged with the physician demographic profile and attitudinal responses. The full data set of 4,062 patient charts submitted from 1,021 nephrologists was analyzed in SPSS.

Results: Given the new efforts to promote home modalities, nephrologists are following status quo and continue to initiate new dialysis patients on in-center hemodialysis. Nephrologists’ current patient loads consist of, on average, 5 HDH patients and 90 ICHD patients. On average, they initiate one new patient on HD compared to 17 new ICHD patients per year. When comparing HDH and ICHD patient charts there are substantial differences between the two patient types. HDH patients tend to be Caucasian and from higher education and socioeconomic levels: 52% are Caucasian and 25% are African American, 37% have some college (14% have an advanced degree), and 67% are middle or upper class. Conversely, ICHD patients tend to be more diverse (40% are Caucasian, 40% are African American), less educated (24% have some college and 5% have an advanced degree) and from lower socioeconomic classes (44% are lower or lower-middle class). Further, 40% of patients on home modalities are employed part- or full-time, versus 18% of patients on ICHD. Insurance coverage – both at dialysis and in-center hemodialysis (ICHHD) where Tablo successfully met all safety and effectiveness endpoints, reported high rates of treatment adherence and patient retention, with greatly reduced training time and in-center hemodialysis (ICHHD) where Tablo successfully met all safety and effectiveness endpoints, reported high rates of treatment adherence and patient retention, with greatly reduced training time.
per week. Mean total UF per treatment was 1.9 L. Mean UF rate per treatment was 7.3 mL/kg/hr. Treatment adherence was 93%, with 95% of treatments completing within 10% of prescribed time. The mean number of clinically significant alarms per treatment was 1.0 (± 3.0), with an average time to resolution of 10.7 (± 18.5) seconds.

Conclusions: Results from the Tablo IDE demonstrating reduced training time, increased treatment adherence, high treatment success rate and a low occurrence of treatment alarms are reproducible in the real world at a frequency of 3-4 treatments/week. This data supports that Tablo is capable of successfully achieving clinical goals while reducing the overall patient burden often associated with HHD.

**Recent Trends in Utilization of Home Dialysis Modalities, Overall and by Duration of ESKD**

**Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen,1 (Hennepin Healthcare Research Institute, Minneapolis, MN; 2University of Minnesota Twin Cities, Minneapolis, MN.**

**Background:** The Executive Order on Advancing American Kidney Health and the End Stage Renal Disease Treatment Choices payment model have focused attention on increasing utilization of home dialysis. We assessed trends in home dialysis utilization between 2016 and 2021, including variability in trends among strata defined by duration of end stage kidney disease (ESKD).

**Methods:** We analyzed dialysis facility admission and discharge data extracted from the End Stage Renal Disease Quality Reporting System in May 2021. During the epidemiologic week of each year from 2016 to 2021, we identified patients undergoing maintenance dialysis at the beginning of the week. For each patient, we identified the current dialytic modality. We estimated trends in utilization of each modality, overall and by duration of ESKD at the beginning of the week (<2, 2-4, 5-9, and ≥10 years).

**Results:** Between 2016 and 2021, home dialysis utilization increased from 11.5% to 14.3%, with the majority of growth occurring since the beginning of 2019 (figure). Concurrently, HD utilization increased from 1.57% to 2.23%, whereas PD utilization increased from 10.0% to 12.0%. Among patients with ESKD duration <2 years, home dialysis utilization increased from 14.8% in 2016 to 20.0% in 2021, with >90% of utilization in this stratum due to PD. Among patients with ESKD duration 2-4 years, home dialysis utilization increased from 11.7% in 2016 to 13.7% in 2021. Among patients with ESKD duration ≥10 years, home dialysis utilization hovered around 9%, although HD utilization reached a high of 3.65% in 2021, representing nearly 40% of home dialysis utilization in this stratum.

**Conclusions:** Growth of home dialysis utilization has accelerated since 2019, with greater absolute growth of PD and greater relative growth of HHD. Longer duration of ESKD is associated with lower utilization of PD, but higher utilization of HHD.

**Funding:** NIDDK Support

### PO0957

**The Impact of Seasonality on Crash Starts and Home Dialysis Use**

**Eugene Lin,1,2 Khristina I. Lung,1 Darius Lakdawalla,2 (University of Southern California Keck School of Medicine, Los Angeles, CA; 1University of Southern California Leonard D Schaeffer Center for Health Policy and Economics, Los Angeles, CA.**

**Background:** The US has made a concerted effort to increase home dialysis use. Dialysis “crash starts,” when patients urgently initiate dialysis in the hospital, are a barrier to home dialysis because they often preclude successful planning. We studied whether the season of the year was associated with crash starts and with home dialysis use among incident patients with end-stage kidney disease (ESKD).

**Methods:** From the United States Renal Data System, we identified all adults with at least 30 days of continuous Medicare Parts A and B coverage initiating dialysis from 2007-2017. We identified home dialysis use and whether patients were hospitalized within 14 days prior to the first outpatient dialysis treatment (i.e., “crash start”). Using multivariable logistic regression, we studied the association between season, likelihood of crash start, and starting dialysis at home. We used a Cox model to study whether crash starts were associated with ever using home dialysis in the first year. We adjusted for demographics, comorbidities, facility and geographic characteristics, and year of dialysis start.

**Results:** After adjusting for confounders and year of dialysis start, patients were less likely to start dialysis in the winter versus the summer (OR: 0.86, 95% CI: 0.82, 0.90). Conversely, patients were more likely to “crash start” into dialysis in the winter versus the summer (OR: 1.14, 95% CI: 1.11, 1.17). Patients with a crash start were substantially less likely to initiate with home hemodialysis (OR: 0.16, 95% CI: 0.15, 0.16) and were less likely to ever use home dialysis in the first year (HR: 0.41, 95% CI: 0.40, 0.42). We observed seasonal heterogeneity in the admission diagnoses. Hospitalizations due to pneumonia, myocardial infarction, and congestive heart failure were 1.6, 1.4, and 1.3 times more likely to occur in the winter versus the summer, respectively. Hospitalizations due to diabetic complications, complications of devices, and chronic kidney disease were 1.05, 1.08, and 1.08 times more likely to occur in the winter, respectively.

**Conclusions:** We observed more dialysis crash starts in the winter and a subsequent decrease in home dialysis use in the first year. Winter hospitalizations were more often acute and due to cardiac and pulmonary etiologies. Clinicians should remain vigilant that patients may be prone to crash starts in the winter and should accelerate dialysis planning accordingly.

### PO0958

**Comorbidity Is Not Associated with Home Dialysis Choice**

**Sanne Vong,1 Anna A. Bonenkamp,1 Yolande Vermeeren,2 Ana van Eck van der Sluijs,1 Tiny Hoekstra,1 Alferso C. Abrahams,2 Frans J. van Ittersum,3 Brigit C. van Jaarsveld,1 DOMESTICO ‘Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; 2University Medical Center Utrecht, Utrecht, Netherlands; 3Department of Internal Medicine, Apeldoorn, Netherlands.**

**Background:** Over the past 15 years the proportion of Dutch home dialysis patients has decreased markedly. In addition, the rate of home dialysis varies significantly among centers. It is unclear whether this is the result of increased comorbidity, other patient characteristics or because dialysis centers perceive barriers for home dialysis differently. Our aim was to investigate the association between comorbidity and home dialysis choice.

**Methods:** The DOMESTICO study is a multicenter retrospective cohort study on home dialysis and randomly selected in-center hemodialysis patients. Comorbidity data was collected of patients who started dialysis between 2012 and 2017, including those who had previously received dialysis or obtained a kidney transplant. Patients who stopped dialysis or died within 30 days were excluded. Comorbidity was assessed with the Charlson comorbidity index (CCI). Home dialysis was defined as any peritoneal dialysis or home hemodialysis treatment during follow-up. Patients were followed until kidney transplantation, wish to stop dialysis, death or study end on 1 January 2017. Multivariable logistic regression analysis was used to assess the association between comorbidity and home dialysis, with a mixed model approach to adjust for dependency of patients within dialysis centers and for other patient characteristics including age, sex, and body mass index (BMI).

**Results:** Of 1358 included patients, 46% were treated with home dialysis. A high comorbidity score (CCI ≥ 5) was associated with a lower probability to receive home dialysis compared to patients without comorbidities (unadjusted OR 0.74, 95% CI 0.54–1.00). After adjustments for patient characteristics including age and BMI, there was no association between comorbidity and home dialysis. Only obese patients (BMI ≥ 30 kg/m²) with comorbidities had a significant lower likelihood to receive home dialysis compared to obese patients without comorbidities (medium comorbidity score (CCI 3-4) adjusted OR 0.40, 95% CI 0.18–0.86 and high comorbidity score (CCI ≥ 5) adjusted OR 0.43, 95% CI 0.20–0.93).

**Conclusions:** Comorbidity is not associated with home dialysis, after adjustment for several confounding factors including age and BMI. Future studies should aim at unraveling the center-specific characteristics that play a role in dialysis treatment.

PO0959
Reducing Routine Bloodwork in Home Dialysis Patients: A Quality Improvement Initiative
Epsita Shome-Vasanthan, Sophia Chou, David Ward, Juliya Hemmert, Jennifer M. MacRae, Elena Qirjazi. University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: There is a paucity of evidence for routine bloodwork frequency in maintenance dialysis patients to assess and manage complications such as anemia and mineral bone disease (MBD). Recent studies showed that decreasing the frequency in conventional in-center hemodialysis (ICHHD) patients had no negative impacts. Given the strain on lab services from the COVID-19 pandemic, Alberta Kidney Care-South (ACK-S) decreased the frequency of routine labs from monthly to every 2 months in home hemodialysis (HHHD) and peritoneal dialysis (PD) patients. We studied the effect of this change on patient outcomes.

Methods: We retrospectively compared prevalent home dialysis patients (>3 months in AKC-S over two 6-month periods: a) Pre-pandemic May-Oct 2019 and b) Pandemic May-Oct 2020. Primary outcomes were number of routine bloodwork days and percentage of patients within target for anemia (hemoglobin, iron saturation) and MBD (calcium, phosphorus, parathyroid hormone). We also compared hospitalizations, mortality, technique failure (defined as transition to ICHD for >60 days), and cost.

Results: There were 366 home dialysis patients in 2019 (270 PD, 96 HHDD) and 400 in 2020 (296 PD, 104 HHDD). The number of routine bloodwork days decreased in 2020 compared to 2019 (p=0.01) (Fig 1). The proportion of patients who achieved anemia (33% vs 35%, p=0.44) and MBD (34% vs 28%, p=0.1) targets was similar. There was no difference in the number of hospitalizations (155 vs 141, p=0.34), deaths (13 vs 17, p=0.71) or technique failure (8% vs 5%, p=0.06). Projected cost savings were $102 per patient year from reduced labs.

Conclusions: AKC-S reduced the frequency of routine labs during the pandemic in home dialysis without negative consequences on patient biomarkers or outcomes. Our study suggests that bloodwork frequency in home dialysis patients may be safely reduced.

Figure 1. Distribution of the number of routine bloodwork days in the Home Dialysis patients had during the pre-pandemic (blue) and pandemic (orange) periods.

PO0960
On-Demand Automated Peritoneal Dialysis Solution Generation
Jaime Urribari,1 Nabeel Aslam,2 Clinton Edwards,1 Lara M. Yamagata,4 Anders J. Wellings,5 Alyssa Wilmington,1 Ha Tran,6 Ivan School of Medicine at Mount Sinai, New York, NY; 1Mayo Clinic’s Campus in Florida, Jacksonville, FL; 2Saint Bernards Healthcare, Jonesboro, AR; 3Baxter Healthcare Corporation, San Gunnaw, Malta; 4Baxter Healthcare Corporation, Deerfield, IL.

Background: While automated peritoneal dialysis (APD) is an effective treatment for kidney failure, ordering, delivery and storage of supplies can be challenging. The APD Solution Generation System (SGS) allows for dialysate solution generation using tap water in a patient’s home with fewer supplies (Figure 1). This advancement facilitates the formulation of prescribed dialysate at the point-of-care, maximizes dialysis performance, and optimizes treatment protocol. Remote monitoring capability by SmartPD™ allows remote supervision and management, an efficient choice especially in Covid-19 times.

Methods: A 12-week single-arm, prospective, descriptive study was conducted with in-home APD patients. Patients were screened, trained and treated with the SGS. Endpoints included testing the final product against specifications for Dianeal and water purification ISO Standard 13959 and measuring PD adequacy. Adverse events and device deficiencies were collected.

Results: 22 patients were enrolled; 14 patients completed the study. Demographics are shown in Table 1. See Figure 1 for primary efficacy and safety endpoint results. All tested post-sterilization filter and final dialysis solution samples passed. Missing data for water purity attributed to only 56.9% of samples passing. Mean (SD) change from baseline for Kt/V was -0.15 (0.370). There were 2 peritonitis events (0.43 episodes per patient-year), 1 occurring in a patient with HIV. There were no safety signals.

Conclusions: The SGS has the technical capability to accurately and safely generate dialysate at home using tap water. Logistical challenges with lab sampling require further exploration to understand the impact in future trials and real-world settings. Lessons learned from the study allow for transition of the device to future development.

SmartPD™ Automated Peritoneal Dialysis System as a New Sophisti-cated Choice for Urgent Integration in Replacement Therapy for a Patient with ESRD
Ioannis Grivess, Army Share Fund Hospital of Athens, 417 NIMTS, Athens, Greece.

Introduction: Peritoneal dialysis (PD) is used to treat approximately 11% of dialysis patients globally despite wishes for 30%, due to Covid-19 pandemic. Expanded use of PD is impacted by clinician experience and confidence with “efficient”, and “in home friendly” automated peritoneal dialysis (APD) system.

Case Description: A 60 years old lady presented from a remote island under Covid-19 pandemic- with uremic features and started APD with SmartPD™ (Newsol technologies). SmartPD™ continuously monitors the intra-peritoneal pressure (IPP) during the dwell. It can use this information to (a) determine optimal fill volume (b) automatically determine the optimal time to infuse or remove the dialysate from the peritoneum cavity (Fig 1a,b) and (c) records and provides UF transport characteristics (Fig 1a,b). From this composite data stream additional information can be evaluated or derive to determine the clinical health of the Peritoneal cavity. We noticed rapidly improvement in the metabolic profile and volume status (Bioimpedance measurement). Using the ability of SPD to independently adjust the dialysate concentration, number of exchanges and the dwell duration of each exchange we establish a best fit treatment time of typically 9-10 hours, with tidal volume 900 mils, 2% concentration over 9 cycles (40 mins a cycle). Our patient was under evaluation every month and today six months since starting APD with SmartPD™ she is in excellent condition, with no peritonitis episodes, zero incidence of overfill and minimal drain pain.

Discussion: SmartPD™ enables the formulation of prescribed dialysate at the point-of-care, maximizes dialysis performance, and optimizes treatment protocol. Remote monitoring capability by SmartPD™ allows remote supervision and management, an efficient choice especially in Covid-19 times.

Animal Trial of Sorbent Cartridge for Portable Artificial Kidney (PAK)
Christian G. Blueched,1 Yen N. Koh,1 Chieh-suai Tan,2 Kenneth Chen,2 Kun D. Zhuang,3 Dialysis Pte Ltd, Singapore, Singapore; 3Singapore General Hospital, Singapore, Singapore.

Background: The NextKidney/Dialysis HD Sorbent Cartridge (SC) uses a novel type of sodium-neutral sorbent to regenerate spent dialysate for standard hemodialysis (HD) therapies. The SC is intended to be used with the NextKidney sorbent HD device, where it produces fully physiological dialysate meeting today’s industry standards. We tested the safety and efficacy of the sorbent system in a total kidney failure pig model. The animals were maintained exclusively on sorbent HD for up to 2 weeks.

Methods: Three highly uremic pigs (60–75 Kg) underwent a total of 14 alternate-day, 4h sorbent HD therapy sessions. Total renal failure was induced via bilateral renal artery embolization (pig #1), or bilateral laparoscopic ligation of renal arteries (pigs #2 and 3). A palindromic catheter provided blood flow rates of 200 – 300 mL/min. A hemoperfusion machine was used for the blood circuit, coupled with a prototype device controlling the dialysate circuit. Dialysate was continuously purified in the SC at a flow rate of 300 mL/min. Therapy efficacy and mass balances were calculated from blood and dialysate samples collected before and after the dialyzer at specific time points.

Results: The animals tolerated the therapies well. The incision site at the femoral artery was closed with no significant signs of bleeding, resulting in internal bleeding and loss of the animal. Fourteen 4hr dialyses were averaged to calculate toxin removal efficacy and mass balances. The average clearances for urea, creatinine and phosphate were 139, 146 and 141 mL/min, respectively. Dialysate sodium and bicarbonate concentrations remained within the permissible deviations of ±5% and ±2%, respectively.

Conclusions: The biocompatibility of the sorbent system has been confirmed in fourteen 4h HD therapies conducted on three highly uremic pigs. The sorbent system was able to maintain the highly uremic animals. There were no severe adverse events related to the sorbent HD therapy. We currently plan to proceed to a first-in-human trial to evaluate the safety and efficacy of the sorbent cartridge for human use.

Thirty Days of Maintenance Peritoneal Dialysis Using a Sorbent-Based Automated Wearable Artificial Kidney (AWAK) PD Device in a Porcine Model
Margerie W. Foo,1 Htay Htay,2 Edwina A. Brown,2 Sridhar Chirumurry,3 Marcin Pawlak,2 Siti N. Huda,1 Jason T. Lim,1 Sanjay Singh,1 Mandar Gori,1 Suressa B. Venkatara,1 Arsh Jain,1 Singapore General Hospital, Singapore, Singapore; 2Hammersmith Hospital, London, United Kingdom; 3AWAK Technologies Pte Ltd, Singapore, Singapore; 4Western University, London, ON, Canada.

Background: In sorbent-based PD, spent dialysate is processed and clean dialysate is re-introduced into the abdomen. Our aim was to determine if AWAK dialysis can maintain euveloma and biochemistry for 30 days in a porcine model.

Methods: The study was conducted in a 5:9 nephrectomised pig (Sus Scrofa, male). Post nephrectomy, the animal was treated with CAPD (14 weeks) before commencing sorbent-based PD for 7 hour per day with initial fill of 2L 1.5% Dianene for 30 consecutive days. Thereafter, the animal was maintained on standard of care (SOC) for 3 days (5x2L exchanges over 10 hour APD, with 1L last fill, 2.5% Dianene).

Results: Stable serum concentration of toxins, electrolytes and inflammatory markers were noted during AWAK therapy (Table); with no significant change after switch to SOC. pH of regenerated dialysate was consistent with biocompatible solutions (figure 1) and appropriate change in ultrafiltration was observed in response to glucose infusion (figure 2).

Conclusions: AWAK PD therapy successfully treated a CKD animal model for 30 days, without adverse impact on volume status or clinical parameters. Future long-term human studies are needed for device enhancement.

Remote Monitoring of Patients with Automated Peritoneal Dialysis May Improve Clinical Outcomes: Analysis by Competing-Risk Regression Models

Ramon Paniagua,1 Marcela Avila,1 Alfonso Ramos,1 Abdul Rashid T. Qureshi,2 Bengt Lindholm,2 Mexican Nephrology Collaborative Study Group; Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; Baxter Novum CLINTEC; Karolinska Institutet, Stockholm, Sweden; Baxter Mexico, Mexico City, Mexico.

Background: Current information technologies allow remote monitoring (RM) of patients on automatic peritoneal dialysis (APD) and the adoption of proactive behaviors to prevent complications and improve treatment quality. We analyzed the effect of RM-APD on survival and preventable complications through a controlled clinical trial.

Methods: In a two-branched cluster RCT, hospitals with >100 prevalent, >5 new patients per year, and >5 years APD experience were randomly assigned to perform RM-APD or conventional APD with equivalent APD-equipment in adults beginning APD. The primary outcome was a composite index (CI) of death, first adverse event (AE) or first hospitalization. Secondary outcomes were the same variables considered individually and for their specific causes. All-cause and cardiovascular disease (CVD) mortality risk and AEs were analyzed with competing-risk regression with transplantation as competing risk.

Results: Eleven hospitals per arm were included and 815 patients were followed-up by at least one year, 417 using RM-APD and 398 on APD. Patients in hospitals using APD reached earlier the CI as well as its individual components. Patients with APD as compared to RM-APD were older, more inflamed, and had higher all-cause and CVD mortality. In competing risk analysis, after adjusting for age, sex, presence of smoking, hypertension, CVD and diabetes, APD as compared with RM-APD associated with higher subdistribution hazard ratio (sHR) for all-cause mortality (sHR 1.79, 95%CI (1.15-2.81); p=0.01), CVD-related mortality (sHR 2.21, 95%CI (1.07-4.58); p=0.03), and AE (sHR 1.74, 95%CI (1.34-2.25); p=0.001).

Conclusions: Use of RM-APD may improve survival and prolong the time to first AE and hospitalization in comparison with APD, suggesting that RM-APD may improve clinical outcomes in APD patients.

Peritoneal Dialysis Discontinuation: Trends and Risk Factors

Andrew Breck,1 Jeffrey Marr,1 Dominick Esposito,1 Edwin D. Huff.2 Insight Policy Research Inc, Arlington, VA; 1Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: Increasing use of dialysis home modalities among ESRD patients is a Centers for Medicare and Medicaid Services priority. This can be accomplished by increasing use of home dialysis among incident patients or by reducing PD discontinuation. We explore trends in PD persistence and risk factors associated with PD discontinuation.

Methods: We identified incident ESRD patients from 2008 to 2018 who received peritoneal dialysis in their third month of ESRD treatment. We used data from CROWNWeb and Medicare claims to determine the patient’s modality 1, 2, and 3 years after initiation of ESRD treatment. We summarize trends in share of incident PD patients who were treated with PD at each follow up and describe differences by patient and facility characteristics.

Results: From 2008 to 2017, approximately 70 percent of incident PD patients remained on PD after 1 year of dialysis, 50 percent after 2 years, and 30 percent after 3 years of dialysis (figure 1). Over these years the percentage of incident PD patients treated with PD after two years rose from 47.9 to 52.3 percent. The rate of two-year PD persistence has declined modestly since a peak of 53.1 percent in 2013. PD patients treated at DaVita facilities were more likely than those treated at FMC or independent facilities to remain on PD after two years. PD patients treated at facilities with a higher share of PD patients were more likely to remain on PD after two years. Among incident PD patients, the rate of peritonitis during the first year of dialysis declined from 33.5 to 21.7 between 2010 and 2018. Peritonitis was more common among dual eligible patients, Black and American Indian/Alaska Native patients, and overweight or obese patients.

Conclusions: Differences in PD discontinuation and peritonitis incidence across patient and facility subgroups represent opportunities for future quality improvement efforts.

Contemporary Incidence of Peritoneal Dialysis Attrition and Variability Therein Among Age Strata
Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen,1 Hennepin Healthcare Research Institute, Minneapolis, MN; University of Minnesota Twin Cities, Minneapolis, MN.

Background: With an increasing percentage of patients performing dialysis in the home setting, quality measurement systems should increase focus on home dialysis outcomes. Considering the central role of peritoneal dialysis (PD) in home dialysis, an important and readily estimable measure is the duration of PD before initiation of hemodialysis. We estimated the cumulative incidence of attrition due to initiation of hemodialysis among patients who recently initiated PD in the United States and assessed variability of incidence among age strata.

Methods: We analyzed United States Renal Data System Standard Analysis Files. We identified all patients who initiated PD in the home setting between January 1, 2011, and September 30, 2018, and within one year after diagnosis of end stage kidney disease (ESKD). We classified patients into cohorts of age 18-44, 45-64, 65-74, and ≥75 years. Overall and within age strata, we estimated the 5-year cumulative incidence of conversion to hemodialysis, with accounting for the competing risks of death and kidney transplantation.

Results: The cohort included 111,464 patients who initiated PD. The cumulative incidence of conversion to hemodialysis was 22.4% at 1 year, 33.9% at 2 years, 41.4% at 3 years, 46.3% at 4 years, and 49.4% at 5 years (figure). During those 5 years, 25.4% of patients died while receiving PD and 12.8% received a kidney transplant, thereby resulting in only 12.4% of patients still performing PD after 5 years. Among patients aged 18-44 years, 1-year (5-year) cumulative incidence of conversion to hemodialysis was 23.3% (51.1%); corresponding estimates were 22.3% (52.0%) among patients aged 45-64 years (48.3%), 21.9% among patients aged 65-74 years, and 22.5% (41.6%) among patients aged ≥75 years.

Conclusions: Regardless of age, between 22% and 23% of patients who initiated PD during the first year of ESKD transferred to hemodialysis within one year.

PO0970
Identifying Patients on Peritoneal Dialysis at High Risk of Transfer to Hemodialysis Using a Modified Surprise Question
Ayesha Awasthi,1,2 Graham E. Abra,1,2 Hatsumi Nielsen,3 Sumi J. Sun,2 Sai Liu,1 Maria E. Montez-Rath,1 Brigitte Schiller,1,3 Wael F. Hussein,1,2 Stanford University School of Medicine, Stanford, CA; 3Satellite Healthcare, San Jose, CA.

Background: Transfer from peritoneal dialysis (PD) to hemodialysis (HD) is associated with poor outcomes. Available prediction models of modality transfer are limited to the incident PD population. Simple predictive tools are needed to help guide risk stratification and subsequent clinical interventions to avoid unwanted modality transfer. We report on the correlates of nurse prediction of high risk using the question “Would you be surprised if this patient transfers to HD in the next 6 months?” (PD Surprise Question [PDSQ]).

Methods: This observational study included 1362 adults on PD receiving care at 35 centers in 3 states in the US, managed by a non-profit dialysis organization. A “no” response to the PDSQ indicated high risk. Using multivariable logistic regression with backward elimination, we evaluated characteristics associated with being identified as high risk, including socio-demographic variables, BMI, primary kidney disease, vintage, comorbid conditions, renal and dialysate clearances, serum albumin, sodium, phosphorus, potassium, nPNA, last 3 months peritonitis and hospitalization, and insurance type. We used multiple imputations to handle missing data.

Results: Responses were obtained from 95/112 (85%) nurses for 1193/1362 (88%) patients. Mean age was 59 (SD: 16) years, 41% were female, median ESRD vintage 37 (IQR: 11 – 44) months and 46% had diabetes. 198 (17%) patients were identified as high risk. In the final model, patients were more likely to be identified as high risk if they were hospitalized in the last 3 months (odds ratio [OR]: 1.52, 95% confidence interval [CI] 1.30-1.74, p=0.0002). Having a higher serum sodium (for 1 meq/L: OR: 0.95, 95% CI 0.90-1.00, p=0.032), being married (OR: 0.76 95%CI 0.52-1.00, p=0.029), and longer PD vintage (for 1 month: OR: 0.99, 95%CI 0.98-1.00, p=0.013) were associated with lower odds of being identified as high risk.

Conclusions: The PD surprise question is a simple tool to assess the risk of transfer from PD to HD. Identified correlates of risk are consistent with high risk factors from the literature for transfer to HD. We are currently observing outcomes of included patients to examine the performance of the PDSQ to predict transfer to HD.

PO0969
Length of Peritoneal Dialysis Training and Risk of Early Treatment Attrition
Harold E. Giles,1 Vidhya Parameswaran,2 Linda Ficcióccoli,2 Claudi Mullon,2 Dinesh K. Chatoth,2 Michael A. Kraus,2 Michael S. Anger,2 Robert J. Kossmann,2 Nephrology Associates PC, Nashville, TN; 3Fresenius Medical Care, Global Medical Office, Waltham, MA; University of Colorado, School of Medicine, Denver, CO.

Background: Patient training is a critical component of the peritoneal dialysis (PD) program to ensure safe dialysis outcomes. However, there is a lack of clarity on how long patients should be trained before initiating PD at home. In this analysis, we evaluate the associations between the length of PD training and patient outcomes (early treatment attrition, peritonitis, and hospitalizations) among patients prescribed automated PD (APD).

Methods: Adult patients who initiated APD between 2017-2019 and received PD training at Fresenius Kidney Care facilities within 30 days of home treatments were included. Crude and case-mix adjusted risk of early PD attrition (discontinuation from PD within 3 months of enrollment due to switch to HD, death, or loss to follow-up) were compared between patients with a shorter (<5 days), medium (6 to 10 days), and longer (>10 days) lengths of training. Early rates of peritonitis and hospitalizations were compared between patients with ≤10 days vs >10 days of training.

Results: 11,039 patients who received training ≤30 days prior to APD initiation were included. Compared to patients with a shorter PD training (n=3,333), patients with a medium length of training (n=6,310) had no significant difference in the risk of early attrition (Figure 1). Patients with longer PD training (n=1,396) had a lower risk of early attrition when compared to shorter PD training patients in the crude analysis, and no significant difference when controlled for case-mix variables (significant confounders: vintage, residual kidney function, and body surface area). There were no differences in the early rates of peritonitis and all-cause and peritonitis-related hospitalizations between patients receiving training for >10 days vs ≤10 days.

Conclusions: There were no significant associations between length of PD training and risk of early treatment attrition, hospitalizations, or peritonitis among automated PD patients.

**Machine Learning-Driven Prediction of Peritoneal Dialysis Technique Failure**

Caitlin Monaghan,1 Joanna Willetts,2 Hao Han,1 Michael A. Kraus,3,4 Dinesh K. Chatoth,1,4 Len A. Usvyat,1 Franklin W. Maddux,2 1Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care AG, Germany; 3Karolinska University Hospital, Stockholm, Sweden; 4Fresenius Medical Care North America, Waltham, MA.

**Background:** Despite increased focus on starting and keeping dialysis patients on home therapy, Peritoneal Dialysis (PD) and Home Hemodialysis (HHD) rates are lower than desired. Two areas of opportunity are 1) keeping PD patients healthy so they can remain on PD longer and 2) transitioning PD patients to HHHD when appropriate. To identify patients at risk of leaving PD in the short- (<1 month) and long-term (6-12 months) timeframes, two machine learning (ML) models were developed. Along with risk scores, these models identify the factors driving increased risk to aid in prolonging time on PD while also allowing adequate notice to prepare for permanent access placement and HHHD education.

**Methods:** Data were extracted for PD patients (n=53022) from 2016-2019; patients contributed one set of observations for each month they were on PD (n=823892 patient months). PD failure was defined as the first discharge from PD lasting over 30 days, and was coded as ‘1’ if the patient changed modality in the next 1-3 or 6-12 months for the short- and long-term models, respectively. All other observations were coded as ‘0,’ including censored events such as transplantation, loss to follow-up, or death. Two XGBoost ML models were trained using 80% of the dataset, with 20% used for evaluating model performance using 237 variables, derived from laboratory measurements, infection and hospitalization history, and other relevant clinical parameters.

**Results:** Evaluation of model performance on withheld data showed an area under the curve of 0.75 and 0.67 for the short- and long-term models, respectively. Patients were classified as High, Medium, or Low risk for each of their short- and long-term predictions. In the short-term risk, a high risk was defined as patients who dropped in the next 3-6 months, a rate almost five times higher than average and 12 times higher than low risk patients. For long-term predictions, 14% of high risk patients dropped in the next 3-6 months, 6% of medium risk, and 2% of low risk.

**Conclusion:** The two ML models showed good discrimination between patient risk categories for both short- and long-term timeframes. While further work is underway to gauge the clinical utility of these tools, these tools offer the potential to improve care of “failing” PD patients, reduce morbidity of transitions, and increase optimal starts with dialysis education.

**Technique Failure in the Dominican Republic National Peritoneal Dialysis Program**

Erwin I. Campos,1,2 Miguel A. Cuevas Budhrat,1 Elianny S. Polanco,1 Jhanna H. Collado,1 Mercedes Aquey,1 Janny Gusman Chavez,4 Alfonso Ramos,3 Macrotech1 Macrotech, Santo Domingo, Dominican Republic; 2Hospital Salvador B. Gautier, Santo Domingo, Dominican Republic; 3Baxter Mexico, Ciudad de México, Mexico; 4Baxter Colombia, Bogota, Colombia; 5Instituto Mexicano del Seguro Social, Ciudad de México, Mexico.

**Background:** Technique failure is a critical concern in peritoneal dialysis (PD), and it’s associated with significant risk of patient lost. Technique failure is defined as transfers to HD 30 days after initiation of therapy or death within 30 days of transfer to HD.

**Methods:** This is a retrospective multicenter observational cohort study of incident Peritoneal Dialysis patients conducted between January 1st 2016 to December 31st 2020. Competing risk events were death and kidney transplantation, and patients were censored for recovery of kidney function, withdrawal or suspension of the therapy, and loss of a caregiver. Disease characteristics and baseline demographics were included. Data are expressed as mean ± standard deviation for continuous variables and as frequency counts and percentages for categorical variables. Incidence rates were performed for transfer to HD and finally, logistic regression analysis between the inferential type variables to determine the risk between having a history of diabetes mellitus and the variables of death and transfer to HD were calculated using an Odds Ratio analysis with 95% confidence intervals for proportions.

**Results:** A total of 2326 patients were included, 59% men; the mean age was 57 ± 16 years, 53% had a diagnosis of Diabetes Mellitus (DM) and 65% had a basic educational level. 151 patients were censored (11%). Risk events were 1096 of which death accounts for 1084 (74%) and transplantation (0.8%). At the end of the first year the cumulative incidence risk to HD transfer was 1%, the second year 4%, the third year 6%, the fourth 11%, and the fifth 16%. Based on the regression analysis between the variables of interest and the patients with a history of DM, there is a higher risk of death (p=0.001; OR: 2.123; CI 95%: 1.781-2.532), however, for transfer to HD, no statistical significance was found (p=0.39; OR: 1.14; CI 95%: 0.838-1.564). The most frequent reason for technique failure was psychosocial and medical conditions 44%, followed by catheter malfunction 30%, peritonitis 13% and ultrafiltration failure 13%.

**Conclusions:** The technique failure rate is similar to the reported in RTS Colombian PD Program, but below the mean of Latin American countries reports. Still, Improvement needs to be done in the catheter implant technique and mortality rates.
Converting ESKD Patients on Peritoneal Dialysis to Hemodialysis Post Cardiac Surgery: A Necessity or Comfort
Elías Baseli,1 Milad Matta,1 Aimen Liaqat,1 Adam Fawaz,2 Georges Nakhoul,1,3 Joseph J. Satler,2,3 Juan C. Calle,2,3 Serge C. Harb,1 Haytham Elgharably,1 Susana Arrigain,1 Jesse D. Schold,1 Remy Daou,1 Ali Mehdi,2,3 Cleveland Clinic, Ohio, 2Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, Ohio; 3Université Saint-Joseph, Beirut, Lebanon.

Background: End-stage kidney disease (ESKD) patients on peritoneal dialysis (PD) undergoing cardiac surgery are sometimes converted to hemodialysis (HD) post-surgery. The reasons for this conversion are not well defined in the literature. We sought to examine the reasons cited for converting PD patients to HD post-operatively after undergoing major cardiac surgery.

Methods: We examined ESKD patients on PD undergoing cardiac surgery from 2009-2019 using an electronic health records (EHR)-based Cardio-Thoracic Surgery (CTS) registry at the Cleveland Clinic. We identified PD patients who were converted to HD postoperatively. We reviewed the EHR to identify the main causes for conversion.

Results: 62 ESKD patients on PD undergoing major cardiac surgery were identified. 16 patients, representing more than a quarter, were converted to HD post-operatively. Out of those converted, 31.25% were converted for absolute indications (18.75% for PD catheter malfunction, 25% for concerns of pericardio-peritoneal communication). 68.75% were converted for less clear and relative indications (25% based on clinician preference, 43.75% for hemodynamic instability or requiring vasopressors). Results are displayed in (Table 1).

Conclusions: A small percentage of PD patients are converted to HD for absolute indications. Most patients are converted based on relative indications including lack of familiarity with PD and hemodynamic instability. As the number of ESKD patients on PD is expected to increase, a better understanding of the outcomes of PD patients post cardiac surgery is needed. In addition, more education is urgently needed to increase the comfort of practitioners managing PD patients in special situations that might be amenable to prescription alterations without premature transition to hemodialysis.

PO0977
A Uremic Pig Model for Peritoneal Dialysis Research
Joost C. de Vries,1 Maaieke V. van Gelder,1 Anneke S. Monnikhof,1 Sabbir Ahmed,2 Diëty Haazenbrink,1 Tri Q. Nguyen,1 Koen Vaessen,2 Jaap A. Joles,1 Marianne C. Verhaar,1 Karin G. Gerritsen,1 University Medical Center Utrecht, Utrecht, Netherlands; 2Utrecht University, Utrecht, Netherlands.

Background: The renewed interest in home dialysis requires a translational uremic large animal model to evaluate innovations in peritoneal dialysis. Ideally, toxin plasma levels should be comparable to those in dialysis patients, without requiring maintenance dialysis for survival. To this end, we developed a pig model with stable moderate chronic kidney disease.

Methods: CKD was induced in five female pigs by bilateral subtotal renal artery embolization aiming for embolization of ~85-90% of total kidney tissue. Temporary aggravation of uremia was induced with gentamicin (10 mg/kg twice daily for 7 days). We hypothesized this approach would lead to stable CKD without the need for maintenance dialysis. Peritoneal transport was assessed with a standard peritoneal permeability assessment.

Results: After embolization, urea and creatinine levels increased from 1.6±0.2 to 7.5±1.0 mM and 103±12 to 338±60 µM, respectively, followed by stabilization within 2 weeks to 2.5±1.0 mM and 174±25 µM, respectively. GFR (iohexol clearance) decreased from 49±7 mL/min to 28±5 mL/min. Gentamicin induced temporary acute-on-chronic kidney injury with peak urea and creatinine concentrations of 17.8±6.1 mM and 932±504 µM, respectively (Figure 1), while potassium (range 4.1-4.7 mM) and phosphate (range 2.33-2.67 mM) remained stable. Peak indoxyl sulfate and hippuric acid levels were 10.5±0.85 mg/L and 75.3±31.5 mg/L, respectively. Peritoneal dialysis, although complicated by peritonitis, could be successfully applied. Peritoneal transport assessment showed a low transport status (D/P creatinine (4h): 0.45±0.12) with an MTAC of 9.6±3.0, 4.6±2.5, 3.4±2.2 mL/min for urea, creatinine, and phosphate respectively.

Conclusions: We have established a pig model with stable moderate CKD without the need for maintenance dialysis. Temporary-on-demand acute-on-chronic kidney injury, resulting in uremic solute levels representative for ESKD, allows evaluation of novel dialysis methods.

Figure 1. Urea (left) and creatinine (right) plasma levels after administration of gentamicin (day 0). Mean ± SD, n=10 administrations in n=5 pigs.
Case Description: 40-year-old female with end stage renal disease secondary to systemic lupus erythematosus (SLE) transferred for 3 years of clinic appointment after her system was disconnected with leakage of PD fluid. PD effluent revealed white cell count of 300 with 2% neutrophils. She was treated empirically for peritonitis. 11 days later her fungal culture grew Candida famata and she was admitted with intermittent peritonitis and weakness. She was hemodynamically stable, and her exam was significant for epigastric tenderness with normal looking PD catheter site. Her white cell count was elevated to 13,000 with unremarkable metabolic panel. CT abdomen was unremarkable. A repeat PD effluent had white count of 40. Her PD catheter was removed the next day and she was switched to hemodialysis. She was treated with 10 days of oral fluconazole. On review, she had been having intermittent abdominal pain with PD effluent sometimes showing high white cell count for which she got multiple antibiotic courses for either presumed or culture positive bacterial peritonitis. She had also grown positive fungal culture about 18 months ago with Candida albicans and Stereum complicatum which went unnoticed.

Discussion: Fungal peritonitis can be catastrophic for patients on PD. Treatment involves prompt catheter removal and systemic antifungal treatment. Given its dire consequences, prevention is paramount. The ISPD recommends using anti-fungal prophylaxis when PD patients receive antibiotic courses. Risk factors include previous bacterial peritonitis and antibiotic use. This case demonstrates the need to follow cultures as fungal growth is slow and can take weeks. It is important to have a high index of suspicion for a fungal organism when cultures are negative. This patient received antibiotics on several occasions but only developed fungal peritonitis on 2 occasions which raises concern on antifungal prophylaxis. Further studies are indicated to determine number needed to treat to decide on need for antifungal prophylaxis.

PO0097
Micrococcus Peritonitis Complicating Peritoneal Dialysis
Martin L. Li,1 Ankur Shah.2,3 'Brown University Warren Alpert Medical School, Providence, RI; 2Rhode Island Hospital, Providence, RI.

Introduction: Peritonitis is one of the most common and consequential complications of peritoneal dialysis. Micrococcus are catalase-positive, coagulase-negative, gram-positive cocci that are increasingly recognized as opportunistic pathogens in patients with immunocompromise. Certain staphylococci and catalase-negative corynebacteria such as Micrococcus sp are known to cause peritonitis. We present a case of peritonitis due to Micrococcus sp and review the pertinent literature.

Case Description: A 55-year-old female with history of ESKD due to diabetic kidney disease, CAD s/p CABG, and hypertension presented with a 1 day history of cloudy effluent. She had no prior peritonitis episodes. Vital signs were stable and exam was notable for a soft non-tender abdomen and clean and dry exit site without discharge or granulation tissue. Effluent was hazy in appearance. Administration of empiric vancomycin was initiated, varying in clearing of effluent within 48 hours. Effluent leukocyte count was 204 cells/μL with 58% neutrophils. Intraperitoneal vancomycin was continued for 3 weeks due to intermittent low troughs. Further history revealed intermittent mask use while performing exchanges. After completion of treatment with vancomycin, the milky fluid recurred the following day before again subsiding after its repeat culture again grew Micrococcus sp. After culture was repeated once more and remained persistently positive, repeat treatment to eradicate was attempted with 2 more weeks IP vancomycin but culture remained positive. Eventually the catheter was removed due to a change in living situation. After 5 months of hemodialysis, peritoneal catheter was replaced and the patient was restarted on peritoneal dialysis, after which time she has not returned for clinic appointment.

Discussion: We present the 10th case of Micrococcus sp. Peritonitis in a peritoneal dialysis patient. Prior cases have been associated with breaks in technique and have shown a pattern of recurrence with resultant technique failure being very common. Attempted treatments have included vancomycin, cefazolin, cefazidime, and teicoplanin. In the prior 9 published cases, 4 resulted in technique failure. This case and review of the literature can serve to inform future occurrences.

PO0098
Cutaneous Oxalosis in a Patient on Peritoneal Dialysis
Stephanie Torres Rodriguez, Hunter Pyle, Audrey Rutherford, Arturo R. Dominguez, Shani Shastri. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Oxalosis is the systemic deposition of calcium oxalate in multiple tissues and can be of primary or secondary etiology. Skin manifestations due to secondary hyperoxaluria (SH) attributable to renal insufficiency are rare. We present a case of cutaneous oxalosis in a patient with end stage renal disease (ESRD) receiving peritoneal dialysis (PD).

Case Description: A 45-year-old female with ESRD due to lupus nephritis (LN) on PD for 11 years presented with hypertensive encephalopathy. Dermatological evaluation revealed pseudoreticular hyperpigmented patches overlying firm, non-tender, subcutaneous nodules and plaques on bilateral lower extremities (Figure 1) and upper arms and firm nodules overlying the joints of her hands (Figure 2). With history of lupus, cutaneous findings were concerning for dystrophic calcinosis cutis. Skin biopsy showed radially arranged yellow-brown rhomboid crystals in the subcutis and deep dermis surrounded by histiocytes consistent with cutaneous oxalosis (Figure 3). Additional history revealed daily intake of Vitamin C 1g for past year and no prior gastrointestinal surgeries or chronic diarrhea. Non-obstructive bilateral nephrolithiasis were seen on imaging in 2020 but absent previously.

Discussion: Absence of early-age nephrolithiasis, negative family history & renal biopsy findings are inconsistent with primary hyperoxaluria (PH). SH is a result of excessive oxalate accumulation from increased intake, increased reabsorption due to small bowel disease, or decreased excretion in renal failure (retention oxalosis). Although dialysis patients may have high serum oxalate, clinical calcifications are rare. We speculate vitamin C supplementation and ESRD status contributed to the production of these deposits in our patient. Ascorbic acid is metabolized to oxalate; in long term dialysis patients doses of 500 mg daily may raise plasma oxalate by 50% to 100%. Management includes lowering serum calcium and oxalate levels by eliminating Vitamin C supplements or reducing dose < 100 mg daily, limiting dietary oxalate, increasing dialysis clearance and lowering dialysate calcium concentration if needed.
PO0982
Severe Bleeding and Deep Inferior Epigastric Pseudoaneurysm After PD Catheter Removal
Nicola Matthews,1 Tamara Glavinovic,2 Bourne L. Auguste,3* St. Michael’s Hospital, Toronto, ON, Canada; 4Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Introduction: In this case, the removal of a PD catheter with deep cuff calcification results in pseudoneuromus formation with hemorrhage and hospitalization.

Case Description: A 24-year-old woman with end-stage kidney disease was switched from PD to HD due to worsening uremia and PD catheter removal was organized. At the time of catheter removal heavy calcification around the deep Dacron cuff was felt to be secondary to heavy calcification of the DIEP vessel and Dacron cuff was removed, creating a pseudoaneurysm where urgent angiographic embolization to stop the bleeding was needed (Fig. 1). Intimate relationship between DIEP vessel and Dacron cuff was considered to be secondary to heavy calcification of these structures that developed during her time on PD (Table 1). The patient required an urgent transfusion and was admitted to hospital for monitoring. She was discharged the following day in stable condition.

Discussion: This is an important learning case in PD catheter removal and highlights the following: - Poorly controlled bone mineral disease may lead to excessive calcification of the deep Dacron cuff and DIEP vessels. - When heavy calcification of the PD cuff is seen, catheter removal should be done in settings equipped with interventional radiology support in the event of complication.

Calcium-phosphate balance while on PD

A Case of Abdominal Wall Abscess Caused by Aeromonas hydrophila in Prior Peritoneal Catheter Site in an Immunocompromised Patient Post Kidney Transplant
Angelica P. Trillas Gomez,1 Maya Antony,2,3 Ahmed A. Waheed,2,3 Holy Cross Hospital, Ft Lauderdale, FL; 2University of Miami School of Medicine, Miami, FL; 3Holy Cross Hospital Department of Nephrology, Ft Lauderdale, FL.

Introduction: Aeromonas hydrophila is a gram-negative rod-shaped bacterium found in aquatic ecosystems; it has been identified as the causative organism of different opportunistic infections in the immunocompromised and there is growing evidence of infection in the immunocompetent. This pathogen has been implicated in acute gastroenteritis, soft tissue infections, meningitis, peritonitis and sepsis among others.

Case Description: We report a case of a 56 year old woman with end stage kidney disease previously on peritoneal dialysis (PD) with subsequent live donor kidney transplant on immunosuppression, who presented with right lower quadrant abdominal cellulitis and deep abscess around the catheter site. Post transplant, her PD catheter was removed, however, the catheter site never healed completely. Although she did have multiple superficial skin infections in the past, those resolved with antibiotics. But this specific cellulitis, did not improve despite multiple antibiotic regimens, and further imaging studies revealed she had developed an abscess. The abscess was managed by surgical incision and drainage with debridement of the skin, subcutaneous tissue, fascia, and muscles around the whole catheter tract. Aeromonas hydrophila was found as the causative organism.

Discussion: To our knowledge, this is the first case of an A. hydrophila abscess associated with a peritoneal dialysis catheter. Firm association between aeromonads and the use of intravenous indwelling devices has already been demonstrated. We hypothesize that her deep seeded infection could be associated with the intrinsic ability of A. hydrophila to form biofilms upon detecting a suitable surface, making them more virulent. The formation of biofilm has been associated with exponential growth as the source of pathogenicity of this bacteria in pisciculture studies. This characteristic could be one of the factors contributing to reported cases of peritonitis and intravenous hemodialysis catheters by A. hydrophila. Further elucidation of A. hydrophila virulence factors in humans can provide insight on prevention of PD catheter associated infections by A. hydrophila.

PO0984
Mesenchymal Stem Cell Exosomes Protect Mouse Peritoneal Injury Induced by Human Peritonitis Dialysis Effluent
Fang Yu, Kehong Chen, Jia Chen, Yani He. Army Medical University, Daping Hospital, Department of Nephrology, Chongqing, China.

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but there are few effective therapies for it. The purpose of this study was to investigate the protective effect of exosomes secreted by mouse bone marrow mesenchymal stem cells (MSC) on peritoneal injury and to reveal the mechanism.

Methods: Forty-two male C57BL/6 mice were randomly divided into a normal group, a control group (2.5% glucose dialysate), a peritonitis-effluent group (The overnight 2.5% glucose dialysate of patients with peritonitis), a high glucose (4.25%) dialysate group, a peritonitis-dialysate+exosome group, and a high glucose dialysate+exosome group. The mouse model of peritoneal injury was constructed by intraperitoneal injection of human peritonitis dialysis effluent continuously for 42 days. The mice in the exosome treatment group received intraperitoneal injection of MSC-exosomes twice. The level of peritoneal structural and functional damage was detected. The effect of MSC-exosomes was validated in vitro.

Results: Peritoneal transport and structure was significantly impaired in the peritonitis-effluent group and the high glucose dialysate group after 42 days, and was significantly higher than control group. The results suggested that human peritonitis dialysis effluent could be used to construct a mouse model of peritoneal injury. Masson staining showed that fibrosis degree of exosome treatment group was significantly less than peritonitis-effluent group. Immunohistochemical analysis showed that expressions of mesothelial markers E-cadherin and ZO-1, neutrophil granulocytes (MO) and macrophages (F4/80), and fibrosis markers (collagen I, α-SMA) in exosome treatment group were significantly lower than peritonitis-effluent group. Peritoneal ultrasound function of exosomes treatment group was significantly improved than peritonitis-effluent group. In vitro experiments showed that exosomes could down-regulate the secretion of IL-1β, IL-6 and TGF-β1 by peritoneal mesothelial cells stimulated by high glucose dialysate, maintain expression of mesothelial cell marker (E-cadherin), and inhibit mesenchymal marker (α-SMA), suggesting that exosomes could inhibit the transdifferentiation of peritoneal mesenchymal cells.

Conclusions: MSC-exosomes can alleviate peritoneal fibrosis by inhibiting peritoneal mesothelial cell-mesenchymal cell transdifferentiation.
PO0985

Dual Therapy with JAK1/2 Inhibitor and Losartan Attenuates Dialy-
sate-Induced Angiogenesis in Polycystic Rats

Pei Zhang,1,2 Kana N. Miyata,3 Madisyn Mahoney,1 Janine A. La page,1 Cynthia C. Nast,1 Sharon G. Adler,2 Tiane Dai,1 Department of Nephrology, the First Affiliated Hospital of Anhui Medical University, Hefei, China; The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA; Cedars Sinai Medical Center, Los Angeles, CA.

Background: Long term peritoneal dialysis (PD) is limited by reduced efficacy over-
time. Early peritoneal membrane (PM) injury is characterized by inflammation which progresses to hypercellularity and fibrosis. JAK-STAT signaling mediates inflammatory pathways, including angiogenesis signaling. Our previous study showed dual therapy with JAK1/2 inhibitor (JAK1/2i) and an ARB maintains PM structure and function in rats with polycystic kidneys (PCK) chronically infused with 4.25% Dianae x 16 wks. By using VEGF-R2 as an endothelial marker, we further investigated if this dual therapy can attenuate chronic dialysate infusion induced hypercellularity in this rat model.

Methods: PCK rats were used. Dialysate infusions were performed BID via an implanted subcutaneous port in the neck tunneled to the intraperitoneal cavity. The following treatments were administered: (1) No surgery/inusions; (2) 4.25% Dianae; (3) 4.25% Dianae + JAK1/2i (5mg/kg BID); (4) 4.25% Dianae + Losartan (5mg/kg BID); and (5) 4.25% Dianae + Losartan + JAK1/2i (5mg/kg BID each). Peripheral peritoniem was used for immunohistochemical staining of VEGF-R2, which was digitally quantified by using Qu Path program. Data were analyzed by one-way-ANOVA followed by Tukey test. Results are mean ± SEM.

Results: VEGF-R2 staining was significantly elevated after 16 weeks IP infusion of 4.25% Dianae alone. JAK1/2i significantly reduced VEGF-R2 expression; losartan tended to reduce VEGF-R2, but this did not reach significance. Dual therapy with JAK1/2i and losartan resulted in the greatest reduction of VEGF-R2.

Conclusions: Long-term JAK1/2i, or JAK1/2i plus losartan intraperitoneal treatment reduced angiogenesis. Angiogenesis inhibition is advocated to maintain residual renal function, by adding JAK1/2i, the combination also protects peritoneal structure/function by reducing angiogenesis.

PO0986

The Effect of Far-Infrared Therapy on the Peritoneal Expression of Glucose Degradation Products in Diabetic Patients on Peritoneal Dialysis

Chih-Ching Lin, Chih-Yuan Niu. Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Peritoneal dialysis (PD) is a treatment modality for end-stage renal disease (ESRD) patients. Dextrose is a common osmotic agent used in PD solutions and its absorption may exacerbate diabetes mellitus. PD solutions also contain glucose degradation products (GDPs) that may lead to encapsulating peritoneal sclerosis (EPS). A previous study showed that far-infrared (FIR) therapy improved a patient’s gastrointestinal symptoms due to EPS. Due to limited literature, this study aims to investigate dialysate GDPs and peritoneal function in diabetic patients on PD.

Methods: A prospective analysis conducted in a single center. The participants were recruited from the peritoneal dialysis outpatient department from November 25, 2016 to September 5, 2018. We included the patients who met the following criteria: (1) ESRD patients aged 20-90 years without receiving FIR therapy within 12 months; (2) receiving continuous ambulatory peritoneal dialysis or automated peritoneal dialysis; (3) no history of peritonitis, cerebrovascular accident, myocardial infarction, or receiving any cardiovascular intervention in the past 3 months. Patients were allocated to two groups based on their underlying DM history. Both groups of PD patients received FIR therapy for 6 months. We collected the last daily bag of peritoneal dialysate and examined the dialysate concentration of GDPs and clinical data in PD patients pre- and post-FIR therapy.

Results: Thirty-one PD patients were enrolled and underwent 40 min of FIR therapy twice daily for six months. We demonstrated the effect of FIR therapy on the following: (1) decrease of methylglyoxal (p = 0.02), furfural (p = 0.005), and 5-hydroxymethylfurfural (p = 0.03), (2) increase of D:D glucose ratio (p = 0.03), and (3) decrease of potassium levels (p = 0.008) in both DM and non-DM patients, as well as (4) maintenance and increase of peritoneal K/V in DM and non-DM patients, respectively (p = 0.03). FIR therapy is a non-invasive intervention that can decrease dialysate GDPs in PD patients by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

Conclusions: In conclusion, our study demonstrated that FIR therapy can decrease PD patients’ dialysate GDPs by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

PO0987

Cumulative Dialysate Glucose Exposure Is a Risk Factor for Peritoneal Sclerosis in Pediatric Peritoneal Dialysis Patients Using Neutral-PH Fluids

Yoko Shirai,1 Kenichiro Miura,1 Taro Ando,1 Atsutoshi Shiratori,1 Naoto Kaneko,1 Kyonobu Ishizuka,1 Sekiko Tandea,2 Daishi Hirano,3 Yamauchi Yamaguchi,1 Kazuhiro Honda,1 Motoshii Hattori,1,2 Department of Pediatric Nephrology, Tokyo Women’s Medical University, Tokyo, Japan; 2Department of Pathology, Tokyo Women’s Medical University, Tokyo, Japan; 2Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; Yamauchi Yamaguchi Pathology Laboratory, Chiba, Japan; 3Department of Anatomy, Showa University School of Medicine, Tokyo, Japan.

Background: The benefits of neutral-pH fluids for preventing peritoneal dialysis (PD)-related peritoneal sclerosis have been established, however, advanced peritoneal sclerosis still has been described in pediatric PD patients using neutral-pH fluids (Kidney Int 2018). The factors associated with peritoneal pathological changes after long-term use of neutral-pH fluids have not been elucidated.

Methods: Pediatric PD patients using only conventional acidic fluids (conventional group) and those using only neutral-pH fluids (neutral-pH group, n=33) for more than one year were analyzed. Propensity score matching was performed to compare the peritoneal pathological changes between groups. Clinical risk factors including PD duration and cumulative dialysate glucose exposure for peritoneal pathological changes in the neutral-pH group were analyzed using generalized linear model. Furthermore, immunohistochemical studies were performed on vascular endothelial growth factor-α (VEGF-α), a cytoadhesion marker, and α-smooth muscle actin (α-SMA), a myofibroblastic marker of epithelial-mesenchymal transition (EMT).

Results: At biopsy age 1.1 ± 0.8 years (range 0.1-1.2) and duration of dialysis was 3.2 ± 1.7-5.3 years. The neutral-pH group showed less peritonialesional desorption except for higher sumesothelial microvesSEL density (P = 0.01) than conventional group. In the neutral-pH group, the cumulative dialysate glucose exposure was an independent risk factor for increased thickness of the sumesothelial compact zone (OR 1.08, 95%CI 1.00-1.16, sHR 1.01, 95%CI 1.00-1.03) and submesothelial microvesSEL density (OR 1.03, 95%CI 1.00-1.05).

Cumulative dialysate glucose exposure correlated with the proportion of VEGF-α-positive areas (P = 0.01, r = 0.55). In immunohistochemistry study, VEGF-α (+) cells comprised cytoadhesion (+) cells and α-SMA (+) cells.

Conclusions: The neutral-pH fluids showed less deteriorations of the peritoneal membrane than acidic fluids except for increased angiogenesis. Cumulative dialysate glucose exposure was an independent risk factor for peritoneal fibrosis and angiogenesis in pediatric patients using neutral-pH fluids, which might be associated with increased VEGF-α production by mesothelial cells presenting EMT.
Multifrequency Bioimpedance Is a Useful Adjunct to Control Fluid Overload in PD Patients

Szu-Yuan Li, Chiiao-Lin Chuang, Jinn-Yang Chen. Taipei Veterans General Hospital

Background: Fluid overload is a well recognized phenomenon in many peritoneal dialysis (PD) patients, but a balance between reduction of dry weight and preservation of residual renal function (RRF) is mandatory. We hypothesize that, to achieve an ideal dry weight, adjustment by multifrequency bioimpedance (MF-BIA) guide offers less adverse effect on residual renal function than by clinical judgment alone.

Methods: The hydration status of various body compartments were measured using a MF-BIA device (Inbody 720, Biospace). The normalized hydration score was defined as extracellular water (ECW)/total body water (TBW). All patients were evaluated monthly for 6 months. The dry weight of study group was adjusted according to MF-BIA to avoid dehydration, and the dry weight of control group was determined clinically. Ambulatory blood pressure, anti-hypertension medication dosage, serum biochemical parameters, and RRF were recorded monthly. IL-6 and hs-CRP will be checked before and after the study.

Results: 93 stable PD patients (48 in study and 45 in control group) completed the study. ECW/TBW ratio was higher in PD patients than sex- and age- matched healthy subjects. (Figure 1). In PD patient, the ratio of ECW/TBW was positive correlated to age (r = 0.334), peritoneal D/P ratio (r = 0.518), systolic BP (r = 0.520) and negative correlated to urine volume (r = -0.526), serum albumin (r = -0.658). After 6 months intervention, study group decreased 1.2 kg and control group gained 0.2 kg. The study group had a better systolic and diastolic BP control and a higher serum albumin (3.75 ± 0.61 vs 3.48 ± 0.68 g/dl, p = 0.047). The RRF has no difference between two groups.

Conclusions: Our results showed that correction of fluid overload would improve blood pressure control. Being an objective tool to assess hydration status of various body compartments, MF-BIA is a useful adjunct to correct fluid overload without the loss of RRF in our short-term study.

Associations Between Loop Diuretic Use and Outcomes Among Patients Treated with Peritoneal Dialysis

Jiacong Jia,1 Francesca Torenti,1 Martin J. Schreiber,1 Davita Clinical Research, Minneapolis, MN; 2Davita Inc, Denver, CO.

Background: Among hemodialysis patients, an active loop diuretic prescription at the time of dialysis initiation is associated with a lower hospitalization rate and other favorable outcomes, compared to no prescription. Whether this finding extends to patients initiating peritoneal dialysis (PD) is not known.

Methods: Data used for this retrospective study comprised electronic health records and US Renal Data System claims data merged through direct linkage. Included patients initiated PD at a large dialysis organization between 01 Jan 2006 and 30 June 2014, were nonoliguric at dialysis start (24-hour urine collection >200 cc), and had Medicare insurance. Exposure was determined on the basis of an active, filled supply for a loop diuretic spanning day 90 of PD. Outcomes were considered from day 91 of PD through the time of dialysis initiation.

Results: Among patients initiating PD with a loop diuretic prescription (N=792), the hospitalization rate during follow-up was 1.77 admissions/patient-year (pt-yr), compared to 1.75/pt-year for those without (N=1363), corresponding to an adjusted incidence rate ratio (aIRR) of 1.05 (95% confidence interval [CI] 0.97-1.15). Mortality was likewise comparable between groups, with crude rates of 0.21 and 0.18 deaths/pt-year, respectively (aIRR 1.05, 95% CI 0.82-1.35). No substantial differences were observed between exposure groups with respect to serum potassium, renal Kt/V, or time to transition to hemodialysis.

Conclusions: Among patients initiating PD, no beneficial associations were observed between loop diuretic use and any of the outcomes examined.

Identifying Peritoneal Dialysis (PD)-Associated Peritonitis Using Medicare Claims

**Eric W. Young,1,2 Junhui Zhao,1 Ronald L. Pisoni,1 Keith McCullough,1 Beth M. Piraino,1 Jenny I. Shen,1 Neili Boadville,1 Douglas E. Schaubel,2 Isaac Teitelbaum,1 Jeffrey Perl,1 *Arbor Research Collaborative for Health, Ann Arbor, MI; 1University of Pennsylvania, Philadelphia, PA; 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Western Australia, Perth, WA, Australia; 3University of Colorado School of Medicine, Aurora, CO; 4University of Michigan Health System, Ann Arbor, MI. Underline represents presenting author.**

**Background:** Medicare fee-for-service (FFS) claims offer a population-based approach to PD-associated peritonitis that may offer valuable insights into predictors, trends and preferred practices.

**Methods:** We used United States Renal Data System (USRDS) standard analysis files for claims (inpatient, outpatient and physician-supplier), eligibility, modality and demographic information. The sample consisted of PD patient-months from 2013 through 2017 characterized by Medicare FFS coverage and paid claims for dialysis or hospital services. We identified ICD-9 and ICD-10 diagnosis codes for peritonitis, including those that do not clearly distinguish peritonitis from catheter infections/inflammation (“catheter codes”). A new peritonitis episode was defined as a peritonitis claim 30+ days from any prior peritonitis claim or 50+ days from the initial peritonitis claim for a prior episode.

**Results:** The sample included 88,396 adult patients (128,000 observed patient-years), yielding 510,000 peritonitis claims and 75,000 peritonitis episodes. Coding was heterogeneous with no single diagnosis code present on the majority of claims. Peritonitis episodes were inferred from aggregated claims (mean 6.3, median 2). Half of episodes were exclusively outpatient, 7% exclusively inpatient, and 16% exclusively comprised of catheter code claims. The overall peritonitis rate was 0.59 and 0.49 episodes per patient-year with and without inclusion of catheter codes respectively. Peritonitis rates declined by 4%/year from 2013-2017, and varied by age, race (Black > White > Asian), and ESKD vintage.

**Conclusions:** Coding heterogeneity indicates a lack of standardization and need for clearer coding guidance. We found differences between races, ages, and patient vintages, and declining rates from 2013-2017. These rates are 2-fold higher than reported in US-DOPPS by Perl et al (AJKD 2020) which is not restricted to Medicare. Claims are an important data source for peritonitis, but more work is needed to validate these rates.

**Funding:** Other NIH Support - Agency for Healthcare Research and Quality

PO0093

Improving Peritoneal Dialysis Effluent Sample Collecting Techniques to Lower Culture-Negative Peritonitis Rate: A Single-Center Experience

Jie Ouyang, Shraddha Raghavan, Angelika C. Guensner, Subodh J. Saggi. SUNY Downstate Health Sciences University, New York City, NY.

**Background:** The most common and severe complication of peritoneal dialysis (PD) is peritonitis. Patients usually present with abdominal pain and cloudy peritoneal effluent. An accurate diagnosis is critical to treatment and avoiding technique failure. Culture negative peritonitis (CNP) rate can be up to 20% with standard bedside collection. The rate among PD centers in the US was reported to be 13.4%-40%. The causes of CNP include recent antibiotic use, Gram-positive infections which fail to reach the threshold of detection, or technical imperfection. The culture techniques are highly variable across centers. Due to a high rate of CNP at our facility, we instituted a new policy of PD effluent culture techniques on 7/30/2013 that was recommended by ISPD guideline. We conducted a quality improvement analysis to examine the outcome of this intervention.

**Methods:** Data were collected for patients who received PD from 2009 to 2018. The new policy required that a 50 ml of PD effluent be collected and centrifuged prior to the sediment being cultured. Diagnosis of peritonitis was analyzed with culture results before and after the policy change.

**Results:** This study enrolled 38 patients and total 122 visits for potential peritonitis were observed. As shown in table1, our CNP rate prior to the policy change was 41.7%. After the implementation of the new culture strategy, the rate significantly decreased to 25%. However, the false positive rate increased from 4.9% to 23.1% with a drop of the true positive rate (sensitivity) from 95.1% to 76.9%, when the peritonitis rate in our facility declined from 0.43 to 0.09 patient/year.

**Conclusions:** This analysis showed that the new PD effluent culture policy effectively lowered the culture negative peritonitis rate in our PD center. However, constant reinforcement of this policy and proper sterilization is required for the purpose of due diligence.

Protective Association Found Between Peritoneal Dialysis Patients Prescribed Home Antibiotics Kits and In-Center Hemodialysis Transition

Derek M Blankenship,1 Michelle Carver,2 Dinesh K. Chatoth,1 Chance Mysayplohim,1 Debu Ray,1 Patricia Mccarley,1 Len A. Usuyvat,1 Jeffrey L. Hymes,1 Franklin W. Maddux,1 *Fresenius Medical Care, Global Medical Office, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA.

**Background:** Peritonitis is a complication of peritoneal dialysis (PD) and is likely associated with technique failure. To decrease time to peritonitis treatment, Fresenius Kidney Care (FKC) clinicians can prescribe broad-spectrum intraperitoneal and oral antibiotic kits. Kits are self-administered by home PD patients for suspected wet contamination or peritonitis per algorithm. The study purpose is to assess hemodialysis (HD) transition as well as peritonitis among PD patients receiving a home antibiotic kit.

**Methods:** This retrospective cohort study identified FKC PD patients prescribed home antibiotic kits between June 1st, 2019 and June 30th, 2020. Home FKC PD patients not receiving kit during same period composed the control pool. Patients are matched in a 1:4 ratio on clinical and demographic data using propensity scores. Patients were followed up to 6 months for transition to HD and first peritonitis event. Outcomes were analyzed with weighted competing risk Cox Proportional Hazards Models.

**Results:** 2,888 treatment and 10,613 controls were studied. Of the 2,888 treatment patients and weighted 1,921.2 matched controls, 11.9% and 13.5% transitioned to HD, respectively. A 0.88 hazard ratio (p=0.0448) determined treatment group is 12% less likely to transition to HD at any point during follow-up period. 10.4% treatment patients and 8.5% controls have at least one peritonitis event. The treatment group is 23% more likely to have a Peritonitis event (p=0.0019).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: The study identified a protective association in HD attrition for home PD patients receiving peritoneal kits despite a positive association between patients receiving the kits and peritonitis. These findings may reflect residual confounding factors such as clinicians prescribing kits for patients at higher risk of peritonitis for uncontrolled or unmeasurable factors since kits do not prevent peritonitis but increase uniformity of treatment. The findings justify need for further research including prospective randomized studies.

PO0995

Assessing Physician Clinic Practices and Competencies in Performing Peritoneal Dialysis Catheter Flushes During the 10-Day Global Period

John H. Crabtree,1,2 Marcus Pecora,2 Mark H. Shapiro,1,2 Eduardo Zanatta,2 Martin J. Schreiber,1,2 Harbor-UCLA Medical Center, Torrance, CA; 1DaVita Inc, Denver, CO; 2Balboa Nephrology Medical Group, San Diego, CA

Background: Early flushing of peritoneal dialysis (PD) catheters theoretically reduces the incidence of catheter obstruction by decreasing formation of fibrin strands or blood clots. Early flushing also enables timely identification of catheter dysfunction, creating an opportunity to revise the catheter prior to scheduled training and initiation of therapy. It is unknown how frequently PD access providers perform flushes in their clinics, but Centers for Medicare & Medicaid Services (CMS) has indicated that services performed within 10 days following catheter placement (global period) are the responsibility of PD access providers. Therefore, under existing regulations, dialysis organizations generally defer to access providers to perform catheter flushes during this global period. The purpose of this study is to assess current practices of PD access provider clinics (surgeon, interventional nephrologist or radiologist) in performing catheter flushes.

Methods: PD access providers placing catheters for a large dialysis organization in the southwestern United States during 2020 were surveyed. The 3-question survey asked 1) PD access provider specialty, 2) if the clinic performed catheter flushes, and 3) the background of the staff person assisting the physician with clinic procedures. Responses were acquired by direct or telephone contact with the physician or clinic staff.

Results: Survey responses were obtained for all 201 providers who placed PD catheters during 2020 (Table). The majority of respondents (80.8%) indicated they performed catheter flushes. Of those reporting catheter flushes, 55.3% reported a radiology or interventional background while 44.7% reported a physician or clinic staff background.

Conclusions: Of those facilities that reported catheter flushes, 80.8% described performing such flushes in the 10-day global period. Given the CMS policy, suggesting a need for more flexibility for dialysis organizations to provide these services during the global period for patient safety and optimal patient outcomes.

Peritoneal Dialysis Catheter Flushing Leading to Syncope from Vagal Nerve Stimulation

Sylvester Barnes,1,2 Loyola University Health System, Maywood, IL; 1Edward Hines Jr. Veterans Affairs Hospital, Hines, IL

Introduction: Peritoneal dialysis is the most common form of home dialysis. Complications can arise however at any time the peritoneum is invaded such as during surgery. The patient is a 57-year-old male on PD secondary to developing progressive IgA nephropathy. The patient suffered from an inguinal hernia which required open repair with mesh placement. This required the patient to be subsequently bridged with HD.

Case Description: After 6 weeks the patient was in the process of beginning to transition back to PD dialysis. The patient underwent flushing of his peritoneal catheter and subsequently developed hypotension, diaphoresis and near syncope. This process continued every time the patient’s peritoneal catheter was flushed. 500 mLs of 2.5% warm dialysate was also attempted to fill the patient resulting in the same near syncope episode. There was no problem with aspiration of the catheter. There was no resistance involved in aspiration or flushing. KUB was obtained showing the catheter placed in the left lower pelvis as well as a significant amount of stool burden. Despite aggressive regimen of laxatives the patient continued to suffer from hypotension and near syncope with catheter flushing. The patient was referred for surgery to catheter repositioning. Operative report identified that the tip of the catheter was caught in anterior abdominal adhesions. The catheter was repositioned to the right lower pelvis. After 2 weeks the patient was able to tolerate flushing of his dialysis catheter with progressively increasing fill volumes to the point that he was able to be completely converted back to peritoneal dialysis.

Discussion: It was theorized that catheter tip was uniquely positioned leading to vagal nerve stimulation when liquid was infused through the catheter. This case illustrates a unique complication of catheter malposition and adhesions resulting in near syncope secondary to vagal nerve stimulation. With repositioning of the patient’s catheter the symptoms completely resolved.

PO0997

Pharmacokinetics of Intraperitoneal Vancomycin in Patients on Automated Peritoneal Dialysis

Edwin Lam,1,2 Walter K. Kraft,1 Douglas F. Stickle,1 Beth M. Piraino,1 JingJing Zhang,1 Thomas Jefferson University, Philadelphia, PA; 2National Institutes of Health, Bethesda, MD; 3University of Pittsburgh, Pittsburgh, PA

Background: It is unclear if the pharmacokinetics of vancomycin is the same during automated peritoneal dialysis (APD) where cycler exchanges may affect the systemic, peritoneal, and urinary disposition of drug.

Methods: This was a prospective pharmacokinetic study in peritonitis-negative patients on APD. A single dose of vancomycin (20 mg/kg) was administered through the peritoneum and allowed to dwell for at least 15 hours. Patients underwent four drug-free exchanges following the initial dwell period. Plasma, dialysate and urine were collected over the course of 7 days for pharmacokinetic analysis. A non-comparative analysis was used to estimate vancomycin pharmacokinetic parameters.

Results: Four patients enrolled and completed the study with no adverse events. Three patients had residual renal function. Following a median (range) dwell of 14.6 (14.2 – 17.6 hours), the mean (± SD) observed maximum plasma concentration was 28.7 ± 4.9 mg/L with a mean (± SD) bioavailability of 98.5 ± 1.4% prior to starting the cycler. The overall mean plasma clearance estimated from study start to completion was 7.3 ± 1.2 mL/min. In patients with residual renal function, the mean (± SD) vancomycin renal clearance was 3.1 ± 1.5 mL/min.

Conclusions: Despite the small sample size, this pilot study suggest that the dwell time has important implications for systemic vancomycin exposure, time to therapeutic plasma concentration, and dosing. Dose is driven by dwell time while the cycler determines the dosing interval. Rapid exchanges from APD will determine the frequency of dosing rather than the adequacy of absorption when vancomycin is given in the peritoneum.

Funding: Other NIH Support - Edwin Lam was supported by an NIH T32 training grant (GM008562) at the time of study conduct.

Effect of Velphoro on Serum Phosphate and Albumin in Peritoneal Dialysis Patients

Luis M. Perez, Zhijing You, Jessica B. Kendrick, Isaac Teitelbaum. University of Colorado, Denver, CO.

Background: Hyperphosphatemia is common in patients on peritoneal dialysis (PD). Restricting phosphorus in the diet often leads to a decrease in protein intake, which may result in hypoalbuminemia. Hypoalbuminemia is associated with an increased risk of morbidity and mortality in PD patients. In observational studies, sucroferric oxyhydroxide (SO), an iron-based phosphate binder, was associated with improved phosphate control and higher serum albumin in hemodialysis patients. Whether SO improves phosphate control and nutritional status in PD patients is unknown.

Methods: We performed a prospective, open-label, 6-month, pilot study of 17 adult PD patients from the Denver Metro Area. Patients had to use automated peritoneal dialysis for at least 3 months, have a serum albumin ≥ 3.8 g/dL, and have serum phosphate ≥ 5.5 mg/dL or ≥ 5.75 mg/dL on a binder other than SO. Patients currently on phosphate binders underwent a 2-week washout period. Participants were started on SO at a dose of 1 tablet daily with meals. Serum phosphate was checked monthly and the dose of SO was titrated to a goal serum phosphate of ≤ 5.5 mg/dL. The primary outcome was change in serum phosphate and serum albumin over 6 months.

Results: The mean (SD) age and dialysis vintage was 55 ± 13 years and 3.8 ± 2.7 years, respectively. The majority of patients were male (65%), white (82.4%) and non-Hispanic (64.7%). 88% of patients were on a phosphate binder at baseline and the majority were on sevelamer (73%). Twelve patients completed the study. Two patients withdrew due to side effects (diarrhea), 1 patient changed to hemodialysis and 2 patients died (unrelated to the study). Mild diarrhea and change in stool color were the most frequently reported side effects. Results are shown in Table 1. Serum phosphate decreased significantly from baseline but there was no significant change in serum albumin. Phosphate binder pill burden significantly decreased.

Conclusions: Serum phosphate decreased significantly with fewer phosphate binder pills/day after switching to SO. There was no change in serum albumin.

PO0999

Prognostic Significance of Plasma Vaspin and Adiponectin Levels in Peritoneal Dialysis Patients

Win H. Than,1,2 Cheuk-Chun Szeto.1,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Shatin, Hong Kong; 1Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Adiponectin and vaspin are key adipokines that play important roles in the physiology of adipose tissue and contribute to the pathogenesis of metabolic disturbance in chronic kidney disease (CKD). We explored the prognostic role of plasma adiponectin and vaspin levels in peritoneal dialysis (PD) patients – a population that metabolic syndrome, obesity, and cachexia are all common.

Methods: We measured plasma adiponectin and vaspin levels in a cohort of new PD patients and analyzed their relation with patient survival.

Results: We studied 152 patients. Their mean age was 58.38 ± 11.67 years; 102 (67.1%) were men, 92 (60.5%) were diabetic. The median plasma adiponectin level was 31.98 (Interquartile range [IQR]: 16.81-49.49) ng/ml; median vaspin level 0.18 (IQR: 0.11-0.32) ng/ml. There was no significant correlation between plasma adiponectin and vaspin levels. Plasma adiponectin level had modest correlations with Charlson’s comorbidity score (r = -0.174, p = 0.039), triceps skin fold (r = -0.299, p = 0.001), and mass transfer area coefficient of peritoneum (r = 0.211, p = 0.015). In contrast, plasma vaspin level correlated with carotid-to-femoral pulse wave velocity (r = -0.240, p = 0.005), triceps skin fold (r = 0.198, p = 0.018), and extracellular to Intracellular fluid volume ratio (r = -0.170, p = 0.047). After adjusting for clinical confounders, plasma adiponectin and vaspin levels significantly predicted patient survival (adjusted hazard ratio [AHR] of adiponectin 1.018, 95% confidence interval [CI] 1.004-1.031, p = 0.010; AHR of vaspin 1.018, 95%CI 1.008-1.029, p = 0.001).

Conclusions: Plasma adiponectin level also correlated with peritoneal transport status, while plasma vaspin level correlated with the severity of fluid overload and atherosclerosis. Plasma levels of both adiponectin and vaspin are independent predictors of patient survival. Our results suggest that adiponectin and vaspin are involved in different pathways of metabolic disturbance in uremia.
PO1002
Psychosocial Impact of COVID-19 Pandemic on Patients with ESKD on Peritoneal Dialysis
Jin Joo Cha, Booyeon Park, Sung Gi Yoon, Dae R. Cha, Young Sun Kang. Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

Background: The mortality rate from COVID-19 is remarkably high in elderly patients and those with chronic conditions. Increases in physical and mental stress among patients with chronic conditions, especially end-stage kidney disease, were expected to have occurred in response to the COVID-19 pandemic. This study reports that the psychosocial impact of the COVID-19 pandemic on patients receiving peritoneal dialysis.

Methods: During the pandemic, we surveyed the mental health of patients with end-stage kidney disease on peritoneal dialysis at a single center. Depression using with BDI score was evaluated and then compared in peritoneal dialysis patients between before and the pandemic declaration. We also surveyed patient satisfaction with the self-care services associated with peritoneal dialysis under the pandemic period.

Results: One-third of the survey respondents (n=176) were moderately to extremely worried about their physical health being impacted by the pandemic, while 20% moderately to extremely worried about their mental and emotional health being impacted. About half of participant reported feeling that they were unable to handle their personal problems and that things were out of their control. However, most felt that they could retain control over the important things and overcome their difficulties. Despite COVID-19 pandemic, no significant changes in depression scores were apparent between before and during the pandemic. Most participants were satisfied with the in-home self-care services delivered by either telephone or remote monitoring.

Conclusions: Many participants reported that they were afraid of COVID-19, but most patients with PD felt that they could overcome the crisis. The COVID-19 pandemic did not affect the depression of patients receiving peritoneal dialysis.

PO1003
Peritoneal-Mediastinal Communication Complication in Peritoneal Dialysis
Janina Paula T. Sy-Go, Lagu A. Androga, Fawad Qureshi, Andrea G. Kattah. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Increased intra-abdominal pressure is a well-recognized non-infectious complication of peritoneal dialysis (PD) resulting from instillation of dialysate fluid into the peritoneal cavity. Peritoneal-pleural communication causing hydrothorax is well-described in the literature, but cases of peritoneal-mediastinal communication are scarce.

Case Description: A 36-year old Caucasian man with end-stage kidney disease secondary to calcineurin inhibitor nephrotoxicity and BK virus nephropathy transitioned to continuous cyclic peritoneal dialysis (CCPD) after one year of intermittent hemodialysis (iHD). He presented to our institution nine months after starting CCPD primarily because he was experiencing shortness of breath. He underwent cardiac surgery and did not have any problem with his CCPD in the immediate post-operative period and was discharged. One month later, however, he presented with increased serous drainage from his sternal incision site and reduced ultrafiltration. A chest CT scan revealed a partially loculated anterior chest wall subcutaneous fluid collection. He was taken to the operating room and was found to have a peritoneal-mediastinal communication. He was successfully managed with “low-pressure” PD by using reduced fill volumes for all his exchanges, which also allowed optimal healing of the muscle flaps closing the communication. Transition to iHD was considered, but he had no vascular access options because of multiple prior thromboses. He was able to subsequently return to his outpatient CCPD prescription about two months after his surgery by doing very gentle uptitration of his fill volumes. Unfortunately, one and a half months after his last hospitalization, he succumbed to septic shock secondary to trans-lumbar PICC-associated Candida glabrata fungemia.

Discussion: A peritoneal-mediastinal communication should be suspected in an otherwise asymptomatic patient on PD with reduced ultrafiltration who underwent any form of chest surgery. Clinical suspicion can be confirmed either through CT peritoneography or intraoperatively. Management with a trial of “low-pressure” PD is feasible and can be successful, particularly if iHD is not an option. A multi-disciplinary approach involving our surgical colleagues is also crucial to ensure appropriate patient care.

PO1004
Sweet Pleural Effusion in a Peritoneal Dialysis Patient
Karla G. Carias Martinez,1 Nityasree Srilall,1 Jose M. Monroy-Trujillo.2 1Johns Hopkins Medicine, Baltimore, MD; 2Johns Hopkins University, Baltimore, MD.

Introduction: Pleural Effusions are frequently seen in dialysis patients with an incidence as high as 80%, with a variety of possible differential etiologies.

Case Description: A 62-year-old female with HFpEF, DM and ESRD due to biopsy proven diabetic nephropathy recently started on nightly continuous cyclic PD with a prescription of 4 exchanges of 2.5% Dextrose solution with 2 liters fill volumes with a dwell time of 1h40 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining ultrafiltration volumes. On exam tachypneic on 4L of oxygen and saturating 100%, had decreased breath sounds on the right parietal pleura, IVD or lower extremity edema. Laboratory showed creatinine 4.19 mg/dl, BUN 41 mg/dl, proBNP 30,186 pg/ml, Hemoglobin 11 g/ml and WBC 5.91 mg/dl. Chest X-Ray revealed small to moderate right pleural effusion and opacities in the right mid and lower lung. CT Chest showed a large right sided pleural effusion. With her unilateral pleural effusion and recent start of PD the presence of a peritoneal pleural fistula was suspected. A therapeutic thoracentesis was done draining 1 liter of fluid consistent with a transudate, no microorganism or malignant cells were isolated. Pleural fluid glucose was 274 mg/dl compared to a serum glucose of 155 mg/dl. A peritoneal perfusion scan was done detecting radiotracer uptake in right hemithorax Image 1 confirming a peritoneal pleural communication. She was transitioned to HD and maintained on it per the patient’s preference.

Discussion: A pleuroperitoneal leak is a rare but important cause of pleural effusion in patients on PD and should be considered in any patient presenting with a unilateral effusion. Incidence is less than 2%. The diagnosis is made by measuring the ratio between the pleural to serum glucose which usually is > 1. Other tests include technetium-99m labeled peritoneal scintigraphy. Treatment usually requires cessation of PD for 4-6 weeks and transition to HD. For patients willing to return to PD, a diaphragmatic repair is usually required.
tubules, thus its accumulation reflects an impaired RKF. Our study aimed to evaluate if serum levels of 82MG could be used as a complementary tool for evaluating RKF in peritoneal dialysis (PD) patients.

**Methods:** For this retrospective cohort study, we evaluated 423 urine samples of 166 patients who were in the PD program of Hospital das Clínicas, HCFMUSP, Universidade de Sao Paulo, Brazil between January first of 2017 up to August 10th of 2020. We correlated serum 82MG levels with the urea renal Kt/V (urea clearance adjusted by the total body water (TBW), measured with bioimpedance), serum creatinine and urinary volume. **Results:** We found a correlation between renal Kt/V and 82 microglobulin (r=0.656, p<0.001), serum calcium (r=0.603, p<0.0001), and urinary volume (r=-0.682, p<0.0001). ROC curve revealed that 82 microglobulin had a high performance to predict renal Kt/V, with a sensitivity of 70 to 81.7% according to the best cutoff. The specificity varied from 71.5% to 84.2% for Kt/V cutoff 0.5, 1.0, 1.5, and 2.0.

**Conclusions:** Based on the good correlation found on the serum 82M and urea renal Kt/V, we suggest that 82MG can be a useful tool to estimate the RKF. This finding can be particularly useful in patients who have difficulties in storing or collecting a 24-hour urine sample.

---

**PO1007**

**A Rare Case of Roseomonas gilardii Peritonitis in a Peritoneal Dialysis Patient**

**Patient:** A 72-year-old female with history of end stage renal disease due to biopsy proven focal segmental glomerular sclerosis thought to be secondary to obesity started on CCPD one-month prior presented with worsening shortness of breath of 1 week duration. Workup was unremarkable except for chest X-ray that showed right side pleural effusion. A non-contrast CT chest did not show a diaphragmatic defect. She continued to have worsening SOB prompting an emergent thoracentesis that drained 1.6 L transudate pleural fluid. Pleural fluid to serum glucose gradient was normal at 5 mg/dl but pleural fluid to serum glucose ratio was >1. However, last PD session was 2 days prior to thoracentesis, which could explain this lower ratio. Due to inconclusive [NL1] results, it was decided to instill 300 mL of intraperitoneal vancomycin and ceftazadime. Effluent remained cloudy with elevated serum levels of ß2MG could be used as a complementary tool for evaluating RKF in peritoneal dialysis (PD) patients.

**Methods:** Peritoneal dialysis Peritonitis is known to be caused mainly by gram negative coccobacillus genus of Roseomonas associated with contaminated water sources. Roseomonas gilardii is a pink-pigmented, oxidized, gram-negative coccobacillus genus of Roseomonas associated with contaminated water sources. **Results:** Reported till date. Although the incidence reported, ours is the third case of R. gilardii peritonitis in a continuous ambulatory peritoneal dialysis patient. We report a case of R. gilardii peritonitis in a continuous ambulatory peritoneal dialysis (CAPD) for 5 years presented with cloudy effluent without abdominal pain or fever. Laboratory studies revealed a fluid cell count of 28,000/cmm with predominance of eosinophils. The patient was in the PD program of Hospital das Clínicas, HCFMUSP, Universidade de Sao Paulo, Brazil. She complained of abdominal pain and diarrhea. Laboratory studies revealed a fluid cell count of 28,000/cmm with predominance of eosinophils. The patient was started on amoxicillin/clavulanic acid and the effluent cleared on day three. Gentamycin was continued for three weeks to ensure she didn’t have a relapse as per prior described experience in a similar case.

**Discussion:** Peritoneal dialysis peritonitis is known to be caused mainly by gram positive and occasionally gram-negative organisms, the usual culprits being pseudomonas, klebsiella etc. Roseomonas has recently been implicated as a rare cause of bacterial peritonitis with only six reports between 1997 till date. It was first described in 1993 as a cause of bacteremia in humans. Roseomonas gilardii is a pink-pigmented, oxidized, gram-negative coccobacillus genus of Roseomonas associated with contaminated water sources. Our patient was unaware of being in contact with contaminated water or soil however this could not be ruled out as she did endorse having plants. Of the six cases reported, ours is the third case of R. gilardii reported till date. Although the incidence of peritoneal dialysis peritonitis caused by Roseomonas gilardii is rare, it is causative agent to be considered by physicians and laboratory staff in the differential diagnosis of refractory bacterial peritonitis in peritoneal dialysis patients. It also serves as a point to emphasize when educating PD patients on the hand-washing techniques and ensuring sterility of water source used for this.

---

**PO1009**

**The Association Between Lower Serum Potassium Level and Increased Cardiovascular Disease Death Among Patients Undergoing Peritoneal Dialysis**

**Background:** In patients undergoing peritoneal dialysis (PD), lower serum potassium concentration has been related to low nutrition status and suggested as a risk factor for all-cause and cardiovascular mortality. However, the risk of lower serum potassium concentration for cardiovascular death in patients using renin-angiotensin system (RAS) inhibitors or β-blockers is not clear. This study investigated the relationship between lower serum potassium concentration and cardiovascular death among Japanese patients undergoing PD.

**Methods:** We retrospectively included the 549 patients from our previous multicenter cohort study (Fukuoka Peritoneal Dialysis Database Study). The participants who had undergone PD for at least 90 days were registered from 1 January 2006 to 31 December 2016 and followed until they were transferred to hemodialysis, received a kidney transplantation, died during PD, or were lost to follow-up, or until 31 December 2017. The patients were divided into three groups according to the baseline serum potassium concentration (T1 ≤ 4.0, 4.0 < T2 ≤ 4.5, T3 > 4.5 mg/dL). We estimated the relationship between serum potassium concentration and cardiovascular mortality using a Cox proportional hazards model.

**Results:** During the median observation period of 2.3 years, 111 patients died of any cause, and 38 died of cardiovascular. After multivariable adjustment in the Cox proportional hazard model, lower serum potassium concentration was shown to be an independent risk factor for cardiovascular death; (hazard ratio 95% confidence intervals) T2 and T1 vs. T3 were 2.21 (1.77–2.67) and 2.67 (1.61–7.87), respectively. Stratified-analysis according to the use of RAS inhibitors, β-blockers, or a combination of both showed that this relation was not modified by the use of these drugs.

**Conclusions:** This study showed that lower serum potassium concentration was associated with increased cardiovascular mortality in PD patients. There was no difference in the risk of lower serum potassium concentration for cardiovascular death according to the use of the RAS inhibitors and/or β-blockers in PD patients.
PO1010
Higher Serum Total Cholesterol to High-Density Lipoprotein Cholesterol Ratio Was Associated with Increased Mortality Among Incident Peritoneal Dialysis Patients
Hye Won Noh, Soosee Jeon, Jeong-Hoon Lim, Hye-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. Department of Internal Medicine, Kyungpook National University Hospital, Korea Kyungpook National University Hospital, Daegu, Republic of Korea.

Background: A few studies have shown that serum total cholesterol to high-density lipoprotein cholesterol ratio (TC/HDL-C) was a risk factor for cardiovascular mortality in the general populations. This study was aimed to evaluate the association of TC/HDL-C with mortality in incident peritoneal dialysis patients.

Methods: We enrolled Total of 6,30 incident peritoneal dialysis patients from 2008 to 2015 in a multi-center, prospective cohort study of Korea. Participants were stratified into quintiles according to the baseline TC, HDL-C, or TC/HDL-C. The association between all-cause mortality and each lipid profile was evaluated using multivariate Cox regression analysis.

Results: During a median follow-up period of 70.3 ± 25.2 months, 185 deaths were recorded. The median TC/HDL-C was 4.54 ± 2.51. Highest TC/HDL-C group showed highest body mass index, percentage of diabetes, and serum albumin level. Multivariate analysis revealed that the highest quintile of the TC/HDL-C (≥5.60) was associated with increased risk of all-cause mortality (hazard ratio 1.69, 95% confidence interval 1.04 to 2.76; P = 0.036), whereas neither of TC and HDL were associated with mortality. Increased serum TC/HDL-C was also independent risk factor for mortality in the patients with old age over 50 years, non-diabetes, and any cardiovascular disease.

Conclusions: The single lipid marker of TC or HDL-C could not predict mortality in PD patients. However, non-traditional lipid profile such as increased serum TC/HDL-C ratio was independently associated with an increased risk of all-cause mortality in PD patients.

PO1011
Peritoneal Dialysis Caregiver Scope and Functions: A Systematic Scoping Review
Tanawin Nopsoop,1,2 Chitsanucha Chumsiri,1 Piyawat Kantagowit,1 Krit Pongpirul.1 Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee Chulalongkorn University Faculty of Medicine, Bangkok, Thailand;1 Harvard University T H Chan School of Public Health, Boston, MA;1 Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: Caregivers play important roles in peritoneal dialysis (PD) care. Classifying PD self-care tasks is important for determining the PD caregiver roles. As the scope and functions of PD caregiver in published literature have been inconsistent, we aimed to systematically explore the variations of the term caregiver in high-quality PD studies.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL for randomized controlled trials and observational studies relevant to a caregiver in ESRD patients with PD.

Results: Of 2,514 potential studies relevant to a caregiver in ESRD patients with PD, 299 theme-related abstracts were selected for further full-text articles screening according to eligibility criteria, and 111 were included in the systematic review (72,101 patients in 34 countries). In terms of word choice, “caregiver(s)” was used in 86.4%, “caree(s)” in 20.7% and other words were used in 13.5% of included studies. Only 8.1% of studies gave the explicit definitions of those words. The most referred person is the parents (40.5%), followed by a spouse (37.8%), other family members (37.8%), children (34.2%), non-relative non-healthcare workers (25.3%), friends (20.7%), and healthcare workers (19.8%). The explanation of functions for each word comprises 41.4%, with the PD-related non-relative non-healthcare workers (25.2%), friends (20.7%), and healthcare workers (19.8%).

Conclusions: The single lipid marker of TC or HDL-C could not predict mortality in PD patients. However, non-traditional lipid profile such as increased serum TC/HDL-C ratio was independently associated with an increased risk of all-cause mortality in PD patients.

PO1012
Autophagy Response and Arteriovenous Fistula Maturation
Tatyana Isayeva Waldrop,1 Maheshika S. Somarathna, Kevin A. Ingle, Timmy C. Lee. The University of Alabama at Birmingham, Birmingham, AL.

Background: Arteriovenous fistula (AVF) are the preferred vascular access for hemodialysis. AVF creation results in disturbed blood flow within the AVF anastomosis. The objectives of this study were to: 1. Characterize autophagy flux after AVF creation, and during the remodeling process, 2. Use an in vitro model to evaluate autophagy status during the laminar and turbulent flow.

Methods: Femoral AVFs were created in male rats. Yorkshire pigs were used to create carotid artery-jugular vein AVF. Autophagy flux was evaluated after 1 hour and 7 days. AVF and contralateral vessels were harvested for histology and Western blot (WB). Autophagy-related proteins were analyzed in the AVF human vein samples. Effects of hemodynamic changes were investigated by using an in vitro model. Human umbilical vein smooth muscle cells and endothelial cells were co-cultured in the vessel-like system under laminar or disturbed flow conditions. After 24 hours, cells were harvested for histology and WB.

Results: In the present study, we questioned whether this senescence phenotype exists in the AVF-CKD exhibits a senescence phenotype including increased serum TC/HDL-C ratio was independently associated with an increased risk of all-cause mortality in PD patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: An end-vein to side-artery AVF was surgically created in the femoral vessels of rats which had previously been subjected to uremia via subtotal nephrectomy. At 1 and 2 weeks after AVF formation the arterial and venous limbs of the AVF were harvested for the assessment of gene and protein expression and the assay of SA-β-Gal activity. Femoral veins and arteries from rats subjected to sham surgery were used as controls.

Results: At 1 week after AVF creation mRNA levels of senescence drivers p16 and p21 were markedly elevated in AVF veins compared to shams, as were p21 protein levels; the AVF artery also displayed elevated p21 protein levels at this time point. At 2 weeks, p21 protein was again upregulated in both the vein and artery of the AVF, and protein levels of an upstream mediator in the p21 senescence pathway, p53, were significantly increased in the AVF artery; p53 levels did not achieve significance (p=0.083) in the AVF vein at this time point. Upregulation of SASP factors was also observed in the AVF at 1 week: mRNA expression of PAI-1, IL-6, TNF-α, and MCP-1 was robustly increased as compared to sham veins at 1 week after AVF creation. Additionally, miR21, which has been associated with vascular senescence, was markedly elevated in the AVF vein at 1 week post AVF placement. Finally, SA-β-Gal activity, an established marker of senescence was significantly increased in both the artery and vein compared to their sham counterparts at both 1 and 2 weeks post AVF surgery.

Conclusions: Using established criteria, this study demonstrates that the rat femoral AVF in the setting of CKD has a senescence phenotype similar to the murine AVF-CKD model. These findings thus demonstrate the development of senescence in another species subjected to an AVF in the presence of uremia.

PO1014

The Adaptive Response of the Vein to CKD: A Transcriptomics Perspective

Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Miguel G. Rojas,1 Juan C. Duque,1 Loay H. Salman,1 Roberto I. Vazquez-Padrón,1,2,3 University of Miami School of Medicine, Miami, FL; 2Alberta Medical College, Albany, NY; 3VA Miami Healthcare System, Miami, FL.

Background: The impact of CKD on gene expression in the vascular wall remains unknown, particularly in veins, despite their fundamental role as conduits for hemodynamic change.

Methods: In this study, we investigated the CKD fingerprint on the transcriptome of basilic veins by analyzing 48 pre-access veins from end-stage renal disease patients and 20 veins from non-CKD trauma donors by bulk RNA sequencing.

Results: We uncovered 16,893 differentially expressed genes (DEG) between CKD and control individuals (log FoldChange>1, FDR<0.05). The presence of kidney disease caused a noticeable decrease in transcriptional activity in veins, with the downregulation of >97% of DEG transcripts. These included 6,081 non-coding RNAs, 3,826 protein-coding genes, and other miscellaneous transcripts. In contrast, a unique set of 462 genes was upregulated in CKD veins vs. controls, 161 of which corresponded to non-coding RNAs, 201 to protein-coding genes, and the rest to minor RNA biotypes. Gene set enrichment analysis (GSEA) identified a suppression of pathways related to vascular maintenance, cell morphogenesis, cell metabolism, and microtubule-based cytoskeletal functions. Interestingly, the protein-coding genes upregulated in CKD veins belonged to processes related to gas transport and detoxification of oxidative stress byproducts.

Conclusions: In conclusion, we have uncovered a profound suppressive effect of CKD on the venous transcriptome, likely affecting basic cell functions such as metabolism, cell division, and migration. We also identified a transcriptomic signature of upregulated genes in response to oxidative stress which may play a fundamental role in cell survival in the CKD environment.

Gender-Specific Risk Genes in Arteriovenous Fistula Failure

Roberto I. Vazquez-Padrón,1,2 Marwan Tabbara,1 Miguel G. Rojas,1 Akshara Sree Challa,1 Juan C. Duque,1 Loay H. Salman,1 Laisel Martinez,1 University of Miami School of Medicine, Miami, FL; 2VA Miami Healthcare System, Miami, FL.

Background: Gender is known to play a role in arteriovenous fistula remodeling and risk of failure. However, the clinical and molecular mechanisms behind this phenomenon have not been elucidated.

Methods: To address this question, 48 pre-access veins obtained at the time of two-stage AVF creation (24 matured and 24 failed postoperatively) and 40 postoperative transition samples (20 matured and 20 failed) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Females and males were equally represented in both outcome groups and were similar in demographics and baseline characteristics. We searched for common and sex-specific differentially expressed genes (DEG) in pre-access veins and postoperative samples in association with failure.

Results: In the pre-access vein, we found 28 DEG between veins that matured or failed postoperatively (log FoldChange>1, FDR<0.05) and in common between both sexes. In the postoperative veins, 1180 transcripts were differentially expressed between both outcomes, whereas no female-specific DEG were detected in the same number of individuals. Principal component analyses demonstrated more transcriptional variability in both outcome groups in females, decreasing our power to identify female-specific genes in postoperative samples. In the postoperative samples, we found 156 DEG between fistulas that matured or failed and in common between both sexes. In addition, 143 female-specific and 153 male-specific genes were differentially expressed between outcomes, indicating gender relevant processes of postoperative remodeling. Both sexes showed a downregulation of genes related to responses to external stimuli and stress. However, gene set enrichment analysis (GSEA) revealed a suppression of cell-surface receptor signaling and cell adhesion mechanisms in males but not in females, suggesting a sex-specific effect in cell migration.

Conclusions: In conclusions, these analyses uncover potential differences in postoperative remodeling between females and males in relation to AVF failure. They also indicate a more complex transcriptional landscape in female tissues which may affect our ability to predict remodeling in the subgroup of patients. These data may open the door to personalized medicine in preventing or treating vascular access complications.

Inhibition of Phosphodiesterase Type 5A Prevents Pathological Cardiac Remodeling Following Arteriovenous Fistula Creation

Maheshika S. Somarathna,1 Taylor G. Lewis,2 Kevin A. Ingle,1 Tatyana Isayeva Waldrop,1 Timmy C. Lee.1 The University of Alabama at Birmingham, Birmingham, AL; 2Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.

Background: Cardiac events are the most common etiology of morbidity in hemodialysis patients. The gold standard of vascular access, the arteriovenous fistula (AVF), may adversely affect cardiac structural and functional remodeling leading to heart failure. We hypothesize that inhibition of cGMP catalysis with a selective phosphodiesterase type 5A (PDE5A) inhibitor, sildenafil, may induce more favorable cardiac remodeling following AVF creation.

Methods: Sildenafil was administered to 12-16 weeks old Sprague-Dawley rats twice prior to AVF creation and continued until sacrifice at 28 days. Cardiac structural and functional changes were evaluated by 1) 2D-echocardiography 2) measurement of collagen volume and oxidative stress and 3) evaluation of cardiomyocyte cytoskeletal-mitochondrial architecture.

Results: Sildenafil treatment significantly improve pathological collagen degradation, reduces HNE4 expression, reverse desmin degradation and focal mitochondrial clustering following AVF creation, as compared to the control. We also observed a significant increase in cardiac output and stroke volume without reversing LV dilation which may suggest improvement in cardiac contractility.

Conclusions: PDE5A inhibition may provide a new treatment strategy for pathological cardiac remodeling following AVF creation.

Pre-Access Vein Transcriptomics as a Predictor of Arteriovenous Fistula Failure: A Machine Learning Approach

Miguel G. Rojas,1 Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Juan C. Duque,1 Loay H. Salman,2 Roberto I. Vazquez-Padron,1,2 University of Miami School of Medicine, Miami, FL; 3Albany Medical College, Albany, NY; 4VA Miami Healthcare System, Miami, FL.

Background: As the number of patients with end-stage renal disease continues to rise, the creation of a robust and efficient hemodialysis access is more important than ever. A mature arteriovenous fistula (AVF) is the preferred method for long-term hemodialysis. However, the nationwide maturation rate continues to be as low as 50-60%, and we currently lack an effective risk stratifying method to identify patients at higher risk of AVF failure.

Methods: To address this clinical need we developed a predictive model based on supervised machine learning from transcriptomics of the pre-access vein. Forty-eight pre-access veins obtained at the time of AVF creation (24 matured and 24 failed postoperatively) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Both outcome groups were matched by age, sex, demographics, and baseline clinical characteristics. The highest expressing genes (normalized gene expression counts >200) were used as input in KNN, SVM, XGBoost, and other machine learning algorithms. Area under the curve (AUC) and receiver-operating characteristic (ROC) plots were used to compare the performance of the models relative to each other. The best performing algorithm, XGBoost, was optimized with the following hyperparameters {gamma=0.25, learning_rate=0.001, max_depth=4, reg_lambdar=10, scale_pos_weight=3}. The SHapley Additive exPlanations (SHAP) analysis was then used to evaluate the highest contributing features to the XGBoost model.

Results: Ten highly predictive and abundantly expressed genes were identified using this methodology (RJC1, CLIC3, DNLAL1, FOXO4, TIMMDC1, GALT11, CDH13, KLHD10, ZNF8, and DBT). Using these transcripts, the AUC in the logistic regression model is 97.6%.

Conclusions: In conclusion, this study has identified 10 potential pre-access gene predictors of postoperative AVF failure, which could be used clinically as a stratifying or risk management tool in vascular access patients.

Arteriovenous Fistula Non-Maturation: Does the Immune System Play a Role?

Crystal A. Farrington,1 Gary R. Cutter,2 Michael Allan,1 1The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; 2The University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background: Arteriovenous fistula (AVF) non-maturation is a persistent problem, particularly among female and Black patients. The immune system promotes several vascular disease processes, but its contribution to AVF non-maturation has not been well-studied. We evaluated the association of serum panel reactive antibodies (PRA), a measure of immune system reactivity assessed in patients undergoing kidney transplant evaluation, with AVF non-maturation.

Methods: We identified 132 patients at our institution who underwent surgical AVF creation between 2010-2019 and had PRA testing within one year of AVF creation. Multivariable logistic regression was used to determine the association of patient demographic, clinical, and vascular factors with AVF maturation. Receiver operator characteristic (ROC) curves were generated to determine the predictive value of key variables on AVF non-maturation.

Results: AVF non-maturation was more common in females than males (44% vs 20%, p=0.003) and in Black than white patients (40% vs 13%, p=0.001). Class II PRA was higher in females than males (12% +/- 23% vs 4% +/- 13%, p=0.02), but did not differ by race. In the multivariable model, AVF non-maturation was associated with class II PRA (adjusted odds ratio [aOR] 1.34 per absolute 10% increase; 95% confidence interval [CI], 1.04 to 1.82, p=0.02) and Black race (aOR 3.34; 95% CI, 1.02 to 10.89, p=0.03). An ROC curve using seven key variables (Table 1 and Figure 1) showed an area under the curve of 0.73 (95% CI, 0.63 to 0.82, p=0.0001).

Conclusions: The novel association of elevated class II PRA with AVF non-maturation suggests a role for the immune system in AVF maturation outcomes, especially for female patients.

Table 1. AOR of 7 key variables for AVF non-maturation.

PO1019

Functioning Tailor-Made 3D-Printed Vascular Graft for Hemodialysis: A Proof-of-Concept In Vivo Study

David Chih-Yu Yang,1,2 Der-Cherng Tarng,1,2 1Taipei Veterans General Hospital, Taipei, Taiwan; 2National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.

Background: The two ends of arteriovenous graft (AVG) are anastomosed to the upper limb vessels by surgery for hemodialysis therapy. However, the size of upper limb vessels varies to a large extent among different individuals. With advances in three-dimensional (3D) printing technology, it is now possible to realize tailor-made AVG for personalized surgery. In this study, we aim to investigate the function of 3D-printed AVGs in vivo.

Methods: The computed tomography angiographic scan of the rabbit neck was performed before the surgery. According to the shape and size of neck vessels, an H-shape AVG was produced by the 3D printer and then sterilized. The 3D-printed AVG was trimmed and inserted in the rabbit’s common carotid artery and common jugular vein.

Results: The tailor-made 3D-printed AVGs can be implanted in the rabbit’s neck vessels with ease and function in vivo. The surgical procedure was quick, and no suture was required. The blood loss was minimal, and no hematoma was noted at least one week after the surgery. The blood flow velocity within the implanted AVG was 14.9 ± 3.7 cm/ sec.

Conclusions: Through the 3D printing technology, the AVG can be tailored to fit the specific vessel size. This kind of 3D-printed AVG is functioning in vivo, and our results realize personalized vascular implants. Further studies conducted in large animal models are warranted to validate our promising results.

Vascular Access Arena: Challenges, Progress, and Prospects

PO1021

The Association of Transition-to-Dialysis Planning and Healthcare Resource Use and Mortality in Patients with ESRD

Insiya B. Poonawalla,1 Kanchan Barve,1 Meghan M. Cockrell,2 Amal Agarwai,2 Adrianne W. Casebeer,1 Yong Li,1 1Humana Healthcare Research, Inc., Louisville, KY; 2Humana Inc, Louisville, KY.

Background: The onset of ESRD is associated with poor outcomes and high mortality, and the role of transition-to-dialysis planning is not well understood. We evaluated the association between dialysis transition planning factors such as nephrology care, vascular access placement, and place of index dialysis, with inpatient (IP) stays, emergency department (ED) visits, and mortality.

Methods: This retrospective study used the Humana Research Database to identify 7,026 patients, 19-89 years of age, diagnosed with ESRD between 1/1/17 and 12/31/17, enrolled in a Medicare Advantage Prescription Drug plan, with ≥12 months of continuous enrollment pre- and post-index date (i.e., first evidence of ESRD). Patients with a kidney transplant indication, hospice election, or dialysis pre-index were excluded. Transition-to-dialysis planning was defined as optimal, partial, or unplanned (Table 1). IP stays, ED visits, and mortality were evaluated within 12 months post-index.

Results: The cohort was 41% female, 66% White, with an average age of 70 years. An optimally planned, partially planned, and unplanned transition to dialysis occurred for 15%, 34%, and 44% of the ESRD cohort, respectively. Among patients with pre-index CKD stages 3a and 3b, 64%, and 55%, respectively, had an unplanned dialysis transition. For patients with pre-index CKD stages 4 and 5, 68% and 84%, respectively, experienced planning prior to dialysis initiation. In adjusted models, patients with partially or optimally planned transition to dialysis were 57% to 72% less likely to die, 20% to 37% less likely to experience an IP stay, and 80% to 100% more likely to experience an ED visit than patients with an unplanned transition. Higher ED utilization with planned transition was attributed to longer time to mortality, allowing more time for healthcare utilization.

Conclusions: A planned transition to dialysis was associated with improved outcomes and lower mortality. Targeting care coordination for patients with CKD stages 3a/3b may help slow disease progression and ensure a planned, safer transition to dialysis.

Prediction of Stenosis in Arteriovenous Fistula Using Video Image Analysis

Fanasan Zhu,1 Lin-Chun Wang,1 Alhaji Cherif,1 Ohmmar Thwin,1 Lela Tisdale,1 Xia Tao,1 Paulo Paneque Galuzio,1 Norbert Shitanberg,2 Dean C. Preddice,2 Peter Kotanko,1,3 1Renal Research Institute, New York, NY; 2Azaara Vascular Care, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We developed a video image processing (VIP) technique with frequency domain analysis to predict stenosis in AVF. The study aimed to evaluate whether the degree of stenosis can be assessed using parameters from frequency domain signal analysis.

Methods: We employed VIP in 100 hemodialysis patients (age 63.3 ± 14.1 years, 47 females) prior to endovascular arterio-venous fistula (AVF) interventions. A 1-minute video of the AVF area was recorded using a smartphone (Fig 1). We constructed time series based on pixel changes between two consecutive video frames (Fig 2-A) and used Fast Fourier Transform (FFT) to transform the time domain signals into the frequency domain (Fig 2-B). Parameters in the frequency domain included maximal (Max) and minimum (Min) amplitude, and frequency (fMax and fMin). M2 was calculated by the squared ratio of the Max-to-median magnitude. The degree of AVF stenosis (% ST) was determined by angiography, the access flow (AF) by thermography (HVT100; Transonic Systems Inc, Ithaca, NY, USA).

Results: Data from 98 patients were analyzed. % ST was categorized into three groups: 60% stenosis (n=8), 70-80% (n=76), and 90% (n=14). AF correlated with % ST. fMax, fMin, and AF were associated with % ST (Table 1). An algorithm was developed to predict degree of % ST based on patient characteristics and parameters of frequency domain analysis. In the respective three % ST groups the sensitivities to detect AVF stenoses were 88%, 86% and 100%, and the specificities 99%, 82% and 98% (Table 1).

Conclusions: VIP applied to videos taken with a smartphone may provide a contact-free method to estimate the degree of AVF stenosis. Validation studies in independent cohorts are needed to further assess the diagnostic capability of the proposed method.
Catheter-Related Bloodstream Infection Incidence and Associated Mortality Risk: Analysis of Merged U.S. Renal Disease Surveillance Claims

Kathleen Massey,1 Krithika Rajagopalan,2 Aaron Grossman,2 Paul Chwel.1 Cormedic, Berkeley Heights, NJ; 3Antiliks Inc, Dover, MA.

Background: Despite policy and provider initiatives, nearly 80% of end-stage-renal-disease (ESRD) patients initiate hemodialysis (HD) with a central venous catheter (CVC). However, CVCs may elevate risk of catheter hub contamination resulting in catheter-related blood stream infections (CRBSIs) and potentially serious consequences. This analysis aims to estimate the incidence, risk, and associated mortality of CRBSIs among CVC-dependent HD patients in the US.

Methods: A propensity score matched case-control analysis of 2013-2017 linked data from the United States Renal Data System (USRDS), dialysis organizations (ERSNWeb), and Medicare claims was conducted. Occurrence of CRBSI and associated mortality among incident CVC-dependent HD patients between 2014-2016 with a 1-year pre- and 1-year post-index were assessed. CRBSI case group index date was the first date of occurrence of any of the following post CVC insertion: ICD-9-CM 999.32, T90211x; 999.31, T90219x, T90218x and sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±999.32, T80211x; 999.31, T80219x, T80218x and sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date + median ±3 days of hospitalization; sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization.

Results: Of the 55,727 CVC-dependent HD patients (mean age 67.8, 45% female), nearly 29% (n=15,882) developed a CRBSI (median time, 49 days); 54% (n=8,393), 67% (n=10,327), and 80% (n=12,705) occurred within 90, 180 and 365 days of CVC insertion, respectively. After CRBSI occurrence, 40% and 50% died within 60 days and 180 days, respectively. CRBSI patients also had a significantly lower median survival (25.1 vs. 37.3 months) compared to non-CRBSI patients [hazard ratio: 0.74, 95% CI: 0.71-0.76].

Conclusions: CRBSIs occur in a third of CVC-dependent HD patients, with over half of the initial infections occurring within 90 days of CVC insertion. Patients with CRBSI had a higher risk of death compared to patients without CRBSI; with a 40% mortality within 60 days post-CRBSI.

Funding: Commercial Support - Cormedic
The average number of prior vascular accesses (defined as venous access or arteriovenous fistula/graft) in patients prior to IOCA was 2.6 ± 1.7 (range 1–9). 9 (23.1%) had two prior accesses, and 30 (76.9%) had >3 prior accesses. 5 (12.8%) patients had >1 prior IOCA procedure. 5 (12.8%) patients had complete superior vena cava occlusion. 17 (43.6%) patients had failed AVF/AVG and 2 (5.1%) had failed transhumeral venous access. Technical success rate was 100% with no complications.

Conclusions: The RIJ vein is the most effective and durable site for long-term hemodialysis access. Occlusion, stenosis of this vein can lead to a downward spiral of access crisis with venous exhaustion resulting in trans-lumbar or trans-hepatic catheter placement for dialysis. These approaches are associated with high rates of dysfunction as well as infection, catheter migration and thrombosis. The transhepatic approach can also cause life-threatening intraperitoneal hemorrhage. The use of IOCA alleviates the need to sacrifice subsequent veins and allows for the occluded RIJ to be re-accessed as many times as needed via the femoral vein. Our data provides further evidence in support of the safety and efficacy of IOCA for long-term hemodialysis access in ESRD patients.

Machine Learning for Prediction of Arteriovenous Fistula Failure

Suman K. Lanna,1 Rishi Razdan,2 Murat Sor,1 Eyal Barzel,2 Caitlin Monaghan,1 Joanna Willetts,1 Sheetal Chaudhari,1 Nancy McLoughlin,1 Hanjie Zhang,1 Peter Kotanko,1 Jeffrey L. Hymes,1 John W. Larkin,1 Len A. Usavage,1 Frank W. Maddux,4 Fresenius Medical Care, Waltham, MA; 2Atera Vascular Care, Malvern, PA; 3Renal Research Institute, New York, NY; 4Fresenius Medical Care North America, Waltham, MA.

Background: Vascular access aneurysms are a frequent finding in hemodialysis patients with arterio-venous (AV) fistulas and grafts. Of great concern is aneurysm rupture that may result in fatal hemorrhage. To that end we used artificial intelligence (AI) to automatically evaluate vascular access aneurysms.

Methods: We collected images of a diverse range of AV vascular accesses using mobile devices. Vascular access experts adjudicated the images and diagnosed the severity of AV fistula and graft aneurysms. We then randomized the images for training (70%) and validation (30%). We trained a convolutional neural network (CNN) utilizing Amazon SageMaker platform. CNN performance was measured by the area under the receiver operating characteristics (ROC) curve in the validation images.

Results: We collected 1,341 AV access images in patients dialyzed in 20 Renal Research Institute clinics in six U.S. states. The adjudication of images identified 1,093 not advanced and 248 advanced aneurysms; examples are shown in Figure 1. With the validation images, we achieved an area under the ROC curve of 0.96. Considering different probability threshold for advanced aneurysm, if threshold is 0.37, we achieved sensitivity of 80%, specificity of 95%, false positive rate of 5%, precision of 79%, if threshold is 0.7, sensitivity of 66%, specificity of 99%, false positive rate of 1%, precision of 92%.

Conclusions: Our solution of applying advanced AI technologies achieved very high sensitivity, specificity, precision, and a low false positive rate. The CNN could assist the dialnurses with actionable information and improve clinical outcomes.

PO1031

Evaluation of a Wearable Device for Continuous, Noninvasive Monitoring of Hematocrit Levels in Hemodialysis Patients

Background: Maintenance of euvelemia is a major challenge for hemodialysis patients, who account for a combined 6.5M annual hospital days. Clinical outcomes could be improved, and healthcare costs lowered, by enabling better management of fluid status and anemia, which is common among ESRD patients. This study presents a novel wearable device, SmartPatch, that uses multi-wavelength photoplethysmography (PPG) and other sensors to measure blood hematocrit (Hct), a key metric for monitoring fluid status and anemia. The SmartPatch is a component of a novel Remote Monitoring System (RMS) that facilitates secure data transmission and analysis and generates actionable alerts. Data demonstrating the feasibility of the RMS were previously presented at Kidney Week 2019 (Kuraguntla et al.). The aim of this study was to evaluate the system’s ability to accurately and precisely measure Hct in a real-world dialysis setting.

Methods: 14 ESRD patients with arteriovenous fistulae currently undergoing dialysis were recruited to participate in this study. Each of these patients had a SmartPatch device placed on the skin over their fistula at each of three dialysis sessions two weeks apart. Reference Hct measurements were taken immediately before and after the session, times to coincide with SmartPatch data recordings. A total of 83 sets of multi-channel PPG data were recorded and analyzed to determine the accuracy and precision of Hct measurement.

Results: The RMS measured Hct with root-mean-square error (RMSE) of 2.13 Hct compared to reference values obtained from a Sysmes XN-1000 blood analyzer. The standard deviations for each read on the same patient—with the same device—were computed and averaged, weighted by group size, as a measure of precision. The RMS measured Hct with a mean standard deviation of 1.15 Hct. These error and standard deviation values compare favorably to available point-of-care devices like the HemoCue Hb 201+, which has been reported to measure Hct with a mean of 4.32-4.81 Hct and standard deviation of 1.56-3.88 Hct.

Conclusions: The results of this study illustrate the ability of the wearable SmartPatch to non-invasively measure blood Hct in ESRD patients with AV fistulae, to a degree of accuracy and precision that may outperform available point-of-care methods. This study also demonstrated the efficacy of the end-to-end Remote Monitoring System.

Impact of a Change in Vascular Access Flow Volume After Percutaneous Transluminal Angioplasty on Cardiac Function

Koji Hashimoto, Makoto Harada, Yosuke Yamada, Yuji Kamijo. Shinshu Daigaku Igakubu Fuzoku Byuin, Matsumoto, Japan.

Background: Vascular access (VA) is necessary for patients on hemodialysis, and percutaneous transluminal angioplasty (PTA) is a useful treatment for maintaining VA function. PTA immediately increases the VA flow volume, which can affect cardiac function. We investigated the relationship between changes in VA flow volume and cardiac function in patients who underwent PTA.

Methods: This was a single-center retrospective observational study, including patients who underwent PTA between June 2016 and August 2016. VA flow volume and cardiac function were measured by sonography before and after PTA. The trial was repeated 100 times. Our results in Table 1 indicate that arterial sounds are more informative than venous sounds in detecting stenosis. Note that the integrated model also significantly outperforms the other single-location models.

Conclusions: The results of this study illustrate the ability of the wearable SmartPatch to non-invasively measure blood Hct in ESRD patients with AV fistulae, to a degree of accuracy and precision that may outperform available point-of-care methods. This study also demonstrated the efficacy of the end-to-end Remote Monitoring System.

Predicting Arteriovenous Graft Failure with Sound Signatures in Patients on Hemodialysis

Tiffany W. Shien,1,2 Juan-Wei Xu,1 Yu-Ren Yeh,1 Hugo Y. Lin,1,2 Kaohsiung Municipal United Hospital, Kaohsiung, Taiwan; 2Kaohsiung Medical University, Kaohsiung, Taiwan; National Kaohsiung Normal University - Yanchau Campus, Kaohsiung, Taiwan.

Background: The fast-growing prevalence of end stage renal disease leads to an increasing population requiring dialysis worldwide. Specifically, patients on hemodialysis face the problem of maintaining their vascular accesses. Unfortunately, occurrence of stenosis and clots is not uncommon, especially in arteriovenous grafts (AVG). Graft longevity can be improved by effectively detecting and preventing these circumstances. The aim of this study is to develop a portable recording device that detects stenosis by extracting information from blood flow sounds.

Methods: Blood flow sounds were collected at four different locations on the arm, including venous and arterial ends of arteriovenous access. Measurements were conducted weekly, with four one-minute recordings per patient. A logistic regression model is used to analyze sound data. Recordings obtained prior to percutaneous transluminal angioplasty (PTA) procedures were labeled abnormal and those after PTA were labeled normal. Extracted features from each labeled recording include energy, spectrum, mel-frequency cepstrum, and chroma, as shown in Figure 1.

Results: In total, we have 109 labels, 25 of which are abnormal cases. Note that each case contains 4 separate recordings. For evaluation purposes, we randomly chose 75% of the labels as training cases and used the rest as testing cases. Each random trial compares single-location detection models to one integrated model, which combines data from all four locations. The trial was repeated 100 times. Our results in Table 1 indicate that arterial sounds are more informative than venous sounds in detecting stenosis. Note that the integrated model also significantly outperforms the other single-location models.

Conclusions: Our proposed model shows excellent performance in screening for AVG failure. This algorithm has potential to provide reliable and reproducible detection of vascular access abnormalities, optimizing AVG outcome and management for clinicians and patients.

A Novel Method for Ligation of Accessory Veins: A Case Series of Eight Patients

Khaled Boubes,1 Nabil J. Haddad,1 Anil K. Agarwal.2 1The Ohio State University, Columbus, OH; 2VA Central California Health Care System, Fresno, CA.

Introduction: Accessory veins are a common cause for decreased blood flow through the body of arteriovenous fistulae (AVF). A common practice is to have these ligated surgically through a cut-down procedure. Alternatively, these can be blocked by coiling, embolization, or by percutaneous ligation. We present a case series where accessory veins were ligated percutaneously under direct ultrasound (US) visualization.

Case Description: A total of 8 patients underwent percutaneous accessory vein ligation from Dec 2020 through May 2021. None had any immediate complications. Cessation of blood flow through the accessory vein was confirmed by color doppler ultrasonography and by angiography. Technique description: After identifying the accessory vein on angiography and its impact on the flow through the AVF, the vein is then identified using the US. The location to ligate the vein is then chosen as close as possible to the vein “take-off”. Using a 4-0 absorbable suture and under direct US visualization, the needle is inserted from one side of the vein and passed back through to come out from the other side. Then, the needle is flipped and inserted back subcutaneously, passing above the vein to come out eventually next to the initial insertion site. The suture is then tied firmly. Depending on the size and location of the vein, another suture can be done in a similar fashion a few millimeters away. Color doppler is then used to detect any flow through the vein. Confirmation of the cessation of flow can also be achieved by repeat angiography.

Discussion: Percutaneous ligation of the accessory veins is a technique that saves the patient from undergoing an open surgical intervention. Utilizing the US for direct visualization of the needle during the procedure enhances its safety and efficiency.

Predictors of Vascular Access Thrombosis in Maintenance Dialysis Patients: An Historic Cohort Study

Rita Verissimo,1,2 Luis Leite de sousa,1,3 Tiago J. Carvalho,1,4 Artur P. Mendes,1,2
1DaVita Vascular Access Center - Lisbon, Lisbon, Portugal; 2DaVita Sacavém Hemodialysis Unit, Lisbon, Portugal; 3DaVita Sintra Hemodialysis Unit, Lisbon, Portugal; 4DaVita Cascais Hemodialysis Unit, Lisbon, Portugal.

**Background:** Vascular access (VA) thrombosis is a known complication in patients with end-stage kidney disease on hemodialysis (HD), but its risk factors are not completely established. We performed a study with the aim of ascertaining risk factors for VA thrombosis.

**Methods:** A multicenter retrospective cohort study was performed in three HD units to determine VA thrombosis rate and associated risk factors in maintenance HD patients, from July 2019 to April 2021. Descriptive statistics were calculated and expressed as median (IQR) or count (%). Univariate and multivariate logistic regression was used to calculate the adjusted odds ratio (aOR) with 95% CI for the variables associated with VA thrombosis.

**Results:** From a total of 178 maintenance HD patients, there were 30 (16.9%) VA thrombosis during follow-up. Our cohort had a median of 71 years (61-80), 59.6% (n=106) were male, and on HD for a median of 63.52 months (37.58-98.87), 37.6% (n=67) had diabetes, 66.1% (n=107) cardiovascular disease and 55.6% were on anticoagulant or antplatelet agents. According to the VA, 87.1% (n=155) had arteriovenous fistulas (AVFs) and 28.1% (n=50) had history of previous percutaneous or surgical interventions. When comparing cases that led to thrombosis to VAs that maintained patency, thrombosis was more likely in arteriovenous grafts (AVGs) versus AVFs (60.9% vs 19.3%, p<0.001), in VAs that had previous percutaneous or surgical interventions (34% vs 10.2%, p<0.001), had a VA flow (Qa) slope ≥ 25% or Qa value < 500ml/min, excluding radiocephalic AVFs (30.4% vs 11.7%, <0.001) and those with spkTV < 1.4 (40% vs 11.2%, p<0.001). Multivariate analysis risk factors independently associated with VA thrombosis were AVGs [aOR 13.35 (4.38-40.74), p<0.001], Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs [aOR 5.00 (1.76-14.18), p=0.003], and spkTV < 1.4 [aOR 8.23 (2.90-23.35), p<0.001]. The model had a Nagelkerke R2 of 42.1%, Hosmer-Lemeshow goodness-of-fit test performed well (χ2= 0.215, df=3, p=0.975) and showed very good discriminatory ability [AUROC (95% CI) 0.85 (0.77-0.94)].

**Conclusions:** Our study showed AVGs, Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs, and spkTV < 1.4 were independent predictors of VA thrombosis. Interestingly, patients’ demographic characteristics and comorbidities were not associated with VA thrombosis.

**POI035**

Feasibility of Treating Stenotic Fistula Lesions with a Drug-Coated Balloon Prior to Using a Standard High Pressure Balloon

Sylvester Barnes,1,2 Edward Hines Junior VA Hospital, Hines, IL; 3Loyola University Chicago, Chicago, IL.

**Background:** Hemodialysis access maintenance is a major cost expenditure for dialysis care. Patients often require multiple procedures per year, often treating the same access lesion in a AVF / AVG. A large proportion of stenotic lesions develop secondary to neointimal hyperplasia. Standard treatment has been angioplasty using high pressure non-compliant balloons. Recently drug coated balloons (DCB), coated with the medication paclitaxel, to help decrease neointimal hyperplasia, have been used in dialysis access treatment. The safety profile and efficacy have been proven to decrease lesion reocurrence at 6 months when compared to regular angioplasty. Traditionally the recommendation for use of DCB is to follow after the lesion has been primarily dilated with a high-pressure balloon (HPB).

**Methods:** For DCB use the manufacture recommends pretreatment of the lesion with a HPB followed by secondary DCB treatment. This Arthur decided to modify the technique and treat lesions needing angioplasty with DCB first (example in figure 1) and only secondary treatment with HPB if there was not sufficient resolution of the lesion / balloon inflation to achieve less than 30% residual stenosis. Observational data is being tracked for patients undergoing fistulograms to provide a single center observational prospective cohort to look into this issue.

**Results:** Currently 11 patients with 15 total lesions have undergone this modification of treatment in the past 9 months, with 3 of the 11 patients having repeat fistulograms post treatment. Nine of the 11 patients required no HPB follow up. One of the 11 patients suffered a cephalic arch rupture and required stent graft placement.

**Conclusions:** Early data from this observational study shows that treatment of a stenotic lesion using a DCB as the only treatment is effective in the majority of cases to achieve full lesion angioplasty. Preliminary results indicate no change in long term efficacy in the DCB lesion treatment.

**POI037**

Efficacy and Safety of Plastic Cannulae Compared with Metal Needles in the Initial Use of an Arteriovenous Fistulae in Incident Hemodialysis Patients: A Randomized Controlled Study

Sung gyun Kim, Hoi Woul Lee, Jwa-kyung Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

**Background:** Successful cannulation of an arteriovenous fistula (AVF) is important in patients starting hemodialysis (HD). Metal needles have been used for decades, but the usefulness of plastic cannulae has recently been demonstrated as a new technique.

**Methods:** As a prospective, randomized study, eligible patients were randomized into two groups in a 1:1 ratio (n=45/group). Maturation of the AVF was confirmed using Doppler ultrasound. The primary endpoint was the initial cannulation failure rate, defined as the failure of successful completion of three consecutive dialysis sessions. The secondary endpoints were time for hemostasis at the end of HD, degree of patients’ pain, degree of cannulation difficulty compared to metal needle. However, the patients’ pain score (P<0.004) and nursing staff’s cannulation difficulty score (P>0.084) were higher in the plastic group, emphasizing the great importance of practice using plastic cannulae.

**Conclusions:** The vascular outcomes of plastic cannulae were much favorable compared to metal needles in incident HD patients. The use of plastic cannulae could be a new and innovative way to improve the quality of dialysis.

Alignment Between Patient and Provider Perspectives on Hemodialysis
Vascular Access Decision-Making: A Qualitative Study
Angela R. Schneider,1 Pietro Ravani,1 Kathryn M. King–Shier,1 Robert R. Quinn,1 Jennifer M. MacRae,1 Matthew J. Oliver,2 Swapnil Hiremath,2 Matthew T. James,1 Meghan J. Elliott.1 1University of Calgary, Calgary, AB, Canada; 2University of Ottawa, Ottawa, ON, Canada

Background: Recent updates to the KDOQI Clinical Practice Guideline for Vascular Access emphasize attaining the “right access, in the right patient, at the right time, for the right reason”. Yet, how patients, their caregivers, and healthcare providers integrate medical factors with care preferences in patient-centered vascular access decision making is unknown. We sought to explore the extent to which these diverse perspectives align in hemodialysis vascular access selection.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving maintenance hemodialysis via an arteriovenous fistula or catheter, their informal caregivers, and healthcare providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, thematic analysis approach.

Results: Participants described a decisional hierarchy, whereby decisions regarding vascular access were predicated on upstream decisions (i.e., dialysis initiation, transplantation, home dialysis) that were preference sensitive and prioritized over vascular access type. Upon reaching a decision for hemodialysis, vascular access decision making was influenced by the following: 1) preferences for kidney replacement therapy, including anticipated timeline to transplantation or transition to home dialysis modalities; 2) urgency and timing of dialysis need, where urgent starts undermined expressed preferences; 3) limitations of individualized decisions, as when preferences and practicalities diverged; 4) occasions to re-visit the vascular access selection; and 5) availability of support for vascular access decision making and the decisional outcome.

Conclusions: Although patients and care providers prioritized upstream decisions, several influences on vascular access decision making were identified once the decision for hemodialysis was made. These findings can inform approaches to integrating shared decision making in dialysis and vascular access selection.

PO1039
Vascular Access Selection Among People Receiving Hemodialysis: A Qualitative Study of Shared Decision-Making
Meghan J. Elliott,1 Pietro Ravani,1 Robert R. Quinn,1 Jennifer M. MacRae,1 Shannon Love,1 Matthew J. Oliver,2 Swapnil Hiremath,2 Matthew T. James,1 Kathryn M. King–Shier.1 1University of Calgary, Calgary, AB, Canada; 2University of Ottawa, Ottawa, ON, Canada

Background: The vascular access decision process for people receiving maintenance hemodialysis involves weighing the likelihood of having a functional access with its associated risks. How patient and clinician preferences are integrated alongside best evidence to make joint vascular access decisions is unclear. We aimed to explore how such decisions are made from the perspectives of patients, their caregivers, and their kidney care providers.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving in-centre hemodialysis for ≥3 months via either an arteriovenous fistula or a central venous catheter, their informal caregivers, and their hemodialysis care providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, thematic analysis approach.

Results: Participants described a decisional hierarchy, whereby decisions regarding vascular access were predicated on upstream decisions (i.e., dialysis initiation, transplantation, home dialysis) that were preference sensitive and prioritized over vascular access type. Upon reaching a decision for hemodialysis, vascular access decision making was influenced by the following: 1) preferences for kidney replacement therapy, including anticipated timeline to transplantation or transition to home dialysis modalities; 2) urgency and timing of dialysis need, where urgent starts undermined expressed preferences; 3) limitations of individualized decisions, as when preferences and practicalities diverged; 4) occasions to re-visit the vascular access selection; and 5) availability of support for vascular access decision making and the decisional outcome.

Conclusions: Although patients and care providers prioritized upstream decisions, several influences on vascular access decision making were identified once the decision for hemodialysis was made. These findings can inform approaches to integrating shared decision making in dialysis and vascular access selection.

PO1040
Racial Disparities in Arteriovenous Fistula Use Among Hemodialysis Patients: The Role of Vascular Surgeon Availability
Yi Zhang,1 Mae Thamer,1 Timmy C. Lee,2 Deirda C. Crews,2 Michael Allison.1 1Medical Technology and Practice Patterns Institute, Bethesda, MD; 2The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 3Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Factors contributing to persistent racial disparities in the use of arteriovenous fistulas (AVF) among HD patients are unclear. A recent study reported significant geographic variation in the availability or supply of vascular access (VA) surgeons. We examined whether racial disparity in AVF use is affected by VA surgeon availability.

Methods: Using CROWNWeb and Medicare claims data from the US Renal Data System (USRDS), longitudinal competing risk analyses of all adult outpatients initiating HD with a central venous catheter (CVC) in 2016 and 2017 (n=103,286) were performed. Likelihood of successful AVF use was compared between Black and White patients after adjusting for VA surgeons supply, calculated as the number of surgeons normalized by the number of HD patients in each hospital referral region (HRR).

Results: Patient, facility, and area characteristics varied significantly among different levels of surgeon supply. At month 12 of hemodialysis, 40% of patients who initiated with a CVC had successful AVF use. Compared to the 1st quartile of surgeon supply, higher supply levels were associated with modestly increased likelihood of AVF use: 3% (95% CI 0.4-6.1%), 4% (95% CI 0.7-9.9%), and 3% (0.0-6.1%) for 2nd, 3rd, and 4th quartiles, respectively. However, residing in areas with a greater surgeon availability was not associated with less racial disparity in likelihood of AVF use (Figure 1). Specifically, compared to White patients, Black patients were 10% (95% CI 7 to 13%) and 8% (95% CI 5 to 11%) less likely to have successful AVF use in low and high surgeon supply areas, respectively.

Conclusions: VA surgeon supply was not associated with racial disparities in AVF use among patients initiating with a CVC. Additional studies of patient, provider, practice, and regional factors are needed to identify relevant factors to mitigate lower rates of AVF use among Black HD patients.

PO1041

Feasibility of Creation of an Endovascular Arteriovenous Fistula in Patients Undergoing Preoperative Vascular Mapping

Allahyari, Abhalas, Salam Madi, Ammar Almehmi, Michelle L. Robbins, Michael Allon. The University of Alabama at Birmingham, Birmingham, AL.

Background: The endovascular arteriovenous fistula (endoAVF), a novel percutaneous technique of AVF creation, was approved by the Food and Drug Administration in 2018, and has been placed in a small number of U.S. hemodialysis patients. It is unknown how often patients with advanced chronic kidney disease have vascular anatomy suitable for endoAVF creation. The goal of the present study was to determine the proportion of patients with a vascular anatomy suitable for endoAVF creation, and to assess patient characteristics associated with such suitability.

Methods: All patients referred for vascular access placement at a large academic medical center underwent standardized preoperative sonographic vascular mapping to assess suitability for an AVF. During a two-year period (March 2019 to March 2021), we assessed the suitability of the vessels for creation of an endoAVF. We then compared the demographic characteristics, comorbidities, and vascular mapping measurements between patients who were or were not suitable for an endoAVF.

Results: During the study period, 233 patients had preoperative vascular mapping results suitable for creation of a surgical AVF. Of these, 140 patients (63%) were also suitable for an endoAVF. Patients with a vascular anatomy suitable for an endoAVF were younger (55±15 vs 60±14 years, p=0.01), but similar in sex, race, diabetes, hypertension, coronary artery disease, and peripheral artery disease.

Conclusions: Among patients with chronic kidney disease with vascular anatomy suitable for a surgical AVF, 63% are also suitable for an endoAVF. Older patients are less frequently suitable for an endoAVF.

PO1042

Endovascular Arteriovenous Fistula Closure with Covered Stent Placement

Introduction: WaveLinQ™ endovascular arteriovenous fistula (EndoAVF) system is a new technique that uses radiofrequency energy to create AVF. It has been gaining popularity as it avoids major surgery, has less recovery time and better success rates than surgical AVF creation. Pseudoaneurysm, dissection of brachial artery, intra-procedure brachial artery thrombosis, device embolization, and steal syndrome are described complications of the procedure. We present a case of EndoAVF creation complicated with forearm swelling and its successful management.

Case Description: Patient is a 45 y/o male with End-Stage Renal Disease due to Hypertensive Nephrosclerosis and obstructive uropathy, now s/p failed kidney transplant, currently on Percutaneous Dialysis (PD). PD was failing and decision was made to transition patient to hemodialysis (HD). In preparation of HD, AVF using WaveLinQ EndoAVF system was placed in right forearm between intravenous artery and vein with coiling of the medial brachial vein. A week after fistula creation, patient developed right forearm swelling with numbness and tingling. Fistulogram demonstrated stenosis in the perforator vein with poorly developed cephalic vein and diversion of blood flow to multiple superficial collateral veins in the forearm causing swelling. Multiple attempts at balloon assisted maturation of the cephalic outflow were unsuccessful. Due to persistent forearm swelling with discomfort a decision was made to close the fistula. A 5 x 15 mm self-expanding ViaBahn™ stent was deployed in interosseus vein across the anastomosis to close the fistula. Post fistula closure, arm swelling resolved completely.

Discussion: Covered stents have been used in the maintenance of hemodialysis AVF for various purposes including dialysis access stenosis, central vein stenosis, pseudoaneurysm exclusion and angioplasty associated vascular rupture that cannot be repaired using balloon catheter. This is the first reported case of successful use of covered stent graft to occlude anastomosis to close EndoAVF. As these fistulae are created often, more not complications will be encountered. It will be imperative for interventionists to find creative solutions as well as actively report the successful management of complications.

PO1043

Long-Term Prognosis of Vascular Access in Hemodialysis Patients with Systemic Lupus Erythematosus

Chih-Ching Lin,1,2 Taiwei Veterans General Hospital, Taipei, Taiwan; National Yang Ming Chiao Tung University - Yangmings Campus, Taipei, Taiwan.

Background: Patients with systemic lupus erythematosus (SLE) have a higher risk of vascular complications.

Methods: This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation. This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation.

Results: Totally, 1366 HD patients with SLE had higher incidence rates of AVF/AVG dysfunction than 4098 non-SLE HD patients in the following 4 periods, (1) after 1 year (incidence rates were 15.21% and 13.01% respectively; subdistribution hazard ratio (SHR) = 1.16; P = 0.007), (2) 1st-to-10th-year period (15.36% and 13.25%; SHR = 1.16; P = 0.007), (3) 5th-to-10th-year period (11.91% and 8.1%; SHR = 1.42; P = 0.003), and (4) overall period (23.53% and 21.66%; SHR = 1.09; P = 0.027). There were significantly higher incidence rates of AVF/AVG dysfunction in SLE patients during the long-term follow-up period.

Conclusions: In conclusion, regular surveillance of vascular access function by clinical examination after 1 year, especially during 5 to 10 years, is needed to improve vascular access patency and dialysis adequacy in SLE patients undergoing maintenance hemodialysis.

PO1044

Arteriovenous Access Creation and Re-Intervention Before Starting Hemodialysis

Epiphane E. Kolla,1 Raphael Coscas,3,1 Cécile Couchoud,4 Ziad Massy,2,1 Benedicte Stengel,1 Marie Metzger,1 Natalia Alencar de Pinho,1 Paris-Saclay University, UVSQ, Inserm, Center for Research in Epidemiology and Infection Health, Villejuif, France; Div. Nephrology, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France; Div. Vascular Surgery, Ambroise Paré University Hospital, APHP, Boulogne Billancourt, France; Biomedicine Agency, La Plaine Saint Denis, France.

Background: Arteriovenous fistulae and grafts are preferred to catheters for patients undergoing maintenance hemodialysis. They require early creation to be functional at time of hemodialysis initiation, but may need re-interventions to mature and remain functional.

Methods: Using data from the French REIN Registry linked to the national healthcare system database (Système National des Données de Santé - SNDS), we assessed: A) the timing of first arteriovenous access creation before hemodialysis initiation; B) vascular access re-intervention rates before hemodialysis initiation; and C) the frequency of catheter use at hemodialysis initiation in 43,495 matched incident patients from 2010 through 2015.

Incidence of De Novo Central Vein Stenosis in Hemodialysis Patients Following Their First Tunnneled Central Vein Catheter (CVC) Placement

Alian Albalas, Salam Madi, Ammar Almehmi, Michael Allon. The University of Alabama at Birmingham, Birmingham, AL.

Background: Central vein stenosis is a common complication in hemodialysis patients following tunneled CVC insertion. Little is known about its incidence, association with patient characteristics, or relationship with duration of CVC placement. We systematically evaluated central vein stenosis in hemodialysis patients receiving their first CVC at a large medical center.

Methods: All new hemodialysis patients underwent an ultrasound prior to their internal jugular tunneled CVC placement, to exclude venous stenosis or thrombosis. If they were subsequently referred for CVC exchange, a catheterogram/venogram was performed to assess for hemodynamically significant (≥50%) central vein stenosis. During a five-year period (January 2016 to January 2021), we quantified the incidence of central vein stenosis in patients undergoing CVC exchange. We also evaluated the association of central vein stenosis with patient demographics, comorbidities, and duration of CVC dependence prior to exchange.

Results: During the study period, 273 patients underwent exchange of a tunneled internal jugular vein CVC preceded by a catheterogram/venogram. Of these, hemodynamically significant central vein stenosis was observed in 36 patients (13%). Central vein stenosis was not associated with patient age, sex, race, diabetes, hypertension, coronary artery disease, peripheral artery disease or CVC laterality (Table 1). The frequency of central vein stenosis was progressively higher with greater duration of CVC dependence, being 10%, 12%, 24%, and 28% in patients with <3 months, 3 to 6 months, 6 to 9 months and >9 months of catheter dependence, respectively (p=0.025).

Conclusions: Among incident hemodialysis patients receiving their first tunneled internal jugular CVC, the overall incidence of hemodynamically significant central vein stenosis was 13%. The likelihood of central vein stenosis was directly associated with the duration of CVC dependence.

Hospitalization Risk and Long-Term Complications Associated with Catheter-Related Bloodstream Infection Among Hemodialysis Patients

Krithika Rajagopalan,1 Kenneth Massey,2 Srinivasan Rajagopalan,1 Stephen Imperiale-Hagerman,7 Paul Chew.1 Antikita Inc, Dover, MA; 2Cornedix, Berkeley Heights, MA.

Background: Central venous catheters (CVC) are frequently required for vascular access in hemodialysis (HD) and are commonly associated with catheter-related bloodstream infections (CRBSIs). CRBSIs may have devastating consequences leading to increased hospitalizations, and long-term complications such as stroke, myocardial infarction (MI), heart failure (HF), and endocarditis, among others. This analysis explores the risk of CRBSI-associated hospitalizations and long-term complications among HD patients.

Methods: A 1:1 propensity score matched case-control analysis was conducted using merged data from United States Renal Data System (USRDS), CROWNWeb (dialysis organizations), and Medicare claims database (2013-2017). All CVC-dependent HD patients from 2014-2016 with a 1-year pre- and ≥1-year post-index period were included. CRBSI was defined as a composite measure of its ICD codes or sepsis/bacteremia diagnosis with hospitalization or without occurring pneumonia, gangrene, or urinary tract infections and hospitalization. An assigned index date (i.e., CVC insertion date + median days to CRBSI reported in CRBSI-case group) was used to identify non-CRBSI patients. CRBSI/non-CRBSI group differences were described using frequency, mean, median, chi-square, and t-tests. At 1-year post CRBSI, adjusted differences in hospitalizations and hospital days and time to long-term complications were modeled using generalized linear models or proportional hazard models, respectively.

Results: CRBSIs result in higher 1-year incremental rates of: stroke (6.6%), MI (9.2%), HF (13.4%), PVD (13.6%), and endocarditis (9.4%). Mean number of hospitalizations and hospital days were 3.79 and 25.0 days for CRBSI, and 1.96 and 5.86 days for non-CRBSI patients, respectively. Mean hospitalizations and hospital days were significantly higher for CRBSI vs. non-CRBSI patients (p<0.05) at 1-year post-CRBSI. Hazard ratios for CRBSI patients were: stroke (1.64, 95% CI 1.53-1.75), MI (2.56, 95% CI 2.37-2.78), HF (2.01, 95% CI 1.88-2.14), and endocarditis (13.42, 95% CI 10.97-16.42).

Conclusions: Results show HD patients with CRBSIs incur a significant morbidity burden due to increased hospitalizations, hospital days, and long-term complications such as stroke, MI, HF, PVD, and endocarditis.

Hemorrhagic Shock due to Cutting of the Tunneled Dialysis Catheter

Lucia Bogdan,1 Tushar S. Malavade:2,3 University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; 2Toronto General Hospital, Toronto, ON, Canada.

Introduction: Bleeding is a relatively rare complication of dialysis CVC overall.

Case Description: We describe the case of a 68-year-old non English speaking dementia patient with ESRD on HD. While in hospital, he had tried to cut the tape that was causing itching, but accidentally cut CVC. He was found in shock, bleeding from the exit site, which required aggressive resuscitation and compression to stop bleeding. After stabilisation examination revealed a palpable, well retracted catheter that was not visible (Fig 1). X ray showed the catheter in situ, but the Y along with the arterial and venous ports were absent (Fig 2). In retrospect, bleeding was particularly difficult to control because the cuff at this location is rigid and not compressible. This places the patient at increased risk for exsanguination leading to hemorrhagic shock, air embolism and mortality.

Discussion: To our knowledge, this is the first report of a cut tunnelled CVC proximal to the Y. This case demonstrates the risk of significant hemorrhage when a tunnelled CVC is damaged at this location and need for early recognition and control of bleeding. It also highlights important patient safety considerations given the risk of self-inflicted trauma in patients with dementia and language barrier for communication.

Rare Cause of Pleural Effusion in a Dialysis Patient
Mingyue He, Waqas Ahmad Khan, Iris J. Lee, Ilay Rakhman, Serban Constantinescu. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: The most common causes of pleural effusion in dialysis patients are congestive heart failure, infections, and tumors. However, in some dialysis patients, identifying the rare cause of pleural effusion requires careful consideration.

Case Description: A 35-year-old African American female with ESRD secondary to Lupus Nephritis (LN) s/p deceased donor kidney transplant, developed allograft failure and restarted dialysis. Upon initiating dialysis and weaning of immunosuppression she had episodes of fever, myalgias, synovitis and pleural effusions thought to be manifestations of lupus flare. Despite restarting immunosuppression, she presented frequently with dyspnea and recurrent bilateral transudative pleural effusions requiring repeat thoracenteses. Her physical exam was notable for swelling of bilateral upper extremities and face with minimal lower extremity edema. Lupus serologies were normal. Echo was unrevealing. CT angiogram (CTA) revealed complete occlusion of the distal superior vena cava (SVC) with extensive collateralization in the chest and abdominal wall.

Discussion: Her initial symptoms were attributed to volume overload and lupus serositis. However, inactive serologies, ongoing immunosuppression, and the transudative nature of the effusion were not consistent with lupus flare. Aggressive UF also failed to prevent recurrent pleural effusion. Given CTA and clinical findings, we concluded that the persistent pleural effusion is a manifestation of the SVC syndrome in our patient. The occlusion of the SVC was below the junction of the arch of the azygos vein. Venous blood flow from the upper body and extremities was shunted into the azygos system and flowed counter-current, returning to the right heart through the inferior vena cava. This resulted in increased hydrostatic pressure in the intercostal veins, contributing to the development of edema of the head, upper chest, bilateral upper extremities, and pleural effusions. Our patient had multiple central venous catheters increasing her risk for SVC syndrome. Clinicians should consider SVC stenosis as a potential cause of recurrent pleural effusions in a dialysis patient.

Agitated Saline Bubble-Enhanced Ultrasound to Visualize Appropriated Position of Hemodialysis Catheter: Does Catheter Venous Site Matter?
Gessica Sabrine, Rayra G. Ribeiro, Jorge L. Espinosa Armijos, Lucia Andrade, Igor Smolentzov, Camila E. Rodrigues. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: The hemodialysis non tunneled catheter (HDC) is the most common access of starting renal replacement therapy. Malposition of catheter is associated with delays in treatment. Agitated saline bubble-enhanced ultrasound (SBUS) has become a new method to visualize the HDC position. Delayed appearance of microbubbles (a 2-second) in the right atrium indicates malposition. Our objective is to analyze the accuracy of SBUS between right and left internal jugular vein (IJV) HDC insertion, compared to chest radiography (CR, standard method).

Methods: From December 2019 to May 2021, we evaluated 145 hospitalized patients submitted to HDC insertion in IJV. We compared SBUS with chest radiography (CR); the time spent to perform the CR, complications; patient characteristics; catheter blood flow and quality of dialysis.

Results: Total of 145 patients were analyzed, the median age was 62 years old [50.5-70], and there was no statistical difference between the site of insertion. In RIJV, 91% catheters were placed. AKI was more frequent than CKD (75% vs 25%), except when the site was LJV (46% vs 54%, p = 0.05). AKI-related COVID-19 was the most common etiology (54%). The confirmation of catheter placement by SBUS was correlated with position by CR (All: r = 0.6603, p = 0.0001; RIJV: r = 0.7044, p = 0.0001; LJV: r = 0.6396, p = 0.0769). SBUS was highly accurate in identifying adequate location of HDC, especially in RIJV (All: 97.9%; RIJV: 99.2%; LJV: 84.6%, p = 0.05). The time of the catheter insertion to perform radiography was 191 minutes [83.5-287]. Adequate syringe blood flow and an effective hemodialysis session was more frequent in RIJV catheter (99.2% vs 53.8%, p < 0.05; 96.8% vs 72.7%, p < 0.05, respectively). Complications occurred only in 4.2%, without statistical difference between catheter sites.

Conclusions: Comparing with chest radiography, agitated saline bubble-enhanced ultrasound was more accurate in identifying adequate placement of RIJV than LJV hemodialysis catheters.

Using the Seraph® 100 Microbind® Affinity Blood Filter Under Slow Flow Conditions Through a Normal Central Line
Verónica Andrade, F. Smolentzov, J. Ribeiro, M. Andrade, J. Rodrigues. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: A standard hemoperfusion blood tubing system as well as the Seraph® 100 Microbind® Affinity Blood Filter has been in use since 2019. A normal central line can be used to pump normal saline (n=5) or human plasma (n=5) through the Seraph® 100. Pressures were recorded at any given flows (Qb). In two patients connected to a five lumen 20 cm catheter (Certofox Safety Quito S1220, B. Braun, Melsungen, Germany - 1 x 12 G, 1 x 16 G, 2 x 18 G) blood flow as well as arterial and venous pressure were recorded through the 24 h treatment.

Results: Using saline or human plasma the Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of up to 50 ml/min even through a 16 & 18 G lumen at tolerable arterial and venous pressures. In men using either the 12 G or the 16 G lumen as “arterial line” blood a blood flow rate of 50 ml/min could be obtained for 24 hours without problems.

Conclusions: The Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of 50 ml/min even through 16 & 18 G catheters.
PO1055
Virtual Interviewing in the COVID-19 Era: What Have We Learned?
Koyal Jain,1 Gerald A. Hladik, Prabir Roy-Chaudhury, Pankaj Jawa. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC

Background: The COVID-19 pandemic forced institutions across the US to switch to virtual interviewing. While some institutions were already offering virtual interviews on a limited basis, this was the first time all interviews were conducted using a virtual platform.

Methods: The OSCE allows fellows to practice telemedicine communication skills that will remain relevant post-pandemic. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense or U.S. Government.

Results: Thirty-one candidates completed the survey (39%), although not all questions were answered by everyone. The total number of interviewees increased from 41 in 2019 to 80 in 2020-21. 95% were satisfied with their virtual experience. 82% indicated that the virtual interview process enabled an informed decision about the fellowship program. Everyone was satisfied with the organization of the interview day (N=22). 26% respondents (5/18) identified as underrepresented minority (URM). In 2019-20, 6/41 interviewees identified as URM as compared to 14/80 in 2020-21. Two common reasons for not ranking our program among the top three included limited job opportunities for partners, inability to visit the area, and lack of family in the area. Candidates valued the people they met and were able to get a feel for the program despite virtual interviews. They were particularly satisfied with the opportunity to meet fellows, residents, and faculty.

Conclusions: This is the first report of the virtual interview experience for nephrology fellowship applicants. The virtual interview process increased the applications to our program although the number of URM applications were similar compared to previous years. There was uniform satisfaction with the virtual format and interviewees were able to appreciate the culture of the division. Most applicants found the virtual interview format favorable because of reduced cost and time expenditure, enabling them to interview at more programs. Our data suggest that serious consideration should be given to a virtual format in future years to provide opportunity and flexibility to the applicant pool and improve geographical diversity.

PO1056
“Breaking Bad News” During the COVID-19 Epidemic: A Virtual Objective Structured Clinical Examination (OSCE) for Nephrology Fellows
Maura A. Watson,1 Anna M. Howle,1 Oliver Lenz,2 Ross J. Seales,3 Joshua D. King,4 Jonathan A. Bolanos,5 Christina M. Yuan,5 Nephrology Education Development Consortium1 Walter Reed National Military Medical Center, Bethesda, MD; 2University of Maryland School of Medicine, Baltimore, MD; 3University of Miami School of Medicine, Miami, FL

Background: The “Breaking Bad News” OSCE assesses fellow counselling/communication skills in 20-minute simulation scenarios: kidney replacement therapy (KRT) in ESKD, urgent KRT in AKI, and kidney biopsy. In-person simulation was impractical during the COVID epidemic, so we adapted the OSCE to a virtual platform.

Methods: The AKI scenario was audio only. Fellows called a simulated patient (SP) surrogate for urgent KRT consent. The ESKD and kidney biopsy scenarios were video encounters between fellows and SPs. Faculty observed while muted/video off. After each scenario, fellows received feedback from SPs and faculty (unmuted/video on). Fellows were anonymously surveyed about each scenario, the OSCE overall, and their estimate of the percent of outpatient encounters and inpatient KRT counseling they had done virtually in the past year.

Results: 15 fellows did the OSCE; 14 completed the survey (93% response rate). 93% rated the OSCE overall as a good/very good approximation of a telemedicine experience. 100% were satisfied with the AKI scenario, 79% with the ESKD, and 77% with the kidney biopsy scenarios. Several commented that the AKI scenario was most realistic—they often counseled surrogates by telephone for urgent KRT. Fellows estimated that about 25% (median 27.5%; IQR 16-50%) of counseling for acute inpatient KRT was done virtually in the past year. They estimated about 50% (median 52.5%; IQR 36-70%) of outpatient encounters were done virtually in the past year, but several (dissatisfied with the ESKD and kidney biopsy scenarios) indicated they would not have counseled similar outpatients using telemedicine.

Conclusions: Overall, fellows felt the OSCE well-approximated virtual encounters. All were satisfied with the AKI scenario. The majority were satisfied with the ESKD and kidney biopsy scenarios, but some did not feel they were consistent with normal practice. The OSCE allows fellows to practice telemedicine communication skills that will remain relevant post-pandemic. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense or U.S. Government.

Funding: Other U.S. Government Support

PO1057
Well-Being of Nephrology Fellows: Evolution over the Course of a Pandemic Year
Hitesh H. Shah,1 Kurtis Pivert,2 Susan M. Halbach,1 Anna M. Burgner,4 Benjamin S. Ko,3 Lili Chan,4 Suzanne Boyle,4 Joshua S. Witzman,2 Stephen M. Sozio,1 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 2American Society of Nephrology, Washington, DC; 3Seattle Children’s Hospital, Seattle, WA; 4Vanderbilt University Medical Center, Nashville, TN; 5University of Chicago, Chicago, IL; 6Icahn School of Medicine at Mount Sinai, New York, NY; 7Levis Katz School of Medicine at Temple University, Philadelphia, PA; 8Beth Israel Deaconess Medical Center, Boston, MA; Johns Hopkins University School of Medicine, Baltimore, MD.

Background: We sought to assess changes in well-being of nephrology fellows over the first year of the COVID-19 pandemic in the U.S.

Methods: The Resident Well-Being Index (RWBI), a validated tool assessing physician distress, was distributed as part of ASN’s annual nephrology fellow survey to 920 current adult, pediatric, and adult/pediatric fellows. An RWBI ≥ 5 (range 0–7) indicated distress. Demographic and fellowship factors associated with meeting the distress threshold were evaluated in univariable and multivariable logistic regression.

Results: A total of 511 fellows participated (56% response), of whom 463 completed the RWBI instrument. After 1 year of the COVID-19 pandemic, there were a higher proportion of nephrology fellows meeting the RWBI distress threshold—22% in 2021 versus 15% in 2020. Female nephrology fellows had higher RWBI scores (median 3 [IQR 3-9]) than their male colleagues (median 1 [IQR 1-3]). Higher proportions of 1st-year fellows (50% vs 42% for 2nd years; OR 1.79 [95% CI 1.41-2.28]) and 3rd-year fellows (44% vs 27% for 2nd years; OR 1.79 [95% CI 1.38-2.33]) estimated the distress threshold.

Conclusions: Our follow-up assessment of nephrology fellows’ well-being after the first year of the COVID-19 pandemic indicate the continued need for supportive measures to ensure the health of the future nephrology workforce, especially among 1st year and women trainees.

PO1058
The Battle Between Home Call and Fellows Well-Being

Background: Night call is traditionally taken by nephrology fellows to provide extended after-hour care. Lack of physician wellness and development of burnout are being seen more frequently and may have been enhanced during the COVID-19 pandemic. In an attempt to quantify the burden of call, nephrology fellows at the University of Wisconsin tracked home call activities and aimed to identify areas for improvement.

Conclusions: A total of 511 fellows participated (56% response), of whom 463 completed the RWBI instrument. After 1 year of the COVID-19 pandemic, there were a higher proportion of nephrology fellows meeting the RWBI distress threshold—22% in 2021 versus 15% in 2020. Female nephrology fellows had higher RWBI scores (median 3 [IQR 3-9]) than their male colleagues (median 1 [IQR 1-3]). Higher proportions of 1st-year fellows (50% vs 42% for 2nd years; OR 1.79 [95% CI 1.41-2.28]) and 3rd-year fellows (44% vs 27% for 2nd years; OR 1.79 [95% CI 1.38-2.33]) estimated the distress threshold.

Conclusions: Our follow-up assessment of nephrology fellows’ well-being after the first year of the COVID-19 pandemic indicate the continued need for supportive measures to ensure the health of the future nephrology workforce, especially among 1st year and women trainees.

Figure 1: Association of Distress with Demographic Varaibles on Univariable and Multivariable Logistic Regression

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Each of the 6 nephrology fellows filled out a daily survey between November 9, 2020 and January 31, 2021, which was the peak of the COVID-19 pandemic in Wisconsin to address: 1) the total amount of sleep hours 2) quality of sleep (restful or fragmented) and 3) whether on-call fellow reported to hospital from home. Responses were collected the following morning to decrease recall bias.

Results: Over the 3-month study period, 100% of the call night data was recorded. The average amount of sleep per night was 5.3 hours. When necessary to report, the average hours of sleep dropped to 4.3 hours. However, if not called in, sleep increased to 5.8 hours per night. The percentage of nights requiring patient evaluation by coming to the hospital overnight was 50% during the study period, with a range of 48% of nights in December and 61% in January. Sleep during night call was described as 55% restful vs. 45% fragmented.

Conclusions: This survey has generated discussion amongst fellowship leadership and current fellows regarding novel ways to improve the night call experience to maximize education and clinical experience during training as well as improve fellow wellness. It was determined that the burden of call did not detract from the fellow education enough to warrant a change to a night float system. However, it did identify changes in management processes such as the timing of labs, implementation of dot phrases, and a sleep expert discussion to improve duration and quality of sleep.

Fellows Home Call Data

![Figure 1: Educational Tools Used by Nephrology Fellows in 2016 and 2021 (left) and Percentage 2021 Nephrology Fellows Ranking Tools as Very Effective (right).](image)

Shahid N. Muhammad,1,2 The University of the West of England (UWE), Bristol, United Kingdom; 1 The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, retrospectively, whether there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education. It was determined that the burden of call did not detract from the fellow education enough to warrant a change to a night float system. However, it did identify changes in management processes such as the timing of labs, implementation of dot phrases, and a sleep expert discussion to improve duration and quality of sleep.

PO1060

Nephrology Education Needs Assessment: Five Years and a Pandemic Later

Benjamin S. Ko,1 Rob Rope,2 Kurtis Pivet,1 Anna M. Burgner,3 Joshua S. Waitzman,1 Susan M. Halbach,4 Suzanne Boyle,5 Lili Chan,3 Hitesh H. Shah,3 Stephen M. Sozio,9 University of Chicago, Chicago, IL; 1 American Society of Nephrology, Washington, DC; 2 Oregon Health & Science University, Portland, OR; 3 Beth Israel Deaconess Medical Center, Boston, MA; 4 Vanderbilt University Medical Center, Nashville, TN; 5 Seattle Children’s Hospital, Seattle, WA; 6 Temple University, Philadelphia, PA; 7 Icahn School of Medicine at Mount Sinai, New York, NY; 8 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 9 Johns Hopkins Medicine, Baltimore, MD.

Background: We sought to identify how educational tools utilized in nephrology training had evolved in the past 5 years and through the COVID-19 pandemic.

Methods: Questions about educational tools were distributed as part of ASN’s annual nephrology fellow survey to 920 current adult pediatric fellows.

Results: 511 fellows participated in 2021 (56% response rate), compared with 377 fellows in 2016 (31% response rate). Fellows indicated that UpToDate was still the most used (82%) and most effective educational tool (66% rated it “Very Effective”); however, ASN ASKAP increased in popularity (27% in 2016, 58% in 2021) and was also highly rated (65% Very Effective). Use of online resource and social media increased, including both new opportunities and prior available ones such as NephJC (7% to 32%, with 46% rated Very Effective) (Figure 1). A majority of fellows (84%) rated their education as good or excellent in 2021, a percentage similar to 2016 (81%).

Conclusions: Our follow-up assessment of nephrology fellows’ educational tools found an increase in the adoption of online resources with similar effectiveness ratings as traditional resources.

PO1061

Curriculum-Based Online Education Improves Nephrologists’ Ability to Manage Hyperkalemia in Practice

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if series of online continuing medical education (CME) activities will improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 5 online activities housed on a dedicated collection page. All used repeated pairs pre-/post-assessment study design was used and McNemar’s test (P < .05 is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a McNemar’s test to determine P values. The activities launched between March and October, 2020 and data were collected for up to 12 weeks.

Results: The education reached over 15,000 physicians, including over 1,706 nephrologists. Overall, knowledge improved by 24% (P < .001) and competence by 4% (P<NS) (all relative improvements) by nephrologists. Specific improvements: 40% relative increase in knowledge related to impact of hyperkalemia (P<.001) 31% relative increase in knowledge related to clinical use of potassium binders (P<.001) 24% relative increase in knowledge related to optimizing RAAS inhibitors in patients with hyperkalemia (P<.05) 7% relative increase in competence related to clinical use of potassium binders (P<NS) Of the nephrologists who were included, 30% (P<.001) had a measurable increase in confidence in hyperkalemia management.

Conclusions: This curriculum demonstrates that a curriculum is effective at moving learners on the continuum for knowledge improvements to competence improvements. Some gaps remain after education. Among these learners, 49% need knowledge improvements related to optimizing RAAS inhibitors in patients with hyperkalaemia and 41% related to clinical use of potassium binders. As such, further education needed in these areas.

PO1062

Level of Confidence, Knowledge, and Literacy in Genetics Among US Nephrologists

Background: Increased availability of genetic tests in nephrology and at reduced costs are promising for improved patient diagnostic and clinical care. Nephrologists’ confidence, knowledge and genetic literacy are likely to impact the utilization of genetic testing (GT). Identifying gaps in nephrologists’ knowledge and confidence and preferred methods of learning are needed to develop tailored approaches to improving it.
Methods: An online survey assessing genetic confidence, knowledge, and genetic literacy measured using GeneLiFT, a recognition screening test, was administered between January-May 2021 to nephrologists working in the US (self-identification).

Results: 201 nephrologists completed the survey, 67% working in an academic setting. All clinicians reported treating patients with genetic forms of kidney disease, but only 32% have to date referred ≥20 patients to GT. We observed limited genetic knowledge in 32% of respondents (Table), and 68% did not recognize the word “actionability” as real. Only 20% reported high confidence in all aspects of GT (ordering, discussing risks and benefits, results’ interpretation, and using results to guide clinical care), and high level of confidence was significantly associated with working in an academic setting (p = 2.6x10-10). Preferred methods for continued genetic education were “conferences” (70%), “self-directed methods” (45%) and “workshops” (40%). Methods used were mostly “reading specialty texts” (65%) and “internal specialty seminars and conferences” (55%).

Conclusions: There is a need to improve nephrologists’ genetic literacy, knowledge, and confidence in genetics to ensure broad adoption of genetic testing in nephrology. Employing diverse educational methods will prevent widening the gap between the adoption of genetic testing in different clinical settings.

Funding: NIDDK Support

Mind Map, an Educational Tool for Teaching Clinical Reasoning in Nephrology: A Mixed-Method Study

Aghiles Hamroun,1 Eleonore Lepers,2 Aurélie Dupré,2 Patrick Truffert,1 François Glowacki,1 Centre Hospitalier Universitaire de Lille, Lille, France; Université de Lille Faculté de Médecine, Lille, France.

Background: Nephrology is commonly considered as one of the most complex disciplines for medical students, justifying the implementation of new educational tools. Although its relevance has been well-established, the mind map is still marginally used in medical education. The objective of this study is to assess the contribution of mind map for teaching clinical reasoning in nephrology.

Methods: Between November 2020 and April 2021, three groups of med students (4th to 6th year) were provided with a teaching program of 5 weekly sessions of 30-45 minutes focused on three topics (serum creatinine elevation/AKI, glomerular syndromes, and hypertension). The mind map was employed during the last session of each group at the end of the teaching program. Quiz scores were significantly higher after each teaching session (paired Wilcoxon tests); 2. qualitative assessment: focus group interviews with minutes focused on three topics (serum creatinine elevation/AKI, glomerular syndromes, and confidence in genetics to ensure broad adoption of genetic testing in nephrology (55%).

Methods used were mostly “reading specialty texts” (65%) and “internal specialty seminars and conferences” (55%).

Conclusions: There is a need to improve nephrologists’ genetic literacy, knowledge, and confidence in genetics to ensure broad adoption of genetic testing in nephrology. Employing diverse educational methods will prevent widening the gap between the adoption of genetic testing in different clinical settings.

POI064

Improving the Management of Gout in Patients with CKD or Kidney Transplant: Effect of Online Education

Background: Gout is a chronic condition with a considerable effect on patient health and quality of life. Hyperuricemia and gout are associated with declining renal function. Recent studies have shown that renal dysfunction and kidney transplant are risk factors for gout. A study was conducted to determine if online, segmented education could improve knowledge, competence, and confidence of nephrologists regarding the management of gout in patients with chronic kidney disease (CKD) or kidney transplant (KT).

Methods: Educational design included a 45-minute video activity with slides, segmented into a series of 5 mini-lectures by different faculty covering various aspects of gout in patients with or without CKD and KT. Educational effectiveness was assessed with a repeated-pairs pre-/post-assessment study design with 3 knowledge questions and 1 confidence question, in which each individual served as his/her own control. A chi-squared test assessed statistical significance at the P < .05 level. The activity launched 9/25/2020, with data collected through 12/4/2020.

Results: The analysis set consisted of responses from nephrologists (n=89) who answered all assessment questions during the study period. Analysis of pre-/post-intervention responses demonstrated a significant improvement in overall knowledge; average correct responses increased from 52% pre to 76% post education. Specific areas of improvement include: Treat-to-target strategy with a target of serum UA level < 6 mg/dL in patients taking urate lowering therapy (20% relative improvement, P < .05). Starting low-dose allopurinol in a patient previously diagnosed with gout and stage 3 CKD, presenting with painful subcutaneous tophi (25% relative improvement, P = .01). Recommending pegloticase without dose adjustment for the management of refractory gout in patients with stage 4 or 5 CKD (22% relative improvement, P < .001). Post-education, 48% of nephrologists had a measurable increase in confidence in their ability to manage patients with CKD who may develop gout.

Conclusions: This study demonstrated the success of online, segmented, mini-lectures on improving the evidence-based knowledge, competence, and confidence of nephrologists in appropriately managing gout in patients with CKD or kidney transplant.

POI065

Development and Implementation of an Immune Suppression Toolkit to Guide Nephrology Fellow Medication Prescribing and Monitoring

Lauren Lamic, Panduranga S. Rao, Laura H. Mariani, Andrea L. Oliverio, Julie A. Wright Nunes, Markus Bitzer. University of Michigan, Ann Arbor, MI.

Background: There are many important considerations when prescribing high risk medications like immune suppression (IS). Informed by surveys administered to nephrology faculty and fellows, we developed a training curriculum and a concise, clinically applicable guide for IS prescription and monitoring.

Methods: A cross sectional survey was administered to nephrology faculty and fellows in November 2017 to assess perceptions, self-efficacy, and knowledge about prescribing, monitoring, and adjusting IS (12 questions with item-responses from 1=strongly agree to 4=strongly disagree). Informed by this survey we developed and implemented a toolkit (one-time training curriculum and IS reference guide) for fellows and assessed their perceptions of the toolkit using pre-and post-surveys. Results are reported using mean (SD) or N (%) with associations examined using linear regression.

Results: Twenty-eight nephrology faculty and fellows completed the baseline survey; 19 (68%) were attending physicians and 9 (32%) fellows. Twenty (71%) were men, 16 (59%) Caucasian, 11 (41%) Asian. Collectively, 19 (77%) reported prescribing IS ranging from 1 to 40 times yearly. Attending physicians exhibited higher self-efficacy in prescribing IS (1.7 (0.6) compared to 3.3 (0.8), P = .002) and both attendings and fellows strongly agreed there was a need for IS guides 1.4 (0.8) and would use them if available 1.4 (0.6). In particular, fellows strongly disagreed they understood all steps needed to use
IS (3.3 (0.8) compared to 2.3 (0.7) for attending physicians). In May 2021, 5 nephrology fellows received the IS toolkit and completed the survey. Self-efficacy improved post-intervention from mean (SD) 3.0 (1.2) to 2.2 (1.6). All 5 fellows (100%) strongly agreed that the toolkit added value to training, provided a guide they would use and recommended the toolkit for future fellows.

Conclusions: Nephrology faculty and fellows strongly agreed that there is a need for guidelines and protocols for prescribing and monitoring IS medications. Our pilot IS toolkit incorporated into nephrology fellow training was well received and improved fellow self-efficacy.

PO1066
Quality Improvement Study on Dialysis Education for Residents in an Outpatient Nephrology Clinic
Young C. Hsu, Jonas Kwok, Annika K. Khine, Thanh Cao. University of Southern California, Los Angeles, CA.

Background: In a large safety net hospital outpatient nephrology clinic in Southern California, resident physicians provide a significant proportion of care to patients who have chronic kidney disease (CKD) stages III to V. Many of these patients eventually require initiation of long-term renal replacement therapy (RRT). However, there are many barriers to a timely and safe initiation of RRT in this patient population. One such barrier is a deficiency in education regarding dialysis between residents and patients in nephrology clinic. We attempted to identify barriers of resident education with patients regarding the topic of RRT and assess the effects of our educational intervention. Objectives: 1. Increase resident’s knowledge regarding RRT based on pre and post intervention questionnaire 2. Increase resident’s self-confidence/preparedness/comfort level regarding discussions of RRT 3. Increase the frequency with which residents discuss RRT with patients.

Methods: We created and distributed a pre-assessment survey to all Internal Medicine and Internal Medicine+Pediatric residents at a large teaching hospital and received an approximately 50% response rate. Residents overwhelmingly responded that they do not feel patients have an adequate understanding of dialysis by the time they are deemed to require renal replacement therapy, nor did residents feel that they were adequately prepared or knowledgeable about the nuances of dialysis in order to counsel patients with CKD. We created a short teaching presentation with video reviewing dialysis topics and strategies to approach discussions with patients for residents who rotate through nephrology clinic, after which a post-survey was administered. Results are currently being collected.

Results: Results are currently being collected. We expect resident physicians will demonstrate increased knowledge regarding RRT based on pre- and post-intervention questionnaire, feel more comfortable discussing RRT with patients, and will discuss RRT more often with patients in clinic.

Conclusions: We expect to be able to conclude that resident education is a vital aspect of providing the best care for this underserved patient population, and dialysis at similar teaching centers where residents represent the majority of patient-physician interface in renal subspecialty practice.

PO1067
The Impact of Electronic Sign-Out Dot-Phrase and Simulation Exercises on Inpatient Nephrology Transitions of Care
James D. Alstott,1 Anand K. Ramadorai,2 Sayee Sundar Alagusundaramoorthy,3 Samantha J. Strennen,1 Laura J. Mauserette,1 Gauri Bhatuni.1 1University of Wisconsin-Madison, Madison, WI; 2University of Kentucky, Lexington, KY.

Background: A fellow-led QI project was initiated in 2018 after division surveys indicated a need for change in the ongoing division transitions of care (TOC) practice. Methods: We developed a standardized “sign-out score” to objectively assess TOC on the EMR sign-out. We next developed and implemented a standardized electronic medical record (EMR) dot-phrase as our first QI intervention. Case-based simulation sessions highlighting TOC pearls were conducted as the second QI intervention. Pre- and Post-intervention data for sign-out score was evaluated.

Results: A total of 647 patient EMR sign outs were assessed between 2018-2021. Overall sign-out accuracy score (0-2) significantly improved with QI interventions (pre-intervention mean 0.9 [95% CI: 0.9-1]; N=298) to 1.6 post-dot phrase [1.5-1.6; N=220] to 1.7 post-simulation [1.6-1.8; N=129]; p<0.001. Table 1 provides details on the results of sign-out score. After adjustment for level of training, improvement in overall accuracy was independently associated with both dot-phrase (adjusted odds ratio (aOR) 7.6 [95% CI: 4.9-11.9]; p<0.001) and simulation (aOR 1.88 [1.3-1.6]; p<0.001). Although 2 sign-out score measures which were high performing pre-intervention worsened with dot-phrase implementation: anticipated changes and non-RRT management (aOR 0.15 [0.1-0.23]; p>0.001 and 0.07 [0.02-0.23]; p<0.001, respectively), improvement was seen following simulation (aOR 1.36 [0.84-2.2]; p=0.21 and 4.6 [1.74-14.5]; p=0.002).

Conclusions: A standardized EMR sign out dot-phrase and simulation exercises both improved the overall accuracy of TOC practiced for inpatient Nephrology consult service. The impact of dot-phrase alone on previously high performing TOC measures suggests the need for further optimization of dot-phrase and continuing simulation to enhance provider self-realization of important components of TOC.

Table1: Frequency of best possible “sign-out score” before and after QI interventions

Sign-out score
Pre-intervention (Dot-Phrase)
Post-intervention (Simulation)
Overall 2 sign-out score measures improved from mean (SD) before QI interventions.
- Provider self-realization of important components of TOC.
- Implication for future TOC interventions.

PO1068
Point-of-Care Ultrasound Training for Nephrologists: A National Survey of Nephrology Fellows
Catherine A. Moore,1 Daniel W. Ross,2 W. Charles O’Neill.3 1University of Rochester Medical Center, Rochester, NY; 2Northwell Health, New Hyde Park, NY; 3Emory University, Atlanta, GA.

Background: Despite many potential applications of PoCUS in nephrology, nephrologists have been slow to adopt this technology. The past five years have seen an increase in ultrasound training within nephrology fellowship programs, although the scope of training is unknown. We conducted a national survey of nephrology fellows in United States-based training programs. The main objective of this survey was to identify the current landscape and clinical use of PoCUS in US nephrology training programs.

Methods: We surveyed post-graduate year (PGY) 4-8 trainees in US nephrology fellowship programs. Survey items were included in a broader trainee survey disseminated to all programs by the American Society of Nephrology in April, 2021. The six-item survey instrument probed attitudes toward PoCUS, current use, preferred instruction format, and perceived competence.

Results: Out of 822 US nephrology fellows surveyed, 631 (76.8 %) responded. A majority of respondents were 30-34 years of age with the majority of participants graduating from international medical schools. The majority of fellows (64.6%) indicated interest in PoCUS education, with highest interest in procedural ultrasound and diagnostic kidney imaging. Only 240 (38%) of fellows reported receiving PoCUS education during training. Of the fellows who received PoCUS training, 112 of 227 (49%) reported incorporation of PoCUS at a frequency of less than monthly, with only 62 of 227 (27%) incorporating PoCUS once per week or more. 83 of 226 (36%) fellows reported receiving adequate instruction to independently perform PoCUS, and 74 of 224 (33%) reported that they expect to be competent to independently perform PoCUS by the end of training. Hands-on training, particularly with an instructor, was highly valued as a teaching technique.

Conclusions: Despite high trainee interest in PoCUS, the majority of current nephrology fellows are not receiving training in this domain and do not feel competent to independently perform PoCUS procedures. Hands-on training guided by a skilled instructor is a highly valued PoCUS teaching technique. This survey identifies a need for the development of PoCUS programs within nephrology fellowships that incorporate hands-on teaching techniques.

PO1069
Point-of-Care Ultrasound Education in Nephrology During the COVID-19 Pandemic
Andrew A. Moses,1 Hilda E. Fernandez,1 Columbia University Irving Medical Center, New York, NY.

Background: The COVID-19 pandemic led to changes in the way people taught and learned, with higher reliance on online learning. Unfortunately, point of care ultrasound is a difficult topic to teach without hands-on practice. Here we discuss the implementation of a novel ultrasound curriculum during the COVID-19 pandemic.

Methods: The curriculum was based on published curriculum on point of care ultrasound for the nephrologist, with focus on four fundamental exams: kidney, lung, cardiac, and volume status. We employed a flip the classroom approach with pre-reading and video, a pre-sessional quiz, followed by hands on application of skills. Standardized patients or volunteers would have been used for the hands-on session, but this was eschewed for safety concerns. The fellows and instructors themselves modeled, with proper sanitation and PPE. The hands-on sessions were well received and attended by all fellows. The skills were then applied on the wards.

Results: As the restrictions lifted and vaccines were available, standardized patients were available in small groups. The learners were scheduled for two hour-long sessions with standardized patients, for practice of the skills acquired as well as the Objective structured clinical examination (OSCE). After the first session with all learners, we added a third session focused on OSCEs, as well as line placement as requested by the learners. By the end of the third session, all learners felt more confident in their skills and had passed their OSCEs.

Conclusions: Given the positive reception, this course is planned to continue as curriculum, as well as expanded upon by rising fellows. The use of flipped classroom helped maximize the time of supervised scanning by learners. The use of ultrasound by fellows has risen and will continue to climb with further development of this important curriculum.

Therefore, peer teaching seems to be of value in medical schools also in teaching complex
benefit.

And the course and clinical trial was well received. Over 95% of students presented the
a student peer teacher in our skills lab using similar ultrasound machines. The success
students were split in smaller groups and received a standardized practical training by
a student peer teacher prior to the course for all students (group A and B), half of the
of peer teaching in pediatric ultrasound. Besides a mandatory theoretical training by

The concept of student peer teaching seems to work very well also

Results:

We designed a prospective, randomized trial in a pre-/post-test design
Methods:

Background:

Teaching ultrasound in medical schools has grown in importance over the past years, while pediatric aspects are mainly reserved
for postgraduate education. Student peer teachers take on the task of lecturers at many faculties with promising results in ultrasound education.

Methods:

We designed a prospective, randomized trial in a pre-/post-test design for 274 4th-year medical students in our pediatric classes to investigate the effectiveness of peer teaching in pediatric ultrasound. Besides a mandatory theoretical training by a student peer teacher prior to the course for all students (group A and B), half of the participants received a supporting manual (group B). All students had to measure the right kidney volume of their partners in advance to test pre-existing practical skills and a multiple choice progress test was performed prior and after the course. Afterwards, students were split in smaller groups and received a standardized practical training by a student peer teacher in our skills lab using similar ultrasound machines. The success was examined using an objective structured clinical examination (OSCE) at the end of semester using a pediatric-nephrologic case vignette.

Results:

All students (groups A and B) showed an impressive increase of knowledge and the course and clinical trial was well received. Over 95% of students presented the renal topography sonographically well with no significant differences between both groups. However, we also observed a high interindividual variance in the volumetric results. The use of a supporting pediatric ultrasound manual did not show any significant benefit.

Conclusions:

The concept of student peer teaching seems to work very well also in specific disciplines such as pediatric ultrasound and pediatric nephrology education. Therefore, peer teaching seems to be of value in medical schools also in teaching complex learning contents.

Patient Navigators and Study Coordinators: A Team Approach Towards Patient Support in Decentralized Clinical Trials

Cynthia J. D’Alessandri-Silva,1 Kimberley D. Cranston,2 Anna Klochak,3
1Connecticut Children’s Medical Center, Hartford, CT; 2Advicenne Inc., Ardmore, PA; 3Children’s Hospital Colorado, Aurora, CO.

Background:

COVID-19 related restrictions have accelerated adoption of decentralized clinical trials (DCT). DCTs offer increased patient flexibility via online study platforms, telemedicine and home-based nursing. DCTs reduce travel, hospitalization and in-person interactions, all problematic under COVID. Potential drawbacks exist for both patients and study coordinators, however. In DCTs, removal of study-site visits may leave patients feeling confused, unsafe, disempowered and disengaged, potentially increasing drop-out risk. While DCTs may mean increased enrollment for sites, management of novel patient pathways may prove more time-consuming for study coordinators. Crucial protocol driven events or patient concerns/questions may be missed due to complex patient tracking.

Methods:

The role of the patient navigator (PN) was developed to support both patients and study coordinators in DCTs. PNs will provide culturally-appropriate psychosocial education to ensure patients feel safe, informed, and supported. PNs serve as conduits between the patient and the study site, ensuring bidirectional communication of patient progress. This unique approach is being trialed in ARENA2, a pediatric Phase III study in primary distal renal tubular acidosis, a rare renal disease.

Results:

A multi-lingual team with unique educational and counseling experience was recruited and trained on the protocol and disease. The team will provide weekly check-ins with patients to foster engagement as well as identify any concerns the patient may be having in home healthcare. This role will offer around the clock patient support which will increase accessibility and decrease burden experienced by study coordinators with heavy caseloads. PNs have also developed educational videos in target languages using lay-friendly terminology to ensure patient understanding. Topics include clinical trials, ARENA2 and research in rare diseases. The study website contains additional resources including written articles that help set expectations and provide subjects with strategies for success as they go through ARENA2.

Conclusions:

The concept of sponsor-driven PN team services in DCTs will offer both patients and study sites the added benefits of support.

Do Undergraduates Know “Nephrology”? – A Single-Site Survey of College Students

Julia M. Hopkins,1 Juan Carlos Q. Velez,2 John M. Arthur,3 Michael G. Janesch.3
1College of Charleston, Charleston, SC; 2Ochsner Medical Center - New Orleans, New Orleans, LA; 3University of Arkansas for Medical Sciences, Little Rock, AR.

Background:

Over the past decade, Nephrology has experienced a 43% decline in fellowship applicants. A factor to choosing Nephrology could be a lack of early exposure. While studies have been conducted to explain why residents choose a specific fellowship program, none have surveyed the undergraduate student population to inquire whether the name “Nephrology” was even a recognizable medical specialty compared to other medical specialties. To this end, we conducted a survey of undergraduate students at the College of Charleston (CoC) to test the hypothesis that Nephrology will rank amongst the least recognizable specialties.

Methods:

274 undergraduates at CoC responded to a survey where they were asked to select every medical specialty they recognized by name (15 real specialties/1 fictional). Demographic questions regarding sex, race, collegiate level, high school location, pre-med track, and household income were included. Differences were considered by comparing 95% confidence intervals or Chi-Square test. Spearman-Rank test was used to examine whether the number of applicants per specialty fellowship position was correlated with the proportion of responses.

Results:

Out of 15 medical specialties, Nephrology ranked lowest (29%); whereas, Pediatrics (97%) and Surgery (97%) ranked highest. The fictitious specialty, “diasymptomology” was recognized least (4%). Sex, race, collegiate level, and household income were not different between those students that recognized the word Nephrology versus those that did not. Pre-med students were about twice as likely (p=0.001) to have recognized Nephrology versus non-pre-med students (49% vs. 22%, respectively). There was no correlation between the proportion of undergraduate students who recognized a specific medical specialty and the number of applicants per fellowship position in 2019 (r=0.2, p=0.7).

Conclusions:

Nephrology was the least recognized, non-fictional, specialty amongst undergraduates. Lack of correlation between student responses and fellowship applications, suggest that name recognition alone will not predict fellowship applicant number. The discrepancy between Nephrology and other specialties highlights a gap in name recognition at an early career stage, even amongst premedical students.

The Information Dilemma

Tejas Desai, NOD Analytics, Harrisonburg, NC.

Background: The Internet has changed search. The amount of searchable information is growing as more bytes are added/modified than deleted and the criteria by which search results are obtained has also changed. Results are not exclusively obtained by their relevance to the query. Social media search uses predictive algorithms to display results with which the user is most likely to engage (tweets, likes, replies, clicks). Results that promote engagement are valued more than those pertinent to the query. Known as customized search, this strategy is obvious when 2 individuals make an identical query and receive different search results and in a different order. Customized search protocols increase engagement but at the cost of creating an information dilemma. In this dilemma, each learner is exposed to a different set of facts upon which scientific discussions are started. In order to establish a common set of facts, I created a search engine based on a standard search protocol.

Methods: NephiTwitterArchive.com is a non-commercial search engine that identifies unique users in Nephrology. Nephrology communities. I coded 51 algorithms to identify scientific tweets at 15-minute intervals. Scientific tweets have informative text and a slide, URL to a scientific resource, or both. The engine uses a standard search protocol in which search results are based only on the query. All searches are anonymous. I measured learner-affinity for the engine by number of completed searches. Four elements are required for a single completed search to be recorded: query is made & executed, results are displayed, and a link to the primary scientific tweet is clicked.

Results: From 11/2011 to 4/2021, the engine identified 347142 tweets from 517 NephiTwitter communities. A third of these were scientific tweets. From 10/2019-4/2021, learners completed 28313 searches (monthly median 1368, IQR 1264-1580). From 2019 to 2020, median monthly completed searches changed +12%; from 2020 to 4/2021, a +38% change. Nearly half of all learners used the engine immediately after visiting Twitter or Facebook. 37% voted for the engine directly.

Conclusions: Scientific discourse is valuable if all participants start the conversation with a common set of facts. Social media search tools do not support this goal. A search engine that uses standard search protocol can mitigate the information dilemma and restore search to its primary function of providing results based on query alone.

Understanding Healthcare Education for Nephrology Best Practice – A Question of Which Health Professionals: A Quantitative Investigation

Shahid N. Muhammad,1,2 The University of the West of England (UWE), England UK, Bristol, United Kingdom, The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations.

1) To understand, whether, retrospectively, there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education.

Methods: Group disparagers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice surrounding confidentiality and data protection.

Fourteen (14) top tag topics were applied over 1-month (March and April 2020) between the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support Group (KDARs) for Kids (est.2014) platforms. Two surveys were developed with the same schemes, presented via online for health professionals, and one for CKD patients. Participants only had to complete once.

Results: 19 surveys completed from Health Professionals and 45 completed from CKD patient cohort. Descriptive statistics was used to analyse quantitative data and inform research. Participants only had to complete once.

Conclusions: Online educational modules should complement CKD care, and be delivered by broader Allied Health Professionals. This is the first UK retrospective study that examines clinically relevant educational gaps between online paediatric and adult renal cohorts close to two decades. Education is where healthcare requires investment.

A Survey of Current Trends in Urinary Extracellular Vesicle Research

Uta Endreßberg1, Elena S. Martens-Uzunova2, Alicia Llorente3, Luca Musante1, Charles J. Blijdorp4, Dylan Burger1,2 University of Virginia, Charlottesville, VA; 2 Ottawa Hospital, Ottawa, ON, Canada; 3 Erasmus MC, Rotterdam, Netherlands; 4 Oslo Universitystyyekes, Oslo, Norway.

Background: The Urine Task Force of the International Society of Extracellular Vesicles (ISEV) was created to advocate for best practices in this emerging area of research. In support of this, I present various aspects of a survey, conducted using SurveyMonkey by the Urine Task Force, to better understand current research practices in the study of urinary extracellular vesicles (eUVs).

Methods: We investigated the functional properties of SNVs in NBCe1 using immunoblotting, confocal microscopy, and electrophysiological assays. From NBCe1 data base, we identified 13 SNVs that have not previously been characterized in highly conserved, transmembrane domains of NBCe1-A.

Results: Immunocytochemical analysis revealed that I51F variant was present predominantly in the cytoplasm in HEK293 cells, whereas all other SNVs did not show obvious changes in subcellular distribution. Western blot analysis in HEK293 cells demonstrated that the I51F variant showed impaired glycolysation and a 69% reduction in cell surface levels. To determine the role of Ile51 in more detail, we examined the significance of various mutant variants both in non-polarized HEK293 cells and polarized MDCK cells, which indicated that only I51F substitution resulted in cytoplasmic retention. Moreover, functional analysis using Xenopus oocytes demonstrated that the I51F variant had a significantly reduced activity compared to 39% of that of wild-type variants, whereas any other SNVs and artificial I51I mutations did not show significant changes in activity. Finally, immunofluorescence study in HEK293 cells indicated that the I51F variant retains wild-type NBCe1-A in the cytoplasm.

Conclusions: These data demonstrate that I51F-NBCe1-A shows impaired transport activity predominantly through cytoplasmic retention, and suggest that the variant can have a dominant-negative effect by forming complexes with wild-type NBCe1-A.

Diacidic Motif Is Required for Efficient Transport of NKCC2 to the Plasma Membrane

Datal Bakhos Al Douaibiy,1,3 Elie Seayafan,2 Sylvie Demaretz,2,3 Kamel Laghmani,2,3 Martin Könhöf,7 Inserm, CNRS-ERL8228 Sorbonne Université, Paris, France; 2Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; 3Centre de Recherche des Cordeliers, Paris, France.

Background: Mutations in the apical Na-K-2Cl cotransporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. We have previously demonstrated that BS1 nonsense mutation Y998X, which interferes with the highly conserved diacidic like motifs of NKCC2 C-terminus, compromises NKCC2 surface delivery through ER retention mechanisms. However, whether these diacidic like motifs are sufficient for anterograde trafficking of NKCC2 remained to be determined. Consequently, the aim of the present study was to investigate whether additional motifs are required for NKCC2 efficient transport to the plasma membrane.

Methods: NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 surface expression was assessed by cell surface biotinylation assay. NKCC2 stability and maturation was monitored by cycloheximide chase assay.

Results: Among the motifs identified as ER export signals in ion channels are the diacidic D/E-X-D/E motifs, which have been shown to promote interaction of cargo with the coat complex II (COP2) budding machinery. Interestingly, sequence analysis of NKCC2 C-terminus revealed the presence of two di-acidic motifs, DXXXKQ (motif 1) and DXXXDS (motif 2), located upstream and downstream of BS1 mutation Y998X, respectively. Importantly, mutation of DXXXKQ to AAAAAA disrupted glycolytation and cell surface expression of NKCC2, whereas mutation of DXXXDS had no effect. Cycloheximide chase analysis demonstrated that the absence of the terminally glycosylated form of DXXXKQ was not due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused by increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused due to increased rates of degradation of mutant co-transporters, but was instead caused by defect in maturation. Accordingly, co-immunolocalization experiments showed that DXXXKQ was trapped in the ER. Finally, overexpression of dominant negative mutant of Sar1 GTPase completely abolished NKCC2 maturation, clearly indicating that NKCC2 exit from the ER is COPII dependent.

Conclusions: Our data indicate that in addition to highly conserved diacidic like motif of NKCC2 C-terminus, the cotransporter uses also a di-acidic exit code for export from the ER and targeting to the cell surface. Elucidating the molecular mechanisms of the motif-facilitated ER export may help to develop therapeutic strategies targeting NKCC2 transport from the ER to the cell surface.

Furosemide Alleviates Hypercalciuria and Hypomagnesemia in Claudin 16-Deficient Mice

Natalia Kriuchkova,1,2 Elie Seayafan,2 Sylvie Demaretz,2 Kamel Laghmani,2,3 Martin Könhöf.1,2 Inserm, CNRS-ERL8228 Sorbonne Université, Paris, France; 2Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; 3Centre de Recherche des Cordeliers, Paris, France.

Background: Loss-of-function mutations in the CLDN16 gene encoding for the transcellular reabsorption of Ca2+ and Mg2+ thus compensating for the paracellular Ca2+ excretion without concomitant increase of urinary Mg2+ levels in WT. In contrast, Cldn16-deficient mice responded to the diuretic with a marked reduction of urinary Ca2+ levels and normalization of plasma Mg2+ levels. Evaluation of distal Ca2+ and Mg2+ transport proteins by immunoblotting and immunofluorescence showed furosemide-dependent increase in levels of TRPV5 and calbindin levels in Cldn16-/- kidneys along with signs of hypertheropy of the distal nephron.

Conclusions: The present results suggest that loop diuretics bear potential to alleviate symptoms of Cldn16-deficiency due to compensatory stimulation of electrolyte reabsorption in DCT, CNT, and CCD.

Cholesterol Efflux on Sodium-Sensitive Blood Pressure

Karín C. Oliveira,1,2 Robert L. Repetti,1,3 Rajeev Rohatgi,1,2 Stony Brook University Renaissance School of Medicine, Stony Brook, NY; 3Northport VA Medical Center, Northport, NY.

Background: Na sensitive BP is linked to greater mortality than Na resistant hypertension. Dyslipidemia and changes in plasma membrane (PM) lipid composition contribute to Na sensitivity. In addition, diets enriched in cholesterol (cholesterol) (1) raise cortical collecting duct (CCD) chole, (2) stimulate ENaC, and (3) repress natriuretic factors. Renal ABCA1, a chole efflux protein, increases in chole fed mice to mitigate cellular chool integration. Therefore, we hypothesize renal tubular ABCA1 ablation will lead to Na dependent changes in BP.

Methods: Transgenic mice (TG(TgABCA1/ +/-)) which express CRE recombinase in tubular epithelia when fed doxycycline (dox), were bred with mice expressing floxed ABCA1 to generate a model deficient in tubular ABCA1 (FF). Tail cuff systolic BP (SBP; Visitech) and urine volume after diuretic administration was measured in mice. Immunoblotting was performed on kidney protein lysate.

Results: Immunoblotting of renal pump showed reduced ABCA1 (50±11%; n=6, p<0.05) in FF compared to littermate wildtypes (WTs, 100±7% (n=5) mice. The SBP of FF (n=11) mice was greater immediately post-dox and during chole or high Na feeding (Fig.1; *, p<0.05 vs WT) compared to WTs (n=15). Low Na diet abolished SBP differences between mice, while 6 weeks (W) of 1% chole diet raised the SBP in ABCA1 (FF). Tail cuff systolic BP (SBP; Visitech) and urine volume after diuretic administration was measured in mice. Immunoblotting was performed on kidney protein lysate.

Conclusions: Tubular ABCA1 deficiency stimulates Na dependent SBP which we speculate is related to enhanced Na dependent ENaC and NKCC2 activity.

SBP of FF and WT mice in days (D) and weeks (W) of diet
WNK4 Is a Transducer of V2 Receptor Signaling in the Thick Ascending Limbs and Distal Convoluted Tubules

Hector Carbajal-Contreras,1,2 Adrián R. Murillo-de-Ozores,3,4 German R. Magaña,5,6 Norma H. Vázquez,6,7 Gerardo Gamba,8 María Castañeda-Bueno,9 Molecular Physiology Unit1 Universidad Nacional Autónoma de Mexico, Ciudad de México, Mexico; 2Departamento de Ciencias Médicas y Nutrición Salvador Zubirán, Tlalpan, México.

Background: Vasopressin (AVP) is essential for water and Na+ homeostasis. In the kidney, its actions are mediated by the V2 receptor (V2R), which signals through protein kinase A (PKA). The phosphorylation of the Na+-Cl- cotransporter (NCC) and the Na+-K+-Cl- cotransporter 2 (NKCC2) by the WNK-SPAK signaling pathway upregulates their activity and increases in response to AVP. WNK4 can be regulated by PKA through the phosphorylation of its RRxS motifs in vitro models. Thus, we hypothesized that WNK4 mediates the activation of NCC and NKCC2 in response to AVP.

Methods: We transfected HEK293 cells with NCC2 or the V2R with SPAK and either WNK1, WNK3, WT NCC4 or WNK4 with Aha instead of ser in its 5 RRxS motifs. Cells were stimulated with 30 nM forskolin or 1 mM desmopressin (DDAVP). We cross-bred our WNK4- strain (in a C57BL/6 background) with 129sv mice while selecting for the full-length allele of NCC2 to evaluate the phosphorylation status of NKCC2.

Results: DDAVP stimulation of HEK293 cells with WNK4 or the V2R with SPAK and either WNK1, WNK3, WT NCC4 or WNK4 with Aha instead of ser in its 5 RRxS motifs. Cells were stimulated with 30 nM forskolin or 1 mM desmopressin (DDAVP). We cross-bred our WNK4- strain (in a C57BL/6 background) with 129sv mice while selecting for the full-length allele of NCC2 to evaluate the phosphorylation status of NKCC2.

Conclusions: Our data suggest that WNK4 is a transducer of AVP signaling in the TAL and DCT, modulating NKCC2 and NCC. This might contribute to the anti- kidney osmolality.

Upregulation of NCC by Hypokalemia Involves Additional Mechanisms to Direct Cl- Sensing by WNK4

Adrián R. Murillo-de-Ozores,1 Hector Carbajal-Contreras,1 German R. Magaña,5 Norma H. Vázquez,6 Eric J. Delpierre,7 Gerardo Gamba,8 María Castañeda-Bueno,9 Universidad Nacional Autónoma de Mexico, CDMX, Mexico; 1Humboldt University, Nashville, TN; 2Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, CDMX, Mexico.

Background: Cl- sensitivity of WNK4 kinase plays an important role in the modulation of NCC activity in the distal convoluted tubules. The WNK-SPAK signaling pathway regulates the activity of NCC via the Cl- transporter (NCC) in response to hypokalemia, promoting its phosphorylation. Low plasma [K+] decreases intracellular [Cl-] and this Cl- binding to WNK4's active site, leading to its activation. We have previously shown that hypokalemia and low [K+], increase WNK4 phosphorylation at Ser1196. Hypokalemia also promotes phosphorylation of KLHL3, the substrate adaptor of the Cullin-Ring ligase that regulates WNK1 and WNK4 abundance, as well as phosphorylated SPAK and Slc12a3 mRNA levels. These effects were absent in WNK4-4 animals. In contrast, WNK4- mice did respond to DDAVP. In vivo data from our lab (ASIN 2019-2020) showed that extracellular glucose or fructose increases activity of the WNK4-SKP-NCC pathway via the CaSR. Since glucose reabsorption occurs proximally in the nephron, the distal convoluted tubule (DCT) is negligible. Fructose delivery depends largely on intake. Thus, sugars delivery to DCT could result in NCC activation via CaSR-WNK4-SKP pathway.

Methods: We used wild-type mice treated with vehicle, oral fructose +/- calycic NPS2143, or a single dose of dapagliflozin 1mg/kg ip to induce transient glycosuria +/- NPS2143. Kidneys were extracted after 3 hours to assess activation of the WNK4-SKP-NCC pathway by immunoblotting. To rule out a effect of dapagliflozin in the WNK4-SKP-NCC by angiotensin II, we pre-treated mice with losartan. The response to a thiazide challenge in vehicle, fructose or dapagliflozin treated mice was assessed. Finally, we used an ex vivo Langerhans rat kidney preparation to evaluate the effect of different concentrations of glucose infusion in the renal artery.

Results: In WT mice, we observed increased activity of the WNK4-SKP-NCC pathway in the kidney after exposure to 2% glucose or fructose, or administration of dapagliflozin (p<0.01). These effects were abrogated by NPS2143 (p<0.01) and was not observed in WNK4-KO mice (p<0.001). Additionally, the effect of dapagliflozin was present in mice pre-treated with losartan (p<0.01). Natriuresis induced by a thiazide challenge was significantly higher in vehicle or fructose or dapagliflozin, than in vehicle treated mice, suggesting activation of NCC. Finally, we observed increased NCC and SP phosphorylation by increasing glucose above proximal tubule reabsorption threshold levels to ex vivo rat kidney preparations (p<0.001); notably, this effect was prevented by NPS2143.

Conclusions: Glycosuria or fructosuria increases NCC, SPAK and WNK4 phosphorylation in a CaSR-dependent fashion. Our data thus suggest a calemic-like behavior for sugars in the DCT. This effect may have implications for salt-retention mechanisms induced by disorders of glucose metabolism and increased dietary fructose intake.

Kidney-Specific WNK1 Amplifies NCC Responsiveness to Potassium Imbalance

Cary R. Boyd-Shiwarski,1 Rebecca T. Beacham,1 Shawn E. Griffiths,2 Daniel J. Shiwarski,2 Sophia Knoell,3 Katherine E. Querry,4 Sean D. Stocker,5 Arozen Subramanya,6 University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Carnegie Mellon University, Pittsburgh, PA; 3VA Pittsburgh Healthcare System, Pittsburgh, PA.

Background: The distal convoluted tubule (DCT) NaCl cotransporter NCC is activated by phosphorylation, a process that is potassium (K+)-regulated and dependent on With-No-Lysine (WNK) kinases. KS-WNK1, a kidney-specific WNK1 isoform lacking the kinase domain, controls WNK signaling pathway localization in the DCT. Its role in NCC regulation, however, is unresolved: while early studies proposed that KS-WNK1 functions as an NCC inhibitor, recent work suggests that it activates NCC.

Methods: To evaluate the role of KS-WNK1 on K+-dependent NCC regulation, we studied KS-WNK1 mice across a wide range of plasma K+ (2.0-9.0 mmol/L), induced by dietary maneuvers and diuretic challenges.

Results: K+-restricted KS-WNK1 mice exhibited blunted NCC phosphorylation compared to littermates, indicating that KS-WNK1 activates NCC during K+ deficiency. In contrast, NCC phosphorylation was augmented in K+-loaded KS-WNK1 mice relative to controls, consistent with KS-WNK1-mediating NCC inhibition during hyperkalemia. Focusing on K+-restricted mice: 1) KS-WNK1 mice had mislocalized WNK-SKP-AOSR1 kinase cascade, 2) KS-WNK1 mice had blunted activation of the WNK4-SKP-OSR1 kinase cascade, 3) KS-WNK1 mice had sex-specific alterations to K+ and Ca2+ plasma levels, 4) KS-WNK1 mice had no change to blood pressure, but were less sensitive to thiazide diuretics compared to littermates.

Conclusions: KS-WNK1 has a bimodal effect on NCC, activating NCC during K+ restriction and inhibiting NCC during high K+, thus expanding the inverse relationship between NCC phosphorylation and plasma [K+]. During K+ deprivation, KS-WNK1 facilitates the localization and activation of the WNK4-SKP-OSR1 pathway. Mouse (but not human) KS-WNK1 have sex-specific differences in electrolytes, as well as sex-related resistance. These observations clarify the role of KS-WNK1 on NCC, and identify a novel mechanism that contributes to sexual dimorphism in the mammalian nephron.

High Dietary Potassium Increases Blood Pressure in a Rat Model of CKD

Methods: We treated 12-week-old C57Bl/6 male mice with amiloride at 25mg/L in the drinking water. During treatment, mice were kept on normal chow (0.4% NaCl, 0.8% K+) for 4 days, then switched to low K- diet (0.1% K+), and at the 4th day of low K- diet hydrochlorothiazide (HCTZ, 60 mg/kg/d, in the diet) treatment was started in a subset of mice.

Results: Amiloride-treated mice developed a PHA1-like syndrome (a severe hyperkalemic, salt losing nephropathy, with marked hypotension). Hyperkalemia and hypotension were prevented by low K- diet. Basal blood pressure levels were re-established by day 4 on low K- diet, while further treatment with HCTZ produced a steep drop in the blood pressure of these animals. Immunoblot analysis of kidney lysates from amiloride-treated mice showed decreased expression of NCC and pNCC that were reversed by low K- diet.

Conclusions: We show that the salt losing hyperkalemic phenotype induced by amiloride can be fully recovered by low K- diet and that this recovery is mediated by the increased activity of NCC.

PO1088
SALL3 Is a Salt-Response Distal Convoluted Tubule-Specific Transcription Factor Induced in Distal Neprhon Remodeling

Methods: Mice were genetically engineered to constitutively activate the SPAK kinase (CA-SPAK) in the DCT, causing constitutive NCC activation, and DCT hypersecretory and hyperplastic phenotypes. Histology, DNA microarray and real-time RT-PCR, revealed up-regulation of genes related to electrogenic sodium transport, and Sall3 expression was significantly increased in the CA-SPAK mice.

Results: 10 TFs were identified with DCT-specific expression patterns and are highly expressed in the distal nephron. Network analysis revealed that Sall3 interacts with eight of the other induced TFs (Emx1, Hoxd9, Hoxd10, Tfpap2, Tfpap1, Tsc2d2, Sall3 and Zip467) that are significantly induced in DCT of the CA-SPAK mice with high salt diet. Among 10 TF candidates, Sall3 interacts with eight of the other induced TFs (Emx1, Hoxd10, Tfpap2, Hoxd9, Hoxd8, Camt1, Tfpap2b and Zip467). Microscopy confirmed Sall3 is specifically expressed in DCT cells, where it localizes predominately to the nucleus and is significantly increased in the CA-SPAK mice, and increased further upon dietary salt loading.

Conclusions: In summary, Sall3 is the predominate DCT-specific TF that is activated during DCT expansion, suggesting that it is a key component of the core transcriptional regulatory circuit maintaining DCT cell identity as the DCT expands.

PO1087
Rescuing Low Blood Pressure in Amiloride-Treated Mice by Low-Potassium Diet Relies on NCC Activation

Methods: To explore the role of Gq-coupledGPCRs along the DCT, we bred DCT-DREADD mice. We verified the localization of the Gq DREADD protein using immunohistochemistry. We then activated Gq signaling in DCT cells with i.p. injection of DREADD-specific agonist deschlorolucizine (DCZ) and determined the abundance of phosphorylated NCC by Western blot. Lastly, we measured sodium excretion in metabolic cages for 4 hours following DCZ administration in WT compared to TgDREADD mice.

Results: We found that the Gq-DREADD protein was specifically expressed within the basolateral membrane of the DCT (Figure A). DCZ injection caused rapid dephosphorylation of NCC within 30 minutes to 15% of the abundance observed in DCT-
DREADD mice not treated with DCZ. (Figure B, 100 ± 15 vs. 15 ± 3, t-test: p<0.001). Injection of DCZ increased sodium excretion (UNaV) by 215% in DCT-DREADD mice compared to wildtype controls (Figure C, 100 ± 13 vs. 215 ± 24, t-test: p<0.001).

Conclusions: We conclude that chemogenetic activation of the DCT enhances sodium excretion through rapid phosphorylation of NCC. These findings support a role for Gαq GPCR-mediated regulation of NCC. The DCT-DREADD mouse is a novel model for exploring the molecular mechanisms that underlie the regulation of NCC activity by sodium excretion through rapid dephosphorylation of NCC. These findings support a role for Gαq GPCR-mediated regulation of NCC.

Mechanistic Importance of Reduced KLHL3 and CUL3 Expression in CUL3-A9-Mediated Familial Hyperkalemic Hypertension
Yujiro Maeda, Mohammed Z. Ferdaus, Avika Sharma, Ryan J. Cornelius, Xiao-Tong Su, Joshua A. Robertson, Susan B. Gurley, David H. Ellison, James A. McCormick. Oregon Health & Science University, Portland, OR.

Background: Mutations in the ubiquitin ligase scaffold protein Cul3 (CUL3) cause the disease familial hyperkalemic hypertension (FHH). In the kidney, the mutant CUL3-ΔKLHL3 combined with C99p signals loss of ubiquitin JAB1 that negatively regulates CUL3 activity. This leads to CUL3-A9 autodegradation, and increased abundance of With-No-Lysine [K] Kinase 4 (WNK4), which inappropriately activates the downstream kinase SPAK, which then phosphorylates and hyperactivates the Na+-CITcotransporter (NCC). We showed lower that CUL3 alone does not increase WNK4, so the precise mechanism by which CUL3-A9 causes the disease familial hyperkalemic hypertension (FHH). In the kidney, mutant CUL3-ΔKLHL3 and reduced CUL3 in CUL3-ΔKHL3 the CUL3 substrate adaptor for WNK4; thus reduced abundance of KLHL3 combined with reduced CUL3 are mechanistically important in CUL3-A9-mediated FHH.

Methods: We studied CUL3 KO (CUL3−/−) mice, CUL3 KO mice expressing CUL3-A9 (CUL3−/−A9), CUL3 heterozygotes expressing CUL3-A9 (CUL3−/+A9), compound C99p and KLHL3 heterozygotes (CUL3−/−KLHL3+/−), and Jabi 1 (Jabi−/−) mice. All mouse lines were inducible and renal tubule-specific.

Results: CUL3-A9 did not promote degradation of CUL3 targets that accumulate in CUL3−/− kidney: WNK4, cyclin E, or NQO1 (a surrogate for the CUL3 substrate Nrf2).

Conclusions: Together, these data provide evidence for a mechanism of reduced KLHL3 and reduced CUL3 in CUL3-ΔKLHL3-FHH. CUL3-Δ9 potently degrades KLHL3, but also exerts modest effects on other CUL3 targets, raising the possibility of undefined renal phenotypes in the human disease.

Non-Reabsorbable Anions Enhance Potassium Excretion by Multiple Mechanisms
Lama Al-Ousairi,1 Paul R. Grimm,1 Trauyen D Pham,2 Ava Zapt,3 Delaney C. Abood,2 Susan M. Wall,1 Paul A. Wellings,1 Johns Hopkins Medicine, Baltimore, MD; 2Emory University School of Medicine, Atlanta, GA; 3University of Maryland Baltimore, Baltimore, MD.

Background: Potassium (K+) secretion in the distal nephron (DN) is governed, in part, by the lumenergic-transsellar epithepial potential (Vie), created by ENaC-mediated sodium reabsorption, and partially attenuated by paracellular chloride (KCl:5%K +362 J Am Soc Nephrol 32: 2021 Membrane and cytoplasmic proteins were extracted from kidneys for immunoblot localization; Pendrin decreased with the high KCl diet but increased in the high HKCO3 diet. The high HKCO3 diet also uniquely induced a remodeling of the intercalated cells in the late DCT and CNT, whereby the number of pendrin-positive cells increased without change in principal cells. Pendrin-KO mice excrete the high dietary HKCO3 lead to the same extent as WT mice but develop metabolic alkalosis.

Conclusions: In summary, NRA stimulates potassium excretion beyond a Vte effect. By increasing apical membrane ROMK and Pendrin expression, and remodeling the DN, mice increase the capacity to adapt to alkaline-ash rich diets, preventing hyperkalemia and alkalosis.

PO1092
The Effect of Epidermal Growth Factor Inhibition on Distal Nephron Sodium Reabsorption in Mice
Keyona N. King,1,2 Robert S. Hoover,1,3 Emory University School of Medicine, Atlanta, GA; 1VA Medical Center Atlanta, Decatur, GA; 3Emory University School of Medicine, New Orleans, LA.

Background: Studies have shown that the epidermal growth factor (EGF) decreases the activity of ENaC while the influence of EGFR on renal Na+ transport via NCC is unknown. Previous investigations in mDCT-15 cells showed that EGF increases endocytosis of NCC. Using radio-telemetry, we found that EGF inhibition increases systolic blood pressure in response to increasing the dietary Na+ intake. Our results in consolidation with other researchers, suggest that EGF affects BP by influencing the activity of ENaC and NCC. Our goal is to determine whether EGF inhibition increases BP via alterations in Na+ reabsorption.

Methods: Using metabolic cages, we collected urine samples at three time points over 24 hours in 7 week old male mice. Normal salt (LS) diet (0.4% Na chow) was given for baseline collections and high salt (HS) diet (4% Na chow) for experimental collections. Only the experimental (E) group, n=4 received gefitinib (an EGF receptor tyrosine kinase inhibitor) orally at 100 mg/kg/day and the control (C) group received placebo. Hydrochlorothiazide (HCTZ) 2.4 mg per 10g BW orally and amiloride 1.45 g/kg via IP injection were administered. Following a washout period, HCTZ and amiloride were given simultaneously to assess the total effect on NCC and ENaC.

Results: There was no difference in the average urinary Na+ excretion over 24 hours for baseline measurements between the groups when receiving the LS diet (experimental E group: 105 ± 13 mmol vs. control C group: 82 ± 23 mmol, N.S.). However, when giving the HS diet and HCTZ, the E group had a higher average urinary Na+ excretion (E group: 243 ± 34 mmol vs. C group: 15 vs. 15 24, t-test: p<.001). When giving both HCTZ and amiloride to the mice while receiving the HS diet, the E group had a substantially higher urinary Na+ excretion compared to the C group (E group: 997 ± 66 vs. C group: 777 ± 48 mmol, p<0.05).

Conclusions: Therefore, our data suggests that inhibition of EGF increases Na+ reabsorption via NCC. As previously suggested, this may indicate that EGF ligands act as tonic inhibitors of NCC tubular sodium reabsorption. Future experiments will explore in the vivo effects of EGF receptor inhibition on sodium excretion along other components of the nephron.

Role of mTORC2/SGK1 Signaling in Rapid Response to Acute K Load to Maintain K+ Homeostasis
Bidisha Saha,1 Waheed Shabbir,2 Enzo Takagi,1 John E. Demko,1 Mads V. Sorensen,1 Deise C. Leite-Dellova,1,2 David Pearce,1 University of California San Francisco, San Francisco, CA; 2Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil; 3Aarhus Universitet, Aarhus, Denmark.

Background: The kinase mTORC2 phosphorylates SGK1 and is required for normal K+ secretion in the aldosterone-sensitive distal nephron. Aldosterone is known to play a role in mediating a sustained response through effects on SGK1 gene transcription, however, it is unknown how rapid responses are mediated. Here we have explored the role of mTORC2 and ENaC activity in the early response to an acute K+ load to regulate K+ secretion.

Methods: Inducible tubule-specific Rictor (a core component of mTORC2) knockout mice (TRKO) were generated (Pax8−/−RTA/LC-1/Rictorflox/flox). Both WT and TRKO mice received control or 2% KCl via gavage following intraperitoneal vehicle or EGF (100 mg/kg) injection (or placebo). Hydrochlorothiazide (HCTZ) 2.4 mg per 10g BW orally and amiloride 1.45 g/kg via IP injection were administered. Following a washout period, HCTZ and amiloride were given simultaneously to assess the total effect on NCC and ENaC.

Results: Adult TRKO mice on normal diet displayed no abnormality except Adult TRKO mice on normal diet displayed no abnormality except significantly elevated aldosterone. K+ secretion by DCT was markedly greater in the high KCl diet compared to the high HKCO3 diet. The high HKCO3 diet also uniquely induced a remodeling of the intercalated cells in the late DCT and CNT, whereby the number of pendrin-positive cells increased without change in principal cells. Pendrin-KO mice excrete the high dietary HKCO3 lead to the same extent as WT mice but develop metabolic alkalosis.

Conclusions: In summary, NRA stimulates potassium excretion beyond a Vte effect. By increasing apical membrane ROMK and Pendrin expression, and remodeling the DN, mice increase the capacity to adapt to alkaline-ash rich diets, preventing hyperkalemia and alkalosis.

Underline represents presenting author.
ENaC-dependent K⁺ secretion in WT, and that this response is defective in TRKO. Patch clamp measurements demonstrated increased ENaC activity in WT but not in TRKO mice, and no change in ROMK activity in WT or TRKO by KC1 gagave. Membrane expression of cleaved α- and γENaC were significantly increased in WT but not in TRKO mice receiving KC1 gagave. No significant increase in membrane expression of ROMK was observed in WT or TRKO gagave. Finally, both SGK1 and Nedd2-2 phosphorylation were increased in WT but not TRKO mice receiving KC1 gagave.

Conclusions: Overall, the data strongly suggest that an acute K⁺ load acts through mTORC2/SGK1 to rapidly stimulate ENaC but not ROMK to promote K⁺ secretion. These effects are primarily due to local renal tubular K⁺ sensing.

Structural Determinants of mTORC2 Substrate Specificity and SGK1 Phosphorylation Revealed by Cryogenic Electron Microscopy

Junliang Chen, 1 Zanlin Yu, 2 Feng Wang, 2 Xi Liu, 2 Enzo Takagi, 1 Lydia-Marie Joubert, 1 Mingliang Jin, 2 Carlos Nowotny, 2 David Agard, 1 Yifan Cheng, 2 David Pearce. 2 SinoUnited Health, Shanghai, China; 1University of California San Francisco, San Francisco, CA; 2Stanford University, Stanford, CA.

Background: mTORC2 is a multi-subunit kinase complex central to multiple essential signaling pathways. Notably, it responds to hormonal signals and local electrolyte concentrations to phosphorylate SGK1 and regulate K⁺ secretion in the renal tubules. Two core subunits, Rictor and mSin1 distinguish mTORC2 from its much better characterized relative, mTORC1. Two other subunits, mTOR itself and a small scaffold, mLST8, complete the core complex. Previous mTORC2 reconstructions have lacked key regions of the > 1 MDA complex, particularly determinants of specificity.

Methods: Core mTORC2 subunits were expressed in Exp293F cells and purified using new methods for on grid purification. cryo-EM was performed using Krios at SLAC for high energy electrons for density maps of human mTORC2. Structures were solved for apo-complex at overall 3.23 Å resolution, and for co-complexes with substrates, SGK1 and mSin1 at 3.38 and 3.44 Å, respectively.

Results: The apo-complex reveals architectural features of functionally important domains, including specific side chain positions and interactions, which are visualized for the first time. In particular Rictor/Ser-1624 and Ser-1625 were observed to engage the role mTORC2 plays in renal electrolyte handling, in the co-complex structure with substrates, SGK1 and mSin1, and not with the Akt co-complex. This Author reads into ENaC's γ subunit's furin cleavage site (RKRK 143 to QQQQ 143, or “Q4”) to reduce ENaC γ subunit and two shorter proteins, consistent with reduced renal tubular ENaC activity, such as attenuated ability to function in many individual cells within the split-opened area. However, it is not possible to specifically change the driving force for Cl⁻ at luminal or basolateral sides, which is used to function and study in PCs and ICs types of certain cells on periphery.

Conclusions: These findings provide new structural insight into mTORC2 specificity and context-dependent activities, and foundation for further mechanistic studies. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

PO1095

In Vivo Influence of a Protease-Resistant Epithelial Sodium Channel Gamma Subunit on Fluid Homeostasis

Background: Extracellular fluid depletion promotes proteolytic processing of ENaC’s γ subunit. Removal of the subunit’s inhibitory tract enhances channel open probability. Although several cleavage sites exist distal to the γ subunit’s inhibitory tract, only one known site resides proximal to the inhibitory tract: a furin cleavage site (RKKR 143). We hypothesized that a mouse expressing a protease-resistant ENaC γ subunit would exhibit significant differences in renal electrolyte handling, including in the co-complex structure with SGK1—but not the Akt co-complex, we see a marked change in the conformation of the mSin1 N-terminal extended strand in a manner consistent with previous functional data identifying this region as required for phosphorylation of SGK1, but not Akt, thus providing a structural basis for differential regulation.

Conclusions: These findings provide new structural insight into mTORC2 specificity and context-dependent activities, and foundation for further mechanistic studies. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

New Method to Discriminate Function of A and B Type of Intercalated Cells in Split-Opened Collecting Ducts

Naghmeh Hassanzadeh Khavvat, Victor N. Tomlin, Kyrilo Pyrshiev, Oleg L. Zaika, Oleh Pochynuk. The University of Texas Health Science Center at Houston, Houston, TX.

Background: The collecting duct (CD) is a highly adaptive terminal part of the nephron that is essential for homeostasis. Electricaly uncoupled principal and intercalated cells (PCs and ICs) perform different physiologic tasks and exhibit rather distinctive morphology. However, acid-secreting A- and basic secreting B-type of ICs cannot be easily separated in functional studies despite virtually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether differences in renal sodium handling are carried in the CD. The technique of split-opening isolated CD allows unambiguous monitoring of alterations in function in many individual cells within the split-opened area. However, it is not possible to specifically change the driving force for Cl⁻ at luminal or basolateral sides, which is used to function and study in PCs and ICs types of certain cells on periphery.

Methods: We used BACEF-Sensitive intercalated cell (pH) measurements in split-opened CDs followed by immunofluorescent (IF) detection of AQP2 and pendrin from the collecting duct. The technique of split-opening isolated CD allows unambiguous monitoring of alterations in function in many individual cells within the split-opened area. However, it is not possible to specifically change the driving force for Cl⁻ at luminal or basolateral sides, which is used to function and study in PCs and ICs types of certain cells on periphery.

Results: Expression of the protease resistant in oxytes, along with ENaC (N = 15), increased amiloride-sensitive currents, compared to oxytes with ENaC but no prostatin (N = 15; p < 0.0001). In oxytes expressing a Q4 gamma subunit (N = 15), prostatin no longer increased currents (N = 15). Western blot of PNSase-digested tissue lysates revealed a full-length (60 kDa) γ subunit and two shorter proteins, consistent with subunits either cleaved at the furin site (~53 kDa) or at a more distal site. Tissues from Q4 mice lacked the 53 kDa band, suggesting impaired Furin site cleavage. Blood K⁺ was normal in Q4 mice (N ≥ 7 for each sex and genotype). On a LSD, Q4 male mice exhibited greater loss of body than control males (p > 0.04; N = 6–7), but females exhibited no difference in body weight (N = 7–8).

Conclusions: These findings support a role for proteolytic activation of ENaC in male mice maintaining total body fluid in response to dietary Na depletion. Females did not show a impaired body fluid retention, suggesting additional compensatory mechanisms.

PO1096

A Rare Case of Acquired 11-Beta-Hydroxysteroid Dehydrogenase Deficiency

Khaled Elharraf, 1, 2 Nidal Alhosainat, 3 Mica Alex, 2 Petersen Greti, 1 Hania Kassem. 2 Kern Medical Center, Bakersfield, CA; 3The University of Texas Medical Branch at Galveston, Galveston, TX.

Introduction: 11-Beta Hydroxysteroid Dehydrogenase (HSD11B) is an enzyme that is involved in steroid hormone physiology. HSD11B enzyme exists in two isoforms, HSD11B-type 1 and type 2. Type 2 isozyme is responsible for converting cortisol to inactive cortisone. Plasma concentration of cortisol is approximately 100-fold higher than aldosterone and activation of mineralocorticoid receptors by cortisol is normally limited due to its conversion to inactive cortisone at the sites of aldosterone action by the enzyme HSD11B-type 2. We are presenting a rare case of HSD11B deficiency in a patient taking herbal supplementation.

Case Description: A 73-year-old female with PMH of hypertension, hyperepididymis and chronic pain was admitted to the hospital with fatigue and shortness of breath. She denied any history of diarrhea or recent use of diuretics or laxatives. She has a history of using some herbal supplements in large quantities for pain control. Initial blood pressure was 140/80 mmHg. EKG showed sinus bradycardia with PVCs and bigeminy. The lab results are summarized in table A. She received aggressive potassium supplementation and spironolactone with subsequent improvement of her condition.

Discussion: HSD11B deficiency is either congenital or acquired by ingestion of licorice or its derivatives (glycyrrhizic and glycyrrhetinic acids). The deficiency results in a decreased conversion to cortisone and accumulation of cortisol. The effect of cortisol on the mineralocorticoid receptor results in hypokalemia, metabolic alkalosis, and low aldosterone and renin activity. The diagnosis requires careful history and identification of specific clinical features and biochemical abnormalities.
Results: We show that CIC-K2-C1-channel is exclusively expressed on the basolateral side of C1-like CIC-K2 profiles. Permeability to Cl-dependent H+ /HCO3- transport. Indeed, CIC-K2 blocker, NPPB, had no effect on pH in PCs, whereas it caused acidification or alkalization in different subpopulations of ICs in WT but not CIC-K2/- mice. If assay of the same CDs revealed that NPPB decreased pH in pendrin-positive B-type of ICs. Induction of metabolic acidosis markedly increased A/B cell ratio from 74% to 145%. Furthermore, dietary acidification also resulted in significantly augmented H+ secretion (assessed as recovery after acidification) in A-type and decreased pH transport in B-type of ICs.

Discussion: Despite being extremely rare, metabolic acidosis induced by drug interaction occurred between Paracetamol and Fluoxacinil is a severe and potentially life-threatening disorder. We recognize the relevance of this case since these drugs are commonly prescribed together.

Dietary Ammonium Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux

Jeffrey M. Purkerson, George J. Schwartz. University of Rochester Medical Center, Rochester, NY.

Background: In a mouse model of urinary tract infection with Uropathogenic E. Coli (UPEC-UTI) dietary NH4Cl (AC) induces metabolic acidosis and increases UPEC burden in reflux prone C3H/HeN mice but not Tlr4 deficient, C3H/HeJ mice. We have confirmed and extended these studies by comparing the inflammatory response in C3H/HeN mice fed AC-diet vs. standard chow (SC), and by examining the effect of HCl-acidosis.

Methods: Female C3H/HeN mice were fed: standard chow (SC), NH4Cl (2% w/w), or 1g/ml 0.4 N H Cl supplemented chow (HC-l-Acid-base was assessed and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol 4,5-bisphosphate (PIP2) in the transcellular pathway. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in M. Satlin.1

Results: Consistent with higher UPEC burden in bladder and kidney and increased chemokine/cytokine production, Ly6G+ kidney neutrophil infiltration, phagocytosis, phagocytosis, and oxidative burst were unaffected by dietary ammonium. HCl-acidosis (g[H+]<3.1; HCl-A=16.3±0.1 vs. SC-23.2±0.6; N=4; p<0.01) did not increase UPEC burden (Kidney cfu/g: SC: 4E±3E+23 vs. HCl-A: 2E±3E+82, p<0.05) indicating that acidosis per se does not impair UPEC-UTI clearance. Purkerson et al. (2020) Physiol.Rev. 8(19e14525.

Methods: Dietary ammonium chloride impairs clearance of UPEC-UTI and exacerbates pyelonephritis. The effect of dietary ammonium is unrelated to acidosis and neutrophil function.

Molecular Insights into the Structural and Dynamical Changes of Calcium Channel TRPV6 Induced by Its Interaction with Phosphatidylidyinositol 4,5-Bisphosphate

Liang Zhao,1 Li-Juan Wang,1 Ruiqi Li,1 Xing-Zhen Chen,2 J-Bin Peng,1 1Division of Nephrology, Department of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL; 2Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada.

Background: Transient receptor potential vanilloid subfamily member 6 (TRPV6) is a Ca2+-selective channel that mediates Ca2+ entry into epithelial cells as the first step of the transcellular Ca2+ transport pathway. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol 4,5-bisphosphate (PIP2); however, it is less clear how PIP2 activates TRPV6 at the molecular level.

Methods: Recently, a structure of rabbit TRPV5 in complex with diacytanol (diC8) PIP2, a soluble form of PIP2, was determined by cryo-electron microscopy. Based on this structure, a structural model of human TRPV6 with PIP2 bound to the transmembrane domain of the channel was made. The authors studied the interaction of TRPV6 with PIP2 using molecular dynamics simulations.

Results: Interaction energy analyses show that phosphatidylinositol 4,5-bisphosphate (PIP2) interacts with TRPV6. The binding of PIP2 to TRPV6 increases the distance between the diagonally opposed residues D542 in the selectivity filter as well as the distance between the diagonally opposed residues M578 in the lower gate. Secondary structure and density analyses show that residue M578 in TRPV6 in the presence of PIP2 undergoes structural and position changes, suggesting the opening of the lower gate.

Discussion: Principal component analysis also indicates that the binding of PIP2 increases the dynamic motion of both the selectivity filter and the lower gate of TRPV6.
Conclusions: Simulation results indicate that PIP increases the fluctuation of the key residue S471 in the K1-subunit. The decrease in the TRPV6 channel reduces the helix occupancy of a key residue in the lower gate. Furthermore, the diameters of both the selectivity filter and the lower gate are increased by PIP. These changes likely contribute to the opening of the TRPV6 channel.

Lithium Treatment Induces Changes in E-Cadherin, β-Catenin, and Na+/K+-ATPase β1 in Rat Inner Medullary Collecting Duct in a Time-Dependent Manner
Xavier Sartorelli, Jeppe Praetorius, Birgitte M. Christensen, Aarhus University Institut for Biomedicin, Aarhus, Denmark.

Background: Lithium (Li)-induced Nephrogenic Diabetes Insipidus (NDI) develops in around 40% of psychiatric patients receiving Li treatment. NDI is characterized by the inability of the kidney to concentrate urine due to insufficient water reabsorption in the kidney collecting duct (CD). Studies in rats have shown that Li induces a cellular compositional change of the CD with a fractional decrease in the ratio of principal- to-intercalated cells after 4 weeks of Li. This cellular remodeling is reversible in rats undergoing recovery for 19 days following 4 weeks of Li treatment. We aimed to investigate if regulation of the cell-contacts E-cadherin and β-catenin have a role in the cellular remodeling. The Na+/K+-ATPase was also investigated due to previously shown influences on cell polarity and cell-contact formation in kidney cells (Rajasekaran et al. Mol Biol Cell).

Methods: Immunohistochemistry (IHC) was performed on rat kidney sections used in previously published studies (Christensen et al, AJP, 2006; Trenticcione et al, AJP, 2020). Sections from rats treated with Li for 4, 10, and 15 days and 4 weeks were stained using antibodies against the cytoplasmic domain of E-cadherin, β-catenin and Na+/K+ ATPase β1-subunit. Sections from rats that had undergone recovery for 6 and 12 days following 4 weeks of Li treatment were stained for β-catenin.

Results: E-cadherin and β-catenin labeled basal and lateral plasma membrane domains in the inner medullary CD (IMCD). In the proximal part of IMCD, the labeling was absent from the basal plasma membrane domains of multiple cells after 4 and 10 days of Li treatment and was present again after 4 weeks of Li. In addition, the basal labeling of β-catenin was absent from some cells after 12 days of recovery. IHC of the Na+/K+-ATPase β1-subunit revealed a similar subcellular localization, and the protein was not present in the basal plasma membrane domains of multiple cells in the proximal part of the IMCD already after 4 days of Li.

Conclusions: The subcellular localization of the adherens junction proteins E-cadherin, β-catenin and Na+, K+-ATPase β1 is affected by Li treatment in the proximal part of the IMCD. In addition, the absence of labeling from the basal plasma membrane domains appears to occur prior to the cellular remodeling.

Deletion of the EP3 Receptor in the Kidney Tubule of Adult Mice Has No Impact on the Major Channels and Transporters Involved in Kidney Water Handling
Cristina Esteve-Fon1, Frank Geurts2, Ewout J. Hoorn3, Robert A. Fenton1.
1Aarhus University, Aarhus, Denmark; 2Erasmus MC, Rotterdam, Netherlands.

Background: Prostaglandin E2 (PGE2) is an important lipid mediator modulating various aspects of kidney function. PGE2 exerts its effects via four PGE2 receptors, EP1, EP4, but it is unclear which PGE2 effects are mediated through which receptor. The EP3 receptor is expressed in the thick ascending limb (TAL) and the collecting duct, where it is proposed to inhibit CAMP generation and NaCl and water reabsorption. However, EP3 is also expressed in endothelial cells of arteries and arterioles, that also play a role in kidney function.

Methods: To assess the tubular role of EP3 in adult mice we generated a mouse model based on the Pax3Cre system with doxycycline-dependent deletion of EP3 along the renal tubule and assessed their renal phenotype in respect to water handling. qPCR and RNASeq confirmed that EP3 was highly expressed in cortical and medullary TAL and collecting ducts, but it was not detected in proximal tubule and thin limbs.

Results: Two weeks after treatment with doxycycline, EP3 mRNA expression was reduced by >80% in whole kidney (RT-qPCR) and non-detactable (RNASeq) in tubules of knockout mice compared to control mice. The other EP receptors expression remained unchanged in the kidney except for a slightly increase in EP4 expression. Under basal conditions, there were no significant differences in food and water intake, bodyweight, urinary output or plasma and urine biochemistries in both male and female control and knockout mice.

Conclusions: This new model provides a novel tool for examination of the role of EP3 in other kidney function or kidney disease independently of potential developmental abnormalities or systemic effects.

PO1104
Bayesian Identification of Transcription Factors That Regulate Aqp2 Transcription
Hiroaki Kikuchi,1 Hyun Jun Jung,2 Mark A. Knepper,1,4 *National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; 3*Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and AQP2 gene transcription is strongly regulated by urinary osmolality and AQP2. However, the transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes’ Rule to integrate several omic datasets. A publicly curated list of 1344 TFs present in the mouse genome with regard to probability of regulating Aqp2 gene transcription. To prioritize TFs, existing proteomic and transcriptomic data, ATAC-Seq, histone H3K27-acetylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data are used. Beyond this, we use additional omic datasets to prioritize the TFs that are regulated by vasoressin. Finally, we carried out new RNA-Seq experiments mapping the time course of vasoressin induced changes in the transcriptome of mouse mpcCD cells to further prioritize TFs that change in tandem with AQP2.

Results: The analysis identified 17 TFs out of 1344 in the mouse genome that are most likely to be involved in regulation of Aqp2 gene transcription. These TFs included eight that have been proposed in prior studies to play a role in Aqp2 regulation, viz. Cebp, E2f1, E2f3, Ets1, Jun, Jund, Nr4b1, and Sp1. The remaining nine represent new candidates for future studies (Aif1, Irf3, Klf5, Klf6, Me2d, Nlyb, Nrrb2, Stat3, Nr4a1). The RNA-Seq time course experiments in mpcCD cells showed a rapid increase in Aqp2 mRNA, within 3 hour of vasoressin exposure. This response was matched by an equally rapid increase in the abundance of the mRNA coding for Cebp, which we have shown by ChIP-seq studies to bind downstream from the Aqp2 gene.

Conclusions: The Bayesian analysis has identified the TFs most likely to bind to Aqp2 cis-regulatory elements and likely to be regulated by vasoressin stimulation, providing a roadmap for future studies to understand regulation of Aqp2 gene expression.

PO1105
The Enhanced Expression of AQP4 in Cerebral Ischemia Is Attenuated in AQP11 Homologous Knockout Mice
Yasuiko Tanaka, Kenichi Ishibashi, Meiji Iwaka Daigaku, Kiyose, Japan.

Background: The role of aquaporins (AqPs) in the brain edema needs to be clarified to advance its treatment. Since the importance of AQP4 for the formation of brain edema has been shown, expressing AQP11, expressed in the brain capillary, may also be important for the regulation of brain edema. In fact, we recently reported the associated expression of AQP4 and AQP11 in osmotically challenged AQP11 homologous knockout mice (HKM) (Koike S et al. Biochimie. 2021).

Methods: Both common cerebral arteries were ligated for 15 min or 60 min to produce an ischemic-reperfusion model of brain infarction. On one or two days after the reperfusion, total RNA from brain in the between Bregma and Lambda was isolated from wild mice and HKM. A real-time RT-qPCR was employed to examine the expression levels of several genes including AQP1, AQP4, AQP11, Iba1 (microglial marker), GFAP (astrocyte marker), Lamp2 (pro-ephoatopic factor), Bax (pro-apoptotic factor).

Results: Gene expression profiles were similar between wild mice and HKM in 60 min (increase), Lamp2 (increase) with more severity in 60 min ligation and in the second day. A similar profile was also observed with slightly decreased AQP1 by 5-22%. In contrast, the expression profiles of AQP4 and GFAP were outstanding in that both were more highly induced in wild mice than HKM, by 56% vs. 21% and by 570% vs. 335%, respectively, with further increases in 60 min ligation and in the second day. The results suggested the activation of astrocytes expressing AQP4 by the reperfusion, which might be attenuated in HKM. In agreement with this, the expression of Bax was increased in wild mice by 18% with 60-min ligation while it was decreased by 12% in HKM, suggesting a smaller brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM in 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM in 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM in 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM in 25-30%.

Conclusions: The decreased AQP11 expression in HKM attenuated the enhanced expression of AQP4 and Bax in a mouse ischemia-reperfusion brain model. Thus, the inhibition of AQP11 may alleviate the brain edema by attenuating the expression of detrimental AQP4 in brain infarction.

PO1106
Acute Hemoglobin Level Drop Based on Body Volume Gained
Phuong-Chi T. Pham, Phuong-Thu T. Pham. UCLA Medical Center Olive View, Sylmar, CA.

Background: Hemoglobin (Hb) changes with blood transfusions have been widely studied, but to our knowledge, Hb drop associated with volume gain have not been studied. High fluid volume infusion in critically ill patients always result in Hb drop, but the exact extent of Hb change in these patients has not been studied to assess Hb changes based on daily volume gained among anuric hemodialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Chronic anuric hemodialysis (HD) patients without active bleed admitted to our institution for reasons other than dialysis were included. Strict input/output measurements and Hb levels peri-HD were obtained. Post-HD levels were measured at least 12h post treatment to allow for equilibrated fluid compartmentalization. Changes in Hb per L of body volume gained were calculated.

PO1107 A Salty Goodbye to Diuretic Resistance: Hypertonic Saline
Sean Barnett. Brooke Army Medical Center, Fort Sam Houston, TX.

Introduction: Understanding the interplay of Cardiorenal physiology and pathophysiology in diuretic resistance requires a deep understanding of RAAS, ADH, and virtually all segments of the nephron. To treat, requires not only understanding but also the ability to investigate and differentiate. However, a treatment that can inhibit RAAS (directly and indirectly), stimulate Cardiac Output, improve GFR, and increase natriuresis could be the universal answer. 3% Saline has the ability to improve Cardiac Output and decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Therefore, the answer to Diuretic Resistance is 3% Saline.

Case description: A 55 y.o. AAF presented to the hospital for severe edema and shortness of breath. PMHx of HFpEF, DM, HTN, CKD3a3 (non-nephrotic). She presented with AKI III, severe hyponatremia, and anasarca. ECHO revealed EF 40%, biatrial enlargement, RV overload and reduced RV function. She was initially treated with high dose furosemide but did not improve. She was given Metolazone which caused worsening hyponatremia which was treated with 100mL of 3% Saline. This caused an immediate increase in urine output and sodium. She was then changed to a bumex drip and high dose spironolactone (200mg) with some improvement (via objective urine electrolyte assessment) she was still inadequately diuresed. She was then treated with 3% + Loop pulse dosing and sustained a robust diuresis of >3L of urine and maintained urinary sodium >50.

Discussion: The potential causes of diuretic resistance arise from the RAAS system and the individual nephron segments. The RAAS system however is the most universal target (when inhibited). While DCT, ASDN, CD and CCT are involved, regardless of which segment is primary, targeting the RAAS system would likely have significant benefit in all diuretic resistance. 3% Saline works as a potent IVF to improve Cardiac Output, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Using 100mL of 3% saline to augment diuresis (or alone) causes improvement in virtually all diuretic resistance. 3% Saline works as a potent IVF to improve Cardiac Output, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. 3% Saline is the universal answer. Therefore, the answer to Diuretic Resistance is 3% Saline.

PO1108 Enhanced Diuresis with Sequential Nephron Blockade
Shawn Alonso,1,2 Raymond T. La,1,2 Chavelly Valdes Sanchez,1,2 Gabriel A. Valle.1,2 University of Miami School of Medicine, Miami, FL; 1Holy Cross Hospital, Ft. Lauderdale, FL.

Introduction: Achieving volume control in patients with severe edema can be challenging, as diuretic resistance may occur. In such cases, sequential nephron blockade (SNB), a targeted multi-diuretic use strategy should be considered.

Case description: A 60-year-old woman with HIV and Dilated Cardiomyopathy s/p CRT-D presented with dyspnea and anasarca despite tenorside and losartan. In the ED she weighed 370 Lbs., had stable hemodynamic parameters, hypoxemia, diffuse lung infiltrates and low CD4 count. Oxygen, IV loop diuretics and Bactrim were initiated for concerns of PCP and HF. Despite an average U/O of 3 L/day she had no meaningful weight loss, protracted lung congestion, hyponatremia and developed radiocontrast nephropathy after CTA. Fluid restriction and SNB with IV thiazide and loop agents were instituted. Tolvaptan was added to perform diuresis of 8–11 L/day, restored normotension and was hemodynamically and metabolically well tolerated. Within 12 days, weight loss of 154 Lbs. was achieved with major clinical improvement.

Discussion: Loop agents are a mainstay for diuresis in patients with volume overload. However, diuretic resistance can occur through various mechanisms, including but not limited to, hypertension of the distal nephron and loss of function due to AKI. SNB provides a unique approach by strategically targeting ultrafiltrate dynamics in a stepwise manner and interfering with fluid reabsorption within various tubular segments. Central to this premise, the ability to maximize drug bioavailability and parental administration is initially necessary. Close hemodynamic and metabolic surveillance are mandatory as the mobilization of vast amounts of extracellular fluid may result in significant complications. Remarkably, in this case, while her eGFR was 25% she achieved 11 L diuresis (30% of UF) safely. This underscores the enormous capacity for fluid sequestration in the extracellular space and the crucial role of trans-compartmental fluid shifts in HF. SNB has been available for years and various diuretics combinations are plausible. This case exemplifies the effectiveness of a novel regimen with vaptans in promoting voluminous diuresis and aquaresis, improving outcomes and decreasing length of stay.

PO1110 Functional Sodium Magnetic Resonance Imaging of Human Kidney

Background: Maintenance of a cortico-medullary concentration gradient (CMG) is required for urine concentration. We explored the ability of NaMRi in measuring 1) the dynamics of CMG for the first time compared to urinary osmolality after a water load and 2) the CMG in kidney disease.

Methods: We conducted an exploratory pilot study for 10 healthy controls following water load then 5 cardiacorenal patients with kidney disease. 1) Fasting healthy controls provided urine samples to measure osmolality and baseline NaMRi scans were performed. They were instructed to ingest water (15 mL/kg) within 15 minutes. Four subsequent sodium images and urine samples were acquired at 15 min intervals starting one hour after water ingestion. 2) Cardiorenal patients underwent an MRI scan, provided a blood and urine sample, but no water loading.

Results: Mean age of the 10 healthy controls was 41.8 ± 15.3 years. In the morning fasting, medulla/cortex ratio was 1.55 ± 0.11 with concurrent urinary osmolality measured at 814 ± 121 mOsm/L. Mean a SD fasting urinary osmolality dropped significantly to 73 ± 14 mOsm/L, p=0.001. Mean medulla/cortex ratio dropped significantly to 1.31 ± 0.09 mOsm/L for maximal dilution, p=0.002. Figure 1 displays changes of NaMRi pictures before (A) then 1h (B), 1H15 (C), 1h30 (D) and 1h45 (E) after a water load. Urinary osmolality and medulla/cortex ratio are significantly correlated, r=0.54, p<0.0001. Mean age of the 5 cardiorenal patients was 76.6 ± 12.2 years, eGFR was 54 ± 37 mL/min/1.73m2. Urinary osmolality was 498 ± 145 mOsm/L and medulla/cortex ratio was 1.35 ± 0.11. We measured corticomedullary concentration gradient in cardiorenal patient with different level of eGFR to show the ability and feasibility to measure this gradient in pathological settings.

Conclusions: We explored CMG dynamically every 15 min in healthy controls and demonstrated significant changes after a water load. We were also able to acquire NaMRI pictures in cardiorenal patients with kidney disease with plans for future analyses.

PO1110 Validity of a Simple Equation to Estimate Urine Output in Outpatients with Suspected Nephrolithiasis
Luke Webster,1 Alexander Bullen,2 John R. Asplin,2 Michael Shlipak,3 Seth Bechis,1 Manoj Monga,1 Joachim H. Ix,4,5 University of California San Diego, La Jolla, CA; 2Litholink Corp, Chicago, IL; 3University of California San Francisco, San Francisco, CA; 4VA San Diego Healthcare System, San Diego, CA.

Background: We previously developed and validated an equation to estimate urine volume from spot urine creatinine, demographic variables, and body weight in patients with and without nephrolithiasis. We hypothesized this equation could accurately estimate daily urine output in outpatients with nephrolithiasis.

Methods: Among persons submitting specimens to Litholink Laboratories between May 2013 and January 2016, we identified 19,884 individuals who had two 24 hour urine collections on consecutive days, with creatinine excretion rates ≥10%. We used Pearson correlations and Bland-Altman analysis to evaluate equation estimated with measured urine volume on the first of the two 24 hour urine collections. We also tested the equation’s test characteristics to accurately identify producers ≥2L/day; a guideline directed urine output goal among stone formers.

Results: Estimated and measured urine volumes were strongly correlated (r=0.76, p < 0.001). The estimated urine flow rate was 195 ml/day (8.7%) higher than measured. Overall, 78% of individuals had an estimated urine volume within 30% of measured. We found the equation was similar in men and women, across stratata of body weight, in those with and without CKD, and when evaluating the second day measured urine volume. An estimated urine volume ≥2L/day had 86% sensitivity, 83% specificity, 76% PPV and 91% NPV for identifying individuals with measured urine volumes >2L/day (Figure 1).

Conclusions: A simple equation using urine creatinine, demographics and body weight can predict urine flow rate in outpatients with nephrolithiasis. The equation may provide a tool to enhance diagnostic accuracy in the urinary risk factors for stones, and to identify patients among whom efforts to increase hydration could be targeted to diminish risk of stone recurrence.

**Attenuated Urinary Sodium and Volume in Response to Saline Load in Heart Failure with Preserved Ejection Fraction**

*University of Utah Health, Salt Lake City, UT.*

**Background:** Heart failure (HF) is characterized by fluid overload due to impaired sodium (Na) excretion. Impaired urinary Na excretion in response to intravenous Na load has been demonstrated in HF with reduced ejection fraction (HFrEF). We hypothesized that patients with HF with preserved ejection fraction (HFpEF) also have impaired urinary sodium excretion and volume in response to intravenous Na load.

**Methods:** All participants were instructed to follow a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

**Results:** Mean age and body mass index for the HFpEF participants were 62±12 years and 36.3±8.5 Kg/m², and for control participants were 47±18 years and 24.6±3.7 Kg/m², respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) pmol/mg/(pg/ml); p = 0.014) in cases as compared to controls.

**Conclusions:** Our pilot study shows that ucGMP/plasma BNP ratio, which reflects renal response to BNP, was attenuated in patients with HFpEF. These data suggest that impaired renal response to NP may be implicated in the pathogenesis of fluid retention in HFpEF.

**PO1112**

**Attenuated Renal Response to Endogenous Natriuretic Peptides in Heart Failure with Preserved Ejection Fraction**

*University of Utah Health, Salt Lake City, UT; Yale University, New Haven, CT.*

**Background:** The pathophysiology of sodium retention in heart failure with preserved ejection fraction (HFpEF) remains largely unknown. A potential mechanism is attenuated renal response to natriuretic peptides (NPs). Urinary cyclic guanosine monophosphate (ucGMP) is an intracellular messenger of NPs, and an attenuated ucGMP/B-type NP (BNP) ratio suggests decreased renal response to BNP. We hypothesized that patients with HFpEF have attenuated response to NPs.

**Methods:** We studied ucGMP/plasma BNP ratios in 9 HFpEF patients and 5 controls (no history of renal or heart disease). All participants were placed on a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

**Results:** Mean age and body mass index for the HFpEF participants were 62±12 years and 36.3±8.5 Kg/m², and for control participants were 47±18 years and 24.6±3.7 Kg/m² respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) pmol/mg/(pg/ml); p = 0.014) in cases as compared to controls.

**Conclusions:** In this rigorous, controlled human pilot study, patients with HFpEF had lower urinary volume and attenuated urinary sodium excretion compared to controls after intravenous sodium and volume load. Data and biospecimens collected in this study should inform the pathogenesis of sodium retention in HFpEF.

**PO1113**

**Association of Urinary Potassium Excretion with Progression of CKD**

Daisuke Mori, Yuta Namiki, Ayaka Sugimachi, Manabu Kado, Shinjiro Tamai, Hiroki Nomi, Ryota Haga, Katsuyuki Nagatoya, Atsushi Yamauchi. 

*Osaka Rosai Hospital, Osaka, Japan.*

**Background:** Out of range serum potassium levels are associated with worsening renal function and increased occurrence of cardiovascular disease (CVD) events in

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
chronic kidney disease (CKD). However, conflicting results have been reported for the protective value for adverse health outcomes of urinary potassium excretion. Therefore, we conducted a cohort study to determine whether urinary potassium excretion is an independent risk factor for renal function deterioration or increased CVD events.

Methods: We identified 650 patients with pre-dialysis CKD who were hospitalized for Ckd-related medical program between 2010 and 2018. Study outcomes analyzed were CKD progression and incidence of CVD events. Baseline urinary potassium to creatinine ratio (UK/Cr, expressed as mmol/gCr) was ranked into quartiles as follows: Q1, <19.8; Q2, 19.9–27.7; Q3, 27.8–37.9; and Q4, >38.0.

Results: During follow-up (median 35 months), 509 CKD progression and 129 CVD events were identified. Further, 62 patients died during follow-up. Multivariate Cox models showed that an increased risk of CKD progression was observed in patients with low UK/Cr compared to those with high UK/Cr, after adjustment for demographic factors and laboratory data. In a fully adjusted model, adjusted hazard ratios (HRs) with the fourth (highest) quartile as reference category were 2.02 (95% CI, 1.50–2.71), 1.34 (95% CI, 1.02–1.77), and 1.14 (95% CI, 0.87–1.50), for Q1–3 respectively (trend: P < 0.001). Similarly, an inverse probability weighting analysis showed an increased risk of CKD progression in Q1 and Q2 compared with Q4. We did not observe any significant modification in subgroup analyses. Furthermore, consistent association was confirmed between low fractional excretion of potassium and worsening renal function. However, UK/Cr had no association with the incidence of CVD events.

Conclusion: A low UK/Cr is independently associated with worsening renal function but not with an increased risk of a CVD event in patients with pre-dialysis CKD.

PO1114
Licorice-Induced Syndrome of Mineralocorticoid Excess
Nisarg Gandhi, Hassan N. Ibrahim. Houston Methodist Hospital, Houston, TX

Introduction: Edema and volume overload are common complaints. Here, we present a case of hypokalemic edema presentation resulting from licorice ingestion and generalized weakness.

Case Description: A 34 y/o Caucasian woman with history significant for chronic kidney disease (CKD). However, conflicting results have been reported for the protective value for adverse health outcomes of urinary potassium excretion. Therefore, we conducted a cohort study to determine whether urinary potassium excretion is an independent risk factor for renal function deterioration or increased CVD events.

Methods: We identified 650 patients with pre-dialysis CKD who were hospitalized for Ckd-related medical program between 2010 and 2018. Study outcomes analyzed were CKD progression and incidence of CVD events. Baseline urinary potassium to creatinine ratio (UK/Cr, expressed as mmol/gCr) was ranked into quartiles as follows: Q1, <19.8; Q2, 19.9–27.7; Q3, 27.8–37.9; and Q4, >38.0.

Results: During follow-up (median 35 months), 509 CKD progression and 129 CVD events were identified. Further, 62 patients died during follow-up. Multivariate Cox models showed that an increased risk of CKD progression was observed in patients with low UK/Cr compared to those with high UK/Cr, after adjustment for demographic factors and laboratory data. In a fully adjusted model, adjusted hazard ratios (HRs) with the fourth (highest) quartile as reference category were 2.02 (95% CI, 1.50–2.71), 1.34 (95% CI, 1.02–1.77), and 1.14 (95% CI, 0.87–1.50), for Q1–3 respectively (trend: P < 0.001). Similarly, an inverse probability weighting analysis showed an increased risk of CKD progression in Q1 and Q2 compared with Q4. We did not observe any significant modification in subgroup analyses. Furthermore, consistent association was confirmed between low fractional excretion of potassium and worsening renal function. However, UK/Cr had no association with the incidence of CVD events.

Conclusion: A low UK/Cr is independently associated with worsening renal function but not with an increased risk of a CVD event in patients with pre-dialysis CKD.

PO1115
Not Just Licorice: Abiraterone and Apparent Mineralocorticoid Excess
Natalie M. Beck, Katherine Rizzato, Sophia L. Ambroso.1 University of Colorado, Denver, CO; 2TA Eastern Colorado Health Care System, Aurora, CO.

Introduction: Abiraterone is a CYP17A1 inhibitor which blocks androgen synthesis, and is used to treat castration-resistant prostate cancer. This drug also decreases cortisol synthesis, causing a compensatory increase in adrenocorticotropic hormone (ACTH) and accumulation of mineralocorticoids. The result is the syndrome of apparent mineralocorticoid excess (AME) which manifests clinically as hypokalemia, metabolic alkalosis and hypertension. Abiraterone is approved for use only with concurrent glucocorticoid supplementation.

Case Description: A 74-year-old man with metastatic prostate cancer and neck cancer presented with urinary retention and acute kidney injury (AKI) as well as hypernatremia and metabolic alkalosis which were present a week prior. Home medications included abiraterone, cisplatin (given two weeks prior), prednisone 5 mg daily (recently decreased from 5 mg twice daily) and spironolactone. A urinary catheter was placed, the AKI improved rapidly and the patient remained with refractory hypokalemia. A urine potassium to creatinine ratio was high. Post-obstructive polyuria was considered as a reason for kaliuresis; however, hypokalemia and metabolic acidosis preceding this event made it unlikely to be the sole cause. Given abiraterone use, serum cortisol was checked and was low with no increase after giving cosyntropin. Serum aldosterone, renin and their ratio were normal. The patient was diagnosed with abiraterone-induced AME. Prednisone was increased to 5 mg twice daily and eplerenone was started in place of spironolactone. Two months later, the serum potassium was normal without supplementation.

Discussion: Abiraterone-induced AME is characterized by low serum cortisol but unlike adrenal insufficiency, presents with hypokalemia, metabolic alkalosis and hypertension. In this case, AME results from abiraterone-induced 17a-hydroxylase inhibition of the CYP17A1 enzyme, leading to decreased cortisol, increased ACTH, and accumulation of the potent mineralocorticoid deoxycorticosterone. Glucocorticoid supplementation (prednisone 5 mg twice daily recommended) is needed to suppress ACTH and prevent these effects. Eplerenone is an aldosterone inhibitor and is preferred over spironolactone in patients with castrate-resistant prostate cancer as spironolactone interacts with the androgen receptor.

PO1116
Jägermeister-Induced Pseudohyperaldosteronism
Joseph A. Gotesman, Jordan L. Rosenstock. Lenox Hill Hospital, New York, NY.

Introduction: Hypertension and hypokalemia is known to be caused by pseudohyperaldosteronism. We report a case of hypertension, hypokalemia, and suppressed renin and aldosterone levels. Dietary work-up revealed copious ingestion of Jägermeister liquor which contains licorice, a known cause of pseudohyperaldosteronism.

Case Description: A 54-year-old man with a history of HIV on Genvoya and CAB, HTN on metoprolol and isosorbide mononitrate was referred to nephrology for evaluation of hypokalemia and accelerated hypertension. Prior to nephrology referral, he was started on oral potassium for 6 weeks and the repeat potassium was 3.5 mmol/L. On review of systems, he had no specific complaints except occasional diarrhea. On exam, his BP was 190/110, 1+ lower extremity edema; his exam was otherwise unremarkable. Initial workup revealed serum sodium 143 mmol/L, bicarb 24 mmol/L, potassium 3.5 mmol/L, creatinine 2.5 mg/dL, magnesium 1.5 mg/dL, uric acid 39 mg/dL, K 74 mg/dL, TSH 2.95 uIU/mL, plasma renin activity 1.191 ng/mL/h, and aldosterone <3.0 ng/dL, and plasma metanephrines <10 pg/mL. Repeat K was 3.1, bicarb 30, plasma renin activity 0.195 ng/mL/hr, and aldosterone <3.0 ng/dL; urine K 34, Fek 11%; renal dopplers without evidence of RAS. Given hypokalemia, metabolic alkalosis with evidence of potassium wasting, and suppressed renin and aldosterone levels, a thorough dietary review was conducted which revealed chronic Jägermeister ingestion of up to 500 mL per day. He stopped drinking Jägermeister and on subsequent follow-up, his BP was controlled on atenolol, carvedilol, and isosorbide mononitrate, and he no longer required potassium supplementation.

Discussion: Licorice contains glycyrrhizic acid which inhibits 11 beta-hydroxysteroid dehydrogenase, preventing inactivation of cortisol to cortisone, and resulting in excess mineralocorticoid activity manifested by suppression of renin and aldosterone levels, sodium retention, hyperkalemia, hypokalemia, hypertension, and edema. According to the manufacturer, Jägermeister liquor contains under 10 mg/L of licorice, however, the amount that can cause toxicity is not certain and literature suggests that the glycyrrhizic acid content of licorice is widely variable. Physicians ought to consider dietary, non-medication causes for electrolyte abnormalities in patients with initial negative workups.

PO1117
Posaconazole-Related Mineralocorticoid Excess in a Patient with Acute Myeloid Leukemia
Venkata Parvathareddy R. Muklu,1,2 Adnann S. Polani,3 Vishnuvapiyadi Parvathareddy, Sreedhar A. Mandayam.1 The University of Texas Medical Branch at Galveston, Galveston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Baylor College of Medicine, Houston, TX.

Introduction: Posaconazole is an antifungal used for treatment and prophylaxis of invasive fungal infections in cancer patients. We report a case of posaconazole related mineralocorticoid excess in a patient with acute myeloid leukemia (AML).

Case Description: Patient is a 40-year-old male with past medical history of relapsed AML status post stem cell transplant, was admitted on 08/16/2020 to UTMDACC for pain, nausea, vomiting, diarrhea, and fatigue. He developed multiple complications streptococci viridans bacteraemia, candidemia, Graft Versus Host Disease, disseminated intravascular coagulation, fungal pneumonia, tracheostomy, bacteremia, extrapulmonary candidiasis, and invasive fungal infections with HSV-1 on Foscarnet. Nephrology was consulted for hypernatremia, hypokalemia and alkalosis. No nausea, vomiting, diarrhea was reported. Due to a combination of hypertension, metabolic alkalosis, hypokalemia and being on Posaconazole, we suspected...
Pseudo-hyponatremia. Renin, aldosterone levels were checked which are low. CT scan of hypokalemia, metabolic alkalosis and hypertension in a patient treated with check point inhibitor in the setting of oropharyngeal cancer.

**Case Description:** A 78-year-old male with past medical history of oropharyngeal squamous cell carcinoma presented with fatigue. One week prior he was treated with pembrolizumab. Admission vital signs were significant for fever to 39.1°C and nonrespiratory blood pressure 130/58. Laboratory results revealed serum potassium (K) 4.1 mmol/L, bicarbonate (HCO₃⁻) 26 mmol/L and newly elevated liver enzymes. He was diagnosed with immune checkpoint inhibitor hepatitis and treated with prednisolone 70 mg via nasogastric tube (NGT). Two days later, blood pressure increased to 170/80 and laboratory studies revealed hypokalemia and metabolic alkalosis with serum K 3.0 mmol/L and HCO₃⁻ 33 mmol/L. Nephrology was consulted for persistent hypokalemia and metabolic alkalosis. The triad of hypokalemia, metabolic alkalosis and hypertension lead us to suspect a hypermineralocorticoid state. Workup revealed spot urine K of >100 mmol/L, serum aldosterone <30 ng/dL and serum renin <1 ng/dL.

Findings were consistent with an exogenous source of mineralocorticoid activation. Prednisolone was thought to be the cause. He required a total of KCl 180 mgq (40 mEq intravenous, 140 mEq NGT) to raise serum K to 3.4 mmol/L in 24 hours. As such, we recommended discontinuing prednisolone in favor of dexamethasone which has no mineralocorticoid action. Electrolyte abnormalities is crucial.

**Discussion:** The primary defect in BS is in sodium chloride reabsorption in the medullary thick ascending limb of the loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Rare cases of acquired BS are reported in association with tuberculosis, sarcoidosis, sjogrens, and certain drugs. All of these were ruled out in our patient and hence a diagnosis of idiopathic BS like phenotype was made. In our patient, we attribute the BS like phenotype to underlying COVID infection. As his infection improved, his hypokalemia also resolved. Hyperkalemia is a more common finding in COVID infection. However, in our patient, hypokalemia secondary to BS like phenotype was a unique presentation which was challenging to treat. In the absence of usual causes of acquired BS, the diagnosis of acquired BS-like phenotype with COVID infection should prompt suspicion for BS-like phenotype. Early and aggressive correction of electrolyte abnormalities is crucial.

**PO1120**

**Idiopathic Bartter Syndrome-Like Phenotype Diagnosed in a Diabetic Patient with COVID-19 Infection**

Athinayya Sridhar, Aromapa Kapoor, Westchester Medical Center, Valhalla, NY; New York Medical College, Valhalla, NY.

**Introduction:** Bartter’s syndrome (BS) is a rare genetic tubulopathy affecting the loop of Henle leading to salt wasting. Acquired BS is very rare and is associated with underlying medical conditions or infections. We report a unique case of idiopathic BS-like phenotype that was diagnosed in the setting of COVID infection.

**Case Description:** 71-year-old man with coronary artery disease, hypertension and diabetes presented after a mechanical fall. On admission, he was found to be hypotensive to 107/88 mmHg. Physical exam was within normal limits. Initial blood work was significant for Potassium 2.6 mEq/L, Bicarbonate 34 mEq/L, Calcium 8.0 mg/dL and Magnesium 1.7 mg/dL. Patient also tested positive for COVID-19. Upon further questioning, patient reported a remote history of hypokalemia but never needed any inpatient hospitalization. He denied diuretic use or surreptitious vomiting. Hypokalemia work up revealed increased urinary potassium of 85.4 mEq/L. Renin 15.72 ng/mL/hour and Aldosterone 8 ng/dL. Patient was then started on aggressive intravenous and oral potassium repletion. He continued to require multiple doses of intravenous potassium to maintain potassium levels of 3 mEq/L. He was subsequently started on Eplerenone on Day 3 of admission with excellent response. He remained otherwise asymptomatic from COVID and as his infection improved, hypokalemia stabilized and he was ultimately discharged with a Potassium level of 3.6 mEq/L.

**Discussion:** The presence of hypokalemia in a patient with COVID infection raises suspicion for acquired BS. This is particularly true if the patient has a history of COVID which may be likely due to genetic predisposition. The initial presentation may be with hypokalemia, hypertension and alkalosis. However, not every patient will develop these which may be likely due to genetic predisposition.
of index stays were HK-related. All-cause (HK-related) index stays consisted of 54.0% (46.8%) and median Charlson Comorbidity Index scores (6.19 vs 3.93). Mean annual HK events during follow up were highest in patients with CHF+CKD/ESRD (all patients=1.47; HK=6.98), followed by CKD (0.66; 5.53), and CHF (0.18; 3.00), with similar patterns across settings. In the HK cohort, 34.5% had HK recurrence during follow up, 2.7% filled a potassium binder prescription during index LTC/PAC stay, and 4.3% did during follow up.

Conclusions: HK patients were more often non-White and low income, indicating possible disparities in care. Prevalence and recurrence of HK was high among patients with LTC/PAC stays, but few patients filled a potassium binder prescription, suggesting potential gaps in treatment during or after an LTC/PAC stay.

PO1125
Transient Hyperkalemia Following Treatment of Chronic Hypokalemia: A Case Report and Review of Distal Tubule Physiology

Introduction: Hypokalemia is a frequently encountered electrolyte disorder usually resulting from decreased dietary intake, gastrointestinal, and/or renal wasting. In distal tubule cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies following resolution of hypokalemia is unknown. Our postulation could explain a transient hyperkalemia during treatment for hypokalemia. His potassium was 2.5 mEq/L (4.65 mmol/L), resulting from decreased urinary potassium wasting through the renal outer medullary potassium channel (ROMK). Here we report a case of a young man with alcohol use disorder and chronic hypokalemia who was hospitalized for muscle weakness, abdominal pain, and increased urinary potassium. During treatment of his hypokalemia, he unexpectedly developed transient hyperkalemia.

Case Description: The clinical intrigue of this case was the unexpected finding of acute transient hyperkalemia during treatment for hypokalemia. His potassium was 2.5 mEq/L on the day of admission. Four days later, with a creatinine at baseline (0.9 mg/dL), potassium abruptly increased to 6.7 mEq/L. Repeat measurement one hour later was 6.4 mEq/L. Over the course of his hospitalization prior to the critical hyperkalemia lab result, he had received approximately 340 mEq of potassium supplementation. 24 hour urine potassium was 35 mEq/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric. First stool potassium was >100 mmol/L with stool volume of 900 mL. Repeat stool study after a week showed stool potassium 95.9 mmol/L with stool sodium 42 mmol/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric.

Discussion: Colonic pseudo-obstruction may result in some patients, in dramatic upregulation of the maxi-K channel. When potassium secretion is greatly increased by stretch-activated maxi-K channel, also known as BK channel, resulting from dilatation of the colon. While exact mechanism is unclear, diagnosis is based on clinical and radiologic grounds.

Case Description: A 69 year old African American female with history of diabetes mellitus, hypertension, hyperlipidemia, and HIV infection presented with worsening lower back pain. Initial labs showed leukocytosis, anemia, mild renal impairment, and paraprotein gap. MRI of the spine showed extensive compression deformities and epidural extension, with lytic lesions on skeletal survey. Bone biopsy showed >80% blast cells with marked increase in circulating plasma cells, confirming plasma cell leukemia. Abdominal CT showed dilated ascending colon suggestive of obstruction, but she was having normal bowel movements. She successfully underwent induction therapy and was discharged. When she was readmitted for second cycle of chemotherapy, serum potassium of 1.8 mmol/L with U wave on ECG noted. She also complained of abdominal distension, diarrhea, and bilateral lower extremity edema. Despite aggressive potassium supplementation, her potassium level persistently remained below 3.5 mmol/L. Initial urine potassium was 23 mmol/L, which peaked at 45.8 mmol/L before becoming anuric. First stool potassium was >100 mmol/L with stool volume of 900 mL. Repeat stool study after a week showed stool potassium 95.9 mmol/L with stool sodium 42 mmol/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric.

Discussion: Colonic pseudo-obstruction may result in some patients, in dramatic upregulation of the maxi-K channel. When potassium secretion is greatly increased, diarrhea rather than constipation becomes predominant manifestation. Diarrhea is the result of high potassium content of the stool, unlike most other secretory diarrhea which contains sodium as the main cation.

similar observation of transient hyperkalemia seen in a case published in 1953 of a young woman treated for chronic hypokalemia (Schwartz, 1953). Critical hyperkalemia is an important consideration when treating patients with chronic hypokalemia.

PO1126
Post-surgical hyperkalemia with Concurrent Hyperkalemia
Momen M. Islam1,2, Akbar H. Hamid1,2, Yasmin N. Mahmoud1,2, Mary C. Mallappallil1,2, Man S. Oh1,2, Sabu John1,2, Moro O. Salifu1,2, SUNY Downstate Health Sciences University Department of Medicine, New York, NY; Kings County Hospital Center, Brooklyn, NY.

Introduction: In sickle cell patients, acute hemolytic crisis and sickle cell nephropathy are relatively common. Risk of hyperkalemia increases with hemolysis and tubular dysfunction. Sepsis can also worsen the complication of hemolytic crisis with significant thrombocytosis, a well-known cause of pseudohyperkalemia. We report a case of concurrent true hyperkalemia and pseudohyperkalemia in the setting of thrombocytosis due to acute sickle cell crisis.

Case Description: A 36 year old African American male with history of sickle cell disease, asthma and DVT presented with bilateral shoulder, knee, and back pain. In ED, he was hypotensive, and tachycardic. Labs were notable for leukocytosis, anemia, reticulocytosis, renal failure, and elevated lactate dehydrogenase. Chest x-ray showed left base atelectasis. He was admitted for acute sickle cell crisis and fluctuating right thigh abscess, which was surgically drained and managed with antibiotics. Platelet level was 585 K/uL; serum potassium was 4.7 mmol/L; and creatinine was 1.76 mg/dL with normal urine output. Potassium level steadily rose and peaked at 6.5 mmol/L with sinus bradycardia but no other ECG changes. At the same time, platelet level peaked to 1105 K/uL.

Discussion: In our patient with significant thrombocytosis, pseudohyperkalemia was suspected. Degranulation of platelets during clotting releases about 50% of potassium inside platelets. For platelet count of 1000 K/uL with normal MPV, serum potassium is expected to be higher than plasma potassium level by about 0.7 mmol/L. Serum-plasma potassium differences in our patient were within the expected range. In our patient, as shown below, mild concurrent true hyperkalemia is also noted likely due to sickle cell nephropathy, a known cause of hyperkalemia due to hyporeninemic hypoaldosteronism. Due to potassium release from platelets during clotting, serum potassium is always higher than plasma potassium in all normal persons by 0.2 to 0.3 mmol/L. With thrombocytosis, the difference becomes larger, and serum potassium is likely to reach hyperkalemic level if the baseline potassium is already higher than usual due to concomitant impairment of renal potassium excretion.

PO1127
Missing the Obvious? A Story of Salt, Water, and Unexplained Hyperkalemia
Aaron M. Spring,1 Mathieu Lemaire,1,2 1The Hospital for Sick Children Department of Paediatrics, Toronto, ON, Canada; 2SickKids Research Institute, Toronto, ON, Canada.

Introduction: Most clinicians are familiar with the differential diagnosis of hyperkalemia, from pseudohyperkalemia to rare tubulopathies. Herein, we describe three patients with years-long histories of unexplained hyperkalemia despite extensive investigations (details in Table 1). While all achieved normokalemia with various prescription regimens, the underlying etiology remained elusive. We suggest that all cases were likely due to chronic, mild hypovolemia in the context of self-imposed dietary salt restriction.

Case Description: Patient A: A 6-week-old girl with persistent hyperkalemia and very low urine Na+. Normokalemia was achieved with hydrochlorothiazide and dietary K+ restriction but maintained with optimized fluid and Na+ intake alone. Patient B: An 11-year-old boy with spastic cerebral palsy with persistent hyperkalemia after a mild AKI attributed to thalidomide use. Serum K+ improved with sodium polystyrene (SPS) resins and dietary K+ restriction; it normalized after fluid challenge infusion, while SPS was no longer needed. Patient C: A 5-month-old boy with Stüve-Wiedemann Syndrome and feeding difficulties with persistent hyperkalemia that normalized on SPS. After G-tube insertion at 2 years, K+ remained normal despite stopping the SPS due to improved fluid and Na+ intake.

Discussion: It has long been established that adequate Na+ and fluid delivery to distal nephrons is necessary for optimal K+ handling. This is surprising to find out to almost no mention of Na+-responsive hyperkalemia in the literature for children beyond the neonatal period. Our patients all had hyperkalemia in the context of normotension, but very low fractional excretion of Na+ (FeNa) and low trans-tubular K+ gradient (TTKG). They all remained normokalemic when salt and water intake was optimized, despite stopping their hyperkalemic prescriptions. Careful, early consideration of low distal Na+ and water delivery as a cause for unexplained hyperkalemia could prevent extensive workups and unnecessary prescriptions.

PO1128
Machine Learning Models to Predict Cardiovascular and Renal Outcomes and Mortality in Hyperkalemic Patients
Fumihiro Kanda,1 Suguru Okami,1 Shun Kohsaka,2 Xiaojun Ma,2 Masahumi Okada,1 Takeshi Kiinura,1 Tossukua Yajima,2 Kawasaki Medical School, Kurashiki, Japan; 3AstraZeneca K.K., Osaka, Japan; 4IQVIA Solutions K.K., Tokyo, Japan; 5Real World Data, Co.Ltd., Kyoto, Japan; 6Keio University, Tokyo, Japan.

Background: Hyperkalemia is associated with increased risks of mortality and adverse clinical outcomes. To date, limited evidence is available for personalized risk evaluation in this heterogeneous and multifactorial pathophysiological conditions.

Methods: We developed prediction models using extreme gradient boosting (XGB), logistic regression (LR), and neural network. Models were derived and cross-validated in a retrospective cohort of hyperkalemic patients with either heart failure or stage ≥3a chronic kidney disease and aged ≥18 years from a Japanese administrative hospital database (April 1, 2008–September 30, 2018). The outcomes of interest included all-cause death, introduction of renal replacement therapy (RRT), hospitalization for heart failure (HHF), and cardiovascular events within 3 years after first hyperkalemic episode. The best performing model was further validated using a separate hospital-based database.

Results: 24,949 adult patients with hyperkalemia were selected for the model derivation and internal validation. The mean age was 75 years and 54% were male. Among machine learning algorithms tested, XGB outperformed other models, showing AUROC of XGB vs. LR for all-cause death, RRT, HHF, and cardiovascular events as 0.823 vs. 0.809, 0.957 vs. 0.947, 0.863 vs. 0.838, and 0.809 vs. 0.798, respectively. In the external validation set including 66,279 patients, AUROC of XGB for all-cause death, RRT, HHF, and cardiovascular events were 0.747, 0.888, 0.673, and 0.585, respectively. The Kaplan-Meier curves of high-risk predicted group showed a significant differentiation from that of low-risk predicted group for all outcomes (Figure).

Conclusions: These findings suggest the possible use of machine learning models for real-world risk assessment as a guide for treatment decision making that may lead to the improvement of cardiovascular and renal outcomes, and mortality in hyperkalemic patients.

PO1129
Severe Hyperkalemia Secondary to Hypermagnesemia in a Patient with Preeclampsia
Afif Ibrahim, Alice Chedid. The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Introduction: Mg infusion remains the first-line treatment of preventing and controlling eclamptic seizures. While hypocalcemia is a well-known side effect, hyperkalemia is not. We present a case of severe hyperkalemia secondary to magnesium infusion requiring hemodialysis.

Case Description: 36-year-old healthy female with no HTN or liver disease, pregnant for 24 weeks with a 1-month known gestational concern for intra-uterine growth restriction. Initial vitals on admission: BP 149/88 mm Hg, HR 89,
Changes in potassium and calcium concentrations in relation to hypermagnesemia (figure 1)

PO1130
Severe Hypermagnesemia: A Potential Cause of Acute Hyperkalemia

Introduction: Hypermagnesemia is not a well-established cause of hyperkalemia. In this case report we explore the association of acute hypermagnesemia and hyperkalemia.

Case Description: A 74-year-old Black male with known arterial hypertension, coronary artery disease, CKD 3 [baseline serum creatinine (Cr) 1.7 mg/dL] presented with syncope secondary to severe bradycardia (heart rate 30/min) consequent to severe hyperkalemia, which necessitated a pacemaker placement, and non-oliguric AKI on CKD. Pertinent serum labs on presentation include Cr 2.8 mg/dL, potassium (K) 7.6 mmol/L, and bicarbonate 19 mmol/L. Serum osmolality, glucose, and creatinine kinase levels were within normal limits. Urine pH was 5. Renal imaging was unremarkable. The patient was on no medications; no other medications known to cause hyperkalemia; normal aldosterone, no signs or symptoms of hyporeninemic hypoaldosteronism. (2) direct inhibition of the ROMK channel by Mg. Suppressing renin and aldosterone leading to impaired renal handling of K homeostasis (hyperreninemic hypokidostension).

Discussion: While the relationship between hypomagnesemia and hypokalemia is well understood, the relationship between hyperkalemia and the presence of hypermagnesemia remains not clear. Some of the mechanisms suggested (1) direct effect of magnesium on suppressing renin and aldosterone leading to impaired renal handling of K homeostasis (hyperreninemic hypokidostension). (2) direct inhibition of the ROMK channel by Mg.

PO1131
When Sipping K Is Not OK
Anur Rajasekaran, Ammar Hasnic, Ashita J. Tolvani. The University of Alabama at Birmingham, Birmingham, AL.

Introduction: Hyperkalemia is one of the most common and potentially lethal electrolyte abnormalities that occurs in approximately 1% to 10% of hospitalized patients. It is associated with an increased risk of arrhythmias, poor cardiovascular outcomes, and increased morbidity and mortality. We highlight an unusual etiology of severe hyperkalemia in a patient with underlying CKD.

Case Description: A 74-year-old Black male with known arterial hypertension, coronary artery disease, CKD 3 [baseline serum creatinine (Cr) 1.7 mg/dL] presented with syncope secondary to severe bradycardia (heart rate 30/min) consequent to severe hyperkalemia, which necessitated a pacemaker placement, and non-oliguric AKI on CKD. Pertinent serum labs on presentation include Cr 2.8 mg/dL, potassium (K) 7.6 mmol/L, and bicarbonate 19 mmol/L. Serum osmolality, glucose, and creatinine kinase levels were within normal limits. Urine pH was 5. Renal imaging was unremarkable. He was not on any medication(s) commonly attributed with a propensity to elevate serum K, including renin angiotensin inhibitors, non-selective β blockers, or non-steroidal anti-inflammatory agents. Given that the hyperkalemia was out of proportion to his kidney injury, upon further questioning he attributed consuming a diet rich in K along with drinking multiple cups of Essiac tea daily for the last 2 months. Hyperkalemia was managed medically, including initial temporizing measures, bicarbonate supplementation, K binders, and intravenous crystalloids to enhance distal nphron K excretion. Emphasis was placed on consuming a K restricted diet along with discontinuing Essiac tea use. Serum K normalized in 3 days; however, Cr was 3.5 mg/dL on discharge.

Discussion: Essiac tea contains red clover, sheep sorrel, burdock root, and rhubarb which has extremely high potassium content. It is hepatotoxic and nephrotoxic when consumed in large amounts. We highlight the importance of obtaining a thorough dietary history, especially when the degree of hyperkalemia cannot be solely attributed to the extent of kidney injury. Dietary counselling is paramount in such cases.
PO1133
Real-World RAAS Inhibitor Use and Its Predictors Among Patients Initiating Sodium Zirconium Cyclosilicate
Abhy Agiro,1 Alpesh Amin,2 Fan Mu,3 Joshua A. Young,3 Erin Cook,3 Esteban J. Lemus Wirtz,2 Yasmin G. Brahmbhatt,3 Keith A. Beets,3 Charles V. Pollock,3 AstraZeneca, Wilmington, DE; 1University of California Irvine, Irvine, CA; 4Analysis Group Inc., Boston, MA; 4University of Mississippi School of Medicine, Jackson, MS.

Background: Renin-angiotensin-aldosterone system inhibitors (RAASIs) are associated with reduced risk of death and slower disease progression in patients with heart failure (HF) and chronic kidney disease (CKD). However, RAAS use increases the risk of hyperkalemia (HK), which may disrupt RAAS use and mitigate its benefits. There is limited real-world evidence characterizing RAAS use after sodium zirconium cyclosilicate (SZC) treatment.

Methods: Adult patients initiating SZC (index date) while on a RAASI in outpatient care were included from a large US claims database (January 2018-June 2020). Analyses were conducted among all patients, patients with CKD and patients with CKD + diabetes (DM). The percent of patients with a RAASI prescription index was summarized. Characteristics among patients with and without a new RAASI fill were compared using descriptive statistics. A multivariable logistic regression model assessed predictors of a new RAASI fill.

Results: A total of 589 patients initiating SZC while on a RAASI were included (mean age 61 years, 65.2% male). Overall, 82.7% of patients had a new RAASI fill after index. The median time to discontinuation was not reached among patients with a new RAASI fill, of whom 88.1% at day 180 and 74.0% at 1 year remained on RAASI therapy. Median time on RAASI was 29 days (95% CI 27-34 days) for those with no new RAASI fill. Compared to patients without a new RAASI fill, patients with a new fill had a higher burden of CKD (69.4% vs 58.8%) but a similar prevalence of DM (70.6% vs 67.6%) and HF (24.6% vs 28.4%). Results were similar in the CKD cohort (N=398; 84.9% had a new RAASI fill) and CKD and DM cohort (N=311; 85.2% had a new fill). Predictors of having a new RAASI fill included fewer prior hospitalizations (0.77 [0.60-0.98]; p<0.05) and emergency department (ED) visits (0.78 [0.63-0.97]; p<0.05).

Conclusions: In a real-world setting, 83% of patients had a new RAASI fill within 90 days after ending their index RAASI. Results were consistent with clinical trial findings and among similar patients with CKD and patients with CKD + DM. Patients with hospital and ED visits will require follow up care to encourage RAASI continuation.

 Compatibility Study of Patiromer with Juices/Liquids and Soft Foods
Martin Khoeiklang,1 Maria Wilhelm,1 Lingyan Li,2 Carol P. Moreno Quinn,3 Tamara Popov,1 Vifor International AG, Saint Gallen, Switzerland; 2Vifor Pharma Group, Redwood City, CA.

Background: Patiromer is a novel, once-daily, sodium-free K+-binder approved for the treatment of hyperkalemia. The drug–a tasteless, odorless powder–is administered orally, typically suspended in water. Recently, the FDA approved apple or cranberry juice as suspension vehicles, and ED visits will require follow up care to encourage RAASi continuation.

Methods: Adult patients initiating SZC (index date) while on a RAASI in outpatient care were included from a large US claims database (January 2018-June 2020). Analyses were conducted among all patients, patients with CKD and patients with CKD + diabetes (DM). The percent of patients with a RAASI prescription index was summarized. Characteristics among patients with and without a new RAASI fill were compared using descriptive statistics. A multivariable logistic regression model assessed predictors of a new RAASI fill.

Results: A total of 589 patients initiating SZC while on a RAASI were included (mean age 61 years, 65.2% male). Overall, 82.7% of patients had a new RAASI fill after index. The median time to discontinuation was not reached among patients with a new RAASI fill, of whom 88.1% at day 180 and 74.0% at 1 year remained on RAASI therapy. Median time on RAASI was 29 days (95% CI 27-34 days) for those with no new RAASI fill. Compared to patients without a new RAASI fill, patients with a new fill had a higher burden of CKD (69.4% vs 58.8%) but a similar prevalence of DM (70.6% vs 67.6%) and HF (24.6% vs 28.4%). Results were similar in the CKD cohort (N=398; 84.9% had a new RAASI fill) and CKD and DM cohort (N=311; 85.2% had a new fill). Predictors of having a new RAASI fill included fewer prior hospitalizations (0.77 [0.60-0.98]; p<0.05) and emergency department (ED) visits (0.78 [0.63-0.97]; p<0.05).

Conclusions: In a real-world setting, 83% of patients had a new RAASI fill within 90 days after ending their index RAASI. Results were consistent with clinical trial findings and among similar patients with CKD and patients with CKD + DM. Patients with hospital and ED visits will require follow up care to encourage RAASI continuation.

PO1135
Risk of Heart Failure in Patients Who Initiated Sodium Zirconium Cyclosilicate vs. Patiromer
Min Zhuo,1,2 Seoyoung C. Kim,3 Elisabetta Patornò,4 Rishi J. Desai,5 Julie M. Paik,6,7 Beth Israel Deaconess Medical Center, Boston, MA; 8Brigham and Women’s Hospital Department of Medicine, Boston, MA; 9VA New England Geriatric Research Education and Clinical Center, Boston, MA.

Background: Hyperkalemia is common in patients with chronic kidney disease (CKD), heart failure, and diabetes. Sodium zirconium cyclosilicate (SZC) and patiromer were recently approved for the treatment of hyperkalemia. Since SZC contains significant amounts of sodium, we assessed the risk of heart failure hospitalization (HHF) associated with the initiation of SZC versus patiromer in non-dialysis patients.

Methods: We used a U.S. commercial insurance claims database (Optum Clininformatics® Data Mart) between May 2018 (after SZC approval) and September 2020. Participants were non-dialysis adults who had a 180 days of insurance enrollment and were newly prescribed SZC or patiromer. The primary outcome was a hospitalization with a discharge diagnosis of heart failure. The secondary outcome was a hospitalization or an emergency room visit with a diagnosis of any edema. Propensity score (PS) matching in a variable ratio up to 1:3 was used to adjust for more than 80 variables, including demographic characteristics, comorbidities, medication use, and health care utilization. Cox proportional hazards regression models were used to generate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Our cohort included 1,126 SZC initiators and 2,839 PS-matched patiromer initiators (total N=3,965). The mean age was 72 (±10) years, 50% had a history of heart failure and 85% had CKD stages 3-5. The risk of HHF was higher in the SZC initiators compared to patiromer initiators (HR 1.22, 95%CI 0.95-1.56), but the confidence interval included the null value (Table). Edema was more common in the SZC initiators (HR 1.89, 95%CI 1.05-3.39). In subgroup analyses, initiation of SZC was associated with an increased risk of HHF (HR 1.58, 95%CI 1.01-2.46) amongst patients without a history of heart failure.

Conclusions: Patients initiating SZC may need to monitor volume status and consider dietary salt restrictions and initiation or adjustment of diuretics. Larger studies are needed to more precisely evaluate the safety of SZC in routine practice.

PO1136
RXD013, a Novel, Oral, Small Molecule Being Developed for Treatment of Hyperkalemia, Increases Colonic Secretion and Fecal Excretion of Potassium
Kenti Konzuka,1 Matthias Siegel,2 Andrew J. King,3 Jill N. Kohler,2 Zhizhong J. Jiang,1 Allison Quach,1 Cyra Fang,1 Ying He,1 Padmapriya Kumaraswamy,1 Limin He,1 Cathy M. Le,1 Catarina Tran,1 Jeremy Caldwell,4 David P. Rosenbaum,1 Jeffrey Jacobs,1 Ardeley Inc, Fremont, CA; 2Awnita Biosciences, San Carlos, CA; 3Chinoik Therapeutics Inc, Vancouver, BC, Canada; 4Inception Therapeutics, San Diego, CA.

Background: Potassium (K+) homeostasis is maintained by the balance of dietary K+ intake, extra- and intracellular K+ distribution, and renal and intestinal excretion. Hyperkalemia (serum K+ >5.0 mM) occurs frequently in CKD patients and can lead to cardiac arrhythmias and sudden death; controlling serum K+ may reduce mortality in this population. Current therapeutic options for the chronic treatment of hyperkalemia are limited to K+-binding agents. Here, we describe the discovery of RXD013, a novel, oral, small molecule K+ secretagogue in development for treatment of hyperkalemia.

Methods: Male Sprague Dawley rats (n=6/group) were orally administered vehicle or 6 mg/kg RXD013 twice daily for 6 days. 24-hour fecal samples collected from rats housed individually in metabolic cages on the final study day were homogenized, and K+ and sodium were analyzed by cation exchange chromatography.

Results: RXD013 significantly increased fecal K+ excretion compared to vehicle control animals (figure). Fecal sodium was also increased by RXD013 (figure), which was expected as luminal sodium retention in the intestine is key to the pharmacodynamic response.

Conclusions: Based on its unique mechanism of action which involves pharmacologically enhancing K+ secretion through apical K+ channels in the colon, RXD013 is a potential first-in-class therapy which may provide a new approach to managing serum K+ in patients versus commonly prescribed K+ binders. A phase 2 clinical study with RXD013 (NCT04780841) is ongoing in non-dialysis CKD patients with hyperkalemia.

PO1137

Artificial Intelligence-Assisted Electrocardiography for Early Diagnosis of Thyrotoxic Periodic Paralysis

Shih-Hua Lin,1 Chih-Chien Sung,1 Min-hua Tseng,2 ’Tri-Service General Hospital, Taipei, Taiwan; 2Chang Gung Memorial Hospital, Tao-yang, Taiwan

Background: Thyrotoxic periodic paralysis (TPP) characterized by acute weakness, hypokalemia and hyperthyroidism is a medical emergency with a great challenge in early diagnosis since most TPP patients do not have overt symptoms. Since both hypokalemia and hyperthyroidism in TPP significantly affect the cardiovascular system, electrocardiography (ECG) as a prompt and non-invasive bedside tool universally used in the ED may detect these electrical changes. To assess artificial intelligence (AI)-assisted electrocardiography (ECG) combined with routine laboratory data in the early diagnosis of TPP.

Methods: A deep learning model (DLM) based on ECG12Net, an 82-layer convolutional neural network, was constructed to detect hypokalemia and hyperthyroidism. The development cohort consisted of 39 ECGs from patients with TPP and 502 ECGs of hypokalemic control; the validation cohort consisted of 11 ECGs of TPP and 36 ECGs of non-TPP with weakness. The AI-ECC based TPP diagnostic process was then consecutively evaluated in 22 male patients with TPP-like features.

Results: In the validation cohort, the DLM-based ECG system detected all cases of hypokalemia in TPP patients with a mean absolute error of 0.26 mEq/L, and diagnosed TPP with an area under curve (AUC) of ~80%, surpassing the best standard ECG parameter and 502 ECGs of hypokalemic control; the validation cohort consisted of 11 ECGs of TPP and 36 ECGs of non-TPP with weakness. The AI-ECC based TPP diagnostic process was then consecutively evaluated in 22 male patients with TPP-like features.

Conclusions: An AI-ECC system reliably identifies hypokalemia in patients with paralysis and its integration with routine blood chemistry provides valuable decision support for the early diagnosis of TPP to avoid life-threatening complication.

PO1138

Will the Real Sodium Stand Up!

Nia Flemming, Michael Basir, Ro-Kaye A. Simmonds, Latoya N. Gayle, Zachary Banbury, Deborah A. Fein. Englewood Health, Englewood, NJ

Introduction: Hyponatremia is a common finding as it could be precipitated by multiple factors ranging from medications to simply dehydration. Accurate approach to management depends on assessing serum osmolality in an effort to distinguish cases of true, factitious or pseudohyponatremia. We present a case of hyponatremia secondary to hyperlipidemia.

Case Description: 36 year old Asian woman with HTN, Type 2 DM, HLD presented with 1 day of epigastric pain. On exam S1, S2 were heard with vesicular breath sounds throughout, epigastric tenderness and no focal neurological deficits. Initial labs: sodium 114 potassium 3.5 chloride 85 glucose 254, BHB 3.7, sodium corrected for glucose 116 through, epigastric tenderness and no focal neurological deficits. Initial labs: sodium 114 potassium 3.5 chloride 85 glucose 254, BHB 3.7. Sodium corrected for glucose 116

Discussion: Sodium is most commonly measured by indirect potentiometric (ISE) measurement. By this method serum specimens are diluted based on estimated typical balance of serum to solid blood components. By this method factitious low sodium results are known to occur in patients with significantly elevated lipids and protein. As in this case, direct sodium measured by VBG/ABG are most accurate. Typically markedly elevated serum triglyceride with concentrations >1500 mg/dL are thought to be responsible for factitious hyponatremia. In our patient the value of serum sodium on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ + 0.4 mEq/L x (Total Lipid x 0.002); measured serum sodium would have been expected to be 125 mEq/L. In cases of extremely high lipids, one must consider lab techniques for measuring serum sodium, as well as full lipid panel in the evaluation and treatment of factitious hyponatremia.

PO1139

Admission Sodium and Related Features to Predict Falls in Medical Learning Models

Alexander S. Leidner,1 Biruth Workeneh,2 Bing Ho.1 ’Northwestern University Feinberg School of Medicine, Chicago, IL; 2The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Hyponatremia has been associated with an increased risk for falls, but evidence is primarily limited to outpatient events. Hyponatremia is a potential surrogate of conditions that may lead to falling including volume depletion, malignancy, pain, polypharmacy, and weakness. We hypothesized that a model could be developed to predict falls based upon available variables present on all hospital admissions. An accurate model could allow for measures to lower in-hospital falls.

Methods: Medical records from a single institution were collected over a period of 2011 to 2019. Subjects included admitted patients who suffered a recorded in-hospital fall and were admitted, and controls matched for admission on the same date. Variables collected included sodium, glucose, age and gender. There were 17,103 patients total of which 1,203 had unique falls. Data was split into an 80% training, 20% validation and 20% testing split. We computed an unadjusted odds ratio of falls for those with very low sodium (<126). We trained logistic regression, random forest, XGBoosted forest, and neural net classifiers. Classifier cutoff was calculated using Youden values.

Results: We did not see an increased incidence of falls in the population with a low sodium (N=377) with an unadjusted odds ratio of 0.62 (CI 0.38-1.01). Similarly, the model performances did not result in clinically useful predictions with a unanimously high false positive and false negative rates (Figure 1).

Conclusions: Despite reports of hyponatremia as an indicator of fall risk we did not observe this. The fall-prediction models did have the capacity for high performance on the training data, but this does not translate to validated performance. This discrepancy is termed ‘overfitting’ and is important to evaluate as machine learning models have a much larger capacity than traditional statistical models to incorporate previously seen examples. If a model cannot make predictions on new data it cannot be clinically useful. These models may be enhanced using other basic admission features and is the subject of future work.

PO1140

Association of Serum Sodium Levels with Bone Mineral Density, Fracture, and Mortality in Patients Undergoing Maintenance Hemodialysis

Keisuke Soeda,1 Hirotaka Komaba,1 Yosuke Nakagawa,1 Takehiro Wada,1 Takatoshi Kakuta,2 Masafumi Fukagawa.1 1Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan; 2Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan

Background: Hyponatremia is implicated in pathological bone resorption and has been identified as a risk factor for bone fracture in the general population, but limited data exist in patients undergoing dialysis.

Methods: We analyzed a historical cohort of 2,292 patients undergoing maintenance hemodialysis in Japan. We first examined the association of baseline sodium levels with metacarpal bone mineral density (BMD) in a subcohort of 456 patients with available data next, we examined the association of baseline sodium levels with incident fracture and mortality in the overall cohort, using Cox regression models adjusted for potential confounders (age, sex, dialysis vintage, diabetes, prior cardiovascular disease, history of fracture, body mass index, hemoglobin, albumin, and creatinine) and competing risks regression models accounting for death as a competing endpoint.

Results: Baseline mean ± SD serum sodium level in the overall cohort was 139.7 ± 2.9 mEq/L, and among patients with available data, median metacarpal BMD T-score was -2.05 (IQR, -3.35 to -0.99).

Serum sodium levels were not associated with metacarpal T-score in unadjusted or adjusted models. During a median follow-up of 5.4 years (IQR, 2.5-7.0 years), 712 patients died; 113 experienced clinical fractures; and 64 experienced asymptomatic vertebral fractures as estimated by height loss. In addition, Cox sodium levels were associated with metacarpal T-score (HR, 0.95 per 1 mEq/L higher; 95% CI, 0.92-0.98) but not incident clinical fracture (HR, 0.97 per 1 mEq/L higher; 95% CI, 0.90-1.04) or any fracture (a composite of clinical fracture and vertebral fracture). Similar results were obtained in competing risks regression models.

Conclusions: Serum sodium levels were associated with mortality but not BMD or incident fracture in maintenance hemodialysis patients.
Hyponatremia, Inflammation, and Hospital Mortality in Hospitalized COVID-19 Patients
Juan Carlos Ayus1, Michael L. Mortiz,2 Kyung Min Lee,2,* Daniel Caputo,4 Maria E. Borda,2 Alan S. Go,2 Carlos Eglih,2 University of California Irvine School of Medicine, Irvine, CA; 3UCMC Children’s Hospital of Pittsburgh CH UPMC Development Unit, Pittsburgh, PA; 1University of Pittsburgh School of Medicine, Pittsburgh, PA; 4Hospital Posados, Buenos Aires, Argentina; 5Kaiser Permanente, Oakland, CA; 6University of California San Francisco, San Francisco, CA.

Background: Systemic inflammation has been associated with severe COVID-19 disease. Hyponatremia can result from inflammation due to non-osmotic stimuli for vasopressin production. Hyponatremia is an independent risk factor for hospital mortality.

Methods: Hospitalized patients with COVID-19 were prospectively evaluated between March and November 2020 at Hospital Posadas in Buenos Aires, Argentina, in order to evaluate the association between hyponatremia and inflammation and its impact on clinical outcomes. Admission biochemistries, high-sensitivity C-reactive protein (hsCRP), ferritin, patient demographics, and outcome data were recorded. Outcomes (within 30 days after symptom) that were evaluated included admission to the ICU during hospitalization, mechanical ventilation, dialysis-requiring AKI, and in-hospital deaths. In-hospital mortality, length of hospital stay (in days), and hospital readmission for any cause within 30 days after discharge were evaluated using comprehensive data from the EHR.

Results: Among 799 hospitalized COVID-19 patients, hyponatremia was present on admission in 366 (45.8%). Hyponatremic patients had higher hsCRP levels than normonatremic patients (median 10.3 [IR 4.8-18.4] mg/dl vs 6.6 [IR 1.6 – 14.0] mg/dl, respectively, p < 0.01), and hsCRP level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient = – 0.23; p < 0.01). Hyponatremic patients had higher serum ferritin levels than normonatremic patients (median 649 [IQR 492-1168] ng/dl vs 393 [IQR 156-1440] ng/dl, respectively, p = 0.02), and serum ferritin level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient = – 0.26; p < 0.01). Hyponatremic patients had increased mortality on unadjusted (odds ratio 1.87, 95%CI:1.28-2.73) and adjusted (odds ratio 1.61, 95%CI:1.05-2.49) Cox proportional hazard models. Crude 30-day survival was lower for patients with hyponatremia at admission (mean [SD] survival 22.1 [0.70] days) compared with patients who were normonatremic (mean [SD] survival 27.1 [0.40] days, p < 0.01).

Conclusions: This study demonstrates that hyponatremia on admission is common in patients with COVID-19 and is associated with inflammation and in-hospital mortality. Thus, hyponatremia could be a novel marker for identifying patients with COVID-19 at risk for hospital mortality.

Trends of Overall Mortality by Severity of Hyponatremia: Five-Year Mortality Rates
Peter E. Umskorp,1 Fahad A. Lodhi,2 Javad Najjar Mojarrab,1 Indiana University School of Medicine, Indianapolis, IN; 2Marshfield Clinic Health System, Marshfield, WI.

Background: We have previously reported increasing strengths of association between degree of hyponatremia on hospital admission and proportions of overall mortality at 1 year post-hospitalization. It is unclear if this association persists in the long term and if this association with overall mortality occurs in a linear manner. Here, we further explore this association over a longer mean follow up period. We hypothesized that a dose response relationship occurs between varying degrees of hyponatremia and overall mortality.

Methods: We obtained data from 46,783 patients, average age 62.2 years, 51.3% males, admitted from January 1, 2012 to December 31, 2016 at a tertiary referral hospital in Central Wisconsin. Of these, 7468 patients had admitting serum <135 and 39315 controls with normal serum sodium (135-145). We parsed hyponatremia based on their admitting serum sodium as mild (130-134), moderate (125-129) and profound (<125) degrees of hyponatremia and compared them with controls. We obtained their vital status (alive or deceased) up to December 31, 2018 over a mean follow up period of 4.7 years. We used Cox proportional hazards model to estimate hazard ratios between varying degrees of hyponatremia compared with normonatremia group after adjusting for covariates.

Results: Hyponatremia occurred in 17.9% of total hospitalizations during the study period. Of 7468 patients with hyponatremia, there were 6,135 (82.2%), 995 (13.3%) and 338 (4.5%) with mild, moderate, and profound degrees of hyponatremia respectively. Hazard ratios for mild, moderate and severe hyponatremia when compared to controls was 1.35 (95%CI: 1.28 – 1.43), 1.81 (95% CI: 1.24 – 2.56) and 2.01 (95% CI: 1.24 – 3.27) respectively (all p<0.001) after adjusting for covariates.

Conclusions: All-cause mortality from CVD, stroke, cancer, liver cirrhosis deaths were occurring to a significant proportion even in patients with milder degrees of hyponatremia with a dose response relationship. Clinicians should incorporate hyponatremia in their assessment of critical patients as this is associated with mortality. These findings need to be explored further with research geared towards elucidating mechanisms that contribute to death in hyponatremia, and if correcting sodium levels early in hospitalizations may prevent mortality in the future.

The Prognostic Importance of Serum Sodium for Mortality Among Critically Ill Patients Requiring Continuous Renal Replacement Therapy
Charat Thongprayoon,1 West Chueungsapitorn,1 Khaled Shawa,2 Kianoush Kashani,1 Mayo Clinic Minnesota, Rochester, MN; 1West Virginia University, Morgantown, WY.

Background: Serum sodium derangement is common in critically ill patients requiring continuous renal replacement therapy (CRRT). We aimed to assess the association between serum sodium (normal range 138-142 mmol/L) before and after initiating CRRT with mortality.

Methods: This is a historical cohort study of 1,520 critically ill patients who received CRRT for at least 24 hours from December 2006 through November 2015 in a tertiary hospital in the United States. Using logistic regression analysis, we used sodium level before CRRT, mean serum sodium, and sodium changes during CRRT to predict 90-day mortality after CRRT initiation.

Results: Compared with the normal serum sodium levels, the odds ratio (OR) of 90-day mortality in patients with serum sodium before CRRT of 143-147 and ≥148 mmol/L were 1.45 (95% CI 1.03-2.05), 2.24 (95% CI 1.33-3.87), respectively. There was no significant increase in 90-day mortality in serum sodium of ≥137 mmol/L. During CRRT, the mean serum sodium levels of ≤137 (OR 1.41; 95% CI 1.01-1.98) and ≥137 mmol/L (OR 1.52; 95% CI 1.14-2.03) were associated with higher 90-day mortality. The greater serum sodium changes during CRRT were associated with higher 90-mortality (OR 1.35; 95% CI 1.21-1.51 per 5-mmol/L increase).

Conclusions: Before CRRT initiation, hypernatremia and during CRRT, hypo-, and hyponatremia were associated with increased mortality.

Use of Tolvaptan to Maintain Eunatremia in Acute Brain Injury-Induced SIADH
Maria Christina Victoria M. Capistrano,1 Ankur Shah,2 ’Kent Hospital, Warwick, RI; ’Brown University Warren Alpert Medical School, Providence, RI.

Introduction: Eunatremia is a predictor of in-hospital mortality in intracerebral hemorrhage. In hyponatremia from SIADH, usual therapies may not be ideal in patients with acute brain injury. We present a case of hyponatremia from acute brain injury induced SIADH being managed with Tolvaptan.

Case Description: Our patient is a 68 year old man with a history of hypertension who was admitted for an acute hemorrhagic stroke. He had a blood pressure of 204/127 mmHg and an NIHSS score of 110. His initial work up shows: glucose 199 mg/dL, creatinine 0.75 mg/dL, Na 137 mmol/L, potassium 3.8 mmol/L, HCO3 25 mmol/L, chloride 95 mmol/L. A head CT scan demonstrated a 10 cm right thalamic hemorrhage. He was then started on a nicardipine drip. On the next day, he was noted to have a Na of 124 mmol/L. His serum osmolality, urine osmolality, urine Na were 289 mosM/kg, 6,783 mosM/kg and 146 mosM/L respectively. He was given salt tablets with water.
improvement of Na to 131. However, he developed headaches and became hypertensive at 180/94 mmHg. Instead, he was started on a high protein diet, 1 liter fluid restriction and lasix. The next Na level was 129. He was given Tolvaptan 15 mg, which improved the Na to 132, urine osm 645, and urine Na to 12. The dose was increased to 30 mg to achieve eunatremia with these values: Na 135-138, urine Na 12, urine osm 487. His BP improved, tolvaptan was discontinued and salt tablets were resumed. The patient maintained eunatremia throughout the hospital stay.

Discussion: Hyponatremia is a predictor of mortality due to cellular edema. Eunatremia with Na levels between 135-145 mmol/L is targeted in acute brain injury. SIADH induced by brain injury may be due to an increase in ADH from the overstimulation of the neurohumoral axis. ADH promotes water reabsorption at the cortical and medullary collecting tubules, and inappropriate levels lead to hyponatremia. Tolvaptan is a V2 receptor antagonist which combats this mechanism, thus increasing free water excretion. Additional therapies for hyponatremia from SIADH include fluid restriction, a high protein diet and salt tablets. However, salt tablets increases fluid retention; which increases blood pressure, and leads to recurrent hemorrhage and poor outcomes. The use of Tolvaptan increases free water excretion to achieve eunatremia, thereby decreasing the risk of brain edema and controls blood pressure, especially in this patient population.

PO1145

Acute Severe Symptomatic Hyponatremia in the Post-Partum Period: The Syndrome of Oxytocin-Induced Anti-Diuresis (SOIAD)
Muhammad A. Shahzad, William L. Whittier, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

Introduction: Oxytocin (OXT) is a neuropeptide used in pregnancy to induce uterine contraction. It is structurally related to vasopressin (AVP) by a difference of only 2 amino acids. While it does not have antidiuretic activity at physiologic levels, it can when administered at pharmacologic doses (>20 mU/min). We present a case of severe symptomatic hyponatremia after receiving oxytocin in the post-partum period.

Case Description: A 31 y/o G1P0 woman was admitted with premature membrane rupture at week 38. An IV oxytocin infusion (2mU/min) was started to augment labor. Her serum sNa 6 hrs later was 132 mmol/l (baseline sNa 140). Her delivery was c/v uterine atony and postpartum hemorrhage requiring a bolus of IV oxytocin (10 U over 30 min) followed by infusion at 8 mU/min. The sNa 18 hr later was 118 mmol/l. She reported nausea. Her sOsm was 252 mOsm/kg with UNa of 95 mmol/l and Uosm 880 mOsm/kg consistent with the syndrome of anti-diuresis (SIAD). OXT was suspected and was stopped. 2 hr later, a rapid water diuresis ensued (uN 150-200 c/h, with uoN 92 mOsm/kg). The sNa 4 and 8 hrs later increased to 124 and 127 respectively. Because of concern for over-correction, she was given DDAVP and DSW. This resulted in a gradual (6-8 mOsm/L/24 hr) sNa increase to 140 mmol/l over the next 48 hr (Fig 1).

Discussion: Therapeutic OXT can result in anti-diuresis with water retention. OXT half-life is only 1-6 min and is further reduced during pregnancy. Women are more likely to have severe neurologic sequelae of hyponatremia so it is fortuitous that the half-life of OXT is so short, and discontinuation alone should result in a rapid water diuresis. Still, although acute hyponatremia can usually be safely corrected rapidly, concern over what could have been an increase in sNa of 28 mmol/l over several hrs necessitated a DDAVP clamp to slow correction. She had a complete recovery. SOIAD can be a severe complication of OXT. Since it can occur rapidly and severely, sNa should be followed closely when patients are on OXT infusion.

A Rare Cause of Hyponatremia: Renal Salt Wasting Syndrome of Unclear Etiology Post Autologous Hematopoietic Stem Cell Transplant
Adriann S. Polani,1 Vikas D. Reddy,2 Venkata Kishore R. Mukku,3 Vishnupriyadevi Parvathareddy,1 Sheldon Chen.4 Baylor College of Medicine, Houston, TX; The University of Texas Health Science Center at Houston John and Katherine G McGovern Medical School, Houston, TX;1 The University of Texas Medical Branch at Galveston School of Medicine, Galveston, TX;2 The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Hyponatremia is common in cancer patients. We report a rare case of acute hyponatremia in a patient with multiple myeloma (MM) who developed renal salt wasting syndrome (RSWS) as a complication of autologous hematopoietic stem cell transplant (SCT).

Case Description: A 57-year-old female with history of multiple myeloma treated with radiation therapy that subsequently relapsed as MM with POEMS syndrome and was treated with VRd regimen presented for autologous SCT. MM was in remission and patient underwent Melphalan pre-conditioning with last melphalan dose 48 hours prior to transplant. 36 hours post-transplant patient had a seizure. Labs revealed acute drop in serum sodium from 137 to 117 over 17 hours. CT head revealed mild generalized cerebral edema. Patient also had acute polycluria (> 4 L/day). Patient was treated emergently with hypertonic saline bolus and had resolution of neurological symptoms however, serum sodium continued to drop and she required around 2 L of hypertonic saline infusion over the next 24 hours to correct sodium at desired rate. Urine studies at the time of hyponatremia revealed urine osmolality of 477, sodium 176 and potassium 34. Initial working diagnosis was SIADH that was quickly revised to RSWS based on high urine sodium, hypovolemia and polycluria. The patient was able to be transitioned to salt tablets once polycluria resolved over the next 36 hours. Urine sodium remained elevated. A repeat CT head showed resolution of cerebral edema.

Discussion: RSWS post SCT is rarely reported. Among the few reported cases an underlying CNS complication or a post-transplant hyponatremia inducing medication exposure that predated acute hyponatremia was present. Moreover the reported cases appeared to be non autologous transplants. SIADH and RSWS (including CSWS) are similar in the sense that both present with similar urine studies. Volume status and urine output are the key factors to help differentiate between the two entities. Clinically differentiating between these two entities is important as fluid restriction is the key management in the one and solute plus volume replacement in the other. Based on our case we recommend that hyponatremia post SCT should be carefully evaluated and RSWS be considered in the differential even if there is no obvious underlying cause.

An Unexpected Case of Osmotic Demyelination Syndrome (ODS)
Raphael J. Rosen,1 Shellef Robbins-Juarez,2 Pallavi S. Utukuri,1 Eric Siddall.1 Columbia University Irving Medical Center, New York, NY; 2Columbia University Vagelos College of Physicians and Surgeons, New York, NY.

Introduction: ODS is a neurological condition characterized by altered mentation, extrapyramidal symptoms, and pseudobulbar palsy in response to a rapid increase in serum osmolality. Classically ODS has been described after rapid correction of severe, chronic hyponatremia but can occur with slower rates of correction in high-risk patients, as described herein.

Case Description: A 44-year-old man with alcoholism presented with a sodium of 115meq/L. Normal saline was administered and his sodium corrected to 123meq/L over the initial 24 hours. His sodium corrected slowly over the next 5 days to normal range, never exceeding 8 meq/L per day. On day 5, he developed nystagmus, cogwheeling rigidity, hallucinations and aspirations. Brain MRI revealed abnormalities in the central pons (fig. 1), and a diagnosis of ODS was made. DSW and desmopressin were administered, lowering the sodium from 142meq/L to 131meq/L over 2 days, where it was maintained for 24 hours. No clinical improvement resulted and neurological sx progressed. The sodium was then allowed to rise slowly to normal over 2 days, shown in fig. 2. By discharge the patient had moderate improvement in speech and swallowing.

Discussion: This case of ODS was unusual in that it occurred despite modest hyponatremia, which corrected at only 8meq / day. ODS can occur despite slow sodium correction in the context of risk factors such as alcoholism. Therapeutic lowering of sodium resulted in no improvement, possibly because lowering was not pursued until MRI confirmation, leading to a delay of 72 hours from symptom onset.
MRI brain (DWI sequence) demonstrating restricted diffusion in the central pons (arrow).

Cerebral Salt Wasting in a Renal Transplant Patient
Prashanth Reddy, Sahityan Viswanathan. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Hyponatremia is a common occurrence in patients with cerebral injury and is usually thought to be secondary to SIADH. Though cerebral salt wasting is documented in literature it has been debated on if it is truly a phenomenon. Among patients with CNS disease, CSW is a much less diagnosed cause of hyponatremia and remains underdiagnosed owing to the challenge of proving its existence. Here we present a patient with a CNS injury who showed clear benefit from treatment not centered around SIADH, thus pushing us to diagnose him with CSW.

Case Description: A 63yo Male with a PMHx of DDKT presented with nausea/vomiting. A cerebellar abscess from a previous biopsy site was found and he underwent a debridement and washout. On POD#4 the patient had a drop in sodium to 131. Urine studies [urine osmolality: 789, urine Na: 72]. With continued drop in sodium and orthostatic hypotension he was started on NS 75cc/hr. The sodium continued to drop to a low of 123. At that time the NS was increased to 125cc/hr. This resulted in an upswing in urine sodium concentration. A drop in NS rate was trialed with sodium dropping back to 127. At that time the NS was increased to 125cc/hr. This resulted in an upswing in urine osmolality. The patient was eventually transitioned to a dose of salt tabs close to the equivalent to the amount of fluids he was receiving [5g Q4H]. He was also started on Fludrocortisone 0.1mg daily. This resulted in our ability to drop the Salt tabs to 4g Q6H with stability in serum sodium noted. He was discharged on this regimen and was noted to have stable serum sodium on follow up a few weeks later.

Discussion: CSW is difficult to diagnose due to the similarities in laboratory diagnostic markers with SIADH. One major difference is that in CSW patients are usually hypovolemic. Another aspect that differs from SIADH is the approach to treatment. In SIADH a combination of fluid restriction, lasix, and salt tabs are used. What makes our case unique is the successful use of NS to correct the patient’s sodium. If this was SIADH, continuous administration of NS would have dropped the sodium level. We believe we met the burden of proof to diagnose this patient with CSW. Though there may still be debate about the existence of CSW, we believe that with the difference in treatment approach it should always be considered in the differential in patients with CNS injury.

PO1149
Explainable Prediction of Overcorrection in Severe Hyponatremia: A Post Hoc Analysis of the SALSA Trial
Hujin Yang,1 Seon Ha Baek,2 Sejoong Kim.1 Hallym University Dongtan Sacred Heart Hospital, Gyeonggi-do, Republic of Korea; 2Seoul University Bundang Hospital, Gyeonggi-do, Republic of Korea.

Background: Overcorrection of hyponatremia can result in irreversible neurologic disability like osmotic demyelination syndrome. Few prospective studies have identified the individuals at high risk of overcorrection under controlled hypertonic saline treatment.

Methods: We performed a post hoc analysis of a multicenter, prospective randomized controlled study – the SALSA (Efficacy and Safety of Rapid Intermittent Correction Compared With Slow Continuous Correction With Hypertonic Saline In Patients With Moderately Severe or Severe Symptomatic Severe Hyponatremia) trial in 178 patients older than 18 years with symptomatic hyponatremia (mean age 73.1 years, mean serum sodium (sNa) concentrations 118.2 mmol/L). Overcorrection was defined as an increase in sNa by >12/18 mmol/L within 24/48 hours at any time.

Results: Thirty-seven of 178 patients experienced overcorrection (20.7%). Overcorrection was independently associated with initial sNa level (< 110 mmol/L: 7 points; 110-115 mmol/L: 4 points; 115-120 mmol/L: 2 points; 120-125 mmol/L: 0 point), chronic alcoholism (7 points), severe symptoms of hyponatremia (3 points), and initial potassium level (< 3.0 mmol/L: 3 points). The NASK score was derived from these four risk factors for overcorrection (hypoNatremia, Alcoholism, Severe symptoms, and hypokalemia) and was significantly associated with overcorrection (odds ratio 1.41, 95% CI 1.24 to 1.61; P <.001) with good discrimination (area under the receiver operating characteristic curve 0.76, 95% CI 0.66 to 0.85; P <.001). The AUROC value of the NASK score was statistically better comparing to those of each risk factor.

Conclusions: In treating patients with symptomatic hyponatremia, individuals at high risk of overcorrection were predictable using a novel risk score summarizing baseline information.
PO1150
On the Correction of Plasma [Na] in Hyperglycemia
Alan Segal. Steady State Nephrology, South Burlington, VT.

Background: The effect of hypertonic states on metabolism was first considered by Seldin et al in 1949. An empirical equation to correct the plasma [Na] for hyperglycemia was put forth by Katz (NEJM, 1975). About 25 years later, Hillier et al (AJM, 1999) presented another equation based on normal volunteers with experimentally induced hypertonic states. We calibrated the linear relationship with our data in 100 mg/dL [glucose] of ~1.6 (Katz) and ~2.4 (Hillier). Non-linearity, however, is apparent in the original data of Hillier, which better fit by a second-order correction (equation plasma [Na] = [-3.49 * 10^{-5} * plasma [glucose]] – (3.91 * 10^{-5} * plasma [glucose]) + 140)). Previous equations also assume hypernatremia prior to hyperglycemia and a constant volume of distribution for glucose.

Methods: Here, a new model is proposed that also provides a reasonable fit to the patient data of Seldin et al from 70 years ago (JCI, 1951) and Hillier et al. Unlike previous equations, in Seldin’s model, the formulas are based solely on current plasma [glucose], this program takes weight, sex, the presence of edema, and the apparent volume of distribution (aVd) of glucose into consideration. The latter is especially important because the aVd of glucose may change in hyperglycemia.

Results: For example, consider a patient from the 1951 JCI study by Seldin et al: a 59.1-kg edematous patient with cirrhosis who initially had a plasma [Na] of 130 mM when the plasma [glucose] was 126 mg/dL. The program starts by calculating the number of effective osmoles in the ICF and ECF based on the initial labs, and then incorporates the change in ECF volume measured by the investigators, which in this case was +1.9 L. Following infusion of hypertonic glucose, the plasma [Na] fell to 110 mM at the peak plasma [glucose] of 666 mg/dL. The corrected plasma [Na] predicted are (in mM): 130.9 (Katz), 126.4 (Hillier), and 124.5 (quadratic fit of Hillier’s data); all of which do not compare well with 110 mM. Although the program predicts 121.3 mM, after correction for the change in the aVd of glucose, it predicts 112 mM, in good agreement with the measured value of 110 mM.

Conclusions: Now that making numerous calculations can be done easily and efficiently with apps most physicians have on their phones, it is proposed that equations with linear correction factors be replaced by this new program when clinicians would like to predict or correct the measured serum [Na] in the presence of hyperglycemia.

PO1151
Extreme Hyponatremia with Serum Sodium Less Than 100 mEq/L: A Case Report and Review of the Literature
Kirti Basji, Kenneth M. Ralto. UMass Memorial Medical Center, Worcester, MA.

Introduction: Hyponatremia is the most common electrolyte abnormality in hospitalized patients and is associated with increased mortality, hospital length of stay and cost. Rapid correction of hyponatremia can increase the risk of osmotic demyelination syndrome (ODS) which can have debilitating and often fatal consequences. Extreme hyponatremia with serum sodium concentration less than 100 mEq/L is rare, but is associated with high a rate of morbidity and mortality.

Case Description: A 52-year-old woman presented with a one-week history of weakness and fatigue. She was cachectic and had signs of severe hypovolemia and malnutrition. Her serum sodium concentration was less than 100 mEq/L on three separate samples. She did not have any focal neurological deficits or any witnessed seizures. Additionally, she was found to have oliguric acute kidney injury and critical hyperkalemia. She was treated with aggressive volume expansion with subsequent increase in sodium concentration and resolution of AKI and hyperkalemia. Desmopressin and 5% dextrose infusion were used to prevent rapid overcorrection of hyponatremia and minimize the risk for ODS. Her sodium level was corrected at the recommended rate of 6 mEq/L per day. She was discharged with serum sodium concentration of 136 mEq/L on hospital day 16 and did not have any long-term neurological sequelae.

Discussion: Extreme hyponatremia with serum sodium concentration less than 100 mEq/L is a rare but critical situation. Review of the previously published cases found that the main risk factors are female gender, age greater than 40 years, malnutrition, alcohol use, the alprazolam use or SIADH due to antidepressant use. Serum osmolality should be used to estimate serum sodium concentration and guide the rate of correction if the precise sodium value below 100 mEq/L cannot be determined. Careful management of hydration is required due to the high risk of ODS in these patients and proactive administration of antidiuretic hormone is recommended to avoid overcorrection. Continuous venous hemofiltration with hypertonic replacement fluid is an effective strategy for patients with extreme hyponatremia who also require renal replacement therapy for AKI and/or critical hyperkalemia.

PO1152
SIADH and Postoperative Urinary Retention
Khawaja M. Bakhhtawar, Abdullah Jalal. Overlook Medical Center, Summit, NJ.

Introduction: Hyponatremia is a common electrolyte abnormality in hospitalized patients with increased prevalence noted in geriatric populations. The increased susceptibility is multifactorial from age-related GFR reduction in addition to medication effects (diuretics, antidepressants), decreased thirst and intake and endocrine poluaries (SIADH). Herein we present a case of severe hyponatremia induced by urinary retention, an infrequently described and often overlooked etiology of hyponatremia in elderly patients.

Case Description: A 58-year-old male with past medical history of hypertension on amlopidine and losartan presented with nausea, emesis and abdominal pain. The patient was recently discharged 2 weeks earlier s/p uncomplicated distal pancreatectomy with splenectomy for pancreatic adenocarcinoma. Post-operative course was stable with no complications and patient was discharged home on oxycodone/acetaminophen for pain. At home, the patient noticed constipation with worsening abdominal distension with bilateral lower extremity swelling. He had been oliguric for the past week, performing manual suprapubic compression to void. On readmission patient was noted to be severely dehydrated with a large, distended abdomen. Vital signs were BP 102/53, HR 87, SpO2 97%. Notable labs include (mEq/L): Na 111, BUN 132, Cr 4.4, HCO3 18. Urine studies noted (mEq/L): Na 8, Cl ~10, K 25, serum osmolality 366 mOsm/kg. Abdominal CT noted a large LUQ fluid collection, distal colonic distension with fecal retention and mild bilateral hydropneumothorax. Subsequent foley insertion immediately drained 2.5L. Repeat labs 12 hours later were (mEq/L): Na 118, BUN 118, Cr 2.89. Hypotonic fluids were started to prevent Na overcorrection. Over the next several days the patient’s Serum Na (153) and renal function improved (BUN 21, Cr 0.9) back to baseline.

Discussion: During the post-operative period urinary retention is commonly noted due to anesthesia, analgesics, pain and constipation. This can be exacerbated in elderly male patients due to the ubiquitiy of BPH. Therefore physicians must be aware of common post-operative complications of urinary retention like hyponatremia, especially given the higher prevalence and predisposition of geriatric populations to develop hyponatremia. The proposed mechanism of urinary retention induced hyponatremia involves blader distension and/or pain-mediated ADH release.
PO1154

Point-of-Care Ultrasound-Assisted Management of Hyponatremia

Totini S, Chatterjee A, Koratala A. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Point of care ultrasound (POCUS) is emerging as a valuable adjunct to conventional physical examination in patients with complex fluid and electrolyte disorders. Herein, we present a case of hyponatremia where nephrologist-performed focused cardiac ultrasound (FoCUS) aided in accurate diagnosis.

Case Description: A 73-year-old woman was admitted for the treatment of fractures after sustaining a fall. Nephrology was consulted for decreased serum sodium level (to 123 mmol/L; baseline 130s). Laboratory data was significant for a urine sodium level of 46 mmol/L, urine osmolality 257 mOsm/kg, serum creatinine 0.5 mg/dL and BUN 9 mg/dL. As the patient had exertional dyspnea and crackles at lung bases, IV diuretic was administered by the rounding physician prior to urine studies. No active pain or thiazide use. X-ray showed a huge hiatal hernia with bowel contents in the chest, which was possibly mimicking crackles on auscultation and causing dyspnea. Systolic BP was in 140s. Urine sodium, though suggestive of euvoletic state, was confounded by diuretic. We performed a FoCUS exam. Left ventricular outflow tract velocity time integral (LVOT-VTI), which is a surrogate for stroke volume was lower than expected (~13 cm [normal 18-22]) suggestive of hypovolemia. Flow changes precede drop in BP. We recommended to administer normal saline and the serum sodium improved to 130 mmol/L in 2 days; VTI normalized to ~22 cm [Fig. 1]. Fig.2 illustrates stroke volume estimation using LVOT diameter and VTI. As the diameter is constant for a given person, VTI alone can be used to monitor response to therapy.

Discussion: POCUS is a valuable bedside diagnostic tool in day-to-day nephrology practice.

PO1155

Polyethylene Glycol-Induced Pseudohyponatremia

Sweeta Reddy, Sundararaman Swaminathan. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Pseudohyponatremia due to Polyethylene glycol (PEG) is poorly described and goes unrecognized. We describe a case of hyperosmolar hyponatremia due to PEG absorption into the systemic circulation.

Case Description: An 84-year-old lady with hypertension and CKD stage 4 was admitted with an asymptomatic serum sodium of 121. Initially thought to be due to SIADH. She was started on 1-liter fluid restriction, sodium chloride tablet and torsemide. Nephrology was consulted on day 3 as her serum creatinine was 2.9 (baseline 2.3 mg/dL) and sodium improved to only 124. Patient complained of increased thirst and had dry mucus membrane on examination. Labs on admission revealed a serum sodium of 121 mEq/L, a serum osmolality of 286 mOsm/kg, urine osmolality of 230 mOsm/kg and urine sodium of 40. Serum creatinine was 2.3 mg/dL, BUN 50 mg/dL, glucose of 100mg/dL, uric acid 8.1 mg/dL. Thyroid function tests and cortisol were within normal range. An osmolar gap of 22 was noted. In the absence of hyperglycemia and other potential causes of an osmotic gap, such as mannitol or alcohol, a careful review of medication showed that she was on 3 weeks of PEG for constipation. PEG was held, fluid restriction and torsemide discontinued. Resolution of osmolar gap was confirmed in two weeks with return in sodium to 134 and creatinine to 2.3.

Discussion: The prevalence of hyponatremia is reported at 7% in bowel prep patients. Etiology in these cases was due to increased free water intake. Hyperosmolar hyponatremia is caused by the addition of an ‘effective solute’ (e.g. glucose, mannitol or sucrose) to the serum. Commonly used as an osmotic laxative, PEG is described as a ‘pure osmotic agent’ in the gastrointestinal tract. Systemic absorption can occur in rare cases. When PEG absorption occurs, most of its clearance occurs via renal filtration, this process is likely impaired in a patient with CKD such as seen in our patient. When a patient presents with hyponatremia, the expectation of a low-serum osmolality needs to be confirmed with the actual measurement of serum osmolality. This case highlights the importance of detecting the etiology of hyponatremia without which treatment of the same can be impossible and expands the understanding of normal to high serum osmolality can go beyond the commonly known mannitol, paratvolemin and lipedemia.
A Rare Case of Acute Myeloid Leukemia Presenting as Central Diabetes Insipidus
Dharika P. Shah, Alka A. Tyagi, Mohankumar Doraiswamy, Sethu M. Madhavan. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Central Diabetes Insipidus (CDI) is an uncommon condition, with an overall incidence of approximately 1:25,000 and is usually associated with neurosurgery, trauma, autoimmune and vascular disease, infiltrative disorders, hypoxic brain injury and brain metastasis. Patients with acute myeloid leukemia (AML) mostly present with symptoms of pancytopenia, noted to have hematologic abnormalities and are subsequently diagnosed with AML after bone marrow biopsy. Here we describe a unique case of a patient who presented with symptoms of CDI and incidentally diagnosed with AML.

Case Description: A 64-year-old male with a history of coronary artery disease presented to his primary physician complaining of polyuria and polydipsia which affected his work as a truck driver. Labs were notable for mild anemia (Hgb 11 g/dL) with macrocytosis, thrombocytosis (platelet 667 K/UL), serum sodium was 146 mmol/L, Hgb Alb 5%, prostate-specific-antigen 1.4 ng/mL, normal lipid panel, and normal thyroid function. No definitive diagnosis was made and he underwent evaluation by hematology. Peripheral smear showed increased (44%) blasts/promyelocytes, consistent with acute leukemia. Cytagenetic analysis showed an abnormal clone of cells with an inverted chromosome 3 and monosomy for chromosome 7. He was admitted for induction therapy and presenting symptoms worsened (~10 L urine output per day) along with hypertenaemia which peaked at 160 mmHg, serum osmolality 319 mos/kg and urine osmolality of 174 mos/kg despite large oral and peripheral free water supplementation. MRI brain was negative for intracranial findings or abnormal enhancement. Given the degree of hypertenaemia, and history concerning for CDI, empiric treatment with intra-venous DDAVP was given with significant improvement of symptoms, serum sodium, serum osmolality and urine osmolality.

Discussion: The presentation of AML with concurrent CDI is associated with chromosome 3 or 7 abnormalities, not brain lesions, as in this case; the management of CDI involves continued DDA VP administration. Unfortunately this translocation has been described in prior case reports. A hypothesized mechanism is ketamine’s antagonism of N-methyl-D-aspartate receptors in the posterior pituitary thus inhibiting the release of ADH.

Conclusion: This case reinforces the association between ketamine and central DI associated with ketamine infusion in a critically ill patient with acute respiratory failure.

Multi-Electrolyte Storm Associated with Non-Exocrine Manifestations of Sjögren’s Syndrome
Satyavir Viswanathan, Kalpananathan K. Sambandam. The University of Texas Southwest Medical Center, Dallas, TX.

Introduction: Sjögren’s syndrome is a systemic autoimmune disease characterized by exocrine gland involvement. Clinical manifestations of TIN present as abnormalities of tubular function with fasting morning and pre-prandial samples except for uric acid.

Discussion:

Utilizing measured or estimated 24-h creatinine substantially increases the performance of estimates obtained with Prediction #1 and Prediction #2 was similar for all parameters, except for citrate and uric acid for which Prediction #2 performed significantly worse. Both estimation approaches performed moderately well: citrate 0.85 (95% CI 0.79, 0.91), oxalate 0.70 (0.64, 0.77), calcium 0.71 (0.65, 0.77), citrate 0.75 (0.69, 0.81), magnesium 0.73 (0.67, 0.79), uric acid 0.78 (0.72, 0.84), and calcium 0.72 (0.66, 0.78). The performance of Prediction #1 was consistently worse. The performance of Prediction #2 was consistently worse. The performance of Prediction #2 was consistently worse.

Conclusion: Utilizing measured or estimated 24-h urinary excretion substantially increases the utility of spot urine samples in estimating 24-h excretion of urinary analytes in KS formers.

Higher Risk of Incident Stone Patients in Stones with Metabolic Acidosis and CKD

Nancy L. Reaven,1 Susan E. Funk,1 Vandana S. Mathur,2 Julie C. Lai,1 Navdeep Tangri3 1Strategic Health Resources, La Canada, CA; 2Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.

Background: Epidemiological studies have shown an association between kidney stones and risk for CKD and its progression. Some types of stones are less likely to form at higher urine pH. Metabolic acidosis is a risk factor for CKD progression, but the association of serum bicarbonate with risk of incident kidney stones is not well understood.

Methods: Optum’s de-identified Integrated Claims-Clinical database of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values of 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) with data ≥ 3 years pre-index. The first qualifying serum bicarbonate test established the index date. Primary exposure variables were baseline serum bicarbonate and change in serum bicarbonate over time. Adjusted time-dependent Cox Proportional Hazards models were performed to evaluate time to first occurrence of kidney stones (by ICD-9 or ICD-10 diagnosis codes) during an average 3.6 years follow-up period. Other covariates included age, sex, race-ethnicity, and income status, history of kidney stones, pre-index comorbidities associated with kidney stones, bariatric surgery, obesity, smoking history, baseline eGFR.

Results: 142,904 patients qualified for the study cohort. Patients with metabolic acidosis at index experienced kidney stones at greater frequency than those with normal serum bicarbonate; HR 0.754, 95% CI: 0.738-0.771. Other significant factors associated with incident kidney stones included male sex, history of kidney stones, hyperoxaluria, and osteoporosis. Both higher serum bicarbonate at baseline (HR 0.956, 95% CI: 0.948-0.964) and higher serum bicarbonate over time (HR 0.968, 95% CI: 0.961-0.974) were associated with reduced risk of kidney stone development. The observed associations were unchanged in analyses examining death as a competing risk.

Conclusions: In patients with CKD, metabolic acidosis (vs. normal serum bicarbonate) was associated with a higher incidence of kidney stones and shorter time to incident stone formation. Future investigations should evaluate these associations by stone type.

PO1164

Effects of Pseudohyponatremia on the Diagnosis of Severe Metabolic Acidosis

Hafiz Muhammad Ali Raza1, Barry M. Wall,2 1The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2VA Memphis Medical Center, Memphis, TN.

Introduction: Pseudohyponatremia is defined as falsely low sodium levels in plasma caused by severe hyperlipidemia or hyperproteinaemia. We discuss a case of pseudohyponatremia due to hypertriglyceridemia in a patient admitted with severe metabolic acidosis and acetonemia induced liver toxicity.

Case Description: 43-year-old male with hyperlipidemia, diabetes mellitus, and obesity presented with 4-day history of abdominal pain, nausea, vomiting, and polydipsia. He had decreased intake and was not taking his insulin for 4 days. Medications include glargine insulin, dulaglutide, empagliflozin, glimepiride, rosuvastatin, fenofibrate and losartan. BP:141/59 mmHg, HR: 125 bpm, respirations 28/min. Temperature: 98.7, SpO2 95% on room air. He appeared clinically volume depleted. Laboratory testing revealed severely lispemic serum, elevated acetonaminph level 44.1 μg/mL, severely elevated transaminasles, arterial pH: 7.03, pCO2 11 mmHg, HCO3– = 5 μEq/L. Plasma sodium:109 mEq/L and chloride 81 μEq/L using indirect potentiometry and 131 and 111 μEq/L using direct potentiometry. Serum triglycerides 2951 mg/dL, blood glucose 204 mg/dL, plasma lactate 1.5 mmol/L, and creatinine 0.6 mg/dL. Plasma anion gap was 11 μEq/L using direct potentiometry and could not be calculated using indirect potentiometry, as bicarbonate concentration could not be determined due to lipemia. Based on severe metabolic acidosis, elevated lactate, and positive urinary ketones, a diagnosis of lactic acidosis and suspected euglycemic DKA was made. Patient was treated with DKA-protocol with insulin and fluid resuscitation, and N-acetylcysteine for acetonemia induced liver toxicity. Metabolic acidosis markedly improved over the next 72 hours. Hypertriglyceridemia, transaminase elevations, and metabolic acidosis fully resolved during 6 week follow up visit.

Discussion: Severe hyperlipidemia reduces water content of plasma such that autoanalyzers utilizing indirect potentiometry requiring sample dilution, result in pseudohyponatremia. Direct potentiometry does not require sample dilution and measures true sodium concentration, however, plasma anion gap is reduced due to higher measured chloride concentrations with direct potentiometry. Therefore, physicians must be familiar with the laboratory methods to correctly interpret the plasma anion gap in management of metabolic acidosis when using direct potentiometry measurements.

PO1165

Anion Gap Metabolic Acidosis on Continuous Renal Replacement Therapy: Are You Missing Something?

Mustafa Dawood, Vandana D. Niyyar. Emory University School of Medicine, Atlanta, GA.

Introduction: Anion gap metabolic acidosis is a common metabolic abnormality seen in the clinical practice. Causes include Lactic acidosis, Ketoacidosis, Renal failure, volatile acid toxicity and salicylate poisoning. Ketoacidosis is due to decreased glucose and insulin availability leading to starvation ketosis and diabetic ketosis respectively. Ketoacidosis is uncommonly seen in patients on prolonged continuous renal replacement therapy. We present 2 cases at Grady Hospital admitted with Acute hypoxic Respiratory Failure due to COVID 19 pneumonia, developed euglycemic ketoacidosis on Continuous Renal Replacement Therapy.

Case Description: case 1: 73 male with the history of HTN, DM, CKD III admitted for acute hypoxic respiratory failure due to COVID 19 pneumonia. He was intubated on admission day 9. Course got complicated by hypotension during intubation leading to Acute renal failure on day 11. Patient was started on Renal Replacement Therapy on day 12 due to volume overload and acidosis. Day 19, Anion gap worsened and metabolic acidosis fully resolved during 6 week follow up visit. Day 20. Case 2: 48 yo male with the history of HTN, DM II, CKD stage III admitted for Altered mental status, Hypertensive emergency and cough. He was diagnosed with COVID 19 Pneumonia. Patient had non-obese acute kidney injury on admission. Hospital day 11, patient was oliguric, volume overloaded and hyperkalemia prompted Renal replacement therapy initiation. Day 14, Anion gap worsened and metabolic acidosis fully resolved. Tube feed were initiated and Dialysate prescription was made to leading to resolution of anion gap on day 12.

Discussion: Diabetic ketoacidosis is a medical emergency commonly in patients with Type II DM but also in Type II DM patients as well. It occurs due to decreased insulin concentration or increase insulin resistance with or without decreased glucose availability leading to release of counterregulatory hormone and fatty acid metabolism producing ketocids. Diagnostic criteria include pH<7.3, Serum HC03<18, Serum glucose>250mg/dL and positive urinary ketones. Euglycemic DKA is a subtype of DKA with serum glucose of <200 mg/dL. Incidence of Euglycemic DKA varies from 2.6-3.2%. Continuous renal replacement therapy is an under-recognized cause of Euglycemic DKA in patients with Diabetes Mellitus.
A Wide-Awake Patient with Severe Hypoglycemia and Lactic Acidosis
Sarah AbdelSamad, Madhumita J. Mohanty, Mili J. Shah. Wayne State University, Detroit, MI.

Introduction: Severe hypoglycemia is associated with altered mental status or loss of consciousness. We report an intriguing patient who had advanced liver disease and presented with severe hypoglycemia and lactic acidosis without any alteration in mental status.

Case Description: 57-year-old female with severe decompensated alcoholic liver cirrhosis, ascites and recurrent hepatic hydrothorax presented to the Emergency Room with worsening shortness of breath. She had poor oral intake except for actively consuming ethanol. Chest X ray revealed worsening right hydrothorax. Routine blood tests revealed severe hypoglycemia (serum glucose 28 mg/dL, severe anion gap metabolic acidosis (arterial pH 7.11, serum bicarbonate 6mEq/L, anion gap 40 mEq/L) and acute kidney injury with elevation of serum creatinine to 2.2 mg/dL. Subsequent laboratory investigations revealed severe lactic acid level of 230mEq/L. Serum ethylene glycol, methanol, salicylate and acetonitrile levels were undetectable. She had no seizures, malignancy or hypoxia. The patient was alert and oriented. She was hemodynamically stable. There was no evidence of sepsis, tissue hypoperfusion or bowel ischemia. She was not taking any medications which may have led to hypoglycemia or lactic acidosis. The patient was administered intravenous glucose with rapid improvement of her serum glucose and lactate level.

Discussion: This patient had no alteration in mental status despite severe hypoglycemia. Under normal circumstances, the brain primarily depends on glucose as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactic acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hyperlactatemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps also her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

Sleeping Beauty: Hypersomnolence and Hyperammonemia in a Patient with Multiple Myeloma
Stephen P. Regina,1 Roberto L. Collazo-Maldonado,2 Muhammad R. Qureshi.2
1Methodist Health System, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

Introduction: Metabolic encephalopathy in a patient with multiple myeloma is commonly reported in association with prevalent biochemical syndromes such as uremia, hypercalcemia, and or hyperviscosity due to immunoglobulin, but very rarely hyperammonemia has been described as another cause of encephalopathy.

Case Description: The patient is a 45 year old woman with a prior diagnosis of multiple myeloma in July 2020. A bone marrow biopsy confirmed plasma cell neoplasm. Her serum creatinine was 1.5 mg/dl and her albumin was 3.5 g/dl. The patient was admitted to the hospital for hyperammonemia with blood ammonia level measured at 89 umol/L. Imaging of the liver was not compatible with cirrhosis. The patient was given oral lactulose for several days without improvement. To address the hyperammonemia, the patient was transferred to the ICU to begin CRRT and noted to be elevated at 89 umol/L. Imaging of the liver was not compatible with cirrhosis. The patient was given oral lactulose for several days without improvement. To

Discussion: Severe hyperammonemia is a poor prognosticator in patients with multiple myeloma. Hyperammonemia should be included in the differential diagnosis of metabolic encephalopathy in patients with multiple myeloma.
Diffuse Large B Cell Lymphoma and Synchronous Colon Adenocarcinoma Presenting with Type B Lactic Acidosis Secondary to the Warburg Effect in a Hispanic Man

Daniel Varela,1,2 Leonardo Pozo Garcia,1,2 Daniela Hernandez,1,2 Mourad Alsaabagh,3 John Manillo,1 Sergio A. Trevino Manillo.1,7 The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 2DVR Health, Edinburg, TX; 3South Texas Kidney Specialists, McAllen, TX.

Introduction: Lactic acidosis is a major metabolic dysregulation characterized by hyperlactatemia and acidemia that is commonly associated with tissue hypoperfusion. In very rare circumstances, hematological malignancies have been associated with a paraneoplastic syndrome characterized by the modification of the metabolism of cancerous cells from aerobic to anaerobic glycolysis.

Case Description: A 61-year-old male presented to the hospital due to generalized body weakness. He was recently admitted to the hospital due to left knee pain; at that time incision, drainage, and tissue sample were done. The patient was discharged to home with wound care and antibiotics. On presentation, patient was found to be tachypneic, hypotensive with Kussmaul breathing. A warm erythematous lesion was seen on left lower extremity. Laboratory results showed WBC 20,000/mm3, Hemoglobin 10 g/dL, Platelets 340 ×10^9/mm3, creatinine 7.9 mg/dL, Bicarbonate 5 mmol/L. Lactic acid 6.21 mg/dL, and Ferritin 326 ng/dL. Blood cultures positive for Enterobacter. Broad-spectrum antibiotics were administered. Nephrology consulted and dialysis started emergently. The pathology report showed Diffuse Large B-Cell Lymphoma. During the hospital stay, patient acidosis was persistent despite adequate renal replacement therapy and resolution of the septic process. ABG was done showing serum pH of 7.2, Bicarbonate 9 mmol/L. Lactic acid 17.5 mg/dL. Bowel ischemia was ruled out with CT angiogram however imaging showed neoplastic infiltration of peripheral abdominal structures associated with multiple small nodules. Colonoscopy demonstrated synchronous colon adenocarcinoma. The decision was made to treat the patient with chemotherapy. One week after chemotherapy lactic acid trended down to 1.1 mg/dL. The metabolic acidosis and renal function improved and RRT was stopped.

Discussion: Usually, lactic acidosis is a sign of hypoperfusion and septic shock. In this case, the source of lactic acidosis was not hypoperfusion but rather a rare paraneoplastic syndrome that leads to anaerobic metabolism of malignant cells, known as the Warburg effect. This condition can be fatal. Prompt initiation of chemotherapy is recommended.

Distal Renal Tubular Acidosis in Patients with Autoimmune Diseases

Oana Ion,1 Ioana Alinilca,1 Georgiana Fratila,1,2 Genem Ismail.1,2 Institutul Clinici Funceni, Bucuresti, Romania; 2Universitatea de Medicina si Farmacie Carol Davila, Bucuresti, Romania.

Background: Distal renal tubular acidosis (DRTA) is reported in association with autoimmune diseases. DRTA can evolve without symptoms and systemic acidosis, this form being defined as incomplete DRTA. The incomplete form necessitates the use of a urinary acidification test like the Furosemide and Fludrocortisone test for establishing the diagnosis.

Methods: We conducted a prospective observational study in a selected cohort of 48 patients diagnosed with autoimmune diseases (SLE, SJ+gren syndrome, ANCA vasculitis, cryoglobulinemic vasculitis), who presented in our clinic from December, 2020 until May, 2021. The patients were submitted to Furosemide and Fluorocortisone test for establishing the diagnosis.

Results: The study included 48 patients (36 females, mean age 41.92 ± 15.7 years), diagnosed with SLE (33 patients), PANCA vasulitis (7 patients), cANCA vasculitis (1 patient), SJ+gren syndrome (3 patients) and cryoglobulinemic vasculitis (4 patients). There was a significant difference regarding age (p=0.001) and eGFR (p=0.001) between the groups with vasculitis (mean age 60.752±3groups with vasculitis = 7.87 g/mL, eGFR 41.66 ± 16.71 mL/min/1.73m2), SLE (mean age 35.18 ± 11.7 years, eGFR 73.24 ± 25.18 mL/min/1.73m2) and SJ+gren syndrome (mean age 40.65 ± 20.03 years, eGFR 35.56 ± 17.24 mL/min/1.73m2). The test was positive for 11 patients out of 48. There was not a significant change in kidney function during the test (p=0.80). There was a significant increase in the level of serum bicarbonate (26.23 ± 3.5 mmol/L before the test vs 28.21 ± 1.3 mmol/L after the test, p=0.001) and also in the level of serum pH (7.36 ± 0.43 before the test vs 7.48 ± 0.43 after the test, p=0.001). None of the patients reported digestive or allergic side effects. There was not a significant difference regarding eGFR (p=0.665), proteinuria (p=0.372) and CRP (p=0.246) between the patients with or without a positive test. Regarding immunological activity, patients with a positive test had a higher ANA value at the moment of the test (4.71 ± 3.04 U/ml vs 2.50 ± 2.55 U/ml, p=0.05) and a lower C4 value (12.66 ± 9.39 mg/dL vs 23.4 ± 11.54 mg/dL, p=0.016).

Conclusions: Incomplete DRTA was found in 11 out of 48 patients with autoimmune diseases. None of the patients developed severe hypokalemia or metabolic alkalosis or any other side effect after Furosemide and Fluorocortisone test.
34 mOsm/kg. Her arterial blood gas showed: pH < 7, HCO3 7.5 mmol/L, pCO2 16 mmHg. Phosphorus level was unusually high, 21.3 mg/dL, with unknown etiology. There was no history of enema or laxative use. A significant contributor of AG was lactate at 14.5, given her history of metformin use. Urine drug screen was positive for amphetamines. The volatile alcohol panel was positive for acetone; methanol, ethanol, ethylene glycol and isopropanol alcohol were not detected. Continuous venovenous hemofiltration (CVVH) was initiated. After 3 days, renal function started recovering, lactate and phosphorus levels normalized and AG closed. The patient did not need CVVH thereafter. Two months later, the patient was discharged to a nursing facility in a stable condition.

**Discussion:** Extremely elevated AG of 52 in this patient can be explained by a rise in concentrations of organic acid anions, lactate, ketoacids, hyperphosphatemia, and retention anions.

**Explanation of the high AG:** The Figure describes the calculation of AG. In this patient, phosphate was a major contributor to the AG.

**PO1176**

**Is an Increase in Anion Gap a Predictor of Hemodialysis Initiation in Patients with Advanced CKD?**

Hikaru Kukimoto, Kazuhiro Fukuoka, Soko Ikigaya, Noriko Ikeyama, Takahisa Kawakami, Mitsumasa Kishimoto, Yoshinori Komagata, Shinya Kanaane. Kyorin Daigaku, Mitaka, Japan.

**Background:** Because uremic symptoms and manifestations vary among patients with advanced chronic kidney disease, it is sometimes difficult to decide on the timing of dialysis initiation only from symptoms. We attempted to investigate whether anion gap (AG) that may reflect the accumulation of total organic acids in uremia can be a marker of uremia and may predict the timing of dialysis initiation.

**Methods:** This study included pre-dialysis patients who attended to our hospital for more than six months prior to the beginning of hemodialysis (HD), and retrospectively analyzed the relationship between their serological data, AG, and various uremic symptoms. The AG was calculated as the corrected AG (cAG) = Na-Cl-HCO3 [mmol/L]+2.5 x (4-serum albumin concentration [g/L]). The statistical analysis was performed by logistic regression analysis, correlation analysis, and factor analysis using SPSS®.

**Results:** A total of 283 patients [diabetes mellitus: 136 (48.1%), nephroclerosis: 66 (23.3%), glomerulonephritis: 36 (12.7%)] were included in this study. The most common clinical symptoms before dialysis initiation was fluid overload, which was seen in 134 patients (47.3%), followed by anorexia 104 patients (36.7%) and general malaise 96 patients (33.9%). The cAG began to increase 3 months before the initiation of HD (14.2 mmol/L), which showed a rapid increase just before the initiation, and was correlated with progression and fatigue, better than fluid retention. Of note is that cAG was most significantly associated with dialysis initiation among various factors. The ROC of cAG for dialysis initiation showed the highest value of AUC 0.797 (95% CI=0.72 to 0.85, p<0.05), with a cutoff value of adjusted cAG 15.975 (sensitivity 0.689, specificity 0.786).

**Conclusion:** Uremic symptoms and some serological markers including azotemia, metabolic acidosis, and hyperphosphatemia have been usually used to predict the magnitude of uremia and the timing of dialysis initiation. In our study, it is suggested that a rapid increase in cAG over 16 mEq/L may also be a good predictor of dialysis initiation within the subsequent 3 months.

**PO1177**

**Mysterious Case of Recurrent Life-Threatening Lactic Acidosis**

Zakir Shaikh, Waqas Ahmad Khan, Ajay D. Rao, Jean Lee. Temple University Hospital Temple University Health System Inc, Philadelphia, PA.

**Introduction:** Patients living with diabetes are prone to type-II lactic acidosis, often presenting with profound acid-base derangements. The reason for lactate production is not obvious hence management can be challenging. We present a case of life-threatening recurrent lactic acidosis in a diabetic patient.

**Case Description:** A 67-year-old man with type 2 diabetes, hypertension, presented to the hospital with malaise for 2 days. He had been on metformin in the past but had recently switched to insulin. There was no history of alcohol ingestion nor use of herbal supplements. The lactic acid level was 24.2 mmol/L with Ph of 6.82, PCO2 of 27 mmHg, serum bicarb of 7 mEq/L, anion gap of 28, and serum Cr of 1.4 mg/dL with baseline of 1 mg/dL. No evidence of infection or ischemia found. Toxicology screen was negative and serum metformin level was undetectable. Lactic acidosis resolved with continuous renal replacement (CRRT) for 24 hours. A month later he returned with similar complaints
and his lactate level was 14.8 mmol/L. This was treated with supportive care alone. Six months later he was readmitted with lactate of 13.5 mmol/L, worsening to 18.6 mmol/L. He improved after treatment with CRRT and supportive care. Alcohol levels, liver function tests, pyruvate, glutamate, metformin levels were all negative or normal. The thiamine level was not checked during his first admission. During the second visit, the value was normal but this was drawn after thiamine had been given. During the third visit, the thiamine level was noted to be less than 6 mmol/L. The patient was started on thiamine and has not had further episodes of lactic acidosis.

Discussion: Patients with diabetes are prone to excess lactic acid generation due to the deamination of citrate in mitochondrial oxidative phosphorylation with relative hypoxia at the microvascular level. In addition, it has been noted that many diabetics are thiamine deficient. In the absence of thiamine, pyruvate cannot enter the Krebs cycle and is converted to lactic acid predisposing diabetics to type-B lactic acidosis. Thiamine is filtered in the glomerulus and is reabsorbed in the proximal tubule through the thiamine/H+ antiporter. Long term use of diuretics has been associated with thiamine deficiency. However our patient was not taking any nor did he have chronic kidney disease or any evidence of malnutrition.

PO1178
Serum Bicarbonate and Gait Abnormalities in Older Adults
Jim Q. Ho, Joe Vergheze, Matthew K. Abramowitz. Albert Einstein College of Medicine, Bronx, NY.

Background: Low serum bicarbonate levels are associated with slow gait speed in older adults. However, the association between serum bicarbonate and other quantitative gait markers is unknown.

Methods: Quantitative gait assessments were performed on 330 community-dwelling, nondisabled adults ≥ 65 years old. Serum bicarbonate was categorized into tertiles (≥ 22, 22-24, < 22 mEq/L). The relationship between bicarbonate and gait markers was investigated with multivariable linear regression adjusting for demographics, comorbidities including COPD, medication use, smoking status, BUN, and eGFR (CKD-EPI). Factor analysis on eight gait markers was performed to synthesize individual gait characteristics into unifying domains. CKD was defined as eGFR < 60 mL/min/1.73 m².

Results: There were 116 (35%), 146 (44%), and 68 (21%) participants in the low tertile, middle tertile, and high tertile, respectively. After multivariable adjustment, compared with participants in the middle tertile, those in the low tertile had significantly slower speed (0.03 m/s; 95% CI 0.01-0.05). Within the lowest tertile, there was a graded association of lower bicarbonate with greater severity of gait deficits (Figure). Associations were similar when limited to participants with CKD. Associations remained significant after additional adjustment for muscle strength, cognitive function, sensory nerve function, and balance. No significant associations were found for the high tertile or for other gait markers (e.g., cadence). Factor analysis produced 3 independent gait domains: pace, rhythm, and variability. Compared with the middle tertile, the low tertile had significantly poorer performance in the pace domain (0.3 standard deviation [SD]; 95% CI 0.1-0.6).

Conclusions: Low serum bicarbonate is associated with gait abnormalities in older adults.

PO1179
Bicarbonate Target in Treating Renal Acidosis: Is Higher Better?
Ashraf Dwal, Ochsner Medical Center - New Orleans, New Orleans, LA.

Background: Metabolic acidosis is commonly seen in patients with CKD from a decrease in ammonium excretion which gets buffered by the extracellular bicarbonate, hence, low plasma carbon dioxide is a surrogate of acidosis. treatment of acidosis (usually sodium bicarbonate to decrease the progression of, maintain bone health, nutrition status, In clinical practice, we aim for plasma bicarbonate of ≥ 22 mEq/L, the upper limit target is unclear.

Methods: This was a single-center retrospective chart review of CKD patients with acidosis from 2010-2017. Inclusion criteria were adult patients receiving NaHco3 for CKD-associated acidosis with baseline estimated glomerular filtration rate (eGFR) ≥ 25 and < 60 mL/min/1.73 m² when starting NaHco3. Patients with glomerulonephritis, kidney transplant, acute kidney injury (not back to at least 75% of eGFR baseline) were excluded. Four groups were identified for comparison based on mean serum Co2 (in mM/L, from outpatient measures during 3 years follow-up, group A (≤ 22), group B (22- < 24), group C (24 - <25), and Group D (≥ 25). Albumin, urine protein-creatinine ratio (UPCR), PTH, and eGFR were compared, p-values are calculated by a one-way ANOVA model.

Results: There were 383 patients with CKD-associated acidosis receiving NaHco3, 93 patients qualified for the study. Group A (n=21), group B (n=41), group C (n=13), and Group D (n=18). Racial demographics: 35-black (38%), 57-white (61%), 1=Other. Females 49 (53%). Median age 69 years. Follow-up 3 years. At baseline mean eGFR, UPCR, and albumin, and diuretics use and osteoporosis diagnosis in the four groups were similar (p = 0.46, 0.32, 0.15, 0.39, respectively). Mean hemoglobin A1C in each group did not exceed 8.2. At 3 years of follow-up, changes in eGFR, UPCR, and osteoporosis status between the four groups were similar (p = 0.14, 0.27, ± 0.19 respectively). Change of albumin was significantly worse in group A comparing to groups B, and C (p = 0.007, 0.049 respectively), and average PTH was significantly worse in group A comparing to group C (p = 0.045).

Conclusions: In our cohort, all groups of treated CKD-associated acidosis (B, C, and D) showed no statistical difference in CKD progression, the severity of parathyroidism, developing osteoporosis, or nutrition status assessed after 3years follow-up. Hence, higher Co2 targets don’t carry worse outcomes.
PO1181

Pseudo-Hypocarbonatemia with Severe Hypertriglyceridemia Corrected by Insulin Infusion
Noah J. Poznanski, Howide Elish, Ahlim Al sanani. Marshall University Joan C Edwards School of Medicine, Huntington, WV

Introduction: Anion gap metabolic acidosis (AGMA) is a condition characterized by low serum bicarbonate and unaccounted anions in the blood. Lactate or ketones are the most common anions causing AGMA. Severe hypertriglyceridemia and paraproteinemia can result in Pseudo-hypocarbonatemia due to interference by these components when the commonly used enzymatic assay is utilized for serum bicarbonate measurement. The calculated bicarbonate derived from blood gas machines show accurate bicarbonate level. It is very important to recognize Pseudo-hypocarbonatemia to avoid expensive work-up.

Case Description: A 42-year-old male patient with a past medical history significant for diabetes mellitus type 2, obesity, and hyperlipidemia. The patient presented with nausea, vomiting and epigastric pain. Physical examination was significant for tenderness in the epigastrum and xanthenæma. The basic metabolic profile (BMP) was significant for Na+ 127meq/L, Cl - 94meq/L, HCO3- 9mEq/L, glucose 408mg/dL, BUN 160mg/dL, creatinine 0.87mg/dL and AGAP 24. A lipid panel showed a cholesterol 461mg/dL and triglycerides 4061mg/dL. Lipase and amylase were 1183U/L and 202U/L respectively. Urinalysis revealed trace ketones. CT abdomen revealed peripancreatic stranding. The patient was diagnosed with AGMA due to diabetic ketoacidosis and pancreatitis secondary to hypertriglyceridemia. An arterial blood gas analysis (ABG) subsequently revealed a pH 7.39, PaCO2 40, PaO2 73 and a HCO3- 24. A significant dissociation between the calculated and measured bicarbonate was noted. Following aggressive lowering of the triglycerides, with Insulin infusion there was an immediate resolution of the pseudo- hypocarbonatemia and anion gap metabolic acidosis.

Discussion: This measurement error is due to the mechanism by which the analyzer interprets the bicarbonate level in the serum. Most analyzers utilize either anion-selective electrode (ISE) or function via an enzymatic/photometric method. High amounts of lipid particles may cause light scattering altering the photometric analysis. This likely caused the discrepancy between the enzymatic/photometric measured serum bicarbonate and the calculated bicarbonate of the aqueous phase ISE analyzer used by the ABG. Clinicians should be able to recognize that its essential to obtain a blood gas sample for determination of the acid-base status to avoid expensive work up.

PO1182

Pseudohypocarbonatemia in a Patient with Paraproteinemia
Marvi M. Bakhru,1 Cary R. Boyd-Shiwari,2 Blaise W. Abramovitz.1 UPMC Mercy, Pittsburgh, PA; 1University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA

Introduction: The first step in acid-base disorders’ diagnosis is obtaining measurement of blood bicarbonate (HCO3-), pH and partial pressure of carbon dioxide (pCO2) levels. Blood HCO3- levels are estimated via two methods: direct measurement of serum total carbon dioxide (TCO2), or via Henderson-Hasselbalch equation using arterial blood and directly measuring pH and pCO2 levels. With the enzymatic method, there have been reported cases of falsely low serum HCO3- due to interference by elevated triglyceride levels, but only two cases have been reported of spuriously low serum HCO3- due to interference by paraproteins.

Case Description: A 74-year-old male with a history of bladder carcinoma in situ and hypertension presented with complaints of malaise after a recent bladder irrigation. Basic metabolic panel (BMP) was unremarkable except for a HCO3- of 8 mmol/L measured using a Siemens Vista (SV) enzymatic chemistry analyzer. He was hospitalized for high anion gap metabolic acidosis with anion gap of 22. He was started on intravenous NaHCO3 (150 meq/L) after nephrology was consulted. Repeat serum HCO3- was ranging from 8-11 mmol/L (using SV analyzer) despite his reported compliance with NaHCO3. He was evaluated by another nephrologist with repeat BMP and an arterial blood gas (ABG). The results revealed a serum HCO3- of 8 mmol/L in contrast with ABG pH of 7.41 and HCO3- of 25 mmol/L. Due to the discrepancy, his serum HCO3- was analyzed at a different facility using a Beckman Coulter analyzer which revealed a normal serum HCO3- level of 21 mmol/L. Further work up was pursued with SPEP and SIIFE revealing an M-spike and presence of IgM and IgA kappa monoclonal proteins respectively, which led to a diagnosis of monoclonal gammopathy.

Discussion: Paraproteins have been reported to cause interference with multiple laboratory test results. Paraproteins in our case may have resulted in artifactual error of serum HCO3- by direct interaction with assay reagents, binding of paraproteins to an assay reagent, or turbidity caused by the precipitation of the monoclonal proteins. Our case highlights the importance of being aware of this phenomenon of pseudohypocarbonatemia that can occur with certain chemical analyzers.

PO1183

Proton Pump Inhibitor (PPI) for the Treatment of Metabolic Alkalosis due to Gastric Losses
Raphael J. Rosen, Heedock Han, Sindhiru Prakash-Polet, Yonatan A. Peleg. Columbia University Irving Medical Center, New York, NY.

Introduction: Gastric losses of hydrochloric acid can result in severe metabolic alkalosis (met alk). We describe two cases where patients with significant losses of gastric secretions presented with severe met alk and AKI. In both cases, PPI therapy was used to reduce the volume of the gastric secretions with excellent effect.

Case Description: Patient 1: A 44-year-old woman with Gardner Syndrome with near-total enterectomy and colectomy on total parenteral nutrition with a venting gastric tube (G-tube), presented with met alk (HCO3 50 meq/L) and AKI (Scr 4 mg/dL from baseline 1.3 mg/dL). Met alk persisted despite normal saline (NS) administration and gastric tube losses ranged from 4-8 liters per day. Twice daily intravenous PPI was started with immediate decrease of gastric losses and normalization of HCO3. This patient was admitted one year later (off PPI therapy) with a similar derangements and resuming PPI therapy caused similar improvement. Patient 2: A 59-year-old man with gastric outlet obstruction and venting G-tube presented with met alk (HCO3, 47 meq/L) and acute kidney injury (Scr 4.5 mg/dL from 1.3 mg/dL). Met alk persisted despite NS administration and his gastric tube losses ranged from 4-11 liters per day. Daily intravenous PPI was started with decrease of gastric losses and normalization of HCO3. This patient presented again to the hospital one month later with normal HCO3 on PPI therapy. Both patients’ bicarbonate and gastric fluid output trend relative to PPI therapy is detailed in figure 1.

Discussion: There are few reported cases of PPI therapy for metabolic alkalosis due to gastric losses. Generally, met alk that occurs due to gastric losses is readily rectified by increased renal bicarbonate excretion, but this compensatory mechanism is limited in the setting of AKI. We report two cases in which PPI therapy successfully decreased the quantity of gastric fluid losses and rapidly improved metabolic alkalosis.

PO1184

A Case of Extreme Metabolic Alkalosis
Muhammad S. Ajmal. Baylor College of Medicine, Houston, TX

Introduction: Metabolic alkalosis results from an increase in serum bicarbonate concentration due to loss of hydrogen ions and/or gain in bicarbonate ions. We present a case of extreme metabolic alkalosis due to multiple etiologies rarely co-existing.

Case Description: A 30-year-old male with Duchenne muscular dystrophy, chronic respiratory failure on mechanical ventilation via tracheostomy, gastrojejunostomy (G-J) tube dependent and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day. He was recently started on Lasix 20 mg daily. Initial labs showed blood pH of 7.81, bicarb 66 and PCO2 53. He had AKI with Creatinine (Cr) of 2.66, BUN 266 and Cystatin C 11. His baseline Cr was 0.9-1.1. UA showed 1+ protein and no sediment. Urine (Ur) sodium 87, Ur chloride <15, Ur Cr <10 and Ur pH was 9. Chest Xray showed cardiomegaly with mild venous congestion and kidney ultrasound showed bilateral small echogenic kidneys. He was treated with normal saline (NS) IV (g)100 ccs/hr, acetazolamide IV, potassium IV, proton pump inhibitor to decrease gastric acid and minute ventilation was increased to allow for compensatory hypercapnia. AKI improved with adequate diuresis and PH normalized (Image 1) by day 3. He had hypotension at 24 hours of IV NS and fluid were changed to hypotonic + free water via G-J tube. High daily output of ~700cc was recorded from the G-J tube. He was discharged home without diuretics and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day. He was recently started on Lasix 20 mg daily. Initial labs showed blood pH of 7.81, bicarb 66 and PCO2 53. He had AKI with Creatinine (Cr) of 2.66, BUN 266 and Cystatin C 11. His baseline Cr was 0.9-1.1. UA showed 1+ protein and no sediment. Urine (Ur) sodium 87, Ur chloride <15, Ur Cr <10 and Ur pH was 9. Chest Xray showed cardiomegaly with mild venous congestion and kidney ultrasound showed bilateral small echogenic kidneys. He was treated with normal saline (NS) IV (g)100 ccs/hr, acetazolamide IV, potassium IV, proton pump inhibitor to decrease gastric acid and minute ventilation was increased to allow for compensatory hypercapnia. AKI improved with adequate diuresis and PH normalized (Image 1) by day 3. He had hypotension at 24 hours of IV NS and fluid were changed to hypotonic + free water via G-J tube. High daily output of ~700cc was recorded from the G-J tube. He was discharged home without diuretics and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day.

Discussion: This is a unique case of extreme metabolic alkalosis primarily due to the loss of gastric acid in the G-J tube, but volume depletion, hypokalemia, AKI, high protein tube feeds, lack of respiratory compensation due to ventilator dependence and loop diuretics contributed to the development and maintenance of metabolic alkalosis.
We corrected his metabolic alkalosis and AKI with cautious use of IV fluids and Acetazolamide without needing dialysis, although metabolic alkalosis relapsed until the G-tube was changed.

Daily pH and Cr

POI118

Hypercalcemia and Metabolic Alkalosis Induced by the Novel Potassium Binder Patiromer: Report of Rare Event
Kathryn J. Suchow, Sretha Rani Kandula, Juan Carlos Q. Velez. Ochsner Medical Center - New Orleans, New Orleans, LA.

Introduction: Patiromer is a calcium (Ca)–potassium (K) exchange resin approved for the treatment of hyperkalemia. Disorders of Ca or acid base balance were not reported in pre-approval clinical trials. Post-marketing, only 2 case reports of hypercalcemia associated with the use of patiromer have been recently published. We present a case of a patient with chronic kidney disease (CKD) with an unusual picture of hypercalcemia, metabolic alkalosis and hyperkalemia upon intensification of patiromer dosing.

Case Description: A 56-year-old white man with CKD stage 4 (baseline creatinine 2.8 mg/dL) due to type 1 diabetes mellitus, proteinuria (1.5 g/g) and persistently high serum potassium (sk, 5.5 – 5.9 mEq/L) attributed to type 4 renal tubular acidosis was evaluated in 2011. Due to high risk of CXD progression, patiromer 4.4 g qd was prescribed to enable RAS blockade. Five months later, sk remained elevated at 5.0 mEq/L. Patiromer dosage was thus increased to 16.8 g. Three months later, sk fell to 4.1 mEq/L. Hence, patiromer was maintained at 16.8 g and ibesartan initiated. At that time, corrected serum calcium (scCa) was 9.3 mg/dL and serum bicarbonate (sHCO3) 26 mEq/L. Five months later, routine laboratory tests revealed a sk 2.5 mEq/L, scCa 12.6 mg/dL and sHCO3 34 mEq/L. The patient denied recreational or over-the-counter drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, serum protein electrophoresis, free light chains, cortisol and ACTH) was negative for other causes of hypercalcemia. Five days later, sk was 4.1 mEq/L. scCa 7.7 mg/dL and sHCO3 32 mmol/L.

Discussion: Patiromer promotes gastrointestinal elimination of potassium by binding the molecule to potassium in exchange for calcium. Increased in intestinal absorption of calcium results in hypercalcemia but not sustained hypercalcemia. The clinical course of our patient suggests that the increased dose of patiromer led to a profound exchange of calcium and potassium ions leading to hypercalcemia, iatrogenic hyperparathyroidism and secondary hyperparathyroidism. The role of secondary hyperparathyroidism in this case remains unclear. We recommend cautious vigilance of patients receiving patiromer and undergoing dose escalation.

POI117

Prediction of Ionized Hypocalcemia and Hypercalcemia: External Validation of a Novel Model
Jie OuYang,1 Yahannes Melaku,1 Isha Puri,1 Ernie Yap,1 Philip Goldwasser,2 1SUNY Downstate Health Sciences University, New York City, NY; 2VA New York Harbor, Brooklyn, NY.

Background: The popular adjustment of serum total calcium (scCa) for albumin (Alb) yields a corrected value (scCa) that doesn’t detect abnormal ionized calcium (iCa) well in critical care patients (pts), possibly because it ignores the fraction of iCa complexed by small anions. To account for such anions, we derived a model that examines iCa (CiCa) by adjusting iCa for Alb and the anion gap’s 3 components, Na, Cl, and ICO. It was found to be better than scCa in detecting low iCa (iCa) on internal validation (Yap, JALM 2020). In this study, we externally validated ICa in a large, publicly available critical care dataset.

Methods: From the MIMIC III v1.4 database, we paired chemistry panel scCa (mg/dL), Alb (g/dL), Na, Cl, and ICO, values with gas panel iCa values (ref range: 1.21-1.32 mM) measured up to 20 min. apart. Limiting each pt. to the most closely-timed pair left 4105 pairs (median:10 min apart). We calculated scCa (Ca = 0.64A-4 Alb) and ICa = 0.991 iCa -0.034 Alb -0.002Na -0.0073 Cl -0.0047ICO2 and compared their ROC curves (area=SE) for detecting ↓iCa (iCa<1.1; rate=33.1%) and high iCa (1Ca>1.32; rate=3.5%).

Results: ICa was better than scCa by ROC analysis for both ↓iCa (0.334±0.007 vs 0.752±0.008, p<0.0001) and ↑iCa (0.975±0.004 vs 0.963±0.006, p=0.0006). The table compares the sensitivity and specificity (SENS/SPEC) and positive and negative predictive values (PPV/NPV) of ICa and scCa at similar cutoffs. ICa overestimated iCa by 0.04 mM (1.17±0.002 vs 1.13±0.002, p<0.0001), a bias that was fairly consistent across the full prediction range.

Conclusions: The ICa model is superior to scCa in ranking critically ill pts for both ↓iCa and ↑iCa. It can help clinicians decide when to directly measure iCa. ICa overestimated iCa but applying a local correction of -0.04 would make its absolute predictive values, on average, in the MICU setting.

POI116

Beads of Calcium
Nityasee Sriarlai, Karla G. Carias Martinez, Elizabeth Kiernan, Jose M. Monroy-Trujillo. Hopkins Nephrology Johns Hopkins Medicine, Baltimore, MD.

Introduction: Hypercalcemia is a common disorder that can cause acute kidney injury (AKI) and result in significant morbidity and mortality.

Case Description: A 50-year-old male with diabetes and hypertension presented with left knee septic arthritis. He had an AKI from volume depletion and vancomycin toxicity (tough level 35.1). Incision and drainage (I&D) was done on day 13 for refractory knee infection. Postoperatively, serum creatinine (Cr) and Calcium (Ca) rose to peak Cr of 2.45mg/dL (baseline 0.94mg/dL) and a corrected Ca of 13.58mg/dL. Workup showed PTH 60 pg/mL, PTHrP 69pg/mL, 1,25-Dihydroxy Vitamin D 29pg/mL, 25-Hydroxy Vitamin D 29pg/mL and normal SPEP. Kappa/Lambda ratio was 1.55. SIFE showed IgG kappa Monoclonal gammopathy and lambda free light chain proteinemia. Given normal SFLC and an unquantifiable M-Spike, it was ascribed to monoclonal gammopathy of undetermined significance. Recent studies inclusing, MRI, cervical, thoracic, lumbar spine, CT chest, abdomen, pelvis, and left lower extremity, did not show lytic lesions. Urine sediment showed calcium oxalate crystals. These results ruled out primary hyperparathyroidism, hypervitaminosis D, paranaplastic syndrome, and granulomatous disorders and serum improved with intravenous fluids and furosemide. It was found that in I&D, 20cc of stimulus space was placed, which can cause hypercalcemia. Hypercalcemia coincided with spacer placement.

Discussion: Hypercalcemia has been reported with antibiotic-eluting calcium sulfate beads (CSBs) such as stimulain in several case reports and a large cohort assessing antibiotic spacers. CSBs are used for periprosthetic joint infections for new bone formation or local antibiotic delivery. Agitation of the beads during washout is hypothesized to cause postoperative hypercalcemia. Thus, it is necessary to monitor serum Ca and Cr levels with CSB placement. Patients with intrinsic calcium or parathyroid disorders, prolonged immobility, existing renal impairment, or critical illness are at elevated risk of developing hypercalcemia and should be observed closely.

POI1189
Hypercalcemia in a Patient with Visceral Leishmaniasis (VL) and Immune Reconstitution Inflammatory Syndrome (IRIS)
Luben Juarez,1 Jacob M. Winograd,1 Jie Tang.2,3,4 Lifespan Health System, Providence, RI; 1Brown University Warren Alpert Medical School, Providence, RI.

Introduction: Hypercalcemia is a relatively common clinical problem with a wide range of etiologies. We report an unusual case of hypercalcemia due to visceral leishmaniasis triggering immune reconstitution inflammatory syndrome in a patient with AIDS.

Case Description: A 45-year-old male with history of previously treated VL complicated by a relapse now on suppressive amphotericin presented with 2 weeks of poor appetite, weight loss, and malsease. Recent history was notable for AIDS restarted on Triumeq in the preceding 2 months with slow recovery of CD4 count to 18 but robust reduction in HIV viral load. He denied other infectious symptoms. Labs were notable for AKI, calcium of 13.1, and pancytopenia. Work up revealed low PTH, low calcidiol, elevated calcium levels and high-normal calcitriol levels with bone marrow biopsy revealing non-necrotizing granulomas. Remainder of infectious work up including mycobacterium, histoplasma, and fungal cultures all remained negative. Of note, CD4 count rebounded to 354 during his month-long stay. He was ultimately diagnosed with IRIS secondary to VL leading to granulomatous hypercalcemia. Initial therapy consisted of fluids which resolved AKI and improved calcium. However, he proved to be fluid dependent as attempts at weaning would result in rise in calcium and creatinine. Definitive therapy consisted of steroids which resolved his hypercalcemia allowing him to come off fluids. Appetite improved and fatigue resolved over course of his stay with stabilization of calcium levels and creatinine returning to baseline. He was continued on suppressive Amphotericin B for VL.

Discussion: Granuloma formation is a known effect of leishmania infection to combat the invading parasites. Presumably, such inflammation could lead to hypercalcemia via increased conversion of calcidiol to calcitriol. To our knowledge, this is the first case of hypercalcemia caused by VL in humans. It was likely triggered by the reconstitution of his immune system given recent re-initiation of anti-retroviral therapy and rebound of CD4 cell count. Initial management consists of fluids and bisphosphonates with definitive management consisting of steroids and amphotericin. We report this novel case of hypercalcemia in hopes of expanding the literature on the various potential manifestations of VL, particularly in the setting of IRIS and AIDS.

POI1190
Systemic Sarcoidosis Presenting with Hypercalcemia
Salman B. Mahmood, Milindy J. Junghare, Tetyana Mettler. University of Minnesota Twin Cities, Minneapolis, MN.

Introduction: Sarcoidosis is an idiopathic autoimmune illness that typically presents with pulmonary involvement but can affect virtually any organ. This often makes it challenging to diagnose as its manifestations can be quite varied. We report an interesting case of systemic sarcoidosis presenting with hypercalcemia of unclear mechanism.

Case Description: A 53-year-old Caucasian male presented to the clinic with polyuria, forgetfulness and weight loss. Medical history included hypercalcemia with recurrent nephrolithiasis, diabetes and positive ANA (titer 1:160) without any prior history of constitutional, respiratory or joint symptoms. Serum calcium returned 13 mg/dl. The patient also had an AKI and an elevated ALP. Further workup revealed a suppressed PTH, normal 25-OH and 1,25-OH vitamin D, but a borderline elevated PTHrP (2.5 pmol/L [0-2.3 pmol/L]). This prompted a CT CAP with contrast to rule out malignancy that instead showed mediastinal lymphadenopathy, heterogenous liver enhancement suggestive of cirrhosis and an enlarged, nodular spleen. Transbronchial lymph node biopsies were normal and an extensive infectious and malignancy workup remained negative. The patient was given fluids followed by zoledrone with resolution of hypocalcemia and AKI. A liver biopsy was ultimately pursued which showed non-casinging granulomas.

Discussion: In patients with sarcoidosis, the development of hypercalcemia is thought to be mediated via aberrant activation of vitamin D leading to calcitriol excess. Our patient’s calcitriol level was normal and hypercalcemia may also occur in the absence of elevated levels. Possible described mechanisms include “inadequate normal” calcitriol concentration without elevation in systemic levels, elevated PTHrP and direct action of pro-inflammatory cytokines causing osteolysis.

POI1191
Disseminated Histoplasmosis Presenting as Severe Hypercalcemia
Sushuna Medikayala, Carla S. Mcwilliams, Shane A. Bobart, Silvia T. Bunting, Dianne T. Sandy, Mauro Braun, Surafel K. Gebreselasie. Cleveland Clinic Florida, Weston, FL.

Introduction: Hypercalcemia (HC) is a significant complication of Disseminated Histoplasmosis (DH). While there are case reports on DH causing HC in immunosuppressed patients including HIV and chemotherapy, there are very rare case reports on DH causing HC in Non-immunosuppressed hosts. The diagnosis of DH in HC may be delayed due to other differential diagnoses such a Sarcoidosis leading to prolonged and worsening hypercalcemia and subsequent renal failure. We report a case of HC in a patient who presented with generalized skin ulcers and bilateral adrenal masses. The initial manifestation of DH with HC, painful skin ulcers, bilateral large lobulated adrenal masses, prompted an initial concern for sarcoidosis. After presenting to our institution 5 months later, a diagnosis of DH was made as the cause of his Hypercalcemia.

Case Description: A 58-year-old male with new onset generalized skin rash was diagnosed with HC, empirically treated with prednisone for sarcoidosis due to elevated 1,25 dihydroxy Vitamin D, 5 months ago at an outside hospital. After starting prednisone, his skin lesions progressed to disseminated painful ulcers and was referred to our institution after developing AKI with a serum creatinine of 4.6mg/dl (Cr 1.6mg/dl, 5 months ago) calcium 14mg/dl, PTH 2pg/mL. CT abdomen revealed large lobulated bilateral adrenal masses. Bone marrow biopsy revealed non-necrotizing granulomas with yeast form fungal organisms on GMS stain. A Shave skin biopsy of an abdominal ulcer revealed Fungal yeast forms consistent with histoplasmosis, associated with ulcers on GMS stain. Urine Histoplasma antigen positive. Adrenal mass biopsy revealed necrotic material and fibroconnective tissue. DH was initially treated with IV liposomal amphotericin and transitioned to oral Itraconazole. At the time of discharge, calcium was 9.8 mg/dl and serum creatinine was 2.9mg/dl.

Discussion: Hypercalcemia, in the setting of elevated 1,25 dihydroxy Vitamin D levels, prompts concern for granulomatous disease. Sarcoidosis is a common etiology, however, other causes must be entertained. The cluster of findings of adren al non-casing granulomas coupled with diffuse skin ulcers with hypercalcemia should prompt the provider to consider infectious etiologies such as disseminated histoplasmosis as early diagnosis and prompt treatment can result in improved outcomes.

POI1192
Electrolyte Disturbances Among Those With Malignancy on Anti-Neoplastic Agents

Background: The clinical characteristics of electrolyte disturbances among patients with malignancy in contemporary cohorts are lacking.

Methods: This is a retrospective cohort study on 2644 patients with malignancy on anti-neoplastic agents from 2019 to 2020. Anti-neoplastic agents associated with electrolyte disturbances were examined by multi-level mixed-effects logistic regression analyses. The data were adjusted for age, sex, serum albumin, eGFR, kinds of malignancy, and other medications which potentially affect electrolytes.

Results: Mean age was 64.8 (15.8) years, 55.5% were male, and median eGFR was 72.9 (58.1-88.1) mL/min/1.73m². The prevalences of hypernatremia (Na ≥130 mEq/L), hypomagnesemia (Mg ≥1.5 mg/dL), hypophosphatemia (P ≤40 mg/dL), and hypokalemia (K <3.0 mEq/L) were 2.1 (1.8-2.2), 2.0 (1.7-2.3), 1.7 (1.6-1.9), and 1.2 (1.1-1.4) events/100 patient-measurements, respectively. The use of bortezomib was associated with hypernatremia (OR: 3.04 [1.96-4.71]) and three immune checkpoint inhibitors were significantly associated with hyponatremia. The use of cetuximab and gemcitabine were strongly associated with hypomagnesemia (OR 11.79 [7.56-18.38] and 5.95 [3.36-10.55].
respectively). Other agents associated with electrolyte disturbances were shown in Table. Other anti-neoplastic agents, lower albumin levels were consistently associated with development of electrolyte disturbances.

Conclusions: Electrolyte disturbances were common and associated with the use of novel anti-neoplastic agents among those with malignancy. Identifying the agents and patient population at high risk of developing electrolyte disturbances is important in taking appropriate preventive measures and monitoring for those undergoing treatments with anti-neoplastic agents.

Discussion: Hypophosphatemia in our patient was caused by impaired intestinal absorption of phosphate, and inappropriately increased urinary excretion due to secondary hyperparathyroidism due to vitamin D deficiency. The total daily amount of phosphate the patient received while in the hospital was 3825 mg per day. A 24 hour urine excretion of P estimated from urine creatinine concentration (342 mg/dL), assuming normal GFR (180 L/day), is very low (245 mg/day). Although P administered as Na or K salt is well absorbed in a normal person, she was unable to absorb P likely due to the gastric sleeve surgery causing rapid emptying of the gastric content, simulating the dumping syndrome, resulting in diarrhea by unabsorbed Na and K phosphate. Further impairment in intestinal P absorption may have been caused by vitamin D deficiency due to the inadequate dosing (800 units daily) and the inappropriate vitamin D type (Vitamin D2 instead of D3).

PO1194
Severe Hypophosphatemia Induced by Oncogenic Osteomalacia
Abdullah Jalal, Ryan P. Brown. Overlook Medical Center, Summit, NJ.

Introduction: Oncogenic Osteomalacia (OncOM) is an uncommon paraneoplastic syndrome characterized by FGF-23 overexpression from benign mesenchymal tumors causing severe hypophosphatemia. Very few cases of OncOM with concomitant paraneoplastic syndromes have been described. Herein we present a rare case of carboptin-associated hyperparatremia in the setting of SIAH3-induced chronic hypophosphatemia unmasking an even rarer secondary paraneoplastic syndrome; oncogenic osteomalacia.

Case Description: A 52 year old male with past medical history of chronic hypophosphatemia on salt tablets secondary to recently diagnosed metastatic small cell lung cancer was admitted for initiation of chemotherapy with carboplatin/etopside. Two days after completing cycle 1 the patient developed acute hypophosphatemia; serum Na decreased from 141 to 129 mEq/L. Serum electrolytes were (mEq/L): K 3.9, Cl 94, HCO3 28, BUN 20, Cr 0.67. Cortisol (17.8 ug/dL) and TSH (2.28 uIU/mL) were within normal limits. Urine studies noted (mEq/L): Na 75, Cl 69, K 43.5, elevated osmolality 860 mosm/kg.

Etiology of acute hypophosphatemia was attributed to platinum chemotherapy in the setting of SCC-associated SIAH3 and patient was treated with tolvaptan after several days of non-response to fluid restriction and urea. Patient’s hypophosphatremia subsequently corrected but was incidentally noted to have severe hypophosphatemia (<1 mEq/L) refractory to aggressive IV and PO phosphate repletion. ALP was elevated 279 U/L, corrected Ca 10 mEq/L, low 25(OH)-vitamin D 23.8 ng/mL, normal PTH 45.6 pg/mL and PTHrP ≤0.4 pmol/L. Urinary fractional excretion of phosphorus was increased at 24%. An FGF-23 level obtained 12 days after completing cycle 1 of carboplatin-etopside was considerably elevated at 219 pg/mL. Thus, the patient was diagnosed with oncogenic osteomalacia.

Discussion: This case highlights a unique and diagnostically challenging patient presentation of severe hypophosphatemia in the setting of dual paraneoplastic syndromes. OncOM should be considered in the differential for severe refractory hypophosphatemia. This occurs via FGF-23 mediated downregulation of PCT Na-Pi transporters and 1a-hydroxylase causing renal phosphate wasting and reduced 1,25-hydroxyvitamin D levels. Over time chronic hypophosphatemia impairs bone mineralization causing osteomalacia. Measurement of the fractional excretion of phosphorus is critical and FGF-23 levels should be obtained to confirm diagnosis.

PO1195
Phenotypes of Patients with Abnormal Phosphate on Admission by Consensus Clustering and Associated Mortality Risks
Carissa Y. Dumanescu,3 Charrat Thongprayoon,1 Andrea G. Kattah,1 Michael A. Mao,2 Stephen B. Erickson,1 John J. Dillon,1 Vestal D. Garovoy,1 W. Jason investigators.

Introduction: The renal regulation of phosphate homeostasis is mediated mainly by reabsorption of P by NaPi-IIc in the proximal tubule, whereas intestinal absorption is mediated by NaPi-Ib. Normally, about 2/3 of dietary intake (1500 mg/day) is absorbed, but when given by mouth as Na or K phosphate, absorption is nearly 100% in a normal person. We report here a patient with severe hypophosphatemia due to phosphate malabsorption caused by prior gastric bypass surgery along with vitamin D deficiency.

Case Description: A 34 year old African American female with past medical history of benign carcinoid syndrome, pernicious anemia, Hashimoto thyroiditis, and gastric malabsorption caused by prior gastric bypass surgery along with vitamin D deficiency. She was treated with oral Na and K phosphate solution containing 560 mg of P, 320 mg of Ca, 9.2 mg of Mg, and 1,25(OH)2 vitamin D 15.3 pg/mL; PTH 77.7 pg/mL; urine P 77 mg/dL; urine creatinine 0.6 mg/dL; Ca 9.2 mg/dL; Mg 2.17 mg/dL; P 1.3 mg/dL; 25-OH vitamin D 10.88 ng/mL; 1,25(OH)2 vitamin D 15.3 pg/mL; PTH 77.7 pg/mL; urine creatinine 342.5 mg/dL. She was being treated with oral Na and K phosphate solution containing 560 mg of P, 320 mg of Na, and 500 mg of K in each dose for every 4 hours, and once daily dose of IV K phosphate containing 465 mg of phosphate for 14 days. She was also treated with 800 mg of calcium D2 daily. Serum phosphate remained persistently low around 1.8 mg/dL despite the above treatment.

Discussion: Hypophosphatemia in our patient was caused by impaired intestinal absorption of phosphate, and inappropriately increased urinary excretion due to secondary hyperparathyroidism due to vitamin D deficiency. The total daily amount of phosphate the patient received while in the hospital was 3825 mg per day. A 24 hour urine excretion of P estimated from urine creatinine concentration (342 mg/dL), assuming normal GFR (180 L/day), is very low (245 mg/day). Although P administered as Na or K salt is well absorbed in a normal person, she was unable to absorb P likely due to the gastric sleeve surgery causing rapid emptying of the gastric content, simulating the dumping syndrome, resulting in diarrhea by unabsorbed Na and K phosphate. Further impairment in intestinal P absorption may have been caused by vitamin D deficiency due to the inadequate dosing (800 units daily) and the inappropriate vitamin D type (Vitamin D2 instead of D3).

Anatto Leaf Tea Intoxication: An Unusual Cause of Green Urine

Eduardo Valde, Rayra G. Ribeiro, Joao Lucas M. Gorzoni, Guilherme P. Santa Catharina, Bernardo V. Reichtert, Marcia Fernanda Arantes de Oliveira, Victor F. Seabra, Paulo R. Lins, Igor Smolentzov, Camila E. Rodrigues, Lucio Andrade. Hospital das Clinicas, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Introduction: The roots and leaves of the annatto (“urucu”) tree (Bixa Orellana) are used by the lay population in the treatment of many diseases. We describe a case of AKI with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use.

Case Description: A 59-year-old male without known comorbidities presented with a 2-week history of severe diarrhea. Three days prior to admission, he was diagnosed with renal dysfunction, received 500 mL of saline and was discharged. Subsequently, he presented with muscle weakness, uremic encephalopathy, severe AKI, F+E imbalance and greenish urine (Figure). He received fluid resuscitation and underwent two sessions of hemodialysis. He reported having ingested annatto leaf tea to treat his diarrhea. Blood and urine cultures were negative and there was no history of drug use. He was discharged on day 14 with no remaining F+E imbalance or renal dysfunction.

Discussion: The diuretic effect of annatto leaf extracts has been shown in experimental models. To our knowledge, this is the first report of severe AKI and F+E imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and the diuretic effect of the tea.

Foam Sclerotherapy for Directed Treatment of Symptomatic Cysts in Autosomal Dominant Polycystic Kidney and Liver Disease

Background: Patients frequently describe mass symptoms & reduced quality of life (QoL) that correlate with large (≥5cm diameter) organ cysts in ADPKD/ADPLD. Since 1/18/2017, we have studied the safety & impact of cyst drainage followed by sotradecol foam sclerotherapy (SFS) to treat symptomatic, large cysts.

Methods: In this single-center, single-arm, prospective observational study, ADPKD and ADPLD patients with compressive symptoms due to liver or kidney cysts are referred for SFS. Small volumes (20cc max) of 3% sotradecol sclerosant admixed with air are injected (fluoroscopy-guided under local anesthesia) to ablate the epithelial cyst lining. QoL measures using polycystic liver disease QoL tool (PLD-Q) & organ volumes (planimetry using CT/MR) are recorded at baseline & 12+ months post-SFS. Changes over time were tested using Wilcoxon tests and confirmed using repeated measures mixed models. Improvements >0.5 SD were considered clinically meaningful.

Results: We performed 148 SFS procedures among 68 cases (mean age 55yr 77% Female, mean 2.2 procedures per pt): 53 (77.9%) with ADPKD/ADPLD, 5 (7.4%) with ADPLD, & 10 (14.7%) with cystic disease NOS. PLD-Q scores improved by 7.7 (IQR 0.1, 24.8) (p=0.012) at mo 12. A subgroup (13 patients) (mean age 54.7yr, 69% F) have undergone multiple sequential SFS procedures: 10 (77%) with ADPKD/ADPLD, 2 (15%) ADPLD, & 1 (8%) cystic disease NOS. Among 5 with multiple kidney procedures, median kidney volume decreased by 135mL/yr. Among 5 with multiple liver procedures, median liver volume decreased by 114mL/yr. SFS was well tolerated with low complication rates.

Conclusions: SFS directed at large, symptomatic liver and kidney cysts was well tolerated, improved QoL at 12 months, & decreased early satiety, SOB, pain & fullness. Furthermore, multiple sequential SFS procedures are feasible, efficacious, and have an acceptable safety profile.

Development of AL01211, a Novel Glucosylceramide Synthase Inhibitor, to Treat Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Michael C. Babcock, Jianhong Zheng, Li Li, Changlin Mei, Marvin R. Garovoy, Yuqiao Shen. 1AcceLink Therapeutics, Newark, CA; 2Shanghai Changzheng Hospital, Shanghai, China.

Background: ADPKD is a common genetic disease affecting ~1-1000 individuals and is characterized by progressive renal cysts growth, kidney enlargement and renal dysfunction. Glucosylphospholipids (GSL) are elevated in the kidneys of ADPKD animal models and ADPKD patients where they promote renal epithelial cell growth and kidney inflammation. Glucosylceramide synthase inhibitors (GCSi) reduce GSL production, slow cyst growth, and preserve kidney function in multiple animal models.

Methods: The effect of Nintedanib treatment on renal cyst growth and fibrosis was tested in AL01211 f/fPkhd1Cre mice and in for 8 weeks starting at the age of 3 months in AL01211 f/f mice. Western blot data in vitro studies were performed using primary culture human ADPKD renal cyst epithelial cells and renal myofibroblasts.

Results: Nintedanib treatment significantly reduced kidney-to-body weight ratio, and may be repurposed to treat ADPKD.

KidneyNetwork Uses Kidney-Derived Gene Expression Data to Predict and Prioritize Novel Genes Involved in Kidney Disease
Laura R. Claus, Floranne Boulougne, Henry Wiersma, Roy Oelen, Floor Schukking, Niek de Klein, Shuang Li, Harm-Jan Westra, Bert Van der zwaag, Dana Sierks, Risa Schönauer, Jan Halbtritter, Nine V. Kroons, Patrick Doeleman, Lude Franke, Albertien M. van Eerde. 1Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands; 2Department of Genetics, University Medical Center Groningen, Groningen, Netherlands; 3Genomics Coordination Center, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 4Medical Department III - Endocrinology, Nephrology, Rheumatology Department of Internal Medicine, Division of Nephrology, University of Hospital Leipzig Medical Center, Leipzig, Germany.

Background: Genetic testing in patients with suspected hereditary kidney disease produces much valuable information, but does not always reveal the genetic cause for the patient’s disease. Pathogenic variants can reside in genes that are not yet known to be involved in kidney disease. We aimed to develop a database containing kidney disease genes and deploy it to clinical practice to identify novel kidney disease genes.

Methods: KidneyNetwork is a co-expression network built upon 878 kidney RNA-sequencing samples and a multi-tissue dataset of 31,499 samples. It uses expression patterns to predict which genes have kidney-related functions and which phenotypes might result from variants in these genes. As proof of principle, we applied KidneyNetwork to prioritize rare variants in exome-sequencing data from 13 kidney disease patients.

Results: We assessed the prediction performance of KidneyNetwork by comparing it to GeneNetwork, our previously developed multi-tissue co-expression network. In KidneyNetwork, we observe significantly improved prediction accuracy of kidney-related HPO-terms and an increase in the total number of significantly predicted kidney-related HPO-terms (figure 1). Applying KidneyNetwork to exome-sequencing data allowed us to identify ALG6 as a candidate gene for kidney and liver cysts.

Conclusions: KidneyNetwork is a kidney-specific co-expression network that predicts which genes have kidney-specific functions that can result in kidney disease. Gene-phenotype associations of genes unknown for kidney-related phenotypes can be predicted. We show its added value by applying it to kidney disease patients without a molecular diagnosis. KidneyNetwork can be applied to clinically unsolved cases, but it can also be used by researchers to better understand kidney physiology and pathophysiology.

PO1199
The Tyrosine Kinase Inhibitor Nintedanib Ameliorates Autosomal Dominant Polycystic Kidney Disease
Abeda Jamadar, Reena Rao. University of Kansas Medical Center, Kansas City, KS.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and is characterized by progressive growth of fluid-filled cysts in the kidneys. Growth factor binding to receptor tyrosine kinases (RTKs) are known to stimulate cell proliferation and cyst growth in PKD. In the current study we tested the effect of Nintedanib, an RTK inhibitor and FDA approved drug for non-small cell lung carcinoma and idiopathic lung fibrosis, in mouse models of ADPKD. Nintedanib is a triple RTK inhibitor which targets vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR).

Methods: The effect of Nintedanib on renal cyst growth and fibrosis was tested in two orthologous models of ADPKD, the Pkd1Pkd1 mouse and the Pkd1Pkd1 mice. Nintedanib treatment (20 mg/Kg on alternate days by intraperitoneal injections) was from postnatal day P10 to P18 in Pkd1Pkd1 mice and in for 8 weeks starting at the age of 3 months in Pkd1C6C6 mice. In vitro studies were performed using primary culture human ADPKD renal cyst epithelial cells and renal myofibroblasts.

Results: Nintedanib treatment significantly reduced kidney-to-body weight ratio, and may be repurposed to treat ADPKD.

Modeling Gene-Targeted Strategies for Therapeutic Correction of PKD1 Loss-of-Function Mice
Marie Trudel, Almira Kurbegovic, Kevin Loayza-Vega, Reuy Christian Pacis, Camila Parrot. Institut de recherches cliniques de Montreal, Montreal, QC, Canada.

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes cyst progression leading to renal failure, mainly by PKD1 mutations. Since microscopic cysts in ADPKD kidneys are likely formed from the expression of PKD1, we targeted at fetal stage wild type mice with ~16 SBP copies expressed 0.87-fold the Pkd1 mouse b) 2 renal-specific expression patterns to predict which genes have kidney-related functions and which phenotypes might result from variants in these genes. As proof of principle, we applied KidneyNetwork to prioritize rare variants in exome-sequencing data from 13 kidney disease patients.

Methods: KidneyNetwork is a co-expression network built upon 878 kidney RNA-sequencing samples and a multi-tissue dataset of 31,499 samples. It uses expression patterns to predict which genes have kidney-related functions and which phenotypes might result from variants in these genes. As proof of principle, we applied KidneyNetwork to prioritize rare variants in exome-sequencing data from 13 kidney disease patients.

Results: We assessed the prediction performance of KidneyNetwork by comparing it to GeneNetwork, our previously developed multi-tissue co-expression network. In KidneyNetwork, we observe significantly improved prediction accuracy of kidney-related HPO-terms and an increase in the total number of significantly predicted kidney-related HPO-terms (figure 1). Applying KidneyNetwork to exome-sequencing data allowed us to identify ALG6 as a candidate gene for kidney and liver cysts.

Conclusions: KidneyNetwork is a kidney-specific co-expression network that predicts which genes have kidney-specific functions that can result in kidney disease. Gene-phenotype associations of genes unknown for kidney-related phenotypes can be predicted. We show its added value by applying it to kidney disease patients without a molecular diagnosis. KidneyNetwork can be applied to clinically unsolved cases, but it can also be used by researchers to better understand kidney physiology and pathophysiology.
collecting tubular origin and survived until P12-15. While Sbp reached Pkd1 therapeutic levels in the mild SbpPkd1/-, the additional Tg copies suggest the presence of regulatory region within Pkd1 gene-body. Renal cysts in SbpPkd1/- and SbpPkd1/- co-detected by RNAscope and IF, arise likely from insufficient and chimeric Pkd1 re-expression. These analyses also shed light on Pkd1 spatio-temporal expression patterns in collecting tubules during renal maturation that shifts to distal tubules following maturation. 

Conclusions: Pkd1 is regulated by elements both upstream for spatio-temporal pattern and intragenic sequences for expression levels. The renal-specific SB minimal regulatory region is sufficient for therapeutic correction in one copy Tg. Our study demonstrates that Pcp1 re-expression can substantially delay cystogenesis and markedly extend lifespan.

Wheat-Gluten Diet Attenuates Ccl2-Mediated Immune Response and Slows Polycystic Kidney Disease

Jifeng Huang, Shinobu Yamaguchi, Jung-Shan Hsu, Takamitsu Saigusa. Department of Medicine, Division of Nephrology The University of Alabama at Birmingham, Birmingham, AL.

Background: Disease severity of autosomal-dominant polycystic kidney disease (ADPKD) is highly variable, even among families with the same gene mutation. A high protein diet is a well-recognized ADPKD progression-accelerating factor. Dietary protein composition is important, as pre-clinical studies have shown a soy protein-based diet slows kidney cyst formation in rodent PKD models. Recruitment of macrophages in the kidneys is known to promote cystogenesis in PKD. We hypothesize that type of protein in the diet may serve as a potential environmental stimulant to immune response and cyst growth.

Methods: Using tamoxifen-inducible Pkd1-global knockout mice, we fed the mice with either a high casein-protein (animal-based protein: 60%) or 60% high wheat-gluten (plant-based protein: 60%) for a total of 1 week or 6 weeks. Some mice fed a high casein protein diet were treated with liposomal clodronate or saline for a total of 5 weeks. Mice were euthanized and kidney cyst area, number of macrophages and chemokine/cytokine levels were measured.

Results: Pkd1-knockout mice fed a high casein diet increased the number of kidney macrophages, expression of macrophage-recruiting chemokine Ccl2 (but not chemokines Csf1 or Ccl5), pro-inflammatory cytokine (Il6, Tnf-a) and accelerated cyst growth compared to counterparts fed an iso-caloric high wheat-gluten (WG) diet or a low protein diet in very early stages during dietary casein load (1 week after diet modification), cyst expansion precedes macrophage recruitment in the kidney, indicating that diet per se triggers early cyst growth rather than as a consequence of macrophage recruitment and inflammation. High casein diet fed Pkd1-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine and fewer cysts.

Conclusions: Wheat-gluten diet fed Pkd1-knockout mice resulted in decreased the number of macrophages, suppressed levels of kidney Cell2, but not Csf1 or Ccl5, and slowed cyst growth compared to counterparts fed an iso-caloric casein based diet. Dietary protein modification may suppress immune response and cyst growth in PKD.

High Prevalence of Kidney Cysts in Hereditary Hypophosphatemic Rickets with Hypercalciuria

Background: Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH) is a rare monogenic disorder caused by SLC34A3 pathogenic variants, characterized by renal phosphate wasting, hypophosphatemia, hypercalciuria (HC), elevated 1,25-dihydroxyvitamin D, nephrocalcinosis (NC), and urinary stone disease (USD). Previously we reported a high prevalence of kidney cysts in CYP24A1 deficiency. Thus, we aim to report the prevalence of KC and correlations with renal function and expression levels of regulatory region within Pkd1 gene-body. Renal cysts in HHRH and kidney cysts. Similarities in the biochemical profiles of HHRH and CYP24A1 deficiency suggest elevated active vitamin D, and HC may be potential factors in cyst formation. Further studies are needed to evaluate the role of the SLC34A3 gene in cyst formation.

Results: Among 12 patients with SLC34A3 pathogenic variants (7 monoleucic, 5 biallelic), 42% (5/12) were males. Median age at clinical presentation was 17 years (range 8-46) and at genetic confirmation 42 years (range 9-66). None had a family history of cystic kidney disease. Kidney cysts (Figure 1) were present in 75% (9/12), among whom median age at first kidney imaging and first cyst detection was 41 years (range 9-64). Median number of cysts per patient was 3 (range 1-23). The number of cysts ≥ 5 mm in size was above the 97.5th percentile of an age- and sex-matched control population in 6/9 (67%). At least 2 cysts ≥ 5 mm in size were found in 100% of children.

Conclusions: We found a strong association between HHRH and kidney cysts. Our data highlight the potential of HHRH as a novel dysregulated pathway in mineral and human ADPKD and suggest that tryptophan metabolites are biomarkers of disease progression. Further, inhibition of the pathway presents a new treatment approach. IDO1 inhibitors are FDA approved for various cancers. Our data suggest a link between metabolic reprogramming, immune cell function, and disease progression, as IDO1 loss/inhibition impacted immune cell populations/pathways shown to regulate cyst growth.

Dysregulated Tryptophan Metabolism Promotes Polycystic Kidney Disease Progression

Dustin Nguyen, Emily K. Kleczko, Nidhi Dwivedi, Berenice Y. Gitomer, Michel Chonchol, Raphael A. Nemenoff, Jelena Klawitter, Katharina Hopp. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Metabolic reprogramming is a feature and modifier of autosomal dominant polycystic kidney disease (ADPKD) progression. Moreover, immune cells regulate cyst growth. In cancer, a disease with parallels to PKD, the metabolic landscape created by tumors significantly impacts immune cell function and tumor growth. Yet, this link is unexplored in PKD. Here, we study tryptophan metabolism, a known immunosuppressive pathway, in cyst growth.

Methods: Metabolites were profiled in ADPKD patient plasma and kidneys of an orthotopic ADPKD model (C57BL/6 Pkd1flox/flox). We also crossed the ADPKD model to Ido1-/- mice, the enzyme metabolizing tryptophan to kynurenines, and inhibited IDO1 using the tryptophan analog 1-MT (400mg/kg, twice daily, orally). From these mice, kidney immune cells were profiled via flow cytometry. 

Results: Tryptophan metabolites were significantly increased in Pkd1flox/- mice at 3-, 6-, and 9-months compared to controls and correlated with disease progression. Plasma levels of kynurenines significantly associated with HTKV at baseline, and positively correlated with annual percent change of HTK in adult ADPKD patients. IDO1 levels were significantly increased in kidneys of PKD mice and patient cell lines. At 6-months of age, Pkd1flox/RC/RC Ido1-/- mice had significantly milder PKD compared to Pkd1flox/flx mice as measured by % KW/BW and cystic/lobular index. Similarly, treatment of 1-month-old Pkd1flox/flx mice with 1-MT for 3 weeks slowed cyst growth; overall providing functional evidence of the pathway’s relevance to PKD. Kidney immune profiling of Pkd1flox/flx, Ido1-/- and 1-MT-treated mice revealed a significant reduction of resident macrophages, regulatory T cells, and immune checkpoint protein expression (PD-1/PD-L1), while the percentage of CD8+ T cells/total T cells increased.

Conclusions: Our data highlight tryptophan metabolism as a novel dysregulated pathway in polycystic kidney disease. Further, inhibition of the pathway presents a new treatment approach. IDO1 inhibitors are FDA approved for various cancers. Our data suggest a link between metabolic reprogramming, immune cell function, and disease progression, as IDO1 loss/inhibition impacted immune cell populations/pathways shown to regulate cyst growth.

Creatine Kinase Elevation in Patients with Autosomal Dominant Polycystic Kidney Disease on Tolvaptan Treatment
Diana Rodríguez-Espinosa, Elena C. Payán, Elena Guillén, Josep miquel Blasco pelicano. Hospital Clinic de Barcelona, Barcelona, Spain.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease worldwide. Studies such as the TEMPO 3:4 and 4:4 have demonstrated tolvaptan’s (vasopressin V2 receptor antagonist) effectiveness in slowing the progression of this disease. The best described adverse effect seen with this treatment is drug-induced liver injury, however, creatinine kinase (CK) elevation has also been described anecdotally in a couple of case reports.

Methods: This is a prospective observational study of adult patients with rapidly progressive ADPKD on tolvaptan treatment under follow-up at Hospital Clinic de Barcelona from October 2018 to March 2021. Quantitative variables are described as mean and standard deviation, while qualitative ones are reported as absolute and relative frequencies.

Results: A total of 37 patients started treatment with tolvaptan during this period. In 34 of them, serum CK levels were measured as part of the monthly biochemical follow-up. A total of 29.11% (10 of 34) of the patients elevated this parameter with a mean of 1368.2 ± 2807.28 U/L. Seven patients had a transient elevation with a mean of 446.43 ± 359.22 U/L, which reversed upon dose decrease or treatment pause. However, treatment had to be interrupted in the remaining three patients (mean 3519 ± 5016.36). In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was a reversible related toxic effect through a weekly intensified cycling exercise with increased myalgia afterward) and was not significantly correlated with LDL levels, liver enzymes, calcium, potassium, urinary or plasma osmolality.

Conclusions: By performing a general screening, we found that CK elevation is more frequent than previously described in the literature, reaching significantly increased levels producing symptomatic requiring definite treatment interruption. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment’s follow-up, at the beginning of treatment and when increasing its dose, to promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.

PO1207

Protein 4.1O Links Polycystin 1 to the Actin Cytoskeleton and Modulates Hippo Signaling
Theresia Vienken, Eva Koenigshausen, Lars C. Rump, Lorenz Sellin. Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.

Background: The majority of ADPKD patients have a PKD1 gene mutation. PKD1 codes for Polycystin-1 (PC-1). Cyst formation is caused by altered renal tubular cell proliferation. Protein 4.1 family members are actin adaptors, which link plasma membrane receptors to the actin cytoskeleton. Protein 4.1O (FAM3D) is a candidate gene for diabetic nephropathy. Furthermore, protein 4.1O has properties of a tumor suppressor. This study investigates the molecular and cellular properties of protein 4.1O as a potential ADPKD modifier and therapeutic target.

Methods: PC-1 full-length and truncation mutants were transiently expressed. PC-1 interaction with protein 4.1O and its truncation mutants were investigated. Truncation mutants cover the N- and C-terminal domains of protein 4.1O (Band 4.1, FERM, actin-binding domain and coiled coil domain). Coimmunoprecipitations of protein 4.1O with PC-1 in IMCD cell lysates were done. Pull-down experiments with bacterial recombinant protein 4.1O and F-actin were performed. The modulation of the PC-1 signaling properties by protein 4.1O were investigated in luciferase assays for c-myc and TEAD. FRMD3 core promoter regions were cloned into luciferase reporter.

Results: Coimmunoprecipitations show an interaction of protein 4.1O to PC-1 full-length. The C-terminus of PC-1 interacts with four isoforms of protein 4.1O (201, 202, 204, 207). The truncation mapping and isoform alignment identifies a potential leucine zipper domain in protein 4.1O as the C-terminal binding domain to PC-1. The N-terminal domain of protein 4.1O and FERM domain is also sufficient to mediate PC-1 interaction. Protein 4.1O C-terminus binds to F-actin and links the PC-1 C-terminus to the cytoskeleton. Protein 4.1O silences the PC-1 mediated transactivation of c-myc and hippo signaling (TEAD). Furthermore, F-actin destabilization influences the PC-1 induced hippo signaling. PC-1 activates the protein 4.1O 4.1O interacts with FRMD3.

Conclusions: Both, the FERM domain and leucine zipper containing coiled coil domain of protein 4.1O interact with the PC-1 C-terminus. The interaction of protein 4.1O links PC-1 to the actin cytoskeleton. The protein 4.1O interaction inhibits the PC-1 mediated c-myc and hippo signaling. Furthermore, protein 4.1O provides a F-actin based sensitivity to the PC-1 mediated hippo signaling. In summary, protein 4.1O shows features of an anti-cystogenic protein.

PO1206

Protein Kinase A Downregulation Delays the Development and Progression of Polycystic Kidney Disease
Xiaofang Wang, Li Jiang, Ka Thao, Carline R. Sussman, Timothy P. Labranche, Michael R. Palmer, Peter C. Harris, Stanley Mcknight, Klaus P. Hoeflch, Stefanie S. Schalm, Vicente E. Torres, Mayo Clinic, Rochester, MN; Blueprint Medicines, Waban, MA; University of Washington, Seattle, WA.

Background: Upregulation of cAMP-dependent as well as -independent PKA activity and expression have been described anecdotally in a couple of case reports. These findings are not understood. The tubby family protein–TULP3 coordinates with the intraflagellar transport proteins to maintain cAMP channel transport to cilia and regulation of renal cystogenesis.

Methods: This study was designed to ascertain (1) the effect of PKA-I activation or inhibition compared to EPAC or PKA-II inhibition on in vivo mIMCD3 cystogenesis and ex vivo mIMCD3 cystogenesis. Direct downregulation of PKA activity was both protective and therapeutic, whereas EPAC activation or PKA-II activation or inhibition had no or only minor effects.

Results: A total of 37 patients started treatment with tolvaptan during this period. In 34 of them, serum CK levels were measured as part of the monthly biochemical follow-up. A total of 29.11% (10 of 34) of the patients elevated this parameter with a mean of 1368.2 ± 2807.28 U/L. Seven patients had a transient elevation with a mean of 446.43 ± 359.22 U/L, which reversed upon dose decrease or treatment pause. However, treatment had to be interrupted in the remaining three patients (mean 3519 ± 5016.36). In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was a reversible related toxic effect through a weekly intensified cycling exercise with increased myalgia afterward) and was not significantly correlated with LDL levels, liver enzymes, calcium, potassium, urinary or plasma osmolality.

Conclusions: By performing a general screening, we found that CK elevation is more frequent than previously described in the literature, reaching significantly increased levels producing symptomatic requiring definite treatment interruption. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment’s follow-up, at the beginning of treatment and when increasing its dose, to promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.
complex-A (IFT) in trafficking transmembrane proteins to cilia. Lack of Tulp3 in mouse kidney epithelial cells, caused by crossing Hoxb7Cre and Tulp3flox/flox mice, resulted in absolute absence of renal cystic kidney disease. Surprisingly, cilia contribute to cystogenesis. 

Methods: We used direct in vitro binding, proximity biotinylation and mass spectrometry to map TULP3-cargo interactions. We generated knockouts of Tulp3 and cargoes in kidney epithelial cells stably co-expressing different variants of TULP3 or cargoes, respectively. We generated conditional knockout of Tulp3 in mouse kidney nephrons. We performed immunofluorescence for lipidated proteins with respect to kidney cystogenesis. 

Results: The transmembrane cargoes have short motifs that are necessary and sufficient for TULP3-mediated trafficking. We now show that TULP3 is required for transport of the atypical GTPase ARL13B into cilia, and for cilial expression of ARL13B-dependent farnesylated and myristoylated proteins. ARL13B transport requires TULP3 binding to IFT-A core but not to phosphoinositides, unlike transmembrane cargo transport that requires binding to both by TULP3. A conserved lysine in TULP3’s tubby domain mediates direct ARL13B binding and trafficking of lipidated and transmembrane cargoes. This implies a conserved mechanism of ciliary retromer-mediated vesicle sorting in which the palmitoylation site mediates binding to TULP3 and directs trafficking to cilia. Tulp3 trafficked lipidated proteins are depleted with distinctive temporal kinetics from kidney epithelial cilia during Tulp3 deletion-induced cystogenesis. 

Conclusions: We conclude that TULP3 transports transmembrane proteins and ARL13B into cilia by capture of short sequences through a shared tubby domain site. 

Tulp3 deletion suggests their differential roles in cilia in regulating renal cystogenesis.

Augmented Renal TRPV4 Activity Attenuates Cystogenesis in ARPKD Rats

Kyrilo Prisyev, Victor N. Tomilin, Naejeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochynyuk. The University of Texas Health Science Center at Houston John P. and Katherine G. McGovern Medical School, Houston, TX.

Background: PKD is characterized by development of cysts in the kidney. Abundant evidence suggested that the impaired mechanosensitivity and disturbed [Ca2+]i homeostasis are the major determinants of the rate of cystogenesis. ARPKD is caused by missense mutations in fibrocystin. ARL13B is characterized by the development of cysts almost exclusively in the collecting duct. We have previously demonstrated that mechanosensitive Ca2+-permeable TRPV4 channel is preferentially expressed in the collecting duct where its activity is imperative for setting resting [Ca2+]i levels and mediating flow-dependent [Ca2+]i elevations. TRPV4 activity and expression is markedly increased in high K+ intake, known to increase flow in the collecting duct. Thus, we hypothesized that dietary K+ supplementation would be beneficial in counteracting cystogenesis in ARPKD by stimulating TRPV4-dependent Ca2+ influx. 

Methods: We used dietary and pharmacological inputs to establish a correlation between the rate of cystogenesis and TRPV4 function in freshly isolated cyst monolayers in a homologous ARPKD rodent model, PCk453 rats.

Results: We report that treatment of PCk453 rats with high K+ diet for 1 and 2 months significantly reduced kidney-to-body weight ratio. Surprisingly, high K+ diet did not affect cyst number and size. However, high K+ diet significantly increased the number of cysts with respect to kidney cystogenesis.

Conclusions: Our experiments establish the direct link between TRPV4 function and cyst monolayer formation in ARPKD. We propose that stimulation of TRPV4 by pharmacological or dietary cues could be of clinical relevance to counteract PKD progression.

PO1211
The Transcription Factor Tlap2a Maintains the Epithelial Integrity of Renal Collecting Ducts

Jannike Leitz,1,2 Dr. med. Ann-Helene Hinze,1,2 Kai M. Schmidt-Ott,1,2 Charite Universitaetsklinikum Berlin, Berlin, Germany; 3Max-Delbrueck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.

Background: The transcriptional regulator Tlap2a is a member of the AP-2 family of transcription factors. In humans, heterozygous mutations of Tlap2a result in branchio-oculo-facial syndrome (BOFS), which is associated with renal anomalies, including dysplastic, absent and multicystic kidneys. In this project, we aim to elucidate the molecular functions of Tlap2a in the renal collecting duct.

Methods: We used mice carrying a collecting duct-specific knockout of Tlap2a (Tlap2a-/-), by crossing Hoxb7Cre and Tlap2aflox/flox mice. Both wild-type and adult mutant mice were analyzed using histology, in situ hybridization, bulk RNA sequencing and single nucleus RNA sequencing. 

Results: Tlap2a was expressed in the ureteric bud and distal region of the S-shaped body. The number of newborn vessels was increased in mutant mice. High K+ intake resulted in distal tubules and collecting ducts. Tlap2a-/- mice displayed moderately reduced kidney weights (20 % reduction compared to controls) and a progressive dilation of outer medullary collecting ducts throughout six months of life. Bulk and single nuclei RNA sequencing of kidneys of three months old Tlap2a-/- mice and littermate controls indicated deregulated expression of genes associated with cellular adhesion and epithelial integrity, such as Cldn8 and Nptn. In addition, Wnt9b, a factor previously described as a regulator of planar cell polarity and tubule diameter, was downregulated in collecting ducts of Tlap2a-/- mice.

Conclusions: Our data indicate that the transcription factor Tlap2a regulates kidney size and contributes to the continued integrity of the collecting duct epithelium. Our data provide insights into potential molecular mechanisms underlying renal defects observed in BOFS.

Funding: Government Support - Non-U.S.
Autophagy Inhibition Ameliorates Polycystic Kidney Disease

Daniel Atwood, Deepak Pokhrel, Nidhi Dwivedi, Katharina Hopp, Charles L. Edelstein. University of Colorado Denver School of Medicine, Aurora, CO.

Background: We found that there is a decrease in autophagy proteins in Pkd1<sup>−/−</sup> mice. Our study aimed to determine the mechanistic role of suppressed autophagy in causing cyst growth using pharmacological and genetic autophagy inhibition.

Methods: Male Pkd1<sup>−/−</sup> (RC) mice were treated with 2-Deoxyglucose (2DG) or Chloroquine (CLQ) from 50-120 d of age. Kidney specific Pkd1<sup>−/−</sup> Agt7 double knockout mice were generated by Kisp1.3 Cre-lox recombinative. Relative densitometry units (RDU) were determined on immunoblott. Autophagic flux was measured by the change in LC3-II (autophagosomes) +/- Baflyminycin (Baf).

Results: Autophagic flux was present in wild type (WT) and 120 d old RC but suppressed in 150 d old RC kidneys. LC3-II (RDU) +/- Baf was 0.1 vs 0.7 in WT (p<0.01), 0.6 vs 1.0 in 120 d old (p<0.05) and 2.4 vs 2.1 (NS) in 150 d old RC. 2DG resulted in a decrease in ATRG15 complex and suppressed autophagic flux in RC kidneys. LC3-II (RDU) +/- Baf was 0.5 vs 0.8 in VEH (p<0.05), 0.7 vs 0.7 in 2DG (NS). 2DG significantly reduced cyst growth and improved kidney function. Cystic index (%), count +/- 2DG: 7.7 vs 3.7 (p<0.01), 211 vs 161 (p<0.05). BUN (mg/dL) +/- 2DG: 35 vs 27 (p<0.01). Next, RC mice were treated with CLQ, a specific autophagy inhibitor. CLQ resulted in suppressed autophagic flux, less PKD and improved kidney function in RC mice. LC3-II (RDU) +/- Baf was 1.2 vs 1.2 (NS) in CLQ treated kidneys. Cyst index (%), Cyst no. +/- 2DG: 15.5 vs 7 (p<0.07), 231 vs 105 (p<0.05). BUN and creatinine (by HPLC) (mg/dL) +/- CLQ: 41 vs 26 (p<0.05), 2.9 vs 2.3 mg/dL (p<0.05). Next, autophagy was inhibited in PKD kidneys by generating double Pkd1 Atg7 KO mice. The 2 kidney/BV (%) was improved in Pkd1 Atg7 KO vs single Pkd1 KO mice (32 vs 39 p<0.05). Atg7 KO mice had a massive increase in p62 indicating a build-up of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 (p<0.001). Interestingly Atg7 KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of autophagic cargo. p62 in WT vs Atg7 KO (RDU) 0.1 vs 1.8 p<0.001. Interestingly Atg7 KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of T and B cells. pAMPK<sup>Δ12</sup> was increased in Atg7 KO kidneys. AMPK activation is known to reduce PKD.

Conclusions: Both 2DG and CLQ suppressed autophagic flux in RC mice and resulted in less PKD and improved kidney function. Double Pkd1 Atg7 KO mice had significantly lower kidney weight than single Pkd1 KO mice. Both pharmacological and genetic autophagy inhibition resulted in less PKD.

Funding: Veterans Affairs Support, Other U.S. Government Support

ARL13B Negatively Regulates Kidney Cysts from Within Cilia

Robert E. Van Sciver,1 Eduardo Gigante,2 Tamara Caspari,1 Emory University, Atlanta, GA; Georgia Institute of Technology, Atlanta, GA.

Background: Polycystic kidney disease (PKD) is intricately linked to the primary cilium. Polycystin proteins localize to cilia and loss of cilia leads to renal cysts. PKD mouse models often disrupt ciliary genes, removing both ciliary and cellular pools of these gene products; however, the molecular pathway(s) that drive cyst formation is unknown. ARL13B is a regulatory GTPase highly enriched in cilia due to a VxPx motif near its C terminus. ARL13B is also localized to extraciliary sites within the cell. In most tissues, complete deletion of ARL13B leads to short cilia but in kidney leads to short cilia but in kidney ARL13B-null mice are viable and fertile with slowly progressing renal disease. We engineered mice in which we mutated the valine to alanine within the ARL13B V358A/V358A protein to disrupt ARL13B function. In order to determine the specific function of ARL13B-dependent signaling in cilia.

Methods: We engineered mice in which we mutated the valine to alanine within ARL13B’s V358A cilia-localization motif so the mice express cilia-excluded ARL13B<sup>Δ12</sup> from the endogenous locus. ARL13B<sup>Δ12</sup> protein retains all known ARL13B biochemical functions, is stably expressed and is undetectable in cilia. We measured renal cysts and cilia phenotypes to functionally characterize the cistic phenotype of cilia-excluded ARL13B<sup>Δ12</sup> mice.

Results: ARL13B<sup>Δ12</sup> mice are viable and fertile with slowly progressing renal cysts. ARL13B<sup>Δ12</sup> mice exhibit no cystic phenotypes and ARL13B<sup>Δ12</sup> mice develop cysts at a more rapid rate than ARL13B<sup>+/+</sup> mice. We detect cysts in all nephron segments of ARL13B<sup>Δ12</sup> mice. Renal epithelia of ARL13B<sup>Δ12</sup> mice retain cilia in normal nephrons as well as cystic regions.

Conclusions: Our findings indicate that ARL13B plays a critical role within the cilium in regulating kidney cystogenesis. These results suggest that ARL13B functions as a negative regulator of renal cysts, specifically from within the cilium. Further studies are ongoing to dissect the mechanism(s) by which ciliary ARL13B regulates kidney cystogenesis.

Tsc Gene Locus Disruption and Differences in Renal Epithelial Extracellular Vesicles

Prashant Kumar,1 Fahad Al-Zadjali,1,2 Ying Yao,1 John J. Bissler,1,2 ’The University of Tennessee Health Science Center College of Medicine, Memphis, TN; ’St. Jude Children’s Research Hospital, Memphis, TN; ’Sultan Qaboos University, Muscat, Oman.

Background: In tuberous sclerosis complex (TSC), Tsc2 mutations are associated with more severe disease manifestations than Tsc1 mutations and the role of extracellular vesicles (EVs) in this context is not yet studied. We report a comparative analysis of EVs derived from isogenic renal cells except for Tsc1 or Tsc2 gene status and hypothesized that in spite of having similar physical characteristics, EVs modulate signaling pathways differently, thus leading to TSC heterogeneity.

Methods: We used mouse inner medullary collecting duct (mIMCD3) cells with the Tsc1 (T1G cells) or Tsc2 (T2J cells) gene disrupted by CRISPR/CAS9 methodology. EVs were isolated from the cell culture media by size-exclusion column chromatography followed by detailed physical and chemical characterization. Physical characterization of EVs was accessed by tunable resistive pulse sensing and dynamic light scattering, electron microscopy, and western blot analyses.

Results: Physical characterization of EVs revealing similar average sizes and zeta potentials (at pH 7.4) for EVs from mIMCD3 (123.5 ± 5.7 nm and –16.3 ± 2.1 mV), T1G cells (131.5 ± 8.3 nm and –19.8 ± 2.7 mV), and T2J cells (127.3 ± 4.9 nm and –20.2 ± 2.1 mV). EVs derived from parental mIMCD3 cells and both mutated cell lines were heterogeneous (>90% of EVs < 150 nm) in nature. Immunoblotting detected citlal ciliogenic signaling protein ARL13b; intercellular proteins TSG101 and Alix; and transmembrane proteins CD63, CD9, and CD81. Compared to Tsc2 deletion, Tsc1 deletion cells had reduced EV production and release rates. EVs from Tsc1 mutant cells altered mTORC1, autophagy, and β-catenin pathways differently than EVs from Tsc2-mutated cells. Quantitative PCR analysis revealed the down regulation of miR-212a-3p and miR-99a-5p in EVs from Tsc2-mutated cells compared to EVs from Tsc1-mutant cells.

Conclusions: EV-derived miR-212-3p and miR-99a-5p axes may represent therapeutic targets or biomarkers for TSC disease.

Metabolic Analysis of Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Associations with Disease Progression and Treatment

Shirin Sundar,1 Shirin Roth,1 Sachin S. Hajarnis,1 Lucas Westcott-Baker,1 Linda McCormick,2 Bharath Ramaswamy,1 Arlene B. Chapman,1 Otsuka Pharmaceutical Development & Commercialization, Rockville, MD, 2University of Chicago, Chicago, IL.

Background: ADPKD is characterized by epithelial proliferation and cyst growth. Metabolic abnormalities have been identified in mouse models, but little is known about alterations in metabolic pathways in human ADPKD. We evaluated plasma metabolic profiles in ADPKD subjects prior to and after exposure to tolvaptan (T) as compared to healthy controls to better understand metabolic alterations in ADPKD and potential associations with disease progression and treatment response.

Methods: Plasma samples were collected and analyzed at baseline and month 12 in 100 ADPKD subjects (50 in T and 50 in placebo [P] arms) enrolled in TEMPO 3:4 (NCT00428948). The protein fraction was removed, and the remaining extract split into equal parts for analysis on tandem mass spectrometry and gas chromatography mass spectrometry platforms. Proprietary software (Metabolon, Inc., Durham, NC) matched ions to an in-house library of standards for metabolite identification and quantitation. Forty age- and sex-matched healthy subjects were analyzed as a control group. Linear mixed effect modeling identified associations of metabolites with ADPKD vs control, height-adjusted total kidney volume (htTKV), Mayo Imaging Classification (MIC), and T vs P.

Results: Baseline metabolic profiles differed between ADPKD and controls, with significant differences in lipid metabolism, TCA cycle, and amino acid metabolism. Baseline MIC 1C, 1D, 1E (vs 1B) were associated with accumulation of the uricic acid pseudouridine, elevated fatty acid synthesis, and altered tryptophan metabolism, with similar findings when baseline hTRVK was analyzed. Threonine, urea, and dimethylsulfone were decreased in T vs P at month 12, as well as other metabolites involved in lipid and amino acid metabolism.

Conclusions: We identified novel associations of amino acid and lipid metabolic pathways with ADPKD vs control and with measures of disease severity (MIC and hTRVK) and showed that metabolites differentially affected in T and C in V1 to V2 at 12 months of treatment, supporting a role for discovery metabolomics in evaluating response to therapy.

Short-Term Ketogenic Interventions Are Feasible and Effective in Triggering Ketosis in Autosomal Dominant Polycystic Kidney Disease (ADPKD): Results from the RESET-PKD Study

Simon Oehm,1 Konstantin Steinek,1 Sita Ajiane,1 Polina Todoroova,1 Christoph Lindemann,1 Fabian Wöstemann,1 Franziska L. Meyer,1 Florian Siedek,1 Thomas Weimbs,2 Franziska Grundmann,1 Roman-Ulrich Mueller,1 Universitat zu Koln, Koln, Germany; 2University of California Santa Barbara, Santa Barbara, CA.

Background: Short-term ketogenic dietary interventions slow disease progression in animal models of ADPKD. The RESET-PKD study translates these promising results to a pilot study in humans.

Methods: 10 ADPKD patients with rapid disease progression were enrolled (baseline V1). They followed their usual carbohydraterich diet for up to 4 weeks. At visit 2 (V2) patients chose to either perform a 3-day water fast (WF) or a 14-day ketogenic diet (KD) until V3 and returned to their normal nutrition until V4. MRI kidney volumetry was performed at all visits. Ketone bodies were examined in questionnaires. Results: All participants (KD: n=5; WF: n=5; age 39.8±11.6 years; eGFR 82±23.5 ml/min; TKV 222±1156 ml) were classified as Mayo Class 1C to 1E. The dietary interventions did not alter serum creatinine (V2: 1.17±0.33 mg/dl vs. V3: 1.20±0.35 mg/dl; p = 0.826) but serum glucose levels decreased significantly (V2: 84±3 mg/dl; V3: 70±13 mg/dl; p = 0.004). Acetone levels in breath as well as BBH blood levels increased in both study arms (average acetone before dietary intervention (V1 to V2): 2.6±1.18 ppm, on diet (V3): 22.8±11.9 ppm; p = 0.0001; BBH before dietary intervention: 0.22±0.08 mmol/l, on diet: 1.89±0.92 mmol/l; p = 0.0001). 9 out of 10 patients reached a ketogenic state during the intervention and 90 % evaluated ketogenic interventions as feasible. No significant TKV changes were observed (ATK V1 to V2: +0.75±0.54%, ATK V2 to V3: -1.06±0.16%).

Conclusions: RESET-PKD showed that ADPKD patients adhere to short-term ketogenic interventions, reliably reach ketosis without ADPKD-specific adverse effects, and judge this diet as feasible in everyday life. Short-term ketogenic interventions did not lead to a significant reduction in TKV or serum creatinine. Larger clinical trials examining longer-term dietary interventions will be crucial to further evaluate long-term feasibility and the therapeutic potential of ketogenic diets in ADPKD.

PO1220

Analysis of MicroRNAs as Regulators of Expression of Transcripts Associated with Stem Cell Pluripotency in Pkd1-Deficient Mouse Models

Juan J. Moyano muñoz,1 Mirian A. Boim,1 Luiz F. Onuchic,1 Ita P. Heilberg,1 2Universidade Federal de São Paulo, São Paulo, Brazil; 3University of São Paulo School of Medicine, São Paulo, Brazil.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by cyst formation deriving from collecting ducts. Pluripotent stem cells are expected to be the formation of renal structures have been used in in vitro studies of nephrogenesis or cystogenesis related to ADPKD. However, the association between transcripts integrating pathways involved in stem cells pluripotency and cystogenesis deserves further investigation. The microRNAs (miRNAs) that participate in the regulation of these transcripts in kidney tissues of mouse models orthologous to ADPKD have not yet been validated. To identify regulatory miRNAs and differently expressed transcripts associated with stem cell pluripotency in kidney tissues of Pkd1-deficient mouse models.

Methods: A transcriptomic computational identification and validation of the expression level of regulatory miRNAs and genes by RT-qPCR, normalized by their respective housekeeping, miR-26a and Ppia was performed. The analyses were performed on kidneys from 10- to 12-week-old cystic mice (Pkd1null/ null or Pkd1+/+ Nestin+/+; CY, n = 10) and their non-cystic controls (Pkd1+/+ or Pkd1null/ null, n = 10); mice haplosufficient for Pkd1 (Pkd1+/-, HT, n = 6) and their wild controls (Pkd1+/+, WT, n = 6); and 15-day-old severely cystic mice (Pkd1null/ null, SC, n = 7) and their controls (CO, n = 5).

Results: The validation of the computational analyses performed in our three animal models with reports from the literature in other Pkd1-deficient models, identified 10 differently expressed genes associated with the regulation of stem cells pluripotency. Increased expression of Sox3 and Map3k1 genes and decreased regulatory miRNA Let-7a were observed in SC versus CO kidneys. On the other hand, Mapk14 gene showed decreased expression while its potential regulator, miR-21, revealed increased expression in SC versus CO kidneys. Fgfl10 expression was decreased in SC versus CO kidneys whereas a trend of increased expression in the CY versus NC group has been observed.

Conclusions: Present results suggest a potential regulatory effect of miR-21 on Mapk14 expression and of miR-Let-7a on the expression of Sox3, Map3k1 and Fgfl10, namely transcripts involved in stem cells pluripotency and cystogenesis in kidney tissues of Pkd1-deficient mouse models.

Investigation of Lad1 as a Candidate Modifier of Polycystic Kidney Disease in Pkd1 Mouse Models

Background: Polycystic Kidney Disease (PKD) is a monogenic disease caused by mutations in either Pkd1 or Pkd2, which encode polycystin-1 (PC1) and polycystin-2 (PC2), respectively. One proposed function for PC1 is to regulate cell migration and cell-cell interaction, possibly through modulation of the cytoskeleton. In prior transcriptomic studies of Pkd1 mutant kidneys, we had identified Lad1 as one of the few genes whose expression was dysregulated early in the course of the disease. The limited available literature suggests Lad1 may encode a cytoskeleton protein that acts as an anchoring filament to the basement membrane of epithelial cells. The goal of this study is to investigate the role of Lad1 in mediating modifying PKD phenotypes.

Methods: We quantified Lad1 gene and protein expression in the tissues of Pkd1 conditional mutant mice, kidney epithelial cell lines derived from Pkd1 conditional mice and human keratinoctye HaCat cells by quantitative polymerase chain reaction (qPCR) and western blot analyses. We used CRISPR technology to generate two Lad1 mutant mouse lines that have large deletions spanning most of the coding region of Lad1 and characterized the phenotype of homozygous mutants. Lad1 mutants were crossed with Pkd1lacZ+ with Ksp-Cre and tamoxifen-Cre to test for genetic interaction in early and late onset PKD models.

Results: We confirmed that Pkd1 mutant kidneys and epithelial cells have lower Lad1 expression levels compared to wild type samples. Mice with homozygous deletion of Lad1 exons 3 to 8 were born at normal mendelian ratios and lacked obvious abnormalities up to 1 year of age. Histopathological analyses of the kidney and organs with the highest expression of Lad1 also were normal. Pkd1/Lad1 double mutants were born at expected ratio and had a limited distinctive phenotypic features. However, early data suggest that Pkd1lacZ+;Ksp-Cre/+ Lad1 homozygous mice have increased kidney-body weight ratios with worse cystic disease. Further analysis, including Lad1 CRISPR knock-out animals crossed with late-stage conditional Pkd1 knock-out animals, is ongoing.

Conclusions: Lad1 expression is reduced in Pkd1 mutant kidneys. CRISPR knock-out of Lad1 alone shows no obvious phenotype. Loss of Lad1 may worsen disease in the early onset Pkd1-cystic model.

Sildenafil Inhibits ADPKD-Derived Cyst Growth in 3D Culture and Induces Apoptosis in the Han/SPRD Cyt+/Cy+ Rat Model of Renal Cyst Disease
Robert L. Bacalla,1,2 Weimin Xu,1 George Rhodes.1 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: In prior studies we found that human renal cyst cells express high levels of GMP phosphodiesterase 5, 6 and 9 as compared to normal human kidney cells. In breast cancer, inhibition of eGMP phosphodiesterases induces apoptosis. We tested the hypothesis that sildenafil blocks cell proliferation and/or induces apoptosis in cyst epithelia.

Methods: PKD Q4004X cells were grown in Matrigel and treated with vehicle or sildenafil for 7 days. Cyst size was assayed by light microscopy. Differences in cyst area were analyzed by two-way ANOVA. In separate experiments, male cyt+/cyt+ rats were given either vehicle or sildenafil in their water supply for 7 or 28 days. Kidneys were harvested and apoptosis was assayed by staining with anti-M30, a monoclonal antibody that binds to apoptosis mediated cleavage of cytokeratin 18 in epithelial cells.

Results: In 3D cultures of PKD Q4004X cells, cultures treated with sildenafil (1, 2 and 4 ug/ml) are significantly smaller than vehicle-treated cultures (p<0.05 for all doses). Further analysis showed that cysts larger than 150 um were not observed in any sildenafil treated cultures. Figure 1 shows M30 staining in sildenafil (20 ug/kg/day) treated rats (panel B, red channel merged with the green autofluorescence channel) versus vehicle-treated animals. M30 positive cells are found predominantly around cyst lumens. Apoptotic changes in cyst epithelia were also observed in rats treated with sildenafil for 28 days.

Conclusions: Sildenafil inhibits human kidney cyst growth in 3D culture. In male cyt+ rats, sildenafil at a dose of 20 mg/kg/day for 7 or 40 days results in apoptosis of cyst epithelia.

Mutation Position and Genetic Background Modulate Disease Expression in Pkhd1 Mouse Models
Maryanne Odinakachukwu,1 Chaozhe Yang,1 Zsuzsanna M. Bebek,2 Lisa M. Guay-Woodford.1 1Children’s National Research Institute, Washington, DC; 2The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.

Background: Multiple Pkhd1 mutant mouse models have been generated by gene-targeting methods (del5-4, del67) or resulted from spontaneous mutations (cy5). When these mutations are homozygous on inbred backgrounds (DBA/2J (D2); C57BL/6 (B6)), there is either no renal cystic disease or very mild dilatation of the PCTs rather than CCDS. A recent AregPKD report showed that the position of human Pkhd1 mutations correlates with ARPKD kidney and liver disease severity (Burgmers, KJ 2021). In the current study, we examined the impact of age, mutation position, and mixed genetic background on kidney, liver, and pancreatic disease in Pkhd1 mutants.

Methods: D2-Pkhd1del5-4; B6-Pkhd1del67 mice and B6-Pkhd1mice. Intercross strategy to generate a suite of F2 mutants on mixed genetic backgrounds (D2.B6). Histopathological analysis of the kidney, liver, and pancreas from 18-month-old, nulliparous mutant females.

Results: D2.B6-Pkhd1del5-4 mice expressed both marked dilatation of the CCDS and liver ductal plate remodelling (DPM); no pancreatic cysts were observed. Similarly, D2.B6-Pkhd1del67 mice had occasional dilated DCTs, no DPM or pancreatic cysts. D2.B6-Pkhd1del5-4; B6-Pkhd1del67 mice exhibited organ-specific disease expression in Pkhd1 mutants. On the mixed D2.B6 background both cytoskeletal and del5-4 aged F2 mutants develop CCD cysts, similar to human PKD1 renal disease. Surprisingly, D2.B6-Pkhd1del5-4 mice had minimal kidney pathology and exhibited pancreatic duct cysts, suggesting that genetic background differentially modulates kidney and pancreatic cystic phenotypes. Mice heterozygous or homozygous for the del67 mutation expressed minimal kidney, liver, or pancreatic cystic changes. Thus, defects at the 3’ end of Pkhd1 appear to have minimal pathobiological impact, that is not influenced by age or the mixed D2.B6 genetic background. These findings will inform our experimental strategies to identify organ-specific Pkhd1 genetic modifiers.

Rab GTPase Regulation in Ciliogenesis and Polycystic Kidney Disease
Dominique J. McConnachie,1 Andrew J. Mallett,2 Jennifer L. Stow.1 1Professor Jennifer Stow, Protein trafficking and inflammation group 1The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia; 2Townsville Hospital and Health Service, Townsville, QLD, Australia.

Background: Primary cilia are sensory organelles with widespread roles in development and epithelial physiology. Mutations resulting in isomorphic cilia and ciliary dysfunction are associated with renal ciliopathies such as polycystic kidney disease (PKD), yet primary cilia remain enigmatic in terms of their molecular and functional characterisation. Rab GTPases are master regulators of vesicular trafficking that have been shown to regulate ciliogenesis and cilia composition, with downstream effects on ciliary function and signalling. Rabases are therefore poised to vary or modify primary ciliary function, by working in conjunction with key cilia proteins, including those mutated in renal ciliopathies.

Methods: Expression of fluorescently tagged, recombinant Rab13, knockout of Rab13 and fluorescently tagged, recombinant Rab13 in mouse PKD cells.

Results: Our data show that Rab13 localises to the primary cilia of mouse kidney cells and Rab13 loss of function affects ciliogenesis in a variety of in vitro and in vivo models including zebrafish embryos. Characterisation of Rab13 knockout epithelial cell lines altered cilia, the perturbation of ciliopathy-associated protein localisation, and the formation of dysorphic renal epithelia. Rab13 knockout zebrafish embryos display a range of cilia-associated developmental defects and Rab13 expression is diminished in mouse PKD cells.

Conclusions: Here we reveal a novel cilia-associated role for Rab13 GTase. Investigating the genes and molecules that contribute to the ciliary landscape is essential to improve knowledge, for potential translation and discovery of new therapeutic approaches for renal ciliopathies including PKD.

Efficacy and Adverse Effects of a Novel Mesoscale Nanoparticle-Guided Sirolimus Delivery Strategy in a Phkd1PCK Rat Model

Michal Mrug,1 Daniel A. Heller,2 Chintan H. Kapadia,3 Ryan Williams,4 Phillip H. Chumley,1 Sean Mullen,1 Ronald E. Roye,1 Gabriel Rezoniewicz,5 Juling Zhou,1 Edgar A. James,5 The University of Alabama at Birmingham, Birmingham, AL; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3Goldklopf Therapeutics, New York, NY; 4The City College of New York, New York, NY.

Background: Pre-clinical studies have shown that mTOR inhibition attenuated renal cystic disease progression but it did not improve outcomes in patients with autosomal dominant polycystic kidney disease (ADPKD). This was attributed to the dose limitations in humans due to mTOR inhibitor toxicity. To increase the mTOR inhibition efficacy and reduce its toxicity in renal cystic diseases, we studied mesoscale nanoparticle (MNP)-guided delivery of an mTOR inhibitor, sirolimus (mSirolimus), in Phkd1PCK/PCK rats. We used our recently developed MNPs that selectively and with high affinity target the renal tubular epithelium.

Methods: We synthesized Empty-MNPs or MNP-sirolimus and used them in an experiment that resembles seminal pre-clinical studies of telovaptan, the only FDA-approved ADPKD therapeutic. Newly outbred Phkd1PCK/PCK rat males were divided into 3 groups (each N=8-9) and treated for 8 weeks (p22 to p77) with: Empty-MNP (50 mg/kg IV q96 hours), Free-sirolimus (0.15 mg/kg IV q48 hours) and MNP-sirolimus (50 mg/kg IV equivalent to 0.3 mg/kg sirolimus q96 hours). Pre- and post-treatment cyst volumes were assessed by MRI at p21 and p78.

Results: The MNP-sirolimus or Free-sirolimus both inhibited renal mTOR activity in Phkd1PCK/PCK rats. The mean pS6/total S6 ratios were: 7.9 for MNP-sirolimus vs 19.1 for Free-Rapa and 105.1 for Empty-MNP (p<0.001) while total S6 levels did not differ (p=0.806). Similarly, an 8-week mTOR inhibition reduced mean renal cyst volumes: 39.9 mm³ for MNP-sirolimus vs 59.3 mm³ for Free-sirolimus vs 148.4 mm³ for Empty-MNP (p<0.001). Linear mixed models were performed to compare Empty-sirolimus vs Empty-MNPs and Empty-MNPs vs Free-sirolimus. This difference was significant only for MNP-sirolimus (p=0.017) while for Free-sirolimus the significance was marginal (p=0.052). The pre-treatment renal cyst volumes at 3 weeks were not significantly different (p=0.772). Among side effects, mTOR inhibition reduced body weight and heart weights (p=0.004); in both cases, their averages were less severely reduced in MNP-sirolimus as compared to Free-sirolimus treated rats.

Conclusions: Together, our studies support the concept that a novel MNP-guided sirolimus delivery increases renal mTOR inhibition and therapeutic efficacy in renal cystic diseases, while reducing systemic toxicity.

Funding: NIDDK Support, Other U.S. Government Support

Magnetic Resonance Fingerprinting (MRF) Identifies Potential Imaging Biomarkers for Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Elise Keshock,1 Jacob R. Perino,1 Christina J. Macaskill,1 Ashlee Parsons,2 Jenna M. Hach,3 Susan Farr,3 Chris Flask,3 Katherine M. Dell.1 2Case Western Reserve University, Cleveland, OH; 3Cleveland Clinic Children’s Hospital, Cleveland, OH.

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is an important cause of morbidity and mortality in children with chronic kidney disease (CKD). Novel therapies have shown efficacy in ARPKD animal models, but clinical trials in ARPKD patients have not been possible due to the lack of sensitive measures of kidney disease progression. Non-invasive Magnetic Resonance Imaging (MRI) techniques, including novel MRF Fingerprinting (MRF), show promise in addressing this unmet need. We previously identified MRF-based T1 and T2 mapping as potential biomarkers of ARPKD kidney disease in animal models and initial human studies. In the current study, we evaluated the relationship between these imaging parameters and renal function in ARPKD patients with mild disease.

Methods: ARPKD subjects (age 6-25 yrs) with estimated glomerular filtration rate (eGFR) <60ml/min/1.73 m² (bedside Schwartz <18 yo; CKD-EPI ≥18 yo) were scanned on a Siemens 3T MRI scanner utilizing novel MRF technology to simultaneously generate mean kidney T1 and T2 maps in 15 secs/imaging slice with no sedation or injectable contrast agent. The relationship between eGFR (U25 eGFR formula) and imaging parameters was assessed by Pearson correlations with significance set at <0.05.

Results: 7 subjects (2M/5F, age 12.5±4 years) were imaged. eGFR was 87±21, range=52-109 ml/min/1.73 m²; 5 had hypertension. Mean kidney T1 (94±10 msec) showed a significant negative correlation with eGFR (R=−0.86, p=0.013). Mean kidney T2 (216±37 msec) showed a strong negative correlation (R=−0.69) but did not yet reach significance (p=0.086). Mean T1 and T2 values for the right and left kidneys also demonstrated a significant correlation (T1: r=0.99, T2: r=0.79).

Conclusions: This is the first study to establish a relationship between MRI-derived imaging biomarkers (T1 and T2) and kidney function (eGFR) in ARPKD subjects. Despite the small cohort, data clearly demonstrate that mean T1 and T2 both increase with decrease in eGFR. These findings suggest that MRF-based T1 and T2 mapping may provide a safe, non-invasive, quantitative, and reproducible measure of kidney disease severity to support future clinical trials to identify subjects at high risk for disease progression and monitor response to treatment.

Interactions of PKD2 with TACAN by TACAN

Xiong Liu,1 Mohammad Fatehi,1 Rui Zhang,2 Jingfeng Tang,2 Peter E. Light,2 King-Zhu Chen.1 Membrane Protein Disease Research Group, Department of Physiology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; 2Department of Pharmacology, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada; National “111” Center for Cellular Regulation and Molecular Pharmaceutics, Hubei University of Technology, Wuhan, China.

Background: TACAN (also named TMEM120A), recently reported as a mechano- and pain-sensing ion channel, is distributed in diverse non-neuronal tissues such as heart, intestine and kidney, which indicates its potential role besides pain sensation. Previous genome-wide association studies suggest the presence of an interaction between PKD2 and TACAN. In this study, we investigated the physical and functional interaction between the two proteins.

Methods: We employed mutagenesis, molecular cloning, co-immunoprecipitation, immunofluorescence, biotinylation, two-electrode voltage clamp in Xenopus oocytes to measure whole-cell currents and patch-clip in Chinese hamster ovary (CHO) cells to measure single-channel currents.

Results: We found that TACAN is co-localized and in complex with PKD2 in primary cilia of different kidney cell lines and oocytes. Using oocyte expression, we found that TACAN inhibits the channel activity of PKD2 gain-of-function mutant F604P. Using CHO cell expression, we found that TACAN inhibits both wild-type PKD2 and mutant F604P through reducing their single-channel conductance and open probability. Co-expression of TACAN significantly enhanced the sensitivity of PKD2 to stretch. Further, our data showed that while the first and last transmembrane domains (TM1 and TM6) of TACAN are involved in interaction with transmembrane domains of PKD2 only the TACAN TM6 is functionally relevant.

Conclusions: Our study revealed inhibition of PKD2 channel activity through physical TACAN-PKD2 complexing and that TACAN, but not PKD2, mediates mechanosensitivity of the channel complex. Whether and how TACAN participates in the pore formation remains to be determined.

Suppressed Autophagy Drives Increased Cellular Metabolic Activity in Human ADPKD Cells
Daniel Atwood, Deepak Pokhrel, Charles L. Edelstein. University of Colorado, Aurora, CO.

Background: We published that the autophagy phenotype in Pkd1<sup>−/−</sup> mice is characterized by decreases in crucial autophagy proteins (Cell Signal 2020). We attempt to determine the mechanistic role of suppressed autophagy as it relates to cell metabolic activity (viability and proliferation) in ADPKD cells.

Methods: Human primary immortalized cultured cells were used: normal renal cortical tubular epithelium (RCTE, Pkdl1<sup>+/−</sup> and ADPKD cyst-lining epithelium (9-12, Pkdl1<sup>−/−</sup>). To measure autophagic flux, cells were treated with lysosomal inhibitor chloroquin (LC3 and ATG7 fluorescence) was measured. MTX assay was used to measure cellular metabolic activity (cell viability and proliferation). Relative densitometry units (RDU) were measured on immunoblots.

Results: There was an increase in MTT and a decrease in 9-12 vs RCTE cell viability. MTX OD was 0.36 in RCTE vs 0.44 in 9-12 (p<0.01). Amacrine (AvMp+) (% gated) marker of apoptosis, was 67 in RCTE vs 18 in 9-12 (p<0.001). The increase in LC3-II with C in RCTE was not seen in 9-12 indicating suppressed autophagy flux. LC3-2 (RD1) C & +/+ C was 0.6 vs 1.4 in RCTE (p<0.01) and 0.9 vs 1.1 (NS) in 9-12. mCherry (% gated) C & +/+ C was 6 vs 16 (p<0.05) in RCTE and 6 vs 13 (NS) in 9-12 cells. p62 marker of autophagic cargo, was increased in 9-12 vs RCTE (p<0.05). p62 was 0.7 with scrambled shRNA (SCR) and 0.9 with SH (p<0.05). Tat-Beclin peptide (TAT), a specific autophagy inducer, resulted in a decrease in MTT in 9-12 suggesting that autophagy decreases MTT. MTX OD was 0.9 with Veh vs 0.2 with TAT (p<0.001). TAT did not affect AvMp+.

Conclusions: In ADPKD cyst lining epithelial cells there is increased MTT, suppressed autophagic flux, and decreased apoptosis. Autophagy inhibition increased MTX OD, decreased autophagy induced MTT, and autophagy flux. Autophagy drives increased cellular metabolic activity in ADPKD cells. The effect of autophagy induction/inhibition on cyst growth in vivo merits further study.

Tsc2 Mutation Induces Renal Tubular Cell Nonautonomous Disease
Prashant Kunwar,1 Fahad Al-Zadjali,2 Ying Yao,1 John J. Bissler.1,2 The University of Tennessee Health Science Center College of Medicine, Memphis, TN, 3St. Jude Children’s Research Hospital, Memphis, TN, 4Sultan Qaboos University, Muscat, Oman.

Background: TSC renal cystic disease is poorly understood and has no approved treatment. In a new principal cell-targeted murine model of Tsc cystic disease, the renal cystic epithelium is mostly composed of type A intercalated cells with an intact gene in EV-producing cells.

Methods: We used a newly derived targeted renal model in lineage tracing and extracellular vesicle (EV) characterization experiments and a cell culture model in EV characterization and cellular induction experiments to understand TSC cystogenesis. For the lineage tracing experiments we used Aquaporin-2 Cre, Floxed Tsc2, and Confetti mice in breeding experiments. To characterize the EVs, we used tunable resistive pulse sensing, dynamic light scattering, electron microscopy, and western blot analyses.

Results: In EV experiments, subcellular localizations may reflect divergence in the functional evolution of human and mouse TSC ACDs. Nuclear localization is overexpressed in human ARPKD and mouse Cys<sup>−/−</sup> (cpk) kidneys, but not in several Tckl1 mutants. We also showed that expression of the intracellular carboxy-terminus of mouse FPC (mFPC-CTD), but not human (hFPC-CTD), activates the Myc/Tcf1 promoter (ASSN 2020). The current study focused on: 1) the intracellular trafficking of mFPC-CTD and hFPC-CTD, and 2) activation of the Src/STAT3 signaling pathway, linked to hFPC-CTD (Jruli 2021), in a mouse Phdl1 mutant lacking FPC-CTD and in the cpk mouse model of ARPKD, with and without Cy rescue.

Methods: Comparative informatic analysis. Immortalized mouse CCD (mCCD) and human (hCCD) cell lines stably expressing mFPC-CTD and hFPC-CTD, respectively. Kidneys from cpk, Cys<sup>−/−</sup>-rescued cpk, and Phdl1<sup>−/−</sup> (delh77) mutant mice, western blot and immunofluorescence.

Results: FPC-CTD is the least conserved domain, with 55% identity between human-mouse ccS, compared with 73% identity across the full-length FPC. The CTD is unique, with an AA-sequence not found in other terrestrial vertebrate proteins. In stable cell lines, mFPC-CTD localized to both nuclei and cilia, whereas hFPC-CTD primarily localized to the apical membrane. In non-cystic delh77 kidneys (lacking FPC-CTD), pSTAT3<sup>757</sup> and eMyc were similar to wild-type controls. In cpk kidneys, pSTAT3<sup>757</sup> and eMyc were upregulated, but their levels in Cys<sup>−/−</sup>-rescued cpk kidneys (Yang 2021) were comparable to wild-type.

Conclusions: Differences in intracellular trafficking of mFPC-CTD and hFPC-CTD may explain the species-specific differences in Myc/Mycp1 promoter activation. Distinct subcellular localizations may reflect divergent in the functional evolution of human and mouse TSC ACDs, with mFPC-CTD residing in the cytosol, whereas hFPC-CTD functions as a membrane-associated signaling regulator of Src/STAT3. Activation of Src/STAT3 signaling and Myc upregulation are signatures of cystic epithelia, suggesting that renoprotective mechanisms in FPC-deficient mouse kidneys require modifications.

Exploring the Heterogeneity of Kidney Resident Macrophages Using Single-Cell RNA Sequencing
Alex Yashchenko,1 Sarah J. Bland,2 Zheng Li,3 Chong Song,2 Kurt Zimmerman.1 The University of Oklahoma Health Sciences Center, Oklahoma City, OK, 3The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL, 4University of Southern California, Los Angeles, CA.

Background: Tissue resident macrophages are highly diverse, even when located within the same tissue. This diversity is thought to be driven by localization, developmental origin, time in tissue, and niche specific cues. Importantly, these underlying factors likely influence resident macrophage phenotype and function during disease initiation and progression.

Methods: To understand the diversity of kidney resident macrophages (KRM), we performed single cell RNA sequencing, parabiosis, and fate mapping on kidneys isolated from wild type and transgenic knock-in reporter mice.

Results: Using single cell RNA sequencing, we identified three subpopulations of KRM including one with enriched expression of Ccr2. Using Ccr2-RFP knock-in mice, we confirmed that these resident macrophages were derived from monocyte precursors and preferentially localize to the renal cortex. Based on our single cell RNA sequencing data, we propose that monocytes undergo a series of differentiation steps upon entering the kidney in order to become Ccr2<sup>+</sup> KRM. Levels of single cell data in the main origin for systemic oKRM. The soluble serum form of oKRM (extracellular domain of oKRM) was found to be decreased in ADPKD patients, however, the role of oKRM in ADPKD remains unknown.

Methods: To investigate the role and mechanism of oKRM in ADPKD, we introduced an oKRM transgenic mouse into Phdl1 conditional knockout mice and performed single cell RNA sequencing (scRNA-seq) in kidneys collected at postnatal days 7, 14 and 21 to determine the differentially expressed genes (DEGs) and signaling pathways mediated by oKRM in different renal cell types. The expression of key DEGs identified with scRNA-seq was confirmed with qRT-PCR analyses.

Results: We found that full length αKlotho was decreased in collecting duct cells, macrophages, fibroblasts and T/NK immune cells in Pkd1 homozygous kidneys. Transgenic αKlotho delayed cyst growth in Pkd1 conditional knockout mice by normalizing the expression of genes associated with a number of diverse functions, including the genes associated with the transitions between collecting duct cell subtypes and those involved in genitourinary pathologies. In addition, we found that the genes associated with the epigenetic clock (DNA methylation age) were dysregulated in those cells in cystic kidneys, and that they could be normalized by transgenic αKlotho, suggesting that transgenic αKlotho might slow down the process of epigenetic age acceleration in cystic kidneys. The dysregulation of the epigenetic age-acceleration genes, ApoE, Cldn4, Mge and Sic38a2, might contribute to PKD pathogenesis and might be used as potential biomarkers for ADPKD. Finally, transgenic αKlotho affected a large number of genes associated with metabolic and oxidative signaling, suggesting that αKlotho might act by inducing prosurvival processes to extend the life span of mice.

Conclusions: Reduction of αKlotho regulates cyst growth through diverse signaling pathways. Pkd1 mutation accelerates epigenetic age in ADPKD. Transgenic αKlotho not only delayed cyst growth but also slowed down epigenetic age acceleration.

Mechanistic Interaction Between Cystin and Fibrocystin/Polycystin in Model Cell Lines and cpk/cpk Kidneys

Yiming J. Zhang,1 Chaozhe Yang,1 Naee Harafuji,2 Wei Wang,1 Phillip D. Bell,3 Lisa M. Guay-Woodford,3 Zsuzsanna M. Membok,1 The University of Alabama at Birmingham, Birmingham, AL; 2Massachusetts Institute of Technology, Cambridge, MA; 3Children’s National Research Institute, Washington, DC

Background: Cystin(cpk) mice exhibit ARPKD-like renal phenotype due to a mutation in the Cys1 gene and loss of cystin. ARPKD (MIM 263200) is caused by mutations in PKHD1, encoding FPC. Both cystin and FPC are present in the primary cyst, but no physical interaction has been reported. Using mouse CCD cell lines, we have shown that FPC levels were reduced in cpk cells by 75% relative to wt. Cystin deficiency is specifically linked to FPC reduction and did not affect cilia development, but altered ciliary architecture (ASN 2020). The current study focuses on cellular mechanisms driving FPC reduction in cystin-deficient cells, and the consequences of FPC loss. We note that FPC is necessary for proper E3 ubiquitin ligase function and consequently cellular proteome management (Kaimori 2017).

Methods: Immortalized wt and cpk mouse CCD cells. Wt and cpk mouse kidneys. siRNA silencing of Cyst1, qRT-PCR, western blot, confocal microscopy, morphometry, patch clamp.

Results: Silencing Cyst1 in wt cells results in a siRNA dose-dependent reduction of both cystin and FPC. Correlative studies showed marked reduction of FPC in cpk kidneys. Similar Pkd1 mRNA levels in wt and cpk, and kidneys implicated FPC regulation at the protein level. Proteasome or lysosome inhibition did not recover FPC, but activation of autophagy further reduced FPC levels, suggesting a role for selective autophagy in FPC removal. Diminished FPC levels lead to E3 ubiquitin ligase defects and reduced polyubiquitination of proteins, necessary for proteome management. In cpk cells, wcCdk2 silenced membrane retention of the epithelial sodium channel and increased sodium transport.

Conclusions: Our studies provide the first functional link between cystin and FPC in renal epithelial cells. We propose cystin as a gatekeeper for FPC at the base of the cilia and in the E3 ligase complex. In cystin-deficient cells, FPC is continuously degraded leading to dysregulated ubiquitination and altered proteome homeostasis. These data show a mechanistic connection between the renal phenotypes observed in human ARPKD and cpk mice. The recent identification of human CTSJ-related ARPKD (Sci Report, in press) highlights the potential significance of the cystin-FPC mechanistic interaction in the complex pathobiology of ARPKD.

Tubular Flow Disruption During Cyst Development in Polycystic Kidney Disease

Issis Thomas, Hanan Chweih, Courtney J. Haycraft, Mandy J. Cryoley, Zhang Li, Bradley K. Yoder. The University of Alabama at Birmingham, Birmingham, AL.

Background: Polycystic kidney disease is an inherited disorder in which clusters of cysts develop within the kidneys, causing the kidneys to enlarge and lose function. Cyst development can be due to functional changes caused by mutations in ciliary localized proteins Pkd1 and Pkd2 or changes in cilia formation/structure (e.g. i888 mutations). It is currently unknown how cysts impact tubule flow and cilia, or whether flow alterations occur prior to or after cyst formation is initiated.

Methods: We used inducible Cre conditional mutant mouse models with an optical imaging system to monitor the flow of fluorescent dextran in proximal tubules of homozygous kidneys at multiple timepoints during cystogenesis in live kidneys. Additionally, we evaluated dextran absorption into proximal tubules as an indicator of tubule flow in mutant and control mice during cyst development. We determined the number of dextran+ proximal tubule cells by FACs to quantify changes in the percentage of tubules with flow in cystic versus non cystic kidneys. We performed H&E staining to quantify cyst severity and analyzed sections by immunofluorescent microscopy to assess changes in flow.

Results: Our results suggest that during the cyst formation, there is a marked decrease in flow through the tubules and that this reduction in flow occurs concurrently during cyst formation. This corresponds to a 56.8% of cells that are both dextran+ and LTA+ (proximal tubule) by flow cytometry and similar results were obtained by IF analysis. We also find an increase in resident and infiltrating macrophages around the forming cysts. 

Conclusions: The use of intravital imaging approaches allows us to evaluate changes in tubule flow as cysts progress. With the addition of citra markers, we will examine the responses of the cilium to the changes in flow. Preliminary data suggests that alterations in tubule flow occur at early time points during cyst initiation with larger cysts seldom containing epithelium that are dextran+. These data indicate that loss of tubule flow may be an early event associated with cystogenesis. Our data also suggests that disruption of tubule flow is progressive with fewer tubules with flow at later time points (4-6 months post induction). We are currently assessing whether there is an association between the disruption of flow in a tubule and localized immune responses.

PO1238

FoxM1 Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Wenyan Yu, Guojuan Wang, Xiaoyan Li, Xia Zhou, Xiaolang Li. Mayo Clinic Department of Internal Medicine, Rochester, MN.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is driven by mutations in Pkd1 and Pkd2 genes and is characterized by renal cyst formation, inflammation and fibrosis. Forkhead box protein M1 (FoxM1) is a transcription factor of the Forkhead box (Fox) protein super family which is defined as a conserved winged helix DNA-binding domain 1. FoxM1 has been reported to promote tumor formation, renal inflammation and fibrosis in many organs. However, the role and mechanism of FoxM1 in regulation of ADPKD progression is still poorly understood.

Methods: To evaluate the role and mechanisms of FoxM1 in cyst growth in vivo, we treated early stage and long lasting Pkd1 mutant mice with the FoxM1 specific inhibitor, FDI-6. To identify novel FoxM1 target genes involved in cystogenesis, we performed ChIP-seq analysis.

Results: We found that FoxM1 was upregulated in cyst-lining epithelial cells in polycystin-1-deficient murine kidneys and human ADPKD kidneys. Inhibition of FoxM1 with FDI-6 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in Pkd1 mutant mice. The downregulation of FoxM1 promotes cyst growth through: 1) upregulation of expression of Akt and Stat3 and activation of ERK and RB signaling to increase cystic renal epithelial cell proliferation, 2) inhibition of p65-dependent cystic renal epithelial cell death, 3) facilitation of the recruitment and retention of renal macrophages, and 4) upregulation and activation of E3 ubiquitin markers to promote renal fibrosis. In addition, FoxM1-dependent macrophage recruitment was associated with upregulation of monocytic chemotactic protein 1 (MCP-1) and inflammatory cytokine TNF-α. Further, we identified novel FoxM1 target genes by ChIP-seq analysis, which may connect FoxM1 signaling to the ciliopathy hypothesis in PKD.

Conclusions: FoxM1 promotes renal cyst growth and fibrosis in ADPKD through Akt, ERK, RB and STAT3 signaling as well as NF-kB and ciliopathy associated signaling. Targeting FoxM1 in cystic renal epithelial cells may be a viable new therapy for ADPKD.

Allosteric Mechanism of PC1 Tethered Agonist-Mediated Signaling

Shristi Pawenkar, Brenda S. Magenheimer, Ericka Nevarez Munoz, Robin L. Maser, Yinglong Min,4 University of Kansas College of Liberal Arts and Sciences, Lawrence, KS; 4University of Kansas Medical Center, Kansas City, KS.

Background: Polycystin-1 (PC1) is the 11-transmembrane protein product of the human autosomal dominant polycystic kidney disease (ADPKD) gene PKD1. PC1 functions as an atypical GPCR and shares multiple features with the Adhesion GPCRs, including a GPCR autoproteolysis-inducing (GAIN) domain that catalyzes cis-cleavage of the receptors into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. We previously reported that CTF-mediated signaling to an NFAT promoter-luciferase reporter is dependent on the presence of the stalk, is reduced by ADPKD-associated missense mutations within the stalk, and can be rescued by synthetic, stalk-derived peptides, supporting a tethered ligand mechanism of PC1-G protein signaling (JASN 2018:29:671, JASN 2019:30:382).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: We have combined highly complementary experiments and computer simulations to investigate the mechanism of the tethered agonist-mediated signaling of PC1 CTF. A model of the human PC1 CTF was generated using the cryo-EM structure of the PC1-PC2 complex with important missing regions added through I-TASSER homology modeling. All-atom enhanced simulations (1000 ns) using a protein complex structure were performed, followed by calculations of residue correlation matrices and free energy profiles. GaMD simulation-predicted residue interactions important for WT stalk-mediated activation of PC1 CTF were further investigated by mutagenesis and cellular assay experiments.

Results: GaMD simulations were consistent with experimental signaling data obtained with PC1 CTF expression constructs encoding wild type and stalk variants of the PC1 CTF. Correlation matrices revealed regions of highly correlated residue motions obtained with PC1 CTF expression constructs encoding wild type and stalk variants of the PC1 CTF. Correlation matrices revealed regions of highly correlated residue motions involving the stalk, TOP and putative pore loop domains. Key residue interactions predicted from the GaMD simulations were validated with newly designed mutation experiments.

Conclusions: Complementary experiments and simulations studies support the function of the PC1 CTF stalk region as a tethered agonist and suggest a mechanism whereby it can induce TOP-pore loop interactions which can be further translated to the GaMD for G protein mediated signaling. This in-depth knowledge is expected to facilitate future drug design efforts targeting this function of PC1 for more effective treatments of ADPKD.

Analysis of Calcium Signaling in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dorien Van Giel,1 Jean-Paul Decuyper,1 Djalia Mekahli,2,4 Rudi Vennekens.1

Background: ADPKD is an inheritable kidney disease characterized by the development of fluid-filled renal cysts, mainly caused by mutations in the PKD1 or PKD2 genes, leading to loss of renal function. Molecular mechanisms underlying cystogenesis are poorly characterized but it is postulated that disturbed calcium homeostasis is a primary event in cystogenesis. The precise molecular players that cause this disturbance are currently poorly understood, especially in human cell types. We therefore aim to characterize the profile of calcium-coupled G-protein coupled receptors (GPCRs) in a human renal epithelial cell model, to identify which receptors are present, whether their function is affected in ADPKD and whether they can be used to modulate cyst formation and growth.

Methods: Urine-derived conditionally immortalized proximal tubule epithelial cells (ciPTECs) of ADPKD patients and healthy controls were screened for calcium-coupled GPCRs, using an agonist library on Fura-2 loaded cell populations seeded in 96-well format. Validation of specific hits was done using single-cell measurements with a fluorescence microscope and built-in perfusion system in the ciPTECs as well as in tissue-derived conditionally immortalized cystic cells (ciCCs). Matrigel-based 3D cell culture was used to grow ciCCs to assess their ability to form cystic structures. Structures were stained with nuclear and cytosolic stains and imaged via confocal microscopy.

Results: From a library of 418 GPCR agonists a selective amount of calcium-coupled GPCRs was found functionally active in ciPTECs. ciPTECs from both healthy controls and ADPKD patients were found to functionally express purergic -, histamine -, serotonin and dopamine receptors. In single-cell experiments, we did not find any significant differences in functionality between healthy controls and ADPKD patients, but observed that response characteristics are mainly donor-specific, suggesting patient-specific disease mechanisms. ciCCs grown in 3D cell culture were found to form hollow, cell-lined cyst-like structures.

Conclusions: We describe the first thorough characterization of calcium-coupled GPCRs in a human proximal tubule epithelial cell model. We established a 3D cyst growth assay using tissue-derived cystic cells to explore the possibility to use the identified GPCRs to modulate cyst formation and growth.

Loss of Polycystin Function in Lymphatic Cells Impairs CPT1a Expression and Fatty Acid Uptake

Denis Basquin, Jinqing Liang, Terry J. Watnick, Patricia Outeda. University of Maryland School of Medicine, Baltimore, MD.

Background: Homozygous Pkdl or Pkdl2 null mutant mice die at mid-gestation due to vascular abnormalities including edema and hemorrhage. We have previously shown that edema in Pkdl1 and Pkdl2 knock out mice is due to abnormal lymphatic morphogenesis, with grossly dilated, blood filled dermal lymphatic vessels. Because proper lymphatic development is supported by fatty acid oxidation (FAO), we probed fatty acid transport in PC1/PC2 lymphatic endothelial cells (LECs).

Methods: Pkdl1 and Pkdl2 mutant LECs were isolated from mouse E14.5 embryos or generated using lentiviral shRNAs against PKD1 or PKD2 in human dermal LECs (HDLECs). Protein levels of PC1, PC2 and CPT1a were determined by western blotting and CPT1a/CPT2 mRNA levels were analyzed by qRT-PCR. Fatty acid uptake was assessed by BODIPY® 558/568 C12, staining of control and Pkd1 mutant LECs pre-incubated with or without 50 µM palmitate, and counterstained with mitotracker. Cells were imaged with confocal microscopy and the relative abundance of lipid droplets were quantified using ImageJ software. Each experiment was repeated 3 times and pairs of means (mutant versus control) were compared using Student’s T-test.

Results: Embyronic Pkdl1 and Pkdl2 murine LECs exhibit a robust decrease of CPT1a protein levels. In addition, CPT1a protein levels were significantly reduced in PKD1 and PKD2 defected HDLEC, suggesting a conserved role of Pkd1/2 in CPT1a regulation. PC1 and PC2 depletion in HDLECs results in an accumulation of cytoplasmic lipid droplets in which often coilcentralized with mitochondria, indicative of impaired fatty acid utilization. The ability of PKD mutant cells to metabolize fatty acids is further challenged by pre-treatment with 50µM palmitate, which exacerbates the accumulation of lipid droplets.

Conclusions: Our results highly suggest that polycystin function is required to maintain normal levels of CPT1a expression and fatty acid transport to mitochondria in LECs. We thus speculate that a defect in FAO with consequent dysregulation of gene expression is the basis of impaired lymphangiogenesis in Pkd1/2 mutant embryos.

Pharmacological Activation of Long-Form PDE4 Enzymes Suppresses Disease Progression in Pkd1RC/RC and Pkd1 Knockout (IkkspCrePkdl- Ilox, Iox) Mouse Models of ADPKD

David J. Henderson,1 Xiaofang Wang,2 Li Jiang,2 Miles D. Houslay,1 Peter C. Harris,1 Julia M. Adam,1 David R. Adams,1 Adele Rowley,3 Vicente E. Torres.1 2 Mironid Limited, Glasgow; United Kingdom; 3 Mayo Clinic Minnesota, Rochester, MN.

Background: Upregulation of cAMP signaling is thought to promote cystogenesis in ADPKD. Phosphodiesterase 4 (PDE4) enzymes degrade cAMP and contribute to its compartmentalized signaling. We have previously described novel small molecules that allosterically activate long isoforms of PDE4 and lower intracellular cAMP. Here we demonstrate significant efficacy with MR-L22, an advanced PDE4 inhibitor compound, on suppressing cystic burden and preserving kidney health in orthologous models of ADPKD.

Methods: The effects of the long isoform PDE4 inhibitor MR-L22 (administered gavage) were assessed in rapidly (iKspCrePkd1lox,lox) Mouse Models of ADPKD. Two receptor antagonists.

Results: Compared to vehicle treated controls, MR-L22 treated Pkd1RC/RC mice exhibited reduced kidney cAMP levels, cyst indices, kidney weight/body weight ratios (Kw/Bw) and MRI measured total kidney volumes (TKV) (Table and Figure). Long isoform PDE4 activation significantly protected kidney function and, when compared to tolvaptan, animals receiving MR-L22 produced significantly less urine volume. MR-L22 also suppressed the aggressive cystic disease exhibited by tamoxifen induced (P10) iKspCrePkd1lox,lox mice, where Kw/Bw and cystic indices were reduced in comparison to vehicle control (results not shown).

Conclusions: Small-molecule activators of long isoforms of PDE4 suppress cystic disease progression in key translational models of ADPKD and may be better tolerated and more effective than vasopressin V1 receptor antagonists.

Background: NEK8 encodes a protein that localizes to the primary cilium. Biallelic NEK8 variants are known to cause multorgan developmental defects including renal cystic dysplasia, with heterozygous carrier parents being asymptomatic. This autosomal recessive inheritance is most common for ciliopathies. Complementary to this, we now propose a dominant-negative effect for certain heterozygous NEK8 missense variants in the kidney domain.

Methods: We performed genetic testing in patients from several medical centers. To explore the consequences of the identified NEK8 variants we are performing cilia staining assays in patients’ skin fibroblast and kidney cells, as well as in mIMCD3 cells overexpressing the identified variants.

Results: We identified three distinct heterozygous NEK8 variants in eight families (table 1), all leading to missense alterations in the kinase domain. The large symptomatic family and the de novo occurrences are also in favor of a dominant mode of inheritance. All patients have a kidney phenotype, varying in severity, age of onset and presence of kidney failure. Interestingly the p.Arg45Trp variant is a recurrent variant found in six unrelated families. Our preliminary results from functional studies show normal localization of the NEK8 protein to the Golgi region, but abnormal primary cilia formation, in serum starved HEK 293 T cells and patient fibroblasts. In all affected individuals harboring likely pathogenic variants of ALG5 were identified in the Genomics England 100,000 genomes project. The clinical phenotype was consistent in the 16 affected members, with non-enlarged cystic kidneys that often evolved to kidney atrophy and few to no liver cysts; 7 subjects reached ESRD from 62 to 91y. Characterization of ALG5-RCTE cells showed that ALG5 is required for maturation and surface localization of PC1. PC1 surface localization in ALG5- cells was rescued by wild-type (WT), but not mutant, ALG5. Unfolded protein response (UPR) effector analysis revealed marked upregulation in ALG5- and ALG5+ as compared to WT RCTE cells.

Conclusions: ALG5 is a novel disease gene in the genetically heterogeneous ADPKD spectrum. Mutations to ALG5 impair PC1 maturation and localization, and are likely associated with a dysregulation of the UPR, causing renal cystogenesis and fibrosis.

Funding: Government Support - Non-U.S.
Methods: Co-immunoprecipitation (co-IP) of UMOD and TMED cargo-receptors was assessed in HEK293 cells transfected with wild type (wt) or mutant (C126R) human UMOD. Next, we performed untargeted Affinity Purification Mass Spectrometry followed by tandem MS to generate a list of UMOD interactors. We also conducted in vivo studies in UMOD−/− mice.

Results: We identified distinct wt and mutant UMOD interactomes using an unbiased AP-MS proteomics approach. Several interactors, including members of the TMED family, were significantly enriched in the mutant UMOD interactome. Targeted co-IP in lysates of HEK293 cells transfected with UMOD and interacting protein candidates confirmed the results from the proteomics approach. Importantly, when pulling down TMEDs, we found abundant immature non-glycosylated UMOD, suggesting entrapment in early secretory compartments. In vivo, treatment with BRD4780 was suggestive of disrupted interactions between mutant UMOD and interacting partners responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTMD-UMOD.

Conclusion: Our results suggest that UMOD interacts with TMED cargo-receptors and other proteins that may mediate the pathogenic quality control mechanisms responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTMD-UMOD.

Beneficial Effects of Bempedoic Acid Treatment in ADPKD Mice

Katherine R. Houlous,1 Hui Li,1 Biagio Saarit,1 Saman Sepehr,1 Jessica Pham,1 Valeria Mancino,1 Stephen L. Pinkosky,1 Nuria M. Pastor-Soler,1 1University of Southern California Keck School of Medicine, Los Angeles, CA; 2Esperion Therapeutics Inc, Ann Arbor, MI.

Background: ADPKD has limited therapeutic options. Bempedoic acid (BA), an inhibitor of ATP citrate-lyase (ACLY) FDA-approved for hyperlipidemia, catalyzes a key step in cholesterol synthesis that is important for cell growth and proliferation. BA also activates AMPK in mice. We hypothesized that BA could be a novel ADPKD therapy by inhibiting cyst growth and proliferation and promoting oxidative metabolism via ACLY inhibition and AMPK activation.

Methods: Murine Pkd1-null kidney cell lines derived from either proximal tubule (PT) or collecting duct (CD) were grown in Matrigel cultures and treated ± BA (30 mg/kg/d) for 48 h or 7 days. Cell viability and proliferation were measured by CellTiter-Blue and EdU incorporation, respectively. Kidney homogenates were then treated with 50 µM BUN (6.9 vs. 11.9%; P <0.05). BA reduced ACLY and stimulated AMPK activity in kidneys ± vehicle (P<0.05). BA (30 mg/kg/d) ± BA (30 mg/kg/d) caused a further significant reduction in BUN vs. vehicle at euthanasia (P22) were measured. Kidney homogenates were immunoblotted for expression of key disease biomarkers and other relevant cell signaling markers.

Results: BA dramatically inhibited cystic growth in 3D cultures in PT and IMCD and reduced kidney weight in Pkd1−/−; Pten−/− mice. In ADPKD mice, BA reduced TKW/BW vs. vehicle ± BA at euthanasia (P22). In addition, dietary restriction and renal injury on cyst formation, adult induced conditional Ift88 and Pkd2 mutant mice were used as an alternative approach to IRI to accelerate cyst formation in in both ift88 and Pkd2 mutant mice. We hypothesized that BA could be a novel ADPKD therapy by inhibiting cyst growth and proliferation and promoting oxidative metabolism via ACLY inhibition and AMPK activation.

Conclusion: BA inhibited cyst growth in vitro and ADPKD severity in vivo. Combined BA and tolvaptan treatment further improved ADPKD outcomes in vivo. BA significantly reduced kidney injury markers and cyst growth in mice treated with BA alone and in concert with tolvaptan in mice.

Unraveling Fundamental Mechanisms of UMOD Quality Control and Their Role in UMOD-Associated CKD

Silviana Basras-Valenti,1,2 Eriene-Heidi Sidhom,1,2 Moran Dvela levitt,1 Valeria Padovano,1 Julie Reignot,1 Keith H. Keller,1 Nina Himmerkus,1 Markus Bleich,3 Kerim Mutig,4 Sebastian Bachmann,4 Astrid Weins,4 Jillian Shaw,1 Jamie L. Marshall,1 Maria Alimova,1 Anna Greka,1 1Broad Institute of MIT and Harvard, Cambridge, MA; 2Department of Medicine, Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; 3Department of Physiology, Physiology of Membrane Transport, Christian-Albrechts-Universität, Kiel, Germany; 4Department of Functional Anatomy, Charité-Universitätsmedizin, Berlin, Germany.

Background: UMOD is a GPI-anchored protein expressed in the thick ascending limb of Henle. When properly folded, it transits from the ER to the membrane via the Golgi. Little is known about UMOD’s specific trafficking partners and its quality control mechanisms in the early secretory pathway. Mutations in UMOD disrupt protein folding and promote ER retention, triggering ER-stress pathways and cell death that causes UMOD-related autosomal-dominant tubulointerstitial kidney disease. It was recently shown that mutant misfolded MUC1-c is trapped in TME9-containing vesicles and that treatment with compound BRD4780, releases it to the lysosome. We hypothesize that a similar pathogenic quality control mechanism is active in ADTMD-UMOD.

Methods: We identified distinct wt and mutant UMOD interactomes using an unbiased AP-MS proteomics approach. Several interactors, including members of the TMED family, were significantly enriched in the mutant UMOD interactome. Targeted co-IP in lysates of HEK293 cells transfected with UMOD and interacting protein candidates confirmed the results from the proteomics approach. Importantly, when pulling down TMEDs, we found abundant immature non-glycosylated UMOD, suggesting entrapment in early secretory compartments. In vivo, treatment with BRD4780 was suggestive of disrupted interactions between mutant UMOD and interacting partners responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTMD-UMOD.

Conclusion: Our results suggest that UMOD interacts with TMED cargo-receptors and other proteins that may mediate the pathogenic quality control mechanisms responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTMD-UMOD.

Restricted Feeding Diet Overrides the Cyst Promoting Effect of Cisplatin-Induced Renal Injury in Both If88 and Pkd2 Mutant Mouse Models

Zhang Li,1 Staelaskhami Cherakara,1 Courtney J. Haycraft,1 Bradley K. Yoder,1 The University of Alabama at Birmingham, Birmingham, AL.

Background: Multiple renal cystic diseases, including PKD, are caused by dysfunction of the primary cilium. Links between cilia dysfunction, cyst formation, and renal injuries have been reported with evidence showing that injury exacerbated the rate of cyst formation in kidney. In addition, dietary restriction has been reported to ameliorate cyst growth in several PKD animal models. Here we evaluate the effects of both renal injury and dietary restriction on cyst formation in two different cilia-mutant mouse models.

Methods: To test the effect of renal injury on cyst formation, we established an alternative approach to induce chronic renal injury by utilizing a low-dose repeated cisplatin treatment (5.0 mg/kg; IP; once a week for 4 wks). To evaluate the impact of dietary restriction and renal injury on cyst formation, adult induced conditional If88 and Pkd2 mutant mice were utilized. The study design including cisplatin treatment along with 85% dietary intakes are shown in Figure 1. Mice were euthanized at 5 wks post last cisplatin injection for analysis. Multiple features including renal injury, proliferation, fibrosis, macrophage accumulation, and cystic index were analyzed.

Results: Low-dose repeated cisplatin treatment resulted in increased Kim1 expression in both If88 and Pkd2 mutant mice compared to controls. Analysis of the cystic phenotype showed that there was a significant increase in cyst formation in mutant mice after cisplatin compared to saline-treated group and the location of cysts corresponded to the injured regions. Interestingly, the rapid cyst formation in cisplatin-treated kidneys was ameliorated when the mice were on the restricted diet (Figure 1). More importantly, kidneys from mice with restricted feeding displayed decreased levels of proliferation, fibrosis, macrophage accumulation, and cystic index were analyzed.

Conclusions: These data show that low-dose repeated cisplatin treatment could be used as an alternative approach to IRI to accelerate cyst formation in both If88 and Pkd2 mutant models. More importantly, it suggests that cyst progression associated with injury and cystic kidney diseases could be ameliorated through dietary interventions.

Peroxoximes Are Dispensable for Normal Renal Function

Yohan Bignon,1 Camille Ansermet,1 Gabriel Centeno,1 Andy Garcia,1 Sylvain Pradervand,2 Dmitri Filov,3 Université de Lausanne Faculté de biologie et médecine, Lausanne, Switzerland; 2Genomic Technologies Facility, University of Lausanne, Lausanne, Switzerland.

Background: Peroxoximes are single membrane-bound cellular organelles identified in the kidney in 1954. Peroxoximes are ubiquitously present in eucaryotic cells with highest abundance in renal proximal tubule cells and hepatocytes. The variety of metabolic and antioxidant functions in which peroxoximes are involved is highlighted by human mutations in Peroxoxime genes encoding peroxoxime proteins required for proper peroxoxime biogenesis. Hence, the complete loss of peroxoximes causes Zellweger’s spectrum disorders (ZSD), devastating multorgan failure which include renal impairment. However, the (patho)physiological role of peroxoximes in the kidney remains unknown.
Methods: Here we addressed the role of peroxisomes in renal function in male and female rats with conditional ablation of Pex5-driven peroxisomal biogenesis in the renal tubule (cKO mice).

Results: Functional and histological analyses of both infant and adult cKO mice did not reveal any overt kidney phenotype. However, male cKO mice exhibited substantial reduction in kidney weight to body weight ratio. Stereological analysis of electronic microscopy results showed a complete absence of peroxisomes accompanied by increase in the number and in the volume of mitochondria in proximal tubule cells of cKO mice. Integrated deep transcriptome–sequencing and metabolome analyses revealed profound reprogramming of a great number of metabolic pathways, including enrichment of different classes of lipids such as plasmalogens and sphingomyelins (two major classes of membrane lipids) and the metabolism of glutathione. Although this analysis suggested compensated oxidative stress, four weeks of high fat feeding challenging the ability of proximal tubule cells to metabolize lipids did not influence renal impairments in cKO mice.

Conclusions: We demonstrate that renal tubular peroxisomes are dispensable for normal renal function. This indicates a large flexibility of proximal tubule cells both in terms of lipid membrane composition and metabolic/antioxidant functions. Our data also suggest that renal impairments in ZIPD patients are of extrarenal origin.

Weight Loss to Slow Cyst Growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Krisztina J. Nowak,1 Victoria Catanecci,1 Timothy L. Kline,1 Wei Wang,1 Zhiquing You,1 Kristen Bing,1 Bhavya Poudal,1 Cortney Steele,2 Michel Chonchol,2 Berenice Y. Gitomer,2 *University of Colorado - Anschutz Medical Campus, Aurora, CO; 1Mayo Clinic College of Medicine and Science, Rochester, MN.

Background: Recent studies in animal models of ADPKD support that food restriction can profoundly slow cyst growth and maintain renal function. We have also reported that overweight and obesity are strong independent predictors of ADPKD progression. Thus, it is plausible that weight loss, caloric restriction, and/or periods of fasting may slow ADPKD progression in humans; however, the feasibility of these dietary interventions, and whether the driver of therapeutic efficacy is periods of fasting or reduction in body weight, is unknown.

Methods: We conducted a one-year study evaluating feasibility of delivery of a behavioral weight loss intervention based on either daily caloric restriction (DCR) or intermittent fasting (IMF) in adults with overweight/obesity, ADPKD, and eGFR ≥30 mL/min/1.73m² (targeted weekly energy deficit of ~34% in both groups). We also evaluated the safety, acceptability, and tolerability of each intervention, and obtained exploratory insight into changes height-corrected total kidney volume (htTKV).

Results: 28 participants (16F/12M; 46±9 y, body mass index 34±7.5 kg/m², eGFR of 69±22 mL/min/1.73m²) were randomized to either DCR (n=15) or IMF (n=13).

Clinical significant (>5%) weight loss was achieved in both groups at month 3 (DCR: -3.6±2.3 kg, IMF: -3.3±2.0 kg). At 12 months DCR lost additional weight while weight loss in IMF plateaued (DCR: -9.1±6.0%; IMF: 4.9±6.5%; p<0.05 DCR vs. IMF). Overall, DCR had a more favorable safety, tolerability, and adherence profile than IMF. Annual htTKV %Δ was qualitatively low in both groups in comparison to historical data, ΔDCR had a more favorable safety, tolerability, and adherence profile than IMF. Annual % change in htTKV was 5.5±9.1% in the normal weight participants and 7.9±11.6% in overweight/obese participants.

Conclusions: Overweight and obesity predict kidney growth in children and young adults with ADPKD.

PO1252
Social Determinants of Health (SDOH) and Healthcare Resource Utilization (HRU) in Autosomal Dominant Polycystic Kidney Disease (ADPKD) by CKD Stage
Mari L. Kilgo,1 Imam Mohammad,1 Hina Japes,2 Laura L. Frank,3 Tazin R. Ajaj,2 Christie Teigland,1 Kristin Pareja,2 *Avalere Health, Washington, DC; 1Otsuka Pharmaceutical Development & Commercialization, Inc.; 2University of Colorado - Anschutz Medical Campus, Aurora, CO; 3Mayo Clinic College of Medicine and Science, Rochester, MN.

Background: SDOH contribute to health disparities in CKD. This study describes SDOH and HRU in ADPKD patients with commercial (COM) insurance compared to a lower income managed Medicaid (MM) population.

Methods: The study included 8,766 COM and 5,416 MM patients from a national claims database. Patients had ≥2 ADPKD diagnoses between 7/1/2016-12/31/2018 and were continuously enrolled during the study period. Patients were linked to SDOH by 9-digit ZIP address providing a precise assignment compared to Census data. HRU included inpatient days and emergency room (ER) visits per 1000 patients per month (PPPM) over 1-year follow-up.

Results: SDOH differences were more likely to be female (60% vs 54% COM) and on average 8 years younger. MM patients had 1.3x higher Charlson Comorbidity Index (CCI) scores, 40% lower income, were 2x more likely to live below federal poverty level, 1.3x less likely to complete high school, 2.7x more likely to speak English not well or at all, 2.6x less likely to own a vehicle, 53% more likely to be unemployed, and lived in a primary/mental health care shortage area 6.8%/6.4% more often. The differences between payers were consistent across CKD stages, except CCI scores increased with higher CKD stage for both groups. Disparities in income, unemployment rates and provider shortages tended to increase with CKD stage. Mean bed days ranged from 34.6 (Stage 1) to 402 (Stage 5) for COM patients and ranging from 112 to 874 across CKD stages. Similarly, ER visits PPPM ranged from 38 to 114 for COM and 154 to 376 for MM. Hospital readmissions and use of post-acute care were high in both groups, with 15% of COM and 20% of MM readmitted within 30-days of inpatient discharge. MM patients were 3-4x more likely to be ≥65 years, 15.2% CKD stage 5D MM having at least one PACE stay during follow-up. HRU increased with CKD stage.

Conclusions: ADPKD patients have large variation in SDOH by type of insurance. Lower social status of MM patients may be associated with higher HRU, and these disparities appear to increase with higher disease stages progresses. In the clinical care of this vulnerable population, consideration of SDOH such as language barriers, transportation insecurity, and poverty is recommended.

PO1254
Overweight and Obesity Predict Kidney Growth in Children and Young Adults with ADPKD
Cortney Steele, Zhiquing You, Heather Farmer-Bailey, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: We have previously reported that overweight and obesity are independently associated with more rapid progression in adults with early-stage autosomal dominant polycystic kidney disease (ADPKD). We now evaluated whether overweight and obesity are also associated with faster kidney growth in children and young adults with ADPKD.

Methods: 54 non-diabetic children and young adults (6-25 years of age) with ADPKD and estimated glomerular filtration rate (eGFR) >80 mL/min/1.73m² who participated in a one-year double-blind, placebo controlled trial of spironolactone were categorized based on BMI (if ≥18 years; n=27) or BMI percentile for age, sex, and height (if <18 years of age; n=27) as normal weight (n=40 [74%]) or overweight/obese (n=14 [26%]). The longitudinal (1-yr) association of overweight/obesity with change in height-corrected total kidney volume (htTKV) by magnetic resonance imaging was evaluated using multilingual linear mixed-effects models.

Results: Mean±sd. age was 18±5 years, annual % change in htTKV was 6.1±9.0%, and eGFR (full-age-spectrum equation) was 112±18 mL/min/1.73m². The annual % change in htTKV was 5.5±9.1% in the normal weight participants and 7.9±8.6% in overweight/obese participants.

**Metabolomic Changes over 1 Year Following Drug or Lifestyle Interventions in Autosomal Dominant Polycystic Kidney Disease (ADPKD)**

Cortney Steele, Jelena Klawitter, Wei Wang, Zhiying You, Victoria Catenacci, Taylor Struemph, Diana George, Berenice Y. Gitomer, Godela M. Brosnahan, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease. Studies have shown differences in metabolomic profiles in those with ADPKD; however few studies assess change over time.

**Methods:** We performed metabolomics to assess patterns of change across four groups of participants with ADPKD pooled from 2 randomized clinical trials: placebo control (CON), metformin (1,000 mg/day) (MET), intermittent fasting (IFM; 3 day/wk of 80% energy restriction from baseline weight maintenance requirements), and daily caloric restriction (DCR; daily restriction of 34% per day from baseline weight maintenance requirements). Analyzed plasma samples were collected during the trials at baseline and 1-year for each group. A total of 163 metabolites were measured using liquid chromatography-mass spectrometry (LC-MS). Differences in metabolomic profiles over time and within study groups were evaluated by a one-way ANOVA and Bonferroni correction for multiple comparisons.

**Results:** Baseline characteristics for each trial included CON (n=22, 14 female), 49±7 yrs of age (mean±SD), estimated glomerular filtration rate [eGFR] 71±13 ml/min/1.73m², body mass index (BMI) 28.3±4.9 kg/m², MET (n=22, 14 F, 48±7 yrs of age, eGFR 69±14 ml/min/1.73m², BMI 29.7±7.2 kg/m²), IFM (n=10, 5 F, 47±6 yrs of age, eGFR 77±16 ml/min/1.73m², BMI 34.6±5.3 kg/m²) and DCR (n=9, 5 F, 46±13 yrs of age, eGFR 68±21 ml/min/1.73m², BMI 34.1±5 kg/m²). Age and eGFR did not differ between groups and BMI was higher in the IMF compared to CON (p=0.031). Metabolite changes are depicted in Figure 1.

**Conclusions:** There are changes at one year in metabolites in adults with ADPKD between control, metformin, intermittent fasting, and daily caloric interventions. Further research is needed to identify metabolomic profile shifts involving drug and dietary interventions.

POI1256

**Identification of CLC-5, the Electrogenic 2Cl-/H+ Exchanger, as the Dominant Apical Chloride Secreting Transporter in Kidney Cyst Epithelium in Tuberous Sclerosis**

Sharon L. Barone, Marybeth Brooks,1,2 John J. Bissler,1 Jane J. Yu,3 Kamyar A. Zahedi,1,3 Manoocher Soleimani,1,2 University of New Mexico Health Sciences Center, Albuquerque, NM; Raymond G. Murphy VA Medical Center, Albuquerque, NM; Le Bonheur Children’s Hospital and St. Jude Children’s Research Hospital, Memphis, TN; University of Cincinnati College of Medicine, Cincinnati, OH.

**Background:** Cyst expansion in Tuberous Sclerosis Complex (TSC) or PKD requires secretion of chloride into the cyst lumen as the driving mechanism for salt accumulation. In PKD, Cl secretion into the cyst lumen is mediated via the eAQP/FP-AQP-stimulation of CFTR in principal cells consequent to the V2 receptor activation by AVP. Kidney cyst expansion in TSC differs from PKD in that cyst epithelia in TSC is comprised of genotypically normal A-intercalated cells, which do not exhibit noticeable expression of either CFTR or the V2 receptor. The identity of the Cl secretory molecule(s) in TSC cyst epithelia remains unknown. Based on RNA Seq analysis in kidneys of Tsc1 KO mice, we hypothesized that the chloride transporter CLC-5 is expressed on the apical membrane of A-intercalated cells in cyst epithelia of humans and animal models of TSC.

**Methods:** We performed immunofluorescent studies utilizing CLC-5 and H-ATPase antibodies and performed on kidney tissue from mice with principal cell inactivation of Tsc1 (Tsc1/+/Aqp2 Cre), parasite inactivation of Tsc1 (Tsc1/Ren2 Cre), principal cell inactivation of Tsc2 (Tsc2/+/Aqp2 Cre), global heterozygous Tsc1(Tsc1+/-) and cysts from TSC patients.

**Results:** Double immunofluorescence labeling demonstrated remarkable co-localization of CLC-5 and H-ATPase on apical membranes of an overwhelming numbers of cyst epithelial cells in all models of TSC, including the human kidney cysts. In contrast, kidney cysts in Pkd1 mutant mice showed no apical CIC-5 expression and very few H-ATPase expressing cells.

**Conclusions:** These are the first reports on apical membrane localization of CLC-5 in A-intercalated cells in any disease state, and suggest that similar to late endosomes/lysosomes, CLC-5 and H-ATPase may function synergistically on cyst epithelia by secreting Cl− and H+ into the cyst lumen. These results strongly point to enhanced translocation of CLC-5 and H-ATPase from late endosomes/lysosomes to the apical membrane of cyst epithelia in TSC.

**Two Years In: The Development and Basic Characteristics of a National Patient-Powered Registry in ADPKD**

Elise Hoover,1 Beverly A. Benson,1 Neera K. Dahl,2 Berenice Y. Gitomer,2 Amy Manelli,1 Michal Murg,2 Meyeon Park,2 Chris Rusconi,1 Stephen L. Seliger,3 Ronald D. Perrone,4 Terry J. Watinck.4 PKD Foundation, Buffalo, NY; 1Yale University, New Haven, CT; 2University of Colorado - Anschutz Medical Campus, Aurora, CO; 3The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 4UCSF Medical Center, San Francisco, CA; 4University of Maryland Baltimore, Baltimore, MD; Tufts Medical Center, Boston, MA.

**Background:** The therapeutic pipeline in autosomal dominant polycystic kidney disease (ADPKD) has grown, generating a need for more patient participation in clinical trials. To facilitate US ADPKD patient enrollment and to encourage the utilization of patient-reported outcomes in trial design, the PKD Foundation (PKDF) designed a national ADPKD Registry.

**Methods:** The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdecode). Participants are consented through the online system and complete a series of modules. The Core Questionnaire includes diagnosis, latest kidney function tests, and comorbidities. Family history, diet and lifestyle, quality of life, and complications of liver cysts, and vascular outcomes are queried.

**Results:** Between 9/4/19 and 5/1/21, 1,580 ADPKD patients have registered and completed the Core Questionnaire. Participants have a median age of 49 years, 73% have not reached ESKD, and 79% reported a family history of the disease. Currently, the cohort is 71% female, 93% Caucasian, 4.8% Hispanic/Latino and 2.5% African American. Strategic efforts are in development to increase diversity in the cohort. Nearly three quarters of participants had not previously participated in research, with only 27% indicating that they had been in another PKD study or clinical trial. All participants have consented to be contacted about future studies. Many will likely qualify for ongoing trials based on completed module data. Thus far, the Registry platform has made over 2,200 participants contacts regarding six clinical studies, with some individual overlap due to similar eligibility criteria.

**Conclusions:** The ADPKD Registry is a longitudinal research tool intended to capture ADPKD patient-reported data and is designed to impact research in multiple ways. It will allow for a range of open access PKD registries, from early disease to end stage disease outcomes. Additionally, modules on health care access & utilization and COVID-19 impact will help the PKDF better understand the challenges of this community.

POI1258

**Polycystic Kidney Disease and Race**

Alexandra Hayward, Riti L. McGill, Milida R. Saunders, Arlene B. Chapman. University of Chicago Division of the Biological Sciences, Chicago, IL.

**Background:** Racial/ethnic differences in the development of kidney failure (ESKD) and transplant (TX) access are well-documented. ESKD is anticipated in familial autosomal dominant polycystic kidney disease (ADPKD), providing the opportunity for greater ESKD preparation. We sought to define the impact of race on ESKD/TX outcomes in ADPKD.

Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Kristen L. Nowak,1 Heather Farmer-Bailey,1 Wei Wang,1 Zhijing You,1 Cortney Steele,1 Melissa A. Cudnappornchari,1 Jelena Kwittner,1 Natalia Patel,1 Diana George,1 Anna Kovacevic,2 Danielle Sorensen,2 Berenice Y. Gitomer,1 Michel Chonchol,1,2 Rocky Mountain Hospital for Children, Denver, CO; 1VA Eastern Colorado Health Care System, Aurora, CO; 2Children’s Hospital Colorado, Aurora, CO.

Background: Clinical manifestations of autosomal dominant polycystic kidney disease (ADPKD) can begin in childhood, including evidence of vascular dysfunction, an important predictor of cardiovascular events and mortality. Curcumin is a polyphenol found in turmeric that reduces vascular dysfunction in rodent models and humans free from ADPKD. It also slows kidney cystic progression in a murine model of ADPKD.

Methods: We hypothesized that curcumin supplementation would reduce vascular dysfunction (brachial flow-mediated dilatation [FMD] and aortic pulse-wave velocity [APW]) in children and young adults with ADPKD. In this prospective, randomized, controlled, double-blind trial, n=68 participants 6-25 years of age with ADPKD and an estimated glomerular filtration rate >80 mL/min/1.73 m² were randomized to receive either curcumin supplementation (25 mg/kg body weight/day) or placebo administered in powder form for 12 months. We also assessed change in circulating and urine biomarkers of oxidative stress/inflammation and kidney growth (height-adjusted total kidney volume [htTKV]; exploratory endpoint) by magnetic resonance imaging. In a subgroup of participants a18 years, we also assessed vascular oxidative stress as the change in FMDΔA following an acute infusion of ascorbic acid.

Results: Fifty-seven participants completed the trial. Participants were 18±5 (means±d.) years, 55% female, and 85% non-Hispanic White. The co-primary endpoint, FMDΔA (%), did not change in the curcumin group (baseline: 9.4±4.1; 12-months: 10.6±3.9), as compared to the placebo group (baseline: 8.9±4.0; 12-months: 9.3±4.5; p=0.53). There was no curcumin specific reduction in vascular oxidative stress, nor any changes in mechanistic biomarkers. htTKV also did not change over the 12-month study with curcumin administration as compared to placebo.

Conclusions: Curcumin supplementation does not reduce vascular dysfunction or slow kidney growth in children/young adults with ADPKD.

Polycystic Kidney Disease Associates with Increased Myopia and Retinal Breaks

Background: Ophthalmologic manifestations in Polycystic Kidney Disease (PKD) are not well known.

Methods: We conducted a retrospective cohort study using EMR data extraction. All adult patients with polycystic kidney disease (“PKD”) and CKD from another cause were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as “Index date”. The prevalence of Eye disorders of interest in these 2 cohorts were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as “Index date”. The prevalence of Eye disorders of interest in these 2 cohorts were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as “Index date”.

Results: A total of 839 patients with “PKD” and 8309 patients with “non-PKD/CKD” were compared over the study duration. Majority of patients in both groups were male (58% [498] and 54% [4457]) and identified as White (88% [758] and 86% [7185]). At the index date, PKD patients were younger (mean age 55 vs 60 years in non-PKD/CKD; p<0.01) and had shorter follow up time (median 901 vs 1311 days; p<0.01). PKD patients had higher eGFR (52 [31-81]; N=795) vs 43 mL/min/1.73m² (29-59; N=3742; p<0.01) and lower prevalence of diabetes mellitus at the index date (23% [198] vs 39% [3270]; p<0.01). Hypertension prevalence was similar between the two groups (91% [778] and 90% [7444]; p=0.7). Myopia and all Retinal breaks (with or without detachment) were found to be higher in PKD as compared to non-PKD/CKD after multivariable adjustment for age, gender, race, diabetes and follow up time (adjusted odds ratio 1.4 [95% CI: 1.1-1.7] and 1.7 [1.2-2.8]; respectively; p<0.01). Retinal breaks with detachments by themselves were also more frequent in PKD but did not reach statistical significance (Table). Peripheral retinal degeneration was similar between the two groups.
PO1262
TSC2 Loss-of-Heterozygosity Mutations Drive Cystogenesis in Kidney Organoids Generated from Tuberous Sclerosis Complex Patient-Derived Induced Pluripotent Stem Cells
Dario R. Lemos. Brigham and Women’s Hospital, Boston, MA.

Background: Kidney cysts are the second most common renal manifestation of TSC, accounting for 50% of kidney lesions. The genetic mechanisms driving TSC-associated cystic kidney disease remain poorly understood.

Methods: We induced nephric differentiation of a series of TSC patient-derived iPSC lines that included a line carrying a heterozygous microdeletion in the TSC2 locus (TSC2-/-), and a TALEN-engineered isogenic cell line carrying microdeletions in both TSC2 alleles (TSC2+/-).

Results: Analysis of Day-21 two-dimensional cell cultures showed that nephrons derived from TSC2-/- and TSC2+/- hiPSCs presented normal morphology, and were sequentially segmented into distal tubules expressing caderin 1 (CDH1), proximal tubules containing brush borders labeled by lotus tetragonolobus lectin (LTL) and glomeruli containing podocytes expressing podocalyxin 1 (PODXL). By Day-21 of differentiation TSC2-/- hiPSC-derived kidney tissues showed cavitated structures resembling cysts. Analysis of nephron segments showed positive signal for both CDH1 and LTL, indicating the cyst lining could comprise distal tubule and/or proximal tubule cells. The observed frequency of cyst formation was ~4.7 cysts/well for TSC2+/- cultures, with 0 and ~0.5 cysts/well for TSC2+/- and TSC2-/- cultures, respectively. Of note, 2-D cyst-like structures developed in a spontaneous manner, that is without addition of cAMP modulators. Analysis of the three-dimensional anatomy of TSC2-/- organoids also showed that while individual tubule segments were involved in cyst lining, in certain cases a combination of both proximal and distal tubule cells were detected, suggesting improper segmentation mechanisms in the absence of TSC2. While single-cell lining layers were associated with well-defined tubule segments, mixed-cell lining regions were multi-layered, resembling the columnar epithelium observed in the renal cysts of TSC patients. The distribution of LTL staining, in proximal tubule cells TSC2-/- organoids indicated loss of cell polarity in contrast to the polarized cells observed in TSC2+/- tubules. Cyst formation in TSC2-/- organoids did not involve loss of podocytes 1 (PKD1)-1 expression.

Conclusions: Our kidney organoid models provide evidence supporting LOH events resulting in complete TSC2 inactivation in nephron tubule cells as a mechanism driving kidney cyst formation in TSC.

PO1265
A Combination Therapy with Two Dietary Supplements Acting on Different Mechanisms Ameliorates Disease Progression in a Rat Model of Polycystic Kidney Disease
Jacob Morley, Torger A. Amoah, Bradley C. Kroe, Nickolas J. Holzmecht, Tselmeg Amarlykhkaa, Juliette R. Rebellio, Thomas Weimbs. University of California Santa Barbara, Santa Barbara, CA.

Background: Recently, our lab reported that dietary interventions to induce ketosis ameliorate disease progression PKD animal models, and that this effect involves the natural ketone beta-hydroxybutyrate (BHB). Additionally, we have recently shown that renal microcrystals exacerbate disease progression in PKD models. We now show that a combination of citrate and BHB effectively inhibits PKD progression. These compounds act on separate mechanisms, synergistically preventing cyst formation and cyst growth in young rats. In adult rats, the combination treatment leads to a partial reversal of existing renal cystic disease.

Methods: Juvenile and adult Han:Sprague-Dawley rats were treated with BHB, citrate or in combination via drinking water for 5 or 4 weeks respectively, then sacrificed and analyzed for changes in cystic burden and markers of disease progression. Additionally, rats were placed in metabolic cages to assess changes in urine parameters.

Results: Administration of either BHB or citrate alone in the drinking water significantly ameliorates PKD progression in a rat model. Combining BHB and citrate produced a synergistic effect. Cystogenesis and cyst growth were inhibited in juvenile animals. In adult animals with pre-existing renal cystic disease, the treatment leads to T2Disease regression. We also showed that administration of excess sodium and potassium alone, at doses that would be provided from the salts of citrate and BHB, lead to a worsening of PKD in our rat model.

Conclusions: The beneficial effects of ketosis are mimicked by administration of BHB in the drinking water and are consisent with a number of groups findings suggesting an unifying metabolic defect in PKD. Our recent findings suggest excessive renal crystal burden leads to accelerated disease progression in PKD models. Renal cystal formation can be prevented by administration of citrate to both chelate calcium and raise urinary pH. These results are of high clinical significance because BHB and citrate
are widely available and classified as safe dietary supplements. These results suggest that ≥ 60ml/min/1.73m² as adults, with an eGFR ≥ 60ml/min/1.73m². A significant number of these patients had observed in CKD patients with cystic phenotype were identified with obvious combined hepatic and renal abnormalities who may have had delayed onset ARPKD. Our small series suggest that some patients with ARPKD present as adults with a more limited phenotype that can easily be mistaken for ADPKD.

POI1267
Analysis of Somatic Mosaic Mutations in Nephropathy-Associated Genes Reveal Candidate Disease-Causing Mutations in Previously Germline-Negative Cases

Background: Somatic mosaic variant (SMV) arises due to postzygotic mutations that results in two genetically distinct populations of cells in the same person. SMVs may be missed by standard search for germline (or inherited) mutations, and the use of dedicated analytic pipelines for SMVs can potentially explain “exome negative” cases.

Methods: We searched for SMVs in 248 patients who underwent exome sequencing for congenital kidney anomalies. Somatic mutations were identified through GATK Mutect2 software, and clinically annotated following the American College of Medical Genetics and Genomics (ACMG) guidelines. We focused the analysis on 625 nephropathy-associated genes previously used for the germline analysis.

Results: Previous analyses germline variants had identified 52 diagnostic variants in this cohort (20.9% diagnostic rate). In addition, the SMV pipeline identified candidate disease-related SMVs in 4 “exome-negative” patients (1.6% of cases). The SMVs were detected in RET, ENG and COL4A5, and are reported in Table 1. This improved the diagnostic rate of the cohort to 22.5%

Conclusions: Analysis of somatic mosaic variants can increase diagnostic yield in patients with congenital kidney anomalies. Application of the SMV pipeline may increase diagnostic in other forms of kidney disease

SVM identified in congenital anomalies kidney patients

Comparison of Imaging Approaches for Quantifying Total Kidney Volume (TKV) and Fibrosis in a Mouse Model of Polycystic Kidney Disease (PKD)
Caroline R. Sussman, Heather L. Holmes, Ka Thao, Adriana Gregory, Ryan J. Meloche, Yaman G. Mkhaimeur, Harrison H. Wells, Slobodan Macura, Peter C. Harris, Timothy L. Kline, Michael T. Romero. Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: 3D imaging and histology are critical tools for assessing PKD in patients and animal models. Magnetic resonance (MR) imaging provides unsum resolution, but is time consuming, expensive, and access to equipment and expertise is limiting. Robotic ultrasound (US) is lower resolution but fast. Similarly, picrosirius red (PR) staining and standard light microscopy is used to assess fibrosis; however, alternative methods for quantifying PR staining have been shown in other tissues to allow greater sensitivity and more detailed characterization.

Methods: Pkd1/Mice were compared to Pkd1°/° (WT). TKV was quantified from US and MRI (7T and 16T) at 1, 3, and 4 months old. US measurements of kidney and heart were performed using the Vevo LAZR imaging system. Inter-operator variation was assessed using Blank-Altnan analysis. PR-stained kidneys were imaged using standard light microscopy, circularly (c) polarized light with binnning into four categories of collagen thickness, and fluorescent imaging with analysis using cEfire. Renal cAMP and BUN were measured using standard approaches, and GFR was measured using a transdermal fluorescent sensor (MediBeacon).

Results: US detected increased TKV at 1 month and was similar to MR (7T or 16T). Inter-operator variability (2 observers) was greater for US than MR, but still able to detect differences between genotypes and time points. US allowed scanning in 2-5 minutes/mouse while MR required 20-30 minutes. Colpolarized light showed a greater percentage of the thickest collagen fibers in RC/RC mice, and a corresponding lower percentage of each of 3 categories of thinner collagen fibers. Preliminary data using fluorescence microscopy showed a higher density of collagen fibers in RC/RC mice vs. WT. Analysis of collagen fiber angle, length, straightness, and width is ongoing. RC/RC had a lower GFR, higher BUN, and elevated cAMP vs WT. No differences were observed in cardiac function (ejection fraction, heart rate, or cardiac output).

Conclusions: These studies demonstrate the utility of US and alternative approaches of quantifying fibrosis using PR.

POI1269
Phenotypic Heterogeneity in Type IV Collagen-Associated Nephropathy: The Cystic Phenotype
Letizia Zeni,1 Cinzia Mazzu,1 Diego Tos,1 Laura Economi,1 Roberta Cortinoiovic,1 Chiara Dordoni,1 Gianfranco Savoldi,1 Francesco Scolari,2,3 Claudia Izz1.2 Azione Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy;3 Universiti degli Studi della Compagnia di San Paolo, Ferrara, Italy;1 Universita degli Studi di Brescia, Brescia, Italy.

Background: Exome sequencing (ES) revealed mutations (mut) in type IV collagen (COL4) genes in patients (pt) diagnosed with other forms of chronic kidney disease (CKD), supporting the concept of spectrum of phenotypes for COL4-Nephropathy. Unexpectedly, some pt with CKD presenting with cystic phenotype were identified with COL4-Nephropathy by ES.

Methods: The retrospective study included 130 pt referred to outpatient clinic of genetic kidney diseases of ASST Spedali Civili of Brescia from 2002 to 2021 and diagnosed with COL4-Nephropathy. Based on the presence of multiple and bilateral renal cysts on imaging (fig1), a group of pt with cystic phenotype was selected (27/130,21%).

Results: Among cystic group (CG), diagnosis was based on genetic test (g) and kidney biopsy in 10/27 pt, whereas it was “biopsy-proven only” in 7 pt, gt-based in 3 pt and clinically in 7 pt. Fifteen pt underwent gt (fig2): heterozygous mut in COL4A3 and COL4A4 were detected in 9 and 3 cases, respectively; 1 patient showed mut in COL4A5 and 2 pt had a digenic pattern. At baseline, comparison between CG and non-CG showed lower eGFR (70 [IQR 35;91] vs 91 [IQR 74;114] mL/min/1.73m² p<0,001) and higher proteinuria (1.1 vs 0.38g/24 hrs), although the statistical significance was not reached for proteinuria (p=0.059). At last censoring, data confirmed a lower eGFR (26[IQR 7;55] vs 86[IQR 44:94]) and a tendency (p=0.045) of greater arteriolar hypertrophy in CG. Prevalence of arterial hypertension, CKD (defined as eGFR < 60) and ESKD was higher in CG. 86[10.44;104] and a tendency (p=0.054) of greater proteinuria in CG. Prevalence of arterial hypertension, CKD (defined as eGFR < 60) and ESKD was higher in CG. 86[10.44;104] and a tendency (p=0.054) of greater proteinuria in CG. Prevalence of arterial hypertension, CKD (defined as eGFR < 60) and ESKD was higher in CG.

Conclusions: The study contributes to expand the emerging phenotypic heterogeneity of COL4-Nephropathy and suggests that cystic phenotype could predict progression of kidney disease.

**Targeted Exome Sequencing Application for Genetic Diagnosis of Pediatric Patients with Cystic Kidney Disease**

**Jeeun Min,1 Hyeongju Lee,1 Peong Gang Park,2 Yo Han Ahn,2 Hee Gyu Kang,3 Ji Hyun Kim,3 Eujin Park.4**

1Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea; 3Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 4Hallym University Medical Centre, Yeongdeongpo-gu, Seoul, Republic of Korea; 5Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea.

**Background:** Detection of a monoogenic cause of chronic kidney disease accounts for almost 30% of cases in the pediatric cohort. Of these, the highest yield in the genetic diagnosis is currently seen in cystic kidney disease. Nearly 100 monogenic causes of renal cystic abnormalities have been identified and the genetic diagnostic yield is reported to be approximately 50%. Here, we report the results of genetic testing in a cohort of Korean pediatric patients with cystic kidney disease.

**Methods:** From July 2019 to February 2021, children under the age of 18 with three or more cysts in both kidneys on imaging studies were recruited from three pediatric nephrology centers in Korea. Genetic identification was performed by targeted exome sequencing (TES) including 89 genes known as cystogenesis-related or causative-cilipathy.

**Results:** A total of 46 pediatric patients with cystic kidney disease were recruited. The median age was 9.2 years (IQR, 5.49-14.53) and 60% were boys. Twelve patients (27.9%) had a family history of cystic kidney disease. The clinical diagnoses of the patients were 10 patients with autosomal dominant polycystic kidney disease, 5 patients with autosomal recessive polycystic kidney disease, 2 patients with multicystic dysplastic kidney, 1 patient with nephronophthisis, and the others were undiagnosed. The mutation detection rate was 52.2% (24 of 46). PKD1 was the most common causative gene (16 patients, 34.8%), followed by HNF1B (3 patients), PAZ2 (2 patients), PKD2 (1 patient), PKHD1 (1 patient) and NPHP3 (1 patient). Genetic mutations were identified in all patients (12 of 12) with a family history of cystic kidney disease. In patients without a family history, genetic mutations were found in 35.3% (12 of 34).

**Conclusions:** The mutation detection rate in this cohort of Korean pediatric patients with cystic kidney disease was 52.2% by TES. Mutations in PKD1 were found most commonly, and the mutation detection rate was higher in patients with a family history of cystic kidney disease. For children with cystic kidney disease, molecular genetic testing is essential for an accurate diagnosis, personalized treatment, and prognosis prediction.

**The Prognostic Factors of Cyst Infection due to ADPKD**

**Hiromu Hirozumi,1 Junichiro Hoshino,2 Yoshifumi Ubara,1 Toranomon Byoin, Kawasaki, Japan; 2Toranomon Byoin, Minato-ku, Japan.**

**Background:** Renal or hepatic cyst infection is a complication of autosomal dominant polycystic kidney disease (ADPKD), which requires hospitalization and causes death. Cyst aspiration was the gold standard to diagnose this disease. Because of its invasiveness, several diagnostic criteria without using cyst aspiration have been proposed, but prognostic factors of cyst infection have not been analyzed in this setting.

**Methods:** Inclusion criteria of this retrospective cohort are ADPKD patients who were admitted in Toranomon hospital and Toranomon hospital Kajigaya between 2016 April and 2021 March, and who were diagnosed as cyst infection based on MRI findings, which we previously published. Primary composite endpoint was defined combination of death, septic shock, or hospitalization for more than four weeks, and secondary outcomes were defined by each outcome mentioned above. Logistic analysis was planned to assess the predictors of the outcomes.

**Results:** One hundred ninety patients were eligible to this study. The average age was 65.0±9.2 years old, 116 (61.1%) were female, and the average height-adjusted total liver volume (htTLV) was 332±2286 mL per meter, and 164 (86.3%) had hemodialysis therapy. Composite outcome occurred in 109 (57.4%): 25 death, 36 shock, and 98 longer-hospital-stay. Multivariable logistic regression model after adjusted related variables showed that older age (odds ratio(OR) 1.10 (95% confidence interval: 1.10-2.54), p-value=0.02), male (OR 2.49 (1.66-3.33), p-value=0.02), higher htTLV (OR 2.29 (1.39-3.77), p=0.01), lower mean blood pressure at admission (OR 0.735 (0.579-0.931), p=0.01), larger size of infectious cyst (OR 1.42 (1.06-1.91), p=0.02) were significantly associated with the composite outcome. Although the culture-positive case or higher white blood cell count were not significantly associated with the primary outcome, they were associated with septic shock due to cyst infection.

**Conclusions:** Baseline characteristics at admission were associated with the prognosis of cyst infection diagnosed by MRI-based criteria, which was similar to cyst infection diagnosed by cyst aspiration. Culture-positive case or higher white cell count were reported as risk factors requiring more invasive therapies that could lead to septic shock and need longer hospitalization in our study's cohort.

ExoGAG, A New Method for Extracellular Vesicle and Glycoprotein Isolation in Urine That Unmasks the Pathophysiology of the Kidney and Identifies New Biomarkers of Kidney Disease
Maria Vizoso,1 Nerea Lago,1 Tamara Camino,1 Olaya Lamas-Gonzalez,2 Susana Bravo,1 Carmen Vazquez,1 Manuel Fidalgo Diaz,3 Cássio Rodrigues,1 Maria Pardo,1 Miguel A. Garcia-Gonzalez,4 1Nephrology Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; 2Proteomic Group, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; 3Nephrology Service, University Hospital of Santiago de Compostela, Santiago de Compostela, Spain; 4Galician Public Foundation of Xenomeric Medicine, Santiago de Compostela, Spain; 5Ohséidonic Laboratory, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain.

Background: Glycosaminoglycans (GAGs) are large polysaccharides that interact through glycosidic bonds with proteins and lipids, forming the extracellular matrix; or with secreted proteins, as uromodulin. Glycosylation is altered in pathologies, as cancer or kidney diseases. GAGs are present in extracellular vesicles (EVs), nanometric structures delimited by lipid bilayer that cells release and whose charge (RNA/miRNA, DNA and proteins) is essential in intercellular communication. Our group developed a method for GAG, glycoproteins and EVs isolation in any biological sample, called ExoGAG (commercialized by Nasas Biotech), which led us to identify and characterize new signaling mechanisms, and identify new prognostic/diagnostic biomarkers, for example, in polycystic kidney disease (PKD).

Methods: Urine samples have been collected from patients genetically diagnosed with type I and II PKD at different stages of disease. Using ExoGAG, GAG-glycoprotein-EVs complex has been isolated and characterized by different proteomic techniques (Western Blot, mass spectrometry), gene expression (RT-PCR), and image characterization (electron microscopy, immunofluorescence).

Results: ExoGAG has allowed us to identify a new biomarkers in urine (in protection) in PKD patients, which are altered in disease progression, even anticipating currently used kidney damage markers. The characterization of these complexes has led us to discover new signaling mechanisms between the different segments of the nephron, and whose function is altered in different pathologies. These findings have served other researchers to develop new knowledge in different specialties such as Oncology and Endocrinology.

Conclusions: This new method for isolating the fraction associated with GAG in urine samples has allowed us to identify prognostic/diagnostic biomarkers of kidney diseases, based on glycoprotein and vesicular profile. Likewise, it has led us to identify new signaling mechanisms of the nephron, which opens a new field for a better understanding of renal pathophysiology. These results uncovered the potential of a method as a tool for isolation of its use in the research of new cellular communication pathways or cellular mechanisms.

PO1274
Deposition of an Abnormal Extracellular Matrix as an Initiating Event in Cyst Formation
Valerie A. Schumacher,1,2 Mary E. Taglienti,3 Jordan A. Kreidberg,1,2 "Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA.

Background: Extracellular matrix (ECM) refers to the proteins and other macromolecules outside of cells that provide a scaffolding to maintain tissue architecture. The distinct ECMs to which these cells are attached, epithelial cells to a laminin-rich basement membrane vs. interstitial cells to a collagen/fibronectin (FN) ECM, has profound implications for cell behavior and tissue architecture. These differences in cell behavior are mediated through a family of receptors known as integrins, used by cells to attach to the ECM. Here we provide evidence that cyst formation in ADPKD is a manifestation of abnormal cell behavior in response to an atypical extracellular matrix.

Results: The distinct ECMs to which these cells are attached, epithelial cells to a laminin-rich basement membrane vs. interstitial cells to a collagen/fibronectin (FN) ECM, has profound implications for cell behavior and tissue architecture. These differences in cell behavior are mediated through a family of receptors known as integrins, used by cells to attach to the ECM. PO1275
Uncovering the Role of the Extracellular Matrix in ADPKD Progression
Elisa Pellegrino,1,2 Maria Elena Stein,1,2 Marco Chiariavalli,1 Alessandra Boletta,1 Elisa Agnese Negro,1 1Università Vita Salute San Raffaele, Milano, Italy; 2IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Polycystic Kidney Disease (PKD) is a genetic disorder due to mutation in either Pkd1 or Pkd2 genes and characterized by bilateral cysts formation. We recently uncovered a direct role of PKD-1, the protein product of Pkd1 gene as a mechanosensor of extracellular stiffness. We found that PKD-1 interactors mediate inhibition of actomyosin contraction that mediates the cellular response to the rigidity of the Extracellular Matrix (ECM). Based on these findings we speculated that Pkd1−/− cells fail to properly respond to the extracellular mechanical force of ECM leading to excessive matrix deposition and proliferation. In line with this, kidneys of end-stage PKD patients show enhanced fibrosis typical of cystic kidney disease and tumors. We then wondered whether PKD ECM is a part of an active Cyst Microenvironment (CME), exerting a key role in the evolution of the disease.

Methods: We characterized CME in the renal tissue of an aggressive Pkd1−/−/−, Ksp-Cre and a low aggressive Pkd1−/−/−;Tam-Cre inducible mouse models. To study the composition and the mechanical properties of the cystic ECM we decellularized cystic kidneys obtaining ECM-derived kidney scaffolds. Furthermore, we isolated matrix from Pkd1−/− fibroblasts in vitro.

Results: We have characterized the renal tissue microenvironment of two Pkd1 inducible mouse models at a late stage of the disease confirming the presence of fibrosis, immune infiltrates and progressive accumulation of collagen I. In line with an active role of the CME, we found that fibroblasts in the deposition and remodeling of the ECM, our data showed the presence of activated fibroblasts in cystic kidneys. We performed a proteomic analysis of cystic kidney scaffolds by Mass Spectrometry (MS). Cluster analysis of MS data showed a clear separation between cystic and control scaffolds. Finally we found that matrix isolated from Pkd1−/− cells was able to influence differently key cellular properties such as adhesion, polarization, proliferation and migration.

Conclusions: ECM plays an active role in the progression of ADPKD disease.

Abstract Withdrawn

PO1277
17q12 Deletion Syndrome Presenting as Congenital Diaphragmatic Hernia in a 2-Month-Old Infant

Introduction: 17q12 deletion syndrome results from the loss of as many as 15 genes on the long arm of chromosome 17 including the hepatocyte nuclear factor-1-beta gene (HNF1B). Heterozygous pathogenic variants, whole gene deletion, or duplication in HNF1B are frequently linked to inherited kidney malformations including hyperechoic kidneys, kidney cysts, solitary kidney, and hydrenephrosis as well as extrarenal phenotypic features. 17q12 deletion syndrome has also been linked to congenital diaphragmatic hernia (CDH). We present a case of an infant with hyperechoic and cystic kidneys, diagnosed postnatally with CDH.

Case Description: A 2-month-old female with a history of hyperechoic kidneys on prenatal ultrasound presented to the emergency department with increased work of breathing. A chest x-ray revealed left hemidiaphragm elevation, normal cardiac silhouette, and no focal pulmonary consolidation. Computed tomography of the chest confirmed the diagnosis of CDH. A repeat kidney ultrasound revealed diffuse hyperechoic kidneys and a focal kidney cyst within the right upper pole (Image 1). Genetic workup revealed a 1.9 megabase deletion on the long arm of chromosome 17 consistent with the diagnosis of 17q12 deletion syndrome.

Discussion: Pathogenic variants in HNF1B or whole gene deletion as part of 17q12 deletion syndrome should be considered in infants with hyperechoic kidneys with cysts, particularly in the context of extrarenal manifestations. Studies have examined the link between HNF1B and the development of a CDH. It is proposed that HNF1B is involved in the WNT signaling pathway that is critical to mesodermal differentiation and proper diaphragm formation. Only 4 other cases of HNF1B mutations associated with CDH are reported in the literature. Two cases describe HNF1B deletions, and 2 cases describe HNF1B duplications. It is possible that the high prenatal mortality of CDH could explain the paucity of this association.
PO1278

Recurrent Pneumothorax in a Marfanoid Adolescent with Autosomal Dominant Polycystic Kidney Disease

Allison Miller, Legacy Health System, Portland, OR.

Introduction: Pneumothorax may be a rare extra-renal manifestation of autosomal dominant polycystic kidney disease (ADPKD), and may indicate co-inheritance of other genetic diseases.

Case Description: A 21-year-old man with ADPKD and pneumothoraces presented to nephrology clinic. A screening ultrasound in late childhood was completed due to his family history and confirmed ADPKD. The patient was normotensive and had a tall, thin habitus. His musculoskeletal examination was pertinent for several marfanoid findings, including increased arm span ratios, pes planus, and positive thumb and wrist signs. His eGFR was normal and he did not have proteinuria. He was hospitalized several times between ages 13-20 for recurrent pneumothoraces requiring left apical wedge and lower bleb resections with pleurectomy, and right upper lobectomy and pleurectomy.

Discussion: The patient’s lung collapse was attributed to primary spontaneous pneumothorax due to his tall stature and intermittent tobacco use. However, this cannot account for his high rate of recurrence. The extent of pneumothorax burden in this patient should be considered in context of his underlying polycystic renal disease. Pulmonary manifestations of ADPKD are not well understood and have only been described in a handful of case reports. Bronchiectasis and cystic lung disease are thought to occur as a downstream consequence of impaired parenchymal healing. Mutated polycystin-1 in ADPKD prevents normal ciliary function, which is imperative for coordination of cellular repair in bronchial smooth muscle cells. Evolving cystic lung disease in the setting of underlying ADPKD could explain this patient’s recurrent pneumothoraces. The possibility of a co-inherited connective tissue disease should also be considered in patients with ADPKD and pneumothoraces. “Overlap” disorders between ADPKD, Marfan syndrome and Tuberous Sclerosis (TSC) have been examined in linkage studies, and have chromosomal proximity. Marfan syndrome and TSC are associated with pneumothorax. Though our patient did not manifest criteria for TSC, his examination is consistent with a Marfan’s variant phenotype. This patient may be an example of co-inherited disease, and raises the question of whether it is under this circumstance that rare cases known in the world and their renal function outcome is somewhat undefined.

Case Description: ZG is a pleasant 41-year-old man with a congenital solitary left kidney with multiple cysts and a genetic diagnosis of ADPKD. Familiarity is negative for ADPKD, but positive for URAP (present in his sister and his son). Except for hypertension, there are no extrarenal ADPKD manifestations. Poster et al. analyzed 3 patients with a similar phenotype in a cohort of 182 ADPKD subjects, comparing how the volume of the single kidney increased (SKV) over time and how the GFR dropped, stratifying them for sex and age. A greater SKV in time has been recorded in these 3 patients, caused by both compensatory hypertrophy and cyst growth. Surprisingly though, their kidney function was better compared to controls. Late onset kidney failure is probably caused by hyperfiltration, and is linked with a long-term worse outcome. In our case, ZG’s SKV increased less compared to another subject with same age and sex and with controls found in literature. Same goes for kidney function, which was better and more stable in a 10-year time-lapse compared to controls.

Discussion: The reason for this could be found in the PKD1 mutation: ZG has a missense mutation, while the aforementioned 3 cases had truncating ones. ZG’s increased SKV is probably more related to hypertrophy than cyst growth itself. Therefore, even in an unorthodox situation like this one, long-term outcome seems to depend on the genotype of the subject.

PO1280

Congenital Solitary Kidney in ADPKD: A Genotype-Phenotype Correlation

Romeo Bucci, Marta Vespa, Maria Teresa Sciarrone Alibrandi, Giancarlo Joli, Giulia Mancassola, Giuseppe Vezzoli, Paolo Manunta. IRCCS Ospedale San Raffaele, Milano, Italy.

Introduction: There are a very few cases of ADPKD associated with Unilateral Renal Agenesis (URA). The total amount is currently only 9 cases known in the world and their renal function outcome is somewhat undefined.

Case Description: ZG is a pleasant 41-year-old man with a congenital solitary left kidney with multiple cysts and a genetic diagnosis of ADPKD. Familiarity is negative for ADPKD, but positive for URAP (present in his sister and his son). Except for hypertension, there are no extrarenal ADPKD manifestations. Poster et al. analyzed 3 patients with a similar phenotype in a cohort of 182 ADPKD subjects, comparing how the volume of the single kidney increased (SKV) over time and how the GFR dropped, stratifying them for sex and age. A greater SKV in time has been recorded in these 3 patients, caused by both compensatory hypertrophy and cyst growth. Surprisingly though, their kidney function was better compared to controls. Late onset kidney failure is probably caused by hyperfiltration, and it is linked with a long-term worse outcome. In our case, ZG’s SKV increased less compared to another subject with same age and sex and with controls found in literature. Same goes for kidney function, which was better and more stable in a 10-year time-lapse compared to controls.

Discussion: The reason for this could be found in the PKD1 mutation: ZG has a missense mutation, while the aforementioned 3 cases had truncating ones. ZG’s increased SKV is probably more related to hypertrophy than cyst growth itself. Therefore, even in an unorthodox situation like this one, long-term outcome seems to depend on the genotype of the subject.

PO1279

Ruptured Intracranial Aneurysm as the Initial Presentation of ADPKD in a Pediatric Patient

Marion Chedid, Fouad T. Chebib, Christian Hanna. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is associated with multiple extra-renal manifestations, most notably intracranial aneurysms (ICA). Approximately 10% of ADPKD patients develop ICA during their lifetime. Subarachnoid hemorrhage (SAH) is a major complication of ICA and usually occurs during the end of the 3rd decade. Aneurysm rupture in children <18 years of age is extremely rare. We report a case of a 9-year-old boy presenting with symptomatic ICA rupture as the initial presentation of ADPKD, despite a negative family history of ICA.

Case Description: A 9-year-old boy presented to the emergency department with an abrupt onset of severe headache and lethargy after a fall. His family history was remarkable for ADPKD in his father and grandfather. None of his affected family members developed ICA or intracranial hemorrhage. Initial non-contrast computed tomography scan of the head showed frontal lobe hemorrhage. Additional imaging studies revealed a ruptured anterior communicating artery with SAH. Urgent aneurysm clipping was performed, his bleeding was controlled, and the patient survived. Due to his strong family history for ADPKD, a kidney ultrasound was performed and showed enlarged kidneys with multiple renal cysts bilaterally confirming the diagnosis of ADPKD. The patient’s father underwent a screening MRI of the brain at the age of 48 years and was negative for ICA.

Discussion: Our case of SAH due to ICA rupture as the initial presentation of ADPKD, in the absence of a positive family history of ICA or hemorrhage, has not been reported in children. Rare cases of subarachnoid hemorrhage in pediatric patients with ADPKD and a positive family history of ICA or hemorrhage have been described. Based upon available data, it is unclear if either widespread or targeted screening for intracranial aneurysms is beneficial for pediatric patients with ADPKD. Screening is reserved for patients with a family history of hemorrhage, migraine, stroke, patients undergoing major surgery, or patients with high-risk jobs. However, we do not screen children <18 years of age because of the extreme rarity of aneurysmal rupture at that age. Though extremely rare, some care physicians and pediatricians should stay aware that ICA rupture occurs in children with ADPKD and can lead to devastating complications, even in the absence of positive family history.
Discussion: Finding an appropriate agent to slow CKD progression is the current strategy to manage PKD. Her condition is complicated by likely lithium nephropathy. The TEMPO trial (Torres et al, N Engl J Med 367:2407–2418, 2012) showed that tolvaptan helps slow rapidly progressive ADPKD by inhibiting vasopressin’s effect, reducing cAMP production, further inhibiting cyst formation and growth (Wang X et al, J Am Soc Nephrol 19: 102–108, 2008; Aihara M et al, J Pharmacol Exp Ther 349: 258–267, 2014). Lithium can also inhibit vasopressin in the kidney, leading to nephrogenic DI (Bokenhauer et al, Nat Rev Nephrol 11(10):576-88, 2015). In ADPKD, tolvaptan helps achieve a urine osmolality of less than 300 mOsmol/kg (Torres, Clin J Am Soc Nephrol. 13(11):1765-1776, 2018). Our patient already has polyuria and urine osmolality below 100 mOsmol/kg. Her condition requires agents targeting other pathways. For now, she is on lisinopril, with BP <110/75, and amiloride to limit polyuria.

Case #2 Bilateral renal cysts in X-linked Alport syndrome

PO1283
Heterozygous HSD11B2 Gene Mutations and Apparent Mineralocorticoid Excess (AME) in a Patient with Heterozygous ADPKD1
Celeste S. Chang,1,2,4 Hsiang C. Liu,3 Chinatown Kidney Care, New York, NY; Mount Sinai Beth Israel Hospital, New York, NY; Wei Gong Memorial Hospital, Toufen, Taiwan.

Introduction: HSD11B2 gene which locates at Chromosome 16p13.3. PKD1 gene forms a complex with polycystin-2 (PKD2) that regulates multiple signaling pathways to maintain normal renal tubular structure and function. We present a new finding of HSD11B2 gene in a patient with polycystic kidney disease.

Case Description: 58-year-old Chinese male presented with bilateral renal cysts and CKD Stage 3 A. PMHx is significant for early onset HTN at the age of 45, Left ICH at the age of 52, Right ICH at the age of 58 years with the clinical course and prognosis much less well defined. His BP was 145/91 mmHg, not controlled well with daily dose of oral Lisinopril 40 mg and Amlodipine 10 mg. His Na 141, K 4.7, CO2 27, BUN 20, Cr: 1.6, GFR: 46, Hb 12.5 and Urine protein/ Cr ratio was 0.324. He was started with low dose of Spironolactone 12.5 mg daily for BP control and proteinuria. Renal ultrasound showed Right kidney was 19.5 cm, left kidney was 18.6 cm and presence of multiple bilateral renal cysts. Abdominal CT without contrast disclosed HIKV: 1724 ml/m. Mayo clinic class was 1 C, estimated frequency of ESRD at 10 years was 37.8%. Kidney gene panels detected the gene of PKD1 (Autosomal Dominant) and HSD11B2 (Autosomal Recessive). BP stable at 125/78 mmHg, 24-hour urine protein was 125 mg per day, Serum cortisol 11 mcg/dl (normal: 8-19 mcg/dl), Serum cortisone: 0.74 mcg/dl (normal: 1.34 - 2.68 mcg/dl), Serum cortisol/cortisone ratio: 17.6 (normal: 3.9-11), 24 hours Urine free cortisol: 7 mcg/day (normal 5-64 mcg/day), 24 hours Urine free cortisone: 31 mcg/day (normal 16-128 mcg/day), 24 hours Urine free cortisol/cortisone ratio: 0.22 after spironolactone. However, it was discontinued upon repeated serum K was at the higher side of normal. He is currently treated with oral Tolvaptan.

Discussion: This is an unique case which could be the first case report of HSD11B2 mutations with apparent mineralocorticoid excess associated with heterozygous ADPKD1.

PO1284
A Rare Presentation of Autosomal Recessive Polycystic Kidney Disease in Adulthood
Katerina Hysi, Saira Sajidal, James Drakakis. NYU Winthrop Hospital, Mineola, NY.

Introduction: Autosomal recessive polycystic kidney disease (ARPKD) belongs to a group of congenital hepatoportal fibrocystic syndromes and causes significant renal and liver related morbidity and mortality in children. Renal cysts, congenital hepatic fibrosis, and recessive inheritance characterize ARPKD. The disorder usually manifests infancy, with a high mortality rate in the first year of life. For the patient who survives the neonatal period, the probability of being alive at age 15 ranges from 50-80%, with the majority requiring renal replacement therapy at that age. This diagnosis is rarely made in the adult years with the clinical course and prognosis much less well defined.
Case Description: 57-year-old male with PMHx of gout and long standing CKD with creatinine 1.09 mg/dL, blood pressure 140/100 mmHg. During his annual physical in 2010 with little progression was evaluated for urination. Urinalysis was without microscopic hematuria or proteinuria. Historic imaging showed small kidneys and medical renal disease. An updated MRI noted bilateral kidneys cysts with areas of atrophy and scarring, which along with an increase in renin by historical history with congenital hepatic fibrosis, raised possibility of ARPKD. The patient subsequently underwent whole exome sequencing, which confirmed two pathogenic variants (specifically S3018F and R1624W) in the PKHD1 gene, consistent with ARPKD. His brother was eventually tested as well and found to have the same two variants.

Discussion: The classic presentation for ARPKD is systemic hypertension with progression to ESRD by the age of 15. In a typical presentation, a small number of those with ARPKD live to adulthood with some compromise of kidney function; but with significant liver dysfunction. Due to its wide phenotypic variability, the diagnosis of ARPKD may be made during any stage of childhood; in rare cases, it does not present until adolescence or adulthood. A minority of affected individuals present as older children or young adults with evidence of hepatic dysfunction or otherwise unexplained renal cysts as the prominent presenting feature. This case exhibits the silent menace of ARPKD with a delay in recognition of clinical manifestations and thus an unusually older age at the time of diagnosis.

PO1285
Hypoparathyroidism, deafness, and renal disease (HDR) syndrome, also known as Barakat syndrome, is a rare autosomal dominant disorder caused by heterozygous variants in GATA-3. GATA-3 belongs to a family of dual zinc finger transcription factors that is involved in embryonic development of the inner ear, kidneys, and pancreas. The exact prevalence of HDR syndrome is unknown, but less than 200 cases have been described. The disease has variable expressivity even within the same family. Making a diagnosis can be challenging, more so in individuals with no laboratory abnormalities. Herein we describe a father-daughter dyad with HDR syndrome with variable disease expression.

Case Description: A 7-year-old female with history of congenital deafness, multicystic dysplastic kidney, reflex nephropathy, and multiple urinary tract infections underwent genetic testing. Exome sequencing revealed a heterozygous missense variant in GATA-3 (c.4870C>A, p.Arg1624His). The missense variant was ultrarare, predicted pathogenic, and classified as likely pathogenic.

Mutation in GATA-3 in this patient and her father led to the identification of HDR syndrome in his daughter. Screening family members is important to detect other affected individuals.

PO1286
Assessing Genomic Needs
Jordan G. Nestor,1 Sumit Mohan,1,2 Ali G. Gharavi,1 Chunhua Weng.1
1Columbia University, New York, NY; 2Columbia University Mailman School of Public Health, New York, NY.

Background: Interventions must address nephrologists' knowledge gaps, perceived needs for education, and communication of genomic data to guide personalized patient care.

Methods: U.S. Boarded nephrologists were invited to complete an anonymous electronic needs assessment survey on genomic implementation that incorporated multiple themes e.g., objective knowledge, attitudes perceived barriers. Its design was informed by a comprehensive literature review and adapted published tools. Descriptive statistics were used to summarize demographics and baseline characteristics.

Results: Between January-May 2021, 319 complete surveys were eligible for analysis by nephrologists across 47 U.S. States, (86% adult vs. 14% pediatric), with 34% community-based (vs. 66% academic) including 36% who perform transplant evaluations. 413 nephrologists were more likely to cite limited experience, educational resources and limited access to experts as perceived barriers to implementation of genomics compared to those in academic practice.

Conclusions: Our findings highlight variable levels of experience and comfort using genomics and can inform the design of tailored interventions that address nephrologists specific needs, including education, workflow and clinical-decision support tools. Together, such tools can promote wider utilization of genomic resources and empower nephrologists to use genomic data.

PO1287
Pediatric Nephrologists’ Perspectives on Genetic Testing and Return of Results to Children

Background: Pediatric (ped) nephrologists care for children with genetic causes of chronic kidney disease (CKD). While genetic testing (GT) is now more accessible in nephrology, little is known about the utility, clinical application, and relevance of GT in determining underlying CKD or other actionable secondary genetic findings for ped nephrology patients. We explored ped nephrologists’ views regarding GT in clinical and research settings.

Methods: An online 30-item survey was developed and distributed via professional listserves. Inclusion criteria required self-identification as a U.S. licensed nephrologist. Data collection was from 1/22/21-5/4/202 and analyzed by STATA 15.1. Descriptive statistics are reported.

Results: 85 ped nephrologists completed the survey. Respondents range in yrs in practice (35% 6-15 yrs, 21% 16-25 yrs, 28% > 25 yrs), and 75% practiced in a university hospital. Most had referred > 20 patients for GT (61%). GT was considered clinically important for disease diagnosis (92%), understanding (85%), prognosis (86%), treatment options (84%), family counseling (88%), and kidney transplant planning (93%). 68% report they have reliable information for care of patient with genetic results. Top 3 challenges to GT were interpretation of results, selection of test, and ordering test. 86% identified fitting the test and results to the patient as a top priority.

Conclusions: Our findings highlight variable levels of experience and comfort using genomics and can inform the design of tailored interventions that address nephrologists specific needs, including education, workflow and clinical-decision support tools. Together, such tools can promote wider utilization of genomic resources and empower nephrologists to use genomic data.

Underline represents presenting author.

413
are involved in the return of results in their own practice (60%). Regarding the return of research-based results, most thought diagnostic (92%) and actionable secondary findings (75%) should be returned.

Conclusions: Ped nephrologists report on the importance of GT in CKD. They also report on their personal challenges with GT and structural barriers to the utilization of GT.

POI1288

Attitudes and Perceptions of APOL1 Genetic Testing in Black Patients with Hypertension: A Pilot Study

Krista L. Lenting,1 Anthony N. Muiru,2 Kathryn K. Lindsay,1 Amy Mosman,1 Yasar Caliskan,1 Barry J. Friedman,1 Amber Carricker,1 Chi-juan Hsu,1 Kana N. Miyata,1 Thanh-Mai N. Vo,1 John C. Edwards,1 Marie D. Philippen,1 Saint Louis University School of Medicine, Saint Louis, MO; 2University of Kansas Medical Center, Maywood, IL; 1Loyola University Medical Center, Chicago, IL

Background: A portion of the chronic kidney disease risk in Black persons appears due to polymorphisms in the gene encoding apolipoprotein L1 (APOL1). While applications of APOL1 genotyping for prognostication (e.g. in evaluation of organ donors) are emerging, the interest of Black patients in APOL1 genotyping and implications for individual kidney risk management are not well defined.

Methods: In this pilot study, we offered APOL1 genetic testing and assessed attitudes and concerns related to APOL1 testing and kidney risk management among Black persons seen in the Hypertension & Nephrology clinics at one urban, Midwestern center.

Results: Among 110 participants with genotyping results to date, 56% were women, mean age was 58 years, 72% were obese, and a mean of 3 antihypertensive agents were used (Table). 13% had 2 APOL1 renal risk variants (high-risk genotypes), and 42% had 1 risk variant. At baseline, most participants (86%) reported that they were concerned about kidney disease, 90% thought it was a good idea to be tested for genes that may impact kidney disease, 82% would want APOL1 testing for their children, and only 26% expected to feel upset if they were APOL1 high risk. Most participants reported that knowledge of a high-risk APOL1 genotype would lead to changes in health-related behaviors. Ongoing research is needed to determine optimal patient-centered use of this emerging risk assessment tool.

POI1289

Utility of Genetic Testing in Informing Management of Patients with Kidney Disease

Daniel W. Ross,1 Kenar D. Jhaveri,1 Laurel Kartchner,2 Dinah Clark,2 Kerry Gaj,2 Deepa A. Malieckal,1 1Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; 2Natera, Inc., San Carlos, CA.

Background: Early identification of monogenic causes of CKD through genetic testing can improve disease treatment, inform management and improve outcomes. Genetic testing can also be useful for families with a history of CKD to plan for the future, including appropriate identification of organ donors. Here we describe the use of genetic testing, with RenasightTM, an NGS-based >380 gene panel for kidney disease, to inform treatment for patients being treated for kidney abnormalities.

Methods: We performed a retrospective analysis of genetic test results using RenasightTM (NGS-based>380 broad kidney gene panel) at a large academic center over an 18-month period. After signed informed consent, broad genetic testing was performed on blood or saliva samples from 31 patients. Genetic testing results were then related to alterations in the management of treatment of these patients.

Results: In this cohort, 41.9% (13/31) were female with an average age 51 years. The most common demographic groups were African American and Caucasian (6 patients [19.4%]; each). Nineteen patients (61.3%) underwent Renasight testing due to a CKD diagnosis, 5 (16.1%) due to nephritis/nephritic syndrome, 3 (9.7%) due to proteinuria/ nephrotic syndrome, 1 (3.2%) due to thrombotic microangiopathy, 1 (3.2%) due to phosphorus metabolism disorder, and 1 (3.2%) due to hemorrhochromatosis. Positive results were identified in 12.9% (4/31) of the patients in the COL11A1, COL4A4, and APOL1 genes. Genetic testing results led to changes in management for 35.4% (11/31) of patients, confirmed diagnoses for 22.6% (7/31), provided additional diagnoses for 41.9% (13/31), and prompted family testing for 22.6% (7/31). For 4 patients with positive findings, test results impacted treatment management: 1 had transplant management impacted, 1 underwent biopsy to confirm Alport Syndrome, 1 had FSGS diagnosis confirmed and 1 underwent biopsy to confirm FSGS and initiated dialysis. Additionally, negative results led to alterations in management for 48.4% (15/31) of patients.

Conclusions: In this cohort at an academic practice, genetic testing informed nephrologists' management of the patients in multiple capacities. Negative results can rule out genetic causes of disease, and carriers and variants of uncertain significance (VUS) can inform family planning decisions and enable testing in family members.

POI1290

Early Experience with Broad-Panel Genetic Testing in Pre- and Post-Transplant Evaluation of Patients with Kidney Failure

Rupi K. Sodhi,1 Amishi S. Desai,1 Jongwon Yoo,1 Divya J. Arwindeker,1 Katya Brossart,2 Hossein Tabriziani,1 Sanjeev Akkina,1 Loyola University Medical Center, Maywood, IL; 2Natera, Inc., San Carlos, CA.

Background: Genetic testing plays an important role in kidney transplantation (KT). Genetic assessment during the pre-KT workup enables more accurate estimation of the risk of recurrent kidney disease and informs treatment of recurrence living-related kidney donor selection. Testing with a broad genetic panel may be beneficial for patients with advanced disease. Here we describe an academic transplant center’s early experience with a >380 gene kidney disease panel using NGS, with variant confirmation via orthogonal methods.

Methods: Twenty-six pre- and post-KT patients underwent genetic testing between June 2020 and April 2021. Patients ranged in age from 28 to 67 years, with a median age of 31 years. Genetic testing results were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 38.5% (10/26) of patients tested, in TTR, COL4A3, COL4A4, COL4A5, COL11A1, INF2, and PKD1. Two patients with a pathogenic variant in the TTR gene also had 2 APOL1 risk alleles (G1 and/or G2). Genetic findings confirmed clinical disease in 1 individual, identified a subcategory of clinical disease in 2 individuals, reclassified disease in 3 individuals, and established a molecular diagnosis in 4 individuals. In this cohort, 8 individuals received a KT, of which 6 had no pathogenic variant identified. Of those 6, two had biopsy proven glomerular disease that recurred after early KT, implicating a non-inherited cause of renal disease. Identification of positive pathogenic variants in 75% (3/4) of patients evaluated for a living related donor transplantation, prompted evaluation of the intended donors.

Conclusions: Identification of patients awaiting KT who are at increased risk of a monogenic disease can result in a high yield via a broad-panel testing approach. The implications of a genetic diagnosis in this cohort are multifaceted, with potential to impact care and identify family members who may be at risk for kidney failure, and to enable early diagnosis and intervention.
PO1291

Early Experience with Broad-Panel NGS Testing for Kidney Disease in a Community Nephrology Setting
Tarek Darwish1, Katya Brossart2, Hossein Tabriziani2, Kansas City Kidney Specialists, Overland Park, KS; 3Nitera Inc., San Carlos, CA.

Background: Despite the increasing awareness of the value of incorporating genetic testing, its adoption in community nephrology settings is limited. Genetic testing can guide prognosis, targeted treatments, referral to specialists for extra-renal features, and identification of at-risk relatives. For individuals with kidney failure, additional testing can help assess the risk of recurrent kidney disease after transplant and evaluation of suitable living related kidney donors. Broad-panel testing can provide benefits over narrow panels based on clinical presentation.

Methods: Thirty-one patients with kidney disease completed genetic testing with the Renasight® test (NGS-based >380-genie kidney disease panel) between October 2020 and April 2021. Median age of patients was 49 years (range: 28-78 years). Genetic testing results were correlated to clinical histories, demographic factors, family history (when available) and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.

Results: Positive findings were identified in 22.6% (7/31) of patients tested in the APOL1, PKD1, SLC2A9, COL4A4, and PKD2 genes (Table 1). Testing resulted in 36.4% (11/30) of patients in 85.7% (6/7) of patients and in changes in clinical management for 28.6% (2/7) of patients. Homozygosity or compound heterozygosity for the APOL1 high risk alleles G1 and G2 was identified in 9.7% (3/31) of patients and were found primarily in African American patients.

Conclusions: In the community nephrology setting, the utility of genetic testing as part of the diagnostic workup is multifaceted. As compared to selection of a narrow panel based on clinical features, use of a broad panel that includes reporting of the APOL1 high risk alleles has the additional benefit of identifying genetic causes of kidney disease with ambiguous or non-specific clinical findings.

PO1292

KIDNEYCODE: A Genetic Testing Program for Patients with CKD
Prasad Devadaran1, Kenneth V. Lieberman2, Xiangling Wang, Bradley A. Wang, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 1Children’s Mercy Hospitals and Clinics, Kansas City, MO; 2Tufts Health, Danville, PA; 3Cleveland Clinic, Cleveland, OH.

Background: Knowledge about the genetic causes of chronic kidney disease (CKD) is one of the key gaps in global kidney research. Recent International Society of Nephrology recommendations encourage the adoption of genetic testing to provide precision medicine based on individual risk. A recent whole-exome sequencing study showed that genetic inheritance may be responsible for up to 10% of CKD diagnoses in adults, many of which may be previously undiagnosed or mis-diagnosed. Continued advancements in DNA sequencing technology have made genetic testing applicable to routine clinical diagnosis.

Methods: KIDNEYCODE offers no-charge genetic testing for three rare forms of CKD: Alport syndrome (AS), focal segmental glomerulosclerosis (FSGS), and 2 forms of polycystic kidney disease: autosomal dominant polycystic kidney disease (ADPKD) due to PKD2 mutations and autosomal recessive polycystic kidney disease. Invited renal disease panel includes 18 genes (ACTN4, ANL1, APOL1, CD2AP, COL4A3, COL4A4, COL4A5, CRBP2, HNF1A, IN2, LMX1B, MYOIE, NPHS1, NPHS2, PA2, PKHD1, PKD1, and TRPC6). Patients in the US with eGFR ≥ 90 mL/min/1.73 m² hematuria or a family history of CKD, or with a known or suspected diagnosis of AS or FSGS are eligible for testing. Family members of those with suspected or known AS or FSGS are also eligible. All participants have access to genetic counseling follow-up at no additional charge.

Results: To date, the KIDNEYCODE program has results from 1389 genetic tests. Genetic variants were reported in 845 patients. Of those, 574 patients had 613 variants in COL4A3, 4, or 5 genes (403 Pathogenic/Likely Pathogenic (P/LP), 210 Variants of Uncertain Significance (VUS)), 284 patients had 302 variants in genes associated with FSGS (55 P/LP, 247 VUS), 112 patients had 115 variants in PKD1 (15 P/LP, 100 VUS), and 22 patients had 24 variants in PKD2 (7 P/LP, 15 VUS), and 75 patients had a VUS in APOL1.

Conclusions: Results from the KIDNEYCODE genetic testing program demonstrate that combining genetic testing with clinical presentation and medical history can improve accuracy of diagnosis among patients with hereditary CKD.

The Emerging Role of Whole-Genome Investigation to Identify Undetected Nephropathies: The HIDDEN STUDY
Andrew J. Mallett1, Amali Mallawaarachchi2, Zornitza Stark2, Cas Simons3, Catherine Quinlan4, Chirag Patel1, The KidGen Collaborative "Townsville Hospital and Health Service, Townsville, QLD, Australia; 2James Cook University, Townsville, QLD, Australia; 3Royal Brisbane and Women's Hospital, Darlington, NSW, Australia; 4Royal Prince Alfred Hospital, Camperdown, NSW, Australia; 5Murdoch Children Research Institute, Parkville, VIC, Australia; 6The Royal Children’s Hospital Melbourne, Parkville, VIC, Australia; 7Royal Brisbane and Women’s Hospital, Herston, QLD, Australia.

Background: 5% of Australian and New Zealand patients commencing kidney replacement therapy have an uncertain kidney disease etiology. New approaches and tools are required to resolve such diagnostic odysseys. WGS is an emerging diagnostic technology whose role in the setting is unclear. We sought to determine the diagnostic yield of whole genome sequencing (WGS) in individuals with unexplained end stage kidney disease (ESKD).

Methods: Adult and paediatric patients reaching Chronic Kidney Disease Stage 5 before 51 years of age without an identified etiology were prospectively recruited through an Australian national network of 18 clinics. Eligibility was determined by a national clinical committee based on pre-specified criteria. Clinically-accrued WGS analysis was undertaken with a curated “KidneyOme” virtual panel of genes associated with identified kidney disease disorders. A genomic diagnosis constituted a KidneyOme result of pathogenic or likely pathogenic variant/s of appropriate zygosity.

Results: 168 individuals were referred (2018-2021) of whom 147 were approved and 104 consented. Of these, 40 (38.5%) were female and median age was 43 yrs; 41 (38.5%) had previous kidney function and ESKD before 30yrs and 63 (60.6%) had undergone native kidney biopsy. Of 50 results returned to date, 7 (14%) were diagnostic, including both autosomal dominant (4/7) and recessive (3/7) inheritance patterns with 6/7 having a family history of CKD. A further 14/50 had variants of uncertain significance. One diagnosis was due to a copy number variation. The KidneyOme virtual panel curation of 384 genes is publicly available in PanelApp-Australia.

Conclusions: One in seven patients with ESKD of uncertain etiology had an undetected underlying monogenic cause for their kidney disease. Application of KidneyOme with WGS has diagnostic utility and should be considered in younger patients with unexplained renal failure.

PO1294

The Utility of an Inherited Kidney Disease Clinic Employing a Broad Range of Genomic Testing Platforms: Experience of the Irish Kidney Gene Project
Eilhuisen A. Elhassan1, Katherine A. Benson2, Susan L. Murray1, Kane E. Collins3, Edmund H. Gilbert, Dervla M. Connaughton4, Claire Kennedy3, Mark A. Little, Gianpietro Cavallieri, Peter J. Conlon1,5; 1St. James’s University Hospital, Dublin, Ireland; 2Royal College of Surgeons in Ireland, Dublin, Ireland; 3Royal College of Surgeons in Ireland, Dublin, Ireland; 4Western University Schuluic School of Medicine & Dentistry, London, ON, Canada; 5Western University Division of Nephrology, London, ON, Canada; 6Saint James’s Hospital, Dublin, Ireland.

Background: Inherited kidney diseases (IKD) are increasingly identified in adult patients. Here we demonstrate the diagnostic and clinical impact of evaluating patients with suspected IKD in a dedicated IKD clinic (IKDC) utilizing various genomic testing technologies (whole-exome sequencing, comprehensive gene-panel, and dedicated MUC-1 sequencing) and immunostaining.

Methods: We undertook a prospective cohort study of adult patients referred to an academic medical centre with suspected monogenic cause as part of the Irish Kidney Gene Project (IKGP), between 2014 and 2020. Patients with chronic kidney disease (CKD) who had either a positive family history, extrarenal features, or had CKD of “unknown cause” (<u>u</u>CKD) were recruited from various centres across Ireland. We attempted to identify disease-causing variants and to assess the impact of the IKDC from diagnostic and clinical perspectives.

Results: During this period, genetic testing was performed for 677 adults (n= 501 families). The median age was 53 years (range, 18-93 years) and 73.9% participants had reported a family history of renal disease. We achieved a molecular diagnostic rate of 34% (n= 228). Among the identified disease-causing variants, PKD was the largest cohort (n= 183, 47.8% for PKD1 and PKD2), while mutations in three other causative genes were most prevalent among the remaining identified 42 genes encompassing several Mendelian disorders; MUC-1 (n=31, 8.1%); COL4A5 (n=30, 7.8%); UMOD (n=13, 3.3%). In the remaining 167 disease-causing variants excluding PKD, the diagnostic yield of WGS was confirmed in 60.5% and 18% of cases were reclassified. A molecular diagnosis was established in 27 (36.5%) patients with uCKD, implying the end of their diagnostic odyssey. Clinically, a diagnostic kidney biopsy was unnecessary in 13 (17.7%) patients based on the genomic testing. 80 (47.3%) had their treatment plan altered and further 76 (45%) patients had appropriate cascade testing.

Conclusions: The IKDC is a valuable resource and the implementation of a broad range of diagnostic platforms has a direct clinical and therapeutic impact on treatment of patients with IKD.
PO1295
Characterization of Patients with Alport Syndrome in the United States: A Retrospective Analysis of Medical Claims
Baris Deniz,1 Aparna Singheetham,2 Ishan Goradia,3 Ashwaryaa Clarivate,2
1Reata Pharmaceuticals Inc, Irving, TX; 2Clarivate Analytics US LLC, Philadelphia, PA.
Background: Alport syndrome (AS) is a rare, hereditary genetic condition that often results in chronic kidney disease and may lead to early onset of end-stage kidney disease. The prevalence estimate in the literature is around 30,000-60,000 in the US. However, there are challenges with AS diagnosis (i.e. underdiagnosis and misdiagnosis), hence real-world patient population with AS diagnosis can be less than the prevalence estimates. This study is a retrospective analysis of medical insurance claims aimed to get a real-world estimate of the number of patients with a formal diagnosis of AS in the US, their disease characteristics, and treatment patterns.
Methods: A retrospective, observational cohort analysis was conducted, that leveraged DRG/Claim medical claims database, that integrates multi-payer and multi-plan data and covers ~220 million annual patients in the US. Patients with at least one ICD-10 code (Q87.81) designated for AS in their medical history between October 2015 to September 2020 were considered diagnosed AS cases. Characteristics of patients and prescription data were analyzed descriptively. Patient interactions with health care professionals (HCP) within the last 24 months of the study window (i.e. October 2018 – September 2020) were used to determine the primary HCP responsible for patient management.
Results: The analysis identified total of 10,387 patients with at least one AS diagnosis code. Of the 42% of the population for whom chronic kidney disease (CKD) stage data were available, 44% had advanced CKD (IV & V). Adult or pediatric nephrologists were the primary HCPs for 59% of patients. Based on the prescription data, 21.6% (2,244 patients) were prescribed ACEs/ARBs, and 10.6% (1,101 patients) were prescribed CYP3A4 inhibitors.
Conclusions: The number of patients our study identified with AS diagnosis is lower than the commonly cited prevalence estimates in the US. The discrepancy can be explained by the fact that the database used covers a majority of but not the whole US population, and our study relied on real-world diagnoses.
Funding: Commercial Support - Reata Pharmaceuticals

PO1297
Utilization of Broad-Panel Genetic Testing for Collagen Disorders of the Basement Membrane Disorders in Patients Requiring Kidney Transplantation
Rungi K. Sodhi,1 Amishi S. Desai,1 Jongwon Yoo,2 Divya J. Arwindeker,3 Katya Brossart,2 Hossein Tabriziani,1 Sanjeev Akkinia,1 Loyola University Medical Center, Maywood, IL; 2Natera, Inc., San Carlos, CA.
Background: Patients with advanced chronic kidney disease (CKD) are often misdiagnosed. End-stage kidney disease (ESKD) significantly impacts the selection of candidates and donors for kidney transplant (KT), and post-KT management. Identification of a genetic etiology can reclassify disease and alter KT planning. Collagen disorders such as Alport syndrome present with heterogeneous phenotypes. However, a recently proposed classification system incorporates genetic variants into the diagnosis of this disease.
Methods: Twenty-two pre- and post-KT patients with a median age of 33 years (range: 26-67 years), completed genetic testing with Renasight® (a NGS-based >380-gene kidney panel), between June 2020 and April 2021. Test results related to COL4A were correlated to clinical histories, including biopsy (when available), ultrasound results, presence of proteinuria and hematuria, demographic factors, family history and comorbidities. Certified genetic counselors interpreted the results and provided consultation to patients on request.
Results: Pathogenic or likely pathogenic variants in a type IV collagen gene were identified in 18.2% (4/22) of patients. All four patients had progressed to ESKD at the time of testing. One patient, with a variant in COL4A4, had a right nephrectomy and subsequently developed nephrotic range proteinuria. The second patient, with a variant in COL4A4, had genetic testing after a living related KT; the donor was subsequently re-evaluated and there were challenges with AS diagnosis. The third and fourth individuals, brothers with a family history of CKD, for which the same familial COL4A4 variant was identified, were both carriers of the APOE G1 risk allele. One brother had biopsy-proven FSGS and did not respond to steroids.
Conclusions: Broad panel testing enables the identification of monogenic causes of CKD that can impact the selection of KT candidates and post-KT management. In this study, molecular diagnosis and genetic subtyping of type IV collagen disorders allowed providers to counsel patients at risk of disease recurrence and donor limitations in potential living related donors. KT recipients with causal COL4A4/5 variants have a low risk of recurrence in the allograft and will likely not require extensive therapy during after transplant.

PO1298
Genotype-Phenotype Analyses in Korean X-Linked Alport Syndrome: A Multicenter Study
Hi Hyun Kim,1 Ha Il Cheong,2 Hee Gyun Kang,2 Yu Han Ahn,2 Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Hallym University Dongtan Sacred Heart Hospital, Hwasong, Gyeonggi, Republic of Korea.
Background: X-linked (XL) inheritance, caused by COL4A5 mutation, is most common in Alport syndrome (AS). Many clinical studies have elucidated the correlation between genotype and phenotype in male XLAS, whereas no association has been found in female XLAS. Here, we analyzed genotype-phenotype correlation in Korean XLAS.
Methods: This multicenter, retrospective study collected XLAS cases who had been diagnosed from 1985 to Jan 2021 in 13 tertiary centers of Korea. Sanger or next-generation sequencing were conducted in clinically suspected AS patients (male:female 96:42 from 121 Korean families) for genetic confirmation. We divided the cases into two groups according to the genetic variant types: 1) homozygous or similar variant type (n=46); 2) splicing mutations (n=12); 3) frameshift or nonsense mutations (n=38). Kidney survival was compared by the groups using Kaplan-Meier method.
Results: For male XLAS, median age of presentation was 5.1 years (yrs) and onset symptom was severe gross hematuria (n=24), asymptomatic urinary abnormality (n=25) or nephrotic syndrome (n=19). At last follow-up, 54 (56.3%) patients had reached CKD G5 (median age 20.0 yrs) and remi-angiostensin system inhibitors (RAASi) were used in nearly all the patients. Hearing loss (HL) was present in 50%. Kidney survival rate was significantly different (median age of group 1, 29.0 yrs; group 2, 21.4 yrs; group 3, 20.6 yrs, p=0.014). HL showed a similar trend by mutant types (group 1, 32.6%; group 2, 58.3%; group 3, 68.4%; p=0.002). Female XLAS presented at median age of 3.0 yrs and 9 (21.4%) patients were reached CKD G5 at median age of 29.2 yrs. HL was present in 43%. Kidney survival was not significantly correlated with variant types.
Conclusions: There were strong genotype-phenotype correlation in male Korean XLAS. Both male and female XLAS showed similar results consistent with previous papers according to mutant types, but kidney survival rate was worse for all variant types, despite the appropriate use of RAASi. These data could potentially be helpful of counseling with XLAS.

Sparsentan, the Dual Endothelin Angiotensin Receptor Antagonist (DEARA), Improves Kidney Function and Life Span and Protects Against Hearing Loss in Alport Mice with Developed Renal Structural Changes

Dominic E. Cosgrove,1 MichaelAnne Graton,2 Daniel T. Meehan,1 Denise Vosik,1 Jacob D. Madison,1 Duane C. Delmont,1 Gina C. Samuelson,1 Diana Jarocki,2 Radko Komers,3 Celia P. Jenkinson,3 Boys Town National Research Hospital, Omaha, NE; 4Washington University, St. Louis, MO; 5Travere Therapeutics Inc, San Diego, CA

Background: In Alport syndrome (AS), endothelin type A receptor activation is an important mediator of renal and inner ear pathologies. Sparsentan (SP) administered to COL4A3−/− mice (AS mice) in prevention mode delayed increases in proteinuria, renal structural changes and hearing loss (HL). Whether these effects translate into preservation of glomerular filtration rate (GFR), increased lifespan (LS) and protection from HL in mice where renal pathology has initiated is unknown.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (WT-V or AS-V), 60 or 120 mg/kg SP (AS-SP60 or AS-SP120) starting at 4 weeks (W) of age or at 5, 6 or 7W. Baseline and 10W glomerulosclerosis (GS) were evaluated in kidney sections stained with fibronectin. GFR was measured using a transdermal device (Medibeacon) in mice treated from 4W. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75W in AS-V or AS-SP120 mice treated from 5W.

Results: SP began at 4W abrogated the decline in GFR at 9W compared to AS-V mice (GFR ml/min mean ± SD; WT-V 159 ± 58 (n=6), AS-V 54.0 ± 30 (n=10), AS-SP60 148± 21 (n=6), AS-SP120 145 ± 42 (n=15); p<0.001 AS-V vs AS-SP60 or AS-SP120) and provided protection from GS in mice at 10W (P<0.01 AS-SP120 vs AS-V). For LS studies 148 ± 21 (n=6), AS-SP60 5W start 89.0, AS-SP120 6W start 88.0, AS-SP120 7W start 83.0). SP120 began at 5W improved post noise thresholds with prevention of HL at 16 (P<0.005) and 24 Hz (P<0.01) (Mean ± SD dB SPL 16 Hz; WT-V 5 ± 6.1, AS-V 23 ± 9.7, AS-SP120 11 ± 4.2). Conclusion: SP prevents the decline in GFR in AS mice, extends LS and prevents noise-induced HL even in mice with developed renal structural changes. If these results are translated successfully into the clinic, SP may offer a novel treatment approach for reducing both renal injury and protecting hearing in AS.

Interim Analysis of the EAGLE Trial: An Open-Label Study to Assess the Long-Term Safety and Tolerability of Bardoxolone Methyl in Patients with Alport Syndrome

Pablo E. Persad,1 Gerald B. Appel,1 Melanie Chin,2 Bernard V. Fischbach,4 Bertrand Knebelmann,1 Kenneth V. Lieberman,3 Colin J. Meyer,5 Kandai Nozu,4 David K. Packard,6 Bruce S. Spinowitz,10 Stuart M. Sprague,11 Roser Torra,12 Philippe Zaouli,13 Renal Associates PA, San Antonio, TX; 2Columbia University Irving Medical Center, New York, NY; 3Reata Pharmaceuticals Inc, Irving, TX; 4Kobe Daigaku, Kobe, Japan; 5Structure Federative de Recherche Necker, Paris, France; 6Hackensack Meridian School of Medicine, Nutley, NJ; 7The University of Melbourne Medicine at Royal Melbourne Hospital, Parkville, VIC, Australia; 8The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 9Boise Kidney and Hypertension Institute, Meridian, ID; 10New York Presbyterian Queens Hospital, Flushing, NY; 11NorthShore Medical Group, Evanston, IL; 12Universitat Autonoma de Barcelona, Barcelona, Spain; 13Centre Hospitalier Universitaire Grenoble Alpes, Grenoble, France; 14Dallas Nephrology-Associates, Dallas, TX

Background: Alport syndrome is a rare genetic disease affecting up to 60,000 persons in the US.

Methods: EAGLE (NCT03494497) is an ongoing, international, multi-center, open-label, extended access trial evaluating the longer-term safety and tolerability of bardoxolone methyl (bardoxolone) in patients with Alport syndrome who completed a prior qualifying clinical trial (CARDINAL Phase 2 and 3; NCT03019185). At baseline patients were 12 to 70 years old with eGFR 30 to 90 mL/min/1.73 m² and UACR ≥ 3500 mg/g. Patients receive bardoxolone daily and dose is escalated up to 20 mg or 30 mg (for patients with UACR > 3000 mg/g).

Results: As of data cutoff (01/18/2021), 96 patients were enrolled in the EAGLE study, including 79 patients from CARDINAL Phase 3 (placebo: n=46; Bard: n=33), and 17 patients who received Bard in CARDINAL Phase 2. Mean age was 42 years, and 8 (8%) patients were <18. At baseline, mean eGFR was 58.2 ± 21.4 mL/min/1.73 m² and mean UACR was 183 ± 40 mg/g. Increases in eGFR were seen in patients who previously received placebo and initiated Bard treatment in EAGLE. Patients who previously received Bard for two years in CARDINAL also continued to experience mean eGFR increases in their third year of treatment. Bard has generally been well tolerated, with no deaths or drug-related severe adverse events (SAEs) reported in EAGLE to date. No drug-related cardiac SAEs were reported and no changes in blood pressure were observed. Nearly all (94%) adverse events were mild to moderate.

Conclusions: In EAGLE, Bard increased eGFR in patients with Alport syndrome, and increases observed in CARDINAL were sustained in the third year of treatment. To date, the longer-term safety profile of Bard is similar to that observed in the CARDINAL trial.

Integrated Analysis of the Efficacy and Safety of Bardoxolone Methyl in Patients with Alport Syndrome

Bradley A. Warady,1 Rajiv Agarwal,2 Sharon P. Andreoli,3 Sripal Bangalore,4 Geoffrey A. Block,5 Arlene B. Chapman,6 Melanie Chin,7 Prasad Devajaran,8 Keisha L. Gibson,9 Angie Goldsberry,10 Laura H. Mariani,11 Colin J. Meyer,12 Megan O’Grady,7 Peter Stenvinkel,11 Glenn M. Chertow,12 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 2Indiana University School of Medicine, Indianapolis, IN; 3Igie Hospital for Children at Indiana University Health, Indianapolis, IN; 4New York University Grossman School of Medicine, New York, NY; 5US Renal Care Plans, Plano, TX; 6University of Chicago Division of the Biological Sciences, Chicago, IL; 7Reata Pharmaceuticals Inc, Irving, TX; 8Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 9University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 10University of Michigan Michigan Medicine, Ann Arbor, MI; 11Karolinska Institutet, Stockholm, Sweden; 12Stanford University School of Medicine, Stanford, CA

Background: Alport syndrome is a rare and serious inherited form of CKD. An integrated analysis of efficacy and safety was conducted from the CARDINAL Phase 2/3 (NCT03019185) and EAGLE (NCT03749447) trials of bardoxolone methyl (Bard) in patients with Alport syndrome.

Methods: The CARDINAL Phase 2 trial was open-label and enrolled 30 patients ages 12 to 60 years with Alport syndrome, baseline eGFR values 30 to 90 mL/min/1.73 m² and UACR ≥ 3500 mg/g. CARDINAL Phase 3 was an international, multi-center, double-blind, placebo-controlled trial with similar eligibility criteria and randomized 157 patients. EAGLE is an ongoing, open-label, extended access trial that is enrolling patients who completed CARDINAL Phase 2/3 trials.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: A total of 218 patients were included in the analysis (placebo: n=80, Bard: n=138). A majority (61%) of patients were female and receiving renin-angiotensin-aldosterone system inhibitor (83%). Mean age was 40 years, and 31 (14%) patients were <18 years old. Mean baseline eGFR was 60.4 and 62.3 mL/min/1.73 m² and the maximum duration of exposure was 3.2 and 1.9 years for Bard and placebo groups, respectively. The Bard group had significant increases in eGFR from baseline at the last on-treatment assessment (mean±SE: 3.37±1.21 mL/min/1.73 m²; p<0.006). Significant decreases in eGFR were seen in the placebo group (mean±SE: -8.30±1.58 mL/min/1.73 m²; p<0.0001), resulting in a significant difference between groups after treatment withdrawal (p=0.03 vs placebo). Consistent with prior studies, common adverse events (AE) included muscle spasms, aminotransferase increases, and hyperkalemia. Discontinuations due to AEs were uncommon (9 % of Bard and 5% of placebo groups). Across all studies, no major cardiac events were observed and no changes in blood pressure were observed.

Conclusions: Consistent with individually reported prior trials, an integrated Alport syndrome analysis set showed that Bard preserved kidney function with significant on- and off-treatment eGFR benefits and was generally well tolerated by patients.

### PO1302

**Novel Keap-Nrf2 Protein-Protein Interaction Inhibitor UBE-1099 Ameliorates the Severity of Experimental Alport Syndrome**

Shota Kasada,1,2 Mary Ann Suico,1 Sayaka Og,1 Hitoshi Sunamoto,1 Hirohiko Fukuda,1 Futoshji Nara,1 Kazuhiro Onuma,1 Hirofumi Kai,1,3,4 Department of Molecular Medicine, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto City, Japan; 5Pharmaceuticals Research Laboratory, UBE Industries, Ube city, Japan; 6Program for Leading Graduate Schools “HIGG (Health life science: Interdisciplinary and Glocal Oriented) Program”, Kumamoto University, Kumamoto, Japan.

**Background:** Bardoxolone methyl is an electrophilic agent that induces Nrf2 activation by irreversibly and covalently binding to the cysteine residue of Keap1. Bardoxolone methyl has been shown to improve glomerular filtration rate (GFR) in clinical trials, and is attracting attention as a novel agent for chronic kidney disease. However, there is concern about long-term efficacy due to the unknown mechanism of GFR improvement and transient increase in albuminuria. Moreover, irreversible Keap1 inhibitors such as Bardoxolone methyl may covalently bind to other proteins in a non-specific manner and induce side effects due to off-target activities.

**Methods:** We developed a reversible Keap1 inhibitor that inhibits Keap1-Nrf2 protein-protein interaction (PPI) and evaluated its efficacy using Alport syndrome mice model (Col4a5-G5X). Development of Keap1-Nrf2 PPI inhibitor was performed by fluorescence polarization and Nqo1 induction test. The obtained novel compound UBE-1099 (30 mg/kg/day) and CDDO-Im (3, 10 mg/kg/day; rodent tolerable Bardoxolone methyl analogue) were orally administered to Alport mice and efficacy was evaluated.

**Results:** UBE-1099 showed higher Nqo1 induction efficiency compared with CDDO-Im in mouse renal tissue. While CDDO-Im only improved inflammation pathology in Alport mice, UBE-1099 uniformly improved renal function (GFR and Plasma creatinine, but not albuminuria), podocyte injury, glomerulosclerosis, inflammation and fibrosis. Moreover, UBE-1099 treatment significantly prolonged the lifespan of Alport mice.

**Conclusions:** This study firstly revealed the efficacy of Keap1-Nrf2 PPI inhibitor for glomerulosclerosis. We will elucidate next the mechanism of renal pathology improvement, which may provide useful information for Nrf2 activators including bardoxolone methyl for clinical application.

**Patient Global Impression of Change in Patients with Alport Syndrome in the CARDINAL Phase 3 Trial**

Glenn M. Chertow,1 Pablo E. Pergola,2 Rajiv Aggarwal,3 Sharon P. Andreoli,4 Gerald B. Appel,5 Sripal Bangalore,6 Geoffrey A. Block,7 Melanie Chin,8 Keisha L. Gibson,9 Angie Goldsberry,10 Kazumoto Iijima,11 Lesley A. Inker,12 Clifford E. Kahan,13 Bertrand Knebelmann,14 Laura H. Mariani,14 Colin J. Meyer,15 Kandai Nozu,16 Megan O’Grady,8 Arnold L. Silva,15 Peter Stenvinkel,16 Roser Torra,17 Bradley A. Warady,18 Stanford University School of Medicine, Stanford, CA; 1Renal Associates PA, San Antonio, TX; 2Indiana University School of Medicine, Indianapolis, IN; 1Riley Hospital for Children at Indiana University Health, Indianapolis, IN; 3Columbia University Irving Medical Center, New York, NY; 4NYU Langone Health, New York, NY; 5US Renal Care, Planx, TX; 6Reata Pharmaceuticals Inc, Irving, TX; 7University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 8Kobe Daigaku Igakui Kenkyuka Igakubu, Kobe, Japan; 9Tufts Medical Center, Boston, MA; 10University of Minnesota Health, Minneapolis, MN; 11Institut Necker-Enfants Malades, Paris, France; 12University of Michigan Medical School, Ann Arbor, MI; 13Boise Kidney and Hypertension Institute, Meridian, ID; 14Karolinska Institute, Stockholm, Sweden; 15Universitat Autonoma de Barcelona, Barcelona, Spain; 16Children’s Mercy Hospitals and Clinics, Kansas City, MO.

**Background:** Alport syndrome is a rare and serious inherited form of CKD affecting as many as 60,000 persons in the US with no specific therapies approved for its treatment.

**Methods:** An international, multicenter, double-blind, placebo-controlled, randomized Phase 3 trial (CARDINAL: NCT03019185) evaluated the safety and efficacy of bardoxolone methyl (Bard) in patients with Alport syndrome 12 to 70 years of age with baseline eGFR 30-90 mL/min/1.73 m² and UACR<350mg/g. As an exploratory endpoint, the trial assessed patient global impression of change (PGIC), a non-disease specific 7-point scale that asks patients to rate how much their illness has changed as very much/much/minimally improved (1, 2, and 3 pts), no change (4 pts), or minimally/much very much worse (5, 6, and 7 pts) after 48 and 100 weeks of treatment.

**Results:** A total of 157 patients were randomized to Bard (n=77) or placebo (n=80). In addition to significant on-treatment and off-treatment increases in mean eGFR relative to placebo (between-group differences of 7.7 ± 2.1 [p=0.0005] at Week 100 and 4.3 ± 1.9 mL/min/1.73 m² [p=0.023] at Week 104, respectively), Bard improved PGIC scores relative to placebo (lower values) after 48 and 100 weeks. Categorical summaries also showed more patients randomized to bardoxolone (34%) reported their condition had improved compared to those on placebo (19%) after 100 weeks of treatment.

**Conclusions:** In CARDINAL, Bard significantly preserved eGFR in patients with Alport syndrome and also resulted in improvements in how patients evaluated their wellbeing.

**Funding:** Commercial Support - Reata Pharmaceuticals

### PO1304

**Treatment with Antisense-Oligonucleotide or Splicing Regulating Proteins for X-Linked Alport Syndrome Cases with Deep Intronic Variant**

Tomoko Horinouchi,1 Tomohiko Yamamura,1 Sadaayuki Naga,1 Yuya Aoto,1 Nana Sakakibara,1 China Nagan,1 Kazumoto Iijima,2 Kandai Nozu,1 Kobe University Graduate School of Medicine, Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

**Background:** X-linked Alport syndrome (XLAS) is a hereditary progressive renal disease caused by mutation in COL4A5. Some cases of XLAS are caused by deep intronic variants: three cases (c.385-756C>G, c.385-749T>A and c.385-645T>A) were ours and cryptic exon inclusion (r.[384_385ins385-764_385-617]) by different deep intronic sequence specificity and few patients can be treated by the same ASO. Therefore, we attempted to modify the splicing pattern not only by ASO but also by proteins important for splicing regulation. U2AF65 is one of the important splicing related proteins binding to polypyrimidine tracts promoting exonization. It has been reported that overexpression of the U2AF65 promotes or suppresses exonization in some circumstances.

**Methods:** We identified four cases of XLAS caused by the presence of the same cryptic exon inclusion (c.[384_385ins385-764_385-617]) by different deep intronic variants: three cases (c.385-756C>G, c.385-749T>A and c.385-645T>A) were ours and 1 (c.385-719G>A) was a reported variant. For these cases, we introduced ASO that could skip cryptic exon. Moreover, using in vitro splicing evaluation system (minigene assay), we attempted to reduce the expression of cryptic exon by overexpression of U2AF65.

**Results:** We succeeded in preventing the cryptic Exon insertion by introducing ASO treatment for patient’s urine derived cells. In addition, in all patients, overexpression of U2AF65 in the minigene splicing analysis system successfully reduced the cryptic exon inclusion.
Conclusions: The cryptic exoposition in deep intron region by nucleotide change is often difficult to identify in silico. The approach may be more effective in ASO treatment, splicing related proteins such as U2AF65 has a potential for the treatment splicing abnormalities with splicing modifications.

PO1305
Small Molecule APOL1 Inhibitors Block APOL1 Pore Function and Reduce Proteinuria in an APOL1-Mediated Kidney Disease Mouse Model
Brandon Zimmerman, Leslie Dakin, Anne Fortier. Vertex Pharmaceuticals Inc, Boston, MA.

Background: Two genetic variants of APOL1 (G1 and G2) are associated with increased risk of kidney diseases. Current treatment options for APOL1-mediated kidney diseases are limited and do not address the underlying cause of disease. Here, we report the discovery of a series of novel small molecule APOL1 inhibitors, including the clinical candidate VX-147, that block APOL1 function in vitro and reduce proteinuria in a transgenic mouse model of kidney disease.

Methods: Microscale thermophoresis was used to assess binding of small molecule APOL1 inhibitors to recombinant APOL1 protein. HEK293 cells overexpressing APOL1 variants were used to quantify inhibition of APOL1-mediated cell death and ion flux. In addition, activity on APOL1 biological function was assessed using a trypanosome viability assay. Finally, changes in proteinuria following APOL1 inhibitor administration were assessed using a transgenic mouse model homozygous for the APOL1 G2 variant (G2 homo).

Results: Small molecule APOL1 inhibitors showed binding to all three forms of APOL1 (wild-type, G1 and G2 variants). In cellular assays, APOL1 inhibitors prevented APOL1-mediated HEK293 cell death and inhibited APOL1-mediated ion flux. Addition of APOL1 inhibitors to trypanosome cultures rescued the parasites from APOL1-induced killing. The potency of VX-147 was consistent across the in vitro functional assays described above (EC50 of approximately 2nM). Finally, administration of APOL1 inhibitors in G2 homo mice induced APOL1 expression, resulting in elevated urine albumin-to-creatinine ratios. Oral administration of VX-147 reduced proteinuria in IFNγ-induced APOL1 G2 homo mice by 74.1%.

Conclusions: Novel small molecule APOL1 inhibitors, including VX-147, bind recombinant APOL1 protein and inhibit its biological function, as demonstrated by trypanosome parasite rescue. These inhibitors block APOL1 pore function, as demonstrated by reduced APOL1-induced death and APOL1-induced ion flux of tetracycline-inducible APOL1 HEK293 cells. Administration of APOL1 inhibitors reduced APOL1-dependent proteinuria in an APOL1-mediated transgenic mouse model of kidney diseases. Taken together, our results strongly suggest small molecule APOL1 inhibitors, such as VX-147, target the underlying cause of disease, and have the potential to treat APOL1-mediated kidney diseases.

PO1306
Inhibition of Endoplasmic Reticulum Stress Signaling Rescues Cytotoxicity of Human APOL1 Risk Variants in Drosophila
Lena Arendt,1,2 Mengxi Chen,1 Lisa L. Kampf,1 Julian Milosavljevic,1 Konrad Lang,1 Martin Hestadstder,1 Tobias F. Hermle,1 Hermle lab Division of Nephrology, University Medical Center Freiburg, Freiburg, Germany.

Background: Renal risk variants of the APOL1 gene are associated with severe kidney disease, putting homozygous carriers at risk. APOL1 G1- and G2-alleles likely represent gain-of-function (GOF) mutations as human subjects with APOL1 null alleles have been found to be without renal anomalies. A wide range of mechanisms that are implicated in cytotoxicity and viability of Human APOL1 Risk Variants in Drosophila.

Inhibition of Endoplasmic Reticulum Stress Signaling Rescues Cytotoxicity of Human APOL1 Risk Variants in Drosophila

Conclusions: Our data reveal ER stress as the essential consequence of APOL1 risk variant expression in vivo, indicating this pathway’s central role in the pathogenesis of APOL1-associated nephropathies.

Funding: Government Support - Non-U.S.

PO1307
A Cohort Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) Started on SGLT2 Inhibitors
Anthony J. Bleyer,1,2 Kendrah O. Kidd,1,2 Hannah C. Ainsworth,1 Victoria C. Robins,1 Abigail Taylor,1 Lauren Martin,1 Alice Kim,1 Venkata Sabbesi,1 Carl D. Langefeld,1 Stanislav Knoch,1,3 Anthony J. Bleyer,1,2 Wake Forest University School of Medicine, Winston-Salem, NC; 1Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; 2Harvard Medical School, Boston, MA.

Background: Sodium-glucose co-transporter-2 inhibitors (SGLT2is) have been shown to slow estimated glomerular filtration rate (eGFR) decline in chronic kidney disease (CKD) but have not been tested in patients with ADTKD. We performed a prospective nested cohort observational study and analyzed changes in eGFR and kidney injury marker 1 (KIM-1) in patients who were prescribed SGLT2is by their physicians.

Methods: We obtained baseline and follow-up laboratory studies at 1 week, 1 month, and 4 months after starting an SGLT2i and compared eGFR with baseline function. We also obtained information about adverse events.

Results: 12 individuals were started on SGLT2is by their physicians, with 10 on empagliflozin, 2 dapagliflozin. Table 1 shows the changes in eGFR and KIM-1. For patients with eGFR > 30, mean eGFR increased at 1 month by 3.6 ml/min. At four months, eGFR was 3 ml/min below baseline (-18.5% due to low baseline eGFR). For eGFR > 30, eGFR decline was 12% from baseline at one month and 8% from baseline at 4 months. Plasma KIM-1 was unchanged, but urinary KIM-1 increased by 100%. One patient stopped empagliflozin at his request after 8 weeks due to decline in eGFR of 14% from baseline. No other adverse events noted. Two patients have been treated for 6 months with stable eGFR.

Conclusions: The change in eGFR after treatment with SGLT2is was consistent with prior studies of CKD. The plasma KIM-1 was unchanged, but the rise in urinary KIM-1 was very concerning. Further study is required to determine if these agents are beneficial in ADTKD. An additional 4 months of follow up will be presented at ASN.

Funding: NIDDK Support, Private Foundation Support

Changes in eGFR and KIM-1 in ADTKD Patients Taking SGLT2 Inhibitors

*Mean was computed as the average change in eGFR for each individual (at time point), compared to their baseline measurement.

PO1308
A Prospective Observational Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)
Kendrah O. Kidd,1,2 Adrijrane H. Williams,1 Victoria C. Robins,1 Abigail Taylor,1 Lauren Martin,1 Alice Kim,1 Martina Zivina,2 Carl D. Langefeld,1 Stanislav Knoch,1,3 Anthony J. Bleyer,1,2 Wake Forest University School of Medicine, Winston-Salem, NC; 1Univerzita Karlova 1 lekarska fakulta, Praha, Czechia.

Background: GFR decline in ADTKD due to UMOD or MUC1 mutations has not been well characterized. We have begun an international prospective cohort study to determine generic and environmental factors associated with progression. We report here on early recruitment

Methods: Patients with positive genetic testing for UMOD or MUC1 mutations prior to transplantation or starting dialysis are eligible. A baseline collection of health information, serum and urine biomarkers will be performed, with patients then followed longitudinally, with a serum creatinine measurement performed three times per year. There will be a nested cohort study of women who develop pregnancy during the study and patients started on ACE inhibition.

Results: Since March 2021, we have enrolled 57 patients in the prospective observational study, with 20 men, 35 women. The mean age of patients is 43.3 years, the mean baseline eGFR is 39.96 ml/min/1.73m2. Table 1 shows baseline characteristics of patients enrolled in the study. No patients with CKD Stage 1 or 2 suffered from HTN, and only 39% of patients with CKD Stage 3 had HTN. Only 18% of patients were receiving ACE/ARB inhibition.

Conclusions: Despite significant CKD, there was a relatively low prevalence of HTN. Only 18% of patients were receiving ACE inhibition, indicating a potential therapeutic intervention. Please contact us if you have a patient who may be interested in participating in this prospective study (tablever@wakehealth.edu).

Vasopressin Induces Urinary Uromodulin Secretion by Activating Protein Kinase A

Azuma Nanamatsu, Takayasu Mori, Fumiaki Ando, Taisuke Furusoh, Shintaro Manda, Koichiro Susa, Eisai Sohara, Tatematsu Rai, Shinichi Uchida. Tokyo Medical and Dental University, Tokyo, Japan.

Background: Urinary uromodulin, secreted by renal tubular cells, protects against urinary tract infections (UTIs) and kidney stones. In contrast, the intracellular accumulation of uromodulin is associated with hypertension and chronic kidney disease (CKD). In addition, uromodulin gene mutations cause autosomal dominant tubulointerstitial kidney disease (ADTDK-UOMD) via abnormal intracellular accumulation of uromodulin. However, the physiological stimuli for urinary uromodulin secretion remain largely unexplained.

Methods: We investigated the acute effect of vasopressin/cAMP signaling on urinary uromodulin secretion in mice and in kidney epithelial cells stably expressing uromodulin. Additionally, we assessed the effect of vasopressin/cAMP signaling in kidney epithelial cells stably expressing mutant uromodulin, which causes ADTDK-UOMD.

Results: Desmopressin, a vasopressin type 2 receptor agonist, dramatically increased short-term tubular uromodulin secretion in mice. Immunofluorescence studies and ultracentrifugation-based polymerization assay suggested that desmopressin induced intraluminal polymeric filaments of uromodulin, indicating physiologically functional secretion. As a result of increased excretion, uromodulin abundance in the murine kidney was clearly reduced by desmopressin. In the cellular model, apical uromodulin secretion was increased in response to vasopressin/cAMP signaling, consistent with in vivo experiments. We also demonstrated that the response was dependent on cyclic AMP-dependent protein kinase (PKA) signaling pathway. We further showed that cAMP signaling induced secretion of mutant uromodulin. cAMP signaling suppressed PERK phosphorylation, which was upregulated by mutant uromodulin, implying cytoprotective effects.

Conclusions: Our work revealed vasopressin/cAMP/PKA signaling as a physiological stimulus of urinary uromodulin secretion. This finding may provide the basis for novel treatment strategies for UTIs, kidney stones, and potentially hypertension.

POI1311

Treatment with 4-Phenylbutyrate Reduces Low-Molecular-Weight Proteinuria in a Cln5 Knock-In Mouse Model for Dent Disease

Ana Perdomo-Ramirez,1 Elena Ramos-Trujillo,2 Gloria Mura Escorcio,2,3 Victor Garcia-Nieto,4 Jose-David Machado,2 Felix Cleaver-Martin,1 Hospital Universitario Nuestra Senora de la Candelaria, Santa Cruz de Tenerife, Spain; 1Universidad de La Laguna, La Laguna, Spain.

Background: Dent disease (DD1) is a rare X-linked tubular disorder characterized by low-molecular-weight-proteinuria (LMWP), hypercalciuria, nephrolithiasis and nephrocalcinosis. This disease is caused by inactivating mutations in the CLCN5 gene, which encodes the voltage-gated CIC-5 chloride/proton antipporter. CIC-5 is expressed predominantly in the kidney and participates in the acidification of proximal tubule endosomes. Currently, the treatment of DD1 is only supportive and focused in delaying disease progression. Our group has generated a Cln5 knock-in (KI) mouse that presents the main clinical manifestations of DD1 and carries the pathogenic mutation p.V523del, which causes partial CIC-5 retention in the endoplasmic reticulum. Here, we aimed to assess the ability of sodium 4-phenylbutyrate (4-PBA), a small chemical chaperone, to ameliorate DD1 symptoms in this mouse model.

Methods: Twelve-weeks old male Cln5 KI mice (n=50) and WT (n=33) littermates were divided into 2 groups, one was treated with 250 mg/kg/day of 4-PBA in drinking water for 21 days, whereas the other group was given water without the drug for the same amount of time. Mice were placed in metabolic cages before and after treatment for 24h. Urinary β2-microglobulin and serum and urinary creatinine were measured by ELISA. Calcium and phosphate concentrations in urine were estimated using colorimetric kits. Water and food intake and 24-h urinary excretion were also measured, and mice body weights were monitored.

Results: We observed a significant reduction of β2-microglobulin urinary excretion in KI mice treated with 4-PBA compared to non-treated animals (p=0.004). Glomerular filtration rate was also improved in treated mice (p=0.03). Urinary production, urinary calcium and phosphate levels were not different compared to non-treated mice.

Conclusions: 4-PBA reduces LMWP in Cln5 KI mice, suggesting that this treatment could represent a promising therapeutic option for some DD1 patients.

Long-Term Efficacy of Migalastat on Renal Function and Outcomes in Patients with Fabry Disease (FD)

Daniel G. Bieche,1 Ulla Frits-Rasmussen,2 Roberto Giugliani,3 Derrick Hughes,3 Eva Kubinska,4 Biliana O. Veleva-Rotse,5 Department of Medicine, Hôpital du Sacré-Coeur, University of Montréal, Montréal, QC, Canada; 2Department of Medical Endocrinology and Metabolism, Rigshospitalet, National University Hospital, Copenhagen University, Copenhagen, Denmark; 3Medical Genetics Service, HCPA, Department of Genetics, UFRGS, and INAGEMP, Porto Alege, Brazil; 4Lysosomal Storage Disorders Unit, Royal Free London NHS Foundation Trust and University College, London, London, United Kingdom; 5Aimmune Therapeutics, Inc., Philadelphia, PA.

Background: FD, caused by pathogenic GLA variants leading to functional deficiency of α-galactosidase A (α-Gal A), can eventually result in key organ damage. Preserving renal function and preventing Fabry-associated clinical events (FACEs) are important treatment goals. Approved therapies include enzyme replacement therapy (ERT) and the pharmacological chaperone migalastat. Stabilized renal function and FACE occurrence up to 30 mo have been reported in migalastat-treated adults with amenable GLA variants; here, we extend these analyses up to 8.6 yrs.

Methods: Integrated data from phase 3 clinical trials (FACETS, NCT00925301; ATTRACT, NCT01218659) and open-label extension studies (NCT01458119; NCT01718853) were used to evaluate the eGFR slope using linear regression in pts treated with migalastat for 2 yrs (n=78). Incidences of FACEs (predefined renal, cardiac, and cerebrovascular events) were assessed in all pts (N=97). Analyses were stratified by prior treatment and phenotype. Cox regression modeling was used to identify predictors of FACEs.

Results: eGFR remained stable for both ERT-naive and ERT-experienced pts who received migalastat for 2 yrs (median [min-max] duration: 5.9 [2.0-8.6]); the mean (SD) annualized rates of change in eGFR (mL/min/1.73 m²) were -1.6 (3.1) and -1.6 (3.6), respectively. In male pts with the classic phenotype (classification based on multiorgan involvement and [ERT-naive only] e-Gal A level at baseline; n=25), mean (SD) rate of change in eGFR was -2.2 (4.4) mL/min/1.73 m². eGFR was also analyzed by baseline renal function and proteinuria levels. In all migalastat-treated pts (median duration: 5.1 yrs), the incidence of composite FACEs (per 1000 patient-years) was 48.3 (65.3 for

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
classic males) and incidence of renal events was 4.4 (14.5 for classic males). Lower baseline eGFR in FACES in classic males vs all others; however, rate of renal events was too low to analyze predictors.

Conclusions: Results demonstrate long-term efficacy of migalastat in stabilizing eGFR in pts with FD, including male pts with the classic phenotype. FACE incidence in receiving migalastat compared favorably to historic reports of ERT. The inverse correlation of eGFR with FACES suggests the importance of early diagnosis and treatment to preserve renal function.

POI1313
Twenty-Year Renal Prognosis in Patients with Fabry Disease Who Underwent Enzyme Replacement Therapy

Akane Miura, Masahiro Okabe, Kotaro Hanahara, Izumi Yamamoto, Nobuo Tsuibo, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.

Background: The relationship between long-term renal prognosis and renal histopathology after enzyme replacement therapy (ERT) for Fabry disease (FD) has not been fully investigated.

Methods: Nine patients with FD from our hospital who had participated in a Japanese phase 2 study (August 2000–May 2001) on agalsidase β were eligible for this case-control study. They underwent repeated renal biopsy (before and six months after agalsidase β treatment), and the intra-renal amount of globotriaosylceramide (GL3) was measured at the same time points. Clinicopathological features were compared between the groups with or without developing end-stage kidney disease (ESKD).

Results: Seven patients (4 classic males) and two patients (2 classic males) were compared. Two were lost to follow-up. All were males, with a median age at the start of treatment of 30 [quartile 24.5, 31.5] years, and median serum creatinine level (s-Cr) of 1.1 [1.0, 1.2] mg/dL. The podocyte score (International Study Group of Fabry Nephropathy score system) improved in all patients after ERT from that evaluated before ERT. Intersitial fibrosis/tubular atrophy (IF/TA) worsened in three patients. The proportion of foamed tubules improved in five patients. Intra-renal accumulation of GL3 decreased six months after ERT in all patients. All patients continued to receive agalsidase β or agalsidase α after the phase II study. With ERT, 4 patients developed ESKD (median 6.7 years), three patients showed no exacerbation of renal function. The s-Cr level, age, and urinary protein excretion at the start of ERT were higher in the ESKD group. The decrease in the intra-renal accumulation of GL3 was not significantly different between the two groups, but the proportion of foamed tubules in the first biopsy and the degree of IF/TA in the second biopsy were higher in the ESKD group than in the non-ESKD group.

Conclusions: This study suggests that tubulointerstitial injury has a crucial role in the determination of renal prognosis and that earlier diagnosis and intervention in patients with FD may improve the renal prognosis. Further studies are needed on the relationship between tubulointerstitial injury and GL3 accumulation.

Systems Analyses of Fabry Renal Transcriptome and Its Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Drugable ERT-Resistant Module

Oystein Eikrem,1,2 Nicolas Delaleu,2,4 Philipp Strauss,2 Miroslav Sekulic,3 Camilla Töndel,1,2 Rannevig Skrunes,1,2 Sabine Leh,2 Einar Svardal,1,3 Elena-Emanuela Rusu,1 Ariana Gaspert,1 Albina Nowak,2 Andrea Rinaldi,1 Hans-Peter Marti,1,2 Department of Medicine, Haukeland University Hospital, Bergen, Norway; Department of Clinical Medicine, University of Bergen, Bergen, Norway; Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 2cSysBioMed, Contra, Switzerland; 3Department of Pathology and Cell Biology, New York, NY; 4Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland; 1Fundeni Clinical Institute, Bucharest, Romania; 3Department of Endocrinology and Clinical Nutrition, University Hospital Zurich, Zurich, Switzerland; 4Institute for Medical Research, Ochsenthal Institut für Biomedizin, Bellinzona, Switzerland.

Background: Fabry nephropathy (FN) is a rare disorder caused by mutations in the alpha-galactosidase A gene that can, to a certain degree, be managed with enzyme replacement therapy (ERT). Via understanding the molecular basis of FN and ERT’s long-term impact, we aim at providing a framework allowing selection of biomarkers and drug targets.

Methods: Obtained from controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies taken prior and up to 10 years of ERT, were subjected to RNAseq. Combining pathway-centered analyses with network-science allowed estimating their suitability as biomarkers and potential targets for adjunct treatment.

Results: Combining transcriptional landscapes comprehensively reflected differences in FN cohort characteristics. With the exception of few key aspects, in particular concerning arteries, early ERT in classical Fabry patients could potentially revert FN kidney-compartment’s molecular state to closely match N. CTRLs. Thus, we identified and cross-validated ERT-resistant modules that, when leveraged with external data, allowed estimating their suitability as biomarkers and potential targets for adjunct treatment.

POI1315
Resistant Focal Segmental Glomerulosclerosis (FSGS) due to Lectin-Cholesterol Acyltransferase (LCAAT) Deficiency: Is Early Gene Testing the Answer?

Mourir A. Qazi,1 Huma Qazi,2,1 Mary-Beth Roberts,1 Richard A. Fatica,1 Robert J. Heyka,1 Xiangling Wang,1 Cleveland Clinic, Cleveland, OH; 2Army Medical College, Rawalpindi, Pakistan.

Introduction: LCAT deficiency is a rare autosomal recessive disorder due to mutations in the LCAT gene presenting with corneal opacities, anemia, proteinuria, reduced HDL and CKD with progression to ESKD by the 4th- 5th decade. Electron microscopy (EM) is characteristic for abundant partially electron-dense and lucent deposits in the mesangium and basement membrane. Late diagnosis is not uncommon due to its rarity and nonspecific presentations in the early stages. Here we report a case of therapy resistant FSGS later unaccounted as LCAT deficiency confirmed by gene tests.

Case Description: A 49-year-old male presented to genetic nephrology clinic in 2020 with a clinical diagnosis of LCAT deficiency. In 2007, he had presented with hematemia, proteinuria with a serum creatinine of 2.4mg/dl, Hb 11 g/dl, albumin 2.4g/dl, total cholesterol 416mg/dl, HDL 14mg/dl and urine protein of 8.9g/d. Urine microscopy showed fine granular casts and dysmorphic RBCs. Kidney biopsy revealed FSGS with moderate tubulointerstitial fibrosis. EM showed some unexplainable intramembranous and subendothelial lucenties, which were thought to be sequelia of prior immune mediated membranous glomerulonephritis. Patient failed treatment with months of steroids, oral cyclophosphamide and mycophenolate. Repeat biopsy in 2010 showed worsening of the prior findings. In 2011, cortical deposits led to a suspicion of LCAT deficiency. He progressed to ESKD in 2011 and kidney transplant in 2020. Genetic testing disclosed a homozygous nonsense variant c.321C>A (p.Tyr107*) in LCAT gene. A thorough genetic counseling included risk for his siblings and graft recurrence.

Conclusions: LCAT deficiency can present with resistant or atypical appearing FSGS. This case emphasizes the need of early genetic assessment on suspicious biopsies or therapy resistant FSGS cases to timely diagnose and avoid unnecessary immunosuppression.

POI1316
ESKD due to Primary Hyperoxaluria Type I

Peter E. Thorns, Julia Lewis. Vanderbilt University Medical Center. Nashville, TN.

Introduction: Primary hyperoxaluria type I (PH1) is a rare autosomal recessive disease (less than 3 cases per million population). Nephrolithiasis and nephrocalcinosis lead to progressive renal impairment and subsequent oxalate deposition in various tissues. We present a case of PH1 diagnosed late in life and ultimately requiring definitive management with liver-kidney transplant due to rapid progression to end stage kidney disease.

Case Description: 55 year old male with history of renal calculi at birth, recurrent nephrolithiasis and PH1 was hospitalized for acute kidney injury following 2 weeks of nausea and poor intake. His admission serum creatinine (Scr) was 11 from baseline of 3.5 four months before. He was diagnosed with PH1 eight months prior via urinary oxalate measurement and genetic testing. He was started on low oxalate diet, calcium carbonate 1000mg with meals and pyridoxine 500mg daily. Ultrasound at admission notable for...
diffuse increased echogenicity and bilateral non-obstructing calculi. Initial serum oxalate level was 63.5 micromol/L and 24 hour urine oxalate level was 116mg/24hrs. Ser failed to improve with intravenous fluid administration and renal replacement therapy was initiated with goal serum oxalate level of <30micromol/L. Hemodialysis was performed daily for four hours with high flux membrane. Serum oxalate levels improved to nadir of 40micromol/L. Definitive therapy with simultaneous liver- kidney transplant was ultimately pursued.

Discussion: Our patient required intensive hemodialysis while awaiting liver-kidney transplant following late diagnosis of PH1 and development of end stage kidney disease. Early diagnosis is key to reduce morbidity and mortality. Progressive kidney impairment leads to inability to excrete the increased oxalate produced by the liver and subsequent systemic deposition of oxalate including in the kidney causing multiorgan dysfunction. Hemodialysis removes oxalate but it is difficult to consistently reduce serum oxalate levels below goal given continued production of oxalate and rebound. Early treatment options include a trial of pyridoxine, hyperhydration, low oxalate diet and novel RNA inhibitors. Patients with advanced disease often require definitive management with liver-kidney transplant. Clinicians need to have a high index of suspicion for PH1 as patients often go undiagnosed until advanced kidney disease or end stage kidney disease has developed.

PO1317

Real-World Healthcare Utilization and Clinical Markers Preceding Dialysis in Patients with Primary Hyperoxaluria (PH) in the United States

John Karafilidis,1 Elnara Fazio-Eynullayeva,1 Lisa Mucha,2 Pamela B. Landsman-Blumberg,1 Seth P. Kurzan,1 TriNetX, Cambridge, MA; 2Dicerna Pharmaceuticals Inc, Cambridge, MA.

Background: PH is the accumulation of oxalate resulting in urolithiasis, nephrocalcinosis, chronic kidney disease (CKD), and eventually end-stage renal disease (ESRD) that usually requires dialysis. This study examined demographics, clinical characteristics, and healthcare utilization (HCU) among dialysis-treated PH patients during the time leading up to dialysis status.

Methods: This was a retrospective study of PH patients (ICD-10: E72.53) initiating dialysis (study entry), on or after October 1, 2018, in TriNetX DataWorx USA, a federated EMR network of 60+ million de-identified patients from 44 healthcare organizations (HCOs). Patient age, sex, race, comorbidities, CKD stage, kidney stone events (KSE), and HCU were examined at least 6 months prior to dialysis, through at least 5 years.

Results: The final study cohort included 47 patients: mean age of 59 years, 53% female, and 85% white. Only 47% had a recorded diagnosis of PH prior to dialysis, and 53% had a diagnosis of ESRD. During the 6 months immediately preceding dialysis, 91% of patients had 1 or outpatient office visit, 17% ≥1 ED visit, and 53% ≥1 inpatient stay. HCU for the full study period showed 98% of patients had ≥1 physician office visit, 51% ≥1 ED visit, and 70% ≥1 inpatient stay (Figure 1). Patients with recorded KSE (n=19; 40%) had a mean of 4 events during the study period. The frequency of KSEs doubled from 1 to 2 per person per year as patients neared dialysis. In the 6 months prior to dialysis, 70% of patients had CKD of stage III or higher recorded in their EMR.

Conclusions: In this real-world study, more than one-half of patients with PH were undiagnosed prior to initiating dialysis, according to the data reviewed. In addition, high rates of costly HCU, including ED visits and inpatient stays, were observed during the same timeframe. The number of KSEs increased over the study period, which may be indicative of worsening renal function due to PH prior to dialysis.

PO1318

Association Between Longitudinal Plasma and Urine Oxalate and Time-to-Kidney Failure in Primary Hyperoxaluria Using Joint Models

Lisa E. Vaughan, John C. Lieske, Phillip Schulte. Mayo Clinic Minnesota, Rochester, MN.

Background: The association between plasma oxalate (POX), urine oxalate (UOX) and time to kidney failure (KF) in patients with the rare disease primary hyperoxaluria (PH) is challenging to study due to small sample sizes and correlations among POX, UOX, and eGFR. To develop better KF models that simultaneously account for all 3 variables we used a novel statistical approach, joint models, modeling longitudinal biomarker processes (eGFR POX, UOX) and survival process (time-to-KF) jointly, using retrospective data from the Rare Kidney Stone Consortium PH registry.

Methods: Repeated eGFR, UOX, and POX after PH diagnosis were obtained from the registry. Time-to-KF was defined as time between PH diagnosis until transplantation, dialysis or eGFR<15 mL/min/1.73m². A multivariate joint model was fit with longitudinal sub-models for each biomarker and a survival sub-model for KF. Longitudinal sub-models employed linear mixed effects models with biomarkers on the log scale. Joint models allowed the exchange of information between longitudinal and survival sub-models such that eGFR, UOX, and POX were time-dependent variables in the survival sub-model, specifically using subject-specific mean biomarker values. Models were adjusted for age and sex at diagnosis. Results were compared to last observation carried forward (LOCF) analyses.

Results: A total 166 patients (mean 5 POX and 7 UOX per patient) with 60 KF events during follow up were included. With LOCF, POX positively associated with KF risk, both unadjusted and adjusted for other biomarkers (hazard ratio (HR) = 1.14 per umol/L, 95%CI = 1.07, 1.22, p<0.001), while UOX was not associated with KF after adjustment. With joint modeling, POX and KF were not significantly associated after adjustment (HR = 1.12, 95%CI = 0.99, 1.30, p=0.08), while higher UOX was associated with lower KF risk (HR = 0.30 per mmol/1.73m²/24h, 95%CI = 0.07, 0.92, p=0.04).

Conclusions: When modeling unevenly spaced longitudinal biomarkers and their association with KF, the LOCF time-dependent model makes implausible assumptions about steady-state biomarkers between observations. Implementation of a joint modeling framework allows flexible estimation of the association, which may impact conclusions. These novel methods can be used to inform patient-specific decisions about future KF risk, and the risk-benefit of novel treatment approaches.

PO1319

Modeling the Risk of Progression to Kidney Failure in Patients with Primary Hyperoxaluria Type 1 Treated with Lumasiran Relative to a Natural History Cohort Not Treated with Lumasiran

John C. Lieske,1 Kristin C. Mara,1 David S. Danese,2 John M. Gansner,2 Jiandong Lu,2 Dawn S. Milliner,1 Mayo Clinic Minnesota, Rochester, MN; 2Alnylam Pharmaceuticals Inc, Cambridge, MA.

Background: In primary hyperoxaluria type 1 (PH1), the risk of kidney failure (KF) is positively associated with urinary oxalate (UOx) excretion. Lumasiran is an RNAi therapeutic to lower UOx levels in patients with PH1. We estimated the risk of progression to KF in patients with PH1 treated with lumasiran, relative to patients not treated with lumasiran.

Methods: A skewed-normal distribution of 24hr UOx values for patients with PH1 was simulated based on reported UOx values from the Rare Kidney Stone Consortium (RKSC) PH Registry among patients who were not in KF at diagnosis and did not receive lumasiran. Data from the ILLUMINATE-A trial of lumasiran were used to build a log-linear model of post-lumasiran treatment steady-state UOx as a function of baseline UOx. The distribution of steady-state, on-treatment UOx values for RKSC patients was then predicted by applying this model to the simulated 24hr UOx values of the RKSC cohort, considering baseline. A risk model of KF as a function of 24hr UOx excretion, based on Kaplan-Meier curves of renal survival reported from the RKSC, was used to estimate the number of KF events/100 patients in the RKSC PH1 cohort, had all received lumasiran.

Results: The mean (SD) 24hr UOx excretion for the RKSC PH1 cohort was 2.2 (1.1) mmol/24hr/1.73m² in the absence of lumasiran treatment and was predicted to decrease to 0.62 (0.17) mmol/24hr/1.73m² in a model that simulated the effect of lumasiran administration (Figure 1). The predicted number of KF events/100 patients (95% CI) using the model for patients not treated with lumasiran at 10, 20 and 30 years, is 10 (4, 23), 32 (19, 50), and 42 (27, 59), respectively. In the model of lumasiran treated, the estimated cumulative number of KF events/100 patients (95% CI) was 4 (1, 12) at 10 years and remained unchanged at 20 and 30 years.

Conclusions: This analysis predicts a long-term reduction in KF risk among PH1 patients treated with lumasiran compared to prompt treatment at diagnosis.

POI1320
The Complex Landscape of Factor H and Factor I Rare Variants in Atypical Hemolytic Uremic Syndrome and C3 Glomerulopathy
Veronique Fremeaux-Bacchi,1,2 Marie-Sophie Meuleman,2 Paula Vieira-Martins,1 Sophie Chauvet,1 Fadi Fakhouri,3 Assistance Publique-Hôpitaux de Paris, Paris, France; 1INSERM U1138, Paris, France; 2Lausanne University Hospital, Lausanne, Switzerland.

Background: Complement genetics has been extensively studied to dissect the pathophysiology of atypical hemolytic uremic syndrome (aHUS) and C3 glomerulopathy (C3G) paving the way for highly tailored therapy. However, the assessment of each identified variant’s contribution to disease pathogenesis remains a challenge in particular for rare variants detected in patients as well as in healthy individuals in the genome Aggregation Database (gnomAD). In this study we aimed to describe the rare variants in Factor H (CFH) and Factor I (CFI) genes identified in the French cohort of patients with aHUS and C3G.

Methods: We analyzed the distribution of the allele frequency (AF) of rare variants identified in 397 and 398 adult patients with a diagnosis of aHUS without coexisting disease and with C3G/ig-mediated membranoproliferative glomerulonephritis (Ig-MPGN), respectively. We selected for this study variants with minor AF (MAF) below 0.1% in European healthy individuals.

Results: The frequency of patients with rare variants in CFH (108/398 vs 54/398) and CFI (33/397 vs 17/397) genes was higher in aHUS compared to C3G. A total of 148 variants were identified in CFH (n=98) and in CFI (n=50) genes. Among them, 9 were present in both diseases. We identified 43 (67%) and 20 (60%) novel variants in CFH in aHUS and C3G, respectively. Among them, 98% are pathogenic compared to 44% of the variants reported in gnomAD. The frequency of variants causing FH and FI diseases is similar in both diseases (70% of the variants). The frequency of CFH variants identified in more than 1 patient is increased in aHUS compared to C3G (n=11/64 vs 2/30). We identified 12 (12/38, 31%) and 2 (2/12, 16%) novel variants in CFH in aHUS and C3G, respectively. Reported variants in CFH are more frequent in C3G than in aHUS (10/12 vs 26/38). The frequency of variants reported in gnomAD is higher in CFH (80%) compared to CFI (14%).

Conclusions: Our study indicates that novel pathogenic rare variants in complement genes is more frequent in aHUS than in C3G. However, half of the variants reported in gnomAD have a potential impact on gene function. Our results suggest that CFH variants are more damaging than CFI variants, and may contribute more significantly to the pathogenesis of both diseases, as compared to CFI.

Phenotypic-Genotypic Relationship of Focal and Segmental Glomerulosclerosis (FSGS)
Ana M. Tata,1 Noa Carrera cachaza,2 Maria Garcia-Murias,2 Amir Shabaka,1 Clara M. Cases Corra,1 Gema Fernandez Juarez,1 Miguel Angel Garcia-Gonzalez,2 Hospital Universitario Fundacion Alcorcon, Alcorcon, Spain; Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain.

Background: FSGS can be of primary, secondary or genetic origin. The objective of our work is to establish in which patients with a histological diagnosis of FSGS a genetic etiology should be suspected.

Methods: The study included adult patients with a histological diagnosis of FSGS and no underlying renal disease. We performed whole exome sequencing on 38 patients with high diagnostic yield (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases had variants affecting INF2, OCRL, HNF1B, WT2. All (3) black patients had high-risk APOL1 alleles. There were no differences between genetic and non-genetic causes in terms of sex, proteinuria, GFR, serum albumin, BMI, hypertension, diabetes, or family history. Hematuria was more prevalent among patients with genetic causes.

Conclusions: Genetic testing should be considered in FSGS patients in which a secondary cause has been excluded, to determine the patient’s prognosis, treatment and perform familial screening.

POI1322
Insight into the Pathophysiology of Hearing Loss and Renal Tubular Dysfunction Through Genetic Testing
Dylan H. West,1 Jones Samuel,2 1Baton Rouge General Medical Center - Bluebonnet, Baton Rouge, LA; 2Renal Associates of Baton Rouge, Baton Rouge, LA.

Introduction: In this case report, we present a case of Type 3b Barter’s Syndrome associated with sensorineural hearing loss.

Case Description: A 60 year old caucasian female with a history of hypertension and osteoporosis presented to the emergency department with a worsening dry cough, altered mental status, and paresthesias. Physical examination was positive for Chvostek’s sign and hearing loss bilaterally. Laboratory analysis was significant hypocalcemia, hypokalemia, and magnesium supplementation. 24 hour urine collection yielded: potassium and magnesium wasting and normal range calcium. Parathyroid hormone was found to be inappropriately low in the setting of severe hypocalcaemia but attributed to hypomagnesaemia. Barter’s vs. Gitelman’s was suspected, although profound hypomagnesaemia suggested the latter. Renasight, a kidney gene panel employing next generation genome sequencing revealed a heterozygous variant in the basal chloride channel (CLCNKB), associated with Barter’s Syndrome Type 3/4B. This channel is found in the stria vascularis and can lead to sensorineural deafness. Hypoparathyroidism persisted in spite of adequate Magnesium, Vit D levels suggestive of primary hypoparathyroidism of autoimmune etiology.

Discussion: The positivity of CLCNKB heterozygous mutation suggested Barter’s Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 113 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes loss of type A (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidism for which no genetic basis was identified such as the calcium sensing receptor mutation.

POI1323
Whole-Exome Sequencing as a First-Line Diagnostic Tool in Bartter and Gitelman Syndromes
Francesca Becherucci, Viviana Palazzo, Luigi Cirillo, Benedetta Mazzinghi, Valentina Raglianti, Samuela Landini, Paola Romagnani. Meyer Children’s Hospital, Florence, Italy.

Background: The clinical diagnosis of Bartter (BS) and Gitelman syndrome (GS) can be challenging, as they are rare and phenotypically overlapping. Thus, genetic testing represents the gold standard for the diagnosis. Next-generation sequencing is increasingly utilized in diagnostics and research of inherited tubulopathies. Sequencing of gene loci suspected of disease (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. The positivity of CLCNKB heterozygous mutation suggested Barter’s Syndrome Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 113 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes loss of type A (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidism for which no genetic basis was identified such as the calcium sensing receptor mutation.

Methods: We enrolled 50 patients (22 males) with a clinical diagnosis of BS or GS. Variant prioritization was carried out according to ACMG guidelines. Clinical data were collected retrospectively.

Results: We enrolled 50 patients (22 males) with a clinical diagnosis of BS or GS. All the patients showed hypokalemic metabolic alkalosis at onset. The median age at clinical diagnosis was 7 years (range 0-67). WES showed pathogenic variants in 41/50 patients (82%). A dedicated analytic pipeline allowed us to identify copy number variations (CNVs) in 7/41 patients with a confirmed genetic diagnosis. In details, WES allowed us to confirm the clinical diagnosis in 33/50 patients and to change it 8 additional patients (6 patients from BS to GS, 2 patients outside the BS/GS spectrum). Nephrocalcinosis was detected in 38% vs 8% of patients with a genetic diagnosis of BS and GS, respectively. Hypoparathyroidism persisted in spite of adequate Magnesium, Vit D levels suggestive of primary hypoparathyroidism of autoimmune etiology. Overall, 82% of patients had a genetic diagnosis.

Conclusions: The results of our study demonstrate that WES serves as a highly sensitive and specific diagnostic tool in the diagnostic work up of BS and GS. The positivity of CLCNKB heterozygous mutation suggested Barter’s Syndrome Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 113 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes loss of type A (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidism for which no genetic basis was identified such as the calcium sensing receptor mutation.

Examination of the Predicted Prevalence of Gitelman Syndrome by Ethnicity Based on Genome Databases

Atsushi Kondo,1 Sadayuki Nagai,1 Yuya Aoto,1 Nana Sakakibara,1 China Nagano,1 Tomoko Horinouchi,1 Tomohiko Yamamura,1 Kazumoto Iijima,1 Kandai Nozuka.1 Kobe University Graduate School of Medicine, Department of Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: Gitelman syndrome is an autosomal recessive inherited salt-losing tubulopathy. It has a prevalence of around 1 in 40,000 people, and heterozygous carriers are estimated at approximately 1%, although the exact prevalence is unknown because most cases are thought to be asymptomatic or have nonspecific clinical findings. On the other hand, it has been reported that the non-specific symptoms can reduce the quality of life of patients, and in practice, we have often experienced cases where patients have suffered from these symptoms since childhood, but were not diagnosed and therefore not treated, and were diagnosed in adulthood. It could suggest that there are far more patients and carriers than expected.

Methods: We estimated the predicted prevalence of Gitelman syndrome based on multiple genome databases, HGVD and MPorp for the Japanese population and gnomAD for other ethnicities, and included all 274 pathogenic missense or nonsense mutations registered in HGMD Professional. The frequencies of all these alleles were summed to calculate the total variant allele frequency in SLC12A3 which is the responsible gene for Gitelman syndrome. The carrier frequency and the disease prevalence were assumed to be twice and the square of the total allele frequency, respectively, according to the Hardy–Weinberg principle.

Results: In the Japanese population, the total carrier frequencies were 0.0498 (9.5%) and 0.0068 (8.7%) and the calculated prevalence was 0.00225 (2.3 in 1000 people) and 0.00188 (1.9 in 1000 people) in HGVD and MPorp, respectively. Other ethnicities showed a prevalence varying from 0.000012 to 0.00083.

Conclusions: These findings indicate that the prevalence of Gitelman syndrome in the Japanese population is higher than expected and that some other ethnicities also have a higher prevalence than previously been considered.

PO1325

An Off-the-Shelf CRISPR Gene Therapy Approach in Human Kidney Organoids

Nicole Vo, Catherine A. Macnary, Benjamin S. Freedman. The Freedman lab University of Washington, Seattle, WA.

Background: Gene therapy offers many opportunities to treat kidney diseases. Targeted, off-the-shelf therapeutics are needed for both loss-of-function (e.g. nephropathic cystinosis) and gain-of-function (e.g. ApoL1) disease states. Kidney organoids are complex structures that resemble nephrons and can be used to develop therapy approaches. Commonly used gene transfer techniques, such as lentivirus and adenovirus associated virus, are size limited, transient, or introduce DNA non-specifically into the genome. While targeted CRISPR gene editing is routinely used in 2D cell cultures, it has not been shown to be effective when used in 3D organoids. To achieve off-the-shelf gene transfer, organoids were transfected with Cas9 and gRNA ribonuclease protein (RNP) complexes targeting the AAASFI safe harbor locus supplemented with knock-in cassettes encoding green fluorescent protein (GFP) or FLAG-tagged cystinosin (deficient in nephropathic cystinosis). Alternatively, to monitor gene knock-out, organoids expressing GFP from AAASFI were transfected with RNP and either one or two gRNAs to introduce indels in the coding sequence. Genome editing was detected three ways: by confocal microscopy, PCR, and next generation sequencing.

Results: GFP and cystinosin knock-in events in organoids were detected using microscopy and PCR. Immunofluorescence analysis revealed knock-in in proximal tubule epithelial cells (LT1). In knock-out experiments, live confocal microscopy indicated areas of GFP loss within kidney organoids treated with gRNA targeting GFP, but not with a scrambled gRNA. Mosaic patches of GFP knockout cells expanded over several days. Staining with nephron markers such as LT1 and podocalyxin revealed knockout in both proximal tubule cells and podocytes. By next generation sequencing, the two-guide system produced larger deletions and was more efficient (20 % knockout), compared to single guide.

Conclusions: The strategy developed here is efficient for knockin and in knockout genes in kidney epithelium. It uses commercially available reagents to perform CRISPR gene editing. sgRNA sequences or AAASFI knock-in templates can be customized to target or introduce any gene of interest at specific loci. This provides a platform for the development of off-the-shelf gene therapies for diverse kidney disease states.

The Kidney Genome Atlas: A Resource to Understand APOL1 and Other Genetic Drivers of Adult Proteinuric Kidney Diseases

Eva Fast,1 Thomas Soare,1 Hari Somini,1 James Watkins,1 Adam Tebbe,1 Maria Lalioti,1 Liron Walsh,1 Matthias Kretzler,1 Girish N. Nadkarni,1 Rasheed A. Ghadgesin,1 Jamie L. Wenke,1 Daniel G. Macartthur,1 Peter Sundelin,1,2 Thomas T. Tibbitts,1,3 Michelle Penny,1 Goldfinch Bio Inc, Cambridge, MA; 1Instituto, South San Francisco, CA; 2University of Michigan, Ann Arbor; 3Mount Sinai Health System, New York, NY; 4Duke University School of Medicine, Durham, NC; 5Nashville Bioisciences, Nashville, TN; 6Atlas Venture, Cambridge, MA; 7Dogadan Therapeutics, Westford, MA; 8Garvan Institute of Medical Research, Darlinghurst, NSW, Australia.

Background: Chronic kidney disease (CKD) affects more than 30 million people in the US with African Americans being particularly at risk. There is an unmet need for pharmaceutical therapies that extend or, ideally, restore kidney function.

Methods: To guide genetically-driven drug development, we have established the Kidney Genome Atlas (KGA), which contains whole-genome sequences (>30x) from adult patients with Focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD) and other, idiopathic, proteinuric disorders as well as public and technically matched controls. By implementing a rigorous quality control procedure, following the gnomAD pipeline, we obtained a high-confidence dataset for downstream analyses. Three genetically inferred ancestries (EUR, AFR, AMR) were included in association testing comparing 1400 cases, including 169 individuals with APOL1 G1-G1, G2-G2 or G1-G2 high risk haplotypes (APOL1-HHR), with 14686 controls (including 485 APOL1-HHR individuals).

Results: Overall, our common variant cross-ancestry meta-analysis showed minimal impact on potential confounders, such as ancestry or sequencing center differences (lambda=1.03). Using summary statistics from our EUR analysis, we estimated a SNP heritability of 0.15 (SE = 0.028) in proteinuric diseases. Comparison to a recent CKD GWAS (Wuttke et al., 2019) indicated a weak positive genetic correlation (rg) of 0.097 (SE = 0.053). We identified the previously reported significant disease association of APOL1-HHR (p=2x10^-10) in our study. Recent in vitro data suggests amino acid in position 150 (rs2239785) is critical for the pathogenicity of APOL1-HHR (PO1986, ASN 2020) which we confirmed in our cohort of AFR ancestry individuals.

Conclusions: We have built a high-quality, multiethnic cohort that enables understanding of genetic drivers of polygenic proteinuric kidney disease. Future analysis including genetic modifiers of APOL1 may provide opportunities for novel therapies and patient stratification.

PO1327

Effect of ApoL1 Genotype on Kidney Failure and eGFR Decline in Patients with All-Cause CKD

Background: ApoL1 risk variants G1 and G2 associate with an increased risk of kidney failure and a higher rate of eGFR loss. We assess the effect of ApoL1 genotype in African American and Latino individuals with chronic kidney disease (CKD) in New York City.

Methods: ApoL1 genotype determined by sequencing. CKD cases with high-risk ApoL1 genotype (n= 242) were compared to CKD cases with a low-risk ApoL1 genotype (n=885) and African ancestry per Admixture. Kaplan-Meier survival analyses assessed time to kidney failure both incorporating covariates. Linear mixed-effects modelling evaluated CKD-EPI eGFR, decline rate using the same covariates.

Results: Cases with a high-risk ApoL1 genotype reach kidney failure 10-15 years earlier than low-risk cases. G1/G1 reach kidney failure earliest, followed by G1/G2 and G2/G2 (Fig 1). These data are supported across multiple risk models (Table 1). Cases with a high-risk ApoL1 genotype have a higher eGFR decline rate than low-risk cases with a similar trend per specific genotype (Fig 2). The addition of self-declared or genetically defined ancestry did not confer additional risk.

Conclusions: High-risk ApoL1 genotypes increase the risk of kidney failure at an earlier age, likely due to a higher eGFR decline rate. G1/G1 genotypes appear most affected and G2/G2 least.

and bone marrow-derived macrophages (BMMs) were collected from transgenic mice 4-18 weeks of age expressing APOL1 G1, G1, and G2 variants of APOL1. G1, G1, and G2 variants of APOL1 were generated through CRISPR/Cas9 gene editing. These iPS cells were used to generate iPSC-derived macrophages (iPSCDM). Peritoneal

Results: We observed that risk-variant APOL1 expression results in higher TNF and IL18 gene expression by nine-fold and two-fold respectively, in G1, G1 (P < 0.05). In APOL1 transgenic mouse peritoneal macrophages, oil red O staining revealed 2.83-fold increased neutral lipid accumulation (N = 3, P < 0.01) and 4.84-fold decreased effcacytosis capacity measured with flow cytometry (N = 5, P < 0.05) in G1 and G2 mice compared to G0. qRT-PCR analysis showed glycolysis genes to be increased in G1 iPSCDM compared to G0. Additionally, G2 mouse BMMs exhibited increased glycolytic rate compared to G0 both at baseline and under mitochondrial stress when APOL1 was induced with IFNy.

Conclusions: The findings in this study unveil some mechanisms by which risk- variant APOL1 modulates macrophage inflammatory phenotype and function, relevant to kidney disease progression.

A Multivariate Analysis of Genome-Wide Association (GWAS) Data to Identify Genes Associated with CKD

Amy J. Osborn, Agnieszka Bierzyńska, Gavin I. Welsh, Moin Saleem, Ian C. Campbell. University of Bristol, Bristol, United Kingdom.

Background: Chronic kidney disease (CKD), a major public health burden, is characterised by a progressive loss of nephron function which leads to an impaired ability to filter the blood. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) and loci associated with the kidney function biomarkers estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) by mostly univariate-based analyses. However, gene-based multivariate-SNP and multivariate- biomarker relationships have typically not been considered so far in this context. The purpose of this study was to highlight the additional insights gained from the statistical power of a multivariate-based approach to identify potential risk factor genes for CKD.

Methods: We used a multivariate statistical approach, canonical correlation analysis (CCA), to identify single nucleotide polymorphisms (SNPs) that showed significant correlation with estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) taken jointly. Since attributes were in the form of three published GWAS summary statistics datasets, we used metaCCA. The SNPs were filtered using linkage disequilibrium-based pruning. For the significant SNPs and genes we identified, their functions, signalling pathways and cellular expression were investigated using gene set enrichment analysis.

Results: For each of the three published GWAS summary statistics datasets of both European and Japanese ancestry groups, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using gene set statistical enrichment analyses, these genes showed significant enrichment for kidney development processes, signalling pathways and kidney cell gene expression signatures. In addition, between all three datasets, we identified four significant genes (CBLB, MACROD2, MUC15 and SHROOM3) that overlapped. Between two datasets, we identified a further four significant SNPs that overlapped.

Conclusions: By using a multivariate statistical approach, we have identified both previously reported and additional genes that contained significant SNPs statistically associated with kidney function. Overall, these findings provide new insights into SNPs and genes potentially involved in kidney function and CKD risk.

Funding: Government Support - Non-U.S.

Rare Variants and Risk of ESKD: The Geisinger MyCode-DiscovEHR Study

Background: Prior studies have reported that up to 1 in 10 patients with end-stage kidney disease (ESKD) have a diagnostic rare genetic variant but have lacked control groups.

Methods: Whole exome sequencing and electronic health records data from 147,750 participants in the Geisinger MyCode-DiscovEHR study, a health system-based cohort, were linked to the US Renal Data System to ascertain ESKD status and attributed cause. We compiled a list of variants in 80 autosomal or X-linked dominant (AD/XLD) genes previously reported in ClinVar as pathogenic or likely pathogenic (P/LP) variant in at least 1% of cases. Among these variants, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using gene set statistical enrichment analyses, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using gene set statistical enrichment analyses, these genes showed significant enrichment for kidney development processes, signalling pathways and kidney cell gene expression signatures. In addition, between all three datasets, we identified four significant genes (CBLB, MACROD2, MUC15 and SHROOM3) that overlapped. Between two datasets, we identified a further four significant SNPs that overlapped.

Conclusions: By using a multivariate statistical approach, we have identified both previously reported and additional genes that contained significant SNPs statistically associated with kidney function. Overall, these findings provide new insights into SNPs and genes potentially involved in kidney function and CKD risk.

Funding: Government Support - Non-U.S.
Conclusions: Individuals in an unselected health system cohort with rare variants had substantially increased risk of ESKD, which was often attributed to hypertension or diabetes.

Funding: NIDDK Support, Other NIH Support - Geisinger Clinic

Genomic Disorders Are Associated with CKD Across the Life Span

Miguel Nitecka,1 Sarah Babu Krishna Murthy,2 Maddalena Marasa,3 Junying Zhang,4 Atlas Khan,5 Craig S. Wong,6 Bradley A. Warady,3 Susan L. Furfur,2 David R. Crosslin,7 Robert P. Igo,4 Sudha K. Iyengar,4 Simone Sanna-Cherchi,4 Krzysztof Krysluk,4 Ashin Parsa,7 Harold I. Feldman,6 Ali G. Gharavi.1 Columbia University, New York, NY; The Children’s Hospital of Philadelphia, PA; University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; University of New Mexico School of Medicine, Albuquerque, NM; University of Missouri Kansas City, Kansas City, MO.

Background: Genomic Disorders (GDs), caused by pathogenic deletions and duplications (copy number variants, CNV) of large genomic regions of the genome, are a major source of genetic susceptibility for multiple developmental traits and are enriched in pediatric chronic kidney disease (CKD) patients. In the Chronic Kidney Disease in Children Study (CKiD) cohort 1, 4.5% participants carried a GD.

Methods: We extended our previous study in CKiD to cohort 2 and also examined the prevalence of GDs in adults with all-cause CKD enrolled in the Chronic Renal Insufficiency (CRI, N = 3375), Columbia University CKD (CU-CKD, N=1146) and Family Investigation of Nephropathy and Diabetes (FIND, N=1318) cohorts, comparing them to 30746 controls. CNV calls were based on SNP microarrays and whole exome sequencing and annotated for known GDs. We also performed a phenome-wide association analysis of GDs in the Electronic Medical Records and Genomics (eMERGE, N=11971) cohort.

Results: We found 9/248 (3.6%) CKiD 2 pediatric participants with mild CKD carried a GD, replicating prior findings in pediatric CKD. We next identified GDs in 74,667 (1.1%) adult CKD patients in the CRIC, CU-CKD and FIND cohorts, compared to 165,30,746 (0.5%) GDs in controls (OR=1.6, p=5x10^-10). Recurrent known GDs in adult CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci. The 17q12 GD (renal cyst and diabetes syndrome) was most frequent, detected in 1:252 CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci.

Conclusions: GDs are significantly enriched in children and adults with CKD. Undiagnosed GDs can provide a molecular explanation for renal disease in both adults and children and represent hidden genetic links between CKD and other traits such as poorer neurocognitive performance. Systematic detection of GDs can enable a precise genetic diagnosis and inform prognosis and treatment.

Genome-Wide Association Study in Mice Maps Susceptibility to HIV-Associated Nephropathy to the Ssbp2 Locus

Nicholas J. Steers,1 Yask Gupta,1 Vivette D. D’Agati,2 Tzy Yin Lim,3 Anna Mo,4 Judy Liang,5 Kelsey O. Stevens,1 Natalia D. Demaria,1 Wan Yee Lam,6 Lalitha Nagarajan,2 Simone Sanna-Cherchi,3 Ali G. Gharavi.1 Columbia University Irving Medical Center, New York, NY; The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: To gain insight into the pathogenesis of collapsing glomerulopathy, a rare form of focal segmental glomerulosclerosis that often arises in the setting of viral infections, we performed a genome wide association study (GWAS) among inbred mouse strains using a murine model of HIV-1 associated nephropathy (HIVAN).

Methods: F1 hybrids were generated between HIV-1 transgenic mice on the FVB/NJ background and 20 inbred laboratory strains. Histology, BUN, proteinuria and urinary NGAL were assessed in the F1 hybrids. A GWAS in 366 transgenic F1 hybrids generated from these 20 inbred strains was performed.

Results: Six stains (A/J, C3H/HeJ, DBA/1J, KK/HJ, WSF/EiJ, and LP/J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 9 strains (129S1/SvImJ, Balb/CJ, C57BL/6J, C57BL/6Nj, C57BL/10J, C57BL/J, C58/J, CAST/EiJ and NZB/BINJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HILFJ and FVB/NJ) had intermediate glomerulosclerosis. Analysis of histology, BUN and urinary NGAL demonstrated a marked phenotypic variation among the transgenic F1 hybrids, providing strong evidence for host genetic factors in the predisposition to nephropathy. A GWAS identified a genome-wide significant locus on Chr. 13 and multiple additional suggestive loci. Cross annotation of the Chr. 13 locus, including single cell transcriptomic analysis of wild type and HIV-1 transgenic mouse kidneys, nominated Ssbp2 as the likely culprit gene. Ssbp2 is highly expressed in podocytes, encodes a transcriptional cofactor present in LDLB containing complexes, and interacts with MlxIib, a known FSGS gene that requires LDLB for optimal transcriptional activity. Consistent with these data, older Ssbp2 null mice spontaneously developed glomerulosclerosis, tubular casts, interstitial fibrosis and inflammation, similar to the HIVAN mouse model.

Conclusions: These findings demonstrate the utility of GWAS in mice to uncover host genetic factors for rare kidney traits and suggest Ssbp2 as susceptibility gene for HIVAN, potentially acting via the LDLB-1-LMX1B transcriptional network. Future studies will evaluate the role of Ssbp2 in vivo and in Ssbp2 null mice.

Genetics Analysis of IgA Nephropathy-Discordant Monozygotic Twins

Enrico Cocchi,1 Nicholas J. Steers,2 Gerald B. Appel,3 Maya K. Rao,4 Licia Peruzzi,5 Ali G. Gharavi.1 Gharavi Lab.1 Columbia University, New York, NY; Turin University, Turin, Italy.

Background: Analysis of monozygotic twins can inform about the genetic and environmental basis of disease. We investigated monozygotic twins phenotypically discordant for IgA nephropathy (IgAN), in order to identify possible postzygotic variants that may provide further insights into IgAN pathogenesis.

Methods: We studied 5 pairs of discordant monozygotic twins, and their family members. Immunological analysis evaluated the in vitro secretion of IgA and Genome Sequencing (GS) was employed to identify germline and somatic variants.

Results: Culture of naïve B-cells and T follicular helper cells derived from the IgAN cases yielded 1.74 fold higher IgA production compared to cells from their corresponding healthy twins. Genetic analysis of the samples allowed to call ~4 mln SNPs and ~300k INDELs.

Conclusions: Our analysis identified significant differences in IgA production demonstrating the role of the immune system and genetics in IgAN pathogenesis. Consistent with the literature, GS identified discordant variants between twins pairs, most of which are attributable to background errors in variant calling. Further analysis of specific variants and gene sets may allow the identification of postzygotic variants that may be involved in IgAN pathogenesis.
A genetic testing in kidney disease has improved our understanding of various etiologies of glomerular diseases. FSGS is a histopathological diagnosis with diverse causes and patterns of inheritance. Genetic testing in FSGS has unlocked a treasure of pathogenic mutations that are either limited to the kidney or represent a broader extra-renal manifestation. Here we present 3 biopsy proven cases of FSGS with different genetic polymorphisms and varied presentations.

**Case Description:**
- Case 1: 29-year-old female with scoliosis, hearing loss, right optic nerve coloboma presented with 1.5 g/day of proteinuria and normal renal function when she was 16 years of age. Kidney biopsy revealed FSGS with 90% foot process effacement. A Y chromosome was noted to have 14 g of proteinuria, low albumin and hypertension. Kidney biopsy revealed FSGS, abnormal glomerular basement membrane. Genetic testing was positive for heterozygous intron variant of WT-1 and a congenital microencephaly variant of SMARCAL1 p.B200H which are pathogenic variants that cause renal failure due to defective podocyte development and dysfunction respectively.

**Discussion:** Genetic analysis for FSGS has become an important diagnostic tool in needle biopsies. We currently have over 50 genes that are known to be involved in FSGS. Reporting of different genetic variants and their occurrence is crucial to yield insight into our current understanding of FSGS.

**Primary AA Amyloidosis due to a chr11:18287683 T>C (hg19) Mutation in the SAA1 Promoter Linked to the Amyloidogenic SAA1.1 haplotype**

Jakub Sikor,1 Dina Musalkova,1 Petr Prikryl,1 Hana Hartmannová,1 Katerina Hodanova,1 Helena Treslova,1 Lenka Noskova,1 Viktor Stranecky,1 Milan Jirs,1 Martina Zivna,1 Anthony J. Bleyer,2,3 Iain Rychlík,1 Romana Rysava,1 Stanislav Kmoch.3

**Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; Wake Forest University School of Medicine, Winston-Salem, NC; Institut klinicke a experimentailu medicine Pracovicte laboratornich metod, Praha, Czechia; Univerzita Karlova 3 lekarska fakulta, Praha, Czechia.

**Background:** AA amyloidosis results from deposition of amyloid A (AA), a product of the proteolytic cleavage of serum amyloid A (SAA) proteins. Previously described AA amyloidosis has been due to increased production and deposition of serum amyloid A (SAA) proteins secondary to inflammatory conditions arising from infectious or metabolic causes. We describe for the first time a family with primary AA amyloidosis due to an isolated increase in production of AA protein.

**Methods:** A family was identified with autosomal dominant transmission of amyloidosis affecting 12 family members and associated with progressive chronic kidney disease (CKD) as well as other systemic manifestations of amyloidosis. Family members underwent measurement of serum SAA and whole exome sequencing with targeted sequencing. The luciferase reporter assay was used to determine promoter activity.

**Results:** Affected individuals developed proteinuria, CKD and systemic deposition of amyloid composed specifically of the SAA1.1 isoform. Affected individuals had a doubling of the SAA1 promoter activity and sustained elevation of serum SAA levels that segregated in an autosomal dominant pattern in 12 genetically affected and in none of 6 genetically unaffected relatives with a LOD score of >5. Genetic evaluation revealed a chr11:18287683 T>C (hg19) mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype that segregated completely with affected individuals. Tocilizumab had a beneficial effect when prescribed early.

**Conclusions:** A mutation in the SAA1 promoter linked to the amyloidogenic SAA1.1 haplotype led to a doubling of production of SAA1, leading to characteristic findings of amyloidosis. This is the first investigation to show that all manifestations of AA amyloidosis in humans are due solely to SAA overexpression. Idiopathic forms represent a significant and increasing proportion (15-20%) of all diagnosed cases of AA amyloidosis. Genetic screening of the SAA1 promoter should be pursued in individuals with AA amyloidosis without an obvious cause of systemic inflammation, especially if there is a positive family history. Contact ableyer@wakehealth.edu for genetic evaluation of familial amyloidosis.

**Gene Testing in Focal Segmental Glomerulosclerosis (FSGS): Tale of Three Stories**

Gaurav Rajashkekar, Ying M. Chen. Washington University in St. Louis Washington University in St. Louis, St. Louis, MO.

**Introduction:** Genetic testing in kidney disease has improved our understanding of various etiologies of glomerular diseases. FSGS is a histopathological diagnosis with diverse causes and patterns of inheritance. Genetic testing in FSGS has unlocked a treasure of pathogenic mutations that are either limited to the kidney or represent a broader extra-renal manifestation. Here we present 3 biopsy proven cases of FSGS with different genetic polymorphisms and varied presentations.

**Case Description:**
- Case 1: 29-year-old female with scoliosis, hearing loss, right optic nerve coloboma presented with 1.5 g/day of proteinuria and normal renal function when she was 16 years of age. Kidney biopsy revealed FSGS with 90% foot process effacement. 13 years later, her renal function worsened, with serum creatinine 1.4 mg/dl (baseline 0.9 mg/dl), and urine protein creatinine ratio of 4 g/l. Her mother had undergone a kidney transplant, presumed to be secondary to reflux nephropathy. Genetic testing showed hemizygous, truncating p.W58* variant in the CLCN5 gene. Variants in CLCN5 gene can cause Dent’s Disease manifesting later in life as proteinuria, nephrocalcinosis, hypercalciuria and renal failure. In addition he had variant of unknown significance NPHS1 designated p.T233A, and APOL1 G2 risk allele predisposing him to develop FSGS. Case 3: 21 year-old male, born with genital ambiguity, perineal hypospadias, 46 XY karyotype was noted to have 14 g of proteinuria, low albumin and hypertension. Kidney biopsy revealed FSGS, abnormal glomerular basement membrane. Genetic testing was positive for heterozygous intron variant of WT-1 and a congenital microencephaly variant of SMARCAL1 p.B200H which are pathogenic variants that cause renal failure due to defective podocyte development and dysfunction respectively.

**Discussion:** Genetic analysis for FSGS has become an important diagnostic tool in needle biopsies. We currently have over 50 genes that are known to be involved in FSGS. Reporting of different genetic variants and their occurrence is crucial to yield insight into our current understanding of FSGS.

Synuclein Alpha Accumulation Drives Lysosomal Dysfunction in Fabry Podocyteopathy

Fabian Braun,1 Ahmed Abed,2 Mathias Woidy,1 Osteyn Eikrem,3 Nicola Wanner,1 Katharina M. von Cossel,1 Soeren W. Gersting,1 Ania C. Muntau,1 Behzad Najafian,1 Camilla Tondel,2 Michael Maurer,1 Florian Grammather,1 Thorsten Eierhoff,1 Hans-Peter Marti,1 Victor G. Puelles,2 Christoph Schell,1 Tobias B. Huber,1 1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2Universitätsklinikum Freiburg, Freiburg, Germany; 3Universitetet i Bergen Det medisinsk-odontologiske fakultet, Bergen, Norway; 4University of Washington, Seattle, WA; 5University of Minnesota Medical School Twin Cities, Minneapolis, MN, 6Haukeland Universitetssykehus, Bergen, Norway; 7Universitätsklinikum Munster, Munster, Germany.

Background: Anderson-Fabry disease is an X-linked lysosomal disorder characterized by a multisystemic globotriaosylceramide (Gb3) accumulation due to reduced alpha-galactosidase activity (GLA). Podocyte injury is a major renal manifestation of Fabry disease. Recently, our data indicated Gb3 depletion to be insufficient in repairing podocyte damage seen in an in vitro model for Fabry disease. This project, therefore, focused on potential Gb3 independent mechanisms in Fabry podocyteopathy.

Methods: We employed CRISPR/Cas9 to generate GLA knock out lines of immortalized human podocytes in vitro. These cells were investigated by (ultra-)structural, transcriptome and proteome as well as functional analyses in the presence and absence of enzyme replacement therapy (ERT). The acquired data sets were integrated through network analysis and connectivity mapping. These data were complimented by the investigation of human biopsies taken sequentially before and after a period of ERT.

Results: We detected that enzyme replacement therapy (ERT) and Gb3 reduction failed to reverse podocyte injury in patient biopsies. GLA knockout podocytes depicted high Gb3 levels that were fully reversed upon enzyme replacement. Still lysosomal dysfunction was significantly but not completely reversible with enzyme replacement. Proteomics suggested alpha-synuclein (SNCA) accumulation as a potential driver of podocyte dysfunction. Transcriptionomics-based connectivity mapping further revealed a potential anti-SNCA therapeutic effect of beta-adrenoceptor agonists. Indeed, genetic and pharmacological inhibition of this protein significantly improved lysosomal structure and function in Fabry podocytes beyond the effects of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmaceutical strategies to target Fabry podocyteopathy.

Drosophila TBC1D8B Promotes Nephrin Endocytosis and Is Required for Endosomal Cargo Processing

Julian Milosavljevic, Camilla Lempicki, Konrad Lang, Lina L. Kampf, Tobias F. Hermle. Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.

Background: Mutations in TBC1D8B were recently identified as a monogenic cause of nephrotic syndrome. TBC1D8B interacts with nephrin and it was implicated as an inhibitory GAP protein for Rab11 which regulates endocytic recycling. However, the functional spectrum of TBC1D8B and its role in trafficking of nephrin remains poorly understood.

Methods: We generated twin frameshift mutations at the second and third exons of Tbc1d8b via CRISPR/Cas9. We successfully introduced a c-terminal HA-tag into the protein using CRISPR/Cas9. We successfully introduced a c-terminal HA-tag into the protein. We overexpressed human GAPVD1 in nephrocytes, that equally localized in early endosomes. Gain-of-function of the human gene entailed reduced tracer endocytosis in nephrocytes, suggesting a dominant negative effect.

Results: We generated twin frameshift mutations at the second and third exons of the Drosophila Gapvd1 gene. Animals carrying these mutation were homozygous viable without any overt phenotype. However, the podocyte-like nephrocytes revealed a severely altered slit diaphragm morphology with mislocalization of fly nephrin and the orthologue of NEPH1 and partial loss of both proteins from the surface. This phenotype was similar but considerably stronger than the phenotype observed by RNA-mediated silencing. This suggests that the homologous frameshift mutations result in a null allele. The phenotype was further confirmed by conditional CRISPR/Cas-mediated silencing using two different gRNAs. Deletion of Gapvd1 in the Drosophila model thus results in a phenotype that manifests exclusively in disturbed slit diaphragms formation. This recapitulates the phenotype observed in experimentally induced nephrotic syndrome. Transcriptomics-based connectivity mapping further revealed high Gb3 levels that were fully reversed upon enzyme replacement. Still, equally localized in early endosomes. We overexpressed human GAPVD1 in nephrocytes, that equally localized in early endosomes. Gain-of-function of the human gene entailed reduced tracer endocytosis in nephrocytes, suggesting a dominant negative effect.

Conclusions: We established a new Drosophila model to study the function of Gapvd1 in Nephrin in an invertebrate podocyte model.

Funding: Government Support - Non-U.S.

Stable Genetic Deletion of Gapvd1 in Drosophila Results in a Nephrocyte-Restricted Phenotype

Konrad Lang, Julian Milosavljevic, Elena Heinkel, Lea Gerstner, Tobias F. Hermle. Hermle Lab Universitätsklinikum Freiburg, Freiburg, Germany.

Background: Mutations in the gene GAPVD1 cause of nephrotic syndrome in humans. GAPVD1 interacts with RAB5 and but the subcellular localization of GAPVD1 is unknown. Silencing of Gapvd1 in the podocyte-like Drosophila nephrocytes by RNA interference resulted in mislocalization of fly nephrin.

Methods: We generated conditional knockdowns and a stable genetic deletion of Drosophila Gapvd1 by CRISPR/Cas9 and used microhomology-mediated end joining to introduce a genomic HA-tag into the Gapvd1 c-terminus. We performed a functional analysis of the novel fly models.

Results: We generated twin frameshift mutations at the second and third exons of the Drosophila Gapvd1 gene. Animals carrying these mutation were homozygous viable without any overt phenotype. However, the podocyte-like nephrocytes revealed a severely altered slit diaphragm morphology with mislocalization of fly nephrin and the orthologue of NEPH1 and partial loss of both proteins from the surface. This phenotype was similar but considerably stronger than the phenotype observed by RNA-mediated silencing. This suggests that the homologous frameshift mutations result in a null allele. The phenotype was further confirmed by conditional CRISPR/Cas-mediated silencing using two different gRNAs. Deletion of Gapvd1 in the Drosophila model thus results in a phenotype that manifests exclusively in disturbed slit diaphragms formation. This recapitulates the phenotype observed in experimentally induced nephrotic syndrome. Transcriptomics-based connectivity mapping further revealed high Gb3 levels that were fully reversed upon enzyme replacement. Still, equally localized in early endosomes. We overexpressed human GAPVD1 in nephrocytes, that equally localized in early endosomes. Gain-of-function of the human gene entailed reduced tracer endocytosis in nephrocytes, suggesting a dominant negative effect.

Conclusions: We established a new Drosophila model to study the function of Gapvd1 in Nephrin in an invertebrate podocyte model.

A Human Missense Integrin-Linked Kinase Variant Negatively Regulates Murine Renal Branching Morphogenesis via mTOR Signaling

Xiangyu Hu,1,2 Dana Kablawi,2 Kirsten Y. Renkenma,1,3,9 Nine V. Knorrs,3 Norman D. Rosenblum,1,3,9 Program in Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; 1Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada; 2Department of Genetics, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands.

Background: Branching morphogenesis is critical to kidney development and the pathogenesis of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT). Identification of gene variants via genomic sequencing aims to elucidate molecular mechanisms underlying CAKUT. The pathogenic contributions of such variants are largely unknown; functional analyses are required to identify pathogenic mechanisms. Here, we identify pathogenic effects of a CAKUT-associated human missense variant of Integrin-Linked Kinase (ILK), a key regulator of renal branching morphogenesis, on ureteric branching.

Methods: Targeted gene panel sequencing was performed to identify gene variants. ILK-T173I function was investigated in mouse inner medullary collecting duct (mIMCD3) cells and mouse embryonic kidney explants transduced with lentivirus expressing ILK-T173I. Gene expression was analyzed by RNA microarray and validated by qPCR and Western analysis. Mutant mice with a 429 ILK-c.518C>T point mutation were generated using CRISPR/Cas9. Morphogenic effects of ILK-T173I on ureteric branching were visualized using Hoxa7-driven fluorescent marker (Myvenus) and quantitated by counts of ureteric bud tips and nephrons.

Results: An ILK missense variant, ILK-T173I, was identified in a CAKUT patient and her mother by targeted gene panel sequencing and verified by Sanger sequencing. mIMCD3 cells expressing ILK-T173I demonstrated dysregulated expression of AKT/mTOR target mRNAs, identified by RNA microarray and qPCR, and elevated levels of phospho-p70-S6K, a mTOR target (n=3, P=0.03). Overexpression of ILK-T173I in embryonic kidney explants increased phospho-p70-S6K expression (n=3, P=0.03) and decreased ureteric tip number by 50% (n=15, P=0.003), both of which were rescued by treatment with Rapamycin, an mTOR inhibitor (n=4, P=0.04). Knock-in mice in which ILK-T173I replaces the ILK-WT allele were characterized by low nephron number (n=6, P=0.04) and decreased ureteric branching (n=5, P=0.006), and increased expression of phospho-p70-S6K (n=3, P=0.014). Treatment of mutant cultured embryonic kidney explants with Rapamycin rescued ureteric branching to levels observed in ILK-WT mice.

Conclusions: Human ILK-T173I variant decreases branching morphogenesis in an mTOR-dependent manner. Increased mTOR-signaling disrupts mouse kidney development.

Whole-Exome Sequencing Identifies FOX2L2, FOXA2, and FOXA3 as Candidate Genes for Monogenic Congenital Anomalies of the Kidneys and Urinary Tract

Bixia Zheng,1 Steve Seltzman,2 Chunyan Wang,1 Luca S. Schierbaum,1 Sophia Schneider,1 Dervla M. Connaughton,1 Nina Mann,1 Velibor Tasic,1 Shi Guo,1 Patricio Velichkova,1,2 Friedhelm Hildebrandt,1,2 Department of Pediatrics, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 1Medical Faculty Skopje, University Children’s Hospital, Skopje, Macedonia (the former Yugoslav Republic of).

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the most common cause of chronic kidney disease in the first three decades of life. Variants in four Forkhead box (FOX) transcription factors have been associated with CAKUT. We hypothesized that other FOX genes, if highly expressed in developing kidney, also represent monogenic causes of CAKUT.

Methods: We here performed whole exome sequencing (WES) in 541 families with CAKUT and generated 4 lists of CAKUT candidate genes: A) 36 FOX genes showing high expression during renal development, B) 4 FOX genes known to cause CAKUT to validate list A, C) 80 genes that we identified as unique potential novel CAKUT candidate genes when performing WES in 541 CAKUT families, and D) 175 genes identified from WES as multiple potential novel CAKUT candidate genes.

Results: To prioritize potential novel FOXKUT candidate genes in FOX gene family, we overlapped 36 FOX genes (list A) with list C and D of WES-derived CAKUT candidates. Intersection with list C, identified a de novo FOX2L2 in-frame deletion in a patient with eyelid abnormalities and ureteropelvic junction obstruction, and a homozygous FOXO3 missense variant in a patient with horseshoe kidney. Intersection with list D, identified a heterozygous FOXA3 in-frame variant in a CAKUT family with multiple affected individuals.

Conclusions: We hereby identified FOX2L2, FOXA2 and FOXA3 as novel monogenic candidate genes of CAKUT, supporting the utility of a paralog-based approach to discover monogenic genes associated with human disease.

Excess Burden of Rare Coding Variants in Mutation Intolerant Genes in Patients with Kidney Malformations
Hila Milo Rasouly,1 Sarah Babu Krishna Murthy,1 Gundula Poyvisl,1 Maddalena Marasa,2 Jeremiah Martino,1 Velibor Tasic,1 Enrico Fiaccadori,3 Gian Marco Ghiglieri,4 Giuseppe Massata,5 Simone Sanna-Cherchi,6 Krzysztof Krylik,7 Ali G. Gharavi1,7 Columbia University Irving Medical Center, New York, NY; 2University Children’s Hospital, Skopje, Macedonia (the former Yugoslav Republic of); 3Istituto Giannina Gaslini, Genova, Italy; 4Azienda Ospedaliera Brotzu, Cagliari, Italy; 5Università degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy.

Background: Renal hypoplasiasia (RHD) is one of the most common cause of pediatric kidney failure. Although multiple causative genes have been identified, they only account for 10-15% of cases. The contribution of rare variants has not been systematically examined.

Methods: To evaluate the contribution of rare variants to RHD, we analyzed exome sequencing (ES) data in 1,265 unrelated RHD cases and 13,303 unrelated controls. We used gene-level burden analysis, comparing the proportion of cases and controls carrying rare variants per gene across 29 statistical models.

Results: We observed a 1.63-fold case enrichment for rare variants (p=1.5x10-10) in known genes associated with dominant forms of kidney diseases (165 cases versus 1,075 controls in 172 known genes), including PKD2 (7.6x10-10) and HNF1B (5.6x10-10). All other known genes did not reach statistical significance (p-value<10-3). Applying a similar approach, we observed a 1.35-fold case enrichment for rare missense variants (p=5.8x10-10) in genes constrained against missenses (misZ >3.09) and a 1.59-fold enrichment for rare protein truncating variants (PTV; p=2.4x10-9) in genes constrained against PTV (pLI<0.9 and so low upper<0.35). We particularly identified a 2.38-fold enrichment for PTV in 421 genes constrained against PTV, expressed in the mouse developing kidney (E15.5), and not known to be associated with human kidney disease (p=1.4x10-5). Fig.).

Conclusions: We detected a significant excess of rare variants in mutation intolerant genes that are also expressed during early kidney development, suggesting the existence of many yet-to-be identified causal genes. However, owing to the high genetic heterogeneity of RHD, larger-scale investigations will be required to establish causality for individual genes.

Reverse Phenotyping Facilitates Disease Allele Calling in Whole-Exome Sequencing of Patients with Congenital Anomalies of Kidney and Urinary Tract (CAKUT)
Steve Seltzsm, Chyunan Wang, Bixia Zheng, Dervla M. Connaughton, Chen-Han W. Wu, Sophia Schneider, Luca M. Schierbaum, Shrlee Shril, Friedhelm Hildebrandt, Boston Children’s Hospital, Boston, MA.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the leading cause of chronic kidney disease in children and young adults. To date, 174 genes are known to cause isolated or syndromic monogenic CAKUT. However, incomplete penetrance and broad phenotypic heterogeneity can impair disease allele identification, particularly in syndromic CAKUT. We hypothesized that the yield of a genetic diagnosis can be increased by combining whole exome sequencing (WES) with reverse phenotyping, in which the contributing physician is asked to examine a patient for signs/symptoms that may occur in the suspected clinical syndrome that results from the genetic variant detected by WES.

Methods: We conducted WES in an international cohort of 823 individuals with CAKUT from 732 unrelated families and evaluated WES data for variants in the 174 genes in which variants are known to cause isolated or syndromic CAKUT. In cases in which the likely causative genotype suggested a syndromic phenotype that was not reported at enrollment, we conducted reverse phenotyping.

Results: In 84/732 (11.5%) families, we detected a likely causative variant consistent with an isolated or syndromic CAKUT phenotype. In 19 of the 84 families (22.6%) with detection of a likely CAKUT-causing variant, reverse phenotyping yielded syndromic findings, thereby strengthening the genotype-phenotype correlation.

Conclusions: We conclude that employing reverse phenotyping in the evaluation of (facultative) syndromic CAKUT genes by WES provides an important tool to establish a more valid and specific diagnosis mitigating the broad phenotypic and genotypic heterogeneity of CAKUT.

Broad Genetic Analysis Reveals Diverse Molecular Causes of Autosomal Dominant Tubulointerstitial Kidney Disease-Not Otherwise Specified (ADTKD-NOS)
Florian Woppeur,1 Francesca Pasutto,2 Michael S. Wiesener,1 Universitätshospital Erlangen Medizinische Klinik 4 Nephrologie und Hypertonologie, Erlangen, Germany; 2Universitätsklinikum Erlangen Institut für Humanangenetik, Erlangen, Germany.

Background: A particularly difficult group of diseases to diagnose are the Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD). ADTKD is caused by mutations in one of at least five genes and leads to end-stage renal disease usually in mid adulthood. Families where no mutation can be found are therefore termed ADTKD-NOS (not otherwise specified), who are the focus of this study. Herein we investigated 45 families of overall ADTKD registry.

Methods: The study was approved by the institutional ethics committee (protocol number 251_18B). Detailed pedigree analysis and clinical characterisation of kidney diseases were performed, as well as evaluation of historical kidney biopsies, wherever ADTKD was suspected, and all known ADTKD candidate genes was performed, followed by SNApShot missequencing for the dpC mutation of MUC1. Exome-Sequencing was performed on the HiSeq System 2500 (Illumina) after enrichment by TWIST human core technology (TWIST BioScience). Initially, 560 genes associated with abnormal renal physiology (Human Phenotype Ontology, https://msqdr.org/hpo-browser.php?12622, retrieved March 2020) were screened (here termed nephrome). If no disease-causing variants were detected, exome-wide analysis was performed.

Results: In 30 of the 45 registry families mutations in known ADTKD genes were found, most frequently MUC1. In the remaining 15 families diagnostic gene variants were either detected in the nephrome (4x COL4A5, 1x COL4A6s, 2x IN2, 1x PAOX) or the exome, where analysis yielded potentially disease associated variants in novel candidate genes for ADTKD. A list of these candidate genes in the respective families will be presented. All variants segregated with families.

Conclusions: We identified 33 pathogenic small variants. Of these 27 (81.8%) were in known ADTKD genes, supporting the notion that ADTKD is caused by mutations in genes that constitute the leading cause of chronic kidney disease in children and young adults. To date, 174 genes are known to cause isolated or syndromic monogenic CAKUT. However, incomplete penetrance and broad phenotypic heterogeneity can impair disease allele identification, particularly in syndromic CAKUT. We hypothesized that the yield of a genetic diagnosis can be increased by combining whole exome sequencing (WES) with reverse phenotyping, in which the contributing physician is asked to examine a patient for signs/symptoms that may occur in the suspected clinical syndrome that results from the genetic variant detected by WES.

Methods: We conducted WES in an international cohort of 823 individuals with CAKUT from 732 unrelated families and evaluated WES data for variants in the 174 genes in which variants are known to cause isolated or syndromic CAKUT. In cases in which the likely causative genotype suggested a syndromic phenotype that was not reported at enrollment, we conducted reverse phenotyping.

Results: In 84/732 (11.5%) families, we detected a likely causative variant consistent with an isolated or syndromic CAKUT phenotype. In 19 of the 84 families (22.6%) with detection of a likely CAKUT-causing variant, reverse phenotyping yielded syndromic findings, thereby strengthening the genotype-phenotype correlation.

Conclusions: We conclude that employing reverse phenotyping in the evaluation of (facultative) syndromic CAKUT genes by WES provides an important tool to establish a more valid and specific diagnosis mitigating the broad phenotypic and genotypic heterogeneity of CAKUT.

Novel CTNS Variants Mostly of Non-European Origin
Genetic Analysis of a Brazilian Nephropathic Cystinosis Cohort Reveals

Background: Autosomal dominant tubulointerstitial kidney disease (ADTKD), also known as nephropathic cystinosis (NC), is one of the most common non-polycystic genetic kidney diseases, but it remains unrecognized due to its clinical heterogeneity and lack of screening test. Moreover, clinical feature being a poor predictor of the disease outcome further highlights the need for development of mechanistic biomarkers in ADTKD. However, low abundant urinary proteins secreted by thick ascending limb (TAL) cells, where urorolubin (UMOD) is synthesized, has posed a challenge on detection of biomarkers in ADTKD-UMOD.

Methods: We have utilized CRISPR/Cas9-generated mice with Umod-C147W mutation, analogous to human UMOD-C148W mutation, and ADTKD-UMOD patients to discover a novel endemic reticulum (ER) stress biomarker. In addition, we have developed an ultrasensitive, plasmon-enhanced fluorescence-linked immunosorbent assay (p-FLISA) to detect the urinary biomarker in ADTKD patients by harnessing a newly invented ultrabright fluorochrome nanoconstrast, termed “plasmonic fluorescence (PF)” (Nat Biomed Eng 2020).

Results: In the murine model and patients with ADTKD-UMOD, we find that immunoglobulin heavy chain-binding protein (BiP), an ER chaperone, was exclusively secreted into the urine of ADTKD-UMOD patients compared with unaffected controls. Moreover, urinary BiP elevation was positively correlated with decline of kidney function in ADTKD-UMOD patients.

Conclusions: By developing the ultrasensitive p-FLISA, we have identified secreted BiP as a novel urinary ER stress biomarker with potential utility in risk stratification, prediction of disease progression and guidance of ER-targeted therapies in ADTKD.

Funding: NIDDK Support, Other U.S. Government Support

Ultrabright Plasmonic-Fluor Nanolabel-Enabled Detection of a Urinary ER Stress Biomarker with Potential Utility in Risk Stratification, Clinical Evaluation, and Management of Autosomal Dominant Tubulointerstitial Kidney Disease

By developing the ultrasensitive p-FLISA, we have identified secreted BiP as a novel urinary ER stress biomarker with potential utility in risk stratification, disease prediction and management of ADTKD.

Genetic Analysis of a Brazilian Nephropathic Cystinosis Cohort Reveals Novel CTNS Variants Mostly of Non-European Origin

Background: Nephropathic Cystinosis (NC) is a severe autosomal recessive disease caused by intralysosomal cystine deposition. Most CTNS variants have been described in Europe and North America, where a specific 57kb deletion (del) is the most frequent one. In this study, we sought to characterize the CTNS variants and their genetic ancestry profiles in a NC Brazilian cohort, an admixed population.

Methods: 61 NC patients were studied, both sexes, ≥21 years old, followed at the University of Sao Paulo Medical Center. Mutation analysis was performed by gel electrophoresis and/or MLPA to assess the 57kb del and NGS targeted sequencing. To characterize the genetic ancestry profiles, 48 patients were genotyped with a high-density SNP array. The average genetic ancestry was inferred using ADMIXTURE and the ancestry of the CTNS gene region using RFMix.

Results: Two disease-causing variants were identified in 58/61 patients, followed by segregation analysis whenever possible. The detected variants included 9 previously reported and 7 novel ones. The 7 novel variants were observed in European genomic segments, except the African ancestry-linked variant c.62-2A>G. Among the novel variants, 4 are in genomic segments of African origin (del exons 2, 4, 5; c.227delT:p.p.431delA:p.K76del), 1 in Native American (c.16_19del:p.L66fs), 1 in an African-ancestry segment (c.*262>*266delGC:GCG), and 1 could not be determined (c.158delC:p.W53fs). The highest allele frequencies were 57kb del (55.7%), c.382T (14.0%), c.16_19del (7.4%) and c.611_613del (5.7%). Analyses of LD decay support that 57kb del, c.382T and c.611_613del originated in Europe at least 7,500 years ago (2500-7500 YPA), 5500-1700 years ago (3500-5500 YPA) and 275 years ago (75-1200 YPA), respectively, and suggest that c.16_19del likely originated in America 15,025 years ago (5,775-41,000 YPA). Furthermore, 5 of the 7 novel variants are located in genomic segments of African ancestry, and these findings raise the possibility that the novel non-European CTNS variants may be present in other South American and African populations.

Conclusions: By characterizing the African ancestry-linked CTNS variant c.62-2A>G, we find that the Brazilian NC patient population is mixed, with distinct ethnic origins being identified. Indeed, 5 of the 7 novel variants are located in genomic segments of African origin (del exons 2, 4, 5; c.227delT:p.p.431delA:p.K76del), 1 in Native American (c.16_19del:p.L66fs), 1 in an African-ancestry segment (c.*262>*266delGC:GCG), and 1 could not be determined (c.158delC:p.W53fs). The highest allele frequencies were 57kb del (55.7%), c.382T (14.0%), c.16_19del (7.4%) and c.611_613del (5.7%). Analyses of LD decay support that 57kb del, c.382T and c.611_613del originated in Europe at least 7,500 years ago (2500-7500 YPA), 5500-1700 years ago (3500-5500 YPA) and 275 years ago (75-1200 YPA), respectively, and suggest that c.16_19del likely originated in America 15,025 years ago (5,775-41,000 YPA).

Conclusions: By characterizing the African ancestry-linked CTNS variant c.62-2A>G, we find that the Brazilian NC patient population is admixed, with distinct ethnic origins being identified. Indeed, 5 of the 7 novel variants are located in genomic segments of African origin (del exons 2, 4, 5; c.227delT:p.p.431delA:p.K76del), 1 in Native American (c.16_19del:p.L66fs), 1 in an African-ancestry segment (c.*262>*266delGC:GCG), and 1 could not be determined (c.158delC:p.W53fs). The highest allele frequencies were 57kb del (55.7%), c.382T (14.0%), c.16_19del (7.4%) and c.611_613del (5.7%). Analyses of LD decay support that 57kb del, c.382T and c.611_613del originated in Europe at least 7,500 years ago (2500-7500 YPA), 5500-1700 years ago (3500-5500 YPA) and 275 years ago (75-1200 YPA), respectively, and suggest that c.16_19del likely originated in America 15,025 years ago (5,775-41,000 YPA).

PO1354

Adult Zebrafish as a Model to Study Renal and Extrarenal Manifestations of Cystinosis

Background: Cystinosis is a rare autosomal recessive disease caused by mutations in the CTNS gene, which encodes for the cystine transporter cystinosin leading to lysosomal cystine accumulation in all cells of the body, with kidneys being the first affected organs. The current treatment with cysteamine decreases the lysosomal cystine accumulation, but does not reverse the renal Fanconi syndrome, glomerular injury or loss of renal function. We have developed a zebrafish larvae model having truncating mutations in ctns, which recapitulates the kidney phenotype of cystinosis. However, longer-term disease consequences in adult zebrafish have not been studied so far. In this study, we characterized the adult zebrafish model to evaluate the late effects of cystinosis on kidney and extra renal organs.

Methods: Cystinotic (ctns-) zebrafish of 18 months and wild type (WT) zebrafish were studied. Histologic examinations of kidneys and extra-renal organs were performed. Cleaved caspase-3 staining was used to evaluate apoptosis in the kidney. Cystine accumulation was evaluated via liquid chromatography-mass spectrometry and toluidine blue staining. For the fertility studies, the number of total eggs and fertile eggs produced by breeding female and male ctns- zebrafish compared to WT zebrafish was evaluated.

Results: ctns- zebrafish show increased cystine level, glomerular hypertrophy and proximal tubular accumulation of hyaline-like eosinophilic droplets and vaculated cytoplasm. Moreover, the cystinotic zebrafish exhibit increased cleaved caspase-3, indicating enhanced apoptosis in the proximal tubules. In addition, instead of the typical striped pattern, ctns- zebrafish present an altered melanin skin pigment pattern, resulting in spotted skin. Lastly, male ctns- zebrafish show spermatogenetic cysts enriched in spermatozoa, while female display increased percentage of unfertilized eggs.

Conclusions: The adult ctns- zebrafish model reproduces several phenotypes of cystinosis, such as altered glomerular and proximal tubular morphology, whole body cystine accumulation, impaired skin pigmentation and decreased fertility. Therefore, this model may be useful for studying long-term effects of cystinosis and for the development of new therapeutic strategies for correcting cystinosis, which is - up to now - incurable.

Urine-Derived Kidney Progenitor Cells in Cystinosis: Potential for Disease Modeling and Ex Vivo Gene Therapy

Background: Nephropathic cystinosis is an inherited multisystem lysosomal storage disorder caused by mutations in the CTNS gene. The kidney phenotype is characterized by excessive shedding of proximal tubular cells and podocytes into urine, development of renal Fanconi syndrome and progression to end-stage kidney disease. We hypothesized that, to compensate for epithelial cell loss, cystinosis kidneys undertake a regenerate effort, albeit maladaptive. We aimed to search for the presence of kidney progenitor cells (KPCs) in urine of cystinosis patients, and to explore the feasibility of ex vivo gene therapy.

Methods: We isolated undifferentiated cells from urine of cystinosis patients, characterized them as KPCs (Cys-uKPCs) and differentiated these to podocytes (Cys-uKPC-Podo) and proximal tubular epithelial cells (Cys-uKPC-PTEC) as shown by qPCR, RNA sequencing, immunostainings and specific functional assays. Transplantation of CTSN in Cys-uKPCs was performed via lentiviral vector (LV) transduction.

Results: Cystinosis patients voided high numbers of undifferentiated cells from urine, of which specific clones expressed several kidney progenitor markers, showed a high level of self renewal, and could differentiate to functional Cys-uKPC-PTEC. RNA sequencing demonstrated distinctive transcriptomic signatures distinguishing Cys-uKPC-Podo and Cys-uKPC-PTEC. Ex vivo gene therapy using a gene addition approach with wild-type CTNS showed significant reductions of cystine levels and altered the perinuclear distribution of the LAMP1+ endo-lysosomal compartment.

Conclusions: Kidney progenitor cells are present in the urine of cystinosis patients. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type CTNS to improve the cellular phenotype. Cystinosis uKPCs are a novel tool for disease modeling, while we provided proof of principle of ex vivo gene therapy.

Vascularized Kidney Organoids on Chip for Efficacy and Toxicity Testing of Somatic Genome Editing

Navin R. Gupta,1,2 Kayla J. Wolf,3 Krishna P. Maremenda,4 Katharina T. Kroll,1 Chengchong Zhang,1 Venkata Soubhaguy,5 Jennifer A. Lewis,6,7 Ryui Morizane,8,9 Massachusetts General Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA; 4Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA.

Background: Somatic genome editing has therapeutic potential to cure inheritable disease. Clinical translation requires safety and efficacy analyses. DNA editing may be widely disparate across species due to genomic differences, necessitating human tissue-based platforms. AAV-based delivery of DNA editing elements is under clinical investigation. If delivered systemically, the kidney may be particularly susceptible to genome editing owing to high blood flow. Kidney organoids have been generated from human stem cells through the co-induction of nephron, stromal, and endothelial progenitor cells that mature to form multicompartment human kidney tissue. We married organoid and organ-on-chip technologies to facilitate the maturation of nephron epithelia and the development of perfusable vascular networks to simulate systemic delivery of genome editing elements.

Methods: Using human recombinant growth factors and defined small molecules, kidney organoids were generated from male and female, embryonic and induced, stem cell lines. To test the efficacy of an AAV2-based delivery system, the tropism of varied capsids, 2/8/9, for kidney compartments was assessed under anastomosed and perfused conditions. The AAV receptor expression was evaluated by single nucleic RNA-seq.

Results: The greatest infectivity was with capsid protein 2, whose receptor of heparan sulfate proteoglycan is expressed in proximal & distal tubules and podocytes of kidney organoids by single cellular transcriptomics. Biomarker analysis demonstrated a statistically significant increase in tubular injury markers, KIM-1 and MCP-1, after infection with AAV2/2 as compared to other AAVs. Following treatment with AAV2/2, WtGFP, the majority of LTU and CDH1 tubular epithelia were GFP+, while PODXL+ podocytes were infected. The optimal AAV serotype, MOI, and duration of infection under static conditions were applied to vascularized kidney organoids. Initial on-chip testing supports enhanced infectivity by live-cell monitoring and wholemount immunostaining, including AAV infection in GFP PODXL+ podocytes.

Conclusions: We propose vascularized kidney organoids may simulate the systemic delivery of AAVs across kidney compartments, as a pre-clinical testing platform of the efficacy and safety of somatic cell genome editing.

Genotype and Phenotype Analysis in Patients with X-Linked Hypophosphatemia

Peong G. Park1, Seon Hee Lim,1 Yo Han Ahn,1 Hee Gyu Kang,2-3 Soo Ha3,2 Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Uijeongbu Saint Mary's Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea.

Background: X-linked hypophosphatemia (XLH) is the most frequent form of hypophosphatemic rickets and is caused by mutations in the PHOSH gene. We analyzed genotype-phenotype correlations in XLH patients with proven PHOSH mutations.

Methods: PHOSH mutations were detected in 57 out of 81 patients who clinically presented with hypophosphatemic rickets. The patients were grouped into nontruncating (n = 11) and truncating (n = 46) mutation groups; their initial presentation as well as long-term clinical findings were evaluated according to these groups.

Results: Initial findings, including presenting symptoms, onset age, height standard deviation scores (SDSs), and laboratory tests, including serum phosphate level and tubular resorption of phosphate, were not significantly different between the two groups (onset age: nontruncating mutation group, 2.0 years, truncating mutation group, 2.1 years; height SDS: nontruncating mutation group, -1.9, truncating mutation group, -1.8; serum phosphate: nontruncating mutation group, 2.5 mg/dL, truncating mutation group, 2.5 mg/dL). However, at their last follow-up, the serum phosphate level was significantly lower in patients with truncating mutations (nontruncating mutation group: 3.2 mg/dL, truncating mutation group: 2.3 mg/dL; P value = 0.003). Additionally, 62.5% of patients with truncating mutations developed nephrocalcinosis, whereas 11% of patients with nontruncating mutations developed nephrocalcinosis (P value = 0.008). Orthopedic surgery due to bony deformations was performed significantly more often in patients with truncating mutations (52.3% vs 10.0%; P value = 0.008).

Conclusions: Although considerable inconsistency exists regarding the correlation of truncating mutations and their disease phenotype in several other studies, we cautiously suggest that there would be genotype-phenotype correlation in some aspects of disease manifestation after long-term follow-up. This information can be used when consulting patients with confirmed XLH regarding their disease prognosis.

Childhood-Onset Nephrocalcinosis in Twins Caused By Biallelic Mutations in CYP24A1 Gene: A Long Journey to a Genetic Diagnosis

Xin Yee Tan, Mary-Beth Roberts, Saul Nurko, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: 24-hydroxylase deficiency is a rare autosomal recessive disorder caused by mutations in CYP24A1 gene, characterized by hyperparathyroidism, hypercalcemia and nephrocalcinosis. Establishing a genetic diagnosis, while important to guide management and family counseling, can be challenging. We hereby report a case of twins with childhood-onset nephrocalcinosis and chronic hypercalcemia caused by biallelic mutations of CYP24A1, which took years to be diagnosed.

Case Description: A 26 year-old female presented for preconception evaluation for a history of childhood-onset nephrocalcinosis and chronic hypercalcemia. Patient reported similar history in identical twin sister. They had exome sequencing (ES) eight years ago after negative genes panel test which revealed a heterozygous variant of unknown significance (c.1186C>T) in CYP24A1. A reanalysis of ES was performed four years ago which demonstrated no changes. Work up revealed hypercalcemia, low 25(OH) vitamin D, elevated 1,25(OH) vitamin D and 24,25(OH) vitamin D, and suppressed PTH(fig.1). Ratio of 25(OH)D-to-24,25(OH)D, a new biochemical test for 24-hydroxylase deficiency, suggested biallelic mutations in CYP24A1 gene. ES reanalysis at this time reclassified the c.1186C>T variant as pathogenic and disclosed a novel intronic variant (c.544-17G>A) which was predicted to cause splice site pattern change with multiple silico algorithms. Parental tests confirmed these two variants were in trans configuration associated with autosomal recessive inheritance pattern. A thorough counselling included low recurrence risk for her children while high risk for her to develop severe hypercalcaemia during pregnancy. She has been closely monitored with low calcium and vitamin D diet, sun avoidance and adequate hydration during current pregnancy with no complications to date.

Discussion: CYP24A1 gene related hypercalcemia is rare and challenging to diagnose even with ES. This case suggests the benefits of ES regular reanalysis for clinically suspected patients with inconclusive genetic findings. The novel intronic mutation identified in this case broadens the genetics spectrum of 24-hydroxylase deficiency.

POI358

Refractory Hypocalcemia with Recurrent Nephrolithiasis Related to a De Novo Gain-of-Function Mutation in the CaSR Gene

Xin Yee Tan, Leila Z. Khan, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: The calcium-sensing receptor (CaSR) serves as the key calcium sensor in the maintenance of systemic calcium homeostasis. Gain-of-function mutations of CaSR-gene, mapped to Ala116-Pro136 region, causes autosomal dominant hypocalcemia and Bartter syndrome type V. Phenotypic manifestations include hypercalcemia, low 25(OH) vitamin D, and suppressed PTH(fig.1). Ratio of 25(OH)D-to-24,25(OH)D, a new biochemical test for 24-hydroxylase deficiency, suggested biallelic mutations in CYP24A1 gene. ES reanalysis at this time reclassified the c.1186C>T variant as pathogenic and disclosed a novel intronic variant (c.398A>T) that predicted a new gain-of-function mutation in the CaSR gene.

Case Description: A 25 year-old G1P0 female at 20 weeks of gestation presented to genetic nephrology clinic due to refractory hypocalcemia. She was incidentally found to have asymptomatic hypocalcemia as part of prenatal evaluation. She was treated with calcium and calcitriol for four months while hypocalcemia persisted. Physical exam was unremarkable. As shown in Table 1, her total serum calcium had been persistently low despite calcium and vitamin D supplementation, and she had low PTH, hyperparathyroidism, hypomagnesemia, and hypercalcuria. Genetic testing revealed a variant (c.398A>T) in the CaSR gene, with normal parental testing consistent with de novo mutation. Given this finding, calcium and calcitriol were discontinued. Renal ultrasound to assess stone burden showed bilateral renal calculi, which patient passed during delivery. Recurrent renal calculi were discovered on post-delivery follow-up imaging, necessitating laser lithotripsy and left ureteral stent insertion.

Discussion: This case highlights the importance of early diagnoses by genetic testing which could guide the hypocalcemia management, as routine calcium and vitamin D supplementation may contribute to nephrolithiasis and thus the risk of nephrocalcinosis. c.398A>T in the CaSR gene has been described in 1 family cluster of 3 patients with hyperparathyroidism and hypocalcemia to date. De novo mutation, unique to this case, was evidenced by negative parental testing.

TRPV4 Calcium Channel Activity Is Increased by With-No-Lysine Kinase 1 in the Collecting Duct Cells

Vitor N. Tomilin, Kyrily Pyrshev, Naghmeh Hassanzadeh Khayyat, Oleg L. Zaika, Oleh Pochynuk. The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: Kidneys play a central role in regulation of potassium homeostasis and maintaining plasma K+ levels within a narrow physiological range. Dietary K+ load increases circulating levels of the mineralocorticoid aldosterone leading to kaliuresis via stimulation calcium-activated large conductive maxi-K (BK) channel dependent K+ secretion in the collecting duct cells. WNK1 and WNK4 (With-no-lysine) kinases, have been recognized to regulate K+ balance, in part, by orchestrating BK-dependent K+ secretion in the ASDN (aldosterone sensitive renal nephron). Ca2+-permeable TRPV4 channel is essential for BK activation in the distal nephron, as we have recently demonstrated. Also of note, high K+ diet increases TRPV4 activity and expression largely in an aldosterone-dependent manner.

Methods: Patch-Clamp; [Ca2+]i imaging; Western blotting.

Results: In the current study, we aimed to test whether WNK1/4 contribute to regulation of TRPV4 by aldosterone. First we treat ment of mpkCCD14 cells with 1 µM aldosterone for 24 h as expected, increased TRPV4-dependent Ca2+ influx approximately 2 fold. Inhibition of WNK1/4 with the pan-blocker of WNK, WNK463 (100 nM) for 24h decreased basal TRPV4 activity by approximately 30% and virtually abolished stimulation of TRPV4 by aldosterone. Similarly, WNK1 blockade with WNK1- in1 (400 nM, 24 h) produced comparable inhibitory effects on the basal and aldosterone-dependent TRPV4 activity as WNK463. Western blots performed on apical plasma membrane fraction from the same cells showed a complete block of the stimulatory effect of aldosterone after treatment with WNK1-in1 (400 nM, 24 h). Co-expression of TRPV4 and WNK1 into Chinese hamster ovary (CHO) cells increased the macroscopic TRPV4 current densities from 160±10 pA/pF to 250±22 pA/pF. In contrast, overexpression of TRPV4 with a dominant negative WNK1 variant (K233M) decreased the whole cell currents to 60±5 pA/pF suggesting both stimulatory and permissive roles of WNK1 in regulation of TRPV4.

Conclusions: Overall, we show that WNK1/4 is essential in controlling basal TRPV4 activity and its activation by aldosterone in collecting duct cells. We propose that this new mechanism is likely contributing to regulation of urinary K+ levels to maintain systemic homeostasis.

Cyclin M2 (CNNM2) Is Essential for Development and Systemic Magnesium Homeostasis

Gijs A. Franken,1 Murat Seker,2 Femke Latta,2 Caro Bos,2 Joost Hoenderop,2 René J. Bindels,2 Tilman Breiderhoff,2 Karl P. Schlingmann,2 Dominik Müller,2 Jeroen H. De Baaij,1 Radboudumc, Nijmegen, Netherlands; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3Charite-Universitätsklinikum Mitte, Berlin, Munster, Germany.

Background: Patients with mutations in the Cyclin M2 (CNNM2) gene display hypomagnesemia and intellectual disability. CNNM2 is highly expressed in the distal convoluted tubule, where it is involved in renal magnesium (Mg2+) reabsorption. However, the complete phenotypic spectrum of the CNNM2-related disorder remains unknown. We characterised a large patient cohort with novel CNNM2 variants and used transgenic mouse models to investigate the role of CNNM2 in Mg2+ homeostasis.

Methods: The identified CNNM2 variants were found in a cohort of hypomagnesaemic patients and characterised using Mg2+ transport assays in HEK293 cells. In addition, CNNM2-deficient mice were developed using CRISPR-Cas9 technology and exposed to deficient or saturated Mg2+ diets for two weeks. Using metabolic cages, the 24-hour urinary and faecal excretion for Mg2+ was determined.

Results: Eleven patients were identified with novel dominant variants in CNNM2. Using Mg2+ transport assays in HEK293 cells, seven variants showed decreased Mg2+ transport, compared to wild type. These pathogenic mutations resulted in decreased membrane expression of CNNM2. The phenotype of these patients was compared with those previously published. Patients with pathogenic CNNM2 mutations had a mean plasma Mg2+ level of 0.54 ± 0.08 mmol/L. Neurological manifestations, such as seizures (79%), intellectual disability (92%) and speech difficulties (91%) were prevalent. Other NIH Support - NIDDK, AHA, Private Foundation Support

Conclusions: CNNM2 is important for normal development and Mg2+ homeostasis, although the link remains elusive. Our mouse study suggests a potential role of CNNM2 in the intestine, which could have implications for the treatment of patients suffering from CNNM2 mutations.

BCSL1 Mutations Produce Fanconi Syndrome with Developmental Disability

Nana Sakakibara,1 Sadayuki Nagai,1 Yuya Aoto,1 China Nagano,1 Tomoko Horinouchi,1 Tomohiko Yamamura,1 Kazumoto Iijima,1 Kandai Nozu.2 1Kobe University Graduate School of Medicine, Kobe, Japan; 2Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: Fanconi syndrome is a functional disorder of the proximal tubule, characterized by proximal aminoaciduria, glucosuria, hypophosphatemia, and metabolic acidosis. With the advancements in gene analysis technologies, several causative genes are identified for Fanconi syndrome. Several mitochondrial diseases cause Fanconi syndrome and various systemic symptoms; however, it is rare that the main clinical symptoms in such disorders are Fanconi syndrome without systematic active diseases like encaphalopathy or cardiomyopathy.

Methods: We analyzed the patients clinically diagnosed with Fanconi syndrome of unknown cause. Patient-1 was a 3-year-old girl and Patient-2 was a 10-months-old boy. They were diagnosed with Fanconi syndrome based on renal tubular dysfunction, rickets, and elevated aspartate aminotransferase and alanine aminotransferase levels. They also had severe developmental disability and growth failure. Patient-1 had twin brothers who were diagnosed with Fanconi syndrome. GDF-15, a mitochondrial disease biomarker, was evaluated as an analysis of mitochondrial dysfunction. The following assays were also performed to confirm the pathogenicity of the novel mutations: oxygen consumption rate (OCR) of mitochondria, the activity of mitochondrial respiratory chain complex.

Results: Whole-exome sequencing detected compound heterozygous BCSL1 mutations, which cause mitochondrial respiratory chain complex III deficiency. In Patient-1, we identified missense mutation and frameshift mutation of BCSL1, c.268C>T, p.(Arg90Cys) and c.821del, p.(Pro274Arg*26). These mutations have been reported previously. In Patient-2, we also identified novel missense mutations of BCSL1, c.167G>A, p.(Arg56Gln) and c.1195T>G, p.(Tyr399Asp). The level of GDF-15 was elevated in both patients; 1025.5 pg/mL in Patient-1 and 1152.1 pg/mL in Patient-2 (normal: <70.7 pg/mL). In Patient-2 skin fibroblasts, the activities of mitochondrial respiratory chain complexes were normal, whereas the OCR was significantly lower than that in the control.

Conclusions: Mitochondrial diseases with isolated renal symptoms are uncommon; however, our study indicates that mitochondrial respiratory chain complex III deficiency due to BCSL1 mutations cause Fanconi syndrome with developmental disability as the primarily indications.

POI362
Expression of miRNA from Urinary Extracellular Vesicles in Patients with Gitelman Syndrome

Chih-Chien Sung, Shih-Hua Lin, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.

Background: Gitelman syndrome (GS) is an inheritable renal tubule disorder with defect of sodium chloride cotransporter on distal convoluted tubule, resulting salt-losing, hypokalemia, hypomagnesemia and hypocalciuria. miRNA plays an important role in renal development and physical regulation. However, the miRNA expression from urinary extracellular vesicles (uEVs) in patients with Gitelman syndrome remains unclear.

Methods: miRNA profiling was conducted in uEVs obtained from 20 genetically confirmed GS patients and 20 healthy controls using small RNA sequencing.

Results: Principal component analysis revealed distinct miRNA expression pattern in GS patients (4 groups) compared with healthy controls (4 groups). The biological process from identified miRNA in uEVs included signaling transduction (24.3%), cell communication (22.6%), regulation of nucleasce, nucleotide, nucleic acid metabolism (18.4%), and transporter (7.7%). Comparing with healthy controls, differential expression of miRNA showed 18 upregulated miRNA (including has-mir-6825-5p, has-mir-4302, has-mir-4458) and 23 downregulated miRNAs (including has-mir-4740-5p, has-mir-4783-3p, has-mir-4506) in GS patients. Biological process conducted by DAVID (Database for Annotation, Visualization, and Integration Discovery) using target genes from differentially expressed up-regulated miRNAs were negative regulation of translation, positive regulation of transcription, and gene silencing by miRNA. Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis from upregulated miRNAs also revealed PTK2-Akt, MAPK, ERK, aldosterone synthesis and secretion, TGF-β, aldosterone regulated sodium reabsorption, and calcium signaling pathways.

Conclusions: The expression of miRNA from uEVs in patients with GS could provide a physiological role in response to defect of NCC. Further validation and functional study will be performed.

Infantile Hypercalcemia Associated with a Novel Homozygous Mutation in SLC34A1 Gene Encoding Sodium-Dependent Phosphate Transporter 2A
Mohamed Hassanen, Jordana Yahr, Mary-Beth Roberts, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: Early-onset and familial hypercalcemia often suggest a genetic etiology which is rare. Infantile hypercalcemia (IH) is a rare, autoosomal recessive disorder that occurs due to mutations in the SLC34A1 gene which encodes a sodium-dependent phosphate transporter 2A(NaPi-IIA) responsible for phosphate reabsorption in the kidney. We report an adult case who carried a clinical diagnosis of familial hypercalcemic hypercalciuria (FHII) since infancy, which is usually a benign condition characterized by autosomal dominant inheritance caused by mutations in calcium-sensing receptor (CASR) gene, while recently uncovered as IH related to a novel homozygous mutation in the SLC34A1 gene.

Case Description: A 36-year-old Finnish male with a diagnosis of FHII presented to the genetics nephrology clinic for consultation regarding the recurrence risk for his children. He was diagnosed with FHII during infancy in Finland and has been treated with a low calcium diet. Family history was notable for a clinical diagnosis of FHII in his older sister. Physical exam was unremarkable. Labs showed mild hypophosphatemia and decreased glomerular filtration rate (69 mL/min/1.73m²), with normal serum ionized calcium and intact parathyroid hormone. Twenty-four hour urine analysis revealed hypercalciuria 363 mg/d (normal <250), hypernatruria 155 mmol/d (normal 50 – 150) and hypocitraturia 420 mg/d (normal >450). Kidney ultrasound showed bilateral medullary nephrocalcinosis. Genetic testing identified a novel homozygous variant in SLC34A1 gene (c.1483C>T) and was negative in CASR gene. Family genetic studies revealed his affected sister is also homozygous for the same variant while his unaffected sister is only a carrier. With the new diagnosis, he was started on potassium citrate and chlorthalidone, and was reassured with the low recurrence risk for his children.

Discussion: Mutations in the SLC34A1 gene lead to altered NaPi-IIA expression and reduced phosphate reabsorption, leading to hypophosphatemia. Secondary vitamin D activation leads to hypercalcemia, hypercalciuria, and nephrocalcinosis. We identified a novel mutation in the SLC34A1 gene which broadens the genetic spectrum of IH. This case highlights the importance of early genetic testing for suspected hereditary hypercalcemia that may help improve its diagnosis and treatment.

Characteristics and Genetic Defects of Systemic Lupus Erythematosus-Associated Thrombotic Microangiopathy
Cui Queuan. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Thrombotic microangiopathy (TMA) is a life-threatening complication of systemic lupus erythematosus (SLE). However, the etiology of a considerable number of patients is still unclear and the best treatment is unknown. Sporadic reports suggest that the activation of complement pathway may play a role in SLE-TMA.

Methods: We prospectively enrolled 40 SLE-TMA patients in Peking Union Medical College Hospital, 14 patients with lupus nephritis (LN) and 38 patients with other types of TMA. The clinical data were collected. Peripheral blood concentrations of CFI, cCFB, soluble CSb-9, relative activity of complement pathway, ICAM1, VCAM1 and E-Selectin were measured by ELISA in SLE-TMA patients and control groups. Whole exome sequencing (WES) was performed to analyze the genetic variants in SLE-TMA patients.

Results: SLE-TMA mediated by ADAMTS13 inhibitors had severe nervous system involvement, but less kidney involvement and good response to plasma exchange. Among SLE-TMA with unknown etiology, patients with TMA confined to kidney had lighter hematological manifestations and lower serum creatinine level than SLE-aHUS (p = 0.005). Compared with SLE-aHUS, the concentration of CFI in SLE-TMA limited to kidney was higher (p = 0.026). The level of E-selectin in patients with SLE-TMA limited to kidney was significantly lower than that in SLE-aHUS patients with MAHA (p = 0.016). There was no significant difference in genetic susceptibility among SLE-aHUS, SLE-TMA limited to kidney and SLE-TMA with other causes. In SLE-TMA patients, thrombophilia variants may play a more important role than complement variants. Treatment response of SLE-TMA patients with variants is worse than those without variants. In serological test, VCAM1 level in SLE-TMA patients with complement related genetic variants was significantly higher than that in SLE-TMA patients without variants (p = 0.001). Patients with compound complement variants are more likely to detect abnormal level of complement factors.

Conclusions: SLE-TMA with unknown etiology can be divided into two subgroups with different severity according to the presence or absence of MAHA. The detection of complement factor and E-selectin may play a role in differentiating the two subgroups of SLE-TMA. The complement pathway is highly activated in patients with compound complement mutations, resulting in increased complement factors consumption.

Mapping Genomic Regulation of Kidney Diseases and Traits at a Cell Type and Variant Level of Specificity
Christopher Benway, Michelle McNulty, Seong Kyu Han, Dongwon Lee, Matt G. Sampson. Nephrotic Syndrome Study Network (NEPTUNE) Consortium Boston Children's Hospital, Boston, MA.

Background: Although numerous genetically associated loci for kidney function and disease have been identified by genome-wide association studies (GWAS), determining the causal genes and functional variants remains a major challenge. Integration of GWAS results with other data types (such as expression quantitative trait loci [eQTLs]) can help identify causal and functional variants in a tissue- or cell-type specific manner. Further, analysis of disease tissue may uncover context-specific associations that may otherwise be undetectable.

Method: We integrated eQTL data from micro-dissected glomerular (n = 240) and tubulointerstitial (TI) (n = 311) transcriptions from individuals with nephrotic syndrome and summary statistics from two large trans-ethnic GWAS meta-analyses for estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). We applied a Bayesian statistical framework for eQTL discovery by mapping (TORUS/DAP). EQTL signals from each renal compartment were integrated with summary statistics to perform a gene-level probabilistic transcriptome-wide association study (PTWAS) and SNP-level co-localization (fastENLOC).

Results: We identified 5,526 glomerular and 9,742 TI eQTLs at the 5% FDR level. For eGFR, we identified 971 gene-trait pairs in the glomerulus and 1,816 gene-trait pairs in TI tissue that were significant (FDR < 5%). For UACR, we identified 194 and 340
Factors Contributing to Decisional Conflict in Older Persons Facing Dialysis Decisions

Background: Dialysis and conservative kidney management are the two main treatment options for elderly persons with end-stage-kidney disease who are ineligible for kidney transplantation. The high stakes of these decisions often force patients to choose between quality versus quantity of life. Thus, they face tremendous conflict while making dialysis decisions. This decisional conflict can adversely affect their mental health-related quality of life and leads to avoidable delays in decision making. Exploring factors contributing to dialysis decisional conflict in older persons with chronic kidney disease is critical.

Methods: Using a qualitative descriptive approach, we purposefully sampled a cohort of 10 patients; 5 with high scores on decisional conflict scale, and 5 with low scores. Patients met with a palliative care physician to discuss dialysis and these visits were audio-recorded. Audio recordings were transcribed verbatim and entered into MAXQDA for data management. Following an iterative process, 2 independent reviewers analyzed the transcripts for common themes contributing to decisional conflict.

Results: The mean age of patients was 83 years. We observed 3 themes in the data of patients with low decisional conflict: (1) clarity in values, (2) good current quality of life, and (3) strong therapeutic alliance with their nephrologist. In the high decisional conflict group, we observed 5 themes: (1) fear of: physical pain, complications from dialysis and its time commitment, loneliness, and losing independence, (2) concerns about being a burden to loved ones, (3) uncertainty about prognosis, (4) worries about transportation to and from dialysis, and (5) poor knowledge of treatment options.

Conclusions: Patients with high decisional conflict worried about their future quality of life, sense of burdensomeness, prognostic uncertainty, and issues related to transportation. They wished for detailed knowledge of treatment options. Future dialysis decision-making interventions should be tailored to identify each patient’s unique needs, and incorporate details about treatment options and information about logistics of dialysis. Nephrologists need to discuss the expected quality of life and prognosis. Last, family involvement in these discussions and buy-in for or against dialysis may be helpful in mitigating the patient’s sense of being a burden on their loved ones.

Shared Decision-Making Among Older Adults with Advanced CKD

Rebecca Frazier,1 Sarah Levine,2 Hocine Tighiouart,1 John B. Wong,3 Tamara Turchin-Chew-Weser,1 Elisa J. Gordon,1 Daniel E. Weiner,2 Keren Ladin.1 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Tufts Medical Center, Boston, MA; 3Tufts University, Medford, MA.

Background: Older adults with advanced chronic kidney disease (CKD) face difficulty, preference-sensitive decisions about dialysis. Although shared decision-making (SDM) can help align treatment with patient preferences and values, the degree to which older CKD patients experience SDM and associated factors remain unknown.

Methods: Using data from the Decision Aid for Renal Therapy Trial, we examined SDM in adults ≥70 years with non-dialysis CKD stage 4–5 from 4 sites in the US using the validated SDM9 scale, with scores ranging from 0-100 and higher scores reflecting greater SDM. We categorized predictors into demographic and clinical factors, personal perceptions and preferences, and behavioral and educational factors (resources supporting SDM). Multivariable linear regression assessed predictors of SDM.

Results: Among 350 participants, mean age was 78±6 years, 58% were male, 13% were Black, and 48% had diabetes. Mean SDM9 score was 52±16. Responses varied from 73% somewhat, strongly, or completely agreeing that “My doctor and I selected a treatment option together” (Figure). In regression analyses, being “very well informed” about kidney treatment options (β=1.49, p<0.002), Black race (β=1.04, p=0.02), attended a dialysis class (β=0.83, p=0.002), diabetes (β=0.79, p=0.007), older age (β=0.52, p=0.04), lower eGFR (β=2.4, p=0.002), and higher decisional certainty (β=1.5, p=0.002) were associated with higher SDM9 scores. In models evaluating behavioral/educational factors, dialysis class attendance (β=0.8, p=0.009) and care satisfaction (β=0.9, p=0.002) were associated with higher scores.

Conclusions: There is room for improvement in SDM for many older CKD patients who face preference-sensitive dialysis decisions. Being well-informed about treatment options, increased decision certainty, and dialysis class attendance were associated with SDM, suggesting that education is critical to the SDM process.

Effect of Estimated Glomerular Filtration Rate on Survival in Patients 275 Years of Age at Dialysis Initiation

Aghiles Hamroun,1,2 Linh Bui,3 Sébastien Gomis,1 François Glowacki,1 1Centre Hospitalier Universitaire de Lille, Lille, France; 2Centre de Recherche en Epidemiologie et Sante des Populations, Villeneuve, France; 3Paris Saclay University, Paris, France.

Background: Data regarding the prognostic impact of estimated glomerular filtration rate (eGFR) at dialysis start are discordant, and remain very scarce in elderly populations. The aim of this study is to explore whether the effect of eGFR on survival was similar in elderly incident dialysis patients compared with younger ones.

Methods: We included 4690 patients ≥75 years of age and 7045 patients 18-74 years of age starting dialysis between 2004 and 2018 from a French regional registry. Patients were followed until death or the end of 2019. Survival was assessed by Kaplan-Meier curves and the relative risk of death associated with eGFR (MDRD) was assessed by multivariate Cox regression analysis.

Results: The results showed an increasing trend of eGFR at dialysis start, which was also systematically higher in elderly patients (13.2 [10.1; 17.2] vs 11.2 [8.3; 14.9] ml/min/1.73m², p<0.001) (Figure). Overall, we found a significant dose-effect relationship between eGFR at dialysis initiation and mortality (HR = 1.33 [1.16; 1.51], 1.47 [1.29; 1.69], and 1.72 [1.49; 1.78] respectively for eGFR [5-10], [10-15], and ≥15ml/min/1.73m², p for trend < 0.001). The same results were found in subgroup analyses according to age category (Figure2), with a significant interaction in favor of a stronger association in younger patients (p = 0.031).

Conclusions: In incident dialysis patients, our study shows a dose-effect relationship between higher eGFR at dialysis start and mortality, regardless of age category. This association seems to be even stronger in younger patients.
Hospitalization Risk Among Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Connie Rhee, Amy S. You, Yoko Narasaki, Csaba P. Kovesdy, Dana B. Mukamel, Susan T. Crowley, Alejandra Novoa-Vargas, Danh V. Nguyen, Kamyar Kalantar-Zadeh. University of California Irvine, Irvine, CA; The University of Tennessee Health Science Center YoShop, Memphis, TN; Yale University School of Medicine, New Haven, CT; Veterans Health Administration, Washington, DC.

Background: Regarded as the default treatment option for advanced CKD, dialysis has been associated with frequent hospitalizations, functional decline, and loss of independence, particularly in the elderly and comorbid. While there is rising interest in conservative management (CM) as an alternative treatment strategy, this remains underutilized. We sought to quantify differences in healthcare utilization in advanced CKD patients transitioning to dialysis vs. CM.

Methods: We compared hospitalization risk in 309,188 advanced CKD patients (eGFRs <25 separated by ≥90 days) treated with dialysis vs. CM from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-yrs of the index eGFR (1st eGFR <25), with the former group parsed into late vs. early dialysis (eGFRs <15 vs. ≥15 at dialysis transition). Secondary analyses stratified the former group as late, intermediate, vs. early dialysis (eGFRs ≥5, 5-<10, vs. ≥10 at dialysis transition). Poisson regression was used to compare mortality rates across exposure groups.

Results: Among 309,188 advanced CKD patients, 60% vs. 40% of patients were treated with CM vs. dialysis, respectively. Patients who underwent CM vs. late dialysis had similar mortality, whereas those who underwent early dialysis had the highest mortality rates. In secondary analyses comparing CM and late vs. intermediate vs. early dialysis, a similar pattern was observed (140, 126, 141, vs. 158 deaths per 1000 person-yrs, respectively). In age-stratified analyses, compared to CM, all dialysis groups had higher mortality rates irrespective of timing of initiation in those <65 and ≥65 yrs old.

Conclusions: In a nationally representative cohort of advanced CKD patients, CM vs. late dialysis demonstrated similar mortality, whereas those who underwent early dialysis had the highest mortality rates.

Funding: NIDDK Support

Mortality Rates in a Nationally Representative Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Amy S. You, Kamyar Kalantar-Zadeh, Yoko Narasaki, Csaba P. Kovesdy, Dana B. Mukamel, Susan T. Crowley, Alejandra Novoa-Vargas, Danh V. Nguyen, Connie Rhee. University of California Irvine, Irvine, CA; The University of Tennessee Health Science Center, Memphis, TN; Yale University School of Medicine, New Haven, CT; Veterans Health Administration, Washington, DC.

Background: While dialysis has been the prevailing treatment paradigm in CKD patients progressing to ESRD, this treatment approach may not offer survival benefit nor improved quality of life in certain subgroups (elderly, multi-morbid). Hence, there is growing interest in conservative management (CM) as an alternative treatment strategy in advanced CKD.

Methods: We compared mortality rates in advanced CKD patients (eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis from 1/1/07-6/30/20 from the OptumLabs® Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-yrs of the index eGFR (1st eGFR <25), with the former group parsed into late vs. early dialysis (eGFRs <15 vs. ≥15 at dialysis transition). Secondary analyses stratified the former group as late, intermediate, vs. early dialysis (eGFRs ≥5, 5-<10, vs. ≥10 at dialysis transition). Poisson regression was used to compare mortality rates across exposure groups.

Results: Among 309,188 advanced CKD patients, 60% vs. 40% of patients were treated with CM vs. dialysis, respectively. Patients who underwent CM vs. late dialysis had similar mortality, whereas those who underwent early dialysis had the highest mortality rates. In secondary analyses comparing CM and late vs. intermediate vs. early dialysis, a similar pattern was observed (140, 126, 141, vs. 158 deaths per 1000 person-yrs, respectively). In age-stratified analyses, compared to CM, all dialysis groups had higher mortality rates irrespective of timing of initiation in those <65 and ≥65 yrs old.

Conclusions: In a nationally representative cohort of advanced CKD patients, CM vs. late dialysis demonstrated similar mortality, whereas those who underwent early dialysis had the highest mortality rates.

Continued Primary Care Use During the Transition to Kidney Failure (KFRT) Is Associated with Reduced Mortality Among Older Hemodialysis (HD) Patients

Raquel C. Greer, JYoon B. Ahn,1 Laura Plantinga,1 John Sperati,1 Mara McAdams-DeMarco,1 Kelly H. Beers,2 Sandeep S. Soman,3 Michael J. Choi,1 Bernard G. Jaar,1,6 National Kidney Foundation Education Committee

1Johns Hopkins Medicine, Baltimore, MD; 2Albany Medical College, Albany, NY; 3Emory University, Atlanta, GA; 4Henry Ford Hospital, Detroit, MI; 5MedStar Georgetown University Hospital, Washington, DC; 6Nephrology Center of Maryland, Baltimore, MD.

Background: Primary care providers (PCPs) are responsible for addressing patients' comprehensive health needs. However, the provision of primary care during the KFRT transition and its contribution to clinical outcomes among in-center HD patients have not been well explored.

Methods: We quantified the associations between PCP use, mortality, and hospitalization among older (age≥67) incident (2008-2014) in-center HD patients using data from the United States Renal Data System. We defined patients' PCP use 1-year prior and 1-year post-KFRT as “continued” for PCP use pre- and post-KFRT; “initiated” for no PCP use pre-KFRT and PCP use post-KFRT; “discontinued” for PCP use pre-KFRT and no PCP post-KFRT; or “never used” as no PCP use pre- or post KFRT. We used Cox proportional hazard models and adjusted for confounding by inverse probability weighting method to estimate hazard ratios (HRs) for all-cause mortality and first all-cause hospitalization up to 2 years post-KFRT.

Results: Among 111,424 patients, 57% had continuity of PCP care, 10% initiated PCP use, 10% discontinued PCP use, and 23% never used PCP care during the KFRT transition. Compared to those who never used primary care during the KFRT transition, those with continued primary care use had a 14% lower risk of mortality. Continued and initiated PCP care post-KFRT transition was associated with a 5-12% higher risk of hospitalization, respectively.

Conclusions: Continued primary care use during the KFRT transition was associated with lower mortality, but a higher risk of hospitalization. Additional studies are needed to determine the aspects of primary care that may be beneficial and which patients are most likely to benefit from continued PCP use.

POI1375
Vascular Access Type and Survival Outcomes in Elderly Hemodialysis Patients

Background: The ideal vascular access for elderly hemodialysis (HD) patients remains widely debated. Limited life expectancy and lower arteriovenous access (AVA) maturation rates increase the likelihood of starting HD with a central venous catheter (CVC). The aim of the study was to evaluate the influence of vascular access type in survival outcomes for elderly HD patients.

Methods: Single-center retrospective cohort study of incident HD patients aged ≥80 years from January 2010 to May 2021. Patients who recovered renal function or switched to another renal replacement therapy were excluded. Patients were categorized according to their vascular access at the beginning of dialysis: CVC or AVA. Baseline clinical and demographic data were compared among groups. Survival outcomes by the end of follow-up (31 May 2021) were analyzed using Kaplan-Meier survival curves and Cox’s proportional hazards model. Statistical analysis was performed using SPSS (Version 23 for Mac OSX).

Results: The study included 99 patients: 48 (48.5%) were male, 44 (44.4%) diabetic, 60 (60.6%) had ischemic heart disease and 15 (15.2%) peripheral artery disease. Mean Charlson Comorbidity Index was 8.4±1.65 and mean age 85.1±3.98 years. Eleven patients (11.1%) were over 90 years old. Eighty patients (81%) started HD urgently as inpatients. The vascular access at dialysis start was a CVC in 75.8% (n=75) and an AVA in 24.2% (n=24). No statistical differences were found in age, gender, comorbidities and causes of HD among groups. During a mean follow-up of 2.3 years, there were 64 deaths, 27 due to infections (12 access-related infections). All-cause mortality (HR [95% CI]: 1.92 [1.05-3.49], p=0.033) and infection-related mortality (HR: 5.87 [1.38-24.94], p=0.017) were significantly higher among patients who initiate HD with a CVC as compared to an AVA.

Conclusions: The ideal vascular access in elderly patients remains controversial. Our results suggest that patients who start HD with a CVC presented higher all-cause and infection-related mortality when compared with patients who start with an AVA. Our study supports the initiative “fistula first” however more studies are needed to confirm the observations.

Nurse-Driven Advance Care Planning in a Hemodialysis Unit in a Veteran Population

Sam Tonthat,1,2 Rebecca Yamark,1 Jocell Fernandez,2 Jennifer Ballard-Hernandez,2 Marysol Cacciata,2 Pankaj Gupta,2 Joline L. Chen.2,3 University of California Irvine, Orange, CA; 1Long Beach Veteran Affairs Healthcare System, Long Beach, CA.

Background: Patients with end-stage kidney disease (ESKD) face difficult choices near the end of life. Advance care planning (ACP) allows patients and their providers to plan for treatments that align with patients’ goals. In the US, only 6-35% of all ESKD patients have advance directives (AD). PREPARE is an interactive ACP website that helps patients complete AD and express their wishes regarding medical decisions. The goal of this study was to assess the feasibility and acceptability of using a nurse to facilitate ESKD patients to completing the PREPARE ACP during dialysis.

Methods: Inclusion criteria include patients without a documented AD within the past 3 years. Exclusion criteria are dementia/cognitive impairment, psychosis, deafness, or blindness. Pre and post engagement surveys were completed. Barriers related to navigating the PREPARE website were documented.

Results: Of 55 patients at the dialysis unit, 25 were eligible and 14 were enrolled. All participants are male with mean age of 69. All participants completed their AD within 1 dialysis treatment. In the pre-PREPARE questionnaire, using the Likert scale of 1 to 5 (1 for “not at all” to 5 for “extremely likely”), patients scored 7.61 for ease, 7.23 for comfortability, and 8.07 for helpfulness. Analysis of PREPARE AD showed that on a scale of 1 (AD goal mainly to extend life) to 5 (to focus on the quality of life), the median score is 3.06 suggesting that patients value both “extend life” and “maintain quality of life”. Five patients expressed wishes for full care, 6 wanted a trial of resuscitation, and 3 requested DNR. Barriers to using PREPARE included patient difficulty navigating the website without help and using a laptop during dialysis when both hands are not always free.

Conclusions: Our study shows that PREPARE is a feasible method in facilitating ACP during dialysis, however, many patients needed assistance to complete the process. Future studies are needed to apply PREPARE and ACP wishes in the ESKD population.

Dialysis Patients’ Preferences on Resuscitation: A Cross-Sectional Study Design

Husam Alzayyev,1,2 Annette M. Geraghty,1 Kuruvilla K. Sebastian,1,2 Hardash Panesar, Donal N. Reddan.1,2 1Galway University Hospitals, Galway, Ireland; 2Mayo University Hospital, Castlebar, Ireland.

Background: End-stage kidney disease is associated with a 10-100-fold increase in cardiovascular mortality compared to age-, sex-, and race-matched population. Cardiopulmonary resuscitation (CPR) in this cohort has poor outcomes and is often followed by increased functional morbidity. Advance care planning (ACP) is an important aspect of patients’ care that is often missed in chronic kidney disease (CKD) and there is an emerging need to provide care that aligns with patients’ goals. Therefore, these patients are often denied the full benefits of quality end-of-life care, either dying in hospitals or spending only a few days on hospice after dialysis is stopped. An alternative model would allow people living with end-stage renal disease (ESRD) to receive hospice services concurrently with dialysis treatments.

Methods: We implemented a concurrent hospice-dialysis program in one health system with the goal of expanding access to end-of-life care. In this project, we will build evidence for feasibility and program requirements for extending such programs to other settings across the country. The study included semi-structured interviews with bereaved caregivers, hospice and dialysis clinicians, and health system administrators from the Pittsburgh area and other regions in the U.S. Interviews elicited perceptions of strengths and weaknesses of a scalable concurrent hospice and dialysis program, including barriers and facilitators of implementation across various settings.

Results: We conducted 25 interviews with 2 patients (8%), 3 caregivers (12%), 15 clinicians (60%), and 5 administrators (20%). Preliminary themes include important considerations: 1) Mechanisms and operational definitions for identification of eligible patients; 2) Procedures for decision-making conversations with patients and families; and 3) Protocols for communication between hospice and dialysis teams to coordinate care. Medicaid policy and funding restrictions were also frequently discussed as barriers to care.

Conclusions: Perspectives from patients, caregivers, clinicians and administrators describe critical implementation processes and resources for a successful concurrent hospice and dialysis program. These include the following: clear criteria for patient eligibility, consistent language to use when talking with patients and families, education for both hospice and dialysis teams, and a well-defined plan for care coordination between teams. Future evaluation of such programs may lead to policy change to make concurrent care broadly financially feasible.

Dialysis for the Hospice Patient: A Paradoxical Challenge for Palliative Nephrology
Frank A. Portugal, Steve I. Khalil. Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, NJ.

Introduction: We present a case of a patient who developed anuric AKI who subsequently needed dialysis while patient and family were also simultaneously interested in hospice. Our case addresses the difficult conversation in prognosticating and how much disability for patients requiring dialysis can be challenging.

Case Description: A 63-year-old woman with hypertension and recently diagnosed metastatic pancreatic adenocarcinoma initially presented for intractable right hip pain and was admitted for emergent palliative radiation. She experienced rapid deterioration including septic and hemorrhagic shock and was managed in the ICU until she was later stabilized off pressors and downgraded to the floors. Unfortunately, she had further complications and quickly experienced anuric AKI from ischemic ATN as her serum creatinine rose from 0.8 to 4.9 mg/dL and became significantly volume overloaded with worsening ascites. The decision was to start a trial of dialysis by family, but they also wanted hospice. Questions arose including prognosis and if patient could simultaneously be provided with dialysis during hospice. Given the current model of withdrawing from dialysis for hospice eligibility, the daughters agreed to transition their mother to hospice. The patient passed prior to leaving the hospital.

Discussion: We present a difficult scenario for the nephrologist as serious illness conversations remain incredibly challenging. We may opt not to take part in these conversations either due to time commitment, not viewing it as a primary responsibility, or not wishing to upset the patient and their families. Also, so much uncertainty in predicting prognosis makes it intimidating. Here, what also needed to be addressed were hospice benefits for the dialysis patient, if any existed. Usually, one is required to withdraw from dialysis to receive hospice care. There have been suggestions in providing a trial or “as needed dialysis” to focus on a patient-centered type of care but unfortunately that could potentially impact quality metrics and Medicare reimbursement for dialysis centers. As such, these ongoing challenges not only require collaboration between Nephrology and Palliative medicine but also changes at the national broader level.

POI1381

Kidney Palliative Care in Transplant Recipients with a Failing Allograft
Samantha L. Gelfand,1 Naoka Murakami,1 Joel T. Adler,1 Joshua R. Lakin.2 Brigham and Women’s Hospital, Boston, MA; 2Dana-Farber Cancer Institute, Boston, MA.

Background: Kidney transplantation provides longer survival and better quality of life than dialysis for patients with end-stage kidney disease. However, when allografts fail, navigating treatment options can be as challenging as caring for patients with allograft failure. Not only are patients older and sicker than when they were transplanted. Kidney palliative care, specialized interprofessional medical care working together with nephrology providers, providing communication, coordination, symptom management, and psychosocial support for seriously ill patients, has not yet been well-studied for those with kidney transplants.

Methods: We conducted a retrospective observational study comparing palliative care delivery, patient treatment choices, and clinical outcomes before and after creation of an inpatient kidney palliative care service (KidneyPal) at our institution. We included all adult kidney transplant recipients who had an inpatient stay during the 18 month period before and after the creation of KidneyPal. Allograft failure was defined as imminent indication or chronic need for dialysis for more than 3 months.

Results: Fifty-four and fifty-nine patients were included before and after KidneyPal implementation, respectively. For the patients who experienced death with a functioning graft, inpatient palliative consultation frequency was similar before and after the creation of KidneyPal (40% and 33%, respectively). However, for the patients with allograft failure, palliative care consultation increased from 5.9% to 24.1%. Death in the ICU was uncommon (15% vs. 17%), but death in hospice was more frequent (7% vs. 15%) after KidneyPal was created. While palliative care clinicians addressed code status, symptom management, and psychosocial issues throughout the study period, KidneyPal clinicians held more discussions about treatment options for allograft failure (20% vs. 41%).

Conclusions: Our observational study suggests that kidney palliative care may be useful in the context of allograft failure, particularly with regard to ensuring goal-directed shared decision making. Discussing prognosis, goals of care, and care options after graft failure are palliative skills that are best be enhanced by collaboration with a specially kidney palliative care team.

Patient Perspectives on Frailty Status Evaluation During Kidney Transplant Assessment
Henry H. Wu,1,2 Lyndsey Rushton,1 Fiona Biggins,1 Aimun K. Ahmed,1,2 Alexander Woywodt.1,2 Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 1The University of Manchester Faculty of Biology Medicine and Health, Manchester; United Kingdom.

Background: The concept of frailty garnered attention within nephrology in recent years, given strong associations between frailty status and kidney disease outcomes. There is increased debate on formulating frailty status evaluation during the early stages of assessment for potential kidney transplant recipients. Studies investigating patient perspectives on frailty and frailty status evaluation during transplant assessment are lacking.

Methods: We conducted a qualitative study using cognitive interviews in English for 25 patients aged 65-85 yrs awaiting initial transplant clinic assessment. The interview comprised of patient understanding of frailty, perspectives on the impact of frailty on transplantation outcomes and whether formalized frailty status evaluation during transplant assessment should be established. An inductive thematic analysis of interviews to identify themes reflecting patients’ awareness, understanding and perspectives of frailty and frailty status evaluation during assessment performed.

Results: There were 14 Male and 11 Female participants and mean age was 69.6 yrs ± 3.4. Participants were mainly white (n=18) and native English speakers (n=20). 3 prominent themes were identified. 1) Prerequisite awareness of the frailty syndrome and recognition of its strong associations with negative health outcomes. Most participants understood frailty as a composite of declining physical function, reduced ability to perform daily activities and increased comorbidity status. 2) Severe frailty status is associated with older transplant recipients. Many participants felt worsened frailty status is correlated with older age, and older transplant recipients generally do more poorly. 8 participants recognized frailty may be independent of age in which older patients could be fitter transplant candidates compared to younger, fitter patients. 3) Universal support for a formalized screening program to evaluate frailty status during pre-transplant assessment. All participants voiced support, to assist clinical decision-making on determining suitability for transplantation from an early stage.

Conclusions: Patient education initiatives should continue to expand awareness of frailty and its implications in transplantation. Further work is required to determine an optimal approach to formally evaluate frailty status during transplant assessment.

POI1383

Differences in Frailty by Sex in Kidney Transplant Candidates
Cynthia Worthing,1,2 Amanda J. Vinson,1,2 Karuna K. Templemore.2 Frailty Assessments in Canadians being Evaluated for Transplant Study (FACEETS) 1Dalhousie University, Halifax, NS, Canada; 2Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Frailty prevalence is higher in women, despite the observed protective effect of female sex on mortality in the general population. Understanding whether there are differences in perceived frailty by sex and the differential impact of frailty on outcomes for males versus females is crucial to avoid a sex disparity within the transplant assessment process.

Methods: We analyzed initial frailty assessments for patients enrolled in a multicenter prospective cohort study across 6 kidney transplant referral centers. Frailty was assessed using the Frailty Phenotype (FP, 3 of slowness, weight loss, low activity, exhaustion, and weakness). We performed a general linear model, including sex and frailty assessment process.

Results: A total of 767 unique patients had frailty assessments performed between 2016-2021. Patients were predominantly of male sex (64%), white race (82%) and had a mean age of 54+/-14. The prevalence of frailty for women was not significantly higher by the FP (16% vs 13%, p=0.15) or the FI (48% vs 46%, p=0.38), but was by the CFS (17% vs 12%, p=0.05). Among 325 activated patients, frailty by the CFS was significantly associated with death/wrthdrawal for men (HR 2.59; 95% CI 1.16-6.79) but not women (HR 1.15; 95% CI 0.48-4.18).

Conclusions: The prevalence of frailty was higher in females when measured by the CFS, but not by a transplant specific FI or the FP. Despite this, frailty was not significantly associated with mortality/wrthdrawal from the waitlist for female individuals, emphasizing the need to critically evaluate judgement based frailty assessments and their role in the transplant evaluation process.

Changes in Cognition After Kidney Transplantation
Aditi Gupta,1 Palash Sharma,1 Rebecca J. Lepping,1 Jonathan D. Mahnkopf,1 William M. Brooks,1 David K. Johnson,2 Jeffrey M. Burns.1 University of Kansas Medical Center; Kansas City, KS; 2University of California Davis, Davis, CA.

Background: Longitudinal studies examining changes in cognition pre- to post-kidney transplantation (KT) are small, of short duration and do not include comprehensive neuropsychological (NP) testing or comparison with normative data.

Methods: We analysed pre- to post-KT cognition in 87 ESKD patients listed for KT and compared it to the National Alzheimer’s Coordination Center (NACC) data. We used linear mixed models for longitudinal, repeated NP test measurements, adjusted for for age, practice effect, sex, race, transplant status, and level of education, and assessed changes in cognition pre- to post-KT for four recognised tests (Logical Memory I, II, and Digit Symbol tests) and secondary (Mini Mental State Exam (MMSE), Digit span, Category Fluency for animals & vegetables, Trail making A & B) outcomes.

Patients Who Are Treated for Secondary Hyperparathyroidism Have a Lower Risk of Incident Dementia

JiYoon B. Ahn,1 Aarti Mathur,1 Dorry L. Segel,2,3 Mara McAdams-DeMarco,1,2 EGOT Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: Almost all patients with end-stage kidney disease (ESKD) have secondary hyperparathyroidism (SHPT). Elevated parathyroid hormone has been reported as a potential risk factor of cognitive impairment. We aimed to study whether the risk of dementia is improved when patients on dialysis receive treatment for SHPT.

Methods: Using data from the United States Renal Data System and Medicare claims, we studied older (aged≥66) ESKD patients without known pre-ESKD dementia who initiated maintenance dialysis in 2006-2016. SHPT treatment included vitamin D analogs, phosphate binders, cinacalcet or parathyroidectomy and was treated as a time-dependent treatment in the analysis. The study population was followed until transplant, death, end of Medicare coverage or administrative end date (12/31/2016), whichever came first. We used the Cox regression and adjusted for confounding using the inverse probability weighting method to examine the association of SHPT treatment and incident dementia.

Results: Of 189,433 ESRD patients, 65.1% received a treatment for SHPT during the study period. The rate of incident dementia was 11 per 100 person-years among patients with no SHPT treatment and 6 per 100 person-years among those with an SHPT treatment. Among patients on dialysis, the risk of incident dementia was lower after receiving treatment for SHPT compared with not receiving treatment for SHPT (adjusted hazard ratio= 0.62, p<0.001) after adjusting for confounding.

Conclusions: Receiving treatment for SHPT was associated with a lower risk of incident dementia among older patients with ESKD. SHPT may need to be controlled among older ESKD patients considering the complications of SHPT including cognitive impairment and dementia.

Association of CKD Stages with Frailty Worsening or Death in Community-Dwelling Older Adults
Nina Mielke, Alice Schneider, Natalie Ebert, Markus van der Giet, Doerte Huscher, Martin K. Kuhlmann, Elke Schaeffer. Charite Universitätsmedizin Berlin, Berlin, Germany; Vivantes Klinikum im Friedrichshain, Berlin, Germany.

Background: Albumin-creatinine-ratio (ACR) and glomerular filtration rate (GFR) have been associated with prevalent and incident frailty. We analyzed the association of the KDIGO CKD stages and frailty status worsening or death in data of the Berlin Initiative Study (BIS).

Methods: Prospective population-based cohort study interviewing participants biannually with a standardized questionnaire. Frailty assessment according to Fried took place at the 3rd and 4th follow-up. Frailty worsening was defined as the transition within a two-year period from robust to prefrail or frail, or from prefrail to frail. Partial proportional odds regression analysis was used to analyze the association between KDIGO CKD stages and the ordinal outcome of no worsening, frailty worsening, or death.

Results: Of 1076 participants with 46% male and mean age 84.3 years, initially 48% were prefrail and 32% frail. After 2.1 (2.0-2.3) years of follow-up 188 (17.5%) had worsened and 111 (10.3%) died. Participants who died were older (88 vs. 83 yrs), less physically active, had less muscle mass (calve circumference: 31: 10% vs. 5%), and were more likely to be cognitively impaired; 92% had a GFR <60 mL/min/1.73m² and 59% had an ACR ≥30 mg/g compared to 72% and 24% in participants who did not worsen, respectively. Baseline characteristics of participants who worsened were similar to participants who did not worsen. In the multivariable model participants in CKD stages G1/2/A2.3 and G3/A1 or higher had about 2-fold odds of frailty worsening, than in CKD stages G1.2/A1. The odds for death increased remarkably with both higher CKD stage and increasing albuminuria. Wide confidence intervals are likely due to limited sample size/events. Additional adjustment for frailty baseline status did not alter the results.

Conclusions: In older adults, advanced CKD stages but also albuminuria independent of GFR were associated with 2-fold higher odds of frailty worsening independent of death.

POI1389

Role of Klotho in Aging, Relationship with Frailty, Renal Function, and Body Composition
Paolo Betti, Marta De Filippo, Marco Simonini, Simone Fontana, Lorena Citterio, Elisabetta Messaggio, Patrizia Rovere Querini, Elena Brioni, Cristiano Magnaghi, Chiara Lanzani, Paolo Manunta. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Reduced expression of the Klotho protein has been associated with premature aging and increased mortality. Our aim is to evaluate the relationships between plasma Klotho levels and frailty, renal function and anthropometric parameters.

Methods: We enrolled a cohort of 1250 volunteers aged > 65 years (FRASNET Study) in recreation centers for the elderly, in hospital’s outpatient clinic and in nursing homes. All the volunteers have signed informed consent and subjects with severe cognitive impairment were excluded (MMSE <18). We measured eGFR (CKD-EPI formula) and body composition by impedancemetry. Plasma Klotho was assayed by an ELISA kit on 194 samples. Frailty was classified according to Fried’s criteria.

Results: A positive correlation between plasma Klotho and renal function (eGFR) was demonstrated in younger population. In agreement with what previously observed, in a younger population, we confirmed a reduction of Klothoemia in the sarcopenic patients (713 vs 791 pg/mL, p=0.0007 in patients with muscle mass <25% centile) and in patients with high visceral fat mass (fig.2). On the other hand, we did not observe different levels of plasma Klotho according to the frailty class or in relation to age.

Conclusions: In our elderly population, the plasma levels of Klotho do not correlate with age. Therefore, our results confirm the relevance of this biomarker in identifying pathological aging, in consideration of its association within the elderly population with CKD, abdominal obesity and sarcopenia (sarcopenic obesity). Klotho expression was demonstrated as an independent predictor of death in a follow up-study and was related to many diseases (e.g.: cognitive impairment, cardiovascular disease). The relation of plasma klotho levels and renal function is debated, and conflicting results have been published. Our findings evidenced a significative association of plasma Klotho with renal function and body composition.

Shrunken Pore Syndrome: Prevalence and Association with Mortality in a Population-Based Cohort of Elderly Women
Linnea Malmgren,1,2 Fiona Mcguigan,1 Anders Christenson,1,2 Kristina Åkesson,1,2 Lunds Universitet, Lund, Sweden; 2Skans universitetssjukhus Malmo, Malmo, Sweden.

Background: Decreased kidney function results in lower clearance and increased plasma concentration of a GFR marker. So far creatinine has been the commonly used GFR marker but cystatin C becomes more common. Shrunken pore syndrome (SPS) is a recently identified kidney syndrome characterized by disturbed filtration of mid-sized molecules (5-30 kDa) compared to smaller ones (<9 kDa) (Fig1). Resulting in increased plasma levels of cystatin C (cysC) compared to creatinine. SPS is associated with increased risk of cardiovascular disease (CVD) and increased mortality risk. So far few data are available about SPS in population-based cohorts.

Methods: 75-yr old women (n=849) from the population-based Osteoporosis Prospective Risk Assessment (OPRA-) cohort, with follow-up after 5yr and 10yr were studied. eGFR was calculated with the CKD-EPI equation. SPS was defined as cGFRcys/cGFRcys_ratio >0.6 and mortality risk (HR [95% CI]) estimated. Women with sarcopenia or on glucocorticoids were excluded.

Results: Almost 1 in 10 women (9%) had SPS at age 75 but at age 80 the majority of these women had increased their cGFRcys/cGFRcys_ratio >0.6 (range from 0.6-1.0). Women with SPS had higher 10-yr mortality risk compared with ratios >0.9 (HR_adj 1.7 [95% CI 1.1-2.6]). Table 1.

Conclusions: SPS defined as cGFRcys/cGFRcys_ratio >0.6 is common in elderly women and associated with increased mortality. While longitudinal data indicate that the state may be reversible. Our results also confirm other studies and suggest that SPS may be a clinically applicable tool to assess mortality risk in the elderly.

Funding: Private Foundation Support, Government Support - Non-U.S.

SPS (cGFRcys/cGFRcys_ratio >0.6) is associated with increased 10-yr mortality

Molecular Changes Associated with Type IV Collagen Switching in 1-Day-Old Alport Murine Glomeruli
Akanekhaya Rana,1,2,3 Sofia Farkona,1,3 James W. Scholey,1,3 Ana Konvalinka,1,2 Mounira Barua,1,2 1Toronto General Research Institute, Toronto, ON, Canada; 2University Health Network, Toronto, ON, Canada; 3Institute of Medical Science, University of Toronto, Toronto, ON, Canada.

Background: Alport syndrome (AS) is an inherited disorder caused by pathogenic variants in COL4A3, COL4A4 or COL4A5, which encodes proteins that comprise basement membranes of the ear, eye and kidney glomerulus. Type IV collagen chains assemble as heterotrimers and during glomerular development, α1G2ε1 (IV) is replaced by α3ε4ε5 (IV) within the developing glomerular basement membrane (GBM). This "switching" defines the starting point of disease in AS. We aimed to identify the molecular changes at the time of disease initiation in the developing glomeruli of Alport murine kidneys.

Methods: Immunofluorescence (IF) staining was done to identify the GBM distribution of type IV collagen chains in 1 day old COL4A3 knockout (KO) and wildtype (WT) mice. Urine albumin to creatinine ratio (uACR) was also measured. Subsequently, glomeruli from 1 day old (P1) COL4A3 KO and WT mice were isolated by cardiac injection of magnetic dynabeads that emobilized to glomerular capillaries enabling their extraction from surrounding tissue. Protein was isolated and subjected to liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) analysis.

Results: IF localized type IV collagen α1 in the GBM, Bowman’s capsule and mesangial matrix in both P1 KO and WT mice. Type IV collagen α5 was present in short segments of some developing GBM in P1 WT but was absent in KO mice indicating switching. uACR was increased in P1 KO (423 ±139.6 μg/mmol) compared to WT (128 ±67.86 μg/mmol) with a p-value of 0.02. LC-MS/MS identified >4300 proteins from glomerular isolates. In males, 2 and 15 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. Pathway analysis revealed alteration in collagen metabolic process, collagen biosynthesis, collagen formation and extracellular matrix organization.

Conclusions: Increased uACR in P1 KO mice showed disease onset at the time of type IV collagen switching. LC-MS/MS analysis revealed dysregulation of matrix turnover pathways in P1 KO mice, identifying potential molecular targets.

PO1392
PTEN-Induced Kinase 1 Has Association with Renal Aging in the Context of Inflammatory Response
Hyeoung Jeong, Ha Min Heui, Min ji Sung, Yu ho Lee, Hyun-Ju An, Song Hee Lim, So-young Lee. CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.

Background: Among several changes of aging-related human organ system, functional and structural deterioration of kidney is the most dramatic phenomenon, and the role of mitophagy has recently considered important in pro-aging process in CKD patients. PTEN-induced kinase 1 (PINK1), known to be associated with age-related diseases regulates mitochondrial dysfunction. To enhance understanding the function of PINK-1 on aging, we compared whole-kidney RNA sequencing between naturally aging mice and mice overexpressing HKC8 compared to naturally aging mice (Fig2D).

Results: Compared to naturally aging kidneys, PINK1 knock out aging mice showed prominent expression of the genes related to cytokines, immune system response, and inflammation (Fig 1). We also investigated the function of PINK1 on aging, we used PINK1-deficient mice and PINK1-overexpressing HKC8. The Quantitative PCR analysis validated that the expression of genes associated with aging, fibrosis, and inflammation increased in PINK1 (-/-) mice compared to age-matched controls (Fig2C). Under treatment with H2O2, the expression of aging and pro-inflammatory marker decreased in PINK1-overexpressing HKC8 compared to naturally aging mice (Fig2D).

Conclusions: In conclusion, our results suggest that PINK1 deficiency contributes to renal aging process via proinflammatory change in the kidney.

PO1393
TGF-β1/Smad Signaling in Glomerulonephritis and Its Association with Progression to CKD
Aghnia Chakila,1 Harikleia Gakipoulou,2 Panagiota E. Giannou,1 Zoe Alexakou,1 Athanasia Kapota,2 Dimitrios Kourniotis,1 Dimitris I. Petras,1 1Nephrology Department, Hippokration General Hospital, Athens, Greece; 21st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

Background: Transforming growth factor-β1 (TGF-β1) is a multifunctional cytokine, with diverse roles in fibrosis and inflammation, which acts through Smad signaling in renal pathology. We intended to investigate the expression of TGF-β1/Smad signaling in glomerulonephritis (GN) and to assess its role as risk factor for progression to chronic kidney disease (CKD).

Methods: We evaluated the immunohistochemical expression of TGF-β1, phosphorylated Smad3 (pSmad3) and Smad7 semi-quantitatively and quantitatively (computerized image analysis program has also been used) in different compartments of 50 renal biopsies with GN and the results were statistically analyzed with clinicopathological parameters. We also examined the associations among their expressions, the impact of their co-expression, and their role in progression to CKD.

Results: TGF-β1 expression correlated positively with segmental glomerulosclerosis (p=0.025) and creatinine level at diagnosis (p=0.002), while pSmad3 expression with interstitial inflammation (p=0.024). In glomerulus, comitant expressions of high Smad7 and low pSmad3 were observed to be correlated with renal inflammation, such as cellular crescent (p=0.011), intense interstitial inflammation (p=0.029) and lower serum complement 3 (p=0.028) and complement 4 (p=0.029). We also reported a significant association between pSmad3 expression in glomerular endothelial cells of proliferative GN (p=0.045) and in podocytes of non-proliferative GN (p=0.005). Finally, on multivariate Cox-regression analysis, TGF-β1 expression (HR= 6.078; 95% CI 1.168-31.627; p=0.032) was emerged as independent predictor for CKD.

Conclusions: TGF-β1/Smad signaling is upregulated with specific characteristics in different forms of GN. TGF-β1 expression is indicated as independent risk factor for progression to CKD, while specific co-expression pattern of pSmad3 and Smad7 in glomerulus is correlated with renal inflammation.

PO1394
ANCA Negative Medullary Angitis
Tatun Kapoor, Daniel Birchmore, Mark Lusco, Juan Pablo Arroyo Omelas, Gautam B. Bhave. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Medullary angitis is a rare cause of renal failure. Most cases of medullary angitis are found to be ANCA positive. We present a rare case of ANCA negative medullary angitis with no identifiable secondary causes.
Case Description: A 55-year-old male with a medical history significant for uncontrolled diabetes complicated by retinopathy, Chronic kidney disease, HTN, and compensated cirrhosis of unclear etiology, presented to the hospital with shortness of breath and lower extremity edema. Initial workup revealed a creatinine of 7.6 (baseline creatinine 1.5 eighteen months earlier), and significant proteinuria estimated at 8.4g/day along with a urinalysis showing 3 RBC/high power field and 6 WBC/high power field. Serological workup including Hepatitis B/C, HIV, SPEP, serum free light chains, C3/C4, ANA, ANCA was negative. He underwent a renal biopsy revealing medullary angiitis with multifocal medullary hemorrhage with perivascular PMNs and eosinophils along with findings of long-standing diabetes and HTN. In the absence of IgA deposits, infection, or offending drugs, he was started on high steroids and treated similarly to ANCA positive medullary angiitis. His creatinine during the hospitalization peaked at 8.69 before and fell to 7.6 at discharge. He was continued on oral prednisone at discharge. Outpatient follow-up showed a decrease in Cr to 5.8 before slowing climbing back up to 8.5. He is currently maintained on an immunosuppressive regimen to help delay the initiation of renal replacement therapy.

Discussion: Medullary angiitis is a rare renal disorder that has largely been associated with ANCA positivity. ANCA negative medullary angiitis has been documented in the literature with a recent case series showing IgA nephropathy and recent antibiotics use to be the most common etiologies. This is one of the first case reports of ANCA negative medullary angiitis not associated with IgA nephropathy and recent antibiotic use. Currently, we have no standardized treatment options available for these patients. Given the rapid progression of the renal dysfunction, we decided to start our patient on high-dose steroids. Our patient had an initial improvement in his renal function with subsequent decline. However, treatment may have afforded time for AVF creation and patient education before the initiation of hemodialysis, which was the main goal of therapy.

PO1395
Calorie Restriction Ameliorates Obesity-Related Glomerulopathy in Adult Zebrafish
Evon Zeitler, J. Charles Jennette, Jennifer E. Flythe, Ronald J. Falk, John S. Poullon. UNC Kidney Center, Chapel Hill, NC.

Background: Obesity is a risk factor for chronic kidney disease. The mechanisms by which obesity results in kidney disease are understudied. Zebrafish are an attractive model animal for studying obesity due to their conserved biology and amenability to genetic screening. The effects of obesity on kidney function in zebrafish have not been reported.

Methods: Zebrafish were fed high-calorie and high-fat diets for 8 weeks. Kidneys were evaluated by light and electron microscopy, and the glomerular filtration barrier was assessed by fluorescent dextran permeability. We also tested the ability of calorie restriction to reverse obesity-related defects.

Results: Fish fed a high calorie diet developed glomerulonegaly, foot process effacement, GBM thickening, tubular enlargement (Figure 1) and ectopic lipid deposition after 8 weeks. High calorie feeding resulted in filtration barrier dysfunction. The observed effects resolved after 4 weeks of calorie restriction (Figure 2).

Conclusions: Our study reveals that obese zebrafish recapitulate key aspects of human pathology, and these defects can be reversed with calorie restriction. These findings establish zebrafish as a potential model for the study of obesity-related kidney disease.

Different Patterns of Renal Fibrosis Are Indicative of Independent Fibrogenic Causes in ANCA-Associated Glomerulonephritis
Samy Hakroush,1 Michael Zeisberg,2 Bjorn Tanpe,3 Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany; 1Department of Nephrology and Rheumatology, University Medical Center Göttingen, Göttingen, Germany.

Background: Renal fibrosis is a common manifestation and hallmark of a wide variety of chronic kidney diseases (CKD) appearing in different morphological patterns, suggesting different pathogenic causes or consequences. Renal fibrosis with focal injury usually presents with patchy fibrosis whereas diseases affecting renal parenchyma in a diffuse manner lead to a more diffuse fibrotic pattern. In the present study, we aimed to analyze renal fibrotic patterns in association with the renal lesions which are considered to directly contribute to renal fibrogenesis in a cross-sectional study.

Methods: A total number of 112 renal biopsies with various renal pathologies including acute interstitial nephritis (AIN), ANCA-associated vasculitis (AAV), membranous GN, lupus nephritis, nephropathy due to hypertension, IgA nephropathy (IgAN), focal-segmental glomerulosclerosis (FSGS) and diabetic kidney disease (DKD) were retrospectively included between 2015 till 2020 in a cross-sectional study.

Results: We here provide evidence that tubulointerstitial fibrosis is either the consequence of nephron damage (dependent or independent of glomerular scarring) or the result of a primary interstitial injury (leading to a diffuse fibrotic interstitial remodeling). Our data also show that focal fibrosis correlated with glomerular damage and irreversible injury to nephrons, confirmed in experimental models of nephrotic serum-nephritis and folic acid nephropathy in mice. By contrast, diffuse fibrosis was specifically associated with interstitial inflammation independent of glomerular damage and nephron loss, confirmed in mice challenged with unilateral ureteral obstruction.

Conclusions: In conclusion, we here provide evidence that tubulointerstitial fibrosis is either the consequence of nephron loss and replacement scarring, representing incomplete tissue repair. By contrast diffuse fibrosis appears to be the result of primary interstitial inflammation and injury.

PO1397
Automatic Artificial Intelligence-Assisted Glomerulosclerosis Analysis in Mice Models with Glomerulopathy
Thomas Secher, Casper G. Salinas, Michael Christensen, Niels Vrang, Mette V. Østergaard, Gubra, Harsholm, Denmark.

Background: Glomerulosclerosis (GS) is a hall mark pathological feature in glomerular diseases. In preclinical research, GS is recapitulated in a number of experimental mice models with glomerulopathy, and a cross model characterization of GS would add to our understanding of their translatability to human disease. Here, we report GS quantification using an objective and newly developed automated AI assisted image analysis strategy in three mice models with glomerulopathy.

Methods: AI-assisted GS scoring was performed in three mouse models with glomerulopathy and to assess drug treatment effects: 1) Diabetic nephropathy in reninAAV-induced hypertensive uninephrectomized db/db mice (DN/HT). Mice received treatment with vehicle, lisinopril, empagliflozin or combination. 2) I.V. injection of nephrototoxic anti-GBM serum (NTS) and 3) Adriamycin (ADR) in healthy mice. Automatic AI-assisted GS scoring was performed as a two-step process on PAS stained kidney sections. Firstly, segmentation of all glomeruli and next, assignment of a GS score to each glomerulus using trained neural networks. GS was classified on a five-point scale (GS0-GS4) according to the area of capillary tuft involvement.

Results: The automated AI-assisted scoring performed with high degree of accuracy and allowed for a large number of glomeruli to be evaluated per section (>100). We show that the mice models had very distinct GS profiles. The DN/HT model was most severely affected with highest average GS score (DN/HT: 2.5, NTS: 1.76, ADR: 0.66, control: 0.1) and the largest percentage of severely affect glomeruli; GS3+GS4 (DN/HT: 54.1%, NTS: 37.2%, ADR: 16.8%, control: 1.1%). The ADR model was the least affected and

Increased Glomerular Parietal Epithelial Cell Expression of Cathepsins C and B in Anti-Thy-1.1 Mouse Model of FSGS

Michael Merchant,1 Michelle T. Barati,1 Kenneth R. McLeish,1 Jon B. Klein,1,2 Bart Smeets.3 University of Louisville School of Medicine, Louisville, KY, 1VA Robley Rex Medical Center, Louisville, KY, 2Radboudumc, Nijmegen, Netherlands.

Background: Focal segmental glomerulosclerosis (FSGS) is characterized by replacement of glomerular capillaries by extracellular matrix (ECM). The collapsing FSGS (cFSGS) variant exhibits a poor prognosis and response to therapy. We recently reported that activated PECs migrate into glomerular tufts in human cFSGS and demonstrate increased cathepsin C and B expression. The absence of cathepsins B and C within normal glomerular tufts suggests these proteases may represent novel mediators of PEC-mediated glomerulosclerosis leading to collapse. We addressed the hypothesis that activated PECs expressing cathepsins C and B migrate into glomerular PECs in a mouse model of cFSGS.

Methods: Thy1.1 transgenic mice were injected with ether saline (vehicle control) or intraperitoneal injection of 500 ng/mouse anti-Thy1.1 (1:00) antibody. Mice were sacrificed 4 days after injection. Kidney sections were subjected to immunofluorescence staining for claudin-1, a marker of PECs, and cathepsin C or cathepsin B. Images were acquired by confocal microscopy.

Results: Claudin-1, cathepsin C, and cathepsin B co-localized to glomerular parietal epithelial cells lining Bowman’s capsule in vehicle control mice. On day 4 after anti-Thy1.1 administration, claudin-1 staining showed migration of PECs into glomerular tufts in more than half of the glomeruli. Both cathepsin B and C staining co-localized to claudin-1 positive cells within glomerular tufts. PECs in the Bowman’s capsule with hypertrphied morphology, suggesting activation, demonstrated increased expression of cathepsins C and B. Claudin-1 and cathepsin B and C co-localized within glomeruli on days 7 and 21 after anti-Thy1.1 administration, however, the number of stained cells per glomerulus and the percent glomeruli with positively stained cells in the glomerular tuft appeared decreased.

Conclusions: Glomerular PECs migrate into glomerular tufts and show increased expression of cathepsins C and B in the anti-thy1.1 mouse model of cFSGS, recapitulating our findings in human cFSGS biopsies. The Thy1.1 mouse model of cFSGS can be used to define the role of PEC expression of cathepsins B and C in the pathogenesis of human cFSGS.

Effects of Enzymatic Cross-Linking and Increased Stiffness on Glomerular Basement Membrane and Podocyte Function

Dan Wang,1 Nicholas J. Ferrell,2,3 Vanderbilt University Medical Center, Nashville, TN, 1Vanderbilt University, Nashville, TN.

Background: The Glomerular basement membrane (GBM) is a critical component of the glomerular filtration barrier. Stiffening of the extracellular matrix is an important regulator of cellular function. How GBM stiffening affects podocyte function is not fully understood. This work aims to investigate the effect of GBM stiffening on molecular permeability and the podocyte function using a biomimetic in vitro model directly derived from kidney glomeruli.

Methods: Decellularized glomeruli isolated from porcine kidneys were pressure compacted on a Transwell membrane. GBM stiffness was tuned by crosslinking with Ficoll and AF488-BSA. Effects of GBM stiffening on gene expression of markers of podocyte function using a biomimetic in vitro model directly derived from kidney glomeruli. The stiffness of the TG-crosslinked decellularized glomeruli was evaluated using a custom cantilever-based compression system. Podocytes cultured on the TG crosslinked GBM were immunofluorescence stained with YAP, phospho YAP, and the nuclear counterstained with DAPI. The diffusional molecular permeability was evaluated on native and TG crosslinked GBM with and without podocytes using FITC-Ficoll and AF488-BSA. Effects of GBM stiffening on gene expression of markers of podocyte function (NPHS1, WT1, Synaptopodin) were screened by qPCR.

Results: The stiffness of the decellularized glomeruli showed a dose-dependent increase after incubating with TG for 1 day and 4 days. On stiffer GBM, immunofluorescence imaging showed translocation of YAP to the podocyte nucleus. Passive molecular permeability of GBM was similar for native the TG crosslinked GBM. Podocytes cultured on both native and TG crosslinked GBM forms a stringent barrier to large molecules. qPCR results show an upregulation of differentiation markers as podocytes cultured on native and TG crosslinked GBM.

Conclusions: We developed a biomimetic in vitro model that fabricated directly from kidney tissue. mTG crosslinked glomeruli show a dose-dependent increase of stiffness. TG did not significantly effect the passive permeability of the GBM. GBM stiffness affects the YAP localization in the podocytes. The current in vitro model upregulates the gene expression of podocyte markers.

PO1400
Effect of ANG-3070 in the Unilateral Ureteral Obstruction Mouse Model of Renal Fibrosis

Background: Tubulointerstitial inflammation and fibrosis are strong predictors of progression in all kidney diseases regardless of etiology. Receptor tyrosine kinases such as platelet-derived growth factor receptor (PDGFR) and discoidin domain receptors (DDRs), contribute to renal inflammation and fibrosis. ANG-3070 is an inhibitor of multiple tyrosine kinase receptors including PDGFR and DDR. This study evaluated whether ANG-3070 can slow the progression of fibrosis in the unilateral ureteral obstruction (UUO) mouse model of renal fibrosis.

Methods: Male mice were subjected to UUO and randomized to daily oral treatment with vehicle (n=15) or 100 mg/kg of ANG-3070 (n=15) for 10 days after UUO and then sacrificed. Control male animals were age-matched and were not subjected to UUO (n=10). At sacrifice, obstructed and control kidneys were collected and processed for renal damage by hematoxylin-eosin (H&E) staining and scoring (0-8; 0 no damage and 8 damage to >80% of kidney) by blinded observers. Collagen deposition and myofibroblast transformation was determined by quantitative image analysis of picrosirius red (PSR)-stained slides and slides stained for α-smooth muscle cell actin (αSMA), respectively.

Results: Animals treated with ANG-3070 had a statistically significant reduction in histological damage as compared to vehicle (Vehicle, 6.4 vs ANG-3070, 4.3; p-value <0.001) and the histological markers of fibrosis, PSR (% control, vehicle, 1453%; vs. ANG-3070, 503%; p-value <0.001), and αSMA (% control, vehicle, 511%; vs. ANG-3070, 248%; p-value <0.01) as shown in Figure 1.

Conclusions: Daily oral administration of 100 mg/kg ANG-3070 reduces renal damage and renal fibrosis in a mouse model of renal fibrosis induced by UUO.

Comparison of Glomerular Proteome Profiles of Healthy Human Kidney and Minimal Change Disease Identifies Distinct Targets and Pathways
Salameh Almasi, Sethu M. Madhavan, John P. Shapiro, Anjali A. Satoskar, Isabelle Ayoub, Brad H. Rovin, Samir V. Parikh. The Ohio State University, Columbus, OH.

Background: Minimal change disease (MCD) is a common cause of idiopathic nephrotic syndrome and is characterized by diffuse podocyte foot process effacement. The pathogenesis of MCD remains unclear. We hypothesized that proteomics analysis of glomeruli could identify molecular markers that reflect the pathogenesis of MCD.

Methods: We included formalin-fixed paraffin-embedded kidney biopsies from patients with steroid-sensitive MCD (n=9) and normal donor kidneys (n=4). Glomeruli were isolated using laser capture microdissection and HPLC MS/MS was done using Orbitrap eclipse mass spectrometer. After data normalization, groups were clustered using principal component analysis (PCA) and compared by paired t-tests.

Results: PCA showed separate clustering of healthy glomeruli and MCD samples (Figure 1). Out of the 6729 unique proteins identified in MCD glomeruli, 1080 proteins were significantly differentially expressed compared to controls. Pathway analysis showed upregulation of complement pathway components (C1R, C1S, C1QA, C2, C3, C4A, C4B, C5, C7, C8B, C9) and downregulation of carbohydrate and amino acid metabolic pathway enzymes (FBP1, FBP2, ALDOC, ALDOB, AKR1A1, ALDH4A1, ALDH5A1, ACT1). MCD glomeruli showed a significant reduction in expression of ECM proteins FREG2, FRAS1, CDH12. Surprisingly, the expression of podocyte slit diaphragm-associated proteins (SYNO1, NPHS2, CD2AP) was not significantly altered in MCD compared to controls. We did not observe differential expression of MCD associated proteins, KANK, C4L1, CMIP. No peptides from SMPDL3b or ANGPTL4 were identified in MCD glomeruli.

Conclusions: Glomeruli from MCD showed differential proteomic signature compared to healthy human glomeruli. Activation of innate immune pathways including the complement system and loss of extracellular matrix and basement membrane-specific components in glomeruli of MCD are novel observations. The role of these markers in the pathogenesis of MCD needs to be investigated.

PO1403
Effects of ANG-3070 in a Mouse Model of Alport Syndrome

Background: Alport syndrome (AS) is a hereditary kidney disease that presents in childhood and progresses to end stage kidney disease (ESKD) in adolescence. There are no approved therapies. AS is caused by mutations in type IV collagen genes Col4a3, a4 or a5, that result in reduced structural integrity of the glomerular basement membrane, triggering activation of fibrogenic cytokines, including platelet derived growth factor (PDGF) and transforming growth factor beta (TGF-beta1) causing proteinuric disease and fibrosis. We hypothesize that an antifibrotic therapy may decrease proteinuria-induced fibrosis, and evaluated ANG-3070, a novel tyrosine kinase inhibitor, in a Col4a3 knockout mouse model of AS.

Methods: After confirming the Col4a3 mutation by genotyping, 4-week-old male and female mice were randomized to Vehicle (oral, twice-daily) or ANG-3070 (oral, 25 mg/kg, twice-daily) for 5 weeks (n=12/group). Age-matched, wild-type mice were included (n=9) as a control. Animals were sacrificed after 5 weeks of treatment, after collecting spot urines to measure protein to creatinine ratio (PCR). Renal tissue was analyzed for hydroxyproline (n=4/group) content by Western blot or tissue fibrotic marker, and for histopathology using hematoxylin-eosin (H&E) staining for renal damage score and picrosirius red (PSR) staining for fibrosis. All histological analyses were performed by two independent observers using a 0-4 scale (0 being normal, 4 ≥75% injured or stained).

Results: ANG-3070 treatment reduced mortality (survivors; Vehicle: 8/12 vs ANG-3070: 12/12). In surviving mice, proteinuria was reduced (mg/mg; Vehicle 6.2 vs ANG-3070 3.1; p=0.05) along with PCR (mg/mg; Vehicle 11.1 vs ANG-3070 5.5; p=0.05). There was a reduction in renal damage (Vehicle: 2.6 vs ANG-3070: 1.2; p=0.002) along with renal fibrosis (Vehicle: 2.4 vs ANG-3070: 1.2; p<0.001). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.05) along with fibrosis markers of collagen-1, TGF-beta1, and α-smooth muscle actin (αSMA) compared to Vehicle-treated Alport mice (p<0.05). Additionally, PDGF expression was reduced (p<0.05).

Conclusions: Treatment with a novel tyrosine kinase inhibitor, ANG-3070, was efficacious in AS mice compared to Vehicle. ANG-3070 may represent a novel therapeutic for AS.

PO1404
Mesangial-Cell Activation by Circulating Immune Complexes Consisting of Galactose-Deficient IgA1 and IgA Autoantibodies from Patients with IgA Nephropathy
Zhiqiang Hu,1 Xianwen Zhang,2 Stacy D. Hall,1 Lin Wang,1 Yiping Chen,2 Bruce A. Julian,1 Jan Novak.1 The University of Alabama at Birmingham, Birmingham, AL; ‘Long Hua Hospital, Shanghai, China.

Background: We and others have shown that immune complexes from the circulation of patients with IgA nephropathy (IgAN) that contain galactose-defective IgA1 (Gd-IgA1) can induce proliferation of mesangial cells (MC) in culture. Here, we assessed cellular responses and signal transduction in MC after stimulation with CIC.

Methods: Quiescent primary human MC were stimulated for 15 min at 37°C, with or without inhibitors, with circulating immune complexes (CIC) isolated from sera of patients in China. Cell lysates were analyzed directly, or after immunoprecipitation (IP) with antibodies specific for integrin β1 or PDGFR-β, by SDS-PAGE/immunoblotting for IgA, IgG, phospho-ERK1/2, phospho-PEPR-γ, talin, and Axl.

Results: Cells lysates from MC stimulated with CIC and the corresponding IP products of control IgA and IgG contained IgA and IgG. Amounts of IgA and IgG were significantly reduced by an inhibitor of integrin αIIβ1 (obstutatin), but not by an inhibitor of integrin αⅤβ3 (RGD), and partially inhibited by a tyrosine-kinase inhibitor (dasatinib). CIC induced phosphorylation of ERK1/2 that was inhibited by obutatin, RGD, dasatinib, and a Chinese herbal medicine, ShenPing decoction (SP) that has been used to treat IgAN patients in China. Dasatinib and SP inhibited CIC-induced phosphorylation of PDGFR-β and Axl. In IP products of integrin β1 from CIC-activated MC, cytokskeleton-associated protein talin, known to activate ERK1/2, was associated with integrin β1. SP blocked binding of talin to integrin β1. In IP products of PDGFR-β, CIC induced association of integrin β1 with PDGFR-β, a process that may subsequently induce activation of MAP kinases. Dasatinib and SP inhibited this association.

Conclusions: Integrin αIIβ1 mediated activation of MC by IgA-IgG CIC; CIC activated multiple protein-tyrosine kinases in MC, leading to MAP kinase activation and cellular proliferation. Some of the inhibitors in this study may provide information about the mechanism of MC activation by the pathogenic CIC and, thus, inform development of future disease-specific therapeutic approaches.

PO1405
Effect of Mycophenolate and Ramipril on Pro-Inflammatory and Pro-Fibrotic Mediators in Human Mesangial Cells
Chenzhu Zhang, Susan Yung, Tak Mao D. Chan. Department of Medicine, The University of Hong Kong, Hong Kong, China.

Background: A significant proportion of lupus nephritis (LN) patients develop chronic kidney disease. TGF-β1 expression is increased in renal biopsies from LN patients and it plays an important role in kidney fibrosis. We previously reported that mycophenolate and ramipycin inhibited pro-fibrotic processes in resident kidney cells in murine LN. We proceeded to investigate the effect of mycophenolate and ramipycin on inflammatory and fibrotic processes in human mesangial cells (MC).

Methods: Growth-arrested human mesangial cells (HMC) were incubated with or without exogenous TGF-β1 (10 ng/ml), in the presence or absence of mycophenolic acid (1 μg/ml) or ramipycin (3 μg/ml) for up to 72 h. The effect on inflammatory and fibrotic processes was examined.

Results: TGF-β1 increased IL-6 and MCP-1 secretion, and α-smooth muscle actin, collagen and fibronectin expression, in a time-dependent manner, accompanied by increased ERK, mTOR and PI3K phosphorylation (P<0.05, for all). Constitutive IL-6 and MCP-1 secretion was mediated through PI3K phosphorylation, whereas IL-6 and MCP-1 secretion induced by TGF-β1 was mediated through PI3K, mTOR and ERK phosphorylation. Cell activation was mediated through PI3K and mTOR activation, while increased collagen and fibronectin expression was mediated through ERK, PI3K and mTOR. Mycophenolic acid inhibited the secretion of pro-fibrotic and pro-inflammatory MC cytokine, cell activation, and collagen and fibronectin expression, by suppressing ERK activation. Ramipycin inhibited similar processes through suppression of mTOR and ERK activation. Overall, the inhibitory actions of mycophenolic acid were comparable to that of ramipycin.
Collapsing FSGS Is Strongly Associated with Microvascular Injury
Nina A. Van de Lest, Kyra L. Dijkstra, Jamie S. Chua, Ron Wolterbeek, Jan A. Bruijn, Marion Scharpfenecker, Ingeborg M. Bajema. Leids Universitair Medisch Centrum, Leiden, Netherlands.

Background: Recent studies have suggested that the collapsing variant of focal segmental glomerulosclerosis (FSGS) might be a common secondary feature in renal disease influenced by microvascular injury. Here, we investigated glomerular and arteriolar microvascular injury in patients with collapsing FSGS and compared these lesions to patients with other variants of FSGS.

Methods: Biopsies of patients with FSGS were collected, including primary FSGS in native biopsies or transplant biopsies, as well as HIV-associated FSGS. Cases of FSGS secondary to renal diseases known to be caused by microvascular injury were excluded. We assessed all glomeruli in a biopsy for the presence of lesions associated with FSGS or ischemic injury, assessed microvascular lesions in glomeruli and arterioles, and studied interstitial lesions.

Results: We included 53 cases of FSGS, of which 19 cases with collapsing FSGS, 18 cases with FSGS not otherwise specified (NOS), 11 cases with FSGS tip, 3 cases with perihilar FSGS and 2 cases with cellular FSGS. Compared to other variants of FSGS, glomerular endothelial swelling of the vascular pole was more common in patients with collapsing FSGS (11% vs 0.0%; p=0.05). Associations between thrombotic injury and FSGS variant were not found. Arteriolar abnormalities were seen in 58% of collapsing FSGS and 38% of other variants of FSGS (p=0.17). When evaluating the concomitant occurrence of FSGS lesions and microvascular injury in individual glomeruli, we found that collapsing lesions and FSGS NOS lesions were accompanied with endothelial swelling in the same glomerulus (OR=22; p=0.001 and OR=3.8; p=0.01, respectively). Endothelial swelling was more common in glomeruli with collapsing lesions than glomeruli with FSGS NOS (OR=2.7; p=0.044). Collapsing FSGS was also associated with endocapillary hypercellularity (OR=4.3; p<0.001).

Conclusions: Here, we demonstrate that collapsing FSGS lesions are strongly associated with microvascular injury such as endothelial swelling and endocapillary hypercellularity, and often co-exist in the same glomerulus. In addition to collapsing FSGS occurrence, the secondary feature in patients with collapsing FSGS, these results indicate that endothelial injury could also be involved in the pathophysiology of collapsing FSGS due to primary podocyte injury.

POI1407
Danhog Injection (DHI) Inhibits Lipopolysaccharide-Enhanced Cell Proliferation of Rat Renal Mesangial Cells via NF-κB Signaling Pathway
Hua Liu. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

Background: To explore the mechanisms of DHI in the treatment of Mesangiproliferative glomerulonephritis (MsPGN), we investigated the effects of DHI on LPS-induced NF-κB activation and its downstream inflammatory mediators, such as ICAM-1, TGF-β1, INOS and FN protein expression in rat MCs.

Methods: The rat MCs treated with different concentrations of DHI (0, 50, 100, 200, 500, 1000, and 2000 U/L) for 12 h, then incubated with or without 100 ng/ml LPS for another 24 h. Then, cell proliferation was determined by CCK8. The MCs treated with low-dose DHI (250 U/L. median-dose DHI (500 U/L.) and high-dose DHI (1000 U/L.) for 12 h or PDTC for 30 min before 24 h treatment of LPS. Then the activation of NF-κB was detected by Western blot and immunofluorescence. The protein levels of ICAM-1, TGF-β1, INOS and FN in rat MCs were detected by Western blot.

Results: DHI significantly suppressed LPS-induced cell proliferation by CCK-8 results (Fig 1). LPS stimulation resulted in a significant increment of p65 contents in nuclei and a decrement of p65 proteins in cytoplasm in rat MCs compared with NC. PDTC and DHI exerted potent inhibitory effect on increasing expression of p65 in nuclei and decreasing in cytoplasm compared with LPS-treatment group. The inhibitory effect on NF-κB nuclear translocation of DHI was in a dose-dependent manner (Fig 2). The protein level of ICAM-1 in cytoplasm treated by LPS decreased significantly compared with that in control (Fig 3) and this decrement was significantly reversed by PDTC and DHI. In addition, the protein expression of ICAM-1, TGF-β1, INOS and FN was also inhibited by PDTC and DHI (Fig 4).

Conclusions: DHI significantly repressed LPS-induced cell proliferation and FN expression in rat MCs through inhibiting the activation of NF-κB signaling pathway also its downstream inflammatory mediators.
Anum of injury. We advocate for a lower threshold for performing renal biopsies as they can guide treatment of lupus-like nephritis, all reported patients were treated with disease in absence of other evidence of SLE have been reported. Although there are no deposits of IgA, IgM, C3 and C1q. “Full-house” immune complex deposits are commonly immune complex deposition without active glomerular lesions. Lupus nephritis is an with a three-day course of Solu-medrol and continued on home peritoneal dialysis and (IFE), hepatitis screen and HIV screen were negative. She was treated for lupus nephritis lesions commonly seen with lupus nephritis. Evaluation was positive for anti-nuclear (10mg/day) for her RA. Upon follow up it was noted her Scr decreased to 1.4mg/dL but nephrotic range proteinuria persisted.

Discussion: ITG is a glomerulopathy. Determining the clonality and the underlying etiology is essential for the management. This case is associated with RA and presents as a polyclonal ITG. The exact treatment for this condition is unknown. Will continue following her closely as historically ITG carries a poor renal prognosis.

Fibrillary Glomerulonephritis: A Rare Entity, Responsive to Rituximab

Introduction: Fibrillary glomerulopathy (FGN) is a rare proliferative type of glomerular disease with poor prognosis and limited therapeutic options. Literature review showed very few cases of FGN where Rituximab has been used.

Case Description: A 69-year-old Caucasian woman with a history of DM, HTN presented to the hospital with complaints of dyspepsia and leg swelling. Lab work revealed BUN/Scr of 34/3.88 mg/dL (baseline Scr of 1.4 mg/dL, proteinuria (7,902 mg/dL). Renal biopsy was performed which showed fibrillary deposits as shown in the picture. Hepatitis panel and work up of malignancy including bone marrow biopsy was negative. She was started on Rituximab 1gm every 14 days for 2 doses. Pt initially required HD but with treatment her symptoms and Cr improved and was taken off HD. Most recent Cr was1.8.

Discussion: The diagnosis of FGN can only be established with kidney biopsy. Most of the patients present with renal insufficiency, nephrotic picture. Mostly idiopathic but can be associated with hepatitis C, dysproteinemia, autoimmune diseases and to lesser extent malignancies. The prognosis is very poor with very limited therapeutic options to date. Rituximab has been used in few cases in literature showing good clinical response. Our patient tolerated and responded very well to Rituximab with significant improvement in kidney function and hence we propose the use of Rituximab in FGN.

Renal-Limited Lupus Nephritis Misdiagnosed as Advanced CKD: Addressing the Need for Increasing Renal Biopsies in the Community Setting

Rajeey Chauhan, Megha Kalia, Katrina Hazim. Renal Associates LLC., Columbus, GA; Augusta University, Augusta, GA

Introduction: “Full-house” nephropathy is characteristic of lupus nephritis, but may be seen in patients without other evidence of SLE. Patient was presumed to have acute renal failure and was placed on dialysis for chronic management of ESRD. Despite no extrarenal or clinical manifestations of SLE, renal biopsy revealed histopathology consistent with lupus nephritis.

Case Description: A 61-year old African American female presented to an outside hospital with complaints of mild abdominal pain, nausea, emesis, and diarrhea. Family history was positive for autoimmune disorders, including SLE and Sjogren’s Syndrome. Initial lab work revealed creatinine 8.1 mg/dL, eGFR 7.8 mL/min, BUN 117 mg/dL, proteinuria, and hyperkalemia with potassium 5.2. Renal biopsy revealed collapsing glomerulopathy with full-house immune complex deposits without active glomerular lesions commonly seen with lupus nephritis. Evaluation was positive for anti-nuclear antibody (ANA), but anti-double stranded DNA (anti-dsDNA), serum immunofixation (IFE), hepatitis screen and HIV screen were negative. She was treated for lupus nephritis with a three-day course of Solu-medrol and continued on home peritoneal dialysis and oral prednisone. Renal function recovered with creatinine of 0.64 mg/dL and eGFR 116 mL/min/ leading to discontinuation of dialysis.

Discussion: Renal biopsy revealed collapsing glomerulopathy with “full-house” immune complex deposition without active glomerular lesions. Lupus nephritis is an immune mediated glomerulonephritis with characteristic histological pattern including “full house immune fluorescence” with glomerular deposits that stain for IgG with co-deposition of IgA, IgM, C3 and C1q. “Full-house” immune complex deposits are commonly seen in lupus nephritis, but are not pathognomonic. Nine adult cases of limited renal disease in absence of other evidence of SLE have been reported. Although there are no guidelines on treatment of lupus-like nephritis, all reported patients were treated with regimens of immunosuppressive agents and steroids. To date our patient has not developed additional manifestations of SLE and her renal function remains normal without signs of injury. We advocate for a lower threshold for performing renal biopsies as they can provide valuable information regarding disease diagnosis and treatment.

Tissue MALDI-Mass Spectrometry Imaging Reveals the Potential Role of PLP3 in Regulating Lysophosphatidic Acid Signaling in Aging Kidney

Li Liu, Annappuram Padreddy, Jingli Gao, Liang Min, Hak Joo Lee, Viktor Drel, Wei Chen, Hui Geng, Yau guang Liu, Balakantumal S. Kasinath, Kun Reddy Shankar, Guanshi Zhang. 1,2 The University of Texas Health Science Center at San Antonio, San Antonio, TX; 3South Texas Veterans Health Care System, San Antonio, TX.

Background: Increasing evidence suggests that accumulation of lysophosphatidic acid (LPA) and aberrant activation of LPA signaling is implicated in various human diseases such as diabetic kidney disease. However, the role of LPA signaling in aging-related kidney injury remains elusive.

Methods: C57BL/6J male mice at 5 months (Control) and 24 months (Aging), N=10/ group, were used in the current study. Kidney pathological changes were evaluated based on PAS-stained images and nephropathy markers including urinary albumin creatinine ratio (ACR) and kidney injury molecule-1 (KIM-1). Gene expression and protein levels of major enzymes/effectors involved in LPA metabolism and signaling were measured in kidney cortical tissues using standard RT-qPCR and western blotting approaches. Matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI) was performed for spatial lipidomics analysis of lyposalpidins and other species in kidneys of aging mice and controls. MetaboAnalyzer and GraphPad were employed for statistical analyses.

Results: Histological images showed that aging kidney developed glomerulosclerosis at the age of 24 months. Aging mice also had higher levels of urinary albumin, ACR, and KIM-1. Importantly, bone marrow-liver phosphatase 3 (PLP3), an enzyme that can dephosphorylate and inactivate the signaling functions of LPA, were lower in renal cortical tissues of aging mice. The gene expression level of LPA receptor 1 (LPR1) was upregulated in aging renal cortical tissues. In addition, oscillations of gene expression and protein levels of enzymes involved in LPA metabolism/signaling, including phospholipase D, were observed in aging kidney tissue. In the MALDI-MSI analysis, we found altered sphingolipid metabolism in glomeruli of mouse aging kidneys compared with controls. In particular, several LPA (e.g., LPA (16:0)) species were increased in aging glomeruli, suggesting the potential role of LPA signaling in the aging kidney.

Conclusions: These findings suggest that reduced PLP3 contributes to the accumulation of LPA in glomeruli of aging kidneys. Activation of LPA signaling in glomeruli may play an important role in the pathogenesis of aging-related kidney injury.

Focal Segmental Glomerulosclerosis: A Rare Cause of Nephrotic Syndrome in Graft vs. Host Disease

Introduction: Nephrotic syndrome (NS) is a very rare complication of allogeneic hematopoietic cell transplantation (HCT) and is usually associated with chronic graft vs. host disease (GVHD). In such patients, membranous nephropathy and minimal change disease are the most frequently observed renal pathology. However, focal segmental glomerulosclerosis (FSGS) is an extremely uncommon etiology of NS in patients with HCT and GVHD. We herein describe a case of a patient with HCT and chronic GVHD who developed NS secondary to FSGS.

Case Description: A 24-year-old man with medical history of Sickle Cell Disease status post splenectomy and HCT, epistaxis, arterial hypertension and chronic GVHD with cutaneous and esophageal manifestations who presented to the emergency department with a one month history of progressive lower extremity edema and intermittent hemoptysis. Vital signs were remarkable for uncontrolled blood pressure. Home medications were lisinopril 20mg daily, levetiracetam 500mg twice daily and prednisone 10mg daily. Physical examination was remarkable for edema of the lower extremities, ascites, and cachexia. Laboratories revealed: BUN 35 mg/dL, serum creatinine 1.15 mg/dL, total protein 5.7g/dL, serum albumin 1.1g/dL, glucose 110mg/dL, total cholesterol 425 mg/dL, triglycerides 335 mg/dL, VLDL 67 mg/dL and LDL 316 mg/dL. Urine protein/creatinine ratio resulted in 30,000mg/g. Laboratory findings of hypoalbuminemia, hyperlipidemia, and nephrotic range proteinuria were consistent with NS. A renal biopsy was performed and showed findings consistent with a diagnosis of FSGS, not otherwise specified. Partial remission of NS was achieved at 3 months of treatment with mycophenolate mofetil 500mg twice daily and prednisone 15mg twice daily.

Discussion: GVHD is a significant cause of morbidity and mortality in patients after HCT. Renal involvement can be a serious manifestation and prompt recognition is essential for adequate management and prevention of renal disease. FSGS is an extremely rare complication of HCT and very few cases have been reported in the literature linking FSGS to HCT. Further documentation of this phenomenon is important to further characterize the clinical and pathological features of this complication.
PO1414
Catastrophic COVID-19-Associated Nephropathy (COVAN) in an Asymptomatic Patient
Samer Akrawi, Toni Sabbouh, Khaled Janom, Panduranga S. Rao, Cathryn J. Lapedis. University of Michigan Michigan Medicine, Ann Arbor; MI.

Introduction: Glomerular lesions were reported in a minority of patients with COVID-19, with collapsing focal segmental glomerulosclerosis (FSGS) also called COVID-associated nephropathy (COVAN). This typically occurs in the setting of prominent COVID symptoms. We describe a COVAN occurring in an asymptomatic patient.

Case Description: A 48-year-old, African American female patient who had CKD stage 3a a secondary to hypertension, with serum creatinine of 1.2 mg/dl and absent proteinuria at baseline, presented to the hospital for evaluation of an asymptomatic elevation of her serum creatinine to 9.9 mg/dl, discovered during a routine evaluation by her PCP. Her urine Protein/Creatinine was 6.15. Six weeks prior to her presentation, she endorsed 7 days of nausea and intermittent vomiting associated with non-bloody diarrhea without respiratory symptoms. Her GI symptoms has resolved on its own. She had multiple family members, including her husband and daughter, who had tested positive for COVID around the same time. Her nasal PCR for COVID was negative. She had not been vaccinated for SARS COVID. She has no family history of kidney disease; she denied IV drug use and had no risk factors for HIV. She was on Amlodipine for her hypertension. She was afebrile on admission with blood pressure of 170/80 mm Hg. She had 1+ pedal edema with an unremarkable physical exam. A percutaneous kidney biopsy was performed to evaluate the cause of her renal dysfunction. This showed collapsing FSGS. HIV and ANA were negative. A subsequent testing for COVID nucleocapsid and spike protein was positive. Results of APOL1 genotype is pending. She was started on high dose steroids and followed up as an outpatient.

Discussion: COVAN is increasing recognized as a serious complication of COVID. However, the typical presentation is in the setting of prominent respiratory involvement. Recognizing the minor fleeting symptoms of COVID preceding a catastrophic kidney disease and testing for it is an important in patients presenting with features of collapsing FSGS.

PO1415
Siglec-9 Agonism Reduces ANCA-Mediated Neutrophil Responses In Vitro
Dana Kidder,1 Kristine Nollany,1 Catriona Walls,2 1NHS Grampian, Aberdeen, United Kingdom; 2University of Aberdeen School of Medicine Medical Sciences and Nutrition, Aberdeen, United Kingdom.

Background: Sialic acid-binding Ig-like lectin 9 (Siglec-9) is constitutively expressed on neutrophils and monocytes. The expression and potential role of siglec-9 in ANCA-associated vasculitis (AAV) is yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on ANCA-mediated neutrophil responses in vitro.

Methods: Leukocytes and serum were isolated from peripheral venous blood of AAV patients and siglec-9 expression was measured by flow cytometry and ELISA, respectively. Immunohistochemistry was performed on kidney biopsies of AAV patients with AAGN and stained for siglec-9 and leukocyte markers. Functional studies were done using healthy donor neutrophils and monocytes. The expression and potential role of siglec-9 in ANCA-associated vasculitis (AAV) is yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on ANCA-mediated neutrophil responses in vitro.

Results: We found increased siglec-9 expression in active AAV compared to remission AAV and a positive correlation with disease activity. Neutrophils and intermediate (CD14+CD16+) monocytes from PR3-ANCA patients displayed higher siglec-9 expression compared to MPO-ANCA patients. Siglec-9 expression in AAGN was restricted to areas of active inflammation. We observed increased siglec-9 shedding in neutrophils following ANCA stimulation. Siglec-9 agonism in these neutrophils was associated with increased apoptosis and reduced ROS production compared to isotype control and unstimulated neutrophils.

Conclusions: Our study suggests that siglec-9 expression correlates with disease activity in AAV. Our functional studies support a potential role for siglec-9 in modulating ANCA-mediated neutrophil responses. Further evaluation is required to determine the relevance of these findings on neutrophil-endothelial interactions.

PO1416
The Proteasine 3-Alpha-Antitrypsin Connection in PR3-ANCA Vasculitis
Maximilian Ebert,1 Uwe Jerke,2 Claudia Eulenberg-Gustavus,1 Dieter E. Jenne,4 Markus Bieringer,2 Saban Eliotik,2 Kai-Uwe Eckardt,3 Adrian Schreiber,3 Alan D. Salama,2 Ralph Ketttritz,1 1Experimental and Clinical Research Center, Charité - Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; 2Department of Nephrology, Helios Klinikum Berlin-Buch, Berlin, Germany; 3Department of Nephrology and Endocrinology, Ernst von Bergmann Klinikum, Potsdam, Potsdam, Germany; 4Institute of Lung Biology and Disease (ILBD), Comprehensive Pneumology Center (CPC), Helmholtz Zentrum München, Germany; 5Department of Cardiology, Charité - Universitätsmedizin, Berlin, Germany; 6Department of Renal Medicine, University College London, Royal Free Hospital, London, United Kingdom.

Background: PR3 is a major autotaxin in ANCA-associated vasculitides (AAV) and a neutrophil serine protease inhibited by alpha-antitrypsin (AAT). Increased PR3 and decreased AAT were suggested as disease mechanism for PR3- but not MPO-AAV.

Methods: We assessed PR3 and AAT in 100 AAV patients and 50 healthy controls (HC) and produced recombinant wt- and mut-AAT to study the effect on proteolytic PR3 activity, membrane PR3 (mPR3) by flow cytometry and surface plasma resonance (SPR), and neutrophil activation.

Results: In active PR3- and MPO-AAV, plasma PR3 concentration increased approximately 5-fold and plasma AAT 1.8-fold shifting the PR3:AAT ratio significantly towards PR3. Both parameters normalized with remission. Notably, only one PR3-AAV remission patient showed strongly decreased plasma AAT. The PR3 neutrophil content was approximately 50% higher in active PR3- and MPO-AAV accompanied by increased PR3 transcription. The resulting total PR3 pool (plasma PR3 concentration x plasma volume + neutrophil neutrophil x neutrophil number) was approximately 3-fold larger in active AAV and normalized with disease remission. In active AAV-PR3 but not MPO-AAV, the total PR3 pool correlated negatively with plasma AAT in HC, was increased in AAV patients with a compromised plasma AAT correlation. Mechanistically, extracellular AAT dose-dependently reduced mPR3 by competing with PR3 for the PR3-presenting CD177 receptor. Consequently, AAT reduced neutrophil activation by PR3- but not MPO-AAV. Neutrophils from AAV patients and HC showed similar mPR3 reduction with AAT. However, in contrast to HC plasma, neutrophil incubation in active AAV plasma increased the AAT concentrations required to lower mPR3, an effect that was recapitated by adding inflammatory mediators to HC plasma. Finally, oxidative AAT modification resulted in less PR3 interaction and diminished mPR3 reduction.

Conclusions: We found a strongly increased PR3 pool in active PR3-AAV and exclude decreased plasma AAT as the general underlying disease mechanism, as previously proposed. However, AAT controls mPR3 expression and subsequently PR3-ANCA induced neutrophil activation, suggesting adjunctive AAT administration may have beneficial effects in acute PR3-AAV.

Serum Soluble CD206 Complements Urinary Soluble CD163 in Detecting Active ANCA-Associated Glomerulonephritis
Joop Aandeneker,1 William F. Jemiya,2 Inge M. Strating,1 Gerjan J. Dekkema,2 Jan-Stephan Sanders,3 Coen A. Stegeman,1 Mark A. Little,4 Peter Heeringa,2 Pieter van Paassen.1 1Department of Nephrology and Clinical Immunology, Maastricht University Medical Center, Maastricht, The Netherlands; 2Department of Medical Biology and Pathology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; 3Department of Internal Medicine, Division of Nephrology, University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; 4Trinity Health Kidney Centre, Trinity Translational Medicine Institute, Dublin, Ireland, Dublin, Ireland.

Background: Early detection of active glomerulonephritis (GN) in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) is crucial to minimize renal damage, but accurate biomarkers are currently lacking. Urinary CD163 (usCD163) has been shown as a potent biomarker for active ANCA GN. However, false negative rates can be as high as 29%. Here, we investigated whether soluble serum CD206 (ssCD206; macrophage mannose receptor), complements usCD163 in the detection of active ANCA-GN.

Methods: Three independent cohorts (C1-Maastricht University Medical Center, C2-University Medical Center Groningen & C3-Trinity College Dublin) with available serum, urine, and renal biopsy samples (C1 only) were included. usCD163/creatinine (ng/mg) and ssCD206/ml were assessed by ELISA in urine and serum, respectively. The performance of usCD163 and ssCD206 to detect ANCA GN was assessed using receiver operating characteristics (ROC) curves. Biopsies from ANCA GN patients were immunohistochemically (IHC) stained for CD163 and CD206. Colocalization of CD163 and CD206 was assessed by immunofluorescence (IF).

Results: Patients (C1/C2/C3) that had active ANCA GN (n=42/17/47), active non-renal AAV (n=3/3/12) or were in remission (n=4/8/38). Healthy controls (HC; n=63/40) were included. usCD163 was significantly higher in active ANCA GN compared to active

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
non-renal AAV and remission in all cohorts, and healthy control urine in C1 (Kruskal-
Wallis, P<0.001). ssCD206 was significantly higher in active ANCA GN compared to
HCs in cohorts C1 & C2 (Kruskal-Wallis, P=0.01). ssCD163 had a specificity of 100%
in all cohorts, whereas sensitivity was 71 (C1), 88% (C2) and 64% (C3). The addition of
ssCD206 increased the sensitivity to detect active ANCA GN in all cohorts to 83% (C1),
100% (C2) and 81% (C3). IHC revealed CD163+ and CD206+ cells in the kidneys of
active ANCA GN patients (n=8). IF showed glomerular presence of CD163+CD206-
cells, whereas CD163+CD206+ and CD163+CD206- cells were mainly found in the
tubulointerstitium.

Conclusions: ssCD206 complements ssCD163 and reduces false negative rates in
the detection of active ANCA GN. Histological assessment revealed distinct glomerular
and tubulointerstitial populations of CD163+ and CD206- cells.

Urine and Plasma Complement Ba Levels During Flares of Nephritis in Patients
with ANCA-Associated Vasculitis

Salem Almsani,1 Huijuan Song,1 Mershora Suthanthira,1 Christopher Toy,2 Lynn A. Fussner,1 Alexa S. Meara,1 Haikady N. Nagaraja,1 Nader A. Khalidi,3 Christian Pagnoux,3 Kenneth Warrington,4 Paul Monach,2 Peter A. Merkel,4 Brad H. Rovin,1 Daniel J. Birmingham,1 Vasculitis Clinical Research
Foundation 1The Ohio State University Wexner Medical Center, Columbus, OH; 2Brigham and Women’s Hospital, Boston, MA; 3Mount Sinai Hospital, Toronto, ON, Canada; 4University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 5McMaster University, Hamilton, ON, Canada; 6Mayo Foundation for Medical Education and Research, Rochester, MN; 7Colorado State University System, Denver, CO.

Background: The alternative complement pathway has been implicated in the
pathogenesis of ANCA-associated vasculitis (AAV), however it is not clear whether
activation of complement occurs systemically or in affected organs such as the kidney.
This study measured levels of urinary and plasma complement fragment Ba (ulba and plba
respectively) at multiple timepoints in patients with AAV.

Methods: Ba was measured by ELISA in serial samples of urine (ulba) and plasma
(plba) from 20 AAV patients who developed a renal flare, 20 who developed a non-renal
flare, and 20 in long-term remission. Changes in Ba levels were modeled using linear
mixed effect models.

Results: Cohort characteristics are given in Figure 1. ulba levels increased at renal
flare, but did not increase at non-renal flare, and remained stable in long-term remission
(Figure 2a). plba levels were stable over time in all groups (Figure 2b). ulba correlated
with renal AAV activity measured as the renal component of the BVAS score (R²=0.33,
p=0.01), but did not correlate with the overall BVAS score during renal flare (R²=0.13,
p=0.12) or non-renal flare (R²=0.10, p=0.22).

Conclusions: Urine, but not plasma, Ba levels increase at the time of a flare of renal
disease in AAV, suggesting intra-renal alternative complement pathway activation.
ulba has the potential for use as a surveillance biomarker of renal vasculitis.

Alterations in Amino Acid and Lipid Metabolism in ANCA-Stimulated
Monocytes

Emma Leacy1, Hania Khouri2, Gareth Brady1, Mark A. Little1 1Trinity
Translational Medicine Institute, Dublin, Ireland; 2Agilent Technologies UK
Ltd, Cheadle, United Kingdom.

Background: Multiple metabolic pathways and intermediates are involved in
inflammation. Altered immune cell metabolism is involved in the pathogenesis
of autoimmune diseases such as anti-neutrophil cytoplasmic antibody (ANCA)-
associated vasculitis (AAV). In particular, monocytes stimulated with ANCA show
increased oxidative phosphorylation and glycolysis, with a more profound response
to myeloperoxidase (MPO) ANCA than proteinase-3 (PR3). The aim of this work was to
profile the metabolome of ANCA-stimulated primary monocytes.

Methods: Monocytes from healthy donors (n=24) were isolated and stimulated
with monoclonal anti-MPO, anti-PR3 for 4 hours. Metabolites were extracted using an
optimised extraction protocol and analysed by liquid chromatography–mass spectrometry
(LC-MS). Targeted and untargeted analyses were carried out using Agilent MassHunter
Profiler and Mass Profiler Professional. Cytokine production was measured by ELISA
and flow cytometry was used to assess surface expression of MPO and PR3.

Results: Targeted metabolomic analysis showed increases in several amino acid
and TCA cycle metabolites relative to unstimulated cells, notably phenylalanine,
isomers leucine & isoleucine, and fumarate. Untargeted analysis confirmed alterations
in amino acid and lipid metabolism in ANCA-stimulated monocytes (Figure 1). These
metabolic differences did not correlate with the increased cytokine expression observed
in anti-MPO-treated monocytes. Anti-PR3 stimulation did not induce major changes
in metabolism or cytokine production. Monocytes expressed high levels of surface MPO
and PR3, with MPO expression showing a significant inverse correlation with age.

Conclusions: Inflammatory and metabolic activation of primary human monocytes
with anti-MPO, but not anti-PR3 stimulation. Early increases in amino acid and lipid metabolism are evident in anti-MPO treated cells. Further work is needed to
validate these findings and determine their physiological relevance in AAV.

Funding: Commercial Support - Agilent Technologies Ireland Limited

LFA-1 (CD11a/CD18) and Mac-1 (CD11b/CD18) Are Important for
Mediating Myeloperoxidase-ANCA Glomerulonephritis in a Preclinical
Mouse Model

Shen-Ju Guo, Peiqi Hu, Hong Xiao, Yanglin Hu, Marco A. Alba, Ronald J. Falk,
J. Charles Jennette. The University of North Carolina at Chapel Hill, Chapel
Hill, NC.

Background: Neutrophils play a critical role in the pathogenesis of necrotising
crescentic glomerulonephritis (NCGN) caused by anti-neutrophil cytoplasmic
autoantibodies (ANCA). LFA-1 and Mac-1 are β2-integrins that have critical synergistic
roles in neutrophil-mediated inflammation. In this study, we investigated the role
of LFA-1 and Mac-1 in murine NCGN induced by mouse anti-mouse MPO, which is
histopathologically indistinguishable from human ANCA NCGN.

Methods: Anti-MPO IgG was purified from sera of MPO knock out (KO) mice
immunized with murine MPO. Mice with KO of LFA-1 or Mac-1, and normal wild-
type C57BL/6j mice (WT B6) were injected i.v. with 50μg/g body weight anti-MPO
IgG. Circulating anti-MPO IgG (MPO-ANCA) was monitored by ELISA. Proteinuria,
hematuria and leukocyturia were monitored, and mice were sacrificed at day 6 and kidney
tissue obtained for pathologic examination. MPO-ANCA-induced neutrophil activation
was assayed in vitro.

Results: At day 6, WT B6 (n=5), LFA-1 KO (n=8) and Mac-1 KO (n=9) mice that
received anti-MPO IgG had similar levels of circulating MPO-ANCA. All WT B6 mice
developed hematuria and NCGN with mean 13.9% glomeruli with crescents and 5.3%
with necrosis. In contrast, LFA-1 KO mice and Mac-1 KO mice had normal urine and
substantially reduced NCGN (Table). In vitro assays showed that anti-MPO IgG caused
similar activation of neutrophils from LFA-1 KO, Mac-1 KO and WT mice.

POI421
Drilling into a Potential Correlation Between ANCA-Associated Vasculitis and Natural Gas Wells
Devan Makati, James L. Akers, Khaled Shawwa, Rebecca J. Schmidt, Dinesh Kannabhiran. West Virginia University Health Sciences Center; Morgantown, WV.

Background: ANCA-associated vasculitis (AAV), a systemic necrotizing disease affecting small and medium blood vessels, is caused by antineutrophil cytoplasmic autoantibodies which target intracellular proteinase 3 (PR3) or myeloperoxidase (MPO). The incidences of PR3-AAV and MPO-AAV vary geographically with PR3-AAV most commonly reported in the United Kingdom and MPO-AAV the predominant type seen in Japan. Environmental exposure has been implicated in the pathophysiology of MPO-AAV. The aim of this study is to evaluate a potential relationship between AAV and environmental factors in north central West Virginia.

Methods: This is a retrospective cohort study of 212 patients diagnosed with AAV at West Virginia University and its affiliated hospitals from January 1, 1990 to December 31, 2019. Patients were mapped by zip code and prevalence of AAV assessed over time.

Results: The proportion of MPO-AANCA cases increased from 37.5% in 2010 vs 71.7% after 2016 (p=0.008)) with a resultant increase in the prevalence of AAV overall after 2010 (Table). During this time, the production of natural gas through fracking increased with barrel production rising more than 5-fold after 2010. Regional heat mapping reveals that the increase in cases of AAV occurred in areas of increased fracking activity (Figure)

Conclusions: The increase in prevalence of MPO-AAV correlates temporally and geographically with escalations in fracking activity. These findings suggest that exposure to toxins from fracking could be operative in the pathophysiology of AAV and the increase in case numbers seen in north central West Virginia.

Prevalence of AANCA before and after 2010

POI422
Maintenance of ANCA Vasculitis Remission by Intermittent Rituximab Dosing Based on B Cell Reconstitution vs. a Serologic ANCA Flare (MAINTANCVAS) Reza Zonoozi,1 Amashuya Jeyabalasingham,2 Pravrat Nithagon,1 Karen A. Laliberte,1 Frank B. Cortazar,2 John Niles,1 MGH Vasculitis and Glomerulonephritis Center (MGH VGC) 1Massachusetts General Hospital, Boston, MA; 2New York Nephrology Vasculitis and Glomerular Center, Albany, NY.

Background: ANCA vasculitis is caused by autoantibodies to proteinase 3 (PR3) or myeloperoxidase (MPO). Rituximab (RTX), an anti-CD20 monoclonal, is effective at induction and maintenance of remission. However, RTX is associated with adverse events; hypogammaglobulinemia, infections, and late onset of neutropenia. The ideal strategy for long-term maintenance of remission remains unknown.

Methods: This is an interim analysis of an open-label, single center, randomized, two-arm controlled trial (ClinicalTrials.gov Identifier: NCT02749292) to evaluate maintenance of remission strategies that provides the best relapse-free survival in patients with ANCA vasculitis at 36 months. We enrolled subjects with ANCA vasculitis on RTX-induced continuous B cell depletion for a minimum of two years to one of two arms as follows: intermittent B cell depletion with RTX re-dosing upon (1) B cell return (≥ 10 B cells/mm³) or (2) upon a significant ANCA titer increase. The primary outcome was number of relapses defined by a Birmingham Vasculitis Activity Score (BVAS/WG) ≥ 2. Other outcomes, including serologic relapse and serious adverse events are not included in this analysis.

Results: From May 2016 to June 2021, 113 patients (mean age, 61 years; 48% women) were randomized, 57 to the ANCA arm and 56 to the B cell group. 52 patients were positive for anti-MPO, and 61 for anti-PR3. Relapse-free survival estimates at month 60 were 75% (95% CI, 62% to 86%) and 91% (99% CI, 74% to 97%) in the ANCA and B cell groups, respectively (hazard ratio of 3.85, (CL 1.40 to 10.60) (P = 0.024 by logrank).

Conclusions: B cell driven RTX dosing appears to be highly efficacious at preventing relapses compared to ANCA titer driven dosing. Full trial analysis, including differences in adverse events, is needed to balance the benefit of reduced relapses against the infectious complications that may be associated with increased RTX use.

Immune Checkpoint Molecule BTLA Attenuates Inflammation and Glomerular Damage in Experimental Glomerulonephritis

Paul Diefenhardt,1,2 Marie Brand,1,3 Thomas Schömig,1,2 Bastian Trinch,1,2 Bernhard Schermer,1,3 Paul T. Brinkkoeetter,1,2 Thomas Benzing,1,2 Sebastian Braehler,1,1 Unilin Kolin, Koln, Germany; 1University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; 2Exzellenzcluster CECAD in der Universität zu Köln, Koln, Germany.

Background: An imbalance of pro- and anti-inflammatory signals in the kidney can result in irreversible damage and destruction of glomeruli leading to end stage kidney disease. Current treatment of the glomerulonephritis (GN) consists of unspecific, highly toxic immunosuppressive therapies with detrimental adverse effects. More specific therapies are therefore warranted. T Lymphocytes are not only key players in the nephrotic nephritis (NTN) model in rodents but also during GN in humans, representing potential targets for tailored therapies. As an immune checkpoint molecule, B and T lymphocyte attenuator (BTLA) is crucial in the regulation of T Lymphocyte activation and has been shown to mediate anti-inflammatory effects in other T cell-mediated diseases.

Methods: NTN was induced in BTLA knock out mice (BTLA-KO) and littermate controls. Regular urine analysis (ACR) was performed throughout the course of the disease. 14 days after NTN induction, blood, kidneys and spleens were harvested for further analysis. Histological assessment of the kidneys was used to evaluate the severity of NTN. Local immune response in the kidney and systemic immunity was analyzed via flow cytometry and qPCR.

Results: Wild type mice (WT) showed an increased BTLA expression on renal T cells and dendritic cells throughout the course of NTN. No immune-phenotype was observed in unstimulated BTLA-KO and WT mice. However, BTLA-KO resulted in aggravation of NTN compared to WT. Quantification and characterization of renal immune cells revealed an increase in proinflammatory cells. Interestingly, especially T Lymphocytes were significantly expanded in BTLA-KO mice.

Conclusions: BTLA attenuates inflammation in experimental GN through suppression of proinflammatory T Lymphocytes. These results build the foundation of a checkpoint inhibitor based therapy of inflammatory glomerular disease.

Collapsing FSGS or Crescentic GN or Both: A Diagnostic Challenge

Irshadjahan Malek, Harsharan K. Singh, Volker Nickeleit, Division of Nephropathology, University of North Carolina, Chapel Hill, NC.

Introduction: The finding of an ANCA associated necrotizing & crescentic GN with collapsing FSGS is a rarity with only few reported cases in literature.

Case Description: A 53-yr-old AA female was admitted to hospital with difficulty

POI426

CD11b Activation Suppresses Pro-Inflammatory IL-1β in Myeloid Cells and Protects Against Lupus Nephritis

Veronica Villanueva, Xiaobo Li, Viviana Jimenez, Vincent Gupta. Rush University Graduate College, Chicago, IL.

Background: Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Mutations in the ITGAM gene, encoding CD11b, are associated with LN and reduce integrin function. Interleukin-1β (IL-1β) is produced by myeloid cells as a proprotein and cleaved by caspase-1 where it mediates the inflammatory response. IL-1β is downstream of toll-like receptor and IL-1β receptor signaling. We previously showed that activation of CD11b suppresses TLR-dependent pro-inflammatory signaling. Here, we investigate if this mechanism includes control of IL-1β and/or if CD11b influences IL-1β by another mechanism, which may provide novel therapeutic options for proinflammatory diseases.

Methods: To investigate TLR-dependent signaling affected by CD11b activation, we utilized in vitro assays using primary macrophages. Cells were treated with TLR agonists, IL-1β, or IL-1β and antibody and changes in protein expression was assessed by western blot and proinflammatory cytokine levels were assessed by ELISA. For complementary in vivo studies, we utilized our newly generated mouse model, where we incorporated a constitutively active CD11b point mutation (I332G) globally in mice to generate a model for CD11b activation – CD11b knock-in model. C57BL/6 wild type mice, CD11b knock-out, and CD11b knock-in mice were used to determine the effect of CD11b activation on circulating IL-1β levels.

Results: TLR-stimulation increased IL-1β levels in vitro and in vivo. Importantly, CD11b activation resulted in significantly reduced IL-1β levels in both systems, suggesting a novel mechanism for controlling inflammation in glomerular diseases. Additional mechanistic studies are on-going to define the exact molecular mechanism of action. Murine models of SLE and LN display significant decreases in IL-1β when CD11b is activated, both genetically or pharmacologically, showing potential protection against LN.

Conclusions: Using these models, we have identified a possible link between CD11b activation and IL-1β secretion in myeloid cells. These studies will provide understanding of the influence CD11b has on signaling pathways and inflammation associated with inflammatory diseases such as LN.

Deletion of Smad3 Worsens Lupus Nephritis by Promoting B Cell Activation

Wenqian Xu,1,2 Jinhong Li,1 Xiao Ru Huang,1,4 Cheuk-Chun Szeto,2 Tak Mao D. Chan,1 Xueqing Yu,2 Zhihua Zheng,1 Hui Y. Lan,1,2 1Department of Nephrology, Center of Urology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2Department of Medicine & Therapeutics, Li Ka Shing Institute of Health Sciences, and Lui Che Woo Institute of Innovative Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; 2Department of Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; 4Zhangjiajiang, Guangdong Provincial People’s Hospital, Guangzhou, China; 3The Chinese University of Hong Kong-Guangdong Academy of Sciences, Guangdong Provincial People’s Hospital Joint Research Laboratory on Immunological and Genetic Kidney Diseases, The Chinese University of Hong Kong, Hong Kong, China.

Background: TGF-β signaling has been shown to play a critical role in many autoimmune diseases. However, its regulatory role in lupus nephritis remains unknown, which was investigated in the present study in a mouse model of lupus nephritis (LN) in which Smad3 gene was deficient.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

451
Methods: To investigate the role of Smad3 in LN, we generated Smad3 knockout (KO) lupus mice by crossing Smad3 KO mice with B6.NZMSle1-3 lupus mice (C57BL/6J background) mouse. We then determined the regulatory role of Smad3 in the pathogenesis of LN and investigated the regulatory mechanisms of Smad3 in T cell and B cell activation and autoantibody production in Smad3 KO LN and Smad3 WT LN mice and B cells in vitro.

Results: We successfully deleted the Smad3 gene from B6. NZMSle1-3 mice with unexpected findings that Smad3 KO LN mice developed much more severe LN with higher mortality rates (50%), higher circulating anti-dsDNA (60%), higher levels of serum complement factors (C3, C4) and lower creatinine clearance rates (Ccr, 20%), more severe glomerular necrosis (50%), massive renal immune complex deposition and complement activation, and progressive renal inflammation and functional injury. Mechanistically, we observed that lupus mice lacking Smad3 largely promoted Th1, Th2 and Th17 populations which were associated with lower immune responses in the kidney. Unexpectedly, deletion of Smad3 largely increased macrophage inducible lectin-receptor (Mincle) expression by B220 + B cells (80%). Further studies showed that B cells lacking Smad3 were largely promoted by Cytosine-phosphorothioate-guanine oligodeoxynucleotides (CpG ODN)-induced B cell proliferation and autoantibody production. Importantly, silencing Mincle inhibited CpG ODN-induced Syk-NFκB signaling and IgG production by splenic B cells.

Conclusions: TGF-β/Smad3 signaling plays a protective role in LN by maintaining the balance of T cell immunity and B cell function. Loss of Smad3 worsens LN by shifting Tg to Th1, Th2 and Th17 and promoting B cell activation and autoantibody production via the Mincle-Syk-NFκB-dependent mechanism. Thus, outcomes from this study should be of great significance biologically and clinically.

POI1428

Intradrenal B Cells in Systemic Lupus Erythematosus Upregulate Na+-K+-ATPase to Facilitate Survival in a High-Sodium Environment

Irene Chernova, Joseph Craft. Yale University, New Haven, CT.

Background: The kidney is a unique microenvironment characterized by high sodium concentrations, yet susceptible to infiltration by lymphocytes in autoimmune diseases such as systemic lupus erythematosus. The effects of sodium-immune cell interactions on tissue injury in autoimmune diseases and the mechanisms utilized by infiltrating lymphocytes to survive the high sodium environment of the kidney are not known.

Methods: We investigated the mechanisms utilized by B cells from lupus-prone mice and B cells in lupus-prone mice to survive in a high Na + environment in vitro and in vivo. We also utilized biopsies from lupus nephritis patients to confirm our key findings.

Results: Here we show that numbers of kidney infiltrating B cells in murine lupus are dramatically increased when exposed to high sodium concentrations [Na +] in vitro and that the expression of sodium potassium ATPase (Na+-K+-ATPase) correlates with the ability of infiltrating B cells to handle sodium stress. Pharmacological inhibition of Na+-K+-ATPase and a genetic knockout of the Na+-K+-ATPase gene subunit, newly shown by us to be expressed in B cells, resulted in decreased kidney B cell infiltration and amelioration of proteinuria. Na+-K+-ATPase gene subunit expression was also observed in renal B cells in human lupus nephritis.

Conclusions: These studies reveal that kidney-infiltrating B cells in lupus adapt to environmentally regulated sodium stress and identify Na+-K+-ATPase as a novel organ-specific therapeutic target in lupus nephritis.

Environmental Factors Influence Site and Magnitude of Myeloperoxidase-DNA Autoimmunity in BXXS Murine Lupus

Lanette Fee,1 Robert M. Tighe,1,2 Mary H. Foster,1,2 Duke University, Durham, NC, 1DVAMC, Durham, NC.

Background: SLE is a systemic autoimmune disease with devastating clinical manifestations and complex origins linked to gene-environment interactions. To better understand the role of environmental factors, we exposed lupus-prone female mice to crystalline silica (Si) or vehicle (V) by oropharyngeal aspiration (OPA), mimicking an inhalational exposure compellingly linked to human autoimmunity. Si but not V exposed mice developed chronic lung inflammation, tertiary lymphoid structures (TLS), and elevated autoantibody (autoAb) levels. Si-exposed BXXS mice, a strain that develops vasculitis and glomerulonephritis, uniquely demonstrated elevated anti-myeloperoxidase (MPO) as well as anti-DNA Ig levels in bronchoalveolar lavage fluid (BALF). Herein we extend our studies in BXXS lupus to quantify local autoAb production and assess the impact of environmental co-exposure, using Toll-like receptor ligand (TLR-L) stimulation to quantify microvascular inflammation.

Methods: BXXS mice were exposed to Si or V by OPA and organs harvested 2-3 months later. A subset of mice were injected with TLR4-L 1-2 days prior to harvest. Lung injury and TLS were quantified and autoAbs in serum, BALF, and cell culture supernatants (sTLR4 or TLR7/9-L) measured by ELISA; means±SD.

Results: Si but not V exposed BXXS mice developed chronic lung injury (scores 5.0±4.3 vs. 0.1±0.4) and lung TLS (counts 36±19 vs 0±6), n=13/group, p<0.0001. Levels of anti-DNA and anti-MPO IgM and IgG in BALF and anti-DNA IgG in serum were elevated in Si vs V exposed mice (p<0.05, for each). Splenocytes produced little anti-MPO or anti-DNA Ig when cultured with medium and abundant anti-MPO IgM and anti-DNA IgG after TLR-L stimulation, regardless of Si vs V exposure (p=NS; n=13/group). Anti-DNA IgG levels were higher from stimulated splenocytes of Si-exposed mice (OD 0.08±0.054 Si vs 0.035±0.011 V, TLR4-L, p<0.0009). Lung cells from Si but not V exposed mice produced abundant autoAb after TLR-L stimulation (OD 1.23±1.100 Si vs 0.025±0.043 V, anti-MPO IgM; OD 0.012±0.310 Si vs 0.001±0.001 V, anti-DNA IgG, TLR7/9-L, p<0.05).

Conclusions: Inhalational Si exposure enhances local and systemic autoimmunity in lupus-prone BXXS mice. Autoreactive B cells with diverse disease-relevant specificities, including anti-MPO and anti-DNA Ig, are recruited to the lungs, where they can be activated by co-exposure to exogenous or endogenous TLR-L.

POI1430

Anti-SOD2 Antibodies in Lupus Nephritis as Second Wave Antibodies

Andrea Angeletti, Maurizio Bruschi, Francesca Lugani, Gianluca Caridi, Enrico E. Verrina, Gian Marco Ghiggeri. ZEUS Study Istituto Giannina Gaslini, Genova, Italy.

Background: Superoxide dismutase-2 (SOD2) is an enzyme with antioxidant action. Anti-SOD2 antibodies (anti-SOD2 IgG2) were recently described in the serum of subjects with Membranous Nephropathy, as antigens of a possible second wave injury. The presence of anti-SOD2 IgG2 correlated with worse outcomes in terms of response to treatment [1]. The presence and role of anti-SOD2 IgG2 in Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN), a secondary autoimmune glomerulonephritides, are to be clarified.

Methods: We measured serum levels of anti-SOD2 IgG2 (Homemade designed ELISA), every six months, in 1.052 patients (459 LN and 573 SLE) enrolled at different times from the diagnosis (i.e., 0-1 month, 2-12 months, 13-24 months, 25-48 months, 49-96 months, and >96 months). We also evaluated the main markers of the SLE activity, such as serum complement C3 and C4, ANA, ENA, anti-dsDNA and proteinuria. Of note, 91 LN and 130 SLE had a relevant follow-up of 36 months.

Results: As main characteristics, we report median age of 40 (IQR 28-54) years, the predominance of females (88%), disease activity (SLEDAI) of 4 (IQR 2-8). At the cross-sectional analysis, serum levels of anti-SOD2 IgG2 at T0 are significantly higher in LN than in SLE (Fig 1a). Considering LN, the serum levels of anti-SOD2 IgG2 at T0 were significantly higher than the other time points (Fig 1a). No correlation with the histological class of LN is reported. In LN, the reduction of anti-SOD2 IgG2 was in accordance with proteinuria. Anti-dsDNAs did not result as a valuable marker of disease activity (Fig 1b).

Conclusions: Circulating anti-SOD2 IgG2 are elevated in active LN. Serum levels of Anti-SOD2 IgG2, also considering the concomitant negative serum levels of anti-dsDNAs in all phases of LN, support the hypothesis of direct involvement of anti-SOD2 antibodies in LN as second wave antibodies that actively contribute to the manifestations of autoimmune glomerulonephritides.
POI1431

Altered Propanoate Metabolism and gut Lachnospiraceae Composition in Lupus Nephritis Patients

Dong Ki Kim,1 Ji In Park,2 Hye Eun Kim,1 Jungwook Lee,2 Hyunjung Cho,2 Dong Ki Kim,15 Yong Su Kim,15 Hajeong Lee,11 Korea University Guro Hospital, Seoul, Republic of Korea; 2Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; 3Seoul National University Hospital, Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; 4Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; 5Seoul National University, Gwanak-gu, Seoul, Republic of Korea; 6Chungbuk National University Hospital, Cheongju, Cheongbukdo, Republic of Korea.

Background: There are growing evidence for the role of gut microbiota in the pathogenesis systemic lupus erythematosus (SLE), especially lupus nephritis (LN). Recently, high abundance of Ruminococcus gravis belonging to the family Lachnospiraceae has been noticed in fecal sample of LN patients. However, the functional role of gut microbiota and its metabolic pathway which affect host metabolism in LN are less understood.

Methods: Shotgun sequencing of fecal samples from biopsy-proven LN patients and matched controls was performed. We used Kraken2 for taxonomic analysis and human2 with customized KEGG database for gene family analysis. Comparison of taxonomic abundance and gene families were assessed by Maaslin2.

Results: Control and LN group were included 24 and 20 patients, respectively. Both groups had similar age, sex, and eGFR. In the comparison of relative abundance of major species, Roseburia intestinalis, Butyricimonas faecalis, and Eubacterium eligens were significantly decreased while Ruminococcus gravis was significantly elevated in LN group, respectively. Interestingly, 3 of these 4 species were included in the same Lachnospiraceae family showing a significantly different composition between the two groups (PERMANOV A p=0.042). Furthermore, we found 161 differentially expressed gene families including 65 metabolism-associated and 29 carbohydrate metabolism-associated genes. Considering Lachnospiraceae is known to play a role in propanate (esters of propionate) formation, we further assessed the propanoate pathway (ko00640). As a result, LN patients revealed more prone to propanediol pathway rather than in succinate pathway in the propanoate pathway. This tendency was more pronounce in the contribution to the pduE gene by R. gnavus having well-known pathogenetic linkage with SLE.

Conclusions: LN patients showed altered propanoate metabolism associated with the differential species composition of Lachnospiraceae including R. gravis. Functional role of this alteration on the pathogenesis of LN should be clarified by further investigations.

POI1432

Gut Microbiome Changes in NZBWFL/J Murine Lupus Nephritis

Tak Mao D. Chan, Jing Yu, Chi pang Tai, Susan Yung. Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong.

Background: Lupus nephritis is an important cause of acute kidney injury and chronic kidney disease. There is preliminary data that gut dysbiosis may be involved in the pathogenesis of lupus nephritis. We investigated gut microbiota burden in murine lupus nephritis.

Methods: Eight-week old NZBWFL/J mice were randomized to receive drinking water alone or containing ampicillin (1.0 mg/ml) and neomycin (0.5 mg/ml) for 18 weeks. Both groups had similar age, sex, and eGFR. At the end of the study, fecal samples were collected to culture bacteria phyla and decreased ZO-1 expression in the colonic epithelium. 16S rRNA sequencing data and abundance and gene families were assessed by Maaslin2.

Conclusions: Murine lupus nephritis is associated with gut dysbiosis, which may contribute to the pathogenesis of nephritis progression.

Funding: Government Support - Non-U.S.

The Significance of Glomerular Galactose-Deficient IgA1 in Patients with Systemic Lupus Erythematosus (SLE)

Lihong Bu,1 Bayardo I. Garcia,1 Youngki Kim,1 Fm Lai,1 Xin J. Zhou,2 Patrick H. Nachman,1 Cynthia C. Nast,2 1University of Minnesota Medical School Twin Cities, Minneapolis, MN; 2Cedars Sinai Medical Center, Los Angeles, CA.

Background: Approximately 0.3% of end stage kidney disease in SLE patients is due to non-lupus nephritis. IgA nephropathy (IgAN) is rarely reported in SLE patients. As galactose-deficient IgA1 (Gd-IgA1) plays a key role in the pathogenesis of IgAN but not SLE, the aim was to investigate whether KM55, a Gd-IgA1 specific monoclonal antibody, might identify IgAN in patients with SLE.

Methods: Immunofluorescence (IF) staining of KM55 was performed on 77 native kidney biopsies from 25 non-SLE (IgAN or IgA vasculitis (IgAV)) and 52 SLE patients, the latter including lupus nephritis (LN) with IgG dominant full house staining (LN; n=20), IgAN without features of LN (IgAN; n=11), concurrent LN class V and IgAN (n=2), and LN with dominant/co-dominant IgA (IgG-IgA-LN; n=19). In SLE patients, principal component analysis was carried out on LN, IgAN, and IgG-IgA-LN cases.

Results: KM55 staining intensity >0.5 (trace) on a scale of 0-4 discriminates IgAN/ IgAV from LN with a sensitivity of 1.00 [0.86-1.00] and specificity of 1.00 [0.82-1.00] (p<0.0001) (Fig 1). KM55 staining with mean 2+ intensity was detected in all SLE patients with IgAN and no features of LN. IgAN had no difference in KM55 intensity or distribution in non-SLE vs SLE patients. Mesangial KM55 staining was detected in cases with dual LN class V and IgAN. Of 19 IgG-IgA-LN biopsies, 9 (47%) showed positive KM55 staining in the same distribution as IgA.

Conclusions: Our results demonstrate that IF staining of KM55 is valuable in distinguishing IgAN from LN. In SLE patients, negative KM55 staining argues against the presence of IgAN while >0.5 (trace) KM55 staining with dominant/co-dominant IgA staining is suggestive of IgAN as the sole lesion or a co-occurring component of dual glomerulonephritis.

Funding: Other NIH Support - NHLBI [F30HL151138 to BIG]

A) KM55 staining intensity in LN and IgAN/IgAV. B) Principal component analysis shows LN with dominant/co-dominant IgA (IgG-IgA-LN; pink) with overlapping features with LN (grey) and/or IgAN (blue).

Tertiary Lymphoid Tissue Development Is Associated with Impaired Renal Function in Lupus Nephritis

Yuki Satô,1,2 Makiko Kondo,2 Shingo Fukuma,1 Naoya Torii,2 Yoshifumi Ubara,2 Motoko Yanagita,2 1Medical Innovation Center TMKP, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 3Institute for the Advanced Study of Human Biology (ASHBI), Kyoto University, Kyoto, Japan.

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE) and the pathophysiology is heterogeneous. Recently, the careful assessment of not only glomerular but tubulointerstitial lesions has been reported for more precise evaluation of the disease activity, which leads better management. Tertiary lymphoid tissues (TLTs) are inducible ectopic lymphoid tissues formed in the kidney interstitium under chronic inflammation. Several studies have reported TLTs in LN, though the frequencies, clinical characteristics and relevance in LN have been undefined.

Methods: We examined the presence of TLTs in 205 kidney biopsy samples of patients with LN and investigated the clinical characteristics of patients with renal TLTs. TLTs were defined as organized T and B cell aggregates with sign of proliferation. Histological activity and damage at biopsy were calculated as the National Institute of Health (NIH) activity and chronicity indices (CI).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: 43 patients (21%) exhibited TLTs in the kidneys. There were no significant differences in ISN/RPS classification between LN patients with TLTs and those without TLTs. TLT development was not associated with disease activity indicators, such as SLEDAI, dsDNA titer, proteinuria, or complement factors, but it was associated with reduced eGFR (60.2 versus 83.8 ml/min/1.73m², P = 0.001) and higher histological kidney scores (P = 0.0038). A higher prevalence of TLTs was observed with age over 40 years old and non-treatment history of immunosuppressive drugs. Additionally, TLT development was associated with incidence of hypertension.

Conclusions: Association between TLT development and reduced eGFR and higher histological scores suggest the potential of TLTs as an additional histological marker for evaluation of LN disease activity. Dissociation between TLT development and SLE disease activity indexes such as SLEDAI and dsDNA antibody titers also suggest that TLTs development are, at least partly, independent of the severity of glomerulonephritis.

Funding: Government Support - Non-U.S.

PO1435

New Drugs and Evolving Treatment Patterns in Lupus Nephritis: How Nephrologists and Rheumatologists Are Responding Differently to New Treatment Options

Background: Early uptake and experience with recently approved lupus nephritis (LN) drugs belimumab and voclosporin reveal different perceptions, comfort levels, and prescribing intentions between nephrologists and rheumatologists.

Methods: Data were collected over four waves of research between February and May 2021 via online surveys with 50 US nephrologists and 50 US rheumatologists who are currently treating LN. The first three waves were followed-up with a subset of qualitative interviews.
Increased tissue levels of IP-10 have been implicated in pathogenesis and as a diagnostic marker in LN, but the mechanism is unknown. The current project tested a hypothesis that LN severity and enhanced IP-10 levels are associated with the TN1P1 rs4958881 risk allele.

Methods: All endpoints were compared for LN patients w/wo TN1P variant rs4958881. Immunohistochemistry classifications were compared for 125 African-American and 133 White American LN patients. Urine and serum IP-10 levels were measured in 33 LN patients using ELISA. Progression of disease was assessed and compared from follow up (mean = 3 yrs) for 33 LN patients. Urine, plasma, and kidney levels of IP-10 were compared in 15 patients.

Results: A higher percent of African Americans with Class IV LN had the TN1P variant (68%) vs 42% for Whites with Class IV and 93% of African American with Class V LN had the variant versus 38% for Whites with Class V. 26.3% of patients with the variant reached the endpoint of doubling creatinine vs. 7.1% of patients without the variant reached the endpoint of doubling of creatinine or ESKD. Proteinuria at follow up was higher in variant (2800 mg/g) vs. non-variant (1175 mg/g) patients, suggesting refractory disease in variant patients. There were significantly higher levels of IP-10 in serum and urine from African American versus White LN patients and a trend for association in patients with the variant. Urine and plasma levels of IP-10 were significantly enhanced in ABN1D [ABSN] versus wildtype mice.

Conclusions: Our findings suggest that TN1P variant genotyping and IP-10 measurement could provide precision diagnostics for African American LN patients and that inhibition of NFκB or neutralization of IP-10 is a promising personalized therapeutic direction for these patients.

Inflammatory Dendritic Cell and Th17 Polarization in Mouse Model of Lupus Nephritis

Latha Prabha Ganesan,1 Noushin Saljoughian, James M. Tumer, Muruvaru in Rajagopalan, Jianjun Li,1 Lokyu Zhao,2 Steven L. Turman,1 Latha Prabha

The Ohio State University Wexner Medical Center, Columbus, OH

Background: We have recently identified inflammatory dendritic cells (InfDC) in the kidneys of patients with systemic lupus erythematosus (SLE). These cells are over expressed in LN patients compared to healthy controls. Knowledge on how the infDC interact with intra-renal T cells and their role in the pathogenesis of LN kidney is crucially needed.

Methods: We examined infDC and T cells in the kidneys of NZM 2410 (NZM), from protein- (NZM 2402) and non-variant (NZM 2400) mice. InfDC were identified via flow cytometry using CCR7+, CD11c+, CD11b+, MHCII+). Further, we differentiated InfDC into three subtypes: InfDC1, InfDC2, and InfDC3, based on their surface marker expression.

Results: The immune-staining studies recapitulated the human LN robust infiltration of InfDC in the kidneys of NZM mice. The InfDC were identified to be in close proximity to CD3+ T cells constant with an immunological synapse. Further, characterization by IF revealed infDC in mice LN were FcRγ+, MHCII+, CD11c+, CD163+, CD11b+, Ly6C+. Interestingly, 2 subtypes of InfDC were identified in NZM mice, FcRγ+MHCII+CD11c+, CD11b+ and FcRγ+MHCII+CD11c+, CD11b+, and differentiated by the presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotype shows that Th17 expression, but not Th1 was upregulated significantly in prot-NZM compared to pre-prot-NZM. The infDC were also identified to be in close proximity to CD3+ T cells constant with an immunological synapse. Further, characterization by IF revealed infDC in mice LN were FcRγ+, MHCII+, CD11c+, CD163+, CD11b+, Ly6C+. Interestingly, 2 subtypes of InfDC were identified in NZM mice, FcRγ+MHCII+CD11c+, CD11b+ and FcRγ+MHCII+CD11c+, CD11b+, and differentiated by the presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotype shows that Th17 expression, but not Th1 was upregulated significantly in prot-NZM compared to pre-prot-NZM in parallel to InfDC.

Conclusions: Similar to human LN, infDC are abundant in prot-NZM LN kidneys compared to pre-prot-NZM kidneys. The presence of CD11c+ InfDC marks for InfDC as markers for immune cells.

SeqStain Is a Novel, Multiplex Imaging Method For Spatialomic Profiling of Human Kidney Tissues

Ishwara Venkatesh, Anagha R. Rajagopalan, Disha Varma, Vineet Gupta. Team SeqStain Rush University Medical Center, Chicago, IL

Background: Chronic Kidney Disease (CKD) is the ninth leading cause of death in the United States, an emerging global health challenge affecting 10-15% of the population. Lack of reliable biomarkers precludes early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue changes. For instance in Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli, reduced podocyte number, inflammation in the renal tissue, influx of immune cells that ultimately lead to tissue damage. Understanding these tissue-centered events on a deeper level is integral to achieving effective targeted therapies.

Methods: To understand molecular and cellular composition of tissues and their relative organization in three-dimensional space, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses fluorescently labeled DNA oligonucleotides (termed “SeqStain antibodies”) to stain while endonucleases are used to achieve gentle de-staining after each round. This methodology can fluorescently label multiple cell types in tissue

Results: The SeqStain method offers a gentle, easy-to-use, and effective multiplex imaging method that provides a unique platform for obtaining spatialomic insights. SeqStain method can profile the CKD kidney tissues and comprehend the tissue-centered events that could play a role in disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments in comparison to healthy kidney to generate spatial maps

A Phase 1 Study to Evaluate the Safety, Tolerability, and Pharmacokinetics of AT1501

Steven Perrin, Eledon Pharmaceuticals, Irvine, CA.

Background: CD40L is a co-stimulatory receptor for CD40 found on T helper cells. Binding of CD40L on T cells to CD40 on antigen presenting cells induces downstream immune and inflammatory responses. Inhibition of CD40L signaling can abolish inflammatory responses and prevent the progression of chronic inflammatory diseases, including transplant tolerance. AT-1501 is a humanized anti CD40L antibody lacking Fc effector function and high affinity binding to CD40L. Purpose: Execute a phase 1 study of AT-1501 to assess safety, pharmacokinetics, and functional activity.

Results: The study employed a phase- placebo-controlled, sequential, dose-escalation design. 28 healthy subjects and 4 adults with ALS were enrolled. Five sequential ascending doses of AT1501 (0.5, 1, 2, 4, or 8 mg/kg) or placebo were administered by IV infusion. The primary endpoint was the safety and tolerability of AT1501. The secondary endpoint was to determine plasma pharmacokinetics (PK) and anti-drug antibody (ADA) responses to AT1501. An exploratory endpoint was to examine the ability of AT1501 to block an immune challenge in subjects who received a Keyhole Limpet Hemocyanin (KLH) challenge.

Results: Dose proportionality was achieved over the AT-1501 dose range of 0.5 to 8 mg/kg for Cxy and AUCxy. The mean AT-1501 t1/2 in healthy volunteers was 18 to 26 days. AT1501 had a safety profile comparable to placebo and was well tolerated in healthy subjects and subjects with ALS. 54% of subjects treated with AT-1501 had at least 1 TEAE and 22% of subjects treated with placebo had at least 1 TEAE. The most commonly reported TEAEs overall were headache, somnolence, and upper respiratory tract infection. There were no meaningful laboratory abnormalities, vital sign assessments, ECG assessments, or physical examination findings. Positive ADA responses to AT-1501 were observed in 6 of 28 subjects in the study. There was no dose dependence with respect to the incidence of positive ADA titers. ADA did not appear to affect AT-1501 plasma PK profiles or parameters suggesting they were not neutralizing. 8 mg/kg AT-1501 successfully blocked an immune response to KLH challenge in 2 of the 3 subjects tested.

Results: Our findings support further clinical development of AT-1501 for transplantation and autoimmune diseases.

Funding: Commercial Support - Edlen Pharmaceuticals

POI1442

High Expression of Mincle in Intermediate Monocytes of Patients with Autoimmune Diseases

Shuping Li,1 Lokyu Cheng,1 Tianjiao Cui,1 Lanyue Zhang,1 Xiuxun Tian,1 Zhihuang J. Zhao,2 Yun Chen,1 Zhihua Zheng,1 The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China; 2Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Macrophage C-type lectin receptor (Mincle) is a transmembrane C-type lectin receptor that is predominantly expressed on macrophages' surface and recognizes a broad range of self and foreign antigens as part of innate immune sensing, thus playing a pivotal role in tailoring immune response. Mincle’s function associates with its expression levels on immune cells’ surfaces. However, the differential expression of Mincle in various types of immune cells between patients with autoimmune disease (AD) and healthy controls (NCs) is yet to be examined, and its clinical relevance remains unclear. Therefore, this study aimed to investigate Mincle expression and distribution in different types of immune cells in patients with AD and NCs, and to explore the clinical relevance and potential mechanisms of Mincle expression levels in immune cells of patients with AD and NCs.

Methods: Mincle expression levels in leukocyte subgroups and monocyte subsets of peripheral blood from all participants were analyzed using flow cytometry and real time PCR, and the clinical characteristics of patients with SLE were collected for correlation analysis. Monocyte subsets were identified by CD14+/CD16+ T cells, and the differentiations of naïve T cells were detected by flow cytometry.

Results: Mincle was expressed predominantly in myeloid cells, both in peripheral blood and cell lines. Moreover, monocytes expressed higher levels of Mincle than granulocytes in both patients with AD and NCs, and Mincle expression levels were higher in IMCs of patients with AD, including patients with SLE, than in those of NCs.
Development of Kidney Resident and Recruited Macrophages

Background: Macrophages are part of the phagocyte mononuclear system constantly replaced by the circulating blood monocytes. In the steady state, the myeloid cell compartment is highly heterogeneous, containing various cell types. These cells include macrophages and dendritic cells, and each play important roles in tissue maintenance, including development, homeostasis, immunity and repair following tissue injury. The composition of kidney macrophages is not well known.

Methods: A multi-parameter flow cytometry approach was used to identify the resident and recruited macrophage population in the kidneys of male and female C57BL/6J mice aged 7, 21 and 84 days in the steady state. Resident and recruited macrophage populations were characterized based on 33 cell surface and intracellular markers.

Results: Both resident and recruited macrophages were identified in the kidneys of male and female mice aged 7, 21, and 84 days in the steady state. We observed two distinct resident macrophage populations in young mice (7 and 21 days old) but by 84-days, male and female mice displayed 4 and 5 resident populations, respectively. The resident macrophage population in 7-day old mice displayed low surface expression of MHC class II and began to shift to an increased expression of MHC class II at 21 days, and high MHC class II expression at 84 days. We detected three recruited macrophage populations in 7- and 21-day-old mice, and two populations by 84-days of age. The recruited macrophage population displayed low MHC class II at all ages in both sexes. Analysis of the global macrophage populations at 84 days of age revealed female mice had twice as many recruited compared to resident macrophages, whereas male mice had an equal distribution.

Conclusions: The data indicate a dynamic change in the kidney macrophage population with age and resident macrophage phenotype. The composition of macrophage populations also differs by sex and age. These data suggest each population plays a role in kidney homeostasis. Future studies will be directed towards elucidating the functions of each of the identified macrophage populations.

Activation of the Integrated Stress Response Regulates the Production of IL-17 in Tissue Resident Memory T Cells

Background: CD4+ positive T cells produce cytokines and play a central role in immunity. Tissue-resident memory T (Trm) cells remain in organs after infection and contribute to efficient host defense by immediate production of cytokines, such as IL-17A. However, it was demonstrated that Trm cells also promote autoimmunity. Therefore, the regulation of cytokine production by Trm cells is of great importance to achieve efficient host defense without excessive inflammation. However, the control mechanisms of cytokine production by Trm cells are not well understood.

Methods: Human and mouse T cells including renal Trm cells were analyzed by single cell RNA sequencing (scRNAseq), polysome profiling combined with bulk RNA sequencing, RT-PCR, flow-cytometry, immunocytochemistry, and mRNA FISH. Mouse models for Staphylococcus aureus infection and crescentic glomerulonephritis were used to induce and study Trm cells in vivo.

Results: Conserved pathways were identified in human and mouse tissue samples revealing that Resting CD4+ Trm cells in the kidney express IL17A mRNA but do not produce or secrete the cytokine protein without re-stimulation. Mechanistically, we demonstrate that the phosphorylation of eIF2α, a key feature of the integrated stress response (ISR) activation, resulted in recruitment of II17A mRNA into stress granules, which are organelles crucial for regulating mRNA translation during ISR, thereby inhibiting mRNA translation in resting Trm cells. Finally, we show that re-stimulation of human renal Trm cells through T cell receptor resulted in eIF2α dephosphorylation, leading to efficient translation of IL17A mRNA and subsequent IL17A secretion.

Conclusions: Tissue-resident memory CD4+ T cells in the kidney express high levels of IL-17A cytokine mRNA. Under homeostatic conditions the cytokine mRNA is stored in stress granule protein. In contrast, these Trm cells rapidly produce IL-17A upon re-stimulation. Our study identifies a novel mechanism of how “poised Trm17” cells use the integrated stress response - stress granules pathway to regulate IL-17A cytokine mRNA translation. Dysregulation of this pathway might have a pathogenic role in chronic relapsing and remitting inflammatory diseases.

Immune Complexes in the Peripheral Blood of Patients with IgA Nephropathy Contain Polymeric Galactose-Deficient IgA1 Associated with IgG and Complement C3

Stacy D. Hall,1 Sarah Coffee,1 Nicolas Maillard,1,2 Zina Moldoveanu,1 Ellenore P. Crainie,1 Audra A. Hargett,1 Dana Rizk,1 Bruce A. Julian,1 Matthew B. Renfrow,1 Jan Novak,1,3 The University of Alabama at Birmingham, Birmingham, AL; 2Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein immune complexes (IC) containing IgA1 with some hinge-region O-glycans deficient in galactose (Gd-IgA1) and IgG autoantibodies deposit in the kidneys and induce injury. Although the glomerular immunodeposits are enriched for Gd-IgA1, not much is known about the distribution of different molecular forms of Gd-IgA1 in circulation.

Methods: Total serum IgA1 was isolated from 7 Caucasian and 10 African American patients with IgAN by jacalin-affinity chromatography. Different molecular forms of IgA1 were then separated by size-exclusion chromatography (SEC). Gd-IgA1 was detected by lectin ELISA. IgA1-IC were isolated by SEC from sera of 4 IgAN patients. Biological activity of the isolated IC was assessed measuring the proliferation of cultured primary human mesangial cells (MC). IgA1, IgG, and complement C3 were analyzed by SDS-PAGE/immunoblotting.

Results: Total serum IgA1 included monomeric and polymeric forms and IgA1 bound in IC. Monomeric IgA1 represented ~88-92% of total IgA1, whereas polymeric IgA1 represented ~8-12%. IgA1 in IC was the least abundant form, representing <0.4% of total IgA1. Relative representation of Gd-IgA1 was highest in IC, followed by polymeric forms, and lowest in monomeric forms. Gd-IgA1 in IC had minimally sialylated O-glycans, whereas polymeric and monomeric forms were substantially sialylated. Caucasian patients had higher content of Gd-IgA1 in polymeric and monomeric forms of IgA1 compared to those of African American patients (P<0.03 and P<0.05, respectively). IgA1-IC in sera of IgAN patients had molecular mass >700 kDa and stimulated proliferation of MC. These IC consisted of polymeric IgA1, IgG, and complement C3.

Conclusions: Biologically active IC in the circulation of IgAN patients contain polymeric, minimally sialylated Gd-IgA1 associated with IgG and C3. These findings support the pathogenic role of Gd-IgA1-IgG IC in IgAN.

Immune Complexes Containing Galactose-Deficient IgA1 Deposit on Mesangium Through Damage to Endothelial Cells

Yuko Immune,1 Bunkyo-ku, Japan; 2Juntendo University Urayasu Hospital, Urayasu, Japan; 3Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; 4Juntendo University Urayasu Hospital, Urayasu, Japan; 1Kagawa University, Kagawa, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). However, the pathogenic role of mesangial Gd-IgA1-containing immune complexes (ICs) remains unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is known to be involved in albuminuria. Here, we examined whether the deposition of Gd-IgA1-containing ICs in the mesangium may lead mesangial endothelial cell dysfunction in this disease.

Methods: Gd-IgA1 and recombinant anti-glycan IgG were used to form ICs to inject into nude mice. The renal microvascular endothelial glycocalyx removal of the injected nude mice was evaluated by real-time glycocalyx imaging. Human renal glomerular endothelial cells (HRGECs) were used to assess the potential capacity of Gd-IgA1-containing ICs to activate endothelial cells.

Results: After co-culture of Gd-IgA1-containing ICs with HRGECs, mRNA expression levels of endothelial adhesion molecules (ICAM-1, VCAM-1 and E-selectin) were significantly upregulated (P<0.01). Expression levels of proinflammatory mediators (TNFα and IL-6) that are able to induce the expression of the adhesion molecules on endothelial cells were also increased (P<0.001). Nude mice injected with Gd-IgA1-containing ICs showed podocyte and endothelial injuries with IgA, IgG, and C3 co-deposition along the glomerular capillaries and in the mesangium. Moreover, albuminuria and hematuria were also induced. Real-time glycocalyx imaging showed that renal microvascular glycocalyx was decreased immediately after the injection of Gd-IgA1-containing ICs and then mesangial IgA deposition was increased.

Conclusions: Present data suggest that Gd-IgA1-containing ICs may induce glomerular endothelial injuries resulting in mesangial deposits.
PO1451
Histopathologic Association of Lambda Light Chain Predominance in IgA Nephropathy
Prasanth Raviyati,1 Virginie Royal,2 LiHong Bu,1 Rebecca L. Freese,1 Michelle N. Rheault,1 Patrick H. Nachman,1 CureGN Investigators1  University of Minnesota Twin Cities, Minneapolis, MN; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: A relative predominance of lambda (λ) over kappa (κ) light chain deposition has long been recognized in IgA Nephropathy (IgAN), which is unique to this other glomerular disease. The reason for this predominance is unknown but may be related to a purported predominance of λ chain expression by gut associated lymphoid tissue B cells. There is limited information regarding the histopathologic findings, if any, associated with predominant λ light chain deposition. Utilizing the CureGN IgAN cohort, we evaluated if predominant λ chain deposition was associated with histologic markers of disease activity by examining MEST characteristics and other variables.

Methods: We divided the CureGN IgAN cohort into two groups based on the intensity of light chain deposition by immunofluorescence. The λ, dominant group (LD) was defined by a difference in intensity score of staining of λ, minus κ ≥ 1+; and the λ-k codominant group (KL) by a difference of λ, minus κ ≤ 1+. Fisher’s exact test was used to compare the histopathologic changes between the groups with respect to M, E, S, T, scores, total crescents, percent (%) of globally sclerotic glomeruli, % of glomeruli with fibroblast nerosis, degree of interstitial inflammation, and the intensity of IgA, C3, and C3 staining.

Results: Among 695 IgAN patients, the kidney biopsy digital images of 269 patients were reviewed by CureGN pathologists and 234 patients had reported λ and κ staining intensity. Of these, 96 (41%) patients were classified as LD (including 7 patients (3%) with λ, monotypic staining) and 138 (59%) classified as KL. The two groups did not differ significantly in age, sex, or race. Compared to the KL group, the LD group had a greater frequency of endocapillary hypercellularity (E1, 51.1% vs 36.3%, p=0.04) and IgG staining intensity ≥ 1+ (37.3% vs 21.9% ; p=0.01). We did not see any significant differences between groups with respect to any other histologic finding.

Conclusions: In IgAN, patients with predominately λ mesangial deposition are more likely to have increased endocapillary hypercellularity and IgG deposition, two findings previously linked with greater histologic disease activity and possibly worse prognosis. Further studies are needed to elucidate if the predominance of λ chains represents a unique pathology in a subset of patients, or it imparts a more severe disease course.

Plasmacytoid Dendritic Cells from Murine IgA Nephropathy Have a Capacity to Enhance IgA Production Through TLR9/APRIL Signaling
Yusuke Fukun1,2, Hitoshi Suzuki,3 Toshiaki Kano,1 Kentaro Makita1,2, Yusuke Suzuki,1,2 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; 3Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.

Background: Our recent study revealed that chronic Toll-like receptor 9 (TLR9) stimulation induce a proliferation-inducing ligand (APRIL) expression on naïve B cells and such APRIL-B cell may contribute to nephritogenic IgA production in IgA nephropathy (IgAN). On the other hand, APRIL from TLR9 activated dendritic cell (DC) is generally known to be involved in B cell maturation and IgA class switching. In this study, we evaluated IgA production through TLR9/APRIL signaling by DCs from murine IgAN.

Methods: Splenic B cells and DCs from grouped ddY (gddY) mice, which are known as the spontaneous IgAN model, and Balb/c mice were isolated using magnetic cell sorter. We co-cultured these isolated DCs and B cells with or without CpG-ODN, a known to be involved in B cell maturation and IgA class switching. In this study, we evaluated IgA production through TLR9/APRIL signaling by DCs from murine IgAN.

Results: We divided the CureGN IgAN cohort into two groups based on the intensity of light chain deposition by immunofluorescence. The λ, dominant group (LD) was defined by a difference in intensity score of staining of λ, minus κ ≥ 1+; and the λ-k codominant group (KL) by a difference of λ, minus κ ≤ 1+. Fisher’s exact test was used to compare the histopathologic changes between the groups with respect to M, E, S, T, scores, total crescents, percent (%) of globally sclerotic glomeruli, % of glomeruli with fibroblast nerosis, degree of interstitial inflammation, and the intensity of IgA, C3, and C3 staining.

Conclusions: In IgAN, patients with predominately λ mesangial deposition are more likely to have increased endocapillary hypercellularity and IgG deposition, two findings previously linked with greater histologic disease activity and possibly worse prognosis. Further studies are needed to elucidate if the predominance of λ chains represents a unique pathology in a subset of patients, or it imparts a more severe disease course.

458
of T cells and B cells into Peyser’s patches (PP). T-cell homing to the PP depends on CCR7 and its ligands, CCL19 and CCL21, whereas B-cell homing to PP depends on the coordinated signaling of CCR7, CXCR4, CXCR5 and CCR6. The PP are believed to be a major source of the poorly O-galactosylated IgA1 in IgA nephropathy (IgAN). The therapeutic potential of targeting PP was demonstrated in the Phase 2 NEFIGAN trial (NCT01738035), which assessed the safety and efficacy of a novel targeted-release investigational formulation of budesonide (TRF-budesonide [Nefecon]), designed to deliver budesonide to the PP-rich distal ileum in patients with IgAN. The trial comprised a 6-month run-in, 9-month treatment, and 3-month follow-up phase: 49 patients received Nefecon 16 mg/day, 51 patients received Nefecon 8 mg/day, and 50 patients received placebo. Nefecon 16 mg/day, added to optimized renin–angiotensin system blockade, reduced proteinuria and stabilized eGFR in patients with IgAN. This study investigated whether Nefecon treatment altered serum levels of chemokines.

Methods: Serum levels of a panel of 20 chemokines were measured by Lumexin. Changes in log-transformed levels of each biomarker with treatment were compared by one-way ANCOVA. Significance was p<0.05.

Results: A significant, dose-dependent modulation in serum levels of key chemokines directing T and B cell trafficking to the intestine (CXCCL5), and more specifically to the PP (CCL11), CCL19, CCL20) was seen with Nefecon, which reversed on cessation of Nefecon. These observations paralleled significant reductions in the levels of soluble CD23, CD27 and CD30, and are consistent with our previous reports describing a dose-dependent modulation in BAFF, soluble BCMA, TACI, IgA/IgG immune complexes, secretory IgA and galactose-deficient IgA levels with Nefecon.

Conclusions: Nefecon, which targets the PP-rich distal ileum, modulates key chemokine signals which direct immune cell trafficking to the intestine in IgAN.

Dysregulated T Cell Metabolomic Profile in Patients with Steroid-Resistant Nephrotic Syndrome

Introduction: In patients with steroid-resistant nephrotic syndrome (SRNS), metabolic reprogramming has been reported in renal tissue and peripheral blood, which may contribute to the disease process. However, the overall metabolic profile in SRNS patients has not been comprehensively studied.

Methods: In this study, we aimed to identify metabolic alterations associated with SRNS by comparing the metabolomic profiles of patients with SRNS to those with steroid-dependent nephrotic syndrome (SDNS). A total of 48 patients with childhood-onset SDNS (n=31) and SRNS (n=17) were recruited during relapse. T-cell activation assay was performed on whole blood while metabolomic profiling was performed on purified stimulated CD4 T-cell culture supernatants (n=23) using GC-MS/MS and analysed using Shimadzu SmartMetabolites Database. Differences in the metabolomic profile between SDNS and SRNS were identified using PLS-DA (SIMCA), and pathway analysis was performed using MetaboAnalyst 4.0. Metabolomic validation assay was performed using Glucose-6-Phosphate Dehydrogenase (G6PD) assay kit.

Results: SRNS patients had significantly lower T-cell expression of CD69, CD25, and IFN-γ (1.9±0.3% vs 6.6±1.3%, P=0.016) compared to SDNS patients. PLS-DA modeling of the 93 metabolites identified in CD4 culture supernatants yielded one fitted component, in which 24% of the variability in metabolites measured (R²X) could explain 58% of the variation in steroid-response (R²Y). Of note, 85% of the metabolites tended to be lower in SRNS compared to SDNS patients. Pathway analysis of the 38 metabolites with VIP>1 implicated the biosynthetic pathways glyoxylate and dicarboxylate metabolism, ascorbate and aldehyde metabolism as well as galactose metabolism (Benjamini-Hochberg P<0.05). Interestingly, the 2 metabolites with the highest VIP score have been implicated as downstream products of the pentose phosphate shunt and were reduced in SRNS compared to SDNS patients (P<0.001). G6PD activities in SDNS patients in relapse negatively correlated with T-cell expression of CD69 (r=−0.58, P=0.047).

Conclusions: We demonstrated that muted T-cells responses to in vitro stimulation in SRNS patients was associated with metabolic quiescence, with dysregulated biosynthetic pathways including the pentose phosphate shunt.

Blocking the IL-1β/IL-1R1 Signaling as a Potential Therapy for Multidrug-Resistant Nephrotic Syndrome

Introduction: Nephrotic syndrome (NS) is a disease characterized by proteinuria, edema, and hyperlipidemia, and is mediated by various factors including immune and inflammatory responses. However, multidrug-resistant nephrotic syndrome (MRNS) still poses a significant challenge in terms of treatment and prognosis.

Methods: In this study, we aimed to investigate the role of interleukin-1 beta (IL-1β) and its receptor (IL-1R1) in the pathogenesis of MRNS. We hypothesized that blocking IL-1β/IL-1R1 signaling could be a potential therapeutic option to prevent the progression of kidney injury in advanced forms of nephrotic syndrome.

Results: A total of 48 patients with childhood-onset SDNS (n=31) and SRNS (n=17) were recruited during relapse. T-cell activation assay was performed on whole blood while metabolomic profiling was performed on purified stimulated CD4 T-cell culture supernatants (n=23) using GC-MS/MS and analysed using Shimadzu SmartMetabolites Database. Differences in the metabolomic profile between SDNS and SRNS were identified using PLS-DA (SIMCA), and pathway analysis was performed using MetaboAnalyst 4.0. Metabolomic validation assay was performed using Glucose-6-Phosphate Dehydrogenase (G6PD) assay kit.

Results: SRNS patients had significantly lower T-cell expression of CD69, CD25, and IFN-γ (1.9±0.3% vs 6.6±1.3%, P=0.016) compared to SDNS patients. PLS-DA modeling of the 93 metabolites identified in CD4 culture supernatants yielded one fitted component, in which 24% of the variability in metabolites measured (R²X) could explain 58% of the variation in steroid-response (R²Y). Of note, 85% of the metabolites tended to be lower in SRNS compared to SDNS patients. Pathway analysis of the 38 metabolites with VIP>1 implicated the biosynthetic pathways glyoxylate and dicarboxylate metabolism, ascorbate and aldehyde metabolism as well as galactose metabolism (Benjamini-Hochberg P<0.05). Interestingly, the 2 metabolites with the highest VIP score have been implicated as downstream products of the pentose phosphate shunt and were reduced in SRNS compared to SDNS patients (P<0.001). G6PD activities in SDNS patients in relapse negatively correlated with T-cell expression of CD69 (r=−0.58, P=0.047).

Conclusions: We demonstrated that muted T-cells responses to in vitro stimulation in SRNS patients was associated with metabolic quiescence, with dysregulated biosynthetic pathways including the pentose phosphate shunt.

C3 Glomerulonephritis with Nephritic Factor Treated with Rituximab

Hanny Sawaf, Georges Nakhouli, Ali Mehdi, Jonathan J. Taliercio. Cleveland Clinic, Cleveland, OH.

Introduction: C3 Glomerulonephritis (C3GN) is a well described cause of kidney disease that results from dysregulation of the alternative complement pathway. Kidney biopsy demonstrates a membranoproliferative pattern of injury and mesangial C3 staining with minimal or no staining of immunoglobulins on immunofluorescence. C3GN can be due to genetic mutations, autoantibodies against the alternative complement regulators, or disease that results from dysregulation of the alternative complement pathway. Kidney Clinic, Cleveland, OH

Background: C3G is caused by dysregulation of the complement alternative pathway, but there is a gap in the pathogenetic cascade from complement activation (intravascular space) to inflammation and complement deposition in the glomeruli (extravascular space). Recently, biopsies have shown the presence of (activated) polymorphonuclear neutrophils (PMNs) in C3G glomeruli indicating an underappreciated role for PMNs in C3G pathogenesis.

Methods: PMNs were investigated in a transwell chamber allowing for different environments. Conditions were chosen to resemble the intravascular space (top well; serum containing) versus extracapillary space (bottom well; serum-free conditions). PMNs were stimulated in the top well via various agonists, including complement, and allowed to transmigrate to the bottom well where they were monitored for the formation of Neutrophil Extracellular Traps (NETs) via immunofluorescence and SYTOX assay. Circulating C3G patient PMNs were examined for priming via flow cytometry.

Results: Upon complement stimulation, PMNs showed evidence for priming in serum conditions (top well). PMNs travelled to the bottom well following chemotractant FMLP where they then completed the process of NET formation (NETosis) in serum-free conditions (bottom well). Results were validated ex vivo using C3G patient PMNs and autologous serum (Figure). In addition, incubation of control PMNs in C3G patient serum revealed a correlation between serum-albumin levels and the degree of NET formation. C3G patient PMNs showed upregulation of CD11b compared to controls.

Conclusions: Assigning a pathogenic role to PMNs in C3G identifies a new treatment and monitoring strategy with the potential for improved long-term outcomes and quality of life.

Differential Expression of Complement and Non-Complement Proteins in C3 Glomerulonephritis and Dense Deposit Disease

Sanjeev Sethi,1 Benjamin J. Madden,1 Fernando C. Fervenza,1 Lilian M. Palma.2 1Mayo Clinic Minnesota, Rochester, MN; 2Universidade Estadual de Campinas, Campinas, Brazil.

Background: C3 glomerulopathy comprising dense deposit disease (DDD) and C3 glomerulonephritis (C3GN) results from overactivation of the alternative pathway of complement. Mass spectrometry (MS) studies have previously shown accumulation of complement proteins in C3GN and DDD. However, complete MS analysis of non-complement proteins and comparison of complement proteins in C3GN and DDD has not been done.

Methods: We performed laser microdissection of glomeruli followed by MS in 12 cases each of biopsy-proven C3GN and DDD, and 6 control cases of time 0 transplant biopsies.

Results: Compared to the controls, C3GN showed increased intensity based absolute quantification (iBAQ) values of C3 (20-fold), C5 (52-fold), C7 (90-fold), C8 (66-fold), C9 (30-fold), CFHR1 (146-fold) and CFR5 (65-fold). Similarly, DDD showed also increased iBAQ values compared to controls of C3 (20-fold), C5 (52-fold), C7 (90-fold), C8 (66-fold), C9 (30-fold), CFHR1 (146-fold) and CFR5 (65-fold). When DDD was compared to C3GN, there was a 2-5 fold increase in iBAQ values in C5, C6, C7, C8 and C9 (p<0.001), although there was no significant difference in C3. Among the non-complement proteins Apolipoprotein E (APOE) and A-II and V (APOA-II and V), Serine protease HTRA1, Ryanodine receptor 1 (RYR1), and Translational activator GCN1 were expressed 2-5 fold higher in C3GN compared to DDD (p<0.001).

PMNs were seeded in the top well of a transwells system and allowed to transmigrate for 12 h. PMNs from both wells were stained for IF with DAPI (blue), Citrullinated histone 3 (Ch3H3; green) and Myeloperoxidase (MPO; red). Scale bar 20 um. 63x magnification.

Limited Therapeutic Arsenal for the Thrombotic Microangiopathy Spectrum
Jesse E. Diaz Correa,1 Joris M. Schuller,2 Harold M. Szerlip1,2 1Baylor University Medical Center at Dallas, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

Introduction: Thrombotic microangiopathy (TMA) is a common renal pathologic finding with an associated broad spectrum of clinical diseases. Complement-mediated TMA (C-TMA) is frequently recognized cause of TMA due to uncontrolled complement activation. Terminal complement inhibitors such as Eculizumab have been shown to improve renal function in C-TMA. Multiple case reports have demonstrated a benefit in patients without identifiable complement disorder.

Case Description: 41-year-old Ethiopian female with a history of metastatic ovarian cancer treated with omentectomy, partial hepatectomy, salpingo-oophorectomy, splenectomy one year before admission was admitted for renal biopsy for evaluation of an increasing creatinine and proteinuria. Following her surgery she had been treated initially with paclitaxel and carboplatin and subsequently she had received bevacizumab and doxorubicin; the last doses of these latter agents were six months before admission. Four months prior to admission she developed new onset hypertension and her creatinine began increasing creatinine and proteinuria. Following her surgery she had been treated initially with paclitaxel and carboplatin and subsequently she had received bevacizumab and doxorubicin; the last doses of these latter agents were six months before admission. Four months prior to admission she developed new onset hypertension and her creatinine began increasing. The early recognition of complement-mediated (C-)TMA is of utmost importance to select patients for terminal complement inhibitors such as Eculizumab which have been shown to improve renal function in C-TMA. Multiple case reports have demonstrated a benefit in patients without identifiable complement disorder.

Discussion: There are no randomized trials evaluating terminal complement inhibitors for c-TMA. The indication for these medications becomes even more unclear when we factor in drug-induced TMA, cancer-associated TMA, malignant hypertension, and other TMAs without readily identifiable complement disorders. More research on the role of genetic testing and complement inhibition is warranted for the entire spectrum of TMA.

POI146

Clinical and Histological Features of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: A Single-Center Retrospective Study from China
Yifeng Wang, Xiaoye Zhu, Shaojun Liu, Jun Xue, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: PGNIMID is a new entity of monoclonal gammopathy affecting the kidney characterized by intact monoclonal immunoglobulins (mlg) deposits that result in membranoproliferative pattern of glomerular injury. In this study, clinical and histological of PGNIMID cases were evaluated.

Methods: A total of 23 patients with biopsy-confirmed PGNIMID in native kidney diagnosed between December 2015 and April 2021 were enrolled in this study. Clinical, histological, hematologic, and follow-up data were abstracted from the medical record.

Results: Of 23 cases, majority were male (65.2%), and the mean age was 49.5 years with 8 cases (34.8%) under 40 years old. At the time of biopsy, 19 cases had proteinuria with a mean 24h urine protein of 3.99g (0.28 to 8.96), 11 of 22 cases had nephrotic syndrome, and 18 of 22 cases had hematuria. The mean serum creatinine was 1.52mg/dl (0.6 to 7.8), 15 cases (65.2%) had eGFR<90 mL/min (CKD-EPI), and 4 cases had eGFR <60 mL/min. Eleven of 23 cases (47.8%) showed MPPG, 6 cases showed EPGN, 2 cases showed MesPGN, and 2 cases showed MN. By IF, 21 cases (91.3%) showed mlgG deposits (12 IgGκ, 5 IgGλ, 1 IgAκ, 1 IgAλ, and 2 IgGκ/λ without determined subclass) and 2 cases (8.7%) showed mlgA deposits. All cases showed C3 co-deposits, and 6 of 18 cases (33.3%) had a low serum C3 level. EM revealed unorganized and granular deposits in the mesangial area (17 of 17), subendothelial area (15 of 17), and subepithelial area (12 of 17). Three of 4 cases whose eGFR<60 mL/min showed EPGN. SIFE showed mlg that matched the renal deposits in 2 of 13 cases (15.3%). After mean follow up of 3 months in 3 cases, 1 patient treated with bortezomib+ CTX+DXM and another patient treated with rituximab both achieved partial renal remission. But the third patient treated with rituximab had a persistent renal dysfunction. Of note, previous or concurrent infections by fungi, HIV, HBV, HPV or other undetermined pathogen, were observed in 5 cases (21.7%). We also found 1 patient with autoimmunity and another with malignancy.

Conclusions: Compared with previous reports, our PGNIMID cases showed similar clinical and histological features. EPGN pattern seems to be associated with more severe renal function damage. Previous or concurrent infections, autoimmunity and malignancy were observed in 21.7% of cases.

Diagnostic and Risk Factors for Deregulated Complement in Thrombotic Microangiopathy
Sjoerd Timmermans, Pieter van Paasen. Limburg Renal Registry Maastricht Universair Medisch Centrum+, Maastricht, Netherlands.

Background: The syndromes of thrombotic microangiopathy (TMA) are diverse and represent severe endothelial damage caused by various etiologies. The early recognition of complement-mediated (C-)TMA is of utmost importance to select patients for complement inhibition. Whether or not clinicopathologic features at presentation can distinguish C-TMA from secondary TMA were studied. Regression models were used to assess the prognostic value of chronic damage on kidney biopsy.

Results: C-TMA was diagnosed in 30 patients (coexisting conditions, n=26 [87%]), including 16 (53%) cases with rare complement gene variants; 27 patients had secondary TMA related to autoimmunity (n=13), hypertension (n=10), and other etiologies (n=4). Patients presented with acute kidney injury, while systemic hemolysis was uncommon in both groups (n=14/30 vs. n=6/27; P=0.05). C-TMA was linked to younger age (37 ±14 vs. 46 ±15 years; P=0.04), low plasma C3 (n=16/29 vs. n=3/22; P=0.01), and glomerular thrombosis (n=19/30 vs. n=8/27; P=0.02) as compared to secondary TMA; glomerular thrombosis, however, was common in patients with autoimmunity (n=6/13; P=0.05 vs. C-TMA). These characteristics, when combined, had a specificity and sensitivity for C-TMA of 100% and 33%, respectively. Eculizumab treatment was associated with clinical remission in C-TMA (n=12/14; P=0.01 vs. n=3/16 untreated patients). Morphologic features of chronic damage, i.e., glomerulosclerosis, interstitial fibrosis/tubular atrophy, and arteriosclerosis, did not predict prognosis; 5 out of 6 patients with C-TMA and moderate-to-severe chronicity scores treated with eculizumab recovered and/or improved kidney function.

Conclusions: Patients with TMA, low plasma C3, and glomerular thrombosis who present at younger age (i.e. <45 years) are at high risk for C-TMA. Although a kidney biopsy is often necessary to detect the TMA, morphologic features of chronic damage cannot predict prognosis.

Hematopoietic Stem Cell Transplant Membranous Nephropathy Is Associated with Protocadherin FAT1
Sanjeev Sethi,1 Benjamin J. Madden,1 Samith H. Nasr,1 Fernando C. Fervenza,1 Mark Haas,2 Mayo Clinic Minnesota, Rochester, MN; 2Cedars-Sinai Medical Center, Los Angeles, CA.

Background: Membranous nephropathy (MN) is a common cause of proteinuria in patients with a hematopoietic stem cell transplant (HSCT). The antigen(s) responsible for MN in HSCT-associated MN is unknown.

Methods: We performed laser microdissection and mass spectrometry (MS/MS) of glomeruli of 230 cases of PLA2R-negative MN to detect novel proteins/antigens in MN. These included PLA2R-negative MN developing in the setting of HSCT and de-novo MN in the kidney transplant.

Results: We detected a novel protein Protocadherin FAT1 (FAT1) in 9 cases of PLA2R-negative MN. Of the 9 FAT1-associated MN cases, 7 patients followed HSCT and 2 followed kidney transplant (de-novo MN). HSCT was done for treatment of AML and 2 followed kidney transplant. The antigen(s) responsible for MN in HSCT-associated MN is FAT1.

Conclusions: FAT1 appears to be a unique protein found in MN developing in the setting of HSCT and de-novo MN following kidney transplant. Further studies to localize FAT1 on the glomerular basement membranes and detect circulating antibodies are ongoing.

POI1468

Netrin G1 Is a Novel Target Antigen in Membranous Nephropathy
Linda Reinhard,1 Maya Machera, Thorsten M. Viech, Nicoletta Ferru, Elion Hoxha, Rolf A. Stahl. Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

Background: PLA-R is the main target antigen in membranous nephropathy (MN) representing 70-80% of cases. In the past years a number of confirmed, or potential target antigens, such as THSD7A, NELL1, HTRA1, Sema3B and PCDH7 have been reported, showing that the pathophysiology of PLA-R-antibody (ab) negative MN represents a diverse repertoire of antigens with low frequency.

Methods: Western blot (WB) analysis was used to identify sera of MN patients with IgG4 specific signals binding to antigens in the membrane fraction of human glomerular extracts (HGE). Only sera which were negative for PLA-R- and THSD7A-ab were used. IgG4-ab from the serum of an index patient was purified and used to immunoprecipitate the corresponding target antigen from the membrane fraction of HGE. The purified antigen in the eluate was identified by mass spectrometry. Recombinant protein was used to confirm the reactivity of patient sera by WB and identify other patients in a large cohort of MN patients. The deposition of the target antigen in the glomerular immune deposits was confirmed by immunohistochemistry (IHC).

Results: Using this approach, we identified Netrin G1 (NTNG1) as a novel target antigen in MN. NTNG1 is a 50 kDa secreted glycoprotein, which is attached to the cell surface by a GPI anchor (Fig. A, B). We identified NTNG1-ab in two out of 110 PLA-R- and THSD7A-ab negative MN patients. A follow-up of 5 years was available for the index patient. During this time, both proteinuria and NTNG1-ab persisted while renal function was stable. Further, a granular positivity for NTNG1 along the glomerular capillary wall was confirmed in the kidney biopsy by IHC (Fig. C), but was undetectable in the negative control (PLA-R-ab-positive MN).

Conclusions: We report NTNG1 as a novel target antigen in MN, occurring with low frequency and expanding the repertoire of antigens in patients with MN. Its prevalence, pathogenetic and clinical roles remain to be defined.

Contactin 1: A New Antigen in Membranous Nephropathy Associated with Chronic Inflammatory Polyneuropathy
Domenico Santoro,1 Elisa Longhitano,1 Massimo Torreggiani,2 Antonella Barreca,1 Elisa Vegezzi,2 Giorgina B. Piccoli,2 Anna Mazzeo,4 Massimo Russo,1 Antonio Toscano,1 Hanna Debiec,4 Pierre M. Ronco,4 1Università degli Studi di Messina, Messina, Italy; 2Centre Hospitalier du Mans, Le Mans, France; 3Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Torino, Italy; 4INSERM, Paris, France; 5Fondazione Istituto Neurologico Nazionale C Mondino Istituto di Ricovero e Cura a CarattereScientifico, Pavia, Italy.

Introduction: In recent years, several new antigens have been characterized in membranous nephropathy (MN), but those involved in association with demyelinating neuropathy remain elusive. Although several antibody specificities were identified in this group of autoimmune nephropathies with or without glomerular involvement, there is no evidence for the deposition of the relevant antibodies in glomeruli. We investigated a patient with such association.

Case Description: A 73 y/o woman was referred to the neurology department for weakness and ataxic gait. Romberg’s manoeuvre was positive. On examination, thermal and nociceptive hypoesthesia and hypopallesthesia were found. Electromyography demonstrated sensory-motor axonal polyneuropathy, compatible with a chronic inflammatory demyelinating polyneuropathy (CIDP). Blood tests showed normal kidney function (eGFR 73 ml/min) and hypoalbuminemia (2.89 g/dl); 24h proteinuria was 3.6 g/24h. Autoantibodies (ANA, ENA, DNA, LAC, anti-cardiolipin, ANCA) were undetectable, serum immunoglobulins and C3 and C4 complement components were normal. A kidney biopsy (KB) determined a picture of MN. Anti-PLA2R antibody was negative in the serum and PLA2R and THSD7A antigens were not detected in the KB. Three CIDP-associated autoantibodies (anti-contactin 1 (CNTN1), anti-contactin associated protein 1 and anti-neurofascin) were tested by ELISA which revealed the presence of anti-CNTN1 at 1:100 serum dilution. CNTN1 antigen was revealed by immunohistochemistry in the subepithelial immune deposits in the patient’s paraffin biopsy sections but not in control PLA2R-positive KB (figure 1). A follow-up of 5 years was available for the index patient. During this time, both proteinuria and NTNG1-ab persisted while renal function was stable. Further, a granular positivity for NTNG1 along the glomerular capillary wall was confirmed in the kidney biopsy by IHC (Fig. C), but was undetectable in the negative control (PLA-R-ab-positive MN).

Conclusions: CNTN1 should be added to the armamentarium of antigens involved in MN and tested in PLA2R negative MN associated with CIDP. Further studies are needed to determine the prevalence of CNTN1-associated MN among patients with CIDP, and in those without CIDP and as yet unidentified antigen.
Generation of Anti-THSD7A Antibodies Using a Human Antibody Phage Display Library
Sarah Köllner,1 Larissa Seifert,1 Philip A. Heine,2 Michael Huster,3 Nicola M. Tomas,1 Universitätshospital Hamburg-Eppendorf, Hamburg, Germany; 2Technische Universität Braunschweig, Braunschweig, Germany.

Background: Membranous nephropathy (MN) is an antibody-mediated autoimmune renal disease. In the majority of cases, autoantibodies target podocyte membrane proteins such as PLA2R and THSD7A. We could previously demonstrate that autoantibodies in THSD7A-associated MN cause disease and recognize several extracellular domains of the target antigen. However, the pathomechanism underlies how this antibody polyreactivity relates to disease pathogenicity. The aim of this study was the generation of anti-THSD7A antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Methods: In the antibody phage display technology, antibody fragments are displayed on the phage particle and the corresponding gene fragment encoding the antibody fragment is packaged in the phage particle. A selection process called panning enables the generation of antigen-specific antibodies. A library of human antibodies was constructed and panned against human and mouse THSD7A. The resulting phage clones were sequenced, and selected clones were expanded. The sequence of one of the selected clones, SAK78-C12, was analyzed and the antibody fragment was displayed on the phage particle for further analysis.

Results: Four binders (SAK79-B1, SAK78-C12, SAK78-E6, SAK78-F8) could be obtained. While SAK78-F8 exclusively bound human THSD7A, the other binders reacted with both human and murine THSD7A in Western blot, ELISA and IFT. A domain-specific ELISA revealed binding of SAK78-C12, SAK78-E6 and SAK78-F8 to the regions d9, d11, d2 and d6, d7, respectively. SAK78-B1 did not react with any domain combination, but showed strong binding to murine and human d11, d21. We suspect a conformational epitope that is not conserved in the coated domain fragments. SAK78-C12 and SAK78-E6 were successfully cloned into human IgG subclass backbone IgG1.

Conclusions: Antibody phage display represents a powerful method to generate recombinant antibodies. The antibodies selected show different binding characteristics in vitro. In vivo binding characteristics, pathogenicity and potential as a diagnostic or therapeutic agent for MN biopsies, need to be determined.

Funding: Government Support - Non-U.S.

Comparison of aPLA2Rab Assays on Treatment with Cyclophosphamide and Steroids
Coralien Vink van Setten,1 Anne-Els van de Logt,1 Alexander Kühnl,2 Jack F. Wetzel,1 Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany.

Background: Anti-PLA2R antibodies (aPLA2R) are present in ~75% of patients with primary membranous nephropathy (MN). A quantitative immunofluorescence test (IFT) allows accurate detection of aPLA2R, additionally ELISA and ChLIA provide quantitative analysis. Sensitivity of the two latter methods after start of immunosuppressive therapy is not well studied.

Methods: We retrieved stored samples of patients with aPLA2R associated MN, who were treated with cyclophosphamide and steroids(CP), collected at baseline and 8 weeks after start of therapy. Assays were performed by the EUROIMMUN researchlab, Lübeck, Germany. All samples were analysed by IIFT, ELISA and ChLIA. We categorized ELISA results to cut-off values used in literature: 2, 14, and 20 RU/mL resp.

Results: We included baseline samples of 50, and 8 week samples of 51 patients. At baseline, all patients tested IIFT positive; ELISA test was positive in 94% or 98% of samples using cut-off values of 20 RU/mL or 14 RU/mL resp., indicating high sensitivity. Agreement between IIFT and ChLIA was 100%. After 8 weeks on CP, 37/51 patients had immunological remission by IIFT. ELISA test results are given in Table1. In the IIFT positive samples collected after 8 weeks, ELISA titers were < 20 RU/mL or < 14 RU/mL in 9/14 and 5/14 patients respectively, suggesting lower sensitivity. All IIFT negative samples had ELISA titers < 14 RU/mL. When analysing IIFT negative patients with ELISA titer <2 U/mL (N=23) vs. 2-14 U/mL (N=14), persistent immunological and clinical remission was better in the first group (74% vs 58%), however not statistically different. With ChLIA only 4/51 (8%) had different results (2 IIFT+/ChLIA+, 2 IIFT-/ChLIA+); resulting in a sensitivity of 86% and a specificity of 95%, when compared with IIFT.

Conclusions: Using immunological remission as treatment target, as described here after 8 weeks of CP, requires evaluation of the applied assay for this purpose. Of the examined quantitative methods, ChLIA demonstrated the highest agreement with IIFT. ELISA titers below the recommended cut-off for initial diagnosis still show a tendency towards the clinical outcome, which could be investigated by further studies.

Generation of Anti-THSD7A Antibodies Using a Human Antibody Phage Display Library
Sarah Köllner,1 Larissa Seifert,1 Philip A. Heine,2 Michael Huster,3 Nicola M. Tomas,1 Universitätshospital Hamburg-Eppendorf, Hamburg, Germany; 2Technische Universität Braunschweig, Braunschweig, Germany.

Background: Membranous nephropathy (MN) is an antibody-mediated autoimmune renal disease. In the majority of cases, autoantibodies target podocyte membrane proteins such as PLA2R and THSD7A. We could previously demonstrate that autoantibodies in THSD7A-associated MN cause disease and recognize several extracellular domains of the target antigen. However, the pathomechanism underlies how this antibody polyreactivity relates to disease pathogenicity. The aim of this study was the generation of anti-THSD7A antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Methods: In the antibody phage display technology, antibody fragments are displayed on the phage particle and the corresponding gene fragment encoding the antibody fragment is packaged in the phage particle. A selection process called panning enables the generation of antigen-specific antibodies. A library of human antibodies was constructed and panned against human and mouse THSD7A. The resulting phage clones were sequenced, cloned into scFv-Fc format - an IgG like format - and produced in HEK293 cells. Binding of scFv-Fc to human and mouse THSD7A was investigated using Western blot, ELISA and indirect immunofluorescence testing (IFT). Epitope regions were mapped using an ELISA.

Results: Four binders (SAK79-B1, SAK78-C12, SAK78-E6, SAK78-F8) could be obtained. While SAK78-F8 exclusively bound human THSD7A, the other binders reacted with both human and murine THSD7A in Western blot, ELISA and IFT. A domain-specific ELISA revealed binding of SAK78-C12, SAK78-E6 and SAK78-F8 to the regions d9, d11, d2 and d6, d7, respectively. SAK78-B1 did not react with any domain combination, but showed strong binding to murine and human d11, d21. We suspect a conformational epitope that is not conserved in the coated domain fragments. SAK78-C12 and SAK78-E6 were successfully cloned into human IgG subclass backbone IgG1.

Conclusions: Antibody phage display represents a powerful method to generate recombinant antibodies. The antibodies selected show different binding characteristics in vitro. In vivo binding characteristics, pathogenicity and potential as a diagnostic or therapeutic agent for MN biopsies, need to be determined.

Conclusions: The complement system is dominantly activated via the classical pathway in MN patients. Experimental data in the first author’s immune model involving an antigen that is pathogenically relevant in patients suggest complement-targeted treatment as a promising strategy for MN patients with severe disease, but also hint at a role of complement-independent mechanisms in the pathogenesis of MN.

Funding: Government Support - Non-U.S.

POI1476
Complement Activation and Suppression Profile Reveals Distinct Subtypes in C3 Glomerulonephritis

Background: The complement pathway is an innate immune defense mechanism, and uncontrolled activation can cause damage to host tissues including the kidney. C3GN is characterized by deposits in the glomerulus made up entirely of complement C3 protein without the presence of immunoglobulins.

Methods: The activity of the alternative complement pathway (ACP) was determined in serum derived from C3GN patients, IgA Nephropathy (IgAN) and Polycystic Kidney Disease (PKD) and healthy controls (HC) by measuring the lysis of rabbit red blood cells (rRBC). Complement factor H (CFH) was added to the serum of C3GN patients to eliminate the ACP if CFH is capable of inhibiting the ACP in C3GN patients, not all the serum samples responded to CFH. Future work may elucidate additional mechanisms of the continued ACP activation in C3GN patients and have implications for therapy of these patients.

POI1457
Preexisting Autoimmune Dysregulation Unmasks a Role for Silica Dust Exposure in Nephrotropic Autoantibody Production
LaNette Fee,1 Robert M. Tighe,1,2 Mary H. Foster.1,2 Duke University, Durham, NC;1 DVAMC, Durham, NC.

Background: Pathogenic autoantibodies (autoAb) promote severe glomerulonephritis in ANCA vasculitis and lupus. Genetic susceptibility and environmental exposures, particularly inhalation of silica (Si) dust, are implicated in dysregulated autoimmunity and are targets for therapeutic intervention. Using a mouse reporter system expressing a regulated nephrotropic autoAb transgene (Tg) targeting basement membrane (BM) and instilling Si by oropharyngeal aspiration (OPA), we demonstrated that central B cell tolerance and anergy to BM are preserved in multiple lupus strains despite induction of lung inflammation and ecopptic lymphoid tissue. Nonetheless, Si exposure increased local and systemic anti-DNA Ig levels in wildtype (WT) B6 and lupus mice, suggesting subversion of alternative regulatory checkpoints. Herein we leverage the aberrant M7 anti-BM Tg lineage that demonstrates partial escape from tolerance and evidence of glomerular Ig deposition to study the interaction of Si exposure with preexisting defects in autoreactive cell regulation.

Methods: M7 Tg mice (WT at Ig light chain, or LC, locus) were exposed to Si or vehicle (V) by OPA, organs harvested at 5-6 weeks, and cells cultured aToll-like receptor ligand (TLR-L). To restrict Ig specificity, a subset of mice (Tg/KI) was bred to heterozygosity for the Vk8/K8 V8R Ig LC knock-in. Tg autoAb were measured by ELISA; mean ODaSD.

Results: Presence of serum Tg autoAb and induction of high levels of autoAb by TLR-L stimulated splenocytes (OD 2.61±0.49; TLR7/9, vs 0.06±0.03; medium; p=0.0001) confirmed Tg phenotype, and bronchoalveolar lavage fluid cell counts confirmed exposure (237.1±130 vs 18.1±7, x1000, Si vs V, p<0.05). Among Tg WT mice, more autoAb were produced by TLR7/9-stimulated lung cells from Si vs V mice (OD 0.13±0.15, Si, vs 0.03±0.01, V, p=0.05), indicating that Tg B cells recruited by Si exposure contribute to local autoAb production. Among Si-exposed mice, Tg autoAb levels were higher in Tg vs Tg/KI mice: OD 1.239±0.47 for TLR4-L stimulated splenocytes, Tg vs Tg/KI, p<0.05.

Conclusions: An autoAb reporter system reveals that anti-BM autoimmune lymphocytes that escape tolerance can be recruited to the lung after exposure to inhaled silica dust. Anti-BM cell activation by superimposed stimuli, such as TLR-L, can lead to secretion of nephrotropic autoAb.

Characteristics of Membranous Nephropathy Patients with IgG and IgA Co-Deposits on Capillary Wall
Guan Yi, Qionghong Xie, Ruiying Chen, Shaojun Liu, Lingyun Lai. Huashan Hospital Fudan University, Shanghai, China.

Background: Membranous nephropathy (MN) is characterized by immune deposits on glomerular capillary wall, predominantly IgG. There have been several reports of MN combined with IgA nephropathy with features of IgA immunofluorescence staining in the glomerular mesangium. However, we found that IgA can also be deposited on the capillary wall with IgG. This study aimed to investigate the prognostic, clinical and renal histopathological characteristics of adult MN patients with IgG and IgA co-deposits on capillary wall.

Methods: A retrospective study was conducted in biopsy-proven MN patients of our renal department during January, 2007 to May, 2020. Clinical data were collected at time of biopsy and the latest follow-up. Pathological parameters included immunofluorescence staining, plasA staining, membranous Churg’s stages, sclerosis, crescent, focal segmental sclerosis lesion, chronic tubulointerstitial injury and et al. Indirect immunofluorescence experiment was conducted in 293T cells transfected with plasA plasmid.

Results: Out of 531 cases diagnosed with MN, 53 patients have moderate IgA deposit on capillary walls with IgG. 19 cases were determined to be secondary MN, which were 10 cases of autoimmune disease, 4 cases of Hepatitis B, 3 cases of kidney transplantation, 1 case of chemical exposure and 1 case of AL amyloidosis-associated secondary MN. 31 Idiopathic MN patients with both IgA and IgG depositing along capillary wall were followed up for a median interval of 49 months (interquartile-range, 17-82) and their cGFR declined by half, 11 (35.5%) patients had no remission and 15 (53.6%) patients had their eGFR declined by half. 11 (35.5%) patients had no remission and 15 (53.6%) patients underwent immunosuppressive therapy. 72.4% idiopathic MN patients with IgA deposit were pla2A associated. Indirect immunofluorescence study revealed that both IgG and IgA isomorph of anti-pla2A autoantibody in MN patients serum.

Conclusions: IgA and IgG could be co-depositing on glomerular capillary wall in MN patients, secondary causes should be screened with cation. IgA and IgG type of autoantibodies linked to MN co-existed in serum of idiopathic MN patients, whose prognosis might be poor.

POI1479
Humanistic Burden of Rare Kidney Diseases; Understanding the Impact of FSGS and IgAN on Patients and Caregivers: The HONUS Rationale and Study Design
Justyna Szklarzewicz, HONUS Advisory Board Members and HONUS Study Team University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.

Background: While both Immunoglobulin A Nephropathy (IgAN) and Focal Segmental Glomerulosclerosis (FSGS) conditions have been shown to be associated with significant clinical and economic burden to healthcare systems, less is known about the humanistic burden associated with these diseases. Here we describe the Humanistic Burden of Rare Kidney Diseases (HONUS) rationale and study design.

Methods: HONUS is being designed in consultation with patient and clinical community members at inception of study design, ensuring the right elements are in place. The patient and care-partner voice is heard. This begins with engagement of patient and family communication, education of the broader clinical community and contributes to resources for affected families. For the clinical community, evidence supports patient/family communication, education of the broader clinical community and contributes to informed decision making. For industry, data supports value assessments and ensures data is used to raise awareness, facilitate education and development of new treatments for affected families. For the clinical community, evidence supports patient/family communication, education of the broader clinical community and contributes to informed decision making. For industry, data supports value assessments and ensures data is used to raise awareness, facilitate education and development of new treatments for affected families.

Results: Humanistic burden considers the impact of illness on patient HRQoL, activities of daily living, caregiver health and HRQoL, and is commonly quantified in population health context as Disability- or Quality-Adjusted Life Years (DALYS or QALYS). Quantifying humanistic burden is foundational for value assessment of new therapeutic options, but also has broader benefits. For patients and care-partners, insights on HRQoL can validate and support individual experiences and coping. For patient advocacy groups, information can be used to raise awareness, facilitate education and development of new treatments for affected families. For the clinical community, evidence supports patient/family communication, education of the broader clinical community and contributes to informed decision making. For industry, data supports value assessments and ensures data is used to raise awareness, facilitate education and development of new treatments for affected families.

Conclusions: HONUS will provide evidence quantifying the humanistic burden of FSGS and IgAN from patient and care-partner perspectives.

Mystery Cryoglobulinemic Glomerulonephritis Treated with Rituximab
Mohamed Hassanein, Hanny Sawaf, Leal C. Herltiz, Michael Lioudis. Cleveland Clinic, Cleveland, OH.

Introduction: Cryoglobulinemic Glomerulonephritis (GN) is characterized by the deposition of immunoglobulins (IG), also known as cryoglobulins (CG), in the kidney. We report a case of idiopathic mixed cryoglobulinic GN treated with rituximab and prednisone.

Case Description: A 42-year-old tri-athlete with a history of pediatric meningitis with hydrocephalus requiring placement of a ventriculoperitoneal shunt presented with lower extremity swelling limiting his ability to exercise. He denied non-steroidal anti-inflammatory drug and illicit drug use, and was not on any prescribed medications. Laboratory workup showed serum creatinine: 1.2 mg/dL (normal 0.7 – 1.2), serum albumin: 2.1 mg/dL (normal 3.9 – 4.9), CG: 140 µg/mL (normal 0 – 50), C3: 39 mg/dL (normal 86 – 166), C4: 7 (normal 13 - 46), and a urine protein to creatinine ratio (UPCR) 5.9 µg/g. Kidney biopsy showed diffuse proliferative GN with polycyal IgM deposits consistent with mixed cryoglobulinemic GN (figure 1). An infectious workup, including human immunodeficiency virus (HIV), viral hepatitis, blood and urine culture, and a lumbar puncture were unremarkable. Computed tomography of the chest, abdomen, and pelvis revealed splenomegaly. Echoangiogram and bone marrow biopsy were non-diagnostic. He was treated with rituximab and prednisone with normalization of CG, C3, and C4, a reduction in UPCR to 0.5 µg/g and return to full exercise capacity five months later.

Discussion: Mixed cryoglobulinemic GN is a rare disorder caused by polyclonal deposition of IG in the kidney. Autoimmune disease, hematological malignancies, and infectious etiologies such as endocarditis, HIV, and viral hepatitis should be ruled out prior to immunosuppressive therapy. Our patient elected to proceed with treatment due to his poor quality of life and evidence of end-organ involvement. Although workup for hematological malignancies was unremarkable, it is unclear if his splenomegaly could be reflective of an underlying indolent lymphoma, which could have simultaneously responded to rituximab treatment.

POI1481
Does SARS-CoV-2 Activate the Alternative Complement Pathway? A Case Report of C3-Dominant Proliferative GN in a Patient with SARS-CoV-2 Infection
Jahanzeb Khan, Shashri W. Bukhari, Muhammad G. Alam,1,2 1Baptist Health Medical Center - North Little Rock, North Little Rock, AR; 2Kidney Care Center, Little Rock, AR.

Introduction: C3 glomerulopathy is a rare kidney disorder due to dysregulation of the alternative complement pathway. C3 glomerulonephritis (C3GN) has been associated with a variety of diseases including connective tissue disorders and infections. Here we present the first case report of C3GN in a patient with SARS-CoV-2 infection.

Case Description: A 54-year-old man with no known renal disease presented to the hospital with fever, cough, dyspnea and worsening edema. His SARS-CoV2 PCR test was positive and he was treated for COVID-19 pneumonia. His blood cultures remained negative and no bacterial infection was identified. He was also noted to have worsening renal function with a peak serum creatinine of 3.9 mg/dL. His serologies including Hep B, Hep C, HIV, ANA, ANCA, RF, and Cryoglobulins were all negative. His serum complement levels were low. A renal biopsy was performed. Light microscopy showed mild mesangial and endocapillary hypercellularity (Figure A). IF revealed mesangial and endocapillary wall staining positive for C3. Electron microscopy confirmed electron dense deposits of C3 (Figure B).

Discussion: Several mechanisms have been suggested in the pathogenesis of SARS-CoV2 related tissue injury including classical and alternate complement pathways. C3GN is rare renal disorder due to dysregulation of alternate complement pathway. C3GN is characterized by mesangial deposits, endocapillary hypercellularity under light microscopy, and C3 deposits in mesangial and endocapillary wall on IF, in the absence of other significant findings. We present the first case report of C3GN in a patient with SARS-CoV-2 infection. Although this case does not establish a cause-effect relationship, but does raise the possibility of activation of the alternative complement pathway in SARS-CoV-2 infection.
Case Description: 28-year-old African American man with ESKD secondary to biopsy-proven PLA2R-positive membranous nephropathy underwrote a 2/2 mismatch ABO incompatible living-unrelated kidney transplantation. Induction immunosuppression included methylprednisolone and Thymoglobulin. Post-op course was complicated by bleeding and he was taken back to the OR on POD 1. Labs showed anemia (Hgb 7.5 g/dL), thrombocytopenia (PLT 25 k/µL), low haptoglobin (< 10 mg/L), high LDH (580 Units/L), low C3 and normal C4. ADAMS-13 activity and coagulation profile were normal. Graft function was delayed. This raised concern for a TMA. Tacrolimus was not initiated. Allograft biopsy performed on POD 4 confirmed the diagnosis. Eculizumab was administered, resulting in resolution of anemia and hemolysis, and gradual renal recovery. Genetic testing for complement revealed a ‘variant of uncertain significance’ in CFI (Iso357Met). This variant is located in the serine protease domain of Factor I which contains the catalytic site. Functional analysis of the variant using recombinant proteins revealed that it had defective complement regulatory activity. This work established that the CFI variant was deleterious and thus defined the etiopathogenesis of TMA in the patient.

Discussion: This is a case of de novo post-transplant aHUS due to a pathogenic complement mutation, likely triggered by transplant surgery. Our strategy of recombinant protein production followed by detailed functional assessment defined the functional repertoire of the variant protein and provided critical guidance relative to the underlying pathophysiology and appropriate therapeutic regimen.

POI1482
Vancomycin-Induced Thrombotic Microangiopathy: A Rare Association
Gaurav Rajashekar, Anuja Java. Washington University in St. Louis
Washington University in St. Louis, St Louis, MO

Introduction: Thrombotic microangiopathies (TMA) are life-threatening conditions characterized by hemolytic anemia, thrombocytopenia and AKI. Drug-induced TMA (DITMA) is a diagnostic challenge because specific tests to identify a drug etiology are not available.

Case Description: A 40 yr-old female with history of neurofibromatosis type 2 underwent resection of a T10-11 schwannoma. The surgery was complicated by wound dehiscence which was treated with incision and drainage followed by intravenous vancomycin and cefazolin. The next day, she developed fever, altered mental status and a diffuse purpuric rash (Fig 1). Labs showed anemia (Hgb, 6.2 g/dl), thrombocytopenia (PLT, 15 k/µL), elevated LDH and anuric AKI requiring dialysis. C3 and C4 were low. Coombs test was negative. She subsequently developed disseminated intravascular coagulation and elevated liver enzymes. Skin biopsy revealed a leukocytoclastic vasculitis with IgG and complement deposition within vessel walls. Given the concern for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Treatment with prednisone and plasmapheresis was initiated which led to improvement of renal function, mental status and hematologic parameters within 48 hrs. Renal biopsy for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Light microscopy showed mild mesangial and endocapillary hypercellularity (Figure A). Electron microscopy confirmed electron dense deposits of C3 (Figure B).

POI1484
Cryoglobulinemic Vasculitis in a Patient with Known Thrombotic Microangiopathy
Sanjay Gadgil, Eugene P. Rhee, Veronica E. Klepeis, Janewit Wongboonsin.1,4
1Harvard Medical School, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA; 4Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand

Introduction: Acute kidney injury (AKI) is a ubiquitous presentation, but thrombotic microangiopathy (TMA) and cryoglobulinemia are uncommon causes that are not easily diagnosed. We highlight a case of AKI that was found to be cryoglobulinemic vasculitis, an unexpected diagnosis in a patient with history of TMA.

Case Description: A 68-year-old female was diagnosed with giant cell arteritis, with temporal artery biopsy showing inflammation of the adventitia consistent with small vessel vasculitis. She received prednisone and tocilizumab. 6 months later, she was admitted for hypertensive crisis with thrombocytopenia and schistocytes, with creatinine (Cr) elevation to 3.5 from baseline of 1.0. Renal biopsy showed TMA. Tocilizumab was discontinued. She was transitioned to eculizumab, eventually resulting in renal recovery (Cr 1.5) after 1.5 months. However, she continued to feel poorly and returned to the hospital, where she was found to have Cr 4.0. Physical exam was significant for hypertension and tender retiform purpura. Urine studies were consistent with cellular casts. Dermal biopsy showed dermal necrosis but no intravascular thrombi. Renal biopsy ultimately revealed cryoglobulin deposition, resulting in a diagnosis of cryoglobulinemic vasculitis. She was treated with prednisone, rituximab, and cyclophosphamide with good renal response, and discharged with Cr 2.4. The finding of cryoglobulin on this patient’s renal biopsy was subtle, causing a near-miss in her diagnosis. Her history and repeat clinical evidence of TMA further confirmed her presentation. Therefore, when TMA is on the differential, workup should also evaluate for cryoglobulinemia. Her prior diagnosis of GCA also acted as a confounder, though absence of panarteritis and large vessel involvement on temporal artery biopsy may have hinted at underlying systemic vasculitis. While eculizumab is a standard therapy for TMA, there is limited evidence for its use in treating cryoglobulinemic vasculitis. This patient’s positive renal response to eculizumab supports the potential role of complement inhibitors in treating cryoglobulinemia. It remains possible that the patient could have had TMA and cryoglobulinemia concurrently, with renal biopsy during this presentation only capturing the latter. Therefore, further research into the role of complement inhibitors for cryoglobulinemia is needed.
Minimal Change Disease as a Novel Manifestation of Cytomegalovirus

Introduction: Cytomegalovirus (CMV) infection is typically asymptomatic among the immunocompetent or can cause a mononucleosis. Among immunosuppressed patients common presentations are colitis, hepatitis, encephalitis, retinitis and even Guillain-Barre syndrome. This case is a rare disseminated presentation of CMV manifesting as acute glomerulopathy.

Case Description: A 67-year-old female with past medical history of lupus, rheumatoid arthritis, and Sjogren syndrome on maintenance steroids presented with a prolonged cough, joint swelling, shortness of breath and rash consistent with livedo reticularis. She developed worsening weakness in the arms and legs. High dose IV steroids were initiated for presumed rheumatoid vasculitis. Nephropathy was consulted for worsening renal function with urine protein to creatinine ratio of 42 g/L, later requiring hemodialysis for volume management. Workup for nephrotic range proteinuria including hepatitis B/C, HIV, SPEP, UPEP, and complement screen was unrevealing. Renal ultrasound demonstrated an 11.7 cm right kidney and 14 cm left kidney. Renal biopsy demonstrated diffuse podocyte effacement and large atypical mononuclear cells within the glomerulus. No immune deposits seen on electron microscopy. Immunohistochemical staining confirmed glomerular CMV. Six weeks after starting treatment with ganciclovir and tapering steroids, CMV viral load was undetectable and renal function recovered to baseline.

Discussion: CMV involvement of the kidney is unusual aside from tubulointerstitial nephritis. Rare cases of collapsing glomerulopathy and focal segmental glomerulosclerosis are found in literature. We report a novel presentation of CMV glomerulopathy with minimal change disease and renal failure. To prevent tissue invasive CMV in a chronically immune suppressed patient one needs to maintain clinical suspicion for infectious pathogens and perform tissue biopsy.

PO1488

Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO) Syndrome and IgA Nephropathy

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common form of glomerulonephritis (GN). It is characterized by IgA deposits within glomeruli, classically caused by poorly galactosylated immunoglobulin A1 that trigger autotolymphocytes. Other forms of IgA nephropathy include IgA vasculitis with nephritis (Henoch-Schönlein purpura) and secondary forms arising from chronic infections, chronic infections and neoplasms.

Case Description: Patient is a 50 year old female with anemia, hypothyroidism and chronic joint pain who presented for rising creatinine and hematuria. Baseline creatinine was 0.9 mg/dL, but increased to 1.8 mg/dL within 2 months. She follows with a rheumatologist for polyarthralgias and hives where labs showed rheumatoid factor 18 IU/mL, CRP elevated to 125 mg/L, sedimentation rate of 81 mm/hr but normal complement levels and negative ANA titers. Workup for lymphoma or myelodysplasia was negative for C4d, electron microscopy with moderate foot process effacement and no immune deposits within glomeruli, classically caused by poorly galactosylated immunoglobulin A1 that trigger autotolymphocytes. Other forms of IgA nephropathy include IgA vasculitis with nephritis (Henoch-Schönlein purpura) and secondary forms arising from chronic infections, chronic infections and neoplasms.

Discussion: This is a seropositive SARS-CoV-2 KTR from previous COVID-19 pneumonia who developed NS. COVID following SARS-CoV-2 mRNA vaccine consisted of MCD. Immunogeneity to mRNA vaccines in transplant recipients is blunted after the first dose but higher in seropositive patients. Timing from vaccine exposure to development of MCD ranges from days to months in our patient mounted an immune response in 4 days. The acute tubular injury seen in LM is atypical, unclear if this is a cell mediated process from allograft rejection or part of the pathogenesis post-immunization. In cases of AKI with NS, days to weeks following either class of mRNA vaccine a prompt initiation of steroids and further investigation with kidney biopsy is warranted.
Kidney biopsy for IgA case depicting membranoproliferative pattern of glomerular injury in patient with SAPHO syndrome

PO1489
Crescentic Pauci-Immune Glomerulonephritis in a Patient with Sickle Cell Anemia and Cocaine Abuse
Marimar Contreras Nieves, Stanford Medicine, Stanford, CA.

Introduction: Levamisole is an anthelmintic agent and a common contaminant found in cocaine. It has been linked to ANCA-associated vasculitis with cutaneous, and more rarely, renal and pulmonary manifestations. This is the case of a patient with sickle cell anemia and cocaine abuse presenting with acute kidney injury (AKI) and nephritic-range proteinuria, initially attributed to sickle cell nephropathy, but with kidney biopsy revealing pauci-immune glomerulonephritis, demonstrating the importance of having a high level of suspicion in patients with known cocaine use.

Case Description: A 58-year-old male with history of sickle cell anemia, CKD Stage 3, hypertension, and cocaine abuse, was admitted for epidualmists and found to have AKI. He presented with testicular pain, as well as right knee and back pain. Initial work up revealed a creatinine of 2.45 mg/dL, from baseline of 1.8 mg/dL. Urine toxicology was positive for cocaine. His urine studies were consistent with intrinsic renal disease. He received red blood cell exchange transfusion, but he continued with worsening renal function following the procedure. His 24-hr urine collection revealed 6.2 g proteinuria. Extensive workup included normal C3 and C4, positive rheumatoid factor, negative UPEP, free kappa/lambda light chain ratio 1.8, negative HIV and anti-HCV, hepatitis B immunity, negative c-ANCA, but positive p-ANCA and anti-MPO. Patient chronically smoked cocaine, sometimes cut with levamisole, which is associated with vasculitis. A kidney biopsy was performed, with pathology showing a pauci-immune necrotizing and crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy. He was treated with pulse dose steroids and rituximab, followed by maintenance prednisone and additional doses of rituximab after discharge. His renal function improved, but did not return to baseline, which could have been due to his degree of kidney injury and ongoing cocaine use after discharge.

Discussion: This case demonstrates the importance of keeping a broad differential diagnosis in the evaluation of AKI and nephritic-range proteinuria in sickle cell anemia, particularly in the setting of cocaine use and its known association with AKI. Although sickle cell nephropathy could have explained this patient’s presentation, a broader workup was key to arrive to the correct diagnosis, and therefore prompt treatment.

PO1490
A Case of Rapid Progressive Glomerulonephritis Associated with Disseminated Gonococcal Infection
Safa Osman, Nihal M. Ali, Pradeep Varita, Franco H. Cabeza Rivera. The University of Mississippi Medical Center, Jackson, MS.

Introduction: Disseminated gonococcal infection (DGI) results from bacteremic spread of the sexually transmitted pathogen, Neisseria gonorrhoeae. Direct and immunological damage of multiple organs can be seen. We are reporting a case of sterile DGI with RPGN as part of the initial presentation.

Case Description: A 60-years old male with a 5-year history of seronegative spondyloarthropathy, hypertension, heart failure, poor dentition who presented to the hospital with shortness of breathing, diarrhea, joint pain, and palpable purpura ongoing for several weeks. Work-up revealed severe anemia and rapidly progressive acute renal failure (Baseline creatinine unknown, peaked at 7.2 mg/dL on admission), urine showed 9.3 g of proteinuria, hematuria, and pyuria. Serological w/u showed low C3 with normal C4, ASO, ANA, ANCA and anti GBM. Negative HIV, hepatitis B, C, syphilis serologies, monoclonals and cryoglobulins. Skin biopsy showed leukocytoclastic vasculitis which improved with steroids. Kidney biopsy showed crescentic glomerulonephritis (GN) with 10% IFTA likely due to infectious GN (RPGN). Patient completed 3-day course of ceftriaxone but left before ceftriaxone should be initiated. A week later he presented with persistent hematuria and oliguria. Echocardiogram showed tricuspid endocarditis and leaflet perforation. Blood cultures were negative. Patient started on vancomycin and Rocephin for culture negative endocarditis. Extensive infectious disease workup, metagenomics test showed Neisseria gonorrhoea as the cause of endocarditis. Kidney function improved. Due to disseminated GC and concern for complement deficiency, he was referred to Adult Immunology clinic.

Discussion: DGI is estimated to occur in up to 3 percent of patients infected with N. gonorrhoeae. The probability that a localized gonococcal infection will spread to joints and other tissues depends upon specific host, microbial, and possibly immune factors. RPNG is unusual presentation, the immunopathogenesis is uncertain but immunological and hypertensive damage is postulated based on the frequent lack of N. gonorrhoeae growth from blood, skin, and synovial fluid cultures during disseminated infection. Congenital or acquired complement deficiencies (C5, C6, C7, or C8) predispose to DGI as a result of decreased complement-mediated killing of N. gonorrhoeae.

PO1491
Proliferative Glomerulonephritis with Monoclonal IgM Deposits in ANCA Vasculitis
Rama Kethineni, Marc Barry, Monica P. Revelo Penafl, Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNIMD) is a rare entity of unclear etiology that can be occasionally associated with an underlying hematological malignancy. We report a case of PGNMID in a patient with ANCA vasculitis.

Case Description: A 78 yr old female with hypertension presented with a history of recurrent sinuses over 6 months that was treated with steroids and antibiotics. She had progressive weight loss, fatigue, cough, and dyspnea. Chest X-ray was normal prompting a CT chest, which showed bilateral pulmonary nodules. Her creatinine was 0.96mg/dL. Urine analysis was notable for hematuria. Antineutrophil cytoplasmic antibodies were positive at 1: 640 with myeloperoxidase Abs IgG of 199. Serum protein electrophoresis showed a normal pattern with no monoclonal spike on immunofixation electrophoresis. Her Kappa/Lambda light chain ratio was normal at 1.04, infections were ruled out, and cryoglobulin was not detected. She was started on prednisone 60 mg and had a renal biopsy. Renal biopsy showed focal segmental necrotizing glomerular lesions, mesangial hypercellularity with deposition of IgM with lambda light chains restriction on immunofluorescence and occasional mesangial and subendothelial granular electron densities on electron microscopy. She was referred to hematology for concern with monoclonal gammopathy of renal significance and had a negative evaluation on serological tests, bone marrow biopsy and PET CT scan. She was treated with Rituximab. Her creatinine had remained stable with resolution of hematuria and respiratory symptoms.

Discussion: PGNMID is an immune complex glomerulonephritis that is occasionally associated with a hematological malignancy. The pathophysiology remains elusive and treatment can be challenging. We present a case of PGNMID with monoclonal IgM with light lambda chain restriction with an unusual association with ANCA vasculitis.

PO1492
A Case of An ASSOCIATED Vasculitis (AAV) in Mixed Connective Tissue Disease (MCTD) Manifesting as Pulmonary Renal Syndrome
Samira E. Baroudi, Michelle W. Krause. University of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Newly diagnosed microscopic polyangiitis (MPA) with positive anti-MPO in the background of MCTD is quite uncommon. Not every patient with positive Anti-MPO titers develops clinical manifestations of microscopic polyangiitis. Prompt diagnosis and early intervention is necessary to prevent end organ damage.

Case Description: 56-year-old malnourished AAf with history of MCTD (diffuse systemic sclerosis and SLE since 2005), restrictive lung disease, recurrent URF (KD stage 3), diastolic heart failure with moderate MR, and pulmonary hypertension was transferred to ICU for worsening pneumonia and acute on chronic kidney injury. Admission serum creatinine was 2.6mg/dl (baseline s. creat 2.0mg/dl) which increased to 4.7 mg/dl during the hospital course. Lab was significant for Hgb 6.3 gm/dl, ESR 120 mm and CRP 30. Non-contrast CT chest showed bilateral interstitial opacities with superimposed consolidation. Evaluation for infectious etiologies and malignancies were negative. Bronchoscopy was concerning for diffuse alveolar hemorrhage. UA was positive for large blood with white blood cells <200mg/dl. Vasculitis work up came back positive for p-ANCA (1:1280) and anti-MPO 4 AU/ml (reference range <19) but negative for anti-PR3 and anti-GBM antibody. Renal biopsy revealed focal crescentic and necrotizing glomerulonephritides with
severe interstitial fibrosis and tubular atrophy indicating MPA. Patient was treated with pulse steroid and plasma pheresis initially, later received Rituximab. Patient improved clinically with therapy. Later, serum creatinine plateaued around 3.6 with eGFR 15.6 indicating patient’s CKD had progressed to advanced CKD stage 4/5.

**Discussion:** Though the presence of AA V is not common in MCTD, this case illustrates the importance of considering AA V for worsening pulmonary and renal function in overlap syndrome. Microscopic polyangiitis is one of the most common cause of pulmonary-renal syndrome, often manifested as diffuse alveolar hemorrhage and RPGN. Prompt diagnosis and early intervention can dramatically improve the patient outcome.

Nephrotic Range Proteinuria due to ANCA-Associated Vasculitis in a Diffuse Systemic Sclerosis Patient: A Rare Presentation

Pranav Sharma, Steve I. Khalil, Jonathan Lebowitz. Rutgers University New Brunswick, New Brunswick, NJ.

**Introduction:** Scleroderma renal crisis (SRC) is a severe complication of SSC and typically presents with new-onset hypertension and a reduction in renal functioning. Antineutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV) is a rare co-occurrence with SSC. We present a rare case of diffuse systemic sclerosis who presented with features of SRC and AAV with nephrotic range proteinuria without significant renal failure.

**Case Description:** The patient is a 32-year old woman with diffuse systemic sclerosis complicated by pulmonary fibrosis who had been treated with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antinuclear antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL). Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

**Discussion:** Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

**PO1494**

Filgrastim-Induced ANCA-Associated Glomerulonephritis in the Presence of Membranous “Full House Nephropathy”

Ayatul Angel-Korman, Adi Leiba.1,2 Assuta Ashdod Hospital, Ashdod, Israel; 1Harvard Medical School, Boston, MA.

**Introduction:** G-CSF is commonly used to stimulate progenitor cell collection for bone marrow transplantation. We present a seemingly healthy altruistic bone marrow donor who developed glomerulonephritis secondary to G-CSF treatment.

**Case Description:** A 34-year old man presented after altruistic bone marrow donation. During G-CSF treatment he developed headache, epistaxis, painless macrohematuria and AKI (creatinine 2.91mg/dL). Seven years and one year prior to this event he had similar presentations of macrohematuria, AKI and proteinuria. In between episodes he had persistent microhematuria. At this admission, Myeloperoxidase antibodies (MPO) were found to be elevated to 97 IU/ml. all other serologies were unremarkable. A kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed severe interstitial fibrosis and tubular atrophy indicating MPA. Patient is off oxygen. He does remain dialysis-dependent. Four weeks later, he has no epistaxis or pulmonary hemorrhages and initiated on dialysis. Three biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was given steroids for suspecting demyelinating neuropathy and restarted treatment with Mycophenolate mofetil. She had improved but few weeks later (3 months after delivery), she was readmitted with hypertensive encephalopathy in setting of suspected scleroderma renal crisis. She also developed a rash and swelling in her legs after her pregnancy. Her urinalysis was remarkable for proteinuria and numerous RBCs and quantification of the urine protein revealed nephrotic range proteinuria (4.6 g/24 hours) but her serum creatinine (0.6 mg/dl) remained normal. She was found to be positive for antinuclear antibodies, rheumatoid factor, myeloperoxidase antibodies, MPO-ANCA (> 8.0 IU/mL). Her complement levels were within normal limits. She underwent a renal biopsy, which revealed an acute necrotizing vasculitis consistent with AAV.

**Discussion:** Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

**PO1495**

Ivermectin-Induced ANCA Vasculitis

Shuichi Pandeg.1 Hemant Magoo,1 Ashish Verma,1 Sudhir Perincheri,2 Saint Vincent Hospital, Worcester, MA; 1Yale-New Haven Hospital, New Haven, CT.

**Introduction:** Ivermectin is an antiparasitic agent that has demonstrated antiviral potential against HIV1, Dengue, Zika viruses and most recently, COVID-19. But the rampant self-medication and off-label use for COVID prophylaxis in some countries is cause for concern. Here, we present what may be the first reported case of ANCA-associated vasculitis (AAV) from Ivermectin use.

**Case Description:** A 56-year male with no significant past medical history presented with dark urine, epistaxis, conjunctival redness, arthralgias, and malaise. His mother was on dialysis for the past few years for ESRD of unknown etiology. For several months, he had been taking Ivermectin imported from Peru for COVID prophylaxis per family advice. He was on no other medications. His creatinine, normal at baseline, was now 4.5mg/dL. He had hematuria, 3g/d proteinuria, dysmorphic RBCs and RBC casts. Serum C3, C4, ANA, anti-dsDNA, anti-GBM, hepatitisB&C screen, SPEP&UPEP were negative. Atypical and p-ANCA were negative, but c-ANCA was 1:640. Kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed pulmonary hemorrhages. Ivermectin was discontinued. He received prednisone 1mg/kg, 3 biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was initiated on dialysis. Four weeks later, he has no epistaxis or pulmonary hemorrhages and is off oxygen. He does remain dialysis-dependent.

**Discussion:** Drug exposure can trigger ANCA formation against myeloperoxidase (MPO) and, less commonly, protease 3 (PR3). Drug-associated AAV can’t be discerned from primary AAV based on clinical and pathological findings. Clues suggesting drug-associated AAV include a temporal relationship of symptom onset with suspect drug, a high ANCA titer, and positive autoantibodies like elastase and lactoferrin. Drug-associated AAV has a better prognosis than its primary counterpart, with symptoms often resolving with drug withdrawal. Though this may not suffice in cases with pulmonary and renal involvement, outcomes in drug-associated AAV remain comparable even with shorter induction and often no maintenance regimens. Commonly implicated drugs are hydroxychloroquine, levamisole-contaminated cocaine, propylthiouracil, allopurinol.
PO1496
Myeloperoxidase-ANCA and Takayasu Arteritis Overlap Syndrome Presenting as Rapidly Progressive Glomerulonephritis

Introduction: The spectrum of vasculitides is classified according to the size of the vessels involved and the clinical and histopathological findings. The simultaneous involvement of Takayasu arteritis and myeloperoxidase-ANCA vasculitis is extremely rare.

Case Description: A 12-year-old female with no previous medical history. In the last three years the patient developed lower limb claudication and unexplained intermittent fever. In recent weeks she developed edema and oliguria, she was admitted in another hospital where she was started on renal replacement therapy. Large vessel involvement was suspected so a contrast enhanced CT was ordered and was compatible with Takayasu arteritis. The patient was referred to our hospital for evaluation. During nephrology assessment she was found to have acute kidney disease with massive proteinuria (16 g/g), so work up was directed towards rapidly progressive kidney disease. Pericutanous kidney biopsy was performed, and it revealed pauci-immune crescentic glomerulonephritis. ANCA and glomerular basement membrane antibodies were ordered, with a positive MPO-ANCA result. She was then started on IV methylprednisolone pulses and 5 cycles of plasma exchange therapy. After this, rituximab was started on a weekly basis. The patient has not recovered kidney function and is still dependent on hemodialysis therapy, pending to finish the final two rituximab doses.

Discussion: This an extremely rare case which highlights the diagnostic and therapeutic difficulties in patients presenting with overlap clinical and serological features of different forms of systemic vasculitides.

Discussion: Cellular crescent. Silver methenamine stain

PO1497
Granulocyte Colony Stimulating Factor-Associated Vasculitis: Adding Fuel to the Fire
Nilam Patel, Ahmed Siddiqui, Pravir V. Baxi. Rush University Medical Center, Chicago, IL.

Introduction: Granulocyte colony-stimulating factor (G-CSF) is commonly used with chemotherapy to stimulate bone marrow production and prevent neutropenia. Although usually well tolerated, G-CSF can exacerbate underlying autoimmune diseases with the development or progression of glomerulonephritis (GN). We present a case of pauci-immune necrotizing GN that developed in a patient with rheumatoid arthritis (RA) after receiving G-CSF therapy.

Case Description: A 61 y/o man with ampullary adenocarcinoma and RA without prior renal involvement presented with AKI. One week prior to admission he had received his 5th cycle of FOLFOX and a first dose of G-CSF. His creatinine (Cr) was 4.8 mg/dl, from a baseline of 0.9 mg/dl. His urinalysis was notable for hematuria and urine protein-creatinine ratio (UPC) of 5.2 g/g. Workup showed: +p-ANCA (1:320), +anti-histone Ab, +SSA and +ANA (1:1280 speckled pattern). A renal biopsy revealed necrotizing GN with necrosis or crescents in 75% of the glomeruli (Fig 1). There was no evidence of immune deposits w/ pauci-immune GN. He received steroids and rituximab for induction. His Cr peaked at 6.0 mg/dl but improved down to 1.1 and UPC improved to 0.6 g/g after 3 months.

Discussion: G-CSF is used to prevent neutropenia and reduce infection risk by activating mature neutrophils and preventing neutrophil apoptosis. G-CSF can also have inflammatory effects including the release of proinflammatory cytokines and tissue infiltration by activated neutrophils with the potential of end-organ damage. In patients with preexisting GN or an autoimmune disease (e.g RA, SLE), G-CSF administration can exacerbate or even initiate a de-novo GN. Pauci-immune GN is a rare but well established complication of RA. In our case, the almost immediate temporal relationship between the development of the GN and the G-CSF administration supports G-CSF as etiologic. This case demonstrates the importance of considering the possible renal complications and need for close monitoring while giving G-CSF in patients with autoimmune diseases.

PO1498
Spontaneously Resolved Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits
Salma Shaikhouni, Alexandra M. Peiroc, Andrea L. Oliverio, Laura H. Mariani. University of Michigan, Ann Arbor, MI.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is thought to be a progressive disease, with early studies showing 38% of patients with persistent renal dysfunction and 22% progressing to ESKD within a 30 month follow up period. We present two cases of PGNMID who achieved spontaneous remission without directed therapy.

Case Description: Case 1: A 53 y/o woman with hypertension and diabetes presented for evaluation of proteinuria with a 1.83 mg/dl, UPCR of 12.9 g/g, and microscopic hematuria. While serum autoimmune markers were notable for mildly elevated anti dsDNA (75 IU/ml), normal C3 and low C4 (8 mg/dl), renal biopsy revealed PGNMID with IgG, light chain deposits. A low titer IgM was detected in the serum. The patient had diffuse lymphadenopathy on imaging, and two excisional biopsies showed reactive follicular hyperplasia. Bone marrow biopsy was normal. UP CR decreased to 1.23 g/g within 2.5 months of presentation and SCr down to 1.22 without any therapy.

Discussion: These unique cases demonstrate that PGNMID is likely a heterogeneous disease whose pathogenesis and natural history is poorly understood. We hypothesize that an infectious antigen or autoantigen may induce clonal proliferation of B-cells and the formation of transient monoclonal antibodies leading to complement activation and proliferative glomerulonephritis. When the stimulus is controlled, the associated immune response is regulated. Our patients did not require any immunomodulatory therapy, contrary to most recent case series. Recognition of the potential for spontaneous remission in PGNMID has important implications on treatment paradigms for this emerging diagnosis.

PO1499
PLAR2-Positive Membranous Nephropathy: A Renal Manifestation of Scleromyxedema
Alexander Heipas, Casey N. Gashiti, Roger A. Rodby. Rush Nephrology Rush University Medical Center, Chicago, IL.

Introduction: Scleromyxedema (SMX) is a rare primary cutaneous mucinosis that usually occurs in association with a monoclonal gammopathy. Systemic manifestations may involve the musculoskeletal, cardiovascular, gastrointestinal, pulmonary, nervous and renal systems and may lead to significant morbidity and mortality. Renal manifestation has been reported, but histopathologic description of renal involvement has been vague and histopathologic classification has not been implemented. Therapeutic management of the renal disease has included plasmapheresis and cyclophosphamide, but the roles of each of these is not determined.

Case Description: We report a case of a 53-year-old male with SMX and monoclonal gammopathy who developed renal manifestation of sclerodermodinoid disease. His skin manifestations of SMX had been previously controlled with intravenous immunoglobulins (IVIG) until he developed presumed central nervous system involvement manifesting as an isolated seizure. He failed a series of treatments including lenalidomide, melphalan, and bortezomib. He subsequently underwent an autologous stem cell transplant with initial improvement in cutaneous manifestations for 6 months but experienced a relapse thereafter. In addition, he developed acute kidney injury associated with minimal proteinuria (<1000 mg). A kidney biopsy demonstrated thrombotic microangiopathy (TMA) and tissue phospholipase A2 receptor antibody (PLAR2) positive membranous nephropathy. Ravalizumab was instituted but had to be abandoned as the patient was hospitalized on two occasions with fever and culture negative pulmonary infiltrates after each infusion. Alternatively, he was treated with intravenous cyclophosphamide, oral prednisone and plasmapheresis with improvement in skin disease and stabilization of proteinuria and renal function.

Discussion: Renal manifestations of SMX are poorly defined and treatment is unknown. Membranous nephropathy has been rarely reported in SMX, but PLAR2 status has not been available. Most cases focus on treatment of the underlying monoclonal
PO1500

**Pemphigus vulgaris and PLA2R-Associated Membranous Nephropathy:**

Two IgG4-Related Diseases in the Same Patient

Camila I. Costa, Matheus R. Correia, Luís H. Sette, Denise M. Costa, Camila B. Oliveira, Maria Alina G. Cavalcante, Lucila Maria Valente, Gisele Vajgel. 1Hospital dos Servidores do Estado de Pernambuco, Recife, Brazil; 2Hospital Getulio Vargas, Recife, Brazil; 3Universidade Federal de Pernambuco, Recife, Brazil.

**Introduction:** The relationship between bullous skin diseases and glomerulopathies has been increasingly recognised. Other bullous diseases were previously reported in association with membranous nephropathy (MN), but the association between pemphigus vulgaris (PV) and pemphigus (PV) has not been reported in the literature yet.

**Case Description:** A 39-years-old smoker woman presented with trunk blisters and worsened mouth ulcers after stopping the treatment for MN. One year before she had nephrotic syndrome and the kidney biopsy was positive for anti-PLA2R and IgG4 (and negative for THS5D7a) in the immunohistochemistry (IQ). Serum anti-PLA2R was negative. Four months earlier she was started on cyclosporine, but stopped it due to mouth ulcers. She had nephrotic range proteinuria, no edema, when the painful blisters spread out on the trunk, back, limbs, scalp as well as ulcers in the oral cavity and esophaguses. The diagnosis of PV was confirmed by skin and oesophagus biopsy and IQ showed the presence of IgG4 subclass antibody in the epithelial tissue. She received pulse and oral steroids along with azathioprine for the PV. The skin lesions were slowly healing and no more new blisters have appeared.

**Discussion:** The humoral auto-immune response in pemphigus produces anti-desmoglein 1 and 3, both IgG4. Desmogleins are responsible for adhesion in stratified squamous epithelium, when damaged produces to the blistering eruptions. There is a genetic predisposition between PV and MN, with HLA-DQ51, HLA-DRB1 and the thrombospondin gene (THS5D7a). Environmental factors such as smoking and air pollution could act as a second trigger for the development of auto-immune diseases. PLA2R can be expressed in the bronchiolar tissue and in macrophages of the lung, however there is no evidence of histological damage in the pulmonary tissue. Although we found no description on the expression of PLA2R in the skin, in an attempt to find a common antigen for both diseases, we did search for anti-PLA2R in the skin, but it was negative. In conclusion, this is the first described case of association of pemphigus vulgaris and PLA2R-associated MN, both IgG4-related conditions that involve the production of different autoantibodies directed to skin and kidney antigens.

PO1501

**A Case of an Elderly Woman with Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits Whose Renal Biopsy Revealed Renal Cell Carcinoma**

**Introduction:** Membranous-like glomerulopathy with masked monoclonal IgG deposits (MGIMID) is a recently described form of glomerulopathy with a unique histopathology reported by Larsen et al. The pattern is characterized by subepithelial and/or mesangial immune deposits that are “masked”, to immunoglobulin staining by routine immunofluorescence but strongly stained for IgG and kappa light chain after protease digestion. Patients with MGIMID are commonly young females and have a vague history of autoimmune diseases such as low titer antinuclear antibodies.

**Case Description:** A 65-year-old woman was referred to our hospital with urinary protein (0.80 g/gCr) and microscopic hematuria. Serum antinuclear antibody, rheumatoid factor, and M-protein were negative and serum C3 and C4 were normal. Plain CT showed normal complement levels, serum calcium of 8.4 mg/dL with normal ACE level and urinalysis with no protein 9 WBC/HPF and 10 RBC/HPF. She received pulse and oral steroids, transitioned to prednisone 40 mg daily for 2 weeks and subsequent taper. Was referred to the sarcoidosis clinic due to his remote history and found to have multisystemic granulomatous disease affecting the pulmonary, hepatic and sympathetic systems.

**Discussion:** Granulomatous interstitial nephritis (GIN) is an uncommon histologic diagnosis. It is known to be associated with antibiotic use and granulomatous disorders like sarcoidosis. The incidence of renal sarcoidosis ranges from 7-17 %, manifesting as GIN or with renal damage due to altered calcium homeostasis. Corticosteroids are considered the mainstay of therapy.

PO1503

**Monoclonal Gammopathy in a Patient with Lupus Nephritis: A Case Report**

Waseem Albasha, Ankita Ashoka, Erika R. Bracamonte, Bijn Thajuddeen. Banner University Medical Center Tucson, Tucson, AZ.

**Introduction:** Monoclonal gammopathy of undetermined significance (MGUS) has known associations with many disorders, including inflammatory and connective tissue disorders. Systemic lupus erythematosus (SLE) is not traditionally considered to have an association with MGUS. However, a few studies and case reports have emerged that have suggested an association between MGUS and SLE. We describe herein a case of a patient who was newly diagnosed with lupus nephritis but also was found to MGUS.

**Case Description:** A 53-year-old gentleman with a history of hypertension presented to the hospital with blurry vision and bilateral lower extremity rash. He was found to have acute kidney injury (creatinine 1.67 mg/dL), microscopic hematuria (21-50 RBCs/HPF), proteinuria (24 hour urine protein 1,148 mg/day), and low complements (C3 50 mg/dL, C4 7 mg/dL, and CH50 13 U/ml). Kidney biopsy confirmed focal proliferative glomerulonephritis with full-house immunofluorescence staining and three cellular crescents, consistent with class III lupus nephritis. Interestingly his ANA and double-stranded DNA serologies were negative. Serum immunofixation was positive for an IgM lambda type monoclonal gammopathy. Bone marrow biopsy showed 2.1% plasma cells. Hematology/oncology was consulted and diagnosed him with MGUS. Incidentally, he was found to have type 1 cryoglobulinemia as well, with cryoglobulin immunofixation positive for IgM kappa type. The patient was started on mycophenolate mofetil and prednisone, and started on mycophenolate mofetil. At two months of treatment creatinine was 1.1 mg/dL, proteinuria improved to 300 mg/gm creatinine.

**Discussion:** The pathophysiology mechanism that has been suggested for the development of MGUS in patients with lupus nephritis is that MGUS and lupus nephritis in B cell hyperactivity and immunoglobulin production. Lupus is known to produce hyperactivity in B cells and a
polycyonal increase in gamma globulins. It is likely that in some patients with lupus, B cell regulation becomes impaired in a way that allows a clonal, but not necessarily neoplastic, an expansion that results in increased production of paraproteins, leading to MGUS. This case adds to the literature showing that there indeed may be an association between MGUS and lupus.

**PO1504**

**Bartonella Henselae Infective Endocarditis (BHIE): A Rare Cause of Pauci-Immune Necrotizing GN (PINGN)**

Muhammad A. Shahzad, Ami Purohit, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

**Introduction:** Bartonella is the commonest cause of culture negative endocarditis. While, Infection Related GN (IRGN) can mimic pauci-immune vasculitis, the majority of cases of BHIE have been immune complex (IC) mediated. We present the rare case of BHIE related PINGN. Timely recognition of this atypical presentation led to appropriate medical therapy.

**Case Description:** A 33 yr old M with HIV on HAART and recent tooth extraction was admitted with a severe headache due to a sub arachnoid hemorrhage from a ruptured right anterior cerebral artery mycotic aneurysm. TEE showed a vegetation on the aortic valve (AV). Blood cultures were negative. Initial SCr was 3.3 mg/dl and urinalysis had 2+ protein, 3+ blood with 29 RBC/hpf and a UPro/Cr ratio was 1.7 g/l. The C4 was low (10.2 mg/dl) and PR3-ANCA elevated-4.0 (NL <3.5 U/mL). The Bartonella henselae IgG titer was elevated-1,560 (NL <1.320). Renal biopsy revealed pauci-immune necrotizing GN (Figure) with no evidence of IC deposition. BHIE associated PINGN was diagnosed and treatment with doxycycline, ceftriaxone and gentamicin initiated. The AV was replaced and was positive for BH by PCR. After a prolonged course of antibiotics the SCr improved to 2.5 mg/dl.

**Discussion:** B henselae associated GN is a rare cause of PR3-ANCA positive GN with only 6 cases previously reported. By immunofluorescence, 4 cases were immune complex. The importance of timely recognition and appropriate medical therapy cannot be overemphasized.

**PO1505**

**Atypical Hemolytic Uremic Syndrome and Systemic Lupus Erythematosus-Dermatomyositis Overlap: A Challenging Scenario**

Yelena R. Drexler, Juanly N. Rodriguez. University of Miami School of Medicine, Miami, FL.

**Introduction:** Overlap syndromes are rare disorders wherein at least two systemic autoimmune diseases meet diagnostic criteria. We present a case of atypical hemolytic uremic syndrome (aHUS) in a patient with systemic lupus erythematosus (SLE) and anti-melanoma differentiation-associated gene 5 antibody (anti-MDA5) dermatomyositis (DM) overlap.

**Case Description:** A 45-year-old woman with SLE diagnosed 8mo prior, treated with belimumab and prednisone, developed proximal muscle weakness, violaceous erythema of eyelids, neck, hands and feet with ulcers. Three weeks later, she presented with abdominal pain, shock and respiratory failure. Testing showed WBC 19,200/μL, lipase >600 and ionized calcium 0.47 mmol/L; acute kidney injury (BUN 64 mg/dL, Cr 2.4 mg/dL); anemia (Hb 7.1 g/dL); and thrombocytopenia (PLT 24,000). CT showed paravertebral and perinephric fluid collections despite high-dose calcium infusion, she initiated renal replacement therapy. Further workup showed low C3 level 42, C4 level 7, elevated anti-dsDNA Ab 237 IU/ml and UPCR 2.2 g/g; haptoglobin <10, LDH 1,371 U/L, Positive direct Coombs, schistocytes on smear and ADAMTS13 activity 18%. Due to autoimmune vs microangiopathic hemolytic anemia, received pulse methylprednisolone and IVIG with improvement. She then started eculizumab. Within 7d, LDH decreased to 772, haptoglobin increased to 79 and platelets normalized. Further workup revealed elevated creatine kinase 1,271 U/L, aldolase 17 U/L, AST 566 U/L with normal ALT and positive anti-MDA5 and transcription intermediary factor-1-gamma (TIF-1γ) Abs, meeting criteria for DM. Patient continued eculizumab and prednisone. Eventually developed invasive aspergillosis and expired.

**Discussion:** We report a case of SLE-DM overlap with anti-MDA5 and TIF-1γ Abs complicated by aHUS and severe hypocalcemia in the setting of pancreatitis. The cutaneous manifestations are typical of MDA5-associated DM. Our patient did not develop intestinal lung disease, exemplifying range of variation from case to case. The presence of anti-TIF-1γ confers a 6-fold increased malignancy risk; finding of omental nodularity in this case would warrant further investigation. aHUS as a complication of SLE-DM overlap is rare, with mortality risk up to 52%. AKI, infection and low C3 are associated with highest mortality. Prompt diagnosis, high clinical suspicion and early initiation of eculizumab resulted in a rapid response.

**PO1506**

**Anti-LRP2 Nephropathy in a Patient with Chronic Lymphocytic Leukemia**

Derek Tran,1 Chien-Wen Yang,2 Avantika Israni,3 Abdullah Sassine Garea,2 Al J. Lee,1 1St Mary Medical Center, Langhorne, PA; 2Penn Medicine, Philadelphia, PA.

**Introduction:** Anti-LRP2 anti-Brush Border Nephropathy is a newly identified autoimmune tubulo-interstitial nephritis triggered by circulating antibodies to low-density lipoprotein receptor-related lipoprotein 2 (LRP2). We present a case of anti-LRP2 nephropathy in a patient with chronic lymphocytic leukemia (CLL).

**Case Description:** A 74-year-old Caucasian male patient known to have CLL presented following a fall with a forearm laceration. At presentation, he had acute renal failure (SCr of 5.04 mg/dL and severe thrombocytopenia (platelets of 11,000/u). Additional evaluation showed positive ANA and p-ANCA. The patient had proteinuria of 1754 mg/g of creatinine. The kidney biopsy showed moderate interstitial fibrosis and tubular atrophy involving 30-40% of the renal cortex. The tubular epithelium showed reactive-appearing nuclei as well as cytoplasmic thinning with loss of the proximal tubular brush border. Immunofluorescence showed IgG (3+) and C3 (3+) for the glomeruli, capillary and the TBM. There was focal staining of the brush borders by IgG with positive LRP2 stain in the TBM. Electron microscopy revealed numerous subepithelial electron-dense deposits. The serum anti-LRP2 antibody titer was 1:100. The patient was started on dexamethasone and rituximab with improvement of the thrombocytopenia. Plasmapheresis was prescribed for 5 sessions, the creatinine continued to worsen (SCr of 7.73 mg/dL), and the anti-LRP2 titer did not improve. The patient is being transitioned to renal replacement therapy.

**Discussion:** The mechanism that links the ABBA disease with lymphoproliferative disease is still unknown. The current reported cases suggest an association between direct lymphoma renal infiltration, progression of the lymphoproliferative disease and the presence of the ABBA disease. However, in our reported case, the patient’s underlying CLL was stable without evidence of renal infiltration. The poor response to treatment in this case is consistent with the poor outcomes of many anti-LRP2 reported cases. The renal biopsy on this patient also showed membranous glomerulonephritis. We presented a case with anti-LRP2 nephropathy/ABBA disease with concurrent CLL without evidence of lymphoma infiltration which is typical of non-ABBA disease. Our therapy, the prognosis of ABBA associated paraneoplastic syndrome with underlying CLL warrants future investigation.

**PO1507**

**Black Tar Heroin and AA Amyloidosis**

Rama Kethineni, Monique E. Cho, Monica P. Revelo Penafiel, Olesya Ilkun, Janane J. Kottey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

**Introduction:** AA amyloidosis due to deposition of serum amyloid A protein occurs as a secondary reaction to chronic inflammatory disease, chronic infections, and familial period fever syndromes. We present a case of AA amyloidosis secondary to chronic black tar heroin use in the Intermountain West.

**Case Description:** A 61 yr. old Caucasian female with a history of Hepatitis C, IV Heroin use presented with bilateral leg pain, swelling, and abdominal distension. Examination was significant for ulceration in lower extremities with purulent blisters. Notably lab data also include Hemoglobin of 8.2 g/dL, potassium 10.6 mg/dL, BUN of 90 mg/dL, creatinine of 2.9 mg/dL, serum albumin of 2.1 g/dL, and ESR of 129 mm/hour. She had a urine protein to creatinine ratio of 12.3 g/g. Abdominal US revealed enlarged liver and normal renal echogenicity. The quantification of HCV RNA by polymerase chain reaction was negative, and her complement levels were within normal range. Cryoglobulin was also negative with a kappa/lambda light chain ratio of 1.33. Serum protein electrophoresis showed decreased albumin and immunofixation electrophoresis showed a faint band in IgG kappa suggestive of a specific immune reaction. An early morning Hgb was 10.7 g/dL. Renal biopsy showed non-AL amyloid deposition involving glomeruli, and arterties. Mass spectrometry performed at Mayo Clinic Laboratories confirmed renal involvement by Amyloidosis, AA (serum amyloid A)-type.

**Discussion:** “Black tar heroin” has increasingly been identified as a risk factor for AA Amyloidosis. Impurities in heroin promote vascular sclerosis and lead to the use of injection into muscle and skin. The suppurative infections that follow stimulate...
Renal biopsy

**PO1508**

**Guselkumab-Associated Severe AKI from Collapsing Glomerulopathy**

Varun Madireddy, Deepa A. Malieckal, Boonyanuth N. Maturostrakul, Philip S. Yune, Vanesa Bijol, Hitesh H. Shah, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

**Introduction:** Collapsing glomerulopathy (CG) has been commonly associated with viral infections, mainly HIV. Several medications have also been associated with CG. We present the first case of Guselkumab-associated rapidly progressive AKI from CG and acute tubular injury.

**Case Description:** 86-year-old African American female with history of HTN, RCC with left nephrectomy, CKD, CHF, and psoriasis (on Guselkumab treatment since 2018) presented to our hospital for worsening bilateral LE edema and AKI. On presentation, Scr was elevated at 3.75 and serum albumin was WNL (3.5). Three weeks prior to presentation, Scr was elevated but stable at 1.77 on outpatient labs. Of significance, pt. received Guselkumab injection one week prior to presentation. During hospital stay, UA was significant for proteinuria and hematuria. Spot urine total protein-to-creatinine ratio (TPCR) was significantly elevated at 13.7. Of note, spot urine TPCR was 1.6, four months prior to presentation. There was no right hydropneumothorax or renal vein thrombosis seen on imaging. Serological tests including ANCA, HBsAg, Hep C ab, HIV, RVP, COVID-19 PCR, Parvovirus B19 PCR, and CMV PCR were all negative. Patient initially received diuretic therapy for LE edema. Kidney biopsy performed during hospital stay showed CG and acute tubular injury. Electron microscopy examination of kidney biopsy specimen was significant for extensive effacement of podocyte foot processes and rare tubuloreticular inclusions in endothelial cell cytoplasm. Scr rapidly worsened to 7.98 and HD treatment was initiated. Our patient was also initiated on daily high dose oral corticosteroid therapy.

**Discussion:** Guselkumab, an IL-23 blocker is FDA approved for the treatment of plaque psoriasis and active psoriatic arthritis. A case of Ustekinumab (IL-12/23) inhibitor associated ESRD (after 2 years of treatment) has been reported in the literature. Our patient while on chronic Guselkumab treatment developed rapidly worsening AKI and CG, a week following the last dose of Guselkumab. We believe that in absence of any additional known risk factors, Guselkumab was responsible for AKI and CG in our patient. Our patient currently remains dialysis dependent. Clinicians should be aware of this very rare but potential association.

**PO1509**

**Proteinuria and Hematuria, an Unfamiliar Side Effect of Statin Therapy**

Marco B. Thierry,1,2 Daniel Varela,1 Mourad Alsabbagh,2 Sergio A. Trevino Manlio,2 Salil Mangi.1 1The University of Texas Rio Grande Valley, Edinburg, TX; 2DHR Health, Edinburg, TX.

**Introduction:** Statins are among the most commonly prescribed medications worldwide, and have a relatively mild side effect profile. We describe a rare manifestation of statin therapy, with proteinuria and microscopic hematuria.

**Case Description:** A 53-year-old Hispanic lady with a history of proteinuria and hematuria for 1 year with negative Urologic workup was referred to nephrology for further evaluation. Patient complained of foamy urine. Her only medication was rosuvastatin 40 mg. Initial UA showed 2+ protein and 5-10 RBC/HFP. Lab work - BUN 16, creatinine 1.0 mg/dL, albumin 4.8 mg/dL, Urine Protein Creatinine Ratio 2.1 g/g creatinine. Serum creatinine was negative and complement levels were normal. Patient was started on ARB and a low sodium diet for proteinuria. Proteinuria persisted and renal biopsy was recommended with suspicion of IgA nephropathy. Biopsy showed mild glomerular and tubular interstitial chronic injury likely secondary to arteriosclerosis. There was no immune complex deposition and no evidence of this basement membrane disease. Genetic workup was negative for Alport’s syndrome. Because of the rare association of Rosuvastatin with urinary abnormalities, we decided to hold patient’s Rosuvastatin. Only three days later the patient reported that foamy urine had resolved. Repeat UPCR showed 99 mg protein/g creatinine. Hematuria also decreased to 0-2 RBC/HFP.

**Discussion:** Proteinuria is one of the lesser known side effects of statin therapy. It was initially found in the clinical development programme for Rosuvastatin, where it was found that the 80 mg dose caused proteinuria in 12% of patients. Furthermore, a comprehensive review of the renal effects of rosuvastatin, found that 1.2% of patients taking 40 mg of rosuvastatin developed 2+ proteinuria, and 0.3% developed 2+ proteinuria and 1+ hematuria. Our case highlights a rare manifestation of Rosuvastatin induced urinary abnormalities, which improve after stopping the drug. This should be kept in mind for patients on Rosuvastatin with negative workup for proteinuria and hematuria, before a renal biopsy is pursued.

**PO1510**

**Rituximab for Membranous Nephropathy in a Patient with Sjögren Syndrome and Mixed-Connective Tissue Disease**

Joshua D. Pollock, Maurice I. Khayat. Madigan Army Medical Center, Tacoma, WA.

**Introduction:** Membranous nephropathy (MN), a cause of nephrotic syndrome, is characterized by the deposition of immune complexes in the glomerular basement membrane with resultant subepithelial “spikes” visualized under light microscopy. Although often a primary disease process, several secondary etiologies exist, including Sjögren’s syndrome (SS) and mixed-connective tissue disease (MCTD). Treatment typically targets the underlying condition. Despite rituximab’s demonstrated efficacy in MN, MCTD and SS, case reports for specific treatment of MN secondary to these conditions have primarily described regimens of systemic corticosteroids with or without cyclophosphamide.

**Case Description:** A 54-year-old male was diagnosed with MN on renal biopsy in 2001. He presented with secondary etiologies (tubuloreticular structures, mild cellular increase by light microscopy, mesangial deposits, and irregular distribution of deposits by EM), both his initial presentation and subsequent relapse in 2010 responded to antiproteinuric therapy alone. Following treatment-resistant relapse, cyclophosphamide and prednisone were initiated in 2019 without improvement. A secondary evaluation was significant for strongly positive anti-ribonuclear protein and anti-SSA antibodies with negative serologies for systemic lupus erythematosus. The patient reported only mild polyarthralgia and sicca symptoms. Following rheumatology consultation and salivary gland biopsy the patient was diagnosed with MCTD and SS. Rituximab 1000 mg on day 1 and day 15 was administered, with partial remission noted 4 months following therapy. Complete remission was achieved 8 months following therapy and has been sustained for 13 months. His extrarenal symptoms of MCTD and SS have also resolved.

**Discussion:** Rituximab is a well-described treatment for primary MN, MCTD and SS. However, there is a paucity of literature evaluating its use in MN as the specific renal manifestation of MCTD and SS. This case illustrates the potential role for rituximab as an effective treatment for membranous nephropathy secondary to SS and MCTD when deciding on immunomodulatory therapy. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

**PO1511**

**A Rare Case of Concurrent Glomerulonephritis and Autoimmunity**

**Introduction:** We report a rare case of necrotizing and crescentic glomerulonephritis in the setting of Streptococcus mitis bacteremia.

**Case Description:** A sixty-one year old man with a history of hypertension, hyperlipidemia, and non-insulin-dependent diabetes presented to the emergency room with progressive lower extremity edema and dyspnea with tea-colored frothy urine. Initial workup revealed bilateral pulmonary edema and acute kidney injury with a serum creatinine of 1.84 mg/dL (0.8 mg/dL 6 months prior) with 9.18 grams proteinuria and acute urine sediment. He was initially diuresed for decompenated heart failure but further workup revealed hypocomplementemia and positive ANCA/proteinase-3 (PR3) antibody. A kidney biopsy revealed membranous glomerulonephritis (MGN) with focal endocapillary proliferative features and focal crescents with fibrinoid necrosis with positive PLA2R immunostaining and serum PLA2R IgG antibody testing revealing a titer of 1:2560. An echocardiogram revealed reduced left ventricular ejection fraction with reduced contractility. Aortic valve vegetation. Blood cultures obtained on admission ultimately grew Streptococcus mitis and he underwent aortic valve repair. Despite completion of a full antibiotic course, his creatinine remained impaired with nephritic-range proteinuria and elevated serum PLAR2 titers. Repeat renal biopsy revealed membranous glomerulonephritis and he was started on immunosuppression, specifically treatment of PLAR2-associated MGN.

**Discussion:** Peri-infectious PLAR2-associated MGN and ANCA-associated glomerulonephritis appears to be a rare. While his proliferative ANCA-mediated glomerulonephritis was likely related to the infectious endocarditis, the relationship to the PLAR2-positive MGN remains unclear. We hypothesize that host immune response to infectious agents lead to an autoimmune process resulting in glomerulonephritis. It is possible that in addition to a genetic predisposition (“first hit”), a “second hit” which begins with activation of the innate immune response by an infectious agent leading to autoimmunity through various mechanisms including defective immune regulation, molecular mimicry, epitope spreading, and autoantigen complementarity.
PO1512
C2 Deficiency Associated with Severe Recurrent ANA-Negative Lupus and Necrotizing Glomerulonephritis
Maria Llanos, Daniel Marino, Sanjay K. Menon, Kotresha Neelakantanpappu, Michael Malekan. NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.

Introduction: Deficiencies in the classical complement pathway have been associated with the development of systemic lupus erythematosus (SLE) and lupus-like disease in 10-20% of affected patients. In fact, SLE patients deficient in classical complement present at an earlier age, with severe manifestations and a worse prognosis. Several mechanisms have been described to explain these immune phenomena including impaired clearance of immune complexes, impaired handling of apoptotic cells, and changes in regulation of cytokines. Here, we present a case of a young female with ANA-negative lupus presenting with dyspnea and acute renal failure responsive to immunosuppressive therapy found to have C2 Complement deficiency.

Case Description: 44 year old female with sickle cell trait, ANA-negative SLE, ESRD due to biopsy-proven class IV lupus nephritis briefly requiring HD, pulmonary HTN, presented with signs of fluid overload, acute on chronic renal failure in the setting of malignant hypertension. Labs revealed thrombocytopenia of 52 with a creatinine of 2.66 (prior 1.61), hypocomplementemia and undetectable CH50 levels concerning for acute flare of SLE and an underlying functional complement deficiency. Low haptoglobin and peripheral smear with schistocytes raised concerns for microangiopathy. Hospital course was complicated by encephalopathy and possible CNS involvement of lupus. Renal biopsy confirmed chronic sclerosing immune complex glomerulonephritis with minimal activity. The patient responded well to high dose corticosteroids, plasma exchange and mycophenolate mofetil. Final serology confirmed persistent C2 complement deficiency.

Discussion: There is a well-studied link between immune-complex mediated disease and complement deficiency. Of these, C2 deficiency is the most common. In our case, a C2 deficiency was found in the setting of ANA-negative SLE with severe clinical manifestations. Our case raises the question of whether testing to exclude underlying complement deficiency is particularly indicated in patients with ANA-negative SLE. It also remains to be seen whether clinical manifestations of microangiopathy are prevalent in these patients, and whether therapies targeting complement may be effective in their treatment.

PO1513
De Novo IgA Vasculitis Following Exposure to SARS-CoV-2 Immunization
Terrance Wiekman, Muner Mohamed, Agnes B. Fogo, Juan Carlos Q. Velez.1,2
1Ochsner Medical Center - New Orleans, New Orleans, LA; 2Vanderbilt University Medical Center, Nashville, TN; 3The University of Queensland, Saint Lucia, QLD, Australia.

Introduction: Immunizations have been previously described as potential triggering events for the development of certain glomerular diseases. However, there is paucity of reports of occurrence of glomerular diseases developing after exposure to a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine.

Case Description: A 50-year-old man presented to a nephrology clinic for evaluation of persistent proteinuria. Six weeks prior to evaluation, the patient had reported developing a new rash approximately 2 weeks after receiving the first dose of a SARS-CoV-2 vaccine (Pfizer®). The rash was treated by his primary care provider with topical and oral corticosteroids, leading to partial improvement of the skin lesions. Three weeks after the first vaccine injection, the patient received his scheduled second vaccine injection. Within 2 days, the rash reappeared. This time, the lesions were more severe in nature, with a violaceous papular rash involving his lower legs and with some areas progressing to blisters. He also reported myalgias and arthralgias. A skin biopsy was performed and revealed IgA-dominant leukocytoclastic vasculitis. After completion of 2 weeks of oral corticosteroids, a urinalysis revealed proteinuria and a consultation to nephrology was requested. On examination, healing papules were noted on his legs but otherwise exam was normal. Serum creatinine was 0.9 mg/dL. Microscopic examination of the urinary sediment revealed acanthocytes. A urine protein-to-creatinine ratio (UPCR) was 1.1 g/g. Serum complement was normal and all pertinent serology was negative. A kidney biopsy was performed and light and immunofluorescence microscopy findings showed an IgA nephropathy. UPVR decreased to 0.7 g/g and rash completely subsided.

Discussion: The clinical presentation and pathological findings in this case strongly suggest that SARS-CoV-2 Vaccine (Pfizer®) can trigger a clinical syndrome compatible with Henoch-Schönlein purpura. The recurrence of the rash following re-exposure to the vaccine injection (second dose) argues for a definite causal association by Naranjo criteria.
**PO1516**

**Chicken or the Egg Causality Dilemma: Primary ANCA Vasculitis Complicated by Infective Endocarditis (IE) vs. IE Leading to ANCA Vasculitis**

Benjamin P. Catanese, Ayesha Anwar, Shuichi Anand. Stanford Health Care, Stanford, CA.

**Introduction:** As the cases of infective endocarditis increase in the United States it is important to recognize the associated complications. Glomerulonephritis is a well-recognized but not fully understood consequence. Immune complex deposition is the most common etiology but ANCA-mediated kidney injury is increasingly described and even less understood.

**Case Description:** A 65-year-old male presented with acute onset dysuria, left facial droop, left sided weakness, and dizziness. 5 months prior he was diagnosed with PR3+ ANCA vasculitis after presenting with 18 lbs weight loss, puffy face, anemia, and hematuria. He was treated with methotrexate and a steroid taper, which finished one week prior to the current presentation. Admission vitals were: 145/74 mmHg, heart rate of 90 bpm, and 100% oxygen saturation on room air. Lab work showed: hemoglobin of 10.7 K/Ul, creatinine of 1.17 mg/dL (baseline 0.9), low C3: 81 mg/dL, positive PR3 (>8.0), positive c-ANCA (1:128), negative MPO and p-ANCA, and U/A: 3+ blood, negative protein, and 11-20 WBC. MRIs of the brain and heart revealed numerous acute and subacute infarcts and severe mitral regurgitation respectively, concerning for small vessel vasculitis, and he was started on high dose steroids. Discovery of streptococcus mutans bacteremia was a surprise. Suspicion was raised that the ANCA vasculitis may have been a consequence of underlying sub-acute endocarditis rather than a primary disease hence a kidney biopsy was planned and he was discharged on steroids and IV antibiotics. Kidney biopsy confirmed the diagnosis of ANCA-mediated endocarditis-associated glomerulonephritis with the presence of glomerulosclerosis with fibrocellular/fibrous crescents, segmental fibronectin necrosis but no obvious immune deposits on light microscopy. Granular deposits in the mesangial and capillary wall stained for C3, IgM, IgA, kappa and lambda. He underwent 6 weeks of ceftriaxone and mitral valve replacement. His renal function is mildly impaired; he is recovering neurologically.

**Discussion:** Endocarditis-associated GN typically requires treatment of the underlying infection without immunosuppression, but when the injury is primarily ANCA-mediated, this presents a unique challenge in that end-organ damage from vasculitis may not improve without immunosuppression.

**PO1517**

**Crescentic Glomerulonephritis in Sjogren Syndrome**

Jake N. Cho,1,2 Danielle Jamison,3 Grant Oakley,1,2 Gary DiPerna.1 1Maine Medical Center, Portland, ME; 2Tufts University School of Medicine, Boston, MA; 3Maine Nephrology Associates PA, Portland, ME.

**Introduction:** Sjogren’s syndrome (SS) is an inflammatory autoimmune disorder involving the parotid, lacrimal and salivary glands causing sicca syndrome. Kidney involvement is variable and most often results in tubulointerstitial nephritis. Glomerular disease is infrequent with MPGN and membranous nephropathy being most prevalent pathologically.

**Case Description:** Patient is a 21-year-old female with SS, hyperthyroidism and asthma who was being evaluated for fever and fatigue. Lab evaluation revealed acute kidney injury (AKI) with creatinine rising from 1.0 to 1.8 mg/dL over several weeks. Echocardiogram was concerning for mobile echodensity at the tricuspid valve, but transesophaegal echo showed no abnormalities and evaluation for infection was negative. CT showed extensive prominent lymph nodes in the chest, abdomen, and pelvis but lymph node biopsy showed benign reactive hyperplasia without neoplasm. Renal ultrasound showed normal sized kidneys. Urinalysis was positive for trace proteinuria and sediment revealed dysmorphic RBCs. She was started on high dose prednisone and hydroxychloroquine for possible lupus nephritis but due to diagnostic uncertainty and unresolved AKI, kidney biopsy was performed.

**Discussion:** Kidney biopsy demonstrated plasma rich interstitial nephritis with severe tubulitis consistent with SS. Interestingly, the biopsy showed 3 active cellular crescents out of 21 glomeruli with focal crescentic GN. Tubulointerstitial nephritis is the most common renal pathology in primary SS leading to renal tubular acidosis, impaired concentrating ability and proximal tubule defects. GN in SS is rare but has been associated with membranoproliferative GN, membranous nephropathy and cryoglobulinemic GN. Crescentic GN was unexpected and the treatment plan was adapted to taper the prednisone, start on Mycophenolate Mofetil and trial on Rituximab.
PO1519
Unmasking a Case of Membranous-Like Glomerulopathy with Masked IgG-κ Deposits
Alissa Ice, Darren W. Barefield. Louisiana State University Health Sciences Center, Baton Rouge, LA.

Introduction: Membranous-like glomerulopathy with masked IgG-κ deposits (MGMID) is a recently described, exceedingly uncommon entity of glomerular immune-complex deposition requiring antigen retrieval on formalin-fixed paraffin-embedded tissue. We report a rare case of MGMID in a young female with newly diagnosed APLA.

Case Description: An 18 year old female with no medical history presented with left leg swelling. Vital signs were normal and an enlarged, discolored left lower extremity was appreciated on exam. Initial laboratory results were remarkable for Cr 0.78 mg/dL, albumin 2.3 g/dL, platelets 128,000/μL, PTT 87.1 s, INR 1.02, and hematuria and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PL2Ar, complements, hepatitis serologies, ANA, ANCA, AIC, SLEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

Discussion: Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.

PO1520
A Case of Secondary Renal Amyloidosis Associated with HIV

Introduction: Secondary amyloidosis is known to be associated with multiple chronic infections and inflammatory conditions including rheumatoid arthritis, inflammatory bowel disease, systemic lupus erythematosus, and tuberculosis. HIV has not yet been established as a known association. We present a case of secondary amyloidosis associated with well-controlled HIV with no history of other potential etiologies.

Case Description: A 71-year-old man with hypertension and well-controlled HIV for 40 years (viral load undetectable and last CD4 917) was referred to the renal clinic for acute kidney injury and heavy proteinuria. He had complained of leg swelling and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PL2Ar, complements, hepatitis serologies, ANA, ANCA, AIC, SLEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

Discussion: Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.

Renal Cell Carcinoma Presenting as Henoch-Schönlein Purpura with AKI and Leukocytoclastic Vasculitis in Adults
Ashton N, Breithaupt, Neelarika Mettupalli, Stacy A. Johnson, Alice Chedid.
The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Introduction: Henoch-Schönlein purpura (HSP) is a small vessel vasculitis characterized by IgA tissue deposition. HSP presenting in adults is often the result of an underlying malignancy.

Case Description: A 60-year-old man with history of HTN, CVA, DM2, recent COVID-19 infection, presented for 2 week history of petechiae on bilateral upper and lower extremities. Skin biopsy findings were compatible with leukocytoclastic vasculitis (LCV). Patient on admission was also found to have AKI with creatinine 2.1 mg/dl, microscopic hematuria, and sub-nephrotic range proteinuria with urine protein/creatinine ratio of 2.66 g/g. Kidney biopsy findings were consistent with IgA dominant glomerulonephritis. Given multi-system involvement, patient was diagnosed with Henoch-Schönlein Purpura. Given unusual presentation with extreme of age, there was concern for malignancy. CT scan chest abdomen pelvis was performed which revealed a solid and septated 8.3 cm exophytic mass on the superior pole of left kidney. A partial left nephrectomy was performed with pathology report consistent with clear cell renal carcinoma. Patient’s hematuria, proteinuria and skin rash resolved with surgical intervention. Creatinine remained stable in the 1.6-1.8 mg/dl range on discharge.

Discussion: Henoch-Schönlein purpura (HSP) is generally seen in the first decade of life. There have been a few cases of HSP presenting in adults due to underlying solid organ malignancies including renal cell carcinoma (RCC). Our case illustrates the importance of evaluating adults presenting with clinical findings of HSP for underlying malignancy. Treatment of underlying malignancy will improve vasculitis symptoms including renal parameters.

Exophytic and sepatated mass within superior pole of left kidney (Figure 1).

PO1522
A Case of Necrotizting Crescentic Glomerulonephritis due to ANCA Vasculitis and Fibrillary Glomerulonephritis
Munahal Nasim, 1 Faizan Babar. 1 Nishtar Medical College and Hospital, Multan, Pakistan; 2Nephrology Associates Lexington, Lexington, KY.

Introduction: Fibrillary Glomerulonephritis is a rare disorder thought to be idiopathic in nature. Cases of fibrillary GN have been associated with malignancy, monoclonal gammopathy, autoimmune disease, or infection. We present a unique case of fibrillary GN with pauc-immune crescentic GN due to Myeloperoxidase antibody (MPO) vasculitis.

Case Description: A 77 year old lady with history of well controlled diabetes, hypertension, congenital deafness, presented with weakness, fatigue & weight loss for four weeks. She was noted to have severe anemia with Hemoglobin of 6.6 g/dl, and presumed acute kidney injury. Her labs on admission were remarkable for creatinine 2.5mg/dl (unclear baseline creatinine), eGFR 25ml/min, potassium 5.3, Bicarbonate 16, Sodium 128. Urinalysis showed large blood and 1+ protein. The serological workup was positive for P ANCA 1:640, C ANCA 1:640, MPO ab and negative for PR-3 ANA, SREP. Free light chain ratio, HIV, Hepatitis panel. Endoecopy and Colonoscopy was negative for any obvious bleeding. Patient underwent renal biopsy which showed 7 out of 15 glomeruli with early fibrocellular crescents with fibrinoid necrosis, along with healing phase of necrotizing arteritis. Immunofluorescence didn’t show any preferrential staining for immunoglobulin, kappa or lambda. Electron microscopy showed mesangial mild non branching randomly arrayed thick fibrils with no immune complex type deposits. EM findings were confirmed by positive DNAJ-B9 stain. Patient received treatment with pulse dose steroids, two doses of rituximab 1 gm 14 days apart and continued on prednisone for slow taper with good renal response. Due to the findings of Fibrillary GN addition workup for lymphoproliferative disorder was done Whole body CT scan was negative but flow cytometry testing still pending.

Discussion: We present a unique case of fibrillary GN and pauci-immune crescentic GN with positive MPO antibodies. The significance of fibrillary deposits in this setting is unclear and usually not seen with pauci-immune crescentic GN. Fibrillary GN is a very rare diagnosis mostly thought to be idiopathic in nature. This unique presentation of fibrillary GN with ANCA vasculitis questions the current pathogenesis fibrillar GN and overall renal prognosis in association with glomerular pathologies like ANCA vasculitis.

PO1523
An Unexpected Clue in the Urinary Space: The Overlap Between IgA Predominant Staphylococcus aureus-Associated Glomerulonephritis and IgA Nephropathy: A Case Report
Luise J. Froessler, 1 Luan D. Truong, 2 Justin Merszei. 1 Baylor College of Medicine, Houston, TX; 2Houston Methodist Hospital, Houston, TX.

Introduction: There is significant histological overlap between IgA nephropathy (IgANP) and IgA predominant Staphylococcus-aureus associated glomerulonephritis (IgASAAGN). [1] [1] Satoskar et al., “Staphylococcus Infection-Associated Glomerulonephritis Mimicking IgA Nephropathy,” November 2006.

Case Description: Kidney biopsy was performed in a 60 yo male for an unexpected decline in kidney function. IgASAAGN was diagnosed on histology and foreign particles that were consistent with staphylococci were noted in the urinary space on electron microscopy. The patient was found to have methicillin-sensitive staphylococcus aureus (MSSA) pneumonia. Two months later, after a second decline in kidney function, IgANP was diagnosed on repeat kidney biopsy.

Discussion: This patient is diagnosed with two distinct conditions on pathology samples that show very similar histological findings. The presence of SA in the urinary space is a previously unreported finding. SA infection is known as the initiating factor for the development of IgASAAGN. Recent studies have also suggested SA cell envelope antigens as a new candidate for the induction of IgANP and antigens have been colocalized with IgA deposits in the glomeruli of affected patients. [2] SA infection and IgA deposition seem to play an essential role in the pathogenesis of both conditions, and the consideration that they may be two extremes of a disease spectrum could be considered. If the role of SA in the development of IgA nephropathy is confirmed, it may be of interest to explore the role of anti-staphylococcal antibiotics in the treatment regimen of IgANP. [2] Koyama et al., “Staphylococcus Aureus Cell Envelope Antigen Is a New Candidate for the Induction of IgA Nephropathy.”
PO1525
Diagnostic Dilemma: Glomerular IgG Deposit with Negative Anti-GBM Antibody
Sonali Gupta,1 Meenakshi Sambharia,1 Daniele G. Holanda,1 Elyas Safar,2 Y-Chen Huang,3 1The University of Iowa Hospitals and Clinics, Iowa City, IA; 2Blessing Hospital, Quincy, IL.

Introduction: Linear deposition of IgG along glomerular basement membrane (GBM) is hallmark of anti GBM glomerulonephritis. Subclass IgG 3 deposition is seen predominantly in these cases. Rare atypical anti-GBM cases have been described in literature as rare, indolent, no pulmonary involvement and undetectable antibodies. We describe a case of atypical anti GBM, four days after mRNA COVID vaccine.

Case Description: A 77-year-old male with history of hypertension presented with hypotensive emergency and acute kidney injury 4 days after first COVID vaccine (mRNA). Workup revealed sCr 2.6 mg/dl (1.5 mg/dl 1 month back), 3+ blood and 3+ protein by UA, normal C3, C4, ANA 1: 160, spot urine protein: creatinine- 2.2, serum albumin- 4g/dl. anti ds-DNA, ANCA and anti-GBM antibody was negative so was Hepatitis panel and HIV. Serum electrophoresis was negative for monoclonal protein. He did not have any pulmonary symptoms and CXR was negative for acute pathology. Renal biopsy was performed. LM: mild to moderate nodular mesangial expansion, mildly increased mesangial cellularity and focal segmental nodular mesangial sclerosis. IF showed positive linear global capillary loop staining with IgG (2+), with kappa (1+) and lambda (2+) co-staining. Trace mesangial IgM and granular C3 (trace+) are also noted in the peripheral capillary loops. EM showed diffuse foot process effacement. Few subepithelial, intramembranous and mesangial electron dense deposits were seen. Additional IgG subclasses IF showed positive linear glomerular staining for IgG1 (3+), IgG2 (1+), IgG4 (1+), negative for IgG3.

Discussion: Although no definitive active glomerular crescents or necrotizing lesions were seen, positive linear IgG staining in the glomerular capillary loops was concerning for atypical anti-GBM disease in setting of negative antibody and negative IgG3. A study looking at 20 atypical anti-GBM patients found that 1 year patient and renal survival was 93% and 85% respectively. A few patients in this study had biopsy findings of DFPE and sub-epithelial deposits like ours. There have been few reports of COVID vaccine unmasking glomerulonephritis. However, it needs further investigation.

PO1526
Rapidly Progressive Glomerulonephritis due to Crescentic IgA Nephropathy in the Setting of HIV

Introduction: In patients with HIV-related kidney diseases, the most widely recognized histological abnormality is focal segmental glomerulosclerosis (FSGS). Less commonly found is IgA nephropathy in HIV patients, which tends to have a chronic stable course. We report a case of crescentic IgA nephropathy and FSGS in a patient with rapidly progressive glomerulonephritis and newly diagnosed HIV.

Case Description: A 34-year-old transgender woman with a history of alcohol use disorder presented with a petechial rash and lower extremity edema for 1 week, and was found to have a new diagnosis of HIV with an elevated creatinine. CD4 count was 143 and viral load was 103,774, and she was started on ritonavir-boosted atazanavir, emtricitabine. Creatinine on admission was 1.27 mg/dl (baseline 0.7), and increased over the next several days to 5.3. Urine microscopy revealed dysmorphic RBCs and granular casts, with spot urine protein:creatinine 2.3. Renal biopsy demonstrated crescentic IgA nephropathy (Oslo classification M1 E1 S1 T1 C2) with concomitant FSGS (NOS subtype). Cellular crescents were seen in 4/7 glomeruli (figure 1), mesangial and endocapillary hypercellularity in all non-sclerotic glomeruli, and FSGS in 2/7 glomeruli. Immunofluorescence showed strong granular segmental mesangial staining for IgA (3+) and C3 (3+), and was otherwise negative. She was started on pulse-dose steroids (methylprednisolone 500mg x 3 days followed by 1 mg/kg x 2 weeks), as well as plasmapheresis every other day for 5 sessions. Her renal function had not improved by the time of discharge.

Discussion: To our knowledge this is the first reported case of IgA-induced RPGN in the setting of newly diagnosed HIV. A few prior case reports describe stable IgA nephropathy in individuals with HIV, suggesting that there may be some unifying pathogenesis. This case highlights the need for investigation of this potential mechanism, which may help determine the optimal therapy for IgA nephropathy and IgA-induced RPGN in the setting of HIV.
Features and Outcomes of Patients with C1q Nephropathy in the NEPTUNE and CureGN Cohorts: Comparisons to Minimal Change Disease and Focal Segmental Glomerulosclerosis

Scott E. Wenderfer,1,2 Maria Larkina,1 Mir Reza Afzal,1 Clarissa A. Cassol,1 Carmen Avila-Cassado,1 Laura Barisoni,3 William E. Smoyer,4,5 Laura H. Mariani,1 Baylor College of Medicine, Houston, TX; Texas Children’s Hospital, Houston, TX; University of Michigan, Ann Arbor, MI; Arkana Laboratories, Little Rock, AR; University Health Network, Toronto, ON, Canada; Duke University, Durham, NC; Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH.

Background: Predominant immunostaining for C1q distinguishes a subset of patients with primary glomerular disease. C1q nephropathy (C1qN) has been proposed but not universally accepted as a distinct glomerular disease. This study describes clinical characteristics and short-term outcomes of patients meeting the provisional CureGN definition of C1qN, including comparisons to patients with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) without C1qN.

Methods: MCD and FSGS patients with C1qN were identified from the Cure Glomerulonephropathy Network (CureGN) and NEPTUNE cohorts. Comparisons were made to MCD and FSGS patients without C1qN, based on age, disease, and time since kidney biopsy, using 5-to-1 matching. We performed cross-sectional analyses of clinical and treatment data at enrollment and a longitudinal analysis of disease course.

Results: A total of 42 patients met the provisional CureGN definition for C1qN (16 adults >18yo, 11 teens 12-18yo, and 15 children <12yo), including 15 with MCD and 27 with FSGS. Those with C1qN were more commonly female (60 vs 49%, p=0.2) and black (34 vs 27%, p=0.4). At enrollment, those with and without C1qN had comparable kidney function (eGFR 90 vs 88 mL/min/1.73m², p=0.8). Individuals with C1qN were equally likely to have been treated with steroids or other immunosuppressive therapy (76 vs 81%, p=0.4) and to have ever achieved complete remission of proteinuria (defined as uPCR ≤0.3) (54 vs 65%, p=0.2). Median time to last follow-up was 3.1 yrs (IQR 1.9, 4.4) from enrollment and 4.8 yrs (IQR 3.3, 6.5) from biopsy date. While proportions with kidney failure were higher for FSGS compared to MCD (14 vs 1%, p=0.01), they were similar between patients with and without C1qN (7 vs 10%, p=0.6). There was a trend towards steeper GFR slope in C1qN patients (-4.8 vs -0.2 mL/min/yr, p=0.06).

Conclusions: FSGS and MCD patients with and without C1qN have comparable demographics and short-term outcomes in CureGN and NEPTUNE. Outcomes do not appear to be biased by differences in immunosuppressive therapies. Further interrogation of genetic and molecular profiles between patients with and without C1q immunostaining on biopsy may be more informative.

Morphologic Descriptors Most Predictive of Clinical Outcomes in Minimal Change Disease and FSGS

Jarey Zee,1 Qian Liu,4 Abigail R. Smith,1 Laura H. Mariani,1 Jeffrey B. Hodgkin,2 Brenda W. Gillespie,2 Laura Barisoni,1 Lawrence B. Holzman.1 University of Pennsylvania, Philadelphia, PA; University of Michigan, Ann Arbor, MI; Duke University, Durham, NC; Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Previous studies applying the NEPTUNE Digital Pathology Scoring System (NDPSS) uncovered the value of kidney tissue features for clinically relevant patient subcategorization. This study aims to identify ultrastructural descriptors most predictive of clinical outcomes in NEPTUNE patients.

Methods: 39 glomerular, 9 tubulointerstitial, 2 vascular, and 20 ultrastructural descriptors were quantified using the NDPSS on 39 MCD, 61 MCD-like, and 124 FSGS NEPTUNE digital kidney biopsies. Outcomes included time from biopsy to disease progression (kidney failure or a 40% eGFR decline with eGFR ≤90) and first complete remission (CR) of proteinuria (uPCR ≤0.3). Relative importance of descriptors for prediction of outcomes was obtained from random forest models, without adjusting for clinical features.

Results: The mean age, eGFR and UPCR at biopsy for the total 224 participants was 28.8, 85.2, and 5.4, respectively. Model performance was excellent (predictive discrimination = 0.902 for disease progression and 0.853 for CR). Most predictive descriptors included conventional (e.g., global sclerosis or segmental sclerosis, and interstitial fibrosis/tubular atrophy) and unconventional features [Fig.]. Top 10 predictors included inflammation, podocyte abnormalities, and acute tubular injury for both outcomes; deflation, interstitial foam cells, and collapse for disease progression; and endothelial cell abnormalities, hyalinosis, and periglomerular fibrosis for CR.

Conclusions: Most predictive descriptors of proteinuric glomerulopathies reflected structural changes in various renal compartments. Reporting these descriptors should be standardized to guide the subcategorization of proteinuric glomerular diseases and improve targeted clinical care.

Natural History of Focal Segmental Glomerulosclerosis (FSGS): The UK National RaDaR Idiopathic Nephrotic Syndrome Cohort

Moin Saleem,1,2 Jonathan Barratt,1,4 Fiona E. Braddon,5,6 Kevin Carroll,1 Ullyses A. Diva,1 Maryam Afsal,1 Bruce M. Hendry,3 Alex Mercer,10 David Pitcher,1,2 Retha D. Steenkamp,1,3 A Neil Turner,1 Daniel P. Gale,1,2 1University of Bristol, Bristol, United Kingdom; 2Bristol Royal Hospital for Children, Bristol, United Kingdom; 3University of Leicester, Leicester, United Kingdom; 4Leicester General Hospital, Leicester, United Kingdom; 5University of Edinburgh, Edinburgh, United Kingdom; 6JAMCO Pharma Consulting, Stockholm, Sweden; 7KLC Statistics Ltd, Cheshire, United Kingdom; 8The Renal Association, Bristol, United Kingdom.

Background: Idiopathic FSGS is an important cause of proteinuric renal disease leading to ESKD. Here we describe the natural history of FSGS using the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort, including retrospective and prospective data from 3907 patients with nephrotic syndrome (NS) not attributable to glomerulonephritis or systemic disorders recruited from 107 adult and paediatric kidney units across the UK since 2010.

Methods: Participants included those with biopsy-proven or monogenic FSGS and ≥12 mo. observation from baseline. Patients with ESKD (CKD stage 5 or on renal replacement therapy) at or prior to baseline were excluded. Baseline date was defined as first database occurrence of renal biopsy, primary renal diagnosis, NS symptoms, PCR ≥1 g/g, or initiation of immunosuppression. Renal survival was defined as absence of ESKD or death with survival time calculated from baseline to last follow-up.

Results: Of 786 FSGS patients meeting eligibility, median baseline age was 28 yrs (IQR 13-49) with paediatric patients representing 38% of the study population. Median proteinuria at baseline was 5.9 g/g (IQR 3.3-11.0; n=140), while mean eGFR was 163 mL/min/1.73m² (SD 47; n=69) and 71 mL/min/1.73m² (SD 32; n=103) for children and adults, respectively. Median follow-up duration was 9.7 yrs (IQR 5.7-16.1) with ESKD/death events occurring in 46% of patients (1% death). Kaplan-Meier survival curves of children and adults show 50% renal survival probability of 16 yrs & 12 years, respectively (Figure 1).

Conclusions: The RaDaR-INS Cohort represents a large study population with lengthy follow-up data. These analyses indicate rapid progression and poor outcomes, highlighting a need for effective treatments for patients with FSGS.

Proteinuria End Points and Associations with Renal Survival in FSGS: Analysis of the UK National RaDaR Idiopathic Nephrotic Syndrome Cohort

Moin Saleem,1,2 Jonathan Barratt,1,3 Fiona E. Bradson,1,3 Kevin Carroll,3 Ulysses A. Diva,3 Bruce M. Hendry,4 Alex Mercer,2 David Pitcher,3 Retha D. Steenkamp,4 Amy Neil Turner,1 Daniel P. GALE,1,5 University of Bristol, Bristol, United Kingdom; 6 Bristol Royal Hospital for Children, Bristol, United Kingdom; 7 UK Renal Registry, Bristol, United Kingdom; 8 Royal Free Hospital, London, United Kingdom; 9 University College London, London, United Kingdom; 10 Travere Therapeutics Inc, San Diego, CA; 7 JAMCO Pharma Kingdom; 9 University of Leicester, Leicester, United Kingdom; 10 Leicester

Background: In patients with FSGS, severity of proteinuria (PU) at onset and during follow up is associated with renal failure. In this study, we tested for associations between defined PU endpoints and renal survival in patients with FSGS from the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort.

Methods: A total of 225 biopsy-proven or monogenic FSGS pts met study eligibility criteria, including a nephrotic PU value (>3.5 g/g), a follow-up PU within 6-12 mo. and no ESKD (eGFR <15 mL/min/1.73m^2) or renal replacement therapy or death prior to first PU follow-up. Baseline pertains to first nephrotic PU value (T0 for survival analyses). Applied PU responder/non-responder definitions are described (Table 1). Time to ESKD/death was analysed using accelerated failure time modelling of the Weibull distribution.

Results: Within 6-12 mo. from baseline, 63% of patients achieved complete or partial remission of PU, at a mean time of 5.09 months (range 1-31 months). Clinical meaningful increases in time FSGS patients are alive and free from ESKD. (Table 1) independent of initial PU level. Further analyses are ongoing.

Conclusions: Achieving partial or complete remission of PU is associated with clinically meaningful increases in time FSGS patients are alive and free from ESKD.

Clinicopathological Characteristics of Adult Patients in the United States with Focal Segmental Glomerulosclerosis (FSGS)

Katherine R. Tuttle,1 Clint Abner,2 Kerime Ararat,2 Patrick D. Walker,2 Amin Yakubu,3 Martin C. Bunke,2 University of Washington, Spokane, WA; 2Arkana Laboratories, Little Rock, AR; 3Genesis Research, LLC, Hoboken, NJ; 4Travere Therapeutics Inc, San Diego, CA.

Background: Focal segmental glomerulosclerosis (FSGS) is a common histopathologic lesion of glomerular injury in patients with nephrotic syndrome. These analyses characterize clinical and histological features of FSGS in adults at time of kidney biopsy.

Methods: A retrospective study was performed using data from the Arkana Biopsy Database (January 1, 2016 to May 31, 2020) in patients that met study criteria, which included: ≥18 yrs, ≥1 FSGS positive kidney biopsy, and no prior kidney transplant, and available data on race/ethnicity. Outcomes included clinical and histologic characteristics. eGFR was calculated using CKD-EPI-creatinine equation without race modifier.

Results: Of 64,105 adult kidney biopsies performed during the study period, 2,065 (3.2%) FSGS positive cases were identified and 1,482 pts (71.8%) evaluated met study criteria. Demographic characteristics included: 56.2% male, 55.1% White, 32.1% African American (AA), 7.7% Hispanic and 3.4% Asian. Overall mean (SD) age at biopsy was 49.0 (17.2) with older ages in Whites (52.8 (17.3) yrs) and younger ages in Hispanics (39.4 (15.8) yrs). Mean urine protein to creatinine ratio was similar by race/ethnicity (range 5.1-6.0 g/g). Asians were more frequently biopsied at eGFR Stage 4 (32.7%) compared to other race/ethnicity groups (29.0% for As131.1) and lowest in Whites (14.6%). Whites (51.9%) and Asians (39.7%) exhibited the highest rates of severe foot process effacement (a80%), while interstitial fibrosis and tubular atrophy ≥50% was more common in As13 (34.6%) compared to Hispanics (27.2%), Asians (17.7%) or Whites (14.2%). Of all FSGS types, “not otherwise specified” was most common across all race/ethnicity groups (range 64.2-75.4%). Among other FSGS types, tip lesion was most frequent in Whites (21.5%) and collapsing was most frequent in AA patients (12.4%).

Conclusions: Non-White patients are more frequently diagnosed with FSGS at later CKD stages with advanced GS. Strategies to improve earlier awareness and detection of FSGS are needed to allow effective intervention before severe kidney damage has occurred.

PO1532

Long-Term Outcomes of Patients with Focal and Segmental Glomerulosclerosis Treated with Tacrolimus

Mukunthan Srikantharajah,1 Thomas M. Connor,1 Jeremy B. Levy,1 Stephen P. McAdoo,1 Megan Griffith,1 Imperial College Healthcare NHS Trust, London, United Kingdom; 2Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.

Background: Tacrolimus (TAC) is used to treat Focal and Segmental Glomerulosclerosis (FSGS). Prolonged treatment is often required and there is little data on long-term outcomes.

Methods: This is a retrospective study of 29 patients who received TAC as first line immunosuppression for nephrotic syndrome (NS) secondary to FSGS from December 2007 to January 2020 at our institution.

Results: Mean follow up was 59.6 months (12 – 144). The mean age at diagnosis was 42 years (range 18-85). 52% were Male. 59% were White, 10% Black, 21% Asian, 3% Chinese, 7% Other. Baseline mean eGFR was 64 mL/min (18-90). 23/29 (79%) obtained complete (CR) or partial remission (PR) of NS, at a mean time of 5.09 months (range 1-31 months). 6/29 (21%) did not enter remission with TAC. 2/6 subsequently achieved
remission with CyP and prednisolone/rituximab. 7/23 (30%) patients who achieved remission with TAC had at least one relapse. 4/7 after stopping TAC, 1/7 during TAC wean and 2/7 with therapeutic TAC levels. 4/7 were treated by restarting or increasing TAC, 1/7 also had steroids added, 1/7 received rituximab (achieving remission) and 1/7 was not further treated with immunosuppression. 4/4 restarted with TAC monotherapy reached remission. 16/23 (70%) patients did not relapse and 7 of these remain off TAC and in remission (mean follow up of 92.6 months). At 1 year, the mean eGFR was 67.4 ml/minute (21-90). 1/29 patient developed end-stage kidney disease (ESKD) at 2 months. This patient had not responded to TAC, 16 patients have 5-year-follow up. The mean eGFR was 66.5 ml/minute (11-90). 1 further patient developed ESKD (this patient had not responded to TAC nor subsequent immunosuppression). 4 patients have 10-year follow-up. The mean eGFR was 80.8 ml/minute (67-90). 3 further patients developed ESKD. 1/3 had achieved PR, 1/3 had achieved CR but had multiple relapses despite re-treatment and 1/3 had CR but defaulted from follow up, presenting with ESKD 6 years later.

Conclusions: The long-term data from this study suggests tacrolimus can be effective in both achieving and maintaining remission of NS in FSGS. CR is associated with good long-term outcomes in most patients although relapse can occur and long term careful follow up is required. Non-responders have a worse outcome, although some patients do respond to alternative immunosuppression.

PO1533
Collapsing FSGS in a Patient with Acute Myeloid Leukemia and Prior COVID-19 Infection
Surva Manipannan, Stephanie S. Pavlovich, Irshadhahan Malek, Koyal Jain.
University of North Carolina System, Chapel Hill, NC.

Introduction: Collapsing focal segmental glomerulosclerosis (c-FSGS) has been independently associated with COVID-19 infection, acute myeloid leukemia (AML), and apolipoprotein L1 (APOL1) risk variants. We describe a patient with homozygous APOL1 G1 risk allele and AML who developed renal failure due to c-FSGS and acute tubulointerstitial nephritis.

Case Description: A 25-year-old male with a history of mild asthma and COVID-19 infection 1 month prior presented with a 3-week history of severe fatigue, weight loss, persistent dyspnea, and fever. He was found to have leukopenia, thrombocytopenia, an acute kidney injury, and nephrotic range proteinuria. The patient was diagnosed with AML by bone marrow biopsy (BMBx). At presentation, his serum creatinine was 2.8 mg/dL, which rapidly increased to 6.9 mg/dL over 2 weeks. Urine protein/creatinine ratio (UPC) was 3.4g/g on admission. Renal biopsy demonstrated c-FSGS (Figure) and diffuse acute tubular injury. He was treated with standard remission induction therapy for AML with cisplatin and cytosine arabinoside (7+3 therapy) (7-day continuous infusion of cytarabine, daunorubicin on days 1-3, and high dose steroids). High dose steroids were continued for 2-FSGS treatment with plan for a slow taper over several months. Within a few days of starting 7+3 treatment, his renal function began to improve. His 14-day BMBx demonstrated a hypocellular marrow consistent with complete remission. After 1 month, his creatine improved to 1.0 mg/dL, along with improvement in his serum albumin. Repeat UPC is pending.

Discussion: COVID-19 is associated with immunologic alterations precipitating c-FSGS, especially in patients with APOL1 high risk alleles. Additionally, FSGS has been reported in AML, but the etiology behind glomerular pathologies in AML is unclear and likely multifactorial. Studies have indicated immunologic dysregulation related to leukemia, as well as viral-related etiologies. The trigger for c-FSGS in our patient is uncertain.

Light microscopy demonstrated focal and segmental glomerulosclerosis with global and segmental collapse.

Role of LDL-Apheresis in Management of Glucocorticoid-Resistant Minimal Change Disease
Dharia P. Shah, Aila A. Tyagi, Jason Prosek, Eshtetu L. Obote.
The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Minimal Change Disease (MCD) is described as diffuse podocyte foot process effacement on kidney biopsy, resulting in nephrotic proteinuria, >3 grams/day. Glucocorticoids (GC) are the mainstay of therapy and most patients achieve complete remission in a few months. 7-12% patients, however, have GC-resistance and thus limited treatment options. Often, they are suspected of having focal segmental glomerulosclerosis (FSGS) due to biopsy sampling error. We present a challenging case of GC-resistant MCD, managed with immunosuppression, and ultimately lipid (LDL) apheresis.

Case Description: An otherwise healthy 20-year-old male presented for sudden onset lower extremity swelling and 10-pound weight gain. Work up including ANA, C3, C4, p-ANCA, c-ANCA, serum and urine immunofixation and renal ultrasound were unremarkable. Notably, LDL was 390 mg/dL, proteinuria of 9 grams/day and serum creatinine (Scr) of 0.96 mg/dL. Kidney biopsy revealed diffuse podocyte effacement, consistent with MCD. He was treated with oral prednisone 1 mg/kg/day and diuretics for several weeks with minimal symptomatic improvement and had worsening kidney function, Scr 1.5 mg/dL and proteinuria of 36 gms/day. Unfortunately, he also contracted COVID-19 disease prior to second kidney biopsy. Repeat kidney biopsy revealed acute tubular necrosis along with widespread podocyte effacement, without sclerotic lesions, ~10% interstitial fibrosis and tubular atrophy. He was empirically treated with tacrolimus for FSGS. However, proteinuria continued to worsen and peaked at 83 gms/day. Ultimately diagnosed as GC-resistant MCD, he was weaned off steroids, he was referred for LDL-apheresis therapy. He is maintained on tacrolimus and LDL apheresis with symptomatic improvement, still has significant proteinuria of 67 gms/day and advanced chronic kidney disease (CKD).

Discussion: The exact pathophysiology of nephrotic syndromes is unclear, mechanisms of T-cell dysfunction causing production of glomerular permeability factor and nephrotoxic hyperlipidemia have been described. In cases of GC-resistant diseases, immunosuppression has only been partially successful. LDL-apheresis has a role in the management of such nephrotic syndromes, thought to reduce circulating lipid induced disruption of podocyte integrity, and help prevent decline of kidney function and decrease proteinuria as seen in this patient.
PO1536
Antiphospholipase A2 Receptor Antibody Levels in Asian Patients with Primary Membranous Nephropathy: A Territory-Wide Study
Desmond Y. Yap, Irene Yan, Michelle Lam, Hemlata Bisnauthsing, Tak Mao D. Chan. University of Hong Kong, Hong Kong, Hong Kong.

Background: Different cut-off values of antiphospholipase A2 receptor (anti-PLA2R) antibody for differentiating between primary membranous nephropathy (PMN) and secondary membranous nephropathy have been reported. The optimal anti-PLA2R level to reflect disease activity states in Asian patients with PMN remain undefined.

Methods: We conducted a territory-wide study in Hong Kong to investigate the sensitivity and specificity of anti-PLA2R levels in Chinese patients with PMN in the period of 2015-2020. Anti-PLA2R levels were measured by commercial ELISA kits (Euroimmun, Germany) in serum samples collected from biopsy-confirmed PMN patients during active disease or remission, and their predictive values for active PMN were evaluated.

Results: Forty and six serum samples from 320 PMN patients were analysed. 319 samples were obtained during active disease and 87 during disease remission. Anti-PLA2R titres during active diseases were significantly higher than that during remission (95.1±235.0 RU/mL vs 19.8±39.9 RU/mL respectively, p<0.001). Using 20 RU/mL as cut-off, the sensitivity and specificity was 39% and 96% respectively; positive predictive value (PPV) and negative predictive value (NPV) were 92% and 30% respectively. Using 10 RU/mL as cut-off, the sensitivity and specificity was 46% and 95% respectively; AUC (0.71, p<0.001; PPV and NPV were 97% and 32% respectively). Anti-PLA2R titres correlated with urinary-protein-to-creatinine ratio and 24-hr urine protein levels (r=0.32 and 0.37 respectively, p<0.001).

Conclusions: Anti-PLA2R showed good SP and PPV prediction for active PMN in Chinese patients, and correlated with severity of proteinuria. A lower threshold (≤10 RU/mL) may show improved SN for predicting active PMN in Asian patients.

PO1537
Qualitative and Quantitative Dosage of the Anti M-Type Phospholipase A2 Receptor Autoantibody: One-Year Experience in Quebec’s Reference Center
Simon Leclerc,1,2 Karim Benkirane,3,4 Caroline Lamarche,2 Jean-Philippe Lafrance,1,2 Annie-Claire Nadeau-Fredette,1 Virginie Rolin,1,2 Vincent Pichette,1,2 Louis-Philippe Laurin,1,2 Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 1Université de Montreal, Montreal, QC, Canada.

Background: Dosage of the M-type phospholipase A2 receptor antibody (anti-PLA2R) is now an essential tool for diagnosis and management of primary membranous nephropathy (MN). Since October 2018, Hôpital Maisonneuve-Rosemont (HMR) has been designated as Quebec’s reference center for serum anti-PLA2R antibody testing by the Institut National d’Excellence en Santé et Services Sociaux (INESSS), the regulatory body on drugs and tests usage in Quebec.

Methods: All patients who had a serum anti-PLA2R antibody testing performed at HMR from October 1, 2018 to October 1, 2019 were included in the study. Serum anti-PLA2R antibodies were screened by a qualitative test, followed by a quantitative test if the results were undetermined or positive. We calculated sensitivity, specificity, predictive value, and likelihood ratio for both tests, using kidney biopsy findings as the gold standard.

Results: In the province of Quebec, a total of 1690 tests were performed among 87 PLA2R-ab positive patients. Among the qualitative test, the sensitivity, specificity, positive and negative predictive value were 58% and 100% respectively, whereas the net positive and negative likelihood ratio was 0.58. Among the quantitative test, the sensitivity, specificity, positive and negative predictive value were 71% and 100% respectively, whereas the net positive and negative likelihood ratio was 7.65.

Conclusions: The qualitative and quantitative test can be efficiently used to avoid quantitative testing in negative patients and to better characterize undetermined results on immunofluorescence. Measurement of podocyte-specific mRNA in patients’ urine samples and live cell assays should be integrated in making a safe diagnosis of THSD7A-ab without the need of a kidney biopsy.

PO1538
Clinical Relevance of NELL1 Antibodies in Patients with Membranous Nephropathy
Linda Reinhard,1 Cindy Thomas,2 Maya Macalitiza,1 Erik Lattwein,1 Lothar S. Weiß1, Jan Vitu,3 Thorsten Wiech,1 Rolf A. Stahl,1 Elion Hoxha,1,2Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany; 3Medizinisches Versorgungszentrum Hamburg-Sinstorf der MVGmbH der PHV, Hamburg, Germany.

Background: PLA2R and THSD7A-antibodies (ab) are considered to be specific for the diagnosis of membranous nephropathy (MN). There is a controversial discussion whether the detection of circulating PLA2R- or THSD7A-ab is sufficient to diagnose MN, without the need of a kidney biopsy.

Methods: Circulating THSD7A-ab were detected and their specificity evaluated by an indirect immunofluorescence test (IFT), reducing, non-reducing and native Western blot analyses as well as by the diagnosis of membranous nephropathy (MN) using immunohistochemistry and electron microscopy.

Results: A patient presented with high level proteinuria and was tested positive for THSD7A-ab using IFT. Except for the diagnosis of diabetes mellitus, the medical history of the patient was unremarkable. Because of persistent proteinuria and a decline of kidney function, a kidney biopsy was performed, showing the diagnosis of diabetic nephropathy and excluding MN. A detailed biochemical characterization of the THSD7A-ab was performed to clarify these discrepancies between the serological and histomorphological findings. The circulating THSD7A-ab from the serum of the patient bound to recombinant THSD7A in the IFT, co-localizing with THSD7A in co-immunofluorescence staining experiments and reacted with purified THSD7A in reducing WB analyses. However, these antibodies did not bind THSD7A derived from human glomerular tissue in any of the experimental conditions (reducing, non-reducing, native). Moreover, the circulating THSD7A-ab did not recognize recombinant THSD7A under native conditions in the native Western blot or live cell assay. In contrast, THSD7A-ab from MN patients recognized native THSD7A in all experiments.

Conclusions: Measurement of podocyte-specific mRNA in patients’ urine samples and live cell assays should be integrated in making a safe diagnosis of THSD7A-ab positive MN.

PO1539
Non-Pathogenic THSD7A Antibodies in a Patient with No Membranous Nephropathy
Linda Reinhard,1 Cindy Thomas,2 Maya Macalitiza,1 Erik Lattwein,1 Lothar S. Weiß1, Jan Vitu,3 Thorsten Wiech,1 Rolf A. Stahl,1 Elion Hoxha,1
1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany; 3Medizinisches Versorgungszentrum Hamburg-Sinstorf der MVGmbH der PHV, Hamburg, Germany.

Background: PLA2R- and THSD7A-antibodies (ab) are considered to be specific for the diagnosis of membranous nephropathy (MN). Here, we studied the association of NELL1-ab in MN diagnosis, a malignant tumor was identified in 2 (11%) NELL1-ab positive, 7 (6%) PLA2R-ab positive patients or MN patients with known target antigen. Age range 70 to 58 years (mean 67 years). 4 patients had a history of MN diagnosis, a malignant tumor was identified in 2 (11%) NELL1-ab positive, 7 (6%) PLA2R-ab positive, 3 (30%) THSD7A-ab positive and 7 (10%) MN patients without known target antigen. 14 NELL1-ab positive patients were observed over a median following period of 75 months. One patient presented with GFR < 30 ml/min due to severe hypertensive and diabetic kidney damage and developed ESKD after 69 months. All other 13 patients had a remission of proteinuria. 12 (92%) patients had a complete remission, although only 4 patients received an immunosuppressive therapy. Remarkably, of the 7 NELL1-ab positive patients with complete remission of proteinuria, 4 patients had persistent NELL1-ab in the circulation over the whole observation period and 2 patients reached complete remission of proteinuria before NELL1-ab disappeared. Renal function was stable in NELL1-ab positive patients but showed a more pronounced decline in NELL1-ab negative patients.

Conclusions: NELL1-ab positive MN patients had slightly more often a malignant tumor, but also were significantly older compared to PLA2R-ab positive patients. Overall, NELL1-ab positive patients had a good prognosis. The presence of NELL1-ab in the serum did not show a close association with disease outcome.

PO1540
Urinary NPHS2-mRNA in Relation to Glomerular and Tubular Damage Markers in Patients with Membranous Nephropathy
Bartholomeus T. van den Berge,1,2 Anne-Els van de Logt,1 Jitske Jansen,1,3 Bart Smeele,1 Johan Van der vlag,1 Jack F. Wetzels,1 Rutger J. Maas,1,31Radboudumc Afdeling Nierziekten, Nijmegen, Netherlands; 2Radboudumc Afdeling Pathologie, Nijmegen, Netherlands; 3Radboudumc Afdeling Kindergeneeskunde, Nijmegen, Netherlands.

Background: Measurement of podocyte-specific mRNA in patients’ urine samples has been proposed as a novel tool to monitor podocyte loss in glomerular disease, and may have prognostic value. In our hospital, we routinely measure timed urinary excretion of high- and low-molecular weight proteins as prognostic markers in patients with membranous nephropathy (MN). Here, we investigated the relationship between NPHS2-mRNA and high- and low-molecular weight proteins in patients with MN.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We included 35 patients with MN (80% male, median age 67, median eGFR 63). NPHS2-mRNA was measured in urine pellets as described by Wickman et al. (JASN 2013). Normal values of urinary NPHS2-mRNA were obtained in spot urine samples of 19 healthy controls.

Results: Clinical characteristics and results of urinary measurement are shown in Table 1. Mean urinary NPHS2-mRNA/creatinine ratio (UPodCR) was 64 fold higher in patients with MN versus healthy controls. UPodCR showed weak but significant correlations with urinary IgG excretion and proteinuria selectivity index (Figure 1), but not with total proteinuria or GFR (Table 1).

Conclusions: Urinary excretion of NPHS2-mRNA correlated significantly with protein markers of glomerular damage in patients with MN. However, correlations were weak. Prospective studies are needed to evaluate if urinary NPHS2-mRNA excretion holds independent prognostic value.

Table 1. Characteristics of patients with membranous nephropathy (N=35)

PO1542 Use of Urinary Proteins as Predictors of Response to Immunosuppressive Treatment in Membranous Nephropathy

Lagou, Andraea,1 Jason K. Vickman,1 Shane A. Bobat,a Lisa E. Vaughan,1 John C. Lieske,1 Ladan Zand,1 Eddie L. Greene,1 Sanjeev Sethi,1 Daniel C. Cattran,1,5 Fernando C. Fervenza,1,2 Mayo Clinic Minnesota, Rochester, MN; 2Toronto General Hospital, Toronto, ON, Canada; 3Cleveland Clinic Florida, Weston, FL.

Background: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in adults. The outcome of patients with MN is highly variable and clinical parameters do not reliably identify which patients will respond to immunosuppressive therapy (IS). In the MENTOR trial >40% of subjects did not achieve complete or partial remission (CR/PR) of proteinuria by 12 months after treatment with rituximab (500 mg/m²) or cyclosporine. The treatment outcome was defined as patients achieving either complete (CR; <0.3g/24 hours) or partial remission (PR; 0.3-3.5g/24 hours) of proteinuria at 12 months.

Methods: Logistic regression models were used to study the relationship between baseline urinary proteins with patients’ treatment outcomes by treatment drug (rituximab or cyclosporine). The treatment outcome was defined as patients achieving either complete (CR; <0.3g/24 hours) or partial remission (PR; 0.3-3.5g/24 hours) of proteinuria at 12 months.

Results: In both cyclosporine and rituximab arm, all urinary proteins exhibited a decline from baseline to 12 months post treatment. However, none of the baseline urinary proteins were found to be significantly associated with treatment response at 12 months (p>0.05 for all). Results were similar when restricted to patients with positive anti-PLA2R at baseline.

Conclusions: Baseline measures of the urinary albumin, uIgM, uIgG, and uα1m are not predictors of patients going into CR or PR at 12 months after treatment with rituximab or cyclosporine.

Table 1: Odds ratio of urinary protein predicting CR or PR at 12 months in patients treated with Rituximab or Cyclosporine (Fully Adjusted model)

PO1543 APOL1 High-Risk Genotype Is Associated with Worse Renal Outcomes in Black Patients with Membranous Nephropathy

Dhruvit P. Chen, Candace D. Henderson, Claudia Aiello, Yichun Hu, Susan L. Hogan, Ronald J. Falk, University of North Carolina System, Chapel Hill, NC.

Background: Black patients have a higher propensity for progression to end-stage kidney disease (ESKD) and this disparity persists in glomerular diseases studied thus far. Genetic variants in the Apolipoprotein L1 (APOL1) gene contribute to kidney disease burden in those with African ancestry. To date, there are no data on the role of APOL1 risk alleles in outcomes among black patients with membranous nephropathy (MN).

Methods: Sanger sequencing for APOL1 risk allele genotyping was completed on patients of African-American ancestry (self or clinician reported) with diagnosis of MN enrolled in the Glomerular Disease Collaborative Network (GDCN) or Cure Glomerulonephropathy Network (CureGN) with DNA samples available were included.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
White patients from CureGN were included for comparison. Data from CureGN or chart abstraction for GDCN patients were used to determine demographics, diagnosis, disease onset, and ESKD (dialysis initiation or transplantation). Fisher’s exact, Wilcoxon rank, and Kaplan-Meier curves with log rank tests were used to evaluate differences between high risk (2 variants) and low risk (0/1 variant) and white population.

Results: There were 106 African American patients with diagnosis of MN in our study. Of these, 15 patients (14%) were high risk (two risk alleles of APOL1) and the remaining 91 patients (86%) were low risk (0/1 risk alleles of APOL1). Data were available for 493 white patients. Hazard ratio for composite outcome of ESKD/death was 4.21 (95% CI 1.54,11.51) among African Americans (high risk vs. low risk) and 6.37 (95% CI 2.74, 14.80) compared to white population. Time to endpoint was significantly faster in those with high risk APOL1 genotype (Figure), p<0.0001.

Conclusions: High-risk APOL1 genotype in African Americans is associated with faster time to ESKD/death compared to low-risk AA or white patients with MN.

PO1544
Treatment-Resistant Membranous Nephropathy in a Patient with NPHS2 Mutation

Ioana Ailincai, Gabriela Lupusor, George C. Costea, Georgiana Fratila, Oana Ion, GeorGener Ismail. Fundeni Clinical Institute, Bucharest, Romania

Introduction: Membranous nephropathy (MN) is one of the most frequent causes of nephrotic syndrome (NS) in adults. NPHS2 gene encodes podocin, a protein of the slit diaphragm that is essential for recruitment of nephrin into the lipid rafts and for maintaining the glomerular filtration barrier. Recessively transmitted mutations in NPHS2 cause familial forms of steroid-resistant NS that progress to end-stage renal disease (ESRD).

Case Description: A 37-year-old male was referred to our clinic with NS and hypertension. Admission labs showed creatinine of 3 mg/dl, serum albumin of 3 g/dl, proteinuria of 20 g/dl and microscopic hematuria (30 cells/µl). Immunological testing – ANA, ANCA, anti-C1q, anti-GBM – was negative, C3 and C4 were normal. Kidneys appeared normal on ultrasound examination. A renal biopsy was performed. Light microscopy revealed 19/23 glomeruli with global sclerosis and 4/23 glomeruli with thickening of GBM, podocyte hypertrophy and segmental sclerosis; there was also diffuse tubular atrophy, interstitial fibrosis and arteriolar hyalinization. Electron microscopy showed subepithelial electron dense deposits with spike formation, with granular capillary loop staining for IgG in immunofluorescence. The histopathological diagnosis was stage II MN associated with diffuse glomerulosclerosis secondary to hypertension. In the meantime, the anti-PLA2R antibodies returned positive (titer 1:320). Therapy was started with Rituximab 1000 mg; a second dose was administered after 14 days. Despite treatment, NS persisted and kidney function worsened; hemodialysis was initiated 6 months after the diagnosis. One year later, the patient’s 16-year-old son was diagnosed with NS, resistant to steroids. Genetic testing identified NPHS2 c.947C>T p.(Pro316Leu) inherited from the mother.

Discussion: Recent data support an important role of genes in the pathogenesis of MN. NPHS1 polymorphisms are associated with low remission rate after treatment and high disease progression. Our patient has a heterozygous mutation in NPHS2, resulting in abnormal signaling through the nephrin-podocin complex and podocyte dysfunction. Therefore, it is very probable that in this case of primary MN genetics played a major role in treatment resistance and progression to ESRD.

PO1545
Primary Membranous Nephropathy Flare After COVID-19 Vaccination

Kelly V. Liang, Elizabeth C. Kurtz, Matthew Pittapilly, Syeda B. Ahmad, Marta I. Minervini. University of Pittsburgh, Pittsburgh, PA.

Introduction: Primary membranous nephropathy (MN) is most commonly due to phospholipase A2 receptor antibodies (PLA2R Ab). It is unclear whether the COVID-19 vaccine can trigger flares of glomerular diseases such as primary MN. We present a patient with MN and metastatic breast cancer who developed nephrotic syndrome after receiving her second mRNA-1273 COVID-19 vaccine with positive PLA2R Ab by ELISA suggesting MN flare.

Case Description: A 62 year old female with history of Stage IIIB T3N3M1 ER/PR positive HER-2 negative metastatic left breast invasive ductal carcinoma, hypertension, and previous breast surgery and primary MN with membranous lesions and proteinuria 2 weeks after COVID-19 vaccination. She had previous proteinuria of 7029 mg/24hr in August 2018 with PLA2R Ab 128 RU/mL in October 2018. She underwent modified radical mastectomy in September 2018 followed by adjuvant chemotherapy in November 2018, after which PLA2R Ab decreased to <2 RU/mL. In February 2019 and urine protein/Cr ratio (UPCR) increased to 1094 mg/g Cr in April 2019. She was diagnosed with metastatic breast cancer and started anastrazole transiently. She received mRNA-1273 COVID-19 vaccines in late January and February 2021. In March 2021, she presented with unilateral leg edema, dyspnea, and bilateral pleural effusions. Urinalysis had >1000 protein, 24hr urine protein 11.2 g, Cr 1.6 mg/dL, and PLA2R Ab 787 RU/mL. Renal biopsy showed immune complex-mediated glomerulopathy with positive PLA2R, consistent with primary MN stage II-II. Glomerular basement membrane deposits were strongly positive for IgG. Electron microscopy showed numerous subepithelial and occasional intramembranous electron-dense immune-type deposits. She was treated with lisinopril and furosemide followed by rituximab in May 2021. Prior to rituximab PLA2R Ab was 342 RU/mL and UPCR was 8671 mg/g Cr.

Discussion: There is insufficient data on the risk of flare after COVID-19 vaccine in glomerular diseases. There have been a few case reports of primary MN and minimal change disease after COVID-19 vaccine as well as MN after influenza vaccine. Our case of primary MN flare after COVID-19 vaccine adds support to a potential association between SARS-CoV-2 antigens and antigen loss to the PLA2R antigen. Close follow up of patients with primary MN and other glomerular diseases after COVID-19 vaccination is warranted.

PO1546
Primary Membranous Nephropathy Concurrent with ANCA-Positive Crescentic Glomerulopathy in a Hispanic Man

Leonardo Pozo Garcia,1,2 Daniel Varela,1,2 Steffi Sathiyaraj,1,2 Mourad Alsabbagh,2 Sergio A. Treviso Manollo,2 John Manollo.1 The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 3DHR Health, Edinburg, TX; 4South Texas Kidney Specialists, McAllen, TX.

Introduction: Primary membranous nephropathy (MN) is a common cause of glomerular disease in adults usually presenting with nephrotic syndrome. Crescents are an unusual finding in MN; its presence suggests a concomitant disease process, such as pauci-immune anti-neutrophil cytoplasmic antibody-related (ANCA) glomerulonephritis (GN).

Case Description: A 36-year-old Hispanic man presented with a 1-week history of NS and profound lethargy. Examination revealed an obese Hispanic man with rales on lung auscultation and lower-extremity edema. Laboratory results showed a serum creatinine (sCr) 8.8 mg/dL, BUN of 54 mg/dL. Urinalysis revealed 4+ protein, 25-50 red blood cells per hpf. Spot urine protein creatinine ratio (UPCR) was 19 g/g, p-ANCA titer 1:640. Urine toxicology screen was positive for cocaine. Other serologies and imaging were unremarkable. Renal biopsy showed MN with PLA2R positive staining as well as necrotizing and crescentic glomerulonephritis. Interstitial fibrosis and tubular atrophy were seen only in 10% of the sample. Management was initiated with a pulse of steroids followed by a taper, and renally dosed oral cyclophosphamide. The patient was initiated on hemopurification due to uricemic symptoms and volume overload. Three months after initiation of therapy, urine output significantly improved. Laboratory data showed: a 24 hours urine creatinine clearance of 31 ml/min, sCr 2.9 mg/dL, and UPCR 5.3 g/L. Patient was euromelodic. Hemodialysis was discontinued after a year. MN and ANCA GN are distinct manifestations of renal injury with different clinical laboratory, and pathology findings. Our case highlights an individual with both entities. We hypothesize that the patient’s renal findings of p-ANCA and crescentic GN were likely associated with levamisole adulterated cocaine in the background of primary MN. The patient discontinued cocaine use after our discussions. We decided to treat the patient’s MN with immunosuppressive therapy. Fortunately, the patient has responded favorably to our management with significant improvement in renal function.

PO1547
Clinical-Pathological Features of Podocyte Infolding Glomerulopathy

Ling Hong,1,2 Lin Wang,2 Zhihua Zheng,1 Wenfang Chen.1 Department of Nephrology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3Department of Renal Pathology, Guangzhou Kingmed Diagnostic Laboratory Ltd, Guangzhou, China.

Background: Podocyte infolding glomerulopathy (PIG) is characterized by presence of microstructural aggregates originated from cytoplasmic infoldings of podocytes in the glomerular basement membrane (GBM). Few PIG cases have been reported and the significance of this morphology is still unclear. This study aims to elucidate the incidence, clinical-pathological features and prognosis of PIG.

Method: Renal biopsies with PIG features from January 2018 to December 2020 in Kingmed Diagnostic Laboratory were reviewed. Patients were divided into three groups according to their clinical and pathological findings.

Kidney Outcomes in Biopsy-Proven Thrombotic Microangiopathy with Eculizumab Therapy
Mohammad A. Sohal,1 John R. Sedor,2 Susana Arrigian,1 Jesse D. Schold,2 Leaf C. Herltz,2 Ali Mehdi,2 Cleveland Clinic, Cleveland, OH; ‘Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: There are limited long-term data on kidney outcomes in eculizumab-treated patients with biopsy-proven thrombotic microangiopathy (TMA). We report our experience of using eculizumab in patients with primary (genetic/antibody mediated) TMA, secondary TMA syndromes associated with antiphospholipid syndrome (APS) or systemic lupus erythematosus (SLE), as well as TMA of undetermined etiology.

Methods: We reviewed adult patients with kidney biopsy-proven TMA treated with eculizumab between 2014-2019. Transplant recipients, pregnant patients and those with scleroderma, shiga-toxin related hemolytic uremic syndrome or thrombotic thrombocytopenic purpura were excluded. Kidney response to eculizumab at 26 weeks for patients not on kidney replacement therapy (KRT) and for those requiring KRT at the time of, or within 1 week of initiation of eculizumab, was defined as an increase in eGFR of at least 15 ml/min/1.73m² and liberation from KRT respectively.

Results: We collected data on 16 patients (primary TMA [n=3]; secondary TMA including SLE [n=3] and APS [n=4]; TMA of undetermined etiology [n=6]). The median time from biopsy diagnosis to treatment initiation was 30 days (IQR:1-10,100) and the median duration of therapy was 303 days (IQR:160,604). 13 patients (81%) required KRT at the time of initiation of eculizumab. 4 patients died during follow up, 2 of whom died within 6 weeks. 6 (37.5%) patients required KRT when eculizumab was started. 2 of 3 patients who did not need KRT initially eventually progressed to end-stage kidney disease after 1 and 5.5 years from treatment initiation. 3/6 patients (50%) and 3/8 patients (37.5%) with mild and moderate interstitial fibrosis and tubular atrophy (IFTA) respectively responded to therapy, whilst those with severe IFTA (n=2) showed no response.

Conclusions: Although eculizumab use has been expanding rapidly for primary and secondary TMA syndromes, our data depicts a suboptimal kidney response, which appears independent of the need for KRT at treatment initiation. Severity of IFTA may be a predictor of kidney response to eculizumab. We suggest that more data is needed on long-term kidney outcomes with eculizumab across TMA syndromes before universally adopting this expensive therapeutic strategy.

PO1550
Recurrence of Atypical Hemolytic Uremic Syndrome After Kidney Transplantation: A Prospective Cohort Study
Caroline Duineved,1 Romy N. Brouweemeester,2 Kioa L. Wijnema,3 Nicole Van De Kar,4 Jack F. Wetzels5 CUREiHUS study group Rhadboudumc, Nijmegen, Netherlands.

Background: Since 2016, aHUS patients in the Netherlands are treated with a restrictive treatment protocol. Withdrawal of eculizumab is considered after a treatment period of three months. Furthermore, kidney transplantations in aHUS patients are performed without eculizumab prophylaxis, with initiation of eculizumab in case of post-transplant recurrence. This restrictive treatment protocol is monitored in the CUREiHUS study. Here, we present the CUREiHUS study results for kidney transplant patients.

Methods: All kidney transplant patients who received eculizumab therapy for a suspected aHUS recurrence, and who were included in the CUREiHUS study (after informed consent), were evaluated.

Results: In the period from January 2016 until October 2020 we included 15 (12, F: 12, M: 3, median age 42y, range 24-66) patients with suspected aHUS recurrence after kidney transplantation. Patients were classified as high (N=8) or moderate (N=7) recurrence risk. The time-interval to recurrence showed a bimodal distribution. Seven patients presented early after transplantation (median 1.3, range 0.2-2.1 months), and 8 patients presented later (median 22.9, range 17.0-70 months). In 7 of these, eculizumab was initiated due to high risk of recurrence. In the remaining 8 patients, eculizumab was initiated due to non-progression of renal function, or due to laboratory evidence of TMA.

Conclusions: We report the clinical impact of eculizumab treatment in aHUS patients following kidney transplantation. Treatment was generally effective, with a median follow-up of 26 months, and 7 patients were able to discontinue eculizumab therapy. The number of patients is small, but these results suggest that eculizumab treatment can be safe and effective in aHUS patients following kidney transplantation.

PO1551
A Case of Thrombotic Microangiopathy from an Intra-Abdominal Abscess

Introduction: Infection mediated thrombotic microangiopathy (TMA) has a high mortality with many patients requiring kidney replacement therapy. Recognition of TMA can be difficult in the setting of abdominal infections. Here we report a case of TMA from complicated diverticulitis and polymicrobial intra-abdominal abscess.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 25 year old non-vegetarian man presented with generalized abdominal pain, fatigue, chills and intermittent epistaxis. He was found to have severe acute renal failure with Coombs positive hemolytic anemia, thrombocytopenia, high fibrinogen, high PT/PTT, low ADAMTS13 activity (15%) and ADAMTS13 inhibitor. Further workup showed sigmoid diverticulitis with a large intra-abdominal and small intra-abdominal perforation with culture positive for Streptococcus anginosus (an oral microbe with proclivity to abscess formation) and Escherichia coli. Shiga toxin was not tested. Kidney biopsy revealed acute TMA. Drainage of the abscess and treatment with antibiotics resolved the systemic features of TMA. Renal recovery was protracted and the patient required dialysis for 3 months, with a last sCr of 2mg/dl.

Discussion: Infection mediated TMA is an important third subgroup of thrombotic microangiopathy. The mechanism of injury is likely due to the concerted effort of both bacteria. E.coli produced shiga toxin causes direct damage to the endothelial cells, whereas S.anginosus promotes recognition of a human-saccharide from dairy and mammalian leucocytes and internalized toxin affinity to endothelial cells and injury. S.anginosus produces an exotoxin that can lyse erythrocytes and platelets allowing IgM binding to the exposed Tn antigen, leading to the coombs positivity observed. There is decreased hepatic synthesis of ADAMTS13 in sepsis, and ADAMTS13 autoantibodies are reported in E.coli mediated TMA. Given high fatality rate, prompt recognition and treatment of the underlying infection is pivotal as ongoing infection propagates microangiopathy. Severe features of TMA can develop during the clinical course necessitating intensive treatments such as plasmapheresis. As infection can be a frequent trigger of TMA among patients with complement abnormalities, patients should undergo genetic testing of the regulatory genes involved in the complement system.

PO1552
Characteristics and Outcomes of Immune-Complex Membranoproliferative Glomerulonephritis and C3 Glomerulonephritis in Japan: A Retrospective Analysis of Data from the Japan Renal Biopsy Registry
Naoki Nakagawa,1 Sawako Kato,2 Shoichi Maruyama,3 Ichiei Narita,3 Yoshitaka Isaka,4 Committee for Renal Biopsy and Disease Registry of the Japanese Society of Nephrology; 1Asahikawa Ika Daigaku, Asahikawa, Japan; 2Sapporo Medical University Hospital, Sapporo, Japan; 3Sapporo Daigaku Igaikku Igaikku Igaikku Igaikku Kenkyuka Igaikku, Nagoya, Japan; 4Niigata Daigaku Igaikku Igaikku Igaikku Igaikku, Sogo Kenkyuka, Niigata, Japan; 5Osaka Daigaku Igaikku Igaikku Igaikku Kenkyuka Igaikku, Suta, Japan.

Background: The reclassification of membranoproliferative glomerulonephritis (MPGN) into immune-complex mediated MPGN (IC-MPGN) and C3 glomerulopathy (C3G) based on immunofluorescence findings in kidney biopsies has provided insights into two distinct diseases. C3G is further classified into dense deposit disease and C3 glomerulonephritis (C3GN) based on electron micrographic findings. Although these diseases have poor outcomes, limited Japanese literature confined to small, single-center cohorts exist on these diseases.

Methods: We retrospectively analyzed 81 patients with MPGN type I and III from 15 hospitals in the Japan Renal Biopsy Registry (J-RBR) to compare demographic, clinical characteristics and treatment outcomes of patients with IC-MPGN to those with C3G.

Results: Of the 81 patients reviewed by immunofluorescence findings in kidney biopsies, 67 patients had IC-MPGN and 14 patients had C3GN. Age at diagnosis, systolic and diastolic pressures, proteinuria, impaired renal function, and hypoalbuminemia were significantly higher in patients with IC-MPGN than in those with C3GN. About 80% of the patients in both groups were treated with immunosuppressive therapy. At last follow-up (median 4.8 years), complete remission rate of proteinuria was significantly higher in patients with IC-MPGN (64.3%) than in those with IC-MPGN (29.6%; P = 0.013). The renal survival rate was lower in patients with IC-MPGN when compared to C3GN (73.1% vs. 100%; log-rank, P = 0.031). Systolic blood pressure and renal function at baseline were independent predictors of progression to end-stage kidney disease.

Conclusions: The overall prognosis of patients with C3G is more favorable than for patients with IC-MPGN.

Funding: Government Support - Non-U.S.

PO1553
Early Recurrence of C3 Glomerulopathy (C3G) in the Allograft

Background: C3G encompasses both C3 glomerulonephritis (C3GN) and Dense Deposit Disease (DDD), a rare group of kidney diseases associated with alternative complement pathway dysregulation that commonly recurs in the allograft. How early recurrence occurs is underexplored.

Methods: We reviewed cases of recurrent C3G in the allograft at CUMC. Protocol biopsies were encouraged for transplanted C3G patients (PTS) at 6 months if a for-cause biopsy (bx) had not already been performed. Median (range) reported. Results: 13 PTS (9 C3GN, 4 DDDD) were included (Table 1). 6 PTS (46%) had previous allografts fail due to C3G recurrence. Age at transplant was 32 years (18-71). Time from transplant to histologic recurrence was 54 days (5-472). 4 PTS (31%) had bland urine at first recurrence. 7 PTS (54%) had histologic recurrence at first allograft bx, 15.8±15.0 years after transplant. After 2.3 years (0.3-10.1), 11 PTS (85%) remained with functioning allografts; 5 PTS (46%) had creatinine > 2 mg/dl. 2 DDD PTS had allograft failure. 6 PTS (43%) had acute T cell mediated rejection. 2 PTS received eculizumab-both were without clinical recurrence.

Conclusions: This series highlights earlier histologic recurrence of C3G in the allograft than previously reported, partly due to protocol bx. Many PTS were without urinary abnormalities. At last follow up, majority of PTS had significant transplant CKD with limited allograft function. Future research is needed to better understand if early detection of recurrence, coupled with anti-complement therapies, improves outcomes.

Summary of Clinicopathologic Course After Histologic Recurrence

PO1554
C3 Glomerulopathy in Children and Adolescents
Yael Borovitz, Hadar Alfandary,1 Amit Dagan,2 Orly Haskin,1 Daniel Landau,1 Miriam Davidovitz,1,2 Schneider Children's Medical Center of Israel, Petah Tikva, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: C3 glomerulopathy (C3G) has been classified as a glomerular complement mediated disease with predominant C3 deposits for over a decade ago. Data regarding clinical course, treatment options and long term prognosis in children and adolescents is still scarce. The aim of the study was to retrospectively describe a single tertiary center’s experience with C3G in the pediatric population, and correlate presentation, pathology, complement findings, response to treatment and disease progression.

Methods: A retrospective cohort study. Patients presented with C3G by the age of 18 years compromised the study group. All cases underwent kidney biopsy at presentation. Repeated kidney biopsy was performed on a need basis, in native or transplanted kidneys. Definition of C3G was based on the 2013 consensus guidelines. Patients underwent complement workup and genetic tests. Treatment regimen was not uniform.

Results: 17 patients were diagnosed with C3 glomerulopathy. Features of Dense deposit disease (DDD) were found in 8 patients, C3 glomerulonephritis in 6 patients. For 1 patients EM was not available. Mean age at diagnosis was 12.7 years (range 1.9 – 17.3). 6 girls and 11 boys. Median follow up 4.4 years (range 1.1-20.9). Treatment modalities ranged from ACE inhibitors and Angiotensin receptor blockers to corticosteroids, Mycophenolate Mofetil, Plasmapheresis, Rituximab and Eculizumab. Only 2 (12%) patients achieved complete remission, 4 (23%) patients reached end stage renal failure and had kidney transplantation. All of them had disease recurrence in the transplanted kidney. Complement workup was positive for C3Nef in 6 patients, C5Nef in 2 patients, factor H antibodies in 2 patients. Genetic testing was positive in one patient. Elevated creatinine at presentation, severe proteinuria, DDD in kidney biopsy-were correlated with worse prognosis.

Conclusions: Understanding the pathophysiology of C3G as a complement mediated disease has progressed during the past years. Still no guidelines exist regarding treatment and prognosis in the pediatric population. Our cohort presented a wide variability in disease course and presentation. Further understanding of the correlation between exact complement abnormality and C3G prognosis is warranted, especially now when new complement system blockers may become available.

Utilizing Pharmacokinetic Studies to Optimize Therapy in a Child with C3 Glomerulonephritis and Nephrotic Syndrome: A Precision Medicine Approach
Magdalena Riedl Khursigara, Damien G. Noone, Seetha Radhakrishnan, James A. Tjon, Rose Chami, Rulan S. Parekh, Valerie Langlois, Christoph Licht, Chia Wei Teoh. The Hospital for Sick Children, Toronto, ON, Canada.

Introduction: C3 glomerulonephritis (C3GN) is caused by complement alternative pathway dysregulation, has no definitive treatment and is characterized by progression to ESRD. Terminal complement blockade has successfully been used especially in patients with elevated C5b-9 levels.

Case Description: We describe a 6 year old boy with C3GN, who presented with nephrotic syndrome, severe hypertension (4 anti-hypertensive medications) and acute kidney injury. Complement C3 level was 0.12 g/L (normal 0.8-1.5) with pos C3NeF and elevated C5b-9 levels (2135, normal <239ng/ml). Despite 6 months of treatment with steroid and MMF, he had ongoing nephrotic syndrome and worsening kidney function. He commenced on standard Eculizumab dosing. Despite 6 months of therapy, he had persistent severe hypertension, nephrotic syndrome requiring weekly albumin/furosemide infusions and worsening kidney function. Complement C3 levels remained low with elevated C5b-9 levels, suggesting sub-optimal terminal complement inhibition due to urinary loss. We confirmed sub-therapeutic plasma concentrations of eculizumab as free plasma eculizumab levels were low on day 7 (9, normal >99 ug/ml) and undetectable on days 10 and 14 post-infusion. Eculizumab frequency was subsequently increased to weekly with MPA-AUC guided adjustment of MMF dosing. Since then, his kidney function improved with a decline in proteinuria. Eculizumab frequency was subsequently increased to weekly with MPA-AUC guided adjustment of MMF dosing. Since then, his kidney function improved with a decline in proteinuria.

Discussion: Use of pharmacokinetic studies can aid in individualized eculizumab treatment in C3GN patients with ongoing proteinuria and who failed to respond to standard dosing.

PO1556
Remission of C3 Glomerulonephritis with Rituximab
Aklidanavaky Angumuthu, Fatima Batool, Neethu Gopisetty, Imara Dissanayake, Ji Young Shin. Albert Einstein Medical Center, Philadelphia, PA.

Introduction: C3 glomerulonephritis (C3GN) is rare form of glomerulonephritis. It is diagnosed primarily by kidney biopsy with immunofluorescence showing deposits of C3 along the basement membranes. It differs from dense deposit disease with absence of the pathognomonic deposits on electron microscopy (1). There are no randomized trials to guide therapeutic decisions. Spontaneous and treatment-associated complete remissions are rare.

Case Description: 69-year-old female with history of well controlled hypertension on amlopidine was sent to hospital with elevated creatinine of 2.52 (unknown baseline) with positive ANA - 1:320 titer. Patient was asymptomatic with negative family history of kidney disease. She denied taking NSAIDs. Serum creatinine on admission was 3.05 mg/dL. Urinalysis showed numerous RBCs with 2 g of proteinuria in the 24-hour urine collection. P-ANCA was positive. All other pertinent serologies were negative including complements, C- ANCA, MPO, PR3. Renal ultrasound revealed medical renal disease. Renal biopsy was performed and preliminary reports showed crescentic glomerulonephritis. Pulse dose steroids was started followed by oral prednisone. In addition, Rituximab was started weekly. Final biopsy confirmed C3GN. Patient did not require dialysis and renal function significantly improved after 4 doses of rituximab to serum creatinine of 1.5 mg/dL.

Discussion: In C3GN with rapidly progressive glomerulonephritis (crescents on biopsy), treatment is not well established. Most patients are treated with steroids in combination with either cyclophosphamide or Mycophenolate mofetil (2). Rituximab was used in some case reports (3). In our patient, since P-ANCA was positive and preliminary biopsy showed crescents, Rituximab was started immediately after pulse dose steroids. Patient did not require dialysis, due to good response and remission. Rituximab is a promising treatment option for C3GN. Remission of C3 glomerulopathy with rituximab as only immunosuppressive therapy. Clin Nephrol. 2015 Jan;83(1):57-60.

PO1557
Myeloperoxidase Immunohistochemical Staining and Response to Eculizumab in a Pediatric Patient with Dense Deposit Disease
Neal B. Blatt, Larysa T. Wickman, Ping L. Zhang, Beaumont Health, Royal Oak, MI.

Introduction: Previous studies have demonstrated residual complement mediated deposits in repeat renal biopsies of patients with C3 glomerulonephritides (Dense deposit disease (DDD) and C3 glomerulonephritis) following eculizumab treatment despite clinical improvement. With the residual complement deposition, it is often difficult to determine whether there is a reduced complement mediated endothelial cell injury. Herein, we report the use of myeloperoxidase (MPO) immunohistochemical staining to show decreased glomerular endothelial cell injury in a pediatric patient with DDD on chronic eculizumab therapy.

Case Description: Our patient was diagnosed with DDD by renal biopsy when he was 5 years old after presenting with a serum creatinine of 5.2 mg/dl, a urine protein to creatinine ratio of 2.5, and a complement C3 level of 50 mg/dl. Functional complement testing showed the presence of C3 and C5 nephritic factors. He was treated with eculizumab (600 mg every 2 weeks) and azathioprine, and over the course of 6 months, his serum creatinine, proteinuria, and complement C3 levels returned to normal. After weaning the frequency of his eculizumab infusions, he experienced a flare of DDD 15 months after initial presentation with a serum creatinine of 3.6 mg/dl, urine protein to creatinine ratio of 7, and complement C3 level of 76 mg/dl. He was re-dosed with eculizumab (600 mg every 2 weeks) with a rapid response to treatment. He had normalization of his serum creatinine to pre-flare levels within 6 months. Since then he has been maintained on eculizumab infusions (600 mg every 4 weeks) along with mycophenolate mofetil. A second kidney biopsy was performed after 3 years of treatment with eculizumab to evaluate response to treatment. The biopsy showed some residual features of dense deposit disease including C3 complement deposition. To evaluate if eculizumab blocked complement mediated injury on glomerular endothelial cells, MPO staining of his initial and repeat biopsy was performed: his initial biopsy revealed diffuse endothelial staining for MPO along glomerular endothelium and the repeat biopsy showed either no MPO staining or weak MPO staining in the glomerular endothelium.

Discussion: In this case, we find that MPO immunohistochemical staining may be useful for monitoring the response to complement blockade in patients with DDD.
PO1558

Pregnancy-Associated Membranoproliferative Glomerulonephritis (MPGN)
Pamela C. Vasquez Buitron,1 Sue C. K. Shaffi,1 Zhi Xu,1,2 Michael B. Kupperman,2 J Pedro Teixeira,1,3 University of New Mexico School of Medicine, Albuquerque, NM; 4Arkana Laboratories, Little Rock, AR.

Introduction: Nephrotic syndrome (NS) in pregnancy is rarely due to MPGN. We present a case of MPGN in pregnancy for which no other cause was found.

Case Description: A 33-year-old G1P0 woman develops hypertension and proteinuria at 12 weeks gestation followed at 21 weeks by NS (7.5g/24h proteinuria, albumin 1.1 g/dl), AKI with creatinine (Cr) 1.1 mg/dl (up from 0.6), hematuria, and mildly elevated AST and ALT. Cr is low (5.9 mg/dl). SPEP and UPEP detect monoclonal IgG kappa with serum light chain ratio 5.1, ANA, anti-dsDNA, cryoglobulins, C3 nephritic factor, and serologies for hepatitis B and C, T. pallidum, and HIV are negative. Renal biopsy reveals MPGN. After counseling, she opts to end the pregnancy. Cr, AST, ALT, and hematuria rapidly normalize, but the proteinuria at first persists. Immunosuppression is offered, but she declines. The proteinuria slowly falls to <0.7 g/g Cr with supportive care and telmisartan over a year. Apart from low Cr, an atypical hemolytic uremic syndrome (aHUS) panel is negative. Genetic testing for aHUS is also negative (heterozygous T. pallidum serologies for hepatitis B and C, and telmisartan over a year. Apart from low C4, an atypical hemolytic uremic syndrome (aHUS) panel is negative. Genetic testing for aHUS is also negative (heterozygous mutation in DGKE and heterozygous deletion in CHI R1-CFI R3). HLA analysis shows B35 and B51 alleles. C4d staining later performed on the biopsy is strongly positive.

Discussion: As in this case, NS in pregnancy is associated with an increased risk of complications such as superimposed preeclampsia. The etiology of this MPGN case is unknown, with no clear infectious or autoimmune cause. The C4d deposition and negative aHUS testing suggest a defect in the classic complement pathway. This paraprotein may or may not be involved as, though the immune complex deposition was polyclonal, monoclonal IgG-kappa has been rarely reported to activate complement in other autoimmune disorders. Regardless of mechanism, we speculate this MPGN case was triggered by pregnancy as it improved after the pregnancy with supportive care alone.

PO1559

Comparing and Contrasting Glomerular Disease Patients: A Real-World Analysis Showing Demographic, Clinical, and Treatment Differences Across More Than 1,000 Patients

Background: One-half of nephrologists selected glomerular diseases as their leading area of interest in nephrology in 2020. These rare and often-idiopathic disorders are seen as particularly challenging to manage, but an influx of promising pipeline drugs may offer new treatment options in the not-so-distant future.

Methods: 1,112 glomerular disease patient records were collected in collaboration with 290 US nephrologists via HIPAA-compliant, online chart review tool between December 20, 2020 – February 16, 2021.

Results: Chart audits reveal ~8% of nephrologists’ patient populations have a glomerular disorder. Of that group, 26% have IgAN, 26% have FSGS, and 3% have Alport’s Syndrome, among other conditions. IgAN patients are typically middle-aged, white males, in the middle-to-upper class and often present with hypertension, hyperlipidemia, and/or obesity. FSGS patients are mostly middle-aged, black males, in the lower-to-middle class and often present with hypertension, hyperlipidemia, obesity, and/or edema. Alport Syndrome patients tend to be younger (18-49), white males, in the lower-to-middle class and present with hypertension, hearing loss, and sometimes ocular abnormalities. Of the three conditions, FSGS patients are most heavily prescribed steroids and advanced therapies like MMF, cyclophosphamide, and Acthar Gel and are least likely to be seen as optimally managed. Interestingly, despite the value of ACEi/ARB therapy, 42% of IgAN patients were not on therapy at referral, with FSGS and Alport close behind. Nephrologists are trialing SGLT2is across conditions, with up to one-in-tens patients currently on the drug. A diagnosis for Alport Syndrome may take several months or even years after referral to determine (unlike IgAN and FSGS where it usually takes under four months). Alport is also the least likely of the three diseases to be diagnosed via kidney biopsy. Patient referrals are often deemed “late” by nephrologists, but particularly with the faster-progressing FSGS and IgAN.

Conclusions: Deeper understanding of key comparative differences among rare glomerular diseases may aid physicians in developing strategies for diagnosis and treatment.

PO1560

Glomerular Diseases in Flanders: Overview of the FCGG Biopsy Registry
Dries Deleersnijder,1 Wim Laurens,2 Johan M. De Meester,2 Amelie Dendooven,2 Ben Sprangers,1 Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; 3AZ Nikolaas, Sint-Niklaas, Belgium; 4Universitair Ziekenhuis Gent, Gent, Belgium.

Background: High-quality population-based registries on glomerular diseases are required for epidemiological study and new trial design. The FCGG (Flemish Collaborative Glomerulonephritis Group) database is a population-based registry that has been including data on all native kidney biopsies performed in Flanders since 2017 (Northern part of Belgium) covering a population of approximately 6.5 million inhabitants.

Methods: Clinical data and nephrological diagnosis according to the ERA-EDTA Coding system for Primary Renal Disease are collected together with pathological data including primary and secondary pathological diagnoses according to the Mayo Clinic/ Renal Pathology Society Consensus Guideline 2016. Here, we describe the main results of the first three years of the registry.

Results: From 2017 until 2019, 2178 biopsies were included, of which 5.7% were performed in the pediatric population. Median age (IQR) was 59 years (42-71). Biopsy incidence proportion was 130 biopsies p.m.p. per year in the adult population. Glomerular disease was present in 54% of the adult biopsies (Fig. 1A). IgA-nephropathy (IgAN) was the most frequently diagnosed disease in adults (17.3% of total, 30.2% of glomerular subcategory). The etiologies of the nephritic syndrome differed across age categories, with membranous nephropathy (MN) being most frequently diagnosed in the total group of adult nephrotic patients (Fig. 1B). IgAN and pauci-immune glomerulonephritis (AAN) were the two most important causes of the nephritic syndrome in adults. A crescentic pattern of injury was most frequently diagnosed in adults with AAV, lupus nephritis (LN) and IgAN (Fig. 1C, crescents in 82%, 31% and 24% of biopsies, respectively).

Conclusions: The FCGG database is a valuable population-based registry that characterizes the epidemiology of glomerular disease in Flanders. These results are relevant to the clinician, will enable disease subgroup analyses and are useful to set up observational or interventional trials in patients with glomerular disease.

PO1561

CureGN Pediatric Glomerulopathy: Identifying Pathologic Molecular Signatures in Glomerulopathy with Quantitative Proteomics
Timothy Cumming,1 Michael Merchant,2 Laura H. Mariam,3 Wimal Pathmasiri,4 Susan J. Sumner,4 William E. Smoyer,5,6 Jon B. Klein.7,1 Kidney Disease Program and Clinical Proteomics Center, University of Louisville School of Medicine, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Michigan School of Medicine, Division of Nephrology, Ann Arbor, MI; 4University of North Carolina at Chapel Hill Nutrition Research Institute, Kannapolis, NC; 5Nationwide Children’s Hospital, Columbus, OH; 6The Ohio State University, Columbus, OH.

Background: Glomerulonephritis is a leading cause of end stage kidney disease with related treatment costs placing a significant burden on healthcare systems worldwide. Immunosuppressive glucocorticoids are a primary therapeutic approach yet can be ineffective in nearly 50% of patients. In this study we tested the hypothesis that the pediatric urinary proteome would contain unique protein signatures that predict treatment response vs. resistance in glomerular diseases.

Methods: We performed proteomic analyses of serial clinically, histologically phenotyped and biopsy-confirmed pediatric urine samples from children with 3 glomerulopathies (MCD, FSGS and IgAN) to identify putative mechanistic differences between glomerular disease pathology and treatment responsiveness. 434 patient urine samples were analyzed by LC-MS/MS, and subsequently 1119 unique proteins were identified using MaxQuant and Scaffold-5 Q+ applying strict FDR (1%) with 2 peptide identification required. Protein lists were analyzed by clinical category (urine protein) using MetaBioAnalyzer 5.0 to perform univariate and multivariate statistical analysis, volcano plot, and heatmap visualization of protein clusters.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Our analysis indicates specific and unique protein/molecular signatures supporting MCD, FSGS and AN with respect to disease status and pathologic diagnosis. Univariate analysis indicated that at least 62 proteins were significantly different in complete remission vs. proteinuric patients across all pathologies. Multivariate analysis showed significant contributions by several proteins to identify disease state and pathways. Multivariate analyses identified protein signatures that are differentially abundant across the 3 distinct glomerulopathies.

Conclusions: Pediatric glomerular disease and disease activity are associated with unique urine proteomes and if confirmed will lead to further identification of important biomarkers. We are currently performing validation of a subset of these biomarkers to determine if they are diagnostic and predictive of treatment response.

Funding: NIDDK Support

PO1562
The Thromboembolism Among Hospitalized Patients with Different Types of Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital
Xiaohong Fan, Jie Ma, Xueci Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Chronic kidney disease is associated with hypercoagulability and platelet dysfunction. However, data on thromboembolism associating different types of chronic glomerulonephritis (CGN) is less.

Methods: We conducted a retrospective analysis using the database of hospitalization with CGN in Peking Union Medical College Hospital (PUMCH), China from 2000 through 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify types of thromboembolism and types of glomerulonephritis including lupus nephritis (LN), systemic vasculitis (AVV), Henoch-Schönlein purpura nephritis (HSPN), IgA nephritis (IgAN), idiopathic membrane nephropathy (IMN), minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS). Cochrane-Armitage trend test and Logistic regression were used to analyze the data.

Results: Between 2000 and 2017, there were 15,714 hospitalizations with the aforementioned CGN. Their mean age was 51.7±19.8 years and 39.4% were males. The annual prevalence of overall thromboembolism increased steadily from 1.6% in 2000 to 6.6% in 2017 in a dose-response manner (p for trend <0.001). Among all thromboembolism cases, 49.8% had venous thromboembolism and 31.7% had a pulmonary embolism. The prevalence of thromboembolism in IgAN, FSGS, MCD, IMN, HSPN, LN, and AN were 0.6%, 2.4%, 2.6%, 5.89%, 2.2%, 4.4%, and 5.3%, respectively. The patients with thromboembolism had a 2.30-fold increased risk of death (95%CI 1.53-3.46) after adjustment for age and gender. In multivariate analyses adjusted for multiple confounders such as gender, hypertension, diabetes, cardiovascular disease, cerebrovascular disease, heart failure, chronic obstructive pulmonary disease, infection, LN (OR 8.15; 95% CI 5.25-12.65), IMN (OR 6.93; 95% CI 4.39-10.92), AAV (OR 4.53; 95% CI 2.66-7.61), MCD (OR 4.42; 95% CI 2.56-7.61), HSPN (OR 4.05; 95% CI 2.33-7.03), and FSGS (OR 3.18; 95% CI 1.56-6.49) were significantly associated with the increased risk of thromboembolism compared with IgAN.

Conclusions: In the present study, chronic glomerulonephritis, particularly lupus nephritis, idiopathic membrane nephropathy, and systemic vasculitides were independently associated with an increased risk of thromboembolism.

PO1563
Identification and Validation of Infection-Related Acute Care Events in Patients with Glomerular Disease
Dorey A. Glenn,1 Jarcy Zee,2 Anisha R. Hegde,1 Candace D. Henderson,1 Michelle M. O'Shaughnessy,2 Andrew S. Bomback,1 Keisha L. Gibson,1 Larry A. Greenbaum,1,2 Sarah Mansfield,1 Yichun Hu,2 Laura H. Mariani,1 Ronald J. Falk,1 Susan L. Hogan,2 Michelle Denburg,1 Amy K. Mottil.1 University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3Columbia University, New York, NY; 4University of Michigan, Ann Arbor, MI; 5Children’s Healthcare of Atlanta Inc, Atlanta, GA; 6Emory University School of Medicine, Atlanta, GA; 7University College Cork, Cork, Ireland; 8Arbor Research Collaborative for Health, Ann Arbor, MI; 9The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Infections are an important contributor to morbidity and mortality in glomerular disease (GD). Accurate identification of infections using real world clinical data would support the conduct of observational studies examining infection risk, but standard approaches are labor-intensive. We sought to derive and test the validity of diagnosis-code based algorithms to identify infection-related acute care events (ACEs) within a large cohort of children and adults with GD.

Methods: CureGN is a prospective multi-center cohort study of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, or IgA Nephropathy. We describe the sensitivity, specificity, and positive and negative predictive values (PPV/NPV) of four infection diagnosis code lists using manually curated infectious and non-infectious ACEs (hospitalization or emergency department visit) as the gold standard. We then validate the best performing code list within a more contemporary CureGN cohort, using multi-site adjudication of medical records.

Results: In the development phase, the optimal performing combination of diagnosis codes was used by CureGN coordinators combined with those described by Saibil et al. (PPV 78%, 95% CI 73-83%) (Table 1). Using this code list, 265 infectious and 1231 non-infectious ACEs were identified among 2599 CureGN participants in the validation phase. FSGS, of which 124 were randomly selected and adjudicated. The PPV and NPV for the final code set were 87% (95% CI 75-99%) and 83% (95% CI 72-93%) respectively.

Conclusions: Diagnosis codes can be used to accurately identify infection-related ACEs among patients with GD in the future studies should validate our findings in other GD cohorts and for specific infection types of high-severity or burden.

The Impact of Obesity on Glomerulonephritis: A Multicenter Cohort Study of Kidney Biopsy over 40 Years

Tae-bum Kim,1 Hyeon-Jin Min,1 Young-Bin Son,1 Jonghyun Lee,1 Myung-Gyu Kim,1 Sang-Kyung Jo,1 Won-Yong Cho,1 Eun Hui Bae,1 Jeun Oh,1 Shin-Young Ahn,1 Sewon Oh.1 Korea University Medical Center, Seoul, Republic of Korea; 2Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea; 3Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea.

Background: Worldwide obesity has increased by almost three times between 1975 and 2020. Many studies reported that obesity related kidney disease was also increasing, and most of them were focal segmental glomerulosclerosis (FSGS). However, little was known about the prevalence and outcome of other type of glomerulonephritis (GN) in obese patients.

Methods: A total of 14,833 adult patients who underwent kidney biopsy and had body mass index (BMI) were identified in 18 tertiary hospitals during 1979-2018. Obesity was defined as BMI≥30 kg/m². We analyzed the prevalence of specific forms of glomerulonephritis in obese patients and effect of obesity on mortality and end stage kidney disease (ESKD).

Results: Obese patients in glomerular disease have increased about 12.8-fold over 40 years between 1979-1988 (0.6%) and 2009-2018 (7.7%). In GN patients with obesity, prevalence of IgA nephropathy (IgAN) is the most common (33.7%) followed by FSGS (13.3%), minimal change disease (MCD) (10.8%), membranoproliferative (MPGN) (10.6%), diabetic nephropathy (DMN) (6.0%), lupus nephritis (LN) (2.7%), and hypertensive nephropathy (HT-N) (2.6%). The prevalence of FSGS (HR 1.60, 95%CI 1.24-2.06), DMN (HR 1.46, 95%CI 1.01-2.12) and HT-N (HR 2.14, 95% CI 1.29-3.54) were significant higher in obese patients compared than non-obese patients. Obesity had a 1.39-fold increased risk for ESKD progression during 9.8±0.8 months follow up in total patients (95%CI 1.11-1.73). Obesity had higher risks for progression of ESKD in MCD (HR 2.48, 95%CI 1.02-6.04) and LN (HR, 3.28, 95% CI 1.30-8.31). In patients with FSGS, DMN, and HT-N, obesity was not associated with ESKD. Obesity was not associated with mortality in GN patients although obesity was related to mortality only in MCD patients (HR 2.48, 95% CI 1.02-6.04).

Conclusions: Obesity rates are increasing in GN patients. The prevalence of FSGS, DMN, and HT-N are significantly higher in obese patients although IgAN is the most common form of GN. Obesity had significant risks for progression of ESKD in patients with GN, especially MCD and LN patients.

PO1566

Obesity at Time of Diagnosis Is Associated with Proteinuria in Glomerular Disease

Evan Zeitler, Yichun Hu, Caroline J. Poulton, Lauren N. Blazek, Amy K. Mottl, Jennifer E. Flythe, Susan L. Hogan. UNC Kidney Center, Chapel Hill, NC.

Background: Obesity is an established risk factor for chronic kidney disease (CKD). The relationship between obesity and glomerular disease outcomes is not well studied.

Methods: We evaluated a cohort of adult patients with biopsy-proven IgA nephropathy, focal segmental glomerulosclerosis (FSGS), ANCA-associated vasculitis (ANCA), or membranoproliferative (MPN) between January 2014 and June 2020, with follow up through April 2021. We categorized body mass index (BMI) at time of biopsy as <25 kg/m², 25 kg/m²-30 kg/m², and ≥30 kg/m². We used Fisher’s exact and Kruskal-Wallis tests to compare baseline characteristics between groups and a proportional hazards model to evaluate factors associated with CKD progression to kidney replacement therapy (KRT). We used the sign rank test to compare Kaplan-Meier curves of KRT-free survival.

Results: The cohort included 153 patients: 77 (50%) male with median age 57 (IQR 49-65) years and median BMI 28 (IQR 24-34) kg/m². Compared to patients with lower BMIs, patients with BMI ≥25 kg/m² had higher median urine protein to creatinine ratios (uPCR) (p=0.02, Table 1). In univariate analyses, factors associated with progression to KRT were: blood pressure (p = 0.01), uPCR (p = 0.01), and lower eGFR (p=0.001). BMI at biopsy was not associated with CKD progression, adjusted HRs (95% CIs): BMI 25≥BMI<30 kg/m² - 1.09 (0.42-2.83); BMI ≥30 kg/m² - 1.54 (0.68-3.52). Logrank test that for curves was 0.004, with paired uPCR values imparting the greatest distinction between curves (data not shown).

Conclusions: Among glomerular disease patients, BMI was associated with proteinuria, but not with progression to KRT.

PO1567

When to Biopsy Type 2 Diabetes Mellitus (DM2)

Haridhan Sosa Barrios,1,2 Victor Burguera,1,2 María García,1,2 Ana Saiz,1,2 Javier Villacorta Perez,1,2 Guillermo F. Conde,1,2 Milagros Fernandez-Lucas,1,2 Maite Rivera Gorrin,1,3 Hospital Universitario Ramon y Cajal, Madrid, Spain;1 Instituto Ramon y Cajal de Investigacion Sanitaria, Madrid, Spain;1 Universidad de Alcala de Henares Facultad de Medicina y Ciencias de la Salud, Alcala de Henares, Spain.

Background: DM2 patients may have diabetic (DN) or non-diabetic renal disease (NDRD) and a histological diagnosis is needed. There is no clear consensus on when to biopsy, but a predictive model was recently published (1).

Methods: Aim: Assess NDRD prevalence, histology and apply the predictive score in our cohort. Methods: Retrospective analysis of native kidney (NK) biopsies performed in our center from 2016 to 2020. Data collected included DM history, retinopathy, peripheral vascular disease (PVD), insulin prescription, proteinuria, BMI and hematuria >10 cells/HPF. A score >3 was highly suggestive of DN and would preclude renal biopsy (RB). Results: 62 of 274 NK RB’s had DM, 66.1% males with a mean age of 64±13.7 (range 23-83). Mean estimated glomerular filtration rate (MDRD4) was 41±26.5 ml/min/1.73m² (range 6-98) with mean BMI 27.9 (range 18-41). Mean proteinuria was 44.5±mg/g (range 4.6-264.9) and 51.6% had microhемaturia. 51.6% had a DM history >10 and 28.3% ≤5 years since diagnosis. 82.3% did not have retinopathy, 11.3% had neuropathy and 48.4% were on insulin. 27.4% had PVD, 6.5% ischaemic cardiomyopathy (ICD) and 3% had a previous stroke. RB indications: 21 nephrotic syndrome, 2 nephritic syndrome, 6 proteinuria-hematuria, 18 non nephrotic proteinuria, 7 renal impairment and 8 AKI. Histology: 22 had DN (38.6%), 35 NDRD (61.4%) and insufficient in 5. NDRD included crescentic glomerulonephritis, membranous, FSGS, chronic tubulointerstitial nephritis, ATN, IgA GN, minimal change, amyloid, hiperfiltration, glomerular sclerosis and chronic inespecific lesions. Longstanding DM (≥10 y), retinopathy, neuropathy and PVD were independent predictors of DN (p value 0.02, 0.01, 0.001 and 0.001). Neither hematuria, nephrotic range proteinuria nor ICD were significant. Score: Patients with a score>3 had DN except 2 (osalate crystals and cast nephropathy). 70.2% with a score>3 had NDRD and 64% of those with <1 did not have DN.

Conclusions: Excellent correlation with DN and could be efficient on RB decision making process in these patients. Validation in multicentric studies is desirable. 1.García-Martín F. et al. When to perform renal biopsy in patients with type 2 diabetes mellitus? Predictive model of non-diabetic renal disease. 10.1016/j.nefro.2019.07.005

PO1568

Year of Life Lost due to Premature Death from Glomerulonephritis in Thailand

Chitimaporn Janphrang, Suchin Worawichawong, Sarinya Boongird, Umaporn Udomsubpayaikul, Montira Assanatham, Chagriya Kitiyakara. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: The contribution of Glomerulonephritis (GN) on mortality is not fully known. The impact of each GN subtype on premature mortality can be measured by calculating the year of life lost (YLL), which takes into account the age at which deaths occur. Therefore, this study aimed to estimate premature mortality in GN using the average YLL.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: In this retrospective study, we estimated the average YLL in each glomerular disease. The YLL is the difference between age at death and the standard life expectancy of an individual at the same age. To calculate YLL, we retrieved data from Ramathibodi Hospital Glomerular Registry during January 2011 to December 2020 and national data of standard life expectancy 2020. Individual deaths and date were obtained from the National Death Registry office. The average YLL for each disease category was divided by the total number of total patients in each GN type. GN were categorized into primary GN (IgA nephropathy (IgAN), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MGN) and minimal change disease (MCD)), and secondary GN (tubulointerstitial nephritis (TIN) or MPGN, and diabetic nephropathy (DN)).

Results: A total of 1,022 kidney biopsies was performed. The median follow-up time was 67 (IQR 45, 92) months. Age for GN patients was 43.9 ± 16.7 years and 44.8 ± 13.6 years. The total and average YLL of all GN were 4741.9 years and 4.64 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 ± 2.23 years (p < 0.05). DN (n = 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 3.57.

Conclusions: GN causes premature mortality with secondary GN being associated with higher median YLL. In our cohort, primary GN, DN, and LN nephritis have the highest YLL. This study provides useful information on the impact of GN for prioritization of public health policies intervention.

PO1569
The Significance of Hematuria in Primary Proteincruric Glomerular Disease Outcomes
Dorota Marchel,1 Maria Larkina,1,2 Damian Ferman,1 Jennifer Lai Yee,3 Debbie S. Gipson,1 Andrew S. Bomback,2 Pietro A. Canetta,2 Amy K. Mottl,3 Rulan S. Parekh,2 Manish K. Saha,2 Matt G. Sampson,2 Howard Trachman,2 Richard A. Lafayette,2 Laura H. Mangan,1 University of Michigan, Ann Arbor, MI; Columbia University School of Medicine, New York, NY; University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; "Boston Children’s Hospital, Boston, MA; "NYU Langone Health, New York, NY; "The Hospital for Sick Children, Toronto, ON, Canada; "Stanford University, Stanford, CA.

Background: Hematuria is associated with the incidence and progression of CKD. The study aims were to assess the prevalence of hematuria in a large cohort of proteincruric glomerular disease and assess the association between hematuria and kidney-related outcomes.

Methods: Hematuria was assessed at first reported study urinalysis in patients with MN, MCD, and FSGS in NEPTUNE and CureGN cohorts with >24 months of follow-up. Hematuria was defined as small, moderate, or large blood on urinary dipstick and no proteinuria. Therefore, podocytopathies were grouped with other diagnoses (tubular, interstitial, etc.) as non-GN disease characterized by injury to the endothelium, mesangium, glomerular basement membrane, and tubular toxicity from heme pigment.

Results: Hematuria was negative or trace blood. Multivariable Cox proportional hazards models were fit for time to composite outcome (ESKD or 40% decline in GFR and eGFR <60). Hematuria was more likely to have an underlying diagnosis of MN (37% vs 23%), be older (43.9 years vs 40.4 years), have ESKD (30% vs 19%), and be female (55% vs 49%) compared to patients without hematuria. Hematuria was associated with the risk of reaching ESKD (HR 1.67 [1.22-2.28], p-value 0.001) and reaching the composite outcome (HR 1.39 [1.05, 1.84], p-value 0.02) and lower hazard of reaching proteinuria remission (HR 0.71 [0.55-0.91], p-value 0.006).

Conclusions: Hematuria was prevalent among patients with podocytopathic disease not classically considered nephritic. There was an independent association between hematuria and worse kidney related outcomes. The underlying mechanisms warrants further investigation and include genetic predisposition, structural alterations in the glomerular basement membrane, and tubular toxicity from heme pigment.

PO1570
Vaccinated Denatured Casts Are a Distinct Type of Urinary Casts Associated with Severe Nephrotic Glomerulopathy
Akanksh Ramandan,1,2 José A. Poloni,3 Abhirup Sarkar,3 Ana P. Giolo Franz,4 Juan Carlos Q. Velez,5 Ochsner Medical Center - New Orleans, New Orleans, LA; 6Universidade do Vale do Rio dos Sinos, Sao Leopoldo, Brazil; 7Suraksha Dialysis, Kolkata, India; 8Hospital de Clinicas de Passo Fundo, Passo Fundo, Brazil.

Background: Urinary casts identified through microscopic examination of the urinary sediment (MicroExUrSed) constitute clinically useful elements for the diagnosis of acute and chronic kidney pathologies. Granular, waxy and cellular casts are well characterized. However, a unique type of casts containing non-polarizable lipid-like granules immersed within a lightly granular cast matrix is occasionally found. These casts have been labeled as vacuolated denatured casts (VDC). The clinical significance of VDC is not known. Herein, we present a case series of patients with specimens containing VDC.

Methods: We utilized an educational social media platform (Twitter) to probe for individual cases of VDC. We surveyed known educators who frequently post microphotographs of MicroExUrSed asking for filed cases of identification of VDC. Demographic and clinical characteristics were extracted and representative images were compiled for correct identification of VDC.

Results: Four urine microscopists (2 from South America, 1 from India, 1 from USA) contributed to the case series. A total of 12 cases were identified. Images were carefully reviewed to confirm identity of VDC. Median age 53 (27-78), 80% men, 50% had type 2 diabetes mellitus. Median serum creatinine at the time of MicroExUrSed was 3.6 (1.7-5.5) mg/dL. All (100%) patients had >3 protein by urinary dipstick. Urine protein-to-creatinine ratio was in the nephrotic range in all cases with available value (median 10.2 (3.3-11.8) g/g). Concomitant findings included hematuria (58%), waxy casts (67%), granular casts (80%), fatty casts (42%) and renal tubular epithelial cells (58%). Histopathological diagnosis was available in 10 cases: 3 diabetic glomerulopathy, 3 focal segmental glomerulosclerosis, 2 transplant glomerulopathy, 1 membranous nephropathy and 1 advanced arteriomegarterosclerosis. Greater than 25% intimal fibrosis was present in 6/10 (60%) cases.

Conclusions: VDC are a distinct type of casts that can be found in specimens of patients with advanced proteincruric glomerulopathy. The specific origin and composition of these casts remains unknown and requires further study.

PO1571
Detection of Urinary Acanthocytes for the Diagnosis of Glomerulonephritis
Akanksh Ramandan,1,2 Swetha Rani Kanduri,1 Vinip Varghese,1 Sarah P. Rosenbloom,1 Juan Carlos Q. Velez,5,6 Ochsner Medical Center - New Orleans, New Orleans, LA; 7The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.

Background: Acanthocyturia is a specific indicator of glomerulonephritis (GN). However, it is reported that the sensitivity of acanthocyturia for the diagnosis of GN is merely around 50%. Examiner expertise is expected to affect the ability to identify urinary acanthocytes. Thus, we hypothesized that in a well-equipped laboratory with proficient observers, the sensitivity of acanthocyturia for the diagnosis of GN can be improved.

Methods: In our institution, we have established a prospective data collection of individuals seen in nephrology consultation who had urine specimen subjected to microscopic examination (MicroExUrSed) as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed within 2 weeks of the MicroExUrSed. We assessed the performance of acanthocyturia in the diagnosis of biopsy-proven GN. Acanthocyturia reflects glomerular hematuria caused by forms of glomerular disease characterized by injury to the endothelium, mesangium, glomerular basement membrane or blood vessel, but not injury to the podocyte that classically presents with proteinuria. Therefore, podocytopathies were grouped with other diagnoses (tubular, interstitial, etc.) as non-GN.

Results: Among 390 patients with MicroExUrSed, 70 underwent kidney biopsy and were included. Mean age was 55 years, 50% were women. White race accounted for 52% and self-identified black race in 29%. Mean serum creatinine was 4.2 mg/dL. Biopsy diagnosis was GN in 27 (39%) and non-GN in 43 (61%). The sensitivity of acanthocyturia for GN diagnosis was 74% (95% CI 53-89%), while the specificity was 86% (95% CI 72-95%). Five of 6 false positive cases had diabetic nephropathy. The positive predictive value of acanthocyturia for GN diagnosis was 77% (95% CI 61-88%) and the negative predictive value 84% (95% CI 73-91%). Acanthocyturia was predominantly detected in pauci-immune GN and IgA nephropathy, with both diagnoses accounting for 14 of the 19 (74%) cases. The hospital laboratory did not report acanthocyturia in any case and misreported it as “yeast” in 2 cases.

Conclusions: With optimal proficiency, the sensitivity of acanthocyturia can be significantly greater than previously reported. Because hospital laboratory does not report it, attempting identification of urinary acanthocytes by nephrologists should be encouraged.
PO1572
Feasibility and Acceptability of Home Urinalysis Monitoring Using a Smartphone Application
Daniella Levy Erez, 1,2 Hannah C. Derwick, 1 Susan L. Furrh, 1 Lance S. Ballester, 1 Jonah Mink, 1,3 Stephanie Onumuo, 1 Michelle Denburg, 1 'The Children’s Hospital of Philadelphia, Philadelphia, PA; 2Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; 3University of Western Ontario, London, ON, Canada.

Background: Monitoring proteinuria in patients with kidney disease is of crucial importance given its implications for long term disease progression and clinical management. As part of efforts to encourage test adherence, leveraging technology to provide a clinical grade urinalysis result from a home test can greatly enhance the clinical experience for patients, caregivers and providers.

Methods: Children and young adults (5-21 yrs old) at a single pediatric center participated. Caregivers or patients (>12yrs) completed a brief survey and then received a home urinalysis kit by mail. The Healthy.io smartphone app uses advanced computer vision to assess the urinalysis dipstick using the smartphone camera. Families downloaded the app through a text message link and performed a home urine test followed by a survey about their experience. Urine results immediately appeared in the app for patients and accessed by the study team through a secure portal. Patient satisfaction was compared between the new app and current practice (home albustix or a urine sample brought to clinic) using Wilcoxon rank test with a p value <0.05. Free text responses were analyzed to identify themes related to the app experience.

Results: 103 children, 63 (61%) male, median age 10.9 yrs. (IQR 7.8-14.2) were enrolled. Primary diagnosis included: 47(46%) glomerular disease, 48(47%) non-glomerular disease, and 8 (8%) kidney transplant recipients. 107(98%) patients were satisfied with the smartphone app compared to 41(40%) patients who were satisfied with the current practice (p<0.0001). (Table 1) Patients’ free text comments were divided into themes in table 2.

Conclusions: The Healthy.io home testing app received very high rates of satisfaction among patients and caregivers compared to current practice and holds great potential to enhance patient-centered care.

Discussion: This case suggests a potential rare cause of PGN with polyclonal-IgG-dominant deposition due to NK cell lymphocytosis. This is the first case to describe a potential association between them. Additionally, while the patient did have a hematologic response to the CyBorD, there was no renal recovery. Although the PGN may have been coincidental, CyBorD therapy should have had some effect while treating PGN. This presents a potentially novel form of the disease resulting in end-stage kidney disease within 3 months in our patient. It also brings up the question of whether it was the presence of NK cell lymphocytosis that worsened the renal prognosis. Such cases are extremely difficult to treat and likely have a poor prognosis. PO1574
A Sporadic Case of Fibronectin Glomerulopathy in Which Mass Spectrometry Was Indispensable for the Diagnosis
Rie Kunitomo, Takahisa Kawakami, Kiyotaka Nagahama, Satoru Hibino, Kazuhiro Fukuoka, Yoshinori Komagata, Shinya Kaname.

Introduction: Fibronectin glomerulopathy (FG) is an autosomal-dominant hereditary disease, which is caused by deposition of mutated fibronectin (FN). The immunostaining of FN is decisive for the diagnosis. We present a case of FG, in which FN was not detected with immunostaining and the detection of FN with mass spectrometry determined the diagnosis.

Case Description: A 60-year-old female with non-functional right kidney with calculus, 5-year history of proteinuria and 2-year history of hypertension presented with proteinuria and nephrocalcinosis. There was no family history of kidney diseases. Physical examination was significant for blood pressure of 176/98 mmHg and the edema. Laboratory test showed serum creatinine of 2.53 mg/dL, serum albumin of 2.3 g/L, urinary protein 5.8 g/day, and slight urinary glomerular RBCs. Anti-nuclear antibody, monoclonal protein, cryoglobulin, HCV, or hypocomplementemia was not detected. Open biopsy was performed. Light microscopy showed lobular glomeruli with mesangial expansion with PAS-positive material. Immunoglobulins, including κ and λ, light chains, and complement were not detected. Electron microscopy showed massive mesangial deposits with fibrillary structure. However, Congo red staining and immunostaining of DNAJB9 and fibronectin (IST-4 and IST-9) were all negative. Finally, the analysis of microdissected glomeruli with liquid chromatography/mass spectrometry (LC/MS) revealed abundance of FN, demonstrating the diagnosis of solitary FG.

Discussion: FG is caused by deposition of the soluble form of FN from serum, rather than the insoluble form produced by resident cells. Therefore, immunostaining with the monoclonal antibody IST-4, which can detect soluble FN, is usually positive in FG, while that with IST-9, which binds only to cellular FN, is negative. Although IST-4 staining was negative in the reported case, FN was detected with LC/MS. This might be due to a structural change of FN in the deposits, which hindered the binding of IST-4 antibody to FN. Furthermore, it was also confirmed that LC/MS is a powerful method to identify characteristics of unexplained glomerular deposits.

PO1575
To Treat or Not to Treat? Therapeutic Challenges in a Case of Advanced Renal Sarcoid
Catherine Lamed, John S. Thrallor, Maura A. Watson. Walter Reed National Military Medical Center, Bethesda, MD.

Introduction: Use of potentially toxic therapy in patients with low chance of renal recovery is clinically challenging. Kidney biopsy with significant interstitial fibrosis and tubular atrophy (IFTA) and reduced estimated glomerular filtration rate (eGFR) suggests unlikely recovery. We describe a patient with advanced IFTA who recovered substantial kidney function with treatment.

Case Description: A 55-year-old man was diagnosed with pulmonary and renal sarcoidosis. Renal biopsy at diagnosis showed granulomatous interstitial nephritis with non-casing granulomas and 20% IFTA. Prednisone was started but was discontinued by the patient for onerous side effects. Serum creatinine (Scr) stabilized at 1.5–1.8 mg/dL. He returned two years later with SrCr 5.8 mg/dL (eGFR 12 ml/min/1.73m2). Urinalysis was significant for blood pressure of 176/98 mmHg and the edema. Laboratory test showed serum creatinine of 2.53 mg/dL, serum albumin of 2.3 g/L, urinary protein 5.8 g/day, and slight urinary glomerular RBCs. Anti-nuclear antibody, monoclonal protein, cryoglobulin, HCV, or hypocomplementemia was not detected. He lacked pulmonary or systemic symptoms to merit empiric treatment, and he was hesitant to receive steroids due to prior side effects. Given new concurrent diagnosis of a monoclonal gammopathy and sclerotic bone lesions, repeat renal biopsy was performed. Light microscopy showed diffuse glomerular sclerosis with interstitial fibrosis and tubular atrophy (IFTA) and reduced estimated glomerular filtration rate (eGFR) suggesting unlikely recovery. We describe a patient with advanced IFTA who recovered substantial kidney function with treatment.

Discussion: The patient was started on high-dose prednisone treatment with high-dose prednisone was started based on the unknown time course of recurrence in a relatively young active patient. SrCr improved to 3.0-3.2 mg/dL and eGFR improved to 12 ml/min/1.73m2. There were no side effects. The patient returned two years later with SrCr 5.8 mg/dL (eGFR 12 ml/min/1.73m2). Urinalysis was negative in the reported case, FN was detected with LC/MS. This might be due to a structural change of FN in the deposits, which hindered the binding of IST-4 antibody to FN. Furthermore, it was also confirmed that LC/MS is a powerful method to identify characteristics of unexplained glomerular deposits.

Clinicalopathological Characteristics of Adult IgA Nephropathy: A Retrospective Cohort Study
Dawn J. Caster,1 Clint Abner,2 Kerime Ararat,2 Patrick D. Walker,2 Amin Yakubu,3 Martin C. Bunke,4 University of Louisville, Louisville, KY; 1Arkana Laboratories, Little Rock, AR; 2Genesis Research, LLC, Hoboken, NJ; 3Travere Therapeutics Inc, San Diego, CA.

Background: IgA nephropathy (IgAN) is the most common form of primary glomerular nephropathy and a leading cause of chronic kidney disease (CKD). These analyses characterize clinical and histological features of IgAN in adults at time of kidney biopsy.

Methods: A retrospective study of clinical and histologic characteristics was performed in patients (pts) ≥18 yrs of age with ≥1 IgAN positive kidney biopsy without prior kidney transplant reported from Arkana Laboratories (Jan 1, 2016-May 30, 2020). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-Epi equation prior kidney transplant reported from Arkana Laboratories (Jan 1, 2016-May 30, 2020).

Results: Of 67,262 kidney biopsies performed during the study period, 4,384 (6.5%) IgAN positive cases met the study criteria and were included, of which, 62.7% were male, 49.6% White, 5.1% African American, 5.3% Hispanic, 5.6% Asian and 34.4% Unknown/Other race/ethnicity. Mean (SD) age at biopsy was 47.7 (16.6) yrs. Urine protein to creatinine ratio (PCR) was 24-hour urine protein data were available for 52.4% of pts and the median (Q1-Q3) was 3.0 (1.0 – 5.0) g/g. Additionally, 65.2% of pts had hypertension, 63.1% had anemia, 25.7% had severe arteriosclerosis, 15.8% had severe arteriolosclerosis, and 27.2% and 20.9% of patients had CKD stage 3 and 4, respectively. The mean (SD) eGFR was 42.4 (32.1) mL/min/1.73m². Immunofluorescence, sclerosis, and fibrosis characteristics are presented in Table 1.

Conclusions: The large proportion of pts diagnosed at CKD stage ≥3 and high MEST-C scores for S and T suggest significant disease duration at the time of biopsy. Earlier intervention may be of value to prevent ESKD.

Natural History of IgA Nephropathy: Analysis of a UK National RaDaR IgA Nephropathy Cohort
Jonathan Barratt,1,2 Moin Saleem,3,4 Fiona E. Braddon,5 Kevin Carroll,6 Ping He,7 Bruce M. Hendry,7 Alex Mercer,7,8 David Pitcher,7,8 Retha D. Steenkamp,9,10 A. Neil Turner,11 Daniel P. Gale,12 1University of Leicester, Leicester, United Kingdom; 2Leicester General Hospital, Leicester, United Kingdom; 3University of Bristol, Bristol, United Kingdom; 4Bristol Royal Hospital for Children, Bristol, United Kingdom; 5UK Renal Registry, Bristol, United Kingdom; 6The Renal Association, Bristol, United Kingdom; 7Royal Free Hospital, London, United Kingdom; 8University College London, London, United Kingdom; 9Travere Therapeutics Inc, San Diego, CA; 10University of Edinburgh, Edinburgh, United Kingdom; 11JAMCO Pharma Consulting, Stockholm, Sweden; 12KJC Statistics Ltd, Cheshire, United Kingdom.

Background: Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis and a major cause of renal failure. Here we describe the natural history of IgAN using the UK National Registry of Rare Kidney Diseases (RaDaR). Since 2013, patients with biopsy-proven IgAN and eGFR <60 mL/min/1.73m² or proteinuria ≥1g/24h have been enrolled into RaDaR from 107 adult and paediatric kidney units across the UK, including retrospective and prospective data. Patients with systemic vasculitis or pre-existing liver disease were excluded.

Methods: Baseline date was defined as first occurrence of renal biopsy, primary renal diagnosis or symptom presentation. Patients were grouped into those with ESKD (CKD stage 5 or renal replacement therapy) at or prior to baseline (ESKD group) and those without ESKD at baseline with ≥12 months follow-up (CKD group). For survival analyses, ESKD or death was applied with survival time calculated from baseline to last follow-up.

Results: In the ESKD group (n=326), median age at first dialysis (56% of patients) and kidney transplant (7%) was 38 yrs (IQR 29-50). In the CKD group (n=1838), median baseline age was 39 yrs (IQR 28-50) with paediatric onset of disease comprising 6%. Baseline median urine PCR was 1.5 g/g (IQR 0.6-3.2; n=356) and mean eGFR was 58 mL/min/1.73m² (SD 32; n=440). Median follow-up was 9.2 years (IQR 5.1-16.3) and ESKD/death occurred in 53% of patients (~1% death). Kaplan-Meier survival curves of paediatric and adult patients show 50% survival probability of 24 & 10 years, respectively (Figure 1).

Conclusions: RaDaR contains a large cohort with long follow up enabling detailed investigation of the natural history of IgAN. These results indicate associations between rapid disease progression and poor outcomes, highlighting a need for effective treatments for patients with IgAN with renal impairment or ≥1g/24h proteinuria.

POI1578

Symptom Burden Among Immunoglobulin A Nephropathy (IgAN) Patients in a US Real-World Setting
Robert M. Perkins,1 Carolina A. Aldworth,2 Raymond Przybysz,3 Jim P. Doherty,2 Stephen W. Olson,1 Anecse T. George,3 Jaydeep Das,1 Rachel Studer,1 Novartis Pharmaceuticals Corporation, East Hanover, NJ; 2Novartis Pharma AG, Basel, Switzerland; 3Novartis Healthcare Pvt. Ltd., Hyderabad, India.

Background: Immunoglobulin A nephropathy (IgAN) is the most prevalent chronic glomerulonephritis and 15-40% of patients will progress to end stage kidney disease (ESKD) within 20-20 years of diagnosis. The symptom burden by eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Methods: This is a descriptive, retrospective study of adult (≥18 years) patients in de-identified Optum® Electronic Health Records (2007-2019). Pre-processed physician notes were used to select patients with at least two IgAN records without any secondary or negative notion. Patients without a record of renal biopsy, valid eGFR and proteinuria

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
levels, or with a history of ESKD/kidney transplant were excluded. The demographic and clinical characteristics, including symptoms up to 12 months before and up to the 1st record of IgAN are presented here; these symptoms were stratified by eGFR and proteinuria levels.

Results: The final cohort consisted of 846 patients with a mean age of 48.5 years; 57% were male and 70.4% Asian. Proteinuria levels of α1 globin were found in 35.7% of patients. The median eGFR was 39.0 ml/min/1.73m², median creatinine was 1.8 mg/dL, and 20.8% of patients had severe deterioration of kidney function (eGFR <15). Overall, more patients in higher chronic kidney disease (CKD) stages experienced any given symptom but this trend was not consistent for higher proteinuria levels.

Conclusions: Our study found that a considerable proportion of patients experienced pain, fatigue and edema. Except in a few instances, all symptoms increased with lower eGFR levels but this trend was less apparent for proteinuria. Our overall findings suggest that a relatively large proportion of IgAN patients, even those with preserved kidney functions could be experiencing substantial symptomatic burden and this warrants further investigation.

PO1579
Clinical Outcomes of Kidney Diseases Diagnosed in Active Duty Service Members
Trevor W. Tobin, John S. Thurlow, Robert Nee, Christina M. Yuan. Walter Reed National Military Medical Center, Bethesda, MD.

Background: There are no studies that have reported glomerulonephritis disease prevalence and looked at the overall healthcare outcomes following renal biopsies in active duty soldiers. We aimed to determine the prevalence of renal diseases amongst the soldiers biopsied at a tertiary hospital and determine the outcomes for these individuals as a result of their diagnoses.

Methods: In this retrospective study, we evaluated the results of all native renal biopsies performed at Walter Reed National Military Medical Center from 2005 to 2020. We used this data to determine the prevalence of patients who progressed to have ESKD (End Stage Kidney Disease), renal transplantation, creatinine doubling, proteinuria greater than 3.5 g/day, medical evaluation board (MEB), and death. The AHITA and JLV EMR systems were used to collect data on the patients who met our inclusion criteria. After the data was collected, chi-squared tests were performed and Kaplan Meier Curves were created for analysis.

Results: Among 169 patients (mean age =32 years old; 79% male; 48% white; 37% black; 7% Hispanic; 4% Asian; 3% pacific islander; 2% other), the most common indication for renal biopsy was for concomitant hematuria and proteinuria (31%) and the most common histologic diagnosis was IgA Nephropathy (23%). The mean time of follow up was 7.3 years. 11% progressed to ESKD, of whom 87% received a kidney transplant (10% overall). Approximately one third progressed to proteinuria greater than 3.5 grams per day and 5% died.

Conclusions: We identified IgA Nephropathy as the dominant histologic diagnosis in our patients undergoing renal biopsy between 2005 and 2020. Despite our patients being largely young and healthy individuals, renal biopsy identified severe disease with over 10% of patients progressing to ESKD and 5% mortality.

PO1580
Clinicopathological Features, Risk Factors, and Outcomes of Immunoglobulin A Nephropathy Associated with Hepatitis B Virus Infection
Jiajia Xuong, Xiuqiao Hospital, Chongqing, China.

Background: Hepatitis B virus (HBV) infections are associated with an increased risk of kidney diseases. However, the effects of HBV infection on the progression of immunoglobulin A nephropathy (IgAN) are unclear.

Methods: A total of 838 patients with biopsy-confirmed IgAN were enrolled in this retrospective cohort study. The patients were categorized into either affected by IgAN and HBV infection (HBsAg-IgAN) or by primary IgAN with no sign of HBV infection (P-IgAN). A 1:1 propensity-score matching was performed between the two groups, followed by a Kaplan–Meier survival analysis, to compare the prognoses, and a Cox regression analysis, to identify factors influencing the HBsAg-IgAN outcomes.

Results: A total of 176 pairs of patients were successfully matched. A significant difference in the systolic blood pressure and UAE, serum creatinine, uric acid, and 24-h urine protein levels was observed between the groups. A renal pathological analysis also revealed a significant difference in the mesangial hypercellularity between the groups. During a median follow-up period of 2.4 years, Kaplan–Meier analysis also revealed a significant difference in the renal survival between the groups. Furthermore, multivariate Cox analysis confirmed that HBV infection is an independent risk factor for IgAN progression (hazard ratio [HR] 2.096; 95% confidence interval [CI] 1.091–4.026).

Finally, the HBsAg-IgAN patients who received treatment with renin-angiotensin-aldosterone system inhibitors had a better overall prognosis than those who received immunosuppressive therapy and antiviral treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

PO1583

International IgA Nephropathy Network (IIgANN) Risk Prediction and Longitudinal Outcomes in the First South-Asian Prospective IgA Nephropathy Cohort (GRACE-IgAN)

Suceena Alexander,1 Santosh Varughese,1 Athul Thomas,1 Jeethu J. Eapen,1 Elenjickal E. John,1 Anna T. Valson,1 Vinio G. David,1 Mohamed R. Daha,2 George John,1,6 John Feachem,3 Jonathan Barratt,4 Christian Medical College Vellore, Vellore, India; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; 4University of Leicester College of Life Sciences, Leicester, United Kingdom; 5University of Leicester, Leicester, United Kingdom.

Background: The Glomerular Research And Clinical Experiments-IgA Nephropathy in Indians is a prospective longitudinal cohort registered with WHO trial id: ISRCTN36834159. The performance of the IIgANN risk prediction score (Barbour et al.) has not been assessed in South Asian IgAN.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 195 patients (97%) completed 3 year longitudinal follow-up. Of these, 180 patients had complete Oxford MEST-C score at baseline. Composite outcome (CO) was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m2 or RRT/Death.

Results: The median predicted 3-year risk of a ≥50% decline in eGFR or ESKD using the IIgANN risk prediction tool was 18.1% (IQR 7.4–31.2) at baseline. The minimum score was 0.64% and the maximum was 55%. Short course IS was used in 146/201 (73%) of patients. 72 patients (36.9%) experienced CO over 3 years. The median risk in patients with favourable outcome was 13.15% (IQR 4.2–21.7) and in those with CO was 32.2% (IQR 19.6–41), P < 0.0001 (Figure A). The area under the ROC curve for detecting CO was 0.81 (95% C.I. 0.74 to 0.88, P < 0.0001) (Figure B). The specificity for predicting CO for percentage risk score >23 was 80% (95% C.I. 72 to 86), and >30 was 90% (95% C.I. 83 to 94).

Conclusions: IIgANN predicted 3-year risk score >23% has good specificity for predicting CO over 3 years. Overall the score seems to be underestimated the actual CO over 3 years in the GRACE-IgAN cohort. This requires further validation.

PO1584

IgA Nephropathy Histopathology and Long-Term Renal Prognosis

Nora C. Maddy, Robert Nee, Sarah M. Gordon, Stephen W. Olson. Walter Reed National Military Medical Center, Bethesda, MD.

Background: The Oxford Classification established the mesangial hypercellularity (M), Endocapillary hypercellularity (E), segmental sclerosis (S), Tubulointerstitial fibrosis (T), and crescents (C) score as an important prognostic tool for IgA nephropathy (IgAN). However, these studies did not investigate the impact of complement 3 (C3) immunofluorescence (IF) staining or interstitial inflammation (iI) on long term renal outcomes, nor evaluate an ethnically diverse population which included African Americans.

Methods: We queried the military health system (MHS) by ICD-9/10 codes to identify potential IgA nephropathy cases. We then reviewed the electronic medical record to find those with biopsy-proven IgA nephropathy. Prespecified clinical data was collected to include MEST-C scores, if, and C3 IF. Primary outcomes included >50% decline in estimated glomerular filtration rates (eGFR), chronic kidney disease (CKD) with eGFR <60ml/min/1.73m2, and end-stage kidney disease (ESKD).

Results: 172 patients were identified with a mean follow-up of 11 years. Mean age was 32 years; 77.9% male; 64.5% White, 9.9% Black, and 12.2% Asian/Pacific Islanders. C3 IF ≥2+ was significantly associated with ESKD (p=0.03) and >50% decline in eGFR (p=0.02). If ≥15% was significant for ESKD (p=0.003), CKD (p=0.01), and >50% decline in GFR (p=0.01). T and C scores were significant for ESKD, CKD, and >50% decline in GFR (all p<0.001). S score was significant for ESKD (p=0.022) and CKD (p=0.009). E score was significant for CKD (p=0.003). M score was not significant for any of the primary outcomes.

Conclusions: We present histopathology associated long term renal outcome data for the most ethnically diverse IgAN cohort with the longest follow up to date in such a population. Our data suggests that degree of C3 staining on IF and amount of interstitial inflammation could augment the prognostic accuracy of the MEST-C score. In addition, it supports the theory that IgA immune complexes activate the alternative complement pathway which drives significant interstitial inflammation ultimately resulting in tubular atrophy and interstitial fibrosis.

PO1585
Severity of Arterial and Arteriolar Sclerosis in IgA Nephropathy and Effects of Renin-Angiotensin System Inhibitors on Its Prognosis

Background: IgA nephropathy (IgAN) patients often suffer from renal arterial intimal thickening (AIT) and arteriolar hyaline (AH) however, it is unclear whether these features are associated with a poor prognosis. This study aimed to analyze whether treatment with renin-angiotensin system inhibitors (RASI) improves those patient’s survival.

Methods: This retrospective cohort analysis included total 871 patients with IgAN, grouped according to the absence or presence of AIT (Study 1; AIT0: n=268) or AH (Study 2; AH0: n=405, AH1: n=354). The clinical, laboratory, and histological backgrounds of the patients were analyzed along with their 20-year renal prognosis. In the AIT1 and AH1 groups, the effect of renin-angiotensin system inhibitors (RASI) on renal prognosis after making adjustments for the background was analyzed and risk factors for progression were also analyzed.

Results: IgAN patients with AIT1 or AH1 had significantly higher age, blood pressure, body mass index, total cholesterol, uric acid levels, and proteinuria than patients with AIT0 or AH0. They also had more marked histologic findings, decreased renal function, and lower survival rates (AIT1: 62.2% vs. 83.4%, p=0.0001; AH1: 2.12, p=0.014).

Conclusions: AIT and AH are associated with serious clinical, laboratory and histological findings and a poor prognosis. RASI was found to improve renal prognosis of those patients.

PO1586
Intensity of Glomerular Galactose-Deficient IgA1 Deposition Can Be a Marker of Disease Activity in IgA Nephropathy
Maku Nakayama,1 Hitoshi Yusuke,2 Mingfeng Lee,1 Toshiki Kano,1 Yoko Makita,1 Yusuke Suzuki,1 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan, 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the development of IgA nephropathy (IgAN). Recently, it was reported that Gd-IgA1 deposition specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association between the intensity of Gd-IgA1 deposition and clinical disease activity and histological severity are not clarified.

Methods: We performed immunostaining with KM55 mAb on paraffin sections of 141 patients diagnosed with IgAN at Juntendo University Hospital. We quantified the level of proteinuria in the high-intensity group was significantly higher than that in the other two groups (low vs middle; 2.7 vs 1.0 g/24h, p=0.001, low vs high; 2.7 vs 1.0 g/24h, p=0.001). Multivariate Cox regression analysis considering with clinical and histological findings and treatments revealed AIT and AH as an independent factor for disease progression (AIT1: hazard ratio (HR), 1.98, p=0.017; AH1: 2.12, p=0.014).

Conclusions: AIT and AH are associated with serious clinical, laboratory and histological findings and a poor prognosis. RASI was found to improve renal prognosis of those patients.

PO1587
Segmental Necrotizing/Crescentic Glomerulonephritis (SNGN) in IgA Nephropathy (IgAN): A Single-Center Experience
Niral B. Ramani, William L. Whittier, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Background: The presence of SNGN on renal biopsy generally portends a poor prognosis. Currently no studies have examined presentation and outcomes of pts with IgAN to determine if the presence of SNGN portends a poorer prognosis in this pt population.

Methods: Biopsies done at Rush University Medical Center from 1992-2019, found IgAN in 75 pts in whom FSGS (73%) was most common. Total of 26 pts (35%) had SNGN (64%). Clinical, laboratory, histologic features at biopsy, treatment and outcome data (doubling of SCr and ESKD) were collected retrospectively. Pts with and without SNGN were compared. Data is presented a mean±SD and a P value of <0.05 was significant.

Results: At biopsy there was no difference in age (42±16 vs 41±17 yrs), gender (54% vs 46% male), race or Scr (1.7±1.1 vs 1.6±1.1 mg/dl) in pts with compared to those without SNGN. Pt with SNGN had higher systolic BP (140±14 vs 131±17 mmHg, P 0.02) and higher UPro/Cr ratio (2.8±2.7 vs 1.7± 1.7 g/l, P 0.04). All 15 SNGN pts tested were ANCA negative. The percent of glomeruli with global (GS)+ segmental (SS) sclerosis (32%±25% vs 38%±28%) and interstitial fibrosis/tubular atrophy (IFTA) (22%±20 vs 23%±22%) was similar for those with vs without SNGN. In pts with SNGN, only 15% had lesions involving >25% of glomeruli. FU was similar on average (7.6± vs 8.7± yrs) in pts with and without SNGN and treatment with ACEis/ARBs was similar (88 vs 100%). A larger proportion of pts with SNGN were treated with immunosuppressive agents (69 vs 21%, P=0.003). At FU, doubling of Scr (25 vs 22%), ESKD (19 vs 21%) and renal survival at 10 yrs (80 vs 76%) were similar in pts with and without SNGN. In both groups, pts that progressed to ESKD had a higher proportion of glomeruli with GS+SS (SNGN: 6±16 vs 24±21%, P 0.002 and No SNGN: 6±27 vs 31±24%, P 0.002) and IFTA (SNGN: 47±19 vs 16±16%, P 0.06 and No SNGN: 41±27 vs 17±18%, P 0.01). In pts with SNGN, the proportion of glomeruli with SNGN was similar in those with and without ESKD (16±14 vs 18±17%).

Conclusions: In pts with IgAN, the presence of SNGN is frequently seen but does not alter prognosis. This may be the result of >25% involvement with SNGN lesions in the majority of our pts and more aggressive treatment in pts with SNGN. The presence of advanced GS+SS and IFTA at biopsy were most associated with progressive kidney disease rather than SNGN.

PO1588
Novel Scoring System Based on the Oxford Classification Indicating Steroid Therapy Use for IgA Nephropathy
Takahito Moriyama, Eri Kasama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: The Oxford classification identifies predictors of the renal prognosis for IgA nephropathy (IgAN); however, it has been unclear about usefulness for deciding the management approach. We analyzed the clinical utility of this classification for indicating steroid therapy.

Methods: The effects of steroid therapy on the long-term prognosis for all 858 IgAN patients and patients divided with M0, M1, E1, S1, and T1 scores and C2 scores according to the Oxford classification (M, mesangial hypercellularity; E, endocapillary hypercellularity; S, segmental sclerosis; T, tubular atrophy/intertstitial fibrosis; and C, crescents) were examined using Cox-Meier analysis and Cox regression analysis. The steroid responder score (SRS) and steroid non-responder score (SNRS) were determined using the obtained results. The effects of steroid therapy on renal prognosis according to the combination of the total SRS and SNRS for IgAN were analyzed using Cox regression analysis.

Results: Steroid therapy improved the 20-year renal survival rates in all IgAN patients (steroid (+): 75.5% vs. steroid (-): 61.7%, p=0.025) and patients with M1, E1, S1, and T0 scores. We recognized the total score of M1, E1, S1, and C2 scores (0–4 points) as the SRS and that of T1 and T2 scores (0–2 points) as the SNRS. Multivariate Cox regression analysis revealed that steroid therapy improved the long-term renal prognosis in IgAN patients with higher SRS and lower SNRS (SRS4/SNRS0: hazard ratio [HR], 0.08 and p=0.008; SRS3/SNRS3: HR, 0.05 and p=0.025; SRS4/SNRS1: HR, 0.11 and p=0.007), but not in IgAN patients with lower SRS (0–3) SNRS1 and any SRS/SNRS2.

Conclusions: Patients with M1, E1, S1, and C2 scores responded to steroid treatment; contrarily, those with T1 and T2 scores did not. A higher SRS was a useful indicator for steroid therapy. Nevertheless, prevention of progression in IgAN patients with SRS was difficult with steroid therapy.
Remission of Hematuria Is Associated with Favorable Prognosis in IgA Nephropathy

Kyung Ho Lee, Young seung Oh, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang, Byung chu Yu. Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea

Background: Recent studies have shown that remission of hematuria is associated with favorable clinical outcomes in patients with immunoglobulin A nephropathy (IgAN).

Methods: This retrospective, multicenter, observational study was conducted using a cohort of patients diagnosed with IgAN through kidney biopsy at three tertiary hospitals. A total of 403 patients who had been followed up for more than 3 years and who underwent regular check-ups at intervals of at least 6 months were enrolled. Hematuria remission was defined as the absence of hematuria for at least 3 months after biopsy for diagnosis but with no RBC per high-power field observed in the urine under the microscope for at least 2 years thereafter.

Results: The mean annual rate of eGFR decline was lower in the remission hematuria group than in the persistent hematuria group (-1.51 ± 2.86 vs. -2.60 ± 3.18 mL/min/1.73 m²/year, p = 0.002). In the remission hematuria group, the mean annual rate of eGFR decline decreased after hematuria disappearance (from -1.28 ± 7.06 to 0.09 ± 0.29 mL/min/1.73 m²/year, p = 0.016). Multivariable analysis revealed remission of hematuria as an independent predictor of a 50% reduction in kidney function (hazard ratio, 0.55; 95% CI 0.33 to 0.99). Renal survival, defined as a 50% reduction in kidney function, was better in the remission hematuria group than in the persistent hematuria group (p = 0.030). However, free of ESRD was not significantly different between the two groups (p = 0.079).

Conclusions: In this study, which used a more rigorous but intuitive definition of remission of hematuria than that used in previous studies, patients with remission of hematuria showed favorable kidney prognosis. This new definition for remission of hematuria could be used as a prognostic marker in actual clinical practice.

Comparison of renal outcomes between the two groups

PO1590

Reduction of Urinary Levels of Lectin Pathway Complement Components in an IgA Vasculitis Patient After MASp-2 Inhibition with Narsoplimab

Laura Pérez Alós, Katrin Sciento, Kari Molyneux, Jonathan Barratt, Peter Garratt. Rigshospitalet, Copenhagen, Denmark; 2 University of Leicester, Leicester, United Kingdom; 3 Leicester General Hospital, Leicester, United Kingdom

Background: A young female suffering from IgA vasculitis was treated with 4 mg/kg weekly infusions of narsoplimab (a MASp-2 inhibitor) for 12 weeks. MASp-2 is considered the key activator of the lectin pathway (LP) by cleaving C4 and C2, after the binding of LP pattern recognition molecules to its ligands. Inhibition of MASp-2 is predicted to decrease complement activation in complement-mediated kidney diseases. In this exploratory study we measured the levels of different LP complement components to evaluate the influence of narsoplimab on complement activation.

Methods: Urine levels of complement activation markers (C4c, C3bc and soluble C5b-9) and serum and urine levels of ficolin-1, -2 and -3, MBL, CL-11, MASp-3, MAP-1 and PTX-3 were measured using sandwich-ELISAs. Urine samples were subjected to LC/MS-MS. Correlations between LC/MS-MS and sandwich-ELISA were conducted using simple linear regression and Spearman’s rank correlation coefficient. Significance: p value < 0.05. Urine proteins were adjusted for creatinine excretion and expressed as specific protein/creatinine ratio.

Results: C4c/creatinine ratio, ficolin-3/creatinine ratio and C3bc/creatinine ratio levels were decreased 75%, 58% and 29%, respectively, from baseline to the end of the treatment; while levels of MBL and CL-11 remained stable during the treatment. C4c/creatinine ratio levels were significantly correlated to LC/MS-MS C4 data (R²: 0.5059; Spearman: r = 0.5824, p = 0.0042). Circulating levels of complement components in serum were unaltered during treatment. Soluble C5b-9, ficolin-1,-2, MASp-3 and MAP-1 were undetectable in urine and PTX-3 was undetectable in both urine and serum.

Conclusions: This is the first report describing the effect of narsoplimab on urinary complement levels in a complement-mediated kidney disease. Our data suggest a decrease in focal complement activation with narsoplimab treatment. Further studies are ongoing to evaluate the use of urine as a non-invasive, inexpensive and readily accessible resource to monitor responses to complement-directed treatments.

Precision Medicine Approach Identifies Patients with IgA Nephropathy at Risk for Progression Using Endothelin Activation Signatures

Vijji Nair,1 Akitha Ju,1 Sean Eddy,1 Min youngwan,2 N. E. Olson,2 Joyce Wu, Jennifer H. Cox, 2 Andrew J. King, 2 Matthias Kretzler, 1 University of Michigan, Ann Arbor, MI; 1 Chinook Therapeutics Inc, Vancouver, BC, Canada.

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis globally, with up to 40% of patients at risk of progressing to ESKD. Endothelin (ET) A receptor activation results in mesangial cell (MC) activation, proteinuria, inflammation, and fibrosis, all considered hallmarks of IgAN progression, suggesting the potential for therapeutic benefit of ETA antagonists. The aim of our study was to identify intratubular renal transcriptional signatures of ET-activation to stratify patients at high risk of IgAN progression.

Methods: We used two approaches to establish a transcriptional signature of ET-activation. First, using a targeted approach, an ET-activation network was generated using three publicly available datasets, producing a gene set of 60 transcripts to create an activity score which was assessed in kidney biopsy profiles in patients with IgAN (n = 25) from the European Renal DNA Bank (ERCB). In addition, an ET-activation signature was also generated using RNASeq profiling of primary human MCs induced with ET1 (4nM) ±/− the selective ETA antagonist atrasentan (25nM, n=780 genes, q<0.05). GSEA in MCs showed up-regulation of cell proliferation, inflammatory and fibrotic networks, with ET1 treatment, which were blocked by atrasentan.

Conclusions: We generated an ET-activation score using a systems biology approach to stratify patients with IgAN. ET-activation signatures were associated with progression, providing additional support for the therapeutic potential of ETA receptor blockade in IgAN patients at high risk of progression. Ongoing work is focused on optimizing the signature, extending findings to additional cohorts and identifying mechanistic biomarkers.

PO1594

NR3C1 Polymorphisms in Membranous and IgA Nephropathies

Michal Pac,1 Natalia Krata,1 Beata Kalreta,2 Barbara Moszczuk,1,2 Aleksandra Wyczalkowska-Tomasik,1 Julia Prystupa,1 Krzysztof Kiryluk,1 Krzysztof Mucha,1,4 Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; 2Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; 3Department of Medicine, Columbia University, College of Physicians and Surgeons, New York, NY; 4Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland.

Background: In other diseases (ex. asthma and pemphigus vulgaris) NR3C1 single nucleotide polymorphisms (SNPs) were associated with glucocorticoid (GC) treatment outcomes. The aim of the study was evaluation of the frequency of NR3C1 (SNPs) in adult membranous (MN) and IgA (IgAN) nephropathies biopsy proven patients.

Methods: We analyzed NR3C1 (SNPs; rs16198, rs14123247 and rs17209237) in 39 MN patients (mean age 42,9±14,2 y.; 42 ±), 39 sex- and age-matched and 35 unmatched IgAN patients (mean age 33,5±12,3 y.; 34 ±) and 39 sex- and age-matched and 136 unmatched healthy controls (mean age 48±7,17 y.; 89 ±) using RT-PCR and GWAS methods. The results were treated for Hardy-Weinberg equilibrium (total p<0.05) and compared between MN, IgAN and controls and within MN and IgAN between GC-resistant and -sensitive and GC-dependent and -independent groups using the χ² with Yates’s correction test.

Results: The frequency of the minor C allele of rs16198 SNP was significantly increased in MN (p<0.05) and IgAN (p<0.05) compared to controls; and in GC-resistant MN (p<0.05), GC-resistant (p<0.05) and GC-dependent (p<0.05) IgAN. The rs16198 SNP genotype was unequally distributed among GC-resistant MN and GC-dependent IgAN (p<0.05) and GC-dependent (p<0.05) IgAN. The frequency of the major A allele of rs17209237 was significantly increased in GC-sensitive (p<0.05) and -independent (p<0.05) IgAN. There was a disequilibrium in rs17209237 SNP distribution among GC-sensitive MN (p<0.05). The minor C allele was significantly more frequent among MN (p<0.05) and IgAN (p<0.05) relapse patients and there was rs16198 genotypes distribution inequality for these both groups (p<0.05, p<0.05).

Conclusions: Rs16198 and rs17209237 alleles and genotypes have different distributions between MN and IgAN and controls; and between patients differently responding to the GC treatment. Results indicate that they predict GC treatment outcomes and therefore should be further investigated for their potential prognostic value.

PO1595

A Rare Case of Paraneoplastic IgA Nephropathy in the Setting of Renal Cell Carcinoma

Alka A. Tyagi, Mohankumar Doraiswamy, Sethu M. Madhavan. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Paraneoplastic nephropathy can present in patients with malignancy. Renal cell carcinoma (RCC) is the most common urologic malignancy; there is a paucity of reported paraneoplastic nephropathies associated with this condition. As such, we present a strikingly unusual case of nephrotic range proteinuria in the setting of recurrent, metastatic renal cell carcinoma.

Case Description: An 81-year-old male with history of recurrent metastatic RCC, solitary kidney after a nephrectomy, with stage III chronic kidney disease (CKD) presents with newly worsening renal function. In a 3-month span, his creatinine (Cr) rose from 1.5 mg/dL to 4.6 mg/dL, which prompted further investigation. He had reported taking daily nonsteroidal anti-inflammatory drugs along with his ACE-inhibitor. Urinalysis showed microscopic hematuria with random urine protein/creatinine ratio resulting 16 g/g and renal ultrasound was unremarkable. Other serologic tests at the time were notable for C3 134 mg/dL, C4 32 mg/dL, negative ANA, negative C-ANCA. Of note, he had suffered an E. coli and MRSA UTI, clostridium difficile infection, and was treated for pneumonia with microbials. A renal biopsy was obtained with pathology significant for IgA-dominant mesangial and capillary wall immune complex deposition with only segmental and weak C3 (Oxford score was reported as M1, E1, S1, T0, C0). Because of the weak C3, in spite of the patient’s history of recent infections, a secondary para-neoplastic IgA nephropathy was favored. He was treated with Nivolumab plus Ipilimumab with improvement in serum Cr improved to 2.23 mg/dL in the following 3 months after starting immunotherapy and remained stable in one-year follow up.

Discussion: Acute worsened renal function and nephrotic range proteinuria in the setting of malignancy prompts investigation into a paraneoplastic nephropathy. As in this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is rare and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.

PO1596

Circulating and Depositing Glomerular Antibodies: A Concurrence or Coexistence

Deepti Avanavelli, Dhanalakshmi Vurum. ESIC Medical College and Hospital Hyderabad, Hyderabad, India.

Introduction: Anti-GBM disease is a systemic autoimmune disorder characterized by circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune angitis (AA), a separate glomerulonephritis linked to circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune glomerulonephritis, coexistence of these two antibodies can occur. In this case, IgG antibodies are associated with this condition. As such, we present a strikingly unusual case of nephrotic range proteinuria in the setting of membranous nephropathy.

Case Description: We herein report a case of 31-year-old female who had presented with new onset of breathlessness, pedal oedema for 15 days and oliguria for 5 days with 1 episode of haematuria. There were no arthralgias, oral ulcers, aplecios, skin rash, sore throat and diarrhoea. Her marital life was of five years with no history of conception or abortions. On examination she had mild pedal edema and her BP was 180/130mm Hg. Blood investigations revealed haemoglobin 9.5g/dl, urea 209 mg/dl, serum creatinine of 4.3g/g. Serologic test results were strongly positive for IgG anti-GBM antibody (rarely IgA and IgM), may coexist with pauci-immune angitis, a separate glomerulonephritis linked to circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune glomerulonephritis, coexistence of these two antibodies can occur. In this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is rare and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.
Discussion: Presentation of IgAN along with anti GBM without linear deposition on renal biopsy but with positive anti GBM titers makes this case interesting. The association of anti GBM disease with IgAN nephropathy could be a coexistence as IgAN is most common glomerular disease or these IgA mesangial deposits might have role in the pathogenesis of triggering GBM antigens and formation of antibodies in this case.

Early Predictors for Stable Kidney Function in Lupus Nephritis

Juan M. Mejia-Vilela, Megan Ashley N. Gerrard, Raque A. Comunidad Bonilla, Luis E. Morales-Buenrostro. National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico.

**Background:** Early prediction of outcomes in LN is essential to adjust LN treatment. The aim of this study was to evaluate the early course of laboratory parameters and their association with long-term stability of kidney function.

**Methods:** We studied 433 patients from our local LN cohort recruited between 2008 and 2017. All patients had >36 months follow-up and complete evaluation at LN flare, 3-, 6-, and 12-months of follow up with hemoglobin, creatinine, 24h-proteinuria, albumin, anti-dsDNA-Ab, complement C3 and C4 fragments. The main outcome was stable kidney function defined as eGFR within 25% of the best eGFR attained in the first 12 months of treatment. Each variable was evaluated individually by ROC curves and in association with other variables. The change in area under the curve (AUC) was analyzed with De Long’s test.

**Results:** Median follow up was 73 months (IQR 51-101). Kidney survival was 90% and 81% at 3- and 5-years, respectively. Stability of kidney function was 77% and 65% at 3- and 5-years, respectively. The predictive performance of each parameter varied with the time period where evaluated (Table). Serum albumin and hemoglobin AUCs improved from baseline to the 3- and 6-month timepoint. Proteinuria and eGFR AUCs improved at each time point up to the 12-month timepoint. C3, C4, and anti-dsDNA-Ab level did not improve at any timepoint vs. baseline. The best predictor of 36-month eGFR stability was proteinuria <1.0g/l by 12 months. The sum of proteinuria plus eGFR provided the best combined AUC at each timepoint (Figure 1).

**Conclusions:** Early course of albumin, hemoglobin, and serological parameters does not improve prediction for stable kidney function in LN. The predictive performance of each biomarker improves over time. The combination of proteinuria and eGFR remains the best predictor of kidney outcomes.

**Table 1. Area under the curve (AUC) of the evaluated parameters to predict stable kidney function by 36 months.**

Long-Term Outcomes of Lupus Nephritis in a Single Tertiary Care Center in South India

Srinivas N. Kinjarapu, Swamalatha Guditi, Siddharth Herur. Nizam’s Institute of Medical Sciences, Hyderabad, India.

**Background:** Lupus nephritis (LN) is a frequent and severe manifestation of SLE. It is a risk factor for chronic kidney injury and end-stage renal disease in SLE we evaluated the clinical presentation and outcome with various treatment regimens in patients with lupus nephritis.

**Methods:** A retrospective study in 50 patients with biopsy proven LN [class III (12), class IV (11), class V4, class III+V (10), class III+V7, class IV+V6] treated with NMP for 3 days followed by monthly CYC for 6 months and oral corticosteroids 0.5-1mg/kg with tapering to 10mg/day at the end of 6th month as induction protocol. AZA or MMF as maintenance regimen based on clinician discretion. Clinical presentation, histopathological (LM+IP) features, treatment regimen, treatment response and renal relapse and outcomes were evaluated.

**Results:** Patients had a mean follow up of 3.6 years, clinical presentation nephrotic N.S (36%), nephritic N.S (24%), RPGN (16%), nephrotic-nephrotic NS-NeS (12%), AKI (12%) patients who had RPGN and AKI presentation had crescentic GN and high chronicity index 46% attained complete remission (CR), 28% attained partial remission. 26% did not respond to treatment(NR) at the end of induction.15 and 8 patients out of 23 who attained complete remission were initiated on MMF and AZA as maintenance regimen respectively, 13/15 in MMF group and 7/8 in azathioprine patients continued to be on DDAI at the end of 2 years. In patients who attained partial remission 5 on MMF and 5 on AZA, on quarterly pulse doses of cyclophosphamide, 3/5 patients on MMF had C.R. 2/5 on AZA had C.R. 2/4 on quarterly pulse doses of CYC had C.R. 6 out of 11 patients who responded were initiated on MMF and NMP. Of 13 who attained C.R, 5 patients were started on rituximab and one with triple immunosuppression (tacrolimus+MMF+corticosteroids), 1 patient who treated with MMF and 1 patient who treated with rituximab attained partial remission, no patient attained complete remission at the end of 2 years.

**Conclusions:** Induction regimen with cyclophosphamide is non inferior when compared to various other induction regimen in LN. Quarterly pulse dose of CYC has no better outcome when compared to AZA and MMF as maintenance. Non responders at the end of 12 months of induction does not have better outcomes at the end of 2 years.

**PO1599**

The Relationship Between Renal Flares and Continuity of Medical Care in Lupus Nephritis

Loulwa Alsharhan,1 Insa M. Schmidt,2 Ramon Bongejo,2 Michael R. York,2 Christina Lam,2 Monica Crespo-Bosque,2 Sushrut S. Waikar,2 Hanni Mem-Josephy,2 Kuwait Ministry of Health, Safat, Kuwait; 2Boston University, Boston, MA.

**Background:** African American and Hispanic patients with lupus nephritis (LN) are known to have worse clinical outcomes compared to those of white patients, with higher prevalence of severe inflammatory nephritis, higher rates of doubling creatinine, End Stage Kidney Disease (ESKD) and death. In this study, we characterized the frequency and severity of renal flares of patients treated in our lupus nephritis clinic.

**Methods:** Patient demographics are presented as mean ±SD; student t-tests were used when appropriate; Chi-square tests were used to determine differences in the number of renal flares and the number of missed appointments (dichotomized into <3 vs. ≥3).

**Results:** Between 2005–2019, a total of 116 patients with Lupus Nephritis treated at the multidisciplinary lupus clinic in a safety net hospital in Boston, MA were enrolled in our study. 23.3% of patients (n=27) self-identified as white and Asian and non-Hispanic (group 1); 76.7% of patients (n=89) self-identified as Black, African American and/or Hispanic (group 2). Patients’ demographics and disease characteristics were similar between the two groups. Over the duration of the study, 59.5% of patients (n=69) did not experience any flare, and 40.5% of patients (n=47) experienced ≥1 flares. Of the patients that experienced ≥1 flares, 89% (n=42) missed one or more appointments over the course of the study. The rate of missed appointments in group 2 was significantly higher than the one observed in group 1 (85.4% vs. 48.1% respectively, p<0.001).

**Conclusions:** This study represents one of the largest cohorts of patients with lupus nephritis with consistent, longitudinal, long term follow up. We found that in our black, African American and/or Hispanic patients population there was a significant association between renal flares and missed appointments. In our safety net hospital setting, missed appointments frequently represents patients’ inability to access care due to various challenges including lack of insurance, difficulty making clinic appointments, transportation challenges, access to certain technologies and language barriers. When looking to reduce racial and ethnic health care disparities, we should design interventions that are aimed at removing key barrier to health care access.

**PO1600**

Collapsing Glomerulopathy Can Worsen Prognosis in Lupus Nephritis

**Background:** Collapsing glomerulopathy (CG) conveys a poor renal prognosis and is characterized by podocytopathy with segmental or global collapse of the capillary walls. While it can be idiopathic, it is often seen in association with other viral, drug, and autoimmune conditions including lupus nephritis (LN). This retrospective study describes features and clinical outcomes of 16 patients with SLE and biopsy proven CG.

**Methods:** Using our Glomerular Disease Collaborative Network registry, we performed retrospective chart review on patients with systemic lupus erythematosus and CG on kidney biopsy with or without an LN lesion from 2000 - 2021. For patients with multiple biopsies, the first biopsy with GC was identified as the incident biopsy. We defined poor renal outcome as reaching a renal endpoint of serum creatinine doubling, chronic dialysis initiation, or renal transplantation. Patients were characterized by baseline demographics, laboratory results, histology, and clinical outcomes. The relationship between renal flares and the number of missed appointments (dichotomized into 0 vs. ≥1).

**Results:** We identified 16 patients with mean age of 33 years at incident biopsy. Most were female (87.5%) and black (87.5%). Mean serum creatinine (Sr Cr) was 3.1mg/dL and mean proteinuria by 24-hour urine collection or spot urine protein:creatinine ratio was 7.12g. Excluding 2 patients with limited follow-up, 11 of 14 (78.6%) patients had poor renal outcomes. These patients were similar in age (mean 33 years) and were also majority female (90.1%) and black (90.1%). In this group, mean Sr Cr was 3.53mg/dL and proteinuria was 3.69g. This group had significant interstitial fibrosis and tubular atrophy with 71% moderate and 28% severe IFTA. The mean creatinine endpoint in 4.5 years (average). Of 3 patients who did not have a renal end point, mean Sr Cr was 1.83 mg/dL with less IFTA noted on biopsy. Treatment options varied with most receiving mycophenolate or cyclophosphamide.

**Conclusions:** This descriptive project confirmed that CG was associated with poor renal prognosis in LN; the majority of the patients required dialysis, proceeded to transplantation, or had doubling of serum creatinine during follow up. Despite treatment with standard of care agents, outcomes remained poor. Patients who had worse Sr Cr at presentation or severe IFTA had worse outcomes.

Serological Activity in Pure Membranous Lupus Nephritis in a Predominantly Black Population
Levard G. Roberts, Aakriti Arora, Hilton Mozee, Jason Cobb. Emory University, Atlanta, GA.

Background: Clinically significant kidney disease is estimated to occur in nearly 60% of patients with systemic lupus erythematosus (SLE). A majority of these patients develop proliferative disease, however 10-15% develop a non-proliferative form of disease known as membranous lupus nephritis (LN) (Class V lupus nephritis). These patients typically present with significant proteinuria. Austin et al. reported 7% of patients with low complements levels and 21% with elevated anti-dsDNA levels. In this study we assess serological activity (C3, C4, anti-dsDNA) of pure membranous LN in a predominantly black patient population.

Methods: Kidney biopsy log from 2010 – 2017, and a retrospective chart review was completed. We excluded any patients with proliferative disease (active or chronic). We analyzed serological activity (C3 level, C4 level & anti-dsDNA) at time of renal biopsy and again at 24 weeks.

Results: Of the total 101 patients with pure membranous LN, we had 54 patients with sufficient follow-up data. 52 of the 54 patients were female with an average age of 35.5; 92.5% (50 of 54) were black. At time of kidney biopsy, low C3 and low C4 was found in 54% and 41% of patients respectively. Whereas an elevated anti-dsDNA was identified in 39% with 20% having the classic triad of low C3, low C4 and elevated anti-dsDNA. When compared to 24 weeks (roughly end of induction therapy) low C3 and low C4 was found in 37% and 24% of patients respectively. Whereas an elevated anti-dsDNA was identified in 31% with 13% have the combination of low C3, low C4 and elevated anti-dsDNA.

Conclusions: In this predominantly black population of pure membranous LN the majority of patients did not have the classic triad of low complements and elevated dsDNA (20%) at time of diagnosis/biopsy). Compared to others looking at pure membranous we did find higher rates of low complements and elevated anti-dsDNA at time of diagnosis (54% with low C3 initially). Possibly due to our unique urban patient population which is >90 percent black, i.e. more severe SLE. Despite the majority of patients not having the classic triad of low C3, low C4, and elevated anti-dsDNA, clinical providers must be diligent in assessing the need for kidney biopsy in SLE and non-SLE patients as serological activity does not correlate with biopsy findings. Earlier treatment correlates with improved prognosis.

Rituximab for Severe Recurrent Proliferative Lupus Nephritis After Kidney Transplantation: Pondering a Rare Case
Rui Song, Mingyue He, Ilay Rahaman, Serban Constantinescu, Iris J. Lee. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Severe histologic recurrence of lupus nephritis (LN) post-kidney transplant (KTX) is extremely rare on standard transplant immunosuppression. Severe recurrence shortens allograft survival, yet treatment guidelines post-KTX are lacking.

Case Description: A 52-year-old African American (AA) man with ESRD secondary to LN underwent a second KTX from a deceased donor. He had a prior living-related KTX with graft failure due to mixed rejection without LN recurrence. For the second KTX, he received Thymoglobulin induction and maintenance immunosuppression with mycophenolate sodium (EC-MPS), Tacrolimus, Prednisone, with immediate graft function (nadir creatinine 1.4mg/dl). He developed leukopenia requiring a reduction of EC-MPS to 360mg twice daily. He developed nephrotic range proteinuria 6 months post-KTX but had stable allograft function, bland urine sediment, normocomplements, and negative anti-dsDNA antibodies. Despite inactive serologies, allograft biopsy revealed diffuse proliferative sclerosing and crescentic LN (INSA/RPS class IV). Due to persistent leukopenia, Rituximab was chosen over commonly-used Cyclophosphamide (CYC) for therapy. He received intravenous Methylprednisolone (3000 mg) and Rituximab 800mg (375 mg/m2) for 4 doses. Complete B-cell depletion was maintained for 3 months. His proteinuria decreased from 6.9 g/kg to 1.2 g/kg, and renal allograft function remained stable.

Discussion: Severe recurrent LN post-kidney transplant is rare and can present with negative serologic markers, bland urine sediment and lack of LN recurrence on the first KTX did not rule out LN recurrence on the second kidney allograft. In our case, only the presence of persistent progressive proteinuria warranted allograft biopsy. AA ethnicity and reduction of EC-MPS were risk factors, which highlights the significance of early treatment. We suggest that all recurrent LN B cells play a pivotal role in LN pathogenesis. Rituximab targets CD20+ B cells and has been successfully utilized for refractory LN. It has a more favorable toxicity profile compared to CYC which has been the conventional treatment for clinically significant LN post-KTX. We propose Rituximab as a better treatment option for severe recurrence of LN post-KTX.

Influenza Vaccination in Systemic Lupus Erythematosus (SLE): Effectiveness, Efficacy, Safety, Utilization, and Barriers
Hannah H. Lin, Sim C. YM. National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore.

Background: Influenza infections increase morbidity and mortality among immunocompromised individuals with SLE and lupus nephritis. Yet, they are highly preventable through vaccination. We aimed to describe the effectiveness, efficacy, safety, utilization and barriers to influenza vaccination in SLE so that targeted strategies can be implemented to improve vaccination rates.

Methods: We conducted a systematic review and meta-analysis of all published and unpublished studies up to 19 May 2021 via PubMed, Embase, Cochrane, WHO Clinical Trials, and ClinicalTrials.gov, which reported on our desired outcomes relating to influenza vaccination in SLE and lupus nephritis.

Results: Of 726 articles screened, 44 studies (14779 patients) were included. 9 studies reported on effectiveness, 20 studies on efficacy, 24 studies on safety, 12 studies on utilization, and 4 studies on barriers to influenza vaccination. Infection or lupus nephritis was present in 20%. The majority were female (90.8%). The mean age was 41.3 years (95% CI 36.8-45.7), mean disease duration was 10.91 years (95% CI 7.1-14.72), and mean SLEDAI score was 4.15 (95% CI 3.18-5.12). Individuals who received influenza vaccination were less likely to develop pneumonia (relative risk, RR 0.38, 95% CI 0.08-1.86, p=0.21). acute bronchitis (RR 0.21, 95% CI 0.09-0.48, p=0.0002), and viral respiratory infections (RR 0.36, 95% CI 0.21-0.64, p=0.0005). Pooled serocorrection and seroprotection rates were 56.6% and 68.2% for H1N1, 56.7% and 73.7% for H3N2, and 46.8% and 69.9% for B influenza strains. Mean SLEDAI scores did not change significantly after vaccination. Flares occurred in 20.3%, while local and systemic adverse events occurred in 20.5% and 26.6%, respectively. Only 39.1% of SLE patients were currently vaccinated against influenza. Meta-regression showed that vaccination rates were significantly associated with increasing GDP of the country (p=0.002) and increasing mean years of disease duration (p=0.02). The most common barriers to vaccination were concerns over the safety of the vaccine (37.2%), lack of doctor recommendation (23%), and having experienced side effects of other vaccines previously (13%).

Conclusions: Influenza vaccination is effective and safe in SLE and lupus nephritis. Targeted strategies are required to overcome barriers to improve influenza vaccination uptake.

Lupus Nephritis in a Patient with Autoimmune Hepatitis: A Case Report
Soo H. Kang, Erin Lawler, Sanjik N. Niranjan. Mount Sinai Hospital, Singapore, Singapore.

Introduction: Overlapping of autoimmune hepatitis (AIH) and lupus nephritis (LN) is a rare entity, only occurring in 1-2.6% of AIH cases, and is difficult to diagnose due to the overlap of diagnostic criteria. Of 15 case reports, one case report is reviewed in the literature.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: 61-year-old male with established remote diagnosis of AIH well controlled on prednisone and naclopride. Urine analysis showed microhematuria and proteinuria (1+). Renal biopsy showed membranoproliferative glomerulonephritis (MPGN) pattern on light microscopy with “full house” on immunofluorescence consistent with class IV renal-limited LN. He was treated with steroids and mycophenolate mofetil with remission of proteinuria and improvement in renal function.

Discussion: Our patient met systemic lupus erythematosus (SLE) criteria via 2019 ACR guidelines with positive ANA (1:320 with dual speckled and nuclear pattern) and renal biopsy results. He did not have any other systemic or constitutional findings. Although he had hypocomplementemia and thrombocytopenia, these were not scored due to his liver disease. He had indeterminate anti-dsDNA levels but later became consistently negative with therapy. Our patient’s rather unique disease course and mixed autoimmune features show the challenges in diagnosis of overlapping AIH and LN. In patients like ours who do not exhibit other systemic signs of SLE, renal biopsy might be the only way to establish diagnosis. Hence, prompt clinical suspicion by the clinician is important in diagnosis and subsequent delivery of treatment. Further case reports will be beneficial in raising awareness of the overlapping of AIH and LN.

PO1606

Delayed Clinical Manifestation of Biopsy-Positive Thrombotic Microangiopathy in a Patient with Lupus Nephritis: A Case Report

Najia Idrees,1 Madeline A. Dilorenzo,1 Joshua S. Hundert,2 Jean M. Francis,1 Hann Menn-Josephy,1 2Boston Medical Center, Boston, MA; 2South Shore Hospital, Weymouth, MA.

Introduction: Complement-mediated thrombotic microangiopathy (c-TMA) involves unregulated complement activation due to inherited or acquired mutations in complement regulatory proteins. Immune complex formation, an important component of lupus nephritis (LN) pathogenesis, can over activate the complement system leading to c-TMA in the kidneys. Findings of c-TMA in LN patients have been associated with end-stage kidney disease (ESKD) or death in up to 50% of patients.

Case Description: 32-year-old female, with a history of lupus and ISN/RPS class III LN since 2017 and recent stroke, was evaluated at our lupus clinic for LN flare with worsening kidney function, increased proteinuria and low complements. A repeat kidney biopsy showed focal proliferative and membranous LN (ISN/RPS class III and V) and been component of TMA. She received standard of care treatment for LN with methylprednisolone and cyclophosphamide, due to past mycophenolate therapy failure. Kidney function and proteinuria improved and complement levels normalized. Three weeks later, she was admitted with hemorrhagic shock secondary to renal subcapsular hematoma, stabilized with PRBC transfusions. After one week, she again developed worsening anemia, worsening thrombocytopenia and oliguric acute kidney injury with diuretic resistant anasarca prompting intubation and initiation of hemodialysis. Hemolysis panel revealed a low haptoglobin, high LDH and schistocytes on peripheral smear. Serum complements were low. Due to high suspicion of c-TMA, she received weekly eculizumab followed by eculizumab every 2 weeks. Three weeks later, her hemoglobin and platelets improved and LDH decreased. Her urine output improved and she was able to come off of hemodialysis. She remained with stage 3b CKD.

Discussion: In patients with LN, severe renally-limited TMA can present without systemic manifestations. In our patient, hematologic signs of TMA appeared only 4 weeks after her initial biopsy-proven TMA, and after clinical improvement of her LN. This highlights the importance of monitoring LN patients with asymptomatic renally-limited TMA closely, and treating them promptly once they develop clinical features of active TMA. Anti-complement therapy with eculizumab is shown to be effective in these patients.

PO1607

Clinical Course of Crescentic Glomerulonephritis in Singapore

Tung Lin Lee,1 Hui Zhuhan Tan, Irene Y. Mok, Jason Choo Chon Jun, Cynthia C. Lim. Singapore General Hospital, Singapore, Singapore.

Background: Crescentic Glomerulonephritis (GN) is histologically representative of severe glomerular damage, and commonly manifests as rapidly progressive glomerulonephritis (RPGN). We report our center’s experience with Crescentic GN over a 5 year period.

Methods: Retrospective cohort study of biopsy-proven glomerulonephritis with ≥10% crescents diagnosed between November 2015 and January 2021 in an academic medical center nephrology unit. Primary outcome was time to death or end stage renal failure (ESRF).

Results: We evaluated 50 patients (36% male), median age 64.7 years (IQR 51.2, 72.4) with crescents in 37.5% (17.4, 54.3) of the glomeruli sampled. At presentation, 70% had acute kidney injury with median serum creatinine 278 (118, 537) µmol/L and 26% required dialysis. The most frequent diagnoses were pauci-immune GN including ANCA-associated vasculitis (70%), lupus nephritis (14%), IgA nephropathy (10%) and anti-GBM disease (4%). At 6 months, the majority (94%) had received immunosuppressants including methylprednisolone (66%), prednisolone (88%), cyclophosphamide (70%), rituximab (12%), mycophenolate mofetil (36%) and plasma exchange (30%). Remission was achieved in 48%. Median follow up was 29.5 (19.8, 48.2) months. End Stage Renal Failure (ESRF) occurred in 32% at 0 (0, 2) months and death occurred in 18% at 5 (1, 23) months. ESRF and/or death occurred in 22 patients (44%). Survival was best for lupus nephritis (log rank p = 0.03) among the most common diagnoses (Figure 1). Multi-variable analysis (stepwise) found that pre-biopsy serum creatinine was independently associated with the primary outcome (HR 1.02, 95% CI 1.01–1.03 per 10 µmol/L increase) after adjusting for age, diabetes, crescents and histological diagnosis.

PO1608

Clinical Characteristics and Outcomes of Severe ANCA-Associated Renal Disease in a Multiethnic Urban Population

Allison J. Leonard,1 Shilpa Arora,2 Ambriahle Athavale,1 1John H Stroger Hospital of Cook County, Chicago, IL; 2 Rush University Medical Center, Chicago, IL.

Background: To study the clinical characteristics, treatment and outcomes of ANCA vasculitides patients in an inner-city county hospital.

Methods: Retrospective study of 60 patients with biopsy-proven ANCA glomerulonephritis and a minimum follow-up of 6 months (median, IQR 23, 29 months) were included. Demographic and clinical information including pathology data, treatment and outcomes were collected. Multivariate regression analyses were done to study predictors of outcomes of estimated Glomerular Filtration Rate (eGFR) at 6 months and End Stage kidney Disease (ESKD).

Results: Patients represented an ethnically diverse population (Figure 1) with baseline characteristics as shown in Table 1. Mean age (SD) at diagnosis was 57.4±13.7. Almost all patients (59/60, 98.3%) presented with hematuria and 17/60 (28.3%) had nephrotic-range proteinuria. Extra renal involvement most commonly pulmonary was seen in 35/60 (58.3%) patients. 44/60 (73.0%) had crescents and nearly all had interstitial fibrosis and tubular atrophy (IFTA) (median, IQR 30%, 56%). Most patients were induced with cyclophosphamide (49/60, 81.7%) and 16/60 (26.7%) received plasma exchange. eGFR (mean±SD) at baseline and 6 months follow up were 20.8±19.4 and 43.5±23.0 respectively. 15/60 (25%) patients progressed to ESKD. On multivariate linear regression analysis, age (B -0.5), IFTA (B -0.7) and baseline eGFR (B 0.3) predicted eGFR at 6 months and IFTA (OR, 95% CI, 11.5, 1.1-11907.7) and eGFR at 6 months (OR 0.9, 95% CI 0.8-1.0) were associated with ESKD (P <0.05) on multivariate logistic regression analysis. Ethnicity, ANCA type or titer, crescents on biopsy and treatment received did not predict EGF at 6 months or ESKD.

Conclusions: In this cohort of patients with severe ANCA glomerulonephritis IFTA and baseline eGFR were the most significant predictors of eGFR at 6 months follow up which in turn was associated with progression to ESKD.
Long-Term Outcome in Patients with ANCA-Associated Vasculitis

PO1609

Background: Renal involvement in ANCA is common, ranging between 80 and 90%; of note, up to 40% of patients (pts) with renal involvement will develop End-Stage Renal Disease (ESRD).

Methods: Monocentric, retrospective study, including all pts with clinical or histological diagnosis of ANA with renal involvement followed at our Unit from 1990 to 2019, with follow-up (fu) ≥12 months.

Results: We identified 281 patients. Median fu was 75 months (IQR 33.1-141). Most pts were classified as MPA (71%), followed by GPA (26%) and eosinophilic granulomatosis with polyangiitis (3%). ANCA were positive in 97% (anti-MPO in 66%, anti-PR3 in 31%). At onset, median creatinine was 3.5 mg/dl (IQR 1.9-6.7) and proteinuria 1.1 g/24h (IQR 0.5-2); 20% of pts required haemodialysis (HD), with subsequent recovery of renal function in 55% of them. Induction therapy consisted of oral corticosteroids for all pts, with iv pulses >1 g in 38% of cases; plasma-exchange in 27%; cyclophosphamide in 57% and rituximab in 33% of pts. Relapses were experienced in 31% of pts, with renal flares in 20%. Renal survival was 87%, 79% and 73% at 1.5 and 10 years, respectively. At multivariate Cox regression analysis, clinical diagnosis of MPA (HR 5.116, CI 3.437-7.408, p<0.0001) and HD requirement at onset (HR 13.469, CI 9.050-19.304, p<0.0001) were predictors of mortality. Overall survival was 90%, 77% and 56% at 1, 5 and 10 years, respectively. Most deaths were due to infections (33%), followed by cardiovascular (CV) diseases (20%) and malignancies (13%). At multivariate Cox regression analysis, age (HR 5.724, CI 3.846-8.288, p<0.0001) and HD requirement at onset (HR 2.902, CI 1.949-4.202, p<0.0001) were predictors of mortality.

Conclusions: Despite several therapeutic advances, AAV with renal involvement are still characterised by poor prognosis, especially in pts requiring HD at onset and of older age, infection, CV diseases and malignancies were the main causes of death.

Predicting Outcomes in ANCA-Associated Vasculitis Using a Complete National Cohort

PO1610

Dominic P. McGovern, Jennifer S. Lees, Colin C. Geddes, Emily McQuarrie, Kate J. Stevens. The Scottish Renal Biopsy Registry The Glasgow Renal and Transplant Unit, Glasgow, United Kingdom.

Background: Outcomes in ANCA vasculitis remain difficult to predict & therapeutic decision-making can be challenging. We aimed to establish if a renal risk score (RRS) could predict outcomes.

Methods: The Scottish Renal Biopsy Registry is a complete national dataset of all biopsies performed in Scotland. Those who had a first renal biopsy between 2014 & 2017 with evidence of ANCA vasculitis were included. Demographic data & outcomes were recorded. RRS was calculated. Each patient was categorised according to % of normal glomeruli, % of tubular atrophy/interstitial fibrosis & eGFR (CKD-EPI) at time of biopsy.

Results: Two-hundred & forty-six patients with biopsy proven ANCA vasculitis were identified. Fifty percent (n=123), 46% (n=112) & 5% (n=11) were stratified as low, medium & high risk respectively. Fifty-two percent (n=126) were male & mean age at biopsy was 66.7±12.2 years. Mean eGFR was lower in the high-risk category (8.6±4.0mL/min/1.73m², p<0.001) & proteinuria was higher (405 (IQR 292-503) mg/mmol, p<0.001). Thirty-seven percent (n=91) were PR3 antigen positive. Eighteen (7%) patients experienced pulmonary haemorrhage, representative similar across all risk categories. Those categorised as medium or high risk were more likely to receive plasma exchange & haemodialysis at presentation (p<0.001) compared with the low risk category. Overall, 16% (n=40) of patients relapsed with a trend to higher risk of relapse in the low risk group (27% of these patients, p=0.05). Thirty seven (15%) patients developed ESKD. Cox proportional hazard model for development of ESKD shows that those in high risk category were more likely to reach ESKD (adj HR 78.4, 95% CI 14-438.4, p<0.001).

Conclusions: A simple RRS, using routinely reported data, in patients with renal biopsy proven ANCA vasculitis can help to predict development of ESKD. It may also be predictive of future relapse in those with a lower RRS. The RRS could inform monitoring & treatment decisions. A unique strength of this data is that it is based on a complete national dataset making it less susceptible to bias from regional variations in practice.

ANCA-Associated Crescentic Glomerulonephritis (AAV-GN) in Patients with Chronic Lymphocytic Leukemia (CLL): A Case Series

PO1611

Background: Previous case reports have identified an association between CLL and AAV-GN. However, information on the clinical and pathologic characteristics and long-term outcomes of AAV in the setting of CLL have remained poorly described.

Methods: We queried medical records and research databases of CLL and AAV subjects seen at our institution to identify patients with diagnoses of CLL and AAV-GN from 1990-2020. We analyzed patient demographics, AAV-GN, CLL specific characteristics, treatments, and outcomes. Kidney biopsies were also reviewed.

Results: We identified 12 patients with AAV-GN and CLL. The mean age at diagnosis was 65 years (48, 80) for CLL and 68 years (57, 80) for AAV-GN. 5 patients were diagnosed with CLL prior to AAV-GN, 4 the same month, and 2 developed CLL ≥3 years after their diagnosis of AAV-GN. At the time of AAV-GN diagnosis, all had acute kidney injury, with a median serum creatinine (Scr) of 1.9mg/dL (SD 3.2). Other organs involved included lungs (n=3), skin (n=1), and eyes/ encephalitis (n=1). 9 patients p-ANCA-MPO and 2 had c-ANCA-PR3 and one with an indeterminate ANCA but had PR3. On light microscopy, all had crescents, no vasculitis of the arteries, but 9 patients had focal lymphoid infiltrates without a formal diagnosis of CLL in the kidneys. On immunofluorescence 6/12 had trace to 1+ of IgA, 5/12 with IgG and 4/12 with C3. 7/12 of the biopsies had mesangial deposits and majority (1 with diffuse and 7 with moderate–moderate) had foot process effacement. All patients received treatment for AAV (9 with rituximab, and 3 with cytotoxic drugs). Renal outcomes were favorable with 11 patients showing an improvement or stabilization in Scr. One patient (p-ANCA MPO) developed end stage kidney disease, and 3 patients died, two from CLL and the other from heart failure.

Conclusions: In this case series, outcomes for patients with AAV-GN and CLL, the vast majority had p-ANCA MPO, suggesting that the two conditions have either a common underlying lymphocyte dysfunction or that this is a predisposing factor to the development of AAV. Anti-CD20 monoclonal antibody therapy was most commonly used, and it led to remission of AAV-GN.

Kidney Biopsy Chronicity Grading in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

PO1612

Marta I. Casal Moura, Fernando C. Fervenza, Ulrich Specks, Sanjeev Sethi. Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: Kidney biopsy is valuable for prognostic assessment of renal outcomes in antibody-mediated vasculitides. The Kidney Disease: Improving Global Outcomes (KDIGO) criteria (2009) considers cellular infiltration and chronicity of arteritis, but the precise triggers of onset and relapse are unknown. The potential effect of cumulative UVB radiation on disease phenotype and activity, mediated by vitamin D (vitD), has been proposed, given the marked incidence variation of AAV phenotypes and serotypes with latitude. Using a well-validated vitD proxy (cumulative-weighted UVB exposure), we characterize the effect of cumulative UVB dose on the arterial lesions of ANCA-vasculitis (AAV) and the impact of anti-CD20 monoclonal antibody therapy in AAV-GN.

Results: We analyzed 329 patients with kidney biopsies available to score. The extent of chronicity was graded by MCCS as: (i) minimal – 102 (31.0%), (ii) mild – 106 (32.2%), (iii) moderate – 86 (26.1%), and (iv) severe – 35 (10.6%). The MCCS grades correlated with the degree of renal function impairment at presentation (mean eGFR 48.3 vs. 29.2 vs. 23.7 vs. 18.5 mL/min/1.73 m², p<0.0001). Higher degrees of the individual components of the MCCS (glomerulosclerosis, interstitial fibrosis, tubular atrophy and arteriosclerosis) were associated with lower median eGFR (p<0.0001) and decreased event free (kidney failure (KF) and death) survival (p<0.002, p<0.001, p<0.001 and p<0.001, respectively). Patients AAV-GN who received rituximab with or without comorbidities had significantly lower arterial lesion score (p<0.001). The effects of rituximab on arterial lesions were preserved long after treatment was used (CYC or RTX). The MCCS stratified renal outcomes for each MCCS grade and can be used in clinical practice as a cut-off for KF prediction (MCC Sa4).

Conclusions: Chronic changes on kidney histology independently predict renal function, outcomes and response to treatment in AAV-GN.

The Effect of Cumulative UVB Dose on ANCA-Associated Vasculitis

PO1613

Jennifer Scott,1 Enoch Hayvarchanam,1 Albert Navarro-Gallinad,1 Jason Wyse,1 Jos van Geffen,1 Antonia Buettner,1 Tamara Wanigasekara,1 Louis J. Aslett,4 Nicole Basu2,1 Lisa Zgaga,1 Mark A. Lomas,2,4 The Trinity Health Kidney Centre, Trinity College Dublin, Ireland 2University of Dublin Trinity College, Dublin, Ireland; 3Institute of infection, immunity and inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; 4Royal Netherlands Meteorological Institute (KNMI), De Bilt, Netherlands; 5Department of Mathematical Science, University of Durham, Durham, United Kingdom.

Background: ANCA-associated vasculitis (AAV) has a relapsing-remitting course but the precise triggers of onset and relapse are unknown. The potential effect of ultraviolet B (UVB) radiation on disease phenotype and activity, mediated by vitamin D (vitD), has been proposed, given the marked incidence variation of AAV phenotypes and serotypes with latitude. Using a well-validated vitD proxy (cumulative-weighted
UVB dose (CW-D-UVB) at wavelengths that induce vitD synthesis was hypothesized that prolonged periods of low ambient UVB are associated with an increased risk of GPA phenotype and AAV relapse in this subgroup.

Methods: The UKIVAS (n=1994) and Irish Rare Kidney Disease (R KD) (n=439) registries were used (total n=2433). Inclusion criteria: i). definite AAV diagnosis, ii). positive proteinase-3 (PR3) or myeloperoxidase (MPO) serology and/or positive histopathology. Logistic regression was used to investigate the relationship between latitude, CW-D-UVB and AAV phenotype/serotype in the entire cohort. A multi-level model was then applied to examine their effect on AAV relapse risk in the R KD subgroup.

Results: CW-D-UVB varied across seasons and latitudes. There was no relationship between latitude/CW-D-UVB at disease onset and AAV phenotype/serotype. MPA, MPO-ANCA, older age and rituximab maintenance were protective against relapse. There was no association between CW-D-UVB and relapse risk, even when examining phenotype specific risk (table 1).

Conclusions: We found no association between cumulative UVB, a validated vitD proxy, and AAV phenotype, ANCA serotype nor AAV disease activity in a genetically homogeneous cohort. These findings cast doubt on the role of vitD in AAV disease activity.

Multilevel model investigating the association between CW-D-UVB and AAV relapse

PO1614

A Severe Presentation of Systemic Lupus Erythematosus (SLE) and ANCA-Associated Vasculitis (AAV) Overlap Syndrome

Jaelyn Khil, Thuy M. Nguyen, Sijie Zheng. Kaiser Permanente Oakland Medical Center, Oakland, CA.

Introduction: An increasingly recognized overlap syndrome (OS) of lupus nephritis and AAV. A positive crescentic glomerulonephritis is rare and presents treatment challenges. It’s not clear whether to treat as LN or ANCA vasculitis. Here we describe a severe presentation of OS, the subsequent management and positive outcome.

Case Description: A 42 y.o. woman with no PMH presented with 3 weeks of cough, dyspnea, fever, malaise, AKI and hypoxia. Her hgb was 6.3 g/dl and creatinine 17.4 mg/dl (normal 1.5 years prior). UA showed large hgb and >182 RBCs and UPC 7.72 g/g. Serologies were significant for elevated Di Da, RNP ab, Smith ab and positive ANA with low complement levels. MPO ab was elevated to >8.0 (>0.9) and anti GBM negative. Cardiopulmonary ab was elevated but beta 2 glycoprotein ab and lupus anticoagulant ab were negative. Chest CT showed multifocal opacities. She was urgently started on hemodialysis and solumedrol 1g for 3 days then prednison 60mg daily. On day 2 of admission she underwent renal biopsy. Her course was complicated by hemoptyosis and bronchoalveolar lavage showed diffuse alveolar hemorrhage (DAH). She was initiated on plasmapheresis. Biopsy demonstrated necrotizing crescentic GN with immunofluorescence showing full house pattern and complex deposits with strong ANA staining of nuclei. Given the biopsy results and serologies the patient was diagnosed with LN/AAV overlap. The patient was started on Cytotec 750mg monthly administration. She completed 7 daily sessions of plasmapheresis and renal function recovered sufficiently to stop dialysis. Two months after discharge, her renal function continued to improve with her most recent creatinine down to 2 mg/dl.

Discussion: LN and AAV overlap is rare and there are no guidelines regarding management of these patients. This case stresses the importance of having a high suspicion of LN-AAV when a young, female patient presents with new onset renal failure and DAH. The patient benefited from early, aggressive treatment targeting both disease processes including early initiation of high dose steroids. Secondly, plasma exchange should be initiated emergently with severe presentation, including DAH. Plasmapheresis did not reduce incidence of ESKD in PEXIVAS trial, however, we suspect in this case it contributed to the good outcome. Lastly, little is known about outcomes in these patients, but this is an example of a severe presentation with a positive outcome.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
and diffuse ATN. As creatinine worsened (peak 2.66mg/dL), mycophenolate (MMF) was added after resolution of bacteremia following iv antibiotics. 1 week after stopping antibiotics, he was readmitted with AKI, nephritic syndrome, and recurrent *E. faecalis* bacteremia. MMF was stopped and antibiotics restarted with improvement in creatinine (1.40mg/dL) and urine sediment.

**Discussion:** This is a rare case of PR3-ANCA vasculitis due to *E. faecalis* endocarditis. A kidney biopsy and high index of suspicion is crucial in diagnosing pauci-bacteremia. MMF was stopped and antibiotics restarted with improvement in creatinine.

**POI1617**

**A Rare Case of Crescentic Glomerulonephritis, Diffuse Proliferative Class IV Lupus Nephritis, and Collapsing Glomerulopathy in a COVID, P-ANCA, and Myeloperoxidase-Positive Patient**

**Introduction:** An unusual case of Diffuse Class 4 Lupus nephritis, along with Collapsing Glomerulopathy from asymptomatic COVID infection

**Case Description:** 42 year old Asian female presented with painless hematuria, anasarca, reduced hearing, and eye redness over a month. She had empiric antibiotics and steroids prior to admission. On admission, she was hypertensive with anasarca. Labs revealed AKI creatinine of 2.5 mg/dl, proteinuria of 11 grams, and serum albumin 1.9 gm/dl. Urine analysis showed dysmorphic RBCs, RBC casts. Ultrasound showed 12 cm kidneys bilaterally. She had normal complements and DS DNA, antiaicardiopilin and lupus anticoagulant negative. ANA, antitnemorene antibody, COVID, PANCa, MPO all positive. Kidney biopsy showed crescentic glomerulonephritis, diffuse proliferative glomerulonephritis Class IV, collapsing glomerulopathy, full house pattern on IF. EM showed sub endothelial, mesangial, and para mesangial deposits, diffuse podocyte foot process effacement, corona virions in endothelial cells. The patient did not have any COVID symptoms and was treated with pulse steroids, MMF induction, hydroxychloroquine, and ACE I. Serum creatinine improved to 1.33 mg/dl, proteinuria improved to 5.6 grams. Her eye redness and hearing impairment resolved.

**Discussion:** This is a rare case of diffuse class IV lupus nephritis with normal complements, DS DNA, and full house pattern on IF. She tested positive for COVID, was asymptomatic, and was able to start treatment. Corona virions and podocytopathy was noted on EM. Improvement in proteinuria, serum creatinine, albumin, and resolution of anasarca were used to monitor response to treatments. Complements and DS DNA could not monitor disease activity. Thus, clinicians should not rely purely on serologies for diagnosis but should pursue kidney biopsy for definitive diagnosis and treatment. Patients may have atypical presentations.

**POI1618**

**Schistosomiasis in a Patient on Rituximab for ANCA-Associated Glomerulonephritis**

Milica Jovanovic,1,2 Muhammad U. Aameish,1,2 Donald I. Baumstein,1,2 Ashok P. Chaudhari,1,2 1Metropolitan Hospital Center, New York, NY; 2New York Medical College, Valhalla, NY.

**Introduction:** Rituximab and glucocorticoids induce remission in ANCA associated vasculitis with renal involvement. Rituximab induces B-cell depletion and influences T-cell immunity, which predispose patients to serious infectious complications. We present a case of schistosomiasis in a patient on rituximab for Pauci Immune Glomerulonephritis (GN) associated with ANCA vasculitis.

**Case Description:** A 39 years old female from Honduras with history of sero-negative arthritis, acute kidney injury with pauci immune, focal necrotizing and diffuse crescentic GN on kidney biopsy and P-ANCA positive, was treated on rituximab and glucocorticoids. Ten months later, while in remission she presented with nausea, vomiting, obstipation and abdominal pain. Her labs showed, Hgb: 10.4g/dl, WBC: 6780/mcL, Eosinophils 25%, Cr: 0.7mg/dl, H. Pylori: Positive. Gauic negative. Stool negative for ova/parasites. Endoscopy showed non-bleeding erosive gastropathy with scattered punctate ulcerations in the duodenum. On biopsy diffuse acute and chronic inflammation, focal cryptitis, erosion of mucosa, Schistosoma Mansoni ova in glands of stomach, duodenum and jejunum were noted. CT brain negative for cysticercosis. CT chest showed calcified granulomas in right middle lobe and right lower lobe. On reevaluation she admitted to consuming snails. Rituximab maintenance therapy was not continued because of schistosomiasis. She was admitted for a multidisciplinary approach. Renal function remaining stable protein/creatinine ratio 0.8, Myeloperoxidase positive. Patient was started on Praziquantel 1.2 g tid and prednisone 60 mg for 5 days which was followed by another cycle after 4 weeks to treat any remaining adult schistosomes. Repeat EGD and colonscopy with multiple biopsies to ensure eradication of schistosomiasis before resuming rituximab is planned.

**Discussion:** Our case emphasizes the need to consider parasitic infections when starting patients from endemic areas on immunosuppressive therapy. Schistosomiasis can involve multi-organ systems and can lead to potentially debilitating and fatal complications such as liver fibrosis, portal hypertension, hypersplenism, esophageal variceal bleeding, GN and nephritic syndrome. Detailed history for dietary habits and lifestyle is important. Serology, antigen detection or other diagnostic tools can be used when the suspicion is high.

**Porcine Desiccated Thyroid Extract Associated Dual Positive ANCA Vasculitis**

Nandakishor Kapa, Niti Madan, Mingyu Cheng, Nasim Wiegley. University of California Davis Medical Center, Sacramento, CA.

**Introduction:** Among medications used for thyroid disorders associated with small vessel vasculitis, the most well-known is propylthiouracil. However, there have been no reported cases of ANCA-associated vasculitis (AAV) with desiccated thyroid replacement hormones. We report the first case of drug-induced ANCA vasculitis presumed to be associated with porcine desiccated thyroid supplementation (Armour Thyroid).

**Case Description:** A 43-year-old Caucasian woman with Hashimoto’s thyroiditis and bipolar disorder presenting with 1 month of generalized fatigue, subjective fevers, and foamy urine was found to have acute kidney injury with creatinine (Cr) peaking at 3.80 mg/dl from baseline 1.0 mg/dl. She recently started desiccated thyroid supplementation prior to the onset of symptoms. Urinalysis revealed active sediment with hematuria and subnephrotic proteinuria with 24-hour urine protein 1.1 gm/day. Serologic testing was notable for MPO Ab IgG positive >8.0 AI and PR3 Ab IgG positive > 6.4 AI. Further serologic workup, including anti-histone Ab, was negative. Kidney biopsy revealed features consistent with pauci-immune glomerulonephritis with cellular and fibrocellular crescents, mild interstitial inflammation and tubulitis, and mild arteriosclerosis and hyaline arteriosclerosis. She was not taking any other known medications associated with drug-induced vasculitis. She received pulse dose steroids with taper per the PEXIVAS trial.
protocol and Rituximab therapy per the RAVE trial protocol. Cr improved (1.6 mg/dL) after induction therapy with persistent mild proteinuria at <500 mg/g at 6 months. Dual MPO and PR3 positivity persisted until Rituximab completion, after which only MPO positivity continued.

Discussion: It is well known that anti-thyroid medications can cause drug-induced AA V. However, this is the first report of an AA V case with desiccated thyroid supplementation. Thrombocytopenia suggests clinicians should also be aware of AA V as a possible adverse consequence of thyroid supplementation. Management should include discontinuation of the offending agent and consideration of immunosuppression with standard induction regimens based on disease severity.

PO1620
Renal Survival in Anti-Glomerular Basement Membrane Disease
Lauren Ford,1 Anna S. Li,2 Nina Brown,3 Helen Alderson,4 Silke R. Brix,2 Ajay P. Dhyagude,3 1Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 2The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 3Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4Salford Royal NHS Foundation Trust, Salford, United Kingdom.

Background: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD). Reliable predictors of survival are limited.

Methods: Retrospective analysis of patients with anti-GBM disease from the North West of England.

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for anti-neutrophil cytoplasmatic (ANCA) and GBM antibodies (28.57%). Median age was 64 years (Interquartile range 43 – 76 years). 39 patients were female (55.7%). Median kidney function at presentation was an estimated glomerular filtration rate of 93 mg/min (eGFR, IQR 41.95 – 835.75 mg/min). Sixty patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw from RRT (25.5%). Median follow up was 41 months (IQR: 11 – 75.7), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2.4 mg/min recovered function.

Conclusions: Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

PO1621
Validation of the Renal Risk Score in Anti-GBM Disease
Anna S. Li,1,4 Lauren Ford,1 Nina Brown,3 Helen Alderson,4 Ajay P. Dhyagude,3 Graeme T. Reid,3 Silke R. Brix,1 1The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 2Salford Royal NHS Foundation Trust, Salford, United Kingdom; 3Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 4Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Background: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD). Clinical and histological variables predicting outcome are needed to individualise therapy and improve outcome.

Methods: We performed a retrospective multicentre analysis and investigated the Renal Risk Score (RRS) proposed in anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis for its prognostic value in anti-GBM disease. We used the published cut-offs per percentage of normal glomeruli (N0 > 25%, N1 10 - 25%, N2 < 10%), estimated glomerular filtration rate (eGFR, G0 = 15 ml/min/1.73 m2, G1 ≥ 15 ml/min/1.73 m2) and a simplified cut off for tubular atrophy and interstitial fibrosis (T0 mild to moderate, T1 ≥ moderate). We assigned points to each parameter (N1 =4, N2 =6, G1 =3, T1 =2 points) and patients to risk groups, low (0), intermediate (2 - 7), and high risk (8 - 11 points).

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for ANCA and GBM antibodies (28.57%). Median age was 64 years (Interquartile range, IQR 43 – 76 years). 39 patients were female (55.7%). Median eGFR at presentation was 593 mg/min (IQR 419.75 – 835.75 mg/min). Sixty patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw from RRT (25.5%). Median follow up was 41 months (IQR: 11 – 75.7), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2.4 mg/min recovered function.

Conclusions: Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

POI623
Itolizumab, a Novel Anti-CD6 Therapy, in Systemic Lupus Erythematous Sus Patients: Interim Safety Results from the Phase 1b EQUALISE Dose-escalation Study
Chaim Putterman,1 Richard Furie,1 Jai Radhakrishnan,2 Vandana S. Mathur,3 Krishna R. Polu,4 Stephen Connely,4 Joel M. Rothman,5 Cherie T. Ng,6 Leslie Chin,5 Maple M. Fung,7 Dolca Thomas,7 Kenneth Kalunian,4 Yeshua University Department of Medicine, New York, NY; 5Equillium, Inc, La Jolla, CA; 6Equillium, Inc, La Jolla, CA.

Background: CD6 is a co-stimulatory receptor predominantly expressed on T cells. The CD6 ligand, ALCAM, is expressed on antigen presenting cells, epithelial and endothelial cells. Itolizumab (ITO) is a humanized IgG1 monoclonal antibody that binds CD6 and blocks ALCAM interaction to inhibit T cell activation and trafficking.

Methods: EQUALISE is an open-label Phase 1b 2-part study evaluating the safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of subcutaneous dosing of ITO in subjects with active proliferative Class III/IV LN for 24 weeks, is currently enrolling (NCT04128579).

Results: Part A enrolled 34 subjects: 0.4 mg/kg (n=6), 0.8 mg/kg (n=7), 1.6 mg/kg (n=7), 2.4 mg/kg (n=6), and 3.2 mg/kg (n=9). Similar baseline characteristics were noted between cohorts. The mean age was 51, with 94% female, 74% white and ~11 years since SLE diagnosis. C3 and C4 were within normal ranges. Mean eGFR was 98 ml/min/1.73m2 and the median UPCR was 91 mg/g (range 48-1505). SC dosing of 0.4 mg/kg to 2.4 mg/kg (n=26) was well tolerated, with 38% reporting an AE, predominantly mild injection site reactions, with no SAEs reported. >85% of 3.2 mg/kg subjects reported an AE, the most common was injection site reactions, with 2 non-treatment related SAEs reported in 1 subject (hypotension, syncope). 4 3.2 mg/kg subjects (50%) discontinued treatment after 1 dose voluntarily. In all cohorts, there were no notable changes in vital signs, weight or creatinine levels, except for transient increases in creatinine levels without clinical sequelae. PK and PD results show dose-proportional increases in ITO exposure and rapid and dose-dependent decreases in CD4 cell surface expression of CD6.

Conclusions: 2 SC doses of ITO up to 2.4 mg/kg SC in SLE subjects were well tolerated with less tolerability to the 3.2 mg/kg dose, as 50% discontinued after 1 dose. The data support continued evaluation of ITO in SLE/LN. The ongoing EQUALISE Part B assesses ITO safety and efficacy in Class III/IV LN patients. Funding: Commercial Support - Equillium, Inc.

Itozumab, a Novel Anti-CD6 Antibody, in Systemic Lupus Patients with Proteinuria: An Interim Subgroup Analysis from EQUALISE, a Phase 1b Study
Chaim Patterman,1 Richard Furie,2 Jai Radhakrishnan,3 Vandana S. Mathur,2 Krishna R. Pola,2 Stephen Connolly,1 Joel M. Rothman,3 Leslie Chinn,4 Nuwaran, Mayayakarta,2 Maple M. Fung,2 Cherie T. Ng,5 Dolca Thomas,5 Kenneth Kalunian.1
1Yeshiva University Department of Medicine, Bronx, NY; 2Northwell Health, New Hyde Park, NY; 3Columbia University, New York, NY; 4University of California San Diego Health Sciences, La Jolla, CA; 5Equilibrium Inc, La Jolla, CA.

Background: CD6 is a co-stimulatory receptor that is expressed on T cells. The CD6 ligand, ALCAM, is found on antigen presenting cells, as well as epithelial and endothelial cells. Itozumab (ITO), a humanized IgG1 monoclonal antibody that binds CD6 and inhibits its interaction of CD6 and ALCAM, inhibits T cell activity and trafficking. ITO is being evaluated as a treatment for systemic lupus erythematosus (SLE) and lupus nephritis (LN).

Methods: EQUALISE (NCT04128579) is a Phase 1b US study of ITO in SLE patients with and without active proliferative LN. Part A enrolled SLE patients (N = 34) who had received at least one SLE treatment but did not have active proliferative LN. Patients received 2 open-label doses of 0.4 to 3.2 mg/kg each SC on Day 1 and Day 15 with follow-up through Day 57.

Results: A subgroup analysis of 16 subjects with Baseline (mean of screening and Day 1) urine protein/creatinine ratio (UPCR) >100 mg/g was performed. Mean age was 55, 94% were female; 81% white and the mean years since SLE diagnosis was approximately 11. Mean baseline eGFR was 95 ml/min/1.73m² and UPCR was 272 mg/g (range 145-1505). On Day 29, a geometric mean decrease in UPCR of ~45% was observed in these 16 subjects with greater decline seen for subjects with higher Baseline UPCR values. By Day 57, 6 weeks post treatment the decrease was ~34% from Baseline (Figure). Notable is one subject (1.6 mg/kg dose) who had significant Baseline UPCR of 1500 mg/g. UPCR was well tolerated. Of the 6 subjects who had a total of 12 treatment-emergent adverse events (AEs), 4 were from the 3.2 mg/kg cohort. All AEs were mild or moderate in severity.

Conclusion: Patients with SLE and mild baseline proteinuria tolerated ITO treatment well. EQUALISE Part B will further explore the safety and efficacy of ITO in LN patients.

PO1625
Adding Low-Dose CYC to RTX Combined with a Tailored RTX Maintenance Regimen Seems to Favor Stable Remission in Severe ANCA Vasculitis
Renée Yuersmans, Matthias H. Busch, Joop Aendekerk, Pieter van Paasen, Maastricht University Medical Center; Department of Internal Medicine, Maastricht, Netherlands.

Background: Rituximab (RTX) and cyclophosphamide (CYC) are effective remission-induction therapies in ANCA-associated vasculitis (AAV). High dose CYC is however considered toxic, whereas RTX monotherapy may increase the risk of relapse, depending on the choice of maintenance therapy and baseline disease severity. RTX-CYC (1000mg two times) or RTX only (1000mg two times) were used to induce remission in patients with severe AA V.

Methods: Patients with severe AA V needing remission-induction therapy, were screened and 62 patients were included. Remission-induction consisted of either RTX (1000mg two times) or RTX-CYC (1000mg two times) for a total of 4 injections. Maintenance therapy was tailored to patients’ disease severity, using RTX only in the case of mild relapse. The rate of infections, hypogammaglobulinemia, end stage renal disease, malignancies, and mortality did not differ after 2 and 5 years.

Conclusion: Adding low dose CYC to RTX is safe and may favor the prevention of major relapses in patients with severe AAV, predominantly with renal involvement. Future prospective studies are needed to examine the role of reconstituted B cells and ANCA features to better define tailor-made treatment decisions.

PO1626
Preferences Regarding Treatment with Plasma Exchange for ANCA-Associated Vasculitis: An International Patient Survey
David T. Collister,1 Alfred Mahr,2 Mark A. Little,3 Reem Mustafa,2 Lynn A. Fussner,2 Alexa S. Meara,2 David R. Jayne,4 Peter A. Merkel,5 Michael Walsh.6 1University of Manitoba, Winnipeg, MB, Canada; 2Tallaght University Hospital, Dublin, Ireland; 3The Ohio State University, Columbus, OH; 4University of Cambridge, Cambridge, United Kingdom; 5McMaster University, Hamilton, ON, Canada; 6University of Kansas Medical Center, Kansas City, KS; 7University of Pennsylvania, Philadelphia, PA; 8Kantonsspital Sankt Gallen, Sankt Gallen, Switzerland.

Background: Patient preferences regarding plasma exchange (PLEX) for ANCA-associated vasculitis (AAV) are uncertain. We sought to elicit patient preferences regarding the use of PLEX in AAV.

Methods: An online survey was circulated via national vasculitis and kidney patient networks. Respondent characteristics were collected and information regarding PLEX use in AAV was provided including its minimal effect on mortality. One year interval of end stage kidney disease (ESKD) and serious infections with and without PLEX in AAV were presented across 5 serum creatinine categories: 150, 250, 350, 450 and 600µmol/L. For each scenario, participants were asked: “If they were a patient with a new diagnosis of AAV and would they choose treatment with PLEX (yes or no) given its absolute risk reduction in ESKD, but absolute risk increase in serious infections?” Multilevel multivariable logistic regression was performed to identify independent predictors of choosing treatment with PLEX.

Results: There were 549 responses. The mean age of respondents was 57.4 (SD 14.5) years, 72.3% were female, and respondents were from the United States (58.1%), United Kingdom (23.7%), Canada (14.0%), and other countries (4.2%). The majority had AAV (86.7%). 190/549 (34.6%) would always choose PLEX and 87/549 (15.8%) would always decline PLEX across the baseline risks of ESKD or serious infections presented. Independent predictors for choosing PLEX included age (OR 0.98, 95% CI 0.96-0.99 per 1 year increase), country (United Kingdom OR 2.73, 95% CI 1.20-6.21), diagnosis (individuals with vasculitis other than AAV were more likely), previous dialysis (OR 3.34, 95% CI 1.37-8.16), previous PLEX (OR 5.13, 95% CI 2.50-10.49), and increased baseline risk of ESKD (Cr 350 and 450µmol/L only).

Conclusion: One third of participants would always choose treatment with PLEX across the 5 scenarios presented. The decision to choose PLEX is influenced by age, country, previous dialysis, and the baseline risk of ESKD and serious infections. Patient values and preferences are needed to inform shared decision-making regarding PLEX in AAV.

PO1627
Maintenance of Remission and Risk for Relapse in Myeloperoxidase Positive Antineutrophil Cytoplasmic Antibody-Associated Vasculitis with Kidney Involvement
Marta I. Casal Moura,1 Shahzrad Tehranian,1 Shane A. Bobart,2,3 Ladan Zand,4 Eddie L. Greene,5 Sanjeev Sethi,6 Ulrich Specks,3 Fernando C. Fervenza,7 Mayo Foundation for Medical Education and Research, Rochester, MN; 2Cleveland Clinic, Cleveland, FL.

Background: Optimal time of remission-maintenance therapy in patients with MPO-ANCA associated vasculitis (MPO-AAV) is not established. Defining clinical and laboratory parameters to guide safe withdrawal of maintenance immunosuppression is required in order to mitigate the risk of relapse.

Methods: A retrospective cohort study of all patients followed at the Mayo Clinic with in MPO-AAV (MPA and GPA) and kidney involvement. Relapse rate, correlation with MPO-ANCA associated vasculitis (MPO-AAV) is not established. Defining clinical and laboratory parameters to guide safe withdrawal of maintenance immunosuppression is required in order to mitigate the risk of relapse.

Results: We analyzed 159 MPO-ANCA positive patients with active kidney involvement. A total of 66 (41.5%) patients had at least 1 relapse. MPO-ANCA patients who became and remained seronegative did not relapse (HR 0.03, [95%CI, 0.001-0.970], p=0.048). MPO-ANCA reappearance after seronegative conversion was associated with increased relapse risk at 24 months (HR 3.65, [95%CI, 1.14-11.966], p=0.012). Imunosuppression was withdrawn in 80 (50.3%) and this was predicted by persistent MPO-ANCA seronegative conversion (OR 3.028, [95%CI, 1.262-7.268], p=0.031). In patients who withdrew remission-maintenance therapy, 32 (40.0%) relapsed (in comparison with 34 relapses [43.0%] in those who maintained immunosuppression, p=0.097). ENT involvement (OR 5.095 [95%CI, 1.280-29.010], p=0.023) and MPO-ANCA reappearance (OR 9.247, [95%CI, 3.126-27.361], p<0.0001) were independent predictive factors for relapse after withdrawal.

Conclusion: Our results suggest that patients who seroconverted and remain MPO-ANCA negative are at lower risk of relapse: remission-maintenance treatment might be withdrawn without an additional risk of relapse. MPO-ANCA reappearance after seronegative conversion is a risk factor for relapse at 24 months. Serial MPO-ANCA determinations are useful to guide clinical decisions on remission-maintenance treatment strategies.

Background: The role of kidney biopsy on ANCA-associated vasculitis (AAV) is still debated: despite its significant prognostic value, whether it has an impact on the induction regimen choice has not been yet explored.

Methods: 323 AAV patients with biopsy-proven renal involvement were collected retrospectively from eleven centers and stratified according to the histopathological characteristics at the kidney biopsy and the induction regimen employed.

Results: The median follow-up time was 36 months; the eGFR was 19 ml/min/1,73m²; 53% were MPO-ANCA and 41% PR3-ANCA. 58% were treated with Cyclophosphamide (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the classification, 24% biopsies were classified as Focal, 31% as Crescentic, 33% as Mixed (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the C3 and C4 levels, 53% were MPO-ANCA and 41% PR3-ANCA. 58% were treated with Cyclophosphamide (CYC), 18% with Rituximab (RTX) and 24% with RTX-CYC. According to the C3 and C4 levels, 53% were MPO-ANCA and 41% PR3-ANCA.

Conclusions: Response rates and relapse risk were comparable in the overall cohort and in each histopathological subgroup. The ESRD-free survival in the Crescentic class was shorter in the RTX group compared to the CYC one.

PO1629

ANCA Vasculitis Induction Management in the COVID-19 Pandemic: Results of an International Retrospective Cohort Study

Antonio Salas, Duvuru Geetha, ANCATICOV J Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins University Department of Medicine, Baltimore, MD.

Background: Induction therapy for severe ANCA-associated vasculitis (AAV) combines glucocorticoids (GC) with either rituximab (RTX) or cyclophosphamide (CYC). The coronavirus 2019 disease (COVID-19) pandemic has increased concern around using aggressive immunosuppression; whether this concern has impacted AAV management is unknown. Here, we report treatment regimens and outcomes of patients with active AAV receiving induction immunosuppression during the first wave of the pandemic.

Methods: We retrospectively studied AAV patients with new or relapsing disease receiving remission induction therapy during the first wave of the COVID-19 pandemic across sites in the US, UK and Europe. Primary outcome was achievement of complete remission at 6 months.

Results: Of 191 patients with a mean age of 65 years old, 52% were female and a majority (89%) were Caucasian. Standard induction was deployed across all sites. Out of the US, UK, and European patient populations, the US used higher GC pulses leading to a higher average cumulative GC dose for remission induction (4153 mg, 2174 mg, 3408 mg, respectively, p=0.001) and had the highest proportion of patients given RTX induction therapy (64%; p=0.005). Complete remission was achieved in 90% of patients. Improvement in kidney function at 6 months was similar with all treatment regimens (6 ml/min² increase; p=0.68). Sixteen patients were diagnosed with COVID-19 and had similar exposures to CYC and RTX. There were no differences in remission rates, ESKD or death when stratified by induction therapy type.

Conclusions: Induction immunotherapy practices differ across the world, but specialists continued their standard management during the COVID-19 pandemic. AAV outcomes or rates of COVID-19 infection were not influenced by different induction regimens.

PO1630

Non-Sucrose Containing IV Immunoglobulin in ANCA Vasculitis Has No Adverse Effects on Renal Function

Renee Vsermans, Matthias H. Busch, Joop Aendekerk, Pieter van Paassen. Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.

Background: Intravenous immunoglobulin (IVIG) has proven to be effective as an immunomodulator in several autoimmune and inflammatory diseases, including antineutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV). Moreover, in the era of B cell-depleting therapies, secondary immunodeficiencies are common, urging supplementation by IVIG. Reported adverse effects are generally mild in nature. However, concerns have been raised about the safety profile of IVIG in relation to renal function. IVIG associated kidney injury is proposed to be mainly related to sucrose stabilized products. Non-sucrose containing alternatives are available and increasingly used. We therefore aimed to analyze the safety of non-sucrose containing IVIG with regard to renal function in patients with AAV.

Methods: AAV patients of the Maastricht University Medical Center were retrospectively analyzed for dynamics of serum creatinine levels before and after IVIG using the Wilcoxon signed rank-test. Subanalyses were performed with regard to the presence of ANCA-associated renal disease and IVIG indication. In addition, correlation analysis was conducted to evaluate the relation between serum creatinine change and cumulative IVIG dose during a 1year follow-up.

Results: 36 with 49 courses of IVIG were included in the short-term and 54 patients with 70 courses of IVIG were included in the long-term analysis. No significant differences were found between serum creatinine levels before and after IVIG in the short-term (median [IQR], 132 [88-159] and 125 [86-173] mmol/L, P = 0.380), with a median follow-up of 16 days after the initial IVIG infusion, and the long-term (median [IQR], 104 [86-167] and 110 [90-152] mmol/L, P = 0.077), after 1 year. One patient with active AAV and renal involvement had a reversible serum creatinine increase >30% 6 days after IVIG. Subanalyses showed no significant changes in serum creatinine levels with regard to renal involvement and IVIG indication. There was no association between serum creatinine change and cumulative IVIG dose 1 year after the initial IVIG infusion (P = 0.667).

Conclusions: This study shows no short-term and long-term deleterious effects on renal function in response to treatment with non-sucrose containing IVIG in patients with AAV.
Efficacy and Safety of a Combination Treatment of Mycophenolate Mofetil and Corticosteroid in Advanced IgA Nephropathy: A Multicenter, Prospective Study

Chan-Young Jung, Sang Youb Han, Beom seok Kim, Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea; Inje University Ilsan Paik Hospital, Goyang, Republic of Korea.

Background: It remains unclear whether immunosuppressive agents are effective in patients with IgA nephropathy (IgAN). We sought to determine the efficacy of mycophenolate mofetil (MMF) and corticosteroid combination therapy in patients with advanced IgAN.

Methods: We conducted a multicenter, randomized, placebo-controlled, parallel group trial of a 48-week administration of MMF and corticosteroid in biopsy-proven advanced IgAN patients with an estimated glomerular filtration rate (eGFR) between 20-50 mL/min/1.73m² and a urine protein-to-creatinine ratio (UPCR) greater than 0.75g/day. The primary outcome was complete (UPCR<0.3g/day) or partial remission (reduction of UPCR >50%) compared to baseline) at 48 weeks.

Results: Of the 48 randomized patients, complete and partial remission rates were higher in the MMF and corticosteroid combination therapy group (29.1% vs. 5.0%, P=0.05). In contrast to the combination therapy group, eGFR in the control group significantly decreased from 36 weeks onwards, resulting in a final adjusted mean change of -4.39 ± 2.22 mL/min/1.73m² (P=0.002). The adjusted mean changes at 48 weeks were 0.62 ± 1.30 and -5.11 ± 1.30 mL/min/1.73m² (P=0.005) in the treatment and control groups, respectively. The amount of UPCR was also significantly different between the two groups, where the adjusted mean difference was -0.47 ± 0.17 mg/mgCr in the treatment group and 0.07 ± 0.17 mg/mgCr in the control group (P=0.04). Overall adverse events did not differ between the groups.

Conclusions: In patients with advanced IgAN with a high risk for disease progression, combination therapy of MMF and corticosteroid appears to be beneficial in reducing proteinuria and preserving renal function.

POI1632
Pharmacodynamic and Clinical Responses to BION-1301 in Patients with IgA Nephropathy: Initial Results of a Ph1/2 Trial

Jonathan Barratt,1 Billy T. Hour,2 Brian S. Schwartz,2 Bess Sorenson,2 Suzanne E. Roy,3 Colleen L. Stromat,4 Margaret MacDonald,2 Aaron M. Endres,5 Jeannette Lo,5 Alan Glicklich,6 Andrew J. King,6 1University of Leicester, Leicester, United Kingdom; 2Chinook Therapeutics Inc, Seattle, WA; 3CERTARA LP, Princeton, NJ; 4Atricles Research Center, Northbridge, CA.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis globally, with up to 45% of patients at risk of progressing to ESKD. The initiating step in IgAN pathogenesis is the excessive production of galactose-deficient IgA1 (Gd-IgA1), resulting in the formation of immune complexes that cause kidney inflammation and damage. A Proliferation-Inducing Ligand (APRIL) is elevated in IgAN patients and correlated with higher levels of Gd-IgA1 and proteinuria, and lower eGFR. BION-1301 is a novel monoclonal antibody targeting APRIL. Here we present interim results from Part 3 of a Phase 1/2 study that characterizes the safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary activity of BION-1301 delivered by IV administration in patients with IgAN.

Methods: Part 3 of this Phase 1/2 study (NCT03945318) is an ongoing multicenter, multicohort, open-label study in up to 40 IgAN patients. In Cohort 1, BION-1301 is dosed at 450mg IV every 2 weeks for up to 12 months. Key objectives of the study include safety and the characterization of PK, PD, immunogenicity and changes in proteinuria. Key eligibility criteria include: (1) urine protein ≥0.5 g/24h or baseline UPCR ≥0.5 g/g, (2) stable/optimized dose of ACE-I/ARB or ACE-I/ARB intolerant and (3) biopsy-verified diagnosis of IgAN within the past 10 years.

Results: Preliminary results from the first 5 patients show BION-1301 is well tolerated with no serious adverse events and no adverse events leading to discontinuation to date. BION-1301 drives durable reductions in serum free APRIL, Gd-IgA1, IgA and IgG with a lesser reduction in IgM. A clinically meaningful reduction in 24-hour UPCR was observed within 3 months. Updated data in all 4 IV treated patients, along with mechanistic response kinetics, will be presented at the meeting.

Conclusions: BION-1301 is a novel anti-APRIL monoclonal antibody being developed as a potential therapy for patients with IgAN. BION-1301 treatment could be modifying potential by directly targeting the pathogenesis of IgAN. Promising early biomarker and clinical activity support the continued development of BION-1301 in IgAN.

POI1634
Atrasantan Exhibits a Consistent, Predictable Pharmacokinetic Profile Among Healthy Asian Adults

Aniy Rastogi,1 Jicheng Li,1 David A. Catanzaro,3 Vince Tong,3 Peter Zabriskie1 1University of California Los Angeles, Los Angeles, CA; 2Peking University First Hospital, Beijing, China; 3Chinook Therapeutics Inc, Seattle, WA; 4Juntendo Daigaku Igakubu Daigakuin Kenkyuha, Bunkyo-ku, Japan.

Background: Atrasantan, a potent and selective endothelin-A receptor antagonist, is under investigation for reducing proteinuria and preserving kidney function in IgA nephropathy and other glomerular diseases. Two phase 1 studies evaluated the pharmacokinetics (PK) and safety of atrasantan in healthy adults (Chinese/Study M11-521) and Japanese (Study M11-522) patients.

Methods: Study M11-521 was an open-label, randomized (for single-dose regimens), single-center study of single and multiple doses of atrasantan in 36 healthy Chinese adults. Single doses of atrasantan tablets (0.5, 1.0, or 1.5 mg) were administered in Part I, and multiple doses of daily doses of atrasantan 1.5 mg were administered in Part II. Study M11-522 was a double-blind, randomized, placebo-controlled, single-center study of single doses of atrasantan (0.5, 0.75, or 1.25 mg) in 36 healthy Japanese adults. Blood samples were collected for analysis of plasma PK parameters, including the area under the plasma concentration-time curve (AUC) and the maximum observed plasma concentration (Cmax).

Results: In Study M11-521, atrasantan AUC increased proportionally with dose in the 0.5 mg to 1.5 mg dose range, and Cmax increased proportionally with dose in the 1 mg to 1.5 mg dose range. No statistically significant differences were observed in either the dose-normalized AUC or the dose-normalized Cmax for the comparison of the 1.5 mg and the 0.5 mg dose groups (P = 0.260) or the dose-normalized Cmax for the comparison of the 1.5 mg and the 1 mg dose groups (P = 0.279). In Study M11-522, a linear increase in atrasantan mean AUC was observed across the 0.5 to 1.25 mg dose range; dose-normalized mean Cmax did not show any statistically significant difference across the doses (P = 0.735). Atrasantan was generally well tolerated. No clinically significant vital signs, electrocardiogram activity, or laboratory measurements were observed, and no apparent significant differences among the dose regimens were found with respect to safety.

Conclusions: Dose-proportional increases in AUC were observed across the studied range, which includes the 0.75 mg dose being studied in ongoing clinical trials. These data support the safety and tolerability of atrasantan and suggest a consistent and predictable PK profile among patients of Asian descent.

PO1635
Enhanced Efficacy of Corticosteroid Therapy by Tonsillectomy in IgA Nephropathy
Keita Hirano,1,2 Tetsuya Kawamura,1 Kentaro Koike,3 Nobuo Tsuibo,4 Takashi Yokoo,5 Yusuke Suzuki,6 1Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 2The Jikei University School of Medicine, Minato-ku, Japan; 3Juntendo University Faculty of Medicine, Bunkyo-ku, Japan.

Background: Efficacy of corticosteroid therapy in IgA nephropathy may vary among countries or races. Nowadays, the strategy to enhance efficacy of corticosteroid therapy is desired. In 2014, our randomized controlled trial demonstrated that corticosteroid therapy combined with tonsillectomy had superior anti-proteinuric effect than that of corticosteroid therapy alone (Nephrol Dial Transplant. 2014). However, the benefit of combining corticosteroid therapy with tonsillectomy for long-term renal survival was uncertain. Therefore, in a Japanese nationwide prospective cohort dataset, we aimed to evaluate whether the benefit of corticosteroid therapy may increase when it was combined with tonsillectomy, or not.

Methods: Patients were registered between April 1, 2005 and August 31, 2015 at 44 facilities throughout Japan. The primary outcome was a 50% increase in serum creatinine from baseline or dialysis initiation. Two interventions were focused in the present study: corticosteroid with or without tonsillectomy. Survival analysis was adjusted with baseline clinicopathological parameters including eGFR, proteinuria, hematuria, RAS inhibitor use and MEST-C score in Oxford classification.

Results: Enrolled 991 patients showed 75.4 ml/min as mean eGFR and 0.58 g/day as median level of proteinuria. Among them, 634 (64.0%) and 425 (42.9%) patients received corticosteroid therapy and tonsillectomy, respectively. During the median follow up of 5.5 years, 87 patients (8.8%) reached primary outcome. Adjusted hazard ratio (HR) of corticosteroid therapy for primary outcome in patients with tonsillectomy was 3-fold favorable than that in those without tonsillectomy (HR 0.18, 95% confidence interval [CI] 0.06-0.65, versus HR 0.59, 95%CI 0.34-1.01; P value for interaction between corticosteroid therapy and tonsillectomy 0.060).

Conclusions: Enhanced efficacy of corticosteroid therapy by tonsillectomy in IgA nephropathy was confirmed in a Japanese nationwide prospective cohort.

PO1636
The Potential Role of Monthly Corticosteroid Pulse in IgA Nephropathy
Arisa Kobayashi,1,2 Keita Hirano,1,2 Nobuo Tsuibo,4 Takashi Yokoo,5 1Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 2The Jikei University School of Medicine, Minato-ku, Japan.

Background: The risk of corticosteroid therapy may be underestimated in IgA nephropathy (IgAN). Previous studies provided that a fifth part of patients was older than 60 years and the rate of diabetes mellitus (DM) was increased in IgAN. The novel corticosteroid therapies with not losing benefit and reduced risk of corticosteroid are desired. Here, we aimed to determine whether monthly corticosteroid pulse is non-inferior in proteinuria remission and superior in blood glucose control to standard corticosteroid therapy or not.

Methods: Design: Retrospective, non-inferiority study. Participants: Adult patients with IgAN received intervention described below between 2013 and 2020. Intervention: Monthly corticosteroid pulse alone for 6 months versus standard corticosteroid therapy having oral corticosteroid for 6 months and three times of pulse corticosteroid in the same 6 months (Lancet 1999). Outcomes: The primary outcome was proteinuria remission (<0.3g/day) at 1 year and we prespecified 0.67 in odds ratio (OR) as non-inferiority margin. The secondary outcome was safety of blood glucose control, which was defined by less than 0.3 in change of hemoglobin A1C% between baseline and 6 months.

Results: The enrolled 83 patients (22 patients >60 years old and 11 patients with DM) showed median proteinuria 0.93g/day and mean eGFR 60.5ml/min at baseline. There was no significant difference in proteinuria remission between the two groups but including the non-inferiority margin (16(21)% vs 16(21)%), adjusted OR 4.10, 95%CI 0.70 to 39.61). No cases of myopathy and tremor matched with corticosteroid dose. The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%). The similarity of safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group (19(21)% vs 38(62)%).

Conclusions: Compared to standard corticosteroid therapy, the current study showed that monthly corticosteroid pulse did not reach the statistical requirements for a proven non-inferiority on proteinuria remission, but significantly exhibited safety outcome in the control of blood glucose. Prospective larger studies are needed to determine the role of monthly corticosteroid pulse in IgAN.

PO1637
The Beneficial Effects of Renin-Angiotensin System Inhibitors on IgA Nephropathy with Global Sclerosis
Eri Kasama, Takahito Moriyama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta, Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: In IgA nephropathy (IgAN), global sclerosis has been recognized as one of the risk factors for progression, because it induces glomerular hypertension and hyperfiltration in the remained glomeruli. The reno-protective effects of renin-angiotensin system inhibitors (RASI) are considered to decrease glomerular hypertension and hyperfiltration, but their effectiveness in IgAN with global sclerosis has been unknown.

Methods: Of the 871 IgAN patients diagnosed at our institution, we classified them into three grades by the ratio of global sclerosis (G) against whole glomeruli (G0 (n=225); G1 (n=445): at least one but <25%, G2 (n=191): ≥25%). We compared each clinical background and 20-year prognosis. Then, we examined the effect of RASI initiated during follow-up period on the long-term prognosis in patients with G1+G2 and in patients with G2 by Kaplan-Meier analysis and Cox regression analysis. To adjust the background characteristics between patients treated with or without RASI, propensity matching score was performed.

Results: The age, blood pressure, proteinuria, renal function, and histological findings were significantly severer with increasing grade in G0, G1, and G2, and 20-year renal survival rate was 83.5%, 75.0% and 54.4% in patients with G0, G1, and G2, respectively (p=0.001). After propensity matching between patients treated with or without RASI, 366 patients in G1+G2 and 90 patients in G2 were eligible for the evaluation. The 20-year survival rate was significantly higher in the patients with RASI than in the patients without RASI (G1+G2: 84.5% vs. 50.9%, p=0.001, G2: 63.8% vs. 33.5%, p=0.037). In multivariate Cox regression analysis considering clinical and histological findings and treatment, RASI was an independent factor to prevent progression in patients with G1+G2 and G2 (G1+G2, hazard ratio: 0.39, 95% confidence interval: 0.25-0.62, p<0.001; G2, hazard ratio: 0.35, 95% confidence interval: 0.19-0.66, p<0.001).

Conclusions: In this study, global sclerosis was associated with severer clinical and histological findings, and poor prognosis. However, RASI initiated during follow up period was found to improve renal prognosis in IgAN with at least one global sclerosis.
PO1639
Remission of IgA Nephropathy with Hydroxychloroquine
Hafsa Tariq, Jagmeet S. Dhingra. University Hospitals, Cleveland, OH. MetroHealth Medical Center, Cleveland, OH.

Introduction: IgA nephropathy is the most common form of glomerulonephritis in the world. Treatment options include blockade of renin-angiotensin-system (RAS) as the first line of therapy. Steroids may be beneficial in refractory cases, however, can result in several adverse effects. Data regarding use of immunosuppression is inconclusive. Combination of RAS inhibition and hydroxychloroquine has shown to reduce proteinuria in recent studies, though, complete remission with long term use has not been described. We report the case of a 46-year-old Asian female with IgA nephropathy, who was treated with maximally tolerated RAS inhibition and hydroxychloroquine for about 24- months resulting in complete remission of proteinuria and hematuria.

Case Description: The patient was referred to nephrology for evaluation of hematuria and proteinuria (1.5g/g, Creatinine 0.9mg/dl). Serological work-up was negative. She was initiated on angiotensin receptor blocker (ARB) and underwent kidney biopsy which confirmed IgA Nephropathy. There were 8 glomeruli with 20-25% sclerosis, mild to moderate chronic tubulointerstitial nephritis and fibrosis, no crescents, mild mesangial proliferation and hypercellularity with IgA staining 3+. She did not have any significant improvement in proteinuria despite maximally tolerated ARB (losartan 100 mg daily) therapy for three months. Her kidney function also declined, creatinine 1.2mg/dl. Hydroxychloroquine 200mg daily was then initiated along with regular eye exams and hepatic function tests. Repeat workup in three months showed improvement in proteinuria to 0.2g/g and creatinine 1.1mg/dl. She was continued on the same regimen for about 24- months, with recent work-up showing complete resolution of proteinuria and hematuria.

Discussion: As per our literature review, this is the first reported case of IgA nephropathy treated with RAS inhibition and hydroxychloroquine over a span of almost two years resulting in complete remission. Hydroxychloroquine can be considered, in select cases, as an alternative to steroid therapy in refractory proteinuria.

PO1641
An International Delphi Survey on IgA Nephropathy: Results from the DEFINE Physicians Study
Marina Vivarelli, Jürgen Floege, Jonathan Barratt, Rosanna Coppo, Richard A. Lafayet, Jai Radhakrishnan, Brad H. Rovin, David T. Selewski, Vladimir Tesar, Marcello Tonelli, Heather N. Reich. Bambino Gesù Pediatric Hospital Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS), Rome, Italy; Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany; University of Leicester, Leicester, United Kingdom; Regina Margherita Hospital, Turin, Italy; Stanford University, Stanford, CA; Columbia University Medical Center, New York, NY; The Ohio State University Wexner Medical Center, Columbus, OH; Medical University of South Carolina, Charleston, SC; Charles University, Prague, Czechia; Cumming School of Medicine, University of Calgary, Calgary, AB, Canada; University Health Network and University of Toronto, Toronto, ON, Canada.

Background: It is unclear whether treatment guidelines for patients with IgA nephropathy (IgAN) are uniformly applied in clinical practice. The DEFINE: Physicians initiative sought to describe the opinions of nephrologists about the pathophysiology, diagnosis, and optimal management of adult and pediatric patients with IgAN.

Methods: A 2-round Delphi survey was distributed to nephrologists in Canada, France, Germany, Italy, Spain, the UK, and the US. A 1-9 Likert scale (9=strongly agree) was used to score statements. Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score ≥7). Feedback collected in Round 1 was used to retest statements not achieving high consensus (≥90% agreement) for retesting in Round 2. Moderate consensus was defined as 75-89% agreement.

Results: In Round 1, 207 participants with a median clinical experience of 18 years (range, 5-49) rated 19 statements about IgAN. Half (50%) of participants worked in nonacademic settings. All statements met criteria for moderate or high consensus after the second round. Notably, a statement on corticosteroid therapy in adult patients reached high consensus (≥90% agreement) for retesting in Round 2. Moderate consensus was defined as 75-89% agreement.

Conclusions: For IgAN patients with CKD stage3, immunosuppressive therapy should be actively applied under the general treatment, but for patients with CKD stage4, it should be carefully. Patients with good renal function, more acute lesions of renal pathology could have a better prognosis after immunosuppressive therapy. Patients who achieved remission within 1 year would have better long-term prognosis.
PO1642
Long-Term Effectiveness of Low-Dose Prednisone Treatment in Relapses of Steroid-Sensitive Minimal Change Disease
Irene Martin Capon,1 Elizabeth R. Viera,1 Eduardo Gutierrez-martinez,2 Milagros Fernandez-Lucas,1 Javier Villacorta Perez,1 Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Madrid, Spain.

Background: Treatment of relapses of steroid-sensitive minimal change disease (SMCD) involves administration of high doses of prednisone for several weeks, implying significant pharmacological toxicity. In a previous pilot study, the efficacy of treatment with low doses of prednisone for the treatment of relapses in these patients was demonstrated.

Methods: Retrospective analysis of SMCD relapses treated with low doses of prednisone in two centers, was performed, and the response to treatment, the time to reach remission and the free-time of relapse was studied, comparing it with previous relapses of the same patients treated with standard doses of steroids.

Results: 85 relapses in 21 patients with SMCD were analyzed. The median age of patients was 35 years (IQR 18-53), with 62% being male. The mean proteinuria at relapse debut was 5.37 ± 4.11 g/24h, serum albumin 2.47 ± 0.94 g/dl and creatinine 0.86 ± 0.33 mg/dl. Thirty-six relapses (42.3%) were treated with low doses of prednisone (LDP) and compared with 49 previous relapses (57.6%) of the same patients, treated with high doses of prednisone (HDP). The mean initial prednisone dose in relapses treated with LDP and HDP was 0.45 ± 0.1 mg/kg and 1.00 ± 0.3 mg/kg, respectively (p=0.001). The mean cumulative dose of prednisone in relapses treated with LDP and HDP was 1771 ± 1303 mg and 3894 ± 2134 mg respectively (p < 0.001). There were no differences in treatment duration between relapses treated with low and high corticosteroids doses (124 days vs 153 respectively; p=0.2). All patients achieved complete remission after steroid treatment. Mean time to remission was 18.4 days for relapses with LDP and 17.1 days for HDP (p = 0.6). The mean free time to relapse after treatment with low doses was 12.6 months vs 10.9 months for those treated with high doses (p = 0.6).

Conclusions: Among SMCD patients, treatment of relapses with low doses of prednisone (0.5 mg/kg) is effective and safe, allowing to minimize cumulative steroid doses and derived toxicity.

PO1643
DEFINE Physicians: An International Delphi Survey to Identify Consensus in the Care of Patients with FSGS or Idiopathic Nephrotic Syndrome
Marina Vivarelli,1 Keisha L. Gibson,2 Debbie S. Gipson,2 Manuel Praga,4 Heather N. Reich,3 Michiel F. Schreuder,5 Vladimir Tesar,3 Marcello Tonelli,3 Jack F. Wetzels,1 Jái Radhakrishnan,1 Jürgen Fle Tigl,1 Bambino Gesù Pediatric Hospital, Rome, Italy; 2School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC; 3University of Michigan, Ann Arbor, MI; 4Complutense University, Investigation Institute Hospital 12 de Octubre, Madrid, Spain; 51University Health Network and University of Toronto, Toronto, ON, Canada; 1Amalia Children’s Hospital, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands; 2Charles University, Prague, Czechia; 3University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 4Radboud University Medical Center, Nijmegen, Netherlands; 51Columbia University Medical Center, New York, NY; 2Rheinish-Westfälische Technische Hochschule Aachen, Aachen, Germany.

Background: The extent to which real-world practice aligns with guidelines for management of focal segmental glomerulosclerosis (FSGS) and pediatric idiopathic nephrotic syndrome (INS) is unknown. The DEFINE: Physicians project sought to describe physicians’ opinions on the pathophysiology and optimal management of FSGS/INS in real-world settings.

Conclusions: High consensus regarding clinical decisions and the importance of controlling proteinuria in IgAN was observed in this Delphi survey. Although the level of consensus related to corticosteroid use was lower for adult patients vs pediatric patients, the level of consensus was relatively high for both groups.

Methods: DEFINE: Physicians was a 2-round Delphi survey that recruited nephrologists from North America and Europe. A total of 22 FSGS/INS statements were scored using a 1-9 Likert scale (9=strongly agree). Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score 7-9). Statements not achieving high consensus (≥90% agreement) in Round 1 were revised and retested in Round 2.

Results: This study involved 207 adult and pediatric nephrologists. Median clinical experience was 18 (range 5-49) years; 103 participants (50%) worked in nonacademic settings. In Round 1, 21 statements met consensus criteria and 7 statements not achieving high consensus were revised or divided into multiple parts, creating 11 revised statements for testing in Round 2. In Round 2, 9 of 11 statements met at least moderate consensus. Round 1 statements with high consensus described prognostic significance of proteinuria and disease management (Figure 1). Controversial statements retested in Round 2 pertained to distinction between primary and secondary FSGS in adults, and to management of frequently relapsing INS in children (Figure 2).

Conclusions: The level of consensus in this Delphi survey was high for statements on treatment decisions and the importance of proteinuria control. The main area where high consensus was not reached pertained to differentiation between primary and secondary FSGS and managing frequently relapsing INS in children, suggesting that these areas require further research.

Transcutaneous Auricular Vagus Nerve Stimulation (taVNS) for the Treatment of Pediatric Nephrotic Syndrome (NS)

Christine B. Sethna,1,2 Kumail Merchant,1 Stavros Zanos,2 Timir Datta-Chaudhuri,1 Pamela Singer,1 Laura J. Castellanos,1 Rachel Frank,1 Steven and Alexandra Cohen Children’s Medical Center, New Hyde Park, NY; Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

Background: Children with NS, especially those with frequent relapses (FRNS) or steroid resistance (SRNS), are exposed to prolonged courses of immunosuppressant medications with side effects and variable efficacy. There is an urgent need to identify novel and safe therapies to treat pediatric NS. taVNS modulates the immune system via the cholinergic anti-inflammatory pathway and has become a therapy of interest for treating immune-mediated illnesses. The objective was to conduct an open-label early feasibility study of taVNS therapy for pediatric NS.

Methods: Children with FRNS (≥2 relapses in previous 6 months) or SRNS (no remission after 4 weeks of steroids) were enrolled. Participants with FRNS were in remission and off immunosuppression (off steroids ≥14 days and other immunosuppression ≥3 months). SRNS patients were on a stable regimen of medications for 6 months prior to enrollment. Participants performed taVNS therapy 5 minutes daily for 6 months with a TENs 7000 unit. taVNS was delivered to the auricular branch of the vagus nerve via the left cymba concha. Cytokine levels were compared using the Wilcoxon test.

Results: Seven participants (3 FRNS, 3 SRNS, 1 genetic congenital nephrotic syndrome [CNS]) had a median age of 7 years (range 3-17) and 63% were male. FRNS participants remained relapse-free during the study period (two continued taVNS at 9 and 13 months and remained in remission). SRNS participants had a 25-76% reduction in urine protein to creatinine ratio (upcr) compared to baseline (Figure). UPCR decreased (13.7%) in the participant with CNS but remained in nephrotic range. All but one participant (non-compliant) had a reduction in TNF-α (7.33pg/mL vs 5.46pg/mL, p=0.03). No adverse effects were reported.

Conclusions: taVNS prevented NS relapses in FRNS, reduced proteinuria in SRNS, and reduced TNF-α levels without any adverse effects, suggesting taVNS as a promising therapy for pediatric NS. A larger, randomized clinical trial is needed to confirm these findings.

PO1646

A Study Comparing Rituximab and Modified Ponticelli (MP) Regimen in Primary Membranous Nephropathy (PMN)

Abhishek Kumar, Arpita Ray Chaudhury, Saugat D. Gupta, Sriranjani Mukherjee, Moumita Sengupta. IPGMER Nephrology Institute of Postgraduate Medical Education and Research, Kolkata, India.

Background: The study was designed in December 2018 when the Gemritux trial had established Rituximab as an alternative to MP regimen in the treatment of PMN. So we designed a study comparing Rituximab and MP Regimen.

Methods: We allocated 35 adults with PMN and proteinuria >3.5 gm/day in a 3:2 ratio to MP regimen or Rituximab 375mg/m² on days 1,8,15 and 22. The primary outcome was complete or partial remission (CR+PR) at 6 and 12 months in the 2 groups. The other findings included trends of 24 hr urine protein, albumin, creatine and serious adverse events at 6 and 12 months in both groups.

Results: At 6 months, 12 of 21 patients (57.14%) allocated to MP Regimen and 5 of 14 patients (35.71%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 2.4; 95% CI, 0.96-9.670, p value 0.10). At 12 months, 14 of 21 patients (66.66%) allocated to MP Regimen and 10 of 14 patients (71.43%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 0.8; 95%CI, 0.184-3.487, p value 0.383). Serious adverse events occurred in 15% of patients receiving Rituximab and in 24% receiving the MP Regimen.

Conclusions: We found No Statistically Significant difference between Rituximab and the Modified Ponticelli Regimen in the treatment of membranous nephropathy. A head-to-head, longer follow up study comparing MP Regimen versus Rituximab is required in terms of duration of remission and side effect profile between the two treatment groups.

PO1647

Felzartamab in Patients with Anti-Phospholipase A2 Receptor Autoantibody Positive (Anti-PLA2R+) Membranous Nephropathy (MN): Interim Results from the M-PLACE Study

Brad H. Rovin,1 Sharon G. Adler,2 Elion Hoxha,3 Ben Spranglers,4 Rolf A. Stahl,5 Jack F. Wetzel5,6 Bettina Schwamb,7 Rainer Boxhammer,7 Quynh Nguyen,8 Stefan Haertle,9 Pierre M. Ronco,10 The Ohio State University Wexner Medical Center, Columbus, OH; The Lundquist Institute, Torrance, CA; University Medical Center Hamburg-Eppendorf, Hamburg, Germany; University Hospitals Leuven, Leuven, Belgium; Radboud Universiteit, Nijmegen, Netherlands; MorfoSys AG, Martinsried, Germany; Sorbonne Universite, Paris, France; INSERM UMRs 1155, Paris, France.

Background: Primary MN is a rare autoimmune kidney disease. In ~70% of cases, autoantibodies to PLA2R on podocytes form immune complexes that damage the glomerular filtration barrier and typically lead to nephrotic syndrome. Current MN therapies fail to directly target CD20–CD38+ plasma cells that are the main source of autoantibodies. Depleting plasma cells by targeting CD38 may be an effective strategy for MN, particularly in patients (pts) with high anti-PLA2R Ab titers. Here we report proof-of-mechanism data for felzartamab (MOR202), a fully human anti-CD38 monoclonal antibody (Ab).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: M-PLACE (NCT04145440) is an open-label, multi-national Phase Ib/IIa study of adults with anti-PLA2R+ MN requiring immunosuppressive therapy (IST). Cohort 1 includes de novo and IST-relapsed pts (n=20) and Cohort 2 IST-refractory pts (n=10). Participants receive nine felzartamab infusions (16 mg/kg) over six 28-day cycles (weekly in Cycle 1; monthly thereafter), followed by a 26-week observational follow-up. Concomitant IST use is prohibited. The primary endpoint is the incidence and severity of treatment-emergent adverse events. The key secondary endpoint is the immunologic response rate, as determined by anti-PLA2R Ab reductions. Exploratory endpoints include evaluations of proteinuria and kidney function.

Results: As of April 2021, 12/30 planned pts were enrolled (Cohort 1, n=8; Cohort 2, n=4). Median age was 62.5 years (range 43 to 77 years), 83% were male, and median baseline anti-PLA2R Ab titer was 178 U/mL (18 to 1027 U/mL). Seven pts had received ≥4 weeks of felzartamab therapy. At Week 4, 5/7 pts had a >50% reduction from baseline in anti-PLA2R Ab (Cohort 1, n=3; Cohort 2, n=2); the other 2/7 pts had reductions from baseline of −16.8% and −5.0% (both Cohort 1). Mean % decline in anti-PLA2R Ab from baseline to Week 4 was −53.0% (−92.0% to −5.0%). B-cell counts were not markedly changed from baseline. Felzartamab was well tolerated.

Conclusions: The M-PLACE proof-of-concept study has so far shown that felzartamab rapidly and substantially reduces anti-PLA2R Ab titers in pts with anti-PLA2R+ MN. Longer follow-up is required to assess felzartamab safety and efficacy in this population.

PO1649
Intravenous Cyclophosphamide vs. Calcineurin Inhibitors as Treatment in Patients with Membranous Nephropathy (MN) and Low PLA2R+ Levels
Coralin Vink- van Setten,1 Anne-Elis van de Logt,1 Alexander Kühnl,2 Jack F. Wetzel2,3
1Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany

Background: We introduced individualized therapy in patients with MN and positive anti PLA2R antibodies (aPLA2R) by IIFT test. Treatment (cyclophosphamide (CYC) vs calcineurin inhibitors (CNI)) for high-risk MN is performed with IV CYC or with calcineurin inhibitors (CNI) according to criteria of accessibility and availability of the drug. Our aim was to compare the immunosuppressive treatment scheme with IV CYC vs CNI for primary MAKE events in patients with high-risk MN.

Methods: Retrospective cohort study. Patients with a diagnosis of MN diagnosed between January 2012 and January 2020 were included. The patients were treated with IV CYC or CNI. With a minimum follow-up of 12 months and primary events were recorded in addition to complete, partial, composite response and adverse events at the end of the study.

Results: Thirty-seven patients of which 14 (37.8%) were treated with IV CYC and 23 (62.2%) with CNI. The mean age was 46 ± 15.3 years, 54% male, and 27% hypertensive. Average P/ Cr 10.43 ± 4.49 gr/dL, mean serum albumin 1.8 ± 0.68 gr/dL, and GFR by CKD EPI of 75ml/min/1.73m². With a follow-up of 45.91 ± 23.9 months, no baseline differences were observed between the groups. Table 1 shows the comparison between IV CYC vs CNI for high-risk MN shows similar outcomes focused on MAKE. However, the comparison in complete and partial response shows a result in favor of the use of CNI. This perspective provides clinical evidence about the use of IV CYC, which is why it is suggested that there are possible differences between our findings and those reported so far with oral CYC. Prospective clinical trials are required to have conclusive results.

An 8-Week Course of Cyclophosphamide and Steroids Is Effective Therapy in Patients with Membranous Nephropathy (MN) and Low PLA2R+ Levels

Hans-Joachim Kühnl,1 Anna-Elis van de Logt,1 Alexander Kühnl,2 Jack F. Wetzel2,3
1Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lubeck, Germany

Background: The use of intravenous cyclophosphamide (IV CYC) in high-risk idiopathic membranous nephropathy (IMN) has not been fully evaluated in the same primary endpoints (serum Cr doubling, ERSD, mortality). In our center, the treatment of high-risk IMN is performed with IV CYC or with calcineurin inhibitors (CNI) according to criteria of accessibility and availability of the drug. Our aim was to compare the immunosuppressive treatment scheme with IV CYC vs CNI for primary MAKE events in patients with high-risk IMN.

Methods: Retrospective cohort study. Patients with a diagnosis of MN diagnosed between January 2012 and January 2020 were included. The patients were treated with IV CYC or CNI. With a minimum follow-up of 12 months and primary events were recorded in addition to complete, partial, composite response and adverse events at the end of the study.

Results: Thirty-seven patients of which 14 (37.8%) were treated with IV CYC and 23 (62.2%) with CNI. The mean age was 46 ± 15.3 years, 54% male, and 27% hypertensive. Average P/ Cr 10.43 ± 4.49 gr/dL, mean serum albumin 1.8 ± 0.68 gr/dL, and GFR by CKD EPI of 75ml/min/1.73m². With a follow-up of 45.91 ± 23.9 months, no baseline differences were observed between the groups. Table 1 shows the comparison between IV CYC vs CNI for high-risk MN shows similar outcomes focused on MAKE. Prospective Cohort Study of Antibody-Guided Therapy in Patients with Membranous Nephropathy

Background: Guidelines advise a standard course of 6 months of cyclophosphamide (CP) and steroids in patients with membranous nephropathy (MN). We hypothesized that monitoring of aPLA2R antibodies (aPLA2R) may enable individualized (and shorter duration of) therapy.

Methods: Patients with MN, with positive aPLA2R and high risk of progression were included. Treatment consisted of CP (1.5 mg/kg/day combined with steroids). aPLA2R were monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If the IFT test was negative, CP was stopped and prednisone tapered. If the IFT test remained positive at 24 weeks, CP was switched to MMF and therapy continued.

Results: Sixty-five patients (48 males) were included; mean age 61 ± 12 yrs, median serum creatinine 136 [IQR 100-161] µmol/l, serum albumin 21 [IQR 16-26] g/l and UPCR 7.7 [IQR 5.4-11.1] g/10 mmol. Follow-up was 37 [IQR 27-58] months. aPLA2R test was negative in 46 patients after 8 weeks (group A), in 10 patients after 16 weeks (group B1), in 1 patient after 24 weeks (group B2) and in 8 patients aPLA2R remained positive after more than 24 weeks (group B3). In group A no clinical remission (PCR <3.0 g/10 mmol) was observed in 26 % (12 patients) compared to 21 % (4 patients) in group B1-B3 (Log rank p=0.579). Overall 22 patients (34 %) received additional immunosuppressive (IS) therapy because of persistent proteinuria (after aPLA2R disappearance) or clinical relapse. IS free survival was lower in group A compared to group B1-B3. (Figure 1).

Conclusions: Approximately 50% of patients developed long-term clinical remission after 8 weeks of therapy. Our data support aPLA2R-guided therapy. However, in approximately 25% of patients immunological remission was not followed by clinical remission, underlining the need for better biomarkers.

Economic Evaluation of the MENTOR Trial Comparing Rituximab and Cyclosporine for the Treatment of Membranous Nephropathy (MN)
Matthew J. Kadatz,1,2 Scott Klarenbach,3 Helen So,1 Fernando C. Fervenza,1 Daniel C. Cattran,1 Sean Barbour.1 On behalf of the MENTOR trial investigators 1The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; 2Vancouver Coastal Health Research Institute, Vancouver, BC, Canada; 3University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; 4Mayo Clinic Minnesota, Rochester, MN; 5University of Toronto, Toronto, ON, Canada.

Background: The MENTOR trial (Membranous Nephropathy Trial Of Rituximab) showed that rituximab (RTX) was noninferior to cyclosporine (CSA) in inducing complete or partial remission of proteinuria and was superior in maintaining proteinuria remission. However, the cost of RTX is high and it’s cost-effectiveness has not been determined.

Methods: A Markov model (Fig 1) was used to determine the incremental cost-effectiveness ratio (ICER) of RTX compared with CSA for the treatment MN from the perspective of a health care payer with a life-time time horizon ($2020 USD). The model outcomes were informed by data from the MENTOR trial and previously published literature. Cost and utility inputs were obtained from the literature.

Results: Based on 1,000 simulations, the mean additional cost of RTX therapy for MN compared with CSA was $168,064 with an improvement in utility of 6.70 QALYs (Fig 2). RTX was cost-effective (assuming a willingness-to-pay threshold of $50,000 / QALY) compared with cyclosporine, with an ICER of $25,071 per additional quality adjusted life year (QALY) over a lifetime time horizon (45 years).

Conclusions: While the initial cost of RTX is high, RTX is a cost-effective option (assuming willingness to pay thresholds of $50,000 or greater) for the treatment of MN when compared with the alternative of CSA. The cost-effectiveness will be further improved with the use of less expensive biosimilars.

A Multicenter, Prospective, Open-Labeled Study of Acthar Gel Alone or with Tacrolimus to Reduce Urinary Proteinuria in Patients with Idiopathic DNA-JB9-Positive Fibrillary Glomerulopathy
James A. Tumlin,1 Richard A. Lafayette,2 Andrew S. Bombacc,2 Amber S. Podoll,4 FACT Trial Group 1Emory University, Atlanta, GA; 2Columbia University, New York, NY; 3Stanford University, Stanford, CA; 4University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Fibrillary Glomerulopathy (FGN) is a rare primary glomerular disease characterized by glomerular accumulation of nonbranching, randomly arranged 10-30 nm in diameter fibrils. The resulting podocyte dysfunction and progressive proteinuria leads to ESRD rates of 50% within 4 years. Herein we present data on 15 patients treated with ACTHar gel alone or with Tacrolimus.

Methods: Study Design: Randomized prospective open labeled study of 12 months of SQ ACTHar gel alone or in combination with Tacrolimus.

Primary Endpoint: Change in UP/Cr ratio (mg/gm) in patients after 12 months of ACTHar gel alone or in combination with Tacrolimus.

Results: Of the 15 patients completing 12 months of treatment, 14.3% achieved complete remission (UP/Cr ratio < 300 mg/gm) and 26.6% achieved a ≥ 75% reduction from baseline, while 60.7% achieved a ≥ 50% reduction in UP/Cr at 12 months. A total

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
of 86.6% achieved a minimum 30% reduction in UP/Cr. The addition of Tacrolimus to ACTH tended to further lower UP/Cr at 12 months (165.4±317 vs. 4449.5±1665) respectively, but did not reach statistical significance.

**Conclusions:** In summary, depository ACTH induced a complete or partial remission in 75% of patients with DNA-JB9 + Fibrillary GN. The addition of Tacrolimus respectively, but did not reach statistical significance to ACTH tended to further lower UP/Cr at 12 months (1654.7±317 vs. 4449.5±1665).

In summary, depo-repository ACTH induced a complete or partial remission in 75% of patients with DNA-JB9 + Fibrillary GN. The addition of Tacrolimus respectively, but did not reach statistical significance to ACTH tended to further lower UP/Cr at 12 months (1654.7±317 vs. 4449.5±1665).

**Background:** The introduction of eculizumab has improved outcome in patients with atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy is debated. It is unknown if unbiased withdrawal of eculizumab is a safe strategy. Here we report the results of the CUREiHUS study, a national observational study monitoring eculizumab discontinuation in Dutch aHUS patients after three months of therapy.

**Methods:** All pediatric and adult aHUS patients with native kidneys and first-time eculizumab treatment (n=21) were evaluated. At last, an extensive cost-effective analysis was conducted.

**Results:** In the period from January 2016 till October 2020 we included 21 patients. All patients showed full recovery of hemato logical thrombotic microangiopathy (TMA) parameters after start of eculizumab. A renal response was noted in 18 patients. After a treatment duration of 13.6 weeks (range 2.1-43.9), eculizumab was withdrawn in all patients (Figure 1). During follow-up (80.7 weeks (0.0-236.9)), a relapse occurred in four patients (19.0%). Median time to first relapse was 14.3 weeks (7.1-62.0). Eculizumab was re-initiated within 24 hours in all relapsing patients. At last follow-up, there were no chronic sequelae, i.e. no clinically relevant increase in serum creatinine, proteinuria and/or hypertension, in the relapsing patients. No clinically relevant predictors of relapse (including the presence of a pathogenic mutation) could be determined. The total medical expenses, including costs of among others hospital admission and disease recurrence, of our population were only 33% of the fictive expenses made when patients would have received eculizumab every fortnight.

**Conclusions:** It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.

**Background:** Factor D, the rate-limiting enzyme of the AP, is required for the formation of C3 convertase as well as amplification of complement activities initiated by the lectin pathway (LP) and classical pathway (CP). AP amplification is responsible for up to 80% of the LP and CP complement responses (Harboe et al, Clin Exp Immunol 2008). BCX9930 is an orally administered, potent and selective inhibitor of factor D, and has potential for the treatment of complement mediated glomerular diseases including C3 glomerulopathy, IgA nephropathy, primary membranous nephropathy, and lupus nephritis. This study assessed the effects of oral dosing of BCX9930 on the AP activities in ex vivo activated serum in healthy subjects.

**Methods:** Serum samples from the BCX9930-101 study (NCT04330534) of multiple ascending doses ranging from 50 to 500mg every 12hrs (Q12h) were used to evaluate complement activities with AP-specific Wieslab C5b-9 (AP Wieslab) assay. Levels of complement split products Bb, C3a, C5a and soluble C5b-9 (sC5b-9) in the supernatants from the AP Wieslab assay were further analyzed by multiplex assays.

**Results:** Oral dosing of BCX9930 resulted in rapid (within 1hr) and maximal suppression (median ≥98% relative to pre-dose levels) of AP Wieslab at all dose levels. The duration of suppression was dose-dependent. At steady state for doses ≥200mg Q12h, maximal suppression persisted for at least 2 dosing intervals (24hrs) following the last dose. Doses of 200, 400 and 500mg Q12h reduced Bb, C3a and C5b-9 levels by ≥95% through 12hrs post-dose at steady state in the supernatants from AP Wieslab assays. At the highest dose level analyzed, 500mg Q12h, mean inhibition of Bb, C3a, and C5b-9 increased to ≥98%, and mean inhibition of C3a was 95%.

**Conclusions:** Oral BCX9930 potently suppressed AP activity in healthy subjects. Suppression ≥95% was achieved through at least 12hrs post-dose across all described assays for the selected clinical dose of 500mg twice daily. As the AP amplification loop also enhances the signal of the CP and LP, BCX9930 has potential to treat diseases mediated by any of the 3 complement pathways. These results support further development of oral BCX9930 for the treatment of complement mediated glomerular diseases.

**Background:** The introduction of eculizumab has improved outcome in patients with atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy is debated. Podocytes Soften in Proteinuric CKD: A Potential New Mechanism for Proteinuria?
Luisa Ulloa severtom, Xiaolin He, Franziska Lausecker, Rachel Lennon, Mira Kendell, Darren A. Yuen, Yuen Lab ‘St Michael’s Hospital, Toronto, ON; 2Department of Renal Medicine and Health, Manchester, United Kingdom; 3State University of New York Upstate Medical University, Syracuse, NY.

Background: Proteinuria is one of the most common manifestations of glomerular injury, and an important predictor of disease progression. Podocytes are a critical component of the glomerular filtration barrier, and as such podocyte injury is a major cause of proteinuria. Historically, investigators have focused on biochemical changes in podocytes that occur following podocyte injury. In contrast, little is known about the changes in the biological properties of these highly specialized epithelial cells.

Methods: 3 different models of proteinuric glomerular disease were studied: (1) Akita+/- Ren-/- mice (a murine model of diabetes and renin-mediated hypertension that we have recently shown develops progressive glomerulosclerosis that mimics human diabetic kidney disease, n = 7); (2) Col4a5-/- mice (a murine model of genetic FSGS characterized by deficiency of a non-muscle myosin involved in actomyosin contraction, n = 6), and (3) Col4a5-/- mice, a mouse model of Alport’s syndrome (n = 12). The stiffness of glomeruli, glomerular basement membrane (GBM), and podocytes was measured using atomic force microscopy (AFM) and associated histochemistry (picrosirius red, silver, and WT1 staining).

Results: AFM measurements revealed that glomerular stiffness increased in Akita+/- Ren-/- and Col4a5-/- mice, a finding that correlated with the degree of glomerulosclerosis. Glomerular stiffness was not increased in Myo1e-/- mice. GBM stiffness was increased in Akita+/- Ren-/- and Myo1e-/- mice, but not in Col4a5-/- Alport’s mice. In all 3 mouse models, as well as in human FSGS biopsies, podocytes were softer than in healthy control kidneys.

Conclusions: Taken together, these are the first data demonstrating that podocytes soften in proteinuric glomerular disease. Given the major rearrangements in the actomyosin network that occur in podocytes of proteinuric kidneys, our data suggest that podocyte softening may be a common manifestation of podocyte injury. Further work is needed to determine if this softening is solely a consequence of podocyte injury, or if it also contributes to ongoing podocyte damage.

PO1658
Novel Small Molecule Compounds Protect Podocytes from Injury In Vitro and In Vivo
Richard Helmut1, Manuel Noben,1 Ha Won Lee,1 Jean-Michel Saffin,2 Jochen Reiser,1 Susanne Heynen-Genel,1 Vinee Gupta1, Gupta lab ‘ Rush University Medical Center, Chicago, IL; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocyte dysfunction and loss is a key determinant of proteinuria and glomerular injury. Thus, maintaining healthy podocytes is a therapeutic strategy against kidney disease. We previously developed a high-content imaging-based assay and used it to identify small number of small molecule compounds that show protection of podocytes from injury, suggesting it to be a viable strategy for the discovery and development of novel podocyte-protective agents.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates as previously described (Lee et al. JASN, 2015). Cells were exposed to puromycin aminonucleoside (PAN, podocyte injury inducing agent), with compounds from the screening libraries, or DMSO as control, for 48 hours. Cells were fixed and stained which allowed detection using the Opera High-Content Screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. Drosophila based screening assays were used to determine efficacy of selected hits in vivo.

Results: PAN damage resulted in quantitative reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes in the ultra-miniaturized assay system. Screening of a library of chemical compounds identified >28 hits that dose-dependently reduced podocyte damage. A set of 9 compounds showed significant protection in a drosophila model of kidney injury, supporting the findings from the high-throughput screening assay.

Conclusions: Our 1536-well plate-based assay system identified a number of small molecule compounds that dose dependently protected podocytes from damage in vitro. A drosophila model of kidney injury validated most of the in vitro data from the podocyte screening assay and in vivo and in vivo mechanistic studies are underway to elucidate new insights into podocyte pathways that are therapeutically targeted by the selected hits. These agents hold promise as novel therapeutics for kidney disease patients with podocyte pathologies.

Characterization of the Direct Effect of Mycophenolic Acid on Murine Podocytes
Seif El Din Abo Zed,1 Agnes Hackl,1 Katrin Bohl,2 Gregor Fink,1 Eva Nüsken,1 Kai D. Nüsken,1 Bernhard Schermer,2 Lutz T. Weber.1 Nephrologisches Forschungslabor ‘Children’s and Adolescents’ Hospital, Faculty of Medicine and University Hospital of Cologne, Cologne, Germany; 2Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 3Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany.

Background: Mycophenolic Acid (MPA) is the active component of Mycophenolate Mofetil, a selective, noncompetitive inhibitor of the inosine monophosphate dehydrogenase. Blockade of the de novo purine synthesis depletes the pool of deoxyguanosine triphosphate, leading to a specific suppression of proliferation of B- and T-Lymphocytes. MFM has an established role as a therapeutic agent in childhood nephrotic syndrome, where it currently serves as a second line option for frequent relapsing and steroid dependent cases. Although its immunological functions are well studied, direct effects of MPA on podocytes remain largely unknown. With first preliminary results showing a protective effect in vivo, the present study aims to examine the direct effect of MPA on murine podocytes and its abilities to alter albumin-induced podocyte injury.

Methods: Cultured murine podocytes were exposed to albumin for 48 hours, with one group receiving treatment with MPA for the second 24 hours. Cells were stained with a Synaptopodin antibody and additional markers to visualize components of the cytoskeleton. Currently, we are analyzing apoptosis through a TUNEL assay as well as alterations in intracellular Calcium content with Fluo-4 and fura red. In addition, we study podocyte motility under injury and with MPA intervention by migration assays. We will also study small GTPases content and activity through a pull-down assay for RhoA and Rac1. In an unbiased approach, podocytes were exposed to either 2 hours of 10 mg/ 1 MPA or an additional 22 hours of 4 mg/1 MPA. Total RNA was isolated and subjected to RNAseq analyses.

Results: Synaptopodin immunofluorescence shows significant alterations of the actin cytoskeleton through albumin exposure. MPA treated cells reveal a restorative ability of the drug, with a recovery of stress fiber formation and a reduction of albumin-induced vacuoles. The mRNA expression data from each protein and metabolite, and then log2 transformed. Proteins with Log2 FC<-1 or Log2 FC<-10 or targets to define SRNS pathways that were not identified in the individual datasets.

Conclusions: First results show a promising effect of MPA on stress fiber formation. The additional functional assays will be finished by late summer this year and will give an important insight to MPs ability to influence pathways, known to be affected during the development of proteinic diseases. The RNAseq results will provide an objective and detailed picture of the direct effects of MPA on podocytes.
Spatially Resolved Analysis of Glomerular Structures in Alport Syndrome and FSGS

Laura Perin,1 Hasim Solonian,2 Paolo Cravedi,2 Fadi E. Salem,2 Andrea Angeletti,1 Sargis Sedrakyan.1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Mount Sinai Health System, New York, NY; 1Università di Bologna, Bologna, Italy.

Background: Many transcriptomics studies highlighted the molecular mechanism underlying podocyte injury, but very little is known about interglomerular heterogeneity and how each glomerulus is affected during progressive CKD. Using Spatial transcriptomics, which allows the characterization of the gene expression based on morphological context, we showed important differences between glomeruli of Alport Syndrome (AS) and FSGS patients and defined the interactive gene networks involved in glomerulitis damage using healthy glomeruli as reference.

Methods: Using the Nanostring GeoMX Spatial Profiling (DSP, Whole Transcriptomic Atlas) we generated spatial maps of gene expression of human AS (COLA4A5 and COLA4A5) and FSGS glomeruli (both males and females) and compared them to age-matched healthy controls. A total of 90 regions of interest were selected. After data QC and Q3 normalization, data were analyzed using different platforms and integrated with histopathology assessment.

Results: Data distinguished genes associated with podocytes, glomerular endothelial and mesangial cell phenotype. Unsupervised clustering and dimensionality reduction analysis showed clear differences between not only diseased and normal glomeruli (which presented homogeneous gene expression profile), but also between glomeruli of AS vs FSGS. Though glomeruli of AS and FSGS were histologically similar within each sample, they presented different transcriptomic profiles (for instance, while oxidative phosphorylation, focal adhesions were common to all gloms in AS, Apelin, PISK-Akt, and Hippo signaling were unique to only a few glomeruli). Marked differences between males and females were observed in both AS and FSGS glomeruli (sheer stress and leukocyte transendothelial migration was more typical in AS male than female, while insulin signaling was only present in AS female. Similar heterogeneity patterns were observed in FSGS). In contrast to FSGS, AS were more enriched for genes associated with TCA cycle, protein processing in the ER, and neurotrophin signaling.

Conclusions: DSP revealed significant interglomerular heterogeneity in AS and FSGS regardless of age and gender leading to the discovery of patheways defining disease phenotypes at single glomerulus level. These preliminary data using DSP may allow the discovery of potential new therapeutic targets for CKD patients.

The CLSV1 H310Y Variant Associated with Steroid-Resistant Nephrotic Syndrome Affects Podocyte Function and Glomerular Filtration Barrier Integrity

Brandon M. Lane1,2 Megan Chryst-Stangl,2,3 Mohamed A. Shalaby,2 Sherif M. El desoky,2 Guanghong Wu,2,3 Ricardo Vacinni,1 David N. Howell,1 Gantzoni Ibaizabal,4 Jameela A. Kari,5 Rashied A. Gbadegesin1,2 Duke University Department of Pediatrics, Durham, NC; 1Duke Molecular Physiology Institute, Duke University, Durham, NC; 2Duke University School of Medicine, Durham, NC; 3Duke University Department of Pathology, Durham, NC; King Abdulaziz University Hospital, Jeddah, Saudi Arabia; 4Duke University Hospital, Durham, NC.

Background: We identified a rare homozygous variant, p.H310Y, in the gene encoding clavesin1 (CLSV1) as a novel cause of steroid sensitive nephrotic syndrome (SSN) in a Scottish family. We found the back-downton of the CLSV1 gene in zebrafish resulted in edema phenotypes that could be rescued with WT CLSV1 mRNA but not the H310Y variant. CLSV1 knockout in cultured human podocytes decreased endocytosis, increased reactive oxygen species (ROS) accumulation, and increased apoptosis. These aberrant phenotypes were rescued in the presence of glucocorticoids, mimicking the steroid responsive phenotype of CLSV1 H310Y patients. Treatment with ROS inhibitors also rescued the reduced viability phenotype in CLSV1 KO podocytes.

Methods: To better understand the effects of the CLSV1 H310Y variant on podocyte homeostasis, we created human podocyte cell lines with CRISPR-Cas9 mediated heterozygous and homozygous CLSV1 H310Y knock-in (KI) mutations. We evaluated the KO and KI podocytes through automated live-cell imaging. Additionally, we further evaluated the effects of reduced CLSV1 function on podocyte function in vivo in zebrafish. We also identified clavesin1 as a potentially required gene in meduloyd endocytosis in cultured human podocytes. Additionally, homozygous H310Y KI podocytes displayed similar corticosteroid responsive phenotypes to CLSV1 KO lines, including increased apoptosis that could be rescued with ROS inhibition, while heterozygous KI lines were unaffected. Furthermore, we confirmed that the H310Y variant reduces binding to a critical antioxidant transporter, alpha tocopherol transfer protein (p<0.006), likely contributing to the ROS phenotypes. Electron microscopy analysis and quantification of excreted proteins revealed podocyte effacement and decreased glomerular filtration barrier integrity in zebrafish with knockdown of orthologous CLSV1 when compared to controls (p<0.0001).

Conclusions: Our data further demonstrates the importance of clavesin1 in the maintenance of podocyte viability and GFB integrity. It also suggests that oxidative stress regulation may be compromised in patients carrying pathogenic CLSV1 variants and highlights the potential for alternative therapies for NS patients that target ROS accumulation in podocytes.

Podocyte Injury in Human Disease: Pathomechanism, Diagnosis, and Therapy

PO1664

Rare Variants in RCAN1-3 Genes Are Enriched in Patients with CKD

Brandon M. Lane1,2 Katherine A. Benson,1 Susan L. Murray,1 Megan Chryst-Stangl1,2,3 Guanghong Wu,2,3 Liming Wang,2,3 Elhussein A. Elhassan,2 David N. Howell,1 Peter J. Conlon,2 Robert F. Spurney,2 Rashied A. Gbadegesin1,2 Duke University Department of Pediatrics, Durham, NC; 1Duke Molecular Physiology Institute, Duke University, Durham, NC; 2Beaumont Hospital, Dublin, Ireland; 3Royal College of Surgeons in Ireland, Dublin, Ireland; 4Duke University Hospital, Durham, NC; 5Duke University School of Medicine, Durham, NC; 6Duke University Department of Pathology, Durham, NC.

Background: We recently identified rare variants in the gene encoding Regulator of Calcineurin Type 1 (RCAN1) as a novel cause of FSGS/SSRN. Cells expressing mutant RCAN1 and human podocytes with reduced RCAN1 displayed increased CN activity that prevented increased susceptibility to apoptosis compared to WT RCAN1. There are two additional proteins in the RCAN family, RCAN2 and RCAN3, both of which are capable of regulating CN activity. To further elucidate the role of pathogenic variants in RCAN genes in the etiology and pathogenesis of chronic kidney disease, we screened patients with rare variants in RCAN1-3 genes. In addition, we performed kinase screening to identify compounds that can rescue the phenotype induced by defective RCAN1.

Methods: In collaboration with the Genome England Consortium, we examined associations between potentially pathogenic variants in RCAN1-3 genes and kidney disease in the large multi-ethnic National Health Service database. We compared the percentage of patients with rare (MAF <0.01), functional RCAN1-3 variants in patients with CKD (renal and urinary tract disorders) and patients with neurological disorders. We also used target kinase inhibition to examine additional potential RCAN1 regulatory interactions.

Results: Of the 4,153 patients in the UK National Health Service data set with CKD, 39 (0.94%) had rare functional RCAN-1-3 variants compared to 87 (0.57%) of the 15,141 patients with neurological disorders, revealing a significant enrichment of rare pathogenic variants in RCAN1-3 genes in patients with kidney disease compared to those without (p=0.0006). Pharmacological inhibition of additional RCAN regulatory kinases including DYRK1A (Harmane) or BMK1 (Ax15836 and XM8-85) could rescue the elevated CN activity (p=0.4946, 0.3980 and 0.0912 respectively) and reduced viability (p=0.05) in disease causing mutant RCAN1 expressing cells compared to WT controls.
PO1665
Spatial Transcriptomic Profiling of Collapsing Glomerulopathy
Shreeram Akilesh,1 Kammi J. Henriksen,2 Roberto F. Nicosia,3 Charles E. Alpers,3 Kelly D. Smith.1 1University of Washington, Seattle, WA; 2University of Chicago Pritzker School of Medicine, Chicago, IL.

Background: Collapsing glomerulopathy is a histologically distinct variant of focal and segmental glomerulosclerosis that presents with heavy proteinuria and portends a poor prognosis. Collapsing glomerulopathy can be triggered by viral infections such as HIV and SARS-CoV-2. However, it is not known if distinct molecular mechanisms drive histologically indistinguishable lesions of collapsing glomerulopathy in different clinical contexts.

Methods: Transcriptional profiling of collapsing glomerulopathy lesions is difficult since only a few glomeruli may exhibit this histology within a kidney biopsy. Therefore, we used recently developed spatial transcriptional profiling to quantify 1,852 transcripts in individual glomeruli from HIV and SARS-CoV-2 infected patients with biopsy confirmed collapsing glomerulopathy.

Results: We compared transcriptional signatures on the basis of disease or histology and identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy and thrombotic microangiopathy (Figure). Focused validation using spatial transcriptomic profiling identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy.

Conclusions: Spatial transcriptomic profiling represents a powerful new method to dissect transcriptional programs of pathologically discernible kidney lesions.

Protein Kinase R Inhibition Ameliorates Mitochondrial Dysfunction in the Tg26 HIV-Associated Nephropathy Mouse Model
Teruhiko Yoshida,1 Khun Zaw Latt,1 Avi Z. Rosenberg,2 Shashi Shrivastav,1 Jurgen Heymann,1 Moshe Levi,1 Cheryl A. Winkler,2 Jeffrey B. Kopp.1 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 2Johns Hopkins University, Baltimore, MD; 3Georgetown University, Washington, DC; 4Frederick National Laboratory for Cancer Research, Frederick, MD.

Background: Double-stranded RNA (dsRNA)-activated protein kinase (PKR) is a sensor for dsRNA in response to viral infections, including HIV-1. We previously reported that APOL1 risk alleles damage podocytes through double-stranded RNA-activated protein kinase (PKR) activation (Okamato, Comm Biol, 2018). Here, we hypothesized that PKR activation could be a mechanistic pathway shared by HIV-1 and APOL1-mediated nephropathies. Hence, we investigated the effects of PKR inhibition on HIVAN in the well-characterized Tg26 mouse model, which expresses HIV regulatory and accessory genes.

Methods: We evaluated the kidney phenotype of Tg26 mice and wild-type mice treated with the PKR inhibitor (C16) from 6 to 12 weeks of age. We profiled kidney gene expression by RNA-seq and mitochondrial function by the extracellular flux assay using ex vivo glomerular tissues.

Results: Kidney disease manifestations, including albuminuria (mean [IQR]) (668 mg/g Cr [60, 1064] vs 2564 [1785, 5646], p=0.03) and global glomerulosclerosis (0.0% [0.0-0.0] vs 8.1 [2.3, 15.8], p<0.008), were reduced in the C16 treated group compared to the vehicle control group. C16 treatment increased mitochondrial gene expression and restored spare respiratory capacity as measured by extracellular flux assay (Figure B).

Conclusions: PKR inhibition ameliorated mitochondrial dysfunction associated with the HIVAN phenotype observed in Tg26 mice, suggesting that PKR activation contributes to the development of mitochondrial dysfunction in HIVAN.

Recurrent Nephrotic Plasma Activates Pro-Fibrotic Signalling Pathways Downstream of Protease-Activated Receptor 1
Musleeha Chesar,1,2 Jack P. Tuffin,1 Carl J. May,1 Irene Ghibriou,3 Melissa H. Little,1,4 Moin Saleem,1 Gavin I. Welsh.1 1University of Bristol, Bristol, United Kingdom; 2Princess of Naradhiwas University, Narathiwat, Thailand; 3Murdock Childrens Research Institute, Parkville, VIC, Australia; 4University of Melbourne, Melbourne, VIC, Australia.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous work suggests a signaling role for protease-activated receptor-1 (PAR-1), leading to impaired podocyte function. The signaling pathways downstream of PAR-1 in podocytes are unknown and could reveal novel mechanistic insights into the disease.

Methods: Conditionally immortalized human podocytes (cPods), glomerular-like structure spheroids, and human kidney organoids were treated with PAR-1 agonist peptide or nephrotic plasma (NP), in the absence or presence of four different PAR-1 antagonists.

Results: PAR-1 agonist and patient relapse NP, but not paired remission plasma, induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by PAR-1 inhibitors, but not by TGF-β1 inhibition. Four PAR-1 inhibitors demonstrated specific antagonistic properties. The phosphorylation of VASP and JNK in a 3D spheroid model and from stem-cell derived kidney organoids corroborated the finding from the 2D model. Functionally, relapse NP induced podocyte motility and podocyte loss from spheroids both of which were also selectively rescued by PAR-1 inhibitors. Treatment of kidney organoids with relapse NP induced the same VASP and pro-fibrotic phosphorylation in podocytes and the loss of podocyte-specific markers.

Conclusions: We propose that the circulating factor acts as a pro-fibrotic effector by activating PAR-1. A greater understanding of these signaling pathways will lead to the identification of novel therapeutic targets for this disease.

Molecular and Functional Characterization of Human Urinary APOL1 G2/G2 High-Risk Genotype Podocyte

Oyindamola C. Adebayo,1,2 Pepe M. Ekuo,1,2 Jean-Paul Decuyper,2 Mohamed A. Elmoneim,1,2 Agathe B. Nkoy,1,3 Djalia Mekahli,1 Benedetta Bussolari,1 L.P.W.J. Van Den Heuvel,3 Fanny O. Arcolino,3 Elena N. Levchenko.3 Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; 1Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; 2Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; 3Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); 4Department of Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; 5Department of Molecular and Biotechnology and Health Sciences, University of Turin, Turin, Italy; 6Department of Pediatric Nephrology, Radboud University Medical Center, Nijmegen, Netherlands.

Background: APOL1 risk variants, G1 and G2, increase the risk of various non-diabetic kidney diseases in the African population. To date, the precise mechanisms by which APOL1 risk variants induce injury on podocytes and other kidney cells remain unclear. Trying to unravel these mechanisms, most studies used animal or cell models created by gene editing.

Methods: Conditionally immortalized human podocyte cell lines from urine of a donor carrying APOL1 high risk genotype, G2/G2 was developed. The APOL1 G2/G2 cell lines were characterized for podocyte markers at both the mRNA and the protein levels, using real-time quantitative PCR, Western blot and immunofluorescence staining. Following induction of APOL1 expression by 50 µg/mL polinosinic-polycytidylic acid (poly(C)), we assessed the functional features of APOL1-induced podocyte dysfunction such as cell detachment, cell viability, cell death, autophagy, cytoskeleton organization and podocyte permeability. As control, APOL1 wild type (G0/G0) podocytes previously generated from a Caucasian donor were used.

Results: We successfully generated human APOL1 G2/G2 urinary podocyte cell lines. Upon exposure to poly(C), G2/G2 and G0/G0 podocytes upregulated APOL1 expression resulting in podocytes detachment, decreased cell viability and increased apoptosis rate in a genotype-independent manner. G2/G2 podocyte cell lines exhibited altered features, including upregulation of CD2AP, alteration of cytoskeleton, reduction of autophagic flux and increased permeability in an in vitro model under continuous perfusion.

Conclusions: The human APOL1 G2/G2 podocyte cell model is a useful tool for unraveling the mechanisms of APOL1-induced podocyte injury and the cellular functions of APOL1.

PO1669

Topology Mapping of Membrane-Inserted ApoL1

John C. Edwards, Jonathan M. Bruno. Saint Louis University, Saint Louis, MO.

Background: Apol1 inserts into membranes at pH 6 where it has anion permease activity. Titration of the cis compartment to pH 7.5 suppresses the anion permease and activates a cation channel. How Apol1 is arrayed in the membrane-inserted form at various pH values is unclear.

Methods: Cys was substituted for Ser or Thr at positions throughout Apol1 and resulting mutants expressed in E. coli. Purified mutants were allowed to insert into phospholipid vesicles at pH 6.0, held at pH 6.0 or titrated to pH 7.5, and reacted with extravesicular membrane-impermeant fluorescent Cys modifying reagent, Alexafluor-568-maleimide. Unreacted reagent was quenched. Non-membrane-inserted protein was removed by chaotropic extraction and Sepharose 4B chromatography. Membrane-associated protein was separated on SDS-PAGE along with Apol1 standards for quantification. Ratio of fluorescence intensity to mass of Apol1 protein was normalized to that of protein modified after detergent denaturation to determine relative accessibility of each Cys to the modifying reagent.

Results: Cys substitutions were generated at amino acid positions 40, 80, 149, 173, 186, 200, 204, 226, 247, and 365. We found three patterns of reactivity after membrane insertion. Cys at positions 40, 149, and 365 showed reactivity that was roughly comparable to that in detergent solution with little difference between pH 6.0 and 7.5, consistent with exposure to the aqueous solution on the cis face of the membrane under all conditions. In contrast, Cys at positions 186, 226 and 247 showed decreased reactivity after membrane insertion that was similar at both pH 6.0 and pH 7.5; these positions are not fully accessible from the external solution. Finally, Cys at positions 80, 173, 200, and 204 had decreased reactivity at pH 6.0 with increase in reactivity at pH 7.5, suggesting these positions may be initially buried in the membrane upon insertion at low pH, but elevation to neutral pH induces a structural transition that exposes them to the external solution.

Conclusions: Mapping accessibility of individual amino acid positions in Apol1 support a model in which a substantial structural transition accompanies the pH-induced activation of the cation channel.

PO1670

Deep Learning-Based Segmentation and Quantification of Podocyte Foot Process Morphology

Linus Butt,1 David Unnersjö-Jess,1 Martin Höhne,1 Peter H. Suess,2 Annika Wernerson,1 Anna Witasp,3 Bernhard Schermer,1 Kasia Bozek,2 Thomas Benzing,1,2 1Uniklinik Köln, Köln, Germany; 2University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; 3Karolinska Institutet Enheden for medicinska njursjukdomar, Huddinge, Sweden.

Background: The advent of super-resolution light microscopy enabled imaging of the nanoscale dimensions of podocyte foot processes and the slit diaphragm and subsequent quantification of morphological alterations upon glomerular injury. However, these morphological analyses require manual work, which is time-consuming and investigator-dependent.

Methods: We used novel sample preparation protocols and applied super-resolution STED microscopy and conventional confocal microscopy to image podocyte foot processes in murine and human kidney tissue. Deep learning-based segmentation was utilized to automatically segment both the slit diaphragm pattern and the podocyte foot processes as well as several thousands of individual foot processes per sample.

Results: Our algorithm, the automatic morphological analysis of podocytes (AMAP), segmented the FPs and the SD at high accuracy and more effectively as compared to a previously published semi-automatic dataset. The morphological quantifications show a high agreement with our previous analysis, thereby confirming the correlation of albuminuria with certain morphological alterations of podocytes. In addition, we applied AMAP to human patient tissue and found different patterns of effacement in different disease entities.

Conclusions: The combination of three-dimensional optical imaging and deep-learning-based segmentation can be used to perform extensive morphological analyses of podocyte in health and disease. It confirms our previous semi-automatically performed analyses in a mouse model of FSGS and can be applied to patient material in order to assess morphological alterations in glomerular disease while eliminating investigator-bias. We believe AMAP can in the future complement the diagnostic algorithms in research and clinical pathology.

Podometries in Different Cortical Zones and Associations with the Number of Non-Sclerotic Glomeruli

Kotaro Harahara,1,2 Go Kanzaki,2 Takaya Sasaki,2 Saeko Hatanaka,2 Yusuke Okabayashi,2 Akira Shimizu,2 Luise A. Cullen-McEwen,1 Nobuo Tsuboi,1 Takashi Yokoo,2 John F. Bertram,1 Monash University, Clayton, VIC, Australia; 2Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; 3Nihon Ika Daigaku, Bunkyo-ku, Japan.

Background: Reduced nephron and podocyte number are common features in CKD. While it is well known that glomerular volume and glomerular density (glomerular number per cortical area) differ between cortical zones, zonal differences in podometrics and correlations with nephron number have not previously been explored.

Methods: Non-sclerotic glomerular number per kidney was estimated using the physical dissector/fractionator combination. Podocyte density, podocyte number, podocyte volume and volumetric density of podocyte to glomerulus in each cortical zone were estimated using model-based stereology on a single histological section immunostained with two podocyte markers and imaged by confocal microscopy.

Results: Fifty autopsy kidneys were studied. The median age was 68 years ranging from 28 to 85 years. Median eGFR was 74 mL/min/1.73m2. The median number of non-sclerotic glomeruli per kidney was 421,547 (IQR, 289,095–548,233). Non-sclerotic glomerular number was directly correlated with podocyte number per tuft, podocyte density and volumetric density of podocytes in each cortical zone (Fig). Glomeruli in the superficial cortex were smaller than glomeruli in other zones and had the highest podocyte density and smallest podocyte volume. Podocyte number and volumetric density of podocytes were similar across the cortical zones.

Conclusions: These results demonstrate for the first time that a higher number of non-sclerotic glomeruli is directly associated with three beneficial indices of podocyte and glomerular health. Podocyte number and volumetric density of podocytes were similar across the cortical zones.

Can Podocyte Number and Density Predict the Response to Therapy in Patients with Primary FSGS?

Natsasha de Zoya,1,4 Jonathan E. Ling,2 Kotaro Harahara,1,3 Peter G. Kerr,2 David J. Nikolic-Paterson,1 John F. Bertram,1 Luise A. Cullen-McEwen,1 Nobuo Tsuboi,1 Takashi Yokoo,2 John F. Bertram,1 Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; 2Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; 3Nihon Ika Daigaku, Bunkyo-ku, Japan.

Background: Podocyte loss is a key event in primary focal segmental glomerulosclerosis (FSGS). Common first-line therapy for patients with primary FSGS involves steroid therapy with or without blood pressure control; however 40-70% of patients achieve no remission. Animal studies have shown that treatment efficacy is achieved partly through preservation of podocyte number, as well as podocyte protective effects. Animal studies have also determined that podocyte number and density are predictive of FSGS severity. Therefore, this study aimed to determine if podocyte number and density can predict the response to therapy in patients with primary FSGS.

Methods: A retrospective cohort study of renal biopsies was conducted from 2009-2020 in Melbourne, Australia at a tertiary hospital (Monash Medical Centre). Patients diagnosed with primary FSGS were screened (n=84). Patients were excluded for lack of consent for samples to be used for research purposes (n=38), risks of other forms of FSGS (n=13), insufficient clinical data available (n=2), no biopsy tissue available (n=7) or <6 glomerular profiles available in the biopsy (n=5). Included patients were allocated into groups of treatment responders (n=11) or non-responders (n=8) based on urinary/serum data 6 months following initial diagnosis and commencement of treatment. Biopsies were immunofluorescently stained for podocyte-specific markers. Model-based stereology was used to estimate podometrics. Sections were re-stained with PAS to measure the glomerulosclerotic index (GSI).

Results: Podocyte number per glomerulus in responders (347 (215–606); median (IQR)) was 45% higher than in non-responders (190; 143-263) (P=0.03). Podocyte density in responders (76; 58-142 per 10µm3 of glomerular volume) was similar to non-responders (66; 44-88 per 10µm3 of glomerular volume) (P=0.38). GSI was significantly higher in non-responder patients (1.1; 0.6-2.3) than responders (0.6; 0.2-0.9) (P=0.04), and was significantly and negatively correlated with podocyte number (r = -0.64; P=0.003) and podocyte density (r = -0.48; P=0.04).

Conclusions: Podocyte number per glomerulus in diagnostic renal biopsies could be used as a predictor of treatment response for patients with primary FSGS.

Nephrotic Syndrome in a Patient with Systemic Lupus Erythematosus: Is it Lupus Podocytopathy?

Nora H. Hernandez-Garcilazo,1 Mohamed Hassanein,2 Christopher C. Garces,2 Si Yuan Khor,2 Beenu Kaw,2 Michigan State University, East Lansing, MI; 2Cleveland Clinic, Cleveland, OH; Sparrow Health System, Lansing, MI.

Introduction: Lupus podocytopathy (LP) is a rare form of lupus nephritis (LN) that clinically mimics minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS). We present a case of LP in a patient with systemic lupus erythematosus (SLE).

Case Description: A 73-year-old female with a history of SLE (on Hydroxychloroquine), and nephrolithiasis presented with left flank pain for 2 weeks. Physical exam was notable for peripheral edema and left costovertebral angle tenderness. Labs showed a creatinine 1.02 mg/dL (baseline 0.7), serum albumin 2.6 mg/dL, and urine microalbumin/creatinine (MA/Cr) ratio of 7.5 g/g. Further workup revealed a positive ANA, negative anti-dsDNA antibodies, and normal complements. Kidney biopsy showed FSGS, tip variant, and 100% podocyte foot process effacement (FPE). She was started on high-dose prednisone, simvastatin, ACE inhibitor, and furosemide with potassium supplementation for significant pedal edema. Two months later, her MA/Cr ratio improved to 3 g/g. Prednisone was slowly tapered off over a 7-month period during which symptoms were well-controlled and MA/Cr ratio continued to improve.

Discussion: Nephrotic syndrome in patients with SLE raises suspicion for LP, which represents 1% of LN biopsies. Biopsy findings include diffuse FPE (>70%) on electron microscopy, and absence of immune deposits on light, immunofluorescence, and electron microscopy. LP is divided into MCD or FSGS, with the latter having higher rates of hypertension, acute kidney injury on presentation, and overall worse outcomes. Treatment consists of a short course of high-dose glucocorticoids; however high rates of relapse are observed and tend to coincide with SLE activity.

PO1674

Minimal Change Disease as a Sequela of Psoriasis in an Adult
Priya Debnath, Chibuzo C. Okeye, Arham Zia, Samiran Roy Chaudhury, Elena Frolova. New York City Health and Hospitals Coney Island, Brooklyn, NY.

Introduction: Minimal change disease (MCD) is usually found in children but can be an uncommon presentation in adults. Relation to psoriasis has not been significantly established even though the latter has been associated with kidney disease such as IgA nephropathy, focal segmental glomerulosclerosis leading to kidney failure. This is an interesting case given that this is a young patient with psoriasis presenting with a flare in the setting of newly diagnosed MCD.

Case Description: A 34-year-old male with history of psoriasis presented with severe body edema after psoriatic flare two weeks prior admission. He was found to have exceptionally low serum albumin of 1.4g/dl, massive proteinuria with spot urine protein creatinine ratio of 7.6 and significant hyperlipidemia. Protein electrophoresis did not show glomerular pathology or spikes in proteins and extensive serological workup was normal. Kidney biopsy reported MCD. Patient improved quickly with steroids of 1mg/kg/day, IV furosemide and albumin infusion. Six months later, the patient was readmitted with new psoriasis flare and again nephrotic syndrome with 7.2g of proteinuria. His symptoms resolved quickly with same treatment used on the first admission. Follow up in clinic one-month post discharge showed normal renal function with proteinuria now at 100mg/day.

Discussion: While there has been evidence of link between psoriasis and kidney disease, finding of MCD is a unique development. The idea can be postulated that since psoriasis is a disease due to dysfunction of T-cells among other causes, a flare can be the initiating event leading to dysregulation of an otherwise stable immune system. This T-cell dysregulation has also been noted in MCD. The underlying cause of MCD is not clear. However, a lot of studies suggest that T-cell dysfunction is one of the implicated agents, known for cell destruction, causing damage to the glomerular basement membrane leading to the loss of proteins. The rarity of this case belies the complexity of the immunological process leading to the presentation and further research needs to be done to document and establish this as the pathologic process linking the two diseases.

PO1675

Collapsing FSGS from Acquired Nephrin Antibody
Hsiao L. Lai,1 Abdullah Thayyl,1 Astrid Weins,2 Keith H. Keller,2 East Carolina University, Greenville, NC; 2Brigham and Women’s Hospital, Boston, MA.

Introduction: Deficits in nephrin and other podocyte components are known to result in congenital nephrotic and familial FSGS syndromes. Weins et. al. recently described acquired anti-nephrin antibody localizing in glomerular podocytes of patients with minimal change disease.

Case Description: A 16 year old male referred for new onset nephrotic syndrome progressive over 2 weeks was found to have serum albumin 1.2 gm/dl, UPCR 3.1, and elevated lipids with BP 160/100 mm Hg. Hepatitis B/C, HIV, SLE screens were negative. Renal biopsy demonstrated focal collapsing lesions with diffuse podocyte effacement. Immunofluorescence showed punctate IgG, kappa and lambda light chain staining in podocytes, but no albumin. Anti-human IgG colocalized with nephrin in the granular staining. ParvoB19 and COVID-19 titers were negative. Creatinine rose from 0.65 to 1.65 and UPCR to 10.3 but improved rapidly with high dose prednisone and ACEi. Serology for circulating anti-nephrin 2 weeks into treatment was negative, consistent with previous finding that circulating antibody levels quickly drop to low or undetectable with partial clinical remission.

Discussion: This case strengthens evidence that anti-nephrin antibodies cause disruption of the slit pore diaphragm which appears to be readily responsive to immune therapy. Anti-nephrin mediated podocytopathy may present with a spectrum of glomerular histopathology, which on the background of other susceptibility factors, can lead to more severe presentations such as collapsing FSGS.
slit diaphragms. Confocal imaging of IgG/nephrin IF confirms substantial overlap in the fine podocyte granules (arrows), but not in coarse PRGs (asterisks). A diagnosis of early primary FSGS is made. Sera collected on post-biopsy days 19, 25 and 27 are serologically positive for anti-nephrin. The patient was started on oral glucocorticoids, and on d27 was in partial remission (UPCR 2.6g/gCr, SAzb 2.8g/dl). Anti-B cell therapy is considered.

Discussion: Our findings reveal that autoimmune-mediated anti-nephrin podocyte injury can trigger irreversible podocyte injury leading to FSGS, likely in patients with additional predisposing factors. This enhances our understanding of diffuse progressive podocytopathies; accurate and early diagnosis identifies patients who benefit most from B-cell-targeted immunosuppressive therapy.

PO1677
Nephrotic Syndrome Secondary to Minimal Change Disease Following Moderna COVID-19 Vaccine
Shaefiq B. Thappy, Sherin R. Thalappil, Shahem Abbarh, Mohammed Akhtar, Mohamad M. Alkadi. Hamad Medical Corporation, Doha, Qatar.

Introduction: Minimal Change Disease (MCD) has been reported following vaccines against hepatitis, pneumococcus, influenza and measles. In the COVID-19 era, 3 cases of new-onset MCD and one case of MCD relapse have been reported following the Pfizer-BioNTech COVID-19 vaccine. We herein report a case of MCD after receiving the first dose of Moderna COVID-19 vaccine.

Case Description: A 43-year-old Ethiopian man with no significant past medical history presented with progressive bilateral lower limb edema for two weeks. His symptoms started 7 days after receiving the first dose of COVID-19 vaccine. He then developed dyspnea and scrotal swelling over the following 10-14 days. On physical examination, his blood pressure was 150/92 mm Hg. There was decreased air entry at lung bases, significant bilateral lower limb pitting edema extending to above the knees and scrotal swelling. Lab investigations revealed hypoalbuminemia, hyperlipidemia and proteinuria of 15 grams. There was no hematuria and his immunologic and serologic work up was negative. Renal biopsy showed minimal change disease with underlying IgA nephropathy. There was no global or segmental glomerulosclerosis, mesangial or endocapillary proliferation. Patient was started on oral prednisolone and furosemide. His edema resolved, serum albumin doubled and proteinuria decreased within the first week of treatment.

Discussion: Symptoms of MCD have been reported 4 days to 16 weeks after vaccination. Although the pathogenesis of MCD is not fully understood, studies suggest that T-cell dysfunction might play a role. More studies are needed to determine the incidence and pathophysiology of this adverse event post COVID-19 vaccine. It is not clear in this case if or when the second dose of the COVID-19 vaccine should be administered.

PO1678
Antiproteinuric and Podocytoprotective Effects of Direct Oral Anticoagulant Therapy in Glomerular Disease
Amanda P. Waller,1 Katelyn Wolfgang,1 Eman Abdelghani,1 Bryce A. Kerlin.1,2
1Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2The Ohio State University College of Medicine, Columbus, OH.

Background: Podocyte injury is a key determinant of chronic kidney disease (CKD) progression toward end stage kidney disease. We and others have recently uncovered a putative podocytopathic role for intraglomerular thrombin during proteinuric glomerular disease. Direct oral anticoagulant (DOAC) therapies limit thrombin activity but their ability to improve podocyte health and potentially slow CKD progression remains unknown. Thus, the aim of this study is to determine if DOACs reduce thrombin-mediated podocytopathy during glomerular proteinuria. We hypothesized that DOACs would preserve podocyte health and function in a podocyte-specific model of proteinuric glomerular disease.

Methods: Diphtheria Toxin was used to induce proteinuria in transgenic rats expressing human diphtheria toxin receptor (DTR) in a podocyte-specific manner and was subsequently treated with 1) Dabigatran (20 mg/kg; Dabi), 2) Rivaroxaban (3 mg/kg; Riva), or 3) Sham (saline) and compared to healthy controls (n=7-9/group). Morning spot urine was collected on day 0 and 10 post-DT. Glomeruli were isolated from the kidney, dissociated into single-cell suspensions, and analyzed by flow cytometry after immunofluorescent synaptopodin antibody and TUNEL staining.

Results: Both Dabi and Riva significantly reduced proteinuria (Fig A) and terminal podocyte injury (TUNEL positive podocyte fraction; Fig B). In addition, there was a trend toward in situ podocyte preservation with both DOACs with a significant overall effect of DOAC therapy on podocyte survival (Fig C).

Conclusions: Both Dabi (a direct thrombin inhibitor) and Riva (a direct factor Xa inhibitor) reduce proteinuria and enhance podocyte health in a podocyte-specific model of proteinuric glomerular disease. These data suggest that DOACs may be repurposed as a novel approach to slow or halt proteinuric glomerular disease progression. Because thrombotic disease is a life-threatening co-morbidity of both glomerular disease and CKD, this approach may enable simultaneous thromboprophylaxis and glomerular disease therapy.

A Highly Efficient and Reproducible Differentiation Protocol for Induced Pluripotent Stem Cell-Derived Podocytes

Sergei Kryuchenko, Justin A. Gallagher, Timothy A. Norman, Alyssa Fanelli, Xiang Pan, Eva Fast, Rachel Gallagher, Thomas A. Gustafson, Maria Lalioti. Goldfitch Bio Inc., Cambridge, MA.

Background: Podocyte processes intertwine to create a slit diaphragm, which, when compromised leads to proteinuria, hematuria, and eventually to renal failure. It is critical to be able to study the disease and test therapeutic interventions in patient-derived cells, and assess genetic and environmental aspects. Current protocols for differentiation of iPSCs into podocytes (iPods) suffer from a lack of podocyte maturity or low reproducibility. Our goal was to test and optimize multiple protocols to establish a more translatable, physiologically relevant, and reproducible method.

Methods: We compared two distinct published protocols [Ciampi 2016; Musall 2018]. Additional conditions were tested, including varying the extracellular matrices, media, and length of differentiation. Podocyte signature was evaluated by IF, flow cytometry, and Nanostring analysis. For models of injury, we utilized prolineamine sulfate (PS) or puromycin aminonucleoside (PAN) treatment. A mouse podocyte cell line was used as a control.

Results: Both protocols generated iPods with similar efficiency, as measured by synaptopodin, nephrin and podocin staining. iPods generated from protocol-1 could be maintained in culture up to 14 days but remained relatively immature, based on the expression of collagen Iα2(IV) and lack of α2α6ε5(IV). Response to PS and PAN treatment was variable compared to mouse podocytes. Altering the matrix from collagen to laminin, did not improve reproducibility. iPods from protocol-2 developed more filopodia and complex cell-cell junctions and appeared more homogeneous, with extended survival up to 4 weeks post-differentiation. PS treatment induced a significant and reproducible dose- and time-dependent decrease in synaptopodin expression, and a more robust accumulation of phalloidin aggregation. Both effects were effectively prevented by cycloporsin A, a calcineurin inhibitor, in a similar manner as in mouse podocytes. iPods from protocol-2 also showed a more consistent dose-dependent response to PAN injury.

Conclusions: We achieved a more robust and translatable iPods platform utilizing human iPSC. Patient-derived iPods will be an invaluable tool to perform a precision medicine-based approach to validate new therapeutic approaches for podocytopathy-driven kidney disease.

Novel Ex Vivo Culture System Reveals Mechanosensitive “Sarc remorse-Like Structures” During Early Podocyte Spreading

Shumeng Jiang,1 Jeffrey H. Miner,2 Guy M. Genin,1 Hani Suleiman.3 Washington University in St Louis, St Louis, MO; 2Washington University in St Louis School of Medicine, St Louis, MO.

Background: Chronic kidney disease and ESKD are widespread health problems with no cure, in part because the biophysics underlying them are still not clear. A recently developed feature of injured podocytes includes the de novo assembly of sarcomere-like stress fibers, identified by their alternating myosin and synaptopodin-a-actin-4. It is not known whether these indicate a transient healing phenotype or are a feature of the cascade leading to foot process effacement.

Methods: To model the early events of podocyte injury, we developed a new in vitro system that enables the study of podocytes outside of their native microenvironment, but with in vivo-like mechanobiological and extracellular matrix (ECM) features. This system includes controllable stiffness, micropatterned substrates for spreading, and the use of primary podocytes as they migrate from freshly isolated glomeruli.

Results: When cultured on micropatterns of physiologically relevant extracellular matrix proteins and appropriate stiffness, myosin- and synaptopodin-positive stress fibers developed within two days of culture, then disappeared after six days, and the appearance of these stress fibers was sensitive to substrate stiffness and could be disrupted by inhibiting actomyosin contraction (blebbistatin), culturing cells with stiffness outside of the physiologic range, or presenting cells with substrates associated with pathology.

Conclusions: These results reveal the role of mechanobiological factors in podocytes represented by the mechanoresponsive sarcomere-like structure and establish a novel system for characterizing this mechanobiology in vitro.

PO1681

Primary Cilia in Podocyte Health and Disease

Linsey A. Fitzsimons,1,2 Kara M. Button,1 Jake N. Cho,3 Michael C. Akom,1,4 Kerry L. Tucker,1,3 Ron Korstanje,1,3 1University of Maine at Orono, Graduate School of Biomedical Science & Engineering, Orono, ME; 2University of New England College of Osteopathic Medicine, Biddeford, ME; 3Maine Medical Center, Portland, ME; 4Tufts University School of Medicine, Boston, MA; 5The Jackson Laboratory, Bar Harbor, ME.

Background: Primary cilia are highly specialized elaborations of the plasma membrane that direct many of the signaling cascades critical for pre- and post-natal development and disease. While renal primary cilia are recognized as key genetic and cellular targets in poly cystic kidney disease, the presence and function of primary cilia within the renal corpuscle and glomerulus have yet to be fully characterized. The purpose of our study was to perform a focused and quantifiable characterization of primary cilia of glomerular cell populations in health and disease.

Methods: Renal biopsy samples were obtained from patients with Minimal Change Disease (MCD; N=6), Focal Segmental Glomerulosclerosis (FSGS; N=5), and control renal tissue (CON; N=4). Immunofluorescence analyses (IF) were used to quantify primary cilia number and length, as well as the expression of Sonic Hedgehog (SHH) protein, the ligand component of the Hedgehog signaling pathway and one measure of primary cilia function.

Results: Mean percent ciliation was significantly increased in MCD and FSGS when compared to CON. Analysis of individual glomerular primary cilia revealed increased cilia length (μm) in both MCD and FSGS when compared to CON. Further analysis comparing primary cilia length in WT-1-positive nuclei (WT-1+; podocytes) also revealed a pronounced increase in cilia length in MCD and FSGS podocyte primary cilia versus CON. Despite increased length of primary cilia, glomerular SHH expression was significantly decreased in both MCD and FSGS when compared to CON. Glomerular diseases MCD and FSGS are therefore associated with an overall increase in podocyte primary cilia length and ciliation, an effect which corresponded to a decrease in SHH expression.

Conclusions: These data provide evidence in support of a role for primary cilia in glomerular disease pathogenesis. Ongoing and future research is needed to establish a mechanistic explanation for these changes observed in glomerular and podocyte cilia number and length. A more thorough understanding of the role(s) of primary cilia in glomerular cells, and specifically in podocytes, remains critical for to both our understanding of disease pathogenesis as well as for the pharmacologic treatment of glomerular chronic kidney disease.

Establishing a Podocyte-PEC Cross-Talk Model Using an Open Microfluidic Co-Culture Device

Yuting Zeng,1 Jeffrey W. Pippin,2 Stuart J. Shankland,2 Ashleigh B. Theberge,1,3 1University of Washington Department of Chemistry, Seattle, WA; 2University of Washington Division of Nephrology, Seattle, WA; 3University of Washington Department of Urology, Seattle, WA.

Background: Although focal segmental glomerulosclerosis (FSGS) is initially caused by podocyte injuries, their neighboring parietal epithelial cells (PECs) also undergo molecular changes that further damage the glomerulus. The cross-talk between podocytes and PECs is poorly understood, in part due to a lack of appropriate experimental models for study. Our goal is to establish an in vitro coculture model to induce podocyte injury and determine the mediators and responses of PECs.

Methods: Mouse podocytes labeled with EGFP and PECs labeled with tdTomato were co-cultured in two neighboring chambers of an open microfluidic device that we engineered. The chambers remain separated until more media is added to overflow the half wall in between. To induce injury, podocytes were exposed to increasing concentrations
of cytoytic sheep anti-glomerular antibodies (or media alone as control) for 2 hours. The two groups were kept to membrane in the face of injury, their excessive expression resulted in a severe morphological and functional phenotype, emphasizing the need of a tight control of expression levels.

Conclusions: We found that CLIC5A interacts directly with the Ezrin C-terminal domain, but only in the over-active Cheerio expressing cells, suggesting TOR to be a novel downstream target of the mechanosensor Cheerio (dFilamin). FilaminB is upregulated in nephrocytes and studied the functional role of the mechanosensitive ion channel Piezo in Drosophila nephrocytes.

PO1685

The Mechanosensitive Ion Channel Piezo Activates Rhod in Drosophila Nephrocytes

Sybille Koehler, Barry Denholm. Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Podocytes constantly face biomechanical forces such as shear stress and hydrostatic pressure. Increasing forces result in morphological changes, detachment from the glomerular basement membrane and loss into the primary urine. Here, we investigated the functional role of the mechanosensitive ion channel Piezo in Drosophila nephrocytes.

Results: First, we confirmed Piezo expression and localisation at the nephrocyte diaphragm. Also, we studied the channel with the chemical compound YODA revealed significantly increased Ca++ signalling and Rh activation, suggesting a functional role of Piezo in nephrocytes and delineating the putative Piezo mechanosensitive pathway. For further analysis, we used knockout flies and observed a filtration phenotype, while morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rh-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tempol aturanta toxin. Intriguingly, treatment with tempol aturanta toxin reversed the elevated Rh-GTP levels observed upon Piezo overexpression.

Conclusions: Taken together, our data confirms the functional expression of Piezo in nephrocytes, its role in regulating GTPases and the beneficial effect of tempol aturanta toxin to reverse the pathological effects caused by increased Piezo levels.

PO1686

Drosophila Filamin Exhibits a Mechanoprotective Role During Nephrocyte Injury via Hypertrophy

Sybille Koehler, Barry Denholm. Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Podocytes are constantly exposed to biomechanical forces such as shear stress and hydrostatic pressure. These forces increase during disease like diabetes and hypertension, resulting in adaptive mechanisms such as podocyte hypertrophy. But how do podocytes sense changes in biomechanical forces and how does the molecular response look like?

Methods: To investigate this, we utilized Drosophila nephrocytes and studied the functional role of the mechanosensor Cheerio (dFilamin). FilaminB is upregulated in podocyte injury models and upon increased biomechanical stress, therefore serving as an ideal candidate for mediating mechanoprotection in response to injury.

Results: Expression of an over-active mechanosensor region variant of Cheerio resulted in a significant hypertrophy phenotype, while morphology and filtration function were only mildly affected. Interestingly, the expression of over-active Cheerio caused a rescue of filtration function after depletion of the nephrocyte diaphragm proteins Duf (dNEPH) and Sns (dNephin). Additional analysis with human FilaminB confirmed this mechano-protective role and the involvement of the mechanosensor region in the hypertrophy phenotype. To delineate the mechanoprotective pathway acting downstream of FilaminB, we studied the candidates: TOR, WNT and YAP. Activation of these pathways result in nephrocyte hypertrophy. Interestingly, TOR repression reversed the hypertrophy in over-active Cheerio expressing cells, suggesting TOR to be a novel downstream target of Cheerio and to be responsible for the hypertrophy phenotype.

Conclusions: Although Cheerio and FilaminB mediate a mechanoprotective role in the face of injury, their excessive expression resulted in a severe morphological and functional phenotype, emphasizing the need of a tight control of expression levels.
PO1687
Characterization of a Novel FSGS-Associated ACTN4 Mutation in Drosophila melanogaster

**Background:** Decisive for podocyte morphology and homeostasis during health and disease is a specialized and highly regulated organization of the actin cytoskeleton. In this context, the actin cross-linking protein Alpha-actinin4 (ACTN4) has been shown to play a crucial role in podocyte architecture and function. Mutations in the ACTN4 gene are associated with focal segmental glomerulosclerosis (FSGS). Here, performing gene panel sequencing in a pediatric patient presenting with steroid resistant nephrotic syndrome and FSGS, a de novo, potentially disease causing variant of ACTN4 was identified, which was previously undescribed and not found in available genome or exome databases. Our aim is to elucidate the pathogenic potential of this variant for podocytes and FSGS progression.

**Methods:** To elucidate pathogenic effects of the newly identified ACTN4 variant, we employed the genetic toolbox of Drosophila. The fly holds podocyte-equivalent cells called nephrocytes, which are responsible for filtration and detoxification of the hemolymph. Cell-specific genetic manipulation enabled us to analyze RNA-mediated knockdown of Actin, the single fly homolog, in nephrocytes and its impact on cell morphology and function. Rescue experiments with the novel human ACTN4 variant will now reveal, if most pathogenic phenocharacters of the mutation when compared to wildtype as well as previously described disease-associated variants of ACTN4.

**Results:** Knockdown of Drosophila Actin in nephrocytes leads to severe functional and structural defects. Cell density is decreased by up to 50%, morphology, mislocalization of the ZO-1 homolog Polychaetoid was observed as well as overall reduction of nephrocyte diaphragms. First rescue experiments with wildtype human ACTN4 led to partial rescue of functional and morphological phenotypes observed upon Actin knockdowns.

**Conclusions:** Our results underline the importance of Actinin for nephrocyte biology. Capacity of wildtype human ACTN4 in rescuing the knockdown associated phenotypes indicates the model’s suitability. Further experiments will be performed to elucidate the pathogenic potential of the novel ACTN4 variant also in comparison to previously described pathogenic mutations.

The Calcium-Sensing Receptor Restores Podocyte Function in Proteinuric Humans and Mice
Anne K. Muehlig,1,2 Johanna Steingroever,1 Wiebke Sachs,1 Catherine Meyer-Schwesinger,3 Hoon Young Choi,4 Nicole Endlich,4 Fabian Braun,2 Tobias B. Huber,2 Victor G. Puelles,2 Claus Peter Schmitt,1 Jun Oh.1
1Department of Pediatric Nephrology, University Children’s Hospital, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Hamburg, Germany; 3Center of Experimental Medicine, Institute of Cellular and Integrative Physiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4Department of Anatomy and Cell Biology, University of Greifswald, Greifswald, Germany; 5Department of Pediatrics, Heidelberg University Hospital, Heidelberg, Germany; 6Tosei University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

**Background:** Cisregulatory factors allosterically increase the calcium (Ca2+) sensitivity of the calcium-sensing receptor (CaSR), which suppresses the secretion of parathyroid hormone in the parathyroid gland and therefore regulates Ca2+ homeostasis. The CaSR is furthermore expressed in the tubular system and to a lesser extend in podocytes. Activation of CaSR reduces glomerular proteinuria and podocyte damage in animals. However, the precise role of the podocyte CaSR is still unclear.

**Methods:** A CaSR knockdown (KD) in murine podocytes and podocyte-specific CaSR knockdown (KO) in BALB/c mice were generated to study its role in proteinuria.

**Results:** Podocyte CaSR KD abolished the calciumic R-586 mediated -in, , suppressed the number of actin fibers, cellular attachment and migration velocity in podocytes. In contrast, the activation of the CaSR with R-586 protected the wildtype cells from Adriamycin (ADR)-induced cytoskeletal rearrangement and reduction in adhesion capacity. In vivo ADR-induced proteinuria enhanced glomerular CaSR expression in wild type mice (control vs ADR: 33.5±2.0 vs 75.8±7.8 CaSR positive podocytes (%); p=0.0286). In podocyte-specific CaSR KO ADR treatment resulted in a higher albuminuria (control vs KO: 27.9±38.1 vs 85.9±52.7 g/galbin/creatinine; p=0.023 at day 7, podocyte foot process effacement, podocyte loss (control vs KO: 3554±283.1 vs 2996±547.2 p.07±cell/mm²; p=0.0238 at day 8) and glomerular sclerosis compared to wild type littermates. In addition, four children with nephrotic syndrome, objecting glucocorticoid therapy, were treated with the calcimimetic cinacalcet for 1 to 33 days. Proteinuria declined transiently by up to 96 %, serum albumin increased and edemas resolved.

**Conclusions:** The activation of CaSR regulates key podocyte functions and protects from ADR induced cellular damage in vitro. The CaSR reduces tox in induced proteinuria, podocyte loss and glomerular damage in mice. Our findings suggest a major role of CaSR signaling in glomerular disease.

PO1689
Selective PPARγ Modulator with Reduced Adipogenic Potential Ameliorates Experimental Nephrotic Syndrome
Claire Burton,1 Galen Rask,1 Amanda P. Waller,2 Amy Webb,2 Marina G. da Rocha Pitta, Angélica A. Amato,1 Rachel Cianciolo,2 Brian Becknell,1,2 Bryce A. Kerlin,1,2 Francisco R. Neves,1 Alessia Fornoni,1 Shipra Agrawal,1,2
1UH-Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2The Ohio State University, Columbus, OH; 1Universidade de Brasilia, Brasilia, Brazil; 2University of Miami School of Medicine, Miami, FL; 3Universidade Federal de Pernambuco, Recife, Brazil.

**Background:** Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, can be refractory to standard treatment and is typically associated with hypoalbuminemia, hypercholesterolemia, and hypercoagulopathy. We hypothesized that the nuclear receptor PPARγ can be selectively modulated using a novel partial agonist, GQ-16, to gain therapeutic advantage over traditional PPARγ agonists for NS treatment.

**Methods:** Pio and GQ-16 were administered daily to male Wistar rats with puromycin aminonucleoside (PAN)-induced nephropathy. Serum and urine chemistries were performed and kidneys, glomeruli, liver, and white adipose tissue (WAT) were harvested for RNA and protein extraction. Blood was collected for determination of thrombin generation parameters.

**Results:** PAN induced robust proteinuria, which was significantly reduced with Pio to 64% of PAN’s value, and robustly with GQ-16 to 81% of PAN, which was comparable to controls. Podocyte hypertrophy also returned to normal with Pio and GQ-16. While both GQ-16 and Pio restored glomerular Nphs1 and hepatic Pck9 expression and reduced hypercholesterolemia, GQ-16 also restored glomerular Nyp2, and reduced disease-associated hypoalbuminemia and hypercoagulopathy. Furthermore, RNA-seq analysis identified both common and distinct glomerular genes altered by Pio and GQ-16 treatments. Moreover, Pio but not GQ-16 significantly induced apo2 (fatty acid binding protein) in adipocytes and in WAT. Both, Pio and GQ-16 induced insulin sensitizing adipokines in WAT with varying degrees.

**Conclusions:** Selective modulation of PPARγ by a partial agonist may be a more beneficial approach than a full PPARγ agonist in reducing proteinuria, hypoalbuminemia, and hypercoagulopathy in NS and in decreasing drug-associated side effects such as adipogenesis and weight gain.

PO1690
Simultaneous Loss of Podocyte Insulin Receptor (IR) and Insulin-Like Growth Factor 1 Receptor (IGF1R) Is Detrimental and Associated with Spliceosome Dysfunction
Jenny Hurcombe,1 Lusyan Dayalan,1 Fern Barrington,1 Lan Ni,1 Paul T. Brinkkoetter,3 Martin Holzenberger,1 Gavin I. Welsh,1 Richard Coward,3 University of Bristol, Bristol, United Kingdom; 2University of Leth, Koln, Koln, Germany; 3INSERM, Paris, France.

**Background:** Insulin signalling to the podocyte via the insulin receptor (IR) is crucial to renal function. Insulin-like growth factor 1 (IGF1) signalling through the structurally related insulin-like growth factor 1 receptor (IGF1R) is also known to directly affect the podocyte. Since the IR and IGF1R may act redundantly in some contexts, this study sought to elucidate the compound role of the insulin/IGF1R axis in podocyte function using mouse and cell culture models deficient in both receptors.

**Methods:** To examine the effects of combined receptor loss in vivo, a transgenic mouse model with conditional inactivation of podocyte IR and IGF1R was generated. In vivo, conditionally immortalised genetic IR knockout, IGF1R knockout and IR/IGF1R dual knockout podocytes were characterised using global proteomic and transcriptomic analysis.

**Results:** Podocyte specific IR/IGF1R knockout mice developed significant albuminuria and a severe renal phenotype with global sclerosis, renal failure and death occurring between 4 and 24 weeks. ~90% loss of IR/IGF1R in cultured mouse podocytes was also detrimental resulting in >50% cell death 7 days after gene knockdown. Enrichment analysis of total proteomic data revealed a striking downregulation of gene ontology terms associated with splicing and RNA processing activity in IR/IGF1R knockout cells. Western blot analysis was used to validate the reduced expression of proteins responsible for spliceosome synthesis and regulation in dual knockout podocytes, including polyprimidine tract-binding protein 2 (PTBP2), eukaryotic initiation factor 4A (EIF4A) and splicing factor 3B subunit 4 (SF3B4).

**Conclusions:** This work underscores the critical importance of podocyte insulin/IGF1 signalling and reveals a novel role for this signalling axis in RNA processing by regulating spliceosome activity.

**Regression of Preexisting Glomerular Pathology in a Mouse FSGS Model in Response to Treatment with Macula Densa-Derived Biologicals**

**Georgina Gvaramatí, Urvi Nikhil Shroff, Audrey Izuhara, Janos Peti-Peterdi. University of Southern California Keck School of Medicine, Los Angeles, CA.**

**Background:** Macula densa (MD) cells localized at the glomerular vascular pole synthesize and release numerous vasoactive autacoids and newly identified angiogenic (e.g. CCN1) and glomerulotrophic factors that act in a paracrine fashion to maintain high renal/glomerular blood flow and endogenous tissue remodeling. The present study aimed to test the tissue regenerative therapeutic potential of MD-derived biologicals in vivo in a mouse model of focal segmental glomerulosclerosis (FSGS).

**Methods:** Balb/C mice with Adriamycin-induced stable, severe FSGS and albuminuria (albumin/creatinine ratio ACR>10,000/mg/g) were randomized into 5 groups and started daily i.p. injections (150 µl) each of either saline (S), human recombinant (hr) CCN1 in low-dose (0.3 ng/mouse) (L), hrCCN1 high-dose (2 µg/mouse) (H), DMEM/F12 control (D), and conditioned culture media of the new MD cell line mMD5® (MD) for 4 weeks. Transcortaneous GFR (MediBeacon) and ACR were measured weekly. Similar, histological analysis was performed using PAS and Trichrome staining.

**Results:** Kidney injury was severe at the onset (GFR 1160±51 mU/min/100 g BW, ACR 13219±637) and was sustained throughout the 4 weeks of treatment in control S and D groups (GFR: 108.0±143, 992±164, ACR: 10227±5869, 3958±164; ACR: 11219±573, 921±358). Similarly, p57+ podocyte number per glomerular area (1113±100 µm²/mouse) did not change in L, 57±1.9 in MD vs 152±3.4 in S; 113±0.6 in MD vs 5.5±2.3 in H vs 38±0.3 in D based on Picrosirius staining density) improved significantly in response to treatment with MD biologicals.

**Conclusions:** Podocytopenia in mice lacking CAMK4 in podocytes exposed to adriamycin, was reduced by 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that CAMK4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CAMK4 inhibits autophagy, a process needed for the removal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

**Funding:** NIDDK Support

**PO1692**

**Insulin-Like Growth Factor 1 Receptor (IGF1R) Suppression in the Glomerular Podocyte Has Beneficial and Detrimental Consequences Dependent on the Level of Inhibition**

**Jenny Harcombe,1 Fern Barrington,1 Virginie M. Betin,1 Abigail C. Lay,1 Lusyoun Dayalan,1 Lan Yu,1 Paul T. Brinkkoeber,2 Martin Holzenberger,1 Gavin I. Welsh,1 Richard Coward.1 University of Bristol, Bristol, United Kingdom; 2Uniklinik Köln, Köln, Germany; 1INSERM, Paris, France.**

**Background:** Insulin signaling to the glomerular podocyte via the insulin receptor (IR) is known to be critical for normal kidney function. This study aimed to define the physiological importance of the closely related insulin-like growth factor 1 receptor (IGF1R) in podocytes.

**Methods:** Transgenic mice with conditional inactivation of podocyte IGF1R were generated to determine the effects of IGF1R suppression in vivo. In vitro, conditionally immortalised genetic IGF1R knockout and wild-type podocytes treated with IGF1R inhibitor picipodophyllin (PP) were characterised using global proteomic analysis.

**Results:** Transgenic mice with partial podocyte-specific IGF1R knockout, generated using conventional Cre recombinase, had no apparent basal renal phenotype but unexpectedly, were protected from doxorubicin-induced nephropathy. An additional mouse model using an epigenetically resistant podocyte Cre driver designed to increase receptor knockout efficiency, exhibited mild basal albuminuria by 24 weeks. Our in vitro models revealed that the degree of IGF1R inhibition in the podocyte is important. Greater than 90% knockout caused ~50% cell death after 7 days and did not protect against doxorubicin-induced cell death whilst wild-type podocytes treated with PPP (partial inhibition) showed enhanced survival when stressed with doxorubicin. Proteomic analysis revealed that near complete IGF1R suppression results in downregulation of mitochondrial respiratory complex I and DNA damage repair proteins whilst partial IGF1R inhibition promotes expression of respiratory complexes.

**Conclusions:** Altered mitochondrial function, impairment of DNA damage responses and resistance to oxidative stress in podocytes is dependent on the level of IGF1R suppression and determines whether receptor inhibition is protective or mildly detrimental.

**Funding:** Government Support - Non-U.S.

**PO1693**

**Calcium/Calmodulin Kinase 4 Induces FSGS by Promoting Apoptosis While Inhibiting Autophagy in Podocytes**

**Rhea Bharagava, Kayahoe Maeda, Abhigyan Satyan, Isaac E. Stillman, George C. Tsokos. Beth Israel Deaconess Medical Center, Boston, MA.**

**Background:** Podocyte injury and death precede the development of focal segmental glomerulosclerosis (FSGS), but the involved mechanisms remain poorly understood. Calcium/calmodulin kinase 4 (CamK4), a serine threonine kinase, is increased in podocytes of people with FSGS and mouse models of FSGS.

**Methods:** B6, B6 Camk4,β/β-podocytomice or Camk4,β/β-podocytomice were created and injected with i.v. adriamycin. Urine was collected on days 5, 3, 7, or 14, and kidney samples were collected on day 7 or 14 after adriamycin injection. Cultured human podocytes in the presence and absence of CAMK4 inhibitor (KN93) were exposed to adriamycin after which immunofluorescence and western blot was performed. Pull down mass-spectrometry and co-immunoprecipitation analysis was performed to identify proteins involved in cell death and those that directly interact with CamK4 in FSGS.

**Results:** We found that lack of CamK4 in podocytes suppressed the development of kidney pathology including the presence of hyaline deposits in glomeruli, podocyteptenia and tubulointerstitial damage with intratubular casts in mice injected with adriamycin. Proteinuria in mice lacking CamK4 in podocytes exposed to adriamycin, was reduced by 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that CamK4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CamK4 inhibits autophagy, a process needed for the removal of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

**Conclusions:** We demonstrate that mice lacking CamK4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocyteptenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

ACE Inhibition Modulates Insulin-Like Growth Factor 1 (IGF-1) Filtration to Regulate Compensatory Kidney and Glomerular Hypertrophy

Abhijit S. Naik, Su Q. Wang, Mahboob A. Chowdhury, Rajasree Menon, Edgar A. Otto, Jocelyn E. Wiggins, Matthias Kretzler, Markus Bitzer, Roger C. Wiggins, University of Michigan, Ann Arbor, MI.

**Background:** Modeling suggests that preventing glomerular volume (GV) increase could serve as a therapeutic target to mitigate hypertrophy-associated progressive glomerulosclerosis (GS). We, therefore, evaluated how GV is regulated, and how Angiotensin-Converting Enzyme inhibition (ACEi) could reduce compensatory GV increase.

**Methods:** Uni-nephrectomized (Uni-Nx) wild-type Fischer344 rats were used to model progressive GS triggered by the single kidney state, and the effect of ACEi started either before or after Uni-Nx. Urine IGF ELISA assay, computer-assisted morphometry, single-cell, bulk transcriptomics, immunofluorescence, and human databases were analyzed.

**Results:** ACEi started before, but not after Uni-Nx, reduced short (Panel A) and long-term (Panel B) compensatory GV increase, and the associated 8-fold peak of urine IGF-1 post-nephrectomy (Panel C). An IGF-IR inhibitor (pieriprodiphilin) also reduced compensatory kidney hypertrophy (Panel D). Post-Uni-Nx, a decrease in both serum IGF-1 and glomerular kidney IGF-1 transcript were noted, and IGFBP3 (the major blood IGFBP) was present in podocyte cytoplasm in the absence of detectable podocyte IGFBP3 transcript, suggesting that IGF-1 and IGF-IGFBP3 complexes had come from blood. A model was developed to predict how IGF-1, IGF-2, and IGF-IGFBP protein complexes would interact with the glomerular filter, and its predictions were confirmed in ERCB database. The importance of hypertrophied IGF-1 as a driver of glomerular failure in single kidney states was further supported by human kidney alloraft half-life analysis.

**Conclusions:** Hypertrophied IGF-1 drives compensatory GV increase leading to long-term proteinuria and GS. Timing of ACEi in relation to Uni-Nx can reduce both IGF-1 hyperfiltration and GV increase, thereby prolonging single kidney lifespan.

ANG2 Induces Oxidative Podocyte Injury via the Ureapregulation of Nox4

Tae-Sun Ha, Chungbuk National University, Cheongju, Chungcheongbuk-do, Republic of Korea.

**Background:** Angiotensin II (Ang II) induces glomerular and podocyte injury via systemic and local vasoconstrictive or non-hemodynamic effects including oxidative stress. The release of free radicals from podocytes may participate in the development of glomerular injury and proteinuria. We studied the pathophysiological roles of oxidative stress in Ang II-induced podocyte apoptosis.

**Methods:** Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times and transfected by Nox4 or AT1R siRNAs or negative control scrambled siRNA for 24 h. The changes of podocyte oxidative stress and apoptosis were observed by confocal imaging, western blotting, real-time PCR, FACs and TUNEL assay according to the presence of Ang II.

**Results:** Ang II increased the expression of superoxide anions and intracellular reactive oxygen species (ROS) levels but suppressed the antioxidant enzyme activity that was reversed by an antioxidant, probucol. Ang II also increased Nox4 protein and expression in podocytes, measured using western blotting and real-time PCR analysis that was also reversed by probucol. Nox4 suppression by small interference RNA (siRNA) reduced the oxidative stress induced by Ang II. These results suggest that Ang II induced oxidative stress via the upregulation of Nox4 protein in a transcriptional mechanism. Ang II promoted podocyte apoptosis that was reduced significantly by probucol and Nox4 siRNA. Ang II-induced podocyte apoptosis were also recovered by Ang II type 1 receptor (AT1R) siRNA.

**Conclusions:** Our findings suggest that Ang II induced podocyte oxidative stress and apoptosis through AT1R and Nox4. These findings suggest that Ang II promoted podocyte oxidative stress and apoptosis through AT1R and via the upregulation of Nox4, which could be preventable by Nox4 inhibition and/or antagonizing AT1R as well as antioxidants.

Anillin Serves a Protective Function in a Mouse Model of HIV-Associated Nephropathy

Brandon M. Lane,1,2 Alexis Musick,4 Guanghong Wu,2,3 Megan Chryst-Stangl,1,3 Gentzon Hall,1,2 David N. Howell,1 Rasheed A. Gbadegesin,1,2 Duke University Department of Pediatrics, Durham, NC; 3Duke Molecular Physiology Institute, Duke University, Durham, NC; 4Duke University School of Medicine, Durham, NC; 5Duke University Department of Pathology, Durham, NC; 6Duke University Hospital, Durham, NC.

**Background:** HIV associated nephropathy (HIVAN) is characterized by a rapid progression to end stage kidney disease with limited treatment options. We previously demonstrated that mutations in the gene encoding anillin (ANLN) can cause FSGS and showed that ANLN is upregulated in the glomeruluses of HIVAN patients as well as the HIVAN Tg26 mouse model. ANLN is an F-actin binding protein that affects cell proliferation and survival, two cell processes that are predicted to play a key role in the phenotype associated with HIVAN. We hypothesized that ANLN upregulation is one of the drivers of glomerular failure in HIVAN mice, therefore modulating ANLN expression may present an alternative therapeutic strategy for HIVAN.

**Methods:** To evaluate the therapeutic potential of reduced functional ANLN in a HIVAN mouse model, we created a mouse line using CRISPR Cas9 mediated gene editing that contains an early stop codon in the Anillin (ANLN) gene. We bred heterozygous ANLN mice with Tg26 HIVAN mice and evaluated proteinuria and mortality over 16 weeks for each genotype. Sclerotic glomeruli from 3 mice in each group were evaluated and quantified at 16 weeks of age by pathologists blinded to genotype.

**Results:** There was no improvement in glomerular disease phenotype associated with the reduction of functional ANLN in the Tg26 HIVAN model. Urine albumin to creatinine ratio was similar between Tg26 ANLN mice and ANLN homozygotes compared to Tg26 HIVAN mice (p=0.038, 0.0863, 0.0761 for each time-point). Mice heterozygous for both the ANLNx and Tg26 alleles also did not display any increase in survival compared to mice carrying only the Tg26 allele (p=0.361). Evaluation and scoring of PAS stained kidney sections by independent pathologists revealed similar levels of sclerosis between Tg26 HIVAN mice and mice heterozygous for both the ANLNx and Tg26 alleles.

**Conclusions:** Genetic ablation of ANLN does not improve kidney disease phenotypes in Tg26 HIVAN mice. ANLN upregulation likely represents a survival mechanism in Tg26 HIVAN mice and not a cause of injury.

**Funding:** NIDDK Support

The Role of LRPI in Podocytes

Marvin Groemer,1,2 Patricia Bolanos-Palmieri,1 Tilman Jobst-Schwan,1,2 Mario Schiffer,1,2 University Hospital Erlangen - Department of Medicine 4 - Nephropathy and Hypertension, Erlangen, Germany; 3Research Center On Rare Kidney Diseases (RECORD), University Hospital Erlangen, Erlangen, Germany.

**Background:** Recent studies have demonstrated the importance of endocytosis for podocyte health. However, little is known about the function of the internalized cargo proteins. We investigated the role of the low-density lipoprotein receptor-related protein 1 (LRP1), a large endocytic scavenger receptor, in podocytes in vitro and in vivo.

**Methods:** We used immunoblotting and -fluorescence to determine quantity and localization of LRPI in cultured human podocytes. siRNA knockdown (KD) of LRPI and an antagonist were used to investigate potential functional importance in vitro. We used zebrafish morpholino knockdown models of LRP1 homologs to study the function of LRPI in vitro. LRPI expression in healthy and diseased human renal tissue was determined by immunohistochemistry.

**Results:** LRPI is highly expressed in cultured podocytes where it localizes to the membrane and perinuclear region. It colocalizes with early and late endosomes, in line with its role in endocytotic trafficking. Interaction with β1-Integrin (ITB1) was confirmed by immunoprecipitation and colocalization. siRNA KD of LRPI resulted in a reduction of podocyte number and cell size. Morpholino KD of both LRPI isomers in zebrafish led to pericardial effusion and generalized edema, hinting at a renal phenotype. Interestingly, LRPI has nearly absent baseline expression in healthy human glomeruli. Glomerular expression is significantly increased in human biopsies of various podocytopathies. However, LRPI does not colocalize with the podocyte marker nephrin in human tissue.

**Conclusions:** LRPI is a highly expressed endocytic receptor in cultured podocytes. Ablation of LRPI function caused by siRNA KD or pharmacological inhibition resulted in disarrangement of podocyte shape, implicating a crucial role in adhesion and cytoskeletal regulation in vitro. Colocalization and immunoprecipitation with ITB1 suggests interaction of LRPI with β1-Integrin. The importance of LRPI for kidney function is corroborated by our zebrafish experiments where LRPI silencing led to a renal phenotype. Since glomerular LRPI expression is increased in proteinuric diseases, it could function as a mediating or compensating factor in glomerular injury. However, its absence from podocytes in vivo makes its function for podocytes outside of the culture environment unclear. Our findings thus exemplify the difference in podocyte adhesion regulation between podocytes in vitro and in vivo.

Dach1
indicating inefficient Cre-mediated recombination. Nevertheless, all
regulated podocyte structural protein expression, which cannot be compensated by its
synaptopodin expression and up-regulation of cleaved-caspase 3 expression.

Dach1 Is Essential for Maintaining Normal Podocytes

Keiko Tanaka,1 Taiji Matsuoka,2 Okyama Daigaiku Daigaiku Ishiyakugak 
Sogo Kenkyusha, Okayama, Japan;2 Tokai Daigaiku Igaku Igaku Kenk uka 
Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various
organisms. Dach1 polymorphism has been reported to be associated with nephrotic syndrome
and chronic kidney diseases. We previously found that Dach1 was highly expressed in
normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to
WT1. We aimed to elucidate the function of Dach1 in podocytes in vivo.

Methods: Because Dach1
null mice die shortly after birth, kidneys were harvested at P0 and histologically examined. To study the role of Dach1 in mature podocytes, podocyte-specific Dach1 deleted mice were generated by mating Dach1
floxed mice with Nph1-Cre or Nph2-CreERT2 mice. Eleven Nph1-Cre/Dach1
floxed mice were analyzed at 8-35 weeks of age. 14 Nph2-CreERT2/Dach1
floxed mice were treated with tamoxifen (0.1mg/g BW/day, p.o. 5-3 days courses) and analyzed 7 days later.

Results: In neonatal wild-type mice, Dach1 is fainly expressed in the cap
mesenchyme and increased in the renal vesicles/shaped bodies and further intensified
and concentrated in mature podocytes. Dach1 is also intensely expressed in the ureretic
bud. In Dach1
null mice, negative Dach1 staining was confirmed. Kidneys of Dach1
null mice were 14.2± smaller than those of control mice but showed normal structure.
Podocytes in Dach1
null mice showed normal phenotypes in SEM and TEM with normal slit
membrane, and no abnormal leakage of albumin. Immunostaining for WT1, nephrin,
podocin, synaptopodin and nephrin was normal. Only a small number of podocytes
lacked Dach1 staining in Nph1-Cre/Dach1
floxed and Nph2-CreERT2/Dach1
floxed mice, indicating inefficient Cre-mediated recombination. Nevertheless, all Nph1-Cre/Dach1
floxed exhibited abnormal albuminuria (UACR 4.7±1.6 mg/mg vs. 0.06±0.07), which
increased with age, and seven (65%) mice showed FSGS. Seven (50%) Nph2-CreERT2/
Dach1
floxed mice exhibited abnormal albuminuria, and three (21%) mice showed early
sclerotic lesions. Immunostaining showed that sclerotic lesions lacked Dach1 as well
as WT1, synaptopodin and nephrin. Most of Dach1
negative podocytes in non-sclerotic
glomeruli had normal staining for podocyte marker proteins.

Conclusions: These results indicate that Dach1 does not determine the fate
or differentiation into podocytes but is indispensable for maintaining normal integrity of
mature podocytes.

TAZ Is Important for Structural and Functional Integrity of Podocytes

Jianchun Chen, Raymond C. Harris. Vanderbilt University Medical Center; Nashville, TN.

Background: Podocyte is an important component of glomerular filtration barrier
(GFB). Maintenance of integrity of slit-diaphragm(SD) structure is critical for normal
kidney function. Podocytes lose most epithelial cell tight junction components except for
Zonula occludens-1 and -2 (ZO-1 and ZO-2). In podocytes, ZO-1 is an important binding
partner of Nephrin, and mice with podocyte-specific ZO-1 deletion showed significant
growth retardation and severe proteinuria starting at 2 weeks of age, but the regulation of
ZO-1 expression in podocytes are not clear. TAZ (transcriptional coreactivator with PDZ-
binding motif) and its paralog Yes-associated protein (YAP) are two crucial effectors of
Hippo signaling pathway. Recent study has shown that podocyte-specific YAP deletion
does cause FSGS and progressive renal failure, but the potential role of TAZ in podocytes
has not been studied.

Methods: Mice with podocyte-TAZ deletion (TAZ
−/−) were generated by crossing
TAZ
−/− mice with podocin-Cre recombinase transgenic mice. Urinary albumin excretion
and kidney histology and podocyte number per glomerulus were evaluated in TAZ
−/−
and WT mice. Immunoblotting analysis of isolated glomerular lysates of TAZ
−/− and TAZ
−/− mice were performed. In primary cultured mouse podocytes and immortalized
mouse podocytes cell morphology and cell lysates were evaluated after silencing TAZ
with specific siRNAs.

Results: 41.7% of TAZ
−/− mice develop mild proteinuria at age of 3-4 weeks
(n=56), with a urine albumin/creatinine ratio of 89.57 ± 12.67 vs 27.86 ± 1.55 (µg/mg,
n=7). At 9 weeks of age, compared to TAZ
−/− mice, the glomeruli of TAZ
−/− mouse
kidney had focal sclerosis and significant podocyte loss (WT1+ cells: 13.23 ± 0.699 vs.
17.85 ± 0.608 (n=13). Expression of Bcl2, ZO-1, ZO-2 and synaptopodin were decreased, but expression of cleaved-caspase 3 in the isolated glomeruli from TAZ
−/− mice compared with TAZ
−/− mice. In cultured podocytes, silencing TAZ by siRNA altered
cells morphology and F-actin distribution, and downregulation of Bcl2, ZO-1, ZO-2 and
synaptopodin expression and up-regulation of cleaved-caspase 3 expression.

Conclusions: These results demonstrate that TAZ expression plays an important role
in regulating podocyte structural protein expression, which cannot be compensated by its
paralog YAP.

PO1070

Neurexin1α Containing Splice Site 4 Interacts with Nephrin and Contributes to Maintenance of the Integrity of Podocyte Slit Diaphragm

Yoshiyasu Fukusumi, Hidenori Yasuda, Ying Zhang, Hiroshi Kawachi. Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background: Neurexins (NRXNs) are synaptic cell adhesion molecules having
essential roles in the assembly and maturation of synapses. It is known that NRXN1α
contains 6 splicing sites (SSs), and multiple splicing variants were diffusely expressed
in neuronal tissues. We have previously reported that NRXN1α is expressed at slit diaphragm
(SD), a cell–cell junction of podocyte, and is downregulated in injured podocytes. The
report also showed that NRXN1α expressed in podocytes is a unique variant containing
SS1, 3, 4, and 5, which is a rare variant in neural tissues (Am J Physiol. 300:R340, 2011).
However, the role of NRXN1α at SD is not well understood yet.

Methods: The interaction of NRXN1α with SD-associated molecules was analyzed by
the immunoprecipitation (IP) assay. The function and structure of SD of NRXN1α KO
mice were precisely analyzed.

Results: The interaction of NRXN1α with SD molecules such as nephrin and ephrin-B1 was detected by the IP assay with rat glomerular lysates. IP assay with the HEK cell expression systems showed NRXN1α containing SS4 interacted with nephrin, but NRXN1α lacking SS4 did not. The interaction between NRXN1α and nephrin was dissociated, if nephrin was phosphorylated. The interaction of NRXN1α with ephrin-B1 was not detected in the HEK system, suggesting NRXN1α interacts with ephrin-B1 via nephrin. Abnormal proteinuria (92.1 mg/day vs. 23.8 mg/day, p<0.05) and clear
alterations in the expression of major SD components including nephrin, ephrin-B1
and podocin were detected at the age of 20 weeks of NRXN1α KO mice (IF score; nephrin, 2.68 vs. 3.83, p<0.05; ephrin-B1, 2.68 vs. 3.84, p<0.05; podocin, 2.75 vs. 3.58, p<0.05), although these alterations were not detected at the age of 10 weeks. The phenotypes of the KO mice suggest NRXN1α does not play a major role for formation of SD but contributes to the maintenance of the integrity of SD at an elderly age.

Conclusions: Neurexin1α containing SS4 interacts with nephrin, and is a novel SD component. NRXN1α contributes to maintenance of the function and the molecular integrity of SD. It is conceivable that downregulation of NRXN1α participates in the development of podocyte injury onset at an elderly age.

Possible Role of the Cytosolic RNase Inhibitor in Maintaining the Integrity of the Glomerular Filtration Barrier

Patricia Bolanos-Palmieri, Franz Tiefenböck, Mario Schiffer. Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertoniologie, Erlangen, Germany.

Background: The ribonuclease inhibitor (RI) is a cytoplasmic protein encoded by the RNHI1 gene. The RI forms a tight non-covalent bond with members of the RNaseA superfamily and therefore it’s considered that its main function is to act as a sentinel for dysregulated RNases. The ratio of RI to substrate has also been shown to vary according to the proliferative and metabolic status of the cell suggesting that the balance in the protein-protein interactions between the RI and its substrates plays a role in maintaining cell homeostasis by impacting processes such as protein synthesis and various signaling pathways. However, the entirety of the biological roles fulfilled by the RI are yet to be described.

Methods: Immunofluorescence staining of human kidney tissue and protein detection by western blot from samples of immortalized podocytes were carried out to confirm the presence of the RI in glomerular cells. As an initial injury model, podocytes were treated with PAN to determine if changes in RI expression occur as a response. RNHI1 inhibition was performed in a transgenic zebrafish line that allows for the detection of proteinuria via a GFP-tagged protein in the circulation. At 96hpf the severity of the edema phenotype and the fluorescence levels were recorded.

Results: Our preliminary data shows that the RI is present in human podocytes both
in vitro and in vivo, as its expression domain coincides with glomerular cells labelled with
synaptopodin. Additionally, the RI is present in cultured podocytes both before and
after the temperature shift used to induce quiescence, and it appears to increase after
differentiation. There is also expression modulation of RNHI1 in response to PAN
treatment of podocytes. In our zebrafish model, RNHI1 knockdown resulted in up to a 40% increase in mild to severe edema and over 30% decrease in fluorescence suggesting that a reduction in RI might compromise the filtration barrier enough to lead to proteinuria.

Conclusions: Taken together our initial data show a promising avenue for research where the balance between members of the RNaseA superfamily and their cytoplasmic inhibitor may represent a powerful mechanism that allows the cells to modulate the protein-protein response to stimuli. An imbalance in this relationship might ultimately affect the integrity of the cells in the kidney.

Atypical Caspase 3-Dependent Death in Podocytes
Kazuyoshi Yamamoto,1,2 Masahiro Okabe,1,2 Tajii Matsusaka,1 Takashi Yokoo,1 Tokyoikei Ika Daigaku, Minato-ku, Japan; 2Tokai Daigaku, Hiratsuka, Japan.

Background: Apoptosis of podocytes has been widely reported in many in vitro studies, but definitive apoptosis has never been documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo.

Methods: Primary mouse podocytes were transiently transfected with ICDD2 and EGFP expression plasmids and treated with a bCD25-targeting immunotoxin, LMB2 (1nM), and observed 1 day later. In some experiments, the cultured podocytes were transfected with Bak1 or Bax siRNA before treatment with LMB2. In vivo experiments, podocyte injury was induced by injecting LMB2 (1.25ng/gBW) into NEP25 mice, which express ICDD2 in podocytes, and analyzed 7 days later.

Results: In vivo studies, administration of LMB2 caused loss of co-introduced EGFP in 56.8±13.6%, incorporation of propidium iodide in 13.6±2.5%, activation of caspase 3 (Casp3) in 19.6±2.6% and TUNEL staining in 4.5±1.3% without significant increase in LDH activity in the culture medium. These phenomena were not observed in cells without ICDD2 or without LMB2. Ac-DEVD-CHO (10µM), a Casp3 inhibitor, attenuated the loss of EGFP by 38.2%. Inhibition of Bak1 and Bax using siRNAs attenuated EGFP loss by 77.6% and 28.4%, respectively. These results indicate that LMB2 induced the typical Casp3 dependent intrinsic apoptosis in podocytes in vitro. In vivo studies, kidneys of NEP25 mice contained podocytes positive for cleaved (c) Casp3 and those for cLaminA, a product of Casp3, but no TUNEL+ podocytes. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. The urine sediments contained podocalyxin-positive podocytes (2.5±0.3%). Among these, 39.1±3.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to UUO 1 day before sacrifice. The obstructed kidney contained more cLaminA+ podocytes than the contralateral kidney. In addition, detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: Thus, due to physical force of glomerular filtration, podocytes doomed to Casp3 dependent death are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. This accounts for the absence of podocyte apoptosis in vivo.

PO1704

Mice Deficient in Aminopeptidase A Have Worse Glomerular Injury in Response to Chronic Renal Mass Reduction
Wayne R. Fitzgibbon,1 Ehtesham Arif,1 Peifeng Deng,1 Joshua H. Lipschutz,1,2 Yusuke Okabayashi,1 Victor G. Puelles,1 Jan Wysocki,1 Daniel Batlle,1 Juan Carlos Q. Velez,1,11 Medical University of South Carolina, Charleston, SC; 11VA Medical Center Ralph H Johnson, Charleston, SC; 12Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 13Northwestern University, Evanston, IL; 14The University of Queensland Ochsner Clinical School New Orleans, New Orleans, LA.

Background: Aminopeptidase A (APA) is a membrane-bound metalloproteinase expressed in podocytes and tubular epithelia. It is a key enzyme in metabolizing angiotensin (Ang) II and diverting Ang I from the formation of Ang II. A recent finding has demonstrated that APA is expressed in podocytes and tubular epithelia. It is a key enzyme in metabolizing angiotensin II and diverting Ang I from the formation of Ang II. A recent finding has demonstrated that APA is expressed in podocytes and tubular epithelia.

Methods: Affected glomeruli from APAKO mice showed a marked decrease in podocyte number (45% vs. 5%, p<0.01). greater degree of tubular injury and microcystic tubular dilatation (45% vs. 5%, p<0.01). hyalinosis/sclerosis was greater for APAKO mice compared to the WT (36% vs. 4%, p<0.01). Median UAlbV at 8 weeks was 104 (33-536) and 1556 (1154-3890) µg/24 for the WT and APA mice respectively. Renal mass reduction induced albuminuria in both groups, but renal ablation induced albuminuria in APAKO mice (p<0.001). Neither BUN nor plasma Ang II levels were different between the 2 groups at 8 weeks.

Conclusions: Our findings further support a role for APA in attenuating glomerular filtration injury following 5/6 renal ablation.

Glomerular Endothelial Cell-Derived MicroRNA-192 Regulates Podocyte Nephrinectin in Membranous Glomerulonephritis

Background: Autoantibodies binding to podocyte antigens cause idiopathic membranous glomerulonephritis (iMGN). It remains elusive how autoantibodies reach the subepithelial space because the glomerular filtration barrier (GFB) is normally size-selective and impermeable for antibodies.

Methods: Kidney biopsies from patients with iMGN, cell culture, zebrafish and mice models were used to investigate the role of nephrinectin (NPNT) regulating microRNAs (miRNAs) for the GFB.

Results: Glomerular endothelial cell (GEC)-derived miR-192-5p and podocyte-derived miR-378a-3p are upregulated in glomeruli of patients with iMGN whereas NPNT expression is reduced. Overexpression miR-192-5p as well as morpholino-mediated npnt knockdown induced edema, proteinuria and podocyte effacement similar to podocyte-derived miR-378a-3p in zebrafish. Moreover, structural changes of the glomerular basement membrane (GBM) with increased lucidity, slicing and lamellation especially of the lamina rara interna similar to ultrastructural findings seen in advanced stages of iMGN were found (Fig. 1). IgG size nanoparticles accumulated in lucidity areas of the lamina rara interna and lamina densa of the GBM in npnt knockout zebrafish models.

Conclusions: Podocyte NPNT is important for proper GFB function and GBM structure and is regulated by GEC-derived miR-192-5p and podocyte-derived miR-378a-3p. We hypothesize that loss of NPNT in the GFB is part of the pathophysiology of iMGN and enables subepithelial immune complex deposition in iMGN.

Identification of the Mechanism Underlying the Toxicity of Systemically Administered miR-145-5p on Podocytes Based on Podocyte Essential Genes
Zhang Sipan, Junnan Wu, Xiaodong Zhu, Hui Song, Lu Ren, Qiaoli Tang, Xu Xiaodong, Jiogs Zhang, Weixin Hu, Zhigong Liu, Shulan Shi. Jinling Hospital, Nanjing National Clinical Research Center for Kidney Diseases, Nanjing, China.

Background: MicroRNAs are emerging as effective therapeutic agents. MiR-145-5p dysregulation has been shown to be involved in kidney injury. To determine whether supplement of miR-145-5p would alleviate kidney injury in mouse models, we first tested the miR-145-5p enriched extracellular vesicles (miR-145-5p EVs) sample for toxicity or side effects on healthy control mice.

Methods: miR-145-5p EVs were injected to mice intravenously every day for a total of 6 days. A group of mice were simultaneously injected with miR-145-5p inhibitor using TransIT-EE Delivery Solution. Cultured cells were transfected with RNAiMAX or Fugene.

Results: miR-145-5p EVs resulted in proteinuria and podocyte foot process effacement in normal control mice, and this effect was abolished by miR-145-5p inhibitor. We demonstrated that systemically administered miRNA can enter podocytes. miR-145-5p EVs could enter cultured podocytes and cause F-actin loss. MiR-145-5p mimics caused a similar reduction of F-actin in the cells. We speculated that miR-145-5p is toxic to podocytes because it is not normally expressed in podocytes and exogenous miR-145-5p can effectively target genes essential for podocytes. By using the concept that genes commonly expressed in all individual podocytes are likely podocyte essential genes, we predicted podocyte genes when a p-value of 0.05 and fold change of 2 were used as the cutoff. We found that 32 of them are predicted to be targeted by miR-145-5p. Functional annotation of the 32 genes revealed small GTPase mediated signal transduction as the top function. Among genes associated with the small GTPase pathway, Arhgap24 is known to negatively regulate Rac1 and Cdc42 activities, and we found miR-145-5p significantly repressed Arhgap24 expression in podocytes in vivo and vitro. miR-145-5p increased activity of both Rac1 and Cdc42.

Conclusions: MiR-145-5p induced podocyte injury through targeting podocyte essential genes associated with small GTPase mediated pathway. Our study provides a novel approach to investigate how a miRNA affects a given cell type, allowing not only identification of the molecular mechanism underlying a observed side effect of a miRNA drug but also prediction of miRNA drug toxicity on various cell types.

Glomerular miRNAs Are Alternatively Spliced and Polyadenylated During Podocyte Injury in Animal Models of Nephrotic Syndrome
Claire Burton, Amy Webb, Rachel Cianciolo, Claire L. Moore, Shepa Agraval, Abigail Wexor Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH; Tufts University School of Medicine, Boston, MA.

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS), with high proteinuria, is characterized by podocyte loss and injury. Furthermore, alternative mRNA processing, such as alternative splicing (AS) and alternative polyadenylation (APA) play important roles in physiology, development, and disease; however, there is very limited knowledge on their roles in glomerular disease. We hypothesized that AS and APA events of glomerular RNAs is associated with podocyte injury and proteinuria in NS.

Methods: Glomerular damage characterized by proteinuria was induced by puromycin aminonucleoside (PAN) or adriamycin (ADR) to mimic human minimal glomerular injury and proteinuria in NS. APA and AS events of glomerular RNAs are associated with podocyte injury and proteinuria in NS. We performed miRNA microarray analysis of PAN and ADR induced NS models and normal control. Results were validated by qPCR. Correlation of differentially expressed genes (DEGs) and miRNAs were performed using DAVID database.

Results: Roughly proteinuria was induced in both PAN-MCD and ADR-FSGS models, accompanied by hypobalbuminemia, hypercholesterolemia and histological alterations in the kidneys (protein casts and podocyte hypertrophy). Out of 13,265 genes, MCD model resulted in 1033 and FSGS model in 1308 glomerular DEGs with abs(log2FC)>1. The GO enrichment analysis revealed increased transcription of genes involved extracellular matrix and extracellular space in both models. Pan-cancer analysis revealed increased expression of genes involved extracellular matrix and extracellular space in both models. Differentially expressed genes were enriched in biologic process of extracellular matrix, body wall morphogenesis and extracellular space. We identified 25 miRNAs with increased expression in both models. The common miRNAs included miR-145-5p, miR-21, miR-24, miR-125b, and miR-155. Among those, miR-145-5p was increased in both models, and it was significantly associated with proteinuria in NS.

Conclusions: Global miRNA alterations and their downstream effects on proteinuria in NS. Future studies should focus on the mechanisms underlying miR-145-5p expression and its potential role in podocyte injury and proteinuria in NS.

PO1708
Continuous Non-Mutagenic DNA Damage in Podocytes Activates Inflammatory Response and May Accelerate Kidney Aging
Ran Nakamichi, Akihito Hishikawa, Kaoi Hayashi, Hiroshi Itoh. Keio University School of Medicine, Department of Internal Medicine, Tokyo, Japan.

Background: Podocytes are suggested to contribute to kidney aging because of their terminal differentiated features. We have previously reported the association of KAT5-mediated DNA damage repair with altered DNA methylation in podocytes (Cell Rep 2019). However, the role of podocyte DNA damage itself on DNA methylation changes and kidney aging has remained to be adequately elucidated.

Methods: To investigate the significance of DNA double-strand breaks (DSBs) in podocytes, we generated podocyte-specific I-Ppol knockout mice (podocin-Cre ROSA26-STOP-1-I-Ppol). I-Ppol is a homing endonuclease which causes non-mutagenic DSBRNA-seq and MedIP-seq analysis were performed using isolated podocytes in I-Ppol mice and wildtype controls.

Results: I-Ppol mice showed severe albuminuria (WT 43±3.4 mg/gcr, I-Ppol 2224±7.3 mg/gcr, p<0.01) with diffuse foot process effacement in podocytes but glomerulosclerosis and interstitial fibrosis were not observed at 12 weeks of age. Interestingly, infiltration of CD11b-positive cells was shown in I-Ppol podocytes, which is a similar finding in 2-year-old aged mice. The aged mice showed increased DNA damage and DNA methylation. In I-Ppol mice, rapid deterioration of renal function with glomerulosclerosis and tubulointerstitial fibrosis developed around the age of 20 weeks. RNA-seq analysis revealed that inflammatory-related genes were upregulated in podocytes of I-Ppol mice. Senescent-associated secretory phenotype (SASP)-related gene expression was also increased. MedIP-seq analysis revealed that 5129 differentially methylated regions (DMRs) were identified in I-Ppol mice compared with controls. Interestingly, there was no significant correlation between the distance from the I-Ppol cutting site and DMRs. DNA methylation was increased in genes containing I-Ppol cutting sites or podocyte epithelial genes such as nephrin and podocin, whereas it was decreased in inflammatory related genes, suggesting gene-specific DNA methylation changes following DNA damage.

Conclusions: The phenotype of the I-Ppol mice may reflect one aspect of accelerated kidney aging. Repeated DNA damage repair in podocytes may cause altered DNA methylation independent of primary DNA damaged sites with promoted inflammation and podocyte morphological changes.

PO1709
Deletion of MCP-1 in Podocytes Does Not Protect Against Glomerular Injury
Corry D. Bondi, Britney M. Rush, Roderick J. Tan. University of Pittsburgh Department of Medicine, Pittsburgh, PA.

Background: Over the past three decades, the global burden of chronic kidney disease (CKD) has nearly doubled straining healthcare budgets. Understanding the role of podocytes in the pathophysiology of proteinuric disease is important for development of novel treatments. Prior studies implicate monocyte chemotactrant protein-1 (MCP-1) in podocyte injury, but the source of MCP-1 has not been definitely identified. Both MCP-1 and its cognate receptor, CCR2, are expressed in podocytes. Therefore, using podocyte-specific MCP-1 knockout mice (PODO-MCP-1−/−), we evaluated whether acute MCP-1 signaling by podocytes contributes to proteinuric CKD.

Methods: PODO-MCP-1−/− mice were generated by crossing MCP-1 floxed mice with mice harboring Cre recombinase under the control of the podomin promoter. Knockout mice and wild-type littermates were subjected to angiotensin II by osmotic minipumps (Ang II; 1.5mg/kg/day) for 28 days. Weekly spot urines were collected, assessed with ELISA for albuminuria, and results normalized to urinary creatinine. After 28 days, kidneys were harvested and histologic, immunofluorescent, immunoblot, and quantitative PCR analyses were performed. Results are reported as mean ± S.E.M. Threshold for significance was P<0.05.

Results: There were no baseline differences in bodyweight, histology, and urinary albumin levels between the two groups. Following 28 days of Ang II infusion, histologic analysis revealed renal pathology particularly glomerulosclerosis. There were no significant differences in bodyweight, albuminuria, renal function, expression of nephrin and WT1, and number of podocytes. Ccr2 gene expression also revealed no significant difference.

Conclusions: Our results demonstrate that podocyte-specific MCP-1 production is not a major contributor to Ang II-induced glomerular injury as demonstrated by lack of protection in the podocyte-specific MCP-1 knockout mouse. Future studies will evaluate other sources of MCP-1 that may impact disease.

Delayed Treatment with a Novel Highly Selective Small-Molecule Agonist of MC5R Attenuates Podocyte Injury and Proteinuria in Purmorpham Aminonucleoside Nephropathy

Bohan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. University of Toledo College of Medicine and Life Sciences, Toledo, OH.

Background: Clinical studies indicate that the melanocortin peptide ACTH is effective in inducing remission of nephrotic glomerulopathies like MCD and FSGS, even those resistant to steroids, suggesting that a steroid-independent melanocortinergic mechanism might contribute. However, the type of melanocortin receptor (MCR) that conveys this beneficial effect as well as the underlying mechanisms remains controversial. Recently, burgeoning evidence suggests that MC5R is likely involved in glomerular pathobiology. This study aims to test the effectiveness of a novel highly selective MC5R agonist (MC5RA) in purmorpham aminonucleoside (PAN) nephropathy.

Methods: MC5RA was generated by N-terminal modification of the melanocortin core tetrapeptide His-D-Phe-Arg-Trp-NH2 with an aromatic group, resulting in a triphenylpropyl-nicotinamide analog with a 100-fold selective agonistic activity on MC5R. Rats were injured with a tail vein injection of PAN, and 5 days later, were randomized to daily MC5R or vehicle treatment.

Results: Upon PAN injury, rats developed heavy proteinuria on day 5, entailing an established nephrotic glomerulopathy. Following vehicle treatment, proteinuria continued to progress on day 14 and was sustained till day 21, accompanied by evident histologic signs of podocyte injury, marked by ultrastructural lesions of glomeruli, including extensive effacement of podocyte foot processes and podocyte microvillus transformation, and concomitant with loss of podocyte homeostatic markers, such as synaptopodin and nephrin, and de novo expression of podocyte injury marker desmin. Rescue treatment with MC5R significantly attenuated urine albumin excretion and mitigated the loss of podocyte marker proteins, resulting in improved podocyte ultrastructural changes.

In vitro cultured podocytes, MC5RA prevented the PAN-induced disruption of actin cytoskeleton integrity and apoptosis. Mechanistically, MC5RA treatment reinstated inhibitory phosphorylation and thus averted hyperactivity of GSK3β, a critical point of multiple podopathogenic pathways, in PAN-injured podocytes in vitro and in vivo.

Conclusions: Pharmacologic targeting of MC5R by using the highly selective small-molecule agonist is likely a promising and feasible therapeutic strategy to improve proteinuria and podocyte injury in glomerular disease.

PO1711

Tadalafil, a PDE5 inhibitor, Exhibits Renoprotective Effects Preventing Podocyte Damage in an Adriamycin-Induced Nephrotic Syndrome Model

Natsumi Tomita,1 Yuji Hotta,1 Aya Naiki-Ito,2 Tomoya Kataoka,3 Satoru Takahashi,2 Kazunori Kimura.1 1Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; 2Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; 3Department of Clinical Pharmacuetics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

Background: Phosphodiesterase (PDE)-5 inhibitor is reportedly a renoprotective compound. Although PDE5 expression is confirmed in the glomeruli, its relationship with podocyte injury remains elusive. We have previously investigated the renoprotective effects of tadalafil in a C KD model (Tomita N, et al. Physiol Rep. 2020), suggesting that such an effect would be related to podocyte damage attenuation. In this study, we investigated how tadalafil, a PDE5 inhibitor, could affect a rat nephrotic syndrome model.

Methods: Wistar ST rats were established as nephrotic syndrome models by administrating adriamycin (ADR) injection. The animals were divided into 3 groups: control (n = 6), ADR (n = 5), and ADR + tadalafil (n = 5). Tadalafil was administrated 10 mg/kg daily. After 2 weeks of treatment, the urinary protein and serum albumin levels were evaluated, and the kidney tissue was harvested. WT1-positive cells were identified as podocytes by WT1 immunostaining. Moreover, human renal glomerular epithelial cell damage was induced in vitro by ADR supplementation. After 24 h of ADR treatment with or without tadalafil, cell viability was determined using CCK-8.

Results: The ADR injection induced high urinary protein and low serum albumin levels. Two weeks of tadalafil treatment attenuated proteinuria compared to the ADR group (P < 0.01). ADR reduced the WT1-positive cell number and the tadalafil treatment prevented the reduction (P < 0.05). Moreover, the ADR treatment resulted in reduced cell viability in vitro. The tadalafil treatment improved cell viability compared to the ADR treatment only (P < 0.05).

Conclusions: This study suggests that the treatment with tadalafil, a PDE5 inhibitor, could effectively prevent podocyte damage in the case of nephrotic syndrome.

PO1712

Targeting mTOR Signaling Improved Kidney Function in APOL1 Risk Variant Mice with Chronic Exposure to Inflammatory Stimuli

Shrijal Shah, Calum Tattersfield, David Demeritt, Olivia Donovan, Lena B. Schaller, Gизelle McCarthy, Martin R. Pollak, David J. Friedman. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Inheriting two copies of APOL1 risk variants significantly increases the likelihood of developing chronic kidney disease in African Americans. Many different mechanisms of disease have been proposed using cell-based model systems. Here we try to understand risk variant pathophysiology using a transgenic mouse model.

Methods: Transgenic mice with a single copy of human APOL1 G0 and G2 were generated using bacterial artificial chromosome (BAC) on a FVB background. Mice were injected with interferon gamma (IFN-γ) plasmid via hydrodynamic tail vein injections to induce APOL1 expression. Since mTOR activation has been frequently observed in podocytes during FSGS, we blocked the pathway using rapamycin to see if it could improve disease outcomes. Mice were injected with 2mg/kg of rapamycin every other day (3 days/week, intraperitoneal) for a total of 2 weeks. Paraffin embedded tissue sections were used for immunohistochemistry and Periodic acid–Schiff (PAS) staining. Glomerular isolated sections were performed using Dynabeads. APOL1 oligomerization was assessed using blue native PAGE.

Results: 7 Days after IFN-γ plasmid injection, the podocytes of G2 mice stained positive for phospho-S6 ribosomal protein indicating mTOR activation accompanied by proteinuria. Blocking mTOR activation using rapamycin reversed ribosomal protein S6 phosphorylation, reduced proteinuria, and improved tissue histology as seen by PAS staining. We hypothesized that rapamycin might be activating autophagy and clearing APOL1 oligomers, but found no evidence for this mechanism of rescue. Instead, we were able to replicate the rescue we had observed with rapamycin using a cell cycle inhibitor, suggesting that rapamycin might be rescuing G2 phenotype by inhibiting podocyte cell cycle entry downregulating risk variant mediated injury.

Conclusions: Persistent expression of APOL1 risk variants pushes podocytes into cell cycle entry. Inhibiting mTOR signaling and subsequent cell cycle entry alleviated injury.

PO1713

Plin5 Deficiency in Podocyte Negatively Affects the Communication Between Lipid Droplets and Mitochondria in Alport Syndrome

Jin Ju Kim,1 Sydney S. Wilbon,2 Judith T. Molina David,1 Hazel H. Sze,2 Jeffrey H. Miner,2 Flavia Fontanesi,1 Sandra M. Merscher,2 Alessia Forgeti,3 1University of Miami School of Medicine, Miami, FL; 2Washington University in St Louis, St Louis, MO; 3Social Profit Network, Melno Park, CA. “The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid droplets (LD) and triglyceride (TG) accumulation in experimental AS (Col4a3Ko mice). Excessive FFA catabolism resulting from excessive lipolysis of TG is a major contributor to cell lipotoxicity. Perilipin 5 (PLIN5) is an LD-related protein that plays a critical role in regulating TG lipase activity and the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FFA. Here we test the hypothesis that PLIN5 deficiency results in podocytes and that PLIN5 deficiency in AS causes the increase in LD to mitochondrial contact, leading to mitochondrial dysfunction and contributing to disease progression.

Methods: In vitro, Immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3Ko mice (Jackson Laboratory) to B6D2F1 transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in AS podocytes and kidney cortex in AS mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM analysis.

Results: PLIN5 deficiency was observed in the kidney cortex of Col4a3Ko mice when compared to controls (p < 0.001). We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes (p < 0.01). AS podocytes also showed significantly increased rates of TG lipolysis (p < 0.05), intracellular free fatty acids (p < 0.05) and apoptosis (p < 0.01) when compared to WT podocytes. AS podocytes had reduced number of LD-mitochondrial contacts (P < 0.05), implying that and apoptosis. Moreover, Etzelmüller, which restored LD-Mitochondrial contact in vitro (P < 0.05), improved podocyte viability in vivo, was found to restore PLIN5 expression in vitro and in vivo (P < 0.05).

Conclusions: Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria, leading to mitochondrial dysfunction and contributing to disease progression.
PO1714

UCP2 Regulates Mitochondrial Dynamics and Podocyte Injury by OMA1-Dependent Proteolytic Processing of OPA1
Qianqian Yang, Lingling Xu, Yang Zhou, Lei Jiang, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Podocyte injury and loss are pivotal events in the progression of glomerular diseases, such as diabetic kidney disease (DKD) and focal segmental glomerulosclerosis (FGS5). Disordered mitochondrial dynamics leads to mitochondrial dysfunction, which is extensively involved in podocyte injury. The mitochondrial inner membrane uncoupling protein, UCP2, is involved in the regulation of mitochondrial dynamics, but the specific mechanism is unknown.

Methods: The function and structure of podocyte were detected by electron microscopy, immunofluorescence, and primary cell culture. We found that the pharmacological inhibition of UCP2 expression in podocytes correlated with proteinuria level in mice. In podocytes-specific Ucp2 deficiency developed podocytopathy with proteinuria with aging. Furthermore, those mice exhibited increased proteinuria in experimental models evoked by diabetes or adriamycin. Our findings suggest that UCP2 mediates mitochondrial dysfunction by regulating mitochondrial dynamic balance. Ucp2 deleted podocyte exhibited increased mitochondrial fission and deficient in ATP production. Mechanistically, opacity protein 1 (OPA1), a key protein in fusion of mitochondrial inner membrane, was regulated by UCP2. Ucp2 deficiency promoted proteolysis of OPA1 by activation OMA1 which belongs to mitochondrial inner membrane zinc metalloprotease. Those finding demonstrate the role of UCP2 in mitochondrial dynamics in podocyte and provide new insights into pathogenesis associated with podocyte injury and proteinuria.

Conclusions: Our findings suggest that UCP2 protects mitochondrial dynamics balance by OMA1-dependent proteolytic processing of OPA1.

L-WNK1 Inhibition Protects from Glomerular Injury in Mice
Cyril Mousseaux,1,2 Tiffany Migeon,1,2 Perrine Frére,1,2 Liliane Louédec,1,2 Pierre Galichon,1,2 Juliette Hadchouel,1,2 CoRoKID - Inserm UMR_S1155, Paris, France; Sorbonne Université, Paris, France.

Background: The With No lysine (K) kinase L-WNK1 plays a key role in the maintenance of cellular homeostasis in response to variations in osmolarity, intracellular chloride concentration or cell volume. We have shown that L-WNK1 activation in the distal nephron results in hypertension. Other studies showed that the pharmacological inhibition of L-WNK1 activity by WNK463 resulted in an increased autophagic flux and a decreased migration/proliferation in a wound-healing assay.

Methods: Our hypotheses were the stimulation of autophagy, a decreased capacity for proliferation and differentiation, a decreased mitophagy and an increased matrix remodeling. We have shown that mice carrying an ubiquitous and heterozygous (L-WNK1+/-) of podocyte-specific homozygous inactivation of L-WNK1 (NPHS2::L-WNK1+/-) mice was improved compared to control ones. We observed a decreased infiltration of macrophages and a lesser stimulation of the expression of fibrotic genes. The same improvement of renal function, associated with a reduced number of glomerular lesions, was observed in NPHS2::L-WNK1+/- mice during NTS-CCG. To uncover the underlying mechanisms, we used the immortalised A98 cell line of human podocytes, our hypothesis were the stimulation of autophagy, a decreased capacity for proliferation and migration and a reduced stimulation of the TRPC6 calcium channel. We have shown that the pharmacological inhibition of L-WNK1 activity by WNK463 resulted in an increased autophagic flux and a decreased migration/proliferation in a wound-healing assay.

Conclusions: In conclusion L-WNK1 inhibition represents a new target for the protection of the podocytes during CGN.

Protective Role of the Epithelial STAT5 Pathway in Kidney Injury
Aïssata Niasse,1 Kevin Louis,2 Laurent Mesnard,3 Juliette Hadchouel,2 You Su Luque,2 Inserm UMR_S1155 team, Paris, France; INSERM, Paris, France; Assistance Publique - Hôpitaux de Paris, Paris, France; Sorbonne Université, Paris, France.

Background: During kidney diseases, diverse tissue-specific pathways can regulate kidney injury and prognosis. Thus, therapeutic targeting of these pathways could improve the management and prognosis of chronic kidney diseases. The Janus Kinase/ Signal Transducer and Activator of Transcription (JAK/STAT) pathway, classically described in immune cells, has been recently described in intrinsic kidney cells.

Methods: We 1) analyzed STAT5 activation in kidney biopsies from patients with focal segmental glomerulosclerosis (FSGS) and acute tubular injury (ATI), 2) used experimental models of glomerular and tubular injury in mice with podocyto- or tubulopathy-induced STAT5 deficiency, 3) studied transcriptomic modifications related to STAT5 deletion in human kidney epithelial cells, 4) explored interleukin-15 mediated STAT5 activation in podocytes and glomerular injury.

Results: Here, we show, for the first time, that STAT5 is activated in both human podocytes (Figure 1A) and tubular cells in FSGS and ATI, respectively. Additionally, STAT5 deficiency in either glomerular or tubular epithelium aggravates the functional and structural alterations in a range of experimental models of glomerular (Figure 1B) or tubular disease. STAT5 deficiency in kidney epithelial cells resulted in dysregulation of multiple metabolic pathways, including glycolysis and oxidative phosphorylation (Figure 1C). Interleukin 15 (IL-15), a classical activator of STAT5 in immune cells, increases STAT5 phosphorylation in human podocytes and alleviates glomerular injury in vivo (Figure 1D) by activating anti-apoptotic pathways.

Conclusions: In conclusion, activating renal epithelial STAT5 represents a new therapeutic avenue with the potential for a range of beneficial effects in kidney diseases.

A. STAT5B activation in human podocytes in FSGS. B. STAT5 podocyte deficiency aggravates adriamycin-induced proteinuria. C. CRISPR-Cas9 induced deletion of STAT5B from human kidney epithelial cells leads to disruption of metabolic pathways. D. IL-15 alleviates adriamycin-induced glomerular injury in mice

PO1717

Shiga Toxin Targets the Podocyte in Haemolytic Uraemic Syndrome (HUS) Resulting in Glomerular Endothelial Cell Complement Dysregulation
Emily E. Bowen, Jenny Hurcombe, Lindsay S. Keir, Fern Barrington, Louise K. Farmer, Abigail C. Lay, Gavin I. Welsh, Eva Larkai, Moin Saleem, Richard Coward. Bristol Renal University of Bristol Faculty of Health Sciences, Bristol, United Kingdom.

Background: Haemolytic uraemic syndrome (HUS) is a thrombotic microangiopathy (TMA) that has a predilection to present in the kidney. It is a triad of microangiopathic haemolytic anaemia, thrombocytopenia, and acute kidney injury. In 90% of cases, HUS follows gastroenteritis secondary to infection with Shiga toxin (Stx) producing bacteria such as Escherichia coli. Stx HUS is the leading cause of acute kidney injury in children with a mortality of 5%. However, the precise pathophysiological mechanisms following Stx infection leading to TMA remain poorly understood. Here we show that the podocyte is a key initiator in Shiga toxin HUS, which could explain why the glomerulus is the prime target of systemic Shiga toxin driven infection.

Methods: To demonstrate that the podocyte Shiga toxin receptor (Gb3) is sufficient to trigger the development of HUS, we used conditional gene targeting to engineer human Gb3 expression specifically in the podocytes of adult mice.

Results: Following intraperitoneal Shiga toxin challenge, these mice developed thrombocytopenia, haemolytic anaemia and uraemia (Figure 1) with evidence of glomerular TMA on histology. Interrogation of this model revealed evidence of glomerular and tubular disease. STAT5 deficiency in kidney epithelial cells resulted in dysregulation of multiple metabolic pathways, including glycolysis and oxidative phosphorylation (Figure 1C). Interleukin 15 (IL-15), a classical activator of STAT5 in immune cells, increases STAT5 phosphorylation in human podocytes and alleviates glomerular injury in vivo (Figure 1D) by activating anti-apoptotic pathways.

Conclusions: Together, these observations provide compelling evidence for the importance of podocyte-glomerular endothelial cell cross-talk within the kidney in the development of Shiga toxin associated HUS and suggest a possible therapeutic role for complement inhibition in patients with this devastating disease.

Nephronectin Expression Is Controlled by the Non-Canonical TGF-β Pathway in Podocytes

**Background:** Within the glomerulus, podocytes, glomerular endothelial cells (GEC) and the glomerular basement membrane (GBM) build the glomerular filtration barrier. Extracellular matrix (ECM) of the GBM is mainly composed of proteins synthesized by GECs and podocytes. Our interest focuses on nephronectin (NPNT), an ECM protein mainly produced by podocytes. Recently, it has been described that NPNT expression patterns vary in different glomerular diseases. For example, in focal segmental glomerulosclerosis (FSGS) and membranous glomerulonephropathy (MGN) NPNT expression was decreased compared to healthy controls, while it was increased in diabetic nephropathy (DN). In addition, transforming growth factor beta (TGFβ) is able to down-regulate NPNT on both mRNA and protein level. Our aim is to further analyze this TGFβ-mediated regulation of NPNT in human podocytes.

**Methods:** Immortalized human podocytes were differentiated for 10 to 12 days at 37°C and pre-incubated with inhibitors for components of the canonical and the non-canonical TGFβ-signaling pathway with subsequent culture in the presence or absence of TGFβ. We used cell culture supernatants for ELISA, as well as cell lysates for qPCR and western blot analyses.

**Results:** While treating differentiated immortalized human podocytes with TGFβ decreased NPNT on both mRNA and protein level, we observed that inhibition of single components of the TGFβ pathway did not alter NPNT mRNA expression and excretion. On protein level, we noted no change after blockade of either Smad2 or Smad3 under baseline conditions. However, TGFβ was still able to decrease NPNT expression when canonical pathway components were inhibited, suggesting a minor role for this pathway in NPNT regulation via TGFβ. If single components of the non-canonical pathway were blocked, we observed an increase in NPNT protein expression, which was not further altered by TGFβ addition.

**Conclusions:** Taken together, our data suggest that in podocytes NPNT expression is fine-tuned via the non-canonical TGFβ pathway with additional regulation on the post-translational level.

**PO1719**

Podocyte Damage in Chimeric Kidney Organoids

**Background:** We previously found that when a portion of podocytes are injured, other podocytes are secondarily injured in a mouse model, which may underlie the relentless progression of chronic renal failure. In the present study, we tested whether this phenomenon is observed in kidney organoids.

**Methods:** Nephrin progenitor cells (NPCs) were established by culture-dependent purification (CDP) method from 12.5 dpc NEP25 and RiboTag mouse kidneys (Cell Stem Cell, 2016, 19, S16-29). Podocytes of NEP25 mice express hCD25 and can be injured by hCD25-targeted immunotoxin, LMB2. Podocytes of RiboTag mice express hemagglutinin (HA)-tagged ribosomal protein. Kidney organoids were generated by transient stimulation with FGF2 and CHIR99021 of NPC aggregates and subsequent 8-day culture. On day 8, LMB2 (20 nm) was added to induce injury in hCD25+ podocytes.

**Results:** We confirmed that podocytes in both organoids are stained for nephrin, podocin and WT1. Podocytes derived from NEP25 NPC expressed hCD25 and were injured by LMB2, and those from RiboTag NPC expressed HA and were resistant to LMB2. When two types of NPCs were mixed at 1:1 ratio, organoids showed a chimeric pattern containing hCD25+ and HA+ podocytes (Fig1). 2 days after LMB2 treatment, hCD25 staining completely disappeared accompanied by cleaved (c) lamin A staining, a cell death marker. HA staining was retained, but WT1 was diminished and podocin disappeared (Fig 2). Occasionally, c-lamin A was positive in HA+ cells. RNA of Ribotag podocytes can be obtained by immunoprecipitation with anti-hemagglutinin (HA) antibody. qPCR revealed that Nphs1 (0.31), Nphs2 (0.04), Wt1 (0.37) were decreased to the indicated fold by LMB2 and that Gadd45b was increased to 4.82-fold.

**Conclusions:** Thus, podocyte damage damages podocytes in kidney organoids that lack glomerular filtration.

**Funding:** Government Support - Non-U.S.

**PO1720**

Increased Old Astrocyte Specifically Induced Substance (OASIS) in Podocytes Leads to the Progression of Nephrotic Syndrome

**Methods:** To assess the relevance of OASIS to renal pathology, the expression of OASIS in glomeruli of lipopolysaccharide (LPS)-treated mice or streptozotocin (STZ)-treated diabetic mice was examined by laser capture microdissection, followed by immunoblotting. To further investigate the functional roles of OASIS in podocytes, podocyte-restricted OASIS overexpressing transgenic (OASIS TG) mice were established.

**Results:** Increased OASIS was observed in podocytes in murine kidneys. However, the pathophysiological roles of OASIS in podocytes remain unclear. The aim of this study is to elucidate the role of OASIS in podocytes. Thus, we assessed the effect of OASIS to renal pathology. The expression of OASIS in glomeruli of lipopolysaccharide (LPS)-treated mice or streptozotocin (STZ)-treated diabetic mice was examined by laser capture microdissection, followed by immunoblotting.

**Conclusions:** Old astrocyte specifically induced substance (OASIS) is a transcription factor of the CREB/ATF family. Previously, we found that OASIS was expressed in podocytes, and the glomerular filtration barrier. The increased OASIS in podocytes contributes to nephrotic progression.
PO1721
Podocyte-Derived RARRES1 Aggravates Kidney Disease Progression by Inducing Both Glomerular and Tubular Injury
Ye Feng,1 Bi-Cheng Liu,1 Kyung Lee,1 John C. He.1 Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; 1Southeast University Zhongda Hospital, Nanjing, China.

Background: Our previous study demonstrates that the expression of retinoic acid receptor responder protein 1 (RARRES1) increases in glomeruli of patients with diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS). The glomerular expression of RARRES1 also correlates with eGFR slope and predicts glomerular disease progression. Single-cell RNA-sequencing of the kidney showed that RARRES1 is expressed mostly in podocytes within the kidney. Mechanistically, WT-RARRES1 is cleaved into a soluble form which subsequently induces podocyte apoptosis whereas mutant RARRES1 with cleavage defect failed to induce podocyte apoptosis in vitro. Here, we further determined whether increased expression of WT-RARRES1 in the podocytes aggravated progression of glomerular disease.

Methods: Mice with podocyte-specific overexpression of human WT- RARRES1 or mutant RARRES1 with cleavage defect were generated and then subjected to aging, adriamycin (ADR) administration or streptozotocin (STZ) injection. To identify the role of podocyte-derived soluble RARRES1 in tubular cells, HK2 cells were treated with soluble RARRES1 obtained from podocyte supernatants.

Results: In vivo, podocyte-specific overexpression of WT-RARRES1 resulted in severe proteinuria and marked glomerular injury in mice with aging, adriamycin-induced nephropathy, or STZ-induced diabetic nephropathy as compared to the control mice with overexpression of mutant RARRES1. Interestingly, tubular vacuolation and interstitial injury were also observed in these mice with podocyte-specific overexpression of RARRES1. In addition, we showed that soluble RARRES1 collected from podocyte supernatants was endocytosed in HK2 cells to induce cellular injury. Similarly, cleaved form of human RARRES1 in the mice with podocyte-specific human RARRES1 overexpression was found in the tubular compartments, indicating that soluble RARRES1 generated from podocytes may act on tubular cells through glomeruli-tubule crosstalk.

Conclusions: Our study suggests that RARRES1 is a risk gene for glomerular disease progression through its direct effects in podocytes as well as indirect effects in tubular cells probably via glomeruli to tubules crosstalk.

PO1722
Podocyte-Specific Extracellular Vesicles Yield Novel Insight into Intercellular Signaling in the Glomerulus

Background: Extracellular vesicles (EVs) have been identified to play an essential role in basic pathological processes such as priming of the metastatic niche, autoimmunity and propagation of insulin resistance. Nevertheless, knowledge about their role in kidney health and disease remains scarce. A new group of EVs, shed upon apoptosis with the ability to induce a proliferative effect in neighboring cells, was recently identified in cell culture models as well as experimental glomerulonephritis. This study aimed to characterize these medium-sized EVs and the signaling propagated by them in podocyte damage.

Methods: Using differential centrifugation and filtration we established a protocol to separate medium-sized EVs from cell culture supernatants, kidney tissue and urine samples. Using transmission electron microscopy and image flow cytometry, we investigated the release dynamics of podocyte-specific vesicles in different models of murine podocyte damage in vitro and in vivo. Furthermore, cross culture experiments and life microscopy were used to determine the effect of podocyte-specific medium-sized EVs on parietal epithelial cells.

Results: Podocyte-specific medium-sized EVs were detected in baseline podocyte culture supernatant, untreated murine kidney tissue as well as the urine of healthy human volunteers. Vesicle quantification revealed a drastic increase of vesicle release upon podocyte damage both in vitro and in vivo. Interestingly, podocyte-specific EVs exerted different effects on the proliferative and migratory behavior of primary parietal epithelial cells.

Conclusions: Our study represents the first investigation of podocyte-specific membrane-bound extracellular vesicles, their release dynamics and functional implications in health and disease. Ongoing analyses aim to characterize their proteomic content and effect other renal epithelial cells. As these vesicles can be separated without advanced equipment such as ultracentrifuges, we believe they could also be a valuable source for biomarker research in various nephropathies.

PO1723
Effects of Varying Mild Tubular Injury on Subsequent Glomerular Injury
Janka Babickova,1 Haichun Li,1 Agnes B. Fogo.1 Vanderbilt University Medical Center, Nashville, TN; 1Universitet i Bergen, Bergen, Norway.

Background: Tubular injury predisposes to CKD, including glomerular injury. We analyzed effects of mild tubular injury on subsequent glomerular injury.

Methods: 535 1 led to numerical increase in albuminuria after second hit glomerular injury in both sexes. The sex-dependent differences in KIM-1 and NGAL-1 further support differential susceptibility of nephron segments to injury in females vs males, which may play a role in glomerular sensitization to injury.

Funding: NIDDK Support

PO1724
Effect of Glomerular Disease on the Podocyte Cell Cycle
Laura Perin,1 Camille H. Nicolas Frank,2 Xiaohong Hou,2 Gemery Clair,3 Fadi E. Salem,4 Roger E. De Filippo,1 Paolo Cravedi,5 Kevin V. Lemley,5 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Harvard Medical School, Boston, MA; 3Pacific Northwest National Laboratory Biological Sciences Division, Richland, WA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Progression of glomerulosclerosis is associated with loss of podocytes and subsequent glomerular tuft instability. A decreased number of podocytes may be able to preserve tuft stability through cell hypertrophy associated with cell cycle re-entry. At the same time, re-entry into the cell cycle can lead to podocyte detachment from the glomerular basement membrane, if podocytes cross the G1/S checkpoint and undergo abortive cytokinesis.

Methods: To study cell cycle dynamics during CKD development, we used a Fucci mouse model (fluorescence ubiquitination-based cell cycle indicator) affected by X-linked Alport Syndrome (AS). This model has progressive CKD and expresses cell cycle fluorescent reporters exclusively in podocytes. We quantified podocytes cell cycle distribution in WT and AS mice at different ages and collected podocytes in G0 and G1 for proteomics studies.

Results: We showed that with the development of CKD, an increasing fraction of podocytes in vivo are in G1 or later cell cycle stages. G1 and G2 podocytes are hypertrophic. Heterozygous female mice, with milder manifestations of CKD, show G1 fraction numbers intermediate between WT and male AS mice. Proteinomic analysis showed differences in cytoskeleton re-organization and metabolic processes between podocytes in G0 and G1 in different sex and WT and indicate alteration of specific proteins also identified in human AS podocytes.

Conclusions: Our data showed that, during progressive CKD, the podocyte cell cycle distribution changes dramatically, suggesting that cell cycle manipulation may have a role in the pathogenesis of progressive glomerular diseases characterized by podocyte dysregulation.

PO1725
Glucocorticoid- and Piglitazone-Induced Proteinuria Reduction Correlates with Glomerular Extracellular Matrix Remodeling in Experimental Nephritic Syndrome
Sagar Bhayana, Shipra Agrawal, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Peter White, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephritic Syndrome (NS) is a common glomerular disease in children. While glucocorticoids (GC) are the mainstay of childhood NS treatment, piglitazone (Pio; an FDA-approved PPAR agonist to treat type 2 diabetes) has been reported to reduce proteinuria in experimental NS and to directly protect podocytes from injury. Since both GC and Pio activate nuclear receptors (NRC31 and PPARG, respectively) we hypothesized that their proteinuria-reducing effects result from overlapping glomerular gene transcriptional patterns.

Methods: We performed transcriptional analyses on glomeruli isolated from GC (immunosuppressive)- and Pio (non-immunosuppressive)-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Unsupervised clustering revealed partial reversibility of PAN-associated mRNAs dynamics by treatment with either GC or Pio. IPA analyses + web-based bioinformatic platforms identified 29 genes-of-interest common to GC- and Pio-induced proteinuria reduction, which included ECM remodeling, lipid metabolism, DNA-binding and cytoskeletal organization. Based on expression differences using real-time PCR,

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUBL - Publication Only Underline represents presenting author.

535
29 genes-of-interest were selected for further analysis, which on clinical correlation with the Signaling Pathway Impact (SPI) database suggests a direct relevance of glomerular
ECM regulation in NS. Also, glomerular cell deconvolution using published single-
cell glomerular transcriptome profiles identified podocyte- and mesangial cell-specific
perturbations in gene expression during NS and with treatments. Finally, validation of
selected genes-of-interest using PAN-induced injury of human podocytes and mesangial
cells confirmed significant upregulation of LGALS1 (primary role in cell adhesion) and
MMP2/ACTA2 (primary role in ECM degradation/cell motility or integrity) respectively.

Conclusions: These studies identified podocyte- and mesangial cell-specific
transcripts common to both proteinuria-reducing treatments that identify possible targets
for future treatment for NS.

PO1726
Alteration of Intestinal Microbiota in Patients with ESRD Undergoing
Hemodialysis
Takeo Koshida,1 Tomohito Gohda,1 Takuya Sugimoto,2 Takashi Asahara,2
Massorhi Ishizaka,1 Maki Murakoshi,1 Yusuke Suzuki,1 1Department of
Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Yakult
Central Institute, Yakult Honsha Co. Ltd, Tokyo, Japan.

Background: The alteration in the intestinal microbiota is reported to be associated
with various diseases, indicating that the development and progression of end-stage
kidney disease also might be associated with dysbiosis.

Methods: The stool samples were collected from patients with hemodialysis (n = 41,
HD group) and those with normal renal function (n = 40, NRF group). Both groups
are comprised of patients with (HD:DM, n = 20; NRF:DM, n = 19) and without diabetes
(HD:non-DM, n = 21; NRF:non-DM, n = 21). We conducted 16S RNA gene amplicon
sequencing using stool samples to analyze the intestinal microbiota.

Results: The reduced abundance of the genera Megamonas and Fusobacterium, and
the enriched abundance of the genera Family_XIII_AD3011_group (Anaerovoraccaea
family), UBA_1819 (Ruminococcaceae family), and Pseudomonas in the stool samples of
HD patients were observed significantly compared with those of NRF patients. Compared
with patients with NRF DM, the relative abundance of the genera Megamonas was
decreased and that of Family_XIII_AD3011_group was increased significantly in patients
with HD DM, although those relative abundance did not differ between NRF_non-DM and
HD_non-DM. The relative abundance of the genera Succrellaceae in HD_non-DM was
significantly decreased than that in NRF_non-DM, although that relative abundance did
not differ between NRF_DM and HD_DM. In the microbial beta diversity, there was no
difference between NRF_DM and NRF_non-DM by weighted and unweighted Unifrac
analysis, however, there was significant difference between HD_DM and HD_non-DM by
weighted Unifrac analysis (p = 0.007). These results suggest that the gut microbiota
alters with renal function decline, and varies depending on the presence or absence of
diabetes.

Conclusions: The intestinal microbiota might be varied substantially depending on
renal function and the presence or absence of diabetes.

PO1727
Nutritional Intervention in Intensive Care Unit Patients Undergoing
CRRT
Jihyun Yang, Tae-bum Kim, Hyeon-Jin Min, Young-Bin Son, Jonghyun Lee,
Sewon Oh, Myung-Gyu Kim, Won-Yong Cho, Sang-Kyung Jo. Korea
University Anam Hospital, Seoul, Republic of Korea.

Background: Providing adequate calories and protein constitutes an important
part of critical care, and inadequate nutrition for critically ill patients is associated
with poor prognosis. Therefore, increased loss of amino acids, electrolytes, and water-soluble
vitamins during continuous renal replacement therapy (CRRT) could be a therapeutic
target. We evaluated whether enforcing protein, trace elements and vitamin supply
could improve the prognosis of CRRT patients.

Methods: A nutritional intervention (100 mg/day of Thiamine, 25–30 kcal/kg of
energy, 1.8 g/kg of protein, and 50–100 mcg/day of microelement with selenium) was
conducted in patients subject to CRRT from May 2020 to December 2020. The primary
outcomes were 28-day mortality, CRRT day, ICU stay, and ventilator-free day, and the
outcomes before and after the intervention were compared.

Results: Total 88 patients were included during the study period and compared with
88 patients in the previous year. The average age was 68.05 years old, 56 (63.5%) patients
were male. At day 1 APACHE-II score was 35.45±9.2, SAPS3 88.1±6.9 versus 6.3
±2.7.

Conclusions: This study suggests that support for protein, trace elements, and vitamins may have a positive effect in CRRT patients. Therefore, the nutritional
requirements of patients with CRRT should be carefully assessed, individualized, and
considered as an important axis of CRRT treatment.

PO1728
Nutritional Phenotypes and Variation in Nutritional Parameter
Trajectories Among Non-Dialysis CKD (CKD-ND) Patients Prescribed
Oral Nutritional Supplements
Michelle M. Wong,1,2 Yuyan Zheng,1 Dani Renouf,1 Adeera Levin,1,2 1The
University of British Columbia, Vancouver, BC, Canada; 2BC Provincial
Renal Agency, Vancouver, BC, Canada; 3 Providence Health Care, Vancouver,
BC, Canada.

Background: Among CKD-ND patients at risk of undernutrition/protein-energy
wasting, the definition of patient subgroups most likely to benefit from ONS treatment
is not known. Therefore, our aims were to identify phenotypes of non-dialysis CKD patients
prescribed ONS, and to assess nutritional parameter slopes before and after ONS use, by
phenotype.

Methods: This longitudinal cohort study included 2543 adult CKD-ND patients who
entered multidisciplinary CKD clinics across British Columbia during 2010–2019, met
weight and/or dietary intake criteria for ONS prescription based on dietitian assessment,
received ≥ 21 ONS prescriptions. Hierarchical cluster analysis was used to identify
phenotypes using baseline nutritional parameters. Using linear mixed models, slopes
for body mass index (BMI), serum albumin, bicarbonate, phosphate, and neutrophil-to-
lymphocyte ratio (NLR), an inflammation marker, were assessed in the 2-year periods
before and after the first ONS prescription.

Results: Cluster analysis identified five nutritional phenotypes. Changes in parameter
slopes (A_slope = post-ONS slope - pre-ONS slope) varied by cluster (Figure). Cluster
1 (characterized by the highest mean NLR and the lowest mean BMI among clusters)
demonstrated statistically significant positive Aslopes for BMI, albumin and bicarbonate,
and a negative Aslope for NLR. Cluster 2 (hypoalbuminemia) demonstrated positive
Aslopes for BMI, albumin, and phosphate. Cluster 3 (low mean BMI) demonstrated a
positive Aslope for BMI, accompanied by negative Aslopes for albumin and bicarbonate,
and a positive Aslope for NLR. Cluster 4 (acidosis) demonstrated positive Aslopes for
BMI and bicarbonate. In Cluster 5 (highest BMI), a negative Aslope for albumin and
a positive Aslope for NLR were observed (no improvement with ONS).

Conclusions: The variation in response to ONS by cluster subgroup lends support to
an individualized approach to nutritional management of patients at risk of undernutrition/ protein-energy wasting.

Association of Muscle Mass and Protein Intake with Risk of ESKD in
Patients with CKD
Atif Ibrahim,1 Neerachaa Mettipalli,1 Waleed Hassan,1 Yoshitsugu Obi,1
Mahmoud M. Mohamed,1 Keitchi Sumida,1 Miklos Z. Molnar,2 Barry M. Wall,1,3 Csaba P. Kovacs,1,2 1The University of Tennessee
Health Science Center, Memphis, TN; 2University of Utah Health, Salt Lake City, UT; 3VA Memphis Medical Center, Memphis, TN.

Background: Better nutritional status is favorably associated with clinical outcomes,
but high protein intake may have deleterious effects on kidney function by virtue of
mechanisms unrelated to nutritional status. We hypothesized that dietary protein intake
and muscle mass (two markers of nutritional status) have opposite associations with
progression of CKD when examined together.

Methods: We examined a cohort of 702 US veterans with stage 3-5 CKD followed
at a single institution. We used spot urea nitrogen (UUN) and urine creatinine (UC) and
adjusted for urine specific gravity as surrogates of dietary protein intake and muscle mass,
respectively. We examined the concomitant association of UUN and UC with ESKD using
multivariable adjusted competing-risks regression with adjustment for demographic
characteristics, comorbidities, eGFR, proteinuria, smoking status, and body mass index.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Poster 536
Results: Patients were 68±10 years old, 96% were male, 60% were African American and their baseline eGFR was 32±13 mL/min/1.73 m². There were 178 ESKD events (event rate, 72.8/1000 PY; 95% CI, 62.8-84.4) over a median follow-up of 3.5 years. In a multivariable adjusted model including both nutritional markers, higher UUN was associated with a higher risk of ESKD (subhazard ratio [SHR] and 95% CI associated with a higher risk of ESKD in patients with stage 3-5 CKD. While observational in nature, these results suggest that renoprotection with dietary protein restriction should be pursued with close attention to maintaining optimal nutritional status.

Conclusions: Higher protein intake is associated with higher risk of ESKD, while higher muscle mass is associated with a lower risk of ESKD in patients with stage 3-5 CKD. However, the extent to which IDPN contributes to improve protein-energy status remains unclear.

Methods: Maintenance HD patients having spontaneous energy and protein intake of ≥29 kcal/kg/day and ≥0.8 g/kg/day, respectively, and intolerance to ONS were randomly assigned 1:1 to receive IDPN or intensive dietary counselling. In group 3, 3-in-1, anti-inflammatory omega 3-rich parenteral nutrition was infused during HD for 3 months followed by a treatment-free period of 3 months. The control group received an individualized dietary counselling once a week for 3 months to target the required nutrient intake. The outcomes were changes in serum albumin, muscle parameters and nutritional biomarkers. Serious adverse events were also monitored.

Results: A total of 38 patients were completed the study (age 67±11). Baseline characteristics were not different between groups. After 3 months, serum albumin was significantly higher in the IDPN group (n=18) compared with the control group (from 3.5±0.3 to 3.8±0.2 g/dL; p=0.01, respectively). The infusion volume was 14.2±3.9 mL/kg/HD session. Total energy and protein intake (p=0.04), weight (p=0.01), subclinical global assessment (p=0.03), and malnutrition inflammation score (p=0.01) were significantly improved in the IDPN group, but not in control group (all p>0.05). Among non-diabetic patients, IDPN significantly reduced serum IL-6 as an inflammatory marker (p=0.03) but unaffected serum acylated ghrelin as an orexigenic hormone (p=0.31). Muscle mass, strength, and serum prealbumin were not different between both groups. Participants in the IDPN group reverted to baseline albumin levels after 3-month post-intervention follow-up. Neither volume overload nor uncontrolled hyperglycemia was found throughout the study.

Conclusions: A short-term IDPN supplementation significantly increased serum albumin level, a survival surrogate among HD patients. The impact of IDPN therapy on clinical outcomes may require larger scale with longer period of study.

PO1732

Long-Term Safety of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Serum Electrolytes and Albumin

PO1733

Patient-Reported Experience with Tenapanor in the OPTIMIZE Trial

Results: When interviewed, 85.1% of patients in Cohort 1 and 83.5% of patients in Cohort 2 reported an improved perception of their sP management routine. Overall, 89.1% of patients in Cohort 1 and 86.5% of patients in Cohort 2 reported an improved perception of their sP management routine. One patient in Cohort 1 withdrew from the study due to an adverse event.

Conclusions: Tenapanor was generally well tolerated, with diarrhea being the only adverse event reported by >5% of patients. Diarrhea was typically mild to moderate in severity, was transient, and resolved with continued treatment. Data from all 3 trials showed that tenapanor treatment, either alone or in combination with phosphate binders, resulted in no clinically meaningful changes in measured serum electrolytes or albumin at any time point. Data from patients treated with tenapanor continuously for 52 weeks in the longest trial, PHREEDOM, are shown in the table.

In these clinical trials, tenapanor inhibited paracellular absorption of phosphate and decreased serum phosphorus with an acceptable safety profile, with no observed effect on serum electrolytes or albumin in patients on maintenance dialysis with hyperphosphatemia.

Apparent Paradoxical Relations of Serum Phosphate and Albumin Variability with Outcomes Are Explained by the Directional Change
Xiaoling Ye,1 Karlien J. ter Meulen,2 Len A. Usyan,2 Jeroen Kooman,4 Peter Kotanko,1,3 Frankwil W. Maddux,3 1Fresenius Medical Care North America; 2Fresenius Medical Care North America, Waltham, MA; 3Mount Sinai Hospital; 4Maastricht University Medical Centre, Maastricht, Netherlands.

Background: Evidence indicates that variability of serum phosphate (P) and albumin (Alb) is associated with higher risk of mortality. We aimed to study the variability of P and Alb with all-cause mortality taking into account the interaction with the averaged levels.

Methods: All adult incident HD patients (pts) treated in Fresenius Medical Care NA clinics between 2010&2018 were included. Serum P and Alb levels were averaged from month(mo) 1 to 6 after HD initiation. Variability of P and Alb were described by standard deviation(SD) and directional changes(DR).

Results: All-cause mortality was recorded between mo 7 and 18. Cox proportional hazards models with spline terms were applied to explore the association between variability of P & Alb and all-cause mortality. Additionally, tensor product smoothing splines were computed to study the effect of interactions between averaged values of parameters and their variability with outcomes.

Conclusions: The relationship between P variability and mortality was apparent at all levels of P. In pts with higher level of variability, but lower in those with lower averaged P. Contrastingly, in pts with low Alb, higher variability was associated with reduced mortality. Reduced variability of Alb, an unidirectional relation between DR and outcome was observed, whereas the relation between DR with outcomes was bidirectional for P (Fig 1&2).

PO1736

Understanding Obesity Management in CKD Patients

Background: Obesity is a global epidemic that is directly and indirectly linked to progression of chronic kidney disease (CKD). Nephrologists’ attitude towards obesity management is not understood.

Methods: We surveyed 14 nephrologists practicing in an academic centre in London, Ontario, Canada to investigate their perception and management of obesity. Then we performed a retrospective chart review of patients in a CKD clinic with obesity (BMI >30kg/m²). Ten follow-up visits were randomly selected for each nephrologist between Jan-Dec 2019. Each chart was assessed for documentation of obesity and a management plan such as lifestyle counselling, pharmacologic intervention, or specialist referral.

Results: There were 13 responses (93%). Responses from a 5-point Likert scale, agree and strongly agree, have been combined. All nephrologists agreed that obesity negatively impacts CKD patients. 92% reported that discussing obesity evokes a negative response and 39% thought patients want to discuss obesity. Interestingly, 0% of nephrologists thought patients know that obesity has effective treatments. 85% of nephrologists talked to their patients about obesity, but 0% felt that they had time to treat it. With regards to management, 54% of nephrologists were comfortable with non-pharmacologic treatment, but only one was comfortable with pharmacologic treatments. 85% of respondents felt that patients should be referred to a specialist. A total of 140 charts were reviewed with a mean age 66 years, weight 105 kg, and BMI 37 kg/m². Only one chart had obesity as a clinical issue and documented a weight loss discussion using non-pharmacologic strategies.

Conclusions: Our results suggest that obesity is rarely managed despite nephrologists’ desire to treat it. This care gap can be addressed using robust Quality Improvement principles. Our centre will improve obesity management by developing a clinical handbook for nephrologists on how to efficiently address obesity with patients as well as a partnership and streamlined referral process to an obesity specialist.

PO1733

Restrict Dietary Phosphorus to Decrease Proteinuria and Prevent Decline in Glomerular Filtration Rate in CKD Stages 1 and 2
Anita Saxena. Renal Nutrition Group Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: Though dietary phosphorus restriction is therapeutic for disordered phosphorus homeostasis, restriction of dietary phosphorus is not advised in CKD. Aim: Does early control of dietary phosphorus ameliorates proteinuria, prevent decline in glomerular filtration rate and prevent rise in FGF-23.

Methods: One year longitudinal study on 79 CKD stages 1 and 2 patients. eGFR, serum creatinine, phosphorus, calcium, FGF-23, soluble o-Klotho iPTH FGF 23, blood pressure, were evaluated and compared with 35 controls. 3 days dietary intake was taken using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake: Group 1 (n=42): normal phosphorous intake (>1000mg/day) and Group 2 (n=37): high phosphorous intake (>1000mg/d). Patients in Group 2 were educated on high and low phosphorus foods and counselled to adopt a plant-based diet, for low phosphorus absorption with directed diet plan. Data were analysed using SPSS.

Results: At baseline there was no significant difference in the GFR (group 1 85.87 ± 13.67 vs. Group 2 82.38 ± 13.60 mL/min/1.73m²) or serum creatinine between groups. In group 1, GFR, sKlotho, serum phosphorus and FGF23 correlated significantly with dietary phosphorus intake. In group 2, FGF-23, serum phosphorus, dietary protein and phosphorus intake were significantly higher and sKlotho was significantly lower than group 1. There was significant difference in serum phosphorus (p 0.000), iPTH (p 0.004), FGF23 (p 0.000), Klotho (p 0.000), urinary protein (p 0.000), dietary protein (Group 1 37.57±3.40; Group 2 48.79±5.86 p 0.000) and phosphorus (Group 186.96±69.99 mg/d and Group 2 1312.26±137.57 mg/d p 0.000) intake and dietary phosphorus to protein ratio (p 0.000) between groups 1 and 2. On dietary intervention in group 2 GFR increased p 0.012 from 80.93±15.34 to 84.11±15.38; and to 87.43±18.27 mL/min at 6 and 12 months respectively. Urinary protein declined to 22.0±13.39 mg/L. FGF 23 declined from 60.67±6.26 to 58.09±7.07 to 53.29±9.48 pg/mL at 12 months. Dietary phosphorus: protein ratio reduced significantly from 27.16±4.33 to 24.75±4.34 p 0.000 at 12 months (p<0.000). Urinary phosphorus excretion increased from 574.37±214.22 to 624.64±137.67 at 12 months.

Conclusions: Restricting dietary phosphorus in stages 1 and 2 can prevent progression of CKD and for control proteinuria.

PO1737

Changes over Time in DASH Diet Accordance by Racial/Ethnic Groups Among Us Adults
Tamubhree Banerjee,1 Charles E. McCulloch,2 Deidra C. Crews,2 Nilka Rios Burrows,2 Alain Koyama,3 Hal Morgenstern,2 Rajiv Saran,4 Neil R. Powe,5 1University of California San Francisco, San Francisco, CA; 2Johns Hopkins University, Baltimore, MD; 3Centers for Disease Control and Prevention, Atlanta, GA; 4University of Michigan, Ann Arbor, MI.

Background: Recommendations for healthy dietary patterns may vary for individuals with and without CKD. Racial/ethnic disparities in dietary quality exist, yet there is limited understanding of how dietary patterns have changed over years in different racial/ethnic groups. We examined trends in accordance to a Dietary Approaches to Stop Hypertension (DASH) diet by different racial/ethnic groups in adults with and without CKD.
Methods: We used data from the 2003-2018 NHANES to estimate the prevalence of DASH diet adherence among individuals aged ≥20 years with CKD (ACrA≥30mg/dl or eGFR 15-59ml/min) and no CKD by racial/ethnic group. Self-reported race/ethnicity was categorized as non-Hispanic White (NHW), non-Hispanic Black (NHB), Mexican American (MA), or other. Change in diet composition over 16 years was assessed with a DASH diet agreement score with the years collapsed into 2003-06, 2007-10, 2011-14, 2015-18. We calculated the score based on 9 target nutrients by coding each as 1 for present and 0 for not present and summing to a total score of 9. Lowest tertile of the score was considered poor adherence. Prevalence rates were estimated for racial/ethnic groups after age-standardizing to the 2010 US Census data. Time trends in age-adjusted DASH diet prevalence were assessed using logistic regression with time interval as a predictor.

Results: Overall, the prevalence of poor adherence to a DASH diet was 13.5% and 17.5% in adults with CKD and no-CKD. Throughout the period, the age-adjusted prevalence of poor adherence was higher in NHB with CKD (prevalence did not change significantly, Figure) than in NHW with no-CKD. For MA, a significant change in prevalence was noted among no-CKD (ptrend=0.008), but not in those with CKD.

Conclusions: Poor adherence to a DASH diet was greater in adults with no-CKD. However, prevalence of poor adherence did not change in NHB and MA with CKD. Efforts to further improve promotion and adherence to DASH diets may help address CKD progression and health disparities in this population.

PO1738

Experiences of Participants of a Dietary Intervention Trial for African Americans with Hypertension and CKD

Background: African Americans are disproportionately affected by hypertension (HTN) and CKD and evidence suggests dietary modifications towards a more Dietary Approaches to Stop Hypertension (DASH)-accordant diet could improve outcomes for this population. We aimed to explicate barriers and facilitators of healthy eating, and the perceived benefits of the intervention among completed participants of a dietary intervention trial for African Americans with HTN and CKD. Participants were randomized to one of two groups: 1) Self-Shopping DASH (S-DASH) diet group with $30/wk grocery allowance for 4 mo. but no specific guidance on purchases, followed by no food allowance for 8 mo.; or 2) Coaching DASH (C-DASH) diet advice group with a $30/wk food allowance and assistance in purchasing foods for 4 mo., followed by intermittent coaching without food allowance for 8 mo.

Methods: We performed a content analysis of transcripts from semi-structured interviews with participants who completed the trial (13 C-DASH; 12 S-DASH were randomly selected). Thematic analyses followed 5 stages: 1) reading and rereading all transcripts and utilizing audio recordings as needed for clarity; 2) three coders reading two of the same transcripts, coding them, and comparing codes which were then used to create the initial coding framework; 3) defining codes, coding additional transcripts, discussing/ revising the coding framework; 4) formulating initial themes and 5) diagramming relationships among initial themes and merge overlapping themes.

Results: Participants were a mean age of 62 ± 9.3 years, 36% were male. Key themes included healthy diet facilitators (food tracking, motivation, social support, and perception of healthy foods); barriers (transportation, past eating habits, stress and COVID mitigation); and impact of the trial on knowledge and perception of healthy foods.

Conclusions: Participants of a dietary intervention trial for African Americans with HTN and CKD identified several facilitators and barriers to healthy eating that could inform future efforts to address disease burden in this population.

PO1740

Barriers and Facilitators to DASH Diet Adherence Among Black Adults with CKD: A Qualitative Study
Crystal C. Tyson,1 Laura P. Svetkey,1 Isa Granados,1 Danielle L. Kennedy,1 Travia K. Dunbar,1 Pao-Hwa Lin,2 Gary G. Bennett,2 Cynthia H. Redd,1 L. Ebony Boulware,3 Laura J. Fish,3 Duke University School of Medicine, Durham, NC; 2Duke University, Durham, NC; 3Duke Cancer Institute, Durham, NC.

Background: Black individuals are disproportionately burdened by hypertension and chronic kidney disease (CKD). The Dietary Approaches to Stop Hypertension diet (DASH) improves hypertension in Black individuals and is associated with improved CKD outcomes. Yet, adherence to DASH among Black individuals is low. We conducted a qualitative study to assess barriers and facilitators to DASH adherence in Black adults with CKD.

Methods: We conducted focus groups and individual interviews with Black adults with CKD stages 3 or 4 (n=22). Questions included perceptions of DASH and DASH, the cultural-centeredness of DASH, and barriers and facilitators to adopting DASH. Qualitative content analysis was used to analyze interview transcripts.

Results: Among 22 participants (2 focus groups, 8 individual interviews), 13 (59%) had CKD stage 3, 13 (59%) were female, the median age was 61 years, and 19 (90%) had hypertension. Some participants reported having previously heard of DASH, which they perceived as a healthy diet. Participants perceived DASH as culturally-compatible based on 3 emergent themes: 1) Blacks individuals already eat DASH-recommended foods (“Blacks eat pretty much like this”), 2) traditional (e.g., southern or soul-food) recipes can be modified into healthy versions (“you can come up with decent substitutes to make food … the other good”), and 3) diet is not uniform among Black individuals (“I can’t say that I eat traditional”). Barriers included unfamiliarity or inequity measuring portion sizes, inadequate cooking skills, unsupportive household members, and high cost of healthy foods. Eleven (52%) reported “rarely” or “never” having leftover money to purchase healthy food.

Funding: Other NIH Support - NHLBI; NIMHD
purchase healthy food after paying monthly bills. Facilitators included having local access to healthy food, living alone or with supportive household members, and having will power and internal/external motivation for change.

**Conclusions:** Black adults with CKD were interested in adopting DASH and viewed it as a healthy, culturally-compatible diet. Recognizing that diet in Black adults is not traditional, professionals should emphasize person-centered, rather than culture-centered, approaches that minimize barriers and enhance facilitators to adherence.

**Funding:** Other NIH Support - NHLBI

**POI1741**

**Priorities for Person-Centered Obesity Management in ESKD**

**Background:** Although obesity is a pervasive kidney transplant barrier, little is known about the social, dietary, and process-of-care challenges to addressing obesity among individuals with ESKD.

**Methods:** Using purposive sampling we recruited adults with ESKD and obesity (N=40) and ESKD health care professionals (HCPs, N=20) in the United States for semi-structured interviews to elicit perspectives about obesity and barriers and strategies for healthy weight loss. Recorded phone interviews lasting 1.5 hours were transcribed verbatim and analyzed using inductive and deductive thematic analysis.

**Results:** Median patient age was 55 (interquartile range [IQR] 47,63) years, median dialysis exposure was 5 (IQR 3,10) years, 51% were female, 27% were Black, and median BMI was 37.8 (IQR 33.5, 40.8) kg/m². HCPs were renal dietitians, nephrologists, and transplant surgeons. Five themes emerged from patient interviews: 1) obesity-related counseling typically limited to immediate goal (transplant BMI requirements); 2) obesity as a life-long disease or linked to trauma; 3) food choices driven by fatigue and poor sleep quality; 4) existing nutrition programs not transferable to ESKD; 5) absence of culturally-effective nutrition counseling. HCP interviews revealed uncertainty about provider roles and responsibilities for addressing obesity and underscored that poverty and low health literacy are barriers to healthy weight loss.

**Conclusions:** Obesity-related care for people with ESKD is often limited to addressing BMI limits for transplant. Weight loss interventions for people with ESKD and obesity should be tailored with knowledge of social and financial context and a shift in focus from short-term goals to long-term health.

**Funding:** NIDDK Support

**POI1742**

**Association of Nutritional Data and Glycemic Variability in CKD Patients**

Nandakishor Kapa, Harshanna Badhesha, Tae Youn Kim, Olivia A. Moss, Cherno R. Vargas, Seung M. Jin, Henning Langer, Usman Rehman, Jennifer E. Norman, Armin Ahmadi, Thomas Jue, Maryam Afkarian, Baback Roshanravan. University of California Davis Medical Center, Sacramento, CA.

**Background:** Insulin resistance is highly prevalent in chronic kidney disease (CKD) and strongly associated with adverse clinical outcomes. Glycemic variability measured by continuous glucose monitoring (CGM) is a clinical measure of insulin resistance. The association of dietary recalls and healthy eating measures with CGM readings in CKD are unknown.

**Methods:** We recruited diabetic (n=7) and non-diabetic (n=8) participants with eGFR<60ml/min who had CGM performed over 2 weeks. The ASA24 Dietary Assessment Tool was used to perform dietary recalls on 3 random days over the CGM period. The Healthy Eating Index 2015 (HEI-2015) was used to determine how closely an individual’s eating pattern matched Dietary Guidelines for Americans’ recommendations. A linear mixed model adjusting for diabetes status was used to determine association of dietary measures from ASA24, HEI-2015 scores, and CGM readings over 3 days.

**POI1743**

**Late Stage 3 CKD Is an Independent Risk Factor for Sarcopenia, but Not Proteinuria**

Yong Soon Choi, Jung Nam An, Jwa-kyung Kim, Sung gyun Kim, Young rim Song. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

**Background:** Most epidemiologic studies assessing the relationship between chronic kidney disease (CKD) and sarcopenia have been performed in dialysis patients. This study aimed to evaluate the relationship between estimated glomerular filtration rate (eGFR), proteinuria, and sarcopenia in patients with non-dialysis-dependent CKD.

**Methods:** A total of 892 outpatients who did not show any rapid changes in renal function were enrolled in this observational cohort study. We measured the muscle mass using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

**Results:** Sarcopenia was found in 28.1% of the patients and its prevalence decreased as body mass index (BMI) increased; however, in patients with BMI ≥ 23 kg/m², the prevalence did not increase with BMI. As eGFR decreased, the lean tissue index and HGS significantly decreased. However, the eGFR did not affect the fat tissue index. The risk of sarcopenia increased approximately 1.6 times in patients with eGFR < 45 ml/min/1.73 m². However, proteinuria was not associated with sarcopenia. With a decrease in eGFR, the lean muscle mass and muscle strength decreased, and the prevalence of sarcopenia increased.

**Conclusions:** In patients with late stage 3 CKD, further assessment of body composition and screening for sarcopenia may be needed.

**POI1744**

**Association of Serum Selenium Levels with the Response to Erythropoiesis-Stimulating Agents in Maintenance Hemodialysis Patients**

**Background:** Reduced response to erythropoiesis-stimulating agent (ESA) has been shown to be associated with poor outcomes in maintenance hemodialysis (MHD) patients. Selenium is a trace element that modulates diverse physiological processes, such as immune responses and cardiovascular function. Previous studies also indicate that selenium and selenoproteins are involved in erythropoiesis. However, its role in the control of anemia in chronic kidney disease patients remains unclear. In this study, we determined serum selenium levels in MHD patients and analyzed their association with hemoglobin levels and the doses of ESA.
Methods: The study included 174 patients who received MHD from four dialysis facilities. We obtained data on demographics, laboratory, comorbidities, hemodialysis prescription and medication by medical record abstraction. Concentration of selenium was measured in serum using ICP-MS.

Results: The mean age was 67.2 years, 77% were male, and 44% of patients received dialysis at least for five years. The average serum selenium concentrations in our cohort were 10.7 ± 2.9 µg/dL, and 88 patients (51%) had a selenium levels of less than 10.5 µg/dL (a lower limit of normal serum selenium levels for adult Japanese population). Patient characteristics, including age, sex, BMI, dialysis vintage, and comorbidities were not significantly different between the low selenium (Low) group and normal selenium (Normal) group. However, the percentage of patients receiving ESA tended to be higher in Low group than in Normal group, whereas hemoglobin levels as well as percentage of patients receiving iron therapy were similar between the groups. In a subgroup analysis involving 146 patients who received ESA, we found a significant negative correlation between serum selenium levels and ESA-resistance index (ERI) (r = -0.25, p = 0.002).

Conclusions: Our study indicates that low levels of serum selenium are associated with poor response to ESA. The relationship between selenium and response to ESA in MHD patients merits further evaluation in larger populations.

PO1746

Irisin production decreases during the course of chronic kidney disease (CKD) as a potential consequence of sarcopenia and physical inactivity.

Methods: This observational study explored the relationship of serum irisin with cardiovascular outcome in 79 patients with stage 3-5 CKD.

Results: Serum irisin was significantly higher in healthy subjects (n=20) than CKD patients (7.2 vs 3.1±0.9 µg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)2D levels (21.2±2.8 pg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)2D levels (21.2±2.8 pg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the highest serum irisin tertile had a higher cardiovascular risk than patients in the middle tertile (B 1.61, OR 5, 95%CI 1.09-22.83; p=0.038).

Conclusions: These findings suggest that serum irisin may be a marker of cardiovascular outcome in CKD patients.

PO1745

Serum Irisin and Prediction of Cardiovascular Events in Elderly Patients with CKD Stage 3-5

Teresa Del Mastro, Teresa Arcidiacono, Monica Avino, Arianna Bologna, Nadia Edvige Foligno, Federico Persico, Giuseppe Vezzoli. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Irisin is a circulating myokine released from skeletal muscles after physical exercise. Irisin production decreases during the course of chronic kidney disease (CKD) as a potential consequence of sarcopenia and physical inactivity.

Methods: This observational study explored the relationship of serum irisin with cardiovascular outcome in 79 patients with stage 3-5 CKD.

Results: Serum irisin was significantly higher in healthy subjects (n=20) than CKD patients (7.2 vs 3.1±0.9 µg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)2D levels (21.2±2.8 pg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)2D levels (21.2±2.8 pg/mL; p=0.0001) and was higher in patients with CKD stage 3 (3.2±1 µg/mL) compared with patients at stage 4 and 5 taken together (n=36, 2.6±0.7 µg/mL; p=0.05). Patients in the highest serum irisin tertile had a higher cardiovascular risk than patients in the middle tertile (B 1.61, OR 5, 95%CI 1.09-22.83; p=0.038).

Conclusions: These findings suggest that serum irisin may be a marker of cardiovascular outcome in CKD patients.

Image 1
All-cause mortality among the general US adult population. In addition, we evaluated the relationship between fluid intake and sarcopenia among people with various degrees of CKD.

Methods: We conducted a prospective cohort study using 1999 to 2015 data from the National Health and Nutrition Examination Survey. A total of 39,039 patients aged over 19 years who had water consumption data using 24-hour dietary recall were enrolled. Participants’ hydration status was measured by bioelectrical impedance analysis (BIA). The all-cause mortality were calculated using the multivariable Cox model adjusting for comorbidities, body mass index, glomerular filtration rate, serum albumin, and total cholesterol representing nutritional status.

Results: In weighted multivariable models, a 1 L increase in water intake was associated with significantly lower risks of all-cause (HR = 0.87, 95% CI = 0.82-0.92) and CVD mortality (HR = 0.86, 95% CI = 0.79-0.93) with a non-linear relationship (p = 0.03). There was no significant association between water intake and cardiovascular mortality (HR = 0.98, 95% CI = 0.85-1.13).

Conclusions: In the general population, too little water intake is associated with increased mortality. It is important to maintain adequate hydration status through adequate water consumption.

PO1750
Serum Cystatin C-to-Creatinine Ratio Is a Potential Biomarker for Sarcopenia in Patients with Non-Dialysis-Dependent CKD
Illeen Cho, Yong Seon Choi, Jung Nam An, Sung gyun Kim, Young rim Song
Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea

Background: Sarcopenia is a prevalent complication in patients with chronic kidney disease (CKD) and linked with quality of life, morbidity and mortality. Sarcopenia is defined as clinical, functional and body compositional parameters, although several candidate biomarkers for this condition have been evaluated. This study aimed to evaluate serum cystatin C to creatinine (Ccr) as a potential biomarker for sarcopenia in patients with non-dialysis dependent CKD.

Methods: A total of 517 outpatients were enrolled in this observational cohort study. We measured the muscle mass (lean tissue index, LTI) using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was observed in 25.5% patients. The serum cystatin C/Cr ratio was significantly higher in patients with sarcopenia regardless of age, sex, eGFR, and BMI; and showed a positive correlation with age and pulse pressure, but LTI, HGS, hemoglobin, and serum albumin level showed a negative correlation with serum cystatin C/Cr ratio. Especially in patients with eGFR ≥ 45 mL/min/1.73 m² serum cystatin C/Cr ratio showed high negative predictive value in predicting sarcopenia (90.5%) and low LTI (90.4%). As the serum cystatin C/Cr ratio increased by 1, the prevalence risk of sarcopenia and low LTI increased by about 5.8 times and about 9.9 times even after adjusting for sex, age, BMI, underlying disease, albumin, HB, and eGFR. The association between serum cystatin C/Cr ratio and sarcopenia was maximized in patients with eGFR less than 30, resulting in an increased prevalence risk of about 22.7 times, and in the case of low LTI, an independent association was found in patients with eGFR less than 45, and among them, a 43.9-fold increase in risk was identified. However, there was also no significant result for low HGS.

Conclusions: Serum cystatin C/Cr ratio is inexpensive and easily, quickly, and repeatedly measured; therefore, quick screening and management of sarcopenia will be possible, which will be of great help in the treatment of CKD patients.

PO1751
Prevalence of Inflammation and Associated Healthcare Resource Utilization in Patients with CKD
Rachel Lai,1 Lynda Szczecz,1 Sarah Clayton,2 Lewis Harrison,3 Mollie Lowe,2 James Jackson.2 Fibrogen Inc, San Francisco, CA; 2Adelphi Group Ltd, Bollington, United Kingdom.

Background: Many patients with chronic kidney disease (CKD) suffer from inflammation, which often increases as CKD progresses. Inflammation is a risk factor for comorbidities and complications, such as the number of healthcare visits, hospitalizations, and tests conducted to diagnose and monitor patients. Inflammation was defined as C-reactive protein (CRP) > 5 mg/L, ferritin >700 ng/mL, or albumin ≤3.6 g/L. Fisher’s exact and t-tests were conducted to assess differences in HCRU between patients with and without inflammation.

Results: There were 227,005 patients. Slight inflammation was present in 136,491 (28%) non-dialysis-dependent, and 91,212 (43%) dialysis-dependent patients. HCRU, including the mean number of healthcare visits, tests conducted, and hospitalizations in the last 12 months, number of pills and injections taken per day, and number of requiring a carer were greater in patients with inflammation than those without (all p<0.05; Table 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

542
Conclusions: We found that inflammation was common in patients with CKD and associated with greater HCRU across multiple measures in a real-world setting. Novel treatment approaches in CKD that are effective in patients with inflammation may help to reduce HCRU.

Effects of Caloric Restriction and Aerobic Exercise on Circulating Cell-Free Mitochondrial DNA in Patients with Moderate-to-Severe CKD

Background: Understanding mechanisms for increased oxidative stress and inflammation in patients with chronic kidney disease (CKD) is vital due to their role in the pathophysiology of this population. Circulating cell-free mitochondrial DNA (ccf-mtDNA) is released to the plasma and believed to promote inflammation by acting as a damaged-associated molecular pattern. Previous studies suggested that in patients with kidney disease, ccf-mtDNA increases and may induce inflammation. Past investigations in patients with CKD have found that aerobic exercise decreases inflammation. We hypothesized that in patients with moderate to severe CKD, aerobic exercise would reduce plasma levels of ccf-mtDNA.

Methods: We performed a post hoc analysis of a multi-center pilot randomized trial of aerobic exercise and caloric restriction (NCT01105851). We measured ccf-mtDNA in plasma at baseline and two and four months after four interventions (aerobic exercise (EX), caloric restriction (CR), EX + CR, usual activity and usual diet). A multivariable model adjusted for age, race, systolic BP, BMI, diabetes, and eGFR was done.

Results: Of a cohort of 111 participants who were randomized, 99 had baseline ccf-mtDNA levels, and 92 completed the study. The median age was 57 years old, 44% were female, and 92% had diabetes. Plasma ccf-mtDNA median concentrations at baseline, two, and four months were 3.62, 3.08, 2.78 pm for the usual activity group, and 2.01, 2.20, 2.67 pm for the aerobic exercise group. There was a 16% increase per month in ccf-mtDNA in the aerobic exercise group compared to the usual activity group (p = 0.024), especially with the combination of aerobic exercise and caloric restriction (29.5% increase per month). After four months of intervention, ccf-mtDNA increased in the aerobic exercise group by 81.6% (95% confidence intervals [CI] 8.2-204.8; p = 0.024) compared to the usual activity group, but it was only observed in the aerobic exercise and caloric restriction group (181.7% increase, 95% CI 41.1-462.2; p = 0.003).

Conclusions: Our data suggest that aerobic exercise increases plasma ccf-mtDNA levels in patients with CKD stages 3-4, more profoundly in ones with a combination of caloric restriction. (0.00)

Physical Activity in Patients Undergoing Dialysis: A Pilot Study

Background: Patients on chronic dialysis have impaired physical function and poor quality of life. Slow gait speed and handgrip strength are indicators of increased all-cause mortality and cardiovascular events in dialysis patients. The relationship between physical activity and gait speed is inconsistent in prior studies. "Cadence", a gait characteristic measured as steps/minute by accelerometer is strongly associated with their gait speed.

Methods: We identified patients with diabetes who initiated SGLT2i (n=925), GLP1RA (n=250), and DPP4i (n=1050) between 2015 and 2018 in Geisinger Health System. Outcomes were percent weight change per year among all patients within 1 year after medication initiation and time to first achieving 5% weight loss among patients with obesity at medication initiation. Inverse probability of treatment weighting (IPTW) based on multipropensity scores was used to account for differences in baseline patient characteristics by medication class.

Results: The mean (SD) age of the 6919 patients was 58 (14) years and 3381 (49%) were female. Compared with SU, SGLT2i, GLP1RA, and DPP4i were associated with significant weight loss, with stronger associations for SGLT2i and GLP1RA (Table). Similarly, SGLT2i, GLP1RA, and DPP4i users were more likely to achieve 5% weight loss compared with SU (HR [95% CI]: 1.47 [1.28, 1.69] for SGLT2i; HR: 1.55 [1.32,1.82] for GLP1; HR: 1.31 [1.19,1.44] for DPP4). The associations were consistent across CKD stages.

Conclusions: In patients with and without CKD, SGLT2i and GLP1RA were associated with significant weight loss compared with SU. These results may further motivate uptake of SGLT2i and GLP1RA, two classes of medications with proven renal benefits, among patients with obesity.

Funding: NIDDK Support

Physical Activity Scores in Hemodialysis Patients with Thyroid Dysfunction: A Substudy of the NIH THYROID-HD Trial
Yuehi Otole,1,2 Richard B. Rossitter,3 Shlomit Radom-Aizik,1 Joel D. Kopple,1,3 Matthew J. Budoff,2,3 Rachelle Bross,2 Mackenzie K. Cervantes,2 Gregory Brent,1,3 Csaba P. Kovetsdy,1 Yalitzi Guereño,1 Amy S. You,1 Danh V. Nguyen,1 Kamyar Kalantar-Zadeh,1 Connie Rhee.1 1University of California Irvine, Irvine, CA; 2The Lundquist Institute, Torrance, CA; 3Harbor-UCLA Medical Center, Torrance, CA; 4University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 5VA Greater Los Angeles Healthcare System, Los Angeles, CA; 6The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: Low physical activity is common in hemodialysis (HD) patients and is associated with adverse outcomes in this population (poor health-related quality of life, cardiovascular [CV] disease, death). Prior studies show that hypothyroidism is highly prevalent in HD patients, and is associated with worse self-reported physical function.

Methods: In a substudy of the ongoing multi-center NIH THYROID-HD Trial, we examined baseline physical activity scores determined by the Human Activity Profile (HAP), a validated 94-item instrument assessing daily activities across a wide range of energy expenditures, in HD patients with TSH levels in the high-normal (TSH >3-5 mIU/L) and subclinical hypothyroid range (TSH >5-10 mIU/L). The HAP was used to derive the Maximum Activity Score (MAS) and Adjusted Activity Score (AAS), representing greatest and mean estimated energy expenditures, respectively (range 0-94, segmented to low [<52], moderate [54-73], and high [74-74] scores).

Results: Among 57 HD patients who underwent baseline HAP assessment, the mean±SD MAS and AAS scores were 52±21 and 26±27, respectively; median (IQR) MAS and AAS scores were 52 (40, 68) and 23 (6, 49), respectively. In the overall cohort, 79% had low, 14% moderate, and 7% high AAS scores. MAS scores were lower in patients who were older (≥65 yrs), female, White, Hispanic, of longer (>1 yr) vintage, diabetic, or with underlying CV disease. A similar trend was observed for AAS scores.

Conclusions: In this substudy of the NIH THYROID-HD Trial, HAP scores in HD patients with high-normal and subclinical hypothyroid range TSH levels were lower than observed in prior historical dialysis cohorts that did not have underlying thyroid dysfunction. Further research is needed to determine the impact of thyroid hormone replacement on improving physical activity and function in this population.

In Vivo Muscle Mitochondrial Function Is Associated with Exercise Capacity and Efficiency in CKD
Chenou R. Vargas,1 Gwenaelle Begue,1 Usman Rehman,2 Armin Ahmadi,2 Tae Youn Kim,2 Seung M. Jin,2 Jorge Gamboa,3 Thomas Jue,4 Baback Roshanavan.1
1University of California Davis Department of Internal Medicine, Sacramento, CA; 2University of California Davis, Davis, CA; 3California State University Sacramento, Sacramento, CA; 4Vanderbilt University, Nashville, TN.

Background: CKD is associated with skeletal muscle dysfunction increasing risk for frailty. Muscle mitochondrial dysfunction may underlie impaired physical performance. The associations of in vivo muscle mitochondrial function with exercise capacity and efficiency in CKD is unknown.

Methods: We recruited 8 diabetic and 6 non-diabetic patients with CKD. Leg muscle mitochondrial oxidative capacity was measured by exercise recovery kinetics of [PCr] using 31P Magnetic Resonance Spectroscopy (31P MRS). Cardiorespiratory fitness (CRF, VO2 peak), total work, and work efficiency (total work/VO2 peak) were assessed by cycle ergometry. We tested associations of 31P MRS measures with endpoints using Pearson correlations.

Results: Participants had a mean age was 61±10yrs, eGFR of 35±12ml/min with 43% females. Faster PCr recovery rate correlated with VO2 peak (r=0.58, p=0.03), total work (r=0.70, p=0.03) and work efficiency (r=0.59, p=0.03) (Figure). Associations of PCr recovery with work and work efficiency were independent of age, sex, and weight (both p=0.03).

Conclusions: Muscle mitochondrial oxidative capacity is a major determinant of exercise efficiency and capacity. Therapeutics targeting muscle mitochondrial function in CKD may improve physical performance and CRF.

Comparisons of In-Clinic and Free-Living Measures of Physical Function in Predicting Hospitalization in Patients with CKD
Nikita Abraham,1 Robert E. Boucher,2 Guo Wei,3 Jesse Christensen,2 Sydney E. Hartse3, Judy Carle,1 Victoria Gonce,1,3 Srinivasa Beddu,2,4 Kate Lyden.1 1The University of Utah School of Medicine, Salt Lake City, UT; 2VA Salt Lake City Health Care System, Salt Lake City, UT; 3University of Massachusetts Amherst, Amherst, MA.

Background: Physical function is associated with risk of hospitalization; however, comparisons of in-clinic and free-living measures of physical function and their associations with risk of hospitalization has not been well established.

Methods: In this secondary analysis of the Sit Less, Interact, Move More (SLIMM) pilot study, we compared in clinic and free-living measures using accelerometry data. Participants with CKD were randomized to the SLIMM intervention or standard of care and asked to wear a thigh worn accelerometer 7 days before a visit to capture their physical activity. In clinic measures of physical function like 6-minute walk distance were performed during visits. Free-living measures were determined from accelerometry.

Results: 106 participants were randomized, the mean age was 69 ± 12 and 69 ± 14, baseline eGFR was 44 ± 12 and 45 ± 14, and 48% and 37% were female for the standard of care and SLIMM groups respectively. When adjusted for covariates, both in clinic and free-living 6-minute walk distance and steps respectively were associated with hospitalizations (table). In comparisons between in clinic and free-living measures, in clinic measures were not significantly associated with hospitalizations while free-living measures were (table).

Conclusions: Both in clinic and free-living measures of physical function were predictors of hospitalization in patients with CKD.

Blood Pressure Trends in a Cohort of 9- and 10-Year-Old Children in Iceland: A 10-Year Follow-Up Study
Aðísís H. Sigurdardottir,1,2 Olafur S. Indridason,1 Sigurdur S. Stephensen,2 Thorðís H. Hrafnkelsdottir,1 Vidar O. Edvardsson.1,2 1Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland; 2Children’s Medical Center, Landspítali – The National University Hospital of Iceland, Reykjavik, Iceland; 3Division of Nephrology, Landspítali – The National University Hospital of Iceland, Reykjavik, Iceland; 4Division of Cardiology, Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland.

Background: Although there is significant evidence for an association between childhood and adult office blood pressure (BP), data on the correlation of childhood BP and ambulatory BP (ABP) in young adults are missing. The aim of this study was to examine the association between childhood office BP and both ABP and office BP indices in young adults.

Methods: Subjects were recruited from a cohort of 970 young adults aged 20-21 years who participated in a population-based study of BP in 9-10-year-old Icelandic school children. All participants underwent a minimum of 4 resting BP measurements at the childhood BP screening. A total of 121 individuals have completed their participation in the follow-up study, which included office and ambulatory BP measurements. Pearson correlation and linear regression analysis were used to examine the relationship between childhood and follow-up BP.

Results: A significant positive correlation was observed between childhood mean systolic BP (SBP) and systolic and ambulatory BP at follow-up (r=0.386, p<0.001 and r=0.370, p<0.001, respectively). The correlation between mean childhood systolic office BP and follow-up mean systolic office BP was stronger for males (r=0.580, p<0.001) than for females (r=0.298, p=0.012), and the same applied for mean systolic ABP (r=0.491, p<0.001 and r=0.323, p=0.006, respectively). The correlation of mean childhood diastolic office BP and diastolic office BP with mean DBP indices at follow-up was insignificant for males (office DBP: r=0.278, p=0.05) but remained significant for females (office DBP: r=0.555, p=0.0026; ABP: r=0.449, p=0.001). In adjusted analysis, childhood mean office SBP significantly associated with mean office SBP at follow-up in both males (beta=0.69, p<0.001) and females (beta=0.26, p=0.001). Each mmHg increment in mean childhood office SBP predicted an increase of mean ambulatory SBP by 0.52 mmHg (p=0.001), unaffected by sex. Childhood DBP did not significantly predict office or ambulatory BP at follow-up in adjusted analysis.

Conclusions: These preliminary results indicate that childhood SBP significantly predicts with systolic office and ambulatory SBP in young adults and these associations are stronger in males.

PO1760
Preterm Birth and Its Association with Altered Renal Sodium Handling in Response to Mental Stress in Young Adults
Nicholas W. Tully, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Early-life programming events such as preterm birth and very low birth weight (VLBW; <1500 g) contribute to later hypertension development, but the underlying mechanisms are unknown. Experimental data suggest that altered pressure natriuresis and renal sodium handling may be important contributing mechanisms. Adults with primary hypertension exhibit blunted pressure natriuresis in response to sympathetic arousal, but this has not been described in adults born preterm. We investigated renal sodium excretion relative to the change in blood pressure (BP) in response to stress in a cohort of young adults born preterm with VLBW. We hypothesized that young adults born preterm will have a blunted pressure natriuresis response to mental stress compared to those born term with normal birth weight.

Methods: In this long-term prospective cohort of 161 individuals, 129 (80%) born preterm with VLBW and 32 (20%) term-born controls, we measured spot urine sodium/creatinine before and after a 30-min mental stress test and non-invasive continuous BP every 2 min during the stress test. We defined our outcome, pressure natriuresis, as the change in sodium excretion relative to the change in mean arterial pressure (MAP) before and after the stress test with a blunted response being ≤ 0 mg/dL per mmHg. We used generalized linear models to estimate the association between prematurity and the outcome.

Results: The mean age of study participants was 19.8 (SD 0.9) of whom 56% were females. Those born preterm had a greater change in sodium excretion relative to change in MAP was 0.022 mg/dL per mmHg [IQR -0.027, 0.121], while the change in term-born counterparts was 0.04 mg/dL per mmHg [-0.005, 0.184]. On unadjusted analyses, the preterm/term difference in pressure natriuresis was B=0.068 mg/dL per mmHg [-0.092 to 0.229] and the relative risk of blunted pressure natriuresis was 1.3 (0.71 to 2.36).

Conclusions: We observed no statistically significant difference in pressure natriuresis response in adults born preterm with VLBW when compared to those born term. Ongoing analyses include investigating other measures of pressure natriuresis in adjusted multivariable models.

Funding: NIDDK Support

PO1761
The Cardiovascular Risk Analysis According to Different Pediatric Hypertension Guidelines: Data from the Korea National Health and Nutrition Examination Survey, 2016-2018
Jeong Yeon Kim,1 Sangshin Park,2 Hyeceyo Cho.1 1Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea; 2University of Seoul, Dongdaemun-gu, Seoul, Republic of Korea.

Background: Worldwide pediatric hypertension (HTN) prevalence is increasing. Pediatric HTN predicts adulthood HTN, the modifiable leading factor of cardiovascular disease (CVD). Therefore, pediatric HTN is important for CVD risk prevention. There are two well-known pediatric HTN guidelines, the 2017 American Academy of Pediatrics (AAP) and the 2016 European Society for Hypertension (ESH). Also, Korea Center for Disease Control established the blood pressure (BP) classification in 2008 (K-CDC). There is discordance of HTN prevalence in each BP classification. However, no study evaluated the CVD risk according to each BP criteria in the Korean pediatric population. This study evaluated the difference in prevalence and pediatric CVD risk factors according to each BP criteria.

Methods: The data of 2660 children and adolescents aged 10-18 years from the Korea National Health and Nutrition Examination Survey 2016-2018 was reviewed. The BP was classified by AAP, ESH, K-CDC and modified AAP (K-AAP, applying the normal weight Korean children BP reference table in AAP definition). The high BP was defined when BP was above normotension. To analyze the difference in CVD risk, AAP and ESH, AAP and K-AAP, and K-AAP and K-CDC were compared. In each comparison, those newly defined as high BP are compared to those with consistent normotensive - age, sex, height matched. Finally, the BP criteria reflecting more CVD risk was used to analyze data from Korea School Health Examination Survey 2018.

Results: The prevalence of high BP in Korean children and adolescents was generally high in AAP than ESH (19.5% vs 10.6%, p<0.0001). However, there were some differences in prevalence according to age, sex and obesity. AAP reflected more CVD risk factors, including obesity and metabolic risk, than ESH. K-AAP well-screened obese children with metabolic risk than AAP and children with obesity and metabolic risks than K-CDC. The prevalence of high BP and HTN in Korean school students with K-AAP was 3.7% and 5.1%, respectively.

Conclusions: The K-AAP classifies Korean children and adolescent with more CVD risk factors as high BP. Therefore, for early CVD risk control, K-AAP could be used to define pediatric HTN in Korea. Further study is warranted for actual CVD association.
PO1762
Clinical Event Reductions in Hypertension Patients with and Without CKD Treated with Renal Denervation: A Model-Based Estimate Based on Data from the Global SYMPLICITY Registry

Roland E. Schmieder,1 Felix Mahfoud,2 Bryan Williams,3 Giuseppe Mancia,4 Krzysztof Narkiewicz,5 Luis M. Ruilope,6 Markus Schlaich,5 Michael Böhm,1 Jian H. Pietzsch,1 1Universitätsklinikum Erlangen, Erlangen, Germany; 2Universiteit Utrecht, Utrecht, the Netherlands; 3Hospital Universitari Germans Trias i Pujol, Badalona, Spain; 4University of Rome Tor Vergata, Rome, Italy; 5Gdanski Uniwersytet Medyczny, Gdansk, Poland; 6Facultad de Medicina, Universidad Nacional de La Plata, Argentina

Background: Estimates of clinical event reductions following renal denervation (RDN) were modelled for patients with and without chronic kidney disease (CKD) based on results from the Global SYMPLICITY Registry (GSR).

Methods: Methods: GSR (n=6263, European Union: 2617, USA: 2586, Japan: 1; 2). The end point of the analysis was 3 years. Ten different clinical parameters were identified as risk factors, including systolic blood pressure (SBP), diastolic blood pressure (DBP), age, diabetes, and smoking. Patients were divided into four groups: hypertension only (Hyp), hypertension with diabetes (Hyp + Dia), hypertension with diabetes and smoking (Hyp + Dia + Sm), and hypertension with diabetes, smoking, and CKD (Hyp + Dia + Sm + CKD). The hazard ratio (HR) for each group was calculated using a Cox proportional hazards model. The HRs were then used to estimate the reduction in clinical events risk in patients with and without CKD.

Results: Results: The estimated HRs for each group were as follows: Hyp: 1.00, Hyp + Dia: 1.24, Hyp + Dia + Sm: 1.34, Hyp + Dia + Sm + CKD: 1.35. The reduction in clinical events risk for patients with CKD was estimated to be 31% compared to patients without CKD.

Conclusion: Conclusion: Renal denervation is a promising treatment for patients with hypertension, especially those with diabetes and CKD.

PO1764
Vascular Function Indices Are Strong Predictors of the Severity and Characteristics of Carotid Atherosclerosis

Ashutosh M. Shukla,1 Lina Ly,2 Malca Joyce,1 Tatiana Orozco,1 Alfredo Ruilope,6 Markus Schlaich,5 Koen Van Doorslaer,7 Robert Pietzsch,8

Background: Background: Carotid atherosclerosis is a major cause of stroke and transient ischemic attack (TIA). It is associated with an increased risk of cardiovascular events. The purpose of this study was to investigate the predictive value of vascular function indices in the evaluation of carotid atherosclerosis.

Methods: Methods: We performed a nationwide population-based study using the national health screening program in South Korea. The study population consisted of 945,243 individuals with and without carotid atherosclerosis. The primary outcome was the presence of carotid plaque. The secondary outcomes were the severity and characteristics of carotid atherosclerosis.

Results: Results: The prevalence of carotid plaque was 49.2% in the entire population. The presence of carotid plaque was significantly associated with age, hypertension, diabetes, and smoking. The severity and characteristics of carotid atherosclerosis were also significantly associated with these factors.

Conclusion: Conclusion: Vascular function indices are strong predictors of the severity and characteristics of carotid atherosclerosis. These findings highlight the importance of monitoring these indices in the management of carotid atherosclerosis.

PO1765
Achievement of Blood Pressure Target and Risk of Major Adverse Cardiovascular and Cerebrovascular Events in Patients with Metabolic Syndrome

Jin,1 Seungyeup Lee,4 Jungheon Bae,2 Alfredo Ruilope,6 Markus Schlaich,5 E. Yaerim Kannenkeril,1 Christian Ott,2 Robert Pietzsch,1 Kristina Streipe,2 Mario Schiffer,1 Roland E. Schmieder,1 1Department of Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nürnberg, Nuremberg, Erlangen, Erlangen, Germany; 2Paracelsus Medical School Nuremberg, Nuremberg, Germany

Background: Background: Metabolic syndrome (MetS) is closely related to adversely affecting the development of atherosclerosis and increasing the risk of cardiovascular disease (CVD) and diabetes. The purpose of this study was to investigate the relationship between MetS and the risk of major adverse cardiovascular and cerebrovascular events (MACCE).

Methods: Methods: We performed a nationwide population-based study using the national health screening program in South Korea. The study population consisted of 945,243 individuals with and without MetS. The primary outcome was the presence of MACCE. The secondary outcomes were the severity and characteristics of carotid atherosclerosis.

Results: Results: The prevalence of MetS was 34.6% in the entire population. The presence of MetS was significantly associated with age, hypertension, diabetes, and smoking. The severity and characteristics of carotid atherosclerosis were also significantly associated with these factors.

Conclusion: Conclusion: MetS is a strong predictor of the development of MACCE and the risk of major adverse cardiovascular and cerebrovascular events. These findings highlight the importance of monitoring these indices in the management of MetS.

PO1766
Relation Between Waist Circumference and Renal Hemodynamic in Healthy Individuals

Agnes Bosch,1 Dennis Kannerkeril,1 Christian Ott,1 Robert Pietzsch,1 Kristina Streipe,2 Mario Schiffer,1 Roland E. Schmieder,1 1Department of Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nürnberg, Nuremberg, Erlangen, Germany; 2Paracelsus Medical School Nuremberg, Nuremberg, Germany

Background: Background: Abdominal adiposity, measured by waist circumference (WC), is associated with increased mortality in individuals with chronic kidney disease. The purpose of this study was to investigate the relationship between WC and renal hemodynamics in healthy individuals.

Methods: Methods: We performed a nationwide population-based study using the national health insurance database of South Korea. The study population consisted of 2,998,127 subjects with and without WC data. The primary outcome was the presence of chronic kidney disease. The secondary outcome was the severity and characteristics of carotid atherosclerosis.

Results: Results: The prevalence of WC > 94 cm was 33% in the entire population. The presence of WC > 94 cm was significantly associated with age, hypertension, diabetes, and smoking. The severity and characteristics of carotid atherosclerosis were also significantly associated with these factors.

Conclusion: Conclusion: WC > 94 cm is a strong predictor of the development of chronic kidney disease and the risk of major adverse cardiovascular and cerebrovascular events. These findings highlight the importance of monitoring these indices in the management of MetS.

Framingham Risk Score and ACC/AHA Pooled Cohort Equation for Prediction of Atherosclerotic Cardiovascular Events in CKD

Benjamin Lidgard,1 Leila R. Zelnick,1 Alan S. Go,1 Kevin D. O’Brien,1 Nisha Bansal.1 University of Washington, Seattle, WA; Kaiser Permanente Southern California, Pasadena, CA.

Background: The Framingham Risk Score and the ACC/AHA Pooled Cohort Equation are used clinically to identify patients at high risk for atherosclerotic cardiovascular disease (ASCVD). The performance of these equations (alone or with clinically available cardiac biomarkers) is unclear in patients with chronic kidney disease (CKD), particularly at more advanced stages. We tested the discrimination of these risk scores and cardiac biomarkers to predict ASCVD in CKD.

Methods: We studied 1027 participants in the Chronic Renal Insufficiency Cohort without ASCVD who were not taking aspirin or statins. Framingham Risk Score, Pooled Cohort Equation, N-terminal pro-brain type natriuretic peptide (NT-proBNP), and highsensitivity troponin T (hsTnT) were measured at baseline. Outcomes were the composite of fatal and non-fatal myocardial infarction (MI) and cardiac death, with or without stroke, over 10 years. We estimated internally valid C-indices using 10-fold cross validation for each risk score and cardiac risk marker overall, and across categories of eGFR.

Results: Among 1027 participants, the mean age was 52 years, and the mean eGFR was 48 mL/min/1.73 m². The C-index (95% CI) was 0.74 (0.69, 0.79) for the Framingham Risk Score, and 0.72 (0.67, 0.78) for the Pooled Cohort Equation. Both risk scores had better discrimination for predicting ASCVD at eGFR >60 mL/min/1.73 m² compared with lower eGFR. HsTnT had comparable discrimination to both risk scores overall. HsTnT alone had comparable discrimination across the spectrum of CKD severity (difference in C-index for lowest vs highest eGFR category for ASCVD 0.04, 95% CI -0.21, 0.14) (Table).

Conclusions: The Framingham Risk Score and Pooled Cohort Equation had moderate discrimination for prediction of ASCVD in CKD and performed better at eGFRs >60 versus <60 mL/min/1.73 m². HsTnT alone had discrimination comparable to each risk score overall, and comparable discrimination across the spectrum of CKD severity.

Further work is needed to develop novel risk scores including cardiac biomarkers specifically for use in CKD.

Nondipping Heart Rate in Patients with CKD
Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.

Background: A decrease in the nocturnal heart rate (HR) decline, nondipping HR (NHR), was reported to be 14% in the general population and related to cardiovascular events and all-cause mortality, however, the clinicopathologic features of chronic kidney disease (CKD) patients with NHR is still unclear. Previous studies have reported that interstitial and/or tubular atrophy (IFTA) was significantly associated with both daytime and nighttime hypertension observed with ambulatory blood pressure monitoring (ABPM). We aimed to investigate the clinicopathologic findings associated with NHR status in patients with CKD.

Methods: We retrospectively identified 135 subjects who underwent ABPM and kidney biopsy simultaneously at our institution, from 2016 to 2019. We excluded patients with age <20 years, end-stage kidney disease, less than 5 glomeruli in the kidney biopsy, and patients taking β-blockers. NHR status was defined as (daytime HR − nighttime HR)/daytime HR >0.1. The percentage of global glomerulosclerosis (GGS%), IFTA, and the severity of arteriosclerosis were scored semi-quantitatively according to the Mayo Clinic/Renal Pathology Society Chronicity Score (CS).

Results: The median age was 51 years [interquartile range: 35–63], 54.0% of which were male, and the median eGFR was 53.0 [30.0–75.0] mL/min/1.73m². NHR status was found in 39 out of 135 patients (28.9%). Patients with NHR were older and had worse renal function, higher blood pressure, lower hemoglobin level, and a larger amount of urinary protein excretion than patients with dipping HR. In terms of histopathological parameters, patients with NHR had more severe GGS%, IFTA, arteriosclerosis, and higher CS (Table 1). In multivariable analysis, GSS% was established as an independent determinant of NHR status after its adjustment according to age, sex, and other statistically significant parameters (β = 1.03 [1.00–1.05], P = 0.02).

Conclusions: NHR status was observed in 28.9% of CKD patients. This study indicates that GSS% is the most relevant histopathological parameter associated with NHR in this population.
Turning the Page on Page Kidney with Dual RAAS Blockade
William J. Assunta,1,2 Jennifer Griffiths,1 Aromma Kapoor,1,2 1Westchester Medical Center Health Network, Valhalla, NY; 2New York Medical College, Valhalla, NY.

Introduction: Page kidney is a rare form of secondary hypertension from activation of the renin-angiotensin-aldosterone (RAAS) axis by compression of renal parenchyma. It can occur with blunt abdominal trauma/procedures, but it can occur spontaneously. Initial treatment is an ACE inhibitor (ACE) or angiotensin receptor blocker (ARB). Surgical intervention is pursued if more conservative measures fail. Procedures carry their own intrinsic risk for morbidity and mortality, particularly in the setting of uncontrolled hypertension. This report details the case of a patient with Page kidney responsive to an unconventional conservative management approach: dual RAAS blockade with ACE + ARB after a lack of response with other agents.

Case Description: The patient is a 55M with a history of end stage renal disease (ESRD) on hemodialysis (HD), atrial fibrillation, and type 2 diabetes mellitus admitted for anemia. The patient was dyspneic and weak with right flank pain. He denied hematemesis, melena, or hematuria. Hemoglobin on admission was 4.7 g/dL with INR of 4.8 (on Coumadin for atrial fibrillation). Vitals were normal except a fever to 38.4 C. A CT scan of the abdomen showed a 16.5cm right retroperitoneal hematoma adjacent to the right kidney with anterior dislocation of the kidney. A CT angiogram showed active extravasation within the hematoma. Coumadin was held and a dose of Vitamin K and two units of blood were given. The patient underwent renal artery embolization. Hemoglobin was stable thereafter. The patient soon developed hypertensive urgency with blood pressure reaching 190/100 mmHg. The patient’s only home medication for blood pressure was Carvedilol. Lisinopril 20mg PO daily was added and increased to maximum dosage, only partially relieving the hypertension. Losartan was added and uptitrated to 100mg PO daily. The patient’s blood pressure normalized with average in 120s systolic by discharge. The patient was continued on this regimen as an outpatient. No hyperkalemia after a lack of response with other agents.

Discussion: Page kidney is a rare but serious form of secondary hypertension from RAAS activation from renal parenchymal compression. Historically, a trial of either an ACE or ARB is indicated, with refractory cases being managed surgically. In this case, dual RAAS blockade was required for blood pressure control, which allowed surgical interventions, and their associated risk of morbidity and mortality, to be avoided.

Persistent of Uncontrolled Hypertension Among Older Women Post Implementation of Hypertension Improvement Program

Emily Walsh,1 Olivia Myers,2 Talar Markossian,2 Holly J. Kramer,2 Katherine Habicht,2 Beatrice D. Probst,1 1Loyola University Chicago Stritch School of Medicine, Maywood, IL; 2Parkinson School of Health Sciences & Public Health, Loyola University Chicago, Maywood, IL; 1Loyola University Medical Center, Maywood, IL.

Background: Age-dependent sex differences in hypertension control have been demonstrated in multiple populations. Four large primary care (PC) practices at Loyola adopted the Target:BP hypertension improvement program in 2018; hypertension control rates increased after adoption. Our study evaluated the impact of the Target:BP program on hypertension control by sex and by age group.

Methods: Analysis used data from 21,864 patients age ≥18 years with a hypertension diagnosis and ≥1 outpatient visit in 2019 to a PC clinic enrolled in Target:BP program. Uncontrolled hypertension was defined as blood pressure ≥140/90 mmHg based on last visit. Mixed effects models were used to calculate adjusted odds of uncontrolled hypertension after adjustment for demographics and co-morbidities. Interaction term of sex*age group (≥65, 66-75, >75 years) in fully adjusted mixed effects models was significant (P < 0.001) so adjusted odds of uncontrolled hypertension were calculated by sex and by age group. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects.

Results: Mean age of patients with hypertension was 64.8 ± 12.7 years; 56.3% were female, 66.6% were White, 21.4% were Black and 11.0% were of Hispanic ethnicity. Among the 5973 (27.3%) with uncontrolled hypertension, 54.7% were female; mean age was 65.2 ± 12.9 years. Adjusted odds of uncontrolled hypertension was significantly higher among women vs. men age 66-75 years (OR 1.33; 95% CI 1.30, 2.28) and age ≥76 years (OR 1.73; 95% CI 1.31, 2.28) vs. age ≤65 years. Figure 1 shows the adjusted proportion of patients with uncontrolled hypertension by sex and by age group.

Conclusions: Despite implementation of a hypertension improvement program, sex disparities in hypertension control persist among older adults.

POI1773

Influence of Biological Sex on Brachial Cuff Blood Pressure Accuracy

Yasmine Abbasou,1 Florence Lamarche,1 Annie-Claire Nadeau-Fredette,2 Molsen Agharazi,3 Francois Madore,3 Remi Goupil,1 1Hôpital du Sacré-Cœur de Montreal, Montreal, QC, Canada; 2Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; 3CHU de Quebec-Universite Laval, Quebec, QC, Canada.

Background: Females have higher risks of cardiovascular events compared to males with similar BP. Our objective was to assess if the accuracy of brachial cuff and central BP measurements towards intra-aortic BP is influenced by biological sex.

Methods: We enrolled 500 patients undergoing coronary angiography for simultaneous measurements of invasive aortic BP with brachial cuff and central BP (Mobil-o-Graph device). Acceptable accuracy was defined as a mean difference between non-invasive and aortic BPs ≤5 ± 5 mmHg. Linear regression and mediation analyses were used to adjust for potential confounders in the relationship between biological sex and BP accuracy.

Results: Of 500 participants, 145 were females. Several characteristics were different in males and females (Table). Brachial cuff systolic BP (SBP) was identical in both groups whereas aortic SBP was 6.2 mmHg higher in females (p<0.001). As such, the brachial cuff SBP was appreciably underestimated the aortic SBP in females but not in males. Type II central SBP was the most accurate BP in females, whereas it was brachial cuff SBP in males. In an adjusted linear regression model, only height and pulse pressure were independently associated with the accuracy of brachial cuff SBP. This effect of sex on accuracy was mostly mediated by height (3.5 mmHg; 95% CI 1.4 to 5.6; 57% mediation) to an extent that the direct effect of sex became non-significant (2.9 mmHg; 95% CI -0.3 to 6.2).

Conclusions: Females have higher aortic SBPs than males with identical brachial SBP, which is mostly mediated by a lower height. This partly explains why females are at higher risk of cardiovascular diseases than males at similar brachial cuff SBP levels.

POI1774

Sex-Specific Associations Between Potassium Intake, Blood Pressure, and Cardiovascular Outcomes in the EPIC-Norfolk Cohort Study

Background: High potassium intake is associated with lower blood pressure and lower risk of cardiovascular disease. Whether these associations differ between men and women and whether they depend on daily sodium intake is unknown.

Methods: We performed an analysis in 11,267 men and 13,696 women from the EPIC-Norfolk cohort. Daily sodium and potassium consumption was estimated from sodium and potassium concentration in spot urine samples by using the Kawasaki formula. Linear and Cox regression were used to explore the association between potassium intake, systolic blood pressure and cardiovascular events (defined as hospitalization or death due to cardiovascular disease).

Results: After adjustment for cofounders, interaction between potassium intake and sex was significantly associated with systolic blood pressure (p=0.001) and cardiovascular events (p=0.035). In women, but not in men, the inverse slope between potassium intake and systolic blood pressure was steeper in those within the highest quintile compared to the lowest quintile of sodium intake (p=0.001 for interaction). In women within the highest quintile of sodium intake, every 1-gram increase in potassium intake was associated with a 2.9 mmHg lower systolic blood pressure. These associations were paralleled with lower risk of cardiovascular events (HR 0.88, 95% CI 0.83-0.94). Conversely, in men, the inverse association between potassium intake and cardiovascular disease was not statistically significant (highest vs. lowest potassium intake tertile: HR 0.94, 95% CI 0.88-1.01).

Conclusions: We demonstrate that the association between potassium intake and both systolic blood pressure and cardiovascular disease is sex-specific. Our data suggests that particularly women may benefit most from a high potassium intake.

Figure 1 Interaction between potassium intake and sodium intake for the outcome systolic BP in men and women

Tryptophan Metabolites Associate with Subclinical and Incident Cardiovascular Disease in CKD
Trista M. Benitez, Elizabeth Vanderwoude, Yun Han, Jaeman Byun, Vetalihe K. Cheofor, Brenda W. Gillespie, Rajiv Saran, Anna V. Mathew. University of Michigan, Ann Arbor, MI

Background: Inflammation and oxidative stress contribute to the increased cardiovascular disease (CVD) burden in CKD patients. Altered tryptophan catabolism via the kynurenic pathway associates with CVD, but the ability of these specific metabolites to act as biomarkers of CVD risk in CKD warrants further research.

Methods: We measured tryptophan metabolites using targeted mass spectrometry in moderate to severe CKD patients (n=325; median follow-up 3 years). Vascular calcification at the coronary artery and aorta was measured using a 4-slice LightSpeed QXI and reported as Agatston scores. Incident CVD events included myocardial infarction, coronary revascularization procedures, stroke, transient ischemic attack, new-onset heart failure, sudden cardiac death, and peripheral vascular disease requiring revascularization or amputation. Multiple linear regression and Cox proportional hazard analyses assessed the relationship of tryptophan metabolites to subclinical markers of CVD and CVD events.

Results: We found that lower baseline tryptophan levels predicted increased aortic calcification in a fully adjusted model controlling for demographics, CVD history, traditional risk factors, renal function, CRP, and serum albumin (p=0.006). Higher baseline levels of anthranilic acid and hydroxyanthranilic acid predicted increased coronary calcification and higher total Agatston score, respectively, in the fully adjusted model (p=0.03 and p=0.03). One unit decrease in serum tryptophan at baseline is associated with 70% decrease in time to incident CVD event when adjusting for demographics, CVD history, risk factors, and renal function (HR: 0.31, p = 0.04). Increased anthranilic acid and quinolinic acid independently reduced time to incident CVD event (HR: 1.88, p=0.02; HR: 0.19, p=0.02, respectively), but were not significant in the fully adjusted model.

Conclusions: Lower tryptophan levels are associated with increased aortic calcification and decreased time to incident CVD events. Higher levels of anthranilic acid, hydroxyanthranilic acid, and quinolinic acid are associated with subclinical CVD. Together, these data demonstrate that catabolism of tryptophan via the kynurenic pathway is associated with subclinical CVD and predicts cardiovascular events in CKD.

High Level of Uromodulin Increases the Risk of Hypertension: A Mendelian Randomization Study
Ruijuan You,1 Lanlan Chen,2 Lubin Xu,1 Hai Tao Li,1 Xiaoqiao Shi,1 Yali Zheng,3 Limeng Chen,1 1Peking Union Medical College Hospital, Dongcheng-qu, China; 2Jilin University, Changchun, China; 3Ningxia Medical University, Yinchuan, China

Background: The association of uromodulin and hypertension was clinically observed, but not proved as a causal relationship. We conducted a two-sample Mendelian randomization analysis to investigate the causal relationship between uromodulin and blood pressure based on the public datasets.

Methods: We selected two SNPs for the uUMOD exposure from the Genome-Wide Association Studies (GWAS) meta-analysis study (N=10884) and sixteen SNPs for the outcome and demonstrated that catabolism of TGFb1 itself. Activins are known to induce inflammation, oxidative stress and fibrosis, all which was accompanied by a reduction in medial thickness. Increased oxidative stress seen in SHR vessels was inhibited by FST. The results were replicated in SHR with established HTN, at least in part by reducing vascular oxidative stress and medial thickening. This manifests as improved vascular function, with decreased hypersensitivity to contractile agents and improved endothelial function. Future work will identify the effects of FST on inflammation, and the role of specific activins in essential HTN.

Follistatin Is a Potential Novel Therapeutic Agent for Essential Hypertension
Ann Kuganan, Marcos S. Leal, Chao Lu, Bo Gao, Jeffrey G. Dickhout, Joan C. Krepsinsky. McMaster University Faculty of Health Sciences, Hamilton, ON, Canada

Background: Follistatin (FST) is an inhibitor of several members of the profibrotic TGFb superfamily. It is highly effective at neutralizing activins, without activity against TGFb1 itself. Activins are known to induce inflammation, oxidative stress and fibrosis, all of which contribute to the vascular dysfunction characteristic of hypertension (HTN). We previously showed that FST inhibits kidney fibrosis, improves kidney function and lowers blood pressure (BP) in a hypertensive chronic kidney disease mouse model. While this is a model of secondary HTN, here we seek to analyze the efficacy of FST in improving BP and vascular structure and function in a model of essential HTN.

Methods: Telemeters were implanted in the abdominal aorta of spontaneously hypertensive rats (SHR), a model of essential HTN, and normotensive control Wistar Kyoto (WKY) rats for wireless BP monitoring. Rats were treated with 0.075mg/kg FST or vehicle IP every other day from 12-20 weeks of age (8 weeks). BP was recorded weekly. First branch mesenteric arteries were harvested for analysis of vascular function using myography, assessed for oxidative stress by DHE, or formalin fixed for IHC.

Results: By the end of the study, FST significantly lowered both systolic and diastolic BP in SHRs (200 +/- 9 over 132 +/- 4 mmHg in control and 189 +/- 2 over 123 +/- 2 mmHg in FST-treated SHRs, P < 0.04 and P < 0.03 respectively). SHR vessels showed increased contractility with the a1adrenergic agonist phenylephrine, which was attenuated by FST. FST induced vasodilation of myogenic-dependent relaxation in SHR vessels was also improved by FST. Structurally, FST-treated vessels had less collagen deposition, assessed by Trichrome, which was accompanied by a reduction in medial thickness. Increased oxidative stress seen in SHR vessels was inhibited by FST.

Conclusions: FST lowers BP in SHR with established HTN, at least in part by reducing vascular oxidative stress and medial thickening. This manifests as improved vascular function, with decreased hypersensitivity to contractile agents and improved endothelial function. Future work will identify the effects of FST on inflammation, and the role of specific activins in essential HTN.

Oscillometric vs. Auscultatory Blood Pressure Measurements and the Impact of Atrial Fibrillation
Ahmed Aburahma, Christopher B. McFadden. Cooper University Health Care, Camden, NJ.

Background: The Hypertension literature recognizes a difference in Oscillometric Blood pressures compared to Auscultatory Blood pressure measurements. These differences are small but increased in patients with Atrial fibrillation. This difference varies in previous studies. Again this Difference is larger in subjects with atrial fibrillation. Current Blood pressure measurement guidelines emphasize the use of an Auscultatory method or repeated oscillometric measures to measure blood pressure in patient with arrhythmias including atrial fibrillation. This recommendation is not consistently implemented in clinical medicine. We aim to quantify the differences in blood pressure readings between oscillometric and auscultatory method and correlate that to presence or absence of atrial fibrillation.

Methods: This is a retrospective study that involved adult patients seen in the outpatient nephrology clinic by one of the investigators (CM) between January 2016 and January 2020. Data collection included age, sex, BMI, atrial fibrillation (AF), CKD stage, diabetes mellitus, blood pressure readings (by both methods, which were done by the investigator (CM) in all antihypertensive patients) and number of blood pressure medications. Information on a total of 200 patients were collected. 100 of those had hypertension with AF while the other 100 had hypertension but no AF to achieve a power of 80% and P value of 0.05.

Results: After using Unpaired t test, the average difference between two methods in hypertensive patients with atrial fibrillation were 29 mmHg in systolic blood pressure (P value of 0.9 and 95% CI from -5.5 to 6.12) and 5.39 mmHg in diastolic blood pressure (P value of 0.0068 and 95% CI from 1.5 to 9.24). On the other hand, the average difference between two methods in hypertensive patients with atrial fibrillation were 6.8 mmHg in systolic blood pressure (P value of 0.018 and 95% CI from 1.18 to 12.5) and 5.04 mmHg in diastolic blood pressure (P value of 0.002 and 95% CI from 1.87 to 8.21).

Conclusions: This study showed a statistical difference between the two methods in measuring the blood pressure of hypertensive patients with atrial fibrillation. A larger study is needed to show no difference between the two methods. For now we need to encourage the use of auscultatory method in measuring the Blood pressure in this group of patients.

PO1781

Single-Nephron Salt Excretion and Nighttime Hypertension: A Cross-Sectional Study in Patients with IgA Nephropathy
Nobuo Tsuibo, Hirokazu Marumoto, Kotoro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Go Kanazaki, Kentaro Koike, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan, Japan.

Background: Abnormalities in diurnal blood pressure variability and renal salt handling may contribute to poor disease outcomes in patients with IgA nephropathy (IgAN). This study examined the relationships between diurnal blood pressure variability and single-nephron urinary salt excretion (SNUSE) in IgAN patients.

Methods: The subjects were IgAN patients who underwent ambulatory blood pressure (ABP) monitoring and 24-hr urine collection during hospitalization for a diagnostic biopsy. In all patients, dietary salt intake was restricted to 6 g/day during hospitalization. Daytime and nighttime hypertension were defined as daytime ABP ≥ 135/85 mmHg and nighttime ABP ≥ 120/70 mmHg, respectively. The total nephron number per kidney was estimated by a combined cortical volume assessment of unenhanced computed tomography images and stereology-based measurements of non-sclerotic glomerular density in a biopsy. SNUSE was calculated by dividing urinary salt excretion per day by the total nephron number of both kidneys.

Results: Among the 112 patients (42 years old, 63.4% male, estimated glomerular filtration rate [GFR] 62.4 mL/min/1.73 m²) included, daytime and nighttime hypertension were defined in 39 (34.8%) and 21 (18.5%) patients, respectively. In patients with nighttime hypertension, the total nephron number per kidney was lower (490,000 vs. 796,000/kidney, p = 0.01) and SNUSE was higher (6.53 vs. 4.22 mmol/day, p = 0.003) than in normotensive patients during nighttime. An increase in SNUSE in patients with nighttime hypertension was associated with advanced tubulointerstitial injury, defined as a T score in the Oxford histopathological classification of IgAN. The single-nephron GFR was comparable among patients with and without hypertension both during the daytime and nighttime and was not associated with a T score.

Conclusions: These results provide evidence that salt excretion per nephron is increased in IgAN patients presenting with nighttime hypertension. The difference in SNUSE was identified in relation to the tubulointerstitial injury without producing a difference in single-nephron GFR values among ABP categories, indicating compensatory changes in tubular salt handling at the single-nephron level.

PO1782

Small Changes in eGFR Are Associated with Different Patterns of 24-Hour Ambulatory Blood Pressure Monitoring in the General Population
Sang Youn Han,1 Sanggon Yoon,1 Seung Ku Lee,2 Chol Shin.1 Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; 1Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

Background: Alteration of circadian blood pressure (BP) rhythm such as non-dipper and reverse dipper pattern is associated with cardiovascular diseases and chronic kidney disease (CKD). However, most studies did not control for kidney function even though kidney function is an important risk factor. In this study, we tried to show 24-h ambulatory blood pressure monitoring (ABPM) patterns based on an eGFR in patients without CKD.

Methods: This study was a cross-sectional study from the data of the Korean Genome and Epidemiology Study, which is ongoing prospective cohort study. A total of 1733 participants (60.0±7.0 years, 938 women) who had an eGFR > 60 ml/min/1.73m² were included. Dipping status was stratified as reverse dipper (<0%), non-dipper (0% to <10%), and dipper (≥10%) based on the night to day ratio of mean BP. They were divided into 4 groups based on quartile of an eGFR (Q4, 128.6±10.6; Q3, 101.5±8.75; Q2, 95.6-87.4; Q1, 87.3±60.5).

Results: The proportion of dipper was progressively decreased from the highest to the lowest eGFR whereas that of reverse dipper and non-dipper significantly increased. (p<0.001). We analyzed the data using logistic regression model in relation to dipper, non-dipper, reverse dipper, and non-dipper plus reverse dipper according to the quartiles of an eGFR. The highest quartile group (Q4) was fixed as the reference. In univariate analyses, Q1 and Q2 groups were significantly associated with increasing odds ratio (OR) with absolute dipper and reverse dipper. Only non-dipper plus reverse dipper, after full-adjustment with age, sex, hypertension, diabetes, body mass index, smoking status, exercise, and alcohol consumption, the lowest eGFR group was significantly associated with reverse dippers and non-dipper plus reverse dippers compared to the highest eGFR group (OR=1.689, 95% CI, 1.005-2.840, OR=1.427, 95% CI, 1.027-1.985, respectively). The significant linear trend of non-dipper plus reverse dipper with a decrease in eGFR was confirmed with the test for trend (P=0.024).

Conclusions: Small changes in eGFR are associated with different pattern of 24-h ABPM in the general population. ABPM could be useful tool to detect patients with non-dipper in this population.

PO1783

Blood Pressure Control and Undiagnosed Hypertension: A Randomized Diagnostic Study Comparing Clinic, Home, and Kiosk Methods
Yoshio N. Hall,1 Melissa L. Anderson,2 Beverly B. Green.1 University of Washington, Seattle, WA; 1Kaiser Permanente Washington Health Research Institute, Seattle, WA.

Background: Undiagnosed hypertension is common and contributes to CKD and cardiovascular morbidity and mortality. We compared prevalence of blood pressure (BP) control and undiagnosed hypertension at 6 months according to different BP measurement methods.

Methods: BP CHECK was a randomized diagnostic study of 510 adults aged 18-85 without diagnosed hypertension or antihypertensive medications, with elevated BP in clinic and at baseline; conducted 2017-2019 in primary care centers of an integrated healthcare system. Randomization occurred into one of three diagnostic regimens: (1) Clinic BP (usual care), (2) Home BP (twice daily for 5 days), or (3) Kiosk BPs (triplicate BPs on 3 days). All participants completed ABPM at baseline. Primary outcomes were changes in systolic BP and diastolic BP; BP control and receipt of a new hypertension diagnosis at 6 months. We further examined whether changes in patient-reported outcomes relating to physical and psychological well-being and behavior were associated with BP control or a new hypertension diagnosis.

Results:Mean baseline BP was similar across groups (150/88 mmHg). Overall, 93% (472/510) of study participants completed the 6-month visit. All groups experienced a reduction in BP (mean reduction: systolic BP = -11.5 mmHg, diastolic BP = -5.5 mmHg) with no significant differences by randomization group. Among 323 participants with hypertension based on ABPM, 156 (48%) achieved BP control (<140/90 mmHg) and 130 (40%) had a new hypertension diagnosis recorded in the EHR at 6 months. Participants with undiagnosed hypertension at 6 months experienced significantly lower reductions in both systolic and diastolic BP, compared to individuals with a new hypertension diagnosis (difference in mean change SBP [95% CI], -5.1 mmHg [-7.8, -2.3], P=0.001; DBP -2.4 mmHg [-4.2, -0.5], P=0.01). Changes in patient-reported outcomes from baseline to 6 months were small, with no significant differences in body weight, intake of fruits/vegetables, or measures of physical health according to randomization group or presence of hypertension diagnosis.

Conclusions: Irrespective of BP measuring method, most participants with high BP control and ABPM diagnostic testing did not receive a hypertension diagnosis or adequate BP control. New strategies are needed to enhance uptake of BP diagnostic testing into clinical practice.

PO1784
Cvit-Line Monitoring Effect on Blood Pressure Control in ESRD Patients Undergoing In-Center Hemodialysis
Maggie Meier, Hassanu Ifikhar, Alexandra Y. Li, Frank J. O. Brien. Washington University in St Louis, St Louis, MO.

Background: Patients with end stage renal disease (ESRD) are admitted to the hospital about twice with a 35% readmission rate. Cardiovascular disease (CVD) makes up 28% of admissions; 38% of patients with CVD admissions have pulmonary edema. Fluid overload in ESRD increases morbidity and mortality. Fluid management improvements have potential to positively impact clinical outcomes in dialysis patients.

Methods: This was a prospective cohort study with adult patients at two outpatient dialysis facilities on the Washington University in St Louis Campus. Our inclusion criteria were patients with consistent 3x weekly in-center hemodialysis defined as 80% attendance in the 30 days prior to the study. A critline protocol was implemented by the treatment team (Figure 1).

Results: Among 58 qualified patients, average age was 59. 77% were African American with male predominance (57%). Average BMI was 29. In the Critline cohort, systolic blood pressure trended down (Figure 2). In the initial 25 weeks, average number of antihypertensive medications per patient decreased from 2.6 to 1.8. The number of admissions for fluid overload stayed at 10, however readmissions decreased from 4 to 1.

Conclusions: Implementing a Critline protocol trended towards improvements in blood pressure and reduced number of antihypertensives medications. Our findings suggest that a protocolized approach to fluid management using critline will improve our patients outcomes.

PO1785
Cardiovascular Functional Changes in Transplant Waitlist Dialysis Patients
Peter E. Umukoru,1 Tzongshi Lu,2 Sharon M. Moe,1 Ranjani N. Moorthi,2 Gordon Megrega,2 Thomas F. Hiemstra,1 Kenneth Lim.1 Indiana University School of Medicine, Indianapolis, IN; 2Brigham and Women's Hospital, Boston, MA; 3University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; 4University of Warwick Warwick Medical School, Coventry, United Kingdom.

Background: The transition to dialysis is a crucial time in patients with advanced chronic kidney disease (CKD), conferring an increased risk for cardiovascular death. We recently showed that VO2peak, an index of cardiovascular functional capacity (CFC) significantly declined in advanced CKD patients following 1-year follow-up in the absence of changes in left ventricular mass index (LVMI). Herein, we hypothesized that initiating dialysis and continuing dialysis could worsen an individual’s CFC over time.

Methods: We conducted a cross-sectional study of 241 CKD stage 5 patients from the Cardiopulmonary Exercise Testing in Renal Failure (CAPER) cohort. VO2peak (primary endpoint) was assessed by cardiopulmonary exercise testing (CPET) in parallel with transthoracic echocardiography.

Results: Of the 241 patients (mean age [SD] age, 48.9 [14.9] years; 154 [65.9%] males), 134 patients were pre-dialysis (mean eGFR [SD], 14.1 [4.4] ml/min/1.73m2). Maximal workload were in tertile 1 of dialysis vintage (0-17 months), n=69 in tertile 2 (18-50 months) and n=66 in tertile 3 (≥51 months). Pre-dialysis patients had an impaired VO2peak of 22.7 [5.2] ml/min/kg, and this significantly declined to 18.5 [5.5] ml/min/kg in tertile 1 dialysis patients compared to the pre-dialysis group, tertile 1 dialysis patients exhibited reduced maximal workload (p=0.003), impaired maximal heart rate (p=0.002), increased LVMi (p=0.001) and markedly elevated FGF23 levels (p=0.01). On assessment of the effects of dialysis vintage, we found an incremental downward trend in VO2peak across the groups (18.5 [5.2] tertile 1, 16.4 [4.7] tertile 2, 16.9 [4.2] ml/min/kg) following exclusion of patients who had prior kidney transplants, however this did not reach statistical significance (p=0.2).

Conclusions: Initiating dialysis in advanced CKD patients is associated with impaired CFC comparable to declines seen in new onset heart failure, making this a critical time for these patients.

PO1786
Major Adverse Limb Events and Mortality After Peripheral Artery Revascularization in Hemodialysis Patients
Ting-yan Lin, 3Shu-Chun Hung. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Revascularization is important for symptom relief and limb salvage in peripheral artery disease, yet limited information exists on the prognosis of hemodialysis patients who receive the procedure. This study sought to determine the incidence and associated factors of major adverse limb events (MALE) after peripheral artery revascularization among hemodialysis patients.

Methods: Hemodialysis patients undergoing peripheral artery revascularization between July 1, 2005, and December 31, 2019, in the Taipei Tzu Chi Hospital were examined for the primary outcome of MALE, defined as severe limb ischemia leading to an intervention or amputation. The secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality. Multivariable-adjusted Cox proportional hazards models were used to explore risk factors associated with development of MALE.

Results: A total of 402 hemodialysis patients were included in the final analysis. Overall, the mean age was 68 years, 56.5% (n = 227) were male, 83.3% (n = 335) had diabetes, and 58.0% (n = 233) had coronary artery disease. During a median follow-up of 2.2 years, 54.0% (n = 217) experienced a subsequent MALE, 33.6% (n = 136) had a MACE, and 54.5% (n = 219) died. Diabetes, coronary artery disease, current smoking, lower body mass index, and higher platelet count or total cholesterol were significantly associated with increased risk of post-procedure MALE.

Conclusions: A significant proportion of hemodialysis patients undergoing peripheral artery revascularization developed a subsequent MALE and MACE or died. Strategies that address risk factors for MALE should be evaluated to improve the outcomes of revascularized hemodialysis patients.

PO1787
Central Blood Pressure Calibration Method and Cardiovascular Risk Prediction According to Sex
Florence Lamarche,1 Mohsen Agharazi,3 Annie-Claire Nadeau-Fredette,7 Francois Madore,1 Remi Goupil.1 Hôpital du Sacre-Coeur de Montreal, Montreal, QC, Canada; 2Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; 3CHU de Quebec-Univeriste Laval, Quebec, QC, Canada.

Background: The accuracy of central BP is improved when calibrated on the mean BP and diastolic BP (C2SBP) compared to calibration on the systolic BP and diastolic BP (C1SBP). Furthermore, preliminary data suggest C2SBP may have the best accuracy in females. We aim to assess whether this enhanced accuracy translates into improved cardiovascular (CV) risk prediction when compared to brachial SBP (bSBP) and C1SBP in the general population and stratified by sex.

Methods: 12,927 participants exempt of known CV disease, with prospective follow-up from administrative databases and central BP measurements were included. The SphygmoCor Px device was used to estimate C1SBP. C2SBP was derived from unprocessed radial pressure waveforms extracted from SphygmoCor output data, which was recalibrated with diastolic BP and 40% form factor derived mean BP. Participants with heart rate >60 were excluded due to incomplete waveform. Major adverse CV events (MACE) comprised myocardial infarction, stroke, heart failure with hospitalization and CV death. Multivariable Cox regressions, differences in area under the curve, net reclassification index and integrated discrimination index were calculated comparing C2SBP to C1SBP and to bSBP.

Results: Over a median follow-up of 10.1 years (IQR 9.9-10.3), there were 2125 MACE (723/7013 females and 860/5934 males). All BP parameters were significantly associated with MACE, regardless of sex. In the overall cohort, risk prediction metrics notably favored C2SBP to bSBP, but were similar to C1SBP. No significant improvement of CV risk prediction was found in sex-stratified analyses (see Table).

Conclusions: C2SBP marginally improved CV risk prediction when compared to bSBP but not C1SBP in the overall cohort only. All three BP parameters were similarly predictive in both sex, although this analysis possibly lacked power. This may be related to the FP-derived MAP (rather than oscillometric MAP), which is highly dependent on the brachial SBP.
PO1788

Suppressed Renin Activity in CKD: Are We Missing Primary Hyperaldosteronism?

Mehdi A. Mohseni,1 Georges Nakhoul,1 Susana Arrigian,1 Jesse D. Schold,2 Jonathan T. Jallaliero,2 George Thomas,2 1 Cleveland Clinic, Cleveland, OH; 2 Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: Primary hyperaldosteronism (PA) is more prevalent than once thought and associated with adverse kidney and cardiovascular outcomes. A prior analysis of the CKD registry at the Cleveland Clinic in patients without a diagnosis of PA showed that the lowest quartile of plasma renin activity (PRA) had more severe hypertension and faster eGFR decline. We hypothesized that some of these patients with suppressed PRA may have undiagnosed PA.

Methods: We reviewed patients in the Cleveland Clinic CKD registry with documented PRA and absolute plasma aldosterone concentration (PAC). Patients in the lowest PRA quartile were identified and stratified by PAC/PRA ratio. A cutoff ratio of ≥20 was considered suggestive of PA regardless of the PAC. Characteristics and outcomes of these two subgroups were compared using t-tests, chi-square tests, Kaplan-Meier analyses and Cox models.

Results: 276 patients were identified for this analysis. Median PRA and PAC were 0.5 μg/L/hr and 8.7 ng/dl respectively. 141 (51%) patients had a PAC/PRA ratio of ≥20 with a median PAC of 14.6 ng/dl in this subgroup. Patients with PAC/PRA of a ≥20 vs. <20 had significantly lower eGFR (mean: 50.7 vs. 55.4 mL/min/1.73 m²; P=0.009), more resistant hypertension (63.1% vs. 48.9%; P=0.044), lower serum potassium values (mean: 3.9 vs. 4.2 mmol/L; P=0.001), and higher serum bicarbonate levels (mean: 26.4 vs. 25.3 mmol/L; P=0.001). With median follow up of 4.2 years, there was no difference in mortality between the two subgroups on adjusted cox model analysis (HR for ≥20 vs.<20: 0.83, 95%CI: 0.47,1.47). No difference in ESKD-free survival at 5 years was noted but the event rate was low (92.6 vs. 91.9 for ≥20 vs.<20: P=0.77).

Conclusions: Our analysis indicates that some CKD patients with suppressed PRA may have underlying PA. More than half of our suppressed PRA cohort had elevated PAC and associated with adverse kidney and cardiovascular outcomes. A prior analysis of the CKD registry at the Cleveland Clinic in patients without a diagnosis of PA showed that the lowest quartile of plasma renin activity (PRA) had more severe hypertension and faster eGFR decline. We hypothesized that some of these patients with suppressed PRA may have undiagnosed PA.

Method:

Results: A total of 13 patients (mean age; 39.2±11.2 years, male: 92.3%, BMI; 26.4±3.9 kg/m², history of hypertension: 92.3%) were included in this study. All patients had higher systolic blood pressure (>120 mmHg), and 12 patients had higher diastolic pressure (>90 mmHg). At admission, 12 patients had kidney injuries, 12 patients had hypertension, 9 patients had acute renal failure, and 1 patient had acute in-farction. The average PRA levels at admission was 20.0±2.8 ng/mL/hr. The average duration from diagnosis to kidney biopsy was 14.4 days. The median eGFR on the day of kidney biopsy was 15.3 [IQR 9.1, 21.7] mL/min/1.73m². PRA was significantly and positively correlated with severity of intimal edema of intrarenal small arteries (r=0.42, p=0.02). However, no association was found between PRA and other histological kidney injury.

PO1790

Cardiovascular and Renal Outcomes of the New Intensive Blood Pressure Target in a CKD Population in Korea

Kyung hwan Jeong,1 Soo-Young Yoon,1 Ji Yoon Kong,2 Daey Kyu Kim,3 Jongho Kim,4 Shinyeong Kang,1 Jin sug Kim,1 Hyeon Seok Hwang,1 Kyung Hee University Medical Center, Seoul, Republic of Korea; 2Kyung Hee University, Seoul, Republic of Korea.

Background: Hypertension is one of the most important modifiable risk factors of cardiovascular disease (CVD) including ischemic heart disease (IHD) and stroke. The 2021 Kidney Disease: Improving Global Outcomes (KDIGO) Clinical Practice Guideline for the Management of Blood Pressure (BP) in CKD recommended a target systolic BP (SBP) <120 mmHg regardless of albuminuria, using standardized office BP measurement. We evaluated the prevalence of cardiovascular events and CKD progression to assess the impact of this intensive BP target for CKD patients in Korea.

Methods: The data of 166,397 adults whose baseline estimated glomerular filtration rate (eGFR) <60 mL/min per 1.73 m² were extracted from the Korean National Health Insurance Service database between 2009 and 2011. The data were adjusted for multiple factors such as age, sex, smoking, eGFR, and anti-hypertensive medications in multivariate Cox proportional hazards regression models. All participants were divided into four SBP categories (<120 mmHg, 120-129 mmHg, 130-139 mmHg, ≥140 mmHg). The primary outcome was CVD risk, and the secondary outcome was the risk of progression to end-stage renal disease (ESRD), especially in need of intermittent hemodialysis (HD).

Results: The mean ages of the each group of CKD patients were 45.1±15.7 years in SBP <120 mmHg group and 52.1±16.0 years in SBP 120-129 mmHg group. 11.1% in SBP >120 mmHg group and 24.6% in SBP 120-129 mmHg group of the participants were already taking anti-hypertensive medications. 112,012 patients (67.3%) had SBP <120 mmHg, and 78,119 patients (46.9%) had SBP ≥130 mmHg. Participants with SBP 120-129 mmHg exhibited a significantly high risk for IHD (hazard ratio (HR), 1.29; 95% confidence interval (CI), 1.03-1.61; P = 0.03) and stroke (HR, 1.57; 95% CI, 1.13-2.18; P <0.001) was compared with the participants with SBP >120 mmHg. Also, the risk of progression to ESRD was also higher (HR, 1.67; 95% CI, 1.46-1.91; P<0.001). Similar cardiovascular findings were observed between the group with SBP<120mmHg and the other groups.

Conclusions: Therefore, the new intensive BP target can be applied to the real clinical practice in CKD population with proper BP monitoring in Korea, and it may eventually reduce the risk of CVD and progression to ESRD in a number of CKD patients.

PO1789

Higher Plasma Renin Activity Level Is Associated with the Severe Intrarenal Arterial Injury in Patients with Hypertensive Emergency

Shu Ushimaru, Sayuri Shirai, Tsutomu Sakurada, Yugo Shibagaki, Daisuke Ichikawa. 1Sei Marianna Ika Daigaku Byoin, Kawasaki, Japan.

Background: It is well known that most patients with hypertensive emergencies have high plasma renin activity (PRA) levels, which indicates the pathophysiology of organ damage. However, the association with intrarenal arterial injury and PRA level has not been well documented.

Method: We herein investigated this association retrospectively in patients who were diagnosed with hypertensive emergency and were also evaluated the PRA and underwent kidney biopsy between April 2001 and September 2019. The severity of intrarenal arterial injury was classified into stage 0 to stage 3 based on the report by Kohagura et al (Hypertens Res. 2013).

Results: A total of 13 patients (mean age: 39.2±11.2 years, male: 92.3%, BMI: 26.4±3.9 kg/m², history of hypertension: 92.3%) were included in this study. All patients had higher systolic blood pressure (>120 mmHg), and 12 patients had higher diastolic pressure (>90 mmHg). At admission, 12 patients had kidney injuries, 12 patients had hypertension, 9 patients had acute renal failure, and 1 patient had acute in-farction. The average PRA levels at admission was 20.0±2.8 ng/mL/hr. The average duration from diagnosis to kidney biopsy was 14.4 days. The median eGFR on the day of kidney biopsy was 15.3 [IQR 9.1, 21.7] mL/min/1.73m². PRA was significantly and positively correlated with severity of intimal edema of intrarenal small arteries (r=0.42, p=0.02). However, no association was found between PRA and other histological kidney injury.

Conclusions: Since vascular injury directly leads to organ damage, its presence calls for urgent need for blood pressure lowering with caution for ischemia. Since biopsy is often not available, PRA can be a good substitute to assess vascular injury in the management of those with acute severe hypertension.
Markers of Kidney Tubular Secretion and Risk of Cardiovascular Disease and Mortality in Persons with CKD in SPRINT

Simon Ascher,1,2 Ronit Katz,3 Rebecca Scherzer,1 Alexander Bullen,4‡,†,‡‡,§,¶,#∗, Joachim H. Is,∗,§,¶ Michael Shlipak,2 Pranav S. Garimella,4 Jesse C. Seegmiller,2 Joachim H. Is,∗,± Michael Shlipak,2 Alexander Bullen,1 Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; 2University of California Davis, Davis, CA; 3University of Washington, Seattle, WA; 4University of California San Diego, University of California San Diego, La Jolla, CA, US, academic, La Jolla, CA; 5Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; 6University of Minnesota Academic Health Center, Minneapolis, MN; 7Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion of organic solutes is essential to the clearance of many drugs, metabolites, and toxins. Whether novel measures of tubular secretion have prognostic value for cardiovascular and mortality risk among hypertensive, nondiabetic persons with CKD is uncertain.

Methods: In 2089 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. We used multivariable Cox proportional hazards models to evaluate associations between secretion scores and risk of cardiovascular disease (CVD) and all-cause mortality.

Results: Mean age at baseline was 73±9 years and mean eGFR was 46±11 ml/min/1.73m2. There were 272 CVD events and 144 deaths during a median follow-up of 3.26 years. In unadjusted analyses, a 1-SD higher secretion score was associated with a lower risk of a composite of pre-specified serious AEs (hypotension, syncope, bradycardia, acute kidney injury, electrolyte abnormalities, and injurious falls) and two outpatient AEs (hyperkalemia and hypokalemia).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was associated with lower AE risk, but this association was not independent of eGFR and albuminuria.

Longitudinal Changes in FGF-23 and High-Sensitivity C-Reactive Protein with Incident CKD in the Accord-BP Trial

Wenjin Liu,1 Yufeng Huang,1 Robert E. Boucher,1 Guo Wei,2 Glenn M. Chertow,3 Srinivasan Beddhu.4,5,6,7 The University of Utah School of Medicine, Salt Lake City, UT; 8VA Salt Lake City Health Care System, Salt Lake City, UT; 9Stanford University, Stanford, CA.

Background: In adults over 50 with increased cardiovascular (CV) risk, intense systolic blood pressure (SBP) lowering reduces the risk of death and major CV events, but increases the risk of incident CKD. Metabolic manifestations of incident CKD related to intensive SBP lowering are unknown. Here we explored the relation between incident CKD and FGF23, an early marker of bone and mineral metabolism, in participants enrolled in the ACCORD-BP trial.

Methods: We included 362 ACCORD BP participants with incident CKD during follow-up. Among participants without kidney intervention arms, control participants were matched for age, sex, race/ethnicity, SBP intervention and glyceremia intervention arms. Incident CKD was defined as a >30% decrease in eGFR to <60 ml/min/1.73m2. Serum concentrations of FGF23 and hs-CRP were measured using Meso Scale Discovery four-parameter immnoassay platform at baseline, month 24 and 48. Close-out dates from baseline were estimated for the average of month 24 and 48/ close-out using mixed effect models with fixed effects for group and visit.

Results: Mean age was 63±9 yrs, 55% women, and 30% non-white. Baseline duration of diabetes was 11±8 yrs, baseline eGFR, FGF23 and hs-CRP in the incident CKD and control groups were 87±17 and 92±19, 76(55,107) and 52(40,76) pg/ml and 3.2 (1.3,7.2) and 3.8(1.3,12.0) µm/l, respectively. Longitudinal changes in these parameters are summarized in the Table and Figure.

### Table: Changes in FGF-23 and hs-CRP in incident CKD and control groups

Carotid Plaque Characteristics and Incident Cognitive Impairment in Hypertensive Adults

L Parker Gregg,1,2 Srinivasan Beddhu,1,4 Robert E. Boucher,1,3 Manjula Kurella Tamura,1 Chun Yuan,1 Jie Sun,6 Niranjani Balu,6 Nicholas M. Pajewski,7 Jeff D. Williamson,2 Sankar D. Navaneethan,1,2 Baylor College of Medicine, Houston, TX; 1Michael E DeBakey VA Medical Center, Houston, TX; 2University of Utah Health, Salt Lake City, UT; 3VA Salt Lake City Health Care System, Salt Lake City, UT; 4Stanford Medicine, Stanford, CA; 5University of Washington, Seattle, WA; 6Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Carotid atherosclerosis is associated with cognitive impairment. We investigated associations of plaque characteristics on carotid magnetic resonance imaging (MRI) with the development of mild cognitive impairment (MCI) or probable dementia.

Methods: In an ancillary study to the Systolic Blood Pressure Intervention Trial (SPRINT), carotid plaque was identified by MRI and characterized as having a lipid-rich necrotic core (NC) or calcification. In the parent study, adjudicated MCI and probable dementia were adjudicated on the basis of neuropsychological testing and proxy reports of cognition-related decline in functional status. We related baseline plaque presence and characteristics of NC or calcification with the incidence of MCI/probable dementia at 3 years of follow-up.

Results: Of 465 participants, 137 (29.5%) had NC plaque. Those with NC plaque were older and more likely to have cardiovascular disease than those without NC plaque. There were 38 MCI/probable dementia outcomes in the entire cohort over 2220 person-years of follow-up. The incidence (95% CI) of a composite outcome of MCI or probable dementia at 3 years was 12.0% (7.5, 18.9) in the NC group and 7.0% (4.6, 10.4) in the no NC group with an absolute risk difference of 5.1% (95% CI -1.2, 11.3, P=0.001). With further adjustment, the absolute risk difference attenuated but the point estimate remained high (Figure). Results for the presence of any plaque or calcified plaque with MCI/probable dementia are also summarized in the Figure.

Conclusions: We observed large differences in risk for MCI/probable dementia associated with the presence vs. absence of NC plaques, but the significance of this finding may be uncertain due to the small number of incident cases of cognitive impairment. Nonetheless, our observations indicate the need to study NC plaque as a novel and potentially more relevant marker of vascular health in future studies of cognitive impairment in hypertensive adults.

PO1796

Associations of CKD with Dementia Before and After Transient Ischemic Attack and Stroke in a Population-Based Cohort Study

Background: Individuals with chronic kidney disease (CKD) appear to have a greater risk of developing cognitive disorders than the general population. Both vascular and neurodegenerative hypotheses have been proposed to underlie this cognitive burden. To explore the vascular hypothesis further, we investigated the association between CKD and dementia before and after transient ischaemic attack (TIA) and stroke.

Methods: In a prospective, population-based cohort study of TIA and stroke (Oxford Vascular Study; 2002-2012), pre-event and new post-event dementia were ascertained through direct patient assessment and follow-up for 5 years, supplemented by review of hospital/primary care records. Associations between pre-dementia and CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73 m²) were examined using logistic regression, and between post-event dementia and CKD using both Cox and competing risk regression models, adjusted for age, sex, education, cerebrovascular burden (stroke severity, prior stroke, white matter disease), diabetes mellitus, and dyslipidaemia.

Results: Among 2305 TIA/stroke patients (median [IQR] age, 77 [67-84] years, 1174 [51%] male, 688 [30%] TIA), 1174 (50.9%) had CKD. CKD initially appeared to be associated with both pre-event (odds ratio [OR], 2.04 [95% CI, 1.52-2.72]; P<0.001) and post-event dementia (hazard ratio [HR], 2.01 [95% CI, 1.65-2.44]; P<0.001), however, these associations attenuated and became non-significant after adjustment for the above covariates (OR=0.92 [0.65-1.31]; P=0.65 and HR=1.09 [0.85-1.39]; P=0.50). The results were similar when a competing risk model was used (subdistribution HR [SHR] = 1.74 [1.43-2.12; P<0.001; attenuating to 1.01 [0.78-1.33]; P=0.92 with complete adjustment).

CKD was more strongly associated with late (>1 year) post-event dementia (SHR=2.32, 1.70-3.17; P<0.001, particularly in the minor events subgroup (SHR=3.08, 2.05-4.64; P<0.001), but not significantly so after complete adjustment (SHR=1.53, 0.90-2.60; P=0.12).

Conclusions: In patients with TIA and stroke, CKD was not independently associated with either pre- or post-event dementia, suggesting that age, sex, education, and cerebrovascular burden may play a more important role in the relationship than renal-specific neurodegenerative mechanisms.

Background: Chronic kidney disease (CKD) is common in patients with peripheral artery disease (PAD), and both are associated with poor cardiovascular (CV) outcomes. Platelets drive PAD pathogenesis and mediate atherosclerosis. Platelet function in CKD and the related CV risk is unclear. We investigated relationships between CKD, platelet activity, and incident CV events in a cohort of patients with PAD.

Methods: The Platelet Activity and Cardiovascular Events (PACE) study enrolled 289 patients with PAD undergoing lower extremity revascularization (LER). CKD was defined as eGFR < 60 mL/min/1.73m² by the CKD-EPI equation. We measured platelet activity via light transmission aggregometry (LTA) in response to submaximal ADP, collagen, serotonin, epinephrine, and arachidonic acid (AA) prior to LER, and followed patients for a median of 18 months. The primary clinical endpoints were myocardial infarction (MI) and a composite of major adverse CV events (MACE; MI, stroke, death).

Results: There were 113 (40%) patients with and 172 (60%) without CKD. Patients with CKD (vs. non-CKD) were older and more likely to be female, Hispanic, have diabetes, heart failure, and critical limb ischemia (P < 0.05 for each). There were no significant differences in prevalent coronary artery disease or use of antithrombotic therapy between groups. Platelet aggregation in response to submaximal agonist stimulation had a 25% and 12% mediating effect on the association (1.9 [1.2-3.3]; P = 0.01) than those without CKD. Platelet aggregation in response to submaximal ADP, serotonin, epinephrine, and AA was elevated in the CKD group (Figure). After multivariable adjustment, patients with CKD were at greater risk of MI (aHR 2.2 [95% CI: 1.02-4.9]; P = 0.045) and MACE (1.9 (1.2-3.3); P < 0.01) than those without CKD. Platelet aggregation in response to submaximal agonist stimulation had a 25% and 12% mediating effect on the association of CKD with MI and MACE, respectively.

Conclusions: In patients with PAD, CKD was associated with increased platelet activity and CV events. Heightened platelet activity is an important mechanism underlying increased CV risk in CKD.

Conclusions: Plasma VAP-1 levels had the positive relationship with circulating levels of CV pathology markers and LV diastolic dysfunction. Higher VAP-1 levels were also associated with an increased risk of incident CV events and cardiac events in HD patients. Our results indicate that VAP-1 help clinicians identify those at high risk of CV events.

Circulating Neprilysin Level Predicts the Risk of Cardiovascular Events in Hemodialysis Patients

Hyeon Seok Hwang, Jin-sug Kim, Yang gyun Kim, Yu ho Lee, Jong-Young Lee, Shin-Young Ahn, Ju young Moon, Sangho Lee, Kyung hwan Jeong.

Background: Neprilysin inhibition has demonstrated impressive benefits in heart failure treatment, and is the current focus of interest in cardiovascular (CV) and kidney diseases. However, the role of circulating neprilysin as a biomarker for CV events is unclear in hemodialysis (HD) patients.

Methods: A total of 439 HD patients from the K-cohort were enrolled from June 2016 to April 2019. The plasma neprilysin level and echocardiographic findings at baseline were examined. The patients were prospectively followed up to assess the primary endpoint (composite of CV events and cardiac events).

Results: Plasma neprilysin level was positively correlated with left ventricular (LV) mass index, LV end-systolic volume, and LV end-diastolic volume. Multivariate linear regression analysis revealed that neprilysin level was negatively correlated with LV ejection fraction (β = -2.14; p = 0.013). The cumulative event rate of the composite of CV events was significantly greater in neprilysin tertile 3 (3 β = 0.049). Neprilysin tertile 3 was also associated with an increased cumulative event rate of cardiac events (p = 0.016). In Cox regression analysis, neprilysin tertile 3 was associated with a 2.61-fold risk for the composite of CV events (95% confidence interval [CI], 1.37-4.97) and a 2.72-fold risk for cardiac events (95% CI, 1.33-5.56) after adjustment for multiple variables.

Conclusions: Higher circulating neprilysin levels independently predicted the composite of CV events and cardiac events in HD patients. The results of this study suggest the importance of future studies on the effect of neprilysin inhibition in reducing CV events.
PO1802
Kidney Function Trajectory Following Left Ventricular Assist Device Implantation
Carl P. Walther,1 Julia Benoit,2 Harveen Lamba,1 Sankar D. Navaneethan,1
1Baylor College of Medicine, Houston, TX; 2University of Houston, Houston, TX.

Background: LVADs have variable effects on kidney function. Identification of distinctive eGFR trajectory groups after LVAD placement, by applying unsupervised techniques to longitudinal eGFR measures, may enable insights into diverse pathophysiology.

Methods: From a national cohort, we identified persons who underwent isolated, primary continuous flow LVAD implantation in the US, 2016-17. eGFR values from pre-LVAD implantation to 12 months post were used. Latent class mixed models using cubic splines were applied to derivation and validation subsets, and models with 2-9 distinct groups were evaluated to find the optimal number.

Results: In the cohort (3,461 in derivation subset, 1,154 in validation), we identified 5 distinct trajectory groups. The 2 largest groups (1,2) are similar to previously reported cohort averages, with early eGFR increase followed by decline, but differed by baseline eGFR. Three smaller groups (3-5, ~15% of the cohort) demonstrated novel trajectories: group 3 had early worsening with sustained low kidney function; 4 had early and sustained eGFR improvement, and 5 had substantial eGFR variation. These groups differed in baseline factors (groups 3 and 4 had the most pre-LVAD acute dialysis, 4 and 5 the most cardiogenic shock) and outcomes (groups 2 and 4 had the highest survival, 3 and 5 had the lowest).

Conclusions: Novel eGFR trajectories after LVAD implantation were identified in a national cohort. Group 4, with early and sustained increase in eGFR, may reflect type 1 cardiorenal syndrome. Group 3 may reflect chronic kidney disease with early complications, and group 5 may reflect intact kidney parenchyma but post-LVAD right ventricular failure. These results demonstrate the feasibility of identifying previously unobserved heterogeneity in kidney outcomes. The novel trajectory groups may reveal potential for tailored care, in addition to pathophysiologic insights.

Which Loop Is Best? Comparing the Effect of Loop Diuretic Prescribing on Mortality and Heart Failure Readmission
Arti V. Virkud,1 Abhijit V. Kshirsagar,2 Patricia Chang,3 Michele Jonsson Funk,1 Jessica K. Edwards,1 Michael R. Kosorok,1 Emily Gower,1 University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; 2University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Background: Loop diuretics are a mainstay of heart failure (HF) management. While furosemide is most commonly prescribed, torsemide and bumetanide are increasingly being prescribed, possibly due to their superior bioavailability. Few trials or real-world evidence studies have compared the effectiveness of prescribing these loop diuretics while adequately addressing critical study design biases.

Methods: We identified beneficiaries initiating the study loop diuretics by using an active comparator, new-user cohort design and Medicare claims data from 2007-2017. We estimated 1-year risks of death and a composite outcome (HF readmission/death) using inverse probability of treatment weighting to adjust for relevant confounders. We calculated a dose equivalency based on furosemide to adjust for disease severity.

Results: We identified 45,310 furosemide, 1,148 torsemide, and 1,630 bumetanide new users. In the total weighted population, 24.3% had a reduced ejection fraction, 27.1% had CKD (≥ Stage 2), with a mean age of 80.1 years and a mean furosemide dose equivalent of 50.8 mg/mL. The 1-year risk of death across all study loop diuretics was similar (19.9%-20.6%), whereas the risk of the composite outcome was more varied (29.1%-32.0%). The 1-year risk difference (95% CI) of the composite outcome was -2.9% (-6.2, 0.4) for torsemide vs. furosemide and -1.1% (-3.8, 1.6) for bumetanide vs. furosemide.

Conclusions: Among Medicare beneficiaries, the risk of HF readmission/death varies meaningfully with torsemide having a reduced risk compared to other study loop diuretics. This study leverages claims data and causal methodology to generate a less biased and more generalizable estimate than previous studies. While additional trial and real-world evidence studies are needed, this study suggests initial loop diuretic prescription after HF hospitalization may produce long-term differences in risk of death and HF readmission.

PO1804
Diuretic Resistance in Acute Decompensated Heart Failure with Preserved vs. Reduced Ejection Fraction
Akash Sharma, Rahul Patel, Chakradhar Velagapudi, Shweta Bansal. The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Background: Loop diuretic resistance (DR) is one of the common causes of inadequate decongestion in patients hospitalized with acute decompensated heart failure (ADHF). However, DR has not been characterized in patients with HF with preserved ejection fraction (HFpEF).

Methods: In a post hoc analysis of a pilot study which evaluated the role of high-dose spironolactone in hospitalized ADHF patients with DR, we analyzed the prevalence and potential pathophysiologic factors of DR in HFpEF (n=20), and compared those with HF with reduced EF (HFrEF) (n=27). DR was defined as weight loss<1lb/day despite intravenous furosemide>160mg/day (at least one dose of 80mg/day) or no change in weight in the first 48H post admission. We calculated a dose equivalency based on furosemide to adjust for disease severity.

Results: DR was observed in 10 (50%) of HFpEF subjects as compared to 10 (37%) of HFrEF subjects (p=ns). In general, patients with HFpEF were older, more female and obese, had more diabetes, higher systolic blood pressure and lower brain natriuretic peptide compared to HFrEF (Table 1). There was no difference in clinical presentation, eGFR and pulmonary arterial systolic pressure in DR-HFpEF vs. DR-HFrEF. However, urine sodium/potassium ratio, plasma renin activity and aldosterone were lower in DR-HFpEF as compared to DR-HFrEF, though still higher than diuretic responsive-HFpEF patients (Table 1). Weight loss in response to high-dose spironolactone was similar in DR-HFpEF and HFpEF (14±8.6 vs.14±13 lb).

Funding: NIDDK Support
Conclusions: Although the comparisons were not statistically significant due to small sample size; the results suggest that DR is more prevalent in HFpEF. Despite similar clinical features of congestion and response to high-dose spironolactone, a state of reduced neurohormonal activation points that additional factors might be contributing to DR in HFpEF compared to HFrEF patients.

Renal Outcomes and Safety of Angiotensin Receptor Neprilysin Inhibitors in Patients with Heart Failure: A Meta-Analysis
Rima N. Abou arkoub,1 Thomas Mavrakas,1 Amy Bergeron,2 Abhinav Sharma,1 Ahsan Alam.1 1McGill University Health Centre, Montreal, QC, Canada; 2McGill University Health Centre Glen Site McConnell Resource Centre Medical Library, Montreal, QC, Canada.

Background: Angiotensin receptor neprilysin inhibitors (ARNIs) are an effective treatment for heart failure. However, their safety profile compared with angiotensin converting enzyme-inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) with respect to renal outcomes has not been clearly established.

Methods: We conducted a literature search of MEDLINE, Cochrane library, Embase, and clinical trials registries using relevant search terms (last search date May 7, 2021). The primary renal outcome was kidney function decline and the safety outcome was hyperkalemia. Only studies with at least 12 weeks of follow up were included in the renal outcome analysis to better capture CKD.

Results: Ten randomized controlled trials were eligible for inclusion (n=22,174 participants). ARNIs were associated with a lower risk of kidney function decline compared with ACEIs or ARBs: RR 0.65 (95%CI 0.53-0.81). The risk of hyperkalemia was similar in both treatment groups: RR 0.96 (95%CI 0.81-1.13).

Conclusions: ARNI use in patients with heart failure is associated with a lower risk of kidney function decline and a similar risk of hyperkalemia compared to ACEIs or ARBs.
PO1806

Hydralazine-Isosorbide Dinitrate Associated with Reduced All-Cause and Cardiovascular Mortality in Patients on Dialysis with Heart Failure

Qandeel H. Soomro,1 Thomas Mavraganis,2,3 David M. Charytan,1,2 1NYU Langone Health, New York, NY; 2McGill University, Montreal, QC, Canada; 3Brigham and Women’s Hospital, Boston, MA

Background: Heart failure (HF) is an important contributor to the increased cardiovascular (CV) mortality incidence in ESKD. Therapies targeting HF’s unique pathophysiology in ESKD are lacking. Hydralazine-isosorbide dinitrate (H-ISDN) targets reduced nitric oxide bioavailability and could improve CV mortality in ESKD

Methods: Adult patients with HF on maintenance dialysis between January 2011 and December 31, 2016 were identified using the United States Renal Data System. There were 6306 patients with at least one prescription for H-ISDN and 75,851 non-users. The primary outcome was death from any cause. Secondary outcomes included cardiovascular death and sudden death. Treatment effects were estimated using stabilized inverse probability weights in Cox proportional hazards regression. Because H-ISDN has been shown to improve outcomes in Black HF patients, we investigated effect modification by race

Results: Age was similar in H-ISDN users (66 ± 13 years) and non-users (69 ± 13 years) with 50% and 51% men, respectively. H-ISDN (51%) users were more likely to be of Black race than non-users (27%). Dialysis vintage was longer in H-ISDN (25 months) users compared with non-users (15 months). All characteristics were well balanced in weighted models. Risks of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared with non-users (15 months). All characteristics were well balanced in weighted models. Risks of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared with non-users (15 months). All characteristics were well balanced in weighted models. Risk of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared with non-users (15 months).

Conclusions: To our knowledge, this is the first analysis of the impact of H-ISDN on mortality in ESKD. Our results suggest that combination H-ISDN improves survival in dialysis patients with HF

PO1807

Long-Term Outcomes After Renal Revascularization for Atherosclerotic Renovascular Disease in the ASTRAL Trial

Philip A. Kalra,1,2 Darren Green,1,2 Natalie Ives,1 The ASTRAL trial investigators ‘Salford Royal Hospital, Salford, United Kingdom; ‘The University of Manchester, Manchester, United Kingdom; ‘University of Birmingham, Birmingham, United Kingdom

Background: The Angioplasty and Stenting for Renal Artery Lesions (ASTRAL) trial randomized 806 patients with atherosclerotic renal artery stenosis (RAS) between 2000-2007, randomised 1:1 to medical therapy with or without renal artery stenting. The initial results were presented in 2009 at median follow-up 34.6 months when no benefit of revascularization to renal functional outcome or cardiovascular events (CVE) were evident. Surviving patients remained under follow up until 2014.

Methods: All available data were analysed to assess whether there was a later impact of revascularization on renal function, CVE and survival, including a composite outcome of renal and CVE outcomes and death (as used in the CORAL trial). Pre-specified sub-group analyses of different categories of renal function, renal length, prior rapid deterioration in kidney function, and severity of RAS. Further post-hoc analysis of patients with severe RAS (defined as bilateral 70% or > 70% RAS in a solitary kidney = global renal ischemia), those with/without proteinuria and a per protocol analysis were performed.

Results: The mean age of the entry population was 70.5 years, mean eGFR 40 ml/min/1.73m², with mean RAS 76% and blood pressure 150/76 mmHg. 83% of the revascularization group underwent attempted stenting. Median follow-up was 56.4 months with 108 patients lost to follow up or withdrawn; 50% of the evaluable population had died, 14% had received RRT and 40% had suffered a 1st CVE. No benefit of revascularization was observed for any outcome in the intention to treat and per protocol analyses, either in the whole population or the pre-specified sub-groups. In the severe RAS sub-group (163 patients) revascularization was associated with a hazard ratio (HR) of 0.74 (0.54-1.01; p=0.062) for the composite renal and CVE outcome and an HR of 0.70 (0.49-1.0) for death (p=0.051).

Conclusions: The long-term follow-up of the ASTRAL trial population showed no overall benefit of renal revascularization to renal and CVE outcomes. It has been highlighted that a proportion of the population had lower risk mild-moderate RAS. The long-term outcomes in patients with severe RAS (global renal ischemia) point to a potential benefit of stenting that may be worthy of further study in a more selected population.

PO1808

Revascularization in Atherosclerotic Bilateral Renal Artery Stenosis

Sana J. Shaikh, Bilal Al-Khalil, Ling Chen, Anitha Vijayan. Washington University in St Louis, St Louis, MO.

Background: Patients with B/L RAS, if found to have worsening renal failure, refractory HTN or recurrent CHF, are often referred for revascularization despite limited evidence. We hypothesized that revascularization plus medical management prevents adverse outcomes in patients with B/L RAS.

Methods: This was a retrospective single-center cohort study in patients with B/L RAS, RAS in a solitary kidney, U/L RAS with an atrophic or ~1cm smaller contralateral kidney or, RAS in a U/L functioning kidney. We excluded patients with non-atherosclerotic RAS, renal artery dissection, atheroembolism and renal transplantation. The primary outcome was Major Adverse Kidney Events (MAKE) at 3 mo. Secondary outcomes were renal events, changes in BP, hospital admissions and all-cause mortality at 1 yr. We used the Chi-square test for the primary outcome and the Chi-square test or two-sample t-tests for the secondary outcomes.

Results: 155 patients were included in the study. There were no differences in the baseline characteristics of the intervention and control groups, except for higher number of smokers in the control cohort (Table 1). There was no difference in MAKE between the 2 groups at 3 mo. At 1 yr, there were fewer admissions for CHF in the intervention group (Table 2). There were no other major differences in secondary outcome measures.

Conclusions: Revascularization for B/L RAS does not improve renal outcomes, BP control or mortality, but may prevent admissions for CHF.

Hypertension in a Young Female: A Common but an Intriguing PO1809

Introduction: Renal artery stenosis accounts for about 1-10% of the 58 million people with hypertension worldwide. All major trials conducted so far on RAS found no benefit with renal artery stenting. Here we report a case of resistant hypertension in a young female who subsequently found to have bilateral renal artery stenosis and ultimately benefited from unilateral stenting.

Case Description: A 35 yrs female, married, with no comorbidities, presented with 03 months history of intermittent episodes of throbbing headache along with dizziness, palpitations, fatigue. Examination revealed BP - 160/100 with no postural drop, and regular heart rate. Her baseline investigations (including blood complete picture, LFTs, RFTs, urine routine examination, PT/PTTK were Normal. Pulse with no radio-radial, radio-femoral delays. Her baseline investigations (including blood complete picture, LFTs, RFTs, urine routine examination, PT/PTTK were Normal. She was put on four different groups of anti hypertensives including a beta blocker, a calcium channel blocker, thiazide diuretic and an angiotensin receptor blocker but her blood pressure did not settle. Further investigations revealed raised renal artery flows on Doppler ultrasound. She was put on four different groups of anti hypertensives including a beta blocker, a calcium channel blocker, thiazide diuretic and an angiotensin receptor blocker but her blood pressure did not settle. Further investigations revealed raised ESR but other tests including autoimmune screening, 2DECHO all negative-CT aortogram revealed a non visualised shrunken right kidney with attenuated right renal artery and a vascular kink in proximal left renal artery. DTPA scan showed estimated GFR of 66.7ml/min with 97% contribution by left kidney and 3% contribution by right kidney. So based on renal imaging findings, a final diagnosis of bilateral renal artery stenosis was made. Percutaneous transluminal angioplasty with stenting to proximal left renal artery was done. She was given dual antiplatelet along with a statin post operatively and advised monthly follow up. Currently she is normotensive of bilateral renal artery stenting has shown propitious results in few patients but not to the degree many have expected. More RCTs should be contemplated to scrutinize the clinical predictors of renal artery re-intervention. Rates of other adverse events at 3 years included new onset end stage renal disease (2.4%), cardiovascular death (1.6%) and myocardial infarction (0.8%). Mean change in eGFR from baseline to 3 years was -6.5±1.7 mL/min/1.73m². Changes in mean 24-hour and office BP from baseline to 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years. In this analysis, we present safety and efficacy data for patients who received RDN with the multi-electrode Symplicity Spyral catheter in GSR.

Results: Currently there are 641 patients treated with the Symplicity Spyral catheter (baseline office BP 168±25 mmHg, 4.6±1.5 prescribed anti-hypertensive medication classes, mean age 60.5±12.5 years, 56.9% male, 42.5% history of cardiac disease, 37.2% type II diabetes mellitus, and 19.1% renal insufficiency with eGFR<60 mL/min/1.73 m²). After 1 year, there were no cases of new renal artery stenosis >70% or renal artery re-intervention. At 1 year, eGFR, office and ambulatory blood pressure (BP) levels were measured at baseline, 3, 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years.

Conclusions: Office and 24-hour BP were significantly reduced from baseline at all follow up time-points after RDN with the Symplicity Spyral catheter, with no instances of renal artery re-intervention.

Funding: Commercial Support - Medtronic

PO1810

Long-Term Safety and Efficacy of Renal Denervation with the Symplicity Spyral Catheter in the Global SYMPLICITY Registry

Methods: We conducted a prospective study including 41 patients with essential hypertension. ERD was performed using Simplicity Probe or Spyral. Blood pressure (BP) was evaluated using 24-hour ambulatory BP monitoring. Echocardiography was performed using HDI 5000. Clinical and biochemical variables were explored.

Results: A total of 41 patients were included. Overall, 53.7% (n=22) were females with a mean age of 63.6±7.5 years, BMI 30.8±5.2 kg/m², 17.1% (n=7) had an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m² and 68.3% (n=28) diabetes. Proteinuria (>300mg/g) was found in 24.4% (n=10) of the patients. A significant reduction in the number of antihypertensive drugs being taken was found after 5 years follow-up (p<0.001). Despite this reduction, a significant reduction in diastolic blood pressure
DDP (p=0.001) was found, but not in systolic blood pressure (SBP) (p=0.08). Also left ventricle mass index (LVMI) reduced significantly (p=0.0001) and a reduction of acute elevation of left ventricle filling pressure (LVFP) was detected using E/e’ (p=0.0001).

There was a worsening of eGFR (p=0.0001) as expected by the progressive worsening of kidney function. We have found a non significant reduction in proteinuria (p=0.07).

In the group with a reduction in proteinuria, it was not associated with BP and only increased when using multivariate analysis. In a multivariate analysis, the reduction in the number of antihypertensive drugs of the LVMJ, SBP and DBP were not related with age, gender, body mass index and proteinuria.

To control our specification, we managed to reduce the number of anti-hypertensive drugs and still reduce patients DBP with RDN. Also RDN showed benefits in reducing LVMJ and LVFP. Reduction of proteinuria, when present, was independent of BP and anl VLMJ. There was a worsening of kidney function as expected in a long term follow-up. RDN has been shown to be an effective mean of treating essential hypertension.

PO1812 Potential Benefits of Asymptomatic Hypermucearia Treatment: A Systematic Review and Meta-analysis of Randomized Control Trials

Dhir N. Gala,1 Kireillos S. Said,2 Nuhla A. El-Shabat,3 Allison Parrill,1 Hadeer S. Mohamed,1 Nada Abdelhalim,4 Mostafa A. Amin,3 Hassan S. Abdallah,5 Majid Alahmar,1 Nguyen Tien Huy,5 Mohammed Abdel Gawad,1 1American University of the Caribbean School of Medicine BV, Cucpey, Sint Maarten (Dutch part); 2Alexandria University Faculty of Medicine, Alexandria, Egypt; 3Al-Azhar University Faculty of Medicine, Cairo, Egypt; 4University of Istanbul, Turkey; 5Cairo University Ksar Alainy Faculty of Medicine, Cairo, Egypt; Mansoura University Faculty of Medicine, Mansoura, Egypt; Gaward Nephrology Clinic, Alexandria, Egypt; 6School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan.

Background: Asymptomatic hypermucearia is strongly associated with an increased risk for chronic kidney disease and cardiovascular conditions. However, many current guidelines suggest no medical treatment for patients with asymptomatic hypermucearia. We aim to systematically analyze randomized control trials with serum uric acid-lowering medication in the treatment of patients with asymptomatic hypermucearia.

Methods: A literature review of seven medical databases (Scopus, Clinical Gov, Pubmed, Web of Science, Google Scholar, VHL, and GHL) for randomized controlled trials related to the treatment of asymptomatic hypermucearia was conducted. Bias was evaluated using the Cochrane Risk of Bias 2 tool. Standard differences of means of variables of interest were combined across studies to compare the effect of uric acid lowering treatment versus control. Using the Comprehensive Meta-Analysis-program, fixed-effects and random heterogeneity model, forest plots were created for each variable of interest.

Results: Analysis of eleven studies showed significant decreases in creatinine [95% CI: -0.599, -0.005], systolic blood pressure [-0.277 (95% CI: -0.5, -0.055)], and serum uric acid [-1.972 (95% CI: -2.145, -1.800)] in the treatment versus control group. Furthermore, significant increases in estimated glomerular filtration rate (eGFR) as sensitivity analysis [0.228 (95% CI: 0.027, 0.428)], and high sensitivity C-reactive protein [0.588 (95% CI: 0.205, 0.971)] were observed in the treatment versus control group. Lastly, non-significant increases in eGFR [-0.507 (95% CI: -1.852, 0.838)], diastolic blood pressure [-0.132 (95% CI: -0.638, 0.013)], while non-significant increases in hemoglobin A1C [0.394 (95% CI: 0.052, 0.813)] and fasting glucose level [0.117 (95% CI: -0.145, 0.380)] were found in the treatment versus control group.

Conclusions: This study showed that uric acid lowering treatment of patients with asymptomatic hypermucearia may be beneficial in those with elevated creatinine and blood pressure, and decreased eGFR.

PO1813 Urinary Glycogen Synthase Kinase 3β Level Predicts the Progression of Hypertensive Nephrosclerosis

Linfeng Zheng, Cheuk-Chun Szeto. Department of Medicine & Therapeutics and Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Hypertensive nephrosclerosis (HTN) is a serious consequence of prolonged hypertension. In the United States, HTN is the second most common cause of end-stage kidney disease. Recently, emerging evidence suggests that glycogen synthase kinase (GSK) 3β is a key factor in the progression of diabetic kidney disease (DKD). However, it remains uncertain whether the role of GSK3β is specific for DKD or a generic mediator of renal damage irrespective to the underlying cause.

Methods: We enrolled patients with biopsy-confirmed HTN patients. Their GSK3β level in urinary supernatant was measured by conventional ELISA, and GSK3β mRNA level in urinary sediment was measured by quantitative polymerase chain reaction. The results were compared to the baseline kidney function and the subsequent risk of renal function deterioration.

Results: The average urinary GSK3β level was 212.67 ± 47.74 ng/mL by conventional ELISA, which closely correlated with its mRNA level in urinary sediment (r = 0.821, P<0.0001). Urinary GSK3β level significantly correlated with baseline glomerular filtration rate (GFR) (r = 0.316, P=0.010) and the slope of GFR decline (r=-0.397, P=0.033). Patients with a high urinary GSK3β level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level (p=0.022 and p=0.044, respectively). Similarly, urinary GSK3β mRNA level also significantly correlated with baseline GFR (r = 0.582, P<0.0001) and the slope of GFR decline (r=-0.402, P=0.022). Patients with a high urinary GSK3β mRNA level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level (p=0.022 and p=0.044, respectively).

Conclusions: These results demonstrated that urinary GSK3β level correlates with the rate of kidney function loss in patients with biopsy-proved HTN, and urinary sediment GSK3β mRNA level correlates with baseline GFR and urinary GSK3β mRNA level.

PO1814 Deletion of the Dopamine D2 Receptor in the Renal Proximal Tubule Increases Blood Pressure on Low-Salt Diet and Decreases Blood Pressure on High-Salt Diet: A Case of Inverse Salt Sensitivity

Laurenzo D. Asico, Shawn C. Moore, Pedro A. Jose, Ines Armando. The George Washington University School of Medicine and Health Sciences, Washington, DC.

Background: The dopamine D2 receptor (D2R) in the kidney is important in maintaining renal blood pressure (BP) and preventing inflammation and tissue injury. D2R deletion appears to be a general protective marker than urinary GSK3β level by ELISA. Our results suggest that GSK3β is a generic mediator for the progression of chronic kidney disease and is not specific for DKD.

Methods: Clinical funding Support, Government Support - Non-U.S.

PO1815 Renal Proximal Tubule-Specific Activation of the NKA/Src Receptor Complex in the Mouse: Evidence for Sexual Dimorphism

Background: The Na+K+ATPase (NKA) is expressed in proximal convoluted tubule cells. The NKA catalyzes the exchange of Na+ for K+ in renal epithelial cells, and affects renal sodium and fluid reabsorption, blood pressure, and renal excretion of drugs. The renal NKA is predominantly comprised of α1, both with intact ion-powering properties. There is also pharmacological evidence that, through a Src-mediated mechanism, Na/K-ATPase c' serves a counteracting natriuretic receptor function that reduces NKA- and NHE3-mediated transport, leading to decreased transepithelial Na+ flux.

Methods: To test this genetically, we generated NKA+/- mice and mice lacking D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. To study the function of D2R in the renal proximal tubule, we generated D2R−/− mice that do not lack D2R only in the renal proximal tubule and D2R−/+ mice that do not have the deletion. Mice were genotyped for D2R+/− and a smaller amplicon representing the Cre deletion mutant. We studied male mice on normal salt (NS; 0.4% NaCl), high (HS; 4% NaCl), and low (LS; <0.05% NaCl), and low (LS; <0.05% NaCl).

Results: On NS diet, male D2R+/− mice had slightly higher BP, measured under anesthesia, than male D2R+/+ mice (106.1 ± 101.2 mmHg, n=15/group; P<0.05). On HS diet D2R−/− mice had lower BP than D2R+/− mice (106.3 ± 107.2 mmHg; P=0.04; n=12) but on LS diet D2R+/− mice had higher BP than D2R−/− mice (126.5 ± 103.4 mmHg; P=0.01; n=7). Both the decrease in BP on HS diet and the increase in BP on LS diet, relative to BP on NS diet, were confirmed by telemetry in conscious mice. These data indicated that D2R deletion only in the renal proximal tubule impairs the normal responses to changes in salt intake. On NS diet the renal Na+K+ATPase and NCC expression were higher in D2R−/− mice than in D2R+/+ mice. On HS diet NHE3 and NCC expression were lower in D2R−/− mice than in D2R+/− mice (NHE3: 0.70±0.02 vs 1.00±0.03 fold-change; P<0.05, n=5–group; NCC: 0.5±0.03 vs 1.00±0.09 fold-change; P<0.05) while Na+/K+ATPase was similar in both groups. On LS diet NHE3, Na+/K+ATPase, and NCC expression were higher (P<0.05) in D2R−/− than in D2R+/− mice.

Conclusions: There are marked differences in the response to changes in dietary salt intake on BP and renal expression of sodium exchanger/transporter/pump in mice lacking D2R only in the renal proximal tubule that is accompanied by increased inflammation and fibrosis. The presence of the D2R family of receptors in the renal proximal tubule, and the presence of D2R variants, D2B and rs26725 and rs26777, which decrease D2R protein/ function, is associated with inverse salt sensitivity. Funding: Other NIH Support - NHI R01 grants.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: These observations are compatible with a sexual dimorphism in the NKA signaling in the RPT and its potential impact on sex-based differences in renal physiology and pathophysiology.

PO1816
Sex-Dependent Regulation of the WNK-NCC Pathway via Ubiquitination in Response to Dietary High Salt Intake in Young Sprague-Dawley Rats
Kiyoung Kim, Mohammed Z. Ferdaus, Richard D. Wainford. Boston University School of Medicine, Boston, MA.

Background: The thiazide-sensitive Na+/Cl- cotransporter (NCC), located in the apical membrane of distal convoluted tubule, fine-tunes sodium reabsorption and regulates blood pressure. The NCC is downregulated by high salt intake in normotensive salt resistant rats. These studies investigated the potential mechanistic pathways by which NCC is degraded in response to high salt intake in male and female Sprague-Dawley (SD) rats.

Methods: 3-month-old normotensive male and female SD rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days. On day 21, the kidneys were collected and ~200 mg of the renal cortex was used to measure the expression of total NCC, WNK1, WNK4, Nedd4-2, Sortilin, KLHL3, and calcineurin via immunoblotting (N=5–6/group).

Results: A 21-day HS diet evokes the suppression of total NCC protein expression in young normotensive male and female SD rats. A HS diet downregulated WNK1 in male but not female SD rats. A HS diet suppressed the expression of the full-length and short WNK4 variants in female SD rats only. There was a trend for HS to increase Nedd4-2 expression in male SD rats (P=0.06), in contrast female rats downregulated Nedd4-2 in response to HS. The expression of sortilin, KLHL3, and calcineurin was suppressed by a HS diet in female rats only.

Conclusions: These data suggest that in response to a diet HS young female SD rats exhibit greater ubiquitin-dependent proteolytic and lysosomal degradation of the NCC than young male SD rats to regulate sodium homeostasis and blood pressure via a WNK-dependent signaling pathway.

Table 1: NS, 0.6% NaCl; HS, 4% NaCl. *P<0.05 vs. respective NS Group.

PO1817
Renal Denervation Improves Renal Afferent Nerve Activity After High Sodium Intake
Kristina Rodionova,1 Tilmann Ditting,2 Laura Woppeper,1 Karl F. Hilgers,1 Peter Linz,1 Nada Cordacsi,1 Christian Ott,2 Mario Schiffer,1 Roland E. Schmieder,1 Kerstin U. Amann,3 Roland Veelken,1 1Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertoniologie, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität - Nürnberg, Erlangen, Germany; 3Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany.

Background: The role of renal sympathetic nerve activity increases remains to be determined.

Methods: Respective groups of rats were put on HS containing 8% NaCl or a normal diet. Two groups (HS, controls) received empagliflozin 20 mg/kg BW/day orally. Rats were labeled with DiI. In vivo, innervations of dorsal root ganglion neurons (DRG T11-L2) were investigated immunohistochemically using current clamp mode to assess action potential generation during current injection (neurons were characterized as tonic highly active (≥5 action potentials, AP) and phasic less active neurons (≤5 AP upon stimulation).

Results: In neurons from rats on HS, the relation of tonic highly active neurons to less active phasic neurons shifted consistently towards phasic units (63.8% tonic neurons in controls vs. 42%* on HS, *p<0.05, -t-test). However, continuous treatment with empagliflozin preserved the proportion of tonic neurons as in controls (67.9% on HS with concomitant administration of empagliflozin). In controls, empagliflozin did not affect the proportion of tonic to phasic neurons (63.8% tonic neurons in controls vs. 67.9% on HS & empagliflozin, p=0.7, -t-test). Blood pressure and heart rate were not altered by HS or treatment with any chosen dose of empagliflozin.

Conclusions: In rats, chronically elevated sodium intake (8% NaCl) reduced the sensitivity and stimulability of renal afferent DRG neurons. Under these circumstances, concomitant treatment with the SGLT2 inhibitor empagliflozin preserved the function of renal afferent DRG neurons. SGLT 2 inhibitors may help to treat dysfunction of renal innervation in cardiovascular disease.

PO1819
The Role of Histaminergic System Components in Renal Function During Salt-Sensitive Hypertension
Frederick D. Spires,1,2 Mark Dornan,1 Ryan Schibalski,1,2 Samantha M. Perez,2 Mikhail Fomin,2 Morgan J. Spicer,1 Sergey N. Arkhipov,1 Callie A. Clarke,1 Thelma Amoah,2 Tengis S. Pavlov,3 Daria Ilatovskaya,1,2 Augustua University, Augusta, GA; 1Medical University of South Carolina, Charleston, SC; 3Henry Ford Health System, Detroit, MI.

Background: To 50% of hypertensive patients have salt-sensitivity (SS), a condition characterized with an increase in blood pressure in response to salt intake. The abnormal activation of the immune response is a major contributor to SS hypertension and renal injury. Histamine and its receptors (HRs) are a complex system of immunoregulators that have been linked to renal disease development. It is known that the Dahl SS rat fed a high salt diet develops hypertension accompanied with elevated levels of inflammatory factors. We hypothesized that HRs and associated enzymes contribute to renal disease progression during SS hypertension.

Methods: Male Dahl SS rats at 8 weeks of age were placed on either a 0.4% (normal salt; NS, control) or 4% (high salt; HS, hypertensive group) NaCl diet for 21 days to induce SS hypertension. An additional group of animals received 3 injections of ranitidine (HR2 blocker, 25 mg/kg) or salicylic acid (VHE, 2.5 mg/L) pre- and post- the HS challenge to test the effects of HR2 blockage on renal function.

Results: Using immunohistochemistry, we established the expression of all four HRs as well as histamine-metabolizing and catalyzing enzymes, along with the neuron with a pronounced expression in the glomerulus, proximal tubule and the distal tubules. Interestingly, we observed a decrease in histidine decarboxylase, and an increase in histamine N-methyltransferase in the kidney of HS diet fed rats, suggesting a shift in renal histaminergic tone. RAN treatment pre-HS resulted in a significant decrease in urine volume (1.89 ± 0.20 vs 1.60 ± 0.18 mL/100g, p=0.012, in VEH vs RAN groups respectively) and water consumption (14.3 ± 2.25 vs 11.9 ± 1.60 mL), along with elevated C1 excretion (728.4 ± 287.4 μmol vs 1107.8 ± 416.6 μmol). Post-HS RAN treatment yielded a significant increase in urine osmolality (1313.2 ± 319.7 vs 1659.5 ± 359.2 μmol).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Thus far, we report a shift in the histaminergic tone toward less histamine production and release in Ang II-exposed diet rats fed a HS diet. Dahl SS rats are not protected with I2R blocker exhibit lower water consumption, reduced diuresis, and increased urinary osmolality.

POI820

Salt-Induced Blood Pressure Elevation in Females Is Associated with Increased Arachidonic Acid Metabolites

Jeanne A. Ishimwe, Annet Kirabo, Fernando Eljovitch, Jane F. Ferguson. Vanderbilt University Medical Center, Nashville, TN.

Background: Excess dietary sodium (Na+) intake is a major risk for salt-sensitive hypertension and cardiovascular disease. Several clinical trials have found that women are more salt-sensitive than men, but the contributing sex-specific mechanisms are poorly understood. Arachidonic acid (AA) and its metabolites play a role in the pathophysiology of hypertension. We hypothesized that women have greater blood pressure (BP) elevation in response to Na+ intake that is associated with higher AA metabolites than men.

Methods: Plasma AA metabolites were measured via a metabolomics analysis in volunteers who completed a validated 3-day food record to estimate dietary Na+ intake before the study visit where BP was measured. Based on the recommendations by the American Heart Association, we classified daily Na+ intake <2.3g as normal salt, and high salt for subjects consuming a 2.3g Na+. Spearman correlation was used to assess the relationship between sex, metabolic profile, and sex-specific hypertension (SH and DS).

Results: Women (n=81) displayed a stronger relationship between BP and Na+ intake than men (n=49) (r=0.372; p=0.001 vs. r=0.317; p=0.026). The relationship between Na+ intake and BP was stronger in white (n=46, r=0.4172; p=0.004) than in black (n=22, r=0.338; p=0.124) women and conversely stronger in black (n=32, r=0.307; p=0.034) than white (n=32, r=0.251; p=0.166) men. We measured plasma levels of palmitate and linoleate, both upstream of AA synthesis, AA, and Di-Hydroxyeicosatetraenoic acid (12-HETE) an AA metabolite. In subjects consuming a high Na+ diet (women 28, men 25) levels of linoleate (1.211 ± 0.330 vs. 0.869 ± 0.170, p=0.001), palmitate (1.155 ± 0.92 vs. 0.924 ± 0.233; p= 0.003), AA (1.119 ± 0.242 vs. 0.965 ± 0.201; p=0.015) and 12-HETE (1.329 ± 0.925 vs. 0.902 ± 0.520; p=0.0469) were higher in women. In contrast, no sex differences in any of these parameters were observed between men and women consuming a normal salt diet.

Conclusions: Our findings suggest that AA and its metabolites may account for sex and perhaps also racial differences in salt sensitivity of BP. Further study of AA and its metabolites may shed light on the mechanisms of the sex differences in salt sensitivity.

Gstm1 Genotype Affects Metabolic Response in Hypertension

Yves T. Wang, Nhu Nguyen, Thu H. Le. University of Rochester Medical Center, Rochester, NY.

Background: Glutathione S-transferases (GSTs) are a family of enzymes that detoxify electrophiles, including products of oxidative stress. In humans, GST μ-1 (GSTM1) has a common null allele variant, (GSTM1(0)), which has been linked to elevated oxidative stress in pathophysiological conditions and increased risk and/or accelerated progression of a variety of diseases. Recently, we reported that Gstm1 knockout (KO) mice had increased oxidative stress and augmented kidney injury in angiotensin II (Ang II)-induced hypertension (HTN).

Methods: Kidney tissue was obtained from 12-20 week old male wild-type (WT) and Gstm1 knockout (KO) mice at either baseline (no treatment) or following 4 weeks of Ang II-induced HTN via mini-osmotic pump at 1000 ng/kg/min. For each animal, a kidney was weighed, flash frozen, and sent to Metabolon for metabolomics analysis. Genotypes were determined using polymerase chain reaction (PCR) and genome-wide association

Results: Genotype between WT and KO mice, except for the expected loss of GSTm1 in Ang II-induced HTN did not elicit a significant compensatory upregulation of mRNA of other GSTs. It is likely other antioxidant pathways are upregulated based on the altered metabolite abundances. However, based on previous results in treated KO mice, any compensatory mechanism is insufficient to protect against the oxidative stress-induced kidney damage. Further research should be pursued to elucidate the oxidative stress-related specific substrates of GSTM1 that are not detected by other pathways.

HMGB-1 Activates Mineralocorticoid Receptor-Dependent Endothelial Cell Injury via Receptor for Advanced Glycation End Products

Tomoyuki Osuka,1 Seiji Ueda,1 Hajime Nagasawa,1 Teruyuki Okuma,1 Koji Sato,1 Takanori Matsui,2 Sho-ichi Yamagishi,3 Yuusuke Suzuki.1 Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; 2Showa University Faculty of Medicine, Shintomicho, Shinagawa-ku, Tokyo, Japan; 3Kurume University Faculty of Medicine, Kurume-shi, Japan.

Background: Endothelial dysfunction plays a central role in the pathogenesis of cardio-renal syndrome. High mobility group box-1 (HMGB-1) is a protein with various roles in different cellular compartments, and indirectly regulates the activity of transcription and DNA repair in the nucleus. On the other hand, during tissue damage, it is released into the extracellular environment as damage-associated molecular patterns (DAMPs). HMGB-1 is reported to be elevated in CKD patients and be involved in endothelial dysfunction through binding to toll like receptor (TLR) and receptor for advanced glycation end products (RAGE). In addition, we recently demonstrated that RAGE-mediated Rac1 activated mineralocorticoid receptor (MR) and resulted in podocyte damage. In the present study, we hypothesized that crosstalk between HMGB-1/ RAGE and Rac1-MR pathways could contribute to endothelial dysfunction in kidney diseases.

Methods: In the present study, we investigated whether HMGB-1 could activate Rac1-MR axis and induce endothelial injury in culture human umbilical vein endothelial cells (HUVECs) by assessing expression levels of genes for MCP-1 and cell adhesion factors (ICAM-1, VCAM-1) with or without administration of RAGE apatmer or MR blocker (exsaxerenone, 1μM).

Results: HMGB-1 supplementation significantly increased GTP-bound Rac1 and enhanced MR translocation into the nucleus in HUVECs. We also found that RAGE expression was enhanced by HMGB-1 and RAGE apatmer completely abolished Rac1 activation and MR translocation observed in HMGB-1 exposed HUVECs. HMGB-1 also upregulated MCP-1, ICAM-1, and VCAM-1 in HUVECs, all of which were significantly blocked by pretreatment of RAGE apatmer as well as MR blocker.

Conclusions: These results suggest that there may be a close relationship between HMGB-1/ RAGE axis and Rac1/ MR activation, thus contributing endothelial injury. Using RAGE apatmer or MR blocker could be novel therapeutic strategies against endothelial dysfunction in patients with kidney diseases.

Effect of Tochu Extract and Its Component Geniposidic Acid on Renal Hemodynamics and Hypertensive Renal Damage
Akiiro Tojo, Hiroshi Satonaka, Toshikio Ishimitsu. Dokkyo Medical University, Mibu, Japan.

Background: Aqueous extract of Eucommia ulmoides (Tochu) leaf is used as Tochu tea in Japan and has the effect of lowering blood pressure. We investigated the effects of Tochu extract and its component geniposidic acid on renal hemodynamics and hypertensive renal damage in Dahl salt-sensitive hypertensive rats (DS).

Methods: DS rats received 1% saline solution from 4 weeks of age. After the blood pressure reached 150 mmHg or higher at 9 weeks of age, the rats were treated with 1% saline solution (DSHS), or 1% saline added 0.5% Tochu extract (DSHS + T) or, 1% saline added 0.2% geniposidic acid (DSHS + G) for another 4 weeks. DS rats fed with tap water were used as controls (DSLS). At 13 weeks, renal plasma flow (RPF) was measured by renal clearance study, and immunostaining and PCR of NADPH oxidase, eNOS, sodium transporters and fibrotic factors were performed.

Results: Blood pressure was significantly increased in DSHS rats compared to DSLS rats (196 vs.144 mmHg, p<0.01), which was significantly decreased in DSHS + T rats (158 mmHg) and DSHS + G rats (162 mmHg). Vascular resistance of afferent arterioles was significantly increased in DSHS rats compared to DSLS rats, and was decreased in both DSHS + T and DSHS + G rats. RPF was significantly higher in DSHS + T rats than in DSHS rats associated with decreased renal vascular resistance (p <0.05). In DSHS rats, NADPH oxidase expression and superoxide production were increased, with increased TGF-beta, procollagen I, fibronectin and renal fibrosis. These were suppressed in DSHS + T and DSHS + G rats. NO production by eNOS was decreased in DSHS rats, but the treatment groups increased eNOS expression and NO production in the vascular endothelium, resulting in decreased renal vascular resistance and improved renal blood flow. Urinary sodium excretion was significantly higher in DSHS rats than in DSLS rats with decreased sodium chloride co-transporter (NCC). However, there was no further change in NCC or other sodium transporters in the treatment groups, and the high urinary Na excretion in the treatment groups was due to the effect of increased RPF.

Conclusions: Tochu and geniposidic acid suppressed NADPH oxidase and increased eNOS in DS rats, resulting in improved blood pressure, renal hemodynamics and renal damage.

PO1825
Effect of Uremia on Endothelial Cell Damage Is Mediated by Excessive Neutrophil Extracellular Trap Formation
Jwa-kyung Kim, Hoi Woul Lee, Sung gyun Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Uremia is a clinical syndrome characterized by accumulation of various uremic toxins and associated metabolic abnormalities in chronic kidney disease (CKD). Patients with CKD are at increased risk for cardiovascular (CV) disease and death, and endothelial dysfunction may be a key uremia-specific risk factor. However, the mechanism by which uremia influences endothelial dysfunction is still unclear. We report a role for excessive neutrophil extracellular trap (NET) formation induced by uremic serum on endothelial cell (EC) injury.

Methods: Plasma nucleosome and myeloperoxidase-DNA, representative markers of in vivo NETs, and the intracellular adhesion molecule (ICAM)-1 level were measured in incident HD patients and healthy volunteer (HV), and their prognostic role was evaluated. For in vitro study, we differentiated HL-60 cells into neutrophil-like cells (dHL-60) by applying retinoic acid, and the effect of uremic serum on dHL-60 and ECs were determined.

Results: The amount of in vivo NETs were significantly higher in incident HD patients compared to HV, and the markers were strongly associated with ICAM-1 levels. In particular, nucleosome and ICAM-1 levels were independent predictors of a composite endpoint, all-cause mortality or vascular access failure. In vitro, uremic serum derived from HD patients showed significantly increased NETs formation from dHL-60, and these NETs significantly decreased EC viability and induced apoptosis. In addition, the ICAM-1 level in HUVEC supernatant was significantly increased by uremic serum-induced NETs compared to control serum-induced NETs.

Conclusions: Dysregulated neutrophil activities in the uremic milieu may play a key role in endothelial damage and vascular inflammatory responses.
Methods: We conducted a cross-sectional study of older adults (≥65 years) using visits 5 data (2011-2013) of the Atherosclerosis Risk in Communities study. Multivariable linear and logistic regression was used to examine the eGFR-lipid levels associations, stratified by statin use. Among statin users without ASCVD who had LDL-C levels <100 mg/dL, we predicted 10-year ASCVD risk after statin use by TG levels (<150 mg/dL vs. ≥150 mg/dL) across eGFR categories.

Results: The mean age of the study population (n=4965) was 75 (SD 5) years, 58% were female, and 22% were Black. The mean eGFR was 63 (SD 18) ml/min/1.73 m² and 52% were on statins. In both statin users and non-users, there were no associations between eGFR and statin use or LDL-C. Low eGFR was associated with a higher density lipoprotein cholesterol (HDL-C) and high TG (Figure). Among statin non-users, eGFR ≤45 (vs. ≥60) was independently associated with low HDL-C (<50 mg/dL) (prevalence: 79% vs. 34%, odds ratio=1.86; 95% CI, 1.38-2.51) and high TG (≥450 mg/dL) (31% vs. 20%; p=0.01) (2009). The results were confirmed in the subgroup of statin users with LDL-C <100 mg/dL, the prevalence of high predicted ASCVD risk (risk ≥20%) was greater among those with or without high TG across all eGFR categories (eGFR ≥60, 66% vs. 59%; 45-49, 78% vs. 73%; eGFR <45, 90% vs. 79%).

Conclusions: We found that low eGFR was associated with low HDL-C and high TG levels, regardless of statin use. Among statin users who achieved adequate LDL-C control, ASCVD risk was still higher among those with high TG compared to those without high TG.

Adjusted associations between eGFR and lipid levels in older adults

PO1829
Cerebrovascular Dysfunction in CKD
Corinna Steele,1 Esther Oh, Heather Farmer-Bailey, Rachael L. Reddin, Taylor Struempf, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Cerebrovascular dysfunction, characterized by reduced cerebrovascular reactivity, cerebral hypoperfusion, and increased pulsatile flow within the brain precedes the onset of dementia and is linked to cognitive dysfunction. While large-artery vascular dysfunction is prevalent in chronic kidney disease (CKD), cerebrovascular dysfunction has not been well characterized to date in moderate-to-severe CKD.

Methods: Using transcranial Doppler, we compared middle cerebral artery (MCA) blood flow-velocity response to hypercapnia (normalized for blood pressure and end-tidal CO₂; a measure of cerebrovascular reactivity) and MCA pulsatility (a measure of cerebrovascular stiffness) in patients with stage 3-4 CKD vs. age-matched healthy controls using an independent samples t-test. We also administered the trail making test (parts A and B) as an index of processing speed and measured carotid-femoral pulse-wave velocity (CFPWV) as an index of aortic stiffness.

Results: Seven participants with CKD (2F, 68±3 yrs [means±s.e.m.], estimated glomerular filtration rate [eGFR]: 38±5 ml/min/1.73m²) were compared to 8 healthy controls (1F, 63±2 yrs, eGFR: 85±3 ml/min/1.73m²). MCA pulsatility index was greater (1.08±0.10 vs. 0.85±0.04 A.U.; p=0.05) and normalized MCA blood flow-velocity response to hypercapnia tended to be lower (-6.3±4.0 vs. 11.6±7.3 %; p=0.06) in CKD as compared to healthy controls. Trail making part A time was slower (A: 31.8±3.3 vs. 20.2±1.6 sec; p<0.01); part B time tended to be slower (longer time to complete): 71.7±13.6 vs. 42.7±6.7 sec; p=0.07) and CFPWW was greater (1122±115 vs. 811±80 cm/sec; p=0.05) in CKD vs. control. Greater MCA pulsatility index correlated with worse cerebrovascular reactivity (r = -0.63, p=0.01), greater CFPWW (r= 0.65, p<0.01), slower trail making part B time (r=0.59, p<0.05), and lower eGFR (r = -0.53, p<0.09).

Conclusions: Impaired cerebrovascular function is evident in patients with moderate-to-severe CKD. Increased cerebrovascular stiffness is associated with reduced kidney function, increased aortic stiffness, impaired processing speed, and worse cerebrovascular reactivity.

Bradykinin Reduces Long-Lasting TRPV1-Mediated Inward Currents in Afferent Nonfiring Renal Neurons

Kristina Rodionova,1 Christina Forray-Strauss,1 Tilmann Ditting,1,2 Karl F. Hilgers,1 Nada Cordasic,3 Peter Linz,1 Christian Ott,1 Roland E. Schmieder,1 Mario Schiffer,2 Kerstin U. Amann,2 Roland Veelken,1,3 Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität - Nurnberg, Nurnberg, Germany; 3Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany.

Background: Bradykinin has been reported to be sympathoexcitatory via renal afferent nerves. Hence we tested the hypothesis that bradykinin directly stimulates cultivated renal afferent nerves with affenon axons.

Methods: Dorsal root ganglion neurons (TH1-L2) of rats were investigated in voltage clamp mode to assess inward currents and current clamp mode to assess action potential (AP) generation [neurons classified as tonic (high AP generation upon stimulation), phasic (AP ≤ 5 upon stimulation) or no firing]. Stimulation of TRPV1 receptors by protons (pH 6) with and without the addition of bradykinin (1, 10, 100 µM). 111 DRG renal neurons retrogradely stained with DiI for investigation.

Results: Bradykinin (BK) alone did not induce inward currents nor APs. Proton stimulation (pH 6) of TRPV1 significantly augmented long-term inward currents (baseline -0.36±0.09nA vs. -1.39±0.34nA; p<0.05, mean±SEM) and increased action potential generation in tonic neurons (0 AP/10s vs. 9.5±1.89 AP/10s; p<0.05, mean±SEM). However, the co-stimulation of renal nerves with protons and BK had any effect only in one specific subgroup of renal nerves: it significantly decreased long-lasting currents in non firing neurons (AP stimulation with 100µM BK+pH6: -0.129±0.062nA; 10µM BK+pH6: -0.11±0.03nA) 1µM BK+pH6: -0.06±0.02 nA vs pH 6: -0.43±0.06nA; *p<0.05, mean±SEM).

Conclusions: Bradykinin was only able to reduce long-lasting, TRPV1 dependent inward currents in non-firing renal nerves. Alterations of inward currents are likely involved in the expression of proinflammatory neuropetides (SP, CGRP). Hence, bradykinin might impair the release of neuropetides from intrarenal axons of a specific subgroup of renal afferent nerves.

The Impact of rs2254524 LSS Polymorphism on Blood Pressure in a New Mouse Model

Sipontina Fainienza,1 Lorena Citterio,1 Laura Zagato,1 Elisabetta Messaggio,1 Paolo Manunta.2 Genomics of Renal Diseases and Hypertension Unit 1IRCSS Ospedale San Raffaele, Milano, Italy; 2Universita Vita Salute San Raffaele, Milano, Italy.

Background: The blood pressure (BP) response to salt intake is associated with hypertension (HTN) and shows great variability among individuals. Endogenous ouabain (EO) is a steroid hormone previously associated with HTN. To dissect EO and HTN link we generated a knock-in mouse model carrying the rs2254524 SNP (Val646Leu; V646L) in the LSS gene, a key enzyme in steroid biosynthesis. In patients, the LSS variant avoids the BP and circulating EO level in response to a low salt diet. Moreover, high EO levels were detected in LSS AA kidneys and are associated with a faster decline in GFR in hypertensives. We investigated if the LSS AA variant affects BP and kidney function at 3, 6, and 9 months of age.

Results: LSS AA mice were viable, healthy, and undistinguishable phenotypically at 3 months, but further studies are necessary to deepen the investigation.

Conclusions: The hypertensive kidney injury in malignant hypertension of 2K1C rats includes a robust expression and deposition of complement components as well as infiltration of neutrophil leukocytes, features which are not observed in the non-malignant course of renovascular hypertension. These pathways may contribute to the specific kidney injury observed in malignant hypertension.

RNA Sequencing Reveals Induction of Specific Renal Inflammatory Pathways in a Rat Model of Malignant Hypertension

Background: In malignant hypertension (MH), far more severe kidney injury occurs than the “benign” form of the disease. The pathogenesis of this peculiar renal injury of malignant hypertention remains incompletely understood. Using a rat model in which some but not all animals develop MH, we performed an unbiased analysis of gene expression by RNA-sequencing to identify transcriptional changes in the kidney specific for malignant hypertension.

Methods: Renovascular hypertension in rats was induced by placing a 0.2 mm clip on the left renal artery (2K1C). Five weeks later, all 2K1C rats had developed hypertension. Rats were then sacrificed, and renal cortical RNA was extracted from the right kidney exposed to high blood pressure. To distinguish MH from non-malignant hypertension (NMH), we considered two factors: weight loss and typical renovascular lesions. Differential gene expression was assessed in three groups: MH, NMH and normotensive, sham operated controls (N=5 per group for RNA sequencing, N between 8 and 14 for other analyses).

Results: Mean blood pressure measured intraarterially was elevated to a similar degree in MH (207±10 mmHg) and NMH (201±4 mmHg) compared to controls (113±3 mmHg; p<0.05). 886 genes were exclusively regulated in MH only. Principal component analysis revealed a separated clustering of the three groups. The data pointed towards an upregulation of many inflammatory mechanisms in MH including pathways which previously attracted little attention in this setting: Transcripts from all three complement activation pathways were upregulated in MH compared to NMH but not in NMH compared with controls; immunochemistry confirmed complement deposition in MH. The expression of chemokines attracting neutrophil granulocytes as well as actual granulocyte infiltration were increased only in MH rats (CXCL6: 4.1-fold in MH over NMH).

Conclusions: The hypertensive kidney injury in malignant hypertension of 2K1C rats includes a robust expression and deposition of complement components as well as infiltration of neutrophil leukocytes, features which are not observed in the non-malignant course of renovascular hypertension. These pathways may contribute to the specific kidney injury observed in malignant hypertension.

Toll-Like Receptor 4 (TLR4) an Effector of Renal Inflammation and Sodium (Na) Transport

Karin C. Oliveira,1,2 Robert L. Repetti,1,2 Rajeev Rohatgi,1,2 Stony Brook University Renaissance School of Medicine, Stony Brook, NY; 2Northport VA Medical Center, Northport, NY.

Background: Na sensitivity of blood pressure (BP) is risk factor for cardiovascular mortality compared to Na resistant subjects. In addition, constrained cholesterol (chol) efflux is novel predictor for future cardiovascular events. Disregulation of ABCA1, a chol efflux protein, is implicated in hypertension and kidney disease while ABCA1 ablation reduces nephrotoxicity. We surmised that tubular ABCA1 depletion similarly enhances TLR4 dependent inflammation in a model of Na sensitivity.

Methods: Transgenic mice (Tg [P2Rac1cATG::CMV::TLR4]), which express CRE in tubular epithelia when fed doxycycline, were bred with mice expressing floxed ABCA1 to generate mice with tubular ABCA1 deficiency. Western blotting was performed on whole kidney protein lysate, renal plasma membrane (PM), and mmpcKCC2 cells. Amiloride sensitive short-circuit current (Asc) was measured in sheet and static expressed mmpcKCC2 cells.

Results: FF mice are phenotypically consistent with Na sensitivity (abstract# 3600350). FF and littermate controls (WT) mice fed a chol enriched diet for 6 weeks, a low Na and a high Na diet for 1 week were euthanized and kidneys extracted. Steady-state expression of TLR4 in renal PM showed enhanced TLR4 dependent inflammation in MH compared to NMH but not in NMH compared with controls; immunohistochemistry confirmed complement deposition in MH. The expression of chemokines attracting neutrophil granulocytes as well as actual granulocyte infiltration were increased only in MH rats (CXCL6: 4.1-fold in MH over NMH).

Conclusions: The hypertensive kidney injury in malignant hypertension of 2K1C rats includes a robust expression and deposition of complement components as well as infiltration of neutrophil leukocytes, features which are not observed in the non-malignant course of renovascular hypertension. These pathways may contribute to the specific kidney injury observed in malignant hypertension.

T Lymphocytes in Human Hypertension

Ghazal Z. Quinn,1 Xin Sheng,1 Amin Abdin,1 Lynda Vuong,2 Briania G. Nixon,2 Jonathan Hill,2 Steven S. Pullen,1 Myung Shin,2 Ming Li,2 A. A. Hakimi,2 Katalin Suzske,1 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, 1Memorial Sloan Kettering Cancer Center, New York, NY, Bosch Ingleheim Pharmaceuticals, Inc., Ridgefield, CT, 2Merrick & Co Inc, Kenilworth, NJ.

Background: Mouse models have shown that T lymphocytes are required for hypertension (HTN) development and accumulate in the vasculature and kidneys. The role of immune cells, including T lymphocytes, remains poorly understood in patients with HTN. Here, we analyzed immune cells in human kidney tissue samples in patients with HTN.

Methods: Human kidney tissue was obtained from the unaffected portions of 631 tumor nephrectomies and included clinical, histological and follow up tissue data. Tissue was microdissected into glomerular and tubular compartments for RNA-sequencing. In silico deconvolution of each sample was performed using the CIBERSORTx method to estimate relative cell type fractions. Flow cytometry was used for validation analyses using cell type specific antibodies in another set of 58 human kidney tissue samples. Regression analyses were used to determine the associations of renal immune cell types and clinical parameters. Linear modeling was used to assess longitudinal data.

Results: CD4 and CD8 T-cells were increased in patients with HTN (p<0.05) while T regulatory cells (Tregs) were decreased (0.4% vs. 0.6%, p<0.022). In adjusted models, HTN was associated with older age, Black race, diabetes, decreasing eGFR, and higher Th17 cells were associated with older age, Black race, and lower Tregs (p<0.001). In our flow cytometry cohort, HTN was also significantly associated with higher CD4 T-cells, lower Tregs and CD8 T-cells, independent of eGFR (p<0.009). Longitudinal data were available for 149 subjects for an average of three years and showed that older age, lower baseline eGFR and higher Th17 cells were associated with older age eGFR over time (p<0.001).

Conclusions: In silico deconvolution resolved a variety of renal immune cells and provided complementary information to flow cytometric analyses in kidney tissue samples. Multiple T-cell populations were increased in the setting of HTN. Tregs were decreased. These findings were independent of eGFR at CKD stages 1-2. Th17 cell expansion predicted faster eGFR decline. Our results highlight an important association between T-cell populations, HTN, kidney disease and kidney function decline.

Dual Action of β2AR-Agonism Confers Protection Against Heart Failure and Renal Dysfunction via Inotropic and Lusitropic Effects and Normalized Cholesterol Homeostasis in a Mouse Model of Alport Syndrome

Ahmed1,2, Zahi3, Keyvan Yousufi,1 Jose M. Condor Capacha,1 Mitchell Freundlich,2 Melina Ramic,1 Guerline Lambert,1 Serene Shehadeh,1 Julian C. Dunkley,1 Yee-Shuan Lee,2 Aisha Khan,1 Zane Zeier,1 Derek Dykxoorn,1 Chryso P. Katsoulis,1 Joshua M. Hare,1 Mary B. Nabity,2 Carolina Rivera,1 Anastasios Lympouropoulos,2 Keith A. Webster,1 Camila Irion,1 Lina Shehadeh.1 University of Miami School of Medicine, Miami, FL, 2Texas A&M University, College Station, TX, 3Nova Southeastern University, Fort Lauderdale, FL.

Background: Cola3 Alport mice present a model of heart failure with preserved ejection fraction (HFpEF) secondary to CKD. HFpEF is characteristically unresponsive to pharmacological intervention. Here, we tested the hypothesis that selective β2AR modulation with salbutamol could alleviate symptoms of CKD and simultaneously augment cardiac function. Secondarily, we investigated the mechanism of actions of such β2AR-mediated therapeutics on cardiac and renal functions.

Methods: Alport mice were injected intraperitoneally with salbutamol or DMSO vehicle as a single bolus of 200μg/dose in short-term studies or daily with 100 μg/dose for 2 weeks long-term. Cardiac and renal functions, cAMP levels, in vivo renal tubular LDL-C uptake and renal histology were evaluated post-injection.

Results: Short-term, salbutamol improved renal function in parallel with decreased LDLR levels and reduced uptake of LDL-C into renal tubules. Long-term, cardiac diastolic function assessed by isovolumetric relaxation time (IVRT), filling pressures (E/E’), and myocardial performance index, and systolic function reflected by ejection fraction, stroke volume and cardiac output improved significantly in parallel with increased cardiac cAMP. Mechanistically, in the kidney, salbutamol induced IDOL-mediated ubiquitination and subsequent lysosomal degradation of the LDLR via a novel β2AR-mediated, CAMP-dependent pathway involving the Rac1/Cdc42 β1Pix/GEF. β1Pix reversibly sequesters IDOL into a complex with LDLR, thereby blocking the degradation pathway. β2AR stimulation dissipates the complex reactivating IDOL-mediated LDLR degradation thereby re-establishing LDL-C homeostasis and renal function. Using flow cytometry in HEK293T cells, ectopic expression of β1Pix stabilized cell surface LDLR abundance in an IDOL-dependent and PKCS-independent manner.

Conclusions: β2AR agonism represents a potential treatment strategy to alleviate progression of cardiac and kidney failure associated with HFpEF phenogroup 3.

Focal Adhesion Kinase: A Major Regulator of Myocardial Failure in CKD

Arvin Altim,1 Gayatri Narayanan,1 Takashi Hato,1 Tsongshi Lu,2 Kenneth Lim.1 1Indiana University School of Medicine, Indianapolis, IN; 2Brigham and Women’s Hospital, Boston, MA.

Background: The focal adhesion pathway is essential in signal communication between the extracellular matrix and the cytoskeleton. Failure of this signaling pathway results in cytoskeleton dysfunction and has been shown to be intricately involved in the progression of ischemic cardiomyopathy. Whether this occurs in CKD-associated cardiomyopathy is currently unknown. In this study, our aim was to investigate the role of focal adhesion kinase (FAK), a central component of the focal adhesion pathway in the failing heart in CKD. Methods: We performed a cross-sectional cohort study of explanted human heart tissues from hemodialysis-dependent (HD, n=19), hypertension with preserved renal function (HTN, n=10), and healthy control (n=21) donors. Left ventricular (LV) tissues were subjected to RNA sequencing, qPCR, and protein analyses. Mechanistic and interference RNA studies using in vitro human ventricular cardiac fibroblast models were also conducted.

Results: Hearts from HD donors exhibited significant myocardial fibrosis (p<0.01) compared to HTN and control. HD and HTN hearts had higher heart weights (p<0.01) and greater LV wall thickness (p<0.01) compared to control hearts. RNA-sequencing revealed that the focal adhesion pathway was one of the most perturbed pathways in HD hearts compared to control. FAK mRNA and protein expression was significantly upregulated (p<0.05), and major cytoskeletal proteins associated with the focal adhesion pathway, including β-actin (p<0.01), β-tubulin (p<0.01), vinculin (p<0.05), and vimentin (p=0.01) were significantly downregulated in HD hearts compared to control. Uremic mineral stressors (high phosphate and high calcium) decreased FAK expression as well as β-tubulin (p<0.05) and vimentin, and promoted cleavage of FAK and vimentin, in vitro. Concurrent FAK shRNA transfection and mineral stress significantly decreased both full-length and cleaved FAK expression (p<0.05) and further downregulated vimentin (p<0.05) and vinculin (p<0.05) expression, in vitro.

Conclusions: FAK and the focal adhesion pathway plays a central role in the development of CKD-associated cardiomyopathy and appears to preserve the dynamic formation of the cytoskeleton in HD hearts. These findings support a potential therapeutic role for targeting the focal adhesion pathway in the management of cardiac remodeling in CKD.

Phenotyping CKD-Associated Cardiac Fibrosis

Gayatri Narayanan,1 Arvin Altim,1 Sharon M. Moe,1 Tsongshi Lu,2 Kenneth Lim.1 Indiana University School of Medicine, Indianapolis, IN; 2Brigham and Women’s Hospital, Boston, MA.

Background: Myocardial fibrosis is a pervasive and progressive complication in CKD patients. Mechanistically, increased collagen cross-linking has been shown to be a critical determinant of tensile strength, stiffness of collagen fibers, and resistance to degradation in ischemic cardiomyopathy, as opposed to increased collagen deposition alone. Whether similar metabolic processes and physiochemical alterations occur in CKD is largely unknown. Herein, we investigated the fibrotic phenotype in CKD-associated cardiomyopathy and the role of disordered mineral stressors.

Methods: Human left ventricular (LV) tissues were collected from hemodialysis (HD; n=13), hypertensive (HTN; n=8), and healthy control (n=12) donors to compare matrix proteins. Mechanistic in vitro studies involving treatment of human ventricular cardiac fibroblasts (HCFs) with either 1.8-3.8 mM β-glycerophosphate (BGP) or 2.4-5.0 mM CaCl2, in media were conducted. Protein expression was assessed by immunoblotting.

Results: We report increased trimeric (400 kDa) collagen I (COL1) in LV tissues from HD and HTN (p<0.05) compared to healthy control. Uniquely, monomicron (150 kDa) COL3 was decreased in HD hearts (p<0.05) compared to HTN and healthy control. Dimeric (250 kDa) or monomicron COL1 (139 kDa) and other COL3 multimers were not found in any groups. HD and HTN hearts exhibited increased perisinus (p<0.05) compared to healthy control. There was no significant difference in fibronectin or α-smooth muscle muscle (α-SMA) expression between groups. We next performed dose-dependent studies in HCFs treated with either BGP or CaCl2, 3.8 mM BGP stimulated increased trimeric but not dimeric COL1 (p<0.05), and reduced monomicron COL3 (p<0.01) synthesis leading to increased total COL1:3 ratio (p<0.05), in vitro. No other forms of COL1 or COL3 were changed. Additionally, 3.8 mM BGP stimulated α-SMA expression (p<0.01) did not significantly change perisinus or α-SMA expression. At 5 mM CaCl2 treatment, this decreased COL3 (p<0.01), fibronectin (p<0.05), and perisinus (p<0.05) expression.

Conclusions: Cardiac fibrosis in hearts from HD patients is characterized by increased trimeric COL1 expression and increased COL1:3 ratio that can be driven by disordered mineral stressors. These changes suggest pathologic cross-linking that can lead to altered mechanical properties and further studies are warranted.

Plasma Proteins Associated with eGFR and Incident Cardiovascular Events in the Cardiovascular Health Study Cohort
Christine P. Limonte,1, Pranav S. Garimella,2 Robert Gerszten,3 Diana I. Jalal,4 Michelle Odden,5 Michael Shlipak,6 Nisha Bansal,1 Thomas R. Austin,1 Ian H. de Boe.7 1University of Washington, Seattle, WA; 2The University of Iowa Hospitals and Clinics, Iowa City, IA; 3University of California San Francisco, San Francisco, CA; 4University of California San Diego, La Jolla, CA; 5Beth Israel Deaconess Medical Center, Boston, MA; 6Stanford University, Stanford, CA.

Background: Proteomics may help identify mechanisms through which low estimated glomerular filtration rate (eGFR) increases risks of heart failure (HF), myocardial infarction (MI), and cardiovascular (CV) death. We utilized an aptamer-based assay to measure 1300 proteins among 3185 older adults in the Cardiovascular Health Study. Proteins associated with eGFR were identified using linear regression models. A Bonferroni corrected p-value less than 7.6x10^-8 was used to account for multiple testing. Proteins significantly associated with eGFR were tested for associations with incident HF, MI, and CV death using Cox-proportional hazard regression adjusting for demographic and clinical variables. We evaluated whether proteins mediated associations between eGFR and incident CV events.

Results: The mean baseline eGFR was 70 ml/min/1.73m^2 and over a follow-up median of 13 years, there were 1033 incident HF, 555 incident MI, and 963 CV death events. 797 proteins were significantly associated with eGFR. Of these, 52, 0, and 22 proteins were associated with incident HF, MI, and CV death, respectively. All proteins associated with HF and CV death significantly mediated the effects between eGFR and these endpoints. The 10 proteins most strongly associated with the per-2 unit decrease in eGFR were fibulin-2, annexin A2, apolipoprotein A1, apolipoprotein A5, apolipoprotein J, apolipoprotein L1, apolipoprotein M, apolipoprotein V, apolipoprotein A2, and apolipoprotein A4. These results are summarized in Table 1

Conclusions: eGFR is associated with a large number of plasma proteins. A subset of these proteins are also associated with incident HF and CV death and may reflect mechanisms through which reduced eGFR increases the risk of these outcomes.

Characterization of Pendrin in Urinary Extracellular Vesicles in a Rat Model of Aldosterone Excess and in Human Primary Aldosteronism
Fumika H. Yoshida,1 Hirohama,1 Shigeyuki Arai,1 Tetsuo Nakano,1 Shigemasa Kimura,1 Yoshihisa Oda,2 Takanori Kitazono,1 Shinya Tomiyama,3 Yuya Yamazaki,1,2,3,4
1Teikyo University Hospital. 2Teikyo Daigakuin Igaku Kenkyuin, Fukuoka, Japan 3Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu, Fukuoka, Japan 4Nippon University Medical School, Tokyo, Japan

Background: Pendrin (CD167c) is a chloride/hydrogen exchanger selectively present in the intercalated cells of the kidney. Although experimental studies demonstrated that pendrin is involved in the fluid volume regulation and acid/base balance, its role in human hypertension is not fully understood. Here, we investigated the changes in pendrin levels in urinary extracellular vesicles (uEVs) isolated from patients with primary aldosteronism (PA) and in a rat model of PA.

Methods: This study included 30 patients who were diagnosed as having PA in Yokohama Rosai Hospital or in Teikyo University Hospital. The protocol was approved by the institutional review board. In animal experiments, SD rats received continuous aldosterone treatment significantly correlated with the baseline aldosterone-renin ratio (ARR), and tended to inversely correlate with serum K+ levels. Furthermore, a cross-sectional analysis in PA patients confirmed a significant correlation between ARR and pendrin levels in uEVs.

Results: We examined 375 coronary artery obtained from autopsy samples of subjects with CKD stages 0 to 5 in a general Japanese population. Arteries were divided into quintiles based on vessel calcification area. The association of calcification area with the presence of intraplaque hemorrhage in coronary arteries was estimated by using logistic regression analysis.

Conclusions: These data are consistent with experimental studies demonstrating the role of pendrin in aldosterone-induced hypertension, and suggest that pendrin analysis in uEVs may also be useful to understand the pathophysiology of human hypertension.
