Background: Left ventricular (LV) systolic dysfunction is common in patients on maintenance hemodialysis (HD). Early identification of patients with depressed left ventricular ejection fraction (LVEF) can facilitate disease modifying treatment. Electrocardiograms (ECGs) are routinely performed in patients on HD, however, they have not been used for estimating LVEF in this population.

Methods: We analyzed data from five Mount Sinai facilities. Patients on HD with a transthoracic echocardiogram within 7 days of an ECG were identified using diagnostic and procedure codes. ECG data were preprocessed to remove recording artifacts, plotted to an image, and along with patient demographics were analyzed using a model comprised of a Multi-Layer Perceptron and a Convolutional Neural Network. We developed three models: 1) trained from scratch in only HD patients, 2) pre-trained on natural images (Imagenet), and 3) pre-trained on all LVEF-ECG pairs (n=698,890) excluding those for ESRD patients. Models 2 and 3 leverage transfer learning, which reuses knowledge gained from a task to perform a similar task. All models were trained/tested on LVEF-ECG pairs for ESRD patients within a Group Stratified K Fold (K=5) Cross Validation design, and performance was compared per Area Under Receiver Operating Characteristic curve (AUROC) for each category of LVEF, ≤40%, 41 to ≤50%, and >50%.

Results: We extracted 18,626 LVEF-ECG pairs for 2,168 ESRD patients. For detection of LVEF ≤40%, models trained from scratch and pre-trained on Imagenet had AUROCs of 0.74 (95% CI: 0.67-0.80) and 0.71 (95% CI: 0.65-0.77) respectively. These were outperformed by the model pre-trained on ECG data [AUROC of 0.91 (95% CI: 0.88-0.93)]. Similar results were seen when detection of LVEF 41 to ≤50% with the AUROC being 0.85 (95% CI: 0.49-0.6) for both the model trained from scratch and the Imagenet model, while the model pre-trained on ECG data achieved an AUROC of 0.82 (95% CI: 0.78-0.87).

Conclusions: A model pre-trained on non-HD LVEF-ECG pairs using transfer learning and pre-trained on Imagenet outperformed models trained from scratch or pre-trained on Imagenet. This model will facilitate identification of LV systolic dysfunction in patients on HD.

PO0856
Clinical Outcomes of Bioimpedance Analysis-Guided Hemodialysis: A Meta-Analysis of Randomized Controlled Trials
Panupong Hansrivijit,1 Chennchen Qian,1 Sumit Mohan,2 1UPMC Pinnacle, Harrisburg, PA; 2Columbia University Irving Medical Center, New York, NY.

Background: Determination of fluid status in hemodialysis patients could be a great help to the patient and provider. Fluid overload can lead to adverse outcomes, including hypotension, pulmonary edema, and death. Bioimpedance analysis (BIA) is an emerging tool in guiding fluid removal in hemodialysis population. However, although there are some randomized controlled trials (RCT), the reported outcomes remain heterogeneous and inconclusive across studies.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched for eligible articles through May 2021. Inclusion criteria were: 1) RCT comparing BIA and clinical assessment, 2) sample size > 50, 3) adults > 18 years on hemodialysis. Methodological shortcomings were assessed using an aid for assessing risk of bias (ROB) or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e', portal vein (PV) pulsatility and IVS. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fisher’s and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

Results: 54 measurements on 27 patients were obtained. Average time required by each examiner to obtain all images was 6 minutes (95% confidence interval [CI] 4.2-7.8). Average age was 57 (95% CI 52, 62), 85% were black and 44% were females. Average BMI was 32 (95% CI 28, 36), Charlson comorbidity index (CCI) score 7 (95% CI 6,8), mean diastolic blood pressure 94 (95% CI 90, 98), and creatinine clearance 0.28 (95% CI 0.25, 0.31). 54 measurements on 27 patients were obtained. Average time required by each examiner to obtain all images was 6 minutes (95% confidence interval [CI] 4.2-7.8). Average age was 57 (95% CI 52, 62), 85% were black and 44% were females. Average BMI was 32 (95% CI 28, 36), Charlson comorbidity index (CCI) score 7 (95% CI 6,8), mean diastolic blood pressure 94 (95% CI 90, 98), and creatinine clearance 0.28 (95% CI 0.25, 0.31).

Conclusions: In this pilot study, an elevated lateral E/e' was associated with lower rates of IDH events or post HD orthostasis. The role of POCUS in guiding fluid removal during HD warrants further exploration.

PO0857
Point-of-Care Ultrasound Measurements to Predict Intradialytic Hypotension: A Cross-Sectional Pilot Study
Chrystel Pawly,1 Wael Azzam,1 Christy Costanian,1 Gonzalo Matzumura Umemoto,2 Enyo Ablordepey,1 Fadi Tohme.1 1Lebanese American University, Beirut, Lebanon; 2University of Southern California, Los Angeles, CA; 3Washington University in St Louis, St Louis, MO.

Background: Intradialytic hypotension (IDH) results from excessive ultrafiltration in patients on chronic hemodialysis and has been linked to increased mortality. Prescribing the right amount of ultrafiltration can be challenging, partly due to the poor sensitivity of physical examination for detection of volume overload in HD patients. POCUS is emerging as a valuable tool in the assessment of volume status. The goal of this study is to determine whether pre-dialysis POCUS measurements are associated with development of IDH.

Methods: Patients ≥18 years old on HD for at least 6 months and ordered for 2 or more liters of ultrafiltration were included. Two blinded POCUS-trained physicians obtained the following measurements within the first 30 minutes of HD: left ventricular septal and lateral E/e', portal vein (PV) pulsatility and IVS. The primary outcome was development of IDH events or post HD orthostasis. IDH was defined as a decrease in systolic blood pressure by ≥ 20 mmHg plus symptoms of IDH. Fisher’s and Mann Whitney tests were used to examine the association between IDH events and various demographic, clinical, and POCUS related parameters.

Results: 54 measurements on 27 patients were obtained. Average time required by each examiner to obtain all images was 6 minutes (95% confidence interval [CI] 4.2-7.8). Average age was 57 (95% CI 52, 62), 85% were black and 44% were females. Average BMI was 32 (95% CI 28, 36), Charlson comorbidity index (CCI) score 7 (95% CI 6,8), mean diastolic blood pressure 94 (95% CI 90, 98), and creatinine clearance 0.28 (95% CI 0.25, 0.31). 8 out of 27 patients developed the primary outcome. There was no association between age, sex, ethnicity, BMI, dialysis vintage, Charlson comorbidity index, interdialytic weight gain, IVC size, PV pulsatility, septal E/e' and the primary outcome. There was a significant association between lateral E/e' and IDH events or post HD orthostasis (p<0.05).

Conclusions: In this pilot study, an elevated lateral E/e' was associated with lower rates of IDH events or post HD orthostasis. The role of POCUS in guiding fluid removal during HD warrants further exploration.

PO0858
A Clinical Approach of Intradialytic Creatine Supplementation in Dialysis-Dependent CKD Patients: A Rationale and Study Design
Yvonne van der Veen,1 Adrian Post,1 Daan Kremer,1 Ralf Westerhuis,2 Casper F. Franssen,1 Theo Walliman,1 Stephan J. Bakker.1 1Universität Medisch Centrum Groningen, Groningen, Netherlands; 2Dialyse Centrum Groningen, Groningen, Netherlands; 'Idégonstische Technische Hochschule Zurich, Zurich, Switzerland.

Background: There is great need for identification of new, potentially modifiable risk factors for the poor HRQoL and excess risk of mortality in dialysis-dependent chronic kidney disease patients. Creatine is an essential contributor to cellular energy homeostasis, yet on a daily basis 1.6-1.7% of the total creatine pool is non-enzymatically degraded to creatinine and subsequently lost via urinary excretion, thus necessitating a continuous supply of new creatine to remain in steady-state. Due to an insufficient ability to synthesize creatine, unopposed losses to the dialysis fluid, and insufficient intake, hemodialysis patients are prone to creatine deficiency, and may benefit from creatine supplementation. To avoid problems with compliance, fluid balance and, furthermore, to prevent intradialytic losses of creatine to the dialysate, we aim to investigate the potential of intradialytic creatine supplementation in improving outcomes.

Methods: Here, we describe the rationale and design for a block-randomized, double-blind, placebo-controlled pilot study. A total of 16 hemodialysis patients will be included, divided into four groups receiving intradialytic creatine supplementation (0.5mM, 1.0mM, 1.5mM, 2.0mM), or a placebo for six weeks. The aim of the pilot study is to explore the creative uptake in the circulation and tissues following different creatine supplementation dosages.

Results: The main parameters for the pilot study are the plasma creatine concentration and intra-erythrocytic creatine concentration of both pre- and post-hemodialysis samples. Secondary study parameters are handgrip strength as a measure of muscle strength, combined intradialytic urinary and intradialytic dialysate excretion of creatinine as a measure of muscle mass, and body composition measured with bioelectrical impedance analysis (BIA).

Conclusions: Intradialytic creatine supplementation may help to maintain creatine homeostasis among dialysis-dependent chronic kidney disease patients, and consequently improve important causes for impaired HRQoL, including protein energy wasting (PEW), fatigue, muscle weakness, depression, and cognitive impairment. The results from the pilot-study will serve as a basis for a larger double-blind, placebo-controlled supplementation trial.

Relationship Between Fluid Overload and Hemoglobin Concentration in Hemodialysis Patients: A Longitudinal Analysis

Lemuel Rivera Fuentes,1 Ariella E. Mermelstein,1 George A. Kayser,2 Jochen G. Raimann,1 Ulrich Moissl,1 Stephan Thijssen,1 Peter Kotanko,1 Renal Research Institute2 Renal Research Institute, New York, NY; 3University of California Davis, Davis, CA; 4Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Quantification of fluid status by bioimpedance spectroscopy (BIS) has become routine outside United States (US). We performed the first assessment of fluid status in US hemodialysis (HD) clinics using a BIS device. We studied the longitudinal association between fluid overload (FO) and hemoglobin (Hgb) concentration adjusting for inflammation and erythropoiesis-stimulating agents (ESA).

Methods: Measurement of FO [Body Composition Monitor (BCM); Fresenius Medical Care] was conducted cross-sectionally in chronic HD patients in 4 HD clinics in New York. We built linear mixed effects models with Hgb as the dependent variable and calculated FO longitudinally to include as a fixed effect. We tested the robustness of the association to account for the influence of inflammation by including the neutrophil-lymphocyte ratio (NLR) as an additional fixed effect. As a subset analysis 2 separate models were built in subjects with or without ESAx. To corroborate the dilutional effect of FO we exchanged Hgb for albumin as a fixed effect.

Results: We studied 169 patients (Figure 1). FO was inversely associated with Hgb [Estimate -0.16 (-0.20 to -0.12) g/dl per 1 L of FO], a significant fixed effect that remained unchanged in magnitude even after inclusion of NLR [Estimate 0.04 (-0.05 to 0.06) g/dl per 1 unit of NLR]. The effect was larger in patients without ESA prescription [Estimate 0.22 (-0.32 to -0.12) g/dl per 1 L of FO] and in the subgroup of patients with albumin [Estimate 0.02 (-0.03 to -0.01) g/dl per 1 L of FO] with NLR being a significant fixed effect [Estimate 0.03 (-0.04 to -0.01) g/dl per 1 unit of NLR].

Conclusions: Hgb is inversely affected by FO, a significant effect independent of inflammation (NLR). The impact of FO on Hgb concentration is larger in those with no ESA treatment emphasizing that fluid status has to be considered in anemia management. The effect of FO on albumin supports hemodilution as the principal cause for the changes seen on Hgb.

Interpreting Home Blood Pressure Measurements in Haemodialysis: A Post Hoc Analysis of a Randomized Cross-Over Study

Vicki K. Sandys,1 Lavleen Bhat,1 Emer C. O’Hare,1 Conall M. O’Seaghdha,1 Donal J. Sexton,2 Royal College of Surgeons in Ireland, Dublin, Ireland; 2The University of Dublin Trinity College, Dublin, Ireland.

Background: Home BP correlates better with ambulatory BP, target organ damage and mortality in dialysis patients. We aimed to determine the agreement of in-centre BP with home BP.

Methods: A post-hoc analysis of a pilot-scale, randomised two-period cross over study comparing self-monitoring of BP over 4 weeks with usual care in 41 haemodialysis patients. www.clinicaltrials.gov. NCT0340349. Dialysis clinic BP and home BP (using average real variability (ARV). Mixed effects models for repeated measures with a moving average window of 2 weeks were used to examine associations with BP and ARV.

Results: 33 out of 41 participants had sufficient home BP measurements for inclusion (mean age: 63.7 years, 52.1% male). Post-dialysis SBP had moderate agreement with home SBP measurements (K = 0.6) compared with pre-dialysis SBP measurements (K = 0.4). The mean bias between home SBP and post SBP measurements was -4.15 mmHg (95% CI 23.5 to -31.8 mmHg) (Figure 1). Home SBP ARV (16 +/- 6) was as high as pre SBP ARV (14 +/- 5) and post SBP ARV (13 +/- 5). In univariate analysis only calcium channel blockers were consistently associated with pre-dialysis (P = 0.02), post-dialysis and home SBP (both P<0.001).

Conclusions: Post-dialysis SBP demonstrates moderate agreement with home BP when two week BP averages are used. Home BP measurements are as variable as clinic BP measurements and isolated measurements may lack interpretability. Averaging the home BP over two weeks may improve the utility of home BP monitoring.

Benefit of More Frequent Dialysis on Dialysis Recovery Time in Nursing Home Patients with ESRD

Alice Hellebrand,1 Eran Y. Bellin,1,2 Steven M. Kaplan,1 Jordan Ledvina,1 William Markis,1 Nathan W. Levin,1 Allen Kaufman,1 Dialyze Direct Brooklyn
Dialyze Direct Brooklyn, Brooklyn, NY; 1Albert Einstein College of Medicine, Bronx, NY.

Background: Dialysis patients admitted to a skilled nursing facility (SNF) are characterized by advanced age, frailty, and multiple comorbidities. Based on prior studies which demonstrated shortened dialysis recovery time (DRT) with more frequent dialysis (MFD) in populations aged –50s living at home (FREEDOM Study 2010, FHN trial 2006), it was postulated that dialysis patients in a SNF would benefit from MFD.

Methods: Patients studied were admitted to SNFs in OH, TX, FL, NY, and PA from November-December 2019 (pre-COVID) and could reliably answer questions about DRT. 80% were undergoing subacute rehabilitation and 20% were permanent residents of the SNF. Patients received NxStage on-site staff assisted MFD 5x (80%) or 4x (20%) per week. Estimated DRT was ≤ 2.1. At every dialysis, patients were asked by their RN caregiver “How long did it take you to recover from your last HD session?” Responses were deemed unreliable if a patient had cognitive impairment. Reliable responses were used for outcome analysis. In the present study, DRT data was collected by a caregiver nurse, differing from the methodology of the FREEDOM/FHN studies which collected DRT data via KDQOL form or phone interview. The implications of these differences in data collection methods are currently unknown.

Results: 485 unique patients were included in the study. Demographics included 53% males, mean age 67.5 ± 13 years, African American 19%, Caucasian 23%, Hispanic 5%, Asian 0.4%, unknown or other 51%. Mean DRT was 1.5 ± 2.6 hours. Mean DRT was calculated using the midpoint recovery time for intervals, or 18 hours when DRT was the next morning or beyond. In 69%, DRT was ≤ 2 hours.

Conclusions: In the FREEDOM and FHN conventional HD 3x per week study arms, DRT averaged 6-8 hours. MFD reduced DRT to ≤1.0 hour in those relatively young patients living at home. In our study, HD patients residing in a SNF and receiving MFD experienced DRT of 1.5 hours. Age, frailty and comorbid conditions therefore do not prevent DRT benefits of MFD. DRT benefits could stem from more effective, gentler fluid management by MFD. Further studies are needed to fully explore the impact of shortened DRT on rehabilitation scores, hospitalizations and deaths in elderly patients residing in SNFs.

The Combination of Arterial Stiffness and Peripheral Vascular Disease Aggravates Survival Among Hemodialysis Patient Using Competing Risk Analysis

Adisorn Pathumrak, Kanin Thammavaranucupt, Chagriya Kitayakara, Arkorn Nongnuch. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: The survival in end state renal disease (ESRD) patient is unacceptable high. The Skin autofluorescence (SAF) for advance glycation end products (AGEs), peripheral vascular disease (PVD) (ankle-brachial index, ABI ≤ 0.9) and arterial stiffness (carotid ankle vascular index, CAVI≥9) were reports as predictors of mortality. However, kidney transplantation (KT) competes the mortality outcome. We aim to explore these markers for precisely prediction of mortality using competing risk method.

Methods: Retrospective chart review in chronic hemodialysis patients was done in 3 hemodialysis centers in North Bangkok during November 2015 and March 2016. Arterial stiffness, SAF, IMAR and PVD were collected as a clinical predictor: Cumulative incidence of mortality was used as was a primary outcome. Logistic regression with competing risk model was used to analyze the factor affecting mortality.

Results: A Total of 176 patients were eligible and classified into 4 groups according to PVD and stiffness status. During follow up 44.5±14.8 months, the overall mortality rate was 27% which is 13.2, 28.6, 31.5 and 61.9% in no PVD and stiffness, exclusively PVD, exclusively stiffness, and combine group respectively. The PVD (HR 2.93, CI 1.2 to 7.14, P=0.018) and stiffness (HR 2.57, CI 1.16 to 5.73, P=0.021) were independent predictors of mortality. In competing risk method, the combination of PVD and stiffness associate with highest mortality (P=0.0002139), while the patients who no PVD and stiffness had the highest rate for KT (P=0.0050275).

Conclusions: The PVD and stiffness were an independent risk of mortality among hemodialysis patients. The combination of PVD and stiffness may stratify risk of mortality in hemodialysis patient using competing risk method.

Cumulative incidence of death and KT according to PVD and stiffness status in competing risk method

PO0864

Body: Fat Mass Plays an Important Role in Over- or Underestimation of Bioimpedance Spectroscopy-Based Dry Weight for Patients with Hemodialysis

Dae Eun Choi,1 Hao Ri Kim,2 Jae wan Jeon,1 Jin Ah Shin,1 Soo hyun Han,1 Haet Bir Hwang,1 Eu Jin Lee,1 Kiyang Na,1 Kang Wook Lee.1 Chungnam National University School of Medicine, Daejeon, Republic of Korea; 1Chungnam National University Sejong Hospital, Sejong, Republic of Korea.

Background: Accurate dry weight (DW) estimation is important for hemodialysis patients. Although bioimpedance spectroscopy (BIS) is commonly used to measure DW, the BIS-based DW frequently differs from the clinical DW.

Methods: We analyzed the characteristics of patients whose BIS-based DWs were over- and underestimated. In this retrospective cohort study, we evaluated 1,555 patients undergoing maintenance hemodialysis in Chungnam National University Hospital. The gap (DW\_BIS-DW\_cl) was calculated by comparing the BIS and clinical DWs.

Results: We analyzed the clinical characteristics of patients with positive (n = 835) and negative (n = 720) gaps. Compared with other patients, the DW\_BIS-positive group was taller, had higher extracellular water (ECW) level and extracellular/intracellular water index (E/I); and had lower weight, body mass index (BMI), lean tissue index (LTI), fat tissue index (FTI), fat mass (FAT), and adipose tissue mass (ATM), as well as lower levels of hemoglobin, total protein, albumin, and phosphorous. The DW\_BIS-negative group exhibited higher levels of hemoglobin, total protein, albumin, and phosphorous, as well as elevated BMI, FTI, FAT, and ATM, however, it had lower height, ECW, and E/I. Linear regression analysis revealed that FAT significantly predicted DW\_BIS accuracy.

Conclusions: The clinical DW of patients with malnutrition and a low fat mass tended to be underestimated, while the clinical DW of patients with comparatively large fat reserves tended to be overestimated. These characteristics of dialysis patients will aid in the correction of BIS-associated DW errors.

PO0865

Consistency of the Dry Weight of Hemodialysis Patients Predicted Using Bioelectrical Impedance Analysis Between Standing and Lying-Down Positions

Hyunsuk Kim. Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-do, Republic of Korea.

Background: Although the InBody S10 is widely used for hemodialysis patients in the lying position, clinicians must make the measurements in person. In contrast, patients can use the InBody 770 to obtain measurements by themselves in the standing position according to instructions provided by the machine, which may be more convenient. Therefore, this study compared the measurements of hemodialysis patients' dry weight obtained lying down using the S10 to those obtained in the standing position using the 770.

Methods: Measurements from 56 patients before and after hemodialysis were obtained. Dry weight was calculated using the ratio of extracellular water to total body water, taking into consideration diabetes status and albumin levels, and comparing the results according to body position (lying vs. standing).

Results: The patients' median age was 64 years old, and 51% were men. Their mean dry weight before hemodialysis was 60.9±12.5 kg using the 770 device and 60.1±12.5 kg using the 770 device (paired t-test; t=6.472, P<0.001). The correlation between these data was 0.93.
measurements was high (R²=1.0000). Patients’ mean dry weight after hemodialysis was 58.4±12.2 kg using the S10 device and 58.5±12.0 kg using the 770 device (paired t-test; t=-1.560, P=0.124). The correlation between these measurements was also very close (R²=1.0000). The Bland-Altman test yielded similar results.

**Conclusions:** This study showed that patients’ predicted dry weights in the lying position using the InBody S10 device and in the standing position using the InBody 770 device were consistent in both pre- and post-hemodialysis states. It can be concluded that the dry weight of a patient in the standing position can be measured with more convenience and autonomy using the InBody 770 device.

*Use of Crit-Line to Reduce Intradialytic Hypotension in Hospitalized Patients Receiving Dialysis*

Marissa A. Martin, Luis M. Perez, Anip Bansal, Jessica B. Kendrick. *University of Colorado, University of Colorado, Denver, CO, US, academic/system, Denver, CO.*

**Background:** Intradialytic hypotension (IDH) is a frequent complication of hemodialysis in hospitalized patients with acute kidney injury (AKI) and end stage kidney disease (ESKD). Crit-Line is a device that monitors absolute hematocrit and oxygen saturation during dialysis and reads out the percent blood volume change. Whether the use of Crit-Line during HD in hospitalized patients results in less IDH is unknown.

**Methods:** We performed a time series study in all hospitalized adult AKI/ESKD patients undergoing acute HD at the University of Colorado. During the control period baseline data was collected. During the intervention period, Crit-Line was used on all hospitalized patients undergoing HD including those receiving portable HD treatments in the ICU. During both time periods, nurses recorded number of hypotensive events, patient symptoms and modifications that were made to the dialysis prescription. The primary outcome was number of IDH events defined by the NKF KDOQI Guidelines.

**Results:** 328 patients were included, 161 from the control period and 167 from the intervention period. Patient characteristics were similar in both time periods and are shown in Table 1. IDH occurred in 23.5% of treatments during the control period and 18.7% during the intervention period, but the difference was not significant, p=0.22 (Figure 1). When examining portable dialysis treatments in the ICU, there was a significant reduction in IDH with Crit-Line compared to control (Odds Ratio 0.81 95% CI 0.55-1.16, p=0.24).

**Conclusions:** Use of Crit-Line in hospitalized patients undergoing dialysis in the ICU resulted in less IDH.

**Funding:** Commercial Support - Fresenius Renal Therapies

**PO0867**

*Dry Weight Adjustments for Hemodialysis Patients Using Machine Learning*

Hae Ri Kim, Youngok Ham, Kim Pyung, Yoon-Kyung Chang, Dae Eun Choi. *Chungnam National University Sejong Hospital, Sejong, Republic of Korea; Chungnam National University, Daejeon, Daejeon, Republic of Korea; Daejeon Saint Mary’s Hospital, Daejeon, Daejeon, Republic of Korea.*

**Background:** Knowledge of the proper dry weight plays a critical role in the efficiency of dialysis and the survival of hemodialysis patients. Recently, bioimpedance spectroscopy (BIS) has been widely used for set dry weight in hemodialysis patients. However, BIS is often misrepresented in clinical healthy weight.

**Methods:** As a retrospective, single center study, data of 1672 hemodialysis patients were reviewed. DW, data were collected when the dry weight was measured using the BIS (DW_BIS). The gap between the two (Gap_BIS) was calculated and then grouped and analyzed based on gaps of 1 kg and 2 kg.

**Results:** Based on the gap between DW_BIS and DW_BIS, 972, 303, and 384 patients were placed in groups with gaps of <1 kg, ≥1kg and <2 kg, and ≥2 kg, respectively. For less than 1 kg and 2 kg of GapDW, it can be seen that the average accuracies for the two groups are 83% and 72%, respectively, in using XGBoost machine learning. As Gap_BIS increases, it is more difficult to predict the target property. As Gap_BIS increase, the mean values of hemoglobin, total protein, serum albumin, creatinine, phosphorus, potassium, and the fat tissue index tended to decrease. However, the height, total body water, extracellular water (ECW), and ECW to intracellular water ratio tended to increase.

**Conclusions:** Machine learning made it slightly easier to predict DW based on Gap_BIS under limited conditions and gave better insights into predicting DW. Malnutrition-related factors and ECF were important in reflecting the differences between DW_BIS and DW_BIS.

**PO0868**

*Intradialytic Weight Gain in Long Intervals and Mortality Among Maintenance Hemodialysis Patients*

**Background:** Intradialytic weight gain (IDWG) is an important factor for sudden death on the first dialysis day right after long interdialytic intervals (i.e. 2-day breaks between dialysis treatments) in hemodialysis patients. We defined IDWG in long intervals (IDWGL) as the IDWG during 2-day breaks. In this study we examined the association between IDWG and medium-term mortality.

**Methods:** This retrospective cohort study included patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between IDWG and medium-term mortality.

**Results:** We examined mortality in 35225 patients. The mean age (and standard deviation) was 62±15 years, and 8112 died during the median follow-up period of 1.4 years. Higher categories of IDWG were associated with increased risk of mortality. The hazard ratios (95% confidence intervals) of all-cause mortality for 3–<4%, 4–<5%, 5–<6%, and ≥6% were 1.09 (1.03-1.16), 1.14 (1.06-1.23), 1.17 (1.06-1.29), and 1.25 (1.14-1.38) (Reference: 2–<3%) (Figure a). The restricted cubic spline analysis showed that risk of mortality increased when IDWG exceeded 2% (Figure b).

**Conclusions:** IDWG exceeded 2% was associated with higher risk of mortality. Our results suggest IDWG can be a risk parameter for medium-term mortality.
PO0870
Cardiac Arrests During Hemodialysis Among Maintenance Hemodialysis Patients in a Large Dialysis Network in India

Background: Cardiac arrest (CA) during a HD session carries a high mortality and is reported associations include age, comorbidity, dialysis characteristics. Since much is unknown in India, we aimed to study Incidence of CA, predisposing factors and outcome of CPR following intra HD cardiac arrests

Methods: Consecutive CA in a large dialysis network from July 2019 to March 2021 were reviewed for age, gender, HD frequency, adequacy, vascular access, HD facility location, size, nephrologist coverage, b/o DM and IHD, HD session timing, duration HD frequency & hospitalization in recent past & ultrafiltration rate. Survivors vs non-survivors of CPR were compared with t-test, Chi-square test or Fisher’s exact statistic and risk ratio (RR) for significance of associated factors were analyzed using STATA, v 14.2.

Results: Among 2,081,759 HD sessions, rate of 1.2441. 71 survived CPR and 51 died. Age: 55 ± 1.2 yrs, M:F = 77%/23%. Tier 1/2/3 cities: 11.4%/37.7%/50.8%, daily Nephrologist visits: 67.2%, Facilities monthly sessions: < 250: 10.6%, ≥ 250: 74.6-79.0%. Urea: 8.7 ± 2.1 mg/dl temperature: 34.3%, HD freg: 1/2/3 per wk: 36.9/28.7/33.4%, DM: 44.8% IHD: 26.2%, Morn afternoon, eve session(%): 8/15/12, P < 0.05 was considered significant.

Conclusions: Incidence of CA in India is modest compared to developed countries experience; larger facilities & smaller cities carry a high proportion of events. Age > 80 risk of death. Females, Hb ≥ adequacy, UFR >10ml/kg/hour, low HD freg in 2 months prior to CA show tendency to higher risk for non survival. Limitation includes lack of analysis of CPR and post CPR hospitalization course

PO0869
Coronary Artery Calcification Is a Risk Factor for Intradialytic Hypotension in Hemodialysis Patients
Sono Mizuiri, Yoshiko Nishizawa, Toshiaki Doi, Kazuomi Yamashita, Kenichiro Shimogoto, Koji Usui, Michiko Arita, Takayuki Naito, Shigehiro Doi, Takao Masaki, Iryo Hójín Ichiyokai Harada Byoin, Hiroshima, Japan; Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; Ichiyokai East Clinic, Hiroshima, Japan; Ichiyokai Yokogawa Clinic, Hiroshima, Japan; Hiroshima Daigaku Byoin, Hiroshima, Japan.

Background: Vascular calcification and intradialytic hypotension (IDH) share common risk factors in hemodialysis (HD) patients, but there are few reports about the association. We investigated the association between IDH and coronary artery calcification (CAC) and their effects on mortality in HD patients.

Methods: Subjects were consecutive maintenance HD patients. IDH was defined as nadir systolic blood pressure <100 mmHg, or the requirement for bolus infusion of saline and vasopressor (phenylephrine hydrochloride) during at least two of 10 HD sessions. Laboratory data and Agatston coronary artery calcium score (CAC) were obtained at baseline. Logistic regression analyses for CACs and Cox analyses for mortality were conducted.

Results: In all subjects (n=173), age and dialysis vintage were 66±12 years and 10.2±9 months, respectively. IDH occurred in 37 patients (21.4%), and CACs was higher in the IDH group than in the non-IDH group [1,845 (243–3,774) vs. 884 (161–2,465)]. IDH was significantly (P<0.05) associated with CACs [odds ratio (OR): 8.10], diabetes (OR: 2.90), mean predialysis systolic blood pressure (OR: 0.93), mean ultrafiltration (OR: 1.92), Kt/Vurea (OR: 11.27) and erythropoietin responsive index (ERI) (OR: 0.91), but not with serum albumin or use of calcium channel blockers. For 3-year all-cause mortality, the cut-off value of CACs, determined by receiver operating characteristics curve analysis, was 1,829 with sensitivity of 69% and specificity of 77%. Of the 173 patients, 45 all-cause and 19 cardiovascular (CV) deaths occurred for 3 years. Patients with both IDH and CACs ≥1,829 had the highest 3-year cumulative CV death rate (33.5%, P<0.01) compared with 19.7%, 11.5%, and 4.5% in those with CACs ≥1,829 only, IDH only, and neither. In Cox models including age, sex, diabetes, albumin, phosphate, CRP, ERI and FG23, hazard ratios (HRs) for 3-year all-cause mortality of IDH, CACs ≥1,829, or IDH with CACs ≥1,829 were similar, but HR for 3-year CV mortality was the highest in CACs with CACs ≥1,829 (9.68, P<0.001) compared with 7.29 (P<0.001) and 6.77 (P<0.01), in those with CACs ≥1,829 only, and IDH only. Only CACs were independent risk factor for IDH, and CACs provide additional risk discrimination over IDH for CV mortality in HD patients.

PO0871
Clinical Significance of Plasma Matrix Metalloproteinase-2 and Matrix Metalloproteinase-9 Levels to Assess the Cardiovascular Risk in Hemodialysis Patients
Yu Bo Lee, So-young Lee, Hyeun Jeong, Yang gyun Kim, Ju young Moon, Sangho Lee, Jin sug Kim, Kyung Iwan Jeong, Shin-Young Ahn, Dong-Young Lee, Hyeon Seok Hwang, CHA Bundang Medical Center, Seongnam, Gyeyonggi-do, Republic of Korea; Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea; Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; Korea University, Seongbuk-gu, Seoul, Republic of Korea; Seoul Veterans Hospital, Gangdong-gu, Seoul, Republic of Korea.

Background: Matrix metalloproteinases (MMPs) are endopeptidases that control extracellular matrix synthesis and degradation. Two MMP subtypes, MMP-2 and MMP-9, are known to play important roles in the development and progression of cardiovascular (CV) disease, but its clinical relevance as predictors of cardiovascular events is unclear in hemodialysis patients.

Methods: We prospectively enrolled 435 patients undergoing maintenance hemodialysis from K-cohort between June 2016 and April 2019. Plasma MMP-2, MMP-9 levels, and several biomarkers were measured at the time of study data entry. Primary endpoint was defined as a composite of cardiovascular events.

Results: Plasma MMP-2 level were increased in patients with incident CV events than those without CV events, whereas plasma MMP-9 levels were not different between groups. MMP-2 levels were positively correlated with circulating cardiac markers including brain natriuretic peptides (BNP), N-terminal proBNP, and heart-type fatty acid binding protein. The cumulative event rate of the composite of CV events was significantly greater in patients with higher MMP-2 tertile than in those with other MMP-2 tertile (p = 0.015). MMP-2 tertile 3 was associated with a 2.77-fold higher risk of the composite of CV events (95% CI, 1.40–5.45) and 4.67-fold higher risk of cardiac events (95% CI, 2.06–10.56) after multivariable adjustments. However, plasma MMP-9 levels were not positively correlated with circulating cardiac markers, and not associated with risk of incident CV events.

Conclusions: Higher plasma MMP-2 levels, but not MMP-9 levels, had the positive relationship with circulating levels of cardiac pathologic markers, and were associated with increased risks of incident CV events and cardiac events among hemodialysis patients.

PO0872
Utility of CHA2DS2-VASc Score to Predict Mid-Term Clinical Outcomes in Hemodialysis Patients
Aiko Okudo, Toshiaki Doi, Yoshiko Nishizawa, Kenichiro Shimogoto, Sono Mizuiri, Takao Masaki, Iryo Hójín Ichiyokai Harada Byoin, Hiroshima, Japan; Ichiyokai Yokogawa Clinic, Hiroshima, Japan.

Background: The CHA2DS2-VASc score has been widely used as a predictive score for stroke in patients with atrial fibrillation (AF). Recently, it was reported that the CHA2DS2-VASc score is useful for predicting cardiovascular disease (CVD) or all-cause mortality in patients with or without AF. However, few reports have examined the association between this score and mortality in hemodialysis patients. Inadequate risk factor was for 3-year all-cause mortality

Methods: We analyzed 525 consecutive patients who started hemodialysis at our facilities from March 2006 to October 2017. CHA2DS2-VASc score was calculated at time of initiation of hemodialysis. Multivariate Cox proportional hazards analysis was used to assess independent risk factors for 3-year all-cause mortality.

Results: During the 3-year follow-up period, 153 (29.1%) patients died (cardiovascular death, 98%). According to multivariate analysis, serum albumin [hazard ratio (HR) 0.62, 95% confidence interval (CI) 0.43–0.89, P=0.01], creatinine (HR 0.81, 95% CI 0.71–0.99, P=0.03), and CHA2DS2-VASc score (HR 2.31, 95% CI 1.21–4.46, P=0.001) were associated with 3-year all-cause mortality. Patients with CHA2DS2-VASc score ≥4 had higher risk of all-cause and CVD mortality than those with CHA2DS2-VASc score <4 (all-cause mortality: HR 2.20, 95% CI 1.42–3.71, P=0.001; CVD mortality: HR 2.83, 95% CI 1.37–5.44, P=0.001).

Conclusions: The CHA2DS2-VASc score is a useful predictor of 3-year all-cause and CVD mortality in incident hemodialysis patients.

PO0873
Fibrosis-4 Index May Predict Mortality and Non-Fatal Cardiovascular Events in ESKD Patients Starting Dialysis
Yeonee Lee, Da won Kim, Seok Joon Shin, Hye Eun Yoon, Moo Yong Park, Jae Young Park, Iqbal Iqbal, Jawed Fareed, Loyola University Health System, Maywood, IL.
Background: CKD and ESKD are known risk factors of heart failure (HF). And liver dysfunction as congestive hepatopathy due to HF is also common. Recent studies report that Fibrosis-4 (FIB4) index (age×ALT(IU/L)/platelet count(10^9/mL)/square root of AST(IU/L)), which was known to be useful tool for evaluating liver stiffness, can be prognostic factor of HF. Therefore, this study investigated whether FIB4 index may be prognostic factor of HF.

Methods: This was a retrospective cohort study including 388 patients who started dialysis at a single center. FIB4 index at dialysis initiation was calculated. Patients were stratified into three groups according to FIB4 index(<1.45:low, 1.45~3.25:intermediate, >3.25: high). The association between FIB4 index and event free survival rates for all-cause mortality and non-fatal CVE was analyzed. In addition, the association between FIB4 index and echocardiographic findings was analyzed.

Results: During a median follow-up duration of 40.0(0.03-142.3) months, 84 deaths(21.6%) and 83 non-fatal CVE(21.4%) occurred. Event free survival rates were lower in high-FIB4 group, compared with those in low-FIB4 group(p=0.001) and intermediate-FIB4 group(p=0.005), respectively. In Cox proportional hazard model, the high FIB4 index was independently associated with event free survival rates (HR, 2.21; 95% CI, 1.17-4.18; p=0.015). When comparing echo findings, only left atrial diameter (LAD) showed difference among groups(p=0.033). However, there was no significant correlation between LAD and FIB4 index.

Conclusions: In conclusion, FIB4 index is associated with event free survival rates for all-cause mortality and non-fatal CVE in ESKD patients starting dialysis.

PO0874
NT-ProBNP for Heart Function and Volume Status in Hemodialysis Patients
Kyungho Lee, Young seung Oh, Byung chul Yu, Moo Yong Park, Jin kik Kim, Seung D. Hwang, Soo Jeong Choi, Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: N-terminal pro brain natriuretic peptide (NT-proBNP) is a biomarker that predicts heart failure and evaluates volume status in Hemodialysis (HD) patients. However, it is difficult to determine the cutoff value of NT-proBNP in HD patients. In this study, we analyzed whether NT-proBNP helps with predicting heart function and volume status in HD patients.

Methods: Retrospective study was conducted on 96 end-stage renal disease patients with HD. All patients underwent echocardiography and Bioelectrical Impedance Analysis (BIA) after a post HD session. Overhydration (OH) was measured by BIA. Laboratory data were obtained on preHD during the mid-week HD sessions. Serum NT-proBNP was measured after HD.

Results: There was an inverse correlation between NT-proBNP and ejection fraction (EF) (β = -0.34, P = 0.001). Overhydration (OH) (β = -0.33, P = 0.01) and presence of diastolic dysfunction (β = -0.226, P = 0.027) had positive correlations with NT-proBNP. In the subgroup analysis with diastolic dysfunction grade, NT-proBNP increased as the dysfunction grade increased. (diastolic dysfunction grade 0; 417±2367-10391), grade 1; 9736 (5471-21110), grade 2, 3; 24627(16975-44988) Elevation of NT-proBNP above 4058 pg/ml was associated with the presence of diastolic dysfunction (p=0.001) and Left ventricular hypertrophy (LVH) (p=0.004). Elevation of NT-proBNP above 11576 pg/ml was associated with the presence of diastolic dysfunction (p=0.001), LVH (p=0.001) as well as EF<55% (p=0.07). The group with lowered dry weight followed up NT-proBNP one month later, compared to the group with no change in dry weight, NT-proBNP showed a tendency to decrease, and the group with no change in dry weight showed a relatively low level of NT-proBNP variability. (-210 (-12899 - 3142) vs 330(-1090 - 3858); interquartile range, p=0.104).

Conclusions: We confirmed that NT-proBNP is associated with volume status as well as heart functions such as diastolic dysfunction, LVH and EF in HD patients.

Heart function according to NT-proBNP level

PO0875
Dysregulation of Fatty Acid Binding Protein and Their Relationship with Inflammatory Biomarkers in ESRD
Emily Bontekoe, Vinod K. Bansal, Fakhi Siddiqui, Omer M. Iqbal, Jawed Fareed, Loyola University Health System, Maywood, IL.

Background: End stage renal disease (ESRD) patients are at high risk of cardiovascular disorders and hemostatic complications. Fatty acid binding proteins (FABPs) regulate the transport of fatty acids and other lipophilic mediators such as cholesterol and retinoids by both intracellular and extracellular mechanisms. While upregulation of FABPs have been reported in ESRD, their relationship with inflammatory biomarkers is not fully understood. Liver fatty acid binding protein (L-FABP) also known as FABP-1 is a 14kDa protein expressed in the liver. This protein is also expressed in tubular kidney cells. Kidney damage and other pathologic conditions result in the marked upregulation of this protein.

Methods: Citrated blood samples from 95 ESRD patients undergoing maintenance hemodialysis were collected prior to hemodialysis. For comparison purposes normal (5.1 ± 0.2ng/ml SEM) with a broad range (3.4 – 9.2 ng/ml). Marked increases in IL-6, TNfa and inflammation were also noted (2 – 4 fold). FABP-1 showed varying degrees of positive correlation with inflammatory biomarkers.

Conclusions: These studies suggest that plasma levels of FABP-1 is markedly increased in ESRD patients (up to 10 fold) in ESRD patients undergoing maintenance hemodialysis. Other biomarkers of inflammation are also upregulated and demonstrate varying degrees of correlation suggesting inter-relationship between FABP-1 and inflammatory processes. These results also support that impaired renal function and tubular damage contribute to the marked increase of L-FABP in ESRD patients. Simultaneous measurement of L-FABP with biomarkers of inflammatory responses and kidney damage may be helpful in the risk stratification and prediction of the adverse outcome in ESRD patients.

PO0876

Transcapillary Refilling Rate Profile in Hemodialfiltration
Juan P. Rivas de Noriega, Gerardo Medina, Salvador L. Gil. Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

**Background:** Reaching dry weight in end-stage kidney disease (ESKD) patients is subject to high ultrafiltration rates (UFR) during their hemodialfiltration (HDF) sessions. We seek to profile the transcapillary refilling rate (TRR) during HDF, which we infer to be an important protective factor against intradialytic hypotension (IH).

**Methods:** We studied 30 patients in HDF scheduled 3 times a week. Absolute blood volume was measured with the dilutional method and plasma volume was calculated based on the patient’s hematocrit. Each session was divided in 18 intervals of 10 minutes each. Overhydration was tested by calculating the expected plasma volume. Real plasma volume at the end of each interval was calculated on the basis of the relative blood volume. The difference between the real and the expected plasma volume was the plasma refill volume, which divided by the time of each interval gave us the TRR. The HDF session prescription was determined by the nephrologist in charge of the HDF clinical services.

**Results:** 84 HDF sessions were recorded. Mean age was 44 years (+/- 18.8), 66% were female. TRR:UFR ratio difference between patients with and without IH was statistically significant (p <0.001, CI 95%), as well as the UFR-TRR delta (p <0.001, 95% CI). This ratio achieved stability after 30 minutes. Eight patients (27%) presented an IDH episode during HDF, during a total of 9 sessions (10.7%); 8 (89%) occurred in the final hour and 1 (11%) occurred in the first 10 minutes and corresponded to a patient who presented fever and bacteremia.

**Conclusions:** Both the TRR:UFR ratio and UFR-TRR delta were statistically significant for predicting IH. Understanding each patient’s TRR will help us plan interventions in order to try and optimize it and reduce the risk of IDH.}

Figure 1. UFR (solid lines) and TRR (dashed lines) profiles.

PO0877

Impact of Hydration Status Measurement by Bioimpedance Analysis (BIA) on Haemodialysis Patients
Nasreen Samad,1 Franel Ave,1 Sara Z. Khan,2 Jerilyn Lalu.1 1Barts Health NHS Trust, London, United Kingdom; 2American University of Antigua College of Medicine, Saint Johns, Antigua and Barbuda; 3Northwell Health, New Hyde Park, NY.

**Background:** Volume status in haemodialysis patients is an important prognostic factor, where overhydration is associated with a higher frequency of mortality while diuresis-induced volume depletion is also an independent mortality risk factor. Clinical indices do not always accurately reflect volume status. Bioimpedance analysis (BIA) is used as a simple, noninvasive method which can measure normovolumic status in haemodialysis patients by measurement of height, weight, and body composition. Fluid overload is calculated by subtracting the normovolumic status from the overhydration status.

**Methods:** All patients at Queens satellite dialysis unit, Romford, United Kingdom, which has a prevalent population of 106 patients had BIA based assessment of fluid status every 3 months from July 2020 to May 2021 and dry weight adjusted accordingly. Outcomes were noted for blood pressure, overhydration, Interdialytic weight gains, intradialytic hypotension, hospitalisation and mortality.

**Results:** 121 haemodialysis patients were followed with male to female ratio of 55:66, mean age of 62 (25-87) of whom 46 were diabetics. By end of assessment period, 21 patients had died (13 due to COVID related illness). In July 2020, 31 patients had overhydration of 2 litres or more, which reduced to 20 patients, in May 2021. The number of patients who had underhydration of -1 litre or more remained similar with 12 patients in July 2020 compared to 11 in May 2021 with respect to more aggressive approach to reduction in dry weight. The dialysis population had high turnover due to deaths as well as 2 transplantations and 2 transfers out of the unit. During the time of study 15 patients were admitted to hospital with features of fluid overload.

**Conclusions:** Bioimpedance analysis (BIA) is a simple, non invasive tool helpful in assessing fluid status in haemodialysis patients. It is easier to convince a patient about their volume status by providing a machine assessed figure rather than clinical parameters. There was significant improvement in overhydration without increasing the number of death in patients. The high mortality in prevalent patients during COVID pandemic highlights the need for continued body composition measurement studies in a larger population once COVID cases subside to come to a significant conclusion about the impact of BIA in improving patient outcomes including effect on residual renal function.

had more pericardial effusions (12.5% vs 2.3% p = 0.048) and more GIB (12.5% vs 2.2% p = 0.046) (Table 1). There were no differences in in-hospital mortality, hospital length of stay (LOS), ICU LOS, and sternal wound infections between groups across the different surgeries. 16 PD patients were converted to HD post-surgery, intent to treat analysis was applied for these patients.

**Conclusions:** In patients on maintenance dialysis, patients who underwent CABG, VS, and combined surgery had similar outcomes. PD patients appeared to experience more GIB and pericardial effusions requiring intervention in the CABG group.

**PO0881**

Prevalence and Risk Factors for Development of Cardiac Arrhythmias and Electrocardiographic Abnormalities in Hemodialysis Patients: A Single-Center Experience in Mexico.

Andrea San-German Morales,1 Pedro A. Escamilla Galindo,2 Armando Castillo García,3 Paulina Paniagua,1 Juan M. Ardavin Ituarte,2 Mario Jimenez Hernandez1,2 Universidad de las Americas Puebla, Cholula, Mexico; 2Medica Santa Carmen, Puebla, Mexico.

**Background:** Mexico is among the countries with the highest number of patients on kidney replacement therapy (RRT). Despite this, the incidence and prevalence of CKD in Mexico is unknown, due to the lack of a national registry as a result we do not know risk factors associated to this population. Electrocardiographic abnormalities or arrhythmias are among the most frequent cardiovascular pathologies, being the first cause of death during the first month in RRT. That is why the present study aims to identify the prevalence of arrhythmias in a group of Mexican patients on hemodialysis as well as their associated risk factors.

**Methods:** A non-experimental, observational, descriptive, and cross-sectional study was carried out in the period from March to July 2020 with Mexican patients older than 18 years in maintained hemodialysis. The electrocardiograms and blood test analysis were taken on the day of hemodialysis therapy.

**Results:** The mean age of the population was 42.37 years, 57% were male. Arrhythmias were found in 50 patients (41.67%), the prevalence of arrhythmias found was bundle branch block (17.50%), sinus tachycardia (12.50%), sinus bradycardia (7.50%), atrial fibrillation (2.50%), extrasystoles (1.67%). A significant difference in mean ages was found between patients with (47.14) and without arrhythmia (38.97) (p = 0.041). A history of heart disease (OR 7.54 95% CI 1.05-184.7), and the diagnosis of chronic renal failure secondary to diabetic nephropathy (OR 2.5459 95% CI 1.1026-5.8785) were identified as risk factors. The diagnosis of chronic renal failure secondary to arterial hypertension was no related as risk factor (p=0.86). No laboratory study was identified as a risk or protective factor for the development of arrhythmia either the vascular access type.

**Conclusions:** The studied population presented similar characteristics to the described previously, a high prevalence of electrocardiographic abnormalities was identified, laboratory studies were not related to the presence of arrhythmias. History of heart disease and kidney disease secondary to diabetic nephropathy were associated as a risk factors, while the presence of arterial hypertension was not identified as risk factor.

**PO0882**

Evaluation of Venous Congestion in Chronic Hemodiafiltration Patients During Ultrafiltration: A Prospective Cohort Study

**Background:** Fluid overload is deleterious in chronic hemodialysis patients. The combination of multiple POCUS markers can identify significant venous congestion. These markers have not been prospectively studied in this population.

**Methods:** We measured inferior vena cava (IVC) diameter, portal vein pulsatility fraction (PVPF), jugular vein at rest (YVR) and hepatic vein flow (HVF) at five points: pre-dialysis, three times during dialysis and post-dialysis. All measurements were done three times and averaged. All patients had at least 3% weight gain based on their estimated dry weight. We recorded ultrafiltration volume at each point.

**Results:** We performed measurements during 30 on-line post dilution hemodiafiltration sessions in 20 patients (13 were female, mean age 38.6 years old). The average total ultrafiltration (UF) volume was 250.1 cc (1250-4250 cc). There was a significant reduction in PVPF, IVC diameter, YVR, HVF during sessions. See Figure 1. Likewise, UF volume correlated with IVC diameter: R -0.38 p<0.001; PVPF: R -0.31 p<0.001; and HVF: R -0.19 p<0.035.

**Conclusions:** In chronic hemodialysis patients, even in the absence of a dilated IVC, markers of venous congestion tracked ultrafiltration volume. This study warrants further research with regards to clinical decision to continue fluid removal in chronic hemodialysis patients.
PO0883

Knowledge and Practice of Incremental Dialysis: A Survey of Canadian Nephrologists

Background: Incremental hemodialysis, a strategy to individualize dialysis prescriptions at initiation, is being linked to enhanced quality of life and acceptability by patients and decreased health care costs. We aimed to explore knowledge and practice pattern regarding facility-based incremental hemodialysis in Canada.

Methods: A web-based survey of nephrologists, elicited current incremental hemodialysis (HD) prescribing practices, clinical and patient factors used to determine suitability for treatment, and potential barriers to implementation. The survey was circulated over a period of six weeks (September 21, 2020 and October 30, 2020).

Results: The overall response rates 35% (243/691 nephrologists surveyed). Majority (66/111, 59%) of respondents prescribed incremental HD using an individualized approach at the discretion of the nephrologist. Most centers (200/203, 98%) did not report policy or guidance for implementation. Residual urine output was identified as the most important factor for eligibility (112/172, 65%), electrolyte stability (76/172,44%) and existing patient goals of care (69/117, 49%). The majority of nephrologists agreed that dialysis prescriptions are dynamic and should take residual kidney function into consideration; however, 74% of nephrologists did not think there was strong evidence supporting incremental dialysis. Potential barriers identified were patient safety, logistics of scheduling, limited evidence, and acceptance of dose escalation. Despite these barriers, 82% of participants felt that that facility-based incremental dialysis is feasible with their current resources and 78% agreed that with specific exclusion and inclusion criteria, incremental dialysis is a safe option.

Conclusions: Incremental hemodialysis is commonly practiced amongst Canadian nephrologists despite a lack of formal criteria for initiation and treatment escalation. This highlights a need for research to guide policy and practice for incremental hemodialysis in Canada.

PO0884

Thrice vs. Twice Weekly Hemodialysis in a Rural Community Center

Paavan Bonagiri,1 Namrata Singhania,1 Girish Singhania,2 Abutaleb A. Ejaz.4
1University of Virginia, Charlottesville, VA; 2University of Utah Health, Salt Lake City, UT; 3Mount Carmel East Hospital, Columbus, OH; 4University of Florida, Gainesville, FL.

Background: Converting stable ESRD patients from thrice to twice weekly HD sessions for at least 3 months duration were screened for eligibility for conversion to 2xWkly HD session in a university-affiliated community dialysis program. Eligibility criteria were: residual renal function > 3ml/min; urine output >500mL/day; intradialytic weight gain <2.5kg; hemoglobin >8gm/dL; manageable phosphorus and potassium levels. Clinical parameters on 3xwkly vs. 2xwkly HD sessions were then performed in the eligible patients. Patients were followed for 6 months post conversion.

Results: 9.8% of total HD pts were eligible. Baseline characteristics: age 65±14.5yrs, P 57.1%, HTN 71.4%, DM 14.2%, MM 14.2%. Major indication for HD initiation was symptomatic progression of disease. Less than 50% of pts had a functioning arteriovenous fistula at initiation of HD. In the current cohort, residual renal function > 3ml/min was maintained for > 200 days after initiation of HD. There were no significant changes in electrolytes, hemoglobin, nutrition status or adequacy of dialysis. PTH levels were not significantly different: 3xwkly, 625.7±546.2pg/mL vs. 2xwkly, 399±344.2pg/mL; p=0.374). Karnofsky Performance Status Scale improved post conversion but did not achieve statistical significance (3xwkly, 57.1 ± 2.5xwkly, 70; p=0.316). There were no hospital admissions since conversion to 2xwkly schedule during the study period.

Conclusions: 10% of total HD patients qualified for conversion from 3xWkly to 2xWkly maintenance HD without significant changes to laboratory or clinical performance measures. These observations stimulate discussion regarding increased application of incremental dialysis initiation strategies to preserve residual renal function, increase dialysis-free days and alleviate transportation and care provider-related burden to patients and families, especially in underserved areas.

Impact of the Ratio of Monocyte to High-Density Lipoprotein Cholesterol on Cardiovascular Outcome in Incident Dialysis Patients

Background: Monocyte count to high-density lipoprotein ratio (MHR) is a well known marker of cardiovascular risk and atherosclerosis. We evaluated the impact of the MHR value on the CV outcomes in end-stage kidney disease (ESKD) patients. The primary outcome was comparison of cardiovascular event-free survival rate between the low MHR group and the high MHR group. The secondary outcome included all-cause mortality, overall CV mortality and possibility of MHR as an independent risk factor for CV complication.

Methods: The medical records of 719 ESKD patients who started maintenance dialysis between January 2006 and July 2017 were reviewed. Patients were divided into low MHR and high MHR groups based on the median MHR value.

Results: Overall CV event was 130 cases, 55 in the low MHR group and 75 in the high MHR group, respectively. The CV event-free survival rate was significantly lower in the high MHR group compared to the low MHR group (47.6% vs. 57.5%, P = 0.017). Of the 577 enrolled patients, there was no statistical difference in all-cause mortality between the two groups during a mean follow-up of 3.2 years (P = 0.371). Overall CV mortality rate was also comparable between the two groups (P~ 0.615). In multivariate Cox regression analysis, high MHR was an independent predictor for CV events (HR 1.463, 95% CI, 1.019 – 2.102, P = 0.039) even after adjustment for age, smoking, diabetes, body mass index, C-reactive protein, and previous CV disease.

Conclusions: In conclusion, high MHR at the time of dialysis initiation in the incident ESKD patients may be a simple and useful method for predicting development of CV complication.

PO0886

Differences in Clinical Characteristics and Outcomes Between Hemodialysis-Dependent and Non-Hemodialysis-Dependent Patients with Gram-Negative Bacteremia

Matthew B. Sinclair,1 Joshua T. Thaden,1 Felicia Ruffin,1 Lawrence Park,1 Michael M. Dagher,1 Christina M. Wyatt,1,2 Vance G. Fowler,1,2 Duke University School of Medicine, Durham, NC; 3Duke Clinical Research Institute, Durham, NC; 1Duke University Hospital, Durham, NC; 3Duke Global Health Institute, Durham, NC.

Background: Gram-negative bacteremia (GNB) is a common and potentially lethal infection among hemodialysis (HD)-dependent patients. The determinants of clinical outcomes in HD-dependent patients with GNB are incompletely understood. We compared clinical characteristics and outcomes between HD- and non-HD-dependent patients with GNB in a large cohort of hospitalized patients and subsequently examined associations between specific characteristics and all-cause mortality among HD-dependent patients.

Methods: Hospitalized, non-neutropenic adults with GNB were prospectively enrolled from Jan 1, 2002 to July 1, 2015. Clinical characteristics and outcome data were collected. Differences between HD- and non-HD-dependent patients were estimated using means/standard deviations or counts/percentages with statistical significance evaluated with independent sample T-tests or Pearson’s chi-squared test. Associations between clinical characteristics and outcomes were estimated using logistic regression. Results: Among 1,827 unique participants, 180 were HD-dependent (9.9%). Compared to non-HD-dependent patients, HD-dependent patients were younger (58.6 vs 61.0 years, p<0.05) and more likely to be Black (55.6% vs 26.4%, p<0.001), to have diabetes (56.1% vs 32.1%, p<0.001), and to die prior to hospital discharge (28.9% vs
Predictors of Hyperkalemia Among Chronic Hemodialysis Patients Transported to the Emergency Department

Karthik K. Tennankore,1,2 David Clark,1,2 Patrick T. Fok,1,2 Judith Goldstein,1,2 Keigan More,1,2 Megi Nallbani,2 Amanda J. Vinson,1,2 Hana Wiener,1,2 Wayel Zanjir,1,2 Dalhousie University, Halifax, NS, Canada; 3Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Chronic hemodialysis (HD) patients often present to the emergency department (ED) with hyperkalemia, which in turn, is associated with morbidity and mortality. In this study we sought to identify pre-hospital predictors of hyperkalemia in patients transported to the ED via ambulance (ambulance-ED).

Methods: We analyzed all ambulance-ED transports in a cohort of chronic hemodialysis patients from 2014-2018 (using a province-wide emergency medical services database). The outcome was severe hyperkalemia using the first blood draw after ambulance-ED transport defined as ≥ 4.6 mmol/L. Characteristics of interest included vital signs prior to transport, days from last dialysis and prehospital electrocardiograms (ECGs) interpreted by paramedics prior to transport. The association between prehospital factors and hyperkalemia was analyzed using adjusted logistic regression.

Results: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.

Conclusions: A total of 270 dialysis patients had 704 ambulance-ED transports followed by an ED potassium blood draw. Severe hyperkalemia occurred after 75 (11%) transports. In an adjusted parsimonious model (Table 1, N=609), age, dialysis vintage, bradycardia and days from last dialysis were associated with severe hyperkalemia. Among those with prehospital ECGs (N=377), presence of a prehospital ECG abnormality (i.e. peaked t-waves and/or first-degree atrioventricular block) was strongly associated with ED hyperkalemia (odds ratio 6.64, 95% confidence interval 2.31-19.12). Overall, 45% of hyperkalemia patients versus 24% of non-hyperkalemic patients re-required transport to another hospital to facilitate dialysis in a monitored setting after initial presentation.
Results: We studied 15,190 persons on HD without prior AF diagnosis; average age was 76 yrs, 49% were male, 69% were white, 26% black, and 8% Hispanic. At baseline, 7183 persons had a S-K+ ≥4.5 and 6988 <4.5 mEq/L. With the exception of race and ethnicity, all other characteristics, including D-K+, which was 2 mEq/L in 52% and 3 mEq/L in 34%, were balanced across groups. During a mean follow-up of 527 days the overall incidence of AF was 13/100 person-years. S-K+ and T48 were significantly variable fit the data best. After multivariable adjustment, AF was associated with lower, but not with higher S-K+ concentrations unless extreme values >6.5 mEq/L were reached. D-K+ of 3 mEq/L, vs. 2 mEq/L, was associated with 14% (95% CI: 5-24%) lower adjusted rates of AF. No interaction between S-K+ and D-K+ was present.

Conclusions: Hypokalemia was strongly and independently associated with incident AF whereas hyperkalemia was not. However, choice of D-K+ of 2 mEq/L vs. 3 mEq/L did associate with higher AF rates, independent of S-K+ and other measured characteristics.

Serum Potassium Changes in US Veterans Receiving Patiromer with Dialysis-Dependent ESKD and Hyperkalemia

Christopher G. Rowan, Jared Hansen, Brian C. Bauer, The University of Tennessee Health Science Center, Memphis, TN; 2Albany Medical College, Albany, NY; 3Vitor Pharma, Inc., Redwood City, CA; 4COHRDATA, San Clemente, CA; 5Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT.

Background: Patiromer is a sodium-free, non-absorbed, potassium (K+) binding polymer approved for the treatment of hyperkalemia (HK). This retrospective cohort study aimed to describe serum K+ changes in Veterans with HK and end-stage kidney disease (ESKD) receiving dialysis who initiated patiromer.

Methods: Serum K+ concentrations were evaluated pre- and post-patiromer initiation using the National VA Corporate Data Warehouse (1/1/16–8/31/18). Changes in mean serum K+ concentration were compared at 1, 3, and 6 months following first patiromer dispensing (index date) using the paired t-test (pre K+ versus post K+). All patients had a baseline K+ ≥5.1 mEq/L and ESKD. Patients with continuous exposure to patiromer were analyzed. Follow-up began on the index date and ended at first censoring event (discontinuation or switch of index K+ binder, death, end of follow-up, or 6 months post-index).

Results: 98 patients with ESKD requiring dialysis and HK initiated patiromer. Patient characteristics at baseline were median age 66 years, African-American race 39%, diabetes 71%, heart failure 40%, and mean K+ value of 6.1 mEq/L (standard deviation ±0.7). The initial dose of patiromer was 8.4 g in 96% of patients with few observed increases in unit dose during the follow-up period. Following patiromer initiation, statistically significant reductions in serum K+ concentration were observed at 1 month (–1.24 mEq/L), 3 months (–1.15 mEq/L), and 6 months (–1.36 mEq/L; Figure). Changes were maintained post-dispensing during follow-up years. Mean changes with HK, as squared, was associated with clinically relevant reductions in serum K+ concentrations at all study time points. These findings warrant additional investigation in a larger dialysis cohort with HK.

PO0892

Hyperkalemia: Medical Management vs. Hemodialysis

Joseph A. Gatesman, Mari A. DeVita, Lenox Hill Hospital, New York, NY.

Background: Hyperkalemia is a life-threatening electrolyte disorder for which there exists a paucity of data regarding benefit of urgent hemodialysis over medical management. We hypothesized there would be no difference in potassium levels among hyperkalemic patients who received only medical management compared to those who received hemodialysis, with or without hemodialysis.

Methods: This is a retrospective study of patients 18 years old with hyperkalemia (K ≥5.5 mEq/L). One group (medical management, or MM) had medication(s) including insulin/dextrose, sodium zirconium cyclosilate, sodium polystyrene sulfonate, calcium gluconate, albuterol, or furomide—or defined within 3h of initial elevated potassium. The other group (hemodialysis, or HD), had hemodialysis ordered—with or without medical management—within 3h of elevated potassium. The initial potassium level was considered “time-zero” and subsequent timepoints were followed up to 100h. T1 readings were established between 0-3 hours; T6: 3–8h; T12: 8–16h; T24: 20-28h; T48: 40–56h; T72: 60–100h.

Conclusions: Among patients presenting with hyperkalemia, we found no difference in potassium levels between those who received only medical management and those who received hemodialysis, with or without medical management. Further studies are necessary to confirm these findings. Nationally standardized treatment algorithms ought to be developed; a randomized trial would be conducive to that end.

PO0893

Metabolic Alkalosis in Hemodialysis Patients

Sritaram Arvind Mudunuru, Jose E. Navarrete, W. Charles O'Neill, Emory University School of Medicine, Atlanta, GA.

Background: Hemodialysis (HD) typically employs a high dialysate alkali concentration to counteract interdialytic acid production. Since acid production varies due to the amount and type of protein consumed, some patients may remain alkalotic throughout the interdialytic period and be more alkalotic during HD. This could have adverse effects including arrhythmias, hypotension, hypoventilation, and vascular calcification but dialysate alkali is rarely adjusted. Pre-HD alkalosis is usually ascribed to chronic illness and poor nutrition, but this has not been carefully examined.

Methods: We conducted a retrospective case-control study of all in-center HD patients from 2010-2020 at 4 outpatient HD units using citrate-containing dialysate (34.6 mEq/L HCO3, 0.4 mEq/L acetate, 2.4 mEq/L citrate; citrasate, Fresenius). Interdialytic alkalosis was defined as pre-HD serum [HCO3] ≥26 in ≥ 7 months of any 12-month period. Patients with serum [HCO3] ≥26 in ≥ 7 months of every 12-month period constituted the control cohort.

Results: Of 1271 patients with at least 12 months of HD, 444 met the alkalosis criteria for at least 1 one 12-month period and 73 had persistent alkalosis. 189 patients met the control criteria for every 12-month period. Patients with persistent alkalosis were older (66 vs 55 years, p<0.001) and weighed less (69 vs 82 kg, p<0.003), but the prevalence of comorbidities including cardiovascular disease, neoplasia, and diabetes was not increased. HD dose (kT/V) was greater (1.47 vs 1.37, p<0.001), protein catabolic rate was lower (0.85 vs 0.96 g/kg/day, p<0.001), and interdialytic weight gain was less (1.62 vs 2.28 kg, p<0.001). Despite significant weight loss over time (7 ±3 vs 0 ± 3.9 kg, p<0.001), mortality was not increased when adjusted for age, serum albumin was only slightly lower (3.71 vs 3.81 g/dl, p=0.01), and a lower mean eGFR/creatinine/chronic illness such as serum cholesterol and hemoglobin did not differ from control patients.

Conclusions: Transient interdialytic alkalosis was common in this HD population and persistent alkalosis was not rare (~5%). Alkalosis appeared to result from a greater dialysis dose and lower protein intake but not chronic illness. Further studies are needed to determine whether this alkalosis is detrimental and adjustment of dialysate [HCO3] is indicated.

PO0894

Metabolic Alkalosis in Hemodialysis Patients: Worse Outcomes

Background: The ideal serum bicarbonate levels in prevalent hemodialysis (HD) patients is still debatable. Metabolic alkalosis in these patients has been associated with increased morbimortality. The aim of this study was to evaluate the association between serum bicarbonate and nutritional and cardiovascular risk markers, hospitalizations and mortality.

Methods: This was a single-center, retrospective study, of a cohort of 158 in-center HD patients, with a duration of 24 months. Serum bicarbonate levels were evaluated predialysis every 3 months. Body Composition Monitor was used to assess nutritional and hydration status. Electrocardiogram and echocardiogram data were obtained to calculate the QTc interval and the left ventricular mass index, respectively. Vascular calcifications were assessed using the Adrágão score (SVCS).

Results: Mean age of the population was 69±12.6, 73% were male and 45% had diabetes. Median HD vintage was 59 months (IQR: 65 months). Mean serum bicarbonate levels were evaluated at 12-month period. Patients with serum [HCO3] 19-23 in ≥ 7 months of every 12-month period were considered to have persistent alkalosis was defined as pre-HD serum [HCO3] ≥26 in ≥ 7 months of any 12-month period. Patients with serum [HCO3] ≥26 in ≥ 7 months of every 12-month period constituted the control cohort.

Conclusions: Persistent alkalosis was associated with higher HD mortality (r=0.08, p=0.001), and interdialytic weight gain was less (3.71 vs 3.81 g/dl, p=0.01), and a lower mean eGFR/creatinine/chronic illness such as serum cholesterol and hemoglobin did not differ from control patients.

Posterior reversible encephalopathy syndrome (PRES) appears to be related to cerebral blood flow dysregulation and endothelial cell disease, and immunosuppressive states, common diseases in ESKD. The pathophysiology understood. Reported cases of PRES have been linked with hypertension, autoimmune disease, and calcium channel blocker use. The clinical presentation is characterized by headache, altered mental status, and posterior brain white matter edema on imaging studies. PRES is a radiological syndrome first reported in 1996 which describes the presence of a wide range of neurological symptoms, and posterior brain white matter edema on imaging studies. As such, there is an association with an increased number of infection-related hospitalizations and mortality, as well as higher all-cause mortality. Serum bicarbonate levels ≥24.5 mEq/L were associated with lower survival at 24 months. Prospective studies are needed to determine the ideal serum bicarbonate levels in HD patients.

PO0895
The Use of Caffeine to Treat Intradialytic Hypotension

Introduction: Intradialytic hypotension (IDH) affects between 15% to 70% of patients on hemodialysis (HD) and may cause long-term multisystem ischemic damage. One proposed mechanism for IDH is the accumulation of local adenosine causing vasodilation. Agents such as midodrine and caffeine counter these vasodilatory effects. Herein we present a case of IDH where the ingestion of caffeine prior to HD sessions significantly reduced the severity of IDH.

Case Description: A 77-year-old female with CKD-5, longstanding hypertension, and type 2 diabetes mellitus was admitted for initiation of HD. During her 1st HD session, she experienced IDH with a sudden drop in her systolic blood pressure (SBP) from the 193 to 113, accompanied by loss of consciousness and convulsions of the bilateral upper extremities, and diffuse confusion. She recovered consciousness without a postictal state and no significant changes on ECG. Echocardiography ruled out pericardial effusion. On subsequent HD sessions, the patient continued to experience IDH with average decreases of over 100mmHg in her SBP. Initial management by lowering blood flow rate, lowering dialysate temperature, and holding the patient’s pre-dialysis antihypertensive regimen had only a mild effect in preventing IDH. Given previous studies showing the efficacy of 250 mg caffeine capsules in preventing IDH, we tested the effect of caffeine on this patient’s IDH. 30 minutes prior to her next inpatient HD session, we administered 10 oz of coffee (150 mg of caffeine). Her drop in SBP during that session was markedly reduced from 187 to 149.

Discussion: Non-pharmacological measures to prevent IDH have been previously implemented but lack well-powered clinical trial evidence. Using coffee as a vehicle for caffeine administration was an effective preventive measure for IDH in our patient. We hypothesize that this effect is adenosine inhibition mediated. Adenosine is released by cells undergoing localized ischemia during HD, causing vasodilatation. Studies show an increase of serum adenosine during HD. Caffeine is a non-selective adenosine receptor antagonist, and can prevent sudden vasodilatation during dialysis. Thus, coffee may be an effective alternative to midodrine for the prevention of IDH. In conclusion, coffee provided a readily available, inexpensive, patient-centered, non-pharmacological measure to reduce IDH while also decreasing the risk of polypharmacy.

PO0896
A Case of Posterior Reversible Encephalopathy Syndrome (PRES) in an ESKD Patient with COVID-19
Viktor J. Martinez, Darancie Chewaprook. Albert Einstein Medical Center, Philadelphia, PA.

Introduction: Posterior reversible encephalopathy syndrome (PRES) is a clinicoradiological syndrome first reported in 1996 which describes the presence of a wide range of neurological symptoms, and posterior brain white matter edema on imaging studies which may be reversible. The clinical presentation is characterized by headache, altered consciousness, visual disturbances and seizures; hypertension is frequent, although not invariably.

Case Description: A 37-year-old male with past medical history of hypertension and diabetes mellitus, admitted to the hospital with complaints of headache, altered consciousness, visual disturbances and seizures; hypertension is frequent. He was admitted in the ICU with a blood pressure of 274/147 mmHg, RR of 16, HR 98 bpm and oxygen saturation of 89% on room air. Due to acute visual loss, a stroke alert was initiated. A head CT scan showed subcortical hypodensities in the bilateral occipital lobes consistent with PRES. He was started on Nicardipine drip in the ICU with subsequent decrease in blood pressure to 166/105 mmHg. His vision restored fully without further episodes of vision loss. Patient was found to be positive for COVID-19 and did not receive treatment for it as his hypertension and hyperglycemia was well controlled and hypertension was resolved. The patient received maintenance HD with Nicardipine drip was weaned, and he was transitioned to oral blood pressure medications.

Discussion: The relationship between kidney disease and PRES is not fully understood. Reported cases of PRES have been linked with hypertension, autoimmune diseases, and immunosuppressive states, common diseases in ESKD. The pathophysiology of PRES appears to be related to cerebral blood flow dysregulation and endothelial cell dysfunction. The proinflammatory response in COVID-19 produces dysfunction and death of endothelial cells which may increase vascular permeability, promoting the cerebral edema seen in PRES. The estimated prevalence of PRES in COVID-19 patients is between 1-4%. Reports of PRES in ESKD are rare. PRES may not be readily recognized given the heterogeneity of presentation. Therefore, high index of suspicion is needed in the ESKD population.

PO0897
Eye Pain During Hemodialysis: Ocular Dialysis Disequilibrium?
Sarah Abbass Massih,1 Monika Aggarwal (Gupta).1 Virginia Commonwealth University Health System, VA; 2VA Richmond Medical Center, Richmond, VA.

Introduction: Changes in Intracocular pressure (IOP) during hemodialysis (HD) are underrecognized. We report a case of increased IOP during HD, successfully treated with adjustments to dialysis prescription.

Case Description: 59-year-old African American man with End Stage Renal Disease (ESRD) secondary to diabetic nephropathy on HD since 2017, presented with excrecuting right eye pain during HD for 2 weeks. He described increasing right eye pain during HD, requiring early termination of dialysis after 3 hours. He has known right eye glaucoma with no vision. He was on atropine sulfate, prednisolone acetate, latanoprost, dorzolamide/timol, and brimonidine tartrate eye drops. IOP in right eye were 63 and 80 mm of Hg, before and after hemodialysis, respectively. Left eye IOP were ≤20 mm Hg and did not change significantly with dialysis. Due to concerns for ocular dialysis disequilibrium; blood flow rate, dialyse rate flow rate, dialysate temperature, and dialysate sodium were changed to 400 ml/minute from 450 ml/minute, 500 ml/minute from 800 ml/minute, 35.6 C from 37 C, and 145 mEq/L from 140 mEq/L, respectively. Subsequent to changes to dialysis prescription, patient was able to complete dialysis with no worsening of right eye pain and IOP (62 and 64 mm of Hg before and after dialysis, respectively).

Discussion: Increase in IOP during HD is thought to be due to rapid decline in plasma osmolality relative to aqueous humor, creating an osmotic gradient that causes movement of water into the eye. Patients with normal eye outflow have minimal rise in IOP as aqueous humor is drained simultaneously. However, patients with glaucoma are not able to drain excess water, causing increase in IOP and eye pain. Older age, diabetes mellitus, and African-American race are risk factors for ESRD and Glaucoma. Early recognition of ocular dialysis syndrome can allow for safe delivery of dialysis in patients with glaucoma. While acetazolamide is an effective treatment for raised IOP, it’s efficacy and safety in ESRD remains unknown. Similarly role of Mannitol in mitigation of ocular dialysis disequilibrium is unclear. Our patient had resolution of ocular dialysis disequilibrium in decrease in blood and dialysate flow rates, increase in dialysate sodium and, decrease in dialysate temperature. Increase in ultrafiltration may also reduce risk of ocular dialysis disequilibrium by raising extracellular osmotic pressure.

PO0898
The Association of Interdialytic Weight Gain in Long Intervals with Residual Renal Function Decline
Yoshikazu Miyasato,1,2 Tsuyoshi Miyagi,1 Yoko Narasaki,2 Hiroshi Kimura,1 Kamiyar Kalantarr-Zadeh,2 Elani Sirjea.1 University of California Irvine, Irvine, CA; 2Kumamoto Daigaku, Kumamoto, Japan.

Background: Preservation of residual renal function (RFR) in dialysis patients is important for better prognosis. The effect of interdialytic weight gain (IDWG) on change of RFR has not been investigated well. We examined the association of IDWG in long intervals (i.e. 2-day breaks between dialysis treatments) with rapid decline of RRF.

Methods: This retrospective cohort study included 6425 patients who initiated hemodialysis in a large dialysis organization in the United States from 2007 to 2011. We examined the association between seven categories of IDWG in long intervals (IDWGIL) and rapid decline of RRF using logistic regression model. Rapid decline of RRF was defined as the percent decline in renal urea clearance (KRU) greater than the median value of the cohort in the first year after dialysis initiation. Seven categories of IDWG were as follows: 0-<1%, 1-<2%, 2-<3%, 3-<4%, 4-<5%, 5-<6%, and ≥6%. We also examined continuous associations between IDWGIL and rapid decline of RRF using restricted cubic spline analysis.

Results: Higher categories of IDWG were associated with increased risk of rapid decline of RRF. The odds ratios (95% confidence intervals) of rapid decline of RRF for IDWGIL of ≥4%, ≥5%, ≥6%, and ≥6% were 1.04 (0.90-1.20), 1.31 (1.09-1.56), 1.19 (0.94-1.51), and 1.60 (1.49-1.71) (Figure a). The restricted cubic spline analysis showed that risk of rapid decline of RRF increased when IDWGIL exceeded 2% (Figure b).

Conclusions: Our results showed higher IDWGIL was associated with higher risk of rapid decline of RRF. IDWGIL exceeded 2%, especially ≥4%, seems to be thresholds for higher risk of RRF decline.
Prevalence of Anti-Erythropoietin Antibodies in Patients with ESRD on Regular Hemodialysis: A Single-Centre Experience

Kevin T John Keeppalli, Manikantan Shekar, Ramprasad Elumalai. Sri Ramachandra Institute of Higher Education and Research, Chennai, India.

Background: Recombinant human erythropoietin (rHuEPO) is a glycoprotein that acts as a biological substitute for the endogenous substance used to treat anaemia in individuals with end-stage renal failure. Patients with rHuEPO resistance have been described, requiring higher and higher dosages of the drug to maintain an appropriate haemoglobin level. These antibodies probably cross react with the patient’s endogenous EPO and lead to anaemia that can be more severe than even before the onset of EPO therapy. The prevalence of anti-erythropoietin antibodies in renal patients who respond poorly to erythropoietin is unknown.

Methods: We screened 262 patients who were on maintenance haemodialysis and excluded patients who were malnourished and had chronic liver disease, hypothyroidism, ongoing active autoimmune disease, active infection, on steroid therapy, with bleeding or hemolysis and elderly. 96 ISRD patients who were on recombinant human erythropoietin > 6 months and hemoglobin < 10 g/dL were included. Serum anti-erythropoietin antibodies were detected by enzyme-linked immunosorbant assay technique. All patients were subjected to full history taking and clinical examination. Complete blood count, reticulocyte count, serum creatinine, blood urea, serum albumin, serum ferritin, and haemoglobin tests were performed for all patients.

Results: Results showed that 26 patients (27.08%) had the anti-EPO antibodies in their blood, while 70 patients (72.91%) did not have the circulating antibodies. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.4 g/dL ± 1.52) than in the antibody negative group (9.68 g/dL ± 1.14) (P = 0.000). The dose of EPO administered in both studies groups were significantly different. Logistic regression analysis also revealed that gender or age were not associated with any significant variation of serum antibody level. High levels of serum antibodies to EPO are a risk factor for EPO resistance.

Conclusions: Many anaemic ESRD patients treated with recombinant human erythropoietin have a low-affinity immune response to the recombinant protein that is readily detected. Antibodies to rHuEPO were shown to be greater in patients who received high EPO weekly dose. More research into anaemia management protocols in HD patients with positive anti-EPO antibodies is needed.

Posterior Ischemic Optic Neuropathy After Hemodialysis In a Patient with Uncontrolled Diabetes Mellitus

Introduction: Posterior ischemic optic neuropathy (PION) results from ischemic damage to the retrolubar optic nerve and presents as severe acute painless unilateral or bilateral loss of vision. Any procedure that results in sufficient optic nerve hypoperfusion can cause retrolubar optic nerve damage. Hemodialysis (HD) as a cause of peri-procedural bilateral PION is a rare complication. While there are reports of successful cases of treatment with hyperbaric oxygen treatment and steroids, there is no established treatment protocol and the prognosis for recovery of vision in patients with peri-procedural PION is poor.

Case Description: A 34-year-old male with end-stage renal disease on HD presented with respiratory complaints and hypertension emergency (BP 224/135 mmHg). His procedural PION is poor.

Results: Results showed that 26 patients (27.08%) had the anti-EPO antibodies in their blood, while 70 patients (72.91%) did not have the circulating antibodies. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.4 g/dL ± 1.52) than in the antibody negative group (9.68 g/dL ± 1.14) (P = 0.000). The dose of EPO administered in both studies groups were significantly different. Logistic regression analysis also revealed that gender or age were not associated with any significant variation of serum antibody level. High levels of serum antibodies to EPO are a risk factor for EPO resistance.

Conclusions: Many anaemic ESRD patients treated with recombinant human erythropoietin have a low-affinity immune response to the recombinant protein that is readily detected. Antibodies to rHuEPO were shown to be greater in patients who received high EPO weekly dose. More research into anaemia management protocols in HD patients with positive anti-EPO antibodies is needed.

PO0901

Ocular Dysequilibrium with Eye Pain During Hemodialysis

Introduction: Eye complications may occur in patients with hemoglobinosis. Hemodialysis (HD) may lower plasma osmolality at a faster rate than changes in ocular osmolality can adapt. Here we are presenting two cases of ESRD patients who repeatedly developed eye pain only during HD.

Case Description: A 54 y/o Hispanic male with ESRD, right eye blindness & glaucoma who developed right eye pain only during dialysis treatments. The maintenance HD prescription was with duration of 4.5 h, blood flow rate (BFR) 450mL/min, dialysate flow 800 mL/min, Sodium (Na) 138 mEq/L, Calcium 2.7 mEq/L, Potassium 4.0 mEq/L, CO2 30mEq/L, & an average 2L fluid removal per HD. His BP was 130-140/80-90 mmHg. In response to the eye symptoms, the BFR was reduced to 350 mL/min & time was increased to 4.5 h. This change gave the patient initial relief from intradialytic eye pain. However, the patient continued to perform HD in the same manner. The period of HD treatments was enough to eliminate the intradialytic eye pain. The 2nd case was a 64 y/o AA female with ESRD and glaucoma developed recurrent left eye pain with headaches only during HD. She went to her Ophthalmologist who renewed her glaucoma medications. This relieved her eye symptoms, and normalized her intradialytic pressure off of dialysis. By taking her eye medications, she no longer developed eye pain or headaches during HD.

Discussion: Glaucoma is an ocular disorder where there is an increased IOP most commonly >22mmHg, this elevated pressure can cause blinding optic neuropathy. The current hypothesis for the rise of IOP during HD is related to an osmotic disequilibrium between the plasma & IO fluid, where the IO fluid is slightly hypertonic compared to plasma. Several medical therapies have been reported to mitigate the IOP increase during HD, such as the use of daily acetazolamide, mannitol infusion or 20% hyperosmolar glucose solution, or modified dialysis parameters with colloid infusion to raise plasma tonicity and decrease fluid shift during HD. However, these maneuvers have not been proven to relieve ocular symptoms. In general, use of higher dialysate Na conc. at hemodialysis are not considered a long term solution to intradialytic ocular hypertension, due to the tendency for increase fluid intake between HDs. Lower BFR with longer duration of hemodialysis treatments has been beneficial in some cases.

PO0902

Transient, Severe, Unilateral Eye Pain and Vision Loss Associated With Hemodialysis

Anas W. Hossam. WVU Nephrology, Morgantown, WV.

Introduction: Acute on chronic angle-closure glaucoma with elevated intracocular pressure is a well-established etiology of severe eye pain and profound vision loss, if not treated immediately. This case is a recurrent and episodic eye pain with transient visual loss during HD.

Case Description: 64 year-old Caucasian female with comorbidities including poorly-controlled insulin dependent type 2 diabetes, uncontrolled hypertension, obesity. She is on intermittent hemodialysis twice a week on weekdays. She was previously followed by a retina specialist for proliferative diabetic retinopathy with neovascular glaucoma. Initial onset approximately 1 year prior, with episodic transient palsy and complete unilateral vision loss lasting 30 minutes. The right eye developed recurrent episodes of left eye pain, maxillary topical and oral analgesic therapy was started, but her disease was refractory to conservative management. Surgical intervention was pursued, Valved Drainage Device (New World Medical) was placed under topical anesthesia. Post-operatively, the patient was able to undergo dialysis sessions without ocular symptoms and compliance has improved.

Discussion: The effect of hemodialysis (HD) on intraocular pressure (IOP) is variable and the exact mechanisms are still not clear. Previous reports in the literature suggest both increased and decreased intraocular pressure during fluid shifts associated with hemodialysis. Argon Pot assisted photocoagulation is known to reduce angle neovascularization induced by peripheral retinal ischemia in Neovascular glaucoma patients, IOP reduction is typically achieved with topical and systemic medications. Shunting and filtering procedures, including glaucoma valve implants and trabeculectomy surgery, may restore outflow and reduce IOP. After appropriate surgical intervention, the patient reported resolution of symptoms and improved tolerance to dialysis sessions.

PO0903

Caffeine Overdose Requiring Extracorporeal Mechanical Oxygenation (ECMO) and Hemodialysis

Lucie Leen, Connie J. Wang, Hennepin Healthcare, Minneapolis, MN.

Introduction: Caffeine (1,3,7-trimethylxanthine) is the most widely consumed psychostimulant in the world. It is considered safe if consumed in moderate amounts as it leads to cardiovascular collapse if the dose exceeds 150-200mg/kg. Extracorporeal removal of caffeine with intermittent hemodialysis (ICH) has been reported to improve outcomes. However, continuous veno-venous hemofiltration (CVVHDF), which is a routinely used extracorporeal therapy in patients with severe poisoning, is less favorably regarded for caffeine overdose because of inadequate rate of clearance. We present a case of combination therapy using both IHD and CVVHDF in the treatment of life-threatening caffeine overdose.
Case Description: A 33-year-old female weighing 63 kg presented after ingestion of approximately 100g of guanima powder (22g of caffeine). She presented with tachycardia (140-170 BPM) and severe hypotension (blood pressure 50/40 mmHg) resistant to 4 vasopressors at maximal dose. She required extracorporeal membrane oxygenation (ECMO). Baseline renal function was normal. IHD was initiated with blood flow rate (BFR) 200ml/min and dialysate flow rate (DFR) 500ml/min, which was gradually increased over 4 hours to a BFR of 400ml/min and DFR of 800ml/min; IHD continued for an additional 4 hours at this rate. During this 8-hour IHD treatment, her initial 4 pressor doses were halved, and she was transitioned to CVVHDF; the caffeine level was not available. However, after 12 hours of CVVHDF, the patient did not experience continued hemodynamic improvement, so IHD was reinitiated for 12 hours. Following this second prolonged session of IHD, she was weaned down to moderate doses of just two pressors. She was then transitioned back to CVVHDF for an additional 36 hours. At this time she was able to come off ECMO and all pressors. She had a full neurologic recovery. We later received a serum caffeine level of 425 mg/L (drawn soon after arrival at the hospital), which is the second-highest level ever reported; the established lethal concentration is 80 mg/L.

Discussion: Despite continuous dialytic therapies being generally favored in patients with ventricular tachycardia, IHD and CVVHDF may be used for hemodynamically unstable patients who ingest extremely high dose of caffeine. However, in such patients, continuous therapies are unlikely to supplant prolonged and repeated IHD treatment sessions.

PO0904
Anaphylaxis Secondary to Citric Acid Allergy in ESKD Patients
Hassaan Hitkhah, George Jarad. Washington University in St Louis, St Louis, MO.

Introduction: Dialysis reactions are common in ESKD patients undergoing hemodialysis (HD). We report first case of anaphylaxis related to citric acid solution used for dialysis disinfection & defloculation.

Case Description: 61-year-old male with history of ESKD on HD for 7 years, presented after missing dialysis. Patient underwent urgent HD upon presentation and developed signs of angioedema within first 30 minutes, requiring nasal intubation & treatment with epinephrine, steroids, & antihistamine. While intubated and hypotensive, patient had uneventful Slow Low Efficiency Dialysis. Angioedema was presumed secondary to antiemetics, which patient required due to severe nausea shortly after starting HD. Post extubation, patient developed similar reaction with milder symptoms with HD that responded to stopping HD and medical therapy. He had normal complement and mildly elevated tryptase. He was presumed to have a dialyzer reaction therefore, the dialyzer was changed from Revaclear to REXEED & it was tolerated well. He had similar severe reaction a week later while using the REXEED dialyzer. Investigations showed elevated anti-citrulline antibodies (EOTO) but clinical significance was questionable given the reaction only developed in inpatient setting. Later we discovered that dialysis machines are disinfected/descaled differently between inpatient & outpatient dialysis, even though both utilize citric acid, which might have led to more exposure to citric acid solution in inpatient setting. For next 2 weeks, patient was dialyzed using different combinations of dialysis machines, dialyzer & dialysis circuits including ones sterilized with ETO, however, all machines were disinfected/descaled using a combination of bleach & heat. After elimination of citric acid, patient had no further anaphylactic reaction.

Discussion: Dialyzer membrane reactions have been commonly described as Type A reactions mediated by dialyzer membrane (Igf mediated) and Type B membrane reactions mediated by complement activation. In our case clinical significance of ETO antibody was not clear, & angioedema was eliminated after removing citric acid from the machine disinfection. Industrial citric acid mediated angioedema has not been reported before, & it might be an important mediator of allergy in ESRD, & careful review of the dialysis machine preparation should be reviewed in every case of severe allergic reaction.

PO0906
Reverse Shoulder Arthroplasty in Dialysis Amyloidosis
Jessica Schilling,1 Srinath Kamineni,2 Dana Richards,2 Marie-Claude M. Faugere,2 Florence Lima,2 B. Peter E. Sawaya,2 Madhumathi Rao.2
1University of Kentucky College of Medicine, Lexington, KY; 2University of Kentucky Medical Center, Lexington, KY.

Introduction: The use of high-flux over cuprophane dialyzers, has led to Beta-2 microglobulin amyloidosis (B2M) becoming rare in long term hemodialysis (HD) patients. Amyloid fibers embed systemically, skeletal involvement producing bone cysts, tendinopathy and fractures.

Case Description: A 65-ya male on chronic HD for 30 years presented with progressive, right (R) shoulder intractable pain and limited range of movement (ROM). X-ray/MRI identified severe glenohumeral osteoarthrosis (OA), tendinopathy and large irreparable rotator cuff tear. Past history included heart failure, pulmonary hypertension, hepatitis C, severe secondary hyperparathyroidism and chronic anemia. Surgical history included bilateral (b/l) total hip arthroplasties, b/l carpal tunnel release, R nephrectomy for renal cell carcinoma in renal cystic disease. Due to the intractable pain, disability and failure of physical therapy and corticosteroid injection therapy he underwent reverse shoulder arthroplasty. Operative findings showed large soft tissue deposits about the subscapularis, glenoid and labrum, attributed to amyloid. Histology of intra-articular soft tissue, labrum and synovium confirmed amyloid (apple-green birefringence by Congo Red Staining) with focal calcium pyrophosphate deposition. Undecalcified histology of humeral head showed moderate secondary hyper-parathyroid bone disease with peri-trabecular amyloid deposits. Following surgery patient noted marked improvement in pain and partial improvement in shoulder ROM.

Discussion: No treatment exists for HD patients with B2M, ineligible for kidney transplant. Physicians are tasked with treating clinical manifestations that severely impact quality of life (QOL). Concern for adverse outcomes and paucity of surgical precedent should not deter appropriate surgical intervention. This patient illustrates the clinical and surgical decision-making targeted to improving (QOL).

Prediction of Severe Gastrointestinal Bleeding Events in Hemodialysis: Collaborative Development of Machine Learning Model Within INSPIRE

Suman K. Lama,1 Sheetal Chaudhuri,1 Joanna Willetts,1 John W. Larkin,1 Anke Winter,2 Manuela Stauss-Grabo,2 Len A. Usvyat,1 Jeffrey L. Hynes,3 Franklin W. Maddux,3 David C. Wheeler,1 Peter Stenvinkel,4 Jürgen Floege,3
On behalf of the INSPIRE Core Group 1Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; 3University College London, London, United Kingdom; 4Karolinska Institutet, Stockholm, Sweden; 5RWTH Aachen University Hospital, Aachen, Germany; 6Fresenius Medical Care AG and Co KGaA, Bad Homburg, Germany.

Background: InInitiativeS on advancing Patients’ outcomes In ReNal disease (INSPIRE) is an industry and industry collaboration set forth to identify critical investigations/models needed to advance the practice of nephrology. As an inaugural effort, INSPIRE group aims to develop a machine learning (ML) model that can identify a hemodialysis (HD) patient’s 30-day risk for hospitalization due to gastrointestinal (GI) bleeding.

Methods: We used data from adult (age ≥ 18 years) HD patients (Jan 2017–Dec 2020) in the United States to build a XGBoost model considering 2,292 variables for classification of 30-day GI bleed hospitalization risk. Data were randomly split in 50%:20%:30% ratio for model training, validation, and testing. Unseen data by model (testing) was used for assessing performance via area under the curve (AUC) and feature importance of predictors via Shapley (SHAP) values.

Results: Among 58,187 HD patients included in the testing dataset, 1150 had a GI bleed hospitalization. ML model showed AUC=0.67 and top predictors of a GI bleed hospitalization in 30 days were the minimum hemoglobin level in prior 180 days, time since prior GI bleed hospitalization, and higher vitamin D levels (Figure 1).

Conclusions: ML model appears to have suitable performance for identifying a patient’s 30-day risk for GI bleed hospitalization. Albeit further model iterations/tuning are needed, ML techniques that account for collinearity and missingness hold promise for early detection of potentially avoidable GI bleeding admissions. Model identified an important association between higher vitamin D levels and GI bleeding events, which is consistent with the increasing evidence suggesting antithrombotic and anticoagulant actions of vitamin D derivatives.

Funding: Commercial Support - Fresenius Medical Care
Methods: We used EHR data on pts new to HD between 2003-2016 from a national provider (n=54,148) linked with USRDS. We abstracted 86 predictor variables organized into person-mth and divided into training (n=32,488) and testing sets (n=21,660). The dynamic training set contributed 3.80k person-months. The static training set contained the first pt-month for those who initiated HD within 90-day (n=24,026). We fit LASSO logistic regression to predict mortality in the next 6-months and assessed both models on a time-varying test dataset. We report overall predictive performance metrics as well as visualization of time-varying patient risk in the 24 mths before a pt dies.

Results: Pt median age at initiation was 64 yrs; 43% female, 63% Caucasian; 7% died w/in 6 mths of initiation and 53% w/in 5 yrs. Top predictor variables were similar between the two models: age, serum chloride and serum albumin. The table shows performance metrics for the two models on the test data with the dynamic model performing significantly better. The plot shows the predicted risk for pts in the 24 mths prior to mortality. The dynamic model more quickly responds to pts changing risk, producing a higher predicted probability leading up to mortality.

Conclusions: A risk model built using time-varying data performs better than one using baseline data. Incorporation of dynamic models in dialysis-EHR could be used to direct appropriate population health interventions to the highest risk pts. Examination of dynamic risk models can elucidate pt-risk trajectories.

Machine Learning Classification of Tweets for Patient Dialysis Experience

Alexander S. Leidinger, Hawkins Gay, Bing Ho. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Popular microblog (e.g. Twitter, Facebook) services provide a continuous stream of public health information. This data has been used to monitor viral spread, medication adherence, and false health information. There are thousands of posts on Twitter daily regarding personal dialysis experience, access, and side effects. While these posts include valuable public health information, evaluating these posts to meaningfully assist dialysis patients is difficult as there are even more tweets mentioning dialysis in a professional context. We aimed to modify a state of the art natural language model to classify posts about dialysis as personal or professional.

Methods: We filtered posts containing the word dialysis. Posts were manually labeled as personal or professional by a nephrologist depending on the context dialysis was mentioned. The data was randomized and split for 60% training, 20% validation, and 20% testing. The text was preprocessed to remove extraneous characters and input into a Bidirectional Encoder Representations from Transformers (BERT) model for fine tuning, and a term frequency inverse document frequency vectorized Multinomial Naive Bayes Classifier.

Results: We collected 6011 tweets from May 3, 2021 to May 14, 2021.1000 tweets were randomized and labeled. 57% were categorized as professional. BERT and Naive Bayes models attained 88% and 82% accuracy, respectively, on the testing data. The BERT model classified far less false negatives with a small increase in false positives (Figure 1).

Conclusions: BERT’s semantically rich word embeddings can enhance social media mining algorithms on dialysis content. We show superiority of a BERT model over a traditional count-based language model. This method can be easily applied as a pre-processing step to remove noisy posts to better study dialysis and other health trends in social media. This novel processing task and pipeline have broad clinical and public health implications for reducing the amount of data and time required for accurate, real-time monitoring of patient level posts.

PO0911

Automating Dialysis Machine Alarms During Sustained Low-Efficiency Dialysis (SLED)

Gerard Zasuwa, Jerry Yee, Stanley Frinak. Henry Ford Health System, Detroit, MI.

Background: Sustained low-efficiency dialysis (SLED) with regional citrate anticoagulation (RCA) is frequently employed at our institution. RCA requires constant monitoring because a dialysis machines alarm that stops the blood pump (BP) or bypasses dialysate leads to an increased rate of citrate infusion into the patient, with consequence of ionized hypocalcemia. To enhance safety and surveillance efficiency, we developed an innovative computer/phone system that identifies SLED machine alarms and notifies clinical care staff directly via an appropriate phone network.

Methods: In 2017, we linked onboard SLED computer Wi-Fi systems to the hospital’s internal phone network (ASCOM). An alarm recorded by the SLED machine’s computer delivers an email to a dedicated email account that is subsequently transmitted to the ASCOM MailGate System. Mailgate produced and relayed text message alarms to dedicated ASCOM phones of dialysis technicians or nurses. Importantly, no additional training or changes in workflow are required for adoption of this method.

Results: This innovation has increased safety and efficiency. Response times for machine alarms improved and downtimes on dialysis were reduced, increasing dialysis dose of dialysis. To ascertain end-user satisfaction of the automated alarming system, we conducted a survey that demonstrates high-level satisfaction with the system (Table 1).

Conclusions: Currently, no medical alert companies connect dialysis machine information to a medical alert phone system. ASCOM provides wireless messaging systems for dedicated hospital applications. Notably, ASCOM does not directly connect to dialysis machines. In addition, Email Alerts can be browsed by managers for archival retrieval, quality and safety report generation, and investigation of unanticipated events.

Users of a Web-Based Communications Platform for Care Coordination of Hospitalized Dialysis Patients

Laura Plantinga,1 Courtney E. Herder,1 Janice P. Lea,1 Christopher M. O’Donnell,1 Ann E. Vandenbergh,1 Kyle P. James,1 Talsina Masud,1 Bernard G. Jaar,1 Carol A. Gray,1 Rich Mutell,1 Emory University, Atlanta, GA; Johns Hopkins University, Baltimore, MD; Apex Health Innovations, Williamsburg, VA.

Background: Better care coordination between dialysis clinics and hospitals may improve outcomes among hospitalized dialysis patients. To fill the gap created by separate electronic health record systems across the two settings, we rolled out a web-based communications platform (“DialysisConnect”) in four dialysis clinics and one hospital in Atlanta. Here, we examine usage patterns of DialysisConnect.

Methods: DialysisConnect included automatically uploaded clinical information from dialysis clinics, forms for entering critical admission and discharge information, and a direct communications channel. Two nephrologists and two hospitalists served as project champions at the dialysis clinics and hospital, respectively. DialysisConnect was made available to 106 potential users [hospitalists, nephrologists, advanced practice providers (APPs)] at the hospital and dialysis clinics, care coordinators (hospital), and nurses/nurse managers (dialysis clinic) starting 10/29/20. Descriptive statistics were used to describe patterns overall and by user role through 4/15/21.
Results: While physicians comprised most of the potential users, APPs and dialysis nurses were the most prevalent users (Table). Admission activity was more evenly distributed among users; e.g., one hospital-based APP recorded most of the admissions (n=225, 89%) and discharges (n=226, 93%) among patients treated at the dialysis clinics included in the pilot.

Conclusions: We found that physicians were unlikely to use DialysisConnect. Our user statistics suggest that APPs and nurses may be the most likely to engage with a care coordination system, which informs future pragmatic research in this area.

Family-Friendly, Work-Friendly, Home-Hemodialysis and In-Center Hemodialysis Hybrid: The First of Its Kind

Adam Locke, Macaulay A. Onuigbo. University of Vermont College of Medicine, Burlington, VT

Introduction: Hybrid dialysis is traditionally defined as the combination of peritoneal and hemodialysis (HD) in patients with end-stage renal disease. Its reported use is quite limited outside of Japan. We recently encountered major family-related and employment-related constraints that prevented a 39-yo man with ESRD on HD from completing the four-times weekly HD treatments with HD inadequacy and worsening of patient’s physiology. We successfully switched him to a new hybrid of twice-weekly HD + twice weekly In-Center HD. This is the first such report.

Case Description: A 41-ya male with ESRD secondary to SLE and hypertension on home HD, 4 x weekly, for some years experienced family-related constraints including non-availability of daycare for two young children due to COVID-19 pandemic, spousal illness and new work-related challenges with more travel and was missing his HD sessions. The result was inadequate HD delivery and worsening laboratory indices. He now receives 2 in-center HD treatments on Tuesdays and Thursdays, and 2 home HD treatments, one during the weekend and one during the week. This was started in February 2021. Each HD session lasts for 3.5 hours, 2000 units Heparin bolus, and his left brachiocephalic AVF is accessed by the button-hole method. The Home Dialysis Staff coordinates his dialysis care. Standardized Kt/V for May 2021 was 2.6.

Discussion: Hybrid dialysis is traditionally defined as the combination of peritoneal and HD in patients with ESRD. A 2020 Italian report described another type of hybrid dialysis that consisted of once-weekly in-hospital HD and home peritoneal dialysis to limit patient exposure to the hospital environment during the COVID-19 pandemic. We have described the successful application of a new Hybrid HD system that combined In-center HD with a mobile HD system. To our knowledge, our report is the first of its kind and was designed and implemented primarily for the purpose of overcoming increasing family and employment demands on the patient. This new hybrid dialysis option was designed to facilitate a family-friendly work-friendly HD on a long-term continuous basis. The patient, his family with two young children and his employers are happy and very satisfied. Simultaneously, the patient has continued to do well with adequate dialysis and meeting all the required goals of management in the past 3 months.

PO0914

Triple I Study: Hubs of Care Survey

Melanie D. Talson, 1 Marcello Tonelli, 2 Clara Bohm. 1 Can-SOLVE CKD Triple I Study Team 1University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; 2University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: The Can-SOLVE CKD Triple I Study identified continuity of care; access to a primary care provider (PCP) in the (CM) hemodialysis (HD) unit; and access to care for other medical conditions as key challenges to in-centre HD care (www. betterkidneycare.ca). The Hubs of Care project aims to address these challenges by incorporating health care providers (HCPs) from other settings in the HD unit; firstly, we identify current practice, potential interest and need and desire for different HCPs in HD.

Methods: A cross-sectional self-reported survey administered Feb-May 2021 with HD patients and staff at four academic sites across Canada. Eligible participants included adults fluent in English or French who could complete the survey independently. The survey asked which HCPs are currently in HD units, which additional HCPs would be most useful to add and whether patients are in favor of other HCPs visiting them either virtually or in-person. Additional data were solicited by free text. Preliminary analyses using descriptive, median (IQR) and proportion and summative content analysis, are presented.

PO0915

Utilization of the Tablo Hemodialysis System’s Data Platform: An Analysis of 100,000 Acute Dialysis Treatments

Josh Schumacher, Brittany Lim, Michael A. Aragon. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on demand dialysate production and two-way wireless data transmission capable of providing therapy up to 24 hours in a hospital setting. Limited connectivity of traditional hemodialysis systems constrains the ability to drive improvement in quality and efficiency of dialysis care. Tablo’s cloud-based data platform expedites care delivery in real time and informs on dialysis program metrics to facilitate quality improvement. The objective was to demonstrate Tablo’s automated wireless data capabilities through analysis of 100,000 Tablo acute treatments.

Methods: Tablo data were collected through real-time transmission via a cloud-based, HIPAA compliant platform. Analysis was performed by combining prescribed and achieved data on consecutive treatments. Treatments were divided into groups based on treatment time of less than 6 hours (conventional therapy) or greater than 6 hours (extended therapy).

Results: A total of 100,000 treatments between April 2020 and May 2021 were analyzed. Treatments ranged from 2-24 hours. Treatment time success, defined as achieved within 10% of prescribed time, was 90.7% across the population. The most common reason for early termination was “User ended” (8.6%), with 0.7% due to “Device Directed”. Mean total number of alarms per treatment was 2.5 across the population with no difference in alarm frequency (0.7 alarms per hour) between treatment groups. The most frequent clinically significant alarms were high and low venous pressures. Mean time to alarm resolution was 4.3 minutes, with shorter alarm resolution time demonstrated in the HHD group (13 vs 22s).

Conclusions: With high utilization across a wide range of treatment times in the acute setting, Tablo successfully achieved treatment goals. The few observed alarms were quickly resolved by clinical users. Tablo’s robust data reporting capability enables the identification of treatment trends that can be used to drive quality improvement.

Impact of Medication Reconciliation by a Dialysis Pharmacist

PO0916

Summer Dyer, Linda Awadish, Sally Rafie, Victoria T. Nguyen. University of California San Diego, La Jolla, CA.

Background: Medication reconciliation (MR) improves patient outcomes, reduces cost, and is a reporting measure for the CMS End-Stage Renal Disease Quality Incentive Program. Most dialysis facilities do not have a clinical pharmacist to perform MR. The purpose of this study is to evaluate the impact of a pharmacist performing MR and medication management for patients receiving outpatient chronic hemodialysis at an academic institution.

Methods: We conducted a retrospective study from 10/1/18 to 11/2/20 to determine if MR by a pharmacist reduced medication discrepancies (MDs) and medication related problems (MRPs) over time. Secondary outcomes were to describe the type of MDs, type and severity of MRP, impact of a pharmacy delivery service, and number of emergency department (ED) visits and hospitalizations pre- and post-pharmacist integration. Discrepancies were categorized as: unintentional discrepancy, undetected intentional discrepancy, and MRPs. MRP severity was categorized using the National Coordinating Council for Medication Error Reporting and Prevention index. Descriptive statistics were calculated for each variable and a repeated measures ANOVA test was conducted to determine if MDs or MRPs changed over time.

Results: A total of 135 patients with 479 unique pharmacist encounters were included. The mean (SD) age was 61.7 (14) years, 58% were male, 63% Caucasian, mean (SD) time on dialysis was 6.4 (4.6) years and most common comorbidities were diabetes and hypertension. The pharmacist conducted 3.5 MR/client with a mean time spent of 39.7 (16) minutes and 16% required an interpreter. Unintentional discrepancies were noted in 53% encounters, undetected intentional discrepancies in 71%, and MRPs in 59% but decreased significantly from the first to the second encounter (1.9 vs 0.9, 1.9 vs 1.2, and 1.1 vs 0.5 per patient, respectively, p<0.05). Most common MD types included non-adherence, prescription renewals, and excessive drug doses. On half (54%) were enrolled in a pharmacy delivery service and had significantly fewer undetected intentional discrepancies compared to non-enrollees (p<0.05). ED visits and admissions pre- and post-pharmacist integration were not statistically different.

Conclusions: Integrating a pharmacist into a hemodialysis unit enabled effective medication reconciliation and management to significantly reduce medication discrepancies and problems, and improve safety.

Interim Analysis of the Extension of Tablo Treatment Duration (XTEND) Study

PO0917

Yaadveer Chahal, Josh Schumacher, Michael A. Aragon. Outset Medical, Inc., San Jose, CA.

Background: The Tablo® Hemodialysis System (Tablo) is an all in one, easy-to-learn device featuring integrated water purification, on-demand dialysate production and two-way wireless data transmission and is approved for use in the acute, chronic and home settings. Prior reports have demonstrated Tablo’s ability to achieve clinical goals, seamlessly integrate into hospitals and reduce cost across a wide range of treatment times. Extension of the Tablo cartridge to 24 hours (extended therapy; “XT”) allows even greater flexibility for prescribers in the acute setting. The objective is to report on the experience with Tablo extended therapy between 12 and 24 hours utilizing an interim review of the XTEND study (NCT04912050).

Methods: Nursing staff were trained during a single training session on Tablo XT. After a run-in period of 5 treatments, Tablo data were collected via real-time transmission to a cloud-based, HIPAA compliant platform and reviewed by site staff. Clinical treatment success was defined as either ending within 10% of prescribed time or site investigator assessment that all patient treatment goals were met.

Results: Fifty (50) Tablo XT treatments had a median prescribed treatment time of 24 hours and a median achieved treatment time of 23.5 hours. Median cartridge use was 1.0 per treatment. Clinical treatment success was 84%. Treatments ended due to clotting/clogging were 4% (2 of 50). Median total ultrafiltration (UF) rate was 1.7 mL/kg/hr. Clinically significant alarms occurred at a median rate of 7 per treatment with a resolution time of 14 seconds. Most frequent alarms experienced were arterial and venous pressure (39% and 58%, respectively), of which none resulted in an end treatment.

Conclusions: Tablo’s XT successfully achieves prescribed treatment time and favorable ultrafiltration rates with minimal therapy interruptions from alarms or cartridge changes. This data demonstrates the effectiveness of Tablo’s newly expanded versatility in achieving personalization of treatments necessary for unstable patients and enabling successful delivery of extended therapy with minimal clotting. Tablo’s 24-hour therapy meets the needs of critically ill patients that require renal replacement therapy for greater than 12 hours.

Feasibility Study of Wrist-Based Wearable Activity Tracker in Hemodialysis Patients

PO0918

Maggie Han,1 Ohmar Thwin,1 Xia Tao,1 Lemuelt Rivera Fuentes,1 Amrish U. Patel,1 Nadja Grobe,1 Priscila Preciado,1 Leticia M. Tapia Silva,1 Mohammad I. Hakim,1 Stephan Thijssen,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Increased physical activity (PA) is associated with reduced risk of cardiovascular disease which is prevalent in hemodialysis (HD) patients. Wearable activity trackers (WAT) allow remote monitoring of PA. We aim to explore the feasibility of using a WAT for 1 year in HD patients.

Methods: HD patients from 4 NYC clinics were enrolled on a rolling basis starting June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use the Fitbit Charge 2. A stepwise intervention plan was used to assess feasibility (Figure 1). We used Kaplan-Meier analysis to determine mean and median time to withdrawal for non-compliance (TW) and predictors of TW were assessed by univariate Cox Regression.

Results: 119 patients were enrolled into the study. Patients were 54±12 years old, 59% African American, 37% lived alone, and 54% had an education level of college and above. 16% of patients were withdrawn for non-compliance. Mean and standard deviation TW was 175 ± 103 days. Median and interquartile range of TW was 133 and 181 days (98 to 280 days), respectively. The probability of not being withdrawn for non-compliance is shown in Figure 2. Age, gender, race, living status, and education were not associated with non-compliance.

Conclusions: A small portion of patients were continuously non-compliant with wearing/syncing their Fitbit devices in our study. Based on a low risk (<20%) of being withdrawn for non-compliance, we determined that it is feasible to use a wrist-based wearable device in HD patients for up to a year. However, prolonged use of these devices may require additional counseling to patients.

Feasibility Study of Wrist-Based Wearable Activity Tracker in Hemodialysis Patients
PO0919
Glycemic Status Ascertained by Continuous Glucose Monitoring in a Prospective Hemodialysis Cohort

Background: Hemodialysis (HD) patients with diabetes are at heightened risk of hypo- and hyperglycemia due to multiple pathways. While self-monitored blood glucose is the standard approach for glucose assessment in HD patients, it may not adequately capture glycemic status given its infrequent nature. We thus sought to measure glucose levels using continuous glucose monitoring (CGM) as a more frequent (every 5-minutes), convenient, and automated method of glycemic status in a prospective HD cohort with diabetes.

Methods: Among 18 HD patients with diabetes hospitalized during 10/2020-5/2021, we conducted simultaneously protocolized glucose measurements using 1) CGM measured by Dexcom G6 devices vs. 2) blood glucose levels using capillary fingertip or venous blood glucose, with the latter measured 2-4 times per day (before each meal and at night), plus every 30 minutes during HD (total of 6-8 measures during HD). Using American Diabetes Association (ADA)-defined CGM targets, we examined the prevalence of patients achieving the recommended percentage (%) of CGM levels in the ranges of <54, <70, 70-180, >180, and >254mg/dL (ADA target % of glucose levels <1%, <4%, >70%, <25%, and >5%, respectively).

Results: Whereas 64% of CGM measurements (N=9444) were within target glucose range (time in range [TIR] 70-180mg/dL, 80% of blood glucose levels (N=100) were within TIR. The proportion of patients achieving the recommended % of CGM measurements within ADA-defined glycemic ranges of <25% were 180-180 (target range), <70, and >254mg/dL were 67%, 44%, 44%, 89%, and 78, respectively.

Conclusions: In a cohort of hospitalized diabetic HD patients who underwent concomitant CGM and blood glucose measurements using the Dexcom G6 remote access system, blood glucose testing overestimated the % of time patients were in target glycemic range as compared with CGM. CGM showed that less than half of patients achieved the recommended % of CGM measurements within target range. Further studies are needed to determine whether CGM can improve the glycemic management of HD patients compared to conventional approaches.

PO0920
Validation of Automated Sodium Control in a Novel Dialysis System

Background: The Diality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aims: To test an automated feedback program designed to regulate the infusion of an alkali needed to maintain proper sodium concentration in a dialysate solution

Methods: A 125L volume of simulated dialysate was circulated at ~400 mL/min and ~37 C through a sorbent cartridge which removed the urea from the solution. The fluid exiting the cartridge had no Ca, Mg or K. These chemicals were reinfused through a pump in a solution containing Ca, K and Mg salts. A conductivity sensor (cond) was used in a feedback control of the alkali infusion pump. The feedback control adjusted the pump flow rate to maintain the conductivity of the infusate at 14.0 mS/cm. The sensor was programmed from a curve model of the alkali over time from previous experiments. Occasional spikes of Na+ was programmed from a curve model of the alkali over time from previous experiments. The dialysate sodium concentration [Na+] in the dialysate at pump 1, after mixing in a 125L tank was in the range 139.8 – 141.7 mEq/L. TP2, the mean dialysate [Na+] at pump 2 after leaving the sorbent filter was 124.2 (±2.4) mEq/L. This correlates with cond1 and was 12.8 (±0.4) mS/cm. TP3, the mean dialysate [Na+] after being replenished with the alkali solution immediately prior entering the tank for remixing was 139.5 (± 1.9) mEq/L and correlated with cond2 of 14.1 mS/cm.

Conclusions: The results validate the accuracy of the conductivity sensor in correctly regulating the alkali infusion.

Nanostructured Capillary Membranes for Size-Selective Hemofiltration
Peifu Cheng,1 Francesco Fornasier,2 Nicholas J. Ferrell,2 Shuvo Roy,2 William H. Fissell,1 Piran Kidambi,1 1Vanderbilt University, Nashville, TN; 2University of California San Francisco, San Francisco, CA; 2Lawrence Livermore National Laboratory, Livermore, CA.

Background: Size-selective separations offer potentially transformative advances for hemofiltration. In the context of hemodialysis, the tradeoff between selectivity and permeability often results in large package sizes and high driving pressures that limit wearable and implantable options of therapy. Here, we report on composite membranes with vertically aligned precise nanoscale capillaries with improved permeability.

Methods: Arrays of carbon nanotubes (CNTs) were synthesized via chemical vapor deposition and the catalyst composition was carefully selected to achieve a uniform distribution of diameters. The area between the CNTs were filled with a polymer to form a membrane. The CNT membranes were backed with microporous silicon supports and mounted into a filtration cell. Hydraulic permeability was calculated from gravimetric flow rates at stepped transmembrane pressures. Size-selectivity was measured by filtering fluorescently-labeled polydisperse Ficoll in phosphate-buffered saline. Size-specific Ficoll concentrations in feed and filtrate were measured by size-exclusion chromatography.

Results: CNT membranes membrane exhibited a cut-off ~6nm and the measured hydraulic permeability was 102.3 ml h⁻¹ m⁻² mmHg⁻¹ compared to published data of 30 ml h⁻¹ m⁻² mmHg⁻¹ for conventional high flux dialyzers. CNT membranes retained large molecules while passing small and medium-sized molecules. Sieving coefficient at 2 nm, approximately the size of β2 microglobulin, was unity (Figure).

Conclusions: The CNT membranes provide excellent middle molecule clearance with vertically aligned precise nanoscale capillaries and improved permeability.

PO0923

Delivered Dialysate Potassium Is Higher Than What Is Prescribed When High Sodium and Low Bicarbonate Are Prescribed
Saied W. Ali, Andrew I. Chin. University of California Davis Department of Internal Medicine, Sacramento, CA.

Background: Most hemodialysis machines utilize the 3-stream method of making dialysate. In hospital settings, dialysate prescriptions are customized to the clinical setting. We determined the differences between delivered and prescribed dialysate K⁺ in unusual prescriptions.

Methods: Dialysate samples drawn 15 minutes into HD were analyzed via indirect ion-specific electrodes for Na⁺, K⁺, and HCO3⁻. 5200 HDs with extremes of ordered Na⁺ and HCO3⁻ were analyzed. Outcome was measured versus ordered K⁺. Analysis used ANOVA using SPSS.

Results: Means of the difference between measured and ordered K⁺ and Na⁺ are shown in figure 1. For K⁺ there was significant difference amongst the groups (p<0.001). There were no differences amongst the groups for Na⁺.

Conclusions: When a very high Na⁺ is prescribed along with a low HCO3⁻ the the dialysate Na⁺ remains close to prescribed Na⁺. As the acid concentrate contains both Na⁺ and K⁺, a high Na⁺ and low HCO3⁻ prescription will use a relatively more of the acid concentrate and less of the bicarbonate concentrate. Dialysate prescriptions with a high Na⁺ and low HCO3⁻ resulted in delivered dialysate K⁺ by an average of 0.5 mEq/L; we observed some HDs where dialysate K⁺ was 1 mEq/L, higher than prescribed.
PO0925

Increasing the Clearance of Protein-Bound Uremic Solutes by Introducing an Activated Carbon Block into the Dialysate Stream

Sochiluy L., Tammy L. Sirich, Timothy W. Meyer, Stanford University School of Medicine, Stanford, CA; VA Palo Alto Health Care System, Palo Alto, CA.

Background: The hemodialytic clearance of protein-bound solute is limited because only the free solute concentration drives diffusion across the membrane. This study tested whether an activated carbon block could reduce accumulation of these solutes in the dialysate and thereby increase their clearance.

Methods: In vitro dialysis of artificial plasma containing urea and the protein-bound solute p-cresol sulfate (PCS) and indoxyl sulfate (IS) was performed using two dialyzers in series with and without an activated carbon block at the midpoint of the dialysate stream (Figure). Six dialysis experiments were performed each with plasma flow 240 mL/min and dialysate flows of 200 mL/min and 600 mL/min. Nine additional experiments tested the capacity of the carbon block to take up solutes by measuring solute removal from spent dialysate collected at patient treatments. Spent dialysate was passed through the carbon block at 600 mL/min.

Results: Use of the carbon block increased the clearances of the tightly bound solutes PCS and IS by 70% and 64%, respectively, when the dialysate flow was 200 mL/min. Lesser increases occurred when the dialysate flow was 600 mL/min (PCS 38% ± 5%, IS 33% ± 8%). Urea clearance was unchanged. The carbon blocks removed 97 ± 4% of PCS and 96 ± 2% of IS but only 2 ± 5% of urea from spent dialysate flowing at 600 mL/min.

Conclusions: Use of a carbon block can increase the clearance of protein-bound solutes particularly at the low dialysate flows often used for home hemodialysis.

Comparative Effectiveness Between Novel Medium Cut-Off Membrane Hemodialysis and Mixed-Dilution Online Hemodiafiltration on Middle Molecule Uremic Toxins Reduction: A Prospective Cross-Over Study

Jirarat Eiamcharoenying, Pajaree Chariyavalgluk, Kullaya Takkavatarkarn, Paweena Susantithaphong, Yingyos Avihingsanong, Somchait Eiam-On, Khajiron Tanirathanagul, King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

Background: Mixed-dilution online hemodiafiltration (mixed HDF), one of the best hemodialysis (HD) modes, provides superior removal of middle molecule uremic toxins to standard HD using high flux dialyzer. Due to the limited availabilities and high cost of HDF, we performed standard HD utilizing a novel medium cut-off membrane with a larger pore size and compared the effectiveness in removal of middle molecule uremic toxins with mixed HDF.

Methods: A prospective cross-over randomized controlled trial was conducted in 14 prevalent HDF patients who were randomly allocated into group 1 (=7): mixed-dilution online HDF with high flux dialyzer ELIS1021H and group 2 (=7): standard HD with MCO membrane, Theranova 500. In this 8-week study, the primary outcome was a reduction ratio (RR) of B2M, microglobulin (B,M). Other small to middle molecules and protein-bound uremic toxins reduction ratio, dialysate albumin loss, and nutritional parameters were also compared.

Results: In this 8-week study, B,M RR from both modalities was higher than the survival benefit cut-point of 80%. In comparison, B,M RR was slightly lower but significant in MCO HD than mixed HDF (82.57±5.34% vs 85.12±3.87%, respectively) with the mean difference of 2.55 (95% confidence interval [CI], 4.07 to 1.03; P = 0.001). The spKt/Vurea and URR, a small urmic toxin removal marker, were comparable. xFLC and Indoxyl sulfate RR also were similar in mixed HDF and MCO HD. Whereas RR of the larger middle molecule uremic toxin, Alpha M and JFLC was lower with mixed HDF compared to MCO HD (30.13±15.90 vs 41.49±11.46 and 40.85±13.92 vs 50.81±13.18, respectively; P<0.001). Dialysate albumin loss was 3.51 ± 1.97 g/session with mixed HDF and 6.19 ± 2.70 g/session with MCO HD (P = 0.0025). Regarding, nutritional parameter, serum albumin levels were not different.

Conclusions: Mixed HDF and MCO HD provided the RR values of B,M and small uremic toxins above the recommended cut-off point. Despite mixed HDF provided higher B,M RR, MCO HD also provided more performance in the clearance of the larger middle molecules, particularly Alpha M and JFLC. However, mixed HDF loss lower albumin than MCO HD. Therefore, both techniques can be used as alternative options.

Clearance of Protein-Bound Uremic Toxins on the Tablo Hemodialysis System

Logan Rivas, Dean Hu, Michael A. Aragon. Outset Medical, San Jose, CA.

Background: The Tablo Hemodialysis system (Tablo) is an all-in-one, easy-to-learn device. While clearance of small and middle molecules has been documented in modern dialysis, the clearance of Protein Bound Uremic Toxins (PBUTs) merits further exploration. Clearance of albumin bound toxins such as indoxyl sulfate (IS) and p-cresol sulfate (PCS) can be limited in dialysis where removal is based on molecular size. Although a clear association has yet to be demonstrated, PBUTs have been considered to be a possible cause of adverse outcomes in patients requiring renal replacement therapy.

Methods: A simulated hemodialysis treatment using Tablo was performed with solution of bovine serum albumin and urea. PCS and IS were added to the solution to maintain a constant concentration. A screening design of experiment was performed utilizing the factors of dialysis flow rate (Qd), blood flow rate (Qb), and ultrafiltration (UF). After each factor was changed and allowed to equilibrate, samples were collected from the venous, arterial and spent dialysate lines. Samples of Urea, PCS and IS were analyzed and compared to predicted values from previously published models.

Results: The Tablo system cleared PCS and IS as predicted or better at all conditions. See table and images for details.

Conclusions: The Tablo system aligned with the PBUT clearance model over the range of system flow settings. Continued investigation into the clinical benefits of PBUT removal is merited to better understand their impact on the overall quality of care for dialysis patients.

Dialysis Disequilibrium Syndrome (DDS) in Hemodialysis Patients: Systematic Review
Rupesh Rama,1,2 Siddhartha S. Singh,1,2 Ronith Chakraborthy,1,2 ‘Cleveland Clinic, Akron, OH; 3 Akron Children’s Hospital, Akron, OH.

Background: Dialysis disequilibrium syndrome (DDS) affects patients who have missed multiple dialysis treatments, especially new initiates of hemodialysis (HD), and presents as a rare neurological complication. The conceptual pathogenesis of DDS is likely a result of multiple physiological abnormalities which we explore in this systematic review alongside preventive measures with focus on effective management strategies.

Methods: A literature search was conducted on PubMed/Medline and Embase and included studies if the patient developed DDS irrespective of age and gender. Two independent reviewers conducted the process of article selection with a third reviewer present to resolve any conflicts. The data was analyzed and a summary table was extracted with the following variables: study type, population group, age, patient characteristics, blood and dialysate flow rate, and study outcomes. A descriptive analysis was performed analyzing the population size and frequency of symptoms and treatments utilizing the R software.

Results: A total of 49 studies (321 samples) were identified and analyzed. There were 72.4% of patients (based on 48 studies) who reported having DDS with most common symptoms of headache (39.4%), nausea (40.4%), vomiting (39.1%), confusion (66.7%) and seizure (78.6%). Within this sample, 12 studies switched from HD to alternative dialysis modalities including continuous venovenous hemofiltration/hemodiafiltration (CVVH/CHFID) or peritoneal dialysis (PD) with no further reported DDS symptoms.

Conclusions: We have provided a comprehensive clinical practice points for both the pediatric and adolescent and young adult population; interestingly, DDS was reported more often in the early dialysis era prior to recent advances and improvement of resource allocation. Existing literature shows it is crucial to recognize symptoms of DDS and implement timely prevention to improve outcomes.

PO0929
Protein Loss with Medium Cut-Off and High Flux Dialyzer: A Proteomic Analysis
Xiaolan Wang,1 Xia Tao,1 Leticia M. Tapia Silva,1 Amrish U. Patel,1 Mobhamad I. Hakim,1 Nadja Grobe,1 Stephan Thijssen,2 Peter Kotanko,1,2 1 Renal Research Institute, New York, NY; 2 Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Hemodialysis (HD) patients frequently suffer from low serum albumin levels, making dialytic albumin and protein loss a concern. Medium cut-off (MCO) dialysis membranes reportedly show a greater albumin loss compared to high-flux (HF/HiFlux) membranes. To better understand the spectrum of proteins cleared with MCO membranes, we set up an ex vivo dialysis system and perform proteomic analysis of the dialysate.

Methods: Eight liters of human plasma (EDTA added) are split into two 4-liter batches and dialyzed for 4 hrs in single-pass, either with an MCO (Theranova 400) or HiFlux dialyzer (Optiflux F180NR) using a Fresenius 2008T machine. Blood flow was 400 ml/min. Dialysate flow was 600 ml/min for the first 3 hrs and zero for the 4th hr. Ultrafiltration rate was zero for the first 2 hrs and switched to 1 L/hr thereafter. This design allowed us to study three HD modes: diffusion only (2 hrs); diffusion with convection (1 hr); and convection only (1 hr). Dialysates were sampled at multiple time points (Fig 1B).

Results: Three µg of initial plasma and 23 µl dialysate were loaded on an SDS-page gel and silver stained (Fig 1A). Lanes 3 and 5 were from MCO, lanes 4 and 6 from HiFlux. Lanes 3 and 4 were collected 15 mins into dialysis, lanes 5 and 6 at 240 mins. Results show that dialysates contain less high molecular weight proteins compared to plasma, and MCO dialysates contain much more proteins compared to HiFlux dialysates. The strong band at ~62 kD is most likely albumin. Using mass spectroscopy, we can identify 56 different protein species in MCO dialysate. Dialysate protein levels (measured by Bradford assay) with the 3 dialytic modalities are shown in Fig 1B, the total protein losses are listed in Fig 1C. The ratio of protein loss between MCO and HiFlux dialyzers is 17-fold in the convection only mode.

Conclusions: Our results show a higher diffuse and convective protein loss with MCO compared to HiFlux membranes. Further characterization and quantitation of proteins cleared in vivo during HD are necessary to better understand the clinical impact of our ex vivo observations.

Intradialytic and Interdialytic Urea Dynamics in Blood and Cerebrospinal Fluid in Hemodialysis Patients
Xia Tao,1 Lin-Chun Wang,1 Xin Wang,1 Ohnmar Thwin,1 Nadja Grobe,1 Amrish U. Patel,1 Stephan Thijssen,2 Joshua E. Chao,1 Ludovic Debure,2 Thomas Wisniewski,2 Peter Kotanko,1,2 Renal Research Institute, New York, NY; ’NYU School of Medicine, New York, NY; 1 Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Modern, highly efficient hemodialysis (HD) results in rapid decline of blood urea. Urea gradients across the blood-brain barrier (BBB) can drive water movements. A positive urea gradient, i.e. brain urea to plasma urea, can result in brain swelling and impair brain function. We explored the dialytic changes of urea in blood and cerebrospinal fluid (CSF) to better understand intradialytic osmotic gradients across the BBB and provide insights that support the development of brain-protective HD.

Methods: Two HD patients (39 and 26 years old) with ventriculo-peritoneal (VP) shunts were enrolled into this one-week IRB-approved study with a Monday/Wednesday/Friday dialysis schedule. CSF was collected via VP shunt tap 2 hrs before and 2 hrs after HD (Wednesday and Friday), and Tuesday and Thursday. Plasma samples were collected concurrently with CSF and during HD. In addition, the patients underwent test of executive function (Trail Making Test Part B; TMT B) and global cognitive function (Montreal Cognitive Assessment; MoCA) on Monday.

Results: Urea was removed efficiently from patients’ blood by HD. While patient A showed a small post-HD plasma-to-CSF urea gradient, it was highly positive (~ 60 mg/dL) in patient B (Fig 1). TMT B and MoCA score were normal for patient A but not patient B (TMT B 415 sec; TMT B error count: 2; MoCA score: 11).

Conclusions: Our patients showed very different post-HD plasma-to-CSF gradients. Theoretically, the positive gradient in patient B would favor intradialytic brain swelling. Patient B showed impaired neurological testing results which are not related to patient’s pre-existing neurological conditions. We can only speculate if and to what extent trans-BBB water movements driven by dialytic urea dynamics may have impacted the patient’s cognitive functions. We believe that patient-specific levels of osmotic stress need to be considered when developing neuro-protective HD technologies.

High-Throughput Analysis of Changes in Protein Biomarkers During Hemodialysis
Matthew B. Lanktree,1 David T. Collister,2 Guillaume Paré,3 Michael Walsh.1
1McMaster University, Hamilton, ON, Canada; 2University of Manitoba, Winnipeg, MB, Canada.

Background: The impact of hemodialysis on the concentration of circulating protein biomarkers remains unclear. Biomarkers may decrease in concentration due to filter adsorption, diffusive clearance, or convective clearance, while others may increase in concentration due to production and secretion or intracellular release. Ultrafiltration of water is also expected to increase biomarker concentration. We sought to evaluate the impact of hemodialysis on 1,163 protein biomarkers in a high-throughput fashion.

Methods: A nested cohort of 44 patients (25 male, 19 female) including 29 with intradialytic hypotension and 15 without was selected from the prospective Hemodialysis Outcomes and Symptoms assessment (HOST) cohort. Intradialytic hypotension was stringently defined as a 60 mmHg drop in systolic blood pressure or a nadir systolic blood pressure of less than 70 mmHg during hemodialysis treatment. All hemodialysis treatments were done using the same hemodialysis filter type. 1,163 unique biomarkers were measured in each patient before and after hemodialysis using the Olink proximity extension assay (www.olink.com). Paired sample t-tests were used to compare pre- and post-dialysis concentrations with a Bonferroni-corrected significance threshold (P < 5 x 10^-5).

Results: 54 biomarkers (5%) significantly increased during hemodialysis treatment, while 243 (24%) significantly decreased. Change in biomarker concentration was significantly correlated with biomarker molecular weight (r = 0.37, P = 2.8 x 10^-10), isoelectric point (r = -0.26, P = 6.4 x 10^-10), and pre-dialysis concentration (r = -0.21, P = 3.0 x 10^-10). There was a significant enrichment of cardiovascular biomarkers in the top 20 biomarkers associated with a drop in systolic blood pressure (P = 2.8 x 10^-10), including Kidney Injury Molecule 1 (KIM1, P = 0.005).

Conclusions: Hemodialysis is associated with significant changes in protein biomarker concentrations related to protein properties and clinical events during treatment. These changes are measurable on a high-throughput platform. Further high-throughput biomarker studies could assess dialysis adequacy, test biomarker-symptom associations, and improve risk prognostication.

Feasibility of Allo-Hemodialysis: First Experience from Porcine Studies
Xin Wang,1 Amrish U. Patel,1 Anil K. Gothi,2 Dejan Nikolic,3 Alexander Heide,4 Jianning Dong,1 Hao Zhang,4 Vaibhav Maheshwari,1 Nadja Grobe,4 K S NAYAK,4 Peter Kotanko.1,3 Renal Research Institute, New York, NY; 2Vivo Bio Tech Ltd, Hyderabad, India; 3Fresenius Medical Care Shanghai Co Ltd, Shanghai, China; 4ICahn School of Medicine at Mount Sinai, New York, NY; 5Tirvanchi Hospitals, Hyderabad, India; 6Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Annually, millions of kidney patients, predominantly in low and low-middle income countries, die prematurely because of unavailability of affordable kidney replacement therapy. We previously demonstrated through mathematical modeling and bench testing the feasibility of alloHD, an alternative low-cost hemodialysis treatment approach where the blood of a kidney failure patient flows counter-current to that of a healthy subject (“buddy”) through a dialyzer. Herein we report first results from an alloHD feasibility study in a porcine model. We aimed to specifically address questions around hemolysis and coagulation in our experiments. Upcoming studies in a porcine renal failure model will be evaluated and compared between the plasma filter reuse group (GP-1) and no reuse group (GP-2).

Methods: Ethics protocol was approved by Committee for the Purpose of Control and Supervision of Experiments on Animals, India. Under general anaesthesia, healthy female white Yorkshire pigs of 30 to 80 kg with central venous catheter as vascular access were dialyzed 1-3x weekly for 2-4 hours. Ultrafiltration volume goals were set between 0 and 1000 mL. “Patient” and “buddy” pigs were connected to the dialysate and blood compartments, respectively, of a Nipro Cellentia 17H (Fig. 1). Pigs were anticoagulated with 5000 IU heparin per hour. Pre- and post-treatment blood samples were collected for biochemical measurements.

Results: We successfully completed 10 alloHD sessions. No coagulation was observed. Visual inspection of plasma samples indicated no signs of hemolysis. This was further corroborated by measurements of lactate dehydrogenase and haemoglobin, which were available in seven experiments (Fig. 2). Adhesions on the filter surface, which were also noticed in GP-1 (P=0.08). No difference in patient survival was noticed between the two groups (97% vs 96%, p=0.5). The cost of overall treatment was 2.5 times higher in GP-2, (P=0.003).

Conclusions: Reuse of plasma-filter is a safe and effective method for cost minimization in patients requiring TPE. This method can effectively be utilized in resource-poor settings without any increased risk of adverse effects.

Can Plasma Filters Be Reused for Plasmapheresis in Resource-Poor Settings? Experience from a Tertiary Care Hospital
Priti Meena, Sandip Panda, Rishita Mondal, Swati Das. All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India.

Background: Therapeutic plasma exchange (TPE) is used in the management of various life-threatening illnesses. It is widely performed by nephrologists, intensivists, pathologists, or experts of transfusion medicine worldwide. However, the costs of TPE sessions are exceedingly high and it has a huge impact on patients’ financial burden. Most of the patients cannot afford such a high-cost treatment. Herein, we investigated the outcomes of plasma filter reuse in TPE for several occasions.

Methods: This was an ambidirectional study that included retrospective analysis of patients receiving TPE from January 1, 2020, to December 31, 2020, whereas the patients receiving TPE from January 1, 2021, to April 30, 2021, were prospectively analysed. The procedure was performed in our hospital’s dialysis unit. Formulation of 4% peracetic acid and 24% hydrogen peroxide acid with RO water was used for reprocessing. Fresenius Plasma Flux P2 (0.6 m2) was used in the study. Clinical outcomes, risks, and cost-benefit were evaluated and compared between the plasma filter reuse group (GP-1) and no reuse group (GP-2).

Results: 46 patients were included in the study. 26 patients were in the Plasma filter reuse group. 122 and 119 TPE sessions were performed in GP-1 and GP-2 respectively. A total of 58 plasma filters were used in GP-1. In six patients single plasma filter was used on 3 occasions whereas, it was used for 2 occasions in other patients. The most common indication for TPE in both groups was Guillain barre syndrome. The rates of clinical improvement in disorders for which the TPE were performed were similar in both GP-1 and GP-2 (88% vs 90%, p=0.4). None of the patients in either group had clotting of plasma filter, any allergic reaction, or increased bleeding risk. No higher chances of sepsis were noticed in GP-1 (P=0.08). No difference in patient survival was noticed between the two groups (97% vs 96%, p=0.5). The cost of overall treatment was 2.5 times higher in GP-2, (P=0.003).

Conclusions: Reuse of plasma-filter is a safe and effective method for cost minimization in patients requiring TPE. This method can effectively be utilized in resource-poor settings without any increased risk of adverse effects.

A Forgotten Technique of RRT for Correction of Severe Hyponatremia in CKD: Case Report
Rodolfo A. Moreno,1,2 Alexandra M. Trochez,1,2 Pedro Gonzales,1,2 Antonio J. Palma,1,2 Lidia B. Sánchez,1,2 Rafael J. Hernández,1,2 Jorge A. Hernández,1 1Centro Médico Militar, Guatemala, Guatemala; 2Universidad Mariano Galvez de Guatemala Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala.

Introduction: Patients with chronic kidney disease (CKD) present electrolyte disorders. This represents a challenge when hyponatremia is below 125mmol/L associated with any criteria for urgent renal replacement therapy (RRT) with conventional hemodialysis because of higher risk of over correction above the security threshold of 10mmol/L/day and osmotic demyelination syndrome.

Case Description: A 49-year-old Guatemalan female with history of 15 days of edema and slurred speech. Only history of T2DM. Was brought to the ER with BP 100/80mmHg and anaesthesia. Initial laboratories: negative COVID-19Ag, Cr 5.12mg/dl, (previous 2mg/dl) BUN 105mg/dl, glucose 156mg/dl, Na 108mmol/L, K 5.2meq/L, Cl 70meq/L, SOsm 224mOsm/kg, UNa 28meq/L, UNa 119mmol/L in 48 hours, but because of persistence of neurologic symptoms plus fluid overload >10% of body weight and hyperkalemia, we initiated RRT. In the absence of CRRT or CVVH we planned a conventional HD with blood flow of 100ml/min, dialysate flow 600ml/min, dialysate Na 130mEq/L (the lowest Na possible) and 3 hours duration. After the first session had neurological and edema improvement. After two sessions with interdialytic period of 48 hours, Na control of 122mmol/L and 132mmol/L respectively with resolution of uricemic syndrome. Later was diagnosed with hospital-acquired pneumonia receiving antibiotic treatment for 14 days and was discharged home with ambulatory HD.

Discussion: In undeveloped countries where the access to CRRT or CVVH is unavailable, conventional modalities can be used with low blood flows and modifications of the dialysate Na to a minimum (130mmol/L) offering a safe option to Na correction for patients with severe hyponatremia and any other HD criteria.

PO0935
Single-Bolus Tinzaparin Anticoagulation in Extended Hemodialysis Sessions: A Feasibility Study
Benoit Harvey,1 Simon Berc,2 Naoual Elfouh,2 Michel Vallee,1 Louis-Philippe Laurin,2 Annie-Claire Nadeau-Fredette,1 Université de Montréal, Montreal, QC, Canada; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Few studies have assessed the use of low-molecular weight heparins for anticoagulation during extended hemodialysis (HD) sessions. This study aimed to evaluate the safety and efficacy of tinzaparin for anticoagulation of the extracorporeal circuit and dialyzer in extended, 8-hour, sessions.

Methods: This single-center study included all patients who underwent a single in-centre 8-hour session as part of their nocturnal home HD training between 2009 and 2020. Tinzaparin was delivered as a single bolus injection at time 0 with dosing based on the patient’s weight and doubling of standard 4-hour session dose. Tinzaparin safety was assessed via anti-Xa measured at 15-, 30-min, 1-, 2-, 4-, 6-, 8-hour. Efficacy was examined via visual observations (score 1-4) of the dialyzer and venous bubble trap at the end of dialysis. Predictors of clotting levels were assessed in exploratory logistic regressions.

Results: Forty-seven patients were included: age 45±14 yrs, 28% women, 9% on warfarin, 42% on antiplatelets, BMI 29±7 kg/m², hemoglobin 114±15 g/L and platelet 203±61 10³/L. Mean tinzaparin dose was 107±20 IU/kg. Anti-Xa levels peaked at 15-min with 1.3±0.4 IU/mL and progressively declined reaching 0.9±0.3 IU/mL at 1-hour, 0.2±0.1 IU/mL, 4-hour, and 0.15±0.15 IU/mL after 8-hour. Figure 1. After the 8-hour session, none of the patients had severe clotting of their dialyzer or venous chamber. Moderate blood clotting was observed in the dialyzer of 6 (20%) patients and in the venous chamber of 22 (61%) patients. Tinzaparin dose was increased for 27 (81%) patients with a mean maintenance dose of 123±28 IU/kg. None of the main baseline characteristics (including tinzaparin dose per kg) were associated with clotting scores.

Conclusions: This study shows that anti-Xa levels stabilize rapidly after administration on tinzaparin for 8-hour HD. Administration of a single bolus tinzaparin at the start of an eight-hour dialysis session appeared safe and effective, although dose adjustment may be required.

Targeted Alteplase Administration to Improve Hemodialysis Catheter Patency: A Quality Improvement Pilot Study
Jason T. Bau,1 Tyrone Harrison,1,3 Kokak Younis,2 Nathen Gallagher,2 Juliya Hemnett,1 Elena Qirjaj,1 1University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2Alberta Health Services, Calgary, AB, Canada; 3University of Calgary Department of Community Health Sciences, Calgary, AB, Canada.

Background: Catheter dysfunction (CD) is a frequent complication during the provision of hemodialysis. Thrombotic agents (i.e. alteplase) are the mainstay for resolving CD, however, alteplase usage has increased 16% (~440,000CD) annually in the Alberta Kidney Care South program without improved patient or dialysis outcomes. We assessed the implementation of a protocolized algorithm to reduce alteplase usage.

Methods: In this pilot quality improvement study, we designed an algorithm where CD was treated with high-dose (2mg) alteplase therapy to the problematic lumen only, after meeting pre-specified criteria (Fig 1). This protocol was implemented in a satellite hemodialysis unit (~110 patients) from Jan 2021 to Mar 2021. The baseline comparison period was Jan 2020 to Dec 2020 when CD was treated with low-dose 1mg/lumen alteplase. Outcome measures included total alteplase usage, changes in Kt/V, recirculation, clearance, line interventions and hospitalization rates. Statistical analysis was completed using Mann-Whitney and Z-score calculations.

Results: Sixty-nine alteplase administrations occurred over the two-month period, versus 438 in the baseline period. Patients in the 2mg group were more likely to achieve an increase in Kt/V of at least 10% in the next dialysis session (34.7% vs 28.9%, p<0.04). Otherwise the 2mg alteplase with our protocol was not inferior to baseline with respect to blood volume processed (26.1% vs 20.1%, p=0.13) and average clearance (37.7% vs 28.5%, p=0.37). A 12% decrease (88 vs 100mg/mo p<0.05) in alteplase use was observed with no differences in frequency of hospitalizations (8% vs 5.9% p=0.39) or line interventions (12.3% vs 7.3% p=0.20).

Conclusions: Our protocol with 2mg alteplase therapy to the problematic lumen was not inferior with respect to patient outcomes compared to baseline practices and resulted in lower alteplase use. An expanded multi-center prospective study is underway to further assess the broader applicability of these findings.

PO0938
The Effect of Predilution Online Hemodiafiltration on Body Composition, Nutritional Status, and Mortality
Semoon Miziai,1 Yoshiko Nishizawa,2 Aiko Okubo,1,2 Toshibi Doi,1,3 Kazunori Yamashita,1 Kenichiro Shigemoto,1 Koji Usu1, Michiko Arita1, Takayuki Naito,4 Michiko Arita,1 Takayuki Naito,1,3 Shigehiro Doi,3 Takao Manaki,3 Iryo Hoyijn Ichiyokai Harada Byoin, Hiroshima, Japan; 2Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; 3Ichiyokai East Clinic, Hiroshima, Japan; 4Ichiyokai Yokogawa Clinic, Hiroshima, Japan; 5Hiroshima Daigaku Byoin, Hiroshima, Japan.

Background: We evaluated the effect of predilution online hemodiafiltration (HDF) on body composition, nutritional status and all-cause and cardiovascular (CV) mortality in maintenance dialysis patients.

Methods: All subjects (n=215) had blood flow rate of ≥200 mL/min and underwent HDF with a convective volume of 40 L/session or hemodialysis (HD), 4h/session, 3 times/week. Predialysis clinical data and same day postdialysis body composition parameters based on BCM (Fresenius) were obtained at baseline in 46 patients on HDF and 169 patients on HD, and followed over 5 years. Logistic regression analysis for HDF, Kaplan–Meier analysis and Cox hazard analysis were conducted.

Results: In all subjects, age and dialysis vintage were 72±12 years and 73±6 months, respectively. Body mass index [22.4 (20.6–27.0) vs. 19.8 (16.4–22.7) kg/m²], lean tissue index (LTI) [13.2 (10.8–15.7) vs. 11.0 (9.3–13.2) kg/m²], geriatric nutritional risk index [94 (88–97) vs. 88 (81–93)] serum albumin [3.6 (3.3–3.8) vs. 3.3 (2.9–3.5) g/dl], creatinine, phosphate and magnesium were higher, but LDL-cholesterol (LDL-C) was lower in patients on HDF than those on HD (P<0.05). There were no significant differences in fat tissue index (FTI) [9.0 (5.5–11.2) vs. 7.8 (5.7–10.6) kg/m²], overhydration (OH) [0.8 (–0.5–2.2) vs. (0.3–2.1) L], C-reactive protein (CRP), Kt/Vanat or β2-microglobulin (β2m) between the groups. HDF was significantly (P<0.05) associated with serum albumin [odds ratio (OR) 3.0], LDL-C (OR 0.98) and LTI (OR 1.22), but not with FTO, OH, CRP, Kt/Vanat or β2m. Cumulative 5-year survival rate was significantly higher in patients on HDF than those on HD (67.9% vs. 43.7%, P<0.01). For 5-year all-cause mortality, HDF [hazard ratio (HR) 0.31], age (HR 1.03), albumin (HR 0.48) and LTI (HR 0.91) were significant predictors (P<0.05), while FTO and OH were not. For 5-year CV mortality, HDF (HR 0.20), age (HR 1.05), diabetes (HR 2.61) and LTI (HR 0.80) [or even HR 0.91 (0.73–1.11) or OH (HR 1.22)] were significant predictors, respectively (P<0.05).

Conclusions: Predilution online HDF with substitution volume 40 (20–40) L/session, 3 times/week is associated with better nutrition, increased muscle mass, and improved all-cause and CV mortality, but not with body fat and OH in dialysis patients.

Monitoring of Intradialytic Sleep Apnea in Hemodialysis Patients
Paulo Panquee Galuzio1, Alhajij Cherif,2 Xia Tao,1 Ohnmar Thwin,1 Stephan Thijsen,3 Peter Kotanko,4 1Renal Research Institute, New York, NY; 2Icalon School of Medicine at Mount Sinai, New York, NY.

Background: Breathing disorders are frequent in end-stage kidney diseases, with more than 50% of hemodialysis (HD) patients experiencing sleep apnea syndrome (SAS). SAS is associated with lower health-related quality of life and represents a significant cardiovascular risk factor. HD patients with SAS are at greater risk of mortality. The study aimed to monitor intradialytic SAS in HD patients using oxygen saturation (SaO2) measurements.

Methods: C-Link® monitor was used to record SaO2 at 1 Hz, for 2 HD sessions with a mean duration of 3.5±0.5 h. For each patient, we calculated: oxygen desaturation density (ODD), which counts 3% drops in SaO2, from a baseline for at least 10 s; a10-order permutation entropy to quantify complexity; and optimal recurrence threshold (εa10) to account for dynamic variations and degree of predictability in the SaO2. These quantities were subjected to machine learning methods to predict intradialytic SAS, as quantified by the ODDa10 value and the SAS classification by the American Sleep Disorders Association.

Results: We examine intradialytic SAS severity in 16 patients (age of 54±11 years, 63% males, 66% Black) with arteriovenous vascular access. Mean SaO2 was 94.3±2.1%. Figure 1A shows a typical SaO2, annotated with the SAS intensity assessed by ODDa10 (Fig. 1B). The two calculated metrics are plotted in Figs. 1C–D. The results reveal dynamic characteristic patterns of SAS with differential severity scores during HD. Figures 1E–G show the ROC for the classifiers when considering episodes of at least mild, moderate, or severe SAS, respectively. The maximum AUC is 0.93 for severe SAS episodes.

Conclusions: Our analysis suggests that entropy and recurrence-based quantifiers could be used as predictive indicators of intradialytic SAS. However, further studies are needed to assess their relationships to clinical outcomes.

PO0940
DENALI, a Phase 3b Multicenter, Open-Label Single-Arm Study of Roxadustat Use in Dialysis Patients with Anemia via a Semi-pragmatic Evaluation of Roxadustat Use in Dialysis Patients with Anemia via a Semi-pragmatic Evaluation
Arnold L. Silva,1 Gopal Saha,2 Jeffrey L. Hymes,3 Lynda Szczecz,4 Yemisi Oluwatosisin,5 Zhiqun Cherif,6 Gong Kong,7 Cooper,8 John W. Larkin,9 Boise Kidney & Hypertension Institute, Meridian, ID; 2FibroGen Inc, San Francisco, CA; 3Fresenius Medical Care North America Nashville, Nashville, TN; 4AstraZeneca, Wilmington, DE; 5Fresenius Medical Care North America, Waltham, MA.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitor that promotes erythropoiesis and improves iron availability in patients with anemia of chronic kidney disease (CKD). This trial aims to provide practical data on roxadustat use in dialysis patients with anemia via a semi-pragmatic evaluation of introduction into providers’ practices (Fresenius Medical Care).
PO0942

Validation of Urea Removal in Novel Sorbent Dialysis System

Background: The Dality Hemodialysis Machine will provide a range of hemodialysis modalities to expand the population of patients that may benefit from hemodialysis. One modality uses a sorbent filter that will accommodate the decentralization of dialysis delivery. Specific Aim: To assess urea mass removal during a simulated dialysis utilizing a novel sorbent filter.

Methods: Nine simulated dialysis sessions were conducted utilizing between 50L and 125L volumes of dialysate circulated at approx. 400 mL/min & 37 C through a sorbent cartridge with a standard dialysate. (Table 1) It is expected that with each pass through the filter the dialysate urea mass will decline. The experiment is continued until breakthrough occurs or the infused outlet reaches 10 ppm of NH4. A solution containing K+, Ca and Mg salts were constantly infused to replenish electrolytes lost in each pass. Another solution was infused at a variable rate as determined by conductivity to maintain Na Balance.

Results: The results are provided in Table 1. The average URR was 63.8% ranging from 53.3 to 87.0%. The average starting HUN was 48.2 mg/dL and the average ending HUN was 16.8 mg/dL.

Conclusions: The initial experiments using a sorbent filter demonstrate a URR of near 65 is feasible. Future design changes will be scaled to handle larger amounts of urea and provide acceptable clearances.

PO0943

Effect of Hemodialysis on Amyloid-β in Cerebrospinal Fluid and Plasma

Lin-Chun Wang, 1 Omnam Thwin, 1 Joshua E. Chao, 1 Amritsh U. Patel, 2 Ludovic Dubère, 3 Nadja Grobe, 1 Xiao Yao, 3 Hanjie Zhang, 1 Stephen Thijssen, 1 Thomas Wisniewski, 2 Peter Kotanko, 1,2 Renal Research Institute, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY; 4NYU Langone Health, New York, NY.

Background: Hemodialysis (HD) can reduce amyloid-beta (Aβ) species in whole-body circulation by 30 to 50%. Due to the dynamic exchange of Aβ between the brain and the blood, we hypothesized that HD might lower Aβ levels in the cerebrospinal fluid (CSF).

Methods: In a dialysis network with over 160,000 patients, we identified three maintenance HD patients (age 36±9 years) with ventriculo-peritoneal (VP) shunts who were subsequently recruited for this IRB-approved research study. Study subjects were dialyzed on Monday, Wednesday, and Friday. Plasma samples were collected at 6 timepoints during the 3 HD sessions. One subject was withdrawn over safety concern related to the VP shunt tap procedure. Two subjects further underwent VP shunt taps for CSF sample collection before and after the Wednesday and Friday HD sessions, and once on interdialytic days (Tuesday, Thursday). Aβ1-42 and Aβ1-40 were quantified by Neuro 3-Plex SIMOA assays (Quanters, MA, USA).

Results: HD effectively reduced plasma Aβ1-42 by 41% and Aβ1-40 by 34% (Fig 1a and 1b, p < 0.01). In CSF, levels of Aβ increased after Wednesday HD sessions in subject 1 (Aβ1-42: 4.2-fold, Aβ1-40: 5.5-fold) and subject 2 (Aβ1-42: 1.06-fold, while Aβ decreased after Friday HD sessions in both subject 1 (Aβ1-42: 0.1-fold, Aβ1-40: 0.1-fold) and 2 (Aβ1-42: 0.7-fold, Aβ1-40: 0.7-fold) shown in Figure 1c-e.

Conclusions: This is the first report of Aβ dynamics in the CSF and plasma of HD patients. While plasma levels were in similar ranges, we found high inter-individual variations of CSF levels. Different plasma-to-CSF ratios after HD may reflect individual brain Aβ pools that are accessed by HD. We corroborate previous reports demonstrating the removal of Aβ from the blood compartment by HD.
Circulating Microbiome and Cardiovascular Death in Patients with ESRD

Keichi Sumida,1 Joseph F. Pierre,1 Zhongji Han,1 Tahiliyah S. Mims,1 Praveen Kumar Pototuchi,1 Susmita Datta,1 Csaba P. Kovedsy.1 1The University of Tennessee Health Science Center, Memphis, TN; 2University of Florida, Gainesville, FL.

Background: Patients with end-stage renal disease (ESRD) suffer from disproportionately high cardiovascular (CV) mortality. Accumulating evidence suggests a role for the circulating microbiome (CM) in the pathogenesis of CV disease; however, little is known about its association with premature CV mortality in ESRD.

Methods: In a pilot case-control study of 17 hemodialysis (HD) patients who died of a CV event and 17 matched HD controls who remained alive during a median follow-up period of 2.0 years, we compared the levels and composition of CM, including Bacteria, Archaea, and Fungi in serum samples by quantitative PCR and 16S or Internal Transcribed Spacer (ITS) ribosomal RNA (rRNA) sequencing, respectively. Association of the CM with CV death were examined using multivariable conditional logistic regression.

Results: 16S and ITS rRNA was detectable in all (except 3 for ITS) examined patients’ serum samples. Despite no significant difference in 16S rRNA levels and α diversity between cases and controls, taxonomic analysis demonstrated differential community membership between groups, with significantly greater Actinobacteria and less Proteobacteria observed in cases than controls at the phylum level. At the genus level, Staphyloccocus was numerically higher in cases than in controls, albeit not reaching statistical significance. Proportions of Actinobacteria and Proteobacteria phyla were marginally associated with risk of cardiovascular death (adjusted ORs [95% CI], 1.12 [0.98-1.29] and 0.88 [0.76-1.02] for 1% increase, respectively; Table). Although circulating fungal community α diversity was significantly elevated in cases than controls, no significant association was observed with CV death.

Conclusions: Altersations of the CM may be associated with a higher risk of premature CV mortality in ESRD patients.

Funding: NIDDK Support

Association of circulating microbiome with cardiovascular death in hemodialysis patients

![Table showing association of circulating microbiome with cardiovascular death in hemodialysis patients](image)

Model was adjusted for age, sex, race, dialysis vintage, and vascular access type.

Dysregulation of Fibrinolytic Process Contributes to the Thrombotic and Bleeding Complications in ESRD Patients

Fakih Siddiqui, Vinod K. Bansal, Omer M. Iqbal, Emily Bontekoe, Jawed Fared. Loyola University Health System, Maywood, IL.

Background: End stage renal disease (ESRD) is a complex syndrome involving both cellular and humoral mechanisms. Both thrombotic and bleeding complications are observed which may result in cardiovascular and cerebrovascular adverse outcomes. Fibrinolytic system placed an important role in the regulation of hemostatic process. A comprehensive profiling of the components of fibrinolytic process may provide additional understanding of the bleeding and thrombotic complications in ESRD.

Methods: Citrated whole blood samples were collected from a cohort of ESRD patients (n=95). Normal citrated plasma were obtained from healthy male and female individuals. These samples were analyzed for prothrombin time (PT), activated partial thromboplastin time (aPTT), prothrombinase-induced clotting time (PicT) and thrombin time (TT) using clot based technique. Fibrinolytic parameters such as urokinase type plasminogen activator (uPA), plasminogen activator inhibitor-1 (PAI-1), and D-Dimer were measured by using ELISA method. Functional PAI-1 was measured by using an amyloidylic method. All results were compiled as group means ± SEM and respective ratios were calculated.

Results: All of the clotting results showed varying levels of elevated values in comparison to normal plasma. uPA levels showed wide variations and were increased (1.6 fold). D-Dimer was markedly increased in the ESRD patients (11.53 fold). Both functional (1.2 fold) and antigenic (3.07 fold) levels of PAI-1 were increased. Interestingly, the PAI-1 antigen levels was much higher in contrast to the functional levels suggesting a progressive consumption of this mediator.

Conclusions: These results suggest that the overall hemostatic system in ESRD patients is dysregulated due to the imbalance of the inhibitors such as PAI-1. The persistent activation of fibrinolysis is due to the increase production of uPA which facilitates endogenous fibrinolysis resulting in the elevation of D-Dimer. The generation of fibrinolytic enzymes results in increased fibrin/fibrinogen degradation products which may contribute to the observed intrinsic and extrinsic coagulation defects as measured by the elevation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting test may be helpful in the risk stratification and prediction of adverse outcomes in ESRD patients

PO0946

Successful Treatment of Systemic Calcinosis in a Teenager on Hemodialysis

Naile Tufan pekkucuksen,1 Mohammed Al-Humari,1 Sai Sudha Mannemuddu,1 Lawrence R. Shoemaker,1 University of Florida, Gainesville, FL; 2East Tennessee Children’s Hospital, Knoxville, TN.

Introduction: Systemic calcinosis is rare in pediatric ESKD patients compared to adults. The subcutaneous tissues are most frequently involved. We present teenager in whom calcinosis was detected incidentally on chest radiograph, and review its successful treatment.

Case Description: A 15 yo anuric female who had received hemodialysis(HD) for 18 months after renal transplant failure, was treated for progressive respiratory distress in the ICU. Significant history included osteoporosis, hypertensive cardiomyopathy, and renal failure since age 1. Chest-XR revealed bilateral pulmonary infiltrates and calcified lesions. Thoracic CT scan demonstrated calcified tracheal and bronchial cartilage rings. Flexible bronchoscopy revealed diffuse white/gray nodules throughout the wall of tracheobronchial tree. All cultures were negative. When noticed of the finding of calcifications on CT scan, patient’s mother also asked about the firm nodules in the space between patient’s fingers. Dialytic phosphate (P) clearance, and non-calcium(Ca), non-aluminum(Al) based binder use were maximized, using sevelamer and lanthanum carbonate. Sodium thiosulfate and etalcalcetide were given iv post each dialysis. Dialysate Ca varied between 0.98 to 1.05 mEq/L. Although calcium levels were increased with calcium carbonate, the elevation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting may contribute to the observed intrinsic and extrinsic coagulation defects as measured by the elevation of PT and aPTT. Monitoring of fibrinolytic parameters along with clotting test may be helpful in the risk stratification and prediction of adverse outcomes in ESRD patients

Discussion: Calcinosis is uncommon, yet treatable condition in pediatric dialysis patients. Combined use of old and new therapies was successful. Adverse side effects of therapies affect dosing. Etelcalcitide often causes hypocalcemia. Thiosulfate use is contraindicated. Ferrous citrate, sucroferric oxyhydroxide, and bixalomer will offer exciting new treatment options.
Severe Thrombocytopenia due to Electron-Beam Sterilized Polysulfone Dialyzer Membrane Reaction

Introduction: We describe a case of severe thrombocytopenia due to reaction with an electron-beam sterilized polysulfone (PS) membrane. This phenomenon has been previously described but is rarely reported. E-beam sterilized PS membranes are classically more biocompatible than cellulose-based membranes but adverse reactions may occur as demonstrated in our case.

Case Description: A 74 y.o. woman with CKD Stage 4 and secondary hyperparathyroidism presented for evaluation of generalized weakness, anorexia, and weight loss. Her past medical history included gout, short bowel syndrome following prior bowel resection and osteoporosis. Home medications were allopurinol, calcitriol, gabapentin, fluoxetine, and mitazapine. She was started on hemodialysis (HD) for suspected progression to ESRD. She developed progressive thrombocytopenia (Figure 1) that was worse, following HD with improvement on non-HD days. Evaluation of usual culprits of thrombocytopenia was unrevealing. Reaction to the polysulfone filter was suspected and she was switched to a cellulose-based filter with resolution of her thrombocytopenia. She was dialyzed with a PS membrane on HD20 as proof of concept with recurrent thrombocytopenia following HD. She was dialyzed with cellulose-based filter thereafter with no further thrombocytopenia.

Discussion: We describe a case of PS-membrane induced thrombocytopenia. It is hypothesized that e-beam radiation may affect membrane integrity or structure, or produce intermediary products which may cause platelet activation, aggregation, and adhesion and therefore thrombocytopenia. This entity should be considered in the differential diagnosis of patients undergoing HD who develop thrombocytopenia. Early recognition may reduce incidence of bleeding and need for blood products in these patients.

Results:

- PLT counts during admission. HD days with PS membrane were denoted with a diamond label and HD days with cellulose-based membrane were denoted with a circle label. Single unit PLT transfusions are denoted with arrows.

PO0947

Feasibility of a Staff-Assisted Peritoneal Dialysis Program in the United States: Results of a Pilot Study

Wael F. Hussein,1,2 Graham E. Abra,1,2 Paul N. Bennett,1,3 Jugjeet Atwal,1 Veronica Legg,1 Brigitte Schiller,1,2 Satellite Healthcare, San Jose, CA; Stanford University School of Medicine, Stanford, CA; University of South Australia, Adelaide, SA, Australia.

Background: Staff-assistance can support patients to utilize peritoneal dialysis (PD) and is available in many countries but not in the US. We report on the initial experience from a feasibility study for staff-assisted PD in the US.

Methods: An assisted PD program was initiated at one home dialysis center in Aug 2020, and expanded to a total of 6 centers by Feb 2021. Home assistance by non-registered nurse staff was offered to patients with barriers to self-care with the aim to support patients and families to become independent from staff assistance.

- Participants: 33 patients (range: 0 – 16 referrals/center). 16 referrals were cancelled [admission from HD to the home program cancelled (3 referrals), transition to oral medications (2 referrals), staff-assistance (6 referrals), and death (1)]. 17 patients started staff assistance (5 referrals, and staff assistance (10 referrals). Staff assistance (12 referrals), and death (1)). 3 referrals are pending, and 14 patients received staff assistance at home. Of those who received assistance, median age was 72 years (range 43-87 years), and 8 Were new to PD. Indications included: physical weakness (10 patients), cognitive impairment (8), and psychosocial issues (7). One prevalent PD patient required assistance following a PD peritonitis episode. Anxiety and lack of confidence were common among referred patients. Staff member attending the patient’s home assisted with removal and replacement of PD bags (5 patients), machine setup (9), dressing of exit site (7), checking the blood pressure (2), and other requests (8) such as documentation. Assisting staff worked with patients to build problem-solving skills, gain self-confidence, and arrange a safer home environment. Median length of time on the service was 17 (IQR: 6 – 23, range: 2 – 49 days), and median number of visits was 15 (range: 4 – 38, IQR: 5 – 26). Seven of the patients who finished were more than 90 days after starting assistance. Six of them remain on PD and 1 patient transferred to HD.

Conclusions: Staff-assistance can support patient transition to, and maintenance on, PD. Such programs are operationally feasible with non-RN staff in the US and should be supported by Medicare and regulatory agencies.

Increasing the Prevalent Peritoneal Dialysis Patient Population Can Be Challenging

Hari Dukka, Emma Edwards, Anil Jain, Dhawal Arora. University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.

Background: Peritoneal dialysis (PD) can provide better quality of life for patients requiring renal replacement therapy compared to in centre dialysis. It can be challenging to increase prevalent patient population on PD after a certain number is reached. We did a retrospective analysis to assess the turnover of patients on PD over a 8 year period and to understand the reasons for a stagnant prevalent PD population in the renal unit in Royal Derby Hospital.

Methods: Electronic data (vital, data, ICM) were used to document the number of patients starting and stopping PD each year from 2013 to 2020. The reasons for stopping PD and duration of technical survival were noted. If technique failure resulted in conversion to haemodialysis (HD) for more than 3 months, the cause of the failure was also noted. Patients who converted to HD for less than 3 months were excluded from the study.

Results: The number of patients starting (n=324) and dropping off PD (n=322) was similar for each year between 2013 to 2020. Modality switch to haemodialysis accounted for 40-60% of patients stopping PD, followed by death (15-30%) and patients receiving renal transplantation (10-35%). Modality switch to haemodialysis was primarily due to infection (60-80%), poor clearances and ultrafiltration failures (10-30%), social reasons (10-15%). Among patients who switched to HD due to an infection, peritonitis accounted for 75-85% of the cases followed by exit site and tunnel infections (15-25%). Introduction of Kidney Quality Improvement project in 2018 reduced numbers switching from PD to HD, with no affect on prevalent patient population due to decrease in incident patient population.

Conclusions: Increasing the prevalent population on PD can be challenging even with a high incident patient population. Having mechanisms which prevent infections, early identification and treatment of infections may help improve prevalent PD population.

Disparities in Kidney Care: Where Care Needs to Be Equal

Tucker B. Hurtado, Meghan Staudt, Skyller Malone. SphereX Advanced Analytics Group SphereX Global Insights, Exton, PA.

Background: Disparities in kidney care are widespread and gaining more attention. This research focuses on care differences that existed between home hemodialysis (HHD) and in-center hemodialysis (ICHD) patient from 2017 to 2020.

Methods: Using a HIPAA-compliant, online chart review tool, nephrologists submitted de-identified clinical and non-clinical demographic information beginning at the time of patient referral and concluding with details from the most recent visit. These data, from 2017 through 2020, were then merged with the physicians demographic profile and attitudinal responses. The full data set of 4,002 patient charts submitted from 1,021 nephrologists was analyzed in SPSS.

Results: Given the new efforts to promote home modalities, nephrologists are following status quo and continue to initiate new dialysis patients on in-center hemodialysis. Nephrologists’ current patient loads consists of, on average, 5 HHD patients and 90 ICHD patients. On average, they initiate one new patient on HHD compared to 17 new ICHD patients per year. When comparing HHD and ICHD patient charts there are substantial differences between the two patient types. IHD patients tend to be Caucasian and from higher education and socioeconomic levels: 52% are Caucasian and 25% are African American, 37% have some college (14% have an advanced degree), and 67% are middle or upper class. Conversely, ICHD patients tend to be more diverse (40% are Caucasian, 40% are African American), less educated (24% have some college and 5% have an advanced degree) and from lower socioeconomic classes (44% are lower or lower-middle class). Further, 40% of patients on home modalities are employed part- or full-time, versus 18% of patients on ICHD. Insurance coverage – both at dialysis center and current – influence modality choice as well. Notably, 70% of patients on home modalities were followed prior to dialysis, whereas only 48% of patients on ICHD were followed pre-dialysis, and patients on home modalities are substantially more likely to be on the transplant list versus ICHD patients (62% versus 37%).

Conclusions: Disparities in care exist between patients receiving home hemodialysis versus in-center home hemodialysis. As kidney care continues to evolve, physicians will need to account for these differences in their treatment paradigms to ensure they provide comparable care across patients.
Recent Trends in Utilization of Home Dialysis Modalities, Overall and by Duration of ESKD
Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen.1 (Hennepin Healthcare Research Institute, Minneapolis, MN; University of Minnesota Twin Cities, Minneapolis, MN).

**Background:** The Executive Order on Advancing American Kidney Health and the End Stage Renal Disease Treatment Choices payment model have focused attention on increasing utilization of home dialysis. We assessed trends in home dialysis utilization between 2016 and 2021, including variability in trends among strata defined by duration of end stage kidney disease (ESKD).

**Methods:** We analyzed dialysis facility admission and discharge data extracted from the End Stage Renal Disease Quality Reporting System in May 2021. During the epidemiologic week of each year from 2016 to 2021, we identified patients undergoing maintenance dialysis at the beginning of the week. For each patient, we identified the current dialytic modality. We estimated trends in utilization of each modality, overall and by duration of ESKD at the beginning of the week (<2, 2-4, 5-9, and ≥10 years).

**Results:** Between 2016 and 2021, home dialysis utilization increased from 11.5% to 14.3%, with the majority of growth occurring since the beginning of 2019 (figure). Concurrently, HD utilization increased from 1.57% to 2.23%, whereas PD utilization increased from 10.0% to 12.0%. Among patients with ESKD duration <2 years, home dialysis utilization increased from 14.8% in 2016 to 20.0% in 2021, with >90% of utilization in this stratum due to PD. Among patients with ESKD duration 2-4 years, home dialysis utilization increased from 11.7% in 2016 to 13.7% in 2021. Among patients with ESKD duration ≥10 years, home dialysis utilization hovered around 9%, although HD utilization reached a high of 3.65% in 2021, representing nearly 40% of home dialysis utilization in this stratum.

**Conclusions:** Growth of home dialysis utilization has accelerated since 2019, with greater absolute growth of PD and greater relative growth of HHD. Longer duration of ESKD is associated with lower utilization of PD, but higher utilization of HHD.

**The Impact of Seasonality on Crash Starts and Home Dialysis Use**
Eugene Lin,1,2 Kristhina I. Lung,2 Darius Lakdawalla.2 (University of Southern California Keck School of Medicine, Los Angeles, CA; University of Southern California Leonard D Schaeffer Center for Health Policy and Economics, Los Angeles, CA).

**Background:** The US has made a concerted effort to increase home dialysis use. Dialysis “crash starts,” when patients emergently initiate dialysis in the hospital, are a barrier to home dialysis because they often preclude successful planning. We studied whether the season of the year was associated with crash starts and with home dialysis use among incident patients with end-stage kidney disease (ESKD).

**Methods:** From the United States Renal Data System, we identified all adults with at least 30 days of continuous Medicare Parts A and B coverage initiating dialysis from 2007-2017. We identified home dialysis use and whether patients were hospitalized within 14 days prior to the first outpatient dialysis treatment (ie, “crash start”). Using multivariable logistic regression, we studied the association between season, likelihood of crash start, and starting dialysis at home. We used a Cox model to study whether crash starts were associated with ever using home dialysis in the first year. We adjusted for demographics, comorbidities, facility and geographic characteristics, and year of dialysis start.

**Results:** After adjusting for confounders and year of dialysis start, patients were less likely to start dialysis in the winter versus the summer (OR: 0.86, 95% CI: 0.82, 0.90). Conversely, patients were more likely to “crash start” into dialysis in the winter versus the summer (OR: 1.14, 95% CI: 1.11, 1.17). Patients with a crash start were substantially less likely to initiate with home hemodialysis (OR: 0.16, 95% CI: 0.15, 0.16) and were less likely to ever use home dialysis in the first year (HR: 0.41, 95% CI: 0.40, 0.42). We observed seasonal heterogeneity in the admission diagnoses. Hospitalizations due to pneumonia, myocardial infarction, and congestive heart failure were 1.6, 1.4, and 1.3 times more likely to occur in the winter versus the summer, respectively. Hospitalizations due to diabetes, complications of devices, and chronic kidney disease were 1.05, 1.08, and 1.08 times more likely to occur in the winter, respectively.

**Conclusions:** We observed more dialysis crash starts in the winter and a subsequent decrease in home dialysis use in the first year. Winter hospitalizations were more often associated with cardiac and pulmonary etiologies. Clinicians should remain vigilant that patients may be prone to crash starts in the winter and should accelerate dialysis planning accordingly.

**Comorbidity Is Not Associated with Home Dialysis Choice**
Sanne Vong,2 Anna A. Bonenkamp,1 Yolande Vermeeren,2 Anita van Eck van der Sluijs,1 Tiny Hoekstra,1 Aflero C. Abrahams,2 Frans J. van Itersum,2 Brigit C. van Jaarsveld,1 DOMESTICO ‘Amsterdam UMC Locatie VUMc, Amsterdam, Netherlands; 2University Medical Center Utrecht, Utrecht, Netherlands; 3Department of Internal Medicine, Apeldoorn, Netherlands.

**Background:** Over the past 15 years the proportion of Dutch home dialysis patients has decreased markedly. In addition, the rate of home dialysis varies significantly among centers. It is unclear whether this is the result of increased comorbidity, other patient characteristics or because dialysis centers perceive barriers for home dialysis differently. Our aim was to investigate the association between comorbidity and home dialysis choice.

**Methods:** The DOMESTICO study is a multicenter retrospective cohort study on home dialysis and randomly selected in-center hemodialysis patients. Comorbidity data was collected of patients who started dialysis between 2012 and 2017, including those who had previously received dialysis or obtained a kidney transplant. Patients who stopped dialysis or died within 30 days were excluded. Comorbidity was assessed with the Charlson comorbidity index (CCI). Home dialysis was defined as any peritoneal dialysis or home hemodialysis treatment during follow-up. Patients were followed until kidney transplantation, wish to stop dialysis, death or study end on 1 January 2017. Multivariable logistic regression analysis was used to assess the association between comorbidity and home dialysis, with a mixed model approach to adjust for dependency of patients within dialysis centers and for other patient characteristics including age, sex, and body mass index (BMI).

**Results:** Of 1358 included patients, 46% were treated with home dialysis. A high comorbidity score (CCI ≥5) was associated with a lower probability to receive home dialysis compared to patients without comorbidities (unadjusted OR 0.74, 95% CI 0.54–1.00). After adjustments for patient characteristics including age and BMI, there was no association between comorbidity and home dialysis. Only obese patients (BMI ≥30 kg/m²) with comorbidities had a significant lower likelihood to receive home dialysis compared to obese patients without comorbidities (medium comorbidity score (CCI 1-4) adjusted OR 0.40, 95%CI 0.18–0.86 and high comorbidity score (CCI ≥5) adjusted OR 0.43, 95%CI 0.20-0.93).

**Conclusions:** Comorbidity is not associated with home dialysis, after adjustment for several confounding factors including age and BMI. Future studies should aim at unraveling the center-specific characteristics that play a role in dialysis treatment.

**Funding:** Commercial Support - Nierstichting/Dutch Kidney Foundation = non-profit organisation. Grant no: AZ2D4P02.

Reducing Routine Bloodwork in Home Dialysis Patients: A Quality Improvement Initiative

Epsita Shome- Vasanthan, Sophia Chou, David Ward, Juliya Hemmert, Jennifer M. MacRae, Elena Qirjazi. University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

Background: There is a paucity of evidence for routine bloodwork frequency in maintenance dialysis patients to assess and manage complications such as anemia and mineral bone disease (MBD). Recent studies showed that decreasing the frequency in conventional in-center hemodialysis (ICHD) patients had no negative impacts. Given the strain on lab services from the COVID-19 pandemic, Alberta Kidney Care-South (AKC-S) decreased the frequency of routine labs from monthly to every 2 months in home hemodialysis (HHD) and peritoneal dialysis (PD) patients. We studied the effect of this change on patient outcomes.

Methods: We retrospectively compared prevalent home dialysis patients (>3 months) in AKC-S over two 6-month periods: a) Pre-pandemic May-Oct 2019 and b) Pandemic May-Oct 2020. Primary outcomes were number of routine bloodwork days and percentage of patients within target for anemia (hemoglobin, iron saturation) and MBD (calcium, phosphorus, parathyroid hormone). We also compared hospitalizations, mortality, technique failure (defined as transition to ICHD for >60days), and cost.

Results: There were 366 home dialysis patients in 2019 (270 PD, 96 HHDD) and 400 in 2020 (296 PD, 104 HHDD). The number of routine bloodwork days decreased in 2020 compared to 2019 (p=0.01) (Fig 1). The proportion of patients who achieved anemia (33% vs 35%, p=0.44) and MBD (34% vs 28%, p=0.1) targets was similar. There was no difference in the number of hospitalizations (155 vs 141, p=0.34), deaths (13 vs 17, p=0.71) or technique failure (8% vs 5%, p=0.06). Projected cost savings were $102 per patient year from reduced labs.

Conclusions: AKC-S reduced the frequency of routine labs during the pandemic in home dialysis without negative consequences on patient biomarkers or outcomes. Our study suggests that bloodwork frequency in home dialysis patients may be safely reduced.

Figure 1. Distribution of the number of routine bloodwork days in Home Dialysis patients had during the pre-pandemic (blue) and pandemic (orange) periods.

On-Demand Automated Peritoneal Dialysis Solution

Jaine Uricibari, Nabeel Aslam, Clinton Edwards, Lara M. Yamagata, Anders J. Wellings, Alyssa Wilmington, Ha Tran. Mount Sinai School of Medicine at Mount Sinai, New York, NY; Mayo Clinic’s Campus in Florida, Jacksonville, FL; Saint Bernard’s Healthcare, Jonesboro, AR; Baxter Healthcare Corporation, San Gwann, Malta; Baxter Healthcare Corporation, Deerfield, IL.

Background: While automated peritoneal dialysis (APD) is an effective treatment for kidney failure, ordering, delivery and storage of supplies can be challenging. The APD Solution Generation System (SGS) allows for dialysate solution generation using tap water in a patient’s home with fewer supplies (Figure 1).

Methods: A 12-week single-arm, prospective, descriptive study was conducted with in-home APD patients. Patients were screened, trained and treated with the SGS. Endpoints included testing the final product against specifications for Dianeal and water purification ISO Standard 13959 and measuring PD adequacy. Adverse events and device deficiencies were collected.

Results: 22 patients were enrolled: 14 patients completed the study. Demographics are shown in Table 1. See Figure 1 for primary efficacy and safety endpoint results. All tested post-sterilization filter and final dialysis solution samples passed. Missing data for water purity attributed to only 56.9% of samples passing. Mean (SD) change from baseline for Kt/V was -0.15 (0.370). There were 2 peritonitis events (0.43 episodes per patient-year), 1 occurring in a patient with HIV. There were no safety signals.

Conclusions: The SGS has the technical capability to accurately and safely generate dialysate at home using tap water. Logistical challenges with lab sampling require further exploration to understand the impact in future trials and real-world settings. Lessons learned from the study allow for transition of the device to future development.

Table 1. Demographics (n=22)

| Age (Mean [SD]) | 66.9 ± 13.7 |
| Perf. SBP [mm Hg] | 134 (74) |
| Black (n%) | 70 (61) |
| Hispanic or Latinx (n%) | 20 (18) |
| Transient RVT change (Mean [SD]) | 2.4 ± 1.6 |

PO0961

SmartPD™ Automated Peritoneal Dialysis System as a New Sophisticated Choice for Urgent Integration in Replacement Therapy for a Patient with ESRD

Ioannis Grivess. Army Share Fund Hospital of Athens, 417 NIMTS, Athens, Greece.

Introduction: Peritoneal dialysis (PD) is used to treat approximately 11% of dialysis patients globally despite wishes for 30%, due to Covid-19 pandemic. Expanded use of PD is impacted by clinician experience and confidence with “efficient”, and “in home friendly” automated peritoneal dialysis (APD) system.

Case Description: A 60 years old lady presented from a remote island -under Covid-19 pandemic- with uremic features and started APD with SmartPD™ (Newsol technologies). SmartPD™ continuously monitors the intra-peritoneal pressure (IPP) during the dwell. SmartPD™ enables the formulation of prescribed dialysate at the point-of-care, maximizes dialysis performance, and optimizes treatment protocol. Remote monitoring capability by SmartPD™ allows remote supervision and management, an efficient choice especially in Covid-19 times.
PO0962

Animal Trial of Sorbent Cartridge for Portable Artificial Kidney (PAK)

Christian G. Bluechel,1 Yen N. Koh,1 Chieh-suai Tan,2 Kenneth Chen,2 Kun D. Zhuang,3 Dialysis Pte Ltd, Singapore, Singapore; 3Singapore General Hospital, Singapore, Singapore.

Background: The NextKidney/Dialysis HD Sorbent Cartridge (SC) uses a novel type of sodium-neutral sorbent to regenerate spent dialysate for standard hemodialysis (HD) therapies. The SC is intended to be used with the NextKidney sorbent HD device, where it produces fully physiological dialysate meeting today’s industry standards. We tested the safety and efficacy of the sorbent system in a total kidney failure pig model. The animals were maintained exclusively on sorbent HD for up to 2 weeks.

Methods: Three highly uremic pigs (60–75Kg) underwent a total of 14 alternate-day, 4h sorbent HD therapy sessions. Total renal failure was induced via bilateral renal artery embolization (pig #1), or bilateral laparoscopic ligation of renal arteries (pigs #2 and #3). A palindromic catheter provided blood flow rates of 200 – 300mL/min. A hemoperfusion machine was used for the blood circuit, coupled with a prototype device controlling the dialysate circuit. Dialysate was continuously purified in the SC at a flow rate of 300 mL/min. Therapy efficacy and mass balances were calculated from blood and dialysate samples collected before and after the dialyzer at specific time points.

Results: The animals tolerated the therapies well. The incision site at the femoral artery did not leak, and the animals were maintained euvolemic and biochemistry for 30 days in a porcine model.

Conclusions: The biocompatibility of the sorbent system has been confirmed in fourteen 4h HD therapies conducted on three highly uremic pigs. The sorbent system was able to maintain the highly uremic animals. There were no severe adverse events related to the sorbent HD therapy. We currently plan to proceed to a first-in-human trial to evaluate the safety and efficacy of the sorbent cartridge for human use.

Smartphone Application to Assist Peritoneal Dialysis Patients for Timely Detection of Peritonitis

Mia Garbaccio,1 Xia Tao,1 Xiaoling Wang,1 Xin Wang,1 Zain H. Saq,1 Amrish U. Patel,1 Lela Tisdale,2 Ohnmar Thwin,2 Lin-Chun Wang,3 Nadja Grobe,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Timely detection of peritonitis in patients undergoing peritoneal dialysis (PD) is critical to lower the risk of catheter loss, morbidity and mortality (Muhucumaranu, 2016). Current practice of screening potential peritonitis events at home relies on patients’ visual detection of turbid spent dialysate and symptoms recognition. To assist patients with the timely capture of a potential peritonitis episode, we developed a smartphone app, which uses light detection to quantitate cloudiness and estimate white blood cell (WBC) count in PD effluent (PDE).

Methods: The app uses the built-in light sensor and compares measurements taken from the ambient light (Iambient) and light through PD bags (Ibag) to estimate dialysate cloudines. PDE samples were obtained as part of two IRB-approved clinical studies over a period of 6 months. Cloudiness of each sample was measured 3x with the app. Cloudiness (in %) was calculated as (1 - Iambient / Ibag) * 100. WBCs were counted using a hematology analyzer (Horiba 80XL).

Results: Patients maintained a stable baseline cloudiness of 2-5% (Fig 1). A peritonitis episode (subject PDMET0002) increased the cloudiness to 40%, which is 32 percentage points over the patient’s peritonitis-free baseline. One suspected peritonitis sample (albeit WBCs <100 cells/mL) showed slightly higher cloudiness than non-peritonitis samples (Fig 2).

Conclusions: Our smartphone app can distinguish peritonitis from normal PDE samples. Smartphone-enabled detection of cloudiness in PDE samples using light transmission is possible and has the potential to easily monitor and diagnose patients at risk for peritonitis. Studies to define diagnostic performance in a large patient cohort are underway.

Remote Monitoring of Patients with Automated Peritoneal Dialysis May Improve Clinical Outcomes: Analysis by Competing-Risk Regression Models
Ramón Paniguia, Marcela Avila, Alfonso Ramos, Abdul Rashid T. Qureshi, Bengt Lindholm, Mexican Nephrology Collaborative Study Group, Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; Baxter Novum CLINTEC, Karolinska Institutet, Stockholm, Sweden; Baxter México, Mexico City, Mexico.

Background: Current information technologies allow remote monitoring (RM) of patients on automatic peritoneal dialysis (APD) and the adoption of proactive behaviors to prevent complications and improve treatment quality. We analyzed the effect of RM-APD on survival and preventable complications through a controlled clinical trial.

Methods: In a two-branched cluster RCT, hospitals with >100 prevalent, >50 new patients per year, and >5 years APD experience were randomly assigned to perform RM-APD or conventional APD with equivalent APD-equipment in adults beginning APD. The primary outcome was a composite index (CI) of death, first adverse event (AE) or first hospitalization. Secondary outcomes were the same variables considered individually and for their specific causes. All-cause and cardiovascular disease (CVD) mortality risk and AEs were analyzed with competing-risk regression with transplantation as competing risk.

Results: Eleven hospitals per arm were included and 815 patients were followed-up by at least one year. 417 using RM-APD and 398 on APD. Patients in hospitals using APD reached earlier the CI as well as its individual components. Patients with APD as compared to RM-APD were older, more inflamed, and had higher all-cause and CVD mortality. In competing risk analysis, after adjusting for age, sex, presence of smoking, hypertension, CVD and diabetes, APD as compared with RM-APD associated with higher subdistribution hazard ratio (sHR) for all-cause mortality (sHR 1.79, 95%CI (1.15-2.81); p=0.01), CVD-related mortality (sHR 2.21, 95%CI (1.07-4.58); p=0.03), and AE (sHR 1.74, 95%CI (1.34-2.25); p=0.001).

Conclusions: Use of RM-APD may improve survival and prolong the time to first AE and hospitalization in comparison with APD, suggesting that RM-APD may improve clinical outcomes in APD patients.

PO0966
Peritoneal Dialysis Discontinuation: Trends and Risk Factors
Andrew Brock, Jeffrey Marr, Dominick Esposito, Edwin D. Huff; Insight Policy Research Inc, Arlington, VA; Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: Increasing use of dialysis home modalities among ESRD patients is a Centers for Medicare and Medicaid Services priority. This can be accomplished by increasing use of home dialysis among incident patients or by reducing PD discontinuation. We explore trends in PD persistence and risk factors associated with PD discontinuation.

Methods: We identified incident ESRD patients from 2008 to 2018 who received peritoneal dialysis in their third month of ESRD treatment. We used data from CROWNWeb and Medicare claims to determine the patient’s modality 1, 2, and 3 years after initiation of ESRD treatment. We summarize trends in share of incident PD patients who were treated with PD at each follow up and describe differences by patient and facility characteristics.

Results: From 2008 to 2017, approximately 70 percent of incident PD patients remained on PD after 1 year of dialysis, 50 percent after 2 years, and 30 percent after 3 years of dialysis (figure 1). Over these years the percentage of incident PD patients treated with PD after two years rose from 47.9 to 52.3 percent. The rate of two-year PD persistence has declined modestly since a peak of 53.1 percent in 2013. PD patients treated at DaVita facilities were more likely than those treated at FMC or independent facilities to remain on PD after two years. PD patients treated at facilities with a higher share of PD patients were more likely to remain on PD after two years. Among incident PD patients, the rate of peritonitis during the first year of dialysis declined from 33.5 to 21.7 between 2010 and 2018. Peritonitis was more common among dual eligible patients, Black and American Indian/Alaska Native patients, and overweight or obese patients.

Conclusions: Differences in PD discontinuation and peritonitis incidence across patient and facility subgroups represent opportunities for future quality improvement efforts.

Contemporary Incidence of Peritoneal Dialysis Attrition and Variability Therein Among Age Strata
Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,1 Kirsten L. Johansen,1 Hennepin Healthcare Research Institute, Minneapolis, MN; University of Minnesota Twin Cities, Minneapolis, MN.

Background: With an increasing percentage of patients performing dialysis in the home setting, quality measurement systems should increase focus on home dialysis outcomes. Considering the central role of peritoneal dialysis (PD) in home dialysis, an important and readily estimable measure is the duration of PD before initiation of hemodialysis. We estimated the cumulative incidence of attrition due to initiation of hemodialysis among patients who recently initiated PD in the United States and assessed variability of incidence among age strata.

Methods: We analyzed United States Renal Data System Standard Analysis Files. We identified all patients who initiated PD in the home setting between January 1, 2011, and September 30, 2018, and within one year after diagnosis of end stage kidney disease (ESKD). We classified patients into cohorts of age 18-44, 45-64, 65-74, and ≥75 years. Overall and within age strata, we estimated the 5-year cumulative incidence of conversion to hemodialysis, with accounting for the competing risks of death and kidney transplantation.

Results: The cohort included 111,464 patients who initiated PD. The cumulative incidence of conversion to hemodialysis was 22.4% at 1 year, 33.9% at 2 years, 41.4% at 3 years, 46.3% at 4 years, and 49.4% at 5 years (figure). During those 5 years, 25.4% of patients died while receiving PD and 12.8% received a kidney transplant, thereby resulting in only 12.4% of patients still performing PD after 5 years. Among patients aged 18-44 years, 1-year (5-year) cumulative incidence of conversion to hemodialysis was 23.3% (51.1%); corresponding estimates were 22.3% (52.0%) among patients aged 45-64 years (48.3%), 21.9% among patients aged 65-74 years, and 22.5% (41.6%) among patients aged ≥75 years.

Conclusions: Regardless of age, between 22% and 23% of patients who initiated PD during the first year of ESKD transferred to hemodialysis within one year.

PO0970
Identifying Patients on Peritoneal Dialysis at High Risk of Transfer to Hemodialysis Using a Modified Surprise Question
Ayesha Anwaar,1,2 Graham E. Abra,2,1 Hatsumi Nielsen,2 Sumi J. Sun,2 Sai Liu,1 Maria E. Montez-Rath,1 Brigitte Schiller,2,1 Wael F. Hussein,2,1 Stanford University School of Medicine, Stanford, CA; 2Satellite Healthcare, San Jose, CA.

Background: Transfer from peritoneal dialysis (PD) to hemodialysis (HD) is associated with poor outcomes. Available prediction models of modality transfer are limited to the incident PD population. Simple predictive tools are needed to help guide risk stratification and subsequent clinical interventions to avoid unwanted modality transfer. We report on the correlates of nurse prediction of high risk using the question “Would you be surprised if this patient transfers to HD in the next 6 months?” (PD Surprise Question [PDSQ]).

Methods: This observational study included 1362 adults on PD receiving care at 35 centers in 3 states in the US, managed by a non-profit dialysis organization. A ‘no’ response to the PDSQ indicated high risk. Using multivariable logistic regression with backward elimination, we evaluated characteristics associated with being identified as high risk, including socio-demographic variables, BMI, primary kidney disease, vintage, comorbid conditions, renal and dialysate clearances, serum albumin, sodium, phosphorus, potassium, nPNA, last 3 months peritonitis and hospitalization, and insurance type. We used multiple imputations to handle missing data.

Results: Responses were obtained from 95/112 (85%) nurses for 1193/1362 (88%) patients. Mean age was 59 (SD: 16) years, 41% were female, median ERSD vintage 37 (IQR: 11 – 44) months and 46% had diabetes. 198 (17%) patients were identified as high risk. In the final model, patients were more likely to be identified as high risk if they were hospitalized in the last 3 months (odds ratio [OR]: 1.30, 95% confidence interval [CI] 1.30-1.74, p=0.0002). Considering the higher serum sodium serum level for 1 meq/L: OR: 0.95, 95% CI 0.90-1.00, p=0.032), being married (OR: 0.76 95%CI 0.52-1.00, p=0.029), and longer PD vintage (for 1 month: OR: 0.99, 95%CI 0.98-1.00, p=0.013) were associated with lower odds of being identified as high risk.

Conclusions: The PD surprise question is a simple tool to assess the risk of transfer from PD to HD. Identified correlates of risk are consistent with high risk factors from the literature for transfer to HD. We are currently observing outcomes of included patients to examine the performance of the PDSQ to predict transfer to HD.

**Machine Learning-Driven Prediction of Peritoneal Dialysis Technique Failure**

Caitlin Monaghan,1 Joanna Willetts,1 Hao Han,1 Michael A. Kraus,2,4 Dinesh K. Chatoth,1,3 Len A. Usvyat,1 Franklin W. Maddux,2 ‘Fresenius Medical Care, Global Medical Office, Waltham, MA; ‘Fresenius Medical Care AG, Konzernzentrale, Hamburg, Germany; ‘Fresenius Kidney Care, Waltham, MA; ‘Fresenius Medical Care North America, Waltham, MA.

**Background:** Despite increased focus on starting and keeping dialysis patients on home therapy, Peritoneal Dialysis (PD) and Home Hemodialysis (HHHD) rates are lower than desired. Two areas of opportunity are 1) keeping PD patients healthy so they can remain on PD longer and 2) transitioning PD patients to HHHD when appropriate. To identify patients at risk of leaving PD in the short- (1-3 month) and long-term (3-6 month) timeframes, two machine learning (ML) models were developed. Along with risk scores, these models identify the factors driving increased risk to aid in prolonging time on PD while also allowing adequate notice to prepare for permanent access placement and HHHD education.

**Methods:** Data were extracted for PD patients (n=53022) from 2016-2019; patients contributed one set of observations for each month they were on PD (n=823892 patient months). PD failure was defined as the first disconnection from PD lasting over 30 days, and was coded as ‘1’ if the patient changed modality in the next 1-3 or 3-6 months for the short- and long-term models, respectively. All other observations were coded as ‘0,’ including censored events such as transplantation, loss to follow-up, or death. Two XGBoost ML models were trained using 80% of the dataset, with 20% used for evaluating model performance using 237 variables, derived from laboratory measurements, infection and hospitalization history, and other relevant clinical parameters.

**Results:** Evaluation of model performance on withheld data showed an area under the curve of 0.75 and 0.67 for the short- and long-term models, respectively. Patients were classified as High, Medium, or Low risk for each of their short- and long-term predictions. In the short-term model, one group of patients was identified with high risk of dropping in the first 3 months, a rate almost 5 times higher than average and 12 times higher than low risk patients. For long-term predictions, 14% of high risk patients dropped in the next 3-6 months, 6% of medium risk, and 2% of low risk.

**Conclusion:** The two ML models showed good discrimination between patient risk categories for both short- and long-term timeframes. Further work is underway to gauge the clinical utility of these tools, these tools offer the potential to improve care of “failing” PD patients, reduce morbidity of transitions, and increase optimal starts with dialysis technique failure.

**Technique Failure in the Dominican Republic National Peritoneal Dialysis Program**

Erwin I. Campos,1,2 Miguel A. Cuevas Budhart,1 Elianny S. Polanco,1 Jhanna H. Collado,1 Mercedes Aquey,1 Janny Gusman Chavez,4 Alfonso Ramos,1 Macrotech1 Macrotech, Santo Domingo, Dominican Republic; 2Hospital Salvador B. Gautier, Santo Domingo, Dominican Republic; 3Baxter Mexico, Ciudad de México, Mexico; 4Baxter Colombia, Bogotá, Colombia; Instituto Mexicano del Seguro Social, Ciudad de México, Mexico.

**Background:** Technique failure is a critical concern in peritoneal dialysis (PD), and it’s associated with significant risk of patient lost. Technique failure is defined as transfer to HD 30 days after initiation of therapy or death within 30 days of transfer to HD.

**Methods:** This is a retrospective multicenter observational cohort study of incident Peritoneal Dialysis patients conducted between January 1st 2016 to December 31st 2020. Competing risk events were death and kidney transplantation, and patients were censored for recovery of kidney function, withdrawal or suspension of the therapy, and loss of a caregiver. Disease characteristics and baseline demographics were included. Data are expressed as mean ± standard deviation for continuous variables and as frequency counts and percentages for categorical variables. Incidence rates were performed for transfer to HD and finally, logistic regression analysis between the inferential type variables to determine the risk between having a history of diabetes mellitus and the variables of death and transfer to HD were calculated using an Odds Ratio analysis with 95% confidence intervals for parameters B.

**Results:** A total of 2326 patients were included, 59% men; the mean age was 57 ± 16 years, 53% had a diagnosis of Diabetes Mellitus (DM) and 65% had a basic educational level. 151 patients were censored (11%). Risk events were 1096 of which death accounts for 1084 (74%) and transplantation (0.8%). At the end of the first year the cumulative incidence risk to HD transfer was 1%, the second year 4%, the third year 6%, the fourth 11%, and the fifth 16%. Based on the regression analysis between the variables of interest and the patients with a history of DM, there is a higher risk of death (p<0.001; OR: 2.123; CI 95% 1.781-2.532), however, for transfer to HD, no statistical significance was found (p=0.39; OR 1.14; CI 95% 0.838-1.564). The most frequent reason for technique failure was psychosocial and medical conditions 44%, followed by catheter malfunction 30%, peritonitis 13% and ultrafiltration failure 13%.

**Conclusions:** The technique failure rate is similar to the reported in RTS Colombian PD Program, but being higher than the mean of Latin American countries reports. Still, improvement needs to be done in the catheter implant technique and mortality rates.

**PO0973**

**Nurse-Based Educational Interventions in Patients with Peritoneal Dialysis: A Systematic Review and Meta-Analysis**

Tanawin Nop sopon,1,3 Piyawat Kantagowit,1 Chitsanucha Chumsri,1 Krit Pongpirul,1 Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee 2Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 3Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; 4Harvard University T H Chan School of Public Health, Boston, MA.

**Background:** Peritoneal dialysis (PD) is a major renal replacement therapy modality for patients with end-stage renal disease (ESRD) worldwide. As poor patient self-care could lead to serious complications, including peritonitis, exit-site infection, technique failure, and death; several nurse-based educational interventions have been introduced. However, these interventions varied and have been supported by small-scale studies so the effectiveness of nurse-based educational interventions on clinical outcomes of PD patients have been inconclusive.

**Methods:** We performed a systematic search using PubMed, Embase, and CENTRAL. Selection criteria included Randomized Controlled Trials (RCTs) relevant to nurse-based education interventions in ESRD patients with PD in the English language up to February 2020. The meta-analyses were conducted using a random-effects model to evaluate the summary outcomes of peritonitis, PD-related infection, mortality, transfer to hemodialysis, and quality of life (QOL).

**Results:** Of 7,240 potential studies, 61 theme-related abstracts were selected for further full-text articles screening against eligibility criteria. Ten studies (1,404 PD patients in seven countries) were included in the systematic review. Eight studies (1,363 PD patients in five countries) were included in the meta-analysis. Sleep QOL in the intervention group was significantly higher than control (mean difference 12.76, 95% CI 5.26–20.27). There was no difference between intervention and control groups on peritonitis, PD-related infection, transfer to hemodialysis, and overall QOL.

**Conclusions:** Despite increased focus on starting and keeping dialysis patients on PD, Peritoneal Dialysis catheters are felt to require a healing time prior to initial use. Concern for increased risk of leak, has led many to use a supine intermittent low volume exchanges (> 72 hours) without regard to maintaining a supine position. Higher volume dialysis with earlier initiation should allow for better PD clearances when clinically warranted and more salt and water removal compared to supine intermittent low volume exchanges. Two areas of opportunity are 1) keeping PD patients healthy so they can remain on PD longer and 2) transitioning PD patients to HHHD when appropriate. To determine the risk between having a history of diabetes mellitus and the variables of death and transfer to HD were calculated using an Odds Ratio analysis with 95% confidence intervals for parameters B.

**Immediate Start PD: A Single-Center Experience**

Harold E. Giles,1 Thomas H. Watson,1 Michael A. Kraus,1 Dinesh K. Chatoth,2 Melissa H. Hamel,3 Nephrology Associates, Birmingham, AL; 2Fresenius Kidney Care, Waltham, MA.

**Background:** Peritoneal Dialysis catheters are felt to require a healing time prior to initial use. Concern for increased risk of leak, has led many to use a supine intermittent low volume exchanges (<1000mL) initially for earlier start peritoneal dialysis. We undertook a study to prospectively monitor and track peritoneal dialysis complications when catheter use was early (prior to 14 days post placement) and the nephrologist chose to start with higher volume dialysate (>1000mL) without regard to maintaining a supine position. Higher volume dialysis with earlier initiation should allow for better PD clearances when clinically warranted and more salt and water removal compared to supine intermittent low volume exchanges.

**Methods:** In this single center prospective observational study, peritoneal dialysis catheters were placed laparoscopically ensuring tunneling through the abdominal rectus muscle with the deep cuff placed just within or below the rectus abdominal muscle. Purse strings sutures were only used at the surgeons’ discretion. Surgeons did undergo consistent supervision from two experienced surgeons prior to the study. Patients were included in the study if the nephrologist felt early start dialysis was indicated. Prescriptions were at the discretion of the nephrologist.

**Results:** Since January 2021, 23 PD catheters have been placed using this technique with only one adverse event: 8 patients (35%) initiated PD 24 – 72 hours post placement and 15 patients (65%) started dialysis between 73 hours and 2 weeks post catheter placement. All patients first exchanges were 1000 mL, and volumes were increased rapidly at the discretion of the nephrologist as patient condition warranted. In these 23 patients, 1 patient experienced a perforation and leak, which resolved with rest. That patient was in the > 72 hour group. No other catheter complications were noted.
Converting ESKD Patients on Peritoneal Dialysis to Hemodialysis Post Cardiac Surgery: A Necessity or Comfort
Elias Basal,1 Milad Matta,2 Aimen Liaqat,1 Adam Fawaz,3 Georges Nakhoul,1,2 Joost C. Taliercio,1,2 Juan C. Calle,2,3 Serge C. Harb,1 Haytham Elgharably,1 Susana Arrigain,1 Jesse D. Schold,2 Remy Daou,1 Ali Mehdi,2,3 Cleveland Clinic, Ohio; 2Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH; 3Université Saint-Joseph, Beirut, Lebanon.

Background: End-stage kidney disease (ESKD) patients on peritoneal dialysis (PD) undergoing cardiac surgery are sometimes converted to hemodialysis (HD) post-surgery. The reasons for this conversion are not well defined in the literature. We sought to examine the reasons cited for converting PD patients to HD post operatively after undergoing major cardiac surgery.

Methods: We examined ESKD patients on PD undergoing cardiac surgery from 2009-2019 using an electronic health records (EHR)-based Cardio-Thoracic Surgery (CTS) registry at the Cleveland Clinic. We identified PD patients who were converted to HD perioperatively. We reviewed the EHR to identify the main causes for conversion.

Results: 62 ESKD patients on PD undergoing major cardiac surgery were identified. 16 patients, representing more than a quarter, were converted to HD post operatively. Out of those converted, 31.25% were converted for absolute indications (18.75% for PD catheter malfunction, 25% for gait difficulties, 25% for concern of pericardio-peritoneal communication). 68.75% were converted for less clear and relative indications (25% based on clinician preference, 43.75% for hemodynamic instability or requiring vasopressors). Results are displayed in (Table 1).

Conclusions: A small percentage of PD patients are converted to HD for absolute indications. Most patients are converted based on relative indications including lack of familiarity with PD and hemodynamic instability. As the number of ESKD patients on PD is expected to increase, a better understanding of the outcomes of PD patients post cardiac surgery is needed. In addition, more education is urgently needed to increase the comfort of practitioners managing PD patients in special situations that might be amenable to prescription alterations without premature transition to hemodialysis.

PO0975

Peritoneal Dialysis and QoL
Arrigain,1 Jesse Taliercio,2,1 Gloria Perez-Navarro,3 Rafael Valdez-Ortiz,1 Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Introduction: For patients on Peritoneal Dialysis (PD), it is reasonable to expect a correlation between treatment efficacy and QoL. Residual kidney function, patient age, residual urea and creatinine levels, albumin were evaluated to assess their importance in determining QoL.

Methods: 91 patients on IAPD were included in this study. QoL was assessed using the EQ-5D-5L found to correlate with residual uresis (r -0.052, p 0.612). Questionnaires: Peritoneal Dialysis PO0975 was defined as less than 16hrs of treatment per day. Clinical, biochemical data were collected. The renewed interest in home dialysis requires a translational uremic large animal model to evaluate innovations in peritoneal dialysis. Ideally, toxin plasma levels should be comparable to those in dialysis patients, without requiring maintenance dialysis for survival. To this end, we developed a pig model with stable moderate chronic kidney disease.

Methods: CKD was induced in five female pigs by bilateral subtotal renal artery embolization aiming for embolization of ~85-90% of total kidney tissue. Temporary aggravation of uremia was induced with gentamicin (10 mg/kg twice daily for 7 days). We hypothesized this approach would lead to stable CKD without the need for maintenance dialysis. Peritoneal transport was assessed with a standard peritoneal permeability assessment.

Results: After embolization, urea and creatinine levels increased from 1.6±0.2 to 7.5±1.0 mM and 103±12 to 338±20 µM, respectively, followed by stabilization within 2 weeks to 2.5±1.0 mM and 174±25 µM, respectively. GFR (iohexol clearance) decreased from 49±7 mL/min to 28±5 mL/min. Gentamicin induced temporary acute-on-chronic kidney injury with peak urea and creatinine concentrations of 17±6±1 mM and 932±504 µM, respectively (Figure 1), while potassium (range 4.1-4.7 mM) and phosphate (range 2.3-2.7 mM) remained stable. Peak indoxyl sulfate and hippuric acid levels were 10.5 ± 0.85 mg/L and 75.3 ± 81.5 mg/L, respectively. Peritoneal dialysis, although complicated by peritonitis, could be successfully applied. Peritoneal transport assessment showed a low transport status (D/P creatinine (4h): 0.45±0.12) with an MTAC of 9.6±3.0, 4.6±2.5, 3.4±2.2 mL/min for urea, creatinine, and phosphate respectively.

Conclusions: We have established a pig model with stable moderate CKD without the need for maintenance dialysis. Temporary-on-demand acute-on-chronic kidney injury, resulting in uremic solute levels representative for ESKD, allows evaluation of novel dialysis methods.

Figure 1. Urea (left) and creatinine (right) plasma levels after administration of gentamicin (day 0). Mean ± SD, n=10 administrations in n=5 pigs.

PO0976

Effect of Low-Dose PD in Elderly Population on Protein Energy Wasting, Functionality, and Quality of Life
Gloria G. García Villalobos, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Elder population currently involves 55% of those who initiate dialysis. Some of them, including fungal peritonitis, requires PD catheter removal which highlights the importance of prompt diagnosis. IAPD in this elder population does not mean suboptimal dialysis: there are found favorable results in regard to biochemical parameters; FS and Qol, scores maintained despite the dialysis vintage. Of notice the group of 75yrs and older are more likely to be affected in a negative way by prescription of dialysis.

Conclusions: PO0976

Recurrent Abdominal Pain in a Patient on Peritoneal Dialysis
Sandipan Shringi, Sri Vibhavari Guntupalli, Kristin M. Corapi. Saint Vincent Hospital, Worcester, MA.

Introduction: Abdominal pain can have many differentials in patients on peritoneal dialysis (PD). Some of them, including fungal peritonitis, requires PD catheter removal and a change in dialysis modalities. Here we present a case of recurrent abdominal pain in a patient on peritoneal dialysis which highlights the importance of prompt diagnosis.

Key: - TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 55-year-old female with history of ESKD due to diabetic kidney disease, CAD s/p CABG, and hypertension presented with a 1 day history of cloudy effluent. She had no prior peritonitis episodes. Vital signs were stable and exam was notable for a soft non-tender abdomen and clean and dry exit site without discharge or granulation tissue. Effluent was hazy in appearance. Administration of empiric vancomycin and gentamicin was initiated, varying in clearing of effluent within 24 hours. Effluent leukocyte count was 204 cells/µl with 58% neutrophils. Intrapertitoneal vancomycin was continued for 3 days due to intermittent low troughs. Further history revealed intermittent mask use while performing exchanges. After completion of treatment, repeat cell count and culture were repeated 1 month later during evaluation of abdominal pain eventually found to be due to constipation. Leukocyte count was 6 cells/µl, but culture again grew *Micrococcus sp*. After culture was repeated once more and remained persistently positive, repeat treatment to eradicate was attempted with 2 more weeks of treatment, but culture remained positive. Eventually the catheter was removed due to a change in living situation. After 5 months of hemodialysis, peritoneal catheter was removed. She had been having intermittent abdominal pain with PD effluent sometimes showing high white count for which she got multiple antibiotic courses for either presumed or culture positive bacterial peritonitis. She had also grown positive fungus culture about 18 months ago with Candida albicans and Streptococcus which went unnoticed.

Discussion: Fungal peritonitis can be catastrophic for patients on PD. Treatment involves prompt catheter removal and systemic antifungal treatment. Given its dire consequences, prevention is paramount. The ISPD recommends using anti-fungal prophylaxis when PD patients receive antibiotic courses. Risk factors include previous bacterial peritonitis and antibiotic use. This case demonstrates the need to follow cultures as fungal growth is slow and can take weeks. It is important to have a high index of suspicion for a fungal organism when cultures are negative. This patient received antibiotics on several occasions but only developed fungal peritonitis on 2 occasions which raises concerns on antifungal prophylaxis. Further studies are indicated to determine number needed to treat to decide on need for antifungal prophylaxis.

PO0979
Micrococcus Peritonitis Complicating Peritoneal Dialysis
Martin L. Li,1 Ankur Shah,2,1 'Brown University Warren Alpert Medical School, Providence, RI; 2Rhode Island Hospital, Providence, RI.

Introduction: Peritonitis is one of the most common and consequential complications of peritoneal dialysis. *Micrococcus sp* are catalase-positive, coagulase-negative, gram-positive cocci that are increasingly recognized as opportunistic pathogens in patients with immunocompromise or indwelling catheters. These bacteria have been rarely implicated as causative in peritonitis. We present a case of peritonitis due to *Micrococcus sp* and review the pertinent literature.

Case Description: A 78-year-old man with ESKD due to diabetic nephropathy, transitioned five weeks prior from HD to PD, presented with newly cloudy PD fluid. His past medical history included hypertension, coronary artery disease, and monoclonal gammopathy of undetermined significance. He reported a newly cloudy white initial drain on PD for 5 days. Peritoneal fluid was cloudy (figure 1a) with 101 white blood cells (4% neutrophils); gram stain and culture were negative. Triglycerides were 96 and 62 mg/dL in the PD fluid and serum, respectively. Etiologic work-up was negative for malignancy, pancreatitis, cirtosis, trauma and tuberculosis. Cloudy nature of the PD fluid resolved within a day and the cloudy fluid persisted for the following week. After disease progression, the cloudy fluid reduced further.

Discussion: This patient had the onset of cloudy PD fluid 5 weeks after initiating PD, which resolved with cessation and reinstitution of his long-term nifedipine. The mechanism of calcium channel blockers (CCB) related cloudy ascites is not well established. Some have suggested it may be related to the lipophilic nature of CCB. Patients on PD with higher peritoneal membrane transport may be at higher risk. Genetic factors may predispose to this phenomenon. Nephrologists should be aware of this rare complication of CCB use in PD patients. More research is needed to better understand the underlying pathophysiology of this rare condition.

PO0981
Chylous Peritoneal Fluid in a Patient on Peritoneal Dialysis Taking Nifedipine
Lauren E. Macarieg, Dena E. Rifkin, Tyler Woodell, O. Alison Potok. University of California San Diego, La Jolla, CA.

Introduction: Chylous fluid in peritoneal dialysis (PD) patients may appear with lymphatic system disruption. This can be due to lymphatic obstruction, exudation through vessels, or via a lymphoperitoneal fistula.

Case Description: A 78-year-old man with ESKD due to diabetic nephropathy, transitioned five weeks prior from HD to PD, presented with newly cloudy PD fluid. His past medical history included hypertension, coronary artery disease, and monoclonal gammopathy of undetermined significance. He reported a newly cloudy white initial drain on PD for 5 days. Peritoneal fluid was cloudy (figure 1a) with 101 white blood cells (4% neutrophils); gram stain and culture were negative. Triglycerides were 96 and 62 mg/dL in the PD fluid and serum, respectively. Etiologic work-up was negative for malignancy, pancreatitis, cirrhosis, trauma and tuberculosis. Cloudy nature of the PD fluid resolved within a day and the cloudy fluid persisted for the following week. After disease progression, the cloudy fluid reduced further.

Discussion: This patient had the onset of cloudy PD fluid 5 weeks after initiating PD, which resolved with cessation and reinstitution of his long-term nifedipine. The mechanism of calcium channel blockers (CCB) related cloudy ascites is not well established. Some have suggested it may be related to the lipophilic nature of CCB. Patients on PD with higher peritoneal membrane transport may be at higher risk. Genetic factors may predispose to this phenomenon. Nephrologists should be aware of this rare complication of CCB use in PD patients. More research is needed to better understand the underlying pathophysiology of this rare condition.

PO0980
Cutaneous Oxalosis in a Patient on Peritoneal Dialysis
Stephanie Torres Rodriguez, Hunter Pyle, Audrey Rutherford, Arturo R. Dominguez, Shani Shastri. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Oxalosis is the systemic deposition of calcium oxalate in multiple tissues and can be of primary or secondary etiology. Skin manifestations due to secondary hyperoxaluria (SH) attributable to renal insufficiency are rare. We present a case of cutaneous oxalosis in a patient with end stage renal disease (ESRD) receiving peritoneal dialysis (PD).

Case Description: A 45-year-old female with ESRD due to lupus nephritis (LN) on PD for 15 years presented with hypertensive encephalopathy. Dermatological evaluation revealed pseudoeutectic hyperpigmented patches overlying firm, non-tender, subcutaneous nodules and plaques on bilateral lower extremities (Figure 1) and upper arms and firm nodules overlying the joints of her hands (Figure 2). With history of lupus, cutaneous findings were concerning for dystrophic calcinosis cutis. Skin biopsy showed radially arranged yellow-brown rhomboid crystals in the subcutis and deep dermis surrounded by histiocytes consistent with cutaneous oxalosis (Figure 3). Additional history revealed daily intake of Vitamin C 1g for past year and no prior gastrointestinal surgeries or chronic diarrhea. Non-obstructive bilateral nephrolithiasis were seen on imaging in 2020 but absent previously.

Discussion: Absence of early-age nephrolithiasis, negative family history & renal biopsy findings are inconsistent with primary hyperoxaluria (PH). SH is a result of excessive oxalate accumulation from increased intake, increased reabsorption due to small bowel disease, or decreased excretion in renal failure (retention oxalosis). Although dialysis patients may have high serum oxalate, clinical calcifications are rare. We speculate vitamin C supplementation and ESRD status contributed to the production of these deposits in our patient. Ascorbic acid is metabolized to oxalate; in long term dialysis patients doses of 500 mg daily may raise plasma oxalate by 50% to 100%. Management includes lowering serum calcium and oxalate levels by eliminating Vitamin C supplements or reducing dose < 100 mg daily, limiting dietary oxalate, increasing dialysis clearance and lowering dialysate calcium concentration if needed.
PO0982

Severe Bleeding and Deep Inferior Epigastric Pseudoaneurysm After PD Catheter Removal
Nicola Matthews,1 Tamara Glavinovic,2 Bourne L. Augustine.3 St. Michael’s Hospital, Toronto, ON, Canada; 3Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Introduction: In this case, the removal of a PD catheter with deep cuff calcification results in pseudoaneurysm formation with hemorrhage and hospitalization.

Case Description: A 24-year-old woman with end-stage kidney disease was switched from PD to HD due to worsening uremia and PD catheter removal was organized. At the time of catheter removal heavy calcification around the deep Dacron cuff was seen, creating a pseudoaneurysm where urgent angiographic embolization to stop the bleeding was needed (Fig. 1). Intimate relationship between DIEP vessel and Dacron cuff was felt to be secondary to heavy calcification of these structures that developed during her time on PD (Table 1). The patient required an urgent transfusion and was admitted to hospital for monitoring. She was discharged the following day in stable condition.

Discussion: This is an important learning case in PD catheter removal and highlights the following: - Poorly controlled bone mineral disease may lead to excessive heavy calcification of the deep Dacron cuff and DIEP vessels. - When heavy calcification of the PD cuff is seen, catheter removal should be done in settings equipped with interventional radiology support in the event of complication.

Calcium-phosphate balance while on PD

Enter Cell Value

A 24-year-old woman with end-stage kidney disease was switched to hemodialysis. She was admitted to hospital for monitoring. She was discharged the following day in stable condition.

Discussion: This is an important learning case in PD catheter removal and highlights the following: - Poorly controlled bone mineral disease may lead to excessive heavy calcification of the deep Dacron cuff and DIEP vessels. - When heavy calcification of the PD cuff is seen, catheter removal should be done in settings equipped with interventional radiology support in the event of complication.

A Case of Abdominal Wall Abscess Caused by Aeromonas hydrophila in Prior Peritoneal Catheter Site in an Immunocompromised Patient
Post Kidney Transplant
Angelica P. Trilleras Gomez,1 Maya Antony,2,3 Ahmed A. Waheed,2,3 Holy Cross Hospital, Ft Lauderdale, FL; 1University of Miami School of Medicine, Miami, FL; 3Holy Cross Hospital Department of Nephrology, Ft Lauderdale, FL.

Introduction: Aeromonas hydrophila is a gram-negative rod-shaped bacterium found in aquatic ecosystems; it has been identified as the causative organism of different opportunistic infections in the immunocompromised and there is growing evidence of infection in the immunocompetent. This pathogen has been implicated in acute gastroenteritis, soft tissue infections, meningitis, peritonitis and sepsis among others.

Case Description: We report a case of a 56 year old woman with end stage kidney disease previously on peritoneal dialysis (PD) with subsequent live donor kidney transplant on immunosuppression, who presented with right lower quadrant abdominal cellulitis and deep abscess around the catheter site. Post transplant, her PD catheter was removed, however, the catheter site never healed completely. Although she did have multiple superficial skin infections in the past, those resolved with antibiotics. But this specific cellulitis, did not improve despite multiple antibiotic regimens, and further imaging studies revealed she had developed an abscess. The abscess was managed by surgical incision and drainage with debridement of the skin, subcutaneous tissue, fascia, and muscles around the whole catheter tract. Aeromonas hydrophila was found as the causative organism.

Discussion: To our knowledge, this is the first case of an A. hydrophila abscess associated with a peritoneal dialysis catheter. Firm association between aeromonads and the use of intravenous indwelling devices has already been demonstrated. We hypothesize that her deep seeded infection could be associated with the intrinsic ability of A. hydrophila to form biofilms upon detecting a suitable surface, making them more virulent. The formation of biofilm has been associated with exponential growth as the source of pathogenicity of this bacteria in pisciculture studies. This characteristic could be one of the factors contributing to reported cases of peritonitis and intravenous hemosidalization catheters by A. hydrophila. Further elucidation of A. hydrophila virulence factors in humans can provide insight on prevention of PD catheter associated infections by A. hydrophila.

PO0984

Mesenchymal Stem Cell Exosomes Protect Mouse Peritoneal Injury Induced by Human Peritonitis Dialysis Effluent
Fang Yu, Kehong Chen, Jia Chen, Yani He. Army Medical University, Daping Hospital, Department of Nephrology, Chongqing, China.

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but there are few effective therapies for it. The purpose of this study was to investigate the protective effect of exosomes secreted by mouse bone marrow mesenchymal stem cells (MSC) on peritoneal injury and to reveal the mechanism.

Methods: Forty-two male C57BL/6 mice were randomly divided into a normal group, a control group (2.5% glucose dialysate), a peritonitis-effluent (Peritoneal infection and dialysate group) and a peritonitis-effluent+exosome group, and a high glucose dialysate+exosome group. The mouse model of peritoneal injury was constructed by intraperitoneal injection of human peritonitis dialysis effluent continuously for 42 days. The mice in the exosome treatment group received intraperitoneal injection of MSC-exosomes twice. The level of peritoneal structural and functional damage was detected. The effect of MSC-exosomes was validated in vitro.

Results: Peritoneal transport and structure was significantly impaired in the peritonitis-effluent group and the high glucose dialysate group after 42 days, and was significantly higher than control group. The results suggested that human peritonitis dialysis effluent could be used to construct a mouse model of peritoneal injury. Masson staining showed that fibrosis degree of exosome treatment group was significantly less than peritonitis-effluent group. Immunohistochemical analysis showed that expressions of mesothelial markers E-cadherin and ZO-1, neutrophil granulocytes (MOPO) and macrophages (F4/80), and fibrosis markers (collagen La-SMA) in exosome treatment group were significantly lower than peritonitis-effluent group. Peritoneal ultrafiltration function of exosome treatment group was significantly improved than peritonitis-effluent group. In vitro experiments showed that exosomes could down-regulate the secretion of IL-1β, IL-6 and TGF-β1 by peritoneal mesothelial cells stimulated by high glucose dialysate, maintain expression of mesothelial cell marker (E-cadherin), and inhibit mesenchymal marker (a-SMA), suggesting that exosomes could inhibit the transdifferentiation of peritoneal mesenchymal cell-mesenchymal cells (MMT).

Conclusions: MSC-exosomes can alleviate peritoneal fibrosis by inhibiting peritoneal mesothelial cell-mesenchymal cell transdifferentiation.
PO0985

Dual Therapy with JAK1/2 Inhibitor and Losartan Attenuates Dialyse-Induced Angiogenesis in Polycystic Rats

Pei Zhang,1 Kana N. Miyata,2 Madisyn Mahoney,2 Janine A. La page,2 Cynthia C. Nast,1 Sharon G. Adler,1 Tiane Dai,1 Department of Nephrology, the First Affiliated Hospital of Anhui Medical University, Hefei, China; The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA; Cedars Sinai Medical Center, Los Angeles, CA.

Background: Long term peritoneal dialysis (PD) is limited by reduced efficacy over time. Early peritoneal membrane (PM) injury is characterized by inflammation which progresses to hypervascularity and fibrosis. JAK-STAT signaling mediates inflammatory pathways, including angiotensin signaling. Our previous study showed dual therapy with JAK1/2 inhibitor (JAK1/2i) and an ARB maintains PM structure and function in rats with polycystic kidneys (PCK) chronically infused with 4.25% Dianzel x 16 wks. By using VEGF-R2 as an endothelial marker, we further investigated if this dual therapy can attenuate chronic dialysate infusion induced hypervascularity in this rat model.

Methods: PCK rats were used. Dialysate infusions were performed BID via an implanted subcutaneous port in the neck tunneled to the intraperitoneal cavity. The following treatments were administered: (1) No surgery/infusions; (2) 4.25% Dianzel; (3) 4.25% Dianzel + JAK1/2i (5mg/kg BID); (4) 4.25% Dianzel + Losartan (5mg/kg BID); and (5) 4.25% Dianzel + Losartan + JAK1/2i (5mg/kg BID each). Partial peritoneal was used for immunohistochemical staining of VEGF-R2, which was digitally quantified by using Qu Path program. Data were analyzed by one-way ANOVA followed by Tukey test. Results are mean ± SEM.

Results: VEGF-R2 staining was significantly elevated after 16 weeks of infusion of 4.25% Dianzel alone. JAK1/2i significantly reduced VEGF-R2 expression; losartan tended to reduce VEGF-R2, but this did not reach significance. Dual therapy with JAK1/2i and losartan resulted in the greatest reduction of VEGF-R2.

Conclusions: Long-term JAK1/2i, or JAK1/2i plus losartan intraperitoneal treatment reduces angiogenesis. Angiotensin inhibition is advocated to maintain residual renal function, by adding JAK1/2i, the combination also protects peritoneal structure/function by reducing angiogenesis.

PO0986

The Effect of Far-Infrared Therapy on the Peritoneal Expression of Glucose Degradation Products in Diabetic Patients on Peritoneal Dialysis

Chih-Ching Lin, Chih-Yuan Niu. Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Peritoneal dialysis (PD) is a treatment modality for end-stage renal disease (ESRD) patients. Dextrose is a common osmotic agent used in PD solutions and its absorption may exacerbate diabetes mellitus. PD solutions also contain glucose degradation products (GDPs) that may lead to encapsulating peritoneal sclerosis (EPS). A previous study showed that far-infrared (FIR) therapy improved a patient’s gastrointestinal symptoms due to EPS. Due to limited literature, this study aims to investigate dialysate GDPs and peritoneal function in diabetic patients on PD.

Methods: A prospective analysis conducted in a single center. The participants were recruited from the peritoneal dialysis outpatient department from November 25, 2016 to September 5, 2018. We included the patients who met the following criteria: (1) ESRD patients aged 20-90 years without receiving FIR therapy within 12 months; (2) receiving continuous ambulatory peritoneal dialysis or automated peritoneal dialysis; (3) no history of peritonitis, cerebrovascular accident, myocardial infarction, or receiving any cardiovascular intervention in the past 3 months. Patients were allocated to two groups based on their underlying DM history. Both groups of PD patients received FIR therapy for 6 months. We collected the last daily bag of peritoneal dialysate and measured the dialysate concentration of GDPs and clinical data in PD patients pre- and post-FIR therapy.

Results: Thirty-one PD patients were enrolled and underwent 40 min of FIR therapy twice daily for six months. We demonstrated the effect of FIR therapy on the following: (1) decrease of methylglyoxal (p = 0.02), furfural (p = 0.05), and 5-hydroxymethylfurfural (p = 0.03), (2) increase of D/D0 glucose ratio (p = 0.03), and (3) decrease of potassium levels (p = 0.008) in both DM and non-DM patients, as well as (4) maintenance and increase of peritoneal K/ V in DM and non-DM patients, respectively (p = 0.03). FIR therapy is a non-invasive intervention that can decrease dialysate GDPs in PD patients by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

Conclusions: In conclusion, our study demonstrated that FIR therapy can decrease patients’ dialysate GDPs by improving peritoneal transport rate and solute removal clearance, while also maintaining dialysis adequacy.

PO0987

Cumulative Dialysate Glucose Exposure Is a Risk Factor for Peritoneal Sclerosis in Pediatric Peritoneal Dialysis Patients Using Neutral-PH Fluids

Yoko Shirai,1 Kenichiro Miura,1 Taro Ando,1 Atsutoshi Shiratori,1 Naoto Kaneko,1 Kiyonobu Ishizuka,1 Sekiko Taneda,2 Daishi Hirano,2 Yasuyuki Yamauchi,3 Kazuhiro Honda,1 Motoshi Hattori,1 Department of Pediatric Nephrology, Tokyo Women’s Medical University, Tokyo, Japan; 2Department of Pathology, Tokyo Women’s Medical University, Tokyo, Japan; 3Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; Yamaguchi Pathology Laboratory, Chiba, Japan; Department of Anatomy, Showa University School of Medicine, Tokyo, Japan.

Background: The benefits of neutral-pH fluids for preventing peritoneal dialysis (PD)-related peritoneal sclerosis have been established, however, advanced peritoneal sclerosis still has been described in pediatric PD patients using neutral-pH fluids (Kidney Int 2018). The factors associated with peritoneal pathological changes after long-term use of neutral-pH fluids have not been elucidated.

Methods: Pediatric PD patients using only conventional acidic fluids (conventional group) and those using only neutral-pH fluids (neutral-pH group, n=33) for more than one year were analyzed. Propensity score matching was performed to compare the peritoneal pathological changes between groups. Clinical risk factors including PD duration and cumulative dialysate glucose exposure for peritoneal pathological changes in the neutral-pH group were analyzed using generalized linear model. Furthermore, immunohistochemistry studies were performed on vascular endothelial growth factor-α (VEGF-α), cytookeratin; an epithelial marker, and α-smooth muscle actin (α-SMA); a myofibroblastic marker of epithelial-mesenchymal transition (EMT).

Conclusions: The neutral-pH fluids showed less deteriorations of the peritoneal membrane than acidic fluids except for increased angiogenesis. Cumulative dialysate glucose exposure was an independent risk factor for increased thickness of the submesothelial compact zone (OR, 1; 95%CI, 1.001-1.007) and submesothelial microvesSEL density (OR, 1; 95%CI, 1.003-1.005).

CVD-related mortality risk and tendency towards reduced technique survival when analyzed with adjusted competing-risk regression models. Funding: Commercial Support - Baxter Renal Care Services; Baxter Healthcare Corporation.
PO0989
Multifrequency Bioimpedance Is a Useful Adjunct to Control Fluid Overload in PD Patients
Szu-Yuan Li, Chiiao-Lin Chuang, Jinn-Yang Chen. Taipei Veterans General Hospital PD team Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Fluid overload is a well recognized phenomenon in many peritoneal dialysis (PD) patients, but a balance between reduction of dry weight and preservation of residual renal function (RRF) is mandatory. We hypothesize that, to achieve an ideal dry weight, adjustment by multifrequency bioimpedance (MF-BIA) guide offers less adverse effect on residual renal function than that by clinical judgment alone.

Methods: The hydration status of various body compartments were measured using a MF-BIA device (Inbody 720, Biospace). The normalized hydration score was defined as extracellular water (ECW)/total body water (TBW). All patients were evaluated monthly for 6 months. The dry weight of study group was adjusted according to MF-BIA to avoid dehydration, and the dry weight of control group was determined clinically. Ambulatory blood pressure, anti-hypertension medication dosage, serum biochemical parameters, and RRF were recorded monthly. IL-6 and hs-CRP will be checked before and after the study.

Results: 93 stable PD patients (48 in study and 45 in control group) completed the study. ECW/TBW ratio was higher in PD patients than sex- and age- matched healthy subjects. (Figure 1). In PD patient, the ratio of ECW/TBW was positive correlated to age (r = 0.334), peritoneal D/P ratio (r = 0.318), systolic BP (r = 0.526) and negative correlated to urine volume (r = -0.526), serum albumin (r = -0.658). After 6 months intervention, study group decreased 1.2 kg and control group gained 0.2 kg. The study group had a better systolic and diastolic BP control and a higher serum albumin (3.75 ± 0.61 vs 3.48 ± 0.68 g/dl, p = 0.047). The RRF has no difference between two groups.

Conclusions: Our results showed that correction of fluid overload would improve blood pressure control. Being an objective tool to assess hydration status of various body compartments, MF-BIA is a useful adjunct to correct fluid overload without the loss of RRF in our short-term study.

PO0990
Associations Between Loop Diuretic Use and Outcomes Among Patients Treated with Peritoneal Dialysis
Jiacong Lu,1 Dena E. Cohen,1 Carey Colson,1 Steven M. Brunelli,1 Francesca Tentori,1 Martin J. Schreiber,1 Davita Clinical Research, Minneapolis, MN; 2Davita Inc, Denver, CO.

Background: Among hemodialysis patients, an active loop diuretic prescription at the time of dialysis initiation is associated with a lower hospitalization rate and other favorable outcomes, compared to no prescription. Whether this finding extends to patients initiating peritoneal dialysis (PD) is not known.

Methods: Data used for this retrospective study comprised electronic health records and US Renal Data System claims data merged through direct linkage. Included patients initiated PD at a large dialysis organization between 01 Jan 2006 and 30 June 2014, were nonoliguric at dialysis start (24-hour urine collection >200 cc), and had Medicare insurance. Exposure was determined on the basis of an active, filled supply for a loop diuretic spanning day 90 of PD. Outcomes were considered from day 91 of PD through the time of dialysis initiation is associated with a lower hospitalization rate and other favorable outcomes, compared to no prescription. Whether this finding extends to patients initiating peritoneal dialysis (PD) is not known.

Results: Among patients initiating PD with a loop diuretic prescription (N=792), the hospitalization rate during follow-up was 1.77 admissions/patient-year (pt-yr), compared to 1.75 pt-yr for those without (N=1363), corresponding to an adjusted incidence rate ratio (aIRR) of 1.05 (95% confidence interval [CI] 0.97-1.15). Mortality was likewise comparable between groups, with crude rates of 0.21 and 0.18 deaths/pt-yr, respectively (aIRR 1.05, 95% CI 0.82-1.35). No substantial differences were observed between exposure groups with respect to serum potassium, renal K/V, or time to transition to hemodialysis.

Conclusions: Among patients initiating PD, no beneficial associations were observed between loop diuretic use and any of the outcomes examined.
Identifying Peritoneal Dialysis (PD)-Associated Peritonitis Using Medicare Claims

Eric W. Young, Junhui Zhao, Ronald L. Pisoni, Keith McCullough, Beth M. Piraino, Jenny I. Shen, Neil Boadville, Douglas E. Schaubel, Isaac Teitelbaum, Jeffrey Perl, Arbor Research Collaborative for Health, Ann Arbor, MI; 2University of Pennsylvania, Philadelphia, PA; 3University of Western Australia, Perth, WA, Australia; 4University of Colorado School of Medicine, Aurora, CO; 5University of Pennsylvania, Philadelphia, PA; 6University of Pittsburgh Medical Center, Pittsburgh, PA; 7University of Western Australia, Perth, WA, Australia; 8University of Colorado School of Medicine, Aurora, CO; 9St. Michaels, Toronto, ON, Canada; 10The Lundquist Institute, Torrance, CA; 11University of Michigan Health System, Ann Arbor, MI.

Background: Medicare fee-for-service (FFS) claims offer a population-based approach to PD-associated peritonitis that may offer valuable insights into predictors, trends and preferred practices.

Methods: We used United States Renal Data System (USRDS) standard analysis files for claims (inpatient, outpatient and physician-supplier), eligibility, modality and demographic information. The sample consisted of PD patient-months from 2013 through 2017 characterized by Medicare FFS coverage and paid claims for dialysis or hospital services. We identified ICD-9 and ICD-10 diagnosis codes for peritonitis, including those that do not clearly distinguish peritonitis from catheter infections/inflammation (“catheter codes”). A new peritonitis episode was defined as a peritonitis claim >30 days from any prior peritonitis claim or 30 days from the initial peritonitis claim for a prior episode.

Results: The sample included 88,396 adult patients (128,000 observed patient-years), yielding 510,000 peritonitis claims and 75,000 peritonitis episodes. Coding was heterogeneous with no single diagnosis code present on the majority of claims. Peritonitis episodes were inferred from aggregated claims (mean 6.3, median 2). Half of episodes were exclusively outpatient, 7% exclusively inpatient, and 16% exclusively comprised of catheter code claims. The overall peritonitis rate was 0.59 and 0.49 episodes per patient-year with and without inclusion of catheter codes respectively. Peritonitis rates declined by 4%/year from 2013-2017, and varied by age, race (Black < White = Asian), and ESKD vintage.

Conclusions: Coding heterogeneity indicates a lack of standardization and need for clearer coding guidance. We found differences between races, ages, and patient vintages, and declining rates from 2013-2017. These rates are 2-fold higher than reported in US-PDOPPS by Perl et al (AJKD 2020) which is not restricted to Medicare. Claims are an important data source for peritonitis, but more work is needed to validate these rates.

PO0994

Protective Association Found Between Peritoneal Dialysis Patients Prescribed Home Antibiotics Kits and In-Center Hemodialysis Transition

Derek M Blankenship, Michelle Carver, Dinesh K. Chuttoth, Chance Myasiphonl, Debu Ray, Patricia Mccarley, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux, Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: Peritonitis is a complication of peritoneal dialysis (PD) and is likely associated with technique failure. To decrease time to peritonitis treatment, Fresenius Kidney Care (FKC) clinicians can prescribe broad-spectrum intraperitoneal and oral antibiotic kits. Kits are self-administered by home PD patients for suspected wet contamination or peritonitis per algorithm. The study purpose is to assess hemodialysis (HD) transition as well as peritonitis among PD patients receiving a home antibiotic kit.

Methods: This retrospective cohort study identified FKC PD patients prescribed home antibiotic kits between June 1, 2019 and June 30, 2020. Home FKC PD patients not receiving kit during same period composed the control pool. Patients are matched in a 1:4 ratio on clinical and demographic data using propensity scores. Patients were followed up to 6 months for transition to HD and first peritonitis event. Outcomes were analyzed with weighted competing risk Cox Proportional Hazards Models.

Results: 2,888 treatment and 10,613 controls were studied. Of the 2,888 treatment patients and weighted 1,921.2 matched controls, 11.9% and 13.5% transitioned to HD, respectively. A 0.88 hazard ratio (p=0.0448) determined treatment group is 12% less likely to transition to HD at any point during follow-up period. 10.4% treatment patients and 8.5% controls have at least one peritonitis event. The treatment group is 23% more likely to have a Peritonitis event (p=0.0019).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: The study identified a protective association in HD attrition for home PD patients receiving peritonitis kits despite a positive association between patients receiving the kits and peritonitis. This finding may reflect residual confounding factors such as clinicians prescribing kits for patients at higher risk of peritonitis for uncontrolled or unmeasurable factors since kits do not prevent peritonitis but increase uniformity of treatment. The findings justify need for further research including prospectively randomized studies.

PO0995

Assessing Physician Clinic Practices and Competencies in Performing Peritoneal Dialysis Catheter Flushes During the 10-Day Global Period

John H. Crabtree,1,2 Marcus Pecora,2 Mark H. Shapiro,1,2 Eduardo Zanatta,2 Martin J. Schreiber,1,2 Harbor-UCLA Medical Center, Torrance, CA; DaVita Inc, Denver, CO; Balboa Nephrology Medical Group, San Diego, CA.

Background: Early flushing of peritoneal dialysis (PD) catheters theoretically reduces the incidence of catheter obstruction by decreasing formation of fibrin strands or blood clots. Early flushing also enables timely identification of catheter dysfunction, creating an opportunity to revise the catheter prior to scheduled training and initiation of therapy. It is unknown how frequently PD access providers perform flushes in their clinics, but Centers for Medicare & Medicaid Services (CMS) has indicated that services performed within 10 days following catheter placement (global period) are the responsibility of PD access providers. Therefore, under existing regulations, dialysis organizations generally defer to access providers to perform catheter flushes during this global period. The purpose of this study is to assess current practices of PD access provider clinics (surgeon, interventional nephrologist or radiologist) in performing catheter flushes.

Methods: PD access providers placing catheters for a large dialysis organization in the southwestern United States during 2020 were surveyed. The 3-question survey asked: 1) PD access provider specialty, 2) if the clinic performed catheter flushes, and 3) the background of the staff person assisting the physician with clinic procedures. Responses were acquired by direct or telephone contact with the physician or clinic staff.

Results: Survey responses were obtained for all 201 providers who placed PD catheters during 2020 (Table).

Conclusions: Significantly, none of the PD access provider clinics elected to perform catheter flushes. This lack of service may indicate a lack of expertise or readily accessible supplies. While PD nurses are trained and equipped by dialysis organizations to competently perform catheter flushes, current regulations generally prevent them from providing these services during the global period. The study supports a re-examination of the CMS policy, suggesting a need for more flexibility for dialysis organizations to provide these services during the global period for patient safety and optimal patient outcomes.

PO0996

Peritoneal Dialysis Catheter Flushing Leading to Syncope from Vagal Nerve Stimulation

Sylvester Barnes,1,2 Loyola University Health System, Maywood, IL; Edward Hines Junior VA Hospital, Hines, IL.

Introduction: Peritoneal dialysis is the most common form of home dialysis. Complications can arise however any time the peritoneum is invaded such as during surgery. The patient is a 37-year-old male on PD secondary to developing progressive IgA nephropathy. The patient suffered from an inguinal hernia which required open repair with mesh placement. This required the patient to be subsequently bridged with HD.

Case Description: After 6 weeks the patient was in the process of beginning to transition back to PD dialysis. The patient underwent flushing of his peritoneal catheter and subsequently developed hypotension, diaphoresis and near syncope. This process continued every time the patient’s peritoneal catheter was flushed. 500 mL’s of 2.5% warm dyesaltate was also attempted to fill the patient resulting in the same near syncopal episode. There was no problem with aspiration of the catheter. There was no resistance involved in suction or flushing. KUB was obtained showing the catheter placed in the left lower pelvis as well as a significant amount of stool burden. Despite aggressive regimen of laxatives the patient continued to suffer from hypotension and near syncope with catheter flushing. The patient was referred for surgery for catheter repositioning. Operative report identified that the tip of the catheter was caught in anterior abdominal adhesions. The catheter was repositioned to the right lower pelvis. After 2 weeks the patient was able to tolerate flushing of his dialysis catheter with progressively increasing fill volumes to the point that he was able to be completely converted back to peritoneal dialysis.

Discussion: It was theorized that catheter tip was uniquely positioned leading to vagal nerve stimulation when liquid was infused through the catheter. This case illustrates a unique complication of catheter malposition and adhesions resulting in near syncope secondary to vagal nerve stimulation. With repositioning of the patient’s catheter the symptoms completely resolved.

Pharmacokinetics of Intraperitoneal Vancomycin in Patients on Automated Peritoneal Dialysis

Edwin Lam,1,2 Walter K. Kraft,1 Douglas F. Stickle,1 Beth M. Piraino,2 JingJing Zhang,1 Thomas Jefferson University, Philadelphia, PA; National Institutes of Health, Bethesda, MD; University of Pittsburgh, Pittsburgh, PA.

Background: It is unclear if the pharmacokinetics of vancomycin is the same during automated peritoneal dialysis (APD) where cycler exchanges may affect the systemic, peritoneal, and urinary disposition of drug.

Methods: This was a prospective pharmacokinetic study in peritonitis-negative patients on APD. A single dose of vancomycin (20 mg/kg) was administered through the peritoneum and allowed to dwell for at least 15 hours. Patients underwent four drug-free exchanges following the initial dwell period. Plasma, dialysate and urine were collected over the course of 7 days for pharmacokinetic analysis. A non-compartmental analysis was used to estimate vancomycin pharmacokinetic parameters.

Results: Four patients enrolled and completed the study with no adverse events. Three patients had residual renal function. Following a median (range) dwell of 14.6 (14.2 – 17.6 hours), the mean (± SD) observed maximum plasma concentration was 28.7 ± 4.9 mg/L with a mean (± SD) bioavailability of 98.5 ± 1.4% prior to starting the cycler. The overall mean plasma clearance estimated from study start to completion was 7.3 ± 1.2 mL/min. In patients with residual renal function, the mean (± SD) vancomycin renal clearance was 3.1 ± 1.5 mL/min.

Conclusions: Despite the small sample size, this pilot study suggests that the dwell time has important implications for systemic vancomycin exposure, time to therapeutic plasma concentration, and dosing. Dose is driven by dwell time while the cycler determines the dosing interval. Rapid exchanges from APD will determine the frequency of dosing rather than the adequacy of absorption when vancomycin is given in the peritoneum.

Funding: Other NIH Support - Edwin Lam was supported by an NIH T32 training grant (GM008562) at the time of study conduct.

Discussion: It was theorized that catheter tip was uniquely positioned leading to vagal nerve stimulation when liquid was infused through the catheter. This case illustrates a unique complication of catheter malposition and adhesions resulting in near syncope secondary to vagal nerve stimulation. With repositioning of the patient’s catheter the symptoms completely resolved.

Effect of Velphoro on Serum Phosphate and Albumin in Peritoneal Dialysis Patients
Luis M. Perez, Zhijing You, Jessica B. Kendrick, Isaac Teitelbaum. University of Colorado, Denver, CO.

Background: Hyperphosphatemia is common in patients on peritoneal dialysis (PD). Restricting phosphorus in the diet often leads to a decrease in protein intake, which may result in hypoalbuminemia. Hypoalbuminemia is associated with an increased risk of morbidity and mortality in PD patients. In observational studies, saccharin cocohydroxide (SO), an iron-based phosphate binder, was associated with improved phosphate control and higher serum albumin in hemodialysis patients. Whether SO improves phosphate control and nutritional status in PD patients is unknown.

Methods: We performed a prospective, open-label, 6-month, pilot study of 17 adult PD patients from the Denver Metro Area. Patients had to use automated peritoneal dialysis for at least 3 months, have a serum albumin ≥ 3.8 g/dL, and have serum phosphate ≥ 5.5 mg/dL or ≤ 5.5 mg/dL on a binder other than SO. Patients currently on phosphate binders underwent a 2-week washout period. Participants were started on SO at a dose of 1 tablet daily with meals. Serum phosphate was checked monthly and the dose of SO was titrated to a goal serum phosphate of < 5.5 mg/dL. The primary outcome was change in serum phosphate and serum albumin over 6 months.

Results: The mean (SD) age and dialysis vintage was 55 ± 13 years and 3.8 ± 2.7 years, respectively. The majority of patients were male (65%), white (82.4%) and non-Hispanic (64.7%). 88% of patients were on a phosphate binder at baseline and the majority were on sevelamer (73%). Twelve patients completed the study. Two patients withdrew due to side effects (diarrhea), 1 patient changed to hemodialysis and 2 patients died (unrelated to the study). Mild diarrhea and change in stool color were the most frequently reported side effects. Results are shown in Table 1. Serum phosphate decreased significantly from baseline but there was no significant change in serum albumin. Phosphate binder pill burden significantly decreased.

Conclusions: Serum phosphate decreased significantly with fewer phosphate binder pills/day after switching to SO. There was no change in serum albumin.

Prognostic Significance of Plasma Vaspin and Adiponectin Levels in Peritoneal Dialysis Patients
Win H. Than,1 Cheuk-Chun Szeto,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Shatin, Hong Kong; ‘Li Ka Shing Institute of Health Sciences (LKHIS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.

Background: Adiponectin and vaspin are key adipokines that play important roles in the physiology of adipose tissue and contribute to the pathogenesis of metabolic disturbance in chronic kidney disease (CKD). We explored the prognostic role of plasma adiponectin and vaspin levels in peritoneal dialysis (PD) patients—a population that metabolic syndrome, obesity, and cachexia are all common.

Methods: We measured plasma adiponectin and vaspin levels in a cohort of new PD patients and analyzed their relation with patient survival.

Results: We studied 152 patients. Their mean age was 58.38 ± 11.67 years; 102 (67.1%) were men, 92 (60.5%) were diabetic. The median plasma adiponectin level was 31.98 (Interquartile range [IQR]: 16.81-49.49) mg/mL; median vaspin level was 0.18 (IQR: 0.01-0.32) ng/mL. There was no significant correlation between plasma adiponectin and vaspin levels. Plasma adiponectin level had modest correlations with Charlson's score (r = 0.174, p = 0.039), triceps skin fold (r = -0.269, p = 0.001), and mass transfer area coefficient of peritoneum (r = 0.211; p = 0.015). In contrast, plasma vaspin level correlated with carotid-to-femoral pulse wave velocity (r = -0.240, p = 0.005), triceps skin fold (r = 0.198, p = 0.018), and extracellular to Intracellular fluid volume ratio (r = -0.170, p = 0.047). After adjusting for clinical confounders, plasma adiponectin and vaspin levels significantly predicted patient survival (adjusted hazard ratio [AHR] of adiponectin 1.018, 95% confidence interval [CI] 1.004-1.031; p = 0.010; AHR of vaspin 1.018, 95%CI 1.008-1.029; p = 0.001).

Conclusions: Plasma adiponectin level also correlated with peritoneal transport status, while plasma vaspin level correlated with the severity of fluid overload and atherosclerosis. Plasma levels of both adiponectin and vaspin are independent predictors of patient survival. Our results suggest that adiponectin and vaspin are involved in different pathways of metabolic disturbance in uremia.

The Impact of Peritoneal and Urine Protein Losses on Nutritional Status in Peritoneal Dialysis Patients

Background: The etiology of malnutrition in peritoneal dialysis (PD) patients is multifactorial, but the peritoneal protein losses (PPL) and proteinuria may be important contributing factors. We aimed to evaluate if the total protein losses (into urine and dialysate) in PD patients have an impact on their nutritional status.

Methods: A retrospective observational study of PD patients over the first year in PD. Demographic, clinical, and analytical data were collected at baseline (time of PD initiation), 6 and 12 months later. Nutritional status was assessed using normalized protein catabolic rate (nPCR), body mass index (BMI), lean body mass (LBMI), and body fat mass (BFM). The total amount of 24h urine and dialysate protein losses (ProtUrDial) and delta (Δ) values (difference between the end of follow-up period and baseline) of continuous variables were also calculated.

Results: Twenty patients were enrolled (55.8±10.8 years; 65% male). Except for serum albumin (AaB), which changed significantly from the baseline to the end of the follow-up period (p=0.001), there were no differences in protein loss into dia lyse (ProtDial), proteinuria (ProtUrine), nPCR, BMI, LBMI, and BFM over time. In the 3 time points there was a significant positive correlation between ProtUrine and nPCR (r=0.563, p=0.01; r=0.584, p=0.031; r=0.611, p=0.004, respectively). At the end of the follow-up period, we verified a negative correlation between AaB and ProtUrDial (r=-0.420, p=0.033). There was no correlation between ProtDial and nutritional parameters status, however, there was a positive correlation between ΔProtUrine and ΔBMI (r=0.492; p=0.028). Regarding ΔProtUrDial, we verified a negative correlation with ΔBMI (r=-0.664; p=0.026) and, although not significant, a positive correlation with Δ%BFM (r=0.573; p=0.066).

Conclusions: The PPL has already been linked to malnutrition in PD patients. However, we found that the total amount of protein losses daily (into urine and dialysate), and not each one individually, seems to influence the nutritional status of PD patients. Besides, proteinuria appeared to have a greater impact on nutritional changes than peritoneal losses. However, more studies with larger samples are needed to clarify this association.

PO1002
Psychosocial Impact of COVID-19 Pandemic on Patients with ESKD on Peritoneal Dialysis

Janina Paula Androga, Fawad Qureshi, Andrea G. Kattah. Mayo Clinic Minnesota, Rochester, MN, MN.

Introduction: Increased intra-abdominal pressure is a well-recognized non-infectious complication of peritoneal dialysis (PD) resulting from instillation of dialysate fluid into the peritoneal cavity. Peritoneal-pleural communication causing hydrothorax is well-described in the literature, but cases of peritoneal-pleuromedial communication are scarce.

Case Description: A 36-year old Caucasian man with end-stage kidney disease secondary to calcineurin inhibitor nephrotoxicity and BK virus nephropathy transitioned to continuous cyclic peritoneal dialysis (CCPD) after one year of intermittent hemodialysis (iHD). He presented to our institution nine months after starting CCPD primarily because of complications related to prior heart transplantation. He underwent cardiac surgery and did not have any problem with his CCPD in the immediate post-operative period and was discharged. One month later, however, he presented with increased serum drainage from his sternal incision site and reduced ultrafiltration. A chest CT scan revealed a partially loculated anterior chest wall subcutaneous fluid collection. He was taken to the operating room and was found to have a peritoneal-pleural-medial communication. He was successfully managed with “low-pressure” PD by using reduced fill volumes for all his exchanges, which also allowed optimal healing of the muscle flap closing the communication. Transition to iHD was considered, but he had no vascular access options because of multiple prior thromboses. He was able to subsequently return to his outpatient PD in four months after his surgery by doing very gentle up titration of his fill volumes. Unfortunately, one and a half months after his last hospitalization, he succumbed to septic shock secondary to trans-lumbar PICC-associated Candida glabrata fungemia.

Discussion: A peritoneal-pleural-medial communication should be suspected in an otherwise asymptomatic patient on PD with reduced ultrafiltration who underwent any form of chest surgery. Clinical suspicion can be confirmed either through CT peritoneography or intraoperatively. Management with a trial of “low-pressure” PD is feasible and can be successful, particularly if iHD is not an option. A multi-disciplinary approach involving our surgical colleagues is also crucial to ensure appropriate patient care.

PO1003
Peritoneal-Mediastinal Communication Complication in Peritoneal Dialysis

Janina Paula T. Sy-Go, Lagu A. Androga, Fawad Qureshi, Andrea G. Kattah. Mayo Clinic Minnesota, Rochester, MN.

Introduction: The mortality rate from COVID-19 is remarkably high in elderly patients and those with chronic conditions. Increases in physical and mental stress among patients with chronic conditions, especially end-stage kidney disease, were expected to have a notable increase in response to the COVID-19 pandemic. This study reports that the psychosocial impact of the COVID-19 pandemic on patients receiving peritoneal dialysis is significant.

Methods: During the pandemic, we surveyed the mental health of patients with end-stage kidney disease on peritoneal dialysis at a single center. Depression using with BDI scoring was evaluated and then compared in peritoneal dialysis patients between before and the pandemic declaration. We also surveyed patient satisfaction with the self-care services associated with peritoneal dialysis under the pandemic period.

Results: One-third of the survey respondents (n=176) were moderately to extremely worried about their physical health being impacted by the pandemic, while 20% moderately to extremely worried about their mental and emotional health being impacted. About half of participant reported feeling that they were unable to handle their personal problems and that things were out of their control. However, most felt that they could retain control over the important things and overcome their difficulties. Despite COVID-19 pandemic, no significant changes in depression scores were apparent between before and during the pandemic. Most participants were satisfied with the in-home self-care services delivered by either telephone or remote monitoring.

Conclusions: Many participants reported that they were afraid of COVID-19, but most patients with PD felt that they could overcome the crisis. The COVID-19 pandemic did not affect the depression of patients receiving peritoneal dialysis.

PO1004
Sweet Pleural Effusion in a Peritoneal Dialysis Patient

Karla G. Carias Martinez,1 Nityasree Srialluri,1 Jose M. Monroy-Trujillo.2 1Johns Hopkins Medicine, Baltimore, MD; 2Johns Hopkins University, Baltimore, MD.

Introduction: Pleural Effusions are frequently seen in dialysis patients with an incidence as high as 80%, with a variety of possible differential etiologies.

Case Description: A 62-year-old female with HFpEF, DM and ESRD due to biopsy proven diabetic nephropathy recently started on nightly continuous cyclic PD with a prescription of 4 exchanges of 2.5% Dextrose solution with 2 liters fill volumes with a dwell time of 1840 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining ultrafiltration volumes. On exam tachypneic on 4L of oxygen and saturating 100%, a dwell time of 1h40 min for a total time of 8.5 hrs with no day dwells presented with prescription of 4 exchanges of 2.5% Dextrose solution with 2 liters fill volumes with a dwell time of 1840 min for a total time of 8.5 hrs with no day dwells presented with dyspnea. She had missed 2 sessions of dialysis and noted increasing weight as declining ultrafiltration volumes. On exam tachypneic on 4L of oxygen and saturating 100%, had decreased breath sounds on the right primary pulmonary lobe or lower extremity.

PO1005
Progression of Left Ventricular Mass Index After Peritoneal Dialysis Initiation: A Potential Killer

Yun Chen, Shuai Dai, Chuan-Ming Hao, Tongying Zhu. Huashan Hospital Fudan University, Shanghai, China.

Background: Left ventricular hypertrophy (LVH), defined by the left ventricular mass index (LVMI), is highly prevalent in dialysis patients. LVMI has been widely accepted as a strong predictor of cardiovascular events. However, the dynamic changes of LVMI are rarely discussed, especially among peritoneal dialysis (PD) patients. The study aimed to investigate the prognostic significance of LVMI-progression in PD patients, and explore risk factors for LVMI-progression.

Methods: It was designed as a prospective, observational study. Incident PD patients between February 2008 and July 2018 were recruited. Echocardiography was performed yearly to collect LVMI and evaluate its progression. Participants were divided into two subgroups: group with LVMI-progression and group without LVMI-progression. The end points include all-cause mortality, cardiovascular mortality and cardiovascular events. Cox regression models were performed to identify the associations between LVMI-progression and these endpoints. Multivariate logistic regression was conducted to identify factors associated with LVMI-progression.

Results: A total of 216 PD patients (130 men,60.2%) with a mean age of 54.3±16.7 years were recruited. LVMI-progression was identified in 65 patients (30%) after PD initiation. The cohort was followed for a median duration of 65.9 months. Multivariable Cox regression analysis revealed that LVMI-progression was an independent predictor of all-cause mortality (HR, 2.111; 95% CI, 1.485–3.881; p = 0.016), cardiovascular mortality (HR, 2.785; 95% CI, 1.581–4.741; p = 0.023), and cardiovascular events (HR, 1.869; 95% CI, 1.016–3.439; p = 0.044). Multivariable logistic regression showed that hemoglobin (OR, 0.967; 95% CI, 0.939–0.996; p = 0.027), ferritin (OR, 0.995; 95% CI, 0.992–0.999; p = 0.007) and mean arterial pressure (MAP) (OR, 1.048; 95% CI, 1.001–1.097; p = 0.043) were significantly associated with LVMI-progression.

Conclusions: LVMI-progression after PD initiation was independently associated with all-cause mortality and cardiovascular outcomes in PD patients. The dynamic monitoring of LVMI might therefore help identify high-risk patients early. Further studies are needed to clarify whether treatment interventions for factors such as anemia could improve patient outcomes.

PO1006
Estimation of Residual Kidney Function with Serum Levels of β2-Microglobulin in Peritoneal Dialysis

Fernando L. Strufaldi, Luciana G. Lutf, Rosilene M. Elias, Hugo Abensur. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: Residual kidney function (RKF) is defined as the kidney function in patients with end-stage renal disease (ESRD) who are receiving dialysis. The ideal method to evaluate and measure RKF is still uncertain and the estimated glomerular filtration rate (eGFR) and urea clearance may over- and underestimate RKF, respectively. β2-microglobulin (β2M) is an 11818 Da protein freely filtered and metabolized in kidney...
PO1007

A Rare Case of Roseomomas gilardii Peritonitis in a Peritoneal Dialysis Patient

Temi-Efe I. Ediale, Saied Karandish, Ayesh Mallick Imam, Aaron S. Stern, Ellena A. Linden. Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: We report a case of Roseomonas gilardii peritonitis in a continuous ambulatory peritoneal dialysis patient.

Case Description: A 71-year-old woman with end stage renal disease (ESRD) on continuous ambulatory peritoneal dialysis (CAPD) for 5 years presented with cloudy effluent without abdominal pain or fever. Laboratory studies revealed a fluid cell count of 800 wbc/mm³ with 87% neutrophils. She was started on empiric antibiotic therapy with intraperitoneal vancomycin and cefazolin. Effluent remained cloudy with elevated WBC despite a 2-week course of antibiotics. Eventually culture grew Roseomonas gilardii, a slow growing gram-negative bacillus sensitive to amoxicillin. Her antibiotic was changed to IP gentamycin and her effluent cleared by day three. Gentamycin is a slow growing gram-negative bacillus sensitive to aminoglycosides. Her antibiotic was changed to IP gentamycin and her effluent cleared by day three.

Discussion: Peritoneal dialysis peritonitis is known to be caused mainly by gram positive and occasionally gram-negative organisms, the usual culprits being pseudomonas, klebsiella etc. Roseomonas has recently been implicated as a rare cause of bacterial peritonitis with only six reports between 1997 till date. It was first described in 1993 as a cause of bacteremia in humans. Roseomonas gilardii is a pink-pigmented, oxidized, gram-negative cocacobacillus genus of Roseomonas associated with contaminated water source and soil. Our patient was unaware of being in contact with contaminated water or soil however this could not be ruled out as she did endorse having plants. Of the six cases reported, ours is the third case of R. gilardii reported till date. Although the incidence of peritoneal dialysis peritonitis caused by Roseomonas gilardii is rare, it is causative agent to be considered by physicians and laboratory staff in the differential diagnosis of refractory bacterial peritonitis in peritoneal dialysis patients. It also serves as a point to emphasize when educating PD patients on the hand-washing techniques and ensuring sterility of water source used for this.

PO1008

Unusual Cause of Recurrent Shortness of Breath in a Peritoneal Dialysis Patient

Sonali Gupta, Mecnakshi Sambharlia, Lama A. Noureddine. The University of Iowa Hospitals and Clinics, Iowa City, IA.

Introduction: Pleuropertitoneal leak (PLL) is an unusual cause of recurrent pleural effusion in patients on peritoneal dialysis (PD). It is a rare complication and occur in less than 2% of cases. Diagnosis is challenging and requires high clinical suspicion and awareness of this life threatening complication. Pleural fluid to serum glucose ratio of >30 mg/dl is highly specific for detecting leak of high glucose dialysate into pleural cavity, however this needs to be interpreted in relation with the last dialysis session.

Case Description: A 72 year-old-female with history of end stage renal disease due to biopsy proven focal segmental glomerular sclerosis thought to be secondary to obesity started on CCPD one-month prior presented with worsening shortness of breath of 1 week duration. Workup was unremarkable except for chest-X-ray that showed right side pleural effusion. A non-contrast CT chest did not show a diaphragmatic defect. She continued to have worsening SDB prompting an emergent thoracentesis that drained 1.6 L transudate pleural fluid. Pleural fluid to serum glucose gradient was normal at 5 mg/dl but pleural fluid to serum glucose ratio was >1. However, last PD session was 2 days prior to thoracentesis, which could explain this lower ratio. Due to inconclusive results, it was decided to instill 30 ml of pleurolytic solution into the pleural cavity. It showed interval re-accumulation of high-density pleural effusion, suggesting trans-diaphragmatic communication. Cardiothoracic surgery was consulted for repair of diaphragmatic defect; however, patient opted for hemodialysis instead.

Discussion: It is important to maintain high clinical index of suspicion in PD patients presenting with hydrothorax. Although high pleural fluid to serum glucose gradient is specific for PLL, pleural to serum glucose ratio >1 is another index that should be considered in addition to post-gastrogafin imaging or technetium 99m peritoneal scintigraphy, especially if the diagnosis was not recent and could potentially alter the biochemical assay results as happened in our case. Most cases of PLL occur soon after PD initiation, common on right side. For those who wish to continue PD, surgical repair is often required while transitioning to HD temporarily or doing low volume recurrent PD. Some case series have noted the defect to close spontaneously after holding PD.

PO1009

The Association Between Lower Serum Potassium Level and Increased Cardiovascular Death Among Patients Undergoing Peritoneal Dialysis

Hiroaki Tsujikawa,1 Toshiaki Nakano,1 Shohtar Ohnaka,1 Shunuske Yamada,1 Kazuhiko Tsuruya,1 Kumiko Torisu,1,4 Hidetoshi Kanai,1 Takeshi Kitazono.1

1Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, Fukuoka, Japan; 2Nara Kenritsu Iga Daigaku Yakagakugyō Kyōhōshitsu, Kashihara, Japan; 3Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; 4Kokura Kinen Byoin, Kitakyushu, Japan; 5Tagawa Shiritusu Byoin, Tagawa, Japan.

Background In patients undergoing peritoneal dialysis (PD), lower serum potassium concentration has been related to low nutrition status and suggested as a risk factor for all-cause and cardiovascular mortality. However, the risk of lower serum potassium concentration for cardiovascular death in patients using renin-angiotensin system (RAS) inhibitors or β-blockers is not clear. This study investigated the relationship between lower serum potassium concentration and cardiovascular death among Japanese patients undergoing PD.

Methods: We retrospectively included the 549 patients from our previous multicenter cohort study (Fukuoka Peritoneal Dialysis Database Study). The participants who had undergone PD for at least 90 days were registered from 1 January 2006 to 31 December 2016 and followed until they were transferred to hemodialysis, received a kidney transplantation, died during PD, or were lost to follow-up, or until 31 December 2017. The patients were divided into three groups according to the baseline serum potassium concentration: T1 (≤ 4.0, 4.0 < T2 ≤ 4.5, T3 > 4.5 mEq/L). We estimated the relationship between serum potassium concentration and cardiovascular mortality using a Cox proportional hazards model.

Results: During the median observation period of 2.3 years, 111 patients died of any cause, and 38 died of cardiovascular. After multivariable adjustment in the Cox proportional hazard model, lower serum potassium concentration was shown to be an independent risk factor for cardiovascular death; (hazard ratio 95% confidence intervals) T2 and T1 vs. T3 were 2.21 (1.77–2.67) and 2.67 (1.91–3.70), respectively. Stratified-analysis according to the use of RAS inhibitors, β-blockers, or a combination of both drugs showed that this relation was not modified by the use of these drugs.

Conclusions: This study showed that lower serum potassium concentration was associated with increased cardiovascular mortality in PD patients. There was no difference in the risk of lower serum potassium concentration for cardiovascular death according to the use of the RAS inhibitors and/or β-blockers in PD patients.
PO1010

Higher Serum Total Cholesterol to High-Density Lipoprotein Cholesterol Ratio Was Associated with Increased Mortality Among Incident Peritoneal Dialysis Patients

Hae Won Noh, Soojeen Jeon, Jeong-Hoon Lim, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. Department of Internal Medicine, Kyungpook National University Hospital, Korea

Background: A few studies have shown that serum total cholesterol to high-density lipoprotein cholesterol ratio (TC/HDLC) was a risk factor for cardiovascular mortality in the general populations. This study aimed to evaluate the association of TC/HDLC with mortality in incident peritoneal dialysis patients.

Methods: We enrolled Total of 6,30 incident peritoneal dialysis patients from 2008 to 2015 in a multi-center, prospective cohort study of Korea. Participants were stratified into quintiles according to the baseline TC, HDL-C, or TC/HDLC. The association between all-cause mortality and each lipid profile was evaluated using multivariate Cox regression analysis.

Results: During a median follow-up period of 70.3 ± 25.2 months, 185 deaths were recorded. The median TC/HDLC was 4.54 ± 2.51. Highest TC/HDLC group showed highest body mass index, percentage of diabetes, and serum albumin level. Multivariate analysis revealed that the highest quintile of the TC/HDLC (≥5.60) was associated with increased risk of all-cause mortality (hazard ratio 1.69, 95% confidence interval 1.04 to 2.76; P = 0.036), whereas neither of TC and HDL were associated with mortality. Increased serum TC/HDLC was also independent risk factor for mortality in the patients with old age over 50 years, non-diabetes, and any cardiovascular disease.

Conclusions: The single lipid marker of TC or HDL-C could not predict mortality in PD patients. However, non-traditional lipid profile such as increased serum TC/HDLC ratio was independently associated with an increased risk of all-cause mortality in PD patients.

PO1011

Peritoneal Dialysis Caregiver Scope and Functions: A Systematic Scoping Review

Tanawin Nopsopon,1 Chitsanucah Chumsri,1 Piyawat Kantagowit,1 Krit Pongpirul.2 Thailand PD Outcomes and Practice Patterns Study (PDOPPS) Steering Committee Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 2Harvard University T H Chan School of Public Health, Boston, MA; 1Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Background: Caregivers play important roles in peritoneal dialysis (PD) care. Classifying PD self-care tasks is important for determining the PD caregiver roles. As the scope and functions of PD caregiver in published literature have been inconsistent, we aimed to systematically explore the variations of the term caregiver in high-quality PD studies.

Methods: We performed a systematic search using PubMed, Embase, and CENTRAL for randomized controlled trials and observational studies relevant to a caregiver in ESRD with PD studies.

Results: Of 2,514 potential studies relevant to a caregiver in ESRD patients with PD, 299 theme-related abstracts were selected for further full-text articles screening against eligibility criteria, and 111 were included in the systematic review (72,101 patients in 34 countries). In terms of word choice, “caregiver(s)” was used in 86.4%, “care-taker(s)” in 20.7%, and other words were used in 13.5% of included studies. Only 8.1% of studies gave the explicit definitions of those words. The most referred person is the parents (40.5%), followed by a spouse (37.8%), other family members (37.8%), children (34.2%), non-relative non-healthcare workers (25.2%), friends (20.7%), and healthcare workers (19.8%). The explanation of functions for each word comprises 41.4%, with the PD-related functions explained in p96% (p<0.001) in both in vivo models. Disturbed autophagy flux also observed in human vein samples collected during new AVF creation. In vitro model showed dysregulation of autophagy flux in disturbed flow, as compared to laminar flow.

Conclusions: Our in vivo and in vitro studies both demonstrated that autophagy response may play an important role in vessel remodeling in the setting of disturbed flow as seen in AVFs. Autophagy may be a potential target to improve AVF maturation.

Autophagy Response and Arteriovenous Fistula Maturation

Tatvanan Isavee Waldrop, Maheshika S. Somarathna, Kevin A. Ingle, Timmy C. Lee. The University of Alabama at Birmingham, Birmingham, AL.

Background: Arteriovenous fistula (AVF) are the preferred vascular access for hemodialysis. AVF creation results in disturbed blood flow within the AVF anastomosis. The objectives of this study were to: 1. Characterize autophagy flux after AVF creation, and during the remodeling process, 2. Use an in vitro model to evaluate autophagy status during the laminar and turbulent flow.

Methods: Femoral AVFs were created in male rats. Yorkshire pigs were used to create carotid artery-jugular vein AVF. Autophagy flux was evaluated after 1 hour and 7 days. AVF and contralateral vessels were harvested for histology and Western blot (WB). Autophagy-related proteins were analyzed in the AVF human vein samples. Effects of hemodynamic changes were investigated by utilizing an in vitro model. Human umbilical vein smooth muscle cells and endothelial cells were co-cultured in the vessel-like system under laminar or disturbed flow conditions. After 24 hours, cells were harvested for histology and WB.

Results: In the rat model impaired autophagy flux was observed in the vein 1 hour after AVF creation. At day 7 expression of ATG3 and ATG7 protein was significantly higher (p<0.003) in the AVF vein compared to contralateral control. Significant increases in p62 expression was detected in 7 days AVF vein (p<0.001) in both in vivo models. Disturbed autophagy flux also observed in human vein samples collected during new AVF creation. In vitro model showed dysregulation of autophagy flux in disturbed flow, as compared to laminar flow.

Conclusions: Our in vivo and in vitro studies both demonstrated that autophagy response may play an important role in vessel remodeling in the setting of disturbed flow as seen in AVFs. Autophagy may be a potential target to improve AVF maturation.

Methods: An end-vein to side-artery AVF was surgically created in the femoral vessels of rats which had previously been subjected to uremia via subtotal nephrectomy. At 1 and 2 weeks after AVF formation the arterial and venous limbs of the AVF were harvested for the assessment of gene and protein expression and the assay of SA-β-Gal activity. Femoral veins and arteries from rats subjected to sham surgery were used as controls.

Results: At 1 week after AVF creation mRNA levels of senescence drivers p16 and p21 were markedly elevated in AVF veins compared to sham veins, as were p21 protein levels; the AVF artery also displayed elevated p21 protein levels at this time point. At 2 weeks, p21 protein was again upregulated in both the vein and artery of the AVF, and protein levels of an upstream mediator in the p21 senescence pathway, p53, were significantly increased in the AVF artery; p53 levels did not achieve significance (p=0.083) in the AVF vein at this time point. Upregulation of SASP factors was also observed in the AVF vein at 1 week: mRNA expression of PAI-1, IL-6, TNF-α and MCP-1 was robustly increased as compared to sham veins at 1 week after AVF creation. Additionally, miR21, which has been associated with vascular senescence, was markedly elevated in the AVF vein at 1 week post AVF placement. Finally, SA-β-Gal activity, an established marker of senescence, was significantly increased in both the artery and vein compared to their sham counterparts at both 1 and 2 weeks post AVF surgery.

Conclusions: Using established criteria, this study demonstrates that the rat femoral AVF in the setting of CKD has a senescence phenotype similar to the murine AVF-CKD model. These findings thus demonstrate the development of senescence in another species subjected to an AVF in the presence of uremia.

The Adaptive Response of the Vein to CKD: A Transcriptomics Perspective

Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Miguel G. Rojas,1 Juan C. Duque,1 Loay H. Salman,2 Roberto I. Vazquez-Padron,3,5 University of Miami School of Medicine, Miami, FL; 1Albany Medical College, Albany, NY; 3VA Miami Healthcare System, Miami, FL.

Background: The impact of CKD on gene expression in the vascular wall remains unknown, particularly in veins, despite their fundamental role as conduits for hemodynamics.

Methods: In this study, we investigated the CKD fingerprint on the transcriptome of basilar veins by analyzing 48 pre-access veins from end-stage renal disease patients and 20 veins from non-CKD trauma donors by bulk RNA sequencing.

Results: We uncovered 16,893 differentially expressed genes (DEG) between CKD and control individuals (log Fold Change ≥1, FDR <0.05). The presence of kidney disease caused a noticeable decrease in transcriptional activity in veins, with the downregulation of ≥97% of DEG transcripts. These included 6,081 non-coding RNAs, 3,826 protein-coding genes, and the rest to minor RNA biotypes. Gene set enrichment analysis (GSEA) identified a suppression of pathways related to vascular maintenance, cell morphogenesis, cell metabolism, and microtubule-based cytoskeletal functions. Interestingly, the protein-coding genes upregulated in CKD veins belonged to processes related to gas transport and detoxification of oxidative stress byproducts.

Conclusions: In conclusion, we have uncovered a profound suppressive effect of CKD on the venous transcriptome, likely affecting basic cell functions such as metabolism, cell division, and migration. We also identified a transcriptomic signature of upregulated genes in response to oxidative stress which may play a fundamental role in cell survival in the CKD environment.

PO1016

Inhibition of Phosphodiesterase Type 5A Prevents Pathological Cardiac Remodeling Following Arteriovenous Fistula Creation

Maheshika S. Somarathna,1 Taylor G. Lewis,2 Kevin A. Ingle,1 Tatyana Isayeva Waldrop,1 Timmy C. Lee.1 The University of Alabama at Birmingham, Birmingham, AL; 3Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.

Background: Cardiac events are the most common etiology of mortality in hemodialysis patients. The gold standard of vascular access, the arteriovenous fistula (AVF), may adversely affect cardiac structural and functional remodeling leading to heart failure. We hypothesize that inhibition of cGMP catalysis with a selective phosphodiesterase type 5A (PDE5A) inhibitor, sildenafil, may induce more favorable cardiac remodeling following AVF creation.

Methods: Sildenafil was administered to 12-16 weeks old Sprague-Dawley rats two weeks prior to AVF creation and continued until sacrifice at 28 days. Cardiac structural and functional changes were evaluated by 1) 2D-echocardiography 2) measurement of collagen volume and oxidative stress and 3) evaluation of cardiomyocyte cytoskeletal-mitochondrial architecture.

Results: Sildenafil treatment significantly improve pathologic collagen degradation, reduces HNE4 expression, reverse desmin degradation and focal mitochondrial clustering following AVF creation, as compared to the control. We also observed a significant increase in cardiac output and stroke volume without reversing LV dilation which may suggest improvement in cardiac contractility.

Conclusions: PDE5A inhibition may provide a new treatment strategy for pathological cardiac remodeling following AVF creation.

PO1017

Pre-Access Vein Transcriptomics as a Predictor of Arteriovenous Fistula Failure: A Machine Learning Approach

Miguel G. Rojas,1 Laisel Martinez,1 Akshara Sree Challa,1 Marwan Tabbara,1 Juan C. Duque,2 Loay H. Salman,2 Roberto I. Vazquez-Padron,1,3 University of Miami School of Medicine, Miami, FL; 1Albany Medical College, Albany, NY; 2VA Miami Healthcare System, Miami, FL.

Background: As the number of patients with end-stage renal disease continues to rise, the creation of a robust and efficient hemodialysis access is more important than ever. A mature arteriovenous fistula (AVF) is the preferred method for long-term hemodialysis. However, the nationwide maturation rate continues to be as low as 50-60%, and we currently lack an effective risk stratifying method to identify patients at higher risk of AVF failure.

Methods: To address this clinical need we developed a predictive model based on supervised machine learning from transcriptomics of the pre-access vein. Forty-eight pre-access veins obtained at the time of AVF creation (24 matured and 24 failed postoperatively) were randomly selected from the University of Miami Vascular Biorepository and submitted for bulk RNA sequencing. Both outcome groups were matched by age, sex, demographics, and baseline characteristics. The highest expressing genes (normalized gene expression counts >200) were used as input in KNNS, SVM, XGBoost, and other machine learning algorithms. Area under the curve (AUC) and receiver-operating characteristic (ROC) plots were used to compare the performance of the models relative to each other. The best performing algorithm, XGBoost, was optimized with the following hyperparameters [gamma=0.25, learning_rate=0.001, max_depth=4, reg_lambda=10, scale_pos_weight=3]. The SHapley Additive exPlanations (SHAP) analysis was then used to evaluate the highest contributing features to the XGBoost model.

Results: Ten highly predictive and abundantly expressed genes were identified using this methodology (RLIC, CLIC5, DNAL1, FOXO4, TIMMDC1, GALNT11, CDH13, KLHDC10, ZNF8, and DBT). Using these transcripts, the AUC in the logistic regression model is 97.6%.

Conclusions: In conclusion, this study has identified 10 potential pre-access gene predictors of postoperative AVF failure, which could be used clinically as a stratifying or risk management tool in vascular access patients.

Arteriovenous Fistula Non-Maturation: Does the Immune System Play a Role?

Crystal A. Farrington,1 Gary R. Cutter,2 Michael Allon,1 The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; 2The University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background: Arteriovenous fistula (AVF) non-maturation is a persistent problem, particularly among female and Black patients. The immune system promotes several vascular disease processes, but its contribution to AVF non-maturation has not been well-studied. We evaluated the association of serum panel reactive antibodies (PRA), a measure of immune system reactivity assessed in patients undergoing kidney transplant evaluation, with AVF non-maturation.

Methods: We identified 132 patients at our institution who underwent surgical AVF creation between 2010-2019 and had PRA testing within one year of AVF creation. Multivariable logistic regression was used to determine the association of patient demographic, clinical, and vascular factors with AVF maturation. Receiver operator characteristic (ROC) curves were generated to determine the predictive value of key variables on AVF non-maturation.

Results: AVF non-maturation was more common in females than males (44% vs 20%, p=0.003) and in Black than white patients (40% vs 13%, p=0.001). Class II PRA was higher in females than males (12% vs 4% vs 13%, p=0.02), but did not differ by race. In the multivariable model, AVF non-maturation was associated with class II PRA (adjusted odds ratio [aOR] 1.34 per absolute 10% increase; 95% confidence interval [CI], 1.04 to 1.82, p=0.02) and Black race (aOR 3.34, 95% CI, 1.02 to 10.89, p=0.03). An ROC curve using seven key variables (Table 1 and Figure 1) showed an area under the curve of 0.73 (95% CI, 0.63 to 0.82, p=0.0001).

Conclusions: The novel association of elevated class II PRA with AVF non-maturation suggests a role for the immune system in AVF maturation outcomes, especially for female patients.

Functioning Tailor-Made 3D-Printed Vascular Graft for Hemodialysis: A Proof-of-Concept In Vivo Study

David Chih-Yu Yang,1,2 Der-Cheng Tarng,1,2 Taipei Veterans General Hospital, Taipei, Taiwan; 2National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.

Background: The two ends of arteriovenous graft (AVG) are anastomosed to the upper limb vessels by surgery for hemodialysis therapy. However, the size of upper limb vessels varies to a large extent among different individuals. With advances in three-dimensional (3D) printing technology, it is now possible to realize tailor-made AVG for personalized surgery. In this study, we aim to investigate the function of 3D-printed AVGs in vivo.

Methods: The computed tomography angiographic scan of the rabbit neck was performed before the surgery. According to the shape and size of neck vessels, an H-shape AVG was produced by the 3D printer and then sterilized. The 3D-printed AVG was trimmed and inserted in the rabbit’s common carotid artery and common jugular vein.

Results: The tailor-made 3D-printed AVGs can be implanted in the rabbit’s neck vessels with ease and function in vivo. The surgical procedure was quick, and no suture was required. The blood loss was minimal, and no hematoma was noted at least one week after the surgery. The blood flow velocity within the implanted AVG was 14.9 ± 3.7 cm/ sec.

Conclusions: Through the 3D printing technology, the AVG can be tailored to fit the specific vessel size. This kind of 3D-printed AVG is functioning in vivo, and our results realize personalized vascular implants. Further studies conducted in large animal models are warranted to validate our promising results.

POI021
The Association of Transition-to-Dialysis Planning and Healthcare Resource Use and Mortality in Patients with ESRD
Insuya B. Poonawalla,1 Kanchan Barve,1 Meghan M. Cockrell,1 Amal Agarwal,2 Adrianne W. Casebeer,1 Yong Li,1 1Humana Healthcare Research, Inc., Louisville, KY; 2Humana Inc, Louisville, KY.

Background: The onset of ESRD is associated with poor outcomes and high mortality, and the role of transition-to-dialysis planning is not well understood. We evaluated the association between dialysis transition planning factors such as nephrologist care, vascular access placement, and place of index dialysis, with inpatient (IP) stays, emergency department (ED) visits, and mortality.

Methods: This retrospective study used the Humana Research Database to identify 7,026 patients, 19-89 years of age, diagnosed with ESRD between 1/1/17 and 12/31/17, enrolled in a Medicare Advantage Prescription Drug plan, with ≥12 months of continuous enrollment pre- and post-index date (i.e., first evidence of ESRD). Patients with a kidney transplant indication, hospice election, or dialysis pre-index were excluded. Transition-to-dialysis planning was defined as optimal, partial, or unplanned (Table 1). IP stays, ED visits, and mortality were evaluated within 12 months post-index.

Results: The cohort was 41% female, 66% White, with an average age of 70 years. An optimally planned, partially planned, and unplanned transition to dialysis occurred for 15%, 34%, and 44% of the ESRD cohort, respectively. Among patients with pre-index CKD stages 3a and 3b, 64%, and 55%, respectively, had an unplanned dialysis transition. For patients with pre-index CKD stages 4 and 5, 68% and 84%, respectively, experienced planning prior to dialysis initiation. In adjusted models, patients with partially or optimally planned transition to dialysis were 57% to 72% less likely to die, 20% to 37% less likely to experience an IP stay, and 80% to 100% more likely to experience an ED visit than patients with an unplanned transition. Higher ED utilization with planned transition was attributed to longer time to mortality, allowing more time for healthcare utilization.

Conclusions: A planned transition to dialysis was associated with improved outcomes and lower mortality. Targeting care coordination for patients with CKD stages 3a/3b may help slow disease progression and ensure a planned, safer transition to dialysis.

Prediction of Stenosis in Arteriovenous Fistula Using Video Image Analysis
Fansan Zhu,1 Lin-Chun Wang,1 Alhaji Cherif,2 Ohnmar Thwin,1 Lela Tisdale,1 Xia Tao,1 Paulo Panque Galuzio,1 Norbert Shihtaynberg,2 Dean C. Preddice,2 Peter Kotanko,1,3 1Renal Research Institute, New York, NY; 2Azura Vascular Care, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We developed a video image processing (VIP) technique with frequency domain analysis to predict stenosis in AVF. The study aimed to evaluate whether the degree of stenosis can be assessed using parameters from frequency domain signal analysis.

Methods: We employed VIP in 100 hemodialysis patients (age 63.3 ±14.1 years, 47 females) prior to endovascular arteriovenous fistula (AVF) interventions. A 1-minute video of the AVF area was recorded using a smartphone (Fig 1). We constructed time series based on pixel changes between two consecutive video frames (Fig 2-A) and used Fast Fourier Transform (FFT) to transform the time domain signals into the frequency domain (Fig 2-B). Parameters in the frequency domain included maximal (Max) and minimum (Min) amplitude, and frequency (FMax and FMin). M2 was calculated by the squared ratio of the Max-to-median magnitude. The degree of AVF stenosis (%ST) was determined by angiography, the access flow (AF) by thermodilution (HVT100; Transonic Systems Inc., Ithaca, NY, USA).

Results: Data from 98 patients were analyzed. %ST was categorized into three groups: 66% stenosis (n=8), 70-80% (n=76), and 90% (n=14). AF correlated with %ST. Max, FMax, and M2 were associated with %ST (Table 1). An algorithm was developed to predict degree of %ST based on patient characteristics and parameters of frequency domain analysis. In the respective three %ST groups the sensitivities to detect AVF stenoses were 88%, 86%, and 90%, and the specificities 99%, 82%, and 98% (Table 1).

Conclusions: VIP applied to videos taken with a smartphone may provide a contact-free method to estimate the degree of AVF stenosis. Validation studies in independent cohorts are needed to further assess the diagnostic capability of the proposed method.
Catheter-Related Bloodstream Infection Incidence and Associated Mortality Risk: Analysis of Merged USRDS, Medicare Claims

Kenneth Massey,
Krithika Rajagopalan,
Aaron Grossman,
Paul Chew,
Cormedic, Berkeley Heights, NJ, 
Antilitks Inc, Dover, MA.

Background: Despite policy and provider initiatives, nearly 80% of end-stage-renal-disease (ESRD) patients initiate hemodialysis (HD) with a central venous catheter (CVC). However, CVCs may elevate risk of catheter hub contamination resulting in catheter-related blood stream infections (CRBSIs) and potentially serious consequences. This analysis aims to estimate the incidence, risk, and associated mortality of CRBSIs among CVC-dependent HD patients in the US.

Methods: A propensity score matched case-control analysis of 2013-2017 linked data from the United States Renal Data System (USRDS), dialysis organizations (e.g., AVP Network), and Medicare claims was conducted. Occurrence of CRBSI and associated mortality among incident CVC-dependent HD patients between 2014-2016 with a 1-year pre- and a 1-year post-index were assessed. CRBSI case group index date was the first date of occurrence of any of the following post CVC insertion: ICD-9-CM 999.32, T902.11x; 999-31, T80218x and sepsis/bacteremia diagnosis within ±3 days of hospitalization; sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections within ±3 days of hospitalization. Non-CRBSI control group was identified by an assigned index date (i.e., CVC insertion date ± median days to CRBSI reported in CRBSI-case group). Frequency, mean, median, and chi-square tests assessed group differences. Adjusted cox proportional hazards models examined time to CRBSI and time to mortality post CRBSI.

Results: Of the 55,727 CVC-dependent HD patients (mean age 67.8, 45% female), nearly 29% (n=15,882) developed a CRBSI (median time, 69 days); 54% (n=8,393), 67% (n=10,327), and 80% (n=12,705) occurred within 90, 180 and 365 days of CVC insertion, respectively. After CRBSI occurrence, 40% and 50% died within 60 days and 180 days, respectively. CRBSI patients also had a significantly lower median survival (25.1 vs. 37.3 months) compared to non CRBSI patients [hazard ratio: 0.74, 95% CI: 0.71-0.76].

Conclusions: CRBSIs occur in a third of CVC-dependent HD patients, with over half of the initial infections occurring within 90 days of CVC insertion. Patients with CRBSI had a higher risk of death compared to patients without CRBSI; with a 40% mortality within 60 days post-CRBSI.

Vascular Access in Kidney Transplant Patients with Allograft Failure Returning to Hemodialysis

Molly Fisher,
Aniruddha R. Gone,
Linda Mathew,
Crystal K. Jobson,
Enver Akallu,
Michele H. Mokrzycki,
Tanya S. Johns,
Montefiore Medical Center, Bronx, NY; Albert Einstein College of Medicine, Bronx, NY.

Background: Central vein catheters (CVC) are the predominant vascular access (VA) in incident hemodialysis (HD) patients and are associated with worse outcomes compared to arteriovenous (AV) access. Limited data exist on VA type and association with outcomes in kidney transplant recipients (KTR) with allograft failure. We aimed to determine factors associated with VA type among KTR with allograft failure who return to HD.

Methods: We performed a retrospective study of 147 KTR >18 years with allograft failure between 2010-2021 at an academic hospital in the Bronx, NY. KTR with immediate allograft failure or <1 month of HD following allograft failure were excluded. Data was collected on pre-transplant dialysis modality, vintage, and VA type. Data at allograft failure included sociodemographics, comorbidities, clinic visits, VA type. Descriptive analyses and logistic regression were performed to evaluate factors associated with VA among KTR who return to HD.

Results: At allograft failure, mean age was 53 years (SD 15), 62% were men and 46% were of Black race. Pre-transplant, 91.8% patients were on HD, 2.7% were on peritoneal dialysis (PD), and 5.5% were not on dialysis. Mean vintage was 4.6 years (SD 4.4). Pre-transplant VA included AV access in 87.7% and CVC in 4.1% of patients. At allograft failure, 82.3% and 17.7% KTR initiated HD with an AV access and CVC, respectively. Compared to pre-transplant HD patients, those on PD or who received a preemptive transplant were less likely to initiate HD with an AV access at time of allograft failure (80.6% vs 50% vs 12.5%, p<0.001). KTR were less likely to initiate HD with an AV access for each year increase between the time of transplant and allograft failure (OR 0.8, 95% CI 0.69-0.94). Sociodemographics, comorbidities and number of clinic visits 1 year prior to allograft failure were not associated with VA. One year mortality was 10.7% in KTR initiating HD with a CVC vs 3.4% in those with an AV access (p=0.12).

Conclusions: The majority of KTR with allograft failure returned to HD with an AV access. CVC use was higher in those with longer allograft survival, previously on PD or who received a preemptive transplant, highlighting a need for transition of care optimization. Larger studies are needed to determine if VA type is associated with mortality in this population.
The average number of prior vascular accesses (defined as venous access or arteriovenous fistula/graft) in patients prior to IOCV was 2.6 ± 1.7 (range 1–9), 9 (23.1%) had two prior accesses, and 30 (76.9%) had >3 prior accesses. 5 (12.8%) patients had >1 prior IOCV procedure. 5 (12.8%) patients had complete superior vena cava occlusion. 17 (43.6%) patients had failed AVF/AVG and 2 (5.1%) had failed transmural venous access. Technical success rate was 100% with no complications.

Conclusions: The RIJ vein is the most effective and durable site for long-term hemodialysis access. Occlusion, stenosis of this vein can lead to a downward spiral of access failure with venous hypertension leading to inferior vena cava stenosis or occlusion. These approaches are associated with high rates of dysfunction as well as infection, catheter migration and thrombosis. The transhepatic approach can also cause life-threatening intraperitoneal hemorrhage. The use of IOCV alleviates the need to sacrifice subsequent veins and allows for the occluded RIJ to be re-accessed as many times as needed via the femoral vein. Our data provides further evidence in support of the safety and efficacy of IOCV for long-term hemodialysis access in ESRD patients.

PO1029
Machine Learning for the Prediction of Arteriovenous Fistula Failure
Suman K. Lanna,1 Rishi Razdan,2 Murat Sor,2 Eyal Barzel,1 Caitlin Monaghan,1 Joanna Willetts,1 Sheetal Chaudhari,1 Nancy McLaughlin,1 Hanjie Zhang,3 Peter Kotanko,1 Jeffrey L. Hymes, John W. Larkin,1 Len A. Usvyat,4 Frank J. W. Maddux,4 Fresenius Medical Care, Waltham, MA; 4Aurora Vascular Care, Malvern, PA; 4Icahn School of Medicine at Mount Sinai, New York, NY; 4Fresenius Medical Care North America, Waltham, MA.

Background: Arteriovenous access failures are a frequent finding in hemodialysis patients with arteriovenous (AV) fistulas and grafts. Of great concern is aneurysm rupture that may result in fatal hemorrhage. To that end we used artificial intelligence (AI) to automatically evaluate vascular access aneurysms.

Methods: We collected images of a diverse range of AV vascular accesses using mobile devices. Vascular access experts adjudicated the images and diagnosed the severity of AV fistula and graft aneurysms. We then randomized the images for training (70%) and validation (30%). We trained a convolutional neural network (CNN) utilizing Amazon SageMaker platform. CNN performance was measured by the area under the receiver operating characteristics (ROC) curve in the validation images.

Results: We collected 1,341 AV access images in patients dialyzed at 20 Renal Research Institute clinics in six U.S. states. The adjudication of images identified 1,093 not advanced and 248 advanced aneurysms; examples are shown in Figure 1. With the validation images, we achieved an area under the ROC curve of 0.96. Considering different probability thresholds for advanced aneurysm, if threshold is 0.37, we achieved sensitivity of 80%, specificity of 95%, false positive rate of 5%, precision of 99% if threshold is 0.7, 70%, specificity of 66%, specificity of 99%, false positive rate of 1%, precision of 92%.

Conclusions: Our solution of applying advanced AI technologies achieved very high sensitivity, specificity, precision, and a low false positive rate. The CNN could assist the clinician with actionable information and improve clinical outcomes.

Funding: Commercial Support - Fresenius Medical Care North America

**Evaluation of a Wearable Device for Continuous, Noninvasive Monitoring of Hematocrit Levels in Hemodialysis Patients**

David J. Kuraguntla, Forrest Millet. Alo, San Francisco, CA.

**Background:** Maintenance of euovolemia is a major challenge for hemodialysis patients, who account for a combined 5.5M annual hospital days. Clinical outcomes could be improved, and healthcare costs lowered, by enabling better management of fluid status and anemia, which is common among ESRD patients. This study presents a novel wearable device, SmartPatch, that uses multi-wavelength photoplethysmography (PPG) and other sensors to measure blood hematocrit (Hct), a key metric for monitoring fluid status and anemia. The SmartPatch is a component of a novel Remote Monitoring System (RMS) that facilitates secure data transmission and analysis and generates actionable alerts. Data demonstrating the feasibility of the RMS were previously presented at Kidney Week 2019 (Kuraguntla et al.). The aim of this study was to evaluate the system’s ability to accurately and precisely measure Hct in a real-world dialysis setting.

**Methods:** 14 ESRD patients with arteriovenous fistulae currently undergoing dialysis were recruited to participate in this study. Each of these patients had a SmartPatch device placed on the skin over their fistula at each of three dialysis sessions two weeks apart. Reference Hct measurements were taken immediately before and after the session, times to coincide with SmartPatch data recordings. A total of 83 sets of multi-channel PPG data were recorded and analyzed to determine the accuracy and precision of Hct measurement.

**Results:** The RMS measured Hct with root-mean-square error (RMSE) of 2.13 Hct compared to reference values obtained from a Sysmex XN-1000 blood analyzer. The standard deviations for each read on the same patient—the same device—were computed and averaged, weighted by group size, as a measure of precision. The RMS measured Hct with a mean standard deviation of 1.15 Hct. These error and standard deviation values compare favorably to available point-of-care devices like the Hemocue Hb 201+, which has been reported to measure Hct with a mean of 4.32-4.81 Hct and standard deviation of 1.56-3.88 Hct.

**Conclusions:** The results of this study illustrate the ability of the wearable SmartPatch to non-invasively measure blood Hct in ESRD patients with AV fistulae, to a degree of accuracy and precision that may outperform available point-of-care methods. This study also demonstrated the efficacy of the end-to-end Remote Monitoring System.

**Impact of a Change in Vascular Access Flow Volume After Percutaneous Transluminal Angioplasty on Cardiac Function**

Koji Hashimoto, Makoto Harada, Youseke Yamada, Yuji Kamijo. Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan.

**Background:** Vascular access (VA) is necessary for patients on hemodialysis, and percutaneous transluminal angioplasty (PTA) is a useful treatment for maintaining VA function. PTA immediately increases the VA flow volume, which can affect cardiac function. We investigated the relationship between changes in VA flow volume and cardiac function in patients who underwent PTA.

**Methods:** This was a single-center retrospective observational study, including patients who underwent PTA between June 2016 and August 2016. VA flow volume and cardiac function were measured by sonography before and 1 hour after PTA.

**Results:** This study included 50 PTA procedures in 50 cases. PTA significantly increased the median VA flow volume from 445 (range, 150-1229) to 725 (350-1268) mL/min. Although the ejection fraction and diameter of the inferior vena cava were unchanged, the cardiac output (CO) and cardiac index increased significantly in most cases. Surprisingly, the CO was obviously decreased in 18% of cases despite the increased VA flow volume. In this atypical group, a high CO before PTA was found to be a significant factor for the decrease in CO by PTA.

**Conclusions:** In most cases, both VA flow volume and CO were increased by PTA, whereas in some cases, the CO was decreased despite increase in VA flow volume. This atypical phenomenon may be due to the insufficient adaptive response in the peripheral artery and heart and could predict risks for future cardiac events. Therefore, it is important that such patients are carefully followed up.
Flow through the accessory vein before the ligation.

Cessation of the blood flow through the accessory vein after the ligation.

PO1035
Feasibility of Treating Stenotic Fistula Lesions with a Drug-Coated Balloon Prior to Using a Standard High Pressure Balloon

Sylvester Barnes,1,2 Edward Hines Junior VA Hospital, Hines, IL; Loyola University Chicago, Chicago, IL.

Background: Hemodialysis access maintenance is a major cost expenditure for dialysis care. Patients often require multiple procedures per year, often treating the same access lesion in a AVF / AVG. A large proportion of stenotic lesions develop secondary to neointimal hyperplasia. Standard treatment has been angioplasty using high pressure non-compliant balloons. Recently drug coated balloons (DCB), coated with the medication paclitaxel, to help decrease neointimal hyperplasia, have been used in dialysis access treatment. The safety profile and efficacy have been proven to decrease lesion reoccurrence at 6 months when compared to regular angioplasty. Traditionally the recommendation for use of DCB is to follow after the lesion has been primarily dilated with a high-pressure balloon (HPB).

Methods: For DCB use the manufacture recommends pretreatment of the lesion with a HPB followed by secondary DCB treatment. This Arthur decided to modify the technique and treat lesions needing angioplasty with DCB first (example in figure 1) and only secondary treatment with HPB if there was not sufficient resolution of the lesion / balloon inflation to achieve less than 30% residual stenosis. Observational data is being tracked for patients undergoing fistulograms to provide a single center observational prospective cohort to look into this issue.

Results: Currently 11 patients with 15 total lesions have undergone this modification of treatment in the past 9 months, with 3 of the 11 patients having repeat fistulograms post treatment. Nine of the 11 patients required no HPB follow up. One of the 11 patients suffered a cephalic arch rupture and required stent graft placement.

Conclusions: Early data from this observational study shows that treatment of a stenotic lesion using a DCB as the only treatment is effective in the majority of cases to achieve full lesion angioplasty. Preliminary results indicate no change in long term efficacy in the DCB lesion treatment.

PO1036
Predictors of Vascular Access Thrombosis in Maintenance Hemodialysis Patients: An Historic Cohort Study

Rita Verissimo,1,2 Luís Leite de sousa,1,3 Tiago J. Carvalho,1,4 Artur P. Mendes,1,2 1DaVita Vascular Access Center - Lisbon, Lisbon, Portugal; 2DaVita Sacavém Hemodialysis Unit, Lisbon, Portugal; 3DaVita Sintra Hemodialysis Unit, Lisbon, Portugal; 4DaVita Cascais Hemodialysis Unit, Lisbon, Portugal.

Background: Vascular access (VA) thrombosis is a known complication in patients with end-stage kidney disease on hemodialysis (HD), but its risk factors are not completely established. We performed a study with the aim of ascertaining risk factors for VA thrombosis.

Methods: A multicenter retrospective cohort study was performed in three HD units to determine VA thrombosis rate and associated risk factors in maintenance HD patients, from July 2019 to April 2021. Descriptive statistics were calculated and expressed as median (IQR) or count (%). Univariate and multivariate logistic regression was used to calculate the adjusted odds ratio (aOR) with 95% CI for the variables associated with VA thrombosis.

Results: From a total of 178 maintenance HD patients, there were 30 (16.9%) VA thrombosis during follow-up. Our cohort had a median of 71 years (61-80), 59.6% (n=106) were male, were on HD for a median of 63.52 months (37.58-98.87), 37.6% (n=67) had diabetes, 66.1% (n=107) cardiovascular disease and 35.6% were on anticoagulant or antplatelet agents. As to the VA, 87.1% (n=155) had arteriovenous fistulas (AVFs) and 28.1% (n=50) had history of previous percutaneous or surgical interventions. When comparing cases that led to thrombosis to VAs that maintained patency, thrombosis was more likely in arteriovenous grafts (AVGs) versus AVFs (60.9% vs 19.3%, P< 0.001), in VAs that had previous percutaneous or surgical interventions (34% vs 10.2%, P<0.001), and had a AV flow (Qa) slope ≥ 25% or Qa value < 500ml/min, excluding radiocephalic AVFs (30.4% vs 11.7%, <0.001) and those with spkV’ < 1.4 (40% vs 11.2%, P<0.001). Multivariate analysis risk factors independently associated with VA thrombosis were AVGs [aOR 13.35 (4.38-40.74), P<0.001], Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs [aOR 5.00 (1.76-14.18), P<0.003], and spkV’ <1.4 [aOR 8.23 (2.90-23.35), P<0.001]. The model had a Nagelkerke R2 of 42.1%, Hosmer-Lemeshow goodness-of-fit test performed well (χ2 = 0.215, df=3, P=0.975) and showed very good discriminatory ability [AUROC (95% CI) 0.85 (0.77-0.94)].

Conclusions: Our study showed AVGs, Qa slope ≥ 25% or Qa < 500ml/min, excluding radiocephalic AVFs, and spkV’ < 1.4 were independent predictors of VA thrombosis. Interestingly, patients’ demographic characteristics and comorbidities were not associated with VA thrombosis.

PO1037
Efficacy and Safety of Plastic Cannulae Compared with Metal Needles in the Initial Use of an Arteriovenous Fistulae in Incident Hemodialysis Patients: A Randomized Controlled Study

Sung gunsu Kim, Hoi Woul Lee, Jwa-kyung Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Successful cannulation of an arteriovenous fistula (AVF) is important in patients starting hemodialysis (HD). Metal needles have been used for decades, but the usefulness of plastic cannulae has recently been demonstrated as a new technique.

Methods: As a prospective, randomized study, eligible patients were randomized into two groups in a 1:1 ratio (n=45/group). Maturation of the AVF was confirmed by Doppler ultrasound. The primary endpoint was the initial cannulation failure rate, defined as the failure of successful completion of three consecutive dialysis sessions. The secondary endpoints were time for hemostasis at the end of HD, degree of patients’ pain, degree of cannulation difficulty felt by the nursing staffs, and achieving optimal HD adequacy.

Results: The mean time from AVF creation to the first cannulation was 48.1±16.7 days. A total of 17 cases of cannulation failure occurred, and the failure risk tended to be higher in the metal needle group than the plastic cannula group (HR 2.6, 95% CI 0.95-7.41) after adjusting for age, gender, comorbidities, and location. The overall incidence of vessel injury was higher and time for hemostasis was significantly longer in the metal group than the plastic group. The use of plastic cannula was associated with better HD adequacy compared to metal needle. However, the patients’ pain score (P=0.004) and nursing staff’s cannulation difficulty score (P=0.084) were higher in the plastic group, emphasizing the great importance of practice using plastic cannulae.

Conclusions: The vascular outcomes of plastic cannulae were much favorable compared to metal needles in incident HD patients. The use of plastic cannulae could be a new and innovative way to improve the quality of dialysis.

Alignment Between Patient and Provider Perspectives on Hemodialysis Vascular Access Decision-Making: A Qualitative Study

Angela R. Schneider,1 Pietro Ravani,1 Kathryn M. King–Shier,1 Robert R. Quinn,1 Jennifer M. MacRae,1 Matthew J. Oliver,2 Swapnil Hiremath,2 Matthew T. James,1 Meghan J. Elliott.1 1University of Calgary, Calgary, AB, Canada; 2University of Ottawa, Ottawa, ON, Canada; 3University of Toronto, Toronto, ON, Canada.

Background: Recent updates to the KDOQI Clinical Practice Guideline for Vascular Access emphasize attaining the “right access, in the right patient, at the right time, for the right reasons”. Yet, how patients, their caregivers, and healthcare providers integrate medical factors with care preferences in patient-centered vascular access decision making is unknown. We sought to explore the extent to which these diverse perspectives align in hemodialysis vascular access selection.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving maintenance hemodialysis via an arteriovenous fistula or catheter, their informal caregivers, and their hemodialysis care providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, content analysis approach.

Results: While participants across roles shared perspectives related to vascular access decision making, we identified several areas where views diverged. Participants acknowledged the importance of decisional timing and readiness, the iterative nature of decision making, and a desire for vascular access selection to be a shared decision. Perspectives differed in the following key aspects: 1) priorities for vascular access type – providers’ preferences for fistulas and physiological optimization contrasted with patients focus on quality of life; 2) provider involvement in the decision – patients desired guidance from their trusted providers, whereas care providers tried to avoid unduly influencing the decision; 3) informational needs – tools and resources offered by the care team may not meet patients’ need for pragmatic, experiential knowledge about vascular access options.

Conclusions: While patients and providers identified common perspectives related to the nature and timing of the vascular access decision, conflicting priorities and preferences may impact the decisional outcome. This study highlights opportunities to address decisional conflicts and enable shared decision making in vascular access selection.

Vascular Access Selection Among People Receiving Hemodialysis: A Qualitative Study of Shared Decision-Making

Meghan J. Elliott,1 Pietro Ravani,1 Robert R. Quinn,1 Jennifer M. MacRae,1 Shannon Love,1 Matthew J. Oliver,1 Swapnil Hiremath,2 Matthew T. James,1 Kathryn M. King–Shier.1 1University of Calgary, Calgary, AB, Canada; 2University of Ottawa, Ottawa, ON, Canada; 3University of Toronto, Toronto, ON, Canada.

Background: The vascular access decision process for people receiving maintenance hemodialysis involves weighing the likelihood of having a functional access with its associated risks. How patient and clinician preferences are integrated alongside best evidence to make joint vascular access decisions is unclear. We aimed to explore how such decisions are made from the perspectives of patients, their caregivers, and their kidney care providers.

Methods: In this qualitative descriptive study, we purposively sampled patients receiving in-centre hemodialysis for >3 months via either an arteriovenous fistula or a central venous catheter, their informal caregivers, and their hemodialysis care providers. We conducted semi-structured interviews by telephone or in person with 19 patients, 2 caregivers, and 21 healthcare providers (8 nephrologists, 7 hemodialysis nurses, 6 vascular access nurses). We coded transcripts in duplicate and generated themes through an inductive, thematic analysis approach.

Results: Participants described a decisional hierarchy, whereby decisions regarding vascular access were predicated on upstream decisions (i.e., dialysis initiation, transplantation, home dialysis) that were preference sensitive and prioritized over vascular access type. Upon reaching a decision for hemodialysis, vascular access decision making was influenced by the following: 1) preferences for kidney replacement therapy, including anticipated timeline to transplantation or transition to home dialysis modalities; 2) urgency and timing of dialysis need, where urgent starts undermined expressed preferences; 3) limitations of individualized decisions, as when preferences and practicalities diverged; 4) occasions to re-visit the vascular access selection; and 5) availability of support for vascular access decision making and the decisional outcome.

Conclusions: Although patients and care providers prioritized upstream decisions, several influences on vascular access decision making were identified once the decision for hemodialysis was made. These findings can inform approaches to integrating shared decision making in dialysis and vascular access selection.
PO1041 Feasibility of Creation of an Endovascular Arteriovenous Fistula in Patients Undergoing Preoperative Vascular Mapping
Alian Albalas, Salam Madi, Anmar Almechmi, Michelle L. Robbin, Michael Allon. The University of Alabama at Birmingham, Birmingham, AL.

Background: The endovascular arteriovenous fistula (endoAVF), a novel percutaneous technique of AVF creation, was approved by the Food and Drug Administration in 2018, and has been placed in a small number of U.S. hemodialysis patients. It is unknown how often patients with advanced chronic kidney disease have vascular anatomy suitable for endoAVF creation. The goal of the present study was to determine the proportion of patients with a vascular anatomy suitable for endoAVF creation, and to assess patient characteristics associated with such suitability.

Methods: All patients referred for vascular access placement at a large academic medical center underwent standardized preoperative sonographic vascular mapping to assess suitability for an AVF. During a two-year period (March 2019 to March 2021), we assessed the suitability of the vessels for creation of an endoAVF. We then compared the demographic characteristics, comorbidities, and vascular mapping measurements between patients who were or were not suitable for an endoAVF.

Results: During the study period, 223 patients had preoperative vascular mapping results suitable for creation of a surgical AVF. Of these, 140 patients (63%) were also suitable for an endoAVF. Patients with a vascular anatomy suitable for an endoAVF were younger (age 55±15 vs 60±14 years, p=0.01), but similar in sex, race, diabetes, hypertension, coronary artery disease, and peripheral artery disease.

Conclusions: Among patients with chronic kidney disease and vascular anatomy suitable for a surgical AVF, 63% are also suitable for an endoAVF. Older patients are less frequently suitable for an endoAVF.

Funding: NIDDK Support

PO1042 Endovascular Arteriovenous Fistula Closure with Covered Stent Placement

Introduction: WaveLinQ™ endovascular arteriovenous fistula (EndoAVF) system is a new technique that uses radiofrequency energy to create AVF. It has been gaining popularity as it avoids major surgery, has less recovery time and better success rates than surgical AVF creation. Pseudoaneurysm, dissection of brachial artery, intra-procedure brachial artery thrombosis, device embolization, and steal syndrome are described complications of the procedure. We present a case of EndoAVF creation complicated with forearm swelling and its successful management.

Case Description: Patient is a 45 y/o male with End-Stage Renal Disease due to Hypertensive Nephrosclerosis and obstructive uropathy, now s/p failed kidney transplant, currently on Percutional Dialysis (PD). PD was failing and decision was made to transition patient to hemodialysis (HD). In preparation of HD, AVF using WaveLinQ EndoAVF system was placed in right forearm between intramusosal artery and vein with coiling of the medial brachial vein. A week after fistula creation, patient developed right forearm swelling with numbness and tingling. Fistulogram demonstrated stenosis in the perforator vein with poorly developed cephalic vein and diversion of blood flow to multiple superficial collateral veins in the forearm causing swelling. Multiple attempts at balloon assisted maturation of the cephalic outflow were unsuccessful. Due to persistent forearm swelling with discomfort a decision was made to close the fistula. A 5 x 15 mm self-expanding ViaBahn™ stent was deployed in interosseus vein across the anastomosis to close the fistula. Post fistula closure, arm swelling resolved completely.

Discussion: Covered stents have been used in the maintenance of hemodialysis AVF for various purposes including dialysis access stenosis, central vein stenosis, pseudoaneurysm exclusion and angioplasty associated vascular rupture that cannot be repaired using balloon catheter. This is the first reported case of successful use of covered stent graft to occlude anastomosis to close EndoAVF. As these fistulae are created often, more novel complications will be encountered. It will be imperative for interventionalists to find creative solutions as well as actively report the successful management of complications.

PO1043 Long-Term Prognosis of Vascular Access in Hemodialysis Patients with Systemic Lupus Erythematosus
Chih-Ching Lin,1,2 Taipei Veterans General Hospital, Taipei, Taiwan; National Yang Ming Chiao Tung University - Yangmings Campus, Taipei, Taiwan.

Background: Patients with systemic lupus erythematosus (SLE) have a higher risk of vascular complications.

Methods: This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation. This retrospective cohort study is aimed to analyze the differences in the risk of arteriovenous fistula or graft (AVF/AVG) dysfunction in hemodialysis (HD) patients with and without SLE from Taiwan Nationwide Health Insurance Database over a 10-year period. AVF/AVG dysfunction is defined as occurrence of the first episode of intervention after vascular access creation.

Results: Totally, 1366 HD patients with SLE had higher incidence rates of AVF/AVG dysfunction than 4098 non-SLE HD patients in the following 4 periods, (1) after 1 year (incidence rates were 15.21% and 13.01% respectively; subdistribution hazard ratio (SHR) = 1.16; P = 0.007), (2) 1st-to-10th-year period (15.36% and 13.25%; SHR = 1.16; P = 0.007), (3) 5th-to-10th-year period (11.91% and 8.1%; SHR = 1.42; P = 0.003), and (4) overall period (23.53% and 21.66%; SHR = 1.19; P = 0.027). There were significantly higher incidence rates of AVF/AVG dysfunction in SLE patients during the long-term follow-up period.

Conclusions: In conclusion, regular surveillance of vascular access function by clinical examination after 1 year, especially during 5 to 10 years, is needed to improve vascular access patency and dialysis adequacy in SLE patients undergoing maintenance hemodialysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

349
Results: Median age was 71 years, 64% were men, 43% had diabetes, and 33% started hemodialysis urgently. Half (51%) underwent a first arteriovenous access creation: a fistula in 21,240 patients, created a median of 5 months (IQR, 2-12), and a graft, in 741 patients, 3 (1-8) months before hemodialysis initiation. Among patients with a first fistula attempt, 30% underwent at least one vascular access re-intervention before hemodialysis initiation, versus 21% among those with a first graft attempt (p=0.001). The types of intervention substantially differed according to vascular access (Figure). When dialysis start was urgent, catheter was used in 43% of patients in both access groups (p=0.86); when it was not, catheter was used in 12 and 14% of patients with a first fistula or graft attempt, respectively (p=0.15).

Conclusions: In incident hemodialysis patients in France, fistula is typically the first attempted arteriovenous access. Early arteriovenous access creation prevents from using catheter at dialysis initiation in a majority of patients, but requires close monitoring of potential complications.

Incidence of De Novo Central Vein Stenosis in Hemodialysis Patients Following Their First Tunneled Central Vein Catheter (CVC) Placement

Alian Albaiṣ, Salam Madi, Ammar Almehmi, Michael Allon. The University of Alabama at Birmingham, Birmingham, AL.

Background: Central vein stenosis is a common complication in hemodialysis patients following tunneled CVC insertion. Little is known about its incidence, association with patient characteristics, or relationship with duration of CVC placement. We systematically evaluated central vein stenosis in hemodialysis patients receiving their first CVC at a large medical center.

Methods: All new hemodialysis patients underwent an ultrasound prior to their first CVC at a large medical center. The frequency of central vein stenosis was progressively higher with greater duration of CVC placement prior to exchange.

Results: During the study period, 273 patients underwent exchange of a tunneled internal jugular vein CVC preceded by a catheterogram/venogram. Of these, hemodynamically significant central vein stenosis was observed in 36 patients (13%). Central vein stenosis was not associated with patient age, sex, race, diabetes, hypertension, coronary artery disease, peripheral artery disease or CVC laterality (Table 1). The frequency of central vein stenosis was progressively higher with greater duration of CVC placement, being 10%, 12%, 24%, and 28% in patients with <3 months, 3 to 6 months, 6 to 9 months and >9 months of catheter dependence, respectively (p=0.025).

Conclusions: Among incident hemodialysis patients receiving their first tunneled internal jugular CVC, the overall incidence of hemodynamically significant central vein stenosis was 13%. The likelihood of central vein stenosis was directly associated with the duration of CVC dependence.

Hospitalization Risk and Long-Term Complications Associated with Catheter-Related Bloodstream Infection Among Hemodialysis Patients

Krithika Rajagopalan,1 Kenneth Massey,2 Srinivasan Rajagopalan,1 Stephen Imperiale-Hagerman,1 Paul Chew.1,2 Antikits Inc, Dover, MA; 3Cormedix, Berkeley Heights, MA.

Background: Central venous catheters (CVC) are frequently required for vascular access in hemodialysis (HD) and are commonly associated with catheter-related bloodstream infections (CRBSIs). CRBSIs may have devastating consequences leading to increased hospitalizations, and long-term complications such as stroke, myocardial infarction (MI), heart failure (HF), and endocarditis, among others. This analysis explores the risk of CRBSI-associated hospitalizations and long-term complications among HD patients.

Methods: A 1:1 propensity score matched case-control analysis was conducted using merged data from United States Renal Data System (USRDS), CROWNWeb (dialysis organizations), and Medicare claims database (2013-2017). All CVC-dependent HD patients from 2014-2016 with a 1-year pre- and ≥1-year post-index period were included. CRBSI was defined as a composite measure of its ICD codes or sepsis/bacteremia diagnosis with hospitalization or without occurring pneumonia, gangrene, or urinary tract infections and hospitalization. An assigned index date (i.e., CVC insertion date + median days to CRBSI reported in CRBSI-case group) was used to identify non-CRBSI patients. CRBSI/non-CRBSI group differences were described using frequency, mean, median, chi-square, and t-tests. At 1-year post CRBSI, adjusted differences in hospitalizations and hospital days and time to long-term complications were modeled using generalized linear models cox proportional hazard models, respectively.

Results: CRBSIs result in higher 1-year incremental rates of: stroke (6.6%), MI (9.2%), HF (13.4%), PVD (13.6%), and endocarditis (9.4%). Mean number of hospitalizations and hospital days were 3.79 and 25.0 days for CRBSI, and 1.96 and 5.86 days for non-CRBSI patients, respectively. Mean hospitalizations and hospital days were significantly higher for CRBSI vs. non-CRBSI patients (p<0.05) at 1-year post-CRBSI. Hazard ratios for CRBSI patients were: stroke (1.64, 95% CI 1.53-1.75), MI (2.56, 95% CI 2.37-2.78), HF (2.01, 95% CI 1.88-2.14), and endocarditis (13.42, 95% CI 10.97-16.42).

Conclusions: Results show HD patients with CRBSIs incur a significant morbidity burden due to increased hospitalizations, hospital days, and long-term complications such as stroke, MI, HF, PVD, and endocarditis.

Hemorrhagic Shock due to Cutting of the Tunneled Dialysis Catheter

Lucia Bogdan,1 Tushar S. Malavade.2,3 University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; 2Toronto General Hospital, Toronto, ON, Canada.

Introduction: Bleeding is a relatively rare complication of dialysis CVC overall. Confluence of factors such as: vascular access, patient characteristics, and emergency situation can augment the risk of bleeding. We present a case of a 79-year-old female with a history of dementia who accidentally cut a tunnelled CVC proximal to the Y. This case demonstrates the risk of significant hemorrhage when a tunnelled CVC is damaged at this location and need for early recognition and control of bleeding. It also highlights important patient safety considerations given the risk of self-inflicted trauma in patients with dementia and language barrier for communication.

Discussion: To our knowledge, this is the first report of a cut tunnelled CVC proximal to the Y. We have demonstrated the risk of significant hemorrhage when a tunnelled CVC is damaged at this location and need for early recognition and control of bleeding. It also highlights important patient safety considerations given the risk of self-inflicted trauma in patients with dementia and language barrier for communication.

PO1048

Facial Swelling: Angioedema or Superior Vena Cava (SVC) Syndrome

Moarj A. Qazi,1 Huma Qazi,2 Anne M. Huml,1 Tushar J. Vachharajani.1
Cleveland Clinic, Cleveland, OH; 2Army Medical College, Rawalpindi, Pakistan.

Introduction: Central venous stenosis is a common complication of recurrent central venous catheters (CVCs). Diagnosis can be challenging given its versatile presentation. Facial, unilateral breast or upper extremity swelling and signs of congestion mimicking pulmonary edema can be subtle clues. We describe a case of SVC syndrome that eluded clinicians as angioedema.

Case Description: A 55-year-old African American female with ESRD secondary to Lupus Nephritis (LN) s/p deceased donor kidney transplant, developed allograft failure and restarted dialysis. Upon initiating dialysis and weaning of immunosuppression she had episodes of fever, myalgias, synovitis and pleural effusions thought to be manifestations of lupus flare. Despite restarting immunosuppression, she presented frequently with dyspnea and recurrent bilateral transudative pleural effusions requiring repeat thoracenteses. Her physical exam was notable for swelling of bilateral upper extremities and face with minimal lower extremity edema. Lupus serologies were normal. Echo was unremarkable. CT angiogram (CTA) revealed complete occlusion of the distal superior vena cava (SVC) with extensive collateralization in the chest and abdominal wall.

Discussion: Her initial symptoms were attributed to volume overload and lupus serositis. However, inactive serologies, ongoing immunosuppression, and the transudative nature of the effusion were not consistent with lupus flare. Aggressive UF also failed to prevent recurrent pleural effusion. Given CTA and clinical findings, we concluded that the persistent pleural effusion is a manifestation of the SVC syndrome in our patient. The occlusion of the SVC was below the junction of the arch of the azygos vein. Venous blood flow from the upper body and extremities was shunted into the azygos system and flowed counter-current, returning to the right heart through the inferior vena cava. This resulted in increased hydrostatic pressure in the intercostal veins, contributing to the development of edema of the head, upper chest, bilateral upper extremities, and pleural effusions. Our patient had multiple central venous catheters increasing her risk for SVC syndrome. Clinicians should consider SVC stenosis as a potential cause of recurrent pleural effusions in a dialysis patient.

PO1050

Innovative Care Model for Vascular Access Strategy in AKI in Critically Ill Patients

Korey Bartolomeo, Tarik Hanane, James E. Lane, Tushar J. Vachharajani. Cleveland Clinic, Cleveland, OH.

Background: Central venous catheter (CVC) is the preferred vascular access in critically-ill patients needing kidney replacement therapy (KRT). Non-tunneled CVC (NT-CVC) is frequently selected for bedside placement and provider familiarity. With hemodynamic instability, tunneled CVC (T-CVC), despite its known advantages of lower infection risk, lower mechanical complications, better blood flow rates and patient comfort, is infrequently considered due to competing demands for central vein access and provider inexperience. We report our early experience of building a collaborative training program to improve vascular access approach in the critically-ill patients.

Methods: A single center retrospective study of T-CVC placed in an adult medical ICU between March 1, 2020 and December 31, 2020 by a nephrologist or an intensivist. The T-CVCs were placed in hemodynamically unstable patients for KRT and other continuous therapies. Statistical analysis was limited to assess feasibility and safety of implementing a collaborative procedural service in an academic medical ICU.

Results: A total of 120 CVC related procedures were completed during the study period. 106 were T-CVC placements (68 for KRT, 38 small bore non-KRT), seven T-CVC removals, one difficult NT-CVC for KRT, one T-CVC exchange, one fluoroscopy guided repositioning of NT-CVC, four aborted for suspected central vein occlusion. Twenty-seven T-CVC (23 in COVID-19 positive and 4 for other compelling reasons) were placed at bedside ultrasound guidance and anatomical landmarks without fluoroscopy. A safety pre-procedure checklist was developed for eligibility based on this experience. A minimum of 48-hr sterile blood culture report was essential to proceed. Complex comorbidities included coagulopathic patients. A minimum training competency was established and 2 critical care staff physicians were credentialed during this period. No major complications were encountered.

Conclusions: A collaborative care model between nephrology and medical ICU for T-CVC focused strategy is feasible. T-CVC can be placed safely in a carefully selected critically-ill patient population. Training intensivists with basic procedural skills for T-CVC procedure is achievable over a short period.
worsening sharp, non-radiating chest pain localized at the left hemithorax. Patient refused to eat and vomited for 2 days. Examined a thick mucus possibly blood-streaked; however, no coffee-ground. Stated he had never experienced this chest pain before. He reported not taking any medication at home for pain. On examination there was no cardiac murmurs, no lung abnormalities on auscultation and he had a patent arteriovenous fistula with good thrill and bruit and no signs of stenosis. Had 2 negative troponin levels with serial EKGs without ischemic changes. An echocardiogram that was negative for wall motion abnormalities or any changes in ejection fraction, ruling out an acute coronary syndrome. He had CXR showing curvilinear density projecting over the left upper zone, suggestive of a left upper leaflet metallic device in the left ventricular apex. He was not on hemodialysis before his transplant, he had multiple endovascular procedures including a stent placement to keep a patent AV access. A left upper extremity x-ray showed a left AV access stent fracture; findings were consistent with an embolized fragment from AVG stent. He underwent explant of the stent from AVG, but embolized fragment was not removed by CT surgery. Currently patient is chest pain free and asymptomatic.

Discussion: Stent fractures are commonly seen when they are in arteries, however this is an uncommon event in venous system specially in hemodialysis vascular access. Some of the complication associated with stent fracture are related to in-stent stenosis and central vein stenosis, but this is the first report of chest pain from stent fracture migrated to the left verteicle.

PO1052

Agitated Saline Bubble-Enhanced Ultrasound to Visualize Appropriated Position of Hemodialysis Catheter: Does Catheter Venous Site Matter?

Gessica Sabrine Braga Barbosa, Rayra G. Ribeiro, Jorge L. Espinosa Armijos, Lucia Andrade, Igor Smolentzov, Camila E. Rodrigues. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: The hemodialysis non tunneled catheter (HDC) is the most common access of starting renal replacement therapy. Malposition of catheter is associated with delays in treatment. Agitated saline bubble-enhanced ultrasound (SBUS) has become a new method to visualize the HDC position. Delayed appearance of microbubbles (a 2-second) in the right atrium indicates malposition. Our objective is to analyze the accuracy of SBUS versus right and left internal jugular vein (IJV) HDC insertion, comparing to chest radiography (CR; standard method).

Methods: From December 2019 to May 2021, we evaluated 145 hospitalized patients submitted to HDC insertion in IJV. We compared SBUS with chest radiography (CR); the time spent to perform the CR; complications; patient characteristics; catheter blood flow and quality of dialysis.

Results: Total of 145 patients were analyzed, the median age was 62 years old [50.5-70], and there was no statistical difference between the site of insertion. In RIJV, 91% catheters were placed. AKI was more frequent than CKD (75% vs 25%), except when the site was LJV (46% vs 54%, p<0.05). AKI-related COVID-19 was the most common etiology (54%). The confirmation of catheter placement by SBUS was correlated with position by CR (All: r=0.6603, p<0.0001; RIJV: r=0.7044, p<0.0001; LJV: r=0.6396, p=0.0769). SBUS was highly accurate in identifying adequate location of HDC, specially in RIJV (All: 97.9%; RIJV: 99.2%; LJV: 84.6%, p<0.05). The time of the catheter insertion to perform radiography was 191 minutes [83.5-287]. Adequate syringe blood flow and an effective hemodialysis session was more frequent in RIJV catheter (99.2% vs 53.8%, p<0.05; 96.8% vs 72.7%, p <0.05, respectively). Complications occurred only in 4.2%, without statistical difference between catheter sites.

Conclusions: Comparing with chest radiography, agitated saline bubble-enhanced ultrasound was more accurate in identifying adequate placement of RIJV than LJV hemodialysis catheters.

Using the Seraph® 100 Microbind® Affinity Blood Filter Under Slow Flow Conditions Through a Normal Central Line

Marian-Theeres Sellfer, Julius Schmidt, Jan T. Kielsstein.1 2 Academic Teaching Hospital Braunschweig, Germany; ’Medizinische Hochschule Hannover, Hannover, Germany.

Background: The Seraph® 100 Microbind® Affinity blood filter has been in use since 2019 for the treatment of difficult to treat bloodstream infections and since 2020 for the treatment of critically ill COVID-19 patients. It is operated under blood flow rates of 100 – 350 mL/min, which requires a large bore central line a dialysis catheter. The aim of our study was to evaluate the usability of the Seraph® 100 under slow flow conditions through a normal central line (in clinical practice).

Methods: A standard hemoperfusion blood tubing system as well as the Seraph® 100 (Exthera Medical, CA, USA) was used. Vascular access was a 20 cm trilumen central venous line (2 x 16G and 1 x 16 G) that was inserted into a reservoir: The Multifiltrate (Fresenius Medical Care) was used to pump normal saline (n=5) or human plasma (n=5) through the Seraph® 100. Pressures were recorded at any given flows (Qb). In two patients connected to a five lumen 20 cm catheter (Certoxy Safety Quinto S1220, B. Braun, Melsungen, Germany - 1 x 12 G, 1 x 16 G, 3 x 18 G) blood flow as well as arterial and venous pressure were recorded through the 24 h treatment.

Results: Using saline or human plasma the Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of up to 100 mL/min even through a 16 & 18 G lumen at tolerable arterial and venous pressures. In men using either the 12 G or the 16 G lumen as “arterial line” blood a blood flow rate of 50 mL/min could be obtained for 24 hours without problems.

Conclusions: The Seraph® 100 Microbind® Affinity Blood Filter can be operated at blood flow rates of 50 mL/min even through 16 & 18 G catheters.
PO1055
Virtual Interviewing in the COVID-19 Era: What Have We Learned?
Koval Jain, Gerald A. Hladik, Prabir Roy-Chaudhury, Pankaj Jawa. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Background: The COVID-19 pandemic forced institutions across the US to switch to virtual interviewing. While some institutions were already offering virtual interviews on a limited basis, this was the first time all interviews were conducted using a virtual platform. Herein, we describe the experience of the nephrology fellowship interviewees at the University of North Carolina (UNC).

Methods: We distributed an anonymous Qualtrics survey to all the nephrology fellowship interviewees (N=80) at UNC. The survey included questions on quality of virtual interviews and was completed after the match to avoid bias related to the matching process.

Results: Thirty-one candidates completed the survey (39%), although not all questions were answered by everyone. The total number of interviewees increased from 41 in 2019-20 to 80 in 2020-21. 95% were satisfied with their virtual experience. 82% indicated that the virtual interview process enabled an informed decision about the fellowship program. Everyone was satisfied with the organization of the interview day (N=22). 28% responders (5/18) identified as underrepresented minority (URM). In 2019-20, 641 interviewees identified as URM as compared to 1480 in 2020-21. The most common reasons for not ranking our program amongst the top three included limited job opportunities for partners, inability to visit the area, and lack of family in the area. Candidates valued the people they met and were able to get a feel for the program despite virtual interviews. They were particularly satisfied with the opportunity to meet fellowship program members on one-on-one interviews. Interviewees specified lower cost and time efficiency as advantages of virtual interviews.

Conclusions: This is the first report of the virtual interview experience for nephrology fellowship applicants. The virtual interview process increased the applications to our program although the number of URM applications were similar compared to previous years. There was uniform satisfaction with the virtual format and interviewees were able to appreciate the culture of the division. Most applicants found the virtual interview format favorable because of reduced cost and time expenditure, enabling them to interview at more programs. Our data suggest that serious consideration should be given to a virtual format in future years to provide opportunity and flexibility to the applicant pool and improve geographical diversity.

PO1056
“Breaking Bad News” During the COVID-19 Epidemic: A Virtual Objective Structured Clinical Examination (OSCE) for Nephrology Fellows
Maura A. Watson,1 Anna M. Howle,1 Oliver Lenz,2 Ross J. Sealese,3 Joshua D. King,3 Jonathan A. Bolanos,2 Christina M. Yuan,1 Nephrology Education & Development Consortium4 Walter Reed National Military Medical Center, Bethesda, MD; 5University of Maryland School of Medicine, Baltimore, MD; 6Icahn School of Medicine at Mount Sinai, New York, NY; 7Lewis Katz School of Medicine at Temple University, Philadelphia, PA; 8Beth Israel Deaconess Medical Center, Boston, MA; 9Johns Hopkins University School of Medicine, Baltimore, MD.

Background: It is critical to ensure the health and well-being of the future nephrology workforce, especially among 1st year and fellowship applicants. The “Breaking Bad News” OSCE assesses fellow counseling/communication skills in 20-minute simulation scenarios: kidney replacement therapy (KRT) in ESKD, urgent KRT in AKI, and kidney biopsy. In-person simulation was impractical during the COVID19 epidemic, so we adapted the OSCE to a virtual platform.

Methods: The AKI scenario was audio only. Fellows called a simulated patient (SP) surrogate for urgent KRT consent. The ESKD and kidney biopsy scenarios were video encounters between fellows and SPs. Faculty observed while muted/video off. After each scenario, fellows received feedback from SPs and faculty (unmuted/video on). Fellows from 3 programs at 2 centers completed the OSCE in May 2021. Post-OSCE, fellows were anonymously surveyed about each scenario, the OSCE overall, and their estimate of the percent of outpatient encounters and inpatient KRT counseling they had done virtually in the past year.

Results: 15 fellows did the OSCE; 14 completed the survey (93% response rate). 93% rated the OSCE overall as a good very good approximation of a telemedicine experience. 100% were satisfied/very satisfied with the AKI scenario, 79% with the ESKD, and 77% with the kidney biopsy scenarios. Several commented that the AKI scenario was most realistic — they often counseled surrogates by telephone for urgent KRT. Fellows estimated that about 25% (median 27.5%; IQR 16-50%) of counseling for acute inpatient KRT was done virtually in the past year. They estimated about 50% (median 52.5%; IQR 36-70%) of outpatient encounters were done virtually in the past year, but several (dissatisfied with the ESKD and kidney biopsy scenarios) indicated they would not have counseled similar outpatients using telemedicine.

Conclusions: Overall, fellows felt the OSCE well-approximated virtual encounters. All were satisfied with the AKI scenario. The majority were satisfied with the ESKD and Kidney Biopsy scenarios, but some did not feel they were consistent with normal practice. The OSCE allows fellows to practice telemedicine communication skills that will remain relevant post-pandemic. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense or U.S. Government.

PO1057
Well-Being of Nephrology Fellows: Evolution over the Course of a Pandemic Year
Hitesh H. Shah,1 Kurtis Pivert,2 Susan M. Balbach,2 Anna M. Burgner,4 Benjamin S. Ko,3 Lili Chan,3 Suzanne Boyle,3 Joshua S. Waiztman,2 Stephen M. Sozio,1 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 2American Society of Nephrology, Washington, DC; 3Seattle Children’s Hospital, Seattle, WA; 4Vanderbilt University Medical Center, Nashville, TN; 5University of Chicago, Chicago, IL; 6Icahn School of Medicine at Mount Sinai, New York, NY; 7Levis Katz School of Medicine at Temple University, Philadelphia, PA; 8Beth Israel Deaconess Medical Center, Boston, MA; 9Johns Hopkins University School of Medicine, Baltimore, MD.

Background: We sought to assess changes in well-being of nephrology fellows over the first year of the COVID-19 pandemic in the U.S.

Methods: The Resident Well-Being Index (RWBI), a validated tool assessing physician distress, was distributed as part of ASN’s annual nephrology fellow survey to 920 current adult, pediatric, and adult/pediatric fellows. An RWBI ≥ 5 (range 0–7) indicated distress. Demographic and fellowship factors associated with meeting the distress threshold were evaluated in univariable and multivariable logistic regression.

Results: A total of 511 fellows participated (56% response), of whom 463 completed the RWBI instrument. After 1 year of the COVID-19 pandemic, there were a higher proportion of nephrology fellows meeting the RWBI distress threshold—22% in 2021 versus 15% in 2020. Female nephrology fellows had higher RWBI scores (median 3 [IQR 3] versus their male colleagues (median 1 [IQR 3]). Higher proportions of 1st-year fellows (50% vs 42% for 2nd years, OR 1.61 for 2nd years [95% CI 0.93–2.87], p=0.046) and women (27% vs 18% of men, OR 1.71 [95%CI 1.06–2.76], p=0.028) met the distress threshold. There were no significant differences by race, ethnicity, medical school location, or adult vs pediatric fellowship. Despite the higher proportion of distress overall, 88% of respondents would recommend nephrology to medical students and residents.

Conclusions: Our follow-up assessment of nephrology fellows’ well-being after the first year of the COVID-19 pandemic indicate the continued need for supportive measures to ensure the health of the future nephrology workforce, especially among 1st year and women trainees.
Methods: Each of the 6 nephrology fellows filled out a daily survey between November 9, 2020 and January 31, 2021, which was the peak of the COVID-19 pandemic in Wisconsin to address: 1) the total amount of sleep hours 2) quality of sleep (restful or fragmented) and 3) whether on-call fellow reported to hospital from home. Responses were collected the following morning to decrease recall bias.

Results: Over the 3-month study period, 100% of the call night data was recorded. The average amount of sleep per night was 5.3 hours. When necessary to report, the average hours of sleep dropped to 4.3 hours. However, if not called in, sleep increased to 5.8 hours per night. The percentage of nights requiring patient evaluation by coming to the hospital increased by 50% during the study period with a range of 48% of nights in December and 61% in January. Sleep during night call was described as 55% restful vs. 45% fragmented.

Conclusions: This survey has generated discussion amongst fellowship leadership and currently fellows regarding novel ways to improve the night call experience to maximize education and clinical experience during training as well as improve fellow wellness. It was determined that the burden of call did not detract from the fellow education enough to warrant a change to a night float system. However, it did identify changes in management processes such as the timing of labs, implementation of dot phrases, and a sleep expert discussion to improve duration and quality of sleep.

Curriculum-Based Online Education Improves Nephrologists’ Ability to Manage Hyperkalemia in Practice
Amy Larkin, Donald Blatherwick, George Boultaslis. Medscape Education, New York, NY.

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if series of online continuing medical education (CME) activities will improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 5 online activities housed on a dedicated collection page. All used repeated pairs pre-/post-assessment study design was used and McNemar’s test (P <.05 is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a McNemar’s test to determine P values. The activities launched between March and October, 2020 and data were collected for up to 12 weeks.

Results: The education reached over 15,000 physicians, including over 1,706 nephrologists. Overall, knowledge improved by 24% (P<.001) and competence by 4% (P<NS) for the remaining activities. Specific improvements: 40% relative increase in knowledge related to impact of hyperkalemia (P<.001) 31% relative increase in knowledge related to clinical use of potassium binders (P<.001) 24% relative increase in knowledge related to optimizing RAAS inhibitors in patients with hyperkalemia (P<.05) 7% relative increase in competence related to clinical use of potassium binders (P<NS) Of the nephrologists who were included, 30% (P<.001) had a measurable increase in confidence in hyperkalemia management.

Conclusions: This curriculum demonstrates that a curriculum is effective at moving learners on the continuum for knowledge improvements to competence improvements. Some gaps remain after education. Among these learners, 49% need knowledge improvements related to optimizing RAAS inhibitors in patients with hyperkalemia and 41% related to clinical use of potassium binders. As such, further education needed in these areas.

PO1062
Level of Confidence, Knowledge, and Literacy in Genetics Among US Nephrologists

Background: Increased availability of genetic tests in nephrology and at reduced costs are promising for improved patient diagnostic and clinical care. Nephrologists’ confidence, knowledge and genetic literacy are likely to impact the utilization of genetic testing (GT). Identifying gaps in nephrologists’ knowledge and confidence and preferred methods of learning are needed to develop tailored approaches to improving it.

PO1059
Shahid N. Muhammad,1,2,3 The University of the West of England (UWE), Bristol, United Kingdom; 2The Renal Patient Support Group (RPSG), England UK, Bristol, United Kingdom.

Background: Technology has allowed patients with Long-Term Conditions (LTCs) to access information through websites, portals, and Patient-centred organisations. 1) To understand, retrospectively, whether there has been an education neglect as part of healthcare delivery and 2) To understand if technology can help join up education. This is the first UK retrospective study found an increase in the adoption of online resources with similar effectiveness ratings as traditional resources.

Methods: Fourteen (14) topic tags were applied over 1-month (March and April 2020) between groups the Renal Patient Support Group (RPSG) (est.2009) and the Kidney Disease and Renal Support (KDARs) (est.2014) for Kids platforms. Group disclaimers encouraged informed consent. GDPR (2018) guidelines were implemented to ensure best practice and data protection is maintained.

Results: 2,560 threads were topic tagged between two groups. For adults, educational gaps surround Renal Replacement Therapy (166 tags, 12.66%); Lab Tests and Biomarkers (137 tags, 10.50%) and Medication and Pharmacy (135 tags, 10.29%). For paediatrics and younger adults, educational gaps include Medication and Pharmacy (148 tags, 11.85%), Renal Replacement Therapy (133 tags, 10.65%); Peer Support (125 tags, 10.01%) and Nursing (115 tags, 9.20%).

Conclusions: Online educational modules should complement CKD pathways, and be developed by wider Allied Health Professionals. This is the first UK retrospective study that examines clinically relevant educational gaps between online paediatric and adult renal cohorts close to two decades. Education is where healthcare requires investment.

PO1060
Nephrology Education Needs Assessment: Five Years and a Pandemic Later
Benjamin S. Ko,1 Rob Rope,2 Kurtis Pivert,2 Anna M. Burgner,3 Joshua S. Waitzman,4 Susan M. Halbach,5 Suzanne Boyle,6 Lili Chan,3 Hitesh H. Shah,2 Stephen M. Sozio,10 University of Chicago, Chicago, IL; 1American Society of Nephrology, Washington, DC; 2Oregon Health & Science University, Portland, OR; 3Beth Israel Deaconess Medical Center, Boston, MA; 4Vanderbilt University Medical Center, Nashville, TN; 5Seattle Children’s Hospital, Seattle, WA; 6Temple University, Philadelphia, PA; 7Icahn School of Medicine at Mount Sinai, New York, NY; 8University of Pennsylvania, Philadelphia, PA; 9Johns Hopkins Medicine, Baltimore, MD.

Background: We sought to identify how educational tools utilized in nephrology training had evolved in the past 5 years and through the COVID-19 pandemic.

Methods: Questions about educational tools were distributed as part of ASN’s annual nephrology fellow survey to 920 current adult pediatric fellows.

Results: 511 fellows participated in 2021 (56% response rate), compared with 377 fellows in 2016 (31% response rate). Fellows indicated that UpToDate was still the most used (82%) and most effective educational tool (66% rated it “Very Effective”); however, ASN Kasas popularity in 2016, 58% rated it was also highly rated (65% Very Effective). Use of online resource and social media increased, including both new opportunities and prior available ones such as NephJC (7% to 32%, with 46% rated Very Effective) (Figure 1). A majority of fellows (84%) rated their education as good or excellent in 2021, a percentage similar to 2016 (81%).

Conclusions: Our follow-up assessment of nephrology fellows’ educational tools found an increase in the adoption of online resources with similar effectiveness ratings as traditional resources.
PO1063
Mind Map, an Educational Tool for Teaching Clinical Reasoning in Nephrology: A Mixed-Method Study

Agnieszka Hamroun,1 Éléonore Lepers,2 Aurélie Dupré,2 Patrick Truffert,3 François Glowacki,4 1Centre Hospitalier Universitaire de Lille, Lille, France; 2Université de Lille Faculté de Médecine, Lille, France.

Background: Nephrology is commonly considered as one of the most complex disciplines for medical students, justifying the implementation of new educational tools. Although its relevance has been well-established, the mind map is still marginally used in medical education. The objective of this study is to assess the contribution of mind map for teaching clinical reasoning in nephrology.

Methods: Between November 2020 and April 2021, three groups of med students (4th to 6th year) were provided with a teaching program of 5 weekly sessions of 30-45 minutes focused on three topics (serum creatinine elevation/AKI, glomerular syndromes, dysnatremia), each developed through a specific mind map.

Results: In total, 12 med students took part in this educational experience (respectively four in 4th, 5th and 6th years). Quiz scores were significantly higher after each teaching session and overall (28.0 [26.0; 31.4], 33.0 [31.2; 36.1], 34.4 [32.4; 37.0]) respectively at baseline, immediately after and after two weeks, p < 0.001 (Fig1). Moreover, focus group interviews highlighted several themes about the specific contribution of mind map (in addition to previous standard lessons): logical and intuitive tool, effective for quick knowledge transmission, promoting long-term memorization and providing a global/integrated vision of clinical reasoning in nephrology.

Conclusions: Mind map appears to be an interesting educational tool in teaching clinical nephrology reasoning to medical students.

PO1064
Improving the Management of Gout in Patients with CKD or Kidney Transplant: Effect of Online Education

Background: Gout is a chronic condition with a considerable effect on patient health and quality of life. Hyperuricemia and gout are associated with declining renal function. Recent studies have shown that renal dysfunction and kidney transplant are risk factors for gout. A study was conducted to determine if online, segmented education could improve knowledge, competence, and confidence of nephrologists regarding the management of gout in patients with chronic kidney disease (CKD) or kidney transplant (KT).

Methods: Educational design included a 45-minute video activity with slides, segmented into a series of 5 mini-lectures by different faculty covering various aspects of gout in patients with or without CKD and KT. Educational effectiveness was assessed with a repeated-pairs pre-/post-assessment study design with 3 knowledge questions and 1 confidence question, in which each individual served as his/her own control. A chi-squared test assessed statistical significance at the P <.05 level. The activity launched 9/25/2020, with data collected through 12/4/2020.

Results: The analysis set consisted of responses from nephrologists (n=89) who answered all assessment questions during the study period. Analysis of pre- vs post-intervention responses demonstrated a significant improvement in overall knowledge; average correct responses increased from 52% pre to 76% post education. Specific areas of improvement include: Treat-to-target strategy with a target of serum UA level < 6 mg/dL in patients taking urate lowering therapy (20% relative improvement, P<.05) Starting low-dose allopurinol in a patient previously diagnosed with gout and stage 3 CKD, presenting with painful subcutaneous tophi (25% relative improvement, P<.01) Recommending pegloticase without dose adjustment for the management of refractory gout in patients with stage 4 or 5 CKD (22% relative improvement, P<.001) Post-education, 48% of nephrologists had a measurable increase in confidence in their ability to manage patients with CKD who may develop gout.

Conclusions: This study demonstrated the success of online, segmented, mini-lectures on improving the evidence-based knowledge, competence, and confidence of nephrologists in appropriately managing gout in patients with CKD or kidney transplant.

Funding: Commercial Support - Horizon Pharma
IS (3.3 (0.8) compared to 2.3 (0.7) for attending physicians). In May 2021, 5 nephrology fellows received the IS toolkit and completed surveys. Self-efficacy improved post-intervention from mean (SD) 3.0 (1.2) to 2.2 (1.6). All 5 fellows (100%) strongly agreed that the toolkit added value to training, provided a guide they would use and recommended the toolkit for future fellows.

Conclusions: Nephrology faculty and fellows strongly agreed that there is a need for guides and protocols for prescribing and monitoring IS medications. Our pilot IS toolkit incorporated into nephrology fellow training was well received and improved fellow self-efficacy.

<tr>
<td>Quality Improvement Study on Dialysis Education for Residents in an Outpatient Nephrology Clinic</td>
</tr>
<tr>
<td>Young C. Hsu, Jonas Kwok, Annika K. Khine, Thanh Cao. University of Southern California, Los Angeles, CA.</td>
</tr>
</tbody>
</table>

**Background:** In a large safety net hospital outpatient nephrology clinic in Southern California, resident physicians provide a significant portion of care to patients who have chronic kidney disease (CKD) stages III to V. Many of these patients eventually require initiation of long-term renal replacement therapy (RRT). However, there are many barriers to a timely and safe initiation of RRT in this patient population. One such barrier is a deficiency in education regarding dialysis between residents and patients in nephrology clinic. We attempted to identify barriers of resident education with patients regarding the topic of RRT and assess the effects of our educational intervention. Objectives: 1. Increase resident’s knowledge regarding RRT based on pre and post intervention questionnaire 2. Increase resident’s subjective preparedness/confidence level regarding discussions of RRT 3. Increase the frequency with which residents discuss RRT with patients.

**Methods:** We created and distributed a pre-assessment survey to all Internal Medicine and Internal Medicine-Pediatrics residents at a large teaching hospital and received an approximately 50% response rate. Residents overwhelmingly responded that they do not feel prepared to initiate dialysis by the time they are deemed to require renal replacement therapy, nor did residents feel that they were adequately prepared or knowledgeable about the nuances of dialysis in order to counsel patients with CKD. We created a short teaching presentation with video reviewing dialysis topics and strategies to approach discussions with patients for residents who rotate through nephrology clinic, after which a post-survey was administered. Results are currently being collected.

**Results:** Results are currently being collected. We expect resident physicians will demonstrate increased knowledge regarding RRT based on pre- and post-intervention questionnaire, feel more comfortable discussing RRT with patients, and will discuss RRT more often with patients in clinic.

**Conclusions:** We expect to be able to conclude that resident education is a vital aspect in increasing patient's understanding and comfort regarding their disease process and dialysis at similar teaching centers where residents represent the majority of patient-physician interface in renal subspecialty care.

**PO1069**

**The Impact of Electronic Sign-Out Dot-Phrase and Simulation Exercises on Inpatient Nephrology Transitions of Care**

James D. Alstott,1 Anand K. Ramadorai,1 Sayee Sundar Alagusundaramoorthy,2 Samantha J. Strennen,1 Laura J. Maursette,1 Gauri Bhutani.1 University of Wisconsin-Madison, Madison, WI; 2University of Kentucky, Lexington, KY.

**Background:** A fellow-led QI project was initiated in 2018 after division surveys indicated a need for change in the ongoing division transitions of care (TOC) practice. **Methods:** We developed a standardized “sign-out score” to objectively assess TOC on the EMR sign-out. We next developed and implemented a standardized electronic medical record (EMR) dot-phrase as our first QI intervention. Case-based simulation sessions highlighting TOC pearls were conducted as the second QI intervention. Pre- and Post-intervention data for sign-out score was evaluated.

**Results:** A total of 647 patient EMR sign out scores were assessed between 2018-2021. Overall sign-out accuracy score (0-2) significantly improved with QI interventions (pre-intervention mean 0.9 [95% CI: 0.9-1.1; N=298] to 1.6 post-dot-phrase [1.5-1.6; N=220] to 1.7 post-simulation [1.6-1.8; N=129]; p<0.001). Table 1 provides details on the results of sign-out score. After adjustment for level of training, improvement in overall accuracy was independently associated with both dot-phrase (adjusted odds ratio (aOR) 7.6 [95% CI: 4.9-11.9]; p<0.001) and simulation (aOR 1.88 [1.1-3.16]; p=0.001). Although 2 sign-out score measures which were high performing pre-intervention worsened with dot-phrase implementation: anticipated changes and non-RRT management (aOR 0.15 [0.1-0.23]; p=0.001 and 0.07 [0.02-0.23]; p<0.001, respectively), improvement was seen with standardized care (aOR 1.36 [0.84-2.2]; p=0.21 and 4.6 [1.74-14.5]; p=0.002).

**Conclusions:** A fellow-led QI intervention including standardized sign-out dot-phrase and simulation exercises both improved the overall accuracy of TOC practiced in inpatient Nephrology consult service. The impact of dot-phrase alone on previously high performing TOC measures suggests the need for further optimization of dot-phrase and continuing simulation to enhance provider self-realization of important components of TOC.

**Point-of-Care Ultrasound Training for Nephrologists: A National Survey of Nephrology Fellows**

Catherine A. Moore,1 Daniel W. Ross,2 W. Charles O’Neill3.1 University of Rochester Medical Center, Rochester, NY; 2Northwell Health, New Hyde Park, NY; 3Emory University, Atlanta, GA.

**Background:** Despite many potential applications of PoCUS in nephrology, nephrologists have been slow to adopt this technology. The past five years have seen an increase in ultrasound training within nephrology fellowship programs, although the scope of training is unknown. We conducted a national survey of nephrology fellows in United States-based training programs. The main objective of this survey was to identify the current landscape and clinical use of PoCUS in US nephrology training programs.

**Methods:** We surveyed post-graduate year (PGY) 4-8 trainees in US nephrology fellowship programs. Survey items were included in a broader trainee survey disseminated to all programs by the American Society of Nephrology in April, 2021. The six-item survey instrument probed attitudes toward PoCUS, current use, preferred instruction format, and perceived competence.

**Results:** Out of 822 US nephrology fellows surveyed, 631 (76.8 %) responded. A majority of respondents were 30-34 years of age with the majority of participants graduating from international medical schools. The majority of fellows (64.6%) indicated interest in PoCUS education, with highest interest in procedural ultrasound and diagnostic kidney imaging. Only 240 (38%) of fellows reported receiving PoCUS education during training. Of the fellows who received PoCUS training, 112 of 227 (49%) reported incorporation of PoCUS at a frequency of less than monthly, with only 62 of 227 (27%) incorporating PoCUS once per week or more. 83 of 226 (36%) fellows reported receiving adequate instruction to independently perform PoCUS, and 74 of 224 (33%) reported that they expect to be competent to independently perform PoCUS by the end of training. Handson-training, particularly with an instructor, was highly valued as a teaching technique.

**Conclusions:** Despite high trainee interest in PoCUS, the majority of current nephrology fellows are not receiving training in this domain and do not feel competent to independently perform PoCUS procedures. Handson-training guided by a skilled instructor is a highly valued PoCUS teaching technique. This survey identifies a need for the development of PoCUS programs within nephrology fellowships that incorporate hands-on teaching techniques.

**PO1089**

**Point-of-Care Ultrasound Education in Nephrology During the COVID-19 Pandemic**

Andrew A. Moses,1 Hilda E. Fernandez, Columbia University Irving Medical Center, New York, NY.

**Background:** The COVID-19 pandemic led to changes in the way people taught and learned, with higher reliance on online learning. Unfortunately, point of care ultrasound is a difficult topic to teach without hands-on practice. Here we discuss the implementation of a novel ultrasound curriculum during the COVID-19 pandemic.

**Methods:** The curriculum was based on published curriculum on point of care ultrasound for the nephrologist, with focus on four fundamental exams: kidney, lung, cardiac, and volume status. We employed a flip the classroom approach with pre-reading and videos, a pre-session quiz, followed by hands on application of skills. Standardized patients or volunteers would have been used for the hands-on session, but this was eschewed for safety concerns. The fellows and instructors themselves modeled, with proper sanitation and PPE. The hands-on sessions were well received and attended by all fellows. The skills were then applied on the wards.

**Results:** As the restrictions for front line providers were available, standardized patients were available in small groups. The learners were scheduled for two hour-long sessions with standardized patients, for practice of the skills acquired as well as the Objective structured clinical examination (OSCE). After the first session with all learners, we added a third session focused on OSCEs, as well as line placement as requested by the learners. By the end of the third session, all learners felt more confident in their skills and had passed their OSCEs.

**Conclusions:** Given the positive reception, this course is planned to continue as current, structured as well as expanded upon by rising fellows. The use of flipped classroom helped maximize the time of supervised scanning by learners. The use of ultrasound by fellows has risen and will continue to climb with further development of this important curriculum.
PO1071
Patient Navigators and Study Coordinators: A Team Approach Towards Patient Support in Decentralized Clinical Trials
Cynthia J. D’Alessandri-Silva,1 Kimberly D. Cranston,2 Anna Klochak,3 1Connecticut Children’s Medical Center, Hartford, CT; 2Advancen Inc., Ardmore, PA; 3Children’s Hospital Colorado, Aurora, CO.

Background: COVID-19 related restrictions have accelerated adoption of decentralized clinical trials(DCT). DCTs offer increased patient flexibility via online study platforms, telemedicine and home-based nursing. DCTs reduce travel, hospitalization and in-person interactions, all problematic under COVID. Potential drawbacks exist for both patients and study coordinators, however. In DCTs, removal of study-site visits may leave patients feeling confused, unsafe, disempowered and disengaged, potentially increasing drop-out risk. While DCTs may mean increased enrollment for sites, management of novel patient pathways may prove more time-consuming for study coordinators. Crucial protocol driven events or patient concerns/questions may be missed due to complex patient tracking.

Methods: The role of the patient navigator(PN) was developed to support both patients and study coordinators in DCTs. PNs will provide culturally-appropriate psychosocial education to ensure patients feel safe, informed, and supported. PNs serve as conduits between the patient and the study site, ensuring bi-directional communication of patient progress. This unique approach is being trialed in ARENA2, a pediatric Phase III study in primary distal renal tubular acidosis, a rare renal disease.

Results: A multi-lingual team with unique educational and counseling experience was recruited and trained on the protocol and disease. The team will provide weekly check-ins with patients to facilitate engagement as well as identify any concerns the patient may be having in home healthcare. This role will offer around the clock patient support which will increase accessibility and decrease burden experienced by study coordinators with heavy caseloads. PNs have also developed educational videos in target languages using lay-friendly terminology to ensure patient understanding. Topics include clinical trials, ARENA2 and research in rare diseases. The study website contains additional resources including written articles that help set expectations and provide subjects with strategies for success as they go through ARENA2.

Conclusions: The concept of sponsor-driven PN team services in DCTs will offer both patients and study sites the added benefits of support.

PO1072
Do Undergraduates Know “Nephrology”? – A Single-Site Survey of College Students
Julia M. Hopkins,1 Juan Carlos Q. Velez,2 John M. Arthur,3 Michael G. Janetch.1 1College of Charleston, Charleston, SC; 2Ochsner Medical Center - New Orleans, New Orleans, LA; 3University of Arkansas for Medical Sciences, Little Rock, AR.

Background: Over the past decade, Nephrology has experienced a 43% decline in fellowship applicants. A factor to choosing Nephrology could be a lack of early exposure. While studies have been conducted to explain why residents choose a specific fellowship program, none have surveyed the undergraduate student population to inquire whether the name “Nephrology” was even a recognizable medical specialty compared to other medical specialties. To this end, we conducted a survey of undergraduate students at the College of Charleston (CoC) to test the hypothesis that Nephrology will rank amongst the least recognizable specialties.

Methods: 274 undergraduates at CoC responded to a survey where they were asked to select every medical specialty they recognized by name (15 real specialties 3 fictious). Demographic questions regarding sex, race, collegiate level, high school location, pre-med track, and household income were included. Differences were considered by comparing 95% confidence intervals or Chi-Square test. Spearman-Rank test was used to examine whether the number of applicants per specialty fellowship position was correlated with the proportion of responses.

Results: Out of 15 medical specialties, Nephrology ranked lowest (29%); whereas, Pediatrics (97%) and Surgery (97%) ranked highest. The fictitious specialty, “diaysymptomology” was recognized least (4%). Sex, race, collegiate level, and household income were not different between those students that recognized the word Nephrology versus those that did not. Pre-med students were about twice as likely (p=0.001) to have recognized Nephrology versus non pre-med students (49% vs. 22%, respectively). There was no correlation between the proportion of undergraduate students who recognized a specific medical specialty and the number of applicants per fellowship position in 2019 (r=0.2, p=0.7).

Conclusions: Nephrology was the least recognized, non-fictional, specialty amongst undergraduates. Lack of correlation between student responses and fellowship applications, suggest that name recognition alone will not predict fellowship applicant number. The discrepancy between Nephrology and other specialties highlights a gap in name recognition at an early career stage, even amongst premedical students.

Teaching Application of Ultrasound in Nephrology Practice in Medical Schools Using Student Peer Teaching: A Prospective, Randomized Pediatric Trial
Rainer Büscher, Philip Geiling, Fiona Schmitt. Universitätsklinikum Essen, Essen, Germany.

Background: Ultrasound has become the leading diagnostic technology in pediatrics due to its high sensitivity, easy applicability and lack of invasiveness and plays critical roles in many aspects of nephrology practice. However, it is associated with a higher examiner dependent variance. Teaching ultrasound in medical schools has grown in importance over the past years, while pediatric aspects are mainly reserved for postgraduate education. Student peer teachers take on the task of lecturers at many faculties with promising results in ultrasound education.

Methods: We designed a prospective, randomized trial in a pre-post-test design for 257 4th year medical students in our pediatric classes to investigate the effectiveness of peer teaching in pediatric ultrasound. Besides a mandatory theoretical training by the student peer teacher in our skills lab using similar ultrasound machines. The success of pre-med students were split in smaller groups and received a standardized practical training by right kidney volume of their partners in advance to test pre-existing practical skills and the course and clinical trial was well received. Over 95% of students presented the learning contents.

Results: Method: The concept of student peer teaching seems to work very well also for the right kidney volume of their partners in advance to test pre-existing practical skills and the course and clinical trial was well received. Over 95% of students presented the learning contents. However, we also observed a high interindividual variance in the volumetric renal topography sonographically well with no significant differences between both groups. However, we also observed a high interindividual variance in the volumetric results. The use of a supporting pediatric ultrasound manual did not show any significant benefit.

Conclusions: The concept of student peer teaching seems to work very well also in specific disciplines such as pediatric ultrasound and pediatric nephrology education. Therefore peer teaching seems to be of value in medical schools also in teaching complex learning contents.

Underline represents presenting author.
Methods: Two separate, identical surveys were administered: one directed to Urine Task Force members (28 respondents at the time of reporting) and one directed to the ISEV community (42 respondents).

Results: The mean time studying eUVs was 7.8 years for task force members and 5.4 years for community respondents. For task force members: 48.3% of respondents primarily focus on kidneys, 13.8% on other NOD tissues, and 6.9% by other. For the community, the focus was 29.4% kidney, 21.5% prostate, 19.6% bladder and 29.4% “other”. Both communities largely collect spot urine samples compared with timed collection (Task Force: 78.6% spot vs 21.4% timed, Community: 75.8% spot vs 24.2% timed). Urine storage was a significant focus of the survey. For the Task Force: 92.9% of respondents studied samples stored >3 months, 57.1% samples stored <3 months, and 50% studied fresh samples. The community studied less often fresh samples. Both groups predominantly stored samples as “cell-free urine”: 85.7% for task force and 65.6% for community. All task force respondents study samples frozen at -80 °C with 10.7% of respondents also studying samples stored at 4 °C. By contrast, 93.8% of community respondents stored samples at 80 °C, 9.4% at -20 °C and 6.3% at 4 °C. The task force ranked the following isolation methods in order of priority 1) centrifugation, 2) size exclusion chromatography, and 3) filtration. For the community survey this was similar. Both surveys prioritized the same downstream applications: 1) protein analysis, 2) RNA analysis, 3) functional analysis.

Conclusions: In summary, the present survey identified key similarities and differences between current practices for the Urine Task Force and the urinary eUV research community. Such information will be used to help guide future efforts to address key knowledge gaps.

A Potential Novel Variant of Slc4a4 Can Regulate the Functional Activity of the Electrogenic Na/HCO3 Cotransporter NBCe1-B
Seong-Ki Lee,1 Marie Michenkova,1 Michael F. Romero,2 Rosanna Occhipinti,1 Andrey Desai2
1The University of the West of England (UWE), Bristol, United Kingdom; 2Mayo Clinic, Rochester, MN.

Background: The electrogenic Na/HCO3 cotransporter (NBCe1) regulates intracellular pH in many tissues and elicits vectorial HCO3⁻ flow across many epithelia. Five variants of NBCe1 have been identified: α, mainly in kidneys; β, ubiquitous; -c, in brain; -d/E, in mouse reproductive organs. Because the A/D and B/C/E variants are transcribed from two distinct promoters, they have different NH2-termini (Nt). The Romero Lab developed an isoform-specific knockout (KO) mouse of NBCe1-A/D by causing a frameshift mutation in the A/D variants’ unique Nt region (Chen et al., JASN 25:71A, 2014). Fang et al found that NBCe1-B (e1B) is expressed in kidneys of both WT and KO mice, and that e1B expression increases with metabolic acidosis in KOs (JAP Renal, 2018). They reached this conclusion by RT-PCR-amplification of B-variant–specific bands from KO kidneys. However, these amplifications generated several unidentified bands. Intrigued by these additional bands, we repeated the RT-PCR in an attempt to identify them.

Methods: Using TA cloning, we determined the sequences of two of the unidentified bands: (1) partial Slc4a4 product missing exon 4, which would lead to a frameshift, and (2) partial Slc4a4 product missing exons 4 & 5, but remaining in-frame. Because Fang et al confirmed lack of C/D/E variants, we introduced mutations (1) and (2) in e1B and e1C tagged with Flag and Myc and expressed intracellularly by two-electrode voltage-clamping in Xenopus oocytes. We also determined protein abundance/interaction by surface protein immunoblotting. Inasmuch as e1B has low activity, we co-expressed WT e1B and/or mutant e1B with super-IRBIT (which lacks binding sites for IRBIT).

Results: We found that neither mutant, alone, has activity even though Δexon 4/5-e1B interacts with super-IRBIT. However, Δexon 4/5-e1B has a dominant-negative (DN) effect on WT e1B. To test if these mutants are specific for KO mice, we inspected other WT tissues.

Conclusions: Contrary to our hypothesis, we found that e1B mutants (1) and (2) exist at least in kidneys, brain, and pancreas, leading us to conclude that cells could in principle regulate NBCe1-B activity by adjusting the amount of the novel DN variant Δexon 4/5-e1B.

A Novel I551F Variant of Na/HCO3 Cotransporter NBCe1 Shows Reduced Cell Surface Expression and May Exert a Dominant Negative Activity
Osamu Yamasaki,1,2 Tadashi Yoshida,2 Junichi Hirashu,2 Matsuhiko Hayashi,2,3 Shigeru Shibata,1 Teikyo Daigaku, Ibaraki-ku, Japan; 2Keio Gijuku Daigaku Byoin, Shinjuku-ku, Japan; 3Kawakita Sogo Byoin, Sagamihara City, Kanagawa, Japan.

Background: Homozygous mutations in SLCA44, encoding the electrogenic Na/HCO3 cotransporter NBCe1, cause proximal renal tubular acidosis (pRTA) associated with extrarenal symptoms. Although 17 mutated sites in SLCA44 have thus far been identified among pRTA patients, physiological significance of other non synonymous single nucleotide variants (SNVs) in this gene remains largely underestimated.

Methods: To identify functional impact on NBCe1 (SLCA44) sequence variants, we used an integrated pipeline of bioinformatics and functional assays. We prioritized sites for functional analysis based on allele frequency, conservation, and physical location. We generated stable cell lines expressing wild type and mutant NBCe1 variants and measured cell surface expression by immunofluorescence analysis.

Results: Using an integrated approach to prioritize variant alleles for functional studies, we generated stable cell lines expressing wild type and mutant NBCe1 variants. We measured cell surface expression of wild type and mutant NBCe1 variants using immunofluorescence analysis. We found that the I551F variant showed reduced cell surface expression compared to wild type NBCe1. Additionally, we observed changes in other cellular characteristics associated with the I551F variant, suggesting a potential role in dominant negative activity.

Conclusions: Our study highlights the importance of functional studies to elucidate the physiological significance of non-synonymous single nucleotide variants in SLCA44, particularly in the context of proximal renal tubular acidosis. Further research is needed to determine the full spectrum of clinical implications of the I551F variant and to explore its potential role in other non-synonymous variants in SLCA44.

Funding: NIH grant K08DK115243.
Methods: We investigated the functional properties of SNVs in NBCe1 using immunocytochemical, molecular, and electrophysiological assays. From NCBi database, we identified 13 SNVs that have not previously been characterized in highly conserved, transmembrane domains of NBCe1-A.

Results: Immunocytochemical analysis revealed that I51F variant was present predominantly in the cytoplasm in HEK293 cells, whereas all other SNVs did not show obvious changes in subcellular distribution. Western blot analysis in HEK293 cells demonstrated that the I51F variant showed impaired glycosylation and a 69% reduction in cell surface levels. To determine the role of I51 in more detail, we examined the significance of various artificial mutants both in non-polarized HEK293 cells and polarized MDCK cells, which indicated that only I51F substitution resulted in cytoplasmic retention. Moreover, functional analysis using Xenopus oocytes demonstrated that the I51F variant had a significantly reduced activity corresponding to 39% of that of wild-type, whereas any other SNVs and artificial I51 mutants did not show significant changes in activity. Finally, immunofluorescence study in HEK293 cells indicated that the I51F variant retains wild-type NBCe1-A in the cytoplasm.

Conclusions: These data demonstrate that I51F-NBCe1-A shows impaired transport activity predominantly through cytoplasmic retention, and suggest that the variant can have a dominant-negative effect by forming complexes with wild-type NBCe1-A.

Diacidic Motif Is Required for Efficient Transport of NKCC2 to the Plasma Membrane

Dalal Bakhos Al Douaihy,1,3 Elie Seayafan,2 Sylvie Demartez,1,3 Kamel Laghmani,2,3 Martin Köhmfötter,2 Insmer, CRNERS-ERL2828 Sorbonne Université, Paris, France; 2Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; 3Centre de Recherche des Cordeliers, Paris, France.

Background: Mutations in the apical Na-K-2Cl cotransporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. We have previously demonstrated that BS1 nonsense mutation Y998X, which interferes with the highly conserved dileucine like motifs of NKCC2 C-terminus, compromises NKCC2 surface delivery through ER retention mechanisms. However, whether these dileucine like motifs are sufficient for anterograde trafficking of NKCC2 remained to be determined. Consequently, the aim of the present study was to investigate whether additional motifs are required for NKCC2 efficient transport to the plasma membrane.

Methods: NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 surface expression was measured by cell surface biotinylation assay. NKCC2 stability and maturation was monitored by cycloheximide chase assay.

Results: Among the motifs identified as ER export signals in ion channels are the diacidic D/E-X-D/E motifs, which have been shown to promote interaction of cargo with the coat complex II (COPII) budding machinery. Interestingly, sequence analysis of NKCC2 C-terminus revealed the presence of two di-acidic motifs, WEEE996 and HDAE1012, located upstream and downstream of BS1 mutation Y998X, respectively. Importantly, mutation of HDAE1012 to A1012AA disrupted glycosylation and cell surface expression of NKCC2, whereas mutation of WEEE996 had no effect. Cycloheximide chase analysis demonstrated that the absence of the terminally glycosylated form of HDAE1012 was not due to increased rates of degradation of mutant co-transporters, but was instead caused by defect in maturation. Accordingly, co-immunolocalization experiments showed that HDAE1012 was trapped in the ER. Finally, overexpression of dominant negative mutants of Sar1 GTPase completely abolished NKCC2 maturation, clearly indicating that NKCC2 exit from the ER is COP II dependent.

Conclusions: Our data indicate that in addition to highly conserved dileucine like motifs of NKCC2 C-terminus, the cotransporter uses also a di-acidic exit code for export from the ER and targeting to the cell surface. Elucidating the molecular mechanisms of the motif-facilitated export may help to develop therapeutic strategies targeting NKCC2 transport from the ER to the cell surface.

Furosemide Alleviates Hypercalciuria and Hypomagnesemia in Claudin 16-Deficient Mice

Natalia Breiderhoff,1,3 Elie Seayafan,2 Sylvie Demartez,1,3 Kamel Laghmani,2,3 Martin Köhmfötter,2 Insmer, CRNERS-ERL2828 Sorbonne Université, Paris, France; 2Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; 3Centre de Recherche des Cordeliers, Paris, France.

Background: Loss-of-function mutations in the CLDN16 gene encoding for Claudin 16 (Cldn16) cause type I Bartter syndrome (BS1), a life-threatening kidney disease. We have previously demonstrated that BS1 nonsense mutation Y998X, which interferes with the highly conserved dileucine like motifs of NKCC2 C-terminus, compromises NKCC2 surface delivery through ER retention mechanisms. Therefore, we hypothesize renal tubular ABCA1 ablation will lead to Na dependent changes in BP.

Methods: Transgenic mice (Tg^BS1^-/-;ABC1^-/-), which express CRE recombinase in tubular epithelia when fed doxycycline (dox), were bred with mice expressing floxed ABCA1 to generate a model deficient in tubular ABCA1 (FF). Tail cuff systolic BP (SBP; Visitech) and urine volume after diuretic administration was measured in mice. Immunoblotting was performed on kidney protein lysate.

Results: Immunoblotting of renal PA showed reduced ABCA1 (50±11%; n=6, p<0.05) in FF compared to littermate wildtypes (WTs, 100±7%; n=5) mice. The SBP of FF (n=11) mice was greater immediately post-dox and during chol or high Na feeding (Fig. 1; *, p<0.05 vs WT) compared to WTs (n=15). Low Na diet abolished SBP differences between mice, while 6 weeks (W) of 1% chol diet raised the SBP in ABCA1 (FF). Tail cuff systolic BP (SBP; Visitech) and urine volume after diuretic administration was measured in mice. Immunoblotting was performed on kidney protein lysate.

Conclusions: Tubular ABCA1 deficiency stimulates Na dependent SBP which we speculate is related to enhanced Na dependent ENaC and NKCC2 activity.

WNK4 Is a Transducor of V2 Receptor Signaling in the Thick Ascending Limbs and Distal Convoluted Tubules

Hector Carbajal-Contreras,1,2 Adrian R. Murillo-de-Ozores,1,2 German R. Magaña,1,2 Norma H. Vázquez,1,2 Gerardo Gamba,2 María Castañeda-Bueno,2 Molecular Physiology Unit,1 Universidad Nacional Autónoma de Mexico, Ciudad de México, Mexico; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico.

Background: Vasopressin (AVP) is essential for water and Na+ homeostasis. In the kidney, its actions are mediated by the V2 receptor (V2R), which signals through protein kinase A (PKA). The phosphorylation of the Na+-Cl cotransporter (NCC) and the Na+-K+-Cl cotransporter (2NCC) by the WNK-SPAK/OSR1 pathway facilitates the activation of NCC and NCC2 in response to AVP. WNK4 can be regulated by PKA through the phosphorylation of its 388 motifs in vitro models. Thus, we hypothesized that WNK4 mediates the activation of NCC and NCC2 in response to AVP.

Methods: We transfected HEK293 cells with NCC2 or the V2R with SPAK and either WNK1, WNK3, WT WNK4 or WNK4 with Ala instead of Ser in its 5 RRS5 motifs. Cells were stimulated with 30 nM forskolin or 1 nM desmopressin (DDAVP). We crossbred our WNK4 strain (in a C57BL/6 background) with 129sv mice while selecting for the full-length allele of NCC2 to evaluate the phosphorylation status of NCC2.

Results: AVP-stimulated NCC2 phosphorylation was increased in WNK4+/+ and WNK4-L319F compared with WT mice. WNK4-L319F mice fed with normal or low K+ diets for 12 hrs. Generation of WNK4-L319F mice with CRISPR/Cas9, which inactivates the full-length allele of NCC2, did not affect total or phosphorylated NCC2 protein levels.

Conclusions: Our data suggest that WNK4 is a transducer of AVP signaling in the TAL and DCT, modulating NCC2 and NCC. This might contribute to the anti-natriuretic effects of this hormone and the increase in medullary osmolality that occurs with antidiuresis.

Funding: Government Support - Non-U.S.

Upregulation of NCC by Hypokalemia Involves Additional Mechanisms to Direct Cl- Sensing by WNK4

Adrian R. Murillo-de-Ozores,1 Hector Carbajal-Contreras,1 German R. Magaña,1 Norma H. Vázquez,1 Eric J. Delpire,2 Gerardo Gamba,2 María Castañeda-Bueno,2 1Universidad Nacional Autónoma de Mexico, CDMM, Mexico; 2Hundert University, Nashville, TN, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMM, Mexico.

Background: Cl-sensitive WNK4 kinase plays an important role in the modulation Na+ homeostasis in the distal convoluted tubules (DCT). WNK4 activates the Na+-Cl- cotransporter (NCC) in response to hypokalemia, promoting its phosphorylation. Low plasma [K+] decreases intracellular [Cl-] and Cl binding to WNK4's active site, leading to its activation. We have previously shown that hypokalemia and low [Cl-] increase WNK4 phosphorylation at S1196 and S1196. Hypokalemia also promotes phosphorylation of KHL3, a residue located on the C-terminal subunit of the Cl- sensing domain. We hypothesized that this Cl- sensing domain facilitates the localization and activation of the WNK-SPAK/OSR1 pathway. Mice deficient in WNK4-L319F have decreased AQP2 expression, but increased pNCC and KS-WNK1 protein levels were observed by immunoblot, and 18S was carried out by Taqman probes. 12 hrs urine collections were conducted and water intake between the groups was equalized using gelled diets.

Results: In HEK293 cells, we found that an increase in phosphorylation of SPAK and NCC2 (in response to hypokalemia, and stimulated with forskolin), WNK4 with mutants, WNK4-L319F and WNK4-R286F with forskolin requires WT NCC. In contrast, phosphorylation of S130 of NCC2 was WNK4-dependent. Cells with WT NCC and the V2R showed an increase in SPAK phosphorylation when stimulated by DDAVP. DDAVP also increased WNK4's phosphorylation at S1196. DDAVP-induced phosphorylation of both total and phosphorylated WNK4, NCC, and NCC2, as well as phosphorylated SPAK and Slc12a3 mRNA levels. These effects were absent in WNK4-/- animals. In contrast, WNK4-L319F mice did respond to DDAVP by increasing AQP2 protein levels. In addition, WNK4-/- mice fed with low K+ diets for 7 days had increased water consumption at baseline and increased urine output when water-restricted, with a tendency towards lower total body water.

Conclusions: Our data suggest that WNK4 is a transducer of AVP signaling in the TAL and DCT, modulating NCC2 and NCC. This might contribute to the anti-natriuretic effects of this hormone and the increase in medullary osmolality that occurs with antidiuresis.

Funding: Government Support - Non-U.S.

PO1084 Calcium-Sensing Receptor-Mediated Activation of the WNK4-SPAK-NCC Pathway by Glucose/Fructose In Vivo and Ex Vivo

Jessica P. Bahena-López,1,2 Lorena L. Rojas,1,2 María Chavez-Canales,2 Ju Hye Lee,2 Silvana Bazúa-Valenti,1 Rocio Bautista,1 Norma H. Vázquez,1 Maria Castañeda-Bueno,2 Gerardo Gamba,1 Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico; 1Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico; 2PECEM, UNAM, Mexico, Mexico; 3Instituto Nacional de Cardiología Ignacio Chavez, Mexico City, Mexico.

Background: NCC is activated via the CaSR-WNK4-NCC pathway. Glucose and other sugars act as positive allosteric modulators of the CaSR. In vitro from our lab (ASN 2019-2020) showed that extracellular glucose or fructose increases activation of the WNK4-Spark-NCC pathway via the CaSR. Since glucose reabsorption occurs proximally in the nephron, the distal cell has little opportunity to function (DCT) is negligible. Fructose delivery depends largely on intake. Thus, sugars delivery to DCT could result in NCC activation via CaSR-WNK4-NCC pathway.

Methods: We used wild-type mice treated with vehicle, oral fructose +/− calcitropic NPS2143, or a single dose of dapagliflozin 1mg/kg i.p to induce transient glycosuria +/− NPS2143. Kidneys were extracted after 3 hours to assess activation of the WNK4-Spark-NCC pathway by immunoblotting. To rule out a effect of dapagliflozin in the WNK4-Spark-NCC pathway by angiotensin II, we pre-treated mice with losartan. The response to a thiazide challenge in vehicle, fructose or dapagliflozin treated mice was assessed. Finally, we used an ex vivo Langerhans rat kidney preparation to evaluate the effect of different concentrations of glucose infusion in the renal artery.

Results: In WT mice, we observed increased activity of the WNK4-Spark-NCC pathway following dDAVP infusion in the kidney after exposure to 20% fructose. Glucose or osmotic stimulation of dapagliflozin (p<0.01). These effects were abrogated by NPS2143 (p<0.01) and was not observed in WNK4-KO mice (p<0.001). Additionally, the effect of dapagliflozin was present in mice pre-treated with losartan (p<0.01). Natriuresis induced by a thiazide challenge was significantly lower in vehicle or fructose, or dapagliflozin, than in vehicle/dapagliflozin, suggesting activation of NCC. Finally, we observed increased NCC and SPARK phosphorylation by infusing glucose above proximal tubule reabsorption threshold levels to ex vivo rat kidney preparations (p<0.001); notably, this effect was prevented by NPS2143.

Conclusions: Glycosuria by fructose increases NCC, SPARK and WNK4 phosphorylation in a CaSR-dependent fashion. Our data thus suggest a calcimetric-like behavior for sugars in the DCT. This effect may have implications for salt-retention mechanisms induced by disorders of glucose metabolism and increased dietary fructose intake.

PO1085 Kidney-Specific WNK1 Amplifies NCC Responsiveness to Potassium Imbalance

Cary R. Boyd-Shiawiski,1 Rebecca T. Beacham,1 Shawn E. Griffiths,1 Daniel J. Shiawiski,2 Sophia Knoell,1 Katherine E. Querry,1 Sean D. Stocker,1 Arohan R. Subramanya,1,2 University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Carnegie Mellon University, Pittsburgh, PA; 3VA Pittsburgh Healthcare System, Pittsburgh, PA.

Background: The distal convoluted tubule (DCT) NaCl cotransporter (NCC) is activated by phosphorylation, a process that is potassium (K+) regulated and dependent on the Na+-Cl- cotransporter (NCC). WNK4, a kidney-specific WNK1 isoform lacking the kinase domain, controls WNK signaling pathway localization in the DCT. Its role in NCC regulation, however, is unresolved: while early studies proposed that WNK1 functions as an NCC inhibitor, recent work suggests that it activates NCC. Here, we show that the role of WNK1 in NCC regulation, we studied KS-WNK1 mice across a wide range of plasma K+ (2.0-9.0 mmol/L), induced by dietary maneuvers and diuretic challenges.

Results: KS-WNK1 KO mice exhibited blunted NCC phosphorylation compared to littersmates, indicating that KS-WNK1 activates NCC during K+ deficiency. In contrast, NCC phosphorylation was augmented in K+-loaded KS-WNK1 mice relative to controls, consistent with KS-WNK1-mediating NCC inhibition during hyperkalemia. Focusing on K+-restricted mice: 1) KS-WNK1 +/- mice had mislocalized WNK-Spark-AKT, 2) KS-WNK1 +/- mice had blunted activation of the WNK4-Spark-OSR1 kinase cascade, 3) KS-WNK1 +/- mice had sex-specific alterations to K+ and Ca2+ plasma levels, 4) KS-WNK1 +/- mice had no change to blood pressure, but were less sensitive to thiazide diuretics compared to littermates.

Conclusions: KS-WNK1 has a bimodal effect on NCC activity, activating NCC during K+ restriction and inhibiting NCC during high K+, thus expanding the inverse relationship between NCC phosphorylation and plasma [K+]. During K+ deprivation, KS-WNK1 facilitates the localization and activation of the WNK4-Spark-OSR1 pathway. Mice (and rats) with WNK1 have sex-specific differences in electrolytes, as well as aldosterone resistance. These observations clarify the role of KS-WNK1 on NCC, and identify a novel mechanism that contributes to sexual dimorphism in the mammalian nephron.

High Dietary Potassium Increases Blood Pressure in a Rat Model of CKD

Martin Gritter,1 Kuangyu Wei,1 Alexander H. Danser,1 Liffert Vogt,2 Martin H. De Borst,1 Ewout J. Hoorn,1 Joris L. Rotmans,1 Erasmus MC, Rotterdam, Netherlands; 2Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; 3Universitair Medisch Centrum Groningen, Groningen, Netherlands; 4Leids Universitair Medisch Centrum, Leiden, Netherlands.

**Background:** Potassium dysregulation is recognized as a major factor in the development and progression of CKD. The aim of this study was to investigate the role of dietary potassium in the early development of CKD in a rat model.

**Methods:** Male Sprague-Dawley rats were fed a low-potassium (0.05%) or high-potassium (2.5%) diet for 8 weeks. Blood pressure, kidney function, and histological changes were assessed.

**Results:** Rats on the high-potassium diet showed a significant increase in blood pressure compared to the low-potassium group. Kidney function tests, including serum creatinine and blood urea nitrogen, were also elevated in the high-potassium group. Histological analysis revealed early signs of tubulointerstitial damage.

**Conclusions:** Dietary potassium plays a significant role in the early development of CKD, highlighting the importance of potassium regulation in the prevention and management of CKD.

**PO1087**

Rescuing Low Blood Pressure in Amiloride-Treated Mice by Low-Potassium Diet Relies on NCC Activation

German R. Magaña,1,2 Hector Carbajal-Contreras,1,2 Adrian R. Murillo-de-Ozores,1,2 Norma H. Vázquez,1 Norma Bobadilla,1 Gerardo Gamba,1 Maria Castañeda-Bueno,1 1Universidad Nacional Autónoma de Mexico, CDMX, Mexico; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, CDMX, Mexico.

**Background:** Amiloride is a diuretic that inhibits the sodium-potassium-2-chloride cotransporter (NCC). This inhibition is associated with hypotension, but the molecular mechanisms underlying this response are not fully understood.

**Methods:** Mice were treated with amiloride and fed diets containing varying levels of potassium. Blood pressure and kidney function were measured.

**Results:** Mice on low-potassium diets showed a significant increase in blood pressure compared to those on high-potassium diets. This effect was reversed by the administration of a potassium-sparing diuretic.

**Conclusions:** The hypotensive response to amiloride is mediated by a decrease in NCC activity, which is further suppressed by low-potassium diets.

**PO1088**

SALL3 Is a Salt-Responsive Distal Convoluted Tubule-Specific Transcription Factor Induced in Distal Neprhon Remodeling

Hyun Jun Jung,1 Eric J. Delpire,2 Paul A. Welling,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Vanderbilt University Medical Center, Nashville, TN.

**Background:** Distal tubular damage is a common feature of chronic kidney disease. The mechanisms underlying these changes are not well understood.

**Methods:** Mice were induced with unilateral ureteral obstruction and fed diets containing varying levels of potassium. Gene expression analysis was performed.

**Results:** Sall3, a transcription factor, was found to be upregulated in distal tubules of mice with unilateral ureteral obstruction and low-potassium diets. Knockdown of Sall3 resulted in blunted tubular remodeling.

**Conclusions:** Sall3 is a key transcription factor in distal tubular remodeling, providing a potential target for therapeutic intervention.

**PO1089**

Chemogenetic Activation of the Distal Convoluted Tubule Enhances Sodium Excretion Through Rapid Dephosphorylation of the Sodium-Chloride Cotransporter

Kevin J. Martz,1 Xiao-Tong Su,1 Yujiro Maeoka,1 Avika Sharma,1 James A. McCormick,1 David H. Ellison,12 Jonathan W. Nelson,1 1Oregon Health & Science University, Portland, OR; 2Veterans Affairs Portland Health Care System, Portland, OR.

**Background:** The distal convoluted tubule (DCT) is a critical site for the regulation of sodium and potassium balance. The mechanisms underlying sodium excretion in this region are not fully understood.

**Methods:** Mice were genetically engineered to express a potassium channel (Gq) in the DCT. The response to a high-sodium diet was assessed.

**Results:** Mice expressing Gq in the DCT showed an increased sodium excretion rate compared to control mice. This effect was reversed by the administration of a potassium channel blocker.

**Conclusions:** Chemogenetic activation of the DCT provides a novel approach to modulating sodium excretion, potentially offering new therapeutic avenues for kidney disease.

Mechanistic Importance of Reduced KLHL3 and CUL3 Expression in Cul3-A9-Mediated Familial Hyperkalemic Hypertension
Yujiro Maeoka, Mohammed Z. Ferdaus, Avika Sharma, Ryan J. Cornelius, Xiao-Tong Su, Joshua A. Robertson, Susan B. Gurley, David H. Ellison, James A. McCormick. Oregon Health & Science University, Portland, OR.
Background: Mutations in the ubiquitin ligase scaffold protein Cullin 3 (CUL3) cause the disease familial hyperkalemic hypertension (FHH). In the kidney, the mutant Cul3Δ–/– mice co-expressed with C99p signalosomes subunits JAB1 that negatively regulates CUL3 activity. This leads to Cul3-A9 autodegradation, and increased abundance of With-No-Lysine [K] Kinase 4 (WNK4), which inappropriately activates the downstream kinase SPAK, which then phosphorylates and hyperactivates the Na+/Cl– cotransporter (NCC). We showed lower that Cul3 alone does not increase WNK4, so the precursor mechanism by which Cul3-A9 causes FHH is unclear. We hypothesized Cul3-A9 degrades Kelch-like 3 (KLHL3), the CUL3 substrate adaptor for WNK4; thus reduced abundance of KLHL3 combined with reduced CUL3 are mechanistically important in Cul3-A9-mediated FHH.
Methods: We studied Cul3 KO (Cul3Δ–/–), mice, Cul3 KO mice expressing CUL3-A9 (Cul3Δ–/–; Cul3-A9), Cul3 heterozygotes expressing CUL3-A9 (Cul3Δ+/–; Cul3-A9), compound Cul3Δ–/– and Cul3Δ+/– heterozygotes (Cul3Δ+/–; Cul3-A9), and Jabi KO (JabiΔ–/–) mice. All mouse lines were inbred and all experiments were performed at 14 weeks of age.
Results: Cul3Δ–/– did not promote degradation of Cul3 targets that accumulate in Cul3Δ–/– kidney: WNK4, cyclin E, or NQO1 (a surrogate for the CUL3 substrate Ntr2). In Cul3Δ–/– mice, Cul3-A9 prevented KLHL3 accumulation seen in Cul3Δ–/– kidney and promoted KLHL3 degradation in Cul3Δ–/– mice. Higher NQO1 and lower cyclin E abundances were observed in Cul3Δ–/– mice compared to control mice. Cul3Δ–/– mice displayed increased WNK4-SPAK activation and phospho-NCC abundance, and FHH-like phenotype with increased plasma [K+] and salt-sensitive blood pressure. Similarly, reduced Cul3 and KLHL3 abundances and increased abundances of WNK4 and phospho-NCC were observed in JabiΔ–/– mice.
Conclusions: Together, these data provide evidence for a mechanism of reduced KLHL3 and reduced Cul3 in Cul3-A9-mediated FHH. Cul3-A9 potently degrades KLHL3, but also exerts modest effects on other Cul3 targets, raising the possibility of unidentified reduced phenotypes in the human disease.

PO1091
Non-Reabsorbable Anions Enhance Potassium Excretion by Multiple Mechanisms
Lama Al-Ousai1, Paul R. Grimm,1, Truyen D Pham,2 Ava Zapf,3 Delaney C. Abood,2 Susan M. Wall,1 Paul A. Welling,1 1Johns Hopkins Medicine, Baltimore, MD; 2Emory University School of Medicine, Atlanta, GA; 3University of Maryland Baltimore, Baltimore, MD.
Background: Potassium (K+) secretion in the distal nephron (DN) is governed, in part, by the lumen-negative transepithelial potential (Vte), created by ENaC-mediated sodium reabsorption, and partially attenuated by paracellular chloride (Cl+) reabsorption. K+ secretion increases when nonreabsorbable ions (NRA), such as HC03 or beta-hydroxybutyrate, replace luminal Cl+. Although this allows an appropriate response to alkaline-ash rich diets, it can drive exaggerated K+ secretion in alkalosis. According to textbook views, NRA facilitates K+ secretion solely by increasing the lumen-negative Vte. However, the effects of NRA on the potassium secretory machinery have not been determined.
Methods: Wild-type C57BL/6J mice were randomized to control (1%K+), potassium chloride (KC15.5%) or potassium bicarbonate (KHCO3:5.5%) diets for 10 days. Physiological, molecular and imaging analysis were performed. Pendrin-KO mice were examined to assess the specific role of pendrin in NRA-mediated potassium excretion.
Results: Consumption of the high KHCO3 diet increased urinary potassium K+ excretion and the trans-tubular K+ gradient (TTK) significantly more than with the high KC1 diet, consistent with an NRA response. Both diets increased aldosterone to the same extent, correlating with similar increases in ENaC expression and proteolytic activation. Surprisingly, the high KHCO3 diet significantly enhanced ROMK protein expression and apical localization in the late distal convoluted tubule and CNT more than the high KC1 diet. The diets also induced opposite changes in Pendrin protein and apical membrane localization.
Conclusions: The high KC1 diet increased urinary K+ excretion in the high KC1 diet increased in the high KHCO3 diet. The high KHCO3 diet also uniquely induced a remodeling of the intercalated cells in the late DCT and CNT, whereby the number of pendrin-positive cells increased without change in principal cells. Pendrin-KO mice excrete the high dietary KHCO3 lead to the same extent as WT mice but develop metabolic alkalosis.

The Effect of Epidermal Growth Factor Inhibition on Distal Nephron Sodium Reabsorption in Mice
Keyona N. King,1 2 Robert S. Hoover,1,2 3Emory University School of Medicine, Atlanta, GA; 4VA Medical Center Atlanta, Decatur, GA; 5Tulane University School of Medicine, New Orleans, LA.
Background: Studies have shown that the epithelial growth factor (EGF) decreases the activity of ENaC while the influence of EGF on renal Na+ transport via NCC is unknown. Previous investigations in mDCT-15 cells showed that EGF increases endocytosis of NCC. Using radio-telemetry, we found that EGF inhibition increases systolic blood pressure in response to increasing the dietary Na+ intake. Our results in consolidation with other researchers, suggest that EGF affects BP by influencing the activity of ENaC and NCC. Our goal is to determine whether EGF inhibition increases BP via alterations in Na+ reabsorption.
Methods: Using metabolic cages, we collected urine samples at three time points over 24 hours in 7 week old male mice. Normal salt (LS) diet (0.4% Na+ was given for baseline collections and high salt (HS) diet (4% Na+ was given for experimental collections. Only the experimental (E) group, n=4 received gefitinib (an EGF receptor tyrosine kinase inhibitor) orally at 100 mg/kg and the control (C) group received placebo. Hydrochlorothiazide (HCTZ) 2.4 mg per 10 kg BW orally and amiloride 1.45 g/kg via IP injection were administered. Following a washout period, HCTZ and amiloride were given simultaneously to assess the total effect on NCC and ENaC.
Results: There was no difference in the average urinary Na+ excretion over 24 hours for baseline measurements between the groups when receiving the LS diet (experimental (E) group: 105 ± 13 mmol vs. control (C) group: 82 ± 23 mmol, N.S.). However, when giving the HS diet and HCTZ, the E group had a higher average urinary Na+ excretion in response to a higher dietary Na+ intake (E group: 24 ± 15 mmol vs. C group: 13 ± 5 mmol, p<0.05). For amiloride with HS diet there was no difference in average urinary Na+ excretion between the groups (E group: 110 ± 127 vs. C group: 92 ± 48 mmol, N.S.). When giving both HCTZ and amiloride to the mice while receiving the HS diet, the E group had a significantly higher urinary Na+ excretion compared to the C group (E group: 997 ± 66 vs. C group: 777 ± 48 mmol, p<0.05).
Conclusions: Therefore, our data suggests that inhibition of EGF increases Na+ reabsorption via NCC. As previously suggested, this may indicate that EGF ligands act as tonic inhibitors of NCC tubular sodium reabsorption. Future experiments will explore the in vivo effects of EGF inhibition on sodium excretion along other components of the nephron.

PO1093
Role of mTORC2/SKGl Signaling in Rapid Response to Acute K Load to Maintain K+ Homeostasis
Bidisha Saha,1 Waheed Shabbir,1 Enzo Takagi,2 John E. Demko,1 Mads V. Sorensen,1 Deise C. Leite-Dellova,2 David Pearce,3 1University of California San Francisco, San Francisco, CA; 2Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil; 3Aarhus Universitet, Aarhus, Denmark.
Background: The kinase mTORC2 phosphorylates SGK1 and is required for normal K+ secretion in the aldosterone-sensitive distal nephron. Aldosterone is known to play a role in mediating a sustained response to changes in SGK1 gene transcription, however, it is unknown how rapid responses are mediated. Here we have explored the role of mTORC2 and ENaC activity in the early response to an acute K+ load to regulate K+ secretion.
Methods: Inducible tubule-specific Rictor (a core component of mTORC2) knockout mice (TRKO) were generated (Pax8-rtTA/LC-1/Rictorflx/flox). Both WT and TRKO mice received control or 2% KCl via gavage following intraperitoneal vehicle or EGF (20 µg, EGF inhibitor) injection. After 30 min (E group) or 48 h (C group) reversal of placebo. Hydrochlorothiazide (HCTZ) 2.4 mg per 10 kg BW orally and amiloride 1.45 g/kg via IP injection were administered. Following a washout period, HCTZ and amiloride were given simultaneously to assess the total effect on NCC and ENaC.
Results: Adult TRKO mice on normal diet displayed no abnormality except significantly elevated aldosterone. K+ administration by gavage triggered markedly greater Na+ excretion and lower K+ excretion in TRKO than WT mice, with differences detectable within 1 h of gavage. Benzamil induced a greater natriuresis in TRKO than WT mice, with more pronounced potassium conservation, consistent with greater ENaC activation in WT than in TRKO. The response of WT occurred rapidly, before significant change in aldosterone. In benzamil-treated mice, the natriuresis and kaliuresis of WT and TRKO mice were comparable, strongly supporting the idea that KC1 inhibited via alterations in Na+ reabsorption and thus the aldosterone system.
Funding: NIDDK Support, VA, NIDDK, NLM.
ENaC-dependent K⁺ secretion in WT, and that this response is defective in TRKO. Patch clamp studies showed similar increased ENaC activity in WT but not in TRKO mice, and no change in ROMK activity in WT or TRKO by KC1 gavage. Membrane expression of cleaved α- and γENaC were significantly increased in WT but not in TRKO mice receiving KC1 gavage. No significant increase in membrane expression of ROMK was observed in WT or TRKO A gavage. Finally, both SGK1 and Nedd2-2 phosphoprotein levels were increased in WT but not TRKO mice receiving KC1 gavage.

Conclusions: Overall, the data strongly suggest that an acute K⁺ load acts through mTORC2/SGK1 to rapidly stimulate ENaC but not ROMK to promote K⁺ secretion. These effects are primarily due to local renal tubular K⁺ sensing.

Structural Determinants of mTORC2 Substrate Specificity and SGK1 Phosphorylation Revealed by Cryogenic Electron Microscopy
Junliang Chen,1 Zannin Yu,2 Feng Wang,2 Xi Liu,1 Enzo Takagi,1 Lydia-Marie Joubert,1 Mingliang Jin,2 Carlos Nowotny,2 David Agard,1 Yifen Cheng,1 David Pearce.2 1SinoUnited Health, Shanghai, China; 2University of California San Francisco, San Francisco, CA; 1Stanford University, Stanford, CA.

Background: mTORC2 is a multi-subunit kinase complex central to multiple essential signaling pathways. Notably, it responds to hormonal signals and local electrolyte concentrations to phosphorylate SGK1 and regulate K⁺ secretion in the renal tubules. Two core subunits, Rictor and mSin1 distinguish mTORC2 from its much better characterized relative, mTORC1. Two other subunits, mTOR itself and a small scaffold, mLST8, complete the core complex. Previous mTORC2 reconstructions have lacked key regions of the > 1 MDA complex, particularly determinants of specificity.

Methods: Core mTORC2 subunits were expressed in Expi293F cells and purified using new methods for no grid purification. cryo-EM was performed using Krios at SLAC for high energy electrons for density maps of human mTORC2. Structures were solved for apo-complex at overall 3.23 Å resolution, and for co-complexes with substrates, SGK1 and AKT, at 3.38 and 3.44 Å, respectively.

Results: The apo-complex reveals architectural features of functionally important domains, including specific side chain positions and interactions, which are visualized for the first time. In particular, Rictor/Ser-1624 and Ser-1625 were observed to engage in hydrogen bond interactions with mTOR Thr-2998, in a manner that provides steric hindrance to binding of Rapamycin, and explains mTORC2 resistance to the effects of this clinically important mTORC1 inhibitor. In addition, mSin1, the other defining subunit of mTORC2, is seen to form extensive contacts with Rictor, including an extended strand, which makes multiple weak contacts with a Rictor helical cluster. Most notably for the apo-complex, Rictor plays a key role in forming the co-complex structure with mLST8—but not the mLST8 complex, we see a marked change in the conformation of the mSin1 N-terminal extended strand in a manner consistent with previous functional data identifying this region as required for phosphorylation of SGK1, but not Akt, thus providing a structural basis for differential regulation.

Conclusions: These findings provide new structural insight into mTORC2 specificity and context-dependent activities, and foundation for further mechanistic studies. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

POI1095

In Vivo Influence of a Protease-Resistant Epithelial Sodium Channel Gamma Subunit on Fluid Homeostasis

Background: Extracellular fluid depletion promotes proteolytic processing of ENaC's γ subunit. Removal of the subunit's inhibitory tract enhances channel open probability. Although several cleavage sites exist distal to the γ subunit's inhibitory tract, only one known site resides proximal to the inhibitory tract: a furin cleavage site (RKRK 143 to QQQQ 143, or "Q4") to reduce ENaC activity in WT but not TRKO post-gavage. Finally, both SGK1 and Nedd2-2 phosphoprotein levels were increased in WT but not TRKO mice receiving KC1 gavage.

Conclusions: Overall, the data strongly suggest that an acute K⁺ load acts through mTORC2/SGK1 to rapidly stimulate ENaC but not ROMK to promote K⁺ secretion. These effects are primarily due to local renal tubular K⁺ sensing.

POI1096

A Rare Case of Acquired 11-Beta-Hydroxysteroid Dehydrogenase Deficiency
Khalid Elharrif,1,2 Nidal Alhossaini,3 Mica Alex,2 Petersen Greti,1 Hania Kassem. 1Kern Medical Center, Bakersfield, CA; 2The University of Texas Medical Branch at Galveston, Galveston, TX.

Introduction: 11-Beta Hydroxysteroid Dehydrogenase (HSD11B1) is an enzyme that is involved in steroid hormone physiology. HSD11B1 enzyme exists in two isoforms, HSD11B1-type 1 and type 2. Type 2 isozyme is responsible for converting cortisol to inactive cortisone. Plasma concentration of cortisol is approximately 100-fold higher than aldosterone and activation of mineralocorticoid receptors by cortisol is normally limited due to its conversion to inactive cortisone at the sites of aldosterone action by the enzyme HSD11B1-type 2. We are presenting a rare case of HSD11B1 deficiency in a patient taking herbal supplementation.

Case Description: A 73-year-old female with PMH of hypertension, hyperlipidemia and chronic pain was admitted to the hospital with fatigue and shortness of breath. She denied any history of diarrhea or recent use of diuretics or laxatives. She has a history of using some herbal supplements in large quantities for pain control. Initial blood pressure was 140/80 mmHg. EKG showed sinus bradycardia with PVCs and bigeminy. The lab results are summarized in table A. She received aggressive potassium supplementation and spironolactone with subsequent improvement of her condition.

Discussion: HSD11B1 deficiency is either congenital or acquired by ingestion of licorice or its derivatives (glycyrrhizic and glycyrrhetinic acids). The deficiency results in a decreased conversion of cortisol to accumulation of cortisol. The effect of cortisol on the mineralocorticoid receptor results in hypokalemia, metabolic alkalosis, and low aldosterone and renin activity. The diagnosis requires careful history and identification of specific clinical features and biochemical abnormalities.

POI1097

New Method to Discriminate Function of A and B Type of Intercalated Cells in Split-Opened Collecting Ducts
Naghmeh Hassanzadeh Khavay, Victor N. Tomilin, Kyrilo Pyrhev, Oleg L. Zaita, Oleh Pochynuk. The University of Texas Health Science Center at Houston, Houston, TX.

Background: The collecting duct (CD) is a highly adaptive terminal part of the nephron in which its essential functions are maintenance of electrolyte homeostasis. Electrically uncoupled principal and intercalated cells (PCs and ICs) perform different physiologic tasks and exhibit rather distinctive morphology. However, acid-secreting A- and base secreting B-type of ICs cannot be easily separated in functional studies despite visually mirrored localization of their transport acid-base systems. Thus, there is no consensus of whether chloride transport is localized to specific CD segment. A BICUC chloride-stimulated cAMP and spironolactone with subsequent improvement of her condition.

Methods: We used BCECF-sensitive intracellular pH (pH) measurements in split-opened CDs followed by immunofluorescent (IF) detection of AQP2 and pendrin from A/B cell type ratio in the CD. The technique of split-opening isolated CD allows unambiguous monitoring of alterations in function in many individual cells within the split-opened area. However, it is not possible to specifically change the driving force for Cl⁻ at luminal or basolateral sides, which is used for established tubule studies to identify IC types of certain cells on periphery.

Results: Expression of the prostatein in oocytes, along with ENaC (N = 15), increased amidolactone-sensitive currents, compared to oocytes with ENaC but no prostatin (N = 15; p < 0.0001). In oocytes expressing a Q4 gamma subunit (N = 15), prostatin no longer increased currents (N = 15). Western blot of PNGase-digested tissue lysates revealed a full-length (60 kDa) γ subunit and two shorter proteins, consistent with subunits either cleaved at the furin site (~53 kDa) or at a more distal site. Tissues from Q4 mice lacking the 53 kDa band, suggesting impaired Furin site cleavage. Blood K⁺ was normal in Q4 mice (N ≥ 7 for each sex and genotypes). On a LSD, Q4 male mice exhibited greater loss of body water than control males (p = 0.04; N = 6-7), but females exhibited no difference in body weight (N = 7-8).

Conclusions: These findings support a role for proteolytic activation of ENaC in male mice maintaining total body fluid in response to dietary Na depletion. Females did not show a impaired body fluid retention, suggesting additional compensatory mechanisms.

Disorder.

Presented with respiratory exhaustion. Hemodialysis was started to correct the acid-base and sodium bicarbonate was started, the patient showed no clinical improvement and of severe malnutrition, and no worsening of kidney function. The patient was screened (pH 7.35; pCO2 16 mmHg; pO2 102 mmHg; HCO3 8 mmol/L; anion gap 22 mmol/L; dose paracetamol (4 g daily), and Flucloxacillin (12 g daily). After 10 days she presented severe pain complaints. In that context, she was started on opioids, NSAIs and high-

We found that metabolic acidosis leads to augmented transport rate and increased total population of A-type in the CD.

PO1098 Piezol in Intercellular Cells (ICs) Mediates Flow-Induced [Ca2+]i Transients in Mouse Cortical Collecting Duct (CCD)
Rolando Carrizosa-Gaytan,1 Stephanie Mutchler,1 Joanne Soong,1 Martanella G. Dalghi,2 Gerard Apodaca,3,5 Thomas R. Kleyman,2 Liu Li,6 (E-mail: Satlin@mountsinai.edu)1 Mount Sinai School of Medicine at Mount Sinai Department of Pediatrics, New York, NY; 2University of Pittsburgh Department of Medicine, Pittsburgh, PA; 3University of Pittsburgh Department of Cell Biology and Physiology, Pittsburgh, PA.

Background: Within the CCD, an acute increase in tubular fluid flow rate (TFFR) exposes principal cells (PCs) and ICs therein to hydrodynamic forces. In response, a biphasic increase in [Ca2+]i is observed, with an immediate high amplitude increase due to release of IP3-sensitive internal Ca2+ stores coupled to extracellular Ca2+ entry at the basolateral membrane. This is followed by a decay to a plateau that is higher than baseline and sustained by luminal Ca2+ entry. This increase in [Ca2+]i is necessary for BK channel-mediated flow induced K+ secretion (FIKS) in the microperfused mammalian CCD. We have recently reported that PIEZO1, a mechanosensitive, Ca2+-permeable channel, is expressed on the basolateral membranes of PCs and ICs in the mouse CCD (Dalghi et al., 2019).

Methods: To examine whether IC PIEZOL expression contributes to the increase in [Ca2+]i triggered by TFFR, we generated a mouse with targeted deletion of PIEZOL in ICs (IC-Piezol-KO).

Results: Immunofluorescence analyses of kidneys harvested from mice (C57BL/6) expressing PIEZOL-tdTomato revealed a significant increase of PIEZO1 expression in ICs from mice fed a high K (HK, 5% K+, n=4) vs. normal K (SK, 1% K+, n=4) diet for 10 days. Fluorescence intensity ratios (FIRs; ratio of the Ca2+ indicator Fura-2 emission signals measured at excitation wavelengths of 340 nm and 380 nm), corresponding to [Ca2+]i, were measured in individually identified PCs and ICs in CCDs isolated from (i) HK-fed IC-Piezo1-KO (n=3), (ii) SK-fed littermate control (n=3), and (iii) HK-fed control (n=3). FIRs in response to the PIEZO1 activator Yoda1 (1 mM). PCs and ICs from HK-fed control mice exhibited a greater increase in [Ca2+]i in response to Yoda1 than SK-fed control mice (p=0.001). However, ICs from HK-fed IC-Piezo1-KO mice exhibited a reduced or absent increase in [Ca2+]i in response to Yoda1 vs. SK-fed control mice (p=0.001). In microperfused CCDs isolated from IC-Piezo1-KO mice, an increase in TFFR did not elicit a typical increase in [Ca2+]i in ICs (p=0.001, n=3 controls and n=4 KOs).

Conclusions: We conclude that Piezo1 is upregulated in the CCD by a HK diet and contributes to the TFFR-induced increase in [Ca2+]i, ICs necessary for FIKS.

PO1099 An Extremely Rare Interaction Between Two Commonly Used Drugs
Maria Teresa Furtado, Catarina A. Gonçalves, Patricia Valerio, Hospital de Sao Bernardo, Setubal, Portugal.

Introduction: The use of Paracetamol and Flucloxacillin can result in an elevated anion gap metabolic acidosis. Interaction between these drugs is a rare disorder that results from accumulation of pyroglutamic acid. Affected patients are usually women with chronic illness, sepsis, and malnutrition.

We found that inhibition of CIC-K2-dependant H+ conductance was observed in cell lines (pH 7.35; pCO2 16 mmHg; pO2 102 mmHg; HCO3 8 mmol/L; anion gap 22 mmol/L; lactate 0.4 mmol/L). Laboratory tests showed hyponatremia of 141g/dl in the context of severe malnutrition, and no worsening of kidney function. The patient was screened for lactic acidosis, ketoacidosis, toxic alcohol ingestion and salicylate poisoning with no positive findings. Finally, we concluded accumulation of pyroglutamic acid secondary to the constant use of flucloxacillin and paracetamol in high doses as the leading cause of elevated anion gap metabolic acidosis. Despite these drugs were immediately stopped and sodium bicarbonate was started, the patient showed no clinical improvement and presented with respiratory exhaustion. Hemodialysis was started to correct the acid-base disorder.

Discussion: Despite being extremely rare, metabolic acidosis induced by drug interaction between Paracetamol and Flucloxacillin is a severe and potentially life-threatening disorder. We recognize the relevance of this case since these drugs are commonly prescribed together.

PO1100 Dietary Ammonium Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux
Jeffrey M. Purkerson, George J. Schwartz. University of Rochester Medical Center, Rochester, NY.

Background: In a mouse model of urinary tract infection with Uropathogenic E. coli (UPEC-UTI) dietary NH4Cl (AC) induces metabolic acidosis and increases UPEC burden in reflux prone C3H-HeN, but not Ctrl deficient, C3H-HeJ mice. We have confirmed and extended these studies by comparing the inflammatory response in C3H-HeN mice fed AC-diet vs. standard chow (SC), and by examining the effect of HCl-acidosis.

Methods: Female C3H-HeN mice were fed: standard chow (SC), NH4Cl (2% w/w; AC), or 1g/mol 0.4 N HCl supplemented chow (HCl-A). Acid-base state was assessed and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol 4,5-bisphosphate (PIP2, a soluble form of PIP2, was determined by cryo-electron microscopy. Based on this molecular model of human TRPV6 with PIP2, a structural model of human TRPV6 was set up. This model was then exposed to hydrodynamic forces. In response, TRPV6 undergoes structural and position changes, suggesting the opening of the lower gate. Recently, a structure of rabbit TRPV5 in complex with dioctanoyl (diC8) phosphatidylinositol 4,5-bisphosphate (PIP2) was determined by electron microscopy. Based on this structure, a structural model of human TRPV5 with PIP2 was set up. This model was then embedded in a 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) lipid bilayer with water molecules added on both sides of the bilayer using CHARMM-GUI. Using the protein disease research group, department of physiology, faculty of medicine and dentistry, university of alberta, edmonton, ab, canada.

Background: Transient receptor potential vanilloid subfamily member 6 (TRPV6) is a Ca2+-selective channel that mediates Ca2+ entry into epithelial cells as the first step of the transepithelial Ca2+ transport pathway. TRPV6 is expressed in the kidney, intestine, and other epithelial tissues, and the dysregulation of this channel has been implicated in cancers. TRPV6 and its close homologue TRPV5 are activated by phosphatidylinositol 4,5-bisphosphate (PIP2); however, it is less clear how PIP2 activates TRPV6 at the molecular level.

Results: Recently, a structure of rabbit TRPV5 in complex with diocetyl (diC8) PIP2, a soluble form of PIP2, was determined by cryo-electron microscopy. Based on this structure, a structural model of human TRPV5 with PIP2 was set up. This model was then embedded in a 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) lipid bilayer with water molecules added on both sides of the bilayer using CHARMM-GUI. Using the AMBER18 software, three 500-ns molecular dynamics simulations were performed for the two systems of TRPV6 with and without PIP2.

Results: Interaction energy analyses show that the distance between the diagonally opposed residues R302, R305, K484, and R584 of TRPV6 play a significant role in the binding of diC8 PIP2. The binding of PIP2 to TRPV6 increases the distance between the diagonally opposed residues D542 in the selectivity filter as well as the distance between the diagonally opposed residues M578 in the lower gate. Secondary structure and density analyses show that residue M578 in TRPV6 in the presence of PIP2 undergoes structural and position changes, suggesting the opening of the lower gate. Principal component analysis also indicates that the binding of PIP2 increases the dynamic motion of both the selectivity filter and the lower gate of TRPV6.
PO1102
Lithium Treatment Induces Changes in E-Cadherin, β-Catenin, and Na+/K+-ATPase β1 in Rat Inner Medullary Collecting Duct in a Time-Dependent Manner
Xavier Sarrant, Jeppe Praetorius, Birgitte M. Christensen, Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark.

Background: Lithium (Li) induced Nephrogenic Diabetes Insipidus (NDI) develops in around 40% of psychiatric patients receiving Li treatment. NDI is characterized by the inability of the kidney to concentrate urine due to insufficient water reabsorption in the kidney collecting duct (CD). Studies in rats have shown that Li induces a cellular compositional change of the CD with a fractional decrease in the ratio of principal-to-intercalated cells after 4 weeks of Li. This cellular remodeling is reversible in rats undergoing recovery for 19 days following 4 weeks of Li treatment. We aimed to investigate if regulation of the cell-contacts E-cadherin and β-catenin have a role in the cellular remodeling. The Na/K-ATPase was also investigated due to previously shown influences on cell polarity and cell-contact formation in kidney cells (Rajasekaran et al. Mol Biol Cell).

Methods: Immunohistochemistry (IHC) was performed on rat kidney sections used in previously published studies (Christensen et al., AJP; 2006; Treviccone et al., AJP, 20: 107, 2020) from sections from rats treated with Li for 4, 10 and 15 days and 4 weeks were stained using antibodies against the cytoplasmic domain of E-cadherin, β-catenin and Na/K-ATPase β1-subunit. Sections from rats that had undergone recovery for 6 and 12 days following 4 weeks of Li treatment were stained for β-catenin.

Results: E-cadherin and β-catenin labeled basal and lateral plasma membrane domains in the inner medullary CD (IMCD). In the proximal part of IMCD, the labeling was absent from the basal plasma membrane domains of multiple cells after 4 and 10 days of Li treatment and was present again after 4 weeks of Li. In addition, the basal labeling of E-cadherin was absent from some cells after 12 days of recovery. IHC of the Na/K-ATPase β1-subunit revealed a similar subcellular localization, and the protein was not present in the basal plasma membrane domains of multiple cells in the proximal part of the IMCD already after 4 days of Li.

Conclusions: The subcellular localization of the adherens junction proteins E-cadherin, β-catenin and Na+, K -ATPase β1 is affected by Li treatment in the proximal part of the IMCD. In addition, the absence of labeling from the basal plasma membrane domains appears to occur prior to the cellular remodeling.

PO1103
Deletion of the EP3 Receptor in the Kidney Tubule of Adult Mice Has No Impact on the Major Channels and Transporters Involved in Kidney Water Handling
Cristina Esteva-Font,1 Frank Geurts,2 Ewout J. Hoorn,3 Robert A. Fenton,4 1Aarhus Universitet, Aarhus, Denmark; 2Erasmus MC, Rotterdam, Netherlands.

Background: Prostaglandin E2 (PGE2) is an important lipid mediator modulating various aspects of kidney function. PGE2 exerts its effects via four PGE2 receptors, EP1, EP4, but it is unclear which PGE2 effects are mediated through which receptor. The EP3 receptor is expressed in the thick ascending limb (TAL) and the collecting duct, where it is proposed to inhibit CAMP generation and NaCl and water reabsorption. However, EP3 is also expressed in endothelial cells of arteries and arterioles, that also play a role in kidney function.

Methods: To assess the tubular role of EP3 in adult mice we generated a mouse model based on the Pax3Cre system with doxycycline-dependent deletion of EP3 along the renal tubule and assessed their renal phenotype in respect to water handling. qPCR and RNAseq confirmed that EP3 was highly expressed in cortical and medullary TAL and collecting ducts, but it was not detected in proximal tubule and thin limbs.

Results: Two weeks after treatment with doxycycline, EP3 mRNA expression was reduced by >80% in whole kidney (RT-qPCR) and non-detetable (RNAseq) in tubules of knockout mice compared to control mice. The other EP receptors expression remained unchanged in the kidney except for a slightly increase in EP4 expression. Under basal conditions, there were no significant differences in food and water intake, bodyweight, urinary output or plasma and urine biochemistry in both male and female control and knockout mice. There were no differences between genotypes in their kidney handling of water during an acute water load, or in their response to the vasopressin V2 receptor agonist Arterenol. Moreover, relative expression levels of the main channels and transporters involved in kidney water handling, including AQP2, AQP3, AQP4, NKKCC2, eNaC and UT-A1, ROMK and Na-K-ATPase remained similar to the control mice.

Conclusions: This new model provides a novel tool for examination of the role of EP3 in other aspects of kidney function or kidney disease independently of potential developmental abnormalities or systemic effects.

Bayesian Identification of Transcription Factors That Regulate Aqp2 Transcription
Hiroaki Kikuchi,1 Hyun Jun Jung,2 Mark A. Knepper,1 1National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; 2Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and Aqp2 gene transcription is strongly regulated by vasopressin. However, the transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes’ Rule to integrate several -omic datasets, most notably a curated list of 1344 TFs present in the mouse genome with regard to probability of regulating Aqp2 gene transcription. To prioritize TFs, existing proteomic and transcriptomic data, ATAC-Seq, histone H3K27-acetylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data are used. Beyond this, we use additional -omic datasets to prioritize TFs that are regulated by vasopressin. Finally, we carried out new RNA-Seq experiments mapping the time course of vasopressin induced changes in the transcription of mouse mpkCCD cells to further prioritize TFs that change in tandem with AQP2.

Results: The analysis identified 17 TFs out of 1344 in the mouse genome that are most likely to be involved in regulation of Aqp2 gene transcription. These TFs included eight that have been proposed in prior studies to play a role in Aqp2 regulation, viz. Cebp, Elf1, Elf3, Ets1, Jun, Jnk, Nrk1, and Sp1. The remaining nine represent new candidates for future studies (Aif1, Irf3, Klf5, Klf6, Nfly, Nrk2b, Stat3, Nrk4a).

Conclusions: The Bayesian analysis has identified the TFs most likely to bind to Aqp2 cis-regulatory elements and likely to be regulated by vasopressin stimulation, providing a roadmap for future studies to understand regulation of Aqp2 gene expression.

PO1105
The Enhanced Expression of AQP4 in Cerebral Ischemia Is Attenuated in AQP11 Heterologous Knockout Mice
Yasuko Tanaka, Kenichi Ishibashi, Meiji Iioka Daigaku, Kyose, Japan.

Background: The role of aquaporins (AQPs) in the brain edema needs to be clarified to advance its treatment. Since the importance of AQP4 for the formation of brain edema has been shown in AQP11, expressed in the brain capillary, may also be important for the regulation of brain edema. In fact, we recently reported the associated expression of AQP4 and AQP11 in osmotically challenged AQP11 heterologous knockout mice (HKM) (Koike S et al. Biochimie. 2021).

Methods: Both common cervical arteries were ligated for 15 min or 60 min to produce an ischemic-reperfusion model of brain infarction. On one or two days after the reperfusion, total RNA in the brain between Bregma and Lambda was isolated from wild mice and HKM. A real-time RT-qPCR was employed to examine the expression levels of several genes including AQP1, AQP4, AQP11, Iba1 (microglial marker), GFAP (astrocyte marker), Lamp2 (pro-apolipotic factor), Bax (pro-apototic factor).

Results: Gene expression profiles were similar between wild mice and HKM in 60a1 (increase), Lamp2 (increase) with more severity in 60 min ligation and in the second day. A similar profile was also observed with slightly decreased AQP1 by 5-22%. In contrast, the expression profiles of AQP4 and GFAP were outstanding in that both were more highly induced in wild mice than HKM, by 56% vs. 21% and by 75% vs. 335%, respectively, with further increases in 60 min ligation and in the second day. The results suggested the activation of astrocytes expressing AQP4 by the reperfusion, which might be attenuated in HKM. In agreement with this, the expression of Bax was increased in wild mice by 18% with 60-min ligation while it was decreased by 12% in HKM, suggesting a smaller brain damage in HKM. Interestingly, AQP11 expression was decreased after reperfusion by 13-25% in wild mice while it was decreased more in HKM in 25-30%. The results suggest that this further AQP11 decrease in HKM may have attenuated the increasing detrimental AQP4 in brain infarction.

PO1106
Acute Hemoglobin Level Drop Based on Body Volume Gained
Phuong-Chi T. Pham, Phuong-Thu T. Pham. UCLA Medical Center Olive View, Sylmar, CA.

Background: Hemoglobin (Hb) changes with blood transfusions have been widely studied, but to our knowledge, Hb drop associated with volume gain have not been studied. High fluid infusion volume in critically ill patients always result in Hb drop, but the general extent of Hb drop may vary among individuals. We undertook a pilot study to assess Hb changes based on daily volume gained among anuric hemodialysis patients.
Methods: Chronic anuric hemodialysis (HD) patients without active bleed admitted to our institution for reasons other than dialysis were included. Strict input/output measurements and Hb levels peri-HD were obtained. Post-HD levels were obtained at least 12h post treatment to allow for equilibrated fluid compartmentalization. Changes in Hb per L of body volume gained were calculated.

Eighty-five individuals were included. Average age 60±7.2 years, 6 males, 4 females, estimated fat free mass (FFM) 49±3.5 Kg, pre-HD Hb 9.7±1.28, post-HD Hb 9.36±1.28 g/dL, positive fluid balance per patient 1182±775 mL, Average Hb drop was -0.19±0.38 g/dL per L of fluid gained, or 0.004±0.12 g/dL/L of fluid gained/ Kg of fluid lost.

Conclusions: Hemoglobin drop with large fluid infusion may be studied in the anuric HD population. Our pilot study indicates thus far that Hb drop may be ~0.2 g/dL/L on average or a maximum of ~0.8 g/dL per liter of positive fluid balance. Additional data are being collected. Our study may help clinicians gauge for possible blood loss during large fluid infusion required for hemodynamically unstable patients.

PO1107
A Salty Goodbye to Diuretic Resistance: Hypertonic Saline
Sean Barnett, Brooke Army Medical Center, Fort Sam Houston, TX.

Introduction: Understanding the interplay of cardiorenal physiology and pathophysiology in diuretic resistance requires a deep understanding of RAAS, ADH, and virtually all segments of the nephron. To treat, requires not only understanding but also the ability to investigate and differentiate. However, a treatment that can inhibit RAAS (directly and indirectly), stimulate Cardiac Output, improve GFR, and increase natriuresis could be the universal answer. 3% Saline has the ability to improve Cardiac Output and decrease SVR, improve renal blood flow, stimulate ANP, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Therefore, the answer to Diuretic Resistance is 3% Saline.

Case Description: A 55 y.o. AAF presented to the hospital for severe edema and shortness of breath. PMHx of HFpEF, DM, ITN, CKD3a3 (non-nephrotic). She presented with AKI II, severe hyponatremia, and anasarca. Echo revealed EF 40%, biatrial enlargement, RV overload and reduced RV function. She was initially treated with high dose furosemide but did not improve. She was given Metolazone which caused worsening hyponatremia which was treated with 100mL of 3% Saline. This caused an immediate increase in urine output and sodium. She was then changed to a bumex drip and high dose spironolactone (200mg) with some improvement (via objective urine electrolyte assessment) she was still inadequately diuresed. She was then treated with 3% + Loop pulse dosing and sustained a robust diuresis of >3L of urine and maintained urinary sodium >50.

Discussion: The potential causes of diuretic resistance arise from the RAAS system and the individual nephron segments. The RAAS system however is the most universal target (when inhibited). While DCT, ASDN, CD and CCT. are involved, regardless of which segment is primary, targeting the RAAS system would likely have significant benefits in all diuretic resistance. 3% Saline works as a potent IVF to improve Cardiac Output, decrease SVR, improve renal blood flow, inhibit RAAS, inhibit ADH, and stimulate ANP. Using 100mL of 3% saline to augment diuresis (or alone) causes improvement in virtually all cardiorenal parameters. The NaCl load directly inhibiting RAAS through distal NaCl delivery (salt load also increases salt wasting), this causes decreased arterial arteriolar constriction and thus further improving GFR. It also stimulates ANP in the RA to inhibit RAAS and ADH indirectly.

PO1108
Enhanced Diuresis with Sequential Nephron Blockade
Shawn Alonso,1,2 Raymond T. La,1,2 Chavelly Valdes Sanchez,1,2 Gabriel A. Vallee,1,2 University of Miami School of Medicine, Miami, FL; 1Holy Cross Hospital, Ft. Lauderdale, FL.

Introduction: Achieving volume control in patients with severe edema can be challenging, as diuretic resistance may occur. In such cases, sequential nephron blockade (SNB), a treatment not considered in the use strategy should be considered.

Case Description: A 60-year-old woman with HIV and Dilated Cardiomyopathy s/p CRT-D presented with dyspnea and anasarca due to torsionde and lossartan. In the ED she weighed 370 Lbs., had stable hemodynamic parameters, hypoxemia, diffuse lung infiltrates and left CDA causes. Oxygen, IV loop diuretics and Bactrim were initiated for concerns of PCP and HF. Despite an average UO of 3 L/day she had no meaningful weight loss after CTA. Fluid restriction and SNB with IV thiazide and loop agents were instituted.

Methods: We conducted an exploratory pilot study for 10 healthy controls following water load then 5 cardiodrenal patients with kidney disease. 1) Fasting healthy controls provided urine samples to measure osmolality and baseline 2Na/Mg scans were performed. They were instructed to ingest water (15 mL/kg) within 15 minutes. Four subsequent sodium images and urine samples were acquired at 15 min intervals starting one hour after water ingestion. 2) Cardiodrenal patients underwent an MRI scan, provided a blood and urine sample, but no water loading.

Results: Mean age of the 10 healthy controls was 41.8 ± 15.3 years. In the morning fasting, medulla/cortex ratio was 1.55 ± 0.11 with concurrent urinary osmolality measured at 814 ± 121 mOsm/L. Mean a SD fasting urinary osmolality dropped significantly to 73 ± 14 mOsm/L, p=0.001. Mean medulla/cortex ratio dropped significantly to 1.31 ± 0.09 mOsm/L for maximal dilution, p=0.002. Figure 1 displays changes of Na/Mg pictures before (A) and after (B). 1H15 (C), 1h30 (D) and 1h45 (E) after a water load. Urinary osmolality and medulla/cortex ratio are significantly correlated, r=0.54, p=0.0001. Mean age of the 5 cardiodrenal patients was 76.6 ± 12.2 years, eGFR was 54 ± 37 mL/min/1.73m2.

Conclusions: We explored CMG dynamically every 15 min in healthy controls and demonstrated significant changes after a water load. We were also able to acquire 2Na/Mg pictures in cardiodrenal patients with kidney disease with plans for future analyses.
PO1111

Attenuated Urinary Sodium and Volume in Response to Saline Load in Heart Failure with Preserved Ejection Fraction

Background: Heart failure (HF) is characterized by fluid overload due to impaired sodium (Na) excretion. Impaired urinary Na excretion in response to intravenous Na load has been demonstrated in HF with reduced ejection fraction (HFrEF). We hypothesized that patients with HF with preserved ejection fraction (HFpEF) also have impaired sodium excretion.

Methods: All participants were instructed to follow a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

Results: Mean age and body mass index for the HFpEF participants were 62+/-12 years and 36.3+/-8.5 Kg/m², and for control participants were 47+/-18 years and 24.6+/-3.7 Kg/m² respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) (pmol/mg)/(pg/ml); p = 0.014) in cases as compared to controls.

Conclusions: In this rigorous, controlled human pilot study, patients with HFpEF had lower urinary volume and attenuated urinary sodium excretion compared to controls after intravenous sodium and volume load. Data and biospecimens collected in this study should inform the pathogenesis of sodium retention in HFpEF.

PO1112

Attenuated Renal Response to Endogenous Natriuretic Peptides in Heart Failure with Preserved Ejection Fraction

Background: The pathophysiology of sodium retention in heart failure with preserved ejection fraction (HFpEF) remains largely unknown. A potential mechanism is attenuated renal response to natriuretic peptides (NPs). Urinary cyclic guanosine monophosphate (ucGMP) is an intracellular messenger of NPs, and an attenuated ucGMP/B-type NP (BNP) ratio suggests decreased renal response to BNP. We hypothesized that patients with HFpEF have attenuated response to NPs.

Methods: We studied ucGMP/plasma BNP ratios in 9 HFpEF patients and 5 controls (no history of renal or heart disease). All participants were placed on a low (2-3 g/d) sodium diet for a week prior to the study. Urinary results were normalized using urine creatinine. Cases and controls were compared using Wilcoxon rank-sum tests.

Results: Mean age and body mass index for the HFpEF participants were 62+/-12 years and 36.3+/-8.5 Kg/m², and for control participants were 47+/-18 years and 24.6+/-3.7 Kg/m² respectively. Plasma BNP tended to be higher (median 54.0 (29.0, 118.0) versus 5.0 (5.0, 34.0) pg/ml; p = 0.15), while ucGMP/plasma BNP ratio was lower (median 0.7 (0.4, 0.8) versus 7.3 (1.7, 8.5) (pmol/mg)/(pg/ml); p = 0.014) in cases as compared to controls.

Conclusions: Our pilot study shows that ucGMP/plasma BNP ratio, which reflects renal response to BNP, was attenuated in patients with HFpEF. These data suggest that impaired renal response to NPs may be implicated in the pathogenesis of fluid retention in HFpEF.

PO1113

Association of Urinary Potassium Excretion with Progression of CKD

Daisuke Mori, Yuta Namiki, Ayaka Sugimachi, Manabu Kado, Shinjiro Tamai, Hiroki Nomi, Ryota Haga, Katsuakira Nagatoya, Atsushi Yamauchi. Osaka Rosai Hospital, Osaka, Japan.

Background: Out of range serum potassium levels are associated with worsening renal function and increased occurrence of cardiovascular disease (CVD) events in
Licorice-Induced Syndrome of Mineralocorticoid Excess
Nisarg Gandhi, Hassan N. Ibrahim. Houston Methodist Hospital, Houston, TX

Introduction: Edema and volume overload are common complaints. Here, we present a case of edema resolution with reduced licorice consumption.

Case Description: A 34 y/o Caucasian woman with history significant for hypothyroidism and recurrent episodes of bronchitis presented for evaluation of recurrent facial, arm, and lower extremity swelling over the past year. She has been evaluated extensively with no etiology found in the past. She takesBuena 0.5 mg at least once weekly when she has swelling. She does not have any evidence of kidney dysfunction, heart failure, liver failure, or evidence of proteinuria on laboratory findings. She has been evaluated by rheumatology and was only found to have a weakly positive ANA with no other associated findings (hematuria, arthralgias, or muscle pain). She denies any shortness of breath or orthopnea. Her vitals were within normal limits (BP: 115/70, Pulse: 55). She is very active and exercises daily. Despite limiting her sodium intake, she continues to have recurrent swelling. On further questioning, she mentioned drinking a tea high in licorice. Her basic metabolic panel shows Na+ at 140, K+ at 4.3, Cl- at 100, and CO2 at 26. Her urinalysis was bland with her urine Na+ < 20. Measured plasma renin and aldosterone activity, shown in the table, were found to be low at baseline. Afternoon free cortisol level was measured to be 0.199. After discontinuation of licorice, she increased back to normal limits with complete resolution of symptoms.

Discussion: Chronic ingestion of licorice is a rare but a known cause of syndrome of mineralocorticoid excess (AME). Licorice contains a steroid, glycyrrhetinic acid, which inhibits the function of the enzyme 11-beta-HSD2. This same enzyme is deficient in AME. This case occurred even when small amounts of licorice (50g per day). Typically, these cases present with hypertension, hypokalemia, metabolic alkalosis, low plasma renin activity, and low plasma aldosterone levels. The only treatment necessary is cessation of licorice and symptoms typically resolve in about 1 week. This case illustrates the importance of obtaining a complete medication history including supplement use.

POI115
Not Just Licorice: Abiraterone and Apparent Mineralocorticoid Excess
Natalie M. Beck,1 Katherine Rizzolo,2 Sophia L. Ambruoso.1,2 University of Colorado, Denver, CO; 1,2 TA Eastern Colorado Health Care System, Aurora, CO.

Introduction: Abiraterone is a CYP17A1 inhibitor which blocks androgen synthesis and is used to treat castration-resistant prostate cancer. This drug also decreases cortisol synthesis, causing a compensatory increase in adrenocorticotropic hormone (ACTH) and accumulation of mineralocorticoids. The result is the syndrome of apparent mineralocorticoid excess (AME) which manifests clinically as hypokalemia, metabolic alkalosis and hypertension. Abiraterone is approved for use only with concurrent glucocorticoid replacement to mitigate these effects. We present a case of refractory hypokalemia resulting from abiraterone use.

Case Description: A 74-year-old man with metastatic prostate cancer and head and neck cancer presented with urinary retention and acute kidney injury (AKI) as well as hyponatremia and metabolic alkalosis which were present a week prior. Home medications included abiraterone, ciprofloxin (given two weeks prior), prednisone 5 mg daily (recently decreased from 5 mg twice daily) and spironolactone. A urinary catheter was placed, the AKI improved rapidly and the patient remained with refractory hypokalemia. A urine potassium-to-creatinine ratio was high. Post-obstructive polyuria was considered as a reason for kaliuresis; however, hypokalemia and metabolic acidosis preceding this event made it unlikely to be the sole cause. Given abiraterone use, serum cortisol was checked and was low with no increase after giving cosyntropin. Serum aldosterone, renin and their ratios were normal. The patient was diagnosed with abiraterone-induced AME. Prednisone was increased to 5 mg twice daily and eplerenone was started in place of spironolactone. Two months later, the serum potassium was normal without supplementation.

Discussion: Abiraterone-induced AME is characterized by low serum cortisol but unlike adrenal insufficiency, presents with hypokalemia, metabolic alkalosis and hypertension. In this case, AME resulted from the inhibition of a 17alpha-hydroxylase activity of the CYP17A1 enzyme, leading to decreased cortisol, increased ACTH, and accumulation of the potent mineralocorticoid deoxycorticosterone. Glucocorticoid supplementation (prednisone 5 mg twice daily recommended) is needed to suppress ACTH and prevent these effects. Eplerenone is an aldosterone receptor blocker and is preferred over spironolactone in patients with castrate-resistant prostate cancer as spironolactone interacts with the androgen receptor.
Pseudo-hyperaldosteronism. Renin, aldosterone levels were checked which are low. CT scan of hyperplasia was not done and reported that hyperplasia. Renal function showed minimal potassium was high significant of renal loss. High 24 hour urine cortisol/cortisol ratio suggestive of mineralocorticoid excess. Posaconazole was changed to Voriconazole on 10/28/20. Due to persistent hypertension, spironolactone was increased and due to hyperkalemia, oral potassium was added. Twelve days after stopping Posaconazole all electrolyte and acid base abnormalities are resolved.

Discussion: Combination of hypokalemia, hypertension and metabolic alkalosis need to suspect mineralocorticoid excess. Posaconazole inhibits 11 beta-hydroxysteroid dehydrogenase-2 which prevents conversion of cortisol to cortisone. Fracal sodium and aldosterone leads to amplification of mineralocorticoid receptor action causing increase in activity, number of epithelial sodium channels (ENaC), Na-K-ATPase channels. Excess uptake of sodium leads to hypertension and creates increased negativity causing K+ and HCO3- to leave the cell. Hypokalemia with hypertension lead us to suspect a hyper mineralocorticoid state. Workup revealed spot urine K of 4.3 mEq/L, bicarbonate (HCO3) 29 mEq/L and newly elevated liver enzymes. He was diagnosed with immune checkpoint inhibitor hepatitis and treated with prednisolone 70 mg via nasogastric tube (NGT). Two days later, blood pressure increased to 170/80 mmHg with severe hypokalemia and alkalosis. Patients with mineralocorticoid excess can be treated with aldosterone receptor antagonist or ENaC blockers or by stopping or decreasing the dose of Posaconazole. Patients on posaconazole need to be monitored for hypokalemia, hypertension and alkalosis. However, not every patient will develop these which may be likely due to genetic predisposition.

POI118
Prednisolone-Related Mineralocorticoid Excess: Case of Hypokalemia and Metabolic Alkalosis
Lauren E. Macaigue, Anna Astashchanka, Rakesh Malhotra, Cynthia Miracle
University of California San Diego, La Jolla, CA

Introduction: We report a case of the mineralocorticoid effect of prednisolone resulting in hypokalemia and metabolic alkalosis in a patient treated with checkpoint inhibitor in the setting of oropharyngeal cancer.

Case Description: A 78-year-old male with past medical history of oropharyngeal squamous cell carcinoma presented with fatigue. One week prior, he was treated with pembrolizumab. Admission vital signs were significant for fever to 39.1°C and normotensive blood pressure 130/88. Laboratory results revealed serum potassium (K+) 4.1 mmol/L, bicarbonate (HCO3) 26 mEq/L and newly elevated liver enzymes. He was diagnosed with immune checkpoint inhibitor hepatitis and treated with prednisolone 70 mg via nasogastric tube (NGT). Two days later, blood pressure increased to 170/80 mmHg and laboratory studies revealed hypokalemia and metabolic alkalosis with serum K+ 3.0 mmol/L and HCO3 33 mmol/L. Potassium was repleted with a total of potassium chloride (KCl) 80 mEq via NGT. The next morning, blood pressure 164/78, serum K+ 2.7 mEq/L and HCO3 33 mmol/L. Nephrology was consulted for persistent hypokalemia and metabolic alkalosis. The triad of hypokalemia, metabolic alkalosis and hypertension lead us to suspect a hyper mineralocorticoid state. Workup revealed spot urine K+ of 100 mmol/L, serum aldosterone <3.0 ng/dL and serum renin <0.1 ng/dL. Findings were consistent with an exogenous source of mineralocorticoid activation. Prednisolone was thought to be the cause. He required a total of KCl 150 mEq (40 mEq intravenous, 140 mEq NGT) to raise serum K+ to 3.4 mmol/L in 24 hours. As such, we recommended discontinuing prednisolone in favor of dexamethasone which has no mineralocorticoid effect. Two days after discontinuation of prednisolone, serum K+ was 5.1 mmol/L and KCl 40 mEq via NGT twice a day and serum HCO3 was 28 mmol/L. Supplemental KCl was discontinued. One week later, serum K+ remained in normal range at 4.1 mmol/L.

Discussion: We documented clinically significant mineralocorticoid effect of prednisolone resulting in hypokalemia and metabolic alkalosis. Physicians should be aware of electrolyte disorders associated with steroid use. With increased use of checkpoint inhibitors, this scenario may be encountered more often. Treatment may require stopping prednisolone and using alternative steroids with no mineralocorticoid checkpoint inhibitors, this scenario may be encountered more often. Treatment may be required.

POI119
From Hypokalemia to Sjögren Syndrome: What a Twist!
Elizabeth Pabon-Vasquez, Jose Rivera Sepulveda. Mayagüez Medical Center, Mayagüez, Puerto Rico.

Introduction: Potassium disorders are one of the many serious conditions that could attempt against a patient’s life. Understanding the clinical presentation, diagnosis, management and treatment of hypokalemia is paramount for the development of successful clinical physician. In addition, being aware of the associations between electrolyte disturbances and rheumatologic conditions increases the benefits of correctly treating and preventing underlying disease.

Case Description: This is the case of a 24-year-old female patient, GIP2-AO, with a past medical history of hypoglycemia and hypokalemia since pregnancy with twins. Patient presented to emergency department with shortness of breath, general malaise, muscle weakness, and unable to ambulate. Physical examination was remarkable for proximal muscle weakness, diminished deep tendon reflexes with intact sensation. Laboratory bloodwork reported positive mycoplasma pneumonia infection, normal anion gap metabolic acidosis with severe bicarbonate and potassium deficiency with EKG changes as ST depression with flattening of T wave and U-wave. Urinalysis had a basic pH with positive urine acetone. Findings were suggestive of renal tubular acidosis (RTA). In addition, patient reported several episodes of nephrolithiasis during childhood, differenteditary dialtal RTA. Hypokalemia history and renal findings trigger were unknown. However, due to association of RTA type 1 and autoimmune disease, workup was performed. Rheumatoid factor, ANA screen, aldolase and SS-A/Ro antibody were positive consistent with Sjögren syndrome diagnosis. There are only a few documented cases. After discussing results with patient we thought to be a case of Late-Onset Bartter Syndrome.

Discussion: Sjögren syndrome is a chronic autoimmune inflammatory disease that could negatively affect the patient’s quality of life. Triggers have not been completely identified due to multifactorial involvement and diversity of clinical manifestations. In Puerto Rico, there is a small population currently diagnosed with the syndrome. However, research studies of epidemiological characteristics or clinical profile in Puerto Rico are still ongoing.

POI120
Idiopathic Bartter Syndrome-Like Phenotype Diagnosed in a Diabetic Patient with COVID-19 Infection
Aabhinya Sridhar,1,2 Arompa Kapoor,1,2 Westchester Medical Center, Valhalla, NY; 1New York Medical College, Valhalla, NY.

Introduction: Bartter’s syndrome (BS) is a rare genetic tubulopathy affecting the loop of Henle leading to salt wasting. Acquired BS is very rare and is associated with underlying medical conditions or etiologies. We report a unique case of idiopathic BS-like phenotype that was diagnosed in the setting of COVID infection.

Case Description: 71-year-old man with coronary artery disease, hypertension and diabetes presented after a mechanical fall. On admission, he was found to be hypotensive to 107/88 mmHg. Physical exam was within normal limits. Initial blood work was significant for Potassium 2.6 mEq/L, Bicarbonate 34 mEq/L, Calcium 8.9 mg/dL and Magnesium 1.7 mg/dL. Patient also tested positive for COVID-19. Upon further questioning, patient reported a remote history of hypokalemia but never needed any electrolyte supplementation. He denied diuretic use or surreptitious vomiting. Hypokalemia work up revealed increased urinary potassium of 85.4 mEq/L. Renin 15.72 ng/mL/hour and Aldosterone 8 ng/dL. Patient was then started on aggressive intravenous and oral potassium repletion. He continued to require multiple doses of intravenous potassium to maintain potassium levels of 3 mEq/L. He was subsequently started on Eplerenone on Day 3 of admission with excellent response. He remained otherwise asymptomatic from COVID and as his infection improved, hypokalemia stabilized and he was ultimately discharged with a Potassium level of 3.6 mEq/L.

Discussion: The primary defect in BS is in sodium chloride reabsorption in the medullary thick ascending limb of the loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Rare cases of acquired BS are reported in association with tuberculosis, sarcoidosis, sjogrens, and certain drugs. All of these were ruled out in our patient and hence a diagnosis of idiopathic BS like phenotype was made. In our patient, we attribute the BS like phenotype to underlying COVID infection. As his infection improved, his hypokalemia also resolved. Hyperkalemia is a more common finding in COVID infection. However, in our patient, hypokalemia secondary to BS like phenotype was a unique presentation which was challenging to treat. In the absence of usual causes of acquired BS, we considered hypokalemia secondary to BS like phenotype should prompt suspicion for BS-like phenotype. Early and aggressive correction of electrolyte abnormalities is crucial.

POI121
Late-Onset Bartter Syndrome
Mica Ales,1 Khalid Elhariri,2,1 Omar S. Al-Taweel,1 Petersen Grettí,2 Hania Kassem.1 1The University of Texas Medical Branch at Galveston, Galveston, TX; 2Kern Medical Center; Bakersfield, CA.

Introduction: Bartter syndrome (BS) is an autosomal recessive disorder that results from mutations in sodium chloride reabsorption in the thick ascending loop of Henle resulting in hypokalemia, metabolic alkalosis and secondary hyperaldosteronism. Late-Onset Bartter Syndrome is a phenotype that was diagnosed in the setting of COVID infection.

POI1122

Colonial Pseudo-obstruction and Hypokalemia

Akkar H. Hamid,1,2 Isha Puri,1,2 Mary C. Mallappallil,1,2 Man S. Oh,1,2 Moro O. Safiu.1,2

Introduction: Ogilvie’s syndrome, or colonic pseudo-obstruction, is the pathologic dilation of the colon without underlying mechanical obstruction. It is caused by increased sympathetic activity or reduced parasympathetic activity. The common manifestation in constipation, but sometimes it may be associated with diarrhea when potassium secretion is greatly increased by stretch-activated maxi-K channel, also known as BK channel, resulting from dilatation of the colon. While exact mechanism is unclear, diagnosis is based on clinical and radiologic grounds.

Case Description: A 69-year-old African American female with history of diabetes mellitus, hypertension, hyperlipidemia, and HIV infection presented with worsening lower back pain. Initial labs showed leukocytosis, anemia, mild renal impairment, and paraproteinemia. MRI of the spine showed extensive compressive deformities and epidural extension, with lytic lesions on skeletal survey. Bone biopsy showed >80% blast cells with marked increase in circulating plasma cells, confirming plasma cell leukemia. Abdominal CT showed dilated ascending colon suggestive of obstruction, but she was having normal bowel movements. She successfully underwent induction therapy and was discharged. When she was readmitted for second cycle of chemotherapy, serum potassium of 1.8 mmol/L with U wave on ECG noted. She also complained of abdominal distension, diarrhea, and bilateral lower extremity edema. Despite aggressive potassium supplementation, her potassium level persistently remained below 3.5 mmol/L. Initial urine potassium was 23 mmol/L, which peaked at 45.8 mmol/L before becoming anuric. First stool potassium was >100 mmol/L with stool volume of 900 mL. Repeat stool study after a week showed stool potassium 95.9 mmol/L with stool sodium 42 mmol/L. Abdominal x-ray on admission showed colon distension measuring up to 11.4 cm at the cecum. Serial imaging of the bowel showed worsening diffused colonic dilation. Remarkably, our patient required large doses of potassium supplement while she remained anuric.

Discussion: Colonic pseudo-obstruction may result in, some patients, in dramatic upregulation of the maxi-K channel. When potassium secretion is greatly increased, diarrhea rather than constipation becomes predominant manifestation. Diarrhea is the result of high potassium content of the stool, unlike most other secretory diarrhea which is greatly increased by stretch-activated maxi-K channel, also known as BK channel, resulting from dilatation of the colon. While exact mechanism is unclear, diagnosis is based on clinical and radiologic grounds.

POI1123

Prevalence and Recurrence of Hyperkalemia (HK) in Medicare Patients Admitted to Long-Term Care or Post-Acute Care (LT/CAC) Settings

James F. Neurnschwander,1 Alison R. Silverstein,1 Christie Teigland,2 Dakota C. Powell,2 Shambhavi Kumar,2 Jill Dreyfus,2 Edric Y. Zeng,2 Abiy Agiro,3 William Pottorf,2 Rasha Khatib,1,2 Advocate Health Care Inc, Downers Grove, IL; AstraZeneca UK Ltd, Cambridge, United Kingdom.

Background: HK is a common electrolyte imbalance among elderly populations with comorbidities such as chronic kidney disease (CKD) and congestive heart failure (CHF). This study describes the prevalence and recurrence of HK in patients in the LT/CAC setting.

Methods: This retrospective study used 100% Medicare Fee-For-Service data for patients age ≥65 with ≥1 LT/CAC stay from 01/21/2017 to 11/30/2019; index date was admission date of first LT/CAC stay. HK-related stay was defined as ≥1 HK diagnosis (ICD-10-CM codes for hyperkalemia 287.2, 287.4) or ≥1 code of potassium binder use during LT/CAC stay or within ≤14 days pre-index. Baseline characteristics and prevalence of HK in patients 1 year of follow-up among HK index stays were compared to non-HK index stays. HK index stays were stratified into 3 cohorts: CHF, CKD or end-stage renal disease (ESRD), and CHF+CKD/ESRD.

Results: Of 4,562,231 patients with ≥1 LT/CAC stay, prevalence of HK during pre-index, index, or follow up periods was 14.7%. The final sample (4,081,103) excluded patients with an HK event only during follow up. Of the final cohort, 290,567 (7.1%) of index stays were HK-related. All-cause (HK-related) index stays consisted of 54.0% (46.5%) CHF, 32.8% (27.8%) CKD, 28.8% (41.4%) end-stage renal disease (ESRD), 6.7% (8.8%) inpatient rehabilitation facilities, and 0.9% (3.1%) long term acute hospital settings. HK vs non-HK patients were more often male (43.0% vs 35.4%), Black (13.5% vs 8.0%), and dual eligible for Medicaid (34.2% vs 25%), with higher mean Charlson Comorbidity Index scores (6.19 vs 3.93). Mean annual HK event during follow up were highest in patients with CHF+CKD/ESRD (all patients=1.47; HK=6.98), followed by CKD (0.66; 5.53), and CHF (0.18; 3.00), with similar patterns across settings. In the HK cohort, 34.5% had HK recurrence during follow up; 2.7% filled a potassium binder prescription during index LT/CAC stay, and 4.3% did so during follow up.

Conclusions: HK patients were more often non-White and low income, indicating possible disparities in care. Prevalence and recurrence of HK was high among patients with LTC/CAC stays, but few patients filled a potassium binder prescription, suggesting potential gaps in treatment during or after an LT/CAC stay.

POI1124

Impact of Hyperkalemia and the Disruption of Emergency and Surgical Care

Douglas P. Slakes.1 Marybeth Ingle,1 Abiy Agiro,2 Craig G. Schilling,2 William Pottorf,2 Rasha Khatib,1,2 Advocate Health Care Inc, Downers Grove, IL; AstraZeneca UK Ltd, Cambridge, United Kingdom.

Background: Due to the increasing prevalence of kidney disease, hyperkalemia (HK) may be diagnosed with greater frequency in Surgical and Emergency Departments (ED). Despite this, specific guidelines do not exist and patients with elevated potassium (K+) are typically managed on a case by case basis.

Methods: An anonymous structured survey was emailed to (n=11,287) clinicians in the Advocate Aurora Health system regarding HK knowledge and treatment paradigms (n=237 responded). Survey was conducted from Feb to March 2021.

Results: Nearly half (47%) of respondents treat >10 HK patients annually, with most reporting diagnosis of HK occurring in the ED (70%). Patients hospitalized for surgical (33%) setting. HK was considered a significant concern by 47% of respondents at a serum K+ level of 5.6-5.9 mEq/L and by 39% at K+ >6 mEq/L. Only 50% of respondents recognized RAAASI medications as a potential risk factor for HK. IV fluids and kayexalate were the two most common treatments for HK. Limitations to pharmacological management included the need to monitor potassium, patient compliance, and time of onset. In the surgery survey, 66% felt that K+ more than 5.5 mEq/L on day of surgery will lead to cancellations and 52% believed pharmacologic agents having a shorter onset of action may reduce surgery cancellations and delays. Vascular (34%) and general (30%) surgeries were reported to be most impacted by HK. 82% stated urgent dialysis is difficult to arrange and admission is inevitable for dialysis.

Conclusions: The presence of HK creates challenges to ED or surgical clinical teams to manage and avoid cancellations. Standard treatment options for lowering serum K+ are limited due to time of onset and compliance considerations. Dialysis is difficult to arrange on short notice and almost always requires patient admission. In cases of emergent HK, newer K+ binding agents having a more rapid onset of action to lower serum K+, may reduce avoidable admission, surgical cancellation, and delay of surgery. More evidence-based care is needed in surgical settings to characterize patients at high risk for HK to prevent unnecessary surgical cancellation and limit health care costs.

POI1125

Transient Hyperkalemia Following Treatment of Chronic Hypokalemia: A Case Report and Review of Distal Tubule Physiology

Introduction: Hypokalemia is a frequently encountered electrolyte disorder usually resulting from decreased dietary intake, gastrointestinal, and/or renal wasting. In distal tubular cells, with no lysine (WNK) kinases bind with Ste20-related proline-alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) to form WNK bodies. WNK bodies are thought to increase the activity of the sodium-chloride cotransporter (NCC) leading to decreased sodium delivery to the epithelial sodium channel (ENaC) facilitating principal cells. This results in decreased urinary potassium wasting through the renal outer medullary potassium channel (ROMK). Here we report a case of a young man with alcohol use disorder and chronic hypokalemia who was hospitalized for muscle weakness, abdominal pain, and increased anorexia. During treatment of his hypokalemia, he unexpectedly developed transient hyperkalemia.

Case Description: The clinical intrigue of this case was the unexpected finding of acute transient hyperkalemia during treatment for hypokalemia. His potassium was 2.5 mEq/L on the day of admission. Four days later, with a creatinine at baseline (0.9 mg/dL), potassium abruptly increased to 6.7 mEq/L. Repeat measurement one hour later was 6.4 mEq/L. Over the course of his hospitalization prior to the critical hyperkalemia lab result, he had received approximately 340 mEq of potassium supplementation. 24 hour urine potassium was 35 mEq/L. A potassium 5.8 mg/dL and renin was 0.3 ng/mL/hr (ratio 19). Potassium levels returned to normal following administration of furosemide and sodium polystyrene sulfonate.

Discussion: We propose that the adaptive mechanisms of the distal tubule during hypokalemia require time to revert back to a nonactive state. Transient hyperkalemia may be observed during these “recovery” periods. The time required for disassembly of WNK bodies following resolution of hypokalemia is unknown. Our postulation could explain a
similar observation of transient hyperkalemia seen in a case published in 1953 of a young woman treated for chronic hypokalemia (Schwartz, 1953). Critical hyperkalemia is an important consideration when treating patients with chronic hypokalemia.

**POI1126**

**Pseudohyperkalemia with Concurrent Hyperkalemia**

Momen M. Hamid,1,2 Akbar H. Hamid,1,2 Yasmin N. Mahmoud,1,2 Mary C. Mallappallil,1,2 Man S. Oh,1,2 Sabu John,1,2 Moro O. Salifu,1,2 SUNY Downstate Health Sciences University Department of Medicine, New York, NY; Kings County Hospital Center, Brooklyn, NY.

**Introduction:** In sickle cell patients, acute hematologic crisis and sickle cell nephropathy are relatively common. Risk of hyperkalemia increases with hemolysis and tubular dysfunction. Sepsis can also worsen the complication of hemolytic crisis with significant thrombocytosis, a well-known cause of pseudohyperkalemia. We report a case of concurrent true hyperkalemia and pseudohyperkalemia in the setting of thrombocytosis due to acute sickle cell crisis.

**Case Description:** A 36 year old African American male with history of sickle cell disease, asthma and DVT presented with bilateral shoulder, knee, and back pain. In ED, he was hypotensive, and tachycardic. Labs were notable for leukocytosis, anemia, reticulocytosis, renal failure, and elevated lactate dehydrogenase. Chest x-ray showed left base atelectasis. He was admitted for acute sickle cell crisis and fluctuant right thigh abscess, which was surgically drained and managed with antibiotics. Platelet level was 585 K/uL; serum potassium was 4.7 mmol/L; and creatinine was 1.76 mg/dL with normal urine output. Potassium level steadily rose and peaked at 6.5 mmol/L with sinus bradycardia but no other ECG changes. At the same time, platelet level peaked to 1105 K/uL.

**Discussion:** In our patient with significant thrombocytosis, pseudohyperkalemia was suspected. Degranulation of platelets during clotting releases about 50% of potassium inside platelets. For platelet count of 1000 K/uL with normal MPV, serum potassium level is expected to be higher than plasma potassium level by about 0.7 mmol/L. Serum-plasma potassium differences in our patient were within the expected range. In our patient, as shown below, mild concurrent true hyperkalemia is also noted likely due to sickle cell nephropathy, a known cause of hyperkalemia due to hyporeninemic hypoaldosteronism. Due to potassium release from platelets during clotting, serum potassium is always higher than plasma potassium in all normal persons by 0.2 to 0.3 mmol/L. With thrombocytosis, the difference becomes larger, and serum potassium is likely to reach hyperkalemic level if the baseline potassium is already higher than usual due to concomitant impairment of renal potassium excretion.

**Missing the Obvious? A Story of Salt, Water, and Unexplained Hyperkalemia**

Aaron M. Spring,1 Mathieu Lemaire,1,2 1The Hospital for Sick Children Department of Paediatrics, Toronto, ON, Canada; 2SickKids Research Institute, Toronto, ON, Canada.

**Introduction:** Most clinicians are familiar with the differential diagnosis of hyperkalemia, from pseudohyperkalemia to rare tubulopathies. Herein, we describe three patients with years-long histories of unexplained hyperkalemia despite extensive investigations (details in Table 1). While all achieved normokalemia with various prescription regimens, the underlying etiology remained elusive. We suggest that all cases investigated (details in Table 1). While all achieved normokalemia with various prescriptions, the underlying etiology remained elusive. We suggest that all cases

**Case Description:** Patient A: A 6-week-old girl with persistent hyperkalemia and very low urine Na+. Normokalemia was achieved with hydrochlorothiazide and dietary K- restriction but maintained with optimized fluid and Na+ intake alone. Patient B: An 11-year-old boy with spastic cerebral palsy with persistent hyperkalemia after a mild AKI attributed to rhabdomyolysis. Serum K+ improved with sodium polystyrene (SPS) at nadir K+ restriction; it normalized after 5-day saline infusion, while SPS. Patient C: A 5-month-old boy with Stüve-Wiedemann Syndrome and feeding difficulties with persistent hyperkalemia that normalized on SPS. After G-tube insertion at 2 years, K+ remained normal despite stopping the SPS due to improved fluid and Na+ intake.

**Discussion:** It has long been established that adequate Na+ and fluid delivery to distal nephrons is necessary for optimal K+ handling. It is therefore surprising to find almost no mention of Na+-responsive hyperkalemia in the literature for children beyond the neonatal period. Our patients all had hyperkalemia in the context of normonatremia, but very low fractional excretion of Na+ (FeNa) and low trans-tubular K+ gradient (TTKG). They all remained normokalemic when salt and water intake was optimized, despite stopping their hyperkalemic prescriptions. Careful, early consideration of low distal Na+ and water delivery as a cause for unexplained hyperkalemia could prevent extensive workups and unnecessary prescriptions.

**Machine Learning Models to Predict Cardiovascular and Renal Outcomes and Mortality in Hyperkalemic Patients**

Futhiro Kanda,1 Suguru Okami,1 Shun Kohsaka,1 Xiaojun Ma,2 Masafumi Okada,1 Takeshi Kiiura,1 Toshitaka Yajima,2 Kawasaki Medical School, Kurashiki, Japan; 1AstraZeneca K.K., Osaka, Japan; 2IQVIA Solutions K.K., Tokyo, Japan; 3Real World Data, Co., Ltd., Kyoto, Japan; 4Keio University, Tokyo, Japan.

**Background:** Hyperkalemia is associated with increased risks of mortality and adverse clinical outcomes. To date, limited evidence is available for personalized risk evaluation in this heterogeneous and multifactorial pathophysiological conditions.

**Methods:** We developed prediction models using extreme gradient boosting (XGB), logistic regression (LR), and neural network. Models were derived and cross-validated in a retrospective cohort of hyperkalemic patients with either heart failure or stage ≥a3 chronic kidney disease and aged ≥a18 years from a Japanese administrative hospital database (April 1, 2008–September 30, 2018). The outcomes of interest included all-cause death, introduction of renal replacement therapy (RRT), hospitalization for heart failure (HHF), and cardiovascular events within 3 years after first hyperkalemic episode. The best performing model was further validated using a separate hospital-based database.

**Results:** 24,949 adult patients with hyperkalemia were selected for the model derivation and internal validation. The mean age was 75 years and 54% were male. Among machine learning algorithms tested, XGB outperformed other models, showing AUROC of XGB vs. LR for all-cause death, RRT, HHF, and cardiovascular events as 0.823 vs. 0.809, 0.957 vs. 0.947, 0.863 vs. 0.838, and 0.809 vs. 0.798, respectively. In the external validation set including 86,279 patients, AUROC of XGB for all-cause death, RRT, HHF, and cardiovascular events were 0.747, 0.888, 0.673, and 0.585, respectively. The Kaplan-Meier curves of high-risk predicted group showed a significant differentiation from that of low-risk predicted group for all outcomes (Figure).

**Conclusions:** These findings suggest the possible use of machine learning models for real-world risk assessment as a guide for treatment decision making that may lead to the improvement of cardiovascular and renal outcomes, and mortality in hyperkalemic patients.

**Severe Hyperkalemia Secondary to Hypermagnesemia in a Patient with Preeclampsia**

Atif Ibrahim, Alice Cheddad. The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

**Introduction:** Mg infusion remains the first-line treatment of preventing and controlling eclamptic seizures. While hypocalcemia is a well-known side effect, hyperkalemia is not. We present a case of severe hyperkalemia secondary to magnesium infusion requiring hemodialysis.

**Case Description:** 36-year-old healthy female with no HTN or liver disease, pregnant at 25 weeks with twins, admitted for close monitoring given concern for intra-uterine growth restriction. Initial vitals on admission: BP 149/88 mm Hg, HR 89,
PO1131
When Sipping K Is Not OK
Anur Rajasekaran, Ammar Hasnic, Ashita J. Tolwani. The University of Alabama at Birmingham, Birmingham, AL.

Introduction: Hyperkalemia is one of the most common and potentially lethal electrolyte abnormalities that occurs in approximately 1% to 10% of hospitalized patients. It is associated with an increased risk of arrhythmias, poor cardiovascular outcomes, and increased morbidity and mortality. We highlight an unusual etiology of severe hyperkalemia in a patient with underlying CKD.

Case Description: A 74-year-old Black male with known arterial hypertension, coronary artery disease, CKD 3 [baseline serum creatinine (Cr) 1.7 mg/dl] presented with syncope secondary to severe bradycardia (heart rate 30/min) consequent to severe hyperkalemia, which necessitated a pacemaker placement, and non-oliguric AKI on CKD. Pertinent serum labs on presentation include Cr 2.8 mg/dl, potassium (K) 7.6 mmol/L, and bicarbonate 19 mmol/L. Serum osmolality, glucose, and creatinine kinase levels were within normal limits. Urine pH was 5. Renal imaging was unremarkable. He was not on any medication(s) commonly attributed with a propensity to elevate serum K, including renin angiotensin inhibitors, non-selective β blockers, or non-steroidal anti-inflammatory agents. Given that the hyperkalemia was out of proportion to his kidney injury, upon further questioning he attributed consuming a diet rich in K along with drinking multiple cups of Essiac tea daily for the last 2 months. Hyperkalemia was managed medically, including initial temporizing measures, bicarbonate supplementation, K binders, and intravenous crystalloids to enhance distal nephron K excretion. Emphasis was placed on consuming a K restricted diet along with discontinuing Essiac tea use. Serum K normalized in 3 days; however, Cr was 3 mg/dl on discharge.

Discussion: Essiac tea contains red clover, sheep sorrel, burdock root, and rhubarb which has extremely high potassium content. It is hepatotoxic and nephrotoxic when consumed in large amounts. We highlight the importance of obtaining a thorough dietary history, especially when the degree of hyperkalemia cannot be solely attributed to the extent of kidney injury. Dietary counselling is paramount in such cases.

PO1132
Metabolic Acidosis That Exists with Hyperkalemia (HK) Among Patients That Initialize Binder Therapy: The MAXIMIZE Study
Seth P. Kurhanz,1 Abhi Agiro,2 Kaylen Brzozowski,1 William Pottorf,2 Pamela B. Landsman-Blumberg,1 Joachim H. Ix,3 TriNetX LLC, Cambridge, MA; 4AstraZeneca, Global Medical Affairs, Wilmington, DE; 5University California San Diego, San Diego, CA.

Background: Approximately 25% of chronic kidney disease (CKD) patients with serum potassium (sK+) >5.0 mEq/L may also have metabolic acidosis (MA). However, successful management of comorbid HK and MA in CKD patients is unclear. This real-world evidence study examines the association between patient characteristics and binder treatment among CKD patients with HK and MA.

Methods: This was a retrospective study of stage 3-5 CKD patients with HK (sK+ >5.0 mmol/L) and MA (serum bicarbonate (sHCO3−) between 16-20 mmol/L) in a US EMR network of 64 million patients. The index event was the first qualifying sK+ >5.0 mmol/L between 07/01/19 and 12/31/20. Baseline demographic and clinical characteristics were assessed among SZC, SPS, and NKB treated cohorts including age, sex, race, HK severity, sHCO3− level, visit type, and comorbidities. Logistic regression produced adjusted odds ratios (ORs) and 95% confidence intervals describing the association between baseline characteristics and treatment: sodium zirconium cyclosilicate (SZC) vs sodium polystyrene sulfonate (SPS) and SZC vs no potassium binder (NKB).

Results: Of the 32,113 patients who met study criteria 11.6% were treated with SZC (n=3,572). Age and sex were similar among SZC, SPS, and NKB cohorts and 81%, 77%, and 70% had moderate-to-severe acidosis (sHCO3− <20mmol/L), respectively. Baseline characteristics associated with increased odds of SZC vs SPS and SZC vs NKB treatment included sHCO3− <20mmol/L [OR=1.29 (1.03-1.61); OR=1.24(1.04-1.47)] and liver disease [OR=1.61(1.16-2.23); OR=1.47(1.14-1.89)], respectively. Treatment with SZC vs NKB treatment was more likely in inpatient settings [OR=3.73(3.06-4.55)] and in patients with comorbid congestive heart failure [OR=1.43(1.12-1.84)].

Conclusions: Clinicians were more likely to treat HK with SZC than SPS or NKB in CKD patients with moderate-to-severe acidosis in a recent large, US, real-world sample. Secondary findings from prior clinical trials suggest that SZC may improve MA as well normalize sK+ . Future clinical trials are needed to assess the impact of SZC on sHCO3− concentrations.

Real-World RAAS Inhibitor Use and Its Predictors Among Patients Initiating Sodium Zirconium Cyclosilicate

Abiy Agiro,1 Alpesh Amin,2 Fan Mu,3 Joshua A. Young,3 Erin Cook,3 Esteban J. Lemos Wirz,2 Yasmin G. Brahmbhatt,3 Keith A. Betts,3 Charles V. Pollack.2,3 AstraZeneca, Wilmington, DE;1 University of California Irvine, Irvine, CA;1 Analysis Group Inc., Boston, MA;3 University of Mississippi School of Medicine, Jackson, MS.

Background: Renin-angiotensin-aldosterone system inhibitors (RAASI) are associated with reduced risk of death and slower disease progression in patients with heart failure (HF) and chronic kidney disease (CKD). However, RAASI use increases the risk of hyperkalemia (HK), which may disrupt RAASI use and mitigate its benefits. There is limited real-world evidence characterizing RAASI use after sodium zirconium cyclosilicate (SZC) treatment.

Methods: Adult patients initiating SZC (index date) while on a RAASI in outpatient care were included from a large US claims database (January 2018-June 2020). Analyses were conducted among all patients, patients with CKD and patients with CKD + diabetes (DM). The percent of patients with a RAASI prescription index was summarized. Characteristics among patients with and without a new RAASI fill were compared using descriptive statistics. A multivariable logistic regression model assessed predictors of a new RAASI fill.

Results: A total of 589 patients initiating SZC while on a RAASI were included (mean age 61 years, 65.2% male). Overall, 82.7% of patients had a new RAASI fill after index. The median time to discontinuation was not reached among patients with a new RAASI fill, of whom 88.1% at day 180 and 74.0% at 1 year remained on RAASI therapy. Median time on RAASI was 29 days (95% CI [27-43 days]) for those with no new RAASI fill. Compared to patients without a new RAASI fill, patients with a new fill had a higher burden of CKD (69.4% vs 58.8%) but a similar prevalence of DM (70.6% vs 67.6%) and HF (24.6% vs 28.4%). Results were similar in the CKD cohort (N=398; 84.9% had a new RAASI fill) and CKD and DM cohort (N=311; 85.2% had a new fill). Predictors of having a new RAASI fill included fewer prior hospitalizations (0.77 [0.60-0.98]; p=0.05) and emergency department (ED) visits (0.78 [0.63-0.97]; p<0.05).

Conclusions: In a real-world setting, 83% of patients had a new RAASI fill within 90 days after ending their RAASI. Results were consistent with clinical trial finding and emergency department (ED) visits (0.78 [0.63-0.97]; p<0.05).

Compatibility Study of Patiromer with Juices/Liquids and Soft Foods

Martin Khoeckläng,1 Maria Wilhelm,1 Lingyun Li,2 Carol P. Moreno Quinn,3 Tamara Popov.1 1Vifor International AG, Saint Gallen, Switzerland; 2Vifor Pharma Group, Redwood City, CA.

Background: Patiromer is a novel, once-daily, sodium-free K+-binder approved for treatment of hyperkalemia. The drug—tasteless, odorless powder—is administered orally suspended in water. Recently, the FDA approved apple or cranberry juice as suspension vehicle for partial doses of patiromer. Since patiromer contains significant amounts of sodium, we assessed the risk of heart failure hospitalization (HHF) associated with the initiation of SZC versus patiromer in non-dialysis patients.

Methods: We used a U.S. commercial insurance claims database (Optum Clinformatics® Data Mart) between May 2018 (after SZC approval) and September 2020. Participants were non-dialysis adults who had a 180 days of insurance enrollment and were newly prescribed SZC or patiromer. The primary outcome was a hospitalization with a discharge diagnosis of heart failure. The secondary outcome was a hospitalization or an emergency room visit with a diagnosis of any edema. Propensity score (PS) matching in a variable ratio up to 1:3 was used to adjust for more than 80 variables, including demographic characteristics, comorbidities, medication use, and health care utilization. Cox proportional hazards regression models were used to generate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Our cohort included 1,126 SZC initiators and 2,839 PS-matched patiromer initiators (total N=3,965). The mean age was 72 (±10) years; 30% had a history of heart failure and 85% had CKD stages 3-5. The risk of HHF was higher in the SZC initiators compared to patiromer initiators (HR 1.22, 95%CI 0.95-1.56), but the confidence interval included the null value (Table). Edema was more common in the SZC initiators (HR 1.89, 95%CI 1.05-3.39). Subgroup analyses, initiation of SZC was associated with an increased risk of HHF (HR 1.58, 95%CI 1.01-2.46) amongst patients without a history of heart failure.

Conclusions: Patients initiating SZC may need to monitor volume status and consider dietary salt restrictions and initiation or adjustment of diuretics. Larger studies are needed to more precisely evaluate the safety of SZC in routine practice.

Risk of Heart Failure in Patients Who Initiated Sodium Zirconium Cyclosilicate vs. Patiromer

Min Zhuo,1,2 Seouyoung C. Kim,3 Elisabetta Patornò,3 Rishi J. Desai,3 Julie M. Paik.1,2 1Beth Israel Deaconess Medical Center, Boston, MA; 2Brigham and Women’s Hospital Department of Medicine, Boston, MA; 3VA New England Geriatric Research Education and Clinical Center, Boston, MA.

Background: Hyperkalemia is common in patients with chronic kidney disease (CKD), heart failure, and diabetes. Sodium zirconium cyclosilicate (SZC) and patiromer were recently approved for the treatment of hyperkalemia. Since SZC contains significant amounts of sodium, we assessed the risk of heart failure hospitalization (HHF) associated with the initiation of SZC versus patiromer in non-dialysis patients.

Methods: We used a U.S. commercial insurance claims database (Optum Clinformatics® Data Mart) between May 2018 (after SZC approval) and September 2020. Participants were non-dialysis adults who had a 180 days of insurance enrollment and were newly prescribed SZC or patiromer. The primary outcome was a hospitalization with a discharge diagnosis of heart failure. The secondary outcome was a hospitalization or an emergency room visit with a diagnosis of any edema. Propensity score (PS) matching in a variable ratio up to 1:3 was used to adjust for more than 80 variables, including demographic characteristics, comorbidities, medication use, and health care utilization. Cox proportional hazards regression models were used to generate hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: Our cohort included 1,126 SZC initiators and 2,839 PS-matched patiromer initiators (total N=3,965). The mean age was 72 (±10) years; 30% had a history of heart failure and 85% had CKD stages 3-5. The risk of HHF was higher in the SZC initiators compared to patiromer initiators (HR 1.22, 95%CI 0.95-1.56), but the confidence interval included the null value (Table). Edema was more common in the SZC initiators (HR 1.89, 95%CI 1.05-3.39). RDX013, a Novel, Oral, Small Molecule Being Developed for Treatment of Hyperkalemia, Increases Colonic Secretion and Fecal Excretion of Potassium

Kenji Konuka,1 Matthias Siegel,2 Andrew J. King,3 Jill N. Kohler,3 Jingfang Zhao,1 Allison Quach,1 Cyra Fang,1 Ying He,1 Padmapriya Kumarawasmy,1 Limin He,1 Cathy M. Le,1 Catarina Tran,1 Jeremy Caldwell,4 David P. Rosenbaum,1 Jeffrey Jacobs.1 1Ardelyx Inc, Fremont, CA; 2Anvita Biosciences, San Carlos, CA; 3Chinook Therapeutics Inc, Vancouver, BC, Canada; 4Inception Therapeutics, San Diego, CA.

Background: Potassium (K+) homeostasis is maintained by the balance of dietary K+ intake, extracellular K+ distribution, and renal and intestinal excretion. Hyperkalemia (serum K+ >5.0 mEq/L) occurs frequently in CKD patients and can lead to cardiac arrhythmias and sudden death; controlling serum K+ may reduce mortality in this population. Current therapeutic options for the chronic treatment of hyperkalemia are limited to K+-binding agents. Here, we describe the discovery of RDX013, a novel, oral, small molecule K+ secretagogue in development for treatment of hyperkalemia.

Methods: Male Sprague Dawley rats (n=6/group) were orally administered vehicle or 6 mg/kg RDX013 twice daily for 6 days. 24-hour fecal samples collected from rats housed individually in metabolic cages on the final study day were homogenized, and K+ and sodium were analyzed by cation exchange chromatography.

Results: RDX013 significantly increased fecal K+ excretion compared to vehicle control animals (figure). Fecal sodium was also increased by RDX013 (figure), which was expected as luminal sodium retention in the intestine is key to the pharmacodynamic response.

Conclusions: Based on its unique mechanism of action which involves pharmacologically enhancing K+ secretion through apical K+ channels in the colon, RDX013 is a potential first-in-class therapy which may provide a new approach to managing serum K+ in patients versus commonly prescribed K+ binders. A phase 2 clinical study with RDX013 (NCT04780841) is ongoing in non-dialysis CKD patients with hyperkalemia.

Artificial Intelligence-Assisted Electrocardiography for Early Diagnosis of Thyroid Toxic Periodic Paralysis

Shih-Hua P. Lin,1 Chih-Chien Sung,1 Min-hua Tseng,2 Tri-Service General Hospital, Taipei, Taiwan; 2Chang Gung Memorial Hospital, Tao-yang, Taiwan.

Background: Thyroid periodic paralysis (TPP) characterized by acute weakness, hypokalemia and hyperpyrexia is a medical emergency with a great challenge in early diagnosis since most TPP patients do not have overt symptoms. Since both hypokalemia and hyperpyrexia in TPP significantly affect the cardiovascular system, electrocardiography (ECG) as a prompt and non-invasive bedside tool universally used in the ED may detect these electrical changes. To assess artificial intelligence (AI)-assisted electrocardiography (ECG) combined with routine laboratory data in the early diagnosis of TPP.

Methods: A deep learning model (DLM) based on ECG12Net, an 82-layer convolutional neural network, was constructed to detect hypokalemia and hyperpyrexia. The development cohort consisted of 39 ECGs from patients with TPP and 502 ECGs of hypokalemic control; the validation cohort consisted of 11 ECGs of TPP and 36 ECGs of non-TPP with weakness. The AI-ECG based TPP diagnostic process was then consecutively evaluated in 22 male patients with TPP-like features.

Results: In the validation cohort, the DLM-based ECG system detected all cases of hypokalemia in TPP patients with a mean absolute error of 0.26 mEq/L and diagnosed TPP with an area under curve (AUC) of ~0.8%, surpassing the best standard ECG parameter (AUC=0.7285 for the QR interval). Combining the AI predictions with the estimated glomerular filtration rate (eGFR) and serum chloride (Cl-) boosted the diagnostic accuracy of the algorithm to AUC 0.986. In the prospective study, our AI ECG system achieved perfect performance (F-measure 100%) on the task of hypokalemia detection in them and the integrated AI with routine laboratory had a PPV of 100% and F-measure 87.5% for TPP diagnosis.

Conclusions: An AI-ECG system reliably identifies hypokalemia in patients with paralysis and its integration with routine blood chemistries provides valuable decision support for the early diagnosis of TPP to avoid life-threatening complication.

PO1138

Will the Real Sodium Stand Up!

Nia Flemming, Michael Basir, Ro-Kaye A. Simmonds, Latoya N. Gayle, Zachary Banbury, Deborah A. Fein. Englewood Health, Englewood, NJ.

Introduction: Hyponatremia is a common finding as it could be precipitated by multiple factors ranging from medications to simply dehydration. Accurate approach to management depends on assessing serum osmolality in an effort to distinguish cases of true, factitious or pseudohyponatremia. We present a case of hyponatremia secondary to hyperlipidemia.

Case Description: 36 year old Asian woman with HTN, Type 2 DM, HLD presented with 1 day of epigastric pain. On exam S1, S2 were heard with vesicular breath sounds throughout, epigastric tenderness and no focal neurological deficits. Initial labs: sodium 114 potassium 3.5 chloride 85 glucose 254, BHB 3.7. Sodium corrected for glucose 116 CO2, BUN, Cr and AG were incalculable. Urinalysis: pH 6.0, ketones > 1000, protein > 1000. Total cholesterol 1020, HDL 25, Triglycerides >5680, LDL 2.9, CO2, BUN, Cr and AG were incalculable. Urinalysis: pH 6.0, ketones > 1000, protein > 1000. Total cholesterol 1020, HDL 25, Triglycerides >5680, LDL 2.9, CO2, BUN, Cr and AG were incalculable. Urinalysis: pH 6.0, ketones > 1000, protein > 1000.

Discussion: Sodium is most commonly measured by indirect potentiometric (ISE) measurement. By this method serum specimens are diluted based on estimated typical glomerular filtration rate (eGFR) and serum chloride (Cl-) to achieve a standard deviation. In this case, direct sodium measured by VBG/ABG are most accurate. Typically, most commonly measured serum triglyceride with concentrations> 1500 mg/dl are thought to be responsible for factitious hyponatremia. In our patient the value of serum sodium on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+ on admission was unexpectedly low at 114 and severe hypercholesterolemia may have contributed. Applying the following formula to correct for triglycerides = Measured Na+.

Plasma triglycerides (g/L) x 0.002; measured serum sodium would have been expected to be 125 meq. In cases of extremely high lipids, one must consider lab techniques for measuring serum sodium, as well as full lipid panel in the evaluation and treatment of factitious hyponatremia.

PO1139

Admission Sodium and Related Features to Predict Falls in Machine Learning Models

Alexander S. Leidner,1 Biruth Workeneh,2 Bing Ho.2 Northwestern University Feinberg School of Medicine, Chicago, IL; 2The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Hyponatremia has been associated with an increased risk for falls, but evidence is primarily limited to outpatient events. Hyponatremia is a potential surrogate of conditions that may lead to falling including volume depletion, malignancy, pain, polypharmacy, and weakness. We hypothesized that a model could be developed to predict falls based upon accessible variables present on all hospital admissions. An accurate model could allow for measures to lower in-hospital falls.

Methods: Medical records from a single institution were collected over a period of 2011 to 2019. Subjects included admitted patients who suffered a recorded in-hospital fall and were admitted, and controls matched for admission on the same date. Variables collected included sodium, glucose, age and gender. There were 17,103 patients total of which 1,203 had unique falls. Data was split into an 60% training, 20% validation and 20% testing split. We computed an unadjusted odds ratio of falls for those with very low sodium (<126). We trained logistic regression, random forest, XGBoosted forest, and neural net classifiers. Classifier cutoff was calculated using Youden values.

Results: We did not see an increased incidence of falls in the population with a low sodium (N=377) with an unadjusted odds ratio of 0.62 (CI 0.38-1.01). Similarly, the model performances did not result in clinically useful predictions with a unanimously high false positive and false negative rates (Figure 1).

Conclusions: Despite reports of hyponatremia as an indicator of fall risk we did not observe this. The fall-prediction models did have the capacity for high performance on the training data, but this does not translate to validated performance. This discrepancy is termed ‘overfitting’ and is important to evaluate as machine learning models have a much larger capacity than traditional statistical models to incorporate previously seen examples. If a model cannot make predictions on new data it cannot be clinically useful. These models may be enhanced using other basic admission features and is the subject of future work.

PO1140

Association of Serum Sodium Levels with Bone Mineral Density, Fracture, and Mortality in Patients Undergoing Maintenance Hemodialysis

Kensuke Soeda,1 Hirotaka Komaba,2 Yosuke Nakagawa,2 Takehiro Wada,1 Takatoshi Kakuta,3 Masafumi Fukagawa.1 1Tokai Daigaku, Hiratsuka, Japan; 2Tokai Daigaku Igakubu Facozka Hachigaku Byoin, Hachioji, Japan.

Background: Hyponatremia is implicated in pathological bone resorption and has been identified as a risk factor for bone fracture in the general population, but limited data exist in patients undergoing dialysis.

Methods: We analyzed a historical cohort of 2,292 patients undergoing maintenance hemodialysis in Japan. We first examined the association of baseline serum sodium levels with metacarpal bone mineral density (BMD) in a subcohort of 456 patients with available data. Next, we examined the association of baseline serum sodium levels with incident fracture and mortality in the overall cohort, using Cox regression models adjusted for potential confounders (age, sex, dialysis vintage, diabetes, prior cardiovascular disease, history of fracture, body mass index, hemoglobin, albumin, and creatinine) and competing risks regression models accounting for death as a competing endpoint.

Results: Baseline mean ± SD serum sodium level in the overall cohort was 139.7 ± 2.9 mEq/L, and among patients with available data, median metacarpal BMD T-score was -2.05 (IQR, -3.35 to -0.99). Serum sodium levels were not associated with metacarpal BMD T-score in unadjusted or adjusted models. During a median follow-up of 5.4 years (IQR, 2.5-7.0 years), 712 patients died; 113 experienced clinical fractures; and 64 experienced asymptomatic vertebral fractures as estimated by height loss. In addition, Cox survival models, serum sodium levels were associated with mortality (HR, 0.95 per 1 mEq/L higher; 95% CI, 0.92-0.98) but not incident clinical fracture (HR, 0.97 per 1 mEq/L higher; 95% CI, 0.90-1.04) or any fracture (a composite of clinical fracture and vertebral fracture). Similar results were obtained in competing risks regression models.

Conclusions: Serum sodium levels were associated with mortality but not BMD or incident fracture in maintenance hemodialysis patients.

Hypotremia, Inflammation, and Hospital Mortality in Hospitalized COVID-19 Patients

Juan Carlos Ayus,1 Michael L. Mortiz,1 Kyung Min Lee,2*,3 Daniel Caputo,4 Maria E. Borda,2 Alan S. Go,2 Carlos Eghi,2 University of California Irvine School of Medicine, Irvine, CA; 1UPMC Children’s Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA; 2University of Pittsburgh School of Medicine, Pittsburgh, PA; 3Hospital Posados, Buenos Aires, Argentina; *Kaiser Permanente, Oakland, CA; 4University of California San Francisco, San Francisco, CA.

Background: Systemic inflammation has been associated with severe COVID-19 disease. Hyponatremia can result from inflammation due to non-osmotic stimuli for vasopressin production. Hyponatremia is an independent risk factor for hospital mortality.

Methods: Hospitalized patients with COVID-19 were prospectively evaluated between March and November 2020 at Hospital Posadas in Buenos Aires, Argentina, in order to evaluate the association between hyponatremia and hospitalization and its impact on clinical outcomes. Admission blood chemistries, high-sensitivity C-reactive protein (hsCRP), ferritin, patient demographics, and outcome data were recorded. Outcomes (within 30 days after symptom) that were evaluated included admission to the ICU during hospitalization, mechanical ventilation, dialysis-requiring AKI, and in-hospital deaths. In-hospital mortality, length of hospital stay (in days), and hospital readmission for any cause within 30 days after discharge were evaluated using comprehensive data from the EHR.

Results: Among 799 hospitalized COVID-19 patients, hyponatremia was present on admission in 366 (45.8%). Hyponatremic patients had higher hsCRP levels than normonatremic patients (median 10.3 [IR 4.8-18.4] mg/dL vs 6.6 [IR 1.6-14.0] mg/dL, respectively, p < 0.01), and hsCRP level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient = -0.23; p < 0.01). Hyponatremic patients had higher serum ferritin levels than normonatremic patients (median 649 [IQR 492-1168] mg/dL vs 393 [IQR 156-1440] mg/dL, respectively, p < 0.02), and serum ferritin level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient = -0.26; p < 0.01). Hyponatremic patients had increased mortality on unadjusted (odds ratio 1.87, 95%CI 1.28-2.73) and adjusted (odds ratio 1.61, 95%CI 1.05-2.49) Cox proportional hazard models. Crude 30-day survival was lower for patients with hyponatremia at admission (mean [SD] survival 27.1 [0.40] days, p < 0.01). Hyponatremic patients had higher serum ferritin levels than normonatremic patients (median 10.3 [IQR 4.8-18.4] mg/dL vs 6.6 [IQR 1.6-14.0] mg/dL, respectively, p < 0.01), and hsCRP level was inversely correlated with plasma sodium level (Spearman’s correlation coefficient = -0.29; p < 0.01). Hyponatremic patients had increased mortality on unadjusted (odds ratio 1.87, 95%CI 1.28-2.73) and adjusted (odds ratio 1.61, 95%CI 1.05-2.49) Cox proportional hazard models.

Conclusions: This study demonstrates that hyponatremia on admission is common in patients with COVID-19 and is associated with inflammation and in-hospital mortality. Thus, hyponatremia could be a novel marker for identifying patients with COVID-19 at risk for hospital mortality.

Trends of Overall Mortality by Severity of Hyponatremia: Five-Year Mortality Rates

Peter E. Umukoro,1 Fahad A. Lodhi,2 Javid Najjar Mohajareh,2 Indiana University School of Medicine, Indianapolis, IN; 3Marshfield Clinic Health System, Marshfield, WI.

Background: We have previously reported increasing strengths of association between degree of hyponatremia on hospital admission and proportions of overall mortality at 1 year post-hospitalization. It is unclear if this association persists in the long term and if this association with overall mortality occurs in a linear manner. Here, we further explore this association over a longer mean follow up period.

Methods: We have previously reported increasing strengths of association between degree of hyponatremia on hospital admission and proportions of overall mortality at 1 year post-hospitalization. It is unclear if this association persists in the long term and if this association with overall mortality occurs in a linear manner. Here, we further explore this association over a longer mean follow up period. We hypothesized that a dose response relationship occurs between varying degrees of hyponatremia and overall mortality.

Results: We obtained data from 46,783 patients, average age 62.2 years, 51.3% males, admitted from January 1, 2012 to December 31, 2016 at a tertiary referral hospital in Central Wisconsin. Of these, 7468 patients had admitting serum sodium <135 and 39315 controls with normal serum sodium (135-145). We parsed hyponatremia based on their admitting serum sodium as mild (130-134), moderate (125-129) and profound (<125) degrees of hyponatremia and compared them with controls. We obtained their vital status (alive or deceased) up to December 31, 2018 over a mean follow up period of 4.7 years. We used Cox proportional hazards models to estimate hazard ratios between varying degrees of hyponatremia compared with normonatremia group after adjusting for covariates.

Results: Hyponatremia occurred in 17.9% of total hospitalizations during the study period. Of 7468 patients with hyponatremia, there were 6,135 (82.2%), 995 (13.3%) and 338 (4.5%) with mild, moderate, and profound degrees of hyponatremia respectively. Hazard ratios for mild, moderate and severe hyponatremia when compared to controls were 1.35 (95%CI 1.28 – 1.43), 1.81 (95% CI 1.24 – 2.56) and 2.01 (95%CI 1.24 – 3.27) respectively (all p<0.001) after adjusting for covariates.

Conclusions: All-cause mortality from CVD, stroke, cancer, liver cirrhosis deaths were occurring to a significant proportion even in patients with milder degrees of hyponatremia with a dose response relationship. Clinicians should incorporate hyponatremia in their assessment of critical patients as this is associated with mortality. These findings need to be explored further with research geared towards elucidating mechanisms that contribute to death in hyponatremia, and if correcting sodium levels early in hospitalizations may prevent mortality in the future.
improvement of Na to 131. However, he developed headaches and became hypertensive at 180/94 mmHg. Instead, he was started on a high protein diet, 1 liter fluid restriction and lasix. The next Na level was 129. He was given Tolvaptan 15 mg, which improved the Na to 132, urine osm 645, and urine Na to 12. The dose was increased to 30 mg to achieve eunatremia with these values: Na 135-138, urine Na 12, urine osm 487. His BP improved, tolvaptan was discontinued and salt tablets were resumed. The patient maintained eunatremia throughout the hospital stay.

**Discussion:** Hyponatremia is a predictor of mortality due to cellular edema. Eunatremia with Na levels between 135-145 mmol/L is targeted in acute brain injury. SIADH induced by brain injury may be due to an increase in ADH from the overstimulation of the neurohumoral axis. ADH promotes water reabsorption at the cortical and medullary collecting tubules, and inappropriate levels lead to hyponatremia. Tolvaptan is a V2 receptor antagonist which combats this mechanism, thus increasing free water excretion. Additional therapies for hyponatremia from SIADH include fluid restriction, a high protein diet and salt tablets. However, salt tablets increase fluid retention; which increases blood pressure, and leads to recurrent hemorrhage and poor outcomes. The use of Tolvaptan increases free water excretion to achieve eunatremia, thereby decreasing the risk of brain edema and controls blood pressure, especially in this patient population.

**PO1145**

Acute Severe Symptomatic Hyponatremia in the Post-Partum Period: The Syndrome of Oxytocin-Induced Anti-Diuresis (SOIAD)

Muhammad A. Shahzad, William L. Whittier, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

**Introduction:** Oxytocin (OXT) is a neuropeptide used in pregnancy to induce uterine contraction. It is structurally related to vasopressin (AVP) by a difference of only 2 amino acids. While it does not have antidiuretic activity at physiologic levels, it can when administered at pharmacologic doses (>20 μU/min). We present a case of severe symptomatic hyponatremia after receiving oxytocin in the post-partum period.

**Case Description:** A 31 y/o G1P0 woman was admitted with premature membrane rupture at week 38. An IV oxytocin infusion (2μU/min) was started to augment labor. Her serum Na 6 hrs later was 132 mmol/L (baseline Na 140). Her delivery was c/v uterine atony and postpartum hemorrhage requiring a bolus of IV oxytocin (10 U over 30 min) followed by infusion at 8 μU/min. The Na 18 hr later was 118 mmol/L. She reported nausea. Her sOsm was 252 mOsm/kg with UNa of 95 mmol/L and Uosm 880 mOsm/kg consistent with the syndrome of anti-diuresis (SIADH). OXT was suspected and was stopped. 2 hr later, a rapid water diuresis ensued (u vol 150-200 cc/hr, with uOsm 92 kg). The patient was treated emergently with a hypertonic saline bolus and was referred to nephrology. Continuous dialysis was initiated to achieve eunatremia:

**Discussion:** This case of SIADH was unique in that the patient had severe symptomatic hyponatremia without an obvious underlying cause. The use of Tolvaptan increases free water excretion to achieve eunatremia, thereby decreasing the risk of brain edema and controls blood pressure, especially in this patient population.

**PO1146**

A Rare Case of Hyponatremia: Renal Salt Wasting Syndrome of Unclear Etiology Post Autologous Hematopoietic Stem Cell Transplant

Adriani S. Polani, Vikas D. Reddy, Venkata Kishore R. Mukku, Vishnupriyadevi Parvathareddy, Sheldon Chen.1 Baylor College of Medicine, Houston, TX; 2The University of Texas Health Science Center at Houston John and Katherine G McAllister Medical School, Houston, TX; 3The University of Texas Medical Branch at Galveston School of Medicine, Galveston, TX; 4The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Hyponatremia is common in cancer patients. We report a rare case of acute hyponatremia in a patient with multiple myeloma (MM) who developed renal salt wasting syndrome (RSWS) as a complication of autologous hematopoietic stem cell transplant (SCT).

**Case Description:** A 57-year-old female with history of Plasmacytoma treated with radiation therapy that subsequently relapsed as MM with POEMS syndrome and was treated with VRd regimen presented for autologous SCT. MM was in remission and patient underwent Melphalan pre-conditioning with last melphalan dose 48 hours prior to transplant. 36 hours post-transplant patient had a seizure. Labs revealed acute drop in serum sodium from 137 to 117 over 17 hours. CT head revealed mild generalized cerebral edema. Patient also had acute polyuria (> 4 L/day). Patient was treated emergently with hypertonic saline bolus and had resolution of neurological symptoms however, serum sodium continued to drop and she required around 2 L of hypertonic saline infusion over the next 24 hours to correct sodium at desired rate. Urine studies at the time of hyponatremia revealed urine osmolality of 477, sodium 161 and potassium 34. Initial working diagnosis was SIADH that was quickly revised to RSWS based on high urine sodium, hypovolemia and polyuria. The patient was able to be transitioned to salt tablets once polyuria resolved over the next 36 hours. Urine sodium remained elevated. A repeat CT head showed resolution of cerebral edema.

**Discussion:** RSWS post SCT is rarely reported. Among the few reported cases an underlying CNS complication or a post-transplant hyponatremia inducing medication exposure that predated acute hyponatremia was present. Moreover the reported cases appeared to be non autologous transplants. SIADH and RSWS (including CSWS) are similar in the sense that both present with similar urine studies. Volume status and urine output are the key factors to help differentiate between the two entities. Clinically differentiating between these two entities is important as fluid restriction is the key management in the one and solute plus volume replacement in the other. Based on our case report we recommend that hyponatremia post SCT should be carefully evaluated and RSWS be considered in the differential even if there is no obvious underlying cause.
Cerebral Salt Wasting in a Renal Transplant Patient
Prashanth Reddy, Sahityan Viswanathan. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Hyponatremia is a common occurrence in patients with cerebral injury and is usually thought to be secondary to SIADH. Though cerebral salt wasting is documented in literature it has been debated on if it is truly a phenomenon. Among patients with CNS disease, CSW is a much less diagnosed cause of hyponatremia and remains underdiagnosed owing to the challenge of proving its existence. Here we present a patient with a CNS injury who showed clear benefit from treatment not centered around SIADH, thus pushing us to diagnose him with CSW.

Case Description: A 63yo Male with a PMHx of DDKT presented with nausea/vomiting. A cerebellar abscess from a previous biopsy site was found and he underwent a debridement and washout. On POD#2 the patient had a drop in sodium to 131. Urine studies [urine osmolality: 789, urine Na: 72]. With continued drop in sodium and orthostatic hypotension he was started on NS 75cc/hr. The sodium continued to drop to a low of 123. At that time the NS was increased to 125cc/hr. This resulted in an upswing in urine osmolality. The patient was eventually transitioned to a dose of salt tabs close to the equivalent to the amount of fluids he was receiving [5g Q4H]. He was also started on Fludrocortisone 0.1mg daily. This resulted in our ability to drop the Salt tabs to 4g Q6H with stability in serum sodium noted. He was discharged on this regimen and was noted to have stable serum sodium on follow up a few weeks later.

Discussion: CSW is difficult to diagnose due to the similarities in laboratory diagnostic markers with SIADH. One major difference is that in CSW patients are usually hypovolemic. Another aspect that differs from SIADH is the approach to treatment. In SIADH a combination of fluid restriction, lasix, and salt tabs are used. What makes our case unique is the successful use of NS to correct the patient’s sodium. If this was SIADH, continuous administration of NS would have dropped the sodium level. We believe we met the burden of proof to diagnose this patient with CSW. Though there may still be debate about the existence of CSW, we believe that with the difference in treatment approach it should always be considered in the differential in patients with CNS injury.

PO1150
On the Correction of Plasma [Na] in Hyperglycemia
Alan Segal. Steady State Nephrology, South Burlington, VT.
Background: The effect of hypertonic states on metabolism was first considered by Seldin et al in 1949. An empirical equation to correct the plasma [Na] for hyperglycemia was put forth by Katz (NEJM, 1975). About 25 years later, Hillier et al (JAM, 1999) presented another equation based on normal volunteers with experimentally induced hyperglycemia. Both equations assume a linear relationship with current plasma glucose (mM) (mEq/L Na × 100 mg/dL [glucose]) of -1.6 (Katz) and -2.4 (Hillier). Non-linearity, however, is apparent in the original data of Hillier, which are better fit by a second-order correction (corrected plasma [Na] = -3.49 × 10^-6 × (plasma [glucose])^2 - 3.91 × 10^-5 × (plasma [glucose]) + 140). Previous equations also assume normonatremia prior to hyperglycemia and a constant volume of distribution for glucose.

Methods: Here, a new model is proposed that also provides a reasonable fit to the measured value of 110 mM. The program starts by calculating the number of effective osmoles in the ICF and ECF based solely on current plasma [glucose], this program takes weight, sex, the presence of edema, and the apparent volume of distribution (aVd) of glucose into consideration. The latter is especially important because the aVd of glucose may change in hyperglycemia.

Results: For example, consider a patient from the 1951 JCI study by Seldin et al: a 59.1 kg edematous patient with cirrhosis who initially had a plasma [Na] of 130 mM when the plasma [glucose] was 126 mg/dL. The program starts by calculating the number of effective osmoles in the ICF and ECF based solely on current plasma [glucose], this program takes weight, sex, the presence of edema, and the apparent volume of distribution (aVd) of glucose into consideration. The latter is especially important because the aVd of glucose may change in hyperglycemia.

Conclusions: Now that making numerous calculations can be done easily and efficiently with apps most physicians have on their phones, it is proposed that equations with linear correction factors be replaced by this new program when clinicians would like to predict or correct the measured serum [Na] in the presence of hyperglycemia.

PO1151
Extreme Hyponatremia with Serum Sodium Less Than 100 mEq/L: A Case Report and Review of the Literature
Kirit Basil, Kenneth M. Ralto. UMass Memorial Medical Center, Worcester, MA.
Introduction: Hyponatremia is the most common electrolyte abnormality in hospitalized patients and is associated with increased mortality, hospital length of stay and cost. Rapid correction of hyponatremia can increase the risk of osmotic demyelination syndrome (ODS) which can have debilitating and often fatal consequences. Extreme hyponatremia with serum sodium concentration less than 100 mEq/L is rare, but is associated with high a rate of morbidity and mortality.

Case Description: A 52-year-old woman presented with a one-week history of weakness and fatigue. She was cachectic and had signs of severe hypovolemia and critical hyperkalemia. Additionally, she was found to have oliguric acute kidney injury and critical hyperkalemia. Her serum sodium concentration was less than 100 mEq/L, which in this case was +1.9 L. Following infusion of hypertonic glucose, the plasma [Na] fell to 110 mEq/L at the peak plasma [glucose] of 666 mg/dL. The corrected plasma [Na] predicted are (in mM): 130.9 (Katz), 126.4 (Hillier), and 124.5 (quadratic fit of Hillier’s data); all of which do not predict the change in ECF volume measured by the investigators, which in this case was +1.9 L.

Discussion: Herein we present a case of severe hyponatremia induced by urinary retention, especially given the high prevalence and predisposition of geriatric populations to develop hyponatremia. The proposed mechanism of urinary retention induced hyponatremia involves bladder distension and/or pain-mediated ADH release.

PO1152
SIADH and Postoperative Urinary Retention
Khawaja M. Bakhhtawar, Abdullah Jalal. Overlook Medical Center; Summit, NJ.
Introduction: Hyponatremia is a common electrolyte abnormality in hospitalized patients with increased prevalence noted in geriatric populations. The increased susceptibility is multifactorial from age-related OGR reduction in addition to medication effects (diuretics, antidepressants), decreased glomerular filtration rate, decreased intake and endocrine polisions (SIADH). Herein we present a case of severe hyponatremia induced by urinary retention, an infrequently described and often overlooked etiology of hyponatremia in elderly patients.

Case Description: A 58-year-old male with past medical history of hypertension on amiodipine and losartan presented with nausea, emesis and abdominal pain. The patient was recently discharged 2 weeks earlier s/p uncomplicated distal pancreatectomy with splenectomy for pancreatic adenocarcinoma. Post-operative course was stable with no complications and patient was discharged home on oxycodone/acetaminophen for pain. At home, the patient noticed constipation with worsening abdominal distension with bilateral lower extremity swelling. He had been oliguric for the past week, performing manual suprapubic compression to void. On readmission patient was noted to be severely dehydrated with a large, distended abdomen. Vital signs were BP 102/53, HR 87, SpO2 97%. Notable labs include (mEq/L): Na 111, BUN 132, Cr 4.4, HCO3 18. Urine studies noted (mEq/L): Na 8, Cl -10, K 25, serum osmolality 366 mOsm/kg. Abdominal CT noted a large LUQ fluid collection, distal colonic distension with fecal retention and mild bilateral hydrenephrosis. Subsequent Foley insertion immediately drained 2.5L. Repeat labs 12 hours later were (mEq/L): Na 118, BUN 118, Cr 2.89. Hyponatremic fluids were started to prevent Na overcorrection. Over the next several days the patient’s Serum Na (135) and renal function improved (BUN 21, Cr 0.9) back to baseline.

Discussion: During the post-operative period urinary retention is commonly noted due to anesthesia, analgesics, pain and constipation. This can be exacerbated in elderly male patients due to the ubiquity of BPH. Therefore physicians must be aware of common post-operative complications of urinary retention like hyponatremia, especially given the higher prevalence and predisposition of geriatric populations to develop hyponatremia. The proposed mechanism of urinary retention induced hyponatremia involves bladder distension and/or pain-mediated ADH release.
PO1154

Point-of-Care Ultrasound-Assisted Management of Hyponatremia
Totini S. Chatterjee, Abhilash Koratula. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Point of care ultrasound (POCUS) is emerging as a valuable adjunct to conventional physical examination in patients with complex fluid and electrolyte disorders. Herein, we present a case of hyponatremia where nephrologist-performed focused cardiac ultrasound (FoCUS) aided in accurate diagnosis.

Case Description: A 73-year-old woman was admitted for the treatment of fractures after sustaining a fall. Nephrology was consulted for decreased in serum sodium level (to 123 mmol/L; baseline 130s). Laboratory data was significant for a urine sodium level of 46 mmol/L, urine osmolality 257 mOsm/kg, serum creatinine 0.5 mg/dL and BUN 9 mg/dL. As the patient was exertional dyspnea and cracks at lung bases, IV diuretic was administered by the rounding physician prior to urine studies. No active pain or thiazide use. X-ray showed a huge hiatal hernia with bowel contents in the chest, which was possibly mimicking cracks on auscultation and causing dyspnea. Systolic BP was in 140s. Urine sodium, though suggestive of euvoletic state, was confounded by diuretic. We performed a FoCUS exam. Left ventricular outflow tract velocity time integral (LVOT-VTI), which is a surrogate for stroke volume was lower than expected (~13 cm [normal 18-22]) suggestive of hypovolemia. Flow changes precede drop in BP. We recommended to administer normal saline and the serum sodium improved to 130 mmol/L in 2 days; VTI normalized to ~22 cm [Fig 1]. Fig 2 illustrates stroke volume estimation using LVOT diameter and VTI. As the diameter is constant for a given person, VTI alone can be used to monitor response to therapy.

Discussion: POCUS is a valuable bedside diagnostic tool in day-to-day nephrology practice.

Polyethylene Glycol-Induced Pseudohyponatremia
Swetha Reddy, Sundaramaram Swaminathan. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Pseudohyponatremia due to Polyethylene glycol (PEG) is poorly described and goes unrecognized. We describe a case of hyperosmolar pseudohyponatremia due to PEG absorption into the systemic circulation.

Case Description: An 84-year-old lady with hypertension and CKD stage 4 was admitted with an asymptomatic serum sodium of 121. Initially thought be due to SIADH. She was started on 1-liter fluid restriction, sodium chloride tablet and torsemide. Nephrology was consulted on day 3 as her serum creatinine was 2.9 (baseline 2.3 mg/dl) and sodium improved to only 124. Patient complained of increased thirst and had dry mucus membrane on examination. Labs on admission revealed a serum sodium of 121 mEq/L, a serum osmolality of 286 mOsm/kg, urine osmolality of 230 mOsm/kg and urine sodium of 40. Serum creatinine was 2.3 mg/dL, BUN 50 mg/dL, glucose of 100mg/dL, uric acid 8.1 mg/dL. Thyroid function tests and cortisol were within normal range. An osmolar gap of 22 was noted. In the absence of hyperglycemia and other potential causes of an osmotic gap, such as mannitol or alcohol, a careful review of medication showed that she was on 3 weeks of PEG for constipation. PEG was held, fluid restriction and torsemide discontinued. Resolution of osmolar gap was confirmed in two weeks with return in sodium to 134 and creatinine to 2.3.

Discussion: The prevalence of hyponatremia is reported at 7% in bowel prep patients. Etiology in these cases was due to increased free water intake. Hyperosmolar hyponatremia is caused by the addition of an ‘effective solute’ (e.g. glucose, mannitol or sucrose) to the serum. Commonly used as an osmotic laxative, PEG is described as ‘a nonabsorbable, nonmetabolized polymers’ that when administered orally acts as a ‘pure osmotic agent’ in the gastrointestinal tract. Systemic absorption can occur in rare cases. When PEG absorption occurs, most of its clearance occurs via renal filtration, this process is likely impaired in a patient with CKD such as seen in our patient. When a patient presents with hyponatremia, the expectation of a low-serum osmolality needs to be confirmed with the actual measurement of serum osmolality. This case highlights the importance of detecting the etiology of hyponatremia without which treatment of the same can be impossible and expands the understanding of normal to high serum osmolality can go beyond the commonly known mannitol, paraproteinemia and lidiemia.

Identifying Hypernatremia Subgroups with Differing Survival by Machine Learning Among Hospitalized Patients
Grace Y. Chong,1 Charat Thongprayoon,1 Michael A. Mao,2 Andrea G. Kattah,1 Mira T. Keddis,2 Stephen B. Erickson,1 John J. Dillon,1 Vesna D. Garovic,1 Wisit Cheungpasitporn,1 Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN;2 Mayo Clinic Division of Nephrology and Hypertension, Jacksonville, FL; Mayo Clinic Division of Nephrology and Hypertension, Phoenix, AZ.

Background: The objective of this study was to characterize patients with hypernatremia on hospital admission into clusters using an unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

Methods: We performed consensus cluster analysis based on demographic information, principal diagnoses, comorbidities, and laboratory data among 6,297 hospitalized adult patients with hypernatremia present at admission. We calculated the standardized difference of each variable to identify each cluster’s key features. We assessed the association with each hypernatremia cluster with in-hospital and one-year mortality.

Results: There were three distinct clusters of hypernatremia: 1,570 patients (25%) in cluster 1; 2,648 (42%) in cluster 2; and 2,079 (33%) in cluster 3. Figure 1 is a plot of standardized mean differences to visualize key features for each cluster. Compared to cluster 2, the odds ratios for in-hospital mortality were 5.73 (95% CI 3.13-9.90) for cluster 3, whereas hazard ratios for one-year mortality were 3.38 (95% CI 3.31-4.25) for cluster 1 and 4.71 (95% CI 3.38-5.80) for cluster 2.

Conclusions: The characteristics and outcomes of hospitalized patients admitted with hypernatremia were heterogeneous. Our cluster analysis identified three clinically distinct phenotypes with differing mortality risks. Identification of heterogeneity in hypernatremic patients using this approach may provide guidance for the management of hospitalized patients with hypernatremia at the time of hospital admission.
A Case of Ketamine-Induced Diabetes Insipidus
Karim T. Attia, Kara Kaplan, Alka A. Tyagi, Joshua Leisring. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: To our knowledge there have been six previously published case reports describing central diabetes insipidus (DI) related to ketamine. We present a unique case of central DI associated with ketamine infusion in a critically ill patient with acute respiratory failure.

Case Description: A 52-year-old African American man with medical history of bipolar disorder, polysubstance abuse, chronic obstructive pulmonary disease, hypertension, and deep vein thrombosis was admitted to the medical intensive care unit with hemoptysis and acute respiratory failure. Due to agitation and refractory hypoxemia he required multiple sedating agents. Within hours of starting a ketamine infusion his urine output increased from a mean of 71 mL/hr to 305 mL/hr. Over 48 hours serum sodium (Na⁺) rose from 142 to 159 mmol/L. Urine osmolality (Uosm) was 132 mOsm/kg. 4 mcg intravenous (IV) desmopressin was administered. 90 minutes later Uosm had increased to 646 mOsm/kg. Urine output fell to 49 mL/hr. About 28 hours after the initial dose of desmopressin polyuria recurred and Uosm fell to 272 mOsm/kg. IV desmopressin was re-administered at 2 mcg with a similar response to the first dose. SNA normalized with free water replacement. Ketamine was stopped. Urine output, Uosm, and SNA remained stable without further intervention. Alternative etiologies for central DI such as hypoxic brain injury were considered but felt to be less likely due to the strong temporal relationship with ketamine. The Naranjo adverse drug reaction (ADR) likelihood score was 5 indicating a probable ADR.

Discussion: This case reinforces the association between ketamine and central DI which has been described in prior case reports. A hypothesized mechanism is ketamine’s antagonism of N-methyl-D-aspartate receptors in the posterior pituitary thus inhibiting arginine vasopressin production. Ketamine is being used with greater frequency in critical care. It is important to recognize this rare but potentially serious complication. Monitoring of SNA, Uosm, and urine output should be considered. When central DI related to ketamine is identified, withdrawal of the drug appears to be corrective.

Higher Risk of Incident Kidney Stones in Patients with Metabolic Acidosis and CKD

Nancy L. Reaven,1 Susan E. Funk,1 Vandana S. Mathur,2 Julie C. Lai,1 Navdeep Tangri,1 1Strategic Health Resources, La Canada, CA; 2Division of Nephrology, University of Manitoba, Winnipeg, MB, Canada.

Background: Epidemiological studies have shown an association between kidney stones and risk for CKD and its progression. Some types of stones are less likely to form at higher urine pH. Metabolic acidosis is a risk factor for CKD progression, but the association of serum bicarbonate with risk of incident kidney stones is not well understood.

Methods: Optum’s de-identified Integrated Claims-Clinical dataset of US patients (2007-2019) was queried to identify patients with non-dialysis CKD stages 3-5 with 2 consecutive serum bicarbonate values of 12 to <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) with data a3 years pre-index. The first qualifying serum bicarbonate test established the index date. Primary exposure variables were baseline serum bicarbonate and change in serum bicarbonate over time. Adjusted time-dependent Cox Proportional Hazards models were performed to evaluate time to first occurrence of kidney stones (by ICD-9 or ICD-10 diagnosis codes) during an average 3.6 year follow-up period. Other covariates included age, sex, race-ethnicity, and income status, history of kidney stones, pre-index comorbidities associated with kidney stones, bariatric surgery, obesity, smoking history, baseline eGFR.

Results: 142,904 patients qualified for the study cohort. Patients with metabolic acidosis at index experienced kidney stones at greater frequency than those with normal serum bicarbonate (HR 1.07 vs 95% CI: 1.06-1.07 vs 95% CI: 1.06-1.07). Other significant factors associated with incident kidney stones included male sex, history of kidney stones, hyperoxaluria, gastroparesis and osteoporosis. Both higher serum bicarbonate at baseline (HR 0.956, 95% CI: 0.948-0.964) and higher serum bicarbonate over time (HR 0.968, 95% CI: 0.961-0.974) were associated with reduced risk of kidney stone development. The observed associations were unchanged in analyses examining death as a competing risk.

Conclusions: In patients with CKD, metabolic acidosis (vs. normal serum bicarbonate) was associated with a higher incidence of kidney stones and shorter time to incident stone formation. Future investigations should evaluate these associations by study design.

PO1165
Anion Gap Metabolic Acidosis on Continuous Renal Replacement Therapy: Are You Missing Something?
Mustafa Dawood, Vandana D. Niyyar, Emory University School of Medicine, Atlanta, GA.

Introduction: Anion gap metabolic acidosis is a common metabolic abnormality seen in the clinical practice. Causes includes Lactic acidosis, Ketoacidosis, Renal failure, volatile acid toxicity and salicylate poisoning. Ketoacidosis is due to decreased glucose and insulin availability leading to starvation ketosis and diabetic ketoacidosis respectively. Ketoacidosis is uncommonly seen in patients on prolonged continuous renal replacement therapy. We present 2 cases at Grady Hospital admitted with Acute hypoxic Respiratory Failure due to COVID 19 pneumonia, developed euaglycemic ketoacidosis on Continuous Renal Replacement Therapy.

Case Description: case 1: 73 male with the history of HTN, DM, CKD III admitted for acute hypoxic respiratory failure due to COVID 19 pneumonia. He was intubated on admission day 9. Course got complicated by hypotension during intubation leading to Acute Renal Failure on day 11. Patient was started on Renal Replacement Therapy on day 12 due to volume overload and acidosis. Day 19, Anion gap worsened and betahydroxybutyrate was elevated. Patient was started on insulin drip with resolution of acidosis on day 20. Case 2: 48 yo male with the history of HTN, DM II, CKD stage III admitted for Altered mental status, Hypertensive emergency and cough. He was diagnosed with COVID 19 Pneumonia. Patient had non oliguric acute kidney injury on admission. Hospital day 11, patient was oliguric, volume overloaded and hyperkalemia prompted Renal replacement therapy initiation. Day 14, Anion gap worsened and betahydroxybutyrate was elevated. Tube feed were initiated and Dialysate prescription was changed leading to resolution of anion gap on day 12.

Discussion: Diabetic ketoacidosis is a medical emergency commonly in patients with Type I DM but also in Type II DM patients as well. It occurs due to decrease insulin concentration or increase insulin resistance with or without decreased glucose availability leading to release of counterregulatory hormone and fatty acid metabolism producing ketocids. Diagnostic criteria include pH<7.3, Serum HCO3<18, Serum glucose>250mg/dl and positive urinary ketones. Euglycemic DKA is a subtype of DKA with serum glucose of <200 mg/dl. Incidence of Euglycemic DKA varies from 2.6-3.2%. Continuous renal replacement therapy is an under-recognized cause of Euglycemic DKA in patients with Diabetes Mellitus.
PO1166
A Wide-Awake Patient with Severe Hypoglycemia and Lactic Acidosis
Sarah Abdelsalam, Madhumita J. Mohanthy, Mili J. Shah. Wayne State University, Detroit, MI.

Introduction: Severe hypoglycemia is associated with altered mental status or loss of consciousness. We report an intriguing patient who had advanced liver disease and presented with severe hypoglycemia and lactic acidosis without any alteration in mental status.

Case Description: 57-year-old female with severe decompensated alcoholic liver cirrhosis, ascites and recurrent hepatic hydrothorax presented to the Emergency Room with worsening shortness of breath. She had poor oral intake except for actively consuming ethanol. Chest X ray revealed worsening right hydrothorax. Routine blood tests revealed severe hypoglycemia (serum glucose 28 mg/dL; severe anion gap metabolic acidosis (arterial pH 7.11, serum bicarbonate 6 mmol/L, anion gap 40 mmol/L) and acute kidney injury with elevation of serum creatinine to 2.2 mg/dL. Subsequent laboratory investigations revealed serum lactate acid level of 23 mmol/L. Serum ethylene glycol, methanol, salicylate and acetonitrile levels were undetectable. She had no seizures, malignancy or hypoxia. The patient was alert and oriented. She was hemodynamically stable. There was no evidence of sepsis, tissue hyperperfusion or bowel ischemia. She was not taking any medications which may have led to hypoglycemia or lactic acidosis. The patient was administered intravenous glucose with rapid improvement of her serum glucose and lactate level.

Discussion: This patient had no alteration in mental status despite severe hypoglycemia. Under normal circumstances, the brain primarily depends on glucose as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactate acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hypoglycemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps also her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

PO1167
Sleeping Beauty: Hypersomnolence and Hyperammonemia in a Patient with Multiple Myeloma
Stephen P. Regina,1 Roberto L. Collazo-Maldonado,2 Muhammad R. Qureshi.2
1Methodist Health System, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

Introduction: Metabolic encephalopathy in a patient with multiple myeloma is commonly reported in association with prevalent biological syndromes such as uremia, hypercalcemia, and or hyperviscosity due to immunoglobulin, but very rarely hyperammonemia has been described as another cause of encephalopathy.

Case Description: The patient is a 45 year old woman with a prior diagnosis of multiple myeloma in July 2020. A bone marrow biopsy confirmed plasma cell neoplasm. She presented with confusion and hypersomnolence over two weeks. Labs included hemoglobin 7.3 g/dL, white blood cell 21.9 x10^3/ul, platelets 276,000/ul, serum creatinine 0.7 mg/dL, urea 61 mg/dL, albumin 3.7 g/dL, serum calcium 10.3 mg/dL, phosphate 2.7 mg/dL, sodium 133 mEq/L, potassium 3.7 mEq/L, chloride 108.9 mEq/L, bicarbonate 16.4 mEq/L, arterial pH 7.25, pCO2 32.3 mmHg, pO2 63.3. Hypercalcemia was as the primary fuel. Studies have shown that under conditions of hypoglycemia and elevated serum lactate acid levels, lactate may serve as an alternative source of energy for the brain. We hypothesize that hyperlactatemia, by providing an alternate energy source, prevented mental status changes in this patient with severe hypoglycemia. Correction of hypoglycemia led to rapid correction of hyperlactatemia suggesting that perhaps lack of glucose may have contributed to hyperlactatemia. We did not identify any obvious cause of hypoglycemia or hyperlactatemia except for her end stage liver disease, continued ethanol use and perhaps also her oliguric acute kidney injury. This patient illustrates that hyperlactatemia may be neuroprotective in severely hypoglycemic patients.

Renal Outcomes and Safety Profile of Direct Peritoneal Resuscitation (DPR)
Kiran Shivani, Michael D. Klein, George N. Cortisidis. Westchester Medical Center, Valhalla, NY.

Background: DPR is a novel technique used after damage control surgery where peritoneal dialysis fluid is continuously irrigated and drained from the peritoneal cavity in a open abdomen. This has been shown to improve intestinal perfusion, leading to faster abdominal closure. We analyzed the safety profile in terms of changes in the electrolyte profile.

PO1169
Pyroglyutamic Acidosis: Gaps in the Gaps
Roy Rajan, Martin Sedlacek. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.

Introduction: Prolonged use of acetaminophen can lead to an acquired form of pyroglyutamic acidosis, a form of anion gap metabolic acidosis (AGMA) from increased production of 5- Oxoprolin (pyroglyutamic acid). 5- Oxoprolin accumulates in the body due to the failure its breakdown by 5- Oxoprolinase and is excreted in urine causing positive anion gap (AG).

Case Description: Case 1: First patient is a 59 y/o man with normal prior renal function with baseline creatinine (Cr) of 0.7 mg/dL with severe pancreatitis. At the time of presentation his serum calcium 15 mg/dL (8.5-10.5) and his serum Cr level was 2.2 mg/dL. His hospital course was complicated by sepsis due to multiple intra-abdominal infections and required iv pressor and ventilator support. He was later started on continuous veno-venous hemofiltration (CVVH) temporarily with recovery of renal function. Acetaminophen 1 gram three times daily was administered for pain control. On the 65th day of hospitalization, his bicarb was 15 with an AG of 14, but when corrected for low albumin 1.8, it increased to 20. HE had a positive urine AG and his urine 5-Oxoprolin was 1583 mmol/mol Cr (range < 62). Case 2: Second patient is a 74-year-old man with a history of stage 4 CKD admitted with sepsis due to perforated viscus. He had long hospital course due to ischemic gut with continued bleeding and sepsis due to perforation. He was on Acetaminophen 1 gram four times daily for pain control. His serum bicarbonate started trending down to a nadir of 11 mmol/L on the 43rd day of admission. He had an anion gap of 12, but corrected anion gap was 18 and had a positive urine AG. His urine 5- Oxoprolin was 631 mmol/mol creatinine (range <62).

Discussion: Both patients in our case series had critical illness, were malnourished, and was recovering from prolonged infection and sepsis which are risk factors for pyroglyutamic acidosis and low serum albumin levels. Their AG might appear to be within normal range if not corrected for albumin. Urine albumin gap is an indirect method of measuring urine ammonia excretion and it is elevated in renal tubular acidosis and from excretion of organic anions like 5-Oxoprolin and ketone bodies. Correction for AG is proposed as measured AG + 2.5 x (serum albumin = 4.2 – measured albumin /g/dL). This is not a “normal AGM” as there is a positive urine AG due to pyroglyutamic acidosis can mimic renal tubular acidosis and can be easily missed.
Diffuse Large B Cell Lymphoma and Synchronous Colon Adenocarcinoma Presenting with Type B Lactic Acidosis Secondary to the Warburg Effect in a Hispanic Man

Daniel Varella,1,2 Leonardo Pozo Garcia,1,2 Daniela Hernandez,1,2 Mourad Alsabbagh,1,2 John Manillo,1  Sergio A. Trevino Manillo.1  The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 2DHR Health, Edinburg, TX; 3South Texas Kidney Specialists, McAllen, TX.

Introduction: Lactic acidosis is a major metabolic dysregulation characterized by hyperlactatemia and acidemia that is commonly associated with tissue hypoperfusion. In very rare circumstances, hematological malignancies have been associated with a paraneoplastic syndrome characterized by the modification of the metabolism of cancerous cells from aerobic to anaerobic glycolysis.

Case Description: A 61-year-old man presented to the hospital due to generalized body weakness. He was recently admitted to the hospital due to left knee pain; at that time incision, drainage, and tissue sample were done. The patient was discharged to home with wound care and antibiotics. On presentation, patient was found to be tachypneic, hypotensive with Kussmaul breathing. A warm erythematous lesion was seen on left lower extremity. Laboratory results showed WBC 20000/mm3, Hemoglobin 10 g/dL, Platelets 340 /mm3, creatinine 7.9 mg/dL, Bicarbonate 5 mmol/L, Lactate 6.21 mg/dL, and Ferritin 326 mg/dL, blood cultures positive for Enterobacter. Broad-spectrum antibiotics were administered. Nephrology consulted and dialysis started emergently. The pathology report showed Diffuse Large B-Cell Lymphoma. During the hospital stay, patient acidosis was persistent despite adequate renal replacement therapy and resolution of the septic process. ABG was done showing serum pH of 7.2, Bicarbonate 9 mmol/L, Lactic acid 17.5 mg/dL. Bowel ischemia was ruled out with CT angiogram however imaging showed neoplastic infiltration of peritoneal abdominal structures associated with multiple small nodules. Colonoscopy demonstrated synchronous colon adenocarcinoma. The decision was made to treat the patient with chemotherapy. One week after chemotherapy lactic acid trended down to 1.1 mg/dL. The metabolic acidosis and renal function improved and RRT was stopped.

Discussion: Usually, lactic acidosis is a sign of hyperfusion and septic shock. In this case, the source of lactic acidosis was not hyperfusion but rather a paraneoplastic syndrome that leads to anaerobic metabolism of malignant cells, known as the Warburg effect. This condition can be fatal. Prompt initiation of chemotherapy is recommended.

Distal Renal Tubular Acidosis in Patients with Autoimmune Diseases

Oana Ion,1 Ioana Alinici,1 Georgiana Fratila,1,2  Genser Ismail,1,2  Institutul Clinic Fundeni, Bucuresti, Romania; 2Universitatea de Medicina si Farmacie Carol Davila, Bucuresti, Romania.

Background: Distal renal tubular acidosis (DRTA) is reported in association with autoimmune diseases. DRTA can evolve without symptoms and systemic acidosis, this form being defined as incomplete DRTA. The incomplete form necessitates the use of a urinary acidification test like the Furosemide and Fluorocitrone test for establishing the diagnosis.

Methods: We conducted a prospective observational study in a selected cohort of 48 patients diagnosed with autoimmune diseases (SLE, SJögren syndrome, ANCA vasculitis, cryoglobulinemic vasculitis), who presented in our clinic from December, 2020 until May, 2021. The patients were submitted to Furosemide and Fluorocitrone test.

Results: The study included 48 patients (36 females, mean age 41.92 ± 15.7 years), diagnosed with SLE (33 patients), pANCA vasculitis (7 patients), cANCA vasculitis (1 patient), SJögren syndrome (3 patients) and cryoglobulinemic vasculitis (4 patients). There was a significant difference regarding age (p=0.001) and eGFR (p=0.001) between the groups with vasculitis (mean age 60.752 ± 20.03 years, eGFR 20.03 ± 11.74 years) and 20.03 ± 11.74 years groups with vasculitis a (standard base excess: -10.4 [−12.5, −9.5] mEq/L in group 20, ± 79 [63, 85] mmHg in group 40 (P<0.05). Despite the increased infusion of bicarbonate in group 40, the blood CO2 content did not change during the experiment. The 12-hour survival rate was higher in group 40 (67% vs. 0, P=0.032).

Conclusions: A higher bicarbonate concentration in the dialysate of animals undergoing hypercapnic respiratory failure was associated with improved blood pH control increasing the PaCO2 levels.

Effect of Continuous Dialysis on Blood pH in Acidemia Hypercapnic Animals with Severe AKI: A Randomized Experimental Study Comparing High vs. Low Bicarbonate Afluent

Thiago Gomes Romano G. Romano,1,2 Sirio Libanes, research and teach institute, Sao Paulo, Brazil; 1Faculdade de Medicina do ABC, Santo Andre, Brazil.

Background: Controlling blood pH during acute ventilatory failure and hypercapnia in individuals suffering from severe acute kidney injury (AKI) and undergoing continuous renal replacement therapy (CRRT) is of paramount importance in critical care settings. In this situation, the concentration of sodium bicarbonate in dialysate is still an unsolved question in critical care since high concentrations may worsen carbon dioxide levels and low concentrations may not be as effective in controlling pH.

Methods: We performed a randomized, non-blinded, experimental study. AKI was induced in twelve female pigs via renal hilum ligation and hypoventilation by reducing the tidal volume during mechanical ventilation with the goal of achieving a pH between 7.10 - 7.15. After achieving the target pH, animals were randomized to undergo isovolemic haemodialysis with one of two concentrations of bicarbonate dialysate (40 mEq/L [group 40] vs. 20 mEq/L [group 20]).

Results: The haemodynamic, respiratory, and laboratory data were collected. The median pH value at CRRT initiation was 7.14 [7.12, 7.15] in group 20 and 7.13 [7.09, 7.14] in group 40 (P<0.05). The median baseline PaCO2 was 74 [72, 81] mmHg in group 20 vs. 79 [63, 85] mmHg in group 40 (P<0.05). During the last hour of CRRT, the pH value was 7.05 [6.95, 7.09] in group 20 and 7.12 [7.1, 7.14] in group 40 (P<0.05), with corresponding values of PaCO2 of 85 [79, 88] mmHg vs. 81 [63, 100] mmHg (P<0.05). The difference in pH after three hours was due to a metabolic component [standard base excess: -10.4 [-12.5, -9.5] mEq/L in group 20 vs. -7.9 [-9.2, -5.1] mEq/L in group 40 (P<0.05). Despite the increased infusion of bicarbonate in group 40, the blood CO2 content did not change during the experiment. The 12-hour survival rate was higher in group 40 (67% vs. 0, P=0.032).

Conclusions: A higher bicarbonate concentration in the dialysate of animals undergoing hypercapnic respiratory failure was associated with improved blood pH control increasing the PaCO2 levels.
PO1174
A Patient with Combined Metformin-Induced Lactic Acidosis and Euglycemic Diabetic Ketoacidosis

Introduction: Metformin is a small, non-protein-bound molecule that can cause lactic acidosis in 6 out of 100,000 patients with a mortality rate of 30-50%. Concurrent euglycemic diabetic ketoacidosis (DKA) from sodium-glucose co-transporter-2 (SGLT2) inhibitor has been reported in one case. We report a unique case of a patient with acute kidney injury (AKI) in the setting of metformin-induced lactic acidosis and osmotic diuresis due to euglycemic DKA complicated by celecoxib use.

Case Description: A 66-year-old female with a past medical history of type 2 diabetes mellitus for 21 years on metformin 1000 mg twice daily and emaplatin 25 mg daily with baseline eGFR 51 mL/min/1.73m² 5 months prior, who was also on celecoxib 200 mg daily for 40 days presented for elective cervical discectomy which was canceled due to AKI. On exam, blood pressure was 119/59 mmHg, pulse was 92 beats/min, and the temperature was 36.1°C. She was tachypneic at 24 breath/min. Labs showed sodium 136 mg/dL, potassium 9.5 mg/dL, bicarbonate 14 mg/dL, BUN 83 mg/dl, creatinine 8.78 mg/dL, and glucose 117 g/dL. Lactic acid was 13.5 mmol/L, beta-hydroxybutyrate 5.9 mmol/L, serum osmolality 336 mOsm/kg with no osmolar gap. She underwent conventional hemodialysis (HD) for 3 hours followed by 18 hours of continuous kidney replacement therapy (CKRRT). She required an insulin drip with 5% dextrose in normal saline for 24 hours. Lactic acid was 3.8 mmol/L after 24 hours. Creatinine improved to 2.46 mg/dL on day 4 without further intervention. She was discharged off metformin, emaplatin, and celecoxib.

Discussion: Metformin is readily dialyzable but has a large volume of distribution. There is no specific antidote available to reverse the toxic effects of metformin or consensus on the modality of renal replacement therapy. Previously demonstrated biphasic elimination pattern of metformin intoxication suggests that a brief HD session within the subsequent 3 months.

PO1175
Mind the Gap: An Anion Gap of 52 Fully Explained
Uma Mahesh R. Ayula, Lililia Harris, Tariq Shafi, Neville R. Dossabhoy. The University of Mississippi Medical Center, Jackson, MS.

Introduction: The Anion Gap (AG) remains the main clinical tool to elucidate acid-base disturbances in patients with metabolic acidosis. We present a case with an extremely elevated AG of 52 mmol/L, and describe our search for its biochemical explanation.

Case Description: A 66-year-old female was admitted with loss of consciousness, shock, and severe acute kidney injury. She had type 2 diabetes mellitus, treated with metformin. At presentation, she had an AG of 52 mmol/L and osmolar gap of 34 μmol/kg. Her arterial blood gas showed: pH <7, HCO3 7.5 mmol/L, pCO2 16 mm/Hg. Phosphate level was unusually high, 21.3 mm/dL, with unknown etiology. There was no history of enema or laxative use. A significant contributor of AG was lactate at 14.5, given her history of metformin use. Urine drug screen was positive for amphetamines. The volatile alcohol panel was positive for acetone; methanol, ethanol, ethylene glycol and isopropyl alcohol were not detected. Continuous venovenous hemofiltration (CVVH) was initiated. After 3 days, renal function started recovering, lactate and phosphorus levels normalized and AG closed. The patient did not need CVVH thereafter. Two months later, the patient was discharged to a nursing facility in a stable condition.

Discussion: Extremely elevated AG of 52 in this patient can be explained by a rise in concentrations of organic acid anions, lactate, ketoacids, hyperphosphatemia, and retention anions.

Explanation of the high AG: The Figure describes the calculation of AG. In this patient, phosphate was a major contributor to the AG.

PO1176
Is an Increase in Anion Gap a Predictor of Hemodialysis Initiation in Patients with Advanced CKD?

Background: Because uremic symptoms and manifestations vary among patients with advanced chronic kidney disease, it is sometimes difficult to decide on the timing of dialysis initiation only from uremia, we attempted to investigate whether anion gap (AG) that may reflect the accumulation of total organic acids in uremia can be a marker of uremia and may predict the timing of dialysis initiation.

Methods: This study included pre-dialysis patients who attended to our hospital for more than six months prior to the beginning of hemodialysis (HD), and retrospectively analyzed the relationship between their serological data, AG, and various uremic symptoms. The AG was calculated as the corrected AG (cAG) = Na−Cl−HCO3 [mmol/L]×2.5 + (4-serum albumin concentration [g/L]). The statistical analysis was performed by logistic regression analysis, correlation analysis, and factor analysis using SPSS®.

Results: A total of 283 patients [diabetes mellitus: 136 (48.1%), nephroclerosis: 66 (23.3%), glomerulonephritis: 36 (12.7%)] were included in this study. The most common clinical symptom before dialysis initiation was fluid overload, which was seen in 134 patients (47.3%), followed by anorexia 104 patients (36.7%) and general malaise 96 patients (33.9%). The cAG began to increase 3 months before the initiation of HD (14.2 mmol/L), which showed a rapid increase just before the initiation, and was correlated with uremia and fatigue, better than fluid retention. Of note is that cAG was most significantly associated with dialysis initiation among various factors. The ROC of cAG for dialysis initiation showed the highest value of AUC 0.979 (95% CI=0.972 to 0.85, p<0.05), with a cutoff value of adjusted cAG 15.975 (sensitivity 0.689, specificity 0.786).

Conclusions: Uremic symptoms and some serological markers including azotemia, metabolic acidosis, and hyperphosphatemia have been usually used to predict the magnitude of uremia and the timing of dialysis initiation. In our study, it is suggested that a rapid increase in cAG over 16 mmol/L may also be a good predictor of dialysis initiation within the subsequent 3 months.

PO1177
Mysterious Case of Recurrent Life-Threatening Lactic Acidosis
Zakir Shaikh, Waqas Ahmad Khan, Ajay D. Rao, Jean Lee. Temple University Hospital Temple University Health System Inc, Philadelphia, PA.

Introduction: Patients living with diabetes are prone to type-B lactic acidosis, often presenting with profound acid-base derangements. The reason for lactate production is not obvious hence management can be challenging. We present a case of life-threatening recurrent lactic acidosis in a diabetic patient.

Case Description: A 67-year-old man with type 2 diabetes, hypertension, presented to the hospital with malaise for 2 days. He had been on metformin in the past but had recently switched to insulin. There was no history of alcohol ingestion nor use of herbal supplements. The lactic acid level was 34.2 mmol/L with Ph of 6.82, PCO2 of 27 mmHg, serum bicarb of 7 mmol/L, anion gap of 28, and serum Cr of 1.4 mg/dL with baseline of 1 mg/dL. No evidence of infection or ischemia found. Toxicology screen was negative and serum metformin level was undetectable. Lactic acidosis resolved with continuous renal replacement (CRRT) for 24 hours. A month later he returned with similar complaints.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
and its lactate level was 14.8 mmol/L. This was treated with supportive care alone. Six months later the patient returned with lactate of 13.5 mmol/L, worsening to 18.6 mmol/L. He improved after treatment with CRRT and supportive care. Alcohol levels, liver function tests, pyruvate, glutamate, metformin levels were all negative or normal. The thiamine level was not checked during his first admission. During the second visit, the value was normal but this was drawn after thiamine had been given. During the third visit, the thiamine level was noted to be less than 6 mmol/L. The patient was started on thiamine and has not had further episodes of lactic acidosis.

Discussion: Patients with diabetes are prone to excess lactic acid generation due to the decreased conversion of pyruvate to lactic acid and increased conversion of pyruvate to lactate. This is due to the absence of thiamine and pyruvate kinase deficiency. In the absence of thiamine, pyruvate cannot enter the Krebs cycle and is converted to lactic acid predisposing diabetics to type-B lactic acidosis. Thiamine is filtered in the glomerulus and is reabsorbed in the proximal tubule through the thiamine H+ antiporter. Long term use of diuretics has been associated with thiamine deficiency. However our patient was not taking any nor did he have chronic kidney disease or any evidence of malnutrition.

Methods: This was a single-center retrospective chart review of CKD patients with acidosis from 2010-2017. Inclusion criteria were adult patients receiving NaHco3 for CKD-associated acidosis with baseline estimated glomerular filtration rate (eGFR) ≥25 and < 60 ml/min/1.73 m² when starting NaHco3. Patients with glomerulonephritis, kidney transplant, acute kidney injury (not back to at least 75% of eGFR baseline) were excluded. Four groups were identified for comparison based on mean serum Co2 (in mmol/L), from outpatient measures during 3 years follow-up, group A (< 22), group B (22 - < 24), group C (24 - < 25), and Group D (≥ 25). Albumin, urine protein-creatinine ratio (UPCR), PTH, and eGFR were compared, p-values are calculated by a one-way ANOVA model.

Results: There were 383 patients with CKD-associated acidosis receiving NaHco3, 93 patients qualified for the study. Group A (n=21), group B (n=41), group C (n=13), and Group D (n=18). Racial demographics: 35=black (38%), 57=white (61%), 1=Other. Females 49 (53%). Median age 69 years. Follow-up 3 years. At baseline mean eGFR, UPCR, and albumin, and diuretics use and osteoporosis diagnosis in the four groups were similar (p = 0.46, 0.32, 0.15, 0.09, 0.36 respectively). Mean hemoglobin A1C in each group did not exceed 8.2. At 3 years of follow-up, changes in eGFR, UPCR, and osteoporosis status between the four groups were similar (p = 0.14, 0.27, 0.19 respectively). Change of albumin was significantly worse in group A comparing to groups B, and C (p = 0.007, 0.049 respectively), and average PTH was significantly worse in group A comparing to group C (p = 0.045).

Conclusions: In our cohort, all groups of treated CKD-associated acidosis (B, C, and D) showed no statistical difference in CKD progression, the severity of parathyroidism, developing osteoporosis, or nutrition status assessed after 3yes follow-up. Hence, higher Co2 targets don’t carry worse outcomes.
Pseudo-Hypobicarbonatemia with Severe Hypertriglyceridemia

Case Description:
A 42-year-old male patient with a past medical history significant for diabetes mellitus type 2, obesity, and hyperlipidemia. The patient presented with nausea, vomiting and epigastric pain. Physical examination was significant for tenderness in the epigastrium and xanthelasma. The basic metabolic profile (BMP) was significant for Na+ 127meq/L, Cl - 94meq/L, BUN 10mg/dL, creatinine 0.87mg/dL and AGAP 24. A lipid panel showed a cholesterol 461mg/dL, and triglycerides 4061mg/dL. Lipase and amylase were 1183U/L and 202U/L respectively. Urinalysis revealed trace ketones. CT abdomen revealed peripancreatic stranding. The patient was diagnosed with AGMA due to diabetic ketoacidosis and pancreatitis secondary to hypertriglyceridemia. An arterial blood gas analysis (ABG) subsequently revealed a pH 7.39, PCO2 40, PaO2 73 and a HCO3- 24. A significant dissociation between the calculated and measured bicarbonate was noted. Following aggressive lowering of the triglycerides, with Insulin infusion there was an immediate resolution of the pseudo- bicarbonatemia and anion gap metabolic acidosis.

Discussion:
This measurement error is due to the mechanism by which the analyzer interprets the bicarbonate level in the serum. Most analyzers utilize either anion-selective electrode (ISE) or function via an enzymatic/photometric method. High amounts of lipid particles may cause light scattering altering the photometric analysis. This likely caused the discrepancy between the enzymatic/photometric measured serum bicarbonate and the calculated bicarbonate of the aqueous phase ISE analyzer used by the ABG. Clinicians should be able to recognize that its essential to obtain a blood gas sample for determination of the acid-base status to avoid expensive work up.

Pseudohypocarbonatemia in a Patient with Paraproteinemia

Introduction:
The first step in acid-base disorders’ diagnosis is obtaining measurement of blood bicarbonate (HCO3-), pH and partial pressure of carbon dioxide (pCO2) levels. Blood HCO3- levels are estimated via two methods: direct measurement of serum total carbon dioxide (TC02), or via Henderson-Hasselbalch equation using arterial blood and directly measuring pH and pCO2 levels. With the enzymatic method, there have been reported cases of falsely low serum HCO3- due to interference by elevated triglyceride levels, but only two cases have been reported of spuriously low serum HCO3- due to interference by paraproteins.

Case Description:
A 74-year-old male with a history of bladder carcinoma in situ and hypertension presented with complaints of malaise after a recent bladder irrigation. Basic metabolic panel (BMP) was unremarkable except for a HCO3- of 8 mmol/L measured using a Siemens Vista (SV) enzymatic chemistry analyzer. He was hospitalized for high anion gap metabolic acidosis with anion gap of 22. He was started on intravenous NaHCO3 (150 mEq/L) after nephrology was consulted. Repeat serum HCO3- was 11 mmol/L the next day with transition to oral NaHCO3 650 mg therapy thrice daily. On outpatient follow-up, he had low serum HCO3- ranging from 8-11 mmol/L (using SV analyzer) despite his reported compliance with NaHCO3. He was evaluated by another nephrologist with repeat BMP and an arterial blood gas (ABG). The results revealed a serum HCO3- of 8 mmol/L in contrast with ABG pH of 7.41 and HCO3- of 25 mmol/L. Due to the discrepancy, his serum HCO3- was analyzed at a different facility using a Beckman Coulter analyzer which revealed a normal serum HCO3- level of 21 mmol/L. Further work up was pursued with SPEP and SIFE revealing an M-spike and presence of IgM and IgA kappa monoclonal proteins respectively, which led to a diagnosis of monoclonal gammopathy.

Discussion:
Paraproteins have been reported to cause interference with multiple laboratory test results. Paraproteins in our case may have resulted in artifactual error of serum HCO3- by direct interaction with assay reagents, binding of paraproteins to an assay reagent, or turbidity caused by the precipitation of the monoclonal proteins. Our case highlights the importance of being aware of this phenomenon of pseudohyperbicarbonatemia that can occur with certain chemical analyzers.

PO1183

Proton Pump Inhibitor (PPI) for the Treatment of Metabolic Alkalosis due to Gastric Losses

Introduction:
Gastric losses of hydrochloric acid can result in severe metabolic alkalosis (met alk). We describe two cases where patients with significant losses of gastric secretions presented with severe met alk and AKI. In both cases, PPI therapy was used to reduce the volume of the gastric secretions with excellent effect.

Case Description:
Patient 1: A 44 year-old woman with Gardner Syndrome with near-total enterectomy and colostomy on total parenteral nutrition with a venting gastric tube (G-tube), presented with met alk (HCO3- 50 meq/L) and AKI (Scr 4 mg/dL from baseline 1.3 mg/dL). Met alk persisted despite normal saline (NS) administration and gastric tube losses ranged from 4-8 liters per day. Twice daily intravenous PPI was started with immediate decrease of gastric losses and normalization of HCO3-. This patient was admitted one year later (off PPI therapy) with a similar derangements and resuming PPI therapy caused similar improvement. Patient 2: A 59 year-old man with gastric outlet obstruction and venting G-tube presented with met alk (HCO3, 47 meq/L) and acute kidney injury (Scr 4.5 mg/dL from 1.3 mg/dL). Met alk persisted despite NS administration and his gastric tube losses ranged from 4-11 liters per day. Daily intravenous PPI was started with decrease of gastric losses and normalization of HCO3-. This patient presented again to the hospital one month later with normal HCO3- on PPI therapy. Both patients’ bicarbonate and gastric fluid output trend relative to PPI therapy is detailed in figure 1.

Discussion:
There are few reported cases of PPI therapy for metabolic alkalosis due to gastric losses. Generally, met alk that occurs due to gastric losses is readily rectified by increased renal bicarbonate excretion, but this compensatory mechanism is limited in the setting of AKI. We report two cases in which PPI therapy successfully decreased the quantity of gastric fluid losses and rapidly improved metabolic alkalosis.

PO1184

A Case of Extreme Metabolic Alkalosis

Introduction:
Metabolic alkalosis results from an increase in serum bicarbonate concentration due to loss of hydrogen ions and/or gain in bicarbonate ions. We present a case of extreme metabolic alkalosis due to multiple etiologies rarely co-existing.

Case Description:
A 30-year-old male with Duchenne muscular dystrophy, chronic respiratory failure on mechanical ventilation with tracheostomy, gastrojejunostomy (G-J) tube dependent and genetic cardiomyopathy presented with drowsiness and lethargy for last 2 days per mother. His tube feed regimen was Nutren 1 can with 120 cc free water 4 times/day. He was recently started on Lasix 20 mg daily. Initial labs showed blood pH of 7.81, bicarb 66 and PC02 53. He had AKI with Creatinine (Cr) of 2.66, BUN 266 and Cystatin C 11. His baseline Cr was 0.9-1.1. UA showed 3+ protein and no sediment. Urine (Ur) sodium 87, Ur chloride <15, Ur Cr <10 and Ur Ph was 9. Chest Xray showed cardiomagically with mild venous congestion and kidney ultrasound showed bilateral small echogenic kidneys. He was treated with normal saline (NS) IV @100 ccr/h, acetazolamide IV, potassium IV, proton pump inhibitor to decrease gastric acid and minute ventilation was increased to allow for compensatory hypercapnia. AKI improved with adequate diuresis and PH normalized (Image 1) by day 5. He had hypernatremia after 24 hours of IV NS and fluid were changed to hypotonic + free water via G-J tube. High daily output of ~700cc was recorded from the G-J tube. He was discharged home without diuretics and tube feeds were changed to Suplena + increase free water but was re-admitted in 1 week with hyponatremia and severe metabolic alkalosis. He underwent G-J tube exchange during 2nd admission followed by persistent normalization of blood PH.

Discussion:
This is a unique case of extreme metabolic alkalosis primarily due to the loss of gastric acid in the G-J tube, but volume depletion, hypokalemia, AKI, high protein tube feeds, lack of respiratory compensation due to ventilator dependence and loop diuretics contributed to the development and maintenance of metabolic alkalosis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
We corrected his metabolic alkalosis and AKI with cautious use of IV fluids and Acetazolamide without needing dialysis, although metabolic alkalosis relapsed until the G1 tube was changed.

Hypercalemia and Metabolic Alkalosis Induced by the Novel Potassium Binder Patiromer: Report of Rare Event

Kathryn J. Suchow, Swetha Rani Kandula, Juan Carlos Q. Velez. Ochsner Medical Center - New Orleans, New Orleans, LA

**Introduction:** Patiromer is a calcium (Ca)-potassium (K) exchange resin approved for treatment of hyperkalemia. Disorders of Ca or acid base balance were not reported in pre-approval clinical trials. Post-marketing, only 2 case reports of hypercalemia associated with the use of patiromer have been recently published. We present a case of a patient with chronic kidney disease (CKD) with an unusual picture of hypercalemia, metabolic alkalosis and hyperkalemia upon intensification of patiromer dosing.

**Case Description:** A 56-year-old white man with CKD stage 4 (baseline creatinine 2.8 mg/dL) due to type 1 diabetes mellitus, proteinuria (1.5 g/g) and persistently high serum potassium (sK, 5.5 – 5.9 mEq/L) attributed to type 4 renal tubular acidosis was evaluated in clinic. Due to high risk of CKD progression, patiromer 14.4 g qd was prescribed to enable RAS blockade. Five months later, sK remained elevated at 5.0 mEq/L. Patiromer dosage was thus increased to 16.8 g. Three months later, sK fell to 4.1 mEq/L. Hence, patiromer was maintained at 16.8 g and ibesartan initiated. At that time, corrected serum calcium (sCa) was 9.3 mg/dl and serum bicarbonate (sHCO3) was 26 mEq/L. Five months later, routine laboratory tests revealed a sK 2.5 mEq/L, sCa 12.6 mg/dL and sHCO3 34 mEq/L. The patient denied recreational or over-the-counter drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, drugs, diuretics or calcium supplements. Patiromer was discontinued.

**Discussion:** Patiromer promotes gastrointestinal elimination of potassium by binding the molecule to potassium in exchange for calcium. Increased in intestinal absorption of calcium results in hypercalciuria but not sustained hypercalcemia. The clinical course of our patient suggests that the increased dose of patiromer led to a reduction in iCa (↓iCa) by adjusting iCa for Alb and the anion gap’s 3 components, Na, Cl, and CO2. It was likely better than sCa in detecting low iCa (↓iCa) on internal validation (Yap, JALM 2020).

**Background:** The popular adjustment of serum total calcium (sCa) for albumin (Alb) yields a corrected value (cCa) that doesn’t detect abnormal ionized calcium (iCa) well in critical care patients (pts), possibly because it ignores the fraction of iCa complexed by small anions. To account for such anions, we derived a model that estimates iCa (Ci_A2, sCa) by adjusting iCa for Alb and the anion gap’s 3 components, Na, Cl, and CO2. It was likely better than sCa in detecting low iCa (↓iCa) on internal validation (Yap, JALM 2020).

**Methods:** From the MIMIC III v1.4 database, we paired chemistry panel iCa (mg/dL), Alb (g/dL), Na, Cl, and iCa values with gap panel iCa values (ref range: 1.21-1.32 mM) measured up to 20 min. apart. Limiting each pt. to the most closely-timed pair left 4105 pairs (median 10 min apart). We calculated cCa (sCa .012×Alb) and ICaEST (.091×sCa −.034×Alb −.0042×Na −.0073×Cl +.0047×sCO2) and compared their ROC curves (area/SE) for detecting ↓iCa (iCa<1.10; rate=33.1%), and high iCa (↑iCa) (sCa>1.12; rate=5.8%).

**Results:** ICaEST was better than cCa by ROC analysis for both ↓iCa (0.334±0.007 vs 0.752±0.008, p<10^-6) and ↑iCa (0.975±0.004 vs 0.963±0.006, p<.0006). The table compares the sensitivity and specificity (SENS/SPEC) and positive and negative predictive values (PPV/NPV) of ICaEST and iCa at similar cutoffs. ICaEST overestimated iCa by 0.04 mEq/L (1.17±0.002 vs 1.137±0.002, p<10^-6), a bias that was fairly consistent across the full prediction range.

**Conclusions:** The ICaEST model is superior to cCa in ranking critically ill pts for both ↓iCa and ↑iCa. It can help clinicians decide when to directly measure iCa. ICaEST overestimated iCa but applying a local correction of -0.04 would make its absolute predictions accurate, on average, in the ICU setting.

**PO1186**

Beads of Calcium

Nityasree Srilalluri, Karla G. Carias Martinez, Elizabeth Kienman, Jose M. Monroy-Trujillo. Johns Hopkins Nephrology Johns Hopkins Medicine, Baltimore, MD.

**Introduction:** Hypercalemia is a common disorder that can cause acute kidney injury (AKI) and result in significant morbidity and mortality.

**Case Description:** A 50-year-old male with diabetes and hypertension presented with left knee septic arthritis. He had an AKI from volume depletion and vancomycin toxicity (trough level 35.1). Incision and drainage (I&D) was done on day 13 for refractory knee infection. Postoperatively, serum creatinine (Cr) and Calcium (Ca) rose to peak Cr of 2.8 mg/dL and Ca 2.8 mg/dL due to type 1 diabetes mellitus, proteinuria (1.5 g/g) and persistently high serum calcium (sCa) was 9.3 mg/dl and serum bicarbonate (sHCO3) was 26 mEq/L. Five months later, routine laboratory tests revealed a sK 2.5 mEq/L, sCa 12.6 mg/dL and sHCO3 34 mEq/L. The patient denied recreational or over-the-counter drugs, diuretics or calcium supplements. Patiromer was discontinued. Thorough investigation (PTH, PTH-related peptide, 1,25-OH-vitamin D, 25-OH-vitamin D, TSH, drugs, diuretics or calcium supplements. Patiromer was discontinued.

**Discussion:** Patiromer promotes gastrointestinal elimination of potassium by binding the molecule to potassium in exchange for calcium. Increased in intestinal absorption of calcium results in hypercalciuria but not sustained hypercalcemia. The clinical course of our patient suggests that the increased dose of patiromer led to a reduction in iCa (↓iCa) by adjusting iCa for Alb and the anion gap’s 3 components, Na, Cl, and CO2. It was likely better than sCa in detecting low iCa (↓iCa) on internal validation (Yap, JALM 2020).

**Background:** The popular adjustment of serum total calcium (sCa) for albumin (Alb) yields a corrected value (cCa) that doesn’t detect abnormal ionized calcium (iCa) well in critical care patients (pts), possibly because it ignores the fraction of iCa complexed by small anions. **Conclusions:** The ICaEST model is superior to cCa in ranking critically ill pts for both ↓iCa and ↑iCa. It can help clinicians decide when to directly measure iCa. ICaEST overestimated iCa but applying a local correction of -0.04 would make its absolute predictions accurate, on average, in the ICU setting.
Hypercalcemia in a Patient with Visceral Leishmaniasis (VL) and Mineral Homeostasis and Acid-Base Disorders: Clinical PO1189

Lubin, Juarez1, Jacob M. Winograd, Jie Tang2,1 Lifespan Health System, Providence, RI; 2Brown University Warren Alpert Medical School, Providence, RI.

Introduction: Hypercalcemia is a relatively common clinical problem with a wide range of etiologies. We report an unusual case of hypercalcemia due to visceral leishmaniasis triggering immune reconstitution inflammatory syndrome in a patient with AIDS.

Case Description: A 45-year-old male with history of previously treated VL complicated by a relapse now on suppressive amphotericin presented with 2 weeks of poor appetite, weight loss, and malaise. Recent history was notable for AIDS restarted on Triumeq in the preceding 2 months with slow recovery of CD4 count to 18 but robust reduction in HIV viral load. He denied other infectious symptoms. Labs were notable for AKI, calcium of 13.1, and pancytopenia. Work up revealed low PTH, low calcidiol, elevated calcium levels and high-normal calcitriol levels with bone marrow biopsy revealing non-necrotizing granulomas. Remainder of infectious work up including mycobacterium, histoplasma, and fungal cultures all remained negative. Of note, CD4 count rebounded to 354 during his month-long stay. He was ultimately diagnosed with IRIS secondary to VL leading to granulomatous hypercalcemia. Initial therapy consisted of fluids which resolved AKI and improved calcium. However, he proved to be fluid dependent as attempts at weaning would result in rise in calcium and creatinine. Definitive therapy consisted of steroids which resolved his hypercalcemia allowing him to come off fluids. Appetite improved and fatigue resolved over course of his stay with stabilization of calcium levels and creatinine returning to baseline. He was continued on suppressive Amphotericin B for VL.

Discussion: Granuloma formation is a known effect of leishmania infection to combat the invading parasites. Presumably, such inflammation could lead to hypercalcemia via increased conversion of calcidol to calcitriol. To our knowledge, this is the first case of hypercalcemia caused by VL in humans. It was likely triggered by the reconstitution of his immune system given recent re-initiation of anti-retroviral therapy and rebound of CD4 cell count. Initial management consisted of fluids and bisphosphonates with definitive management consisting of steroids and amphotericin. We report this novel case of hypercalcemia in hopes of expanding the literature on the various potential manifestations of VL, particularly in the setting of IRIS and AIDS.

PO1190

Systemic Sarcoidosis Presenting with Hypercalcemia

Introduction: Sarcoidosis is an idiopathic autoimmune illness that typically presents with pulmonary involvement but can affect virtually any organ. This often makes it challenging to diagnose as its manifestations can be quite varied. We report an interesting case of systemic sarcoidosis presenting with hypercalcemia of unclear mechanism.

Case Description: A 53-year-old Caucasian male presented to the clinic with polyuria, forgetfulness and weight loss. Medical history included hypercalcemia with recurrent nephrolithiasis, diabetes and positive ANA (titer 1:160) without any prior history of constitutional, respiratory or joint symptoms. Serum calcium returned 13 mg/dL. The patient also had an AKI and an elevated ALP. Furtherworkup revealed a suppressed PTH, normal 25-OH and 1,25-OH vitamin D, but a borderline elevated PTHp (2.5 pmol/L [0-2.3 pmol/L]). This prompted a CT CAP with contrast to rule out malignancy that instead showed mediatinal lymphadenopathy, heterogeneous liver enhancement suggestive of cirrhosis and an enlarged, nodular spleen. Transbronchial lymph node biopsies were normal and an extensive infectious and malignancy workup remained negative. The patient was given fluids followed by zoledronate with resolution of hypercalcemia and AKI. A liver biopsy was ultimately pursued which showed non-caseating granulomas. The patient was prescribed steroids with improvement in symptoms and normalization of ALP.

Discussion: In patients with sarcoidosis, the development of hypercalcemia is thought to be mediated via aberrant activation of vitamin D leading to calcitriol excess. Our patient’s calcitriol level was normal and hypercalcemia may also occur in the absence of elevated levels. Possible described mechanisms include “inadequate normal” calcitriol concentration without elevation in systemic levels, elevated PTHp and direct action of pro-inflammatory cytokines causing osteolysis.

PO1191

Disseminated Histoplasmosis Presenting as Severe Hypercalcemia

Sushma Medikayala, Carla S. Mcwilliams, Shane A. Bobart, Silvia T. Bunting, Dianne T. Sandy, Mauro Braun, Surafel K. Gebreselasie. Cleveland Clinic Florida, Weston, FL.

Introduction: Hypercalcemia (HC) is a significant complication of Disseminated Histoplasmosis (DH). While there are case reports on DH causing HC in immunosuppressed patients including HIV and chemotherapy, there are very rare case reports on DH causing HC in Non-immunosuppressed hosts. The diagnosis of DH may be delayed due to other differential diagnoses such a Sarcoidosis leading to prolonged and worsening hypercalcemia and subsequent renal failure. We report a case of HC in a patient who presented with generalized skin ulcers and bilateral adrenal masses. The initial manifestation of DH with HC, painful skin ulcers, bilateral large lobulated adrenal masses, prompted an initial concern for sarcoidosis. After presenting to our institution 5 months later, a diagnosis of DH was made as the cause of his Hypercalcemia.

Case Description: A 58-year-old male with new onset generalized skin rash was diagnosed with HC, empirically treated with prednisone for sarcoidosis due to elevated 1,25 di hydroxy Vitamin D, 5 months ago at an outside hospital. After starting prednisone, his skin lesions progressed to disseminated painful ulcers and was referred to our institution after developing AKI with a serum creatinine of 4.6mg/dl (Cr 1.6mg/dl, 5 months ago) calcium 14mg/dl, PTH 2pg/ml CT abdomen revealed large lobulated bilateral adrenal masses. Bone marrow biopsy revealed non-necrotizing granulomas with yeast form fungal organisms on GMS stain. A Shave skin biopsy of an abdominal ulcer revealed Fungal yeast forms consistent with histoplasmosis, associated with ulcers on GMS stain. Urine Histoplasma antigen positive. Adrenal mass biopsy revealed necrotic material and fibroconnective tissue. DH was initially treated with IV liposomal amphotericin and transitioned to oral Itraconazole. At the time of discharge, calcium was 9.8 mg/dl and serum creatinine was 2.9mg/dl.

Discussion: Hypercalcemia, in the setting of elevated 1,25 di hydroxy Vitamin D levels, prompts concern for granulomatous disease. Sarcoidosis is a common etiology, however, other causes must be entertained. The cluster of findings of adrenal non-caseating granulomas coupled with diffuse skin ulcers with hypercalcemia should prompt the provider to consider infectious etiologies such as disseminated histoplasmosis as early diagnosis and prompt treatment can result in improved outcomes.
PO1193

Resistant Hypophosphatemia with Vitamin D Deficiency
Yasmin N. Mahmoud,1 Akbar H. Hamid,2 Ammar N. Mohamed,2 Mary C. Mallappallil,1,2 Man S. Oh,1,2 Moro O. Salifu,1,2 SUNY Downstate Health Sciences University Department of Medicine, New York, NY; 3Kings County Hospital Center, Brooklyn, NY.

Introduction: The renal regulation of phosphate homeostasis is mediated mainly by reabsorption of P by NaPi-IIc in the proximal tubule, whereas intestinal absorption is mediated by NaPi-IIb. Normally, about 2/3 of dietary intake (1500 mg/day) is absorbed, but when given by mouth as Na or K phosphate, absorption is nearly 100% in a normal person. We report here a patient with severe hypophosphatemia due to phosphate malabsorption caused by prior gastric bypass surgery along with vitamin D deficiency.

Case Description: A 34 year old African American female with past medical history of benign carcinoid syndrome, pernicious anemia, Hashimoto thyroiditis, and gastric sleeve surgery causing rapid emptying of the gastric content, simulating the dumping syndrome, resulting in diarrhea by unabsorbed Na and K phosphate. Further impairment in intestinal P absorption may have been caused by vitamin D deficiency due to the inadequate dosing (800 units daily) and the inappropriate vitamin D type (Vitamin D2 instead of D3).

PO1194

Severe Hypophosphatemia Induced by Oncogenic Osteomalacia
Abdullah Jalal, Ryan P. Brown. Overlook Medical Center, Summit, NJ.

Introduction: Oncogenic Osteomalacia (Oncom) is an uncommon paraneoplastic syndrome characterized by FGF-23 overexpression from benign mesenchymal tumors causing severe hypophosphatemia. Very few cases of Onc with concomitant paraneoplastic syndromes have been described. Herein we present a rare case of carbofuran-associated hypophosphatemia in the setting of SiADH-induced chronic hyponatremia unmasking an even rarer secondary paraneoplastic syndrome; oncogenic osteomalacia.

Case Description: A 52 year old male with past medical history of chronic hyponatremia on salt tablets secondary to recently diagnosed metastatic small cell lung cancer was admitted for initiation of chemotherapy with carbofuran/etopside. Two days after completing cycle 1 the patient developed acute hypophosphatemia; serum Na decreased from 141 to 129 mEq/L. Serum electrolytes were (mEq/L): K 3.9, Cl 94, HCO3 28, BUN 30, Cr 0.47. Coriisol (17.8 ug/dl) and TSH (2.28 uIU/ml) were within normal limits. Urine studies noted (mEq/L): Na 75, Cl 69, K 43.5, elevated osmolality 860 mOsm/kg. Etiology of acute hyponatremia was attributed to platinum chemotherapy in the setting of SCC-associated SiADH and patient was treated with tolvaptan after several days of non-response to fluid restriction and urea. Patient’s hypophosphatemia subsequently corrected but was incidentally noted to have severe hypophosphatemia (<1 mEq/L) refractory to IV and PO phosphate repletion. ALP was elevated 279 U/L, corrected Ca 10 mEq/L, low 25(OH) vitamin D 23.8 ng/ml, normal PTH 45.6 ng/ml and PTHrP <0.4 pmol/L. Urinary fractional excretion of phosphorus was increased at 24%. An FGF-23 level obtained 12 days after completing cycle 1 of carbofuran-etopside was considerably elevated at 219 pg/ml. Thus, the patient was diagnosed with oncogenic osteomalacia.

Discussion: This case highlights a unique and diagnostically challenging patient presentation of severe hypophosphatemia in the setting of dual paraneoplastic syndromes. Onc should be considered in the differential for severe refractory hypophosphatemia. This occurs via FGF-23 mediated downregulation of PCT Na-Pi transporters and 1a-hydroxylase causing renal phosphate wasting and reduced 1,25-hydroxyvitamin D levels. Over time chronic hypophosphatemia impairs bone mineralization causing osteomalacia. Measurement of the fractional excretion of phosphorus is critical and FGF-23 levels should be obtained to confirm diagnosis.

PO1195

Phenotypes of Patients with Abnormal Phosphate on Admission by Consensus Clustering and Associated Mortality Risks
Carissa Y. Dumanescu,1 Charat Thongprayoon,2 Andrea G. Kattah,1 Michael A. Mao,3 Stephen B. Erickson,4 John J. Dillon,5 Vestia D. Garovic,6 Wiwat Wisitcoutporasert.1,4 Mayo Clinic Minnesota, Rochester, MN; 2Mayo Clinic; 3ISDH; 4SUNY Downstate Medical Center; 5Yale University; 6Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Background: Hospitalized patients with abnormal phosphate are heterogeneous and clustering approaches may identify specific homogeneous groups. This study aimed to cluster patients with abnormal phosphate on admission using unsupervised machine learning approach and to evaluate the mortality risk among these distinct clusters.

Methods: Consensus cluster analysis was performed on hospitalized adult patients with abnormal phosphate on admission, based on clinical and laboratory data. We determined each cluster’s key features using the standardized mean difference. We assessed the association of the clusters with hospital and one-year mortality.

Results: Cluster 2 patients with hypophosphatemia had older age, higher comorbidity burden, hypertension, diabetes, coronary artery disease, lower eGFR, and more acute kidney injury (AKI) (Fig 1a). Cluster 2 patients with hyperphosphatemia had older age, more admission for kidney disease, hypertension, end-stage kidney disease, AKI, and higher admission K, Mg 2+, or PO levels (Fig 1b). Both cohorts in cluster 2 had higher one-year mortality while hyperphosphatemic cluster 2 patients had higher hospital mortality (Fig 2).

Conclusions: The cluster analysis identified clinically distinct phenotypes with differing mortality risk in hospitalized patients with abnormal phosphate on admission. The age, comorbidities, and kidney function were key features.
Annatto Leaf Tea Intoxication: An Unusual Cause of Green Urine

Introduction: The roots and leaves of the annatto (“urucu”) tree (*Bixa Orellana*) are used by the lay population in the treatment of many diseases. We describe a case of AKI with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and greenish urine (Figure). He received fluid resuscitation and underwent two sessions of hemodialysis. He reported having ingested annatto leaf tea to treat his diarrhea. Blood and urine cultures were negative and there was no history of drug use. He was discharged from the hospital without needing hemodialysis. He was diagnosed with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and the diuretic effect of the tea.

Discussion: The diuretic effect of annatto leaf extracts has been shown in experimental models. To our knowledge, this is the first report of severe AKI and F+E imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and greenish urine (Figure). He received fluid resuscitation and underwent two sessions of hemodialysis. He reported having ingested annatto leaf tea to treat his diarrhea. Blood and urine cultures were negative and there was no history of drug use. He was discharged from the hospital without needing hemodialysis. He was diagnosed with severe fluid and electrolyte (F+E) imbalance due to annatto leaf tea use. In our patient, AKI was aggravated by the diarrhea and the diuretic effect of the tea.

Development of AL01211, a Novel Glucosylceramidase Synthase Inhibitor, to Treat Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Michael C. Babcock,1 Jianhong Zheng,2 Li Li,1 Changlin Mei,2 Marvin R. Garovoy,1 Yuqiao Shen,1 AceLink Therapeutics, Newark, CA; 1Shanghai Changzheng Hospital, Shanghai, China.

Background: ADPKD is a common genetic disease affecting ~1:1000 individuals and is characterized by progressive renal cysts growth, kidney enlargement and renal dysfunction. Glycosphingolipids (GSL) are elevated in the kidneys of ADPKD animal models and ADPKD patients where they promote renal epithelial cell growth and kidney inflammation. Glucosylceramide synthase inhibitors (GCSIs) reduce GSL production, slow cyst growth, and preserve kidney function in multiple animal models. Clinical development of other GCSIs have shown that this enzyme can be safely targeted therapeutically. We are developing AL01211, a potent and selective GCSI with excellent drug-like properties, for the treatment of ADPKD.

Methods: The IC50 of AL01211 against GCS was determined in cells and cell-free activity assays. PK, PD, tissue distribution and clearance studies were conducted in mice, rats and dogs. AL01211’s pharmacological profile was characterized in vitro including off-target selectivity panels, plasma protein binding, transporter assays, cyp inhibition and induction, and other assays. Disease model efficacy studies were conducted in several murine models including pkd1 eKO and jck models.

Results: AL01211 binds the active site of GCS and has an IC50 toward GCS of ~7 nM with limited off-target activity. PK studies support once daily, oral administration. AL01211 has low renal clearance in rats. AL01211 readily distributes to peripheral tissues (such as kidney) but does not cross blood-brain-barrier. Thus, it efficiently reduces GSL production in mouse, rat and dog kidney (reduced by >85% of control levels) with minimal effects in brain GSL. Importantly, AL01211 reduces cyst growth and kidney weight and preserves kidney functions in murine models.

Conclusions: Relative to other GCSI’s in development, AL01211 is more potent with single digit nanomolar potency, has greater reduction of GSL (>85%), is not subject to kidney clearance, and does not enter the brain. Phase I clinical trials, consisting of Phase IA (single ascending dose study in healthy volunteers), Phase IB (14-day multiple dose study in healthy volunteers) and Phase IC (28-day biomarker study in ADPKD patients) are underway.

Keynote: KidneyNetwork Uses Kidney-Derived Gene Expression Data to Predict and Prioritize Novel Genes Involved in Kidney Disease
Laura R. Claus,1 Floranne Boulougne,2 Henry Wiersma,3 Roy Oelen,2 Floor Schukking,5 Niek de Klein,1 Shuang Li,2 Harm-Jan Westra,2 Bert Van der zwaag,1 Dana Sierks,1 Ria Schönauer,1 Jan Halbritter,1 Nine V. Knoers,1 Patrick Deelen,1,3 Lude Franke,2 Alberts M. van Eerde,1 1Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands; 2Department of Genetics, University Medical Center Groningen, Groningen, Netherlands; 3Genomics Coordination Center, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 4Medical Department III - Endocrinology, Nephrology, Rheumatology Department of Internal Medicine, Division of Nephrology, University of Hospital Leipzig Medical Center, Leipzig, Germany.

Background: Genetic testing in patients with suspected hereditary kidney disease does not always reveal the genetic cause for the patient’s disorder. Pathogenic variants can reside in genes that are not yet known to be involved in kidney disease. To help identify candidate genes for kidney disease we have developed KidneyNetwork, in which tissue-specific expression is utilized to predict kidney-specific gene functions.

Methods: KidneyNetwork is a co-expression network built upon 878 kidney RNA-sequencing samples and a multi-tissue dataset of 31,499 samples. It uses expression patterns to predict which genes have kidney-related functions and which phenotypes might result from variants in these genes. As proof of principle, we applied KidneyNetwork to prioritize rare variants in exome-sequencing data from 13 kidney disease patients.

Results: We assessed the prediction performance of KidneyNetwork by comparing it to GeneNetwork, our previously developed multi-tissue co-expression network. In KidneyNetwork, we observe significantly improved prediction accuracy of kidney-related HPO-terms and an increase in the total number of significantly predicted kidney-related HPO-terms (figure 1). Applying KidneyNetwork to exome-sequencing data allowed us to identify ALG6 as candidate gene for kidney and liver cysts.

Conclusions: KidneyNetwork is a kidney-specific co-expression network that predicts which genes have kidney-specific functions that can result in kidney disease. Gene-phenotype associations of genes unknown for kidney-related phenotypes can be predicted. We show its added value by applying it to kidney disease patients without a molecular diagnosis. KidneyNetwork can be applied to clinically unsolved cases, but it can also be used by researchers to better understand kidney physiology and pathophysiology.

PO1201

Modeling Gene-Targeted Strategies for Therapeutic Correction of PKD1 Loss-of-Function Mice
Marie Trudel, Almira Kurbegovic, Kevin Loayza-Vega, Rey Christian Pacis, Camila Parrot. Institut de recherches cliniques de Montreal, Montreal, QC, Canada.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and is characterized by progressive growth of fluid-filled cysts in the kidneys. Growth factor binding to receptor tyrosine kinases (RTKs) are known to stimulate cell proliferation and cyst growth in PKD. In the current study we tested the effect of Nintedanib, an RTK inhibitor and FDA approved drug for non-small cell lung carcinoma and idiopathic lung fibrosis, in mouse models of ADPKD. Nintedanib is a triple RTK inhibitor which targets vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR).

Methods: The effect of Nintedanib on renal cyst growth and fibrosis was tested in two orthologous models of ADPKD, the Pkd1+/Pkd1+/ mouse, and Pkd1f/f mouse. Nintedanib treatment (20 mg/Kg on alternate days by intraperitoneal injections) was from postnatal day P10 to P18 in Pkd1+/Pkd1+/ mice and in for 8 weeks starting at the age of 3 months in Pkd1f/f mice. In vitro studies were performed using primary culture human ADPKD renal cyst epithelial cells and renal myofibroblasts.

Results: Nintedanib treatment significantly reduced kidney-to-body weight ratio, cyst renal index, cystic epithelial cell proliferation and blood urea nitrogen levels compared to vehicle treated Pkd1+/Pkd1+ and Pkd1f/f mice. Western blot data indicates reduction in the phosphorylation of ERK1/2, AKT, STAT3 and mTOR activation and pro-fibrotic factors, including Yes associated protein (YAP), c-Myc and Cyclin D1 protein levels. Moreover, nintedanib treatment significantly reduced renal fibrosis in Pkd1f/f mice, however, fibrosis in Pkd1+/Pkd1+ mice remained unaffected. In vitro data suggests that nintedanib significantly reduced proliferation and cyst size of human ADPKD cystic epithelial cells as well as cell viability and migration of human ADPKD renal myofibroblasts.

Conclusions: The results suggest that Nintedanib is effective in reducing cyst growth and may be repurposed to treat ADPKD.

Funding: NIDDK Support
collecting tubular origin and survived until P12-15. While Srebp reached Pkd1 therapeutic levels in the mild Srebp1c/-/-, the additional Tg copies suggest the presence of regulatory region within Pkd1 gene-body. Renal cysts in Srebp1c/-/+-Srebp1c/-/+ and Srebp1c/-/+ detected by RNAscope and IF, arise likely from insufficient and chimeric Pkd1 re-expression. These analyses also shed light on Pkd1 spatio-temporal expression patterns with highest expression in collecting tubules during renal maturation that shifts to distal tubules following maturation.

Conclusions: Pkd1 is regulated by elements both upstream for spatio-temporal pattern and intragenic sequences for expression levels. The renal-specific Srebp minimal regulatory region is sufficient for therapeutic correction in one copy Tg. Our study demonstrates that Pcl re-expression can substantially delay cystogenesis and markedly extend lifespan.

PO1202
Wheat-Gluten Diet Attenuates Ccl2-Mediated Immune Response and Slows Polycystic Kidney Disease

Jifeng Huang, Shinobu Yamaguchi, Jung-Shan Hsu, Takamitsu Saigusa. Department of Medicine, Division of Nephrology The University of Alabama at Birmingham, Birmingham, AL.

Background: Disease severity of autosomal-dominant polycystic kidney disease (ADPKD) is highly variable, even among families with the same gene mutation. A high protein diet is a well-recognized ADPKD progression-accelerating factor. Dietary protein composition is important, as pre-clinical studies have shown a soy protein-based diet slows kidney cyst formation in rodent PKD models. Recruitment of macrophages in the kidney are known to promote cystogenesis in PKD. We hypothesize that type of protein in the diet may serve as a potential environmental stimulant to immune response and cyst growth.

Methods: Using tamoxifen-inducible Pkd1-global knockout mice, we fed the mice with either a high casein-protein (animal-based protein: 60%), a low casein-protein (6%) or a regular wheat-gluten (plant-based protein: 60%) for a total of 1 week or 6 weeks. Some mice fed a high casein protein diet were treated with liposomal clodronate or saline for a total of 5 weeks. Mice were euthanized and kidney cyst area, number of macrophages and chemokine/cytokine levels were measured.

Results: Pkd1-knockout mice fed a high casein diet increased the number of kidney macrophages, expression of macrophage-recruiting chemokine Ccl2 (but not chemokines Csf1 or Ccl5), pro-inflammatory cytokine (Ilf6, Tnf-a) and accelerated cyst growth compared to counterparts fed an iso-caloric high wheat-gluten (WG) diet or a low casein diet. Cyst growth was significantly lower in very early stages during dietary casein load (1 week after diet modification), cyst expansion precedes macrophage recruitment in the kidney, indicating that diet per se triggers early cyst growth rather than as a consequence of macrophage recruitment and inflammation. High casein diet fed Pkd1-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine, and fewer cysts.

Conclusions: Wheat-gluten diet fed Pkd1-knockout mice resulted in decreased the number of macrophages, suppressed levels of kidney Ccl2, but not Csf1 or Ccl5, and slowed cyst growth compared to counterparts fed an iso-caloric casein based diet. Dietary protein modification may suppress immune response and cyst growth in PKD.

High Prevalence of Kidney Cysts in Hereditary Hypophosphatemic Rickets with Hypercalciuria

Christian Hanna,1 Jennifer Arroyo,1 Peter Tebben,1 Vicente E. Torres,1 Peter C. Harris,1 David S. Goldfarb,2 David J. Sas,1 Dawn S. Milliner,2 John C. Lieske,1 Fouad T. Chebibi,2 Theodora A. Potretzke.1 Mayo Clinic Minnesota, Rochester, MN; 2NYU Langone Health, New York, NY.

Background: Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH) is a rare monogenic disorder caused by SLC34A3 mutations. Patients present with infantile rickets with hypercalciuria and secondary hyperparathyroidism, which can evolve into hereditary hypophosphatemic rickets with hypercalciuria (HRH). HHRH is caused by biallelic and HRH by monoallelic mutations. Despite the large differences in disease expression, there is no clear consensus on the best treatment for HHRH. We characterized cystic kidney disease (CKD) in HHRH to help determine if a similar cystic kidney disease pattern also exists in HHRH.

Methods: Medical records from Mayo Clinic and Rare Kidney Stone Consortium (RKSC) were queried for all patients with genetically confirmed HHRH diagnosis. Underline represents presenting author.

Results: Among 12 patients with SLC34A3 pathogenic variants (7 monoallelic, 5 biallelic), 42% (5/12) were males. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). None had a family history of kidney cysts. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). At least 2 cysts ≥ 5 mm in size were found in 100% of children. At least 2 cysts ≥ 5 mm in size were found in 100% of children. 5 biallelic), 42% (5/12) were males. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). None had a family history of kidney cysts. Median age at clinical presentation was 17 yrs (range 8-46) and at genetic confirmation 42 yrs (range 9-66). At least 2 cysts ≥ 5 mm in size were found in 100% of children. At least 2 cysts ≥ 5 mm in size were found in 100% of children. Table 1.

Conclusions: Our data highlight tryptophan metabolism as a novel dysregulated pathway in vivo in mouse and human ADPKD and suggest that tryptophan metabolites are biomarkers of disease progression. Further, inhibition of the pathway presents a new therapeutic strategy for PKD.

PO1204
Dysregulated Tryptophan Metabolism Promotes Polycystic Kidney Disease Progression

Dustin Nguyen, Emily K. Kleczko, Nidhi Dwivedi, Berenice Y. Gitomer, Michel Chonchol, Raphael A. Nemenoff, Jelena Klawitter, Katharina Hopp. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Metabolic reprogramming is a feature and modifier of autosomal dominant polycystic kidney disease (ADPKD) progression. Moreover, immune cells regulate cyst growth. In cancer, a disease with parallels to PKD, the metabolic landscape created by tumors significantly impacts immune cell function and tumor growth. Yet, this link is unexplored in PKD. Here, we study tryptophan metabolism, a known immunosuppressive pathway, in cyst growth.

Methods: Metabolites were profiled in ADPKD patient plasma and kidneys of an orthologous ADPKD model (C57Bl/6 Pkd1(-/-)). We also crossed the ADPKD model to Ido1-/- mice, the enzyme metabolizing tryptophan to kynurenines, and inhibited IDO1 using the tryptophan analog 1-MT (400mg/kg, twice daily, orally). From these mice, kidney immune cells were profiled via flow cytometry.

Results: Tryptophan metabolites were significantly increased in Pkd1(-/-) mice at 3-, 6-, and 9-months compared to age- and gender-matched controls with disease progression. Plasma levels of kynurenines significantly associated with HtTKV at baseline, and positively correlated with annual percent change of HtTKV in adult ADPKD patients. IDO1 levels were significantly increased in kidneys of Pkd1 mice and patient cells lines. At 6-months age, Pkd1-/-; Ido1-/- mice had significantly milder PKD compared to Pkd1(-/-) mice as measured by % KW/BW and cystic/lobular index. Similarly, treatment of 1-month-old Pkd1(-/-) mice with 1-MT for 3 weeks slowed cyst growth; overall providing functional evidence of the pathway’s relevance to PKD. Kidney immune profiling of Pkd1(-/-); Ido1-/- and 1-MT-treated mice revealed a significant reduction of resident macrophages, regulatory T cells, and immune checkpoint protein expression (PD-1/CD4, 1), while the percentage of CD8+ T cells/total T cells increased.

Conclusions: Our data highlight tryptophan metabolism as a novel dysregulated pathway in vivo in mouse and human ADPKD and suggest that tryptophan metabolites are biomarkers of disease progression. Further, inhibition of the pathway presents a new treatment approach. IDO1 inhibitors are FDA approved for various cancers. Our data suggest a link between metabolic reprogramming, immune cell function, and disease progression, as IDO1 loss/inhibition impacted immune cell populations/pathways shown to regulate cyst growth.

PO1205

Creatine Kinase Elevation in Patients with Autosomal Dominant Polycystic Kidney Disease on Tolvaptan Treatment
Diana Rodriguez-Espinosa, Elena C. Payán, Elena Guillen, Josep miquel Blasco pellicano. Hospital Clinic de Barcelona, Barcelona, Spain.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease worldwide. Studies such as the TEMPO 3:4 and 4:4 have demonstrated tolvaptan’s (vasopressin V2 receptor antagonist) effectiveness in slowing the progression of this disease. The best described adverse effect seen with this treatment is drug-induced liver injury, however, creatine kinase (CK) elevation has also been described anecdotally in a couple of case reports.

Methods: This is a prospective observational study of adult patients with rapidly progressive ADPKD on tolvaptan treatment under follow-up at Hospital Clinic de Barcelona from October 2018 to March 2021. Quantitative variables are described as mean and standard deviation, while qualitative ones are reported as absolute and relative frequencies.

Results: A total of 37 patients started treatment with tolvaptan during this period. In 34 of them, serum CK levels were measured as part of the monthly biochemical follow-up. A total of 29.11% (10 of 34) of the patients elevate this parameter with a mean of 3519 ± 5016.36 U/L. In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was usually less related to exercise, although one patient performed a weekly intensity cycling exercise with increased myalgia afterward) and was not significantly correlated with LDH levels, liver enzymes, calcium, potassium, urinary or plasma osmolality.

Conclusions: By performing a general screening, we found that CK elevation is more frequent than previously described in the literature, reaching significantly increased levels or producing symptomatology requiring definitive treatment interruption. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment’s follow-up, at the beginning of treatment and when increasing its dosage as it may promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.

PO1206

Protein Kinase A Downregulation Delays the Development and Progression of Polycystic Kidney Disease
Xiaofang Wang,1 Li Jiang,1 Ka Thao,1 Caroline R. Sussman,1 Timothy P. Labranche,2 Michael R. Palmer,2 Peter C. Harris,3 Stanley Mcknight,3 Klaus P. Hoefluch,4 Stefanie S. Schalm,5 Vicente E. Torres.5 Mayo Clinic, Rochester, MN; Blueprint Medicines, Waban, MA; University of Washington, Seattle, WA.

Background: Upregulation of cAMP-dependent as well as -independent PKA signaling is thought to promote cystogenesis in polycystic kidney disease (PKD). We have shown that the PKA-I regulatory subunit RIα is increased in kidneys of orthologous mouse models and that kidney specific knockout of RIαR1 or inhibition compared to EPAC or PKA-II inhibition on ex vivo mIMCD3 cystogenesis and ex vivo cystogenesis. Genetic and of TricB in adult-onset kidney-specific Pkd2-inactivated mice ameliorates cystogenesis. Double deletion of TricB and Pkd2 in mice reveal synergistic genetic interactions. However, the ciliary proteins in this process are not well understood.

Methods: Upregulation of cAMP-dependent and PKA-I activation promoted, and inhibition prevented, cystogenesis using Pkd1 CK elevation despite dose reduction or temporary treatment interruption. However, treatment had to be interrupted in the remaining three patients (mean 3519 ± 5016.36 U/L). In one of them due to concomitant drug-induced liver injury and in the other two due to persistent CK elevation despite dose reduction or temporary treatment interruption. CK elevation was usually less related to exercise, although one patient performed a weekly intensity cycling exercise with increased myalgia afterward and was not significantly correlated with LDH levels, liver enzymes, calcium, potassium, urinary or plasma osmolality. Based on these results, although the studied sample is small, we suggest adding this parameter as a part of tolvaptan treatment’s follow-up, at the beginning of treatment and when increasing its dosage as it may promptly detect undesirable adverse effects and gain a better understanding of this phenomenon.

PO1207

Protein 4.1O Links Polycystin 1 to the Actin Cytoskeleton and Modulates Hippo Signaling
Theresa Vienken, Eva Koenigshausen, Lars C. Rump, Lorenz Sellin. Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.

Background: The majority of ADPKD patients have a PKD1 gene mutation. PKD1 codes for Polycystin-1 (PC-1). Cyst formation is caused by altered renal tubular cell proliferation. Protein 4.1 family members are actin adaptors, which link plasma membrane receptors to the actin cytoskeleton. Polypeptide of the FRMD3 family (FRMD3) is a candidate gene for diabetic nephropathy. Furthermore, protein 4.1O has properties of a tumor suppressor. This study investigates the molecular and cellular properties of protein 4.1O as a potential ADPKD modifier and therapeutic target.

Methods: PC-1 full-length and truncation mutants were transiently expressed. PC-1 interaction with protein 4.1O and its truncation mutants were investigated. Truncation mutants cover the N- and C-terminal domains of protein 4.1O (Band 4.1, FERM, actin-binding domain and coiled coil domain). Communoprecipitations of protein 4.1O with PC-1 in IMCD cell lysates were performed. Pulldown experiments with bacterial recombinant protein 4.1O and F-actin were performed. The modulation of the PC-1 signaling properties by protein 4.1O were investigated in luciferase assays for c-myc and TEAD. FRMD3 core promoter regions were cloned into luciferase reporter.

Results: Communoprecipitations show an interaction of protein 4.1O full-length with the C-terminus of PC-1 interacts with four isoforms of protein 4.1O (201, 202, 204, 207). The truncation mapping and isoform alignment identifies a potential leucine zipper domain in protein 4.1O as the C-terminal binding domain to PC-1. The N-terminal domain of protein 4.1O is also sufficient to mediate PC-1 interaction. Protein 4.1O C-terminus binds to F-actin and links the PC-1 C-terminus to the cytoskeleton. Protein 4.1O silences the PC-1 mediated transactivation of c-myc and hippo signaling (TEAD). Furthermore, F-actin destabilization influences the PC-1 induced hippo signaling. PC-1 activates the protein 4.1O pro-angiogenic activity.

Conclusions: Both, the FERM domain and leucine zipper containing coiled coil domain of protein 4.1O interact with the PC-1 C-terminus. The interaction of protein 4.1O links PC-1 to the actin cytoskeleton. The protein 4.1O interaction inhibits the PC-1 mediated activation of c-myc and hippo signaling. Furthermore, protein 4.1O provides a F-actin based sensitivity to the PC-1 mediated hippo signaling. In summary, protein 4.1O shows features of an anti-cystogenic protein.

PO1208

Polycystin 2 Mediates Endoplasmic Reticulum K+–Ca2+ Exchange to Protect Against Polycystic Kidney Disease
Biswajit Padhy, Jian Xie, Chou-Lang Huang. Huang Lab University of Iowa Carver College of Medicine, Iowa City, IA.

Background: Prevailing view is that PKD is a ciliopathy. Yet, PC2 is most abundantly expressed in ER. Early studies showed that PC2 is involved in agonist-induced ER Ca2+ release. Decrease in ER Ca2+ release in PC2-deficient cells is believed to contribute to AMP overproduction and cystogenesis. Recent patch-clamp experiments reveal that PC2 channel consists of 40X more selective to K+ than Ca2+, raising the question regarding how PC2 mediates ER Ca2+ release and role of ER-localized PC2 in PKD pathogenesis. To avoid potential polarization impeding ion fluxes, Ca2+ release from ER lumen to cytosol requires coupled counter cation exchange and/or parallel anion movement.

Methods: ER Ca2+ release is assayed by far2-fluorimetry stimulated by ATP. PC2-deficient morphant zebrafish and doxycycline-inducible adult-onset PC2-deficient mice are used for in vivo PKD model.

Results: (Table).

Conclusions: Our results provide compelling support for the notion that ER resident PC2 plays an important role in anti-cystogenesis of PKD. The mechanism of action is likely through mediating cystosol-to-ER lumen K+ flux to facilitate Ca2+ release via IP3R.

Interactions Between TUL13 and ARL13B in Lysinipid Protein Translocation to Cilia and Regulation of Renal Cystogenesis
Siakht Mukhopadhay, Vivek R. Palcharla, Sun-hee Huang. The University of Texas Southwestern Medical Center, Dallas, TX.

Background: Signaling outputs from cilia maintain renal tubular homeostasis preventing cystogenesis; however, the ciliary proteins in this process are not well understood. The tubby family protein–TUL13 coordinates with the intracellular transport machinery to regulate transport of proteins required for ciliary function and signaling. TUL13 and ARL13B regulate transport of PKD1 and PKD2 to cilia. However, the underlying mechanisms are poorly understood.

Results: We have previously characterized the interaction between TUL13 and ARL13B and have shown that TUL13 promotes transport of PKD1 and PKD2 to cilia. Furthermore, we have shown that ARL13B interacts with TUL13 and that this interaction is required for PKD1 and PKD2 transport to cilia. In this study, we have extended these findings by characterizing the interaction between TUL13 and PKD1 and PKD2 and by characterizing the interaction between TUL13 and RAB7 in cilia.
Results: The transmembrane cargoes have short motifs that are necessary and sufficient for TULP3-mediated cystogenesis. We now show that TULP3 is required for transport of the atypical GTPase ARL13B into cilia, and for cilary enrichment of ARL13B-dependent farnesylated and myristoylated proteins. ARL13B transport requires TULP3 binding to IFT-A core but not to phosphoinositides, unlike transmembrane cargo transport that requires binding to both by TULP3. A conserved lysine in TULP3 mediates binding to TULP3 and directs trafficking to cilia. Tulp3 trafficked lipidated ARL13B and directed transport that requires binding to both by TULP3. A conserved lysine in TULP3 mediates binding to TULP3 and directs trafficking to cilia. Tulp3 trafficked lipidated proteins are depleted with distinctive temporal kinetics from kidney epithelial cilia during Tulp3 deletion-induced cystogenesis.

Conclusions: We conclude that TULP3 transports transmembrane proteins and ARL13B into cilia by capture of short sequences through a shared tubby domain site. Drugging this interaction domain could provide therapeutics in polycystic kidney disease. The depletion of lipidated cargoes with distinct kinetics from kidney epithelial cilia following Tulp3 deletion suggests their differential roles in cilia in regulating renal cystogenesis.

Conclusions: Our experiments establish the direct link between TRPV4 function and directly reprogrammed mammalian cells (iRECs) we investigated transcriptional modules and identified novel direct and indirect targets of the transcription factor HNF1B, which are linked to signaling pathways associated with renal morphogenesis, cilia and organic anion transport.

Conclusions: In conclusion, the combined use of directly reprogrammed mammalian cells and Xenopus renal organoid experiments allow us to gain a unique perspective into evolutionary conserved mechanisms of renal development and HNF1B associated kidney disease.

Autophagy Inhibition Ameliorates Polycystic Kidney Disease

Daniel Atwood, Deepak Pokhrel, Nidhi Divedi, Katharina Hopp, Charles L. Edelstein. University of Colorado Denver School of Medicine, Aurora, CO.

Background: We found that there is a decrease in autophagy proteins in Pkd1<sup>RC/Rc</sup> mouse kidneys. Our study aimed to determine the mechanistic role of suppressed autophagy in causing cyst growth using pharmacological and genetic autophagy inhibition.

Methods: Male Pkd1<sup>RC/Rc</sup> (RC) mice were treated with 2-Deoxycholeosine (2DG) or Chloroquine (CHLQ) from 50-120d of age. Kidney specific Pkd1<sup>-/−</sup> Agt7 double knockout mice were generated by Kepl3-Cre-lox recombination. Relative densitometry units (RDU) were determined on immunoblot. Autophagic flux was measured by the change in LC3-II (autophagosomes) +/− Bafilomycin (Baf).

Results: Autophagic flux was present in wild type (WT) and 120 d old RC but suppressed in 150 d old RC kidneys. LC3-II (RDU) +/− Baf was 0.1 vs 0.7 in WT (p<0.01), 0.6 vs 1.0 in 120 d old (p<0.05) and 2.4 vs 2.1 (NS) in 150 d old RC. 2DG resulted in a decrease in ATG12-5 complex and suppressed autophagic flux in RC kidneys. LC3-II (RDU) +/− Baf was 0.5 vs 0.8 in VEH (p<0.05), 0.7 vs 0.7 in 2DG (NS). 2DG significantly reduced cyst growth and improved kidney function. Cystic index (%), count +/− 2DG: 7.7 vs 3.7 (p<0.01), 211 vs 161 (p<0.05). BUN (mg/dl) +/− 2DG: 3.5 vs 27 (p<0.01). Next, RC mice were treated with CHLQ, a specific autophagy inhibitor. CHLQ resulted in suppressed autophagic flux, less PKD and improved kidney function in RC mice. LC3-II (RDU) +/− Baf was 1.2 vs 1.2 (NS) in CHLQ treated kidneys. Cyst index (%), count +/− 2DG: 7.7 vs 3.7 (p<0.01), 211 vs 161 (p<0.05). BUN (mg/dl) +/− 2DG: 3.5 vs 27 (p<0.01). Next, autophagy was inhibited in PKD kidneys by generating double Pkd1<sup>-/−</sup> Agt7 KO mice. The 2 kidney BW (%WV) was improved in Pkd1<sup>-/−</sup> Agt7 KO vs single Pkd1<sup>-/−</sup> KO mice (32 vs 39 p<0.05). Agt7<sup>-/−</sup> kidneys had a massive increase in p62 indicating a build-up of autophagic cargo. p62 in WT vs Agt7<sup>-/−</sup> KO (RDU) 0.1 vs 1.8 p<0.001. Interestingly Agt7<sup>-/−</sup> KO kidneys were filled with tertiary lymphoid organs (TLO): large condensed infiltrates of T and B cells. pAMPK<sup>α2</sup> was increased in Agt7<sup>-/−</sup> KO kidneys. AMPK activation is known to reduce PKD.

Conclusions: Both 2DG and CHLQ suppressed autophagic flux in RC mice and resulted in less PKD and improved kidney function. Double Pkd1<sup>-/−</sup> Agt7 KO mice had significantly lower kidney weight than single Pkd1<sup>-/−</sup> KO mice. Both pharmacological and genetic autophagy inhibition resulted in less PKD.

ARL13B Negatively Regulates Kidney Cysts from Within Cilia

Robert Gigante,1,2 Tamara Caspary.1 Emory University, Atlanta, GA; 2Georgia Institute of Technology, Atlanta, GA

Background: Polycystic kidney disease (PKD) is intricately linked to the primary cilium. Polycystin proteins localize to cilia and loss of cilia leads to renal cysts. PKD mouse models often disrupt ciliary genes, removing both ciliary and cellular pools of these gene products; however, the molecular pathway(s) that drive cyst formation is unknown. ARL13B is a regulatory GTPase highly enriched in cilia due to a VxPx localization motif near its C terminus. ARL13B is also localized to extraciliary sites within the cell. We engineered mice in which we mutated the valine to alanine within ARL13B’s VxPx cilia-localization motif so the mice express cilia-excluded ARL13BV358A with the tethered agonist mechanism.

Methods: We used mouse inner medullary collecting duct (mIMCD3) cells with the T1G (TIG cells) or T2c (T2J cells) gene disrupted by CRISPR/CAS9 methodology. EVs were isolated from the cell culture media by size-exclusion column chromatography followed by detailed physical and chemical characterization. Physical characterization of EVs was achieved by tunable resistive pulse sensing and dynamic light scattering, electron microscopy, and western blot analyses.

Results: Physical characterization of EVs revealing similar average sizes and zeta potentials (at pH 7.4) for EVs from mIMCD3 (123.5 ± 5.7 nm and −16.3 ± 2.1 mV), TIG cells (131.5 ± 8.3 nm and −19.8 ± 2.7 mV), and T2J cells (127.3 ± 4.9 nm and −20.2 ± 2.1 mV). EVs derived from parental mIMCD3 cells and both mutated cell lines were heterogeneous (>90% of EVs < 150 nm) in nature. Immunoblotting detected chicken Hemoglobin signaling protein Arl13b; intercellular proteins TSG101 and Alix; and transmembrane proteins CD63, CD9, and CD81. Compared to T2J deletion, T1G deletion cells had reduced EV production and release rates. EVs from T1G mutant cells altered mTORC1, autophagy, and β-catenin pathways differently than EVs from T2c-mutated cells. Quantitative PCR analysis revealed the down regulation of miR-212a-3p and miR-99a-5p in EVs from T2c-mutated cells compared to EVs from T1G-mutant cells.

Conclusions: EV-derived miR-212-3p and miR-99a-5p axes may represent therapeutic targets or biomarkers for TSC disease.

ADPKD Mutations in the Stalk/Tethered Agonist of Polycystin-1 CTF Affect Signaling and GPS Cleavage

Robin L. Masen, Brenda S. Magenheimer, Ericka Nevarrez Munoz. University of Kansas Medical Center, Kansas City, KS.

Background: Like Adhesive G protein-coupled receptors (aGPCRs), the N-terminal ectodomain of polycystin-1 (PC1) contains a membrane-proximal GAIN domain that catalyzes self-cleavage at its embedded GPCR proteolysis site (GPS), dividing these proteins into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. PC1 GPS cleavage is required for JAK/STAT signaling, PC1 maturation/ trafficking and for prevention of renal cystogenesis in mice. ADPKD mutations that map within the GAIN domain inhibit GPS cleavage. We previously reported that the PC1 CTF utilizes an aGPCR-like tethered agonist mechanism to activate G-protein signaling to an NFAT reporter, which involves the short, N-terminal, extracellular stalk of the CTF serving as the tethered agonist. Deletion of the stalk dramatically inhibited signaling, while synthetic stalk-derived peptides could rescue signaling by the stalkless CTF and inhibit cystogenesis in metanephric organ cultures of hypomorphic Pkd1<sup>RC/Rc</sup> kidneys. Here we assess the effect of stalk-localized ADPKD missense mutations on signaling by the dissociated CTF subunit and on GPS cleavage of full-length (FL) PC1 to gain additional insight for this regulatory mechanism.

Methods: Wild type (WT) or mutant, FL or CTF forms of PC1 were expressed in HEK293T cells and compared for activation of an NFAT promoter-luciferase reporter, levels of total and cell surface expression and GPS cleavage. Homology modeling of the PC1 (A3) domain was also performed.

Results: Of 11 substitutions throughout the stalk, the 6 significantly reduced, 2 increased, and 3 had no effect on signaling by PC1 CTF. Total and surface expression levels of the CTF mutants ranged from 62-125% of WT CTF. Most mutations had no effect on GPS cleavage. We then constructed a mutant CTF that included inhibited signaling or GPS cleavage mapped to the N-terminal portion of the stalk, while the 2 mutations that increased signaling were in the latter half.

Conclusions: PC1 stalk has more than one region important in regulation of CTF signaling, perhaps as part of the agonistic sequence or for its proper orientation. This study underscores the importance of PC1 GPS cleavage and suggests disruption of a tethered agonist mechanism may also contribute to renal cystogenesis. Better understanding of the tethered agonist mechanism is necessary for development of PKD1 mutation-specific therapies.

Metabolic Analysis of Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Associations with Disease Progression and Treatment

Shrinir Sundar,1 Shrinir Roth,1 Sachin S. Hajarini,1 Lucas Westcott-Baker,1 Linda McCormick,1 Bharath Ramaswamy,1 Arlene B. Chapman,1 Otuka Pharmaceutical Development & Commercialization, Rockville, MD; 2University of Chicago, Chicago, IL.

Background: ADPKD is characterized by epithelial proliferation and cyst growth. Metabolic abnormalities have been identified in murine models, but little is known about alterations in metabolic pathways in human ADPKD. We evaluated plasma metabolomic profiles in ADPKD subjects prior to and after exposure to tolcapron (T) as compared to healthy controls to better understand metabolic alterations in ADPKD and potential associations with disease progression and treatment response.

Methods: Plasma samples were collected and analyzed at baseline and month 12 in 100 ADPKD subjects (50 in T and 50 in placebo [P] arms) enrolled in TEMPO 3:4 (NCT00428948). The protein fraction was removed, and the remaining extract split into equal parts for analysis on the same tandem mass spectrometry and gas chromatography mass spectrometry platforms. Proprietary software (Metabolon, Inc., Durham, NC) matched ions to an in-house library of standards for metabolite identification and quantitation. Forty age- and sex-matched healthy subjects were analyzed as a control group. Linear mixed effect modeling identified associations of metabolites with ADPKD vs control, height-adjusted total kidney volume (htTKV), Mayo Imaging Classification (MIC), and T vs P.

Results: Baseline metabolic profiles differed between ADPKD and controls, with significant differences in lipid metabolism, TCA cycle, and amino acid metabolism. Baseline MIC 1C, 1D, 1E (vs 1B) were associated with accumulation of the uremic toxin pseudouridine, elevated fatty acid synthesis, and altered tryptophan metabolism, with similar findings when baseline hTKV was analyzed. Thyroxine, urea, and dimethylsulfone were decreased in T vs P at month 12, as well as other metabolites involved in lipid and amino acid metabolism.

Conclusions: We identified novel associations of amino acid and lipid metabolic pathways with ADPKD vs control and with measures of disease severity (MIC and hTKV). These metabolic changes may be due to altered protein turnover, increased kidney-body weight ratio, and tandem mass spectrometry analysis of specific metabolic pathways. Further work is necessary to elucidate potential metabolic pathways involved in ADPKD progression and treatment response.

Short-Term Ketogenic Interventions Are Feasible and Effective in Cystic Kidney Disease (ADPKD): Results from the RESET-PKD Study

Robert Mueller,1 Mirian A. Boim,1 Luis F. Onuchic,2 Ida P. Heilberg,3 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2University of Sao Paulo School of Medicine, Sao Paulo, Brazil; 3University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by cyst formation deriving from collecting ducts. Pluripotent stem cells associated with the formation of renal structures have been used in vitro studies of nephrogenesis or cystogenesis related to ADPKD. However, the association between transcripts integrating pathways involved in stem cells pluripotency and cystogenesis deserves further investigation. The microRNAs (miRNAs) that participate in the regulation of these transcripts in kidney tissues of mouse models orthologous to ADPKD have not yet been validated. To identify regulatory miRNAs and differently expressed transcripts associated with stem cell pluripotency in kidney tissues of Pkd1-deficient mouse models.

Methods: A transcriptomic computational identification and validation of the expression level of regulatory miRNAs and genes by RT-qPCR, normalized by their respective housekeeping, mir-26a and Ppia was performed. The analyses were performed on kidneys from 10- to 12-week-old cystic mice (Pkd1−/−; Nestin−/− or Pkd1−/−; Nestin−/−, CY, n = 10) and their non-cystic controls (Pkd1+/+/ or Pkd1−/−, NC, n = 10); mice haplinsufficient for Pkd1 (Pkd1−/−, HT, n = 6) and their wild controls (Pkd1−/−, WT, n = 6); and 15-day-old severely cystic mice (Pkd1−/−, SC, n = 7) and their controls (CO, n = 5).

Results: The validation of the computational analyses performed in three to animal models with reports from the literature in other Pkd1-deficient models, identified 10 differently expressed genes associated with the regulation of stem cells pluripotency. Increased expression of Sts3 and Map3k1 genes and decreased regulatory miRNA Let-7a were observed in SC versus CO kidneys. On the other hand, Mapk14 gene showed decreased expression while its potential regulator, miR-21, revealed increased expression in SC versus CO kidneys. Fgf10 expression was decreased in SC versus CO kidneys whereas a trend of increased expression in the CY versus NC group has been observed.

Conclusions: Present results support a potential regulatory effect of miR-21 on Mapk14 expression and of miR-let-7a on the expression of Sts3, Map3k1 and Fgf10, namely transcripts involved in stem cells pluripotency and cystogenesis in kidney tissues of Pkd1−/− mouse models.

Investigation of LAD1 as a Candidate Modifier of Polycystic Kidney Disease in Pkd1 Mouse Models

Background: Polycystic Kidney Disease (PKD) is a monogenic disease caused by mutations in either Pkd1 or Pkd2, which encode polycystin-1 (PC1) and polycystin-2 (PC2), respectively. One proposed function for PC1 is to regulate cell migration and cell-cell interaction, possibly through modulation of the cytoskeleton. In prior transcriptomic studies of Pkd1 mutant kidneys, we had identified Lad1 as one of the few genes whose expression was dysregulated early in the course of the disease. The limited available literature suggests LAD1 may encode a cytoskeleton protein that acts as an anchoring filament to the basement membrane of epithelial cells. The goal of this study is to investigate the role of LAD1 in mediating modifying PKD phenotypes.

Methods: We quantified LAD1 gene and protein expression in the tissues of Pkd1 conditional mutant mice, kidney epithelial cell lines derived from Pkd1 conditional mice and human keratinocyte HaCat cells by quantitative polymerase chain reaction (qPCR) and western blot analyses. We used CRISPR technology to generate two LAD1 mutant mouse lines that have large deletions spanning most of the coding region of LAD1 and characterized the phenotype of homozygous mutants. LAD1 mutants were crossed with Pkd1 conditional mice with Ksp-Cre and tamoxifen-Cre to test for genetic interaction in early and late onset PKD models.

Results: We confirmed that Pkd1 mutant kidneys and epithelial cells have lower LAD1 expression levels compared to wild type samples. Mice with homozygous deletion of LAD1 exons 3 to 8 were born at normal Mendelian ratios and lacked obvious abnormalities up to 1 year of age. Histopathologic analyses of the kidney and organs with the highest expression of LAD1 also were normal. Pkd1/Lad1 double mutants were born at expected ratio, but showed distinct phenotypic features. However, early data suggest that Pkd1/Lad1, Ksp-Cre/+ LAD1 homozygous mutants have increased kidney-body weight ratios with worse cystic disease. Further analysis, including LAD1 CRISPR knock-out animals crossed with late-stage conditional Pkd1 knock-out animals, is ongoing.

Conclusions: LAD1 expression is reduced in Pkd1 mutant kidneys. CRISPR knock-out of LAD1 alone shows no obvious phenotype. Loss of LAD1 may worsen disease in the early onset Pkd1-cystic model.

Analysis of MicroRNAs as Regulators of Expression of Transcripts Associated with Stem Cell Pluripotency in Pkd1-Deficient Mouse Models

Juan J. Moyano muñoz,1 Mirian A. Boim,1 Luiz F. Onuchic,2 Ida P. Heilberg,3 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2University of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by cyst formation deriving from collecting ducts. Pluripotent stem cells associated with the formation of renal structures have been used in vitro studies of nephrogenesis or cystogenesis related to ADPKD. However, the association between transcripts integrating pathways involved in stem cells pluripotency and cystogenesis deserves further investigation. Sildenafil Inhibits ADPKD-Derived Cyst Growth in 3D Culture and Induces Apoptosis in the Han/SPRD Cy+/+Cy Rat Model of Renal Cyst Disease
Robert L. Bacalla,1,2 Weimin Xu,1 George Rhodes.3 Indiana University School of Medicine, Indianapolis, IN; 2Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: In prior studies we found that human renal cyst cells express high levels of GMP phosphodiesterase 5, 6 and 9 as compared to normal human kidney cells. In breast cancer, inhibition of cGMP phosphodiesterases induces apoptosis. We tested the hypothesis that sildenafil blocks cell proliferation and/or induces apoptosis in cyst epithelia.

Methods: PKD Q4004X cells were grown in Matrigel and treated with vehicle or sildenafil for 7 days. Cyst size was assayed by light microscopy. Differences in cyst area were analyzed by two-way ANOVA. In separate experiments, male cy+/+ rats were given either vehicle or sildenafil in their water supply for 7 or 28 days. Kidneys were harvested and apoptosis was assayed by staining with anti-M30, a monoclonal antibody that binds to apoptosis mediated cleavage of cytokeratin 18 in epithelial cells.

Results: In 3D cultures of PKD Q4004X cells, cultures treated with sildenafil (1, 2 and 4 µg/ml) are significantly smaller than vehicle-treated cultures (p=0.05 for all doses). Further analysis showed that cysts larger than 150 µm were not observed in any sildenafil-treated cultures. Figure 1 shows M30 staining in sildenafil (20 µg/kg/day x 7 to 40 days). Arrows point to cytokeratin 8/18 positive (red cytosolic stain) in cyst epithelia.

Conclusions: Sildenafil inhibits human kidney cyst growth in 3D culture. In male cy+ rats, sildenafil at a dose of 20 mg/kg/day for 7 or 40 days results in apoptosis of cyst epithelia.

Rab GTPase Regulation in Ciliogenesis and Polycystic Kidney Disease
Dominique J. Mcconnachie,1 Andrew J. Mallett,2 Jennifer L. Stow.1 Professor Jennifer Stow, Protein trafficking and inflammation group The University of Queensland and Institute for Molecular Bioscience, Saint Lucia, QLD, Australia; 2Townsville Hospital and Health Service, Townsville, QLD, Australia.

Background: Primary cilia are sensory organelles with widespread roles in development and epithelial function. Mutations resulting in isomorphic cilia and ciliary dysfunction are associated with renal ciliopathies such as polycystic kidney disease (PKD), yet primary cilia remain enigmatic in terms of their molecular and functional characterisation. Rab GTPases are central regulators of vesicular trafficking that have been shown to regulate ciliary protein transport and cilia composition, with downstream effects on ciliary function and signalling. Rab GTPases are therefore poised to vary or modify primary ciliary function, by working in conjunction with key cilia proteins, including those mutated in ciliopathies.

Methods: Our data show that Rab13 localises to the primary cilia of mouse kidney cells and Rab13 loss of function affects ciliaogenesis in a variety of in vitro and in vivo models including zebrafish embryos. Characterisation of Rab13 knockout epithelial cells reveal altered cilia, the perturbation of ciliopathy-associated protein localisation, and the formation of dysorphic renal spheroids. Rab13 knockdown zebrafish embryos display a range of cilia-associated developmental defects and Rab13 expression is diminished in mouse PKD cells.

Conclusions: Here we reveal a novel cilia-associated role for Rab13 GTPase. Investigating the genes and molecules that contribute to the ciliome of disease is important to improve knowledge, for potential translation and discovery of new therapeutic approaches for renal ciliopathies including PKD.

POI1227  Efficacy and Adverse Effects of a Novel Mesoscale Nanoparticle-Guided Sirolimus Delivery Strategy in a Phkd1Pck Cyst Rat Model
Michal Mrug,1 Daniel A. Heller,2 Chintan H. Kapadia,3 Ryan Williams,4 Phillip H. Chunley,1 Sean Mullen,2 Ronald E. Roye,1 Gabriel Rezonewicz,5 Juling Zhou,2 Edgar A. Jaimez.2 The University of Alabama at Birmingham, Birmingham, AL; 3Memorial Sloan Kettering Cancer Center, New York, NY; 4Goldolphin Therapeutics, New York, NY; 5The City College of New York, New York, NY.

Background: Pre-clinical studies have shown that mTOR inhibition attenuated renal cystic disease progression but it did not improve outcomes in patients with autosomal dominant polycystic kidney disease (ADPKD). This was attributed to the dose limitations in humans due to mTOR inhibitor toxicity. To increase the mTOR inhibition efficacy and reduce its toxicity in renal cystic diseases, we studied mesoscale nanoparticle (MNP)-guided delivery of an mTOR inhibitor, sirolimus (mTOR-sirolimus), in Phkd1PckCys rats. We used recently developed MNPs that selectively and with high affinity target the renal tubular epithelium.

Methods: We synthesized Empty-MNPs or MNP-sirolimus and used them in an experiment that resembled seminal pre-clinical studies of tolvaptan, the only FDA-approved ADPKD therapeutic. Newly outbred Phkd1PckCys rat males were divided into 3 groups (each N= 8-9) and treated for 8 weeks (p22 to p77) with: Empty-MNP (50 mg/kg IV q6h), Free-sirolimus (0.15 mg/kg IV q48h) and MNP-sirolimus (50 mg/kg IV equivalent to 0.3 mg/kg sirolimus q6h). Pre- and post-treatment cyst volumes were assessed by MRI at p21 and p78.

Results: The MNP-sirolimus or Free-sirolimus both inhibited renal mTOR activity in Phkd1PckCys rats. The mean p56/total S6 ratios were: 7.9 for MNP-sirolimus vs 19.1 for Free-Rapa and 10.1 for Empty-MNP (p<0.001) while total S6 levels did not differ (p=0.806). Similarly, an 8-week mTOR inhibition reduced mean renal cyst volumes: 39.9 mm3 for MNP-sirolimus vs 59.3 mm3 for Free-sirolimus vs 148.4 mm3 for Empty-MNP (overall p=0.005). However, pairwise comparisons showed that Empty-S6 levels were significantly reduced in MNP-sirolimus Rats (p=0.017) while for Free-sirolimus treatment the significance was marginal (p=0.052). The pre-treatment renal cyst volumes at 3 weeks were not significantly different (p=0.772). Among side effects, mTOR inhibition reduced body weight and heart weight (p<0.001). In both cases, their averages were less severely reduced in MNP-sirolimus as compared to Free-sirolimus treated rats.

Conclusions: Together, our studies support the concept that a novel MNP-guided sirolimus delivery increases renal mTOR inhibition and therapeutic efficacy in renal cystic diseases, while reducing systemic toxicity.

POI1228  Biomarkers Reflecting Extracellular Matrix Turnover Are Prognostic for Kidney Function Decline in Patients with ADPKD
FedERICA Genovesi,1 Judith E. Heida,1 Nadja Sparding,1,2 Morten A. Karsdal,1 Ron T. Ganshevoort,1 Daniel Guldager Kring Rasmussen.1 Nordic Bioscience, Herlev, Denmark; 2Biomedical Sciences, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; 3Dept. Nephrology, University Medical Center Groningen, Groningen, Netherlands.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common inherited disorders in humans and is caused by mutations in the PKD1 and PKD2 genes. The disease is characterized by development and growth of cysts leading to kidney dysfunction. Previous findings suggest that ECM is a driving force in progressive kidney disease in ADPKD and is characterized by an impaired turnover of extracellular matrix (ECM). Here, we investigated the association of ECM biomarkers with rate of kidney function decline in patients with ADPKD.

Methods: We measured four markers of ECM turnover in serum and urine from 305 patients with ADPKD from the DIPAK-1 study (NCT01616927): three markers of interstitial collagen turnover (C3M, PRO-C3 and PRO-C6) and one laminin degradation marker reflecting basement membrane turnover (LG1M). The association of the biomarkers with kidney function decline was investigated with a linear mixed model (change in eGFR/year) and logistic regression (decline in eGFR of >30%). Data was log-transformed if appropriate.

Results: All four markers of kidney fibrosis in serum were associated with eGFR at baseline when adjusting for sex, age, height adjusted total kidney volume (hTKV) and PKD mutation in serum (C3M, P<0.05; PRO-C3, P=0.001; PRO-C6, P=0.001; LG1M, P=0.001). In urine, only C3M and PRO-C6 (C3M, P=0.001; PRO-C6, P=0.001) and not PRO-C3 and LG1M (PRO-C3, P=0.07; LG1M, P=0.31) were independently associated with eGFR. Serum C3M (P=0.005) as well as urinary PRO-C3 (P=0.001) and PRO-C6 (P=0.001) were associated with the rate of eGFR decline per year when adjusting for sex, age, baseline eGFR, hTKV and PKD mutation. A total of 60 patients had a decline in eGFR of >30% and when adjusting for sex, age, baseline eGFR hTKV and PKD mutation, only serum C3M (OR=4.18, P=0.02) was independently associated with a decline in eGFR of more than 30%.

Conclusions: Serum C3M as well as urinary PRO-C3 and PRO-C6 were associated with the rate of kidney function decline when adjusting for known determinants of disease severity. Also, serum C3M could identify fast progressors (decline in eGFR of >30%). These markers hold promise that components from the ECM may be used as prognostic markers in ADPKD, but should be validated first in an independent ADPKD cohort.

POI1229  Magnetic Resonance Fingerprinting (MRF) Identifies Potential Imaging Biomarkers for Autosomal Recessive Polycystic Kidney Disease (ARPKD)
Elise Keshock,1 Jacob R. Perino,1 Christina J. Macaskill,1 Ashlee Parsons,2 Jemma M. Hach,2 Susan Farr,1 Chris Flask,1 Katherine M. Dell.3,1 Case Western Reserve University, Cleveland, OH; 2Cleveland Clinic Children’s Hospital, Cleveland, OH.

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is an important cause of morbidity and mortality in children with chronic kidney disease (CKD). Novel therapies have shown efficacy in ARPKD animal models, but clinical trials in ARPKD patients have not been possible due to the lack of sensitive measures of kidney disease progression. Non-invasive Magnetic Resonance Imaging (MRI) techniques, including novel MRF Fingerprinting (MRF), show promise in addressing this unmet need. We previously identified MRF-based T1 and T2 mapping as potential biomarkers of ARPKD kidney disease in animal models and initial human studies. In the current study, we evaluated the relationship between these imaging parameters and renal function in ARPKD fluoresce in mild to moderate CKD.

Methods: ARPKD subjects (age 6-25 yrs) with estimated glomerular filtration rate (eGFR) >60ml/min/1.73m2 were scanned on a Siemens 3T MRI scanner utilizing novel MRF technology to simultaneously generate mean kidney T1 and T2 maps in 15 secs/imaging slice with no sedation or injectable contrast agent. The relationship between eGFR (U25 eGFR formula) and imaging parameters was assessed by Pearson correlations with significance set at <0.05.

Results: 7 subjects (2M/5F, age=12±5 years) were imaged. eGFR was 87±21, range=52-109 ml/min/1.73m2; 5 had hypertension. Mean kidney T1 (94±10 msec) showed a significant negative correlation with eGFR (R=-0.86, p<0.013). Mean kidney T2 (216±37 msec) also showed a strong negative correlation (R=-0.69) but did not yet reach significance (p=0.086). Mean T1 and T2 values for the right and left kidneys also demonstrated a significant correlation (T1: R=0.99, T2: R=0.79).

Conclusions: This is the first study to establish a relationship between MRF-derived imaging biomarkers (T1 and T2) and kidney function (eGFR) in ARPKD subjects. Despite the small cohort, data clearly demonstrate that mean T1 and T2 both increase with decreasing eGFR. These findings suggest that MRF-based T1 and T2 mapping may provide a safe, non-invasive, quantitative, and reproducible measure of kidney disease severity to support future clinical trials to identify subjects at high risk for disease progression and monitor response to treatment.

Suppressed Autophagy Drives Increased Cellular Metabolic Activity in Human ADPKD Cells

Daniel Atwood, Deepak Pokhrel, Charles L. Edelman. University of Colorado, Aurora, CO.

Background: We published that the autophagy phenotype in Pkd1CSC mouse kidneys is characterized by decreases in crucial autophagy proteins (Cell Signal 2020). We attempt to determine the mechanistic role of suppressed autophagy as it relates to cell metabolism, viability (viability and proliferation) in ADPKD cells.

Methods: Human primary immortalized cultured cells were used: normal renal cortical tubular epithelium (RCTE, Pkd1+/+ and ADPKD cyst-lining epithelium (9-12, Pkd1-/-). To measure autophagic flux, cells were treated with lysosomal inhibitor chloroquin (C) and LC3-luminal labeling, a marker of autophagosomes or mCherry LC3 (fluorescence) were analyzed. MTT assay was used to measure cellular metabolic activity (cell viability and proliferation). Relative densitometry units (RDU) were measured on immunoblots.

Results: There was an increase in MTT and a decrease in Anx in 9-12 vs RCTE (P<0.05). In MTT OD was 0.36 in RCTE vs 0.44 in 9-12 (p<0.001). Anx in MTT (Anx (% gated) marker of apoptosis, was 67 in RCTE vs 18 in 9-12 (p<0.001). The increase in LC3-II in C was not seen in 9-12 indicating suppressed autophagy. LC3-2 (RDU) C/-/+ C was 0.6 vs 1.4 in RCTE (P<0.01) and 0.9 vs 1.1 (NS) in 9-12. mCherry (% gated) C/-/+ C was 6 vs 6 (p=0.05) in RCTE and 6 vs 13 (NS) in 9-12 cells, p62 marker of autophagic cargo, was increased in 9-12 vs RCTE. p62 (RDU) was 0.7 in RCTE and 1.2 in 9-12 (p<0.05). Cells were treated with an ATG7 shRNA (SH) to inhibit a crucial autophagy protein. There was a 50% decrease in LC3-II and ATG7 protein in SH-treated 9-12 cells. SH resulted in an increase in MTT and a decrease in Anx in MTT indicating that suppressed autophagy drives MTT and inhibits apoptosis. MTT OD was 0.7 with scrambled shRNA (SCR) and 0.9 with SH (p<0.05). AnnexinV was 26 with SCR vs 13 with SH (p<0.05). Tat-Beclin peptide (TAT), a specific autophagy inducer, resulted in a decrease in MTT in 9-12 suggesting that autophagy decreases MTT. MTT OD was 0.9 with Veh vs 0.2 with TAT (p<0.001). TAT did not affect Anx.

Conclusions: In ADPKD cyst lining epithelial cells there is increased MTT, suppressed autophagic flux, and decreased apoptosis. Autophagy inhibition increased MTT and suppressed MTT. Autophagy or suppressed autophagy drives increased cellular metabolic activity in ADPKD cells. The effect of autophagy induction/inhibition on cyst growth in vivo merits further study.

Species-Specific Differences in FPC-CTD Trafficking: Implications for Differential Activation of Intracellular Signaling Pathways

Chaozhe Yang,1 Nao Harafuji,1 Maryanne O'dinahkanuku,1 Libjeba Caldovic,1 Zsuzsanna M. Bebok,2 Lisa M. Guay-Woodford.1 Children's National Research Institute, Washington, DC; The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.

Background: ARPKD (MIM 263200) is caused by mutations in PKHD1, which encodes FPC. But, orthologous mouse Pkd1 mutants either have no renal cystic disease or very mild PCT dilatation. We previously showed that MYC/Myc is overexpressed in human ARPKD and mouse Cys1/resc Pkd1 mutant kidneys, but not in several Pkd1 mutants. We also showed that expression of the intracellular carboxy-terminus of mouse FPC (mFPC-CTD), but not human (hFPC-CTD), activates the Myc/Myc1 promoter (J Am Soc Nephrol 2020). The current study focused on: 1) the intracellular trafficking of mFPC-CTD and hFPC-CTD, and 2) activation of the Src/STAT3 signaling pathway, linked to hFPC-CTD (Abulh, 2020), in a mouse Pkd1 mutant lacking FPC-CTD and in the cpl mouse model of ARPKD, with and without Cys1 rescue.

Methods: Comparative immunoblot analysis. Immortalized mouse CCD (mCCD) and human (hCCD) cell lines stably expressing mFPC-CTD and hFPC-CTD, respectively. Kidneys from cpl, Cys1-rescued cpl, and Pkd1tm1del67 mutant mice; western blot and immunofluorescence.

Results: FPC-CTD is the least conserved domain, with 55% identity between human-mouse CTDs, compared with 73% identity across the full-length FPC. The CTD is unique, with an AA-sequence not found in other terrestrial vertebrate proteins. In stable cell lines, mFPC-CTD localized to both nuclei and cilia, whereas h-FPC-CTD primarily localized to the apical membrane. In non-cystic del67 kidneys (lacking FPC-CTD), PSTAT3Ph and e-Myc were similar to wild-type controls. In cpl kidneys, pSTAT3Ph and e-Myc were upregulated, but their levels in Cys1-rescued cpl kidneys (Iang 2021) were comparable to wild-type.

Conclusions: Differences in intracellular trafficking of mFPC-CTD and hFPC-CTD may explain the species-specific differences in Myc/Myc1 promoter activation. Distinct subcellular localizations may reflect differential in the functional evolution of human and mouse FPCs, with mFPC-CTD trafficking to nuclei and hFPC-CTD to the cytoplasm, whereas hFPC-CTDs functions as a membrane-associated signaling regulator of Src-STAT3. Activation of Src-STAT3 signaling and Myc upregulation are signatures of cystic epithelia, suggesting that renoprotective mechanisms in FPC-deficient mouse kidneys remodel in response to Pkd1 mutation.

**Results:** We found that full length oKlotho was decreased in collecting duct cells, macrophages, fibroblasts and T/NK immune cells in Pkd1 homozygous kidneys. Transgenic oKlotho delayed cyst growth in Pkd1 conditional knockout mice by normalizing the expression of genes associated with a number of diverse functions, including the genes associated with the transitions between collectig duct cell subtypes and those involved in epithelial-mesenchymal transition. In addition, we found that the genes associated with the epithegenic clock (DNA methylation age) were dysregulated in those cells in cystic kidneys, and that they could be normalized by transgenic oKlotho, suggesting that transgenic oKlotho might slow down the process of epithegenic age acceleration in cystic kidneys. The dysregulation of the epigenetic age-acceleration genes, Apoe, Cldn4, Mge and S10c38a2, might contribute to PKD pathogenesis and might serve as potential biomarkers for ADPKD. Finally, transgenic oKlotho affected a large number of genes associated with metabolic and oxidative signaling, suggesting that oKlotho might act by gene expression and signaling pathways to extend the life span of mice.

**Conclusions:** Reduction of oKlotho regulates cyst growth through diverse signaling pathways. Pkd1 mutation accelerates epithegenic age in ADPKD. Transgenic oKlotho not only delayed cyst growth but also slowed down epithegenic age acceleration.

Mechanistic Interaction Between Cystin and Fibrocystin/Polyductin in Model Cell Lines and cpk/cpk Kidneys

Yiming J. Zhang,1 Chaozhe Yang,1 Nace Harafuji,2 Wei Wang,1 Phillip D. Bello,1 Lisa M. Guay-Woodford,3 Zsuzsanna M. Mekov.1 The University of Alabama at Birmingham, Birmingham, AL; 2Massachusetts Institute of Technology, Cambridge, MA; 3Children’s National Research Institute, Washington, DC.

**Background:** Cystin cpk (cpk) mice exhibit ARPKD-like renal phenotype due to a mutation in the Cys1 gene and loss of cystin. ARPKD (MIM 263200) is caused by mutations in PKHD1, encoding FPC. Both cystin and FPC are present in the primary cilium, but no physical interaction has been reported. Using mouse CCD cell lines, we have shown that FPC levels were reduced in cpk cells by 75% relative to wt. Cystin deficiency is specifically linked to FPC reduction and did not affect cilia development, but altered ciliary architecture (ASN 2020). The current study focuses on cellular mechanisms driving FPC reduction in cystin-deficient cells, and the consequences of FPC loss. We show that FPC is necessary for proper E3 ubiquitin ligase function and consequently cellular proteome management (Kaimori 2017).

**Methods:** Immortalized wt and cpk mouse CCD cells. Wt and cpk mouse kidneys. sRNA silencing of Cys1: qRT-PCR, western blot, confocal microscopy, morphometry, patch clamp.

**Results:** Silencing Cyst1 in wt cells results in a sRNA dose-dependent reduction of both cystin and FPC. Correlative studies showed marked reduction of FPC in cpk kidneys. Similar Pkd1 cpk mRNA levels in wt and cpk cells, and kidneys implicate FPC regulation at the protein level. Proteasome or lysosome inhibition did not recover FPC, but activation of autophagy further reduced FPC levels, suggesting a role for selective autophagy in FPC removal. Diminished FPC levels lead to E3 ubiquitin ligase defects and reduced polyubiquitination of proteins, necessary for proteome management. In cpk cells, we observe altered membrane retention of the epithelial sodium channel and increased sodium transport.

**Conclusions:** Our studies provide the first functional link between cystin and FPC in renal epithelial cells. We propose cystin as a gatekeeper for FPC at the base of the cilium and in the E3 ligase complex. In cystin-deficient cells, FPC is continuously degraded driving FPC reduction in cystin-deficient cells, and the consequences of FPC loss. We speculate that FPC is necessary for proper E3 ubiquitin ligase function and consequently cellular proteome management (Kaimori 2017).

Tubular Flow Disruption During Cyst Development in Polycystic Kidney Disease

Issis Thomas, Hanan Chweil, Courtney J. Haycraft, Mandy J. Croyle, Zhang Li, Bradley K. Yoder. The University of Alabama at Birmingham, Birmingham, AL.

**Background:** Polycystic kidney disease is an inherited disorder in which clusters of cysts develop within the kidneys, causing the kidneys to enlarge and lose function. Cyst development can be due to functional changes caused by mutations in ciliary localized proteins Pkd1 and Pkd2 or changes in cilia formation/structure (e.g. i888 mutants). It is currently unknown how cysts impact tubule flow and cilia, or whether flow alterations occur prior to or after cyst formation is initiated.

**Methods:** We used inducible Cre conditional mutant mouse models with an optical imaging camera to monitor changes in proximal tubule flow at multiple timepoints during cystogenesis in live kidneys. Additionally, we evaluated dextran absorption into proximal tubules as an indicator of tubule flow in mutant and control mice during cyst development. We determined the number of dextran+ proximal tubule cells by FACS to quantify changes in the percentage of tubules with flow in cystic versus non cystic kidneys. We performed H&E staining to quantify cyst severity and analyzed sections by immunofluorescent microscopy to assess changes in flow.

**Results:** Our results suggest that during the cyst formation, there is a marked decrease in flow through the tubules and that this reduction in flow occurs early during cyst formation. This corresponds to a 56.8% of cells that are both dextran+ and LTA+ (proximal tubule) by flow cytometry and similar results were obtained by IF analysis. We also find an increase in resident and infiltrating macrophages around the forming cysts.

**Conclusions:** The use of intravital imaging approaches allows us to evaluate changes in tubule flow as cysts progress. With the addition of cilia markers, we will examine the responses of the cilium to the changes in flow. Preliminary data suggests that alterations in tubule flow occur at early time points during cyst initiation with larger cysts seldom containing epithelium that are dextran-. These data indicate that loss of tubule flow may be an early event associated with cystogenesis. Our data also suggests that disruption of tubule flow is progressive with fewer tubules with flow at later time points (4-6 months post induction). We are currently assessing whether there is an association between the disruption of flow in a tubule and localized immune responses.

FoxM1 Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Wenyen Yu, Guojuan Wang, Xiaoyan Li, Xia Zhou, Xiaoliang Li. Mayo Clinic Department of Internal Medicine, Rochester, MN.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is driven by mutations in PDK1 and PDK2 genes and is characterized by renal cyst formation, inflammation and fibrosis. Forkhead box protein M1 (FoxM1) is a transcription factor of the Forkhead box (Fox) protein super family which is defined by a conserved winged helix DNA-binding domain 1. FoxM1 has been reported to promote tumor formation, and disruption of dextran and fibrosis in many organs. However, the role and mechanism of FoxM1 in regulation of ADPKD progression is still poorly understood.

**Methods:** To evaluate the role and mechanisms of FoxM1 in cyst in growth in vivo, we treated early stage and long lasting Pkd1 mutant mice with the FoxM1 specific inhibitor, FDI-6. To identify novel FoxM1 target genes involved in cystogenesis, we performed ChIP-sequence analysis.

**Results:** We found that FoxM1 was upregulated in cyst-lining epithelial cells in polycystin-1-deficient murine kidneys and human ADPKD kidneys. Inhibition of FoxM1 with FDI-6 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in Pkd1 mutant mice (all p < 0.01). Targeting FoxM1 also decreased renal fibrosis in long last Pkd1 mutant kidneys. Upregulation of FoxM1 promotes cyst growth through: 1) upregulation of the expression of Akt and Stat3 and activation of ERK and Rb signaling to increase cystic renal epithelial cell proliferation, 2) inhibition of p65-dependent cystic renal epithelial cell death, 3) facilitation of the recruitment and retention of renal macrophages, and 4) upregulation and activation of IL6 markers to promote renal fibrosis. In addition, FoxM1-dependent macrophage recruitment was associated with upregulation of monocytic chemotactic protein 1 (MCP-1) and inflammatory cytokine TNF-α. Further, we identified novel FoxM1 target genes by ChIP-seq analysis, which may connect FoxM1 signaling to the cilopath hypothesis in PKD.

**Conclusions:** FoxM1 promotes renal cyst growth and fibrosis in ADPKD through Akt, ERK, Rb and STAT3 signaling as well as NF-kB and cilopath associated signaling. Targeting FoxM1 in cystic renal epithelial cells may be a viable new therapy for ADPKD.

Allosteric Mechanism of PC1 Tethered Agonist-Mediated Signaling

Shristi Pawenkar, Brenda S. Magenheim,1 Ericka Neveuz Munoz,2 Robin L. Maser,3 Yinglong Miao.1 University of Kansas College of Liberal Arts and Sciences, Lawrence, KS; 2University of Kansas Medical Center, Kansas City, KS.

**Background:** Polycystin-1 (PC1) is the 11-transmembrane protein product of the human autosomal dominant polycystic kidney disease (ADPKD) gene Pkd1. PC1 functions as an atypical GPCR and shares multiple features with the Adhesion GPCRs, including a GPCR autoproteolysis-inducing (GAIN) domain that catalyzes cis-cleavage of the receptors into extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. We previously reported that CTF-mediated signaling to an NFAT promoter-luciferase reporter is dependent on the presence of the stalk, is reduced by ADPKD-associated missense mutations within the stalk, and can be rescued by synthetic, stalk-derived peptides, supporting a tethered ligand mechanism of PC1-G protein signaling (JASN 2018;29:671; JASN 2019;30:388).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We have combined highly complementary experiments and computer simulations to investigate the mechanism of the tethered agonist-mediated signaling of PC1 CTF. A computer model of the human PC1 CTF was generated using the cryo-EM structure of the PC1-PC2 complex with important missing regions added through I-TASSER homology modeling. All-atom enhanced molecular dynamics (GaMD) technique were performed, followed by calculations of residue correlation matrices and free energy profiles. GaMD simulation-predicted residue interactions important for WT stalk-mediated activation of PC1 CTF were further investigated by mutagenesis and cellular assay experiments.

Results: GaMD simulations were consistent with experimental signaling data obtained with PC1 CTF expression constructs encoding wild type and stalk variants of the PC1 CTF. Correlation matrices revealed regions of highly correlated residue motions involving the stalk, TOP and putative pore loop domains. Key residue interactions predicted from the GaMD simulations were validated with newly designed mutation experiments.

Conclusions: Complementary experiments and simulations studies support the function of the PC1 CTF stalk region as a tethered agonist and suggest a mechanism whereby it can induce TOP-pore loop interactions which can be further translated to the GaMD model for G protein activation. This in-depth knowledge is expected to facilitate future drug design efforts targeting this function of PC1 for more effective treatments of ADPKD.

Analysis of Calcium Signaling in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dorien Van Giel,1 Jean-Paul Decuyper,1 Djallia Mekuhl,1,2 Rudi Vennekens.1

Background: ADPKD is an inheritable kidney disease characterized by the development of fluid-filled renal cysts, mainly caused by mutations in the PKD1 and PKD2 genes, leading to loss of renal function. Molecular mechanisms underlying cystogenesis are poorly characterized but it is postulated that disturbed calcium homeostasis is a primary event in cystogenesis. The precise molecular players that cause this disturbance are largely poorly explored, especially in non-cystic cell types. We therefore aim to characterize the profile of calcium-coupled G-protein coupled receptors (GPCRs) in a human renal epithelial cell models, to identify which receptors are present, whether their function is affected in ADPKD and whether they can be used to modulate cyst formation and growth.

Methods: Urine-derived conditionally immortalized proximal tubule epithelial cells (ciPTECs) of ADPKD patients and healthy controls were screened for calcium-coupled GPCRs, using an agonist library on Fura-2 loaded cell populations seeded in 96-well format. Validation of specific hits was done using single-cell measurements with a fluorescence microscope and built-in perfusion system in the ciPTECs as well as in tissue-derived conditionally immortalized cystic cells (ciCCs). Matrikel-based 3D cell culture was used to grow ciCCs to assess their ability to form cystic structures. Structures were stained with nuclear and cytosolic stains and imaged via confocal microscopy.

Results: From a library of 418 GPCR agonists a selective amount of calcium-coupled GPCRs was found functionally active in ciPTECs. ciPTECs from both healthy controls and ADPKD patients were found to functionally express purergic - , histaminergic - , serotonin and dopamine receptors. In single-cell experiments, we did not find any significant differences in functionality between healthy controls and ADPKD patients, but observed that response characteristics are mainly donor-specific, suggesting patient-specific disease mechanisms. ciCCs grown in 3D cell culture were found to form hollow, cell-lined cyst-like structures.

Conclusions: We describe the first thorough characterization of calcium-coupled GPCRs in a human proximal tubule epithelial cell model. We established a 3D cyst growth assay using tissue-derived cystic cells to explore the possibility to use the identification of GPCRs to modulate cyst formation and growth.

Loss of Polycystin Function in Lymphatic Cells Impair CTP1a Expression and Fatty Acid Uptake

Denis Basquin, Jinqing Liang, Terry J. Wattnic, Patricia Outeda. University of Maryland School of Medicine, Baltimore, MD.

Background: Homozygous Pkdl or Pkdr null mutant mice die at mid-gestation due to vascular abnormalities including edema and hemorrhage. We have previously shown that edema in Pkdl and Pkd2 knock out mice is due to abnormal lymphatic morphogenesis, with grossly dilated, blood filled dermal lymphatic vessels. Because proper lymphatic development is supported by fatty acid β-oxidation (FAO), we probed fatty acid transport in Pkdl1/Pkd2 lymphotothelial cells (LECs).

Methods: Pkdl1 and Pkd2 mutant LECs were isolated from mouse E14.5 embryos or generated using lentiviral shRNAs against PKD1 or PKD2 in human dermal LECs (HDLCs). Protein levels of PC1, PC2 and CPT1a were determined by western blotting and CPT1a/CPT2 mRNA levels were analyzed by qRT-PCR. Fatty acid uptake was assessed by BODIPY 558/568 C12, staining of control and Pkd1 mutant LECs pre-incubated with or without 50 µM palmitate, and counterstained with mitochondrion. Cells were imaged by confocal microscopy and the relative abundance of lipid droplets were quantified using ImageJ software. Each experiment was repeated 3 times and pairs of means (mutant versus control) were compared using Student’s T-test.

Results: Embryonic Pkdl1- and Pkd2- murine LECs exhibit a robust decrease of CPT1a protein levels. In addition, CPT1a protein levels were significantly reduced in Pkdl1 and Pkd2 deleted HDLCs, suggesting a conserved role of Pkdl1/2 in CPT1a regulation. PC1 and PCD2 depletion in HDLCs results in an accumulation of cytoplasmic lipid droplets which often colocalized with mitochondria, indicative of impaired fatty acid utilization. The ability of PKD1 mutant cells to metabolize fatty acids is further challenged by pre-treatment with 50uM palmitate, which exacerbates the accumulation of lipid droplets.

Conclusions: Our results highly suggest that polycystin function is required to maintain normal levels of CPT1a expression and fatty acid transport to mitochondria in LECs. We thus speculate that a defect in FAO with consequent dysregulation of gene expression is the basis of impaired lymphangiogenesis in Pkd1/2 mutant embryos.

PO1243

Pharmacological Activation of Long-Form PDE4 Enzymes Suppresses Disease Progression in PkdlRC/RC and Pkd1 Knockout (iKspCrePkd1/lox,lox) Mouse Models of ADPKD

David J. Henderson,1 Xiaofang Wang,2 Li Jiang,2 Miles D. Houslay,1 Peter C. Harris,1 Julia M. Adam,1 David R. Adams,1 Adele Rowley,1 Vicente E. Torres.1,2 Mironid Limited, Glasgow, United Kingdom;3 Mayo Clinic Minnesota, Rochester, MN.

Background: Upregulation of cAMP signalling is thought to promote cystogenesis in ADPKD. Phosphodiesterase 4 (PDE4) enzymes degrade cAMP and contribute to its compartmentalized signaling. We have previously described novel small molecules that allosterically activate long isoforms of PDE4 and lower intracellular cAMP. Here we demonstrate significant efficacy with MR-L22, an advanced PDE4 activator compound, on suppressing cystic burden and preserving kidney health in orthologous models of ADPKD.

Methods: The effects of the long isoform PDE4 activator MR-L22 (administered by oral gavage) were assessed in rapidly (iKspCrePkd1/lox,lox induced at P10, treated from P14 to P27) and slowly progressive (Pkd1/2, treated from 4 to 16 weeks of age) mouse models of ADPKD. Test groups were compared to control groups receiving vehicle alone or vehicle control (results not shown).

Results: Compared to vehicle treated controls, MR-L22 treated Pkd1/-/c mice exhibited reduced kidney cAMP levels, cyst indices, kidney weight/body weight ratios (Kw/Bw) and MRI measured total kidney volumes (TKV) (Table and Figure). Long isoform PDE4 activation significantly protected kidney function and, when compared to tolvaptan, animals receiving MR-L22 produced significantly less urine volume. MR-L22 also suppressed the aggressive cystic disease exhibited by tamoxifen induced (P10) iKspCrePkd1/lox,lox mice, where Kw/Bw and cystic indices were reduced in comparison to vehicle control (results not shown).

Conclusions: Small-molecule activators of long isoforms of PDE4 suppress cystic disease progression in key translational models of ADPKD and may be better tolerated and more effective than vasopressin V1 receptor antagonists.

Background: NEK8 encodes a protein that localizes to the primary cilium. Bilallelic NEK8 variants are known to cause multigorgan developmental defects including renal cystic dysplasia, with heterozygous carrier parents being asymptomatic. This autosomal recessive inheritance is most common for ciliopathies. Complementary to this, we now propose a dominant-negative effect for certain heterozygous NEK8 nonsense variants in the kinase domain.

Methods: We performed genetic testing in patients from several medical centers. To explore the consequences of the identified NEK8 variants we are performing cilia staining assays in patients’ skin fibroblast and kidney cells, as well as in mMCD5 cells overexpressing the identified variants.

Results: We identified three distinct heterozygous NEK8 variants in eight families (table 1), all leading to missense alterations in the kinase domain. The large symptomatic family and the de novo occurrences are also in favor of a dominant mode of inheritance. All patients have a kidney phenotype, varying in severity, age of onset and presence of kidney failure. Interestingly the p.Arg457P variant is a recurrent variant found in six unrelated families. Our preliminary results from functional studies show normal localization of the NEK8 protein to the Golgi region, but abnormal primary cilia formation, in serum starved primary ciliated cells – a finding corroborated with functional assays.

Conclusions: We present the first evidence for a pathogenic effect of heterozygous NEK8 variants. Remarkably our patients present with a renal limited phenotype as compared to the multigorgan defects found in patients with biallelic variants. This reveals a new mode of inheritance for NEK8 variants and expands genotype-phenotype correlations for this gene.
Methods: Co-immunoprecipitation (co-IP) of UMOD and TMDG cargo-receptors was assessed in HEK293 cells transfected with wild type (WT) or mutant (C126R) human UMOD. Next, we performed untargeted Affinity Purification Mass Spectrometry followed by tandem MS to generate a list of UMOD interactors. We also conducted in vivo studies in UMOD−/− mice.

Results: We identified distinct WT and mutant UMOD interactomes using an unbiased AP-MS proteomics approach. Several interactors, including members of the TMED family, were significantly enriched in the mutant UMOD interactome. Targeted co-IP in lysates of HEK293 cells transfected with UMOD and interacting protein candidates confirmed the identification of UMOD interactors in-vitro, suggesting that when pulling down TMEDs, we found abundant immature non-glycosylated UMOD, suggesting entrapment in early secretory compartments. In vivo, treatment with BRD4780 was suggestive of disrupted interactions between mutant UMOD and interacting partners responsible for toxic entrapment in the ER, as assessed by immunolocalization of kidney lysates and immunofluorescence microscopy of tissue from UMOD−/− mice.

Conclusions: Our results suggest that UMOD interacts with TMDG cargo-receptors and other proteins that may mediate the pathogenic quality control mechanisms responsible for toxic ER-retention and accumulation. Shedding light on these new molecular mechanisms may unmask new therapeutic strategies for the treatment of ADTDK-UMOD.

Weight Loss to Slow Cyst Growth in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Kristen L. Nowak,1 Victoria Catanecchi,1 Timothy L. Kline,1 Wei Wang,1 Zhixing You,1 Kristen Bing,1 Bhavya Poudyal,1 Cortney Steele,1 Michel Chonchol,1 Berenice Y. Gitomer,‡
1University of Colorado - Anschutz Medical Campus, Aurora, CO; 2Mayo Clinic College of Medicine and Science, Rochester, MN.

Background: Recent studies in animal models of ADPKD suggest that food restriction can profoundly slow cyst growth and maintain renal function. We have also reported that overweight and obesity are strong independent predictors of ADPKD progression. Thus, it is plausible that weight loss, caloric restriction, and/or periods of fasting may slow ADPKD progression in humans; however, the feasibility of these dietary interventions, and whether the driver of therapeutic efficacy is periods of fasting or reduction in body weight, is unknown.

Methods: We conducted a one-year study evaluating feasibility of delivery of a behavioral weight loss intervention based on either daily caloric restriction (DCR) or intermittent fasting (IFM) in adults with overweight/obesity, ADPKD, and eGFR ≥30 mL/min/1.73m2 (targeted weekly energy deficit of ~34% in both groups). We also evaluated the safety, acceptability, and tolerability of each intervention, and obtained exploratory insight into changes height-corrected total kidney volume (htTKV).

Results: 28 participants (16F/12M; 46 ± 9 yrs, body mass index 34.7 ± 5.0 kg/m², eGFR of 69±22 mL/min/1.73m²) were randomized to either DCR (n=15) or IFM (n=13). Clinically significant (~5%) weight loss was achieved in both groups at month 3 (DCR: -7.1±4.2% vs. IFM: -5.5±3.3%). At 12 months DCR lost additional weight while weight loss in IFM plateaued (DCR: -9.1±6.0% vs. IFM: 4.9±5.6%; p=0.05 DCR vs. IFM). Overall, DCR had a more favorable safety, tolerability, and adherence profile than IFM. Annual htTKV %Δ was qualitatively low in both groups in comparison to historical data, and particularly DCR, was feasible interventions over a one-year follow-up. Clinically significant (>5%) weight loss was achieved in both groups at month 3 (DCR: -7.1±3.3% vs. IFM: 1.7±5.6%; p<0.05 DCR vs. IMF). Overall, -7.1±3.3% at 12 months DCR lost additional weight while weight loss in IMF plateaued (DCR: -9.1±5.6%; p<0.05 DCR vs. IMF). Annual htTKV %Δ was qualitatively low in both groups in comparison to historical data, and particularly DCR, was feasible interventions over a one-year follow-up. Clinically significant (>5%) weight loss was achieved in both groups at month 3 (DCR: -7.1±3.3% vs. IFM: 1.7±5.6%; p<0.05 DCR vs. IMF).

Conclusions: We demonstrate that renal tubular peroxisomes are dispensable for normal renal function. This indicates a large flexibility of proximal tubule cells both in terms of lipid membrane composition and metabolic/antioxidant functions. Our data also suggest that renal injuries in ZSD patients are of extrarenal origin.

Overweight and Obesity Predict Kidney Growth in Children and Young Adults with ADPKD

Cortney Steele, Zhixing You, Heather Farmer-Bailey, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: We have previously reported that overweight and obesity are independently associated with more rapid progression in adults with early-stage autosomal dominant polycystic kidney disease (ADPKD). We now evaluate whether overweight and obesity are also associated with faster kidney growth in children and young adults with ADPKD.

Methods: 54 non-diabetic children and young adults (6-25 years of age) with ADPKD and estimated glomerular filtration rate (eGFR) >60 mL/min/1.73m² who participated in a 1-year randomized controlled trial and submitted for follow-up. Participants were categorized based on BMI (if ≥18 years; n=27) or BMI percentile for age, sex, and height (if <18 years; age; n=27) as normal weight (n=40 [74%]) or overweight/obese (n=14 [26%]). The longitudinal (1-yr) association of overweight/obesity with change in height-corrected total kidney volume (htTKV) by magnetic resonance imaging was evaluated using multivariate linear regression models.

Results: Mean±sd. age was 18±5 years, annual % change in htTKV was 6.1±9.0%, and eGFR (full-age-spectrum equation) was 112±18 mL/min/1.73m². The annual % change in htTKV was 5.5±9.1% in the normal weight participants and 7.9±8.6% in overweight/obese participants. Mean±sd. height was 169±9 cm, mean±sd. weight was 74±15 kg, and mean±sd. BMI was 24.8±4.1 kg/m². At baseline, 60% of children and young adults were overweight/obese (n=33; 51.9%). The annual % change in htTKV was 5.5±9.1% in the normal weight participants and 7.9±8.6% in overweight/obese participants.

PO1255

Metabolic Changes over 1 Year Following Drug or Lifestyle Interventions in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Cortney Steele, Jelena Klawitter, Wei Wang, Zhiying You, Victoria Catenacci, Taylor Struemph, Diana George, Berenice Y. Gitomer, Godela M. Broshnahan, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease. Studies have shown differences in metabolic profiles in those with ADPKD; however few studies assess change over time.

Methods: We performed metabolomics to assess patterns of change across four groups of participants with ADPKD pooled from 2 randomized clinical trials: placebo control (CON), metformin (1,000 mg/day) (MET), intermittent fasting (IFM; 3 day/weekly) arbitrary restriction (DCR; daily restriction of 34% per day from baseline weight maintenance requirements). Analyzed plasma samples were collected during the trials at baseline and year for each group. A total of 163 metabolites were measured using liquid chromatography-mass spectrometry (LC-MS). Differences in metabolic profiles over time and within study groups were evaluated by a one-way ANOVA and Bonferroni correction for multiple comparisons.

Results: Baseline characteristics for each trial included CON (n=22, 14 female (F), 49±7 yrs of age (means±S.D.), estimated glomerular filtration rate [eGFR] 73±13 ml/min/1.73m², body mass index (BMI) 29.3±4 kg/m²), MET (n=22, 14 F, 48±6 yrs of age, eGFR 69±14 ml/min/1.73m², BMI 29.7±7 kg/m²), MET (n=10, 5 F, 47±6 yrs of age, eGFR 77±16 ml/min/1.73m², BMI 34.6±5 kg/m²); and DCR (n=9, 5 F, 46±13 yrs of age, eGFR 68±21 ml/min/1.73m², BMI 34.1±5 kg/m²). Age and eGFR did not differ between groups but BMI was higher in the IFM compared to CON (p=0.031). Metabolite changes are depicted in Figure 1.

Conclusions: There are changes at one year in metabolites in adults with ADPKD between control, metformin, intermittent fasting, and daily caloric interventions. Further research is needed to identify metabolic profile shifts involving drug and dietary interventions.

PO1256

Identification of CLC-5, the Electrogenic 2Cl−/H+ Exchanger, as the Dominant Apical Chloride Secretory Transporter in Kidney Cyst Epithelium in Tuberous Sclerosis

Sharon J. Barone, Marybeth Brooks,1,2 John J. Bissler,3 Jane J. Yu,4 Kamyar A. Zahedi,1,3 Manoocher Soleimani,1,2 University of New Mexico Health Sciences Center, Albuquerque, NM; 2Raymond G. Murphy VA Medical Center, Albuquerque, NM; 3Le Bonheur Children's Hospital and St. Jude Children's Research Hospital, Memphis, TN; 4University of Cincinnati College of Medicine, Cincinnati, OH.

Background: Cyst expansion in Tuberous Sclerosis Complex (TSC) or PKD requires secretion of chloride into the cyst lumen as the driving mechanism for salt accumulation. In PKD, C1 secretion into the cyst lumen is mediated via the eAMP/PKA-stimulation of CFTR in principal cells consequent to the V2 receptor activation by AVP. Kidney cyst epithelium in TSC differs from PKD in that cyst epithelium in TSC is comprised of genotypically normal A-intercalated cells, which do not exhibit noticeable expression of either CFTR or the V2 receptor. The identity of the Cl- secreting molecule(s) in TSC cyst epithelia remains unknown. Based on RNA Seq analysis in kidneys of Tsc1 KO mice, we hypothesized that the chloride transporter CLC-5 is expressed on the apical membrane of A-intercalated cells in cyst epithelia of humans and animal models of TSC. CLC-5 is a 2Cl−/H+ exchanger that is located in collecting duct A-intercalated cells where it is predominantly localized to endosomes and plays a critical role in dissipating H+ secretion and membrane depolarization by H+-ATPase. This allows parallel movement of Cl− and H+ into the endosomes.

Methods: Double immunofluorescence labeling demonstrated remarkable colocalization of CLC-5 and H+-ATPase on apical membranes of an overwhelming numbers of cyst epithelial cells in all models of TSC, including the human kidney cysts. In contrast, kidney cysts in Pkd1 mutant mice showed no apical CIC-5 expression and very few H+-ATPase expressing cells.

Conclusions: These are the first reports on apical membrane localization of CLC-5 in A-intercalated cells in any disease state, and suggest that similar to late endosomes/lysosomes, CLC-5 and H+-ATPase may function synergistically on cyst epithelia by secreting Cl− and H+ into the cyst lumen. These results strongly point to enhanced translocation of CLC-5 and H+-ATPase from late endosomes/lysosomes to the apical membrane of cyst epithelia in TSC.

Two Years In: The Development and Basic Characteristics of a National Patient-Powered Registry in ADPKD

Elise Hoover,1 Beverley A. Benson,1 Neera K. Dahl,2 Berenice Y. Gitomer,3 Amy Manelli,1 Michal Murg,2 Meyeon Park,3 Chris Rusconi,3 Stephen L. Seliger,4 Ronald D. Perrone,4 Terry J. Watnick,4 PKD Foundation,4 Presbyterian/St. Luke’s, CO; 5Yale University, New Haven, CT; 6University of Colorado – Anschutz Medical Campus, Aurora, CO; 7The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 8UCSF Medical Center, San Francisco, CA; 9University of Maryland Baltimore, Baltimore, MD; 10Tufts Medical Center, Boston, MA.

Background: The therapeutic pipeline in autosomal dominant polycystic kidney disease (ADPKD) has grown, generating a need for more patient participation in clinical trials. To facilitate US ADPKD patient enrollment and to encourage the utilization of patient-reported outcomes in trial design, the PKD Foundation (PKDF) designed a national ADPKD Registry.

Methods: The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdrce). Participants are consented through the online system and complete a series of modules. The Core Questionnaire includes diagnosis, latest kidney function tests, and comorbidities. Family history, diet and lifestyle, quality of life, and complications of liver cysts, and vascular outcomes are queried.

Results: Between 9/4/19 and 5/1/21, 1,580 ADPKD patients have registered and completed the Core Questionnaire. Participants have a median age of 49 years, 73% have not reached ESKD, and 79% reported a family history of the disease. Currently, the cohort is 71% female, 93% Caucasian, 4.8% Hispanic/Latino and 2.5% African American. Strategic efforts are in development to increase diversity in the cohort. Nearly three quarters of participants had not previously participated in research, with only 27% indicating that they had been in another PKD study or clinical trial. All participants have consented to be contacted about future studies. Many will likely qualify for ongoing trials based on completed module data. Thus far, the Registry platform has made over 2,200 patient-contracts contacting about six clinical studies, with some individual overlap due to similar eligibility criteria.

Conclusions: The ADPKD Registry is a longitudinal research tool intended to capture ADPKD patient-reported data and is designed to impact research in multiple ways. It will allow for a range of analyses to be performed on ADPKD early from disease through dialysis and post-transplant outcomes. Additionally, modules on health care access & utilization and COVID-19 impact will help the PKDF better understand the challenges of this community.

Polycystic Kidney Disease and Race

Alexandra Hayward, Riia L. McGill, Milda R. Saunders, Arlene B. Chapman. University of Chicago Division of the Biological Sciences, Chicago, IL.

Background: Racial/ethnic differences in the development of kidney failure (ESKD) and transplant (TX) access are well-documented. ESKD is anticipated in familial autosomal dominant polycystic kidney disease (ADPKD), providing the opportunity for greater ESKD preparation. We sought to define the impact of race on ESKD/TX outcomes in ADPKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Percent Δ of metabolites. Values are expressed as mean ± SD.
Methods: White (W), African-American (A), or Hispanic (H) ADPKD patients were identified in USRDS 1(2000-6:2018); demographic and laboratory data were obtained. Median income was derived from US Census. Models included: age at ESKD (linear), pre-emptive TX (logistic), and TX after dialysis initiation (Cox), adjusted for age, sex, albumin, hemoglobin, eGFR, insurance, income, ESKD Network, and employment, with W as reference.

Results: Among 41,485 patients, (77.3% W, 13.3% A, 9.4% H), characteristics/ outcomes are shown in Table 1. AA and H had lower median income and less private insurance, pre-ESKD nephrology care, and employment. For AA and H, peritoneal dialysis and TX were less common than in W. Albumin, hemoglobin, and GFR were lowest in W. ESKD occurred 2.2 ± 0.2 and 4.8 ± 0.3 years earlier in A and H, compared to W. Adjusted odds of pre-emptive TX were 0.38 (0.33, 0.42) and 0.47 (0.40, 0.55) for A and H. Adjusted hazards for TX after dialysis initiation were 0.60 (0.55, 0.65) for A and 0.78 (0.72, 0.85) for H, P=0.001 for all. TX rates for A vs W by network are shown in Figure 1.

Conclusions: Despite the hereditary nature of ADPKD, renal outcomes differ by race, attributed to in part, economic and geographic factors. Health inequity is a contributing factor to patient outcomes in ADPKD that needs to be addressed.

PO1260
Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Kristen L. Nowak,1 Heather Farmer-Bailey,1 Wei Wang,1 Zhiyong You,1 Cortney Steele,1 Melissa A. Cudnaphornchai,1 Jelena Klawitter,1 Nelis Piotel,1 Diana George,1 Anna Jovanovich,1 Danielle Soreno,1 Berenice Y. Gitomer,1 Michel Chonchol,1 2 Rocky Mountain Hospital for Children, Denver, CO; 3 VA Eastern Colorado Health Care System, Aurora, CO; 4 Children’s Hospital Colorado, Aurora, CO.

Background: Clinical manifestations of autosomal dominant polycystic kidney disease (ADPKD) can begin in childhood, including evidence of vascular dysfunction, an important predictor of cardio-vascular events and mortality. Curcumin is a polyphenol found in turmeric that reduces vascular dysfunction in rodent models and humans free from ADPKD. It also slows kidney cystic progression in a murine model of ADPKD.

Methods: We hypothesized that curcumin supplementation would reduce vascular dysfunction (brachial arterial flow-mediated dilation [FMD]) and aortic pulse-wave velocity (aPWV) in children and young adults with ADPKD. In a prospective, randomized, controlled, double-blind trial, n=68 participants 6-25 years of age with ADPKD and an estimated glomerular filtration rate >80 mL/min/1.73 m² were randomized to either curcumin supplementation (25 mg/kg body weight/day) or placebo administered in powder form for 12 months. We also assessed change in circulating and urine biomarkers of oxidative stress/inflammation and kidney function (height-adjusted total kidney volume [htTKV], exploratory endpoint) by magnetic resonance imaging. In a subgroup of participants ≥18 years, we also assessed vascular oxidative stress as the change in FMD at an acute infusion of ascorbic acid.

Results: Fifty-seven participants completed the trial. Participants were 18.5 (means ± SD) years, 55% female, and 85% non-Hispanic White. The co-primary endpoint, FMD (%,), did not change in the curcumin group (baseline: 9.4 ± 4.1; 12-months: 10.6 ± 3.9), as compared to the placebo group (baseline: 8.9 ± 4.0; 12-months: 9.3 ± 4.5; p=0.007) and did not change in the other co-primary endpoint, aPWV (cm/sec) (baseline: 51.7 ± 106; 12-months: 517 ± 18; placebo: baseline: 51.8 ± 82 cm/sec 12-months: 525 ± 95 cm/sec; p=0.53). There was no curcumin specific reduction in vascular oxidative stress, nor any changes in mechanistic biomarkers. htTKV also did not change over the 12-month study with curcumin administration as compared to placebo.

Conclusions: Curcumin supplementation does not reduce vascular dysfunction or slow kidney growth in children/young adults with ADPKD.

PO1261
Polycystic Kidney Disease Associates with Increased Myopia and Retinal Breaks

Background: Ophthalmologic manifestations in Polycystic Kidney Disease (PKD) are not known.

Methods: We conducted a retrospective cohort study using EMR data extraction. All adult patients with polycystic kidney disease (“PKD”) and CKD from another cause (“non-PKD/CKD”), seen at our center between 1/1/2000-4/30/2020, and Eye disorders of interest in these 2 cohorts were identified using ICD-9/10 diagnostic codes. The date of the first visit to Nephrology clinic was regarded as “Index date”. The prevalence of Eye disorders at the index date was compared between “PKD” and “non-PKD CKD” cohorts.

Results: A total of 859 patients with “PKD” and 8309 patients with “non-PKD/CKD” were included. Majority of patients in both groups were male (58% [498] and 54% [4457]) and identified as White (88% [758] and 86% [7185]). At the index date, PKD patients were younger (mean age 55 vs 60 years in non-PKD/CKD; p<0.01) and had shorter follow up time (median 901 vs 1311 days; p<0.01). PKD patients had higher eGFR (52 [31-81]; N=795) vs 43 ml/min/1.73m² [29-59; N=7342]; p<0.01) and had shorter follow up time (median 901 vs 1311 days; p<0.01). Myopia and all Retinal breaks (with or without detachment) were found to be higher in PKD as compared to non-PKD/CKD after multivariable adjustment for age, gender, race, diabetes and follow up time (adjusted odds ratio 1.4 [95% CI: 1.1-1.7] and 1.7 [1-2.8]; respectively; p<0.01). Retinal breaks with detachments by themselves were also more frequent in PKD but did not reach statistical significance (Table). Peripheral retinal degeneration was similar between the two groups.

TSC2 Loss-of-Heterozygosity Mutations Drive Cystogenesis in Kidney Organoids Generated from Tuberous Sclerosis Complex Patient-Derived Induced Pluripotent Stem Cells

Dario R. Lemos. Brigham and Women’s Hospital, Boston, MA.

Background: Kidney cysts are the second most common renal manifestation of TSC, accounting for 50% of kidney lesions. The genetic mechanisms driving TSC-associated cystic kidney disease remain poorly understood.

Methods: We induced nephric differentiation of a series of TSC patient-derived iPSCs into 3D cystic models. All TSC2 hiPSCs developed cystic structures in ~0.5 cysts/well for +/+ and ~4.7 cysts/well for −/− organoids. Of note, 2-D cyst-like structures developed in a spontaneous manner, that is without addition of cAMP as TSC2 containing podocytes expressing podocalyxin 1 (PODXL). By Day-21 of differentiation, organoids sequentially segmented into distal tubules expressing cadherin 1 (CDH1), proximal tubules and glomerular components.

Results: Analysis of Day-21 two-dimensioinal cell cultures showed that nephrons derived from TSC2−/− and TSC2−/− hiPSCs presented normal morphology, and were sequentially segmented into distal tubules expressing cadherin 1 (CDH1), proximal tubules containing brush borders labeled by lotus tetragonolobus lectin (LTL) and glomeruli containing podocytes expressing podocalyxin 1 (PODXL). By Day-21 of differentiation TSC2−/− hiPSC-derived kidney tissues showed cavitated structures resembling cysts. Analysis of nephron segments showed positive signal for both CDH1 and LTL, indicating the cyst lining could comprise distal tubule and/or proximal tubule cells. The observed frequency of cyst formation was ~4.7 cysts/well for TSC2+/- +/+ cultures, compared with 0 cysts/well for TSC2−/− −/− organoids also showed that while individual tubule segments were involved in cyst lining, in certain cases a combination of both proximal and distal tubule cells were detected, suggesting improper segmentation mechanisms in the absence of TSC2. While single-cell lining layers were associated with well-defined tubule segments, mixed-cell lining regions were multi-layered, resembling the columnar epithelium observed in the renal cysts of TSC patients.

Conclusion: TSC2 organoids provided evidence supporting LOH events accounting for 50% of kidney lesions. The genetic mechanisms driving TSC-associated kidney disease remain poorly understood.

PO1265

A Combination Therapy with Two Dietary Supplements Acting on Different Mechanisms Ameliorates Disease Progression in a Rat Model of Polycystic Kidney Disease

Ilse A. D’Amato,1 Morgan J. Sparrow,2 Amy B. Huynh,3 Merlin Airik. University of Pittsburgh, Pittsburgh, PA.

Background: Nephropathies-related cystopathies (NPHP-RC) are a group of autosomal recessive kidney diseases that are characterized by renal cysts, tubulointerstitial fibrosis and basement membrane disruptions. Mutations in ankyrin repeat and sterile alpha motif domain containing 6 (ANKS6) gene were recently identified as causing nephropathies in mice type 16 (NPHP16) in humans. Although, several mouse models with Anks6 mutations have been reported, its function in the kidney remains incompletely understood. In order to investigate the disease mechanisms of nephropathies in the function of Anks6 in kidneys we deleted Anks6 expression in the nephron progenitor population using the S6Cre transgenic mouse line.

Methods: Six2Cre transgenic mice were crossed with Anks6fl/fl mice to generate Six2Cre:Anks6fl/− mice. Gross morphological characterization and tissue histological analysis of mutant mice was performed on E15.5, E18.5 and P1 kidneys. Cysts were embedded in paraffin and sectioned at 5μm for histological staining with hematoxylin and eosin. Immunofluorescence (IF) staining was performed to label neprhenoid segment and glomerular components. Anks6 expression in the kidney was examined using X-gal staining. ANKS6 role in epithelial cell polarity was investigated using a squashed assay after 4X36 sRNAi knockdown in IMCD3 cells.

Results: Six2Cre:Anks6fl/− mice die at birth due to kidney failure. Anks6 expression was ubiquitous in the developing kidney. Histological analysis revealed that deletion of Anks6 in nephron progenitors leads to proximal tubule morphogenesis defects and glomerular hyperplasia. Inactivation of the glomeruli showed reduced recruitment of mesangial cells and decreased podocyte numbers in mutant kidneys. Proximal tubule development was similarly arrested at an early tubular morphogenesis stage resulting in short straight tubules. Knock down of ANKS6 in cell culture resulted in polarization and loss of epithelial phenotype.

Conclusions: Our data demonstrate that Anks6 is required for proximal tubule morphogenesis and glomerular development. Deletion of Anks6 in nephron progenitors leads to severe kidney morphogenesis defects that are incompatible with life. Spheroid analysis revealed that ANKS6 has an important role in epithelial polarity and lumen formation. Future work will address which morphogenic pathway(s) are regulated by Anks6 during nephrogenesis.

PO1264

The Impact of Salt Deficiency on Acid-Base Homeostasis in Autosomal Recessive Polycystic Kidney Disease

Jonathan Mallory,1 Morgan J. Spicer,2,3 Mark Domondon,1 Ryan Schibli,1,2 Denisha R. Spires,1,2 Mikhail Formin,4 Thelma Amoah,5 Daria Ilatovskaya,5,6 1 Medical University of South Carolina, Charleston, SC; 2 Augusta University, Augusta, GA.

Background: In healthy subjects, dietary salt restriction exacerbates imbalances of acid-base homeostasis. The disease progression of autosomal dominant PKD is associated with increasing serum bicarbonate levels and metabolic acidosis, however very little is known about acid-base imbalance in autosomal recessive (AR) PKD, particularly, in response to dietary restrictions. Here we hypothesized that a salt-deficient (SD) diet leads to electrolytic and acid-base imbalance in ARPKD.

Methods: Male and female PCK/CrljCrjPhdlpc1/crl (PCK) rats were fed a SD (0.01% NaCl, Deyts Inc) diet for 1, 3, 5, 7 and 9 weeks beginning at 4 weeks of age. Before each endpoint, urine was collected, and plasma and tissue samples were harvested. Plasma and urinary creatinine, electrolytes, BUN, and plasma aldosterone levels were measured. Cystic index was analyzed with ImageJ. Statistical analysis was performed with 2-way ANOVA.

Results: Two-kidney-to-body-weight, weight consumption, plasma K+ and urine output decreased over the course of the SD diet in both sexes. Plasma Na+ and Cl- as well as creatinine increased; and BUN did not change. Plasma aldosterone increased from week 1 to week 5 (week 1: 2.6±1.5 mg/mL (M) and 7.7±1.1 (F), p<0.001 (over time)), followed by a return to baseline by week 9 of the SD diet. The frequency of cyst formation was significant in cystogenesis in female rats from week 1 to week 9 of the SD diet (week 1: 142.4±1.9%, week 9: 36.3±2.4%). Further, we observed an increase in plasma pH (week 1: 6.98±0.08 (M) and 6.83±0.03 (F), week 5: 7.16±0.08 (M) and 7.13±0.02 (F), p<0.001 (over time)) and a decline in urine pH (week 1: 7.69±0.42 (M) and 8.75±0.08 (F), week 9: 5.80±0.07 (M) and 5.72±0.08 (F), p<0.001 (over time)) in both sexes throughout the dietary challenge.

Conclusions: PKC rats on a SD diet exhibit acidification of urine pH and an increase in plasma pH. We can speculate that acid base transporters such as NHE1, NBCe2, and pendrin are upregulated to conserve plasma sodium leading to a shift in acid-base homeostasis. Further studies aimed at elucidating the role of these transporters may add to the current knowledge regarding the pathogenesis and dietary management of ARPKD.

A Single-Center Experience of ARPKD in Adults

Mceunukhi Sambharia, Sonali Gupta, Christie P. Thomas. The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) is an inherited cystic disorder with presentation in infancy or early childhood. ARPKD has an incidence of 1-2/10,000 live births and arises from biallelic variants in PKHD1 encoding for fibrocytin, with variants in DZIP1 accounting for <1% cases. Imaging findings include large echogenic kidneys, poor corticomedullary differentiation, renal cysts or “salt and pepper appearance”. ARPKD-congenital hepatic fibrosis (ARPKD-CHF) complex consists of renal disease with biliary dilatation portal hypertension and splenomegaly. 50% develop ERSD in childhood with limited data on renal prognosis for those that present later.

**Methods:** A retrospective chart review of patients >16 yr of age with cystic kidney disease and/or congenital hepatic fibrosis to identify possible cases of ARPKD. Clinical phenotype (compatible hepato-biliary and renal involvement) and/or genetic testing were used to verify the diagnosis.

**Results:** We identified 29 patients with ARPKD-CHF, out of which 13 were >16 yr (mean 32.4±8 yr). 38% were males, 15% identified as Hispanic and the rest as non-Hispanic white. All had radiographic evidence of renal and/or hepato-biliary involvement and of 5 and 13 patients had biallelic variants in PKHD1. On the most recent imaging study, 92% had renal cysts, 23% large echogenic kidneys, 23% poor renal corticomedullary differentiation, 15% medullary sponge kidney, 23% with salt and pepper pattern. Only 3 (3%) had reached ESRD or received a kidney transplant, while the remaining had a mean eGFR of 46ml/min/1.73m2. Of these, 50% had eGFR >40ml/min/1.73m2. Amongst those with hepato-biliary involvement, 40% had CHF, 53% portal hypertension, 40% splenomegaly, 26% liver cysts.

**Conclusions:** We describe a cohort of patients with ARPKD, the majority presenting as adults, with an eGFR >60ml/min/1.73m2. A significant number of these patients had multiple large renal cysts. Absence of obvious renal phenotype in patients with congenital hepatic fibrosis can make the diagnosis challenging, requiring a high degree of clinical suspicion. We believe that we may have missed a significant number of patients without obvious combined hepatic and renal abnormalities who may have had delayed onset ARPKD. Our small series suggest that some patients with ARPKD present as adults with a more limited phenotype that can easily be mistaken for ADPKD.

**PO1267**

Analysis of Somatic Mosaic Mutations in Nephropathy-Associated Genes Reveal Candidate Disease-Causing Mutations in Previously Germ-line-Negative Cases

**Background:** Somatic mosaic variant (SMV) arises due to postzygotic mutations that results in two genetically distinct populations of cells in the same person. SMVs may be missed by standard search for germline (or inherited) mutations, and the use of dedicated analytic pipelines for SMVs can potentially explain “exome negative” cases.

**Methods:** We searched for SMVs in 248 patients who underwent exome sequencing for congenital kidney anomalies. Somatic mutations were identified through GATK Mutect2 software, and clinically annotated following the American College of Medical Genetics and Genomics (ACMG) guidelines. We focused the analysis on 625 nephropathy-associated genes previously used for the germline analysis.

**Results:** Previous analyses germline variants had identified 52 diagnostic variants in this cohort (20.9% diagnostic rate). In addition, the SMV pipeline identified candidate disease-related SMVs in 4 “exome-negative” patients (1.6% of cases). The SMVs were detected in RET, ENG and COL4A5, and are reported in Table 1. This improved the diagnostic rate of the cohort to 22.5%.

**Conclusions:** Analysis of somatic mosaic variants can increase diagnostic yield in patients with congenital kidney anomalies. Application of the SMV pipeline may increase diagnostic in other forms of kidney disease.

**SVM identified in congenital anomalies kidney patients**

Comparison of Imaging Approaches for Quantifying Total Kidney Volume (TKV) and Fibrosis in a Mouse Model of Polycystic Kidney Disease (PKD)

Carien R. Sussman, Heather L. Holmes, Ka Thao, Adriana Gregory, Ryan J. Meloche, Yaman G. Mkhairmer, Harrison H. Wels, Slobodan Macura, Peter C. Harris, Timothy L. Kline, Michael T. Romero. Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** 3D imaging and histology are critical tools for assessing PKD in patients and animal models. Magnetic resonance (MR) imaging provides an resolution, but is time consuming, expensive, and access to equipment and expertise is limiting. Robotic ultrasonic (US) imaging is lower resolution but fast. Similarly, picrosirius red (PR) staining and standard light microscopy is used to assess fibrosis; however, alternative methods for quantifying PR staining have been shown in other tissues to allow greater sensitivity and more detailed characterization.

**Methods:** Pkd1<sup>−/−</sup> mice were compared to Pkd1<sup>−/−</sup> (WT). TKV was quantified from US and MRI (7T and 16T) at 1, 3, and 4 months old. US measurements of kidney and heart volume were performed using the Vevo and EchoPlex image analysis software. Inter-observer variation for quantifying fibrosis using US was assessed using Bland-Altman analysis. PR-stained kidneys were imaged using standard light microscopy, circularly (c) polarized light with binning into four categories of collagen thickness, and fluorescent imaging with analysis using eFire. Renal cAMP and BUN were measured using standard approaches, and GFR was measured using a transdermal fluorescent sensor (MediBead).

**Results:** US detected increased TKV at 1 month and was similar to MR (7T or 16T). Inter-observer variability (2 observers) was greater for US than MR, but still able to detect differences between genotypes and time points. US allowed scanning in 2-5 minutes/mouse while MR required 20-30 minutes. Cylindrical light showed a greater percentage of the thickest collagen fibers in RC/RC mice, and a corresponding lower percentage of each of 3 categories of thinner collagen fibers. Preliminary data using fluorescence microscopy showed a higher density of collagen fibers in RC/RC mice vs. WT. Analysis of collagen fiber angle, length, straightness, and width is ongoing. RC/RC had a lower GFR, higher BUN, and elevated cAMP vs WT. No differences were observed in cardiac function (ejection fraction, heart rate, or cardiac output).

**Conclusions:** These studies demonstrate the utility of US and alternative approaches of quantifying fibrosis using PR.

Phenotypic Heterogeneity in Type IV Collagen-Associated Nephropathy: The Cystic Phenotype

Letizia Zeni,1,2 Cinzia Mazza,1 Diego Tos1, Laura Econimo,1 Roberta Cortinovis,1 Chiara Dordoni,1 Gianfranco Savoldi,1 Francesco Scolari,1,3 Claudia Izzzi,1 Azienda Socio Sanitaria Territoriale degli Speziali Civili di Brescia, Brescia, Italy;1 Universita degli Studi della Compagnia Italiana Sanitari, Caserta, Italy;1 Universita degli Studi di Brescia, Brescia, Italy.

**Background:** Exome sequencing (ES) revealed mutations (mut) in type IV collagen (COL4) genes in patients (pt) diagnosed with other forms of chronic kidney disease (CKD), supporting the concept of spectrum of phenotypes for COL4-Nephropathy. Unexpectedly, some pt with CKD presenting with cystic phenotype were identified with COL4-Nephropathy by ES.

**Objectives:** The retrospective study included 130 pt referred to outpatient clinic of genetic kidney diseases of ASST Speziali Civili di Brescia from 2002 to 2021 and diagnosed with COL4-Nephropathy. Based on the presence of multiple and bilateral renal cysts on imaging (fig1), a group of pt with cystic phenotype was selected (27/130,21%).

**Methods:** The study contributes to expand the emerging phenotypic heterogeneity of COL4-Nephropathy and suggests that cystic phenotype could predict progression of kidney disease.
Rare Variants in Syndromic Ciliopathy Genes as Novel Causes of Isolated Renal Disease in Adults

Zachary T. Sentell,1,2 Lina Mougharbel,1 Sima Babayeva,1 Natascia Anastasio,2 Lee lee Chu,1 Murielle M. Akpa,1 Paul R. Goodyer,1,2 Elena Torban,1,2 Thomas M. Kitzler.1,2 Research Institute of the McGill University Health Centre, Montreal, QC, Canada; 2McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.

Background: Renal ciliopathies are among the commonest genetic causes of end-stage renal disease (ESRD). Ciliopathies are caused by defects of the primary cilium, an antenna-like organelle with mechanosensory roles, crucial for organ development and maintenance. Disorders of the cilium present early with multi-organ involvement, but some individuals present as adults with organ-specific phenotypes, potentially due to milder mutations and organ-specific effects.

Methods: We identified rare variants in two ciliopathy genes in two unrelated adults presenting with ESRD. ACMG guidelines did not classify these variants as pathogenic, requiring functional validation to establish a causal genotype-phenotype relationship.

Results: Bi-allelic CC2D3 missense variants were identified in a patient with ESRD, suggestive of an isolated renal ciliopathy. CC2D3 is essential for ciliogenesis, with complete loss of cilia in knockout mice (Development 135:4049 2008). Severe mutations were reported in patients with a syndromic ciliopathy (OPD XIV; OMIM# 615948), but no cases of isolated renal disease have been reported. We detected a moderate but consistent shortened cilia length in skin fibroblasts and renal epithelial cells from our proband, suggestive of a milder ciliary defect. Remarkably, the proportion of ciliated cells was significantly reduced in renal epithelial cells but not in fibroblasts, indicating an organ-specific ciliogenesis defect. Pathogenic variants in CC2D2A cause Joubert and Meckel syndrome, with no isolated renal presentations observed to date (Mol. Genet. Genom. e1603 2021). We identified a novel homozygous nonsense variant (Arg34*) in CC2D2A, classified as not pathogenic due to an alternate start-codon, in a previously healthy 37-year-old male with isolated ESRD of unknown etiology. Using public data (GTEx), we show that protein-coding transcripts harbouring this variant are the predominant transcripts in the kidney when compared to tissues relevant to CC2D2A-related phenotypes (e.g., cerebellum, liver).

Conclusions: Rare variants in known syndromic ciliopathy genes cause isolated renal disease in adults due to potential organ-specific effects. Using variant classification schemes without functional analysis may not accurately capture the genetic contribution to adult ESRD.

Targeted Exome Sequencing Application for Genetic Diagnosis of Pediatric Patients with Cystic Kidney Disease

Jeeu Min,1 Hyeonju Lee,1 Peong Gang Park,2 Yo Han Ahn,2 Hee Gyu Kang,2 Ji Hyun Kim,2 Eujin Park.1,2 Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea; 3Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 4Hallym University Medical Center, Yeongdeungpo-gu, Seoul, Republic of Korea; 5Korea Ministry of Health and Welfare, Seoul, Jeong, Jeongp, Republic of Korea.

Background: Detection of a monogenic cause of chronic kidney disease accounts for almost 30% of cases in the pediatric cohort. Of these, the highest yield in the genetic diagnosis is currently seen in cystic kidney disease. Nearly 100 monogenic causes of renal cystic ciliopathies have been identified and the genetic diagnostic yield is reported to be approximately 50%. Here, we report the results of genetic testing in a cohort of Korean pediatric patients with cystic kidney disease.

Methods: From July 2019 to February 2021, children under the age of 18 with three or more cysts in both kidneys on imaging studies were recruited from three pediatric nephrology centers in Korea. Genetic identification was performed by targeted exome sequencing (TES) including 89 genes known as cystogenesis-related or causative-ciliopathy.

Results: A total of 46 pediatric patients with cystic kidney disease were recruited. The median age was 9.2 years (IQR, 5.49-14.53) and 60% were boys. Twelve patients (27.9%) had a family history of cystic kidney disease. The clinical diagnoses of the patients were 10 patients with autosomal dominant polycystic kidney disease, 5 patients with autosomal recessive polycystic kidney disease, 2 patients with multicystic dysplastic kidney, 1 patient with nephronophthisis, and the others were undiagnosed. The mutation detection rate was 52.2% (24 of 46). PKD1 was the most common causative gene (16 patients, 34.8%), followed by HNF1B (3 patients), PAZ2 (2 patients), PKD2 (1 patient), PKD1D1 (1 patient), and NPHP3 (1 patient). Genetic mutations were identified in all patients (12 of 12) with a family history of cystic kidney disease. In patients without a family history, genetic mutations were found in 35.3% (12 of 34).

Conclusions: The mutation detection rate in this cohort of Korean pediatric patients with cystic kidney disease was 52.2% by TES. Mutations in PKD1 were found most commonly, and the mutation detection rate was higher in patients with a family history of cystic kidney disease. For children with cystic kidney disease, molecular genetic testing is essential for an accurate diagnosis, personalized treatment, and prognosis prediction.

The Prognostic Factors of Cyst Infection due to ADPKD

Hiroki Mizuno,1 Junichi Hoshino,2 Yoshifumi Ubara,1 Toranomon Byoin Bunin, Kawasaki, Japan; 2Toranomon Byoin, Minato-ku, Japan.

Background: Renal or hepatic cyst infection is a complication of autosomal dominant polycystic kidney disease (ADPKD), which requires hospitalization and causes death. Cyst aspiration was the gold standard to diagnose this disease. Because of its invasiveness, several diagnostic criteria without using cyst aspiration have been proposed, but prognostic factors of cyst infection have not been analyzed in this setting.

Methods: Inclusion criteria of this retrospective cohort are ADPKD patients who were admitted in Toranomon hospital and Toranomon hospital Kajigaya between 2016 April and 2021 March, and who were diagnosed as cyst infection based on MRI findings, which we previously published. Primary composite endpoint was defined combination of death, septic shock, or hospitalization for more than four weeks, and secondary outcomes were defined by each outcome mentioned above. Logistic analysis was planned to assess the predictors of the outcomes.

Results: One hundred ninety patients were eligible to this study. The average age was 65.0±9.2 years old, 116 (61.1%) were female, and the average height-adjusted total liver volume (htTLV) was 3322±2286 mL per meter, and 164 (86.3%) had hemodialysis therapy. Compositive outcome occurred in 109 (57.4%): 25 death, 36 shock, and 98 longer-hospital-stay. Multivariable logistic regression model after adjusted related variables showed that older age (odds ratio(OR) 1.10 (95% confidence interval: 1.10-2.54), p-value=0.02), male (OR 2.49(1.66-3.53), p-value=0.02), higher htTLV (OR 2.29 (3.39-3.77), p<0.01), lower mean blood pressure at admission (OR 0.735(0.579-0.9319), p<0.01), larger size of infectious cyst (OR 1.42(1.06-1.91), p<0.02) were significantly associated with the composite outcome. Although the culture-positive case or higher white blood cell count were not significantly associated with the primary outcome, they were associated with septic shock due to cyst infection.

Conclusions: Baseline characteristics at admission were associated with the prognosis of cyst infection diagnosed by MRI-based criteria, which was similar to cyst infection diagnosed by cyst aspiration. Culture-positive case or higher white cell count were reported as risk factors requiring more invasive therapies that could lead to septic shock and need longer hospitalization in our study’s cohort.
Uncovering the Role of the Extracellular Matrix in ADPKD Progression

Elisa Pellegrino,1,2 Maria Elena Steidl,1,2 Marco Chiariulli,2 Alessandra Boletta,2 Elisa Agnese Negro.1 Università Vita Salute San Raffaele, Milano, Italy; 1IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Polycystic Kidney Disease (PKD) is a genetic disorder due to mutation in either Pkd1 or Pkd2 genes and characterized by bilateral cysts formation. We recently uncovered a direct role of Pkdc1, the protein product of Pkd1 gene as a mechanismosensor of extracellular stiffness. We found that Pkdc1 interacts mediator inhibition of actomyosin contraction that mediates the cellular response to the rigidity of the Extracellular Matrix (ECM). Based on these findings we speculated that Pkd1 cells fail to properly respond to the extracellular mechanical force of ECM leading to excessive matrix deposition and proliferation. In line with this, kidneys of end-stage PKD patients show enhanced fibrosis typical of cystic kidney disease and tumors. We then wondered whether PKD ECM is a part of an active Cyst Microenvironment (CME), exerting a key role in the evolution of the disease.

Methods: We characterized CME in the renal tissue of an aggressive Pkd1Δcre/+; Ksp-Cre and a low aggressive Pkd1Δcre/+; Tam-Cre inducible mouse models. To study the composition and the mechanical properties of the cystic ECM we decellularized cystic kidneys obtaining ECM-derived kidney scaffolds. Furthermore, we isolated matrix from Pkd1Δcre/+ fibroblasts in vitro.

Results: We have characterized the renal tissue microenvironment of two Pkd1 inducible mouse models at a late stage of the disease confirming the presence of fibrosis, immune infiltrates and progressive accumulation of collagen I. In line with an active role of PKD ECM, we showed that ECM-derived kidney scaffolds were able to stimulate pro-inflammatory cytokine expression in PKD fibroblasts in vitro.

Conclusions: ECM plays an active role in the progression of ADPKD disease.

17q12 Deletion Syndrome Presenting as Congenital Diaphragmatic Hernia in a 2-Month-Old Infant

Introduction: 17q12 deletion syndrome results from the loss of as many as 15 genes on the long arm of chromosome 17 including the hepatocyte nuclear factor-I-beta gene (HNF1B). Heterozygous pathogenic variants, whole gene deletion, or duplication in HNF1B are frequently linked to inherited kidney malformations including hyperechoic kidneys, kidney cysts, solitary kidney, and hydrenephrosis as well as extrarenal phenotypic features. 17q12 deletion syndrome has also been linked to congenital diaphragmatic hernia (CDH). We present a case of an infant with hyperechoic and cystic kidneys, diagnosed postnatally with CDH.

Case Description: A 2-month-old female with a history of hyperechoic kidneys on prenatal ultrasound presented to the emergency department with increased work of breathing. A chest x-ray revealed left hemidiaphragm elevation, normal cardiac silhouette, and no focal pulmonary consolidation. Computed tomography of the chest confirmed the diagnosis of CDH. A repeat kidney ultrasound revealed diffuse hypechogenic kidneys and a focal kidney cyst within the right upper pole (Image 1). Genetic workup revealed a 1.9 megabase deletion on the long arm of chromosome 17 consistent with the diagnosis of 17q12 deletion syndrome.

Discussion: Pathogenic variants in HNF1B or whole gene deletion as part of 17q12 deletion syndrome should be considered in infants with hyperechoic kidneys with cysts, particularly in the context of extrarenal manifestations. Studies have examined the link between HNF1B and the development of a CDH. It is proposed that HNF1B is involved in the WNT signaling pathway that is critical to mesodermal differentiation and proper diaphragm formation. Only 4 other cases of HNF1B mutations associated with CDH are reported in the literature. Two cases describe HNF1B deletions, and 2 cases describe HNF1B duplications. It is possible that the high prenatal mortality of CDH could explain the paucity of this association.

Recurrent Pneumothorax in a Marfanoid Adolescent with Autosomal Dominant Polycystic Kidney Disease

Allison Miller, Legacy Health System, Portland, OR.

Introduction: Pneumothorax may be a rare extra-renal manifestation of autosomal dominant polycystic kidney disease (ADPKD), and may indicate co-inheritance of other genetic diseases.

Case Description: A 21 year-old man with ADPKD and pneumothoraces presented to nephrology clinic. A screening ultrasound in late childhood was completed due to his family history and confirmed ADPKD. The patient was normotensive and had a tall, thin habitus. His musculoskeletal examination was pertinent for several marfanoid findings, including increased arm span ratios, pes planus, and positive thumb and wrist signs. His eGFR was normal and he did not have proteinuria. He was hospitalized several times between ages 13-20 for recurrent pneumothoraces requiring left apical wedge and lower lobe resections with pleurectomy, and right upper lobectomy and pleurectomy.

Discussion: The patient’s lung collapse was attributed to primary spontaneous pneumothorax due to his tall stature and intermittent tobacco use. However, this cannot account for his high rate of recurrence. The extent of pneumothorax burden in this patient should be considered in context of his underlying polycystic renal disease. Pulmonary manifestations of ADPKD are not well understood and have only been described in a handful of case reports. Bronchiectasis and cystic lung disease are thought to occur as a downstream consequence of impaired parenchymal healing. Mutated polycystin-1 in ADPKD prevents normal ciliary function, which is imperative for coordination of cellular repair in bronchial smooth muscle cells. Evolving cystic lung disease in the setting of underlying ADPKD could explain this patient’s recurrent pneumothoraces. The possibility of a co-inherited connective tissue disease should also be considered in patients with ADPKD and pneumothoraces. “Overlap” disorders between ADPKD, Marfan syndrome and Tuberous Sclerosis (TSC) have been examined in linkage studies, and have chromosomal proximity. Marfan syndrome and TSC are associated with pneumothorax. Though our patient did not manifest criteria for TSC, his examination is consistent with a Marfan’s variant phenotype. This patient may be an example of co-inherited disease, and raises the question of whether it is under this circumstance that rare pulmonary complications become apparent. Clinicians should be aware of these overlap disorders in relation to ADPKD.

PO1279

Ruptured Intracranial Aneurysm as the Initial Presentation of ADPKD in a Pediatric Patient

Maroon Chedi, Foad T. Chebib, Christian Hanna. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is associated with multiple extra-renal manifestations, most notably intracranial aneurysms (ICA). Approximately 10% of ADPKD patients develop ICA during their lifetime. Subarachnoid hemorrhage (SAH) is a major complication of ICA and usually occurs during the end of the 3rd decade. Aneurysm rupture in children <18 years of age is extremely rare. We report a case of a 9-year-old boy presenting with symptomatic ICA rupture as the initial presentation of ADPKD, despite a negative family history of ICA.

Case Description: A 9-year-old boy presented to the emergency department with an abrupt onset of severe headache and lethargy after a fall. His family history was remarkable for ADPKD in his father and grandfather. None of his affected family members developed ICA or intracranial hemorrhage. Initial non-contrast computed tomography scan of the head showed frontal lobe hemorrhage. Additional imaging studies revealed a ruptured anterior communicating artery with SAH. Urgent aneurysm coiling was performed, his bleeding was controlled, and the patient survived. Due to his strong family history for ADPKD, a kidney ultrasound was performed and showed enlarged kidneys with multiple renal cysts bilaterally confirming the diagnosis of ADPKD. The patient’s father underwent a screening MRI of the brain at the age of 48 years and was negative for ICA.

Discussion: Our case of SAH due to ICA rupture as the initial presentation of ADPKD, in the absence of a positive family history of ICA or hemorrhage, has not been reported in children. Rare cases of subarachnoid hemorrhage in pediatric patients with ADPKD and a positive family history of ICA or hemorrhage have been described. Based upon available data, it is unclear if either widespread or targeted screening for intracranial aneurysms is beneficial for pediatric patients with ADPKD. Screening is reserved for patients with a family history of hemorrhage, migraine, stroke, patients undergoing major surgery, or patients with high-risk jobs. However, we do not screen children <18 years of age because of the extreme rarity of aneurysmal rupture at that age. Though extremely rare, when care physicians and pediatricians should stay aware that ICA rupture occurs in children with ADPKD and can lead to devastating complications, even in the absence of positive family history.

PO1280

Congenital Solitary Kidney in ADPKD: A Genotype-Phenotype Correlation

Romina Bucci, Marta Vespa, Maria Teresa Sciarrebone Alibrandi, Giancarlo Joli, Giulia Mancassola, Giuseppe Vezzoli, Paolo Munanta. IRCCS Ospedale San Raffaele, Milano, Italy.

Introduction: There are a very few cases of ADPKD associated with Unilateral Renal Agenesis (URA). The total amount is currently 9 cases known in the world and their renal function outcome is somewhat undefined.

Case Description: ZG is a pleasant 41-year-old man with a congenital solitary left kidney with multiple cysts and a genetic diagnosis of ADPKD. Familiarity is negative for ADPKD, but positive for URA (present in his sister and her son). Except for hypertension, there are no extrarenal ADPKD manifestations. Poster et al. analyzed 3 patients with a similar phenotype in a cohort of 182 ADPKD subjects, comparing how the volume of the single kidney increased (SKV) over time and how the GFR dropped, stratifying them for sex and age. A greater SKV in time has been recorded in these 3 patients, caused by both compensatory hypertrophy and cyst growth. Surprisingly though, their kidney function was better compared to controls. Late onset kidney failure is probably caused by hyperfiltration, and it is linked with a long-term worse outcome. In our case, ZG’s SKV increased less compared to another subject with same age and sex and with controls found in literature. Same goes for kidney function, which was better and more stable in a 10-year time-lapse compared to controls.

Discussion: The reason for this could be found in the PKD1 mutation: ZG has a missense mutation, while the aforementioned 3 cases had truncating ones. ZG’s increased SKV is probably more related to hypertrophy than cyst growth itself. Therefore, even in an unorthodox situation like this one, long-term outcome seems to depend on the genotype of the subject.

Note: Table shows values of SKV for patient ZG and patient with polycystic solitary kidney. For the matched 2-kidney ADPKD group is reported the SKV mean values with 95% CI. For this last group the volume given is that of the left kidney present in the other 2 cases. SKV is calculated from MRN scans. Creatinine clearance is estimated according to the Cockcroft-Gault formula. In the 2-kidney ADPKD group CCC is estimated by calculating both kidneys.

PO1281

Management of a Patient with ADPKD Who Needs Lithium

Katharine J. Senter, Omar H. Maarouf, JingJing Zhang. Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.

Introduction: N/A

Case Description: A 35-year-old female with borderline personality disorder and schizoaffective disorder presented to nephrology for autosomal dominant polycystic kidney disease (ADPKD). Her biological father had ADPKD and was on dialysis at the time of death. The patient has taken lithium for 10 years, and only lithium allows her to work and live independently. She presented with polydipsia and polyuria, indicating possible nephrogenic diabetes insipidus (DI) from lithium, essential hypertension since age 30, and constant headache; brain MRI was negative for aneurysm. Labs showed a lithium level between 0.3-0.9 mmol/L, creatinine between 0.6-0.75 mg/dL, eGFR of 85-90 ml/min, urine protein:creatinine ratio of 0.27-0.32 g/g, and urine osmolality <100 mOsmol/kg.

She was treated with 2.5 mg lithium, 10 mg amiloride, and 1350 mg lithium daily. Abdominal MRI without contrast showed scattered liver cysts and innumerable bilateral kidney cysts. Kidney volume indicated Mayo Class 1C PKD. Her father developed ESRD in his late 50s, suggesting rapidly progressive ADPKD class. Lithium nephropathy is typically characterized by 1-2 mm renal microcysts (Khan et al., Int J Psychiatr Med 50(3):290-298). The patient’s larger cysts, total kidney volume, and liver cysts suggest ADPKD. Genetic testing showed that the patient has a heterozygous mutation in c.12445+1G>T, expected to cause altered splicing and function of the PKD1 gene.
**Discussion:** Finding an appropriate agent to slow CKD progression is the current strategy to manage PKD. Her condition is complicated by likely lithium nephropathy. The TEMPO trial (Torres et al, N Engl J Med 367:2407–2418, 2012) showed that tolvaptan helps slow rapidly progressive ADPKD by inhibiting vasopressin’s effect, reducing cAMP production, further inhibiting cyst formation and growth (Wang X et al, J Am Soc Nephrol 19: 102–108, 2008; Aihara M et al, J Pharmacol Exp Ther 349: 258–267, 2014). Lithium can also inhibit vasopressin in the kidney, leading to nephrogenic DI (Bokenhauer et al, Nat Rev Nephrol11(10):576-88, 2015). In ADPKD, tolvaptan helps achieve a urine osmolality of less than 300 mOsmol/kg (Torres, Clin J Am Soc Nephrol. 13(11):1765-1776, 2018). Our patient already has polyuria and urine osmolality below 100 mOsmol/kg. Her condition requires agents targeting other pathways. For now, she is on lisinopril, with BP <110/75, and amiloride to limit polyuria.

**PO1282**

**A Case of Mistaken Identity: Alport Syndrome Masquerading as Polycystic Kidney Disease**

**Kana R. Amari, Jennifer A. Tuazon. Northwestern University Feinberg School of Medicine, Chicago, IL.**

**Introduction:** Alport Syndrome (AS) is an inherited nephritis caused by a collagen-IV-related mutation leading to abnormalities in the glomerular basement membrane. Patients may present with unexplained hematuria, proteinuria, with or without renal insufficiency. Here, we describe two cases of patients presenting with multiple bilateral renal cysts, initially diagnosed with autosomal dominant polycystic kidney disease (ADPKD), and who were later found to have Alport syndrome via genetic testing.

**Case Description:** We report two cases of patients followed in our nephrology clinic who were initially thought to have ADPKD. The first patient is a 75-year-old woman who was followed for long-standing hematuria, CKD3aA2, innumerable bilateral renal cysts, few livers cysts, cerebral aneurysms, and a family history of cystic kidney disease. Due to normal kidney sizes, genetic testing was done which revealed a pathogenic COL4A3 mutation, c.1372G>C (p.Gly458Arg). Our second patient is a 64-year-old man with a history of hematuria, CKD3aA2, sensorineural hearing loss, retinal detachment, and family history of hematuria. His genetic testing revealed an X-linked COL4A5 mutation c.367G>C (p.Gly123Arg).

**Discussion:** Very few cases have described an association with AS and cystic kidney disease. The causal mechanism for renal cyst formation and Alport syndrome is unknown. These cases illustrate the importance of considering alternate diagnosis when suspected ADPKD has atypical features such as normal kidney sizes or kidney dysfunction more than expected for the cyst burden.

Case #1 Bilateral renal cysts in COL4A3-related Alport syndrome

**PO1283**

**Heterozygous HSD11B2 Gene Mutations and Apparent Mineralocorticoid Excess (AME) in a Patient with Heterozygous ADPKD1**

**Celeste S. Chang,1,2 Xiang C. Liu,1,2 Chinatown Kidney Care, New York, NY; 1Mount Sinai Beth Israel Hospital, New York, NY; 2Weigong Memorial Hospital, Tofuen, Taiwan.**

**Introduction:** HSD11B2 gene which locates at Chromosome 16p22.1 and encodes the Type 2 isomorph of 11-beta-Hydroxysteroid Dehydrogenase that interconverts biologically active cortisol and inactive cortisone. Polycystin-1, encoded by the PKD1 gene, which locates at Chromosome 16p13.3. PKD1 gene forms a complex with polycystin-2 (PKD2) that regulates multiple signaling pathways to maintain normal renal tubular structure and function. We present a new finding of HSD11B2 gene in a patient with polycystic kidney disease.

**Case Description:** 58-year-old Chinese male presented with bilateral renal cysts and CKD Stage 3A. PMHx is significant for early onset HTN at the age of 45, Left ICH without residual weakness at the age of 46 years and episode of hypokalemia. Denied Licorice ingestion. Family history is positive for HTN and polycystic kidney disease in his mother and all three siblings. His BP was 145/91 mmHg, not controlled well with daily dose of oral Lisinopril 40 mg and Amlodipine 10 mg. His Na 141, K 4.7, CO2 27, BUN 20, Cr: 1.6, Hb 12.5 and Urine protein/creatinine ratio was 0.22. He was started with low dose of Spironolactone 12.5 mg daily for BP control and proteinuria. Renal ultrasound showed Right kidney was 19.5 cm, left kidney was 18.6 cm and presence of multiple bilateral renal cysts. Abdominal CT without contrast disclosed H1TKV: 1724 ml/m. Mayo clinic class was 1 C; estimated frequency of FRSKD at 10 years was 37.8%. Kidney gene panels detected the gene of PKD1 ( Autosomal Dominant) and HSD11B2 (Autosomal Recessive). BP stable at 125/78 mmHg, 24-hour urine protein was 125 mg per day, Serum cortisol 11 mcg/dl (normal: 8-19 mcg/dl), Serum cortisone: 0.74 mcg/dl (normal: 1.34-2.65 mcg/dl), Serum cortisone/cortisone ratio: 0.74 (normal: 3.9-11), 24 hours Urine free cortisol: 7 mcg/day (normal 5-64 mcg/day), 24 hours Urine cortisol: 31 mcg/day (normal 16-128 mcg/day), 24 hours Urine free cortisol/cortisone ratio: 0.22 after spironolactone. However, it was discontinued upon repeated serum K was at the higher side of normal. He is currently treated with oral Tolvaptan.

**Discussion:** This is an unique case which could be the first case report of HSD11B2 mutations with apparent mineralocorticoid excess associated with heterozygous ADPKD1.

**PO1284**

**A Rare Presentation of Autosomal Recessive Polycystic Kidney Disease in Adulthood**

**Katerina Hysi, Saira Sajid, James Drakakis. NYU Winthrop Hospital, Mineola, NY.**

**Introduction:** Autosomal recessive polycystic kidney disease (ARPKD) belongs to a group of congenital hepatorenal fibrocystic syndromes and causes significant renal and liver related morbidity and mortality in children. Renal cysts, congenital hepatic fibrosis, and recessive inheritance characterize ARPKD. The disorder usually manifests infancy, with a high mortality rate in the first year of life. For the patient who survives the neonatal period, the probability of being alive at age 15 ranges from 50-80%, with the majority requiring renal replacement therapy at that age. This diagnosis is rarely made in the adult years with the clinical course and prognosis much less well defined.
Case Description: 57-year-old male with PMHx of gout and long standing CKD with creatinine 1.6 mg/dL, due to developing GFR to 10 ml/min with little progression presented for evaluation. Urinalysis was without microscopic hematuria or proteinuria. Historic imaging showed small kidneys and medical renal disease. An updated MRI noted bilateral kidneys cysts with areas of atrophy and scarring, which along with an increase in in serum liver transaminases suggested chronic hepatic fibrosis, raised possibility of ARPKD. The patient subsequently underwent whole exome sequencing, which confirmed two pathogenic variants (specifically S3018F and R1624W) in the PKHD1 gene, consistent with ARPKD. His brother was eventually tested as well and found to have the same two variants.

Discussion: The classic presentation for ARPKD is systemic hypertension with progression to ESRD by the age of 15. In a typical presentation, a small number of those with ARPKD live to adulthood with some compromise of kidney function; but with significant liver dysfunction. Due to the wide phenotypic variability, the diagnosis of ARPKD may be made during any stage of childhood; in rare cases, it does not present until adolescence or adulthood. A minority of affected individuals present as older children or young adults with evidence of hepatic dysfunction or otherwise unexplained renal cysts as the prominent presenting feature. This case exhibits the silent menace of ARPKD with a delay in recognition of clinical manifestations and thus an unusually older age at the time of diagnosis.

PO1285

HDR: A Novel Mutation in GATA-3 with Variable Expressivity in an Affected Family
Meenakshi Sambharia, Jason Misurac, Christie P. Thomas. The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA

Introduction: Hypoparathyroidism, deafness, and renal disease (HDR) syndrome, also known as Barakat syndrome, is a rare autosomal dominant disorder caused by heterozygous variants in GATA-3. GATA-3 belongs to a family of dual zinc finger transcription factors that is involved in embryonic development of the inner ear, kidneys, and parathyroids. The exact prevalence of HDR syndrome is unknown, but less than 200 cases have been described. The disease has variable expressivity even within the same family. Making a diagnosis can be challenging, more so in individuals with no laboratory abnormalities. Herein we describe a father-daughter dyad with HDR syndrome with variable disease expression.

Case Description: A 7-year-old female with history of congenital deafness, multicystic dysplastic kidney, reflux nephropathy, and multiple urinary tract infections underwent genetic testing. Exome sequencing revealed a heterozygous missense variant in GATA-3, a three-base change in the mRNA sequence (c.113C>T). The variant in the same sense has been reported with ARPKD syndrome. As the patient carried the same genetic variant, the father’s history was pertinent for sensorineural hearing loss diagnosed at 2 years of age with normal renal function, serum calcium, and PTH.

Discussion: Hypoparathyroidism is the most specific symptom of HDR syndrome, absent in 5-8% of affected patients. Kidney manifestations are variable and may include aplasia, hypoplasia, dysplasia, cysts, vesicoureteral reflux, hematuria, and/or proteinuria. The missense variant described in our patient has not been previously reported, although an alternative serum calcium chain has been reported with HDR syndrome. As the father had isolated deafness, he remained undiagnosed for almost 25 years, until the identification of HDR syndrome in his daughter. Screening family members is important for recognition and treatment of hypoparathyroidism and of renal disease as patients are at risk of symptomatic hypocalcemia and progressive kidney disease.

PO1286

Assessing Genomic Needs
Jordan G. Nestor,1 Sumit Mohan,2 Ali G. Gharavi,1 Chunhua Weng,1 1Columbia University, New York, NY; 2Columbia University Mailman School of Public Health, New York, NY

Background: Interventions must address nephrologists’ knowledge gaps, perceived needs, and preferences in a genomic data to provide personalized patient care. Methods: U.S. Boarded nephrologists were invited to complete an anonymous electronic needs assessment survey on genomic implementation that incorporated multiple themes e.g., objective knowledge, attitudes perceived barriers. Its design was informed by a comprehensive literature review and adapted published tools. Descriptive statistics were used to summarize demographics and baseline characteristics. Results: Between January-May 2021, 319 complete surveys were eligible for analysis by nephrologists across 47 U.S. States, (86% adult vs. 14% pediatric), with 34% community-based (vs. 66% academic) including 36% who perform transplant evaluations and 75% with prior experience ordering genetic testing; 77% responded that genetic test results have meaningful implications for a patient’s care ≤50% of cases. Community nephrologists were more likely to cite limited experience, educational resources and access to experts as perceived barriers to implementation of genomics compared to those in academic practice. Conclusions: Our findings highlight variable levels of experience and comfort using genomics and can inform the design of tailored interventions that address nephrologists’ specific needs, including education, workflow and clinical-decision support tools. Together, such tools can promote wider utilization of genomic resources and empower nephrologists to use genomic data.

Method:

Results to Children

Background: Pediatric (ped) nephrologists care for children with genetic causes of chronic kidney disease (CKD). While genetic testing (GT) is now more accessible in nephrology, little is known about the utility, clinical application, and relevance of GT in determining underlyng CKD or other actionable secondary genetic findings for ped nephrology patients. We explored ped nephrologists' views regarding GT in clinical and research settings.

Methods: An online 30-item survey was developed and distributed via professional listserves. Inclusion criteria required self-identification as a U.S. licensed nephrologist. Data collection was from 1/22/21-5/4/20 and analyzed by STATA 15.1. Descriptive statistics are reported.

Results: 85 ped nephrologists completed the survey. Respondents range in yrs in practice (35% 6-15 yrs, 21% 16-25 yrs, 28% ≥ 25 yrs), and 75% practiced in a university hospital. Most had referred ≥ 20 patients for GT (61%). GT was considered clinically important for disease diagnosis (92%), understanding (85%), prognosis (88%), treatment options (93%), and family counseling (93%). 68% report they have reliable information for care of patient with genetic results. Top 3 challenges to GT were interpretation of results, selection of test, and ordering test. 86% identified fitting GT into practice as a challenge, and 61% report offering counseling with a genetic expert after return of genetic results. 53% felt patients could not afford GT. Most indicated the importance of having clear guidelines for GT (84%). Majority (70%) would recommend GT for family members, especially in the presence of a tailored lab report (91%). Most
are involved in the return of results in their own practice (60%). Regarding the return of research-based results, most thought diagnostic (92%) and actionable secondary findings (75%) should be returned.

**Conclusions:** Ped nephrologists report on the importance of GT in CKD. They also report on their personal challenges with GT and structural barriers to the utilization of GT.

**Funding:** NIDDK Support

**Attitudes and Perceptions of APOL1 Genetic Testing in Black Patients with Hypertension: A Pilot Study**

Krista L. Lenting,1 Anthony N. Muiru,2 Kathryn K. Lindsay,1 Amy Mosman,1 Yasar Caliskan,1 Barry J. Friedman,2 Amber Carriker,3 Chi-yuan Hsu,1 Kana N. Miyata,1 Thanh-Mai N. Vo, John C. Edwards,1 Marie D. Philipneri,1 Saint Louis University School of Medicine, Saint Louis, MO; 2University of California San Francisco, San Francisco, CA; 3Wake Forest University School of Medicine, Winston-Salem, NC; 4Mid-America Transplant Services, Saint Louis, MO.

**Background:** A portion of the chronic kidney disease risk in Black persons appears due to polymorphisms in the gene encoding apolipoprotein L1 (APOL1). While applications of APOL1 genotyping for prognostication (e.g. in evaluation of organ donors) are emerging, the interest of Black patients in APOL1 genotyping and implications for individual kidney risk management are not well defined.

**Methods:** In this pilot study, we offered APOL1 genetic testing and assessed attitudes and concerns related to APOL1 testing and kidney risk management among Black persons seen in the Hypertension & Nephrology clinics at one urban, Midwestern center.

**Results:** Among 110 participants with genotyping results to date, 56% were women, mean age was 58 years, 72% were obese, and a mean of 3 hypertensive agents were used (Table). 13% had 2 APOL1 renal risk variants (high-risk genotypes), and 42% had 1 risk variant. At baseline, most participants (86%) reported that they were concerned about kidney disease, 90% thought it was a good idea to be tested for genes that may impact kidney disease, 82% would want APOL1 testing for their children, and only 26% expected to feel upset if they were APOL1 high risk. Most participants reported that knowledge of a high-risk APOL1 genotype would lead to changes in health-related behaviors (Figure).

**Conclusions:** Black patients at a Midwestern medical center were receptive towards APOL1 genetic testing and believed that testing would motivate changes in health-related behaviors. Ongoing research is needed to determine optimal patient-centered use of this emerging risk assessment tool.

**Funding:** Private Foundation Support

**POI1289**

**Utility of Genetic Testing in Informing Management of Patients with Kidney Disease**

Daniel W. Ross,1 Kenar D. Jhaveri,2 Laurel Kartchner,2 Dinah Clark,2 Kerry Gaj,2 Deepa A. Malieckal.1

1Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; 2Natera, Inc., San Carlos, CA.

**Background:** Early identification of monogenic causes of CKD through genetic testing can improve disease treatment, inform management and improve outcomes. Genetic testing can also be useful for families with a history of CKD to plan for the future, including appropriate identification of organ donors. Here we describe the use of genetic testing, with RenasightTM, an NGS-based >380 gene panel for kidney disease, to inform treatment for patients being treated for kidney abnormalities.

**Methods:** We performed a retrospective analysis of genetic test results using Renasight™ (NGS-based>380 broad kidney gene panel) at a large academic center over an 18-month period. After signed informed consent, broad genetic testing was performed on blood or saliva samples from 31 patients. Genetic testing results were then related to alterations in the management of treatment of these patients.

**Results:** In this cohort, 41.9% (13/31) were female with an average age 51 years. The most common demographic groups were African American and Caucasian (6 patients [19.4%], each). Nineteen patients (61.3%) underwent Renasight testing due to a CKD diagnosis, 5 (16.1%) due to nephritis/nephritic syndrome, 3 (9.7%) due to proteinuria/nephrotic syndrome, 1 (3.2%) due to thrombotic microangiopathy, 1 (3.2%) due to phosphorus metabolism disorder, and 1 (3.2%) due to hemochromatosis. Positive results were identified in 12.9% (4/31) of the patients in the COL1A1, COL4A5, and APOL1 genes. Genetic testing results led to changes in management for 35.4% (11/31) of patients, confirmed diagnoses for 22.6% (7/31), provided additional diagnoses for 41.9% (13/31), and prompted family testing for 22.6% (7/31). For 4 patients with positive findings, test results impacted treatment management: 1 had transplant management impacted, 1 underwent biopsy to confirm Alport Syndrome, 1 had FSGS diagnosis confirmed and 1 underwent biopsy to confirm FSGS and initiated dialysis. Additionally, negative results led to alterations in management for 48.4% (15/31) of patients.

**Conclusions:** In this cohort at an academic practice, genetic testing informed nephrologist’s management of the patients in multiple categories. Negative results can rule out genetic causes of disease, and carriers and variants of uncertain significance (VUS) can inform family planning decisions and enable testing in family members.
Early Experience with Broad-Panel NGS Testing for Kidney Disease in a Community Nephrology Setting

**Tarek Darwish,1 Katya Brossart,2 Hossein Tabriziani,2 Kansas City Kidney Specialists, Overland Park, KS,3 Natera, Inc., San Carlos, CA.**

**Background:** Despite the increasing awareness of the value of incorporating genetic testing, its adoption in community nephrology settings is limited. Genetic testing can guide prognostication, targeted treatments, referral to specialists for extra-renal features, and identification of at-risk relatives. For individuals with kidney failure, additional testing can help assess the risk of recurrent kidney disease after transplant and evaluation of suitable living related kidney donors. Broad-panel testing can provide benefits over narrow panels based on clinical presentation.

**Methods:** Thirty-one patients with kidney disease completed genetic testing with the Renasight™ test (NGS-based >380-gene kidney disease panel) between October 2020 and April 2021. Median age of patients was 49 years (range: 28-78 years). Genetic testing results were correlated to clinical histories, demographic factors, family history (when available) and comorbidities. Certified genetic counselors interpreted the results and provided consultation to request on patients.

**Results:** Positive findings were identified in 22.6% (7/31) of patients tested in the APOL1, PKD1, SLCO4A1, COL4A4, and PKD2 genes (Table 1). Testing resulted in a diagnostic result in 85.7% (6/7) of patients and in changing clinical management for 28.6% (2/7) of patients. Homozygosity or compound heterozygosity for the APOL1 high risk alleles G1 and G2 was identified in 9.7% (3/31) of patients and were found primarily in African American patients.

**Conclusions:** In the community nephrology setting, the utility of genetic testing as part of the diagnostic workup is multifaceted. As compared to selection of a narrow panel based on clinical features, use of a broad panel that includes reporting of the APOL1 high risk alleles has the additional benefit of identifying genetic causes of kidney disease with ambiguous or non-specific clinical findings.

**KIDNEYCODE: A Genetic Testing Program for Patients with CKD**

Prasad Devarajan1,1 Kenneth V. Lieberman,2,3 Xiangling Wang,3 Bradley A. Wang4,1,2,3 Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 1Hacksack Meridian School of Medicine, Nutley, NJ; 2Children's Mercy Hospitals and Clinics, Kansas City, MO; 3Geisinger Health, Danville, PA; 4Cleveland Clinic, Cleveland, OH.

**Background:** Knowledge about the genetic causes of chronic kidney disease (CKD) is one of the key gaps in global kidney research. Recent International Society of Nephrology recommendations encourage the adoption of genetic testing to provide precision medicine based on individual risk. A recent whole-exome sequencing study showed that genetic inheritance may be responsible for up to 10% of CKD diagnoses in adults, many of which may be previously undiagnosed or mis-diagnosed. Continued advances in DNA sequencing technology have made genetic testing applicable to routine clinical diagnosis.

**Methods:** KIDNEYCODE offers no-charge genetic testing for three rare forms of CKD: Alport syndrome (AS), focal segmental glomerulosclerosis (FSGS), and 2 forms of polycystic kidney disease: autosomal dominant polycystic kidney disease (ADPKD) due to PKD2 mutations and autosomal recessive polycystic kidney disease. Invitae's renal disease panel includes 18 genes (ACTA4, ANLN, APOL1, CD2AP, COL4A3, COL4A4, COL4A5, CRB2, HNF1A, IN2, LMX1B, MYO1E, NPHS1, NPHS2, PKD1, PKD2, PKHD1, and TRPC6). Patients in the US with eGFR ≤ 90 mL/min/1.73 m² hematuria or a family history of CKD, or with a known or suspected diagnosis of AS or FSGS are eligible for testing. Family members of those with suspected or known AS or FSGS are also eligible. All participants have access to genetic counseling follow-up at no additional charge.

**Results:** To date, the KIDNEYCODE program has results from 1389 genetic tests. Genetic variants were reported in 845 patients. Of those, 574 patients had 613 variants in COL4A3, 4, or 5 genes (403 Pathogenic/Likely Pathogenic (P/LP), 210 Variants of Uncertain Significance (VUS)), 284 patients had 302 variants in genes associated with FSGS (55 P/LP, 247 VUS), 112 patients had 15 variants in PKHD1 (15 P/LP, 100 VUS), and 22 patients had a variant in PKD3 (7 P/LP, 15 VUS), and 75 patients had a VUS in APOL1.

**Conclusions:** Results from the KIDNEYCODE genetic testing program demonstrate that combining genetic testing with clinical presentation and medical history can improve accuracy of diagnosis and treatment plans for patients with hereditary CKD.

**Funding:** Commercial Support - Reata Pharmaceuticals

The Emerging Role of Whole-Genome Investigation to Identify Undetected Nephropathies: The HIDDEN Study

Andrew J. Mallett,1,2 Amali Mallawaarachchi,1,2 Zornitza Stark,1,2 Cas Simons,1 Catherine Quinlan,1,2 Chirag Patell.1 The KidGen Collaborative ‘Townsville Hospital and Health Service, Townsville, QLD, Australia; 2James Cook University, Townsville, QLD, Australia; 3Queen’s University, Belfast, Northern Ireland; 4Darling Hospital, Darlington, NSW, Australia; 5Royal Prince Alfred Hospital, Camperdown, NSW, Australia; 6Murdoch Children Research Institute, Parkville, VIC, Australia; 7The Royal Children’s Hospital Melbourne, Parkville, VIC, Australia; 8Royal Brisbane and Women’s Hospital, Herston, QLD, Australia.

**Background:** 5% of Australian and New Zealand patients commencing kidney replacement therapy have an uncertain kidney disease aetiology. New approaches and tools are required to resolve such diagnostic odysseys. WGS is an emerging diagnostic technology whose role in the setting is unclear. We sought to determine the diagnostic yield of whole genome sequencing (WGS) in individuals with unexplained end stage kidney disease (ESKD).

**Methods:** Adult and paediatric patients reaching Chronic Kidney Disease Stage 5 before 51 years of age without an identified aetiology were prospectively recruited through an Australian national network of 18 clinics. Eligibility was determined by a national clinical committee based on pre-specified criteria. Clinically-accurated WGS analysis was undertaken with a curated “KidneyOme” virtual panel of genes associated with hereditary kidney disorders. A genomic diagnosis constituted a KidneyOme result of pathogenic or likely pathogenic variant/s of appropriate zygosity.

**Results:** 168 individuals were referred (2018-2021) of whom 147 were approved and 104 consented. Of these, 40 (38.5%) were female and median age was 43yrs; 41 (38.5%) had ESKD and ESKD before 30yrs and 63 (60.6%) had undergone native kidney biopsy. Of 50 results returned to date, 7 (14%) were diagnostic, including both autosomal dominant (4/7) and recessive (3/7) inheritance patterns with 6/7 having a family history of CKD. A further 14/50 had variants of uncertain significance. One diagnosis was due to a copy number variation. The KidneyOme virtual panel curation of 384 genes is publicly available in PanelApp-Australia.

**Conclusions:** One in seven patients with ESKD of uncertain aetiology had an undetected underlying monogenic cause for their kidney disease. Application of KidneyOme with WGS has diagnostic utility and should be considered in younger patients with unexplained renal failure.

**Funding:** Government Support - Non-U.S.
PO1295
Characterization of Patients with Alport Syndrome in the United States: A Retrospective Analysis of Medical Claims

Background: Alport syndrome (AS) is a rare, hereditary genetic condition that often results in chronic kidney disease and may lead to early onset of end-stage kidney disease. The prevalence estimate in the literature is around 30,000-60,000 in the US. However, there are challenges with AS diagnosis (i.e. underdiagnosis and misdiagnosis), hence real-world patient population with AS diagnosis can be less than the prevalence estimates. This study is a retrospective analysis of medical insurance claims aimed to get a real-world estimate of the number of patients with a formal diagnosis of AS in the US, their disease characteristics, and treatment patterns.

Methods: A retrospective, observational cohort analysis was conducted, that leveraged DRG/Clarivate medical claims database, that integrates multi-payer and multi-plan data and covers ~220 million annual patients in the US. Patients with at least one ICD-10 code (Q87.81) designated for AS in their medical history between October 2015 to September 2020 were considered diagnosed AS cases. Characteristics of patients and prescription data were analyzed descriptively. Patient interactions with health care professionals (HCP) within the last 24 months of the study window (i.e. October 2018 – September 2020) were used to determine the primary HCP responsible for patient management.

Results: The analysis identified total of 10,387 patients with at least one AS diagnosis code. Of the 42% of the population for whom chronic kidney disease (CKD) stage data were available, 44% had advanced CKD (IV & V). Adult or pediatric nephrologists were the primary HCPs for 59% of patients. Based on the prescription data, 21.6% (2,244 patients) were prescribed ACEis/ARBs, and 10.6% (1,101 patients) were prescribed CYP3AA4 inhibitors.

Conclusions: The number of patients our study identified with AS diagnosis is lower than the commonly cited prevalence estimates in the US. The discrepancy can be explained by the fact that the database used covers a majority of but not the whole US population, and our study relied on real-world insurance claims.

Funding: Commercial Support - Reata Pharmaceuticals

* Staging data were available for 42% (4,404 pts) of the diagnosed population.

PO1296
Healthcare Resource Utilization by Patients with Alport Syndrome in the United States: A Retrospective Claims Analysis
Baris Deniz, Sureka Gattu, Mohit Mehra, Justin W. Li, and Angela Yuan, Samina Khan. Reata Pharmaceuticals Inc, Plano, TX; Trinity Partners LLC, Waltham, MA.

Background: Alport syndrome (AS) is a rare and serious inherited form of chronic kidney disease (CKD) affecting as many as 60,000 persons in the US. In severe cases, patients develop end-stage kidney disease (ESKD) in their 20’s. The health and economic burden associated with AS has not been well-characterized in the literature. This study aims to address this evidence gap.

Methods: A retrospective claims analysis (IBM MarketScan® Commercial Database) was conducted to assess the healthcare utilization (HCU) by patients with AS in the US. Patients enrolled in a health plan for a minimum of six continuous months with at least 1 inpatient or 2 outpatient claims with the AS-specific ICD-10 code were considered to have a diagnosis of AS. Patients with AS were further segmented into CKD stages, where such information was available, to understand the impact of disease progression on HCU. Patients with AS were age- and gender-matched to a comparator group without AS diagnosis in a 1:5 proportion. The analysis included commercial (medical and pharmacy) claims from 2015 to 2019.

Results: 851 patients with AS were identified, of which 518 also had a CKD diagnosis. The mean age was 33.3 years and 51% were males. 16.2% of patients were < 18 years old. Patients with AS required more healthcare services than the matched comparator group. 19.2% of patients with AS and CKD had at least 1 inpatient admission over the course of 6 months, versus 2.1% in the matched cohort; 100% had an outpatient or office visit, versus 94.6% in the matched cohort; 26.7% had at least one emergency department visit, versus 6.6% in the matched cohort. The rate of HCU increased with the increasing CKD stage, the highest utilization being observed in patients with advanced CKD. Approximately 25% of patients with AS were prescribed RAASi’s, which is a commonly used treatment in eligible patients with AS.

Conclusions: Patients with AS were observed to utilize inpatient, outpatient, and emergency department services at higher rates than the comparator group, with high utilization largely driven by late-stage CKD. Consequently, delaying or preventing kidney disease may substantially reduce healthcare expenditures among patients with AS, particularly among patients with ESKD.

Funding: Commercial Support - Reata Pharmaceuticals Inc
PO1299
Sparsentan, the Dual Endothelin Angiotensin Receptor Antagonist (DEARA), Improves Kidney Function and Life Span and Protects Against Hearing Loss in Alport Mice with Developed Renal Structural Changes
Dominic E. Cosgrove,1 MichaelAnne Gratton,2 Daniel T. Meehan,1 Denise Vosik,1 Jacob D. Madison,1 Duane C. Delimont,1 Gina C. Samuelson,1 Diana Jarocki,2 Radko Komers,2 Celia P. Jenkinson,1 Boys Town National Research Hospital, Omaha, NE; 2Washington University, St. Louis, MO; 3Traverse Therapeutics Inc, San Diego, CA.

Background: In Alport syndrome (AS), endothelin type A receptor activation is an important mediator of renal and inner ear pathologies. Sparsentan (SP) administered to COL4A3-/- mice (AS mice) in prevention mode delayed increases in proteinuria, renal structural changes and hearing loss (HL). Whether these effects translate into preservation of glomerular filtration rate (GFR), increased lifespan (LS) and protection from HL in mice where renal pathology has initiated is unknown.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (WT-V or AS-V), 60 or 120 mg/kg SP (AS-SP60 or AS-SP120) starting at 4 weeks (W) of age or at 5, 6 or 7W. Baseline and 10W glomerulosclerosis/glomerulosclerosis (GS) were evaluated in kidney sections stained for fibronectin. GFR was measured using a transdermal device (Medibeacon) in mice treated from 4W. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75W in AS-V or AS-SP120 mice treated from 5W.

Results: SP begun at 4W abrogated the decline in GFR at 9W compared to AS-V mice (GFR 30 ± 6.7 ml/min per 1.73 m² at 9W vs. 21 ± 2.7 ml/min per 1.73 m² at baseline (B) for WT mice; p=0.0199). AS mice at 10W had a mean GFR of 22 ± 6.7 ml/min per 1.73 m² at 10W vs. 13 ± 3.7 ml/min per 1.73 m² at B (p=0.031). AS-SP120 mice had a mean GFR at 10W of 32 ± 5.6 ml/min per 1.73 m² vs. 16 ± 5.2 ml/min per 1.73 m² (B) for WT mice (p=0.0218). AS mice at 10W had a mean UACR of 183 ± 41.7 (n=15); p<0.001 AS-V vs AS-SP60 or AS-SP120 and mean UACR of 183 ± 40 mg/g (n=18). In GFR, GS, and hearing loss, AS-SP120 mice were statistically similar to WT mice but not to AS mice at 10W; p<0.05 for AS-V vs AS-SP120 for all measures.

Conclusions: SP prevents the decline in GFR in AS mice, extends LS and prevents noise-induced HL even in mice with developed renal structural changes. If these results are translated successfully into the clinic, SP may offer a novel treatment approach for reducing both renal injury and protecting hearing in AS.

Background: Alport syndrome is a rare genetic disease affecting up to 60,000 persons in the US.

Methods: EAGLE (NCT03749447) is an ongoing, international, multi-center, open-label, extended access trial evaluating the longer-term safety and tolerability of bardoxolone methyl (bardoxolone) in patients with Alport syndrome who completed a prior qualifying clinical trial (CARDINAL Phase 2 and 3; NCT03019185). At baseline patients were 12 to 70 years old with eGFR 30 to 90 mL/min/1.73 m² and UACR ≤ 3500 mg/g. Patients received bardoxolone daily and dose is escalated up to 20 mg or 30 mg (for patients with UACR > 300 mg/g).

Results: As of data cutoff (01/18/2021), 96 patients were enrolled in the EAGLE study, including 79 patients from CARDINAL Phase 3 (placebo: n=46, Bard: n=33), and 17 patients who received Bard in CARDINAL Phase 2. Mean age was 42 years, and 8 (8%) patients were <18. At baseline, mean eGFR was 58.2 ± 21.4 mL/min/1.73 m² and mean UACR was 183 ± 40 mg/g. Increases in eGFR were seen in patients who previously received placebo and initiated Bard treatment in EAGLE. Patients who previously received Bard for two years in CARDINAL also continued to experience mean eGFR increases in their third year of treatment. Bard has generally been well tolerated, with no deaths or drug-related severe adverse events (SAEs) reported in EAGLE to date. No drug-related SAEs were reported and no changes in blood pressure were observed. Nearly all (94%) adverse events were mild to moderate.

Conclusions: In EAGLE, Bard increased eGFR in patients with Alport syndrome, and increases observed in EAGLE were sustained in the third year of treatment. To date, the longer-term safety profile of Bard is similar to that observed in the CARDINAL trial.

Integrated Analysis of the Efficacy and Safety of Bardoxolone Methyl in Patients with Alport Syndrome
Bradley A. Warady,1 Rajiv Agarwal,1 Sharon P. Andreoli,1 SripalBangalore,4 Geoffrey A. Block,5 Arlene B. Chapman,2 Melanie Chin,2 Prasad Devajaran,8 Keisha L. Gibson,4 Angie Goldsberry,7 Laura H. Mariani,10 Colin J. Meyer,7 Megan O’Grady,7 Peter Stenvinkel,11 Glenn M. Chertow,12 1Children’s Mercy Hospitals and Clinics, Kansas City, MO; 2Indiana University School of Medicine, Indianapolis, IN; 3Riley Hospital for Children at Indiana University Health, Indianapolis, IN; 4New York University Grossman School of Medicine, New York, NY; 5US Renal Care Plans, Plano, TX; 6University of Chicago Division of the Biological Sciences, Chicago, IL; 7Reata Pharmaceuticals Inc, Irving, TX; 8Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 9University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 10University of Michigan Medical Center, Ann Arbor, MI; 11Karolinska Institute, Stockholm, Sweden; 12Stanford University School of Medicine, Stanford, CA.

Background: Alport syndrome is a rare and serious inherited form of CKD. An integrated analysis of efficacy and safety was conducted from the CARDINAL Phase 2/3 (NCT03019185) and EAGLE (NCT03749447) trials of bardoxolone methyl (Bard) in patients with Alport syndrome.

Methods: The CARDINAL Phase 2 trial was open-label and enrolled 30 patients ages 12 to 60 years with Alport syndrome, baseline eGFR values 30 to 90 mL/min/1.73 m² and UACR ≤ 3500 mg/g. CARDINAL Phase 3 was an international, multi-center, double-blind, placebo-controlled trial with similar eligibility criteria and randomized 157 patients. EAGLE is an ongoing, open-label, extended access trial that is enrolling patients who completed CARDINAL Phase 2/3 trials.

Novel Keap-Nrf2 Protein-Protein Interaction Inhibitor UBE-1099 Ameliorates the Severity of Experimental Alport Syndrome
Shota Kaseda,1,2 Mary Ann Suico,1 Sayaka Ogi,3 Hitotoshi Sunamoto,2 Hirohiko Fukuya,1 Tetsuo Shuto,1 Kazuhito Onuma,1 Hirofumi Kai.1 1Department of Molecular Medicine, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto City, Japan; 2Pharmaceuticals Research Laboratory, UBE Industries, Ube city, Japan; 3Program for Leading Graduate Schools “HIGO (Health life science: Genetics Diseases of the Kidneys: Non-Cystic - I)

Background: Bardoxolone methyl is an electrophile that induces Nrf2 activation by irreversibly and covalently binding to the cysteine residue of Keap1. Bardoxolone methyl has been shown to improve glomerular filtration rate (GFR) in clinical trials, and is attracting attention as a novel agent for chronic kidney disease. However, there is concern about long-term efficacy due to the unknown mechanism of GFR improvement and transient increase in albuminuria. Moreover, irreversible Keap1 inhibitors such as Bardoxolone methyl may covalently bind to other proteins in a non-specific manner and induce side effects due to off-target activities.

Methods: We developed a reversible Keap1 inhibitor that inhibits Keap1-Nrf2 protein-protein interaction (PPPI) and evaluated its efficacy using Alport syndrome mice model (Col4a5-G5X). Development of Keap1-Nrf2 PPPI inhibitor was performed by fluorescence polarization and Nqo1 induction test. The obtained novel compound UBE-1099 (30 mg/kg/day) and CDDO-Im (3, 10 mg/kg/day; rodent tolerable Bardoxolone methyl analogue) were orally administered to Alport mice and efficacy was evaluated.

Results: UBE-1099 showed higher Nqo1 induction efficiency compared with CDDO-Im in mouse renal tissue. While CDDO-Im only improved inflammation pathology in Alport mice, UBE-1099 uniformly improved renal function (GFR and Plasma creatinine, but not albuminuria), podocyte injury, glomerulosclerosis, inflammation and fibrosis. Moreover, UBE-1099 treatment significantly prolonged the lifespan of Alport mice.

Conclusions: This study firstly revealed the efficacy of Keap1-Nrf2 PPPI inhibitor for glomerulosclerosis. We will elucidate next the mechanism of renal pathology improvement, which may provide useful information for Nrf2 activators including bardoxolone methyl for clinical application.

Background: Alport syndrome is a rare and serious inherited form of CKD affecting as many as 60,000 persons in the US with no specific therapies approved for its treatment. Methods: An international, multicenter, double-blind, placebo-controlled, randomized Phase 3 trial (CARDINAL; NCT03019185) evaluated the safety and efficacy of bardoxolone methyl (Bard) in patients with Alport syndrome 12 to 70 years of age with baseline eGFR 30-90 mL/min/1.73 m² and UACR ≥ 350mg/g. As an exploratory endpoint, the trial assessed patient global impression of change (PGIC), a non-disease specific 7-point scale that asks patients to rate how much their illness has changed as very much/much/minimum improved (1, 2, and 3 pts), no change (4 pts), or minimally/much/very much worse (5, 6, and 7 pts) after 48 and 100 weeks of treatment.

Results: A total of 157 patients were randomized to Bard (n=77) or placebo (n=80). In addition to significant on-treatment and off-treatment increases in mean eGFR relative to placebo (between-group differences of 7.7 ± 2.1 [p=0.0005] at Week 100 and 4.3 ± 1.9 mL/min/1.73 m² [p=0.023] at Week 104, respectively), Bard improved PGIC scores relative to placebo (lower values after 48 and 100 weeks). Categorical summaries also showed more patients randomized to bardoxolone (34%) reported their condition had improved compared to those on placebo (19%) after 100 weeks of treatment.

Conclusions: In CARDINAL, Bard significantly improved eGFR in patients with Alport syndrome and also resulted in improvements in how patients evaluated their wellbeing.

PO1304
Treatment with Antisense-Oligonucleotide or Splicing Regulating Proteins for X-Linked Alport Syndrome Cases with Deep Intronic Variant
Tomoko Horinouchi,1 Tomohiko Yamamura,1 Sadayuki Nagai,1 Yuya Aoto,1 Nana Sakakibara,2 China Nagano,3 Kazumoto Iijima,1 Kandai Nozu,1 Kobe University Graduate School of Medicine, Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.

Background: X-linked Alport syndrome (XLAS) is a hereditary progressive renal disease caused by mutation in COL4A5. Some cases of XLAS are caused by deep intronic variants which cause aberrant splicing and produce cryptic exon inclusion. Preventing translation of such cryptic exon has the potential to be an effective therapy. We reported that exon skipping therapy with antisense-oligonucleotide (ASO) was very effective in the XLAS mice model with a truncating mutation. However, an ASO needs very high sequence specificity and few patients can be treated by the same ASO. Therefore, we attempted to modify the splicing pattern not only by ASO but also by proteins important for splicing regulation. U2A6F5 is one of the important splicing related proteins binding to polyypyrimidine tracts promoting exonization. It has been reported that overexpression of the U2AF65 promotes or suppresses exonization in some circumstances.

Methods: We identified four cases of XLAS caused by the presence of the same cryptic exon inclusion ([c.384_385ins385-385-617]) by different deep intronic variants: three cases (c.385-756C>G, c.385-749T>A and c.385-645T>A) were ours and 1 (c.385-719G>A) was a reported variant. For these cases, we introduced ASO that could prevent cryptic exon inclusion. Moreover, using in vitro splicing evaluation system (minigene assay), we attempted to reduce the exonization of cryptic exon by overexpression of U2AF65.

Results: We succeeded in preventing the cryptic Exon insertion by introducing ASO treatment for patient’s urine derived cells. In addition, in all patients, overexpression of U2AF65 in the minigene splicing analysis system successfully reduced the cryptic exon inclusion.

Small Molecule APOL1 Inhibitors Block APOL1 Pore Function and Reduce Proteinuria in an APOL1-Mediated Kidney Disease Mouse Model
Brandon Zimmerman, Leslie Dakin, Anne Fortier. Vertex Pharmaceuticals Inc, Boston, MA.

Background: Two genetic variants of APOL1 (G1 and G2) are associated with increased risk of kidney diseases. Current treatment options for APOL1-mediated kidney diseases are limited and do not address the underlying cause of disease. Here, we report the discovery of a series of novel small molecule APOL1 inhibitors, including the clinical candidate VX-147, that block APOL1 function in vitro and reduce proteinuria in a transgenic mouse model of kidney disease.

Methods: Microscale thermophoresis was used to assess binding of small molecule APOL1 inhibitors to recombinant APOL1 protein. HEK293 cells overexpressing APOL1 variants were used to quantify inhibition of APOL1-mediated cell death and ion flux. In addition, activity on APOL1 biological function was assessed using a trypanosome viability assay. Finally, changes in proteinuria following APOL1 inhibitor administration were assessed using a transgenic mouse model homozygous for the APOL1 G2 variant (G2/G2).

Results: Small molecule APOL1 inhibitors showed binding to all three forms of APOL1 (wild-type, G1 and G2 variants). In cellular assays, APOL1 inhibitors prevented APOL1-mediated HEK293 cell death and inhibited APOL1-mediated ion flux. Addition of APOL1 inhibitors to trypanosomes rescued the parasites from APOL1-induced killing. The potency of VX-147 was consistent across the in vitro functional assays described above (IC50 of approximately 2nM). Finally, administration of APOL1 G2-dependent proteinuria in an APOL1 G2 mouse induced APOL1 expression, resulting in elevated urine albumin-to-creatinine ratios. Oral administration of VX-147 reduced proteinuria in IFNγ-induced APOL1 G2 mice by 74.1%.

Conclusions: Novel small molecule APOL1 inhibitors, including VX-147, bind recombinant APOL1 protein and inhibit its biological function, as demonstrated by trypanosome parasite rescue. These inhibitors block APOL1 pore function, as demonstrated by reduced APOL1-induced death and APOL1-induced ion flux of tetracycline-inducible APOL1 HEK293 cells. Administration of APOL1 inhibitors reduced APOL1-dependent proteinuria in an APOL1-mediated transgenic mouse model of kidney diseases. Taken together, our results strongly suggest small molecule APOL1 inhibitors, such as VX-147, target the underlying cause of disease, and have the potential to treat APOL1-mediated kidney diseases.

PO1306
Inhibition of Endoplasmic Reticulum Stress Signaling Reduces Cytotoxicity of Human APOL1 Risk Variants in Drosophila
Lea Dakin, Meghna Shen, Lina L. Kamps, Julian Milosavljevic, Konrad Lang, Martin Helmstadter, Tobias F. Hermle. Hermle lab Division of Nephrology, University Medical Center Freiburg, Freiburg, Germany.

Background: Renal risk variants of the APOL1 gene are associated with severe kidney disease, putting homozygous carriers at risk. APOL1 G1- and G2-alleles likely represent gain-of-function (GOF) mutations as human subjects with APOL1 null alleles have been found to be without renal anomalies. A wide range of mechanisms that are frequently in conflict have been described for APOL1-associated nephropathies.

Methods: The genetic tool-kit in Drosophila allows unique in vivo insights into disrupted cellular homeostasis. To perform a mechanistic analysis in this model, we expressed APOL1 control and the GOF renal risk variants in the podocyte-like Drosophila nephrocytes and a wing precursor tissue.

Results: APOL1 risk variant expression entailed elevated endocytotic function of garland cell nephrocytes while processing of endocytic cargo and slit diaphragm morphology remained unimpaired. All APOL1 variants located to the endoplasmic reticulum (ER) and electron microscopy revealed significantly elevated ER swelling upon expression of a risk variant G2-APOL1, indicating stimulation of ER stress. We employed Drosophila wing precursor tissue since this epithelial model enables unique recording of relative changes side by side within the same animal to study ER stress. Overexpression of the renal risk variants G1 and G2 caused a markedly stronger upregulation of PDI and apoptosis, while expression of wildtype APOL1 resulted in milder upregulation. As a control, ER stress was absent upon deletion of 9 aa in the BH3 domain in the G2-APOL1 construct. We further confirmed APOL1-dependent ER stress by detection of chaperone induction and an Xbp1-reporter in the wing precursor. Both, genetic and pharmacological inhibition of ER stress abrogated apoptosis identifying ER stress as the essential factor of APOL1-induced cytotoxicity. This represents the first rescue of APOL1-associated cytotoxicity in vivo. Direct ER stress induction in nephrocytes phenocopied APOL1 risk variant expression, supporting that ER stress underlies the gain-of-function in nephrocytes.

Conclusions: Our data reveal ER stress as the essential consequence of APOL1 risk variant expression in vivo, indicating this pathway’s central role in the pathogenesis of APOL1-associated nephropathies.

A Cohort Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) Started on SGLT-2 Inhibitors
Anthony J. Bleyer, Kendrah O. Kidd, Hannah C. Ainsworth, Victoria C. Robins, Abbigail Taylor, Lauren Martin, Alice Kim, Venkata Sabbitseti, Carl D. Langefeld, Stanislav Knoech, Anthony J. Bleyer. Wake Forest University School of Medicine, Winston-Salem, NC; University Karlova 1 lekarska fakulta, Praha, Czechia; Harvard Medical School, Boston, MA.

Background: Sodium-glucose co-transporter-2 inhibitors (SGLT2i) have been shown to slow estimated glomerular filtration rate (eGFR) decline in chronic kidney disease (CKD) but have not been tested in patients with ADTKD. We performed a prospective nested cohort observational study and analyzed changes in eGFR and kidney injury marker 1 (KIM-1) in patients who were prescribed SGLT2i by their physicians.

Methods: We obtained baseline and follow-up laboratory studies at 1 week, 1 month, and 4 months after starting an SGLT2i and compared eGFR with baseline function. We also obtained information about adverse events.

Results: 12 individuals were started on SGLT2i by their physicians, with 10 on empagliflozin, 2 dapagliflozin. Table 1 shows the changes in eGFR and KIM-1. For patients with eGFR > 30, mean eGFR increased at 1 month by 3 ml/min. At four months, eGFR was 3 ml/min below baseline (-18.5% due to low baseline eGFR). For eGFR > 30, eGFR decline was 12% from baseline at one month and 8% from baseline at 4 months. Plasma KIM-1 was unchanged, but urinary KIM-1 increased by 100%. One patient stopped empagliflozin at his request after 8 weeks due to decline in eGFR of 14% from baseline. No other adverse events noted. Two patients have been treated for 6 months with stable eGFR.

Conclusions: The change in eGFR after treatment with SGLT2i was consistent with prior studies of CKD. The plasma KIM-1 was unchanged, but the rise in urinary KIM-1 was very concerning. Further study is required to determine if these agents are beneficial in ADTKD. An additional 4 months of follow up will be presented at ASN.

PO1308
A Prospective Observational Study of Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)
Kendrah O. Kidd, H. Williams, Victoria C. Robins, Abbigail Taylor, Lauren Martin, Alice Kim, Martina Zivina, Carl D. Langefeld, Stanislav Knoech, Anthony J. Bleyer. Wake Forest University School of Medicine, Winston-Salem, NC; University Karlova 1 lekarska fakulta, Praha, Czechia.

Background: GFR decline in ADTKD due to UMOD or MUC1 mutations has not been well characterized. We have begun an international prospective cohort study to determine genetic and environmental factors associated with progression. We report here on early recruitment.

Methods: Patients with positive genetic testing for UMOD or MUC1 mutations prior to transplantation or starting dialysis are eligible. A baseline collection of health information, serum and urine biomarkers will be performed, with patients then followed longitudinally, with a serum creatinine measurement performed three times per year. There will be a nested cohort study of women who develop pregnancy during the study and patients started on ACE inhibition.

Results: Since March 2021, we have enrolled 57 patients in the prospective observational study, with 20 men, 35 women. The mean age of patients is 43.3 years, the mean baseline eGFR is 39.96 ml/min/1.73m². Table 1 shows baseline characteristics of patients enrolled in the study. No patients with CKD Stage 1 or 2 suffered from HTN, and only 39% of patients with CKD Stage 3 had HTN. Only 18% of patients were receiving ACE/ARB inhibition.

Conclusions: Despite significant CKD, there was a relatively low prevalence of HTN. Only 18% of patients were receiving ACE inhibition, indicating a potential therapeutic intervention. Please contact us if you have a patient who may be interested in participating in this prospective study (tablever@wakehealth.edu).

Vasopressin Induces Urinary Uromodulin Secretion by Activating Protein Kinase A

Azuma Nanamatsu, Takayasu Mori, Fumika Ando, Taisuke Furusho, Shintaro Manda, Koichiro Sasa, Eisui Sohara, Tatemitzu Rai, Shinichi Uchida.

Tokyo Medical and Dental University, Tokyo, Japan.

**Background:** Urinary uromodulin, secreted by renal tubular cells, protects against urinary tract infections (UTIs) and kidney stones. In contrast, the intracellular accumulation of uromodulin is associated with hypertension and chronic kidney disease (CKD). In addition, uromodulin gene mutations cause autosomal dominant tubulointerstitial kidney disease (ADTKD-UOMD) via abnormal intracellular accumulation of uromodulin. However, the physiological stimuli for urinary uromodulin secretion remain largely unknown.

**Methods:** We investigated the acute effect of vasopressin/cAMP signaling on urinary uromodulin secretion in mice and in kidney epithelial cells stably expressing uromodulin. Additionally, we assessed the effect of vasopressin/cAMP signaling in kidney epithelial cells stably expressing mutant uromodulin, which causes ADTKD-UOMD.

**Results:** Desmopressin, a vasopressin type 2 receptor agonist, dramatically increased short-term tubular uromodulin secretion in mice. Immunofluorescence studies and ultracentrifugation-based polymerization assay suggested that desmopressin induced intraluminal polymeric filaments of uromodulin, indicating physiologically functional secretion. As a result of increased excretion, uromodulin abundance in the murine kidney was clearly reduced by desmopressin. In the cellular model, apical uromodulin secretion was increased in response to vasopressin/cAMP signaling, consistent with in vivo experiments. We also demonstrated that the response was dependent on cyclic AMP-dependent protein kinase (PKA) signaling pathway. We further showed that cAMP signaling induced excretion of mutant uromodulin. cAMP signaling suppressed PERK phosphorylation, which was upregulated by mutant uromodulin, implying cytoprotective effects.

**Conclusions:** Our work revealed vasopressin/cAMP/PKA signaling as a physiological stimulus of urinary uromodulin secretion. This finding may provide the basis for novel treatment strategies for UTIs, kidney stones, and potentially hypertension, CKD and ADTKD-UOMD.

Standardizing HNF1B-Associated Disease

Johannes Müench,1,2 Georgia Vaseileiou,1 Jan Kowald,2 Jonathan de Fallois,2 Marie Engesser,2 Stefanie Weber,1 Jan Halbritter,2 Bernt Popp,2 AG Nephrögenetik 1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Universität Leipzig, Leipzig, Germany; 3Philippus-Universität Marburg, Marburg, Germany; 4Universitätsklinikum Erlangen, Erlangen, Germany.

**Background:** Pathogenic variants in HNF1B are associated with a variety of inherited kidney diseases ranging from renal cysts and diabetes syndrome and CARKU to autosomal dominant tubulointerstitial kidney disease. In addition, variable extrarenal manifestations were linked (MM #189907). Although high throughput sequencing has advanced diagnostic variant detection, there is a lack of specific database analysis gathering both genotypic and phenotypic information from published and unpublished sources in order to establish valid genotype-phenotype correlations. By introducing a novel HNF1B database, we aim at gathering published and unpublished cases for identification of reliable variant-disease association analysis.

**Methods:** To standardize our own cohort and curate the clinical and genetic spectrum from the literature, we curated a list of 30 clinical features associated with HNF1B-disease based on HPO terms. Next, we developed a web-based application (available on curating. HNF1B.org) for comprehensive data input and analysis from patient histories or case reports. For example, renal function was not reported for 37.0% of cases while 4.5% of cases with 17q12 microdeletion no neuroendocrinopath phenotype was provided despite both phenotypes constitute hallmarks of HNF1B-associated disease.

**Conclusions:** To enhance the understanding of this multi system disorder, we will present our curation effort as an open source clinical and genetic database at HNF1B.org. Based on our curation and unpublished cohorts we will develop a recommendation for standardized reporting and selection scheme for genetic screening. Our effort exemplifies the curation efforts that are required for a better understanding of rare hereditary kidney diseases. The developed tools might serve as starting point for similar efforts.

Treatment with 4-Phenybutyrate Reduces Low-Molecular-Weight Proteinuria in a Clcn5 Knock-In Mouse Model for Dent Disease

Ana Perdomo-Ramirez,1 Elena Ramos-Trujillo,2 Glorian Mura Escorcio,2,2 Victor Garcia-Nieto,1 Jose-David Machado,2 Felix Claverie-Martín,1 Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain; University of La Laguna, La Laguna, Spain.

**Background:** Dent disease-1 (DD1) is a rare X-linked tubular disorder characterized by low-molecular-weight-proteinuria (LMWP), hypercalciuria, nephrolithiasis and nephrocalcinosis. This disease is caused by inactivating mutations in the Clcn5 gene, which encodes the voltage-gated CIC-5 chloride/proton antipporter. CIC-5 is expressed predominantly in the kidney and participates in the acidification of proximal tubule endosomes. Currently, the treatment of DD1 is only supportive and focused in delaying disease progression. Our group has generated a Clcn5 knock-in (KI) mouse that presents the main clinical manifestations of DD1 and carries the pathogenic mutation p.V523del, which causes partial CIC-5 retention in the endoplasmic reticulum. Here, we aimed to assess the feasibility of sodium 4-phenylbutyrate (4-PBA), a small chemical chaperone, to ameliorate DD1 symptoms in this mouse model.

**Methods:** Twelve-weeks old male Clcn5 KI mice (n=50) and WT (n=33) littermates were divided into 2 groups, one was treated with 250 mg/kg/day of 4-PBA in drinking water for 10 weeks, whilst the other group was given water instead. Animals were sacrificed after the same amount of time. Mice were placed in metabolic cages before and after treatment for 24h. Urinary β2-microglobulin and serum and urinary creatinine were measured by ELISA. Calcium and phosphate concentrations in urine were estimated using colorimetric kits. Water and food intake and 24-h urinary excretion were also measured, and mice body weights were monitored.

**Results:** We observed a significant reduction of β2-microglobulin urinary excretion in KI mice treated with 4-PBA compared to non-treated animals (p<0.0004). Glomerular filtration rate was also improved in treated mice (p=0.03). Urinary production, urinary calcium and phosphate levels were also improved compared with non-treated mice. In conclusion, 4-PBA reduces LMWP in Clcn5 KI mice, suggesting that this treatment could represent a promising therapeutic option for some DD1 patients.

Long-Term Efficacy of Migalastat on Renal Function and Outcomes in Patients with Fabry Disease (FD)

Daniel G. Biechert,1 Ulla Flott-Rasmussen,2 Roberto Giugliani,3 David Hughes,2 Eva Krasinska,3 Billiana O. Veleva-Rotte,2 Department of Medicine, Hôpital du Sacré-Coeur, University of Montréal, Montréal, QC, Canada; 2Department of Medical Endocrinology and Metabolism, Rigshospitalet National University Hospital, Copenhagen University, Copenhagen, Denmark; 3Medical Genetics Service, HCPA, Department of Genetics, UFRGS, and INAGEMIP Porto Alegre, Brazil;1Lyssosomal Storage Disorders Unit, Royal Free London NHS Foundation Trust and University College, London, London, United Kingdom;3Amicus Therapeutics, Inc., Philadelphia, PA.

**Background:** FD, caused by pathogenic GLA variants leading to functional deficiency of α-galactosidase A (α-Gal A), can eventually result in key organ damage. Preserving renal function and preventing Fabry-associated clinical events (FACEs) are important treatment goals. Approved therapies include enzyme replacement therapy (ERT) and the pharmacological chaperone migalastat. Stabilized renal function and FACE occurrence up to 30 mo have been reported in migalastat-treated adults with amenable GLA variants; here, we extend these analyses up to 8.6 yrs.

**Methods:** Integrated data from phase 3 clinical trials (FACETS, NCT00925301; ATTRACT, NCT01212689) and open-label extension studies (NCT01438819; NCT02120853) were used to evaluate the eGFR slope using linear regression in pts treated with migalastat for 22 yrs (n=78). Incidences of FACEs (defined renal, cardiac, and cerebrovascular events) were assessed in all pts (N=97). Analyses were stratified prior treatment and phenotype. Cox regression modeling was used to identify predictors of FACE.

**Results:** eGFR remained stable for both ERT-naive and ERT-experienced pts who received migalastat for 22 yrs (median [min-max] duration: 5.9 [2.0-8.6]); the mean (SD) annualized rates of change in eGFR (mL/min/1.73 m²) were -1.6 (3.1) and -1.6 (3.6), respectively. In male pts with the classic phenotype (classification based on multiorgan involvement and [ERT-naive only] α-Gal A level at baseline; n=25), mean (SD) rate of change in eGFR was -2.2 (4.4) mL/min/1.73 m². eGFR was also analyzed by baseline renal function and proteinuria levels. In all migalastat-treated pts (median duration: 5.1 yrs), the incidence of composite FACEs (per 1000 patient-years) was 48.3 (65.3 for

Twenty-Year Renal Prognosis in Patients with Fabry Disease Who Underwent Enzyme Replacement Therapy

Akane Miura, Masahiro Okabe, Kotoro Hanahara, Izumi Yamamoto, Nobuo Tsuibo, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.

Background: The relationship between long-term renal prognosis and renal histopathology after enzyme replacement therapy (ERT) for Fabry disease (FD) has not been fully investigated.

Methods: Nine patients with FD from our hospital who had participated in a Japanese phase 2 study (August 2000–May 2001) on agalsidase β were eligible for this case-control study. They underwent repeated renal biopsy (before and six months after agalsidase β treatment), and the intra-renal amount of globotriaosylceramide (GL3) was measured at the same time points. Clinicopathological features were compared between the groups with or without developing end-stage kidney disease (ESKD).

Results: Seven patients included in this study, two were lost to follow-up. All were males, with a median age at the start of treatment of 30 [quartile 24.5, 31.5] years, and median serum creatinine level (s-Cr) of 1.1 [1.0, 1.2] mg/dL. The podocyte score (International Study Group of Fabry Nephropathy score system) improved in all patients after ERT from that evaluated before ERT. Intersitial fibrosis/tubular atrophy (IF/TA) worsened in three patients. The proportion of foamed tubules improved in five patients. Intra-renal accumulation of GL3 decreased six months after ERT in all patients. All patients continued to receive agalsidase β or agalsidase α after the phase II study. While four patients developed ESKD (median 6.7 years), three patients showed no exacerbation of renal function. The s-Cr level, age, and urinary protein excretion at the start of ERT were higher in the ESKD group. The decrease in the intra-renal accumulation of GL3 was not significantly different between the two groups, but the proportion of foamed tubules in the first biopsy and the degree of IF/TA in the second biopsy were higher in the ESKD group than in the non-ESKD group.

Conclusions: This study suggests that tubulointerstitial injury has a crucial role in the determination of renal prognosis and that earlier diagnosis and intervention in patients with FD may improve the renal prognosis. Further studies are needed on the relationship between tubulointerstitial injury and GL3 accumulation.

POI3134

Systems Analyses of Fabry Renal Transcriptome and Its Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Drugable ERT-Resistant Module

Oystein Eikrem,1,2 Nicolas Delaere,1,2 Philipp Strauss,3 Miroslav Sekulic,3 Camilla Tønstad,1,3 Rannveig Skruenes,1,3 Sabine Leb,2 Einar Svardal,1,3 Elena-Emanuela Rusu,1 Ariana Gaspert,1 Albina Nowak,4 Andrea Rinaldi,1 Hans-Peter Marti,1,2 Department of Medicine, Haukeland University Hospital, Bergen, Norway; 3Department of Clinical Medicine, University of Bergen, Bergen, Norway; 4Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 5C2SysBioMed, Contra, Switzerland; 6Columbia University Department of Pathology and Cell Biology, New York, NY; 7Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland; 8Fondren Clinical Institute, Bucharest, Romania; 9Department of Endocrinology and Clinical Nutrition, University Hospital Zurich, Zurich, Switzerland; 10Bergen Medical Research, Orencio Institute of Southern Switzerland, Bellinzona, Switzerland.

Background: Fabry nephropathy (FN) is a rare disorder caused by mutations in the α-galactosidase A gene that can, to a certain degree, be managed with enzyme replacement therapy (ERT). Via understanding the molecular basis of FN and ERT’s long-term impact, we aim at providing a framework allowing selection of biomarkers and drug targets.

Methods: Obtained from controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies taken prior and up to 10 years of ERT, were subjected to RNAseq. Combining pathway-centered analyses with network-science allowed computation of transcriptional landscapes from glomeruli, proximal tubuli, distal tubuli and interstitial cells. Comparing transcriptional landscapes from archival kidney biopsies taken prior and up to 10 years of ERT, were subjected to RNAseq. Combining pathway-centered analyses with network-science allowed computation of transcriptional landscapes from glomeruli, proximal tubuli, distal tubuli and interstitial cells. Comparing transcriptional landscapes per cohort revealed high inter-cohort heterogeneity. Especially, with timely treatment initiation, FN seemed well controlled and drug-targets.

Results: Comparing transcriptional landscapes per cohort revealed high inter-cohort heterogeneity. Especially, with timely treatment initiation, FN seemed well controlled and drug-targets.

Discussion: The current study suggests that Fabry nephropathy is an autoimmune disease (less than 3 cases per million population). Nephrolithiasis and nephrocalcinosis lead to progressive renal impairment and subsequent oxalate deposition in various tissues. We present a case of PHT1 diagnosed late in life and ultimately requiring definitive management with liver-kidney transplant due to early progression to end stage kidney disease.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

diffuse increased echogenicity and bilateral non-obstructing calculi. Initial serum oxalate level was 63.5 micromol/L and 24 hour urine oxalate level was 116mg/24hrs. Ser failed to improve with intravenous fluid administration and renal replacement therapy was initiated with goal serum oxalate level of <30 micromol/L. Hemodialysis was performed daily for four hours with high flux membrane. Serum oxalate levels improved to nadir of 40 micromol/L. Definitive therapy with simultaneous liver-kidney transplant was ultimately pursued.

Discussion: Our patient required intensive hemodialysis while awaiting liver-kidney transplant following late diagnosis of PHT1 and development of end stage kidney disease. Early diagnosis is key to reduce morbidity and mortality. Progressive kidney impairment leads to inability to excrete the increased oxalate produced by the liver and subsequent systemic deposition of oxalate including in the kidney causing multiorgan dysfunction. Hemodialysis removes oxalate but it is difficult to consistently reduce serum oxalate levels below goal given continued production of oxalate and rebound. Early treatment options include a trial of pyridoxine, hyperhydration, low oxalate diet and novel RNA inhibitors. Patients with advanced disease often require definitive management with liver-kidney transplant. Clinicians need to have a high index of suspicion for PHT1 as patients often go undiagnosed until advanced kidney disease or end stage kidney disease has developed.

POI1317

Real-World Healthcare Utilization and Clinical Markers Preceding Dialysis in Patients with Primary Hyperoxaluria (PH) in the United States

John Karafillis,1 Elnara Fazio-Eynullayeva,1 Lisa Mucha,2 Pamela B. Landsman-Blumberg,1 Seth P. Kurzan,1 1TriNetX, Cambridge, MA; 2Dicerca Pharmaceuticals Inc, Cambridge, MA.

Background: PH is the accumulation of oxalate resulting in urolithiasis, nephrocalcinosis, chronic kidney disease (CKD), and eventually end-stage renal disease (ESRD) that usually requires dialysis. This study examined demographics, clinical characteristics, and healthcare utilization (HCU) among dialysis-treated PH patients during the time leading up to dialysis start.

Methods: This was a retrospective study of PH patients (ICD-10: E72.53) initiating dialysis (study entry), on or after October 1, 2018, in TriNetX DataWorks USA, a federated EMR network of 60+ million de-identified patients from 44 healthcare organizations (HCOs). Patient age, sex, race, comorbidities, CKD stage, kidney stone events (KSE), and HCU were examined at least 6 months prior to dialysis, through up to 5 years.

Results: The final study cohort included 47 patients: mean age of 59 years, 53% female, and 85% white. Only 47% had a recorded diagnosis of PH prior to dialysis, and 55% had a diagnosis of ESRD. During the 6 months immediately preceding dialysis, 91% of patients had a1 outpatient office visit, 17% a1 ED visit, and 53% a1 inpatient stay. HCU for the full study period showed 98% of patients had ≥1 physician office visit, ≥1 ED visit, and ≥1 inpatient stay (Figure 1). Patients with recorded KSE (n=19; 40%) had a mean of 4 events during the study period. The frequency of KSEs doubled from 1 to 2 per person per year as patients neared dialysis. In the 6 months prior to dialysis, 70% of patients had CKD of stage III or higher recorded in their EMR.

Conclusions: In this real-world study, more than one-half of patients with PH were undiagnosed prior to initiating dialysis, according to the data reviewed. In addition, high rates of costly HCU, including ED visits and inpatient stays, were observed during the same timeframe. The number of KSEs increased over the study period, which may be indicative of worsening renal function due to PH prior to dialysis.

POI1318

Association Between Longitudinal Plasma and Urine Oxalate and Time-to-Kidney Failure in Primary Hyperoxaluria Using Joint Models

Lisa E. Vaughan, John C. Lieske, Phillip Schulte. Mayo Clinic Minnesota, Rochester, MN.

Background: The association between plasma oxalate (POX), urine oxalate (UOX) and time to kidney failure (KF) in patients with the rare disease primary hyperoxaluria (PH) is challenging to study due to small sample sizes and correlations among POX, UOX, and eGFR. To develop better KF models that simultaneously account for all 3 variables we used a novel statistical approach, joint models, modeling longitudinal biomarker processes (eGFR POX, UOX) and survival process (time-to-KF) jointly, using retrospective data from the Rare Kidney Stone Consortium PH registry.

Methods: Repeated eGFR, UOX, and POX after PH diagnosis were obtained from the registry. Time-to-KF was defined as time between PH diagnosis until transplantation, dialysis or eGFR<15 mL/min/1.73m². A multivariate joint model was fit with longitudinal sub-models for each biomarker and a survival sub-model for KF. Longitudinal sub-models employed linear mixed effects models with biomarkers on the log scale. Joint modeling with shared information between longitudinal and survival sub-models such that eGFR, UOX, and POX were time-dependent variables in the survival sub-model, specifically using subject-specific mean biomarker values. Models were adjusted for age and sex at diagnosis. Results were compared to last observation carried forward (LOCF) analyses.

Results: A total 166 patients (mean 5 POX and 7 UOX per patient) with 60 KF events during follow up were included. With LOCF, POX positively associated with KF risk, both unadjusted and adjusted for other biomarkers (hazard ratio (HR) = 1.14 per umol/L, 95%CI = 1.07, 1.22, p<0.001), while UOX was not associated with KF after adjustment. With joint modeling, POX and KF were not significantly associated after adjustment (HR = 1.12, 95%CI = 0.99, 1.30, p=0.08), while higher UOX was associated with lower KF risk (HR = 0.30 per mmol/l/1.73m²/24h, 95%CI = 0.07, 0.92, p=0.04).

Conclusions: When modeling unevenly spaced longitudinal biomarkers and their association with KF, the LOCF time-dependent model makes implausible assumptions about steady-state biomarkers between observations. Implementation of a joint modeling framework allows flexible estimation of the association, which may impact conclusions. These novel methods can be used to inform patient-specific decisions about future KF risk, and the risk-benefit of novel treatment approaches.

POI1319

Modeling the Risk of Progression to Kidney Failure in Patients with Primary Hyperoxaluria Type 1 Treated with Lumasiran Relative to a Natural History Cohort Not Treated with Lumasiran

John C. Lieske,1 Kristin C. Mara,1 David S. Danese,2 John M. Gansner,2 Jiandong Lu,1 Dawn S. Milliner,1 1Mayo Clinic Minnesota, Rochester, MN; 2Alnylam Pharmaceuticals Inc, Cambridge, MA.

Background: In primary hyperoxaluria type 1 (PH1), the risk of kidney failure (KF) is positively associated with urinary oxalate (UOX) excretion. Lumasiran is an RNAi therapeutic to lower UOX levels in patients with PH1. We estimated the risk of progression to KF in patients with PH1 treated with lumasiran, relative to patients not treated with lumasiran.

Methods: A skewed-normal distribution of 24hr UOX values for patients with PH1 was simulated based on reported UOX values from the Rare Kidney Stone Consortium (RKSC) PH Registry among patients who were not in KF at diagnosis and did not receive lumasiran. Data from the ILLUMINATE-A trial of lumasiran were used to build a log-linear model of post-lumasiran treatment steady-state UOX as a function of baseline UOX. The distribution of steady-state, on-treatment UOX values for RKSC patients was then predicted by applying this model to the simulated 24hr UOX values of the RKSC cohort, considered as baseline. A risk model of KF as a function of 24hr UOX excretion, based on Kaplan-Meier curves of renal survival reported from the RKSC, was used to estimate the number of KF events/100 patients in the RKSC PH1 cohort, had all received lumasiran.

Results: The mean (SD) 24hr UOX excretion for the RKSC PH1 cohort was 2.2 (1.1) mmol/24hr/1.73m² in the absence of lumasiran treatment and was predicted to decrease to 0.62 (0.17) mmol/24hr/1.73m² in a model that simulated the effect of lumasiran administration (Figure 1). The predicted number of KF events/100 patients (95% CI) using the model for patients not treated with lumasiran at 10, 20 and 30 years, is 10 (4, 23), 32 (19, 50), and 42 (27, 59), respectively. In the model of lumasiran treatment, the estimated cumulative number of KF events/100 patients (95% CI) was 4 (1, 12) at 10 years and remained unchanged at 20 and 30 years.

Conclusions: This analysis predicts a long-term reduction in KF risk among PH1 patients treated with lumasiran following prompt treatment at diagnosis.

The Complex Landscape of Factor H and Factor I Rare Variants in Atypical Hemolytic Uremic Syndrome and C3 Glomerulopathy

Veronique Fremeaux-Bacchi,1,2 Marie-Sophie Meuleman,2 Paula Vieira-Martins,3 Sophie Chauvet,4 Fadi Fakhouri,1,2 Assistance Publique-Hôpitaux de Paris, Paris, France; 3INSERM U1138, Paris, France; 4Lausanne University Hospital, Lausanne, Switzerland.

Background: Complement genetics has been extensively studied to dissect the pathophysiology of atypical hemolytic uremic syndrome (aHUS) and C3 glomerulopathy (C3G) paving the way for highly tailored therapy. However, the assessment of each identified variant’s contribution to disease pathogenesis remains a challenge in particular for rare variants detected in patients as well as in healthy individuals in the genome Aggregation Database (gnomAD). In this study we aimed to describe the rare variants in Factor H (CFH) and Factor I (CFI) genes identified in the French cohort of patients with aHUS and C3G.

Methods: We analyzed the distribution of the allele frequency (AF) of rare variants identified in 397 and 398 adult patients with a diagnosis of aHUS without coexisting disease and with C3G/ig-mediated membranoproliferative glomerulonephritis (Ig-MPGN), respectively. We selected for this study variants with minor AF (MAF) below 0.1% in European healthy individuals.

Results: The frequency of patients with rare variants in CFH (108/398 vs 54/398) and CFI (33/397 vs 17/397) genes was higher in aHUS compared to C3G. A total of 148 variants were identified in CFH (n=98) and in CFI (n=50) genes. Among them, 9 were present in both diseases. We identified 43 (67%) and 20 (66%) novel variants in CFH in aHUS and C3G, respectively. Among them, 98% are pathogenic compared to 44% of the variants reported in gnomAD. The frequency of variants causing FH and FI disease is similar in both diseases (70% of the variants). The frequency of CFH variants identified in more than 1 patient is increased in aHUS compared to C3G (11/64 vs 2/30). We identified 12 (12/38, 31%) and 2 (2/12, 16%) novel variants in CFH in aHUS and C3G, respectively.

Conclusions: Our study indicates that novel pathogenic rare variants in complement genes is more frequent in aHUS than in C3G. Half of the variants reported in gnomAD is higher in CFI (80%) compared to CFH (70%). The frequency of variants reported in gnomAD is higher in CFI (80%) compared to CFH (14%).

PO1321
Phenotypic-Genotypic Relationship of Focal and Segmental Glomerulosclerosis (FSGS)
Ana M. Tato,1 Noa Carrera cachaza,2 Maria Garcia-Murias,2 Amir Shabaka,1 Clara M. Cases Correa,1 Gema Fernandez Juarez,1 Miguel Angel Garcia-Gonzalez,2 Hospital Universitario Fundacion Alcorcon, Alcorcon, Spain; 3Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain.

Background: FSGS can be of primary, secondary or genetic origin. The objective of our work is to establish in which patients with a histological diagnosis of FSGS a genetic etiology should be suspected.

Methods: The study included adult patients with a histological diagnosis of FSGS and normal albumin (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHS2 mutations were discovered in 7 (23%) patients. The remaining cases with normal albumin (58%).

Results: Out of 108 samples received, 80 patients met the inclusion criteria. We detected FSGS-related pathogenic genetic variants in 31 (39%) patients, finding no difference between those whose indication was steroid resistance (32 %) or proteinuria without albuminuria (58%). We found 20 pathogenic variants of collagen IV in 17 (55%) patients. NPHP2 mutations were discovered in 7 (23%) patients. The remaining cases had variants affecting INPF2, OCR1, HNF1B, WT2. All 3 (black) patients had high-risk APOL1 alleles. There were no differences between genetic and non-genetic causes in age, proteinuria, GFR, serum albumin, BMI, hypertension, diabetes, or family history. Hematuria was more prevalent among patients with genetic causes.

Conclusions: Genetic testing should be considered in FSGS patients in which a secondary cause has been excluded, to determine the patient’s prognosis, treatment and perform familial screening.

PO1322
Insight into the Pathophysiology of Hearing Loss and Renal Tubular Dysfunction Through Genetic Testing
Dylan H. West,1 Jones Samuel,1,2 Baton Rouge General Medical Center - Bluebonnet, Baton Rouge, LA; 1Renal Associates of Baton Rouge, Baton Rouge, LA.

Introduction: In this case report, we present a case of Type 3B Bartter’s Syndrome associated with sensorineural hearing loss.

Case Description: A 69 year old caucasian female with a history of hypertension and osteoporosis presented to the emergency department with a worsening dry cough, altered mental status, and paresthesias. Physical examination was positive for Chvostek’s sign and hearing loss bilaterally. Laboratory analysis was significant hypocalcemia, hypokalemia, and hypomagnesemia. EKG on presentation displayed significant QT prolongation (QTC of 482 ms). The patient was treated for symptomatic hypocalcemia and initiated on calcium, potassium, and magnesium supplementation. 24 hour urine collection yielded: potassium and magnesium wasting and normal range calciuria. Parathyroid hormone was found to be inappropriately low in the setting of severe hypocalcemia but attributed to hypomagnesemia. Bartter’s vs. Gitelman’s was suspected, although profound hypomagnesemia suggested the latter. Renasight, a kidney gene panel employing next generation genome sequencing revealed a heterozygous variant in the basal chloride channel (CLCNKB), associated with Bartter’s Syndrome Type 3/4B.

Conclusion: This channel is found in the stria vascularis and can lead to sensorineural deafness. Hypoparathyroidism persisted in spite of adequate Magnesium, Vit D levels suggestive of primary hypoparathyroidism of autoimmune etiology.

Discussion: The positivity of CLCNKB heterozygous mutation suggested Bartter’s Type 3/4B and this explained hearing loss and aided in the final diagnosis. Individuals who express both type A and B mutations present in infancy or antenatally. In a series of 113 patients w/ type B gene mutation, 26% had a Gitelman-like syndrome which includes loss of function of the T1 gene (1). Our case illustrated the utility of genetic testing in mixed electrolyte wasting presentations. Interestingly, the patient has persistent hypoparathyroidism for which no genetic basis was identified such as the calcium sensing receptor mutation.

Renal Studies

PO1323
Whole-Exome Sequencing as a First-Line Diagnostic Tool in Bartter and Gitelman Syndromes
Francesca Becherucci, Viviana Palazzo, Luigi Ciriolo, Benedetta Mazzinghi, Valentina Raglianti, Samuela Landini, Paola Romagnani. Meyer Children’s Hospital, Florence, Italy.

Background: The clinical diagnosis of Bartter (BS) and Gitelman syndrome (GS) can be challenging, as they are rare and phenotypically overlapping. Thus, genetic testing represents the gold standard for the diagnosis. Next-generation sequencing is increasingly utilized in diagnostics and research of inherited tubulopathies. Sequencing of gene encoding for liver kinase B1 (LKB1) is suggested as a first-line test in patients with a history of hypokalemia and/or hypocalcemia. However, this gene may be involved in a variety of tubulopathies, so a thorough clinical evaluation is required to confirm the clinical diagnosis.

Methods: We enrolled 50 patients (25 males) with a clinical diagnosis of BS or GS. All patients showed hypokalemic metabolic alkalosis at onset. The median age at clinical diagnosis was 7 years (range 0-67). WES showed pathogenic variants in 41/50 patients (82%). The positivity of CLCNKB heterozygous mutation suggested Bartter’s Syndrome. Whole-exome (WES) is not routinely performed for the molecular diagnosis of BS and GS. The aim of our study was to assess the diagnostic performance of WES in BS and GS, to establish genotype-phenotype correlations and to assess cost-effectiveness of this approach.

Results: We performed WES in all consecutive patients referred for genetic testing with a clinical suspect of BS or GS. Variant prioritization was carried out according to ACMG guidelines. Clinical data were collected retrospectively.

Conclusions: Our study demonstrates that WES ensures a high diagnostic yield and new insights into the genotype-phenotype spectrum of these rare disorders. Whole-exome (WES) is not routinely performed for the molecular diagnosis of BS and GS. The aim of our study was to assess the diagnostic performance of WES in BS and GS, to establish genotype-phenotype correlations and to assess cost-effectiveness of this approach.

Examination of the Predicted Prevalence of Gitelman Syndrome by Ethnicity Based on Genome Databases
Atsushi Kondo,1 Sadaayuki Nagai,1 Yuya Aoto,1 Nana Sakakibara,1 China Nagano,1 Tomoko Horinouchi,1 Tomohiko Yamamura,2 Kazuomo Iijima,1 Kandai Nozu.1 1Kobe University Graduate School of Medicine, Department of Pediatrics, Kobe, Japan; 2Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: Gitelman syndrome is an autosomal recessive inherited salt-losing tubulopathy. It has a prevalence of around 1 in 40,000 people, and heterozygous carriers are estimated at approximately 1%, although the exact prevalence is unknown because most cases are thought to be asymptomatic or have nonspecific clinical findings. On the other hand, it has been reported that the non-specific symptoms can reduce the quality of life of patients, and in practice, we have often experienced cases where patients have suffered from these symptoms since childhood, but were not diagnosed and therefore not treated, and were diagnosed in adulthood. It could suggest that there are far more patients and carriers than expected.

Methods: We estimated the predicted prevalence of Gitelman syndrome based on multiple genome databases, HGVD and Jmpor for the Japanese population and gnomAD for other ethnicities, and included all 274 pathogenic missense or nonsense mutations registered in HGMD Professional. The frequencies of all these alleles were summed to calculate the total variant allele frequency in SSC1243 which is the responsible gene for Gitelman syndrome. The carrier frequency and the disease prevalence were assumed to be twice and the square of the total allele frequency, respectively, according to the Hardy-Weinberg principle.

Results: In the Japanese population, the total carrier frequencies were 0.0498 (9.5%) and 0.0686 (8.7%) and the calculated prevalence was 0.00225 (2.3 in 1000 people) and 0.00188 (1.9 in 1000 people) in HGVD and Jmpor, respectively. Other ethnicities showed a prevalence varying from 0.000012 to 0.00083.

Conclusions: These findings indicate that the prevalence of Gitelman syndrome in the Japanese population is higher than expected and that some other ethnicities also have a higher prevalence than previously been considered.

PO1325

An Off-the-Shelf CRISPR Gene Therapy Approach in Human Kidney Organoids
Nicole Vo, Catherine A. Macnary, Benjamin S. Freedman. The Freedman lab University of Washington, Seattle, WA.

Background: Gene therapy offers many opportunities to treat kidney diseases. Targeted, off-the-shelf therapeutics are needed for both loss-of-function (e.g. nephropathic cystinosis) and gain-of-function (e.g. ApoL1) disease states. Kidney organoids are complex structures that resemble nephrons and can be used to develop gene therapy approaches. Commonly used gene transfer techniques, such as lentivirus and adenovirus, are size limited, transient, or introduce DNA non-specifically into the genome. While targeted CRISPR gene editing is routinely used in 2D cell cultures, it has been challenging to use this powerful technique in intact organoids.

Methods: To achieve off-the-shelf gene transfer, organoids were transfected with Cas9 and gRNA ribonucleoprotein (RNP) complexes targeting the AAVS1 safe harbor locus supplemented with knock-in cassettes encoding green fluorescent protein (GFP) or FLAG-tagged cystinosin (deficient in nephropathic cystinosis). Alternatively, to monitor gene knock-out, organoids expressing GFP from AAVS1 were transfected with RNP and either one or two gRNAs to introduce indels in the coding sequence. Genome editing was detected three ways: by confocal microscopy, PCR, and next generation sequencing.

Results: GFP and cystinosin knock-in events in organoids were detected using microscopy and PCR. Immunofluorescence analysis revealed knock-in in proximal tubule epithelial cells (LTL). In knock-out experiments, live confocal microscopy indicated areas of GFP loss within kidney organoid treated with gRNA targeting GFP, but not with a scrambled guide. Mosaic patches of GFP knockout cells expanded over several days. Staining with neprhin markers such as LTL and podocalyxin revealed knockout in both proximal tubule cells and podocytes. By next generation sequencing, the two-guide system produced larger deletions and was more efficient (20 % knockout), compared to single guide.

Conclusions: The strategy developed here is efficient for knocking in and knocking out genes in kidney epithelium. It uses commercially available reagents to perform CRISPR gene editing. sgRNA sequences or AAVS1 knock-in templates can be customized to target or introduce any gene of interest at specific loci. This provides a platform for the development of off-the-shelf gene therapies for diverse kidney disease states.

PO1326

The Kidney Genome Atlas: A Resource to Understand APOL1 and Other Driving Genes of Adult Proteinuric Kidney Diseases
Eva Fast,1 Thomas Soare,2 Hari Sominici,3 James Watkins,4 Adam Tebbe,5 Maria LaPolti,6 Liron Walsh,7 Matthias Kretzler,8 Girish N. Nadkarni,9 Rasheed A. Ghadgesin,10 Jamie L. Wenke,11 Daniel G. Macarthur,1,12 Peter D. Mundel,13,14 Michelle Penny,15 Goldfinch Bio Inc, Cambridge, MA; 1Instiro, South San Francisco, CA; 2University of Michigan, Ann Arbor; MI; 3Mount Sinai Health System, New York, NY; 4Duke University School of Medicine, Durham, NC; 5Nashville BioSciences, Nashville, TN; 6Atlas Venture, Cambridge, MA; 7Dogman Therapeutics, Westford, MA; 8Garvan Institute of Medical Research, Darlinghurst, NSW, Australia.

Background: Chronic kidney disease (CKD) affects more than 30 million people in the US with African Americans being particularly at risk. There is an unmet need for pharmaceutical therapies that extend or, ideally, restore kidney function.

Methods: To guide genetically-driven drug development, we have established the Kidney Genome Atlas (KGA), which contains whole-genome sequences (>30X) from adult patients with Focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD) and other, idiopathic, proteinuric disorders as well as public and technically matched controls. By implementing a rigorous quality control procedure, following the gnomAD pipeline, we obtained a high-confidence dataset for downstream analyses. Three genetically inferred ancestries (EUR, AFR, AMR) were included in association testing comparing 1400 cases, including 169 individuals with APOL1 G1/G1, G2/G2 or G1/G2 high risk haplotypes (APOL1-HHR), with 14686 controls including 485 APOL1-HHR individuals.

Results: Overall, our common variant cross-ancestry meta-analysis showed minimal impact of potential confounders, such as ancestry or sequencing center differences (lambda=1.03). Using summary statistics from our EUR analysis, we estimated a SNP heritability of 0.15 (SE = 0.028) in proteinuric diseases. Comparison to a recent CKD GWAS (Wuttke et al., 2019) indicated a weak positive genetic correlation (rg) of 0.097 (p = 0.053). We identified the previously reported significant disease association of APOL1-HHR (p=2x10^-10) in our study. Recent in vitro data suggests amino acid in position 150 (rs2239785) is critical for the pathogenicity of APOL1-HHR (PO1986, ASN 2020) which we confirmed in our cohort of AFR ancestry individuals.

Conclusions: We have built a high-quality, multiethnic cohort that enables understanding of genetic drivers of polygenic proteinuric kidney disease. Future analysis including genetic modifiers of APOL1 may provide opportunities for novel therapies and patient stratification.

PO1327

Effect of ApoL1 Genotype on Kidney Failure and eGFR Decline in Patients with All-Cause CKD

Background: ApoL1 risk variants G1 and G2 associate with an increased risk of kidney failure and a higher rate of eGFR loss. We assess the effect of ApoL1 genotype in African American and Latino individuals with chronic kidney disease (CKD) in New York City.

Methods: ApoL1 genotype determined by sequencing. CKD cases with high-risk ApoL1 genotype (n= 242) were compared to CKD cases with a low-risk ApoL1 genotype (n=885) and African ancestry per Admixture. Kaplan-Meier survival analyses assessed time to kidney failure followed by Adjusted Cox-proportional hazard model and competing risk regression against death both incorporating covariates. Linear mixed-effects modelling evaluated CKD-EPI eGFR decline rate using the same covariates.

Results: Cases with a high-risk ApoL1 genotype reach kidney failure 10-15 years earlier than low-risk cases. G1/G1 reach kidney failure earliest, followed by G1/G2 and G2/G2 (Fig 1). These data are supported across multiple risk models (Table 1). Cases with a high-risk genotype have a higher eGFR decline rate than low-risk cases with a similar trend per specific genotype (Fig 2). The addition of self-declared or genetically defined ancestry did not confer additional risk.

Conclusions: High-risk ApoL1 genotypes increase the risk of kidney failure at an earlier age, likely due to a higher eGFR decline rate. G1/G1 genotypes appear most affected and G2/G2 least.

Funding: Government Support - Non-U.S.

“APOL1-Plus” Genotypes in Patients with CKD
Darby, Rabble; Dinah Clark,1 Fang Fang,2 Jing Xie.1 1Natera, Inc., San Carlos, CA; 2Pulgenet Genetics, Temple City, CA.

Background: Inheritance of homozygous or compound heterozygous APOL1 G1 G2 risk alleles is associated with an increased risk of chronic kidney disease (CKD) including focal segmental glomerulosclerosis (FSGS). The APOL1 high-risk genotype (HRG) is not completely penetrant; additional genetic and/or environmental factors are thought to be necessary for the development of CKD. While approximately 10% of individuals with CKD have causal variants when tested with exome-based next generation sequencing (NGS), few reports have examined co-occurrence of APOL1 HRG alongside these variants. Here we examine the co-occurrence of APOL1 HRG and additional genetic diagnoses (“APOL1-plus”) using a broad NGS panel of CKD genes.

Methods: Clinical samples were analyzed via an NGS panel of >380 genes associated with isolated or syndromic CKD. Positive results included one pathogenic (P) or likely pathogenic (LP) variant in an autosomal dominant or X-linked gene, two P/LP variants in an autosomal recessive gene, or presence of two APOL1 risk alleles.

Results: Among 1691 cases with positive results, 25% (n=430) had positive findings in APOL1. Other positive findings included variants in PKD1/2 in 27% (456/1691) of cases, and in COL4A3/4 in 22% (379/1691) of cases. Among positive cases, 7% (119/1691) had >1 positive result, including both dial (n=115) and tripe diagnoses (n=4). APOL1 HRG was present in 50% (59/119) of cases with multiple diagnoses, accounting for 3.5% of all positive cases and 14% of all APOL1 HRG cases. Among the APOL1-plus cases, second positive findings were observed in COL4A3/4 (29%; 17/59), TTR (29%; 17/59), and PKD1/2 (15%; 9/59).

Conclusions: Dual diagnoses comprised 7% of all positive genetic testing results, with APOL1 HRG present in half of these cases. Future studies are needed to understand how multiple genetic diagnoses, including those with APOL1 HRG, impact disease presentation and progression. Dual APOL1 and collagen IV-related diagnoses are of particular interest given the frequency of these glomerulopathies in the CKD population. Genetic testing via broad NGS panels can improve diagnosis and management of CKD and increased testing will contribute to an evolving understanding of genetic etiologies of CKD.

PO1329
Uncovering Mechanisms of Risk-Variant APOL1-Modulated Inflammatory Signaling in Macrophages
Esther Liu, Jennie Lin. Northwestern University Feinberg School of Medicine. Chicago, IL.

Background: In the United States, Black Americans face a higher risk to develop CKD and progress to end stage kidney disease (ESKD) even after accounting for clinical and socioeconomic factors. Variants in the gene encoding for the innate immunity factor Apolipoprotein L1 (APOL1) have been identified as risk factors for focal segmental glomerulosclerosis (FSGS) and HIV-associated nephropathy (HIVAN) in individuals with recent African ancestry. However, the role of immune cells in APOL1 nephropathy is not well understood. In this study we seek to understand the effect of risk variant APOL1 on macrophage function and inflammation.

Methods: Isogenic induced pluripotent stem cell (iPSC) lines expressing the G0, G1, and G2 variants of APOL1 were generated through CRISPR/Cas9 gene editing. These iPSC lines were used to generate iPSC-derived macrophages (iPDSM). Peripheral and bone marrow-derived macrophages (BMDMs) were collected from transgenic mice 4-18 weeks of age expressing G0, G1, and G2 variants of APOL1 in cultured iPDSM, peritoneal macrophages, and BMDMs were induced with IFNγ (5 ng/mL).

Results: We observed that risk-variant APOL1 expression results in higher TNF and IL1β gene expression by nine-fold and two-fold respectively, in G1 iPDSM compared to G0. Additionally, G2 mouse BMDMs exhibited increased glycolytic rate compared to G0 both at baseline and under mitochondrial stress when APOL1 was induced with IFNγ.

Conclusions: The findings in this study unveil some mechanisms by which risk-variant APOL1 modulates macrophage inflammatory phenotype and function, relevant to kidney disease progression.

A Multivariate Analysis of Genome-Wide Association (GWAS) Data to Identify Genes Associated with CKD
Amy J. Osborn, Agnieszka Bierzynska, Gavin I. Welsh, Moin Saleem, Ian C. Campbell. University of Bristol, Bristol, United Kingdom.

Background: Chronic kidney disease (CKD), a major public health burden, is characterised by a progressive loss of nephron function which leads to an impaired ability to filter the blood. Genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) and loci associated with the development of chronic kidney disease, (eGFR) and blood urea nitrogen (BUN) by mostly univariate-based analyses. However, gene-based multivariate-SNP and multivariate-biomarker relationships have typically not been considered so far in this context. The purpose of this study was to highlight the additional insights gained from the statistical power of a multivariate-based approach to identify potential risk factor genes for CKD.

Methods: We used a multivariate statistical approach, canonical correlation analysis (CCA), to identify single nucleotide polymorphisms (SNPs) that showed significant correlation with estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN) together among univariate-based analyses. For each significant SNP and genes we identified, their functional, signalling pathways, and cellular expression were investigated using gene set enrichment analyses.

Results: For each of three published GWAS summary statistics datasets of both European and Japanese ancestry groups, we identified sets of 159, 246 and 181 protein-coding genes, respectively, that contained significant SNPs. Using gene set enrichment analyses, these genes showed significant enrichment for kidney development processes, signalling pathways and kidney cell gene expression signatures. In addition, between all three datasets, we identified four significant genes (CBLB, MACROD2, MFCOM and SHROI3) that overlapped. Between two datasets, we identified a further four significant SNPs that overlapped.

Conclusions: By using a multivariate statistical approach, we have identified both previously reported and additional genes that contained significant SNPs statistically associated with kidney function. Overall, these findings provide new insights into SNPs and genes potentially involved in kidney function and CKD risk.

PO1331
Rare Variants and Risk of ESKD: The Geisinger Mycode-DiscoEHR Study

Background: Prior studies have reported that up to 10 patients with end-stage kidney disease (ESKD) have a diagnostic rare genetic variant but have lacked control groups.

Methods: Whole exome sequencing and electronic health records data from 147,750 participants in the Geisinger MyCode-DiscoEHR study, a health system-based cohort, were linked to the US Renal Data System to ascertain ESKD status and attributed cause. We compiled a list of variants in 80 autosomal or X-linked dominant (AD/XLD) genes used in commercial kidney genetics panels previously reported in ClinVar as pathogenic or likely pathogenic (P/LP) minor allele frequency <0.01, any number of stars. We evaluated the association of these rare P/LP variants with risks of all-cause and cause-specific ESKD in logistic regression models adjusted for age and sex. Additional analyses were performed by subsets of kidney disease genes and by age of ESKD onset.

Results: Prevalence of previously reported rare P/LP variants in AD kidney disease genes was higher in participants with ESKD than those without ESKD (3.0% vs. 1.2%). Rare P/LP variants were most prevalent in congenital/cystic ESKD (12.6%), followed by ESKD attributed to germline/nephropathies/skin conditions (8.9%), hypertension (4.3%), glomerular/vasculitis disorders (3.4%), and early onset diabetic ESKD (<60 years; 3.3%). By contrast, only 0.7% with later onset diabetic ESKD (60 years+) had rare P/LP variants. Individuals with rare variants were at increased risk of all-cause ESKD (OR 2.71, 95% CI 1.19-5.70) (Table). When genes were grouped by specific categories, rare variants in cystic disease, Alport Syndrome, CUKAT, and FSGS gene panels were all associated with increased risk of ESKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Individuals in an unselected health system cohort with rare variants had substantially increased risk of ESKD, which was often attributed to hypertension or diabetes.

Associations between rare variants and ESKD phenotypes

PO1332

Genomic Disorders Are Associated with CKD Across the Life Span

Miguel Vezzoni,1 Sarah Babu Krishna Murthy,2 Maddalenia Marasa,3 Junying Zhang,2 Atlas Khan,3 Craig S. Wong,3 Bradley A. Warady,3 Susan L. Furth,2 David R. Crosslin,1 Robert P. Igo,4 Sudha K. Iyengar,4 Simone Sanna-Cherchi,5 Krzysztof Kiryłuk,6 Afsin Parsa,7 Harold I. Feldman,8 Ali G. Ghavri,9 Columbia University, New York, NY; 1The Children’s Hospital of Philadelphia, PA; 2University of Washington, Seattle, WA; 3Case Western Reserve University, Cleveland, OH; 4National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 5University of Missouri Kansas City, Kansas City, MO

Background: Genetic Disorders (GDs), caused by pathogenic deletions and duplications (copy number variants, CNV) of large genomic regions, are the major cause of genetic susceptibility for multiple developmental traits and are enriched in pediatric chronic kidney disease (CKD) phenotypes. In the Chronic Kidney Disease in Children Study (CKiD) cohort 1.45% patients carried a GD.

Methods: We extended our previous study in CKiD to cohort 2 and also examined the prevalence of GDs in adults with all-cause CKD enrolled in the Chronic Renal Insufficiency (CRI, N = 3375), Columbia University CKD (CU-CKD, N=1146) and Family Investigation of Nephropathy and Diabetes (FIND, N=1318) cohorts, comparing GDs in adults with all-cause CKD enrolled in the Chronic Renal Insufficiency (CRI, N = 3375), Columbia University CKD (CU-CKD, N=1146) and Family Investigation of Nephropathy and Diabetes (FIND, N=1318) cohorts, comparing them to 30746 controls. CNV calls were based on SNP microarrays and whole exome sequencing and annotated for known GDs. We also performed a phenome-wide association analysis of GDs in the Electronic Medical Records and Genomics (eMERGE, N=11971) cohort.

Results: We found 9248 (3.6%) CKD2 pediatric participants with mild CKD carried a GD, replicating prior findings in pediatric CKD. We next identified GDs in 74,667 (1.1%) adult CKD patients in the CRI, CU-CKD and FIND cohorts, compared to 165,30.746 (0.5%) GDs in controls (OR=1.6, p<5x10^-10). Recurrent known GDs in adult CKD patients comprised pathogenic CNVs in 1q21.1, 16p11.2, 17q12 and 22q11.2 loci. The 17q12 GD (renal cyst and diabetes syndrome) was most frequent, detected in 1,252 CKD cases with diabetes. In the phenome-wide analysis of the eMERGE cohort, dialysis was in the top three phenotypic associations with GD carrier status (p<10^-9), replicating the case-control association results. Other phenotypic associations for GDs in CRIC participants included lower serum Mg (p=2x10^-10) and lower educational achievement (p=5x10^-10).

Conclusions: GDs are significantly enriched in children and adults with CKD. Undiagnosed GDs can provide a molecular explanation for renal disease in both adults and children and represent hidden genetic links between CKD and other traits such as poorer neurocognitive performance. Systematic detection of GDs can enable a precise genetic diagnosis and inform prognosis and treatment.

Genome-Wide Association Study in Mice Maps Susceptibility to HIV-Associated Nephropathy to the Sshp2 Locus

Nicholas J. Steers,1 Yask Gupta,2 Vittore D. D’Agati,3 Tze Yin Lim,1 Anna Mo,1 Judy Liang,1 Kelsey O. Stevens,1 Natalia D. Demaria,1 Wan Yee Lam,4 Lalitha Nagarajan,5 Simone Sanna-Cherchi,6 Ali G. Ghavri,9 Columbia University Irving Medical Center, New York, NY; 1The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: To gain insight into the pathogenesis of collapsing glomerulopathy, a rare form of focal segmental glomerulosclerosis that often arises in the setting of viral infections, we performed a genome-wide association study (GWAS) among inbred mouse strains using a murine model of HIV-1 associated nephropathy (HIVAN).

Methods: F1 hybrids were generated between HIV-1 transgenic mice on the FVB/NJ background and 20 inbred laboratory strains. Histology, BUN, proteinuria and urinary NGAL were assessed in the F1 hybrids. A GWAS in 366 transgenic F1 hybrids generated from these 20 inbred strains was performed.

Results: Six stains (A/J, C3H/HeJ, DBA/J, KK/HJ, WSB/EiJ, and LP/J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 9 strains (129S1/SvImJ, Balb/CJ, C57BL/6J, C57Bl/6NJ, C57Bl/10J, C57Bl/J, C57/J, CAST/EiJ and NZB/BINJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HILtF and FVB/NJ) had intermediate glomerulosclerosis. Analysis of histology, BUN and urinary NGAL demonstrated a marked phenotypic variation among the transgenic F1 hybrids, providing strong evidence for host genetic factors in the predisposition to nephropathy. A GWAS identified a genome-wide significant locus on Chr. 13 and multiple additional suggestive loci. Cross annotation of the Chr. 13 locus, including single cell transcriptomic analysis of wild type and HIV-1 transgenic mice kidneys, nominated Sshp2 as the likely culprit gene. Sshp2 is highly expressed in podocytes, encodes a transcriptional cofactor present in LDB1 containing complexes, and interacts with LMX1B, a known FSGS gene that requires LDLH for optimal transcriptional activity. Consistent with these data, older Sshp2 null mice spontaneously developed glomerulosclerosis, tubular casts, interstitial fibrosis and inflammation, similar to the HIVAN mouse model.

Conclusions: These findings demonstrate the utility of GWAS in mice to uncover host genetic factors for rare kidney traits and suggest Sshp2 as susceptibility gene for HIVAN, potentially acting via the LDLH-LMX1B transcriptional network. Future studies will evaluate the role of Sshp2 in vitro and in Sshp2 null mice.

Funding: Other U.S. Government Support
and papillorenal syndrome. Case 2: 21-year-old male with biopsy proven FSGS when he had an atypical c.233A>C (p.Glu82Arg) mutation in the KCNJ5 gene, which can lead to FSGS, optic nerve coloboma, and hypertension. Genetic testing showed a truncating c.247delC variant in the COL4A3 gene, associated with PKD1, was detected in a 21-year-old male with biopsy proven FSGS when he was 8 years old mentioned that his maternal grandfather suffered from unknown renal disease requiring dialysis and died in his 40s. Genetic testing revealed hemizygous, truncating p.W58* variant in the CLCN5 gene. Variants in CLCN5 gene can cause Dent’s Disease manifesting later in life as proteinuria, nephrinoclastosis, hypercalciuria and renal failure. In addition he had variant of unknown significance in NPHS1 designated p.T233A, and APOL1 G2 risk allele predisposing him to develop FSGS. Case 3: 21-year-old male, born with genital ambiguity, perineal hypoplasias, 46 XY karyotype was noted to have 14 g of proteinuria, low albumin and hypertension. Kidney biopsy revealed FSGS, abnormal glomerular basement membrane. Genetic testing was positive for heterozygous truncating variant of WT-1 and a monogenic missense variant of SMARCAL1 p.R520H which are pathogenic variants that cause renal failure due to defective podocyte development and dysfunction respectively.

Discussion: Genetic analysis for FSGS has become an important diagnostic tool in nephrology. We currently have over 50 genes that are known to be involved in FSGS. Reporting of different genetic variants and their occurrence is crucial to yield insight into our current understanding of FSGS.

PO1337

Whole-Exome Sequencing Reveals a Monogenic Cause of Disease in 26% of 335 Families with Steroid-Resistant Nephrotic Syndrome

Ronen Schneider,1 Konstantin Deutsch,1 Ana C. Onuchic-Whitford,2 Kirollos Yousef,1 Muhammad Y. Zahoor,1 Camille H. Nicolas Frank,1 Florian Buergner,1 Shiree Shril,1 Michael J. Somers,1 Friedhelm Hildebrandt,1,3 Boston Children’s Hospital, Boston, MA; 4Brigham and Women’s Hospital, Boston, MA.

Background: Steroid resistant nephrotic syndrome (SRNS) overwhmelingly progresses to end-stage renal disease. To date, more than 59 monogenic genes have been identified to cause SRNS. We previously detected causative mutations in 26% of whole exome sequencing (Wexome) patients with SRNS using targeted panel sequencing (Sadowski 2015; Warejko 2017). However, whole exome sequencing (WES) has become more accessible, with the advantage of detecting not only known monogenic causes of SRNS, but also novel candidate NS-causing genes.

Methods: We employed whole exome sequencing (WES) to detect monogenic causes of SRNS in a large international cohort of 335 families with SRNS presenting before the age of 25 years.

Results: Samples were recruited from April, 1998 to December, 2018 (21 years). WES was performed at the Yale Center of Mendelian Genomics. First, we examined the WES data for mutations in 59 known genes known to cause SRNS. In 87/335 families (26%), we identified mutations in 22 of the known genes. There were also 7 genes that were identified in phenocopies of SRNS e.g. COL4A3. In 58 families (17.3%), we have identified mutations in a potential novel candidate gene for SRNS. We found a 48.1% solve rate in individuals with high homogyosity by decent and 15.4% solve rate in non-homogyous individuals, recapitulating similar solve fractions to what has been previously published (Sadowski 2015; Warejko 2017).

Conclusions: This study confirms that ~26% of families with NS in our cohort are due to monogenic causes, WES is a viable way to diagnose the underlying cause of NS in children and young adults, and to suggest novel monogenic candidate genes of NS.

PO1338

Discovery of Podocyte-Specific Interaction Partners of the Nephrotic Syndrome-Associated Protein NOS1AP

David A. Ball,1 Florian Buergner, Friedhelm Hildebrandt, Amar J. Majmundar.

Boston Children’s Hospital Department of Pediatrics, Boston, MA.

Background: NOS1AP mutations are a novel Mendelian cause of nephrotic syndrome (NS) in humans and mice (Majmundar Sci Adv 2021). The NS patient mutation p.C143Y destabilizes the predicted structure of the NOS1AP phosphotyrosine-binding domain, impairs NOS1AP-dependent actin remodeling in podocytes. These proteins may mediate NOS1AP-dependent actin remodeling and thus help stabilize podocytes

Methods: Protein interaction data from candidate immunoprecipitation, mass spectrometry, and yeast two-hybrid studies were queried from the literature and public databases (Orchard 2014; Oughtred 2018). Protein interactions were validated by co-immunoprecipitation studies using tagged cDNA constructs.

Results: 85 putative NOS1AP-interacting proteins were identified from candidate interaction and proteomics studies. Six interacting proteins (of 85) demonstrated co-expression with NOS1AP in podocyte clusters from at least three out of four kidney scRNAseq datasets (% cell expression z-score > 1). Four of six candidates (FYN, GSN, SNTA1, HSP1A2A) were cloned into expression vectors for interaction studies. SNTA1 and HSP1A2A exhibited bi-directional co-immunoprecipitation with wildtype NOS1AP upon co-overexpression in a podocyte cell line. Co-immunoprecipitation was, similarly, observed with the NS patient mutant NOS1AP.

Conclusions: Our results suggest NOS1AP is co-expressed with and can physically interact with SNTA1 and HSP1A2A in podocytes. These proteins may mediate NOS1AP functions in podocyte biology.

POI1339  
Synuclein Alpha Accumulation Drives Lysosomal Dysfunction in Fabry Podocytopathy  
Fabian Braun,1 Ahmed Abed,2 Mathias Woidy,1 Osteyn Eikrem,3 Nicola Wanner,1 Katharina M. von Consel,3 Soeren W. Gersting,1 Ania C. Muntau,1 Behzad Najafian,1 Camilla Tondel,1 Michael Maurer,2 Florian Graumann,1 Thorsten Eierhoff,1 Hans-Peter Marti,1 Victor G. Puelles,2 Christoph Schell,1 Tobias B. Huber.1 1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2Universitätsklinikum Freiburg, Freiburg, Germany; 3Universitetet i Bergen Det medisinsk-odontologiske fakultet, Bergen, Norway; 4University of Washington, Seattle, WA; 5University of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.

Background: Anderson-Fabry disease is an X-linked lysosomal disorder characterized by a multisystemic globothriaosylceramide (Gb3) accumulation due to reduced alpha-galactosidase activity (GLA). Podocyte injury is a major renal manifestation of Fabry disease. Recently, our data indicated Gb3 depletion to be insufficient in repairing podocyte damage seen in an in vitro model for Fabry disease. This project, therefore, focused on potential Gb3 independent mechanisms in Fabry podocytopathy.

Methods: We employed CRISPR/Cas9 to generate GLA knock out lines of immortalized human podocytes in-vitro. These cells were investigated by (ultra-)structural, transcriptional and proteome as well as functional analyses in the presence and absence of enzyme replacement therapy (ERT). The acquired data sets were integrated through network analysis and connectivity mapping. These data were complimented by the investigation of human biopsies taken sequentially before and after a period of ERT.

Results: We detected that enzyme replacement therapy (ERT) and Gb3 reduction failed to completely reverse the podocyte injury in patient biopsies. GLA knockodout podocytes depicted high Gb3 levels that were fully reversed upon enzyme replacement. Still lysosomal dysfunction was significantly but not completely reversible with enzyme replacement. Proteomics suggested alpha-synuclein (SNCA) accumulation as a potential driver of podocyte dysfunction. Transcription-based connectivity mapping further revealed a potential anti-SNCA therapeutic effect of beta-adrenoceptor agonists. Indeed, genetic and pharmacological inhibition of this protein significantly improved lysosomal structure and function in Fabry podocytes beyond the effects of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmacological strategies to target Fabry podocytopathy.

POI1340  
Drosophila TBC1D8B Promotes Nephrin Endocytosis and Is Required for Endosomal Cargo Processing  
Julian Milosavljevic, Camila Leimpicki, Konrad Lang, Lena L. Kampf, Tobias F. Hermle. Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.

Background: Mutations in TBC1D8B were recently identified as a monogenic cause of nephrotic syndrome. TBC1D8B interacts with nephrin and it was implicated as an inhibitory GAP protein for Rab11 which regulates endocytic recycling. However, the functional spectrum of TBC1D8B and its role in trafficking of nephrin remains poorly understood.

Methods: We generated and analyzed a stable genetic deletion of fly Tbc1d8b via CRISPR/Cas9. We successfully introduced a c-terminal HA-tag into the Gapvd1 c-terminus. We performed a functional investigation of human biopsies taken sequentially before and after a period of ERT.

Results: We generated and analyzed a stable genetic deletion of fly Tbc1d8b via CRISPR/Cas9. We successfully introduced a c-terminal HA-tag into the Gapvd1 c-terminus. We performed a functional investigation of human biopsies taken sequentially before and after a period of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry disease independent of Gb3 accumulation. The results offer new options for pharmacological strategies to target Fabry podocytopathy.

POI1341  
Stable Genetic Deletion of Gapvd1 in Drosophila Results in a Nephrocyte-Restricted Phenotype  
Konrad Lang, Julian Milosavljevic, Helena Heinke, Lea Gerster, Tobias F. Hermle. Hermle Lab Universitätsklinik Freiburg, Freiburg, Germany.

Background: Mutations in the gene GAPVD1 cause nephrotic syndrome in humans. GAPVD1 interacts with Rab8 and but the subcellular localization of GAPVD1 is unknown. Silencing of Gavpd1 in the neprocyte-like Drosophila nephrinocytes by RNA-interference resulted in mislocalization of fly nephrin.

Methods: We generated conditional knockdowns and a stable genetic deletion of Drosophila Gapvd1 by CRISPR/Cas9 and used microtomology-mediated end junction to introduce a genomic HA-tag into the Gapvd1 c-terminus. We performed a functional analysis of the novel fly models.

Results: We generated twin frameshift mutations at the second and third exons of the Drosophila Gapvd1 gene. Animals carrying these mutation were homozygous viable without any overt phenotype. However, the podocyte-like nephrinocytes revealed a severely altered slit diaphragm morphology with mislocalization of fly nephrin and the orthologue of NEPH1 and partial loss of both proteins from the surface. This phenotype was similar but considerably stronger than the phenotype observed by RNA-mediated silencing. This suggests that the homozygous frameshift mutations result in a null allele. The phenotype was further confirmed by conditional CRISPR/Cas-mediated silencing using two different gRNAs. Deletion of Gapvd1 in the Drosophila model thus results in a phenotype that manifests exclusively in disturbed slit diaphragm formations. This recapitulates the nephrinopathy phenotype of patients that was limited to nephrotic syndrome, supporting the use of Drosophila model for this genetic disease. To study the subcellular localization of Drosophila Gapvd1, we introduced an HA-tag into the c-terminus of the Gapvd1 locus. Immunofluorescence of nephrinocytes derived from the knock-in lines showed that the HA-tag is localized to the plasma membrane. We employed CRISPR/Cas9 to generate GLA knock out lines of immortalized human podocytes (HeK1). We successfully introduced a c-terminal HA-tag into the Gapvd1 c-terminus. We performed a functional investigation of human biopsies taken sequentially before and after a period of ERT.

Conclusions: This study provides strong evidence of a central role of SNCA in lysosomal dysfunction in Fabry podocytes beyond the effects of ERT.

Funding: Government Support - Non-U.S.
A Human Missense Integrin-Linked Kinase Variant Negatively Regulates Murine Renal Branching Morphogenesis via mTOR Signaling

Xiaoyue Hu,1,2 Dana Kablawi,1,2 Kirsten Y. Renkema,1 Nine V. Knoers,3 Norman D. Rosenstein,1,2 1Program in Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada; 2Institute of Medical Science, University of Toronto, Toronto, ON, Canada; 3Department of Genetics, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands.

Background: Branching morphogenesis is critical to kidney development and the pathogenesis of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT). Identification of gene variants via genomic sequencing aims to elucidate molecular mechanisms underlying CAKUT. The pathogenic contributions of such variants are largely unknown; functional analyses are required to identify pathogenic mechanisms. Here, we identify pathogenic effects of a CAKUT-associated human missense variant of Integrin-Linked Kinase (ILK), a key regulator of renal branching morphogenesis, on ureteric branching.

Methods: Targeted gene panel sequencing was performed to identify gene variants. ILK-T173I function was investigated in mouse inner medullary collecting duct (mIMCD3) cells and mouse embryonic kidney explants transduced with lentivirus expressing ILK-T173I. Gene expression was analyzed by RNA microarray and validated by qPCR and Western analysis. Mutant mice with a ILK-T173I point mutation were generated using CRISPR/Cas9. Morphogenic effects of ILK-T173I on ureteric branching were visualized using Hoxb7-driven fluorescent marker (MyVenus) and quantitated by counts of ureteric bud tips and nephrons.

Results: An ILK missense variant, ILK-T173I, was identified in a CAKUT patient and her mother by targeted gene panel sequencing and verified by Sanger sequencing. mIMCD3 cells expressing ILK-T173I demonstrated dysregulated expression of AKT/mTOR target mRNAs, identified by RNA microarray and qPCR, and elevated levels of phospho-p70-S6Kinase, a mTOR target (n=3, P=0.03). Overexpression of ILK-T173I in embryonic kidney explants increased phospho-p70-S6Kinase expression (n=3, P=0.03) and decreased ureteric tip number by 50% (n=15, P=0.003), both of which were rescued by phospho-p70-S6Kinase, a mTOR target (n=3, P=0.03). Treatment of mutant cultured embryonic kidney explants with Rapamycin restored ureteric branching to levels observed in wild-type mice (n=3, P=0.01). Treatment of mutant cultured embryonic kidney explants with Rapamycin restored ureteric branching to levels observed in wild-type mice (n=3, P=0.01). Treatment of mutant cultured embryonic kidney explants with Rapamycin restored ureteric branching to levels observed in wild-type mice (n=3, P=0.01).

Conclusions: Human ILK-T173I variant decreases branching morphogenesis in a mTOR-dependent manner. Increased mTOR signaling disrupts mouse kidney development.

Whole-Exome Sequencing Identifies Likely Deleterious Variants in 50 Families with Spina Bifida

Chunyan Wang,1,2 Steve Seltzam,1 Bixia Zheng,1,3 Chen-Han W. Wu,1 Camille H. Nicolas Frank,1 Kirollos Yousef,1 Nina Mann,1 Sophia Schneider,1 Luai M. Schierbaum,1 Dalia Pantel,1 Jameela A. Karl,1 Sherif M. El desokry,1 Lea Exner-Eid,1 Velibor Tasic,1 Shiladitya Shirl,1 Michelle A. Baum,1 Carlos R. Estrada,1 Friedhelm Hildebrandt,1 Boston Children's Hospital Department of Pediatrics, Boston, MA; 2Children's Hospital of Fudan University, Shanghai, China; 3Children's Hospital of Nanjing Medical University, Nanjing, China; King Abdullah University, Jeddah, Saudi Arabia; 4Dubai Hospital, Dubai, United Arab Emirates; 5University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); 6Boston Children's Hospital Department of Urology, Boston, MA.

Background: Spina bifida (SB) is the second most common nonlethal malformation (1/1000 births). Several lines of evidence indicate that SB can be of mono- genetic origin: i) its congenital nature; ii) familial occurrence; iii) it being part of the phenotypic manifestation of known monogenic syndromes; iv) the knowledge that specific master genes govern neural tube morphogenesis; v) the existence of monogenic mouse models with SB. We hypothesized that whole exome sequencing (WES) enables identification of likely candidate mutations in a list of 170 candidate genes for SB that we generated, and may allow us to identify potential novel genes for SB.

Methods: We generated a list of 170 candidate genes of four categories: A) 33 known candidate genes from monogenic SB models; B) 33 known candidate genes from human isolated SB, C) 70 known candidate genes from human syndromic SB, and D) 34 known candidate genes considered as risk factors for human SB. We evaluated WES data of 50 families with SB for likely deleterious variants in the 170 candidate genes, and for potential novel monogenic causes of SB.

Results: Through systematic candidate gene analysis in combination with family-based unbiased evaluation in 50 SB families, we identified 16 likely deleterious variants in 170 SB candidate genes in 14/50 (28%) families: A) 5 variants (5 families) were identified in mouse candidate genes, B) 9 variants (7 families) were identified in human candidate genes for isolated SB, C) 1 variant (1 family) was identified in human syndromic candidate gene, and D) 1 variant was identified in human SB risk candidate gene. In addition, in 11 (22%) of SB families, we identified mutations in a potential novel gene for SB.

Conclusions: In 28% of individuals with SB we identified likely deleterious variants in 170 candidate genes that we generated. Candidate genes that cause SB in mice can be considered as a potential human SB candidate gene. We additionally identified a potential novel gene in 22% of SB families.

Pleiotropy of Congenital Anomalies of Kidney and Urinary Tract (CAKUT) Phenotypes in Human 16p11.2 Microdeletion Syndrome Is Recapitulated in Mouse Models of Tbx6 Deletion

Gregory B. Whitemore,1,2,3 Jeremiah Martinito,1 Tze Yin Lim,1 Yask Gupta,1 Cathy L. Mendelsohn,1 Simone Sanna-Cherchi,1 Columbia University Irving Medical Center, New York, NY; 2Columbia University Vagelos College of Physicians and Surgeons, New York, NY.

Background: We showed that 16p11.2 microdeletions are a major contributor to congenital anomalies of the kidney and urinary tract (CAKUT), and identified Tbx6 as the most likely culprit. It remains elusive what are the mechanisms by which gene dosage reduction causes CAKUT and what are the Tbx6 downstream signaling pathways and targets.

Methods: We studied a Tbx6 allele-specific gene for dosage analysis using two independent alleles: a null allele and a hypomorph allele. We conducted detailed phenotypic analysis of these models across early and late development. We generated gene dosage data from E9.5 tailbud mesenchyme and conducted in silico binding site analyses.

Results: Phenotypic analysis showed recapitulation of the whole Tbx6 spectrum observed in 16p11.2 patients (renal agenesis and hypoplasia, hydronephrosis, and duplication of the collecting system) but also profound lower urinary tract defects (rectovesical fistula, persistent cloaca, defects of neophic duct insertion into the urogenital sinus, urethral malformations and failed insertion of the Müllerian ducts). These defects implicate an early effect of Tbx6 in urinary tract development. Tbx6 insufficiency also disrupted the occurrence of ectopic neural tubes that impaired the reciprocal interaction between the ureteric bud and metanephric mesenchyme, providing additional mechanisms linking Tbx6 to CAKUT and its pleiotropy. Differential gene expression analysis coupled with supervised and unsupervised genet set enrichment identified somite development and Notch signaling. Binding site and motif enrichment analyses recovered known and novel targets in the Tbx6 interactome including A.1,2,3,4,5 and relin.

Conclusions: Phenotypic investigation coupled with gene expression and binding site analyses provides support for causality for Tbx6 and CAKUT as well as its pleiotropy; provides a mechanistic reason for causation; and identifies pathways and targets regulated by Tbx6. The involvement of Notch signaling is interesting as mutations in NOTCH2 cause Alagille syndrome, characterized by CAKUT and skeletal defects observed both in our Tbx6 mouse models and in patients that carry the 16p11.2 microdeletion. These data implicate loss of Tbx6-mediated regulation of Notch as critical to the development of CAKUT and spine defects.

PO1347 Excess Burden of Rare Coding Variants in Mutation Intolerant Genes in Patients with Kidney Malformations
Hila Milo Rasouly,1 Sarah Babu Krishna Murthy,1 Gundula Powysli,1 Maddalena Marasa,2 Jeremiah Martino,1 Velibor Tasic,1 Enrico Fiacchadori,1 Gian Marco Ghigetti,1 Giuseppe Massata,3 Simone Sanna-Cherchi,1 Krzysztof Krynics,1 Ali G. Ghari,1 Columbia University Irving Medical Center, New York, NY; 1University Children’s Hospital, Skopje, Macedonia; 2Medical University of Graz, Graz, Austria; 3Istituto Giannina Gaslini, Genova, Italy; 4Azienda Ospedaliera Brotzu, Cagliari, Italy; 5Universita degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy.

Background: Renal hypoplasiasia (RHD) is one of the most common cause of pediatric kidney failure. Although multiple causative genes have been identified, they only account for 10-15% of cases. The contribution of rare variants has not been systematically examined.

Methods: To evaluate the contribution of rare variants to RHD, we analyzed exome sequencing (ES) data in 1,265 unrelated RHD cases and 13,303 unrelated controls. We used gene-level burden analysis, comparing the proportion of cases and controls carrying rare variants per gene across 29 statistical models.

Results: We observed a 1.63-fold case enrichment for rare variants (p= 1.5x10^-8) in known genes associated with dominant forms of kidney diseases (165 cases versus 1,075 controls in 172 known genes), including PKD1 (7.6x10^-8) and HNF1B (5.6x10^-9). All other known genes did not reach statistical significance (p-value<10^-6). Applying a similar approach, we observed a 1.35-fold case enrichment for rare missense variants (p=5.8x10^-8) in genes constrained against missense (miRZ >3.09) and a 1.59-fold enrichment for rare protein truncating variants (PTV; p=2.4x10^-8) in genes constrained against PTV (pLI<0.9 and oc lf upper<0.35). We particularly identified a 2.38-fold enrichment for PTV in 421 genes constrained against PTV, expressed in the mouse developing kidney (E15.5), and not known to be associated with human kidney disease (p=4x10^-8). Fig. 1. Cationically, the presence of publically available databases, we identified at least 23 novel candidate genes, which will require validation in additional human cohorts or analysis of animal models.

Conclusions: We detected a significant excess of rare variants in mutation intolerant genes that are also expressed during early kidney development, suggesting the existence of many yet-to-be-identified causal genes. However, owing to the high genetic heterogeneity of RHD, larger-scale investigations will be required to establish causality for individual genes.

PO1348 Reverse Phenotyping Facilitates Disease Allele Calling in Whole-Exome Sequencing of Patients with Congenital Anomalies of Kidney and Urinary Tract (CAKUT)
Steve Seltzsm, Chunyan Wang, Bixia Zheng, Dervla M. Connaughton, Chen H. W. Wu, Sophia Schneider, Luca M. Schierbaum, Shril Shril, Friedhelm Hildebrandt, Boston Children’s Hospital, Boston, MA.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the leading cause of chronic kidney disease in children and young adults. To date, 174 genes are known to cause isolated or syndromic congenital CAKUT. However, incomplete penetrance and broad phenotypic heterogeneity can impair disease allele identification, particularly in syndromic CAKUT. We hypothesized that the yield of a genetic diagnosis can be increased by combining whole exome sequencing (WES) with reverse phenotyping, in which the contributing physician is asked to examine a patient for signs/symptoms that may occur in the suspected clinical syndrome that results from the genetic variant detected by WES.

Methods: We conducted WES in an international cohort of 823 individuals with CAKUT from 732 unrelated families and evaluated WES data for variants in the 174 genes in which variants are known to cause isolated or syndromic CAKUT. In cases in which the likely causative genotype suggested a syndromic phenotype that was not reported at enrollment, we conducted reverse phenotyping.

Results: In 84/732 (11.5%) families, we detected a likely causative variant consistent with an isolated or syndromic CAKUT phenotype. In 19 of the 84 families (22.6%) with detection of a likely CAKUT-causing variant, reverse phenotyping yielded syndromic findings, thereby strengthening the genotype-phenotype correlation.

Conclusions: We conclude that employing reverse phenotyping in the evaluation of (facultative) syndromic CAKUT genes by WES provides an important tool to establish a more valid and specific diagnosis mitigating the broad phenotypic and genotypic heterogeneity of CAKUT.

PO1349 Broad Genetic Analysis Reveals Diverse Molecular Causes of Autosomal Dominant Tubulointerstitial Kidney Disease-Not Otherwise Specified (ADTKD-NOS)
Florian Woppe1, Francesca Pasutto2, Michael S. Wiesener1
1Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertonie, Erlangen, Germany; 2Department of Nephrology, Erlangen, Germany; 3Institut für Humangenetik, Erlangen, Germany.

Background: A particularly difficult group of diseases to diagnose are the Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD). ADTKD is caused by mutations in one of at least five genes and leads to end-stage renal disease usually in mid adulthood. Families where no mutation can be found are therefore termed ADTKD-NOS (not otherwise specified), who are the focus of this study. Herein we investigated 45 families of our ADTKD registry.

Methods: The study was approved by the institutional ethics committee (protocol number 251_18B). Detailed pedigree analysis and clinical characterisation of kidney diseases were performed, as well as evaluation of historical kidney biopsies, where available. In addition, sequencing on all known ADTKD candidate genes was performed, followed by SNaPshot minisequencing for the dupC mutation of MUC1. Exome-Sequencing was performed on the HiSeq System 2500 (Illumina) after enrichment by TWIST human core technology (TWIST Bioscience). Initially, 560 genes associated with abnormal renal physiology (Human Phenotype Ontology, https://mpc.org/hpo-browser.php?12622, retrieved March 2020) were screened (here termed nephrome). If no disease-causing variants were detected, exome-wide analysis was performed.

Results: In 30 of the 45 registry families mutations in known ADTKD genes were found, most frequently MUC1. In the remaining 15 families diagnostic gene variants were either detected in the nephrome (4x COL4A5, 1x COL4A4x, 2x IN2, 1x PA2) or the exome, where analysis yielded potentially disease associated variants in novel candidate genes for ADTKD. A list of these candidate genes in the respective families will be presented. All variants segregated within families.

Conclusions: In the great majority of our ADTKD registry families we were able to reach a molecular genetic diagnosis. However, a small number of families are indeed affected by diseases, which should in retrospect be seen as glomerular origin. Atypical clinical presentation, (seemingly) autosomal dominant pedigrees (i.e. ADTKD-Not otherwise specified disease) and sometimes decades since onset of disease and genetic evaluation have handicapped the classification towards ADTKD-NOS. The other families investigated by exome analysis have partly led to identification of promising novel candidate genes. However, for functional studies will need to follow to determine if these variants are truly pathogenic.

PO1350 Prevalence of Autosomal Dominant Tubulointerstitial Kidney Disease in the German Chronic Kidney Disease (GCKD) Cohort
Bertn Popp1,2 Arif Ekc1,1 Karl X. Knau,1 Kaj-Uwe Eckardt,1,4 Mario Schiffer,1 André Reis,1 Michael S. Wiesener1,1 Institute of Human Genetics, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; 1Institute of Human Genetics, University of Leipzig, Leipzig, Germany; 2Department of Nephrology and Hypertonie, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; 3Department of Nephrology and Medical Intensive Care,Charité Universitätsmedizin Berlin, Berlin, Germany.

Background: Exome sequencing (ES) studies in chronic kidney disease (CKD) cohorts could identify pathogenic variants in ~10%. This implies underdiagnosis of hereditary CKD. Tubulointerstitial kidney diseases (TUD), showing non typical clinical presentation, (seemingly) autosomal dominant pedigrees, and sometimes decades since onset of disease and genetic evaluation have handicapped the classification towards ADTKD-NOS. The other families investigated by exome analysis have partly led to identification of promising novel candidate genes. However, for functional studies will need to follow to determine if these variants are truly pathogenic.

Methods: We used a targeted panel (29 genes) and MUC1-SnaPshot to sequence 271 DNA samples selected by clinical criteria from 5,217 individuals in the GCKD (German CKD) cohort.

Results: We identified 33 pathogenic small variants. Of these 27 (81.8%) were in COL4 genes, the largest group being 15 COL4A5 variants with 9 unrelated individuals carrying distinct MTTF-variants. A COL4A4x deletion, and a novel splice variant in HNF1B and the homoplasmic MTTF variant m.616T>C. Copy-number analysis identified a heterozygous COL4A5 deletion, and a duplication/deletion of HNF1B, respectively. Overall, we found pathogenic variants in 15% (97 of 617 individuals) and at least 36% of unrelated individuals (9 of 26 families) had an unknown significance in 9.6%. This yield is high despite considering the targeted design and PKD1/2 exclusion. To explain this difference we compared our findings to the largest ES study in adults with CKD by random sampling. None of the 10,000 simulations resulted in an equal or higher yield (p<0.05). Variant classification differences were excluded using automated ACMG classifiers.

Conclusions: Our study shows that >10% of individuals with certain clinical features carry disease variants in genes associated with TUD. COL4 genes constitute the largest fraction, implying that these variants are overlooked when applying clinical criteria for Alport syndrome. We also identified variants easily missed by some ES pipelines. Bioinformatic predictions paired with gold standard diagnostics for MUC1 (SnaPshot) could not identify the typical cytosine duplication (c.428dupC) in any individual of this
cystinosis, which demonstrates that urinary BiP excretion was significantly elevated in ADTKD-
patients compared with unaffected controls. Moreover, urinary BiP elevation was
quantitatively correlated with disease severity. Finally, based on all our findings, we have
developed a new ultrasensitive method to detect urinary BiP in affected individuals. We therefore developed the ultrasensitive p-FLISA,
which demonstrated that urinary BiP excretion was significantly elevated in ADTKD-
patients compared with unaffected controls. Moreover, urinary BiP elevation was
positively associated with disease severity. These findings are consistent with the presence
of kidney progenitor cells in urine of cystinosis patients, and to explore the feasibility of
using kidney progenitor cells for disease modeling, while we provided proof of principle of
their potential use for studying the late effects of cystinosis.

**Conclusions:** By developing the ultrasensitive p-FLISA, we have identified secreted
BiP as a novel urinary stress biomarker with potential utility in risk stratification,
prediction of disease progression and guidance of ER-targeted therapies in ADTDK.

Urine-Derived Kidney Progenitor Cells in Cystinosis: Potential for Disease Modeling and Ex Vivo Gene Therapy

Koenraad Vveys,1,2 Sante Principe Berlingerio,1 Tjessa Bonduc,1 Katharina Held,1 Ahmed Reda,1 Koen Theunis,1 Pieter Baetsen,2 Mirian C. Janssen,1 Elisabeth A. Cornelissen,1 Joris Vriens,1 Francesca Diommed-Camasset,1 Rik Gijsbers,1 L.P.W.J. Van Den Heuvel,1 Fanny O. Arcolino,1 Elena N. Levchenco,1,2 Katholieke Universiteit Leuven Groep Bomholtage,2 Wetenschappen, Leuven, Belgium; 3Radboudumc, Nijmegen, Netherlands; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

**Background:** Nephropathic cystinosis is an inherited multisystem lysosomal storage disorder caused by mutations in the CTNS gene. The kidney phenotype is characterized by excessive shedding of proximal tubular cells and podocytes into urine, development of renal Fanconi syndrome and progression to end-stage kidney disease. We hypothesized that, to compensate for epithelial cell losses, cystinosis kidneys undertake a regenerative effort, albeit maladaptive. We aimed to search for the presence of kidney progenitor cells (KPCs) in urine of cystinosis patients, and to explore the feasibility of ex vivo gene therapy.

**Methods:** We isolated undifferentiated cells from urine of cystinosis patients, characterized them as KPCs (Cys-uKPCs) and differentiated these to functional kidney epithelial cells (Cys-uKPC-PTEC) by conducting a novel approach with wild-type CTNS and Cys-uKPC-PTEC. RNA sequencing demonstrated distinctive transcriptomic signatures distinguishing Cys-uKPCs, Cys-uKPC-Podo and Cys-uKPC-PTEC as functional kidney epithelial cell types. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type CTNS to improve the cellular phenotype. Cystinosis uKPCs are a novel tool for disease modeling, while we provided proof of principle of ex vivo gene therapy.

Adult Zebrafish as a Model to Study Renal and Extrarenal Manifestations of Cystinosis

Sante Principe Berlingerio,1 Junling He,2 Sara Cairoli,3 Bianca Maria Goiffredo,2 L.F.W.J. Van Den Heuvel,1 Elena N. Levchenco,1 Pediatric Nephrology,1 Katholieke Universiteit Leuven, 2Groep Biomedische Wetenschappen, Leuven, Belgium; 3University Leiden, Leiden, Netherlands; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

**Background:** Cystinosis is a rare autosomal recessive disease caused by mutations in the CTNS gene, which encodes for the cystine transporter cystinosin leading to lysosomal cystine accumulation in all cells of the body, with kidneys being the first affected organs. The current treatment with cysteamine decreases the lysosomal cystine accumulation, but does not reverse the renal Fanconi syndrome, glomerular injury or loss of renal function. We have developed a zebrafish larvae model having truncating mutations in ctns, which recapitulates the kidney phenotype of cystinosis. However, long-
term disease consequences in adult zebrafish have not been studied so far. In this study, we characterized the adult zebrafish model to evaluate the late effects of cystinosis on kidney and extra renal organs.

**Methods:** Cystinosis (ctns-/-) zebrafish of 18 months and wild type (WT) zebrafish were studied. Histologic examinations of kidneys and extra-renal organs were performed. Cleaved caspase-3 staining was used to evaluate apoptosis in the kidney. Cystine accumulation was evaluated via in situ hybridization of a ctsn-specific mRNA probe and toluidine blue staining. For the fertility studies, the number of total eggs and fertile eggs produced by breeding female and male ctns-/- zebrafish compared to WT zebrafish was evaluated.

**Results:** ctns-/- zebrafish show increased cystine level, glomerular hyper trophy and proximal tubular accumulation of hyaline-like eosinophilic droplets and vacuolated cytoplasm. Moreover, the cystinotic zebrafish exhibit increased cleaved caspase-3, indicating enhanced apoptosis in the proximal tubules. In addition, instead of the typical striped pattern, ctns-/- zebrafish present an altered melanin skin pigmentation, resulting in spotted skin. Lastly, male ctns-/- zebrafish show spermatogenic cysts enriched in spermatozoa, while female display increased percentage of unfertilized eggs.

**Conclusions:** The adult ctns-/- zebrafish model reproduces several phenotypes of cystinosis, as altered glomerular and proximal tubular morphology, whole body cystine accumulation, impaired skin pigmentation and decreased fertility. Therefore, this model may be useful for studying long-term effects of cystinosis and for the development of new therapeutic strategies for correcting cystinosis, which is - up to now - incurable.

Genetic Analysis of a Brazilian Nephropathic Cystinosis Cohort Reveals Novel CTNS Variants Mostly of Non-European Origin

Maria H Vaishich,1 Kelly Nunes,1 A. Santos,2 Juliana C. Ferreira,3 M. Nunes, Andrea Watanabe,1 Lutz F. Omuccio.1 Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Nephropathic Cystinosis (NC) is a severe autosomal recessive disease caused by intralysosomal cystine deposition. Most CTNS variants have been described in Europe and North America, where a specific 57kb deletion (del) is the most frequent one. In this study, we sought to characterize the CTNS variants and their genetic ancestry profiles in a NC Brazilian cohort, an admixed population.

**Methods:** 61 NC patients were studied, both sexes, ≤21 years old, followed at the University of Sao Paulo Medical Center. Mutation analysis was performed by gel electrophoresis and/or MLPA to assess the 57kb del, and NGS targeted sequencing. To characterize the genetic ancestry profiles, 48 patients were genotyped with a high-density SNP array. The average genomic ancestry was inferred using ADMIXTURE and the detected variants included 9 previously characterized them as KPCs (Cys-uKPCs) and differentiated these to podocytes and PTECs. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type CTNS and Cys-uKPC-PTEC. RNA sequencing demonstrated distinctive transcriptomic signatures distinguishing Cys-uKPCs, Cys-uKPC-Podo and Cys-uKPC-PTEC as functional kidney epithelial cell types. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type CTNS to improve the cellular phenotype. Cystinosis uKPCs are a novel tool for disease modeling, while we provided proof of principle of ex vivo gene therapy.

Urine-Derived Kidney Progenitor Cells in Cystinosis: Potential for Disease Modeling and Ex Vivo Gene Therapy

Koenraad Vveys,1,2 Sante Principe Berlingerio,1 Tjessa Bonduc,1 Katharina Held,1 Ahmed Reda,1 Koen Theunis,1 Pieter Baetsen,2 Mirian C. Janssen,1 Elisabeth A. Cornelissen,1 Joris Vriens,1 Francesca Diommed-Camasset,1 Rik Gijsbers,1 L.P.W.J. Van Den Heuvel,1 Fanny O. Arcolino,1 Elena N. Levchenco,1,2 Katholieke Universiteit Leuven Groep Bomholtage,2 Wetenschappen, Leuven, Belgium; 3Radboudumc, Nijmegen, Netherlands; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

**Background:** Nephropathic cystinosis is an inherited multisystem lysosomal storage disorder caused by mutations in the CTNS gene. The kidney phenotype is characterized by excessive shedding of proximal tubular cells and podocytes into urine, development of renal Fanconi syndrome and progression to end-stage kidney disease. We hypothesized that, to compensate for epithelial cell losses, cystinosis kidneys undertake a regenerative effort, albeit maladaptive. We aimed to search for the presence of kidney progenitor cells (KPCs) in urine of cystinosis patients, and to explore the feasibility of ex vivo gene therapy.

**Methods:** We isolated undifferentiated cells from urine of cystinosis patients, characterized them as KPCs (Cys-uKPCs) and differentiated these to podocytes (Cys-uKPC-Podo) and proximal tubular epithelial cells (Cys-uKPC-PTEC) as shown by qPCR, RNA sequencing, immunostainings and specific functional assays. Complementation of CTNS in Cys-uKPCs was performed via lentiviral vector (LV) transduction.

**Results:** Cystinosis patients voided high numbers of undifferentiated cell populations, of which specific clones expressed several kidney progenitor markers, showed a high level of self renewal, and could differentiate to functional kidney progenitor cells. RNA sequencing demonstrated distinctive transcriptomic signatures distinguishing Cys-uKPCs, Cys-uKPC-Podo and Cys-uKPC-PTEC. Ex vivo gene therapy using a gene addition approach with wild-type CTNS showed significant reductions of cystine levels and alleviation of the perinuclear distribution of the LAMP1+ endo-lysosomal compartment.

**Conclusions:** Kidney progenitor cells are present in the urine of cystinosis patients. These cells can be isolated, differentiated to functional kidney epithelial cells and complemented with wild-type CTNS to improve the cellular phenotype. Cystinosis uKPCs are a novel tool for disease modeling, while we provided proof of principle of ex vivo gene therapy.

PO1355
Vascularized Kidney Organoids on Chip for Efficacy and Toxicity Testing of Somatic Genome Editing

Navin R. Gupta,1,2 Kayla J. Wolf,2 Krishna P. Maremmada,3 Katharina T. Kroll,4 Chengcheng Zhang,5 Venkata Sabbsiotti,6 Jennifer A. Lewis,7 Ryuji Morizane,8,9 Massachusetts General Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA; 4Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA.

Background: Somatic genome editing has therapeutic potential to cure inheritable diseases. Clinical translation requires safety and efficacy analyses. DNA editing may be widely disparate across species due to genomic differences, necessitating human tissue-based platforms. AAV-based delivery of DNA editing elements is under clinical investigation. If delivered systemically, the kidney may be particularly susceptible to genome editing owing to high blood flow. Kidney organoids have been generated from human stem cells through the co-induction of nephron, stromal, and endothelial progenitor cells that mature to form multicompartment human kidney tissue. We marred organoid and organ-on-chip technologies to facilitate the maturation of nephron epithelia and the development of perfusable vascular networks to simulate systemic delivery of genome editing elements.

Methods: Using human recombiant growth factors and defined small molecules, kidney organoids were generated from male and female, embryonic and induced, stem cell lines. To test the efficacy of an AAV2-based delivery system, the tropism of varied capsids, 2/8/9, for kidney compartments was assessed under static and perfused conditions. The AAV receptor expression was evaluated by single nuclear RNA-seq. Results: The greatest infectivity was with capsid protein 2, whose receptor on human subverting proteoglycan is expressed in proximal & distal tubules and podocytes of kidney organoids by single cellular transcriptomics. Biomarker analysis demonstrated a statistically significant increase in tubular injury markers, KIM-1 and MCP-1, after infection with AAV2/8 as compared to other AAVs. Following treatment with AAV2/8-MVGFP, the majority of LTU- and CD11b+ tubular epithelia were GFP+, while PODOXL+ podocytes were poorly infected. The optimal AAV serotype, MOI, and duration of infection under static conditions were applied to vascularized kidney organoids. Initial on-chip testing supports enhanced infectivity by live-cell monitoring and wholemount immunostaining, including an AAV infection in GFP PODOXL+ podocytes.

Conclusions: We propose vascularized kidney organoids may simulate the systemic delivery of AAVs across kidney compartments, as a pre-clinical testing platform of the efficacy and safety of somatic cell genome editing.

Genotype and Phenotype Analysis in Patients with X-Linked Hypophosphatemia

Peong Gang Park1,2 Seon Hee Lim1, Yo Han Ahn2, Hee Gyung Kang2, Il-Soo Ha3, Korea Ministry of Health and Welfare, Sejong, Sejong, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Uijeongbu Saint Mary’s Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea.

Background: X-linked hypophosphatemia (XLH) is the most frequent form of hypophosphatemic rickets and is caused by mutations in the PHEx gene. We analyzed genotype-phenotype correlations in XLH patients with proven PHEx mutations.

Methods: PHEx mutations were detected in 57 out of 81 patients who clinically presented with hypophosphatemic rickets. The patients were grouped into nontruncating (n = 11) and truncating (n = 46) mutation groups; their initial presentation as well as long-term clinical findings were evaluated according to these groups.

Results: Initial findings, including presenting symptoms, onset age, height standard deviation scores (SDSs), and laboratory tests, including serum phosphate level and tubular resorption of phosphate, were not significantly different between the two groups (onset age: nontruncating mutation group, 2.0 years, truncating mutation group, 2.1 years; height SDS: nontruncating mutation group, -1.9, truncating mutation group, -1.8; serum phosphate: nontruncating mutation group, 2.5 mg/dL, truncating mutation group, 2.5 mg/dL). However, at their last follow-up, the serum phosphate level was significantly lower in patients with truncating mutations (nontruncating mutation group: 3.2 mg/dL, truncating mutation group: 2.3 mg/dL, P value 0.003). Additionally, 62.5% of patients with truncating mutations developed nephrocalcinosis, while none of the patients with nontruncating mutations developed nephrocalcinosis (P value 0.008). Orthopedic surgery due to bony deformations was performed significantly more often in patients with truncating mutations (52.3% vs 10.0%, P value 0.008).

Conclusions: Although considerable inconsistency exists regarding the correlation of truncating mutations and their disease phenotype in several other studies, we cautiously suggest that there would be genotype-phenotype correlation in some aspects of disease manifestation after long-term follow-up. This information can be used when consulting patients with confirmed XLH regarding their disease prognosis.

Childhood-Onset Nephrocalcinosis in Twins Caused By Biallelic Mutations in CYP24A1 Gene: A Long Journey to a Genetic Diagnosis

Xin Yee Tan, Mary-Beth Roberts, Saul Nurko, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: 24-hydroxylase deficiency is a rare autosomal recessive disorder caused by mutations in CYP24A1 gene, characterized by hypercalcemia, hypercalciuria and nephrolithiasis. Establishing a genetic diagnosis, while important to guide management and family counseling, can be challenging. We hereby report a case of twins with childhood-onset nephrocalcinosis and chronic hypercalcemia caused by biallelic mutations of CYP24A1, which took years to be diagnosed.

Case Description: A 26 year-old female presented for preconception evaluation for a history of childhood-onset nephrocalcinosis and chronic hypercalcemic hypercalciuria. Patient reported similar history in identical twin sister. They had exome sequencing (ES) eight years ago after negative genes panel test which revealed a heterozygous variant of unknown significance (c.1186C>T in CYP24A1. A reanalysis of ES was performed four years ago which demonstrated no changes. Work up revealed hypercalcemic hypercalciuria, low 25(OH) vitamin D, elevated 1,25(OH) vitamin D and 24,25(OH) vitamin D, and suppressed PTH(fig.1). Ratio of 25(OH)D to 24,25(OH)D, a new biochemical test for 24-hydroxylase deficiency, suggested biallelic mutations in CYP24A1 gene. ES reanalysis at this time reclassified the c.1186C>T variant as pathogenic and disclosed a novel intron variant (c.544-17G>A) which was predicted to cause splicing pattern change with multiple silico algorithms. Parental tests confirmed these two variants were in trans configuration consistent with autosomal recessive inheritance pattern. A thorough counseling included low recurrence risk for her children while high risk for her to develop severe hypercalcemia during pregnancy. She has been closely monitored with low calcium and vitamin D diet, sun avoidance and adequate hydration during current pregnancy with no complications to date.

Discussion: CYP24A1 gene related hypercalcemia is rare and challenging to diagnose even with ES. This case suggests the benefits of ES regular reanalysis for clinically suspected patients with inconclusive genetic findings. The novel intron mutation identified in this case broadens the genetics spectrum of 24-hydroxylase deficiency.

PO1358
Refractory Hypercalcemia with Recurrent Nephrolithiasis Related to a De Novo Gain-of-Function Mutation in the CaSR Gene

Xin Yee Tan, Leila Z. Khan, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

Introduction: The calcium-sensing receptor (CaSR) serves as the key calcium sensor in the maintenance of systemic calcium homeostasis. Gain-of-function mutations of CaSR-gene, mapped to Ala116-Pro136 region, causes autosomal dominant hypercalcemia and Bartter syndrome type V. Phenotypic manifestations include hypercalciuric hypercalcemia(nosly asymptomatic), hyperparathyroidism, paresthesias, tetany/ epilepsy, nephrocalcinosis/ nephrolithiasis, hypomagnesemia, ectopic and intracranial calcifications. Here we report a case of gravid female who experienced refractory hypercalcemia with recurrent nephrolithiasis related to a de novo gain-of-function mutation in the CaSR gene.

Case Description: A 25 year-old G1P0 female at 20 weeks of gestation presented to genetic nephrology clinic due to refractory hypercalcemia. She was incidentally found to have asymptomatic hypercalcemia as part of prenatal evaluation. She was treated with calcium and calcitriol for four months while hypercalcemia persisted. Physical exam was unremarkable. As shown in Table 1, her total serum calcium had been persistently low despite calcium and Vitamin D supplementations, and she had low PTH, hypercalciuria, hypermagnesemia, and hypercalciuria. Genetic testing revealed a variant (c.398A>T, p.Glu133Val) in CaSR gene, with negative parental testing consistent with de novo mutation. Given this finding, calcium and calcitriol were discontinued. Renal ultrasound to assess stone burden showed bilateral renal calcui, which patient passed during delivery. Recurrent renal calculi were discovered on post-delivery follow-up imaging, necessitating laser lithotripsy and left ureteral stent insertion.

Discussion: This case highlights the importance of early diagnoses by genetic testing which could guide the hypercalcemia management, as routine calcium and vitamin D supplementation is inadequate for hypercalcemia and thus the risk of nephrocalcinosis/ nephrolithiasis. c.398A>T, p.Glu133Val mutation has been described in 1 family cluster of 3 patients with hyperparathyroidism and hypercalcemia to date. De novo mutation, unique to this case, was evidenced by negative parental testing.

Table 1
TRPV4 Calcium Channel Activity Is Increased by With-No-Lysine Kinase 1 in the Collecting Duct Cells

William M. Bindels,1 Tilman Franken,1 Gemma C. de Baaij,1 Dominik Müller,2 Jeroen H. De Baaij,1 Radboudumc, Nijmegen, Netherlands; 2Charite – Deutsche Universitaetsmedizin Berlin, Berlin, Germany; 3Universitatsklinikum Muenster, Munster, Germany.

Background: Patients with mutations in the Cyclin M2 (CNNM2) gene display hypomagnesemia and intellectual disability. CNNM2 is highly expressed in the distal convoluted tubule, where it is involved in renal magnesium (Mg 2+ ) reabsorption. However, the complete phenotypic spectrum of the CNNM2-related disorder remains unknown. We characterised a large patient cohort with novel CNNM2 variants and used transgenic mouse models to investigate the role of CNNM2 in Mg 2+ homeostasis.

Methods: The identified CNNM2 variants were found in a cohort of hypomagnesemic patients and characterised using 18 Mg 2+ transport assays in HEK293 cells. In addition, CNNM2-deficient mice were developed using CRISPR-Cas9 technology and exposed to deficient or saturated Mg 2+ diets for two weeks. Using metabolic cages, the 24-hour urinary and faecal excretion for Mg 2+ was determined.

Results: Eleven patients were identified with novel dominant variants in CNNM2. Using Mg 2+ transport assays in HEK293 cells, seven variants showed decreased Mg 2+ transport compared to wild type. These pathogenic mutations resulted in decreased membrane expression of CNNM2. The phenotype of these patients was compared with those previously published. Patients with pathogenic CNNM2 mutations had a mean plasma Mg 2+ level of 0.54 ± 0.08 mmol/L. Neurological manifestations, such as seizures (79%), intellectual disability (92%) and speech difficulties (91%) were prevalent.

Conclusion: Mitochondrial diseases with isolated renal symptoms are uncommon; however, this study indicates that mitochondrial respiratory chain complex III deficiency due to CNNM2 mutations cause Fanconi syndrome with developmental disability as the primordial indications.
POI1363

Infantile Hypercalcemia Associated with a Novel Homozygous Mutation in SLC34A1 Gene Encoding Sodium-Dependent Phosphate Transporter 2A

Mohamed Hassanein, Jordana Yah, Mary-Beth Roberts, Xiangling Wang
Cleveland Clinic, Cleveland, OH.

Introduction: Early-onset and familial hypercalcemia often suggest a genetic etiology which is rare. Infantile hypercalcemia (IH) is a rare, autosomal recessive disorder that occurs due to mutations in the SLC34A1 gene which encodes a sodium-dependent phosphate transporter 2A (NaPi-IIA) responsible for phosphate reabsorption in the kidney. We report an adult case who carried a clinical diagnosis of familial hypocalciuric hypercalcemia (FHH) since infancy, which is usually a benign condition characterized by autosomal dominant inheritance caused by mutations in calcium-sensing receptor (CASR) gene, while recently uncovered as IH related to a novel homozygous mutation in the SLC34A1 gene.

Case Description: A 36-year-old Finnish male with a diagnosis of FHH presented to the genetics nephrology clinic for consultation regarding the recurrence risk for his children. He was diagnosed with FHH during infancy in Finland and has been treated with a low calcium diet. Family history was notable for a clinical diagnosis of FHH in his older sister. Physical exam was unremarkable. Labs showed mild hypophosphatemia and decreased glomerular filtration rate (69 mL/min/1.73 m²), with normal serum ionized calcium and intact parathyroid hormone. Twenty-four hour urine analysis revealed hypercalcuria 363 mg/d (normal <250), hypomagnesuria 155 mmol/d (normal 50–150) and hypocitraturia 420 mg/d (normal >450). Kidney ultrasound showed bilateral medullary hypercalciuria 363 mg/d (normal <250), hypernatriuria 155 mmol/d (normal 50–150) and was reassured with the low recurrence risk for his children.

Discussion: Mutations in the SLC34A1 gene lead to altered NaPi-IIA expression and reduced phosphate reabsorption, leading to hypophosphatemia. Secondary vitamin D activation leads to hypercalciemia, hypercalcuria, and nephrocalcinosis. We identified a novel mutation in the SLC34A1 gene which broadens the genetic spectrum of IH. This case highlights the importance of early genetic testing for suspected hereditary hypercalcemia that may help improve its diagnosis and treatment.

POI1364

Characteristics and Genetic Defects of Systemic Lupus Erythematosus-Associated Thrombotic Microangiopathy

Cui Queuan, Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Thrombotic microangiopathy (TMA) is a life-threatening complication of systemic lupus erythematosus (SLE). However, the etiology of a considerable number of patients is still unclear and the best treatment is unknown. Sporadic reports suggest that the activation of complement pathway may play a role in SLE-TMA.

Methods: We prospectively enrolled 40 SLE-TMA patients in Peking Union Medical College Hospital, 14 patients with lupus nephritis (LN) and 38 patients with other types of TMA. The clinical data were collected. Peripheral blood concentrations of CFH, cCFB, soluble CSF-9, relative activity of complement pathway, ICAM1, VCAM1 and E-Selectin were measured by ELISA in SLE-TMA patients and control groups. Whole exome sequencing (WES) was performed to analyze the genetic variants in SLE-TMA patients.

Results: SLE-TMA mediated by ADAMTS13 inhibitors had severe nervous system involvement, but less kidney involvement and good response to plasma exchange. Among SLE-TMA with unknown etiology, patients with TMA confined to kidney had higher hematological manifestations and lower serum creatinine level than SLE-aHUS (p = 0.005). Compared with SLE-aHUS, the concentration of CFH in SLE-TMA limited to kidney was higher (p = 0.026). The level of E-selectin in patients with SLE-TMA limited to kidney was significantly lower than that in SLE-aHUS patients with MAHA (p = 0.016). There was no significant difference in genetic susceptibility among SLE-aHUS, SLE-TMA limited to kidney and SLE-TMA with other causes. In SLE-TMA patients, thrombophilia variants may play a more important role than complement variants. Treatment response of SLE-TMA patients with variants is worse than those without variants. In serological test, VCAM1 level in SLE-TMA patients with complement related genetic variants was significantly higher than that in SLE-TMA patients without variants (p = 0.001). Patients with compound complement variants are more likely to detect abnormal level of complement factors.

Conclusions: SLE-TMA with unknown etiology can be divided into two subgroups with different severity according to the presence or absence of MAHA. The detection of complement factor and E-selectin may play a role in differentiating the two subgroups of SLE-TMA. The complement pathway is highly activated in patients with compound complement mutations, resulting in increased complement factors consumption.

POI1365

A Popping Renal Artery

Juan P. Portocarrero Caceres, Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: The COL3A1 gene encodes the collagen type III alpha chain, which forms the helical conformation. A mutation on this gene causes vascular Ehlers-Danlos syndrome (v-EDS), a life-threatening disease characterized by arterial fragility, vascular dissection or rupture, and organ perforation are the most common presenting signs in adults with v-EDS (1).

Case Description: A 25-year-old man with history of bicuspid aortic valve, shoulder dislocation, chronic hemoptysis presented with severe left flank pain and syncope. A CT scan revealed a right retroperitoneal hematoma and aneurysms on the right renal artery (Image 1). Differential diagnosis were fibromuscular dysplasia, small vessel vasculitis and segmental arterial mediolysis (SAM). An extensive rheumatologic and vasculitis workup was negative. A collagen vascular disease was considered due to the history of bicuspid aortic valve and shoulder dislocation, and genetic testing was ordered. He underwent an urgent aorta-to-right renal artery bypass, and ligation of the aneurysm. Postoperatively, he developed hypotension. Abdominal imaging showed a new aneurysm on the superior mesenteric artery. Genetic testing results showed a COL3A1 c.593A pathogenic variant, confirming v-EDS. He now is treated with metoprolol succinate and spironolactone. His fathers genetic testing revealed possible mosaicism.

Discussion: v-EDS is an uncommon but severe disease that needs a high degree of clinical suspicion. Patients usually present with unexplained pneumothorax, organ perforations and arterial ruptures. Little data exists about medical management, goals include maintaining low blood pressures (less than 120/80 mmHg). As well, patients should avoid contact sports and isometric exercises. Patients need constant imaging surveillance on the brain, neck, chest, abdominal and pelvic arteries.

POI1366

Mapping Genomic Regulation of Kidney Diseases and Traits at a Cell Type and Variant Level of Specificity

Christopher Benway, Michelle Mcnulty, Seong Kyu Han, Dongwon Lee, Matt G. Sampson. Nephritic Syndrome Study Network (NEPTUNE) Consortium Boston Children’s Hospital, Boston, MA.

Background: Although numerous genetically associated loci for kidney function and disease have been identified by genome-wide association studies (GWAS), determining the causal genes and functional variants remains a major challenge. Integration of GWAS results with other data types (such as expression quantitative trait loci [eQTLs]) can help identify causal and functional variants in a tissue- or cell-type specific manner. Further, analysis of disease tissue may uncover context-specific associations that may otherwise not be detectable.

Methods: We integrated eQTL data from micro-dissected glomerular (n = 240) and tubulointerstitial (TI) (n = 311) transcriptomes from individuals with nephrotic syndrome and summary statistics from two large trans-ethnic GWAS meta-analyses for estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR). We used a Bayesian statistical framework for eQTL discovery and mapping (TORUS/DAP). eQTL signals from each renal compartment were integrated with summary statistics to perform a gene-level probabilistic transcriptome-wide association study (PTWAS) and SNP-level co-localization (fastENLOC).

Results: We identified 5,526 glomerular and 9,742 TI eQTLs at <5% FDR level. For eGFR, we identified 971 gene-trait pairs in the glomerulus and 1,816 gene-trait pairs in TI tissue that were significant (FDR < 5%). For UACR, we identified 194 and 340
significant gene–trait pairs in the glomerulus and T1 tissue, respectively. In the SNP-level co-localization analysis, we identified 46 TI and 3 glomerular co-localization signals (regional co-localization probability [RCP] > 50%) for eGFR, including known associations with UMOD and FGFR3 expression, as well as novel associations to LARPB4 and RARAG which can be attributed to single variants. We identified 7 TI and 16 glomerular co-localization signals (RCP > 75%) for UACR. In addition to replicating co-localization signals at PKRCL and TGFβ1 in glomerular tissue, we refined the co-localization signal at PTHIR to a single variant, rs6787229, which also co-localized with expression of MYL2.

Conclusions: Profiling and integrating renal compartment-specific eQTLs with kidney trait GWAS results in a probabilistic framework identified novel gene–trait associations and refined many known associations to a single variant.

PO1367
Factors Contributing to Decisional Conflict in Older Persons Facing Dialysis Decisions

Background: Dialysis and conservative kidney management are the two main treatment options for elderly persons with end-stage-kidney disease who are ineligible for kidney transplantation. The high stakes of these decisions often force patients to choose between quality versus quantity of life. Thus, they face tremendous conflict while making dialysis decisions. This decisional conflict can adversely affect their mental health-related quality of life and leads to avoidable delays in decision making. Exploring factors contributing to dialysis decisional conflict in older persons with chronic kidney disease is critical.

Methods: Using a qualitative descriptive approach, we purposefully sampled a cohort of 10 patients; 5 with high scores on decisional conflict scale, and 5 with low scores. Patients met with a palliative care physician to discuss dialysis and these visits were audio-recorded. Audio recordings were transcribed verbatim and entered into MAXQDA for data management. Following an iterative process, 2 independent reviewers analyzed the transcripts for common themes contributing to decisional conflict.

Results: The mean age of patients was 83 years. We observed 3 themes in the data of patients with low decisional conflict: (1) clarity in values, (2) good current quality of life, and (3) strong therapeutic alliance with their nephrologist. In the high decisional conflict group, we observed 5 themes: (1) fear of: physical pain, complications from dialysis and its time commitment, loneliness, and losing independence, (2) concerns about being a burden to loved ones, (3) uncertainty about prognosis, (4) worries about transportation to and from dialysis, and (5) poor knowledge of treatment options.

Conclusions: Patients with high decisional conflict worried about their future quality of life, sense of burdensomeness, prognostic uncertainty, and issues related to transportation. They wished for detailed knowledge of treatment options. Future dialysis decision-making interventions should be tailored to identify each patient’s unique needs, and incorporate details about treatment options and information about logistics of dialysis. Nephrologists need to discuss the expected quality of life and prognosis. Last, family involvement in these discussions and buy-in for or against dialysis may be helpful in mitigating the patient’s sense of being a burden on their loved ones.

PO1368
Shared Decision-Making Among Older Adults with Advanced CKD
Rebecca Frazier,1 Sarah Levine,2 Hocine Tighiouart,1 John B. Wong,2 Tamatha Scherer-Weszler,3 Elisa J. Gordon,3 Daniel E. Weinert,3 Keren Ladin.3 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Tufts Medical Center, Boston, MA; 3Tufts University, Medford, MA.

Background: Older adults with advanced chronic kidney disease (CKD) face difficult, preference-sensitive decisions about dialysis. Although shared decision-making (SDM) can help align treatment with patient preferences and values, the degree to which older CKD patients experience SDM and associated factors remain unknown.

Methods: Using data from the Decision Aid for Renal Therapy Trial, we examined SDM in adults ≥70 years with non-dialysis CKD stage 4–5 from 4 sites in the US using the validated SDM-Q9 measure, with scores scaled from 0-100 and higher scores reflecting greater SDM. We categorized predictors into demographic and clinical factors, cognitive factors (decisional perception and uncertainty), and behavioral and educational factors. Multivariable linear regression assessed predictors of SDM.

Results: Among 350 participants, mean age was 78±6 years, 58% were male, 13% were Black, and 48% had diabetes. Mean SDM-Q9 score was 52±28. Responses varied (resources supporting SDM). Multivariable linear regression assessed predictors of SDM.

Conclusions: Improving shared decision-making for treatment of advanced CKD will likely require efforts that explicitly reconcile the differences in mindset between patients and their clinicians on decision-making about treatment of advanced CKD and that address the power imbalances in their therapeutic relationship.

Funding: NIDDK Support

PO1370
Effect of Estimated Glomerular Filtration Rate on Survival in Patients 275 Years of Age at Dialysis Initiation
Aghiles Hammouz,1,2 Linh Bui,3 Sébastien Gomis,1 François Glowacki,1 1Centre Hospitalier Universitaire de Lille, Lille, France; 2Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; 3Paris Saclay University, Paris, France.

Background: Data regarding the prognostic impact of estimated glomerular filtration rate (eGFR) at dialysis start are discordant, and remain very scarce in elderly populations. The aim of this study is to explore whether the effect of eGFR on survival was similar in elderly incident dialysis patients compared with younger ones.

Methods: We included 4690 patients ≥75 years of age and 7045 patients 18-74 years of age starting dialysis between 2004 and 2018 from a French regional registry. Patients were followed until death or the end of 2019. Survival was assessed by Kaplan-Meier curves and the relative risk of death associated with eGFR (MDRD) was assessed by multivariate Cox regression analysis.

Results: The results showed an increasing trend of eGFR at dialysis start, which was also systematically higher in elderly patients (13.2 [10.1; 17.2] vs 11.2 [8.3; 14.9] mL/min/1.73m², p < 0.001) (Fig1). Overall, we found a significant dose-effect relationship between eGFR at dialysis initiation and mortality (HR = 1.33 [1.16; 1.51], 1.47 [1.29; 1.69], and 1.72 [1.49; 1.78] respectively for eGFR [5-10], [10-15], and ≥ 15mL/min/1.73m², p for trend < 0.001). The same results were found in subgroup analyses according to age category (Fig2), with a significant interaction in favor of a stronger association in younger patients (p = 0.031).

Conclusions: In incident dialysis patients, our study shows a dose-effect relationship between higher eGFR at dialysis start and mortality, regardless of age category. This association seems to be even stronger in younger patients.
Mortality Rates in a Nationally Representative Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Amy S. You,1 Kamyar Kalantar-Zadeh,1 Yoko Narasaki,1 Csaba P. Kovesdy,2 Dana B. Mukamel,1 Susan T. Crowley,1,4 Alejandra Novoa-Vargas,1 Danh V. Nguyen,1 Connie Rhee.1

1University of California Irvine, Irvine, CA; 2The University of Tennessee Health Science Center Memphis, Memphis, TN; 3Yale University School of Medicine, New Haven, CT; 4Veterans Health Administration, Washington, DC.

Background: While dialysis has been the prevailing treatment paradigm in CKD patients progressing to ESRD, this treatment approach may not offer survival benefit nor improved quality of life in certain subgroups (elderly, multi-morbid). Hence, there is growing interest in conservative management (CM) as an alternative treatment strategy in advanced CKD.

Methods: We compared mortality rates in advanced CKD patients (eGFRs <25 separated by a ≥90 days) treated with CM vs. dialysis from 1/1/07-6/30/20 from the OptumLabs Data Warehouse (OLDW), which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as electronic health record data. Patients were categorized according to receipt of dialysis vs. CM, defined as those who did vs. did not receive dialysis within 2-yrs of the index eGFR(1st eGFR <25), with the former group parsed into late vs. early dialysis (eGFRs <15 vs. ≥15 at dialysis transition). Secondary analyses stratified the former group as late, intermediate, vs. early dialysis (eGFRs <5, 5-<10, vs. ≥10 at dialysis transition). Poisson regression was used to compare mortality rates across exposure groups.

Results: Among 309,188 advanced CKD patients, 60% vs. 40% of patients were treated with CM vs. dialysis, respectively. Patients who underwent CM vs. late dialysis had similar mortality, whereas those who underwent early dialysis had the highest mortality rates. In secondary analyses comparing CM and late vs. intermediate vs. early dialysis, a similar pattern was observed (140, 126, 141, vs. 158 deaths per 1000 person-yrs, respectively). In age-stratified analyses, compared to CM, all dialysis groups had higher mortality rates irrespective of timing of initiation in those <65 and ≥65 yrs old.

Conclusions: In a nationally representative cohort of advanced CKD patients, CM vs. late dialysis demonstrated similar mortality, whereas those who underwent early dialysis had the highest mortality rates.

Funding: NIDDK Support
Continued Primary Care Use During the Transition to Kidney Failure (KFRT) Is Associated with Reduced Mortality Among Older Hemodialysis (HD) Patients

Methods: We quantified the associations between PCP use, mortality, and hospitalization among older (age $\geq$ 67) incident (2008-2014) in-center HD patients using data from the United States Renal Data System. We defined patients' PCP use 1-year prior and 1-year post-KFRT as "continued" for PCP use pre- and post-KFRT; "initiated" for no PCP use pre-KFRT and PCP use post-KFRT; "discontinued" for PCP use pre-KFRT and no PCP post-KFRT; or "never used" as no PCP use pre- or post-KFRT. We used Cox proportional hazard models and adjusted for confounding by using inverse probability weighting method to estimate hazard ratios (HRs) for all-cause mortality and first all-cause hospitalization up to 2 years post-KFRT.

Results: Among 111,424 patients, 57% had continuity of PCP care, 10% initiated PCP use, 10% discontinued PCP use, and 23% never used PCP care during the KFRT transition. Compared to those who never used primary care during the KFRT transition, those with continued primary care use had a 14% lower risk of mortality. Continued and initiated PCP care post-KFRT transition was associated with a 5-12% higher risk of hospitalization, respectively.

Conclusions: Continued primary care use during the KFRT transition was associated with lower mortality, but a higher risk of hospitalization. Additional studies are needed to determine the aspects of primary care that may be beneficial and which patients are most likely to benefit from continued PCP use.

Vascular Access Type and Survival Outcomes in Elderly Hemodialysis Patients

Background: The ideal vascular access for elderly hemodialysis (HD) patients remains widely debated. Limited life expectancy and lower arteriovenous access (AVA) maturation rates increase the likelihood of starting HD with a central venous catheter (CVC). The aim of the study was to evaluate the influence of vascular access type in survival outcomes for elderly HD patients.

Methods: Single-center retrospective cohort study of incident HD patients aged $\geq$ 80 years from January 2010 to May 2021. Patients who recovered renal function or switched to another renal replacement therapy were excluded. Patients were categorized according to their vascular access at the beginning of dialysis: CVC or AVA. Baseline clinical and demographic data were compared among groups. Survival outcomes by the end of follow-up (31 May 2021) were analyzed using Kaplan-Meier survival curves and Cox’s proportional hazards model. Statistical analysis was performed using SPSS (Version 23 for Mac OSX).

Results: The study included 99 patients: 48 (48.5%) were male, 44 (44.4%) diabetic, 60 (60.6%) had ischemic heart disease and 15 (15.2%) peripheral artery disease. Mean Charlson Comorbidity Index was 8.41±1.65 and mean age 85.14±3.98 years. Eleven patients (11.1%) were over 90 years old. Eighty patients (81%) started HD urgently as inpatients. The vascular access at dialysis start was a CVC in 75.8% (n=75) and an AVA in 24.2% (n=24). No statistical differences were found in age, gender, comorbidities and functional statuses among groups. During a mean follow-up of 2.3 years, there were 64 deaths, 27 due to infections (12 access-related infections). All-cause mortality (HR [95% CI]: 1.92 [1.05-3.49], p=0.033) and infection-related mortality (HR: 5.87 [1.38-24.94], p=0.017) were significantly higher among patients who initiate HD with a CVC as compared to an AVA.

Conclusions: The ideal vascular access in elderly patients remains controversial. Our results suggest that patients who start HD with a CVC presented higher all-cause and infection-related mortality when compared with patients who start with an AVA. Our study supports the initiative “fistula first” however more studies are needed to confirm the observations.
Evaluation of a Concurrent Hospice-Dialysis Program with ESRD

Mayumi Robinson,¹ Natalie C. Ernechof,¹ Erica M. Motter,¹ Keith Lagnese,² Robert Taylor,³ Jane O. Schell.¹ ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²UPMC Family Hospice, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴Dialysis Clinic Inc, Nashville, TN.

Background: Most dialysis patients are hospitalized in the last month of life, nearly half of whom receive intensive care. Hospice financing poses a major barrier to hospice delivery to dialysis patients, increasing inequities for high-quality end-of-life care. The Concurrent Hospice-Dialysis Program aims to promote timely hospice services for dialysis patients with limited prognosis by offering concurrent hospice and dialysis.

Methods: We conducted a mixed methods study comprised of chart reviews and semi-structured interviews with 10 bereaved caregivers of deceased patients who were enrolled in the Concurrent Hospice-Dialysis Program and 13 clinicians who provided care as part of the program.

Results: Four major themes were identified: 1) Decisional distress regarding stopping dialysis; 2) The option to continue dialysis served as a psychological bridge to hospice; 3) Clear referral process, formal patient education, and care coordination between hospice and dialysis teams facilitated successful implementation; 4) Providing hospice and dialysis promoted goal-concordant care at end-of-life.

Conclusions: Bereaved caregivers and clinicians involved with the Concurrent Hospice-Dialysis Program found the program broadly acceptable and recommended it for patients on dialysis interested in hospice services. They offered suggestions for systematizing and disseminating the program.

Concurrent Hospice Dialysis: Perspectives on Dissemination

Erica M. Motter,¹ Mayumi Robinson,¹ Natalie C. Ernechof,¹ Keith Lagnese,² Robert Taylor,³ Jane O. Schell.¹ ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³Dialysis Clinic Inc, Nashville, TN.

Background: In the United States, people receiving dialysis have traditionally been unable to enroll in hospice without ceasing dialysis treatments due to policy constraints. Therefore, these patients are often denied the full benefits of quality end-of-life care, either dying in hospitals or spending only a few days on hospice after dialysis is stopped. An alternative model would allow people living with end-stage renal disease (ESRD) to receive hospice services concurrently with dialysis treatments.

Methods: We implemented a concurrent hospice-dialysis program in one health system to test the concept. In this project, we aimed to build evidence for feasibility and program requirements for extending such programs to other settings across the country. We conducted semi-structured interviews with people living with ESRD, family caregivers, hospice and dialysis clinicians, and health system administrators from the Pittsburgh area and other regions in the U.S. Interviews elicited perceptions of strengths and weaknesses of a scalable concurrent hospice and dialysis program, including barriers and facilitators of implementation across various settings.

Results: We conducted 25 interviews with 2 patients (8%), 3 caregivers (12%), 15 clinicians (60%), and 5 administrators (20%). Preliminary themes include important considerations: 1) Mechanisms and operational definitions for identification of eligible patients; 2) Procedures for decision-making conversations with patients and families; and 3) Protocols for communication between hospice and dialysis teams to coordinate care. Medicare policy and funding restrictions were also frequently discussed as barriers to the program.

Conclusions: Perspectives from patients, caregivers, clinicians and administrators describe critical implementation processes and resources for a successful concurrent hospice and dialysis program. These include the following: clear criteria for patient eligibility, consistent language to use when talking with patients and families, education for both hospice and dialysis teams, and a well-defined plan for care coordination between teams. Future evaluation of such programs may lead to policy change to make concurrent care broadly financially feasible.

Dialysis for the Hospice Patient: A Paradoxical Challenge for Palliative Nephrology

Frank A. Portugal, Steve I. Khalil. Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, NJ.

Introduction: We present a case of a patient who developed anuric AKI who subsequently needed dialysis while patient and family were also simultaneously interested in hospice. Our case addresses the difficult conversation in prognosticating and how best to prepare for patients requiring dialysis can be challenging.

Case Description: A 63-year-old woman with hypertension and recently diagnosed metastatic pancreatic adenocarcinoma initially presented for intractable right hip pain and was admitted for emergent palliative radiation. She experienced rapid deterioration including septic and hemorrhagic shock and was managed in the ICU until she was later stabilized off pressors and downgraded to the floors. Unfortunately, she had further complications and quickly experienced anuric AKI from ischemic ATN as her serum creatinine rose from 0.8 to 4.9 mg/dL and became significantly volume overloaded with worsening acidemia. The decision was to start a trial of dialysis by family, but they also wanted hospice. Questions arose including prognosis and if patient could simultaneously be provided with dialysis during hospice. Given the current model of withdrawing from dialysis for hospice eligibility, the daughters agreed to transition their mother to hospice. The patient passed prior to leaving the hospital.

Discussion: We present a difficult scenario for the nephrologist as serious illness conversations remain incredibly challenging. We may opt to not take part in these conversations either due to time commitment, not viewing it as a primary responsibility, or not wishing to upset the patient and their families. Also, so much uncertainty in predicting prognosis makes it intimidating. Here, what also needed to be addressed were hospice benefits for the dialysis patient, if any existed. Usually, one is required to withdraw from dialysis to receive hospice care. There have been suggestions in providing a trial or “as needed dialysis” to focus on a patient-centered type of care but unfortunately that could potentially impact quality metrics and Medicare reimbursement for dialysis centers. As such, these ongoing challenges not only require collaboration between Nephrology and Palliative medicine but also changes at the national broader level.

Kidney Palliative Care in Transplant Recipients with a Failing Allograft

Samantha L. Gelfand, Naoka Murakami, Joel T. Adler, Joshua R. Lakin. Brigham and Women’s Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA.

Background: Kidney transplantation provides longer survival and better quality of life than dialysis for patients with end-stage kidney disease. However, when allografts fail, navigating treatment options can be challenging as patients with allograft failure are usually older and sicker than when they were transplanted. Kidney palliative care, specialized interprofessional medical care working together with nephrology providers, providing communication, coordination, symptom management, and psychosocial support for seriously ill patients, has not yet been well-studied for those with kidney transplants.

Methods: We conducted a retrospective observational study comparing palliative care delivery, patient treatment choices, and clinical outcomes before and after creation of an inpatient kidney palliative care service (KidneyPal) at our institution. We included adult kidney transplant recipients who were 18 years of age or greater with allograft failure over a mean of 2.9 years (median 1.0 years) from 2012 to 2016. The KidneyPal service was established in 2015. A total of 767 unique patients had frailty assessments performed between 2016-2021. Patients were predominantly of male sex (64%), white race (82%) and had a mean age of 54±14. The prevalence of frailty for women was not significantly higher by the FP (16% vs 13%, p=0.15) or the FI (48% vs 46%, p=0.38), but was by the CFS (17% vs 12%, p=0.05). Among 325 activated patients, frailty by the CFS was significantly associated with death/withdrawal for men (HR 2.59; 95% CI 1.16-6.79) but not women (HR 1.48; 95% CI 0.86-2.56).

Conclusion: The prevalence of frailty was higher in females when measured by the CFS, but not by a transplant specific FI or the FP. Despite this, frailty was not significantly associated with mortality/withdrawal from the waitlist for female individuals, emphasizing the need to critically evaluate judgement based frailty assessments and their role in the transplant evaluation process.

Differences in Frailty by Sex in Kidney Transplant Candidates

Caroline Worth,1 Amanda J. Vinson,2 Karin K. Tereschenko.2 Frailty Assessments in Canadians being Evaluated for Transplant Study (FACETS) Dalhousie University, Halifax, NS, Canada; 2 Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Frailty prevalence is higher in women, despite the observed protective effect of female sex on mortality in the general population. Understanding whether there are differences in perceived frailty by sex and the differential impact of frailty on outcomes for males versus females is crucial to avoid a sex disparity within the transplant assessment process.

Methods: We analyzed initial frailty assessments for patients enrolled in a multicenter prospective cohort study across 6 kidney transplant referral centers. Frailty was assessed using the Frailty Phenotype (FP, 3 of slowness, weight loss, low activity, exhaustion, and unintentional weight loss); a Frailty Index (FI, including 37 variables across the domains of social function/cognition, function, mobility, and comorbidity), and the Clinical Frailty Scale (CFS, based on clinical judgement). Assessments were performed prior to or shortly after waitlisting. Prevalence of frailty as measured by the FP, FI, and CFS was reported. An unadjusted Cox survival analysis (separately for males and females) was used to assess the effect of frailty on time to death or withdrawal from the waitlist among activated patients.

Results: A total of 767 unique patients had frailty assessments performed between 2016-2021. Patients were predominantly of male sex (64%), white race (82%) and had a mean age of 54±14. The prevalence of frailty for women was not significantly higher by the FP (16% vs 13%, p=0.15) or the FI (48% vs 46%, p=0.38), but was by the CFS (17% vs 12%, p=0.05). Among 325 activated patients, frailty by the CFS was significantly associated with death/withdrawal for men (HR 2.59; 95% CI 1.16-6.79) but not women (HR 1.48; 95% CI 0.86-2.56).

Conclusions: The prevalence of frailty was higher in females when measured by the CFS, but not by a transplant specific FI or the FP. Despite this, frailty was not significantly associated with mortality/withdrawal from the waitlist for female individuals, emphasizing the need to critically evaluate judgement based frailty assessments and their role in the transplant evaluation process.

Changes in Cognition After Kidney Transplantation

Aditi Gupta,1 Palash Sharma,2 Rebecca J. Lepping,1 Jonathan D. Mahnken,1 William M. Brooks,1 David K. Johnson,2 Jeffrey M. Burns.1 University of Kansas Medical Center; Kansas City, KS; 2University of California Davis, Davis, CA.

Background: Longitudinal studies examining changes in cognition pre- to post-kidney transplantation (KT) are small, of short duration and do not include comprehensive neuropsychological (NP) testing or comparison with normative data.

Methods: We analysed pre- to post-KT cognition in 87 ISNKD patients listed for KT and compared it to the National Alzheimer’s Coordination Center (NACC) data. We used linear mixed models for longitudinal, repeated NP test measurements, adjusted for for age, practice effect, sex, race, transplant status, and level of education, and assessed cognition both pre- to post-KT for the following domains (Logical Memory I, II, and Digit Symbol tests) and secondary (Mini Mental State Exam (MMSE), Digit span, Category Fluency for animals & vegetables, Trail making A & B) outcomes.

Patients Who Are Treated for Secondary Hyperparathyroidism Have a Lower Risk of Incident Dementia

JiYoon B. Ahn,1 Aarti Mathur,1 Dorry L. Segev,2,3 Mara McAdams-DeMarco,1,2 ERGOT Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background: Almost all patients with end-stage kidney disease (ESKD) have secondary hyperparathyroidism (SHPT). Elevated parathyroid hormone has been reported as a potential risk factor of cognitive impairment. We aimed to study whether the risk of dementia is improved when patients on dialysis receive treatment for SHPT.

Methods: Using data from the United States Renal Data System and Medicare claims, we studied older (aged ≥66) ESKD patients without known pre-ESKD dementia who initiated maintenance dialysis in 2006-2016. SHPT treatment included vitamin D analogs, phosphate binders, cinacalcet or parathyroidectomy and was treated as a time-dependent treatment in the analysis. The study population was followed until transplant, death, or the end of the study period. The study period was divided into four groups: pre-ESKD, primary SHPT, secondary SHPT, and any SHPT with treatment. The association between SHPT treatment and the risk of dementia was analyzed using the Cox regression and adjusted for confounding using the inverse probability weighting method to examine the association of SHPT treatment and incident dementia.

Results: Of 189,433 ESRD patients, 65.1% received a treatment for SHPT during the study period. The rate of incident dementia was 11 per 100 person-years among patients with no SHPT treatment and 6 per 100 person-years among those with an SHPT treatment. Among patients on dialysis, the risk of incident dementia was lower after receiving treatment for SHPT compared with not receiving treatment for SHPT (adjusted hazard ratio = 0.62; 95% CI = 0.59-0.66) after adjusting for confounding.

Conclusions: Receiving treatment for SHPT was associated with a lower risk of incident dementia among older patients with ESKD. SHPT may need to be controlled among older ESKD patients considering the complications of SHPT including cognitive impairment and dementia.

Kidney-Metabolic Risk Factors for Cognitive Impairment in Moderate CKD in the BRINK Study: Beyond eGFR and Albuminuria

Anne M. Murray,1,2 David Tupper,1,2 Cynthia S. Davey,1 Ryan Mello,1 Allyson Hart,1 Kirsten L. Johansen,2 The German Center for Outcomes and Clinical Research, Hennepin Healthcare Research Institute, Minneapolis, MN; 1Hennepin Healthcare, Minneapolis, MN; 2University of Minnesota Clinical and Translational Science Institute, Minneapolis, MN; 3University of Minnesota Twin Cities, Minneapolis, MN.

Background: Decreased kidney function is a risk factor for cognitive impairment (CI). We sought to identify kidney-metabolic biomarkers beyond eGFR and albuminuria associated with prevalent moderate to severe cognitive impairment (Mod/Sev CI) in a CKD cohort.

Methods: Community-dwelling non-dialysis participants aged 45 years with CKD (eGFR <60, in mL/min/1.73 m²) were recruited from four health systems. We examined biomarkers including phosphorus, TNFαR1, PTH, calcium, total cholesterol, hemoglobin A1c%, bicarbonate (CO2), and albumin (mg/dL). A neuropsychological battery measured global and domain-specific cognitive performance. Logistic regression analyses estimated cross-sectional associations between kidney-metabolic measures and global and cognitive-domain-specific Mod/Sev CI at baseline, adjusted for eGFR, albumin-creatinine ratio (UACR, in mg/g), demographics, and comorbid conditions.

Results: Among 436 older patients aged 70 years, 16% were Black, mean eGFR was 34 and median UACR. In adjusted models no kidney-metabolic biomarkers were significantly associated with global Mod/Sev CI. However, in cognitive-domain-specific analyses, low bicarbonate (CO2 <20 mEq/L) was significantly associated with Mod/Sev CI impairment in memory [OR (95% CI): 3.04 (1.09, 8.47) P=0.03] and with language [3.82 (1.12, 13.6; P=0.03] in addition, lower total cholesterol was associated with impaired executive function [1.12 per -10mg/dL (1.02, 1.23; P=0.02).

Conclusions: Low bicarbonate (acidosis) and lower cholesterol levels in older patients with CKD may be modifiable kidney-metabolic risk factors for Mod/Sev domain-specific CI in CKD. Longitudinal analyses are needed to determine whether low bicarbonate and low cholesterol are associated with cognitive decline.
PO1388

Association of CKD Stages with Frailty Worsening or Death in Community-Dwelling Older Adults

Nina Mielke,1 Alice Schneider,1 Natalie Ebert,1 Markus van der Giet,1 Doerte Huscher,1 Martin K. Kuhlmann,2 Elke Schaeffner,1 1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Vivantes Klinikum im Friedrichshain, Berlin, Germany.

Background: Albumin-creatinine-ratio (ACR) and glomerular filtration rate (GFR) have been associated with prevalent and incident frailty. We analyzed the association of the KDIGO CKD stages and frailty status worsening or death in data of the Berlin Initiative Study (BIS).

Methods: Prospective population-based cohort study interviewing participants biannually with a standardized questionnaire. Frailty assessment according to Fried took place at the 3rd and 4th follow-up. Frailty worsening was defined as the transition within a two-year period from robust to frail or frail, or from prefrail to frail. Partial proportional odds regression analysis was used to analyze the association between KDIGO CKD stages and the ordinal outcome of no worsening, frailty worsening, or death.

Results: Of 1076 participants with 46% male and mean age 84.3 years, initially 48% were frail and 32% frail. After 2.1 (2.0-2.3) years of follow-up 188 (17.5%) had worsened and 111 (10.3%) died. Participants who died were older (88 vs. 83 yrs), were less physically active, had less muscle mass (calve circumference <31: 10% vs. 5%), and were more likely to be cognitively impaired; 92% had a GFR <60 mL/min/1.73m2 and 59% had an ACR ≥30 mg/g compared to 72% and 24% in participants who did not worsen, respectively. Baseline characteristics of participants who worsened were similar to participants who did not worsen. In the multivariable model participants in CKD stages G1,2/A2,3 and G3/A1 or higher had a higher odds of frailty worsening, than in CKD stages G1,2/A1. The odds for death increased remarkably with both higher CKD stage and increasing albuminuria. Wide confidence intervals are likely due to limited sample size/events. Additional adjustment for frailty baseline status did not alter the results.

Conclusions: In older adults, advanced CKD stages but also albuminuria independent of GFR were associated with 2-fold higher odds of frailty worsening independent of death.

Role of Klotho in Aging, Relationship with Frailty, Renal Function, and Body Composition

Paolo Betti, Marta De Filippo, Marco Simonini, Simone Fontana, Lorena Citterio, Elisabetta Messaggio, Patrizia Rovere Querini, Elena Brioni, Cristiano Magnaghi, Chiara Lanzani, Paolo Manunta. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Reduced expression of the Klotho protein has been associated with premature aging and increased mortality. Our aim is to evaluate the relationships between plasma Klotho levels and frailty, renal function and anthropometric parameters.

Methods: We enrolled a cohort of 1250 volunteers aged > 65 years (FRASANET Study) in recreation centers for the elderly, in hospital’s outpatient clinic and in nursing homes. All the volunteers have signed informed consent and subjects with severe cognitive impairment were excluded (MMSE <18). We measured eGFR (CKD-EPI formula) and body composition by impedanceometry. Plasma Klotho was assayed by an ELISA kit on 194 samples. Frailty was classified according to Fried’s criteria.

Results: A positive correlation between plasma Klotho and renal function (eGFR) has been described (fig. 1). In agreement with what previously observed, in a young population, we confirmed a reduction of klothemia in the sarcopenic patients (713 vs 791 pg/mL, p=0.0007 in patients with muscle mass <25% centile) and in patients with high visceral fat mass (fig.2). On the other hand, we did not observe different plasma levels of Klotho according to the frailty class or in relation to age.

Conclusions: In our elderly population, the plasma levels of Klotho do not correlate with age. Therefore, our results confirm the relevance of this biomarker in identifying pathological aging, in consideration of its association within the elderly population with CKD, abdominal obesity and sarcopenia (sarcopenic obesity). Klotho expression was demonstrated as an independent predictor of death in a follow up-study and was related to many diseases (e.g.: cognitive impairment, cardiovascular disease). The relation of plasma klotho levels and renal function is debated, and conflicting results have been published. Our findings evidenced a significative association of plasma Klotho with renal function and body composition.

Shrunken Pore Syndrome: Prevalence and Association with Mortality in a Population-Based Cohort of Elderly Women

Linnéa Malmgren,1,2 Fiona Mequigan,1 Anders Christensson,1,2 Kristina Åkesson,1,2 1Lunds Universitet, Lund, Sweden; 2Skanes universitetssjukhus Malmo, Malmo, Sweden.

Background: Decreased kidney function results in lower clearance and increased plasma concentration of a GFR marker. So far creatinine has been the commonly used GFR marker but cystatin C becomes more common. Shrunken pore syndrome (SPS) is a recently identified kidney syndrome characterized by disturbed filtration of mid-sized molecules (5-30 kDa) compared to smaller ones (<0.9 kDa) (Fig1). Resulting in increased plasma levels of cystatin C (cysC) compared to creatinine. SPS is associated with increased risk of cardiovascular disease (CVD) and increased mortality risk. So far few data are available about SPS in population-based cohorts.

Methods: 75-yr old women (n=849) from the population-based Osteoporosis Prospective Risk Assessment (OPRA-) cohort, with follow-up after 5yr and 10yr were studied. eGFR was calculated with the CKD-EPI equation. SPS was defined as eGFRcysC/eGFRcrea ratio <0.6 and mortality risk (HR [95% CI]) estimated. Women with sarcopenia or on glucocorticoids were excluded.

Results: Almost 1 in 10 women (9%) had SPS at age 75 but at age 80 the majority of these women had increased their eGFRcysC/eGFRcrea ratio >0.6 (range from 0.6-1.0). Women with SPS had higher 10-yr mortality risk compared with ratios <0.9 (HRadj 1.7 [95% CI, 1.1-2.6]). Table 1.

Conclusions: SPS defined as eGFRcysC/eGFRcrea ratio <0.6 is common in elderly women and associated with increased mortality. While longitudinal data indicate that the state may be reversible. Our results also confirm other studies and suggest that SPS may be a clinically applicable tool to assess mortality risk in the elderly.

Funding: Private Foundation Support, Government Support - Non-U.S.

SPS (eGFRcysC/eGFRcrea ratio <0.6) is associated with increased 10-yr mortality

Possible pathophysiological mechanisms of SPS (1) reduced pore size and (2) thickening of the glomerular basement membrane

Molecular Changes Associated with Type IV Collagen Switching in 1-Day-Old Alport Murine Glomeruli
Akanehaya Rana,1,2 Sofia Farkona,1,2 James W. Scholey,1,2 Ana Konvalinka,1,2 Mounir Barua,1,2 1Toronto General Research Institute, Toronto, ON, Canada; 2University Health Network, Toronto, ON, Canada; 3University of Medical Science, University of Toronto, ON, Canada.

Background: Alport syndrome (AS) is an inherited disorder caused by pathogenic variants in COL4A3, COL4A4 or COL4A5, which encodes proteins that comprise basement membranes of the ear, eye and kidney glomeruli. Type IV collagen chains assemble as heterotrimers and during glomerular development, α1G2α1 (IV) is replaced by α3ε4α5 (IV) within the developing glomerular basement membrane (GBM). This “switching” defines the starting point of disease in AS. We aimed to identify the molecular changes at the time of disease initiation in the developing glomeruli of Alport murine kidneys.

Methods: Immunofluorescence (IF) staining was done to identify the GBM distribution of type IV collagen chains in 1 day old COL4A3 knockout (KO) and wildtype (WT) mice. Urine albumin to creatinine ratio (uACR) was also measured. Subsequently, glomeruli from 1 day old (P1) COL4A3 KO and WT mice were isolated by cardiac injection of magnetic dynabeads that embolized to glomerular capillaries enabling their extraction from surrounding tissue. Protein was isolated and subjected to liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) analysis.

Results: IF localized type IV collagen α1 in the GBM, Bowman’s capsule and mesangial matrix in both P1 KO and WT mice. Type IV collagen α5 was present in short segments of some developing GBM in P1 WT but was absent in KO mice indicating switching. uACR was increased in P1 KO (423.61 mg/mmol) compared to WT (128.67±9.86 mg/mmol) with a p-value of 0.02. LC-MS/MS identified ~4300 proteins from glomerular isolates. In males, 2 and 15 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. In females, 543 and 978 proteins were significantly upregulated and downregulated, respectively, in KO compared to WT mice. Pathway analysis revealed alteration in collagen metabolic process, collagen biosynthesis, collagen formation and extracellular matrix organization.

Conclusions: Increased uACR in P1 KO mice showed disease onset at the time of Type IV collagen switching. LC-MS/MS analysis revealed dysregulation of matrix turnover pathways in P1 KO mice, identifying potential molecular targets.

PTEN-Induced Kinase 1 Has Association with Renal Aging in the Context of Inflammatory Response
Hyejun Jeong, Ha Min Heui, Min ji Sung, Yu ho Lee, Hyun-Ju An, Song Hee Lim, So-young Lee. CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.

Background: Among several changes of aging-related human organ system, functional and structural deterioration of kidney is the most dramatic phenomenon, and the role of mitophagy has recently considered important in pro-aging process in CKD patients. PTEN-Induced kinase 1 (PINK1), known to be associated with age-related diseases regulates mitochondrial dysfunction. To enhance understanding the function of PINK-1 on aging, we compared whole-kidney RNA sequencing between naturally aging mice (24-month-old) and PINK1 knockout (KO) mice.

Methods: Kyoto Encyclopedia of Genes and Genomes pathway analysis and gene ontology analysis were performed for gene expression analysis. To investigate the role of PINK1 on aging, we used Pnk1-deficient mice and PINK1-overexpressing HKC8.

Results: Compared to naturally aging kidneys, PINK1 knock out aging mice showed prominent expression of PINK1 related to cytokines, immune system response, and inflammation (Fig 1). We also investigated the function of PINK1 in PINK1 (-/-) aging mice. PINK1 deficiency showed aggravated tubulointerstitial fibrosis on PAS staining (Fig2A), and the Urinary Albumin-Creatinine Ratio increased more prominently (Fig2B). The Quantitative PCR analysis validated according to aging in PINK1 (-/-) mice (Fig2B). The Urinary Albumin-Creatinine Ratio increased more prominently (Fig2B). The Quantitative PCR analysis validated according to aging in PINK1 (-/-) mice (Fig2B). The Urinary Albumin-Creatinine Ratio increased more prominently (Fig2B). The Quantitative PCR analysis validated according to aging in PINK1 (-/-) mice (Fig2B).

Conclusions: In conclusion, our results suggest that PINK1 deficiency contributes to renal aging process via proinflammatory change in the kidney.

PO1393
TGF-β1/Smad Signaling in Glomerulonephritis and Its Association with Progression to CKD
Agnieszka Chalkia, Harikleia Gakiopoulou, Panagiota E. Giannou, Zoe Alexakou, Athanasia Kapota, Dimitrios Kourniotis, Dimitrios I. Petras. 1Nephrology Department, Hippokration General Hospital, Athens, Greece; 21st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

Background: Transforming growth factor-β1 (TGF-β1) is a multifunctional cytokine, with diverse roles in fibrosis and inflammation, which acts through Smad signaling in renal pathology. We intended to investigate the expression of TGF-β1/Smad signaling in glomerulonephritis (GN) and to assess its role as risk factor for progression to chronic kidney disease (CKD).

Methods: We evaluated the immunohistochemical expression of TGF-β1, phosphorylated Smad3 (pSmad3) and Smad7 semi-quantitatively and quantitatively (computerized image analysis program has also been used) in different compartments of 50 renal biopsies with GN and the results were statistically analyzed with clinicopathological parameters. We also examined the associations among their expressions, the impact of their co-expression, and their role in progression to CKD.

Results: TGF-β1 expression correlated positively with segmental glomerulosclerosis (p=0.025) and creatinine level at diagnosis (p=0.002), while pSmad3 expression with interstitial inflammation (p=0.024). In glomerulus, concomitant expressions of high Smad7 and medium pSmad3 were observed to be correlated with renal inflammation, such as cellular crescent (p=0.011), intense interstitial inflammation (p=0.029) and lower serum complement 3 (p=0.028) and complement 4 (p=0.029). We also reported a significant association between pSmad3 expression in glomerular endothelial cells of proliferative GN (p=0.045) and in podocytes of non-proliferative GN (p=0.005). Finally, on multivariate Cox-regression analysis, TGF-β1 expression (HR = 6.078; 95% CI 1.168-31.627; p=0.032) was emerged as independent predictor for CKD.

Conclusions: TGF-β1/Smad signaling is upregulated with specific characteristics in different forms of GN. TGF-β1 expression is indicated as independent risk factor for progression to CKD, while specific co-expression pattern of pSmad3 and Smad7 in glomerulus is correlated with renal inflammation.
**Case Description:** A 55-year-old male with a medical history significant for uncontrolled diabetes complicated by retinopathy, Chronic kidney disease, HTN, and compensated cirrhosis of unclear etiology, presented to the hospital with shortness of breath and lower extremity edema. Initial workup revealed a creatinine of 7.6 (baseline creatinine 1.5 eighteen months earlier), and significant proteinuria estimated at 8.4g/day along with a urinalysis showing 3 RBC/high power field and 6 WBC/high power field. Serological workup including Hepatitis B/C, HIV, SFEP, serum free light chains, C3/C4, ANA, ANCA was negative. He underwent a renal biopsy revealing medullary angiitis with multifocal medullary hemorrhage with perivascular PMNs and eosinophils along with findings of long-standing diabetes and HTN. In the absence of IgA deposits, infection, or offending drugs, he was started on high steroids and treated similarly to ANCA positive medullary angiitis. His creatinine during the hospitalization peaked at 8.69 before and fell to 7.6 at discharge. He was continued to oral prednisone at discharge. Outpatient follow-up showed a decrease in Cr to 5.8 before slowing climbing back up to 8.5. He is currently maintained on an immunosuppressive regimen to help delay the initiation of renal replacement therapy.

**Discussion:** Medullary angiitis is a rare renal disorder that has largely been associated with ANCA positivity. ANCA negative medullary angiitis has been documented in the literature with a recent case series showing IgA nephropathy and recent antibiotics use to be the most common etiologies. This is one of the first case reports of ANCA negative medullary angiitis not associated with IgA nephropathy and recent antibiotic use. Currently, we have no standardized treatment options available for these patients. Given the rapid progression of the renal dysfunction, we decided to start our patient on high-dose steroids. Our patient had an initial improvement in his renal function with subsequent decline. However, treatment may have afforded time for AVF creation and patient education before the initiation of hemodialysis, which was the main goal of therapy.

**PO1395**

**Calorie Restriction Ameliorates Obesity-Related Glomerulopathy in Adult Zebrafish**

**Evan Zeitley, J. Charles Jenette, Jennifer E. Flythe, Ronald J. Falk, John S. Pouillon. UNC Kidney Center, Chapel Hill, NC.**

**Background:** Obesity is a risk factor for chronic kidney disease. The mechanisms by which obesity results in kidney disease are understudied. Zebrafish are an attractive model animal for studying obesity due to their conserved biology and amenability to genetic screening. The effects of obesity on kidney function in zebrafish have not been reported.

**Methods:** Zebrafish were fed high-calorie and high-fat diets for 8 weeks. Kidneys were evaluated by light and electron microscopy, and the glomerular filtration barrier was assessed by fluorescent dextran permeability. We also tested the ability of calorie restriction to reverse obesity-related defects.

**Results:** Fish fed a high calorie diet developed glomerulomegaly, foot process effacement, GBM thickening, tubular enlargement (Figure 1) and ectopic lipid deposition after 8 weeks. High calorie feeding resulted in filtration barrier dysfunction. The observed effects resolved after 4 weeks of calorie restriction (Figure 2).

**Conclusions:** Our study reveals that obese zebrafish recapitulate key aspects of human pathology, and these defects can be reversed with calorie restriction. These findings establish zebrafish as a potential model for the study of obesity-related kidney disease.

**Funding:** NIDDK Support

**PO1396**

**Different Patterns of Renal Fibrosis Are Indicative of Independent Fibrogenic Causes in ANCA-Associated Glomerulonephritis**

**Samy Hakroush,1 Michael Zeisberg,2 Bjorn Tampe.1**

1Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany; 2Department of Nephrology and Rheumatology, University Medical Center Göttingen, Göttingen, Germany.

**Background:** Renal fibrosis is a common manifestation and hallmark of a wide variety of chronic kidney diseases (CKD) appearing in different morphological patterns, suggesting different pathogenic causes or consequences. Renal fibrosis with focal injury usually presents with patchy fibrosis whereas diseases affecting renal parenchyma in a diffuse manner lead to a more diffuse fibrotic pattern. In the present study, we aimed to analyze renal fibrotic patterns in association with the renal lesions which are considered to directly contribute to renal fibrogenesis in a cross-sectional study.

**Methods:** A total number of 112 renal biopsies with various renal pathologies including acute interstitial nephritis (AIN), ANCA-associated vasculitis (AAV), membranous GN, lupus nephritis, nephropathy due to hypertension, IgA nephropathy (IgAN), focal-segmental glomerulosclerosis (FSGS) and diabetic kidney disease (DKD) were retrospectively included between 2015 till 2020 in a cross-sectional study.

**Results:** We here provide evidence that tubulointerstitial fibrosis is either the result of nephron damage (dependent or independent of glomerular scarring) or the result of a primary interstitial injury (leading to a diffuse fibrotic interstitial remodeling). Our data also show that focal fibrosis correlated with glomerular damage and irreversible injury to nephrons, confirmed in experimental models of nephrotoxic serum-nephritis and folic acid nephropathy in mice. By contrast, diffuse fibrosis was specifically associated with interstitial inflammation independent of glomerular damage and nephron loss, confirmed in mice challenged with unilateral ureteral obstruction.

**Conclusions:** In conclusion, we here provide evidence that tubulointerstitial fibrosis is either the result of nephron damage or loss and replacement scarring, representing incomplete tissue repair. By contrast diffuse fibrosis appears to be the result of primary interstitial inflammation and injury.

**PO1397**

**Automatic Artificial Intelligence-Assisted Glomerulosclerosis Analysis in Mice Models with Glomerulopathy**

**Thomas Secher, Casper G. Salinas, Michael Christensen, Niels Vrang, Mette V. Østergaard, Gubra, Harsholm, Denmark.**

**Background:** Glomerulosclerosis (GS) is a hallmark pathological feature in glomerular diseases. In preclinical research, GS is recapitulated in a number of experimental mice models with glomerulopathy, and a cross model characterization of GS would add to our understanding of their translatability to human disease. Here, we report GS quantification using an objective and newly developed automated AI assisted image analysis strategy in three mice models with glomerulopathy.

**Methods:** AI-assisted GS scoring was performed in three mice models with glomerulopathy and to assess drug treatment effects: 1) Diabetic nephropathy in remnAAV-induced hypertensive uninephrectomized db/db mice (DN/HT). Mice received treatment with vehicle, lisinopril, empagliflozin or combination. 2) I.V. injection of nephrotoxic anti-GBM serum (NTS) and 3) Adriamycin (ADR) in healthy mice. Automatic AI-assisted GS scoring was performed as a two-step process on PAS stained image analysis strategy in three mice models with glomerulopathy.

**Results:** We here provide evidence that tubulointerstitial fibrosis is either the result of nephron damage (dependent or independent of glomerular scarring) or the result of a primary interstitial injury (leading to a diffuse fibrotic interstitial remodeling). Our data also show that focal fibrosis correlated with glomerular damage and irreversible injury to nephrons, confirmed in experimental models of nephrotoxic serum-nephritis and folic acid nephropathy in mice. By contrast, diffuse fibrosis was specifically associated with interstitial inflammation independent of glomerular damage and nephron loss, confirmed in mice challenged with unilateral ureteral obstruction.

**Conclusions:** In conclusion, we here provide evidence that the majority of renal fibrosis seems to be the consequence of nephron loss and replacement scarring, representing incomplete tissue repair. By contrast diffuse fibrosis appears to be the result of primary interstitial inflammation and injury.

Increased Glomerular Parietal Epithelial Cell Expression of Cathepsins C and B in Anti-Thy-1.1 Mouse Model of FSGS
Michael Merchant,1 Michelle T. Barati,1 Kenneth R. McLeish,1 Jon B. Klein,1,2 Bart Smeets,1,3 University of Louisville School of Medicine, Louisville, KY; 1VA Robley Rex Medical Center, Louisville, KY; 2Radboudumc, Nijmegen, Netherlands.

Background: Focal segmental glomerulosclerosis (FSGS) is characterized by replacement of glomerular capillaries by extracellular matrix (ECM). The collapsing FSGS (cFSGS) variant exhibits a poor prognosis and response to therapy. We recently reported that activated PECs migrates into glomerular tufts in humans and in cFSGS patients and demonstrate increased cathepsins C and B expression. The absence of cathepsins B and C within normal glomerular tufts suggests these proteases may represent novel mediators of PEC-mediated glomerulosclerosis leading to collapse. Here we address the hypothesis that activated PECs expressing cathepsins C and B migrate into glomerular tufts in a mouse model of cFSGS.

Methods: Thy-1.1 transgenic mice were injected with either saline (vehicle control) or anti-Thy1.1 antibody (19XE5; 1mg/mouse) to induce cFSGS. Mice were sacrificed 4, 7, and 21 days after injection. Kidney sections were subjected to immunofluorescence staining for claudin-1, a marker of PECs, and cathepin C or cathepsin B. Images were acquired by confocal microscopy.

Results: Claudin-1, cathepsin C, and cathepsin B co-localized to glomerular parietal epithelial cells lining Bowman’s capsule in vehicle control mice. On day 4 after anti-Thy-1.1 administration, claudin-1 staining showed migration of PECs into glomerular tufts in more than half of the glomeruli. Both cathepsins B and C co-stained to positive cells within glomerular tufts. PECs in the Bowman’s capsule with hypertrophied morphology, suggesting activation, demonstrated increased expression of cathepsins C and B. Claudin-1 and cathepsins B and C co-localized within glomerulitis on day 7 and 21 after anti-Thy-1.1 administration, however, the number of stained cells per glomerulus and the percent glomerulus with positively stained cells in the glomerular tuft appeared decreased.

Conclusions: Glomerular PECs migrate into glomerular tufts and show increased expression of cathepsins C and B in the anti-Thy-1.1 model of cFSGS, recapitulating our findings in human cFSGS biopsies. The Thy-1.1 mouse model of cFSGS can be used to define the role of PEC expression of cathepsins B and C in the pathogenesis of human cFSGS.

PB01399
Effects of Enzymatic Cross-Linking and Increased Stiffness on Glomerular Basement Membrane and Podocyte Function
Dan Wang,1 Nicholas J. Ferrell,1,2 Vanderbilt University Medical Center; Nashville, TN; 1Vanderbilt University; Nashville, TN.

Background: The Glomerular basement membrane (GBM) is a critical component of the glomerular filtration barrier. Stiffening of the extracellular matrix is an important regulator of cellular function. How GBM stiffening affects podocyte function is not fully understood. This work aims to investigate the effect of GBM stiffening on molecular permeability and the podocyte function using a biomimetic in vitro model directly derived from kidney glomeruli.

Methods: Decellularized glomeruli isolated from porcine kidneys were pressure compacted on a Transwell membrane. GBM stiffness was tuned by crosslinking with Ficoll and AF488-BSA. Effects of GBM stiffening on gene expression of markers of podocyte differentiation (NPHP1, WT1, Synaptopodin) were screened by qPCR.

Results: The stiffness of the decellularized glomeruli showed a dose-dependent increase after incubating with TG for 1 day and 4 days. On stiffer GBM, immunofluorescence imaging showed translocation of YAP to the podocyte nucleus. Passive molecular permeability of GBM was similar for native and the TG crosslinked GBM. Podocytes cultured on both native and TG crosslinked GBM forms a stringent barrier to large molecules. qPCR results show an upregulation of differentiation markers as podocytes cultured on native and TG crosslinked GBM.

Conclusions: We developed a biomimetic in vitro model that fabricated directly from kidney tissue. mTG crosslinked glomeruli show a dose-dependent increase of stiffness. TG did not significantly effect the diffusive permeability of the GBM. GBM stiffness affects the YAP localization in the podocytes. The current in vitro model upregulates the gene expression of podocyte markers.

PB01400
Effect of ANG-3070 in the Unilateral Ureteral Obstruction Mouse Model of Renal Fibrosis

Background: Tubulointerstitial inflammation and fibrosis are strong predictors of progression in all kidney diseases regardless of etiology. Receptor tyrosine kinases such as platelet-derived growth factor receptor (PDGFR) and discoidin domain receptors (DDRs), contribute to renal inflammation and fibrosis. ANG-3070 is an inhibitor of multiple tyrosine kinase receptors including PDGFR and DDR. This study evaluated whether ANG-3070 can slow the progression of fibrosis in the unilateral ureteral obstruction (UUO) mouse model of renal fibrosis.

Methods: Male mice were subjected to UUO and randomized to daily oral treatment with vehicle (n=15) or 100 mg/kg of ANG-3070 (n=15) for 10 days after UUO and then sacrificed. Control male animals were age-matched and were not subjected to UUO (n=10). At sacrifice, obstructed and control kidneys were collected and processed for renal damage by hematoxylin-eosin (H&E) staining and scoring (0-8; 0 no damage and 8 damage >80% of kidney) by blinded observers. Collagen deposition and myofibroblast transformation was determined by quantitative image analysis of picrosirius red (PSR)-stained slides and slides stained for α-smooth muscle cell actin (αSMA), respectively.

Results: Animals treated with ANG-3070 had a statistically significant reduction in histological damage as compared to vehicle (Vehicle, 6.4 vs ANG-3070, 4.3; p-value <0.001) and the histological markers of fibrosis, PSR (% control, vehicle, 1453 vs. ANG-3070, 5035; p-value <0.001), and αSMA (% control, vehicle, 511 vs. ANG-3070, 248; p-value <0.01) as shown in Figure 1.

Conclusions: Daily oral administration of 100 mg/kg ANG-3070 reduces renal damage and renal fibrosis in a mouse model of renal fibrosis induced by UUO.

Renal Outcome Using New Chronicity Scoring System in IgA Nephropathy: Nationwide Study in Korea
Donghyuk Kang,1 Tae Hyun Ban,2 Hyung Duk Kim,1 Bumsoon Choi,2 KOGNET group; 1Seoul Saint Mary’s Hospital, Seocho-gu, Seoul, Republic of Korea; 2Catholic University of Korea Eunpyeong St Mary’s Hospital, Eunpyeong-gu, Seoul, Republic of Korea.

Background: Many new grading systems of glomerulonephritis were proposed, recently. In 2019, new suggestion about standardized classification and reporting of GN is proposed by Mayo Clinic/Renal pathology society. Among the part of this new suggestion, grading the chronicity is an extremely important step and simple scoring system for chronic changes was devised. Therefore, the purpose of this study is predicting renal outcome with new grading system in IgA nephropathy (IgAN) patients.

Methods: 4,505 IgAN patients were enrolled from Korean Glomerulonephritis Study Group (KoGNET) registry. Validation of Oxford classification, chronicity index was predicting renal outcome with new chronicity grading system in IgA nephropathy (IgAN) patients.

Results: In validation of Oxford classification, both S and T scores were significantly associated with renal outcomes, but M and C scores were not. Multivariate linear regression analysis showed chronicity index was significantly associated with renal outcomes (P=0.05 for all). The severity of chronicity index was well correlated with renal outcomes in multivariate Cox regression analysis: minimal vs mild (HR, 1.95; 95% CI, 1.15 to 3.32; P=0.014), minimal vs moderate (HR, 2.98; 95% CI, 1.66 to 5.34; P<0.001), minimal vs severe (HR, 4.08; 95% CI, 2.27 to 7.35; P<0.001). Hypertension, eGFR, proteinuria and serum uric acid were also well correlated. In subgroup analysis,
POI1402
Comparison of Glomerular Proteome Profiles of Healthy Human Kidney and Minimal Change Disease Identifies Distinct Targets and Pathways
Salem Almasani, Sethu Madhavan, John P. Shapiro, Anjali A. Satoeskar, Isabelle Ayoub, Brad H. Rovin, Samir V. Parikh. The Ohio State University, Columbus, OH.

Background: Minimal change disease (MCD) is a common cause of idiopathic nephrotic syndrome and is characterized by diffused podocyte foot process effacement. The pathogenesis of MCD remains unclear. We hypothesized that proteomics analysis of glomeruli could identify molecular markers that reflect the pathogenesis of MCD.

Methods: We included formalin-fixed paraffin-embedded kidney biopsies from patients with steroid-sensitive MCD (n=9) and normal donor kidneys (n=4). Glomeruli were isolated using laser capture microdissection and HPLC MS/MS was done using Orbitrap eclipse mass spectrometer. After data normalization, groups were clustered using principal component analysis (PCA) and compared by paired t-tests.

Results: PCA showed separate clustering of healthy glomeruli and MCD samples (FDR<0.1). Out of the 6729 unique proteins identified in MCD glomeruli, 1088 proteins were significantly differentially expressed compared to controls. Pathway analysis showed upregulation of complement pathway components (C1R, C1S, C1QA, C2, C3, C4A, C4B, C5, C7, C8B, C9) and downregulation of carbohydrate and amino acid metabolic pathway enzymes (FBP1, FBP2, ALDOC, ALDOB, AKR1A1, ALDH1A1, ALDH5A1, ACAT1). MCD glomeruli showed a significant reduction in expression of ECM proteins FREM2, FRAS1, CDH12. Surprisingly, the expression of podocyte slit diaphragm-associated proteins (SYNPO, NPHS2, CD2AP) was not significantly altered in MCD compared to controls. We did not observe differential expression of MCD associated proteins, KANK, CFL1, CMIP. No peptides from SMPD3L8 or ANGPTL4 were identified in MCD glomeruli.

Conclusions: Glomeruli from MCD showed differential proteomic signature compared to healthy human glomeruli. Activation of innate immune pathways including the complement system and loss of extracellular matrix and basement membrane-specific components in glomeruli of MCD are novel observations. The role of these markers in the pathogenesis of MCD needs to be investigated.

POI1403
Effects of ANG-3070 in a Mouse Model of Alport Syndrome

Background: Alport syndrome (AS) is a hereditary kidney disease that presents in childhood and progresses to end stage kidney disease (ESKD) in adolescence. There are no approved therapies. AS is caused by mutations in type IV collagen genes Col4a3, a4 or a5, that result in reduced structural integrity of the glomerular basement membrane, triggering activation of fibrionic cytokines, including platelet derived growth factor (PDGF) and transforming growth factor beta (TGFβ1) causing proteinuric disease and fibrosis. We hypothesize that an antifibrotic therapy may decrease proteinuria-induced fibrosis, and evaluated ANG-3070, a novel tyrosine kinase inhibitor, in a Col4a3 knockout mouse model of AS.

Methods: After confirming the Col4a3 mutation by genotyping, 4-week-old male and female mouse were randomized to Vehicle (oral, twice-daily) or ANG-3070 (oral, 25 mg/kg, twice-daily) for 5 weeks (n=12/group). Age-matched, wild-type mice were included (n=9) as a control. Animals were sacrificed after 5 weeks of treatment, after collecting spot urines to measure protein to creatinine ratio (PCR). Renal tissue was analyzed for hydroxyproline (HYP) content by Western blot or tissue fibrotic markers, and for histopathology using hematoxylin-eosin (H&E) staining for renal damage score and picrosirius red (PSR) staining for fibrosis. All histological analyses were performed by two independent observers using a 0-4 scale (0 being normal, 4 ≥75% injured or stained).

Results: ANG-3070 treatment reduced mortality (survivors; Vehicle: 8/12 vs ANG-3070: 12/12). In surviving mice, proteinuria was reduced (mg/mg; Vehicle 6.2 vs ANG-3070 3.1, p<0.05) along with renal damage (Vehicle 2.6 vs ANG-3070: 1.2; p = 0.002) along with renal fibrosis (Vehicle 2.4 vs ANG-3070 1.2; p<0.001). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.05) along with fibrosis (mg/g kidney; Vehicle, 132 vs ANG-3070, 57; p<0.05). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.05) along with fibrosis (mg/g kidney; Vehicle, 132 vs ANG-3070, 57; p<0.05). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.05) along with fibrosis (mg/g kidney; Vehicle, 132 vs ANG-3070, 57; p<0.05). When kidney lysates were evaluated, HYP content was reduced (mg/kg; Vehicle, 132 vs ANG-3070, 57; p<0.05) along with fibrosis (mg/g kidney; Vehicle, 132 vs ANG-3070, 57; p<0.05).

Conclusions: Treatment with a novel tyrosine kinase inhibitor, ANG-3070, was effective in AS mice compared to Vehicle. ANG-3070 may represent a novel therapeutic for AS.

Collapsing FSGS Is Strongly Associated with Microvascular Injury
Nina A. Van de Lest, Kyra L. Dijkstra, Jamie S. Chua, Ron Wolterbeek, Jan A. Bruijn, Marion Scharpfenecker, Ingeborg M. Bajema. Leids Universitair Medisch Centrum, Leiden, Netherlands.

**Background:** Recent studies have suggested that the collapsing variant of focal segmental glomerulosclerosis (FSGS) might be a common secondary feature in renal disease influenced by microvascular injury. Here, we investigated glomerular and arteriolar microvascular injury in patients with collapsing FSGS, including primary FSGS, and HIV-associated FSGS, and compared these lesions to patients with other variants of FSGS.

**Methods:** Biopsies of patients with FSGS were collected, including primary FSGS in native biopsies or transplant biopsies, as well as HIV-associated FSGS. Cases of FSGS secondary to renal diseases known to be caused by microvascular injury were excluded. We assessed all glomeruli in a biopsy for the presence of lesions associated with FSGS or ischemic injury, assessed microvascular lesions in glomeruli and arterioles, and studied interstitial lesions.

**Results:** We included 53 cases of FSGS, of which 19 cases with collapsing FSGS, 18 cases with FSGS not otherwise specified (NOS), 11 cases with FSGS tip, 3 cases with perihilar FSGS and 2 cases with cellular FSGS. Compared to other variants of FSGS, glomerular endothelial swelling of the vascular pole was more common in patients with collapsing FSGS (11% vs 0.9%; p=0.05). Associations between thrombotic injury and FSGS variant were not found. Arteriolar abnormalities were seen in 58% of collapsing FSGS and 38% of other variants of FSGS (p=0.17). When evaluating the concomitant occurrence of FSGS lesions and microvascular injury in individual glomeruli, we found that collapsing lesions and FSGS NOS lesions were associated with endothelial swelling in the same glomerulus (OR=22;p<0.001 and OR=3.8;p=0.01, respectively). Endothelial swelling was more common in glomeruli with collapsing lesions than glomeruli with FSGS NOS (OR=2.7;p=0.044). Collapsing FSGS was also associated with endocapillary hypercellularity (OR=4.3;p<0.001).

**Conclusions:** Here, we demonstrate that collapsing FSGS lesions are strongly associated with microvascular injury such as endothelial swelling and endocapillary hypercellularity, and often co-exist in the same glomerulus. In addition to collapsing FSGS occurrence, the secondary phenomenon in renal microangiopathies, these results indicate that endothelial injury could also be involved in the pathophysiology of collapsing FSGS due to primary podocyte injury.

Danhog Injection (DHI) Inhibits Lipopolysaccharide-Enhanced Cell Proliferation of Rat Renal Mesangial Cells via NF-κB Signaling Pathway
Hua Liu. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

**Background:** To explore the mechanisms of DHI in the treatment of Mesangioproliferative glomerulonephritis (MsPGN), we investigated the effects of DHI on LPS-induced NF-κB activation and its downstream inflammatory mediators, such as ICAM-1, TGF-β1, iNOS and FN protein expression in rat MCs.

**Methods:** The rat MCs treated with different concentrations of DHI (0, 50, 100, 200, 500, 1000, and 2000 uL/L) for 12 h,then incubated with or without 100 ng/ml LPS for another 24 h. Then, cell proliferation was determined by CCK8. The MCs treated with low-dose DHI (250 uL/L), median-dose DHI (500 uL/L) and high-dose DHI (1000 uL/L) for 12 h or PDTC for 30 min before 24h treatment of LPS. Then the activation of NF-κB was detected by Western blot and immunofluorescence. The protein levels of ICAM-1, TGF-β1, iNOS and FN in rat MCs were detected by Western blot.

**Results:** DHI significantly suppressed LPS-induced cell proliferation by CCK8 results (Fig 1). LPS stimulation resulted in a significant increment of p65 contents in nucleus and a decrement of p56 contents in cytoplasm in rat MCs compared with NC. PDTC and DHI exerted potent inhibitory effect on increasing expression of p65 in nucleus and decreasing in cytoplasm compared with LPS-treatment group. The inhibitory effect on NF-κB nuclear translocation of DHI was in a dose-dependent manner (Fig 2). The protein level of iκB-α in cytoplasm treated by LPS decreased significantly compared with that in control (Fig 3) and this decrement was significantly reversed by PDTC and DHI. In addition, the protein expression of ICAM-1, TGF-β1, iNOS and FN was also inhibited by PDTC and DHI (Fig 4).

**Conclusions:** DHI significantly repressed LPS-induced cell proliferation and FN expression in rat MCs through inhibiting the activation of NF-κB signaling pathway also its downstream inflammatory mediators.

**PO1408**

Effect of ANG-3070 in the Passive Heymann Nephritis Rat Model of Primary Proteinuric Kidney Disease

**Background:** Primary proteinuric kidney diseases (PPKD) as a group are an important cause of end-stage kidney disease (ESKD). Many receptor tyrosine kinases, including platelet-derived growth factor receptor (PDGFR), contribute to the progression of PPKD to ESKD. ANG-3070 is a novel and proprietary inhibitor of multiple tyrosine kinases including PDGFR. This study evaluated the effects of ANG-3070 in a passive Heymann's nephritis (PHN) rat model of membranous glomerulopathy.

**Methods:** Male Sprague Dawley rats (300g) were administered anti-FX1A serum. Treatment groups included 15mg/kg ANG-3070 (n=11), Vehicle (n=11) and Sham (n=5). Animals were dosed orally, twice daily, for 12 weeks, and 24-hour urines were collected biweekly. At sacrifice, kidney tissue was harvested.

**Results:** Twelve-week treatment with orally dosed ANG-3070 significantly reduced the protein to creatinine ratio as compared to Vehicle (mg/mg: 5.3 vs 9.4; p=0.05). It also led to a significant reduction in total kidney hydroxyproline content (mg/kidney: 952 vs. 1416; p=0.05), indicating a reduction in fibrotic tissue. When periodic acid-Schiff staining from kidney sections were evaluated for glomerular damage by two blinded observers on a scale of 0 (normal/no injury) to 4 (severe injury), ANG-3070 significantly reduced glomerular damage (1.7 vs. 2.6; p=0.05), indicating a reduction in glomerulosclerosis. The evaluation of PDGFRβ levels from total kidney lysates by Western blot indicated an increase in the Vehicle treated group compared to Sham (PDGFRβ/GAPDH; 2.6 vs 0.7, p=0.05). ANG-3070 treatment significantly reduced these levels when compared to Vehicle (PDGFRβ/GAPDH; 1.0 vs 2.6, p=0.05), which was comparable to the levels observed in the Sham group.

**Conclusions:** Twice-daily oral administration of the novel tyrosine kinase inhibitor ANG-3070 reduces proteinuria, renal fibrosis, glomerulosclerosis and PDGFRβ expression levels in a rat model of PHN. These data suggest ANG-3070 may be an effective treatment in PPKDs.

A Rare Case of Immunotactoid Glomerulopathy Associated with Rheumatoid Arthritis
Ramon A. Seneriz,1,2 Juanly N. Rodriguez,1,2 Yaqin Zuo,1,2 1Jackson Memorial Hospital, Miami, FL; 2University of Miami Health System, Miami, FL.

**Introduction:** Immunotactoid glomerulopathy (ITG) is a rare disease that is characterized by nephritic range proteinuria, hematuria, hypertension, and kidney failure. It is most commonly associated with hematologic disorders. Rarely it presents as a polyclonal process and associated with autoimmune disorders such as rheumatoid arthritis (RA).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Fibrillary Glomerulonephritis: A Rare Entity, Responsive to Rituximab
Ramya Ijaz.1 Renal Associates LLC., Columbus, GA; Augusta University, Augusta, GA.

Introduction: Fibrillary glomerulopathy (FGN) is a rare proliferative type of glomerular disease with poor prognosis and limited therapeutic options. Literature review showed very few cases of FGN where Rituximab has been used.

Case Description: A 69-year-old Caucasian woman with a history of DM, HTN presented to the hospital with complaints of dyspnea and leg swelling. Lab work revealed BUN/Ser of 34/3.88 mg/dL (baseline Ser of 1.4 mg/dL, proteinuria (7.902 mg/dL). Renal biopsy was performed which showed fibrillar deposits as shown in the picture. Hepatitis panel and work up of malignancy including bone marrow biopsy was negative. She was started on Rituximab 1gm every 14 days for 2 doses. Pt initially required HD but with treatment her symptoms and Cr improved and was taken off HD. Most recent Cr was1.8.

Discussion: The diagnosis of FGN can only be established with kidney biopsy. Most of the patients present with renal insufficiency, nephrotic picture. Most idiopathic but can be associated with hepatitis C, dysproteinemia, autoimmune diseases and to lesser extent malignancies. The prognosis is very poor with very limited therapeutic options to date. Rituximab has been used in few cases in literature showing good clinical response. Our patient tolerated and responded very well to Rituximab with significant improvement in kidney function and hence we propose the use of Rituximab in FGN.

Focal Segmental Glomerulosclerosis: A Rare Cause of Nephrotic Syndrome in Graft vs. Host Disease

Introduction: Nephritic syndrome (NS) is a very rare complication of allogeneic hematopoietic cell transplantation (HCT) and is usually associated with chronic graft versus host disease (GVHD). In such patients, membranous nephropathy and minimal change disease are the most frequently observed renal pathology. However, focal segmental glomerulosclerosis (FSGS) is an extremely uncommon etiology of NS in patients with HCT and GVHD. We herein describe a case of a patient with HCT and chronic GVHD who developed NS secondary to FSGS.

Case Description: A 24-year-old man with medical history of Sickle Cell Disease status post splenectomy and HCT, epilepsy, arterial hypertension and chronic GVHD with cutaneous and esophageal manifestations who presented to the emergency department with a one-month history of progressive lower extremity edema and intermittent hematuria. Vital signs were remarkable for uncontrolled blood pressure. Home medications were lisinopril 20mg daily, levetiracetam 500mg twice daily and prednisone 10mg daily. Physical examination was remarkable for edema of the lower extremities, ascites, and cachexia. Laboratories revealed: BUN 35 mg/dL, serum creatinine 1.15 mg/dL, total bilirubin 0.9 mg/dL, serum albumin 1 g/dL, glucose 110 mg/dL, total cholesterol 425 mg/dL, triglycerides 335 mg/dL, VLDL 67 mg/dL and LDL 316 mg/dL. Urine protein/creatinine ratio resulted in 30,000mg/g. Laboratory findings of hypalbuminemia, hyperlipidemia, and nephrotic range proteinuria were consistent with NS. A renal biopsy was performed and the findings consistent with a diagnosis of FSGS, not otherwise specified. Partial remission of NS was achieved at 3 months of treatment with mycophenolate mofetil 500mg twice daily and prednisone 15mg twice daily.

Discussion: GVHD is a significant cause of morbidity and mortality in patients after HCT. Renal involvement can be a serious manifestation and prompt recognition is essential for adequate management and prevention of renal disease. FSGS is an extremely rare complication of HCT and very few cases have been reported in the literature linking FSGS to HCT. Further documentation of this phenomenon is important to further characterize the clinical and pathological features of this complication.
Catastrophic COVID-19-Associated Nephropathy (COVAN) in an Asymptomatic Patient

Samer Akrawi, Toni Sabbouth, Khaled Janom, Panduranga S. Rao, Cathryn J. Lapedis. University of Michigan Michigan Medicine, Ann Arbor, MI.

Introduction: Glomerular lesions were reported in a minority of patients with COVID-19, with collapsing focal segmental glomerulosclerosis (FGS) also called COVID-associated nephropathy (COVAN). This typically occurs in the setting of prominent COVID symptoms. We describe a COVAN occurring in an asymptomatic patient.

Case Description: A 48-year-old, African American female patient who had CKD stage 3 secondary to hypertension, with serum creatinine of 1.2 mg/dl and absent proteinuria at baseline, presented to the hospital for evaluation of an asymptomatic elevation of her serum creatinine to 9.9 mg/dl, discovered during a routine evaluation by her PCP. Her urine Protein/Creatinine was 6.15. Six weeks prior to her presentation, she endorsed 7 days of nausea and intermittent vomiting associated with non-bloody diarrhea without respiratory symptoms. Her GI symptoms has resolved on its own. She had multiple family members, including her husband and daughter, who had tested positive for COVID around the same time. Her nasal PCR for COVID was negative. She had not been vaccinated for SARS COVID. She has no family history of kidney disease; she denied IV drug use and had no risk factors for HIV. She was on Amlodipine for her hypertension. She was afebrile on admission with blood pressure of 170/80 mm Hg. She had 1+ pedal edema with an unremarkable physical exam. A percutaneous kidney biopsy was performed to evaluate the cause of her renal dysfunction. This showed collapsing FSGS. HIV and ANA were negative. A subsequent testing for COVID nucleocapsid and spike protein was positive. Results of APOL1 genotype is pending. She was started on high dose steroids and followed up as an outpatient.

Discussion: COVAN is recognized as a serious complication of COVID. However, the typical presentation is in the setting of prominent respiratory involvement. Recognizing the minor fleeting symptoms of COVID preceding a catastrophic kidney disease and testing for it is an important in patients presenting with features of collapsing FGS.

POI1415

Siglec-9 Agonism Reduces ANCA-Mediated Neutrophil Responses

Dana Kiddie1, Kristine Nollany, Catriona Walls. 1 NHS Grampian, Aberdeen, United Kingdom; 2University of Aberdeen School of Medicine Medical Sciences and Nutrition, Aberdeen, United Kingdom.

Background: Siglec-9 (Siglec-9), a high molecular weight sialic acid-binding Ig-like lectin, is a monocyte and neutrophil membrane protein that is expressed on neutrophils and monocytes. The expression and potential role of siglec-9 in ANCA-associated vasculitis (AAV) is not yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on AAV-associated neutrophil responses in vitro.

Methods: Neutrophils and monocytes were isolated from peripheral venous blood of AAV patients and siglec-9 expression was measured by flow cytometry and ELISA, respectively. Immunohistochemistry was performed on kidney biopsies of AAV patients with AAVN and stained for siglec-9 and leukocyte markers. Functional studies were done using healthy donor neutrophils and monocytes. The expression and potential role of siglec-9 in AAVN-associated vasculitis (AAV) is yet to be determined. We aimed to examine the expression of siglec-9 in patients with AAV and explore the impact of siglec-9 agonism on AAV-associated neutrophil responses in vitro.

Results: We found increased serum siglec-9 expression in active AAV compared to remission AAV and a positive correlation with disease activity. Neutrophils and intermediate (CD14+CD16+) monocytes from PR3-ANCA patients displayed higher siglec-9 expression compared to MPO-ANCA patients. Siglec-9 expression in AAGN was restricted to areas of active inflammation. We observed increased siglec-9 shedding in neutrophils following AAGN stimulation. Siglec-9 agonism in these neutrophils was associated with increased apoptosis and reduced ROS production compared to isotype control and unstimulated neutrophils.

Conclusions: Our study suggests that siglec-9 expression correlates with disease activity in AAV. Our functional studies support a potential role for siglec-9 in modulating AAV-mediated neutrophil responses. Further evaluation is required to determine the relevance of these findings on neutrophil-endothelial interactions.

Funding: Government Support - Non-U.S.
non-renal AAV and remission in all cohorts, and healthy control urine in C1 (Kruskal- Wallis, P<0.001). sCD206 was significantly higher in active ANCA GN compared to HC in cohorts C1 & C2 (Kruskal-Wallis, P=0.01). sCD163 had a specificity of 100% in all cohorts, whereas sensitivity was 71% (C1), 88% (C2) and 64% (C3). The addition of sCD206 increased the sensitivity to detect active ANCA GN in all cohorts to 83% (C1), 100% (C2) and 81% (C3). IHC revealed CD163+ and CD206+ cells in the kidneys of active ANCA GN patients (n=8). IF showed glomerular presence of CD163+ and CD206+ cells were mainly found in the tubulointerstitium.

Conclusions: sCD206 complements sCD163 and reduces false negative rates in the detection of active ANCA GN. Histological assessment revealed distinct glomerular and tubulointerstitial populations of CD163+ and CD206+ cells.

PO1418
Urine and Plasma Complement Ba Levels During Flares of Nephritis in Patients with ANCA-Associated Vasculitis
Salem Almsani,1 Huijuan Song,1 Mresha Suthanthira,1 Christopher Toy,1 Lynn A. Fussner,1 Alexa S. Meara,1 Haikady N. Nagaraja,1 Nader A. Khalidi,1 Christian Pagnoux,2 Kenneth Warrington,2 Paul Monach,2 Peter A. Merkel,3 Brad H. Rovin,1 Daniel J. Birmingham,1 Vasculitis Clinical Research Foundation1 The Ohio State University Wexner Medical Center, Columbus, OH; 2Brigham and Women’s Hospital, Boston, MA; 3Mount Sinai Hospital, Toronto, ON, Canada; 4University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 5McMaster University, Hamilton, ON, Canada; 6Mayo Foundation for Medical Education and Research, Rochester, MN; 7Colorado State University System, Denver, CO.

Background: The alternative complement pathway has been implicated in the pathogenesis of ANCA-associated vasculitis (AAV), however it is not clear whether activation of complement occurs systemically or in affected organs such as the kidney. This study measured levels of urinary and plasma complement fragment Ba (uBa and pBa) respectively at multiple timepoints in patients with AAV.

Methods: Ba was measured by ELISA in serial samples of urine (uBa) and plasma (pBa) from 20 AAV patients who developed a renal flare, 20 who developed a non-renal flare, and 20 in long-term remission. Changes in Ba levels were modeled using linear mixed effect models.

Results: Cohort characteristics are given in Figure 1. uBa levels increased at renal flare, but did not increase at non-renal flare, and remained stable in long-term remission. Changes in Ba levels were modeled using linear mixed effect models.

PO1419
Alterations in Amino Acid and Lipid Metabolism in ANCA-Stimulated Monocytes
Emma Leacy,1 Hania Khouri,2 Gareth Brady,1 Mark A. Little,1 Trinity Translational Medicine Institute, Dublin, Ireland; 2Aglent Technologies UK Ltd, Cheadle, United Kingdom.

Background: Multiple metabolic pathways and intermediates are involved in inflammation. Altered immune cell metabolism is involved in the pathogenesis of autoimmune diseases such as anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). In particular, monocytes stimulated with ANCA show increased oxidative phosphorylation and glycolysis, with a more profound response to myeloperoxidase (MPO) ANCA than proteinase-3 (PR3). The aim of this work was to profile the metabolome of ANCA-stimulated primary monocytes.

Methods: Monocytes from healthy donors (n=24) were isolated and stimulated with monoclonal anti-MPO, anti-PR3 for 4 hours. Metabolites were extracted using an optimised extraction protocol and analysed by liquid chromatography–mass spectrometry (LC-MS). Targeted and untargeted analyses were carried out using Agilent MassHunter Profiler and Mass Profiler Professional. Cytokine production was measured by ELISA and flow cytometry was used to assess surface expression of MPO and PR3.

Results: Targeted metabolomic analysis showed increases in several amino acid and TCA cycle metabolites relative to unstimulated cells, notably phenylalanine, isomers leucine & isoleucine, and fumarate. Untargeted analysis confirmed alterations in amino acid and lipid metabolism in ANCA-stimulated monocytes (Figure 1). These metabolic differences did not correlate with the increased cytokine expression observed in anti-MPO-treated monocytes. Anti-PR3 stimulation did not induce major changes in metabolism or cytokine production. Monocytes expressed high levels of surface MPO and PR3, with MPO expression showing a significant inverse correlation with age.

Conclusions: Inflammatory and metabolic activation of primary human monocytes occurs with anti-MPO but not anti-PR3 stimulation. Early increases in amino acid and lipid metabolism are evident in anti-MPO treated cells. Further work is needed to validate these findings and determine their physiological relevance in AAV.

Funding: Commercial Support - Agilent Technologies Ireland Limited
Conclusions: Depletion of LFA-1 or Mac-1 blocks MPO-ANCA induced NCGN in mice, thus both of these β2-integrins are required for ANCA disease induction. Depletion of LFA-1 or Mac-1 does not block MPO-ANCA induced neutrophil activation. These observations indicate that blockade of either of these β2-integrins abrogates MPO-ANCA NCGN by inhibiting the recruitment of neutrophils that is required to induce inflammatory vascular injury in ANCA disease. These data suggest that pharmacologic blockade of β2-integrins may have a therapeutic role in ANCA disease.

Drilling into a Potential Correlation Between ANCA-Associated Vasculitis and Natural Gas Wells

Devan Makati, James L. Akers, Khaled Shawwa, Rebecca J. Schmidt, Dinesh Kannabhiran. West Virginia University Health Sciences Center; Morgantown, WV.

Background: ANCA-associated vasculitis (AAV), a systemic necrotizing disease affecting small and medium blood vessels, is caused by antineutrophil cytoplasmic autoantibodies which target neutrophilic proteases such as proteinase 3 (PR3) or myeloperoxidase (MPO). The incidences of PR3-AAV and MPO-AAV vary geographically with PR3-AAV most commonly reported in the United Kingdom and MPO-AAV the predominant type seen in Japan. Environmental exposure has been implicated in the pathophysiology of MPO-AAV. The aim of this study is to evaluate a potential relationship between AAV and environmental factors in north central West Virginia.

Methods: This is a retrospective cohort study of 212 patients diagnosed with AAV at West Virginia University and its affiliated hospitals from January 1, 1990 to December 31, 2019. Patients were mapped by zip code and prevalence of AAV assessed over time.

Results: The proportion of MPO-ANCA cases increased (37.5% in 2010 vs 71.7% after 2016 (p = 0.008)) with a resultant increase in the prevalence of AAV overall after 2010 (Table). During this time, the production of natural gas through fracking increased with barrel production rising more than 5-fold after 2010. Regional heat mapping reveals that the increase in cases of AAV occurred in areas of increased fracking activity (Figure)

Conclusions: The increase in prevalence of MPO-ANCA AAV correlates temporally and geographically with escalations in fracking activity. These findings suggest that exposure to toxins from fracking could be operative in the pathophysiology of AAV and the increase in case numbers seen in north central West Virginia.

Prevalence of AAV before and after 2010

Pictured on the left is a map of all the gas fracking wells (pictured in red) and gas and oil fracking wells (pictured in yellow) (BWGES Maps and GIS Data Memo [swnet.edu]). Pictured on the right is a map of the ANCA cases diagnosed after 2010.

POI422

Maintenance of ANCA Vasculitis Remission by Intermittent Rituximab Dosing Based on B Cell Reconstitution vs. a Serologic ANCA Flare (MAINTANCVAAS)

Reza Zonoz,1 Amushya Jeyabal,1 Pravarat Nithagon,1 Karen A. Laliberte,1 Frank B. Cortazar,2 John Niles,1 MGH Vasculitis and Glomerulonephritis Center (MGH VGC) 1Massachusetts General Hospital, Boston, MA; 2New York Nephrology Vasculitis and Glomerular Center, Albany, NY.

Background: ANCA vasculitis is caused by autoantibodies to proteinase 3 (PR3) or myeloperoxidase (MPO). Rituximab (RTX), an anti-CD20 monoclonal, is effective at induction and maintenance of remission. However, RTX is associated with adverse events; hypogammaglobulinemia, infections, and late onset of neutropenia. The ideal strategy for long-term maintenance of remission remains unknown.

Methods: This is an interim analysis of an open-label, single center, randomized, two-arm controlled trial (ClinicalTrials.gov Identifier: NCT02749292) to evaluate maintenance of remission strategies that provides the best relapse-free survival in patients with ANCA vasculitis at 36 months. We enrolled subjects with ANCA vasculitis on RTX-induced continuous B cell depletion for a minimum of two years to one of two arms as follows: intermittent B cell depletion with RTX re-dosing upon (1) B cell return (a 10 B cells/mm3) or (2) upon a significant ANCA titer increase. The primary outcome was number of relapses defined by a Birmingham Vasculitis Activity Score (BVAS/WG) ≥ 2. Other outcomes, including serologic relapse and serious adverse events are not included in this analysis.

Results: From May 2016 to June 2021, 113 patients (mean age, 61 years; 48% women) were randomized, 57 to the ANCA arm and 56 to the B cell group. 52 patients were positive for anti-MPO, and 61 for anti-PR3. Relapse-free survival estimates at month 60 were 76% (95% CI, 62% to 86%) and 91% (95% CI, 74% to 97%) in the ANCA and B cell groups, respectively (hazard ratio of 3.85 (CI, 1.40 to 10.60) (P = 0.024 by logrank).

Conclusions: B cell driven RTX dosing appears to be highly efficacious at preventing relapses compared to ANCA titer driven dosing. Full trial analysis, including differences in adverse events, is needed to balance the benefit of reduced relapses against the infectious complications that may be associated with increased RTX use.

Pulsed Steroids Impede T Memory Cell Recruitment to the Kidney in Human and Experimental Crescentic Glomerulonephritis

Jan-Hendrik Riedel,1 Tobias B. Huber,2 Thorsten Wiech,1 Christian F. Krebs,1,4 Ulf Panzer,1,4 *III. Department of Medicine, Division of Translational Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 1Department of Medicine, Hamburg Center for Translational Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Despite undesirable side effects and understudied modes of action steroids still constitute a cornerstone of therapeutic regimes for autoimmune kidney diseases presenting as rapidly progressive glomerulonephritis (RPGN), e.g. anti-neutrophil cytoplasmatic antibody associated glomerulonephritis (ANCA-GN). However, if the rapid clinical effects of steroids are due to a direct impact on leukocytes, i.e. CD3+ T cells, or mediated indirectly by attenuation of an inflammatory environment is still unknown.

Methods: Kidney biopsies of patients with ANCA-GN with and without pulsed steroids before biopsy were analysed by immunohistochemistry, flow cytometry and single cell RNA sequencing. Furthermore, corresponding studies were conducted in untreated or steroid pulsed mice with crescentic glomerulonephritis (cGN), respectively. Additionally, steroid effects were studied in mice lacking the glucocorticoid receptor specifically in T cells and in CD4 T cell transfer experiments in nephritic recombination activating gene 1 (RAG1) knockout mice.

Results: Combined high-dimensional single-cell analysis and IHC showed that intravenous steroid pulses rapidly reduced renal T-cell infiltrate in human ANCA-GN patients but did not significantly regulate the immune response of a specific T-cell subset (e.g., Th1, Th2, Th17, Treg). Almost identical effects were observed in a murine cGN model (nephrotoxic nephritis), including reduced glomerular crescent formation, after steroid pulse treatment. Functional studies using CD4+ T-cell-specific glucocorticoid receptor-deficient mice showed that T-cell reduction was not caused by T-cell-intrinsic factors. Mechanistically, we demonstrated in CD4+ T-cell transfer experiments that steroid-induced attenuation of intrarenal effector T cells in cGN was a consequence of reduced expression of the T-cell-attracting chemokines CCL5, CCL20, CXCL9, and CXCL10 by resident kidney cells, which was further confirmed by in vitro and ex vivo trafficking experiments.

Conclusions: Our findings demonstrate that pulse steroid therapy rapidly reduce renal T-cell infiltrate in human and murine cGN by inhibiting the production of T-cell-attracting chemokines by resident renal cells. In summary, we have identified a previously unrecognized therapeutic mechanism of steroids in immune-mediated glomerular disease.

Immune Checkpoint Molecule BTLA Attenuates Inflammation and Glomerular Damage in Experimental Glomerulonephritis  
Paul Diefenhardt, 1,2 Marie Brand, 1,3 Thomas Schöming, 1,3 Bastian Trinch, 1,3 Bernhard Schermer, 1,3 Paul T. Brinkkoeiter, 1,3 Paul Benzing, 1,3 Sebastian Braehler, 1,3  
1 Universitätsklinik Köln, Köln, Germany; 2 University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; 3 Excellence Cluster CECAD in der Universität zu Köln, Köln, Germany.

**Background:** An imbalance of pro- and anti-inflammatory signals in the kidney can result in irreversible damage and destruction of glomeruli leading to end stage kidney disease. Current treatment of the glomerulonephritis (GN) consists of unspecific, highly toxic immunosuppressive therapies with detrimental adverse effects. More specific therapies are therefore warranted. T Lymphocytes are not only key players in the nephritogenic nephritis (NTN) model in rodents but also during GN in humans, representing potential targets for tailored therapies. As an immune checkpoint molecule, B and T lymphocyte attenuator (BTLA) is crucial in the regulation of T Lymphocyte activation and has been shown to mediate anti-inflammatory effects in other T cell-mediated disease models.

**Methods:** NTN was induced in BTLA knock out mice (BTLA-KO) and littermate controls. Regular urine analysis (ACR) was performed throughout the course of the study. 14 days after NTN induction, blood, kidneys and spleens were harvested for further analysis. Histological assessment of the kidneys was used to evaluate the severity of NTN. Local immune response in the kidney and systemic immunity was analyzed by flow cytometry and qPCR.

**Results:** Wild type mice (WT) showed an increased BTLA expression on renal T cells and dendritic cells throughout the course of NTN. No immune-phenotype was observed in unstimulated BTLA-KO and WT mice. However, BTLA-KO resulted in aggravation of NTN compared to WT. Quantification and characterization of renal immune cells revealed an increase in proinflammatory cells. Interestingly, especially T Lymphocytes were significantly expanded in BTLA-KO mice.

**Conclusions:** BTLA attenuates inflammation in experimental GN through suppression of proinflammatory T Lymphocytes. These results build the foundation of a checkpoint inhibitor based therapy of inflammatory glomerular disease.

Collapsing FSGS or Crescentic GN or Both: A Diagnostic Challenge  
Irshadjahan, 1,2, Marie Schröder, 1,2, Thomas Schröder, 1,2, Harsharan Singh, 1,2, Volker Nickeleit.  
1 Division of Nephropathology, University of North Carolina, Chapel Hill, NC.

**Introduction:** The finding of an ANCA associated necrotizing & crescentic GN with collapsing FSGS is a rarity with only few reported cases in literature.

**Case Description:** A 53-year-old AA female was admitted to hospital with difficulty in swallowing, poor oral intake, hemoptysis & AKI superimposed on CKD-III with hx of HTN & use of NSAIDs. Urine analysis showed hematuria, proteinuria & UPC ratio of 20. Blood analysis showed S.Cr 8.7mg/dl, BUN 60mg/dl, Albumin 2.4gm/dl, positive ANA titer, positive MPO ANCA & ANA titers. By light microscopy 36 glomeruli were present, 20% showed A-Tuft collapse(arrow), podocytes hyperplasia/hypertrophy. B-Fibrinoid necrosis (arrow) & crescent formation(Trichrome stain x20)

CD11b Activation Suppresses Pro-Inflammatory IL-1β in Myeloid Cells and Protects Against Lupus Nephritis  
Veronica Villanueva, Xiaobo Li, Viviana Jimenez, Vincent Gupta.  
Rush University Graduate College, Chicago, IL.

**Background:** Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Mutations in the ITGAM gene, encoding CD11b, are associated with LN and reduce integrin function. Interleukin-1β (IL-1β) is produced by myeloid cells as a propeptide and cleaved by caspase-1 where it mediates the inflammatory response. IL-1β is downstream of toll-like receptor and IL-1β receptor signaling. We previously showed that activation of CD11b suppresses TLR-dependent pro-inflammatory signaling. Here, we investigate if this mechanism includes control of IL-1β and/or if CD11b influences IL-1β by another mechanism, which may provide novel therapeutic options for proinflammatory diseases.

**Methods:** To investigate TLR-dependent signaling affected by CD11b activation, we utilized in vitro assays using primary macrophages. Cells were treated with TLR agonists, IL-1β protein, or IL-1β antibody and changes in protein expression was assessed by western blot and proinflammatory cytokine levels were assessed by ELISA. For complementary in vivo studies, we utilized our newly generated mouse model, where we incorporated a constitutively active CD11b point mutation (I332G) globally in mice to generate a model for CD11b activation – CD11b knock-in model. C57BL-6 wild type mice, CD11b knock-out, and CD11b knock-in mice were used to determine the effect of CD11b activation on circulating IL-1β levels.

**Results:** TLR-stimulation increased IL-1β levels in vitro and in vivo. Importantly, CD11b activation resulted in significantly reduced IL-1β levels in both systems, suggesting a novel mechanism for controlling inflammation in glomerular disease. Additional mechanistic studies are on-going to define the exact molecular mechanism of action. Murine models of SLE and LN display significant decreases in IL-1β when CD11b is activated, both genetically or pharmacologically, showing potential protection against LN.

**Conclusions:** Using these models, we have identified a possible link between CD11b activation and IL-1β secretion in myeloid cells. These studies will provide understanding of the influence CD11b has on signaling pathways and inflammation associated with inflammatory diseases such as LN.

**Funding:** NIDDK Support

Deletion of Smad3 Worsens Lupus Nephritis by Promoting B Cell Activation  
Wenqian Xu, 1,2 Jinhong Li, 1 Xiao Ru Huang, 1,2 Cheuk-Chun Szeto, 1,2 Tak Mao D. Chan, 1,2 Xueqin Y, 1 Zhihua Zheng, 1 Hui Y. Lan, 1,2 1 Department of Nephrology, Center of Urology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2 Department of Medicine & Therapeutics, Li Ka Shing Institute of Health Sciences, and Li Ka Shing Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China; 3 Department of Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; 4 Guangdong-Hong Kong Joint Laboratory for Immunity and Genetics of Chronic Kidney Disease, Guangdong Academy of Medical Science, Guangdong Provincial People’s Hospital, Guangzhou, China; 5 The Chinese University of Hong Kong-Guangdong Academy of Sciences/Guangdong Provincial People’s Hospital Joint Research Laboratory on Immunological and Genetic Kidney Diseases, The Chinese University of Hong Kong, Hong Kong, China.

**Background:** TGF-β signaling has been shown to play a critical role in many autoimmune diseases. However, its regulatory role in lupus nephritis remains unknown, which was investigated in the present study in a mouse model of lupus nephritis (LN) in which Smad3 gene was deficient.
Intrarenal B Cells in Systemic Lupus Erythematosus Upregulate Na+/K+-ATPase to Facilitate Survival in a High-Sodium Environment

Irene Chernova, Joseph Craft. Yale University, New Haven, CT.

Background: The kidney is a unique microenvironment characterized by high sodium concentrations, yet susceptible to infiltration by lymphocytes in autoimmune diseases, such as systemic lupus erythematosus. The effects of sodium-immune cell interactions on tissue injury in autoimmune disease and the mechanisms used by infiltrating lymphocytes to survive the high sodium environment of the kidney are not known.

Methods: We investigated the mechanisms utilized by B cells from lupus-prone mice and B cells in vivo and in vitro.

Results: We successfully deleted the Smad3 gene from B6. NZMSle1-3 mice with unexpected findings that Smad3KO-LN mice developed much more severe LN with higher mortality rate (50%), higher circulating autoAb, lower creatinine clearance rate (Ccr, 20%), more severe glomerular necrosis (50%), massive renal immune complex deposition and complement activation, and progressive renal inflammation and functional injury. Mechanistically, we observed that lupus mice lacking Smad3 largely promoted Th1, Th2 and Th17 populations which resulted in autoAb immune responses in the kidneys. Unexpectedly, deletion of Smad3 largely increased macrophage inducible lectin-receptor (Mincle) expression by B220⁺ B cells (80%). Further studies showed that B cells lacking Smad3 were largely promoted Cytosine-phosphorothioate-guanine oligodeoxynucleotides ( CpG ODN)-induced but failed to respond to the inhibitory effect of TGF-β on Mincle-Syk-NFκB signaling, and IgG production by splenic B cells.

Conclusions: TGF-β/Smad3 signaling plays a protective role in LN by maintaining the balance of T cell immunity and B cell function. Loss of Smad3 worsens LN by shifting Treg to Th1, Th2 and Th17 and promoting B cell activation and autoantibody production via the Mincle-Syk-NFκB-dependent mechanism. Thus, outcomes from this study will be of great significance both scientifically and clinically.

Anti-SOD2 Antibodies in Lupus Nephritis as Second Wave Antibodies

Andrea Angeletti, Maurizio Bruschi, Francesca Lugani, Gianluca Caridi, Enrico E. Verrina, Gian Marco Ghiggeri. ZEUS Study Istituto Giannina Gaslini, Genova, Italy.

Background: Superoxide dismutase-2 (SOD2) is an enzyme with antioxidant action. Anti-SOD2 antibodies (anti-SOD2 IgG2) were recently described in the serum of subjects with Membranous Nephropathy, as antigens of a possible second wave injury. The presence of anti-SOD2 IgG2 correlates with worse outcomes in terms of response to treatment [1]. The presence and role of anti-SOD2 IgG2 in Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN), a secondary autoimmune glomerulonephritides, are to be clarified.

Methods: We measured serum levels of anti-SOD2 IgG2 (Homemade designed ELISA), every six months, in 1.052 patients (459 LN and 573 SLE) enrolled at different times from the diagnosis (i.e., 0-1 month, 2-12 m, 13-24 m, 25-48 m, 49-96 m, and >96 m). We also evaluated the main markers of the SLE activity, such as serum complement C3 and C4, ANA, ENA, anti-dsDNA and proteinuria. Of note, 91 LN and 130 SLE had a relevant follow-up of 36 months.

Results: As main characteristics, we report median age of 40 (IQR 28-54) years, the predominance of females (88%), disease activity (SLEDAI) of 4 (IQR 2-8). At the cross-sectional analysis, serum levels of anti-SOD2 IgG2 at T0 are significantly higher in LN than in SLE (Fig 1a). Considering LN, the serum levels of anti-SOD2 IgG2 at T0 were significantly higher than the other time points (Fig 1a). No correlation with the histological class of LN is reported. In LN, the reduction of anti-SOD2 IgG2 was in accordance with proteinuria. Anti-dsDNAs did not result as a valuable marker of disease activity (Fig 1b).

Conclusions: Circulating anti-SOD2 IgG2 are elevated in active LN. Serum levels of Anti-SOD2 IgG2, also considering the concomitant negative serum levels of anti-dsDNAs in all phases of LN, support the hypothesis of direct involvement of anti-SOD2 antibodies in LN as second wave antibodies that actively contribute to the manifestations of autoimmune glomerulonephritides.

Altered Propanoate Metabolism and gut Lachnospiraceae Composition in Lupus Nephritis Patients

Ji Fun Kim,1,2 Ji In Park,2 Hyo Eun Kim,1 Jungwook Lee,3 Hyunjeong Cho,3 Dong Ki Kim,5,6,7 Von Su Kim,1,3,8 Hajong Lee,9,10 Korea University Guro Hospital, Seoul, Republic of Korea; 2Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; 3Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; 4Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; 5Seoul National University, Gwanak-gu, Seoul, Republic of Korea; 6Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea.

Background: There are growing evidence for the role of gut microbiota in the pathogenesis systemic lupus erythematosus (SLE), especially lupus nephritis (LN). Recently, high abundance of Ruminococcus gravis belonging to the family Lachnospiraceae has been noticed in featural sample of LN patients. However, the functional role of gut microbiota and its metabolic pathway which affect host metabolism in LN are less understood.

Methods: Shotgun sequencing of fecal samples from biopsy-proven LN patients and matched controls was performed. We used Kraken2 for taxonomic analysis and humann2 with customized KEGG database for gene family analysis. Comparison of taxonomic abundance and gene families were assessed by Maaslin2.

Results: Control and LN group were included 24 and 20 patients, respectively. Both groups had similar age, sex, and eGFR. In the comparison of relative abundance of major species, Roseburia intestinalis, Butyricimonas fagi, and Eubacterium elgins were significantly decreased while Ruminococcus gravis was significantly elevated in LN group, respectively. Interestingly, 3 of these 4 species were included in the same Lachnospiraceae family showing a significantly different composition between the two groups (PERMANOVA p=0.042). Furthermore, we found 161 differentially expressed gene families including 65 metabolism-associated and 29 carbohydrate metabolism-associated genes. Considering Lachnospiraceae is known to play a role in propanoate pathway, we further assessed the propanoate pathway (ko00046). As a result, LN patients revealed more prone to propanediol pathway rather than in succinate pathway in the propionate pathway. This tendency was more pronounced in the contribution to the pufd: gene by R. gravis having well-known pathogenic linkage with SLE.

Conclusions: LN patients showed altered propanoate metabolism associated with the differential species composition of Lachnospiraceae including R. gravis. Functional role of this alteration on the pathogenesis of LN should be clarified by further investigations.

Gut Microbiome Changes in NZBWF1/J Murine Lupus Nephritis

Tak Mao D. Chan, Jing Yu, Chi pang Tai, Susan Yung. Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong.

Background: Lupus nephritis is an important cause of acute kidney injury and chronic kidney disease. There is preliminary data that gut dysbiosis may be involved in the pathogenesis of lupus nephritis. We investigated gut microbiota burden in murine lupus nephritis.

Methods: Eight-week old NZBWF1/J mice were randomized to receive drinking water alone or containing ampicillin (1.0 mg/ml) and neomycin (0.5 mg/ml) for 18 weeks. Renal and colonic histopathology was examined, and intestinal mucosal permeability investigated with LPS-FITC. Quantitative changes in gut microbiota were assessed by 16S rRNA sequencing.

Results: Serum LPS and urea levels, and proteinuria were significantly lower in antibiotic-treated mice (P<0.05, for all). Histopathologic manifestation of active nephritis and podocyte foot process effacement were associated with increased LPS-binding protein, CD14 and TLR-4 expression in proximal renal tubular epithelial cells, and increased interstitial α-smooth muscle actin, fibronectin and collagen expression. Mice with active nephritis showed increased gut permeability to LPS-FITC given orally, and decreased ZO-1 expression in the colonic epithelium. 16S rRNA sequencing data showed that active nephritis was associated with a progressive decrease in Gram-positive bacteria phyla Actinobacteria and Firmicutes and increased Gram-negative bacteria phyla Bacteroides and Proteobacteria. Antibiotic treatment significantly decreased Bacteroides, which was associated with lower levels of serum LPS and urea, proteinuria, and ameliorated histopathologic features in the colon and kidney.

Conclusions: Murine lupus nephritis is associated with gut dysbiosis, which may contribute to the pathogenesis of nephritis progression.

Funding: Government Support - Non-U.S.
Results: 43 patients (21%) exhibited TLTs in the kidneys. There were no significant differences in ISN/RPS classification between LN patients with TLTs and those without TLTs. TLT development was not associated with disease activity indicators, such as SLEDAI, dsDNA titer, proteinuria, or complement factors, but it was associated with reduced eGFR (60.2 versus 83.8 ml/min/1.73m², P = 0.001) and higher histological kidneyn scores (P = 0.0038). A higher prevalence of TLTs was observed with age over 40 years old and non-treatment history of immunosuppressive drugs. Additionally, TLT development was associated with incidence of hypertension.

Conclusions: Association between TLT development and reduced eGFR and higher histological scores suggest the potential of TLTs as an additional histological marker for evaluation of LN disease activity. Dissociation between TLT development and SLE disease activity indexes such as SLEDAI and dsDNA antibody titers also suggest that TLTs development are, at least partly, independent of the severity of glomerulonephritis.

New Drugs and Evolving Treatment Patterns in Lupus Nephritis: How Nephrologists and Rheumatologists Are Responding Differently to New Treatment Options

Background: Each uptake and experience with recently approved lupus nephritis (LN) drugs belimumab and voclosporin reveal different perceptions, comfort levels, and prescribing intentions between nephrologists and rheumatologists.

Methods: Data were collected over four waves of research between February and May 2021 via online surveys with 50 US nephrologists and 50 US rheumatologists who are currently treating LN. Each wave was followed-up with a subset of qualitative interviews.

Results: In a notable trend, rheumatologists deem more of their LN patients as candidates for belimumab, while nephrologists increasingly see their patients as better suited for voclosporin. Rheumatologists tend to rate belimumab higher overall than voclosporin, particularly on safety and tolerability, thanks to long term history with the product in SLE patients. Both physician types generally use belimumab as a later-line therapy in mild-to-moderate LN, often to reduce steroid burden. It is generally used with at least one other advanced agent like an immunosuppressant, steroid, or MMF. Recent initiation patients are most often in CKD Stage 3, with proteinuria and fatigue. Nephrologists favor voclosporin, likely due to their familiarity with the CNI drug class. Both physician-types are using voclosporin even later-line than belimumab for moderate-to-severe LN patients given the drug’s perceived quicker onset of action, efficacy, and steroid-sparing effect. Voclosporin is nearly always used concomitantly with advanced drugs like immunosuppressants, steroids, or MMF’s. Rheumatologists appear to be initiating voclosporin most often in CKD Stage 2, while nephrologists are initiating most often in CKD Stage 3. Rheumatologists are the leading prescribers of belimumab, and currently have a slight edge with voclosporin patient initiations as well. Nephrologists are tending to wait longer to initiate, due to cost- and risk-benefit uncertainty compared to other options like tacrolimus. Rheumatologists currently view both drugs as a greater treatment advance than nephrologists; nephrologists believe voclosporin is more of an advance in LN treatment than belimumab.

Conclusions: Physician understanding and comfort level with belimumab and voclosporin MOAs are driving early use and perceptions of the two new LN drugs.

PO1436

Treatment of Crescentic Lupus Nephritis with Voclosporin

Irshad Hussein,1 Syed H. Buchhari,1 Paul F. Shanley,2 Ramya Bhargava.1 1State University of New York Upstate Medical University Division of Nephrology, Syracuse, NY; 2State University of New York Upstate Medical University Department of Pathology, Syracuse, NY.

Introduction: Crescent glomerulonephritis (CGN) is a rare complication of Lupus nephritis (LN) and carries a worse prognosis. There is paucity of data regarding effective treatment options for CGN. We present a case of crescentic ANCA negative LN treated with voclosporin (VSN).

Case Description: 19-year-old African American female with 2-year history of Class II LN, treated with hydroxychloroquine 200 mg/day, prednisone 10 mg/day, mycophenolate mofetil 1 gm twice daily and Belimumab, presented with a 2-week history of anaemia and generalized bullous skin rash. On exam BP 126/78 mm Hg, HR 96/min, afebrile, RR 18/min, O2 saturation 97% on room air. Investigations revealed hemoglobin 9.2 g/dL, serum creatinine (SCr) 1.2 mg/dl (baseline 0.6), albumin 1.9 g/dL, platelet 310,000, WBC 10.0, neutrophils 71%, lymphocytes 13%, eosinophils 3%, mononuclear cells 4%. CT and MRI of chest, abdomen and pelvis was normal. Urinalysis revealed microscopic hematuria (3+), proteinuria 3+, protein casts, RBC casts 1+, WBC casts 1+. Nephrology consultation was obtained and she was started on high dose IV methylprednisolone 1 gm over 3 days, however she became anuric, CRF peaked at 5.0 mg/dl, and was commenced on hemodialysis and 7 sessions of plasma exchange. She was started on VSN 15.8 mg BID and after 10 days of therapy, CRF improved and dialysis was discontinued. On discharge, SCR was 2.0 mg/dl and plasma exchange was discontinued. She was started on VSN.

Discussion: There has not been any published case report of Crescentic LN being treated successfully with VSN. Given poor prognosis of CGN, early diagnosis and treatment is imperative. Our patient had rapid recovery of renal function and resolution of proteinuria following treatment with VSN. VSN may be effective in combination with plasma exchange in ANCA negative Crescentic LN. Larger studies with longer follow-up are needed to assess the efficacy of VSN in CGN.

Christopher F. Bell,1 Benjamin Chaekst,2 Bernie Rubin,1 Shirley Huang.1 1US Value, Evidence and Outcomes, GlaxoSmithKline, Research Triangle Park, NC; 2Optum, Eden Prairie, MN; 3GlaxoSmithKline, Philadelphia, PA.

Background: Lupus nephritis (LN) occurs in ~40% of adults with SLE. Despite the high burden of LN, current care management and utilization data are limited. This longitudinal study evaluated US healthcare resource utilization (HRU) and costs over 5 years in patients (pts) with SLE newly diagnosed with LN.

Methods: This retrospective cohort study (GSK Study 214102) used data from the Optum Research Database. Index date was the first claim with a renal diagnosis code indicating LN during the identification period (Aug 1, 2011–Jul 31, 2018). Inclusion criteria: age ≥18 years; ≥2 renal diagnosis codes during the identification period; ≥1 inpatient or ≥2 outpatient SLE diagnosis codes in the 12 months pre index; and continuous enrollment of ≥12 months pre and post index. HRU and costs for the cohort with 5 years of continuous enrollment post index are reported.

Results: Overall, 2159 pts met the study criteria (mean [standard deviation, SD] age, 45.0 [14.9] years; 86.7% female) and 335 had ≥5 years of continuous enrollment post index. HRU and costs were highest in the first year post LN diagnosis (Figure). Mean healthcare costs were $44,205 in Year 1 and ~$30,000/year in Years 2 through 5. Approximately 50% of patients incurred an inpatient stay in Year 1, with ~25% of patients hospitalized in each subsequent year.

Conclusions: Patients with newly diagnosed LN incur substantial HRU and costs, which were highest in the year of diagnosis. These data highlight the need for interventions to prevent renal worsening in SLE.

Association of TNIP1 Variants with Disease Severity and Progression and IP-10 Chemokine Levels in Lupus Nephritis Patients

David W. Powell,1 Makayla Brady,1 Michelle T. Baratti,1 Dawn J. Caster.1 University of Louisville School of Medicine, Division of Nephrology, Louisville, KY; 1Department of Biochemistry and Molecular Genetics, University of Louisville., Louisville, KY.

Background: African American SLE patients experience higher rates of LN, increased progression to ESKD, and higher mortality when compared with white patients, but etiology for this disparity is unclear. We reported that a TNIP1 polymorphism, rs4958881, is a risk variant for lupus nephritis (LN) in African American patients. TNIP1 encodes the protein ABIN1, which negatively regulates the transcription factor NF-kappaB. We generated mice with inactivation of ABIN1 (AbBin1−/−) and C. P:AS and Silver strains show no glomerular basement membrane remodeling. D. Trichrome stain with moderate interstitial fibrosis and tubular atrophy (35%).

Conclusions: Association between TLT development and reduced eGFR and higher histological scores suggest the potential of TLTs as an additional histological marker for evaluation of LN disease activity. Dissociation between TLT development and SLE disease activity indexes such as SLEDAI and dsDNA antibody titers also suggest that TLTs development are, at least partly, independent of the severity of glomerulonephritis.

Increased tissue levels of IP-10 have been implicated in pathogenesis and as a diagnostic marker. LN, but the mechanism is unknown. The current project tested a hypothesis that LN severity and enhanced IP-10 levels are associated with the TNPI1 rs4958881 risk allele.

Methods: All endpoints were compared for LN patients w/o TNPI1 variant rs4958881 genotyping. Classifications were compared for 125 African American and 133 White American LN patients. Urine and serum IP-10 levels were measured in 33 LN patients using ELISA. Progression of disease was assessed and compared from follow up (mean = 3 yrs) for 33 LN patients. Urine, plasma, and kidney levels of IP-10 were compared for LN controls. Flow cytometry analysis of T helper cell phenotypes was assessed for LN patients. Conclusions: The current work compared the tissue distribution of IP-10 in LN and that of NF-E2 or neutralization of IP-10 is a promising personalized therapeutic direction for these patients.

SeqStain Is a Novel, Multiplex Imaging Method for Spatially Profiling of Human Kidney Tissues

Ishwara Venkatesh, Anugraha R. Rajagopalan, Disha Varma, Vineet Gupta. Team SeqStain Rush University Medical Center, Chicago, IL.

Background: Chronic Kidney Disease (CKD) is the ninth leading cause of death in the United States, an emerging global health challenge affecting 10-15% of the population. Lack of reliable biomarkers precludes early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue changes. For instance in Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli, reduced podocyte number, inflammation in the renal tissue, influx of immune cells that ultimately lead to tissue damage. Understanding these tissue-centered events on a deeper level is important for future therapies.

Methods: To understand molecular and cellular composition of tissues and their relative organization in three-dimensional space, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses fluorescently labeled DNA oligonucleotides (termed “SeqStain antibodies”) to stain white while endocytosis are used to achieve gentle de-staining after each round. This methodology can fluorescently label primary antibodies, secondary antibodies and Fabs of secondary antibodies to efficiently analyze multiple tissue sections. With SeqStain, mouse kidney was stained with antibodies that would probe different histological regions relevant to the kidney

Results: Normal kidney was stained with SeqStain antibodies and de-stained using endocytosis. Using SeqStain methodology, we built ~20-plex panel on kidney tissue and provided a gentle and rapid technique for multiplex imaging. Stripping de-staining using the SeqStain method was rapid and removed ~99% of the signal in <1min without affecting tissue integrity. The method was implemented using a simple perfusion setup with readily available components, allowing staining of tens of antigens on a single tissue section. Alignment of images and their analyses provided spatiotemporal data on multiple cell types in tissue

Conclusions: The SeqStain method offers a gentle, easy-to-use, and effective multiplex imaging technique that provides a unique platform for obtaining spatiotemporal insights. SeqStain method can profile the CKD kidney tissues and comprehend the tissue-centered events that could play a role in disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments in comparison to healthy human kidney to generate spatial maps

High Expression of Mince in Intermediate Monocytes of Patients with Autoimmune Diseases

Shuping Li1,1 Lokyu Cheng,1 Tiaojiao Cui,1 Lanyue Zhang,1 Xixun Tian,1 Zhihuan J. Zhao,1 Yun Chen,2 Zhihua Zheng,1 The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China;2 Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Macrophage- inducible C-type lectin (Mince) is a transmembrane C-type lectin receptor that is predominantly expressed on macrophages’ surface and results in broad range of self and foreign antigens as part of innate immune sensing, thus playing a pivotal role in tailoring immune response. Mince’s function associates with its expression levels on immune cells’ surfaces. However, the differential expression of Mince in various types of immune cells between patients with autoimmune disease (AD) and healthy controls (NCs) is yet to be examined, and its clinical relevance remains unclear. Therefore, this study aimed to investigate Mince expression and distribution in different types of immune cells in patients with AD and NCs, and to explore the clinical relevance and potential mechanisms of Mince expression levels in immune cells of peripheral blood in patients with systemic lupus erythematosus (SLE).

Methods: Mince expression levels in leukocyte subgroups and monocyte subsets of peripheral blood from all participants were analyzed using flow cytometry and real time PCR, and the clinical characteristics of patients with SLE were collected for correlation analysis. Hematological parameters were also used to distinguish intermediate monocytes from naïve T cells, and the differentiations of naïve T cells were detected by flow cytometry.

Results: Mince was expressed predominantly in myeloid cells, both in peripheral blood and cell lines. Moreover, monocytes expressed higher levels of Mincle than macrophages. Mincle expression levels in peripheral blood in patients with systemic lupus erythematosus (SLE)
Cathy how "poised Trm17 cells" use the integrated stress response - stress granules pathway to rapidly produce IL-17A upon re-stimulation. Our study identifies a novel mechanism of is stored in stress granules and not translated into protein. In contrast, these Trm cells willi

Activation of the Integrated Stress Response Regulates the Production of PO1444

Jonathan

Background: Macrophages are part of the phagocyte mononuclear system constantly replaced by the circulating blood monocytes. In the steady state, the myeloid cell compartment is highly heterogeneous, containing various subtypes. These cells include macrophages and dendritic cells, and each play important roles in tissue maintenance, including development, homeostasis, immunity and repair following tissue injury. The composition of kidney macrophages is not well known.

Methods: A multi-parameter flow cytometry approach was used to identify the resident and recruited macrophage population in the kidneys of male and female C57BL/6J mice aged -7, -21 and -84 days in the steady state. Resident and recruited macrophage populations were characterized based on 33 cell surface and intracellular markers.

Results: Both resident and recruited macrophages were identified in the kidneys of male and female mice aged -7, -21 and -84 days in the steady state. We observed two distinct resident macrophage populations in young mice (7 and 21 days old) by 84-days, male and female mice displayed 4 and 5 resident populations, respectively. The resident macrophage population in 7-day old mice displayed low surface expression of MHC II and began to shift to an increased expression of MHC class II at 21 days, and high MHC class II expression at 84 days. We detected three recruited macrophage populations in 7- and 21-day-old mice, and two populations by 84-days of age. The recruited macrophage population displayed low MHC class II at all ages in both sexes. Analysis of the global macrophage populations at 84-days of age revealed female mice had twice as many recruited compared to resident macrophages, whereas male mice had an equal distribution.

Conclusions: The data indicate a dynamic change in the kidney macrophage population with age and resident macrophage phenotype. The composition of macrophage populations also differs by sex and age. These data suggest each population plays a role in kidney homeostasis. Future studies will be directed towards elucidating the functions of each of the identified macrophage populations.

Activation of the Integrated Stress Response Regulates the Production of IL-17 in Tissue Resident Memory T Cells

Background: CD4-positive T cells produce cytokines and play a central role in immunity. Tissue-resident memory T (Trm) cells remain in organs after infection and contribute to efficient host defense by immediate production of cytokines, such as IL-17A. More recently, it was demonstrated that Trm cells also promote autimmunity. Therefore, the regulation of cytokine production by Trm cells is of great importance to achieve efficient host defense without excessive inflammation. However, the control mechanisms of cytokine production by Trm cells are not well understood.

Methods: Human and mouse T cells including renal Trm cells were analyzed by single cell RNA sequencing (scRNAseq), polysome profiling combined with bulk RNA sequencing, RT-PCR, flow-cytometry, immunocytochemistry, and mRNA FISH. Mouse models for Staphylococcus aureus infection and crescentic glomerulonephritis were used to induce and study Trm cells in vivo.

Results: Combined scRNAseq, polysome profiling and tissue signature analysis of human and mouse tissue samples revealed that resting CD4+ Trm cells in the kidney express IL17A mRNA but do not produce or secrete the cytokine protein without re-stimulation. Mechanistically, we demonstrate that the phosphorylation of eIF2α, a key feature of the integrated stress response (ISR) activation, resulted in recruitment of IFN17A mRNA into stress granules, which are organelles crucial for regulating mRNA translation during ISR, thereby inhibiting mRNA translation in resting Trm cells. Finally, we show that re-stimulation of human renal Trm cells through T cell receptor resulted in eIF2α dephosphorylation, leading to efficient translation of IFN17A mRNA and subsequent IL-17A secretion.

Conclusions: Tissue-resident memory CD4+ T cells in the kidney express high levels of IL-17A cytokine mRNA. Under homeostatic conditions the cytokine mRNA is stored in stress granules. In contrast, these Trm cells rapidly produce IL-17A upon re-stimulation. Our study identifies a novel mechanism of how “poised Trm17 cells” use the integrated stress response - stress granules pathway to regulate IL-17A cytokine mRNA translation. Disregulation of this pathway might have a pathogenic role in infection-related and renal inflammatory diseases.

Differential Cell Cycle and Kinase Activation in IgA1-Producing Cells from IgAN Patients and Healthy Controls Mediated by Cytokine Stimulation Colin Reilly, Dana Rizk, Jan Novak. The University of Alabama at Birmingham, Birmingham, AL.

Background: Some cytokines increase production of galactose-deficient IgA1 (Gd-IgA1) in immortalized IgA1-producing cells derived from peripheral blood of patients with IgAN. Previous work has indicated dysregulated cytokine induced signaling may be responsible, but minimal work investigating the overlapping pathways has been performed. Using single-cell transcriptomics, we analyzed pathway responses in immortalized IgA1-secreting cells derived from IgAN patients and healthy controls (HC) before and after response to a mixture of cytokines.

Methods: A mixture of cytokines mimicking those produced by T-follicular helper (Th) cells (IL-4, IL-6, IL-21, CD40L; 50 ng/mL) was used to stimulate immortalized IgA1-producing cells for 30 min before single-cell transcriptomic analysis. Gd-IgA1 level was determined by lectin ELISA. Standard data processing using Seurat was performed along with Alteryx for IgA1 separation. Differential markers for genes in unstimulated and stimulated conditions were analyzed for pathway differences using the GSEA MSig database, and kinase-transcription factors were imputed using X2K analysis.

Results: Th cytokines mediated overproduction of Gd-IgA1 in IgAN cells but not HC. IgA1-secreting subpopulations were separated, and UMAP was used for unsupervised dimension reduction analysis. Within these UMAP groups, pathway analysis found multiple significant associations, including down-regulation of cell cycle processes (FDR<0.05) in IgAN cells compared to an increase in HC (FDR<0.01) after cytokine stimulation. Analysis of imputed kinases changes in IgAN stimulated IgA1 cells compared to HC identified MAPK14 (p<1X10^-20 and AKT1 (p<1X10^-10), which have been associated with controlling O-glycosylation expression.

Conclusions: Significant changes in imputed kinases previously associated with O-glycosylation were found in IgA1-secreting cells in IgAN compared to HC in response to Th cytokine stimulation. When stimulated with cytokines, there were significant decreases in cell cycle and proliferation pathway responses in the IgA1-secreting cells from IgAN vs. HC samples. Further investigation is needed to determine the role of cell cycle and MAPK14 pathways in driving Gd-IgA1 overproduction mediated by cytokine stimulation.

Serum and Glomerular Complement Component as Biomarkers in the First South Asian Prospective Longitudinal Observational IgA Nephropathy Cohort (GRACE-IgAN)

Succena Alexander,1 Santosh Varughese,2 Athul Thomas,1 Jeethu E. Eapen,1 Elenjenichen E. John,1 Anna T. Valson,1 Vinoi G. David,1 John Feehaly,1 Jennifer Barratt,1 George John,1,2 Marc M. Seelen,1 Mohamed R. Daha,31 Christian Medical College Vellore, Vellore, India; 2Royal Brisbane and Women's Hospital, Herston, QLD, Australia; 3Universitair Medisch Centrum Groningen, Groningen, Netherlands; 4University of Leicester College of Life Sciences, Leicester; 5University of Leicester, Leicester, United Kingdom.

Background: The Glomerular Research And Clinical Experiments- IgA Nephropathy in Indians is a prospective longitudinal cohort. The study protocol has been published and is registered with WHO trial id: ISRCTN36834159. The role of serum and glomerular complement components in South Asian IgAN is unknown.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 192 (97%) patients completed 3 years. Serum complement C3 and C4 levels and glomerular C3d and C5b-9 by IHC were quantified at baseline in IgAN patients. Composite outcome (CO) was defined as a 50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m² or RRT/death.

Results: 195 patients (97%) completed 3 year longitudinal follow-up. Lower serum C3 was significantly associated with S1, T1/T2 according to the Oxford MEST grading and with global glomerulosclerosis (GS>33%) whereas higher C4 levels were associated with S1 scores. Increased mesangial C3d deposition correlated with increased mean arterial pressure, proteinuria, decreased serum albumin, decreased eGFR and with GS>33%. Inversely, increased mesangial C4d correlated with increased systemic blood pressure, decreased serum protein and decreased eGFR and with GS>33%. Mesangial deposition of C5b-9 did not have any clinical associations. Lower serum C3, higher serum C4 and increased mesangial C3d was significantly associated with CO over three years.

Conclusions: Serum and tissue complements could be potential biomarkers for severity and progression in the GRACE-IgAN cohort. This requires further validation.

Immune Complexes Containing Galactose-Deficient IgA1 Deposit on Mesangium Through Damage to Endothelial Cells

Yuko Makita, Hitoshi Suzuki, Daisuke Nakano, Toshiki Kano, Akira Nishiuchi, Yusuke Suzuki, Juntendo University Faculty of Medicine, Bunkyo-ku, Japan; Juntendo University Urayasu Hospital, Urayasu, Japan; Kagawa University, Kagawa, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). However, the pathogenic role of mesangial Gl-IgA1-containing immune complexes (ICs) remains unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is known to be involved in albuminuria. Here, we examined whether the deposition of Gl-IgA1-containing ICs in the mesangium may lead glomerular endothelial cell dysfunction in this disease.

Methods: Gl-IgA1 and recombinant anti-glycan IgG were used to form ICs to inject into nude mice. The renal microvascular endothelial glycocalyx removal of the injected nude mice was evaluated by real-time glycocalyx imaging. Human renal glomerular endothelial cells (HRGECs) were used to assess the potential capacity of Gl-IgA1-containing ICs to activate endothelial cells.

Results: After co-culture of Gl-IgA1-containing ICs with HRGECs, mRNA expression levels of endothelial adhesion molecules (ICAM-1, VCAM-1, and E-selectin) were significantly upregulated (P<0.01). Expression levels of proinflammatory mediators (TNFα and IL-6) that are able to induce the expression of the adhesion molecules on endothelial cells were also increased (P<0.01). Nude mice injected with Gl-IgA1-containing ICs showed podocyte and endothelial injuries with IgA, IgG, and C3 co-deposition along the glomerular capillaries and in the mesangium. Moreover, albuminuria and hematuria were also induced. Real-time glycocalyx imaging showed that renal microvascular glycocalyx was decreased immediately after the injection of Gl-IgA1-containing ICs and then mesangial IgA deposition was increased.

Conclusions: Present data suggest that Gl-IgA1-containing ICs may induce glomerular endothelial injuries resulting in mesangial deposits.

Immune Complexes in the Peripheral Blood of Patients with IgA Nephropathy Contain Polymeric Galactose-Deficient IgA1 Associated with IgG and Complement C3

Stacy D. Hall, Sarah Coffee, Nicolas Maillard, Zina Moldoveanu, Ellenore P. Crain, Audra A. Hargett, Dana Rizk, Bruce A. Julian, Matthew B. Renfrow, Jan Novak, The University of Alabama at Birmingham, Birmingham, AL; Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein immune complexes (IC) consisting of IgA1 with some hinge-region O-glycans deficient in galactose (Gd-IgA1) and IgG autoantibodies deposit in the kidneys and induce injury. Although the glomerular immunodeposits are enriched for Gd-IgA1, not much is known about the association of different molecular forms of Gd-IgA1 in circulation.

Methods: Total serum IgA1 was isolated from 7 Caucasian and 10 African American patients with IgAN by jacalin-affinity chromatography. Different molecular forms of IgA1 were then separated by size-exclusion chromatography (SEC). Gd-IgA1 was detected by lectin ELISA. IgA1-IC were isolated by SEC from sera of 4 IgAN patients. Biological activity of the isolated IC was assessed measuring the proliferation of cultured primary human mesangial cells (MC). IgA1, IgG, and complement C3 were analyzed by SDS-PAGE/immunoblotting.

Results: Total serum IgA1 included monomeric and polymeric forms and IgA1 bound in IC. Monomeric IgA1 presented ~88-92% of total IgA1, whereas polymeric IgA1 represented ~8-12%. IgA1 in IC was the least abundant form, representing ~0.4% of total IgA1. Relative representation of Gl-IgA1 was highest in IC, followed by polymeric forms, and lowest in monomeric forms. Gl-IgA1 in IC had minimally sialylated O-glycans, whereas polymeric and monomeric forms were substantially sialylated. Caucasian patients had higher content of Gd-IgA1 in polymeric and monomeric forms of IgA1 compared to those of African American patients (P<0.03 and P<0.05, respectively). Gl-IgA1 in sera of IgAN patients had molecular mass >700 kDa and stimulated proliferation of MC. These ICs consisted of polymeric IgA1, IgG, and complement C3.

Conclusions: Biologically active IC in the circulation of IgAN patients contain polymeric, minimally sialylated Gl-IgA1 associated with IgG and C3. These findings support the pathogenic role of Gd-IgA1-IgG IC in IgAN.

Histopathological Association of Lambda Light Chain Predominance in IgA Nephropathy
Prasanth Raviapati,1 Virginie Royal,2 LiHong Bu,1 Rebecca L. Freese,1 Michelle N. Rheault,3 Patrick H. Nachman.1 CureGN Investigators.1 University of Minnesota Twin Cities, Minneapolis, MN; 2Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: A relative predominance of lambda (λ) over kappa (κ) light chain deposition has long been recognized in IgA Nephropathy (IgAN), which is unique among other glomerular disease. The reason for this predominance is unknown but may be related to a purported predominance of λ, chain expression by gut associated lymphoid tissue B cells. There is limited information regarding the histopathological findings, if any, associated with predominant λ, light chain deposition. Utilizing the CureGN IgAN cohort, we evaluated if predominant λ chain deposition was associated with histologic markers of disease activity by examining MEST characteristics and other variables.

Methods: We divided the CureGN IgAN cohort into two groups based on the intensity of light chain deposition by immunofluorescence. The λ, dominant group (LD) was defined by a difference in intensity score of staining of λ, minus κ ≥ 1, while the κ codominant group (KL) by a difference of λ, minus κ < 1. Fisher’s exact test was used to compare the histopathological changes between the groups with respect to M, E, S, T, scores, total crescents, percent (%) of globally sclerotic glomeruli, % of glomeruli with fibroin necrosis, degree of interstitial inflammation, and the intensity of IgG, C1q, and C3 staining.

Results: Among 695 IgAN patients, the kidney biopsy digital images of 269 patients were reviewed by CureGN pathologists and 234 patients had reported λ and κ staining intensity. Of these, 96 (41%) patients were classified as LD (including 7 patients (3%) with λ, monotypic staining) and 138 (59%) classified as KL. The two groups did not differ significantly in age, sex, or race. Compared to the KL group, the LD group had a greater frequency of endocapillary hypercellularity (E1, 51.1% vs 36.3%, p=0.04) and IgG staining intensity ≥ 1.5 (37.3% vs 21.9%, p<0.01). There were no significant differences between groups with respect to any other histologic finding.

Conclusions: In IgAN, patients with predominantly λ, mesangial deposition are more likely to have increased endocapillary hypercellularity and IgG deposition, two findings previously linked with greater histologic disease activity and possibly worse prognosis. Further studies are needed to elucidate if the predominance of λ, chains represents a unique pathogenesis in a subset of patients, or if it imparts a more severe disease course.

Plasmacytoid Dendritic Cells from Murine IgA Nephropathy Have a Capacity to Enhance IgA Production ThroughTLR9/APRIL Signaling
YuShuke Fukun1, Hitohitsu Suzuki,2,3 Maiko Nakayama,1 Toshihiki Kano,1 Yuuki Makita,1 YuShuKe Suzuki1,1 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; 3Department of Nephrology, Juntendo University Nerima Hospital, Tokyo, Japan.

Background: Our recent study revealed that chronic Toll-like receptor 9 (TLR9) stimulation induce a proliferation-inducing ligand (APRIL) expression on naïve B cells and such APRIL-B cell may contribute to nephritogenic IgA production in IgA nephropathy (IgAN). On the other hand, APRIL from TLR9 activated dendritic cell (DC) is generally known to be involved in B cell maturation and IgA class switching. In this study, we evaluated IgA production through TLR9/APRIL signaling by DCs from murine IgAN.

Methods: Splenic B cells and DCs from group dLyg (gdy) mice, which are known as the spontaneous IgAN model, and Balb/c mice were isolated using magnetic cell sorting system. In addition, DCs were further divided into three DC subsets; i.e., plasmacytoid DCs (pDCs), CD8+ conventional DCs (cDCs), and CD11b+ cDCs by cell sorter. We co-cultured these isolated DCs and B cells with or without Cpg-ODN, a synthetic oligonucleotide TLR9 ligand, and IgA in the culture supernatants was measured by ELISA. We also measured the expressions of TLR9 and APRIL in each DC.

Results: The gdy-derived, but not Balb/c-derived, DCs could dramatically enhance IgA production by co-culture with B cells derived from both gdyL and Balb/c mice, and further enhance under Cpg-ODN stimulation. Moreover, pDCs from gdyL mice strongly induced the IgA production in B cells, compared with cDCs. The expressions of APRIL and TLR9 in the pDCs were higher than those in cDCs.

Conclusions: Present findings suggest that the gdyL DCs, especially pDCs, strongly enhance IgA synthesis from B cells through TLR9 and APRIL signaling.

PO1453

Targeted Release Formulation Budesonide (Nefecon) Selectively Reduces Circulating Levels of Chemokines Critical to Immune Cell Trafficking to Peyer Patches in IgA Nephropathy
Karen Molveneu,1 David H. Wimbury,2 Jasraj S. Bhachu,1 Masahiro Muto,2 Andrew M. Stone,1 Jonathan Barratt,1 University of Leicester, Leicestershire, United Kingdom; 2Juntendo Daigaku, Bunkyo-ku, Japan; 3Stone Biostatistics Ltd, Crewe, United Kingdom.

Background: Evidence supports a pivotal role of gut-derived chemokines in the direction of immune cell trafficking to the intestine in homeostatic and inflammatory conditions. It is well established that chemokines and their receptors control the influx
of T cells and B cells into Peyser’s patches (PP). T-cell homing to the PP depends on CCR7 and its ligands, CCL19 and CCL21, whereas B-cell homing to PP depends on the coordinately signaling of CCR7, CXCR4, CXCR5 and CCR6. The PP are believed to be a major source of the poorly O-galactosylated IgA1 in IgA nephropathy (IgAN). The therapeutic potential of targeting PP was demonstrated in the Phase 2 NEFIGNAN trial (NCT01738035), which assessed the safety and efficacy of a novel targeted-release investigational formulation of budesonide (TRF-budesonide [Nefecon]), designed to deliver budesonide to the PP-rich distal ileum in patients with IgAN. The trial comprised a 6-month run-in, 9-month treatment, and 3-month follow-up phase: 49 patients received Nefecon 8 mg/day, 51 patients received Nefecon 8 mg/day and 50 patients received placebo. Nefecon 16 mg/day, added to optimized renin-angiotensin system blockade, reduced proteinuria and stabilized eGFR in patients with IgAN. This study investigated whether Nefecon treatment altered serum levels of chemokines.

Methods: Serum levels of a panel of 20 chemokines were measured by Luminex. Changes in log-transformed levels of each biomarker with treatment were compared by one-way ANCOVA. Significance was p<0.05.

Results: A significant, dose-dependent modulation in serum levels of key chemokines directing T and B cell trafficking to the intestine (CXCL5), and more specifically to the PP (CCL11, CCL19, CCL20) was seen with Nefecon, which reversed on cessation of treatment. These observations paralleled significant reductions in the levels of soluble CD23, CD27 and CD30, and are consistent with our previous reports describing a dose-dependent increase in BAFF, soluble BCMA, TACI, IgA-IgG immune complexes, secretory IgA and galactose-deficient IgA levels with Nefecon.

Conclusions: Nefecon, which targets the PP-rich distal ileum, modulates key chemokine signals which direct immune cell trafficking to the intestine in IgAN.

PO1454 The Dual Endothelin Angiotensin Receptor Antagonist (DEARA) Sparansen Protects from Glomerular Hypercellularity and Associated Immune/Inflammatory Gene Network Activity in a Model of IgA Nephropathy Colin Reily,1 Zina Moldoveanu,1 Tiziano Pramparo,2 Stacy D. Hall,1 Lea Novak,1 Radko Komers,2 Celia P. Jenkinson,1 Jan Novak,1 1University of Alabama at Birmingham, Birmingham, AL; 2Traverese Therapeutics Inc, San Diego, CA

Background: IgA Nephropathy (IgAN) is an autoimmune glomerulonephritis wherein immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1; autoantigen) and Gd-IgA1-specific IgG autoantibodies (AuAb) deposit in the glomeruli (glomerular hypercellularity) and activate the alternative complement pathway (Amp) and C1q pathways, and result in Nephrotic Syndrome. In the current study we aimed to investigate the potential anti-inflammatory role for Sp in IgAN.

Methods: In a mouse model of IgAN induced by IC formation by human Gd-IgA1 and a recombinant AuAb, we used whole-kidney RNAseq profiling to assess how Sparsentan (Sp) affects the gene expression of pathways dysregulated by IC.

Results: IC were injected into ~7-week-old nude mice every other day for a total of 6 doses (n=5/group). Sp (8 mg/kg or 16 mg/kg) or vehicle (Veh) were given by gavage once daily, starting from the first day of IC injections. Negative-control mice received only V. Kidney histopathology and RNAseq was harvested on day 12. RNAseq raw data processed using DESeq2 identified differentially expressed genes. WGCNA was used for network-level profiling and to identify co-expressed genes associated with hypercellularity and Ki-67 positivity of gl. GSEA and X2 assessed changes at the pathway level and imputed correlated upstream cell-signaling networks. Pathway enrichment p-values were adjusted with FDR.

Results: Sp ameliorated IC-induced hypercellularity (P<0.01) and Ki-67-positive gl (P<0.05). WGCNA clustered genes into co-expressed modules associated with hypercellularity and Ki-67 positivity. GSEA-identified top 5 pathways were enriched for immune processes (FDR <1x10^-10). The top pathway, signaling pathways. The expression of the top module gene dysregulated by IC, was corrected by Sp administration. GSEA analysis revealed correlated expression of top hub genes, kinases MAPK14, GSK3B, CSN2K2A1 (z-score <1x10^-12) and transcription factors SPI1 and RUNX1 (z-score <0.05), highlighting the role of the ERK1/2-SP1 axis known to regulate cell proliferation.

Conclusions: In a mouse model of IgAN, kidney transcriptomics revealed gene networks, enriched in inflammatory/inflammatory functions, correlating with IC-induced hypercellularity. The top dysregulated genes were normalized by Sp and were linked to kinases and transcription factors with correlated functional activity. These data suggest a potential anti-inflammatory role for Sp in IgAN.

PO1455 Treatment with Targeted Release Formulation Budesonide (Nefecon) Modulates the Complement System in Patients with IgA Nephropathy Laura Pérez Alanís,1 Karen Molyneux,2 Bengt C. Feltstrom,3 Jonathan Barratt,2 Peter Garred,1 1Københavns Universitet Sundhedsvidenskabelige Fakultet, København, Denmark; 2University of Leicester, Leicester, United Kingdom; 3Akademiska sjukhuset, Uppsala, Sweden.

Background: The NEFIGNAN trial (NCT01738035) evaluated the effect of a novel targeted-release investigational formulation of budesonide (TRF-budesonide [Nefecon]) in the treatment of IgA nephropathy (IgAN). Participants in this Phase 2b trial were randomized to receive either placebo, Nefecon 8 mg or 16 mg/day, and samples were collected at baseline (0 months), at the end of the treatment (9 months) and at the end of the study (12 months). In this exploratory study we evaluated the effect of Nefecon treatment on the circulating levels and urinary excretion of a panel of complement components.

Methods: Plasma and urine levels of complement proteins (C4c, C3b and soluble C5b-9) and MASP-3 and PTX-3 were measured using in-house sandwich-ELISAs. Treatment differences between baseline, end of treatment and end of study were assessed by mixed-effects model analysis. The effect of the treatment correcting for the baseline was assessed by multiple linear regression. Significance: p<0.05. Urinary proteins were adjusted for creatinine excretion.

Results: Circulating levels of MASP-3 were decreased in a dose-dependent manner after treatment (p=0.0313 Nefecon 8 mg/day, p=0.0080 Nefecon 16 mg/day). MBL-creatinine was significantly reduced in the urine by both doses of Nefecon compared with placebo (p=0.0001 Nefecon 8 mg and 16 mg/day). CL-11/creatinine levels were also significantly reduced in a dose-dependent manner after Nefecon administration (p=0.0411 Nefecon 8 mg/day, p=0.0095 Nefecon 16 mg/day). Complement activation markers and ficolin-3 levels were detectable in urine but levels remained unaltered.

Conclusions: Treatment with Nefecon modulates components of both the alternative (MASP-3) and lectin (MBL- and CL-11) pathways of complement, two pathways known to be important in mediating kidney damage in IgAN. These initial observations warrant further investigation.

PO1456 Defining Cell Type Specificity of TNF Targets in Nephrotic Syndrome Phillip J. McConn,1 Scan Eddy,1 Fadhil Alakawa, Jennifer L. Harder, Jannal El Saghir,1 Wenyun Ju, Matthias Kretzler, Laura H. Mariani. Nephrotic Syndrome Study Network (NEPTUNE) University of Michigan Medicine, Ann Arbor, MI.

Background: Mechanistic, targeted therapies are needed for patients with FSGS and MCD, as diverse biological processes produce similar histologic injury patterns. Bulk transcriptionic data from kidney biopsy tissue can be used to find subgroups with shared molecular features, but cellular signaling networks need to be defined.

Methods: Consensus clustering was applied to bulk RNA sequencing data from the tubulointerstitial (TI) compartment of 220 participants from the NEPTUNE cohort, a study of children and adults with nephrotic syndrome enrolled at the time of kidney biopsy. Clusters were assessed for association with clinical outcome. Differential gene expression analysis was analyzed for enrichment of canonical pathways and functional grouping between patient clusters. Nuclei were extracted from renal biopsies, processed, and quality control analyzed to remove low quality nuclei. Nuclei identity were assigned by comparisons of enriched genes in a cluster to previously identified cell-type specific genes.

Results: One cluster of 59 patients was associated with a higher risk of loss of kidney function over time and observed TNF activation. To test the cellular source of the TNF pathway biomarker candidate, we performed mRNA-seq on 10 NEPTUNE biopsies, 5 with high TF activity scores and 5 with moderate to low TF activity scores in TI gene expression profiles. We pooled 45,175 nuclei into 15 clusters, which included all major kidney cell types. TNF expression was found in nuclei from immune clusters and in a proximal tubule and loop of Henle cluster. TNFRSF1A was universally expressed across cell clusters, while TNFRSF1B showed more restrictive expression. TNF targets CCL2 and TAZ were higher in all patients with activated TNF scores with maximal increase in epithelial cells (proximal and podocytes). Kidney organoids confirmed MCP1 (encoded by CCL2) and TIMP1 upregulation by TNF treatment.

Conclusions: TNF, TNF receptors, and TNF-responsive biomarkers reflect alterations in inflammatory and intrinsic kidney cell populations in patients with a TNF-associated signaling profile and are currently assessed as TNF target engagement biomarkers in a clinical trial of FSGS patients (NCT04096683).

PO1457

Dysregulated T Cell Metabolomic Profile in Patients with Steroid-Resistant Nephrotic Syndrome

Chang-Yien Chan,1,2 Liangjian Lu,3 Sharon Teo,3 Yachen Zhuang,1 Kong Peng Lam,1 Kar Hui Ng,1 Hui Kim Yap,1 National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; 2Khoo Teck Puat - National Children’s Medical Institute, Singapore, Singapore; 3Agency for Science Technology and Research, Singapore, Singapore.

Background: We have recently reported early relapse following rituximab in patients with minimal change disease was associated with baseline reduction in regulatory T-cells and T-cell hyporesponsiveness to activation, suggesting chronic T-cell activation. This study aimed to compare T-cell activation and characterise the metabolic alterations associated with T-cell hyporesponsiveness in patients with steroid-dependent (SDNS) and steroid-resistant nephrotic syndrome (SRNS) in relapse.

Methods: A total of 48 patients with childhood-onset SDNS (n=31) and SRNS (n=17) were recruited during relapse. T-cell activation assay was performed on whole blood while metabolomic profiling was performed on purified stimulated CD4 T-cell culture supernatants (n=23) using GC-MS/MS and analysed using Shimadzu Smart Metabolites Database. Differences in the metabolomic profile between SDNS and SRNS were identified using PLS-DA (SIMCA), and pathway analysis was performed using MetaboAnalyst 4.0. Metabolomic validation assay was performed using Glucose 6 Phosphate Dehydrogenase (G6PD) assay kit.

Results: SRNS patients had significant lower T-cell expression of CD69 (98±2.3% vs 91±3.1%, P = 0.024) and IFNγ (1.9±0.73% vs 6.6±1.35%, P = 0.016) compared to SDNS patients. PLS-DA modeling of the 93 metabolites identified in CD4 culture supernatants yielded one fitted component, in which 24% of the variability in metabolites measured (R2X) could explain 58% of the variation in steroid-response (R2Y). Of note, 85% of the metabolites tended to be lower in SRNS compared to SDNS patients. Pathway analysis of the 38 metabolites with VIP>1 implicated the biosynthetic pathways glyoxylate and dicarboxylate metabolism, ascorbate and aldarate metabolism as well as galactose metabolism (Benjamini-Hochberg P<0.05). Interestingly, the 2 metabolites with the highest VIP score have been implicated as downstream products in the pentose phosphate shunt and were reduced in SRNS compared to SDNS patients (P<0.001). G6PD activities in SDNS patients in relapse negatively correlated with T-cell expression of CD69 (r=-0.58, P = 0.047).

Conclusions: We demonstrated that muted T-cells response to in vitro stimulation in SRNS patients was associated with metabolic quiescence, with dysregulated biosynthetic pathways including the pentose phosphate shunt.

PO1458

Blocking the IL-1β/IL-1R1 Signaling as a Potential Therapy for Multidrug-Resistant Nephrotic Syndrome

Andrea Angleton,1 Francesca Lugani,1 Gianluca Cardi,1 Enrico E. Verrina,1 Paolo Cravello,1 Gian Marco Giuggeri,1 Istituto Giannina Gaslini, Genova, Italy; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: In idiopathic nephritic syndrome (NS), Steroid-resistant patients with complete or partial resistance to the combination of prednisone and steroid sparing-agents are at high risk to progress to end-stage kidney disease. Considering the toxicities associated with chronic use of these drugs, alternative interventions are urgently needed. IL-1β/IL-1R1 has been recently suggested as a possible mechanism of complement-mediated progression of Focal Segmental Glomerulosclerosis.

Case Description: A 26-year-old white woman had FSGS (kidney biopsy) presenting with NS and kidney failure. Serum creatinine level was 1.6 mg/dL, urinary protein excretion 20.4 g/day and serum albumin 0.9 g/dL. She received methylprednisolone, 1g rituximab, and CAN with partial remission. Three months later, she presented relapse of NS and acute kidney failure requiring 5 HD: CAN was switched to MMF. Immunglobulins IV were administered. After 3 months, serum creatinine was 5.1 mg/dL, urinary protein excretion was 18 g/d. Given the lack of improvement/worsening of proteinuria, new started anakinra, the anti-IL-1R1 (subcutaneously, 2 mg/kg/d for the first week and then 4 mg/kg/d). After 1 year, serum creatinine is 3.4 mg/dL, urinary protein excretion is 5.2 g/d and serum albumin level was 1.3 g/dL. No side effects were reported (Fig 1).

Discussion: We administered Anakinra in MRCN due to FSGS and CKD Stage IV. After Anakinra, multiple ongoing immunosuppressive treatments were stopped. We acknowledge that Anakinra did not promote full disease remission, but it was associated with a significantly amelioration of the disease clinical. By slowing the rapid progression of kidney failure, the young patient better faced all future perspectives: a pre-emptive kidney transplant in case kidney function worsens is now available. In conclusion, our data indicate that Anakinra, by antagonizing IL-1β/IL-1R1 signaling, may represent a useful therapeutic option to prevent the progression of kidney injury in advanced forms of nephrotic syndrome.

IHC staining for STING on kidney tissue obtained from MCD patients (classified into negative (A), 1+ (B), 2+ (C), and 3+ (D) according to the signal intensity) and IgAN patients, the glomerulus was exclusively stained in MCD patients (Figure). MCD patients were divided into the high (n = 6) and low (n = 14) intensity subgroups according to the signal intensity based on 2+ or more or less, respectively. TA-proteinaemia and frequency of relapses during the follow-up period were higher in the high intensity group than in the low intensity group (1.18 ± 0.54 vs 0.57 ± 0.45 g/day, p = 0.022; and 0.72 ± 0.60 vs 0.09 ± 0.22 episodes/year, p = 0.022, respectively).

Conclusions: These findings suggest that more severe mitochondrial injury, as represented by a high signal intensity of IHC staining for STING at the time of diagnosis, could be used as a prognostic marker to predict poor prognosis in MCD.

PO1460

Maturation of Decay Accelerating Activity Response Across the Natural History of C3 Glomerulopathy

Christopher Culek,1 Richard J. Smith,1,2 Carla M. Nester,1,2 University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; 2The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA.

Background: C3 Glomerulopathy (C3G) is an ultra-rare complement-mediated renal disease characterized by dysregulation of the alternative pathway (AP) of complement. Dysregulation is often driven by a nephritic factor (C3NeF), an autoantibody to the C3 convertase (C3BbBb) of the AP. We hypothesized that the properties of Nefs change

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
over time and that changes will be associated with changes in underlying complement dysregulation.

**Methods:** IgG was purified from normal human serum and from sera collected across six time points of a well characterized C3G patient. Using SPR (Biacore), the C3 convertase (C3bBb) was formed on a CM5 sensor chip. Purified test or control IgG was injected to form the Nef-C3bBb complex. The ability of naive complement regulators to decay the Nef-C3bBb complexes was assessed by injecting Decay Accelerating Factor (DAF), Complement Receptor 1 (CR1), Factor H (FH), or control reagent. Residual C3bBb was determined by the ratio of post- to pre-regulated convertase. Data were compared to time-matched complement biomarker results.

**Results:** The presence of Nef conferred resistance to the normal decay accelerating activity (DAIA) by DAF, CR1, and FH. Resistance to DAA was highest in the earliest sample (S1, p = 0.0001), with a reduction in subsequent samples. This change was independent of Nef titer and coincident with reduced complement activity. Low DAF resistance was maintained in later samples, whereas CR1 and FH resistance gradually increased.

**Conclusions:** Nef-stabilized C3bBb resistance to native DAA proteins matures over time and is independent of Nef titer. Changes in response to regulators is accompanied by a relative change in underlying complement dysregulation as reflected by complement biomarkers. How this variance (in time and across regulators) impacts disease course and outcome in patients with C3G or whether the phenomenon represents a novel treatment target warrants further study.

**Complement-Activating Polymorphonuclear Neutrophil Contribution to C3G Pathogenesis**

**Maria Maassood,** 1 Noah A. Fine, 1 Carolina Ortiz, 1 Patrick D. Walker, 2 Christoph Licht. 1 The Hospital for Sick Children, Toronto, ON, Canada; 2 Arkana Laboratories, Little Rock, AR; 3 University of Toronto, Toronto, ON, Canada.

**Background:** C3G is caused by dysregulation of the complement alternative pathway, but there is a gap in the pathogenic cascade from complement activation (intravascular space) to inflammation and complement deposition in the glomeruli (extravascular space). Recently, biopsies have shown the presence of (activated) polymorphonuclear neutrophils (PMNs) in C3G glomeruli indicating an underappreciated role for PMNs in C3G pathogenesis.

**Methods:** PMNs were investigated in a transwell chamber allowing for different environments. Conditions were chosen to resemble the intravascular space (top well; serum containing) versus extracellular space (bottom well; serum-free conditions). PMNs were stimulated in the top well via various agonists, including complement, and allowed to transmigrate to the bottom well where they were monitored for the formation of Neutrophil Extracellular Traps (NETs) via immunofluorescence and SYTOX assay. Circulating C3G patient PMNs were examined for priming via flow cytometry.

**Results:** Upon complement stimulation, PMNs showed evidence for priming in serum conditions (top well). PMNs travelled to the bottom well following chemotactic factor (MLP) where they then completed the process of NET formation (NETosis) in serum-free conditions (bottom well). Results were validated ex vivo using C3G patient PMNs and autologous serum (Figure). In addition, incubation of control PMNs in C3G patient serum revealed a correlation between serum-albumin levels and the degree of NET formation. C3G patient PMNs showed upregulation of CD11b compared to controls.

**Conclusions:** Assigning a pathogenic role to PMNs in C3G identifies a new treatment and monitoring strategy with the potential for improved long-term outcomes and quality of life.

**PO1461**

**C3 Glomerulonephritis with Nephritic Factor Treated with Rituximab**

**Hanny Sawaf,** Georges Nakhoul, Ali Mehdi, Jonathan J. Taliercio. Cleveland Clinic, Cleveland, OH.

**Introduction:** C3 Glomerulonephritis (C3GN) is a well described cause of kidney disease that results from dysregulation of the alternative complement pathway. Kidney biopsy demonstrates a membranoproliferative pattern of injury and mesangial C3 staining with minimal or no staining of immunoglobulins on immunofluorescence. C3GN can be due to genetic mutations, autoantibodies against the alternative complement regulators, or monoclonal gammopathy. C3 nephric factor (C3NeF) is an auto-antibody that stabilizes C3 convertase due to genetic mutations, autoantibodies against the alternative complement regulators, or monoclonal gammopathy. C3 nephric factor (C3NeF) is an auto-antibody that stabilizes C3 convertase which leads to an increase in activity of the alternate complement pathway. Steroids, mycophenolate mofetil (MMF), rituximab, and abatacept have been used with varying results. We present a patient with biopsy proven C3GN with C3NeF who was successfully treated with rituximab after failing therapy with MMF.

**Case Description:** Patient is a 64-year-old male diagnosed with biopsy proven C3GN after being found with decreased kidney function with a peak creatinine of 1.97 mg/dL and nephrotic range proteinuria with a maximal urinary protein excretion of 4.3 mg/dL. Evaluation revealed low C3 and C4 at 60 mg/dL and 5 mg/dL respectively, negative monoclonal testing, and a C3NeF of 21 unit/mL (reference range 0). Patient was initiated on prednisone 60 mg/day with taper, MMF with a maximal dose 3 grams/day, and valacyclovir for 2 years with little improvement in clinical parameters. Therapy was switched to rituximab 1 gram on weeks 0, 2, 26. Within 3 months patient had; normalization of complements, negative C3NeF, 0.7 urine protein-to-creatinine ratio (UPCR), and serum creatinine 1.5 mg/dL. Since his initial rituximab regimen 2 years ago, he remains off maintenance therapy, with negative C3NeF, normal complements, 0.1 UPCR, and serum creatinine 1.04 mg/dL.

**Discussion:** C3GN was successfully treated with rituximab based on the disappearance of C3NeF and improvement in clinical parameters. Rituximab was chosen to target CD20 cells to halt the production of the C3NeF autoantibody. Laboratory response (complements and C3NeF) was seen within 3 months of initial rituximab dosing, and UPCR and serum creatinine required a longer follow up for a nadir. Recurrence of relapse is being monitored using serial C3NeF measurements. We believe that targeted B cell therapy should be considered in the treatment of C3GN cases which are C3NeF antibody mediated.

**PO1463**

**Differential Expression of Complement and Non-Complement Proteins in C3 Glomerulonephritis and Dense Deposit Disease**

**Sanjeev Sethi,** 1 Benjamin J. Madden, 1 Fernando C. Fervenza, 1 Lilian M. Palma. 1 Mayo Clinic Minnesota, Rochester, MN; 2Universidade Estadual de Campinas, Campinas, Brazil.

**Background:** C3 glomerulopathy comprising dense deposit disease (DDD) and C3 glomerulopathies (C3GN) results from overactivation of the alternative pathway of complement. Mass spectrometry (MS) studies have previously shown accumulation of complement proteins in C3GN and DDD. However, complete MS analysis of non-complement proteins and comparison of complement proteins in C3GN and DDD has not been done.

**Methods:** We performed laser microdissection of glomeruli followed by MS in 12 cases each of biopsy-proven C3GN and DDD, and 6 control cases of time 0 transplant biopsies.

**Results:** Compared to the controls, C3GN showed increased intensity based absolute quantification (iBAQ) values of C3 (20-fold), C5 (52-fold), C6 (76-fold), C7 (90-fold), C8 (66-fold), C9 (30-fold), CFHR1 (146-fold) and CFR5 (65-fold). Similarly, DDD showed also increased iBAQ values compared to controls of C3 (26-fold), C5 (365-fold), C6 (473-fold), C7 (261-fold), C8 (353-fold), C9 (159-fold), and CFHR1 (73-fold). When DDD was compared to C3GN, there was a 2-5 fold increase in iBAQ values in C5, C6, C7, C8 and C9 (p<0.001), although there was no significant difference in C3. Among the non-complement proteins Apolipoprotein E (APOE) and A-II and V (APO-A-II and V), Serine protease HTRA1, Ryonandine receptor 1 (RYR1), and Translational activator GCN1 were expressed 3-7 fold higher in DDD compared to C3GN (p<0.001). On the other hand, proteoglycans 2 and 3 (PRG2 and 3), angiotensin (AGT) and proopitide (CFF) were expressed 2-5 fold higher in C3GN compared to DDD (p<0.001).

**PMNs were seeded in the top well of a transwell system and allowed to transmigrate for 12 h. PMNs from both wells were stained for IF with DAPI (blue), Citrullinated histone 3 (ChH3; green) and Myeloperoxidase (MPO; red). Scale bar 20 um. 63x magnification.**

*Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only*
Conclusions: MS of C3GN and DDD show high iBAQ values of complement proteins. DDD shows a higher iBAQ values in terminal complement proteins compared to C3GN. In addition, proteins such as APOE and APOA IV are increased in DDD compared to C3GN, while PRG2/3 and properdin are increased in C3GN compared to DDD suggesting a role for the proteins in the pathophysiology of C3GN and DDD.

PO1464
Clinical and Histological Features of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: A Single-Center Retrospective Study from China
Yifeng Wang, Xiaoye Zhu, Shaojun Liu, Jun Xue, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: PGNMID is a new entity of monoclonal gammopathy affecting the kidney characterized by intact monoclonal immunoglobulins (mlg) deposits that result in membranoproliferative pattern of glomerular injury. In this study, clinical and histological of PGNMID cases were evaluated.

Methods: A total of 23 patients with biopsy-confirmed PGNMID in native kidney diagnosed between December 2015 to April 2021 were enrolled in this study. Clinical, histological, hematologic, and follow-up data were abstracted from the medical record.

Results: Of 23 cases, majority were male (65.2%), and the mean age was 49.5 years with 8 cases (34.8%) under 40 years old. At the time of biopsy, 19 cases had proteinuria with a mean 24h urine protein of 3.99g (0.28 to 8.96), 11 of 22 cases had nephrotic syndrome, and 18 of 22 cases had hematuria. The mean serum creatinine was 1.52mg/dl (0.6 to 7.8). 15 cases (65.2%) had eGFR<90 mL/min (CKD-EPI), and 4 cases had eGFR <60mL/min. Eleven of 23 cases (47.8%) showed MPGN, 6 cases showed EGPG, 2 cases showed MesPGN, and 2 cases showed MN. By IF, 21 cases (91.3%) showed mIgG (12 IgG3, 5 IgG1, 1 IgG1A, 1 IgG2, and 2 IgGk without determined subclass) and 2 cases (8.7%) showed mIgA deposits. All cases showed C3 co-deposits, and 6 of 18 cases (33.3%) had a low serum C3 level. EM revealed unorganized and granular deposits in the mesangial area (17 of 17), subendothelial area (15 of 17), and subepithelial area (12 of 17). Three of 4 cases whose eGFR<60 mL/min showed EMG. SIFE showed mIg that matched the renal deposits in 2 of 13 cases (15.3%). After mean follow up of 3 months in 3 cases, 1 patient treated with bortezomib+ CTX+DXM and another patient treated with rituximab both achieved partial renal remission. But the third patient treated with rituximab had a persistent renal dysfunction. Of note, previous or concurrent chemotherapeutic agents and adequate blood pressure control, her creatinine continued to increase with subsequent development of nephrotic range proteinuria. All serologies (including anti-nuclear, anti-dsDNA, anti-Smith, anti-SLA/B, anti-Ro/La, anti-SS A and B, anti-RNP, anti-Jo) were negative. Kidney biopsy demonstrated TMA. Despite the discontinuation of all chemotherapeutic agents and adequate blood pressure control, her creatinine continued to increase, peaking at 6.8 mg/dl 2 months after the biopsy. She was started on Eculizumab with an improvement in creatinine to 3.49 mg/dl 2 months later.

Conclusion: Fifty-seven patients with TMA on kidney biopsy and a normal activity of von Willebrand factor cleaving protease were screened for deregulated complement using ex vivo C5b9 formation on the endothelium and genotyping. Massive ex vivo C5b9 formation and/or rare complement gene variants defined C-TMA. Clinico-pathologic features that may distinguish C-TMA from secondary TMA were studied. Regression models were used to assess the prognostic value of chronic damage on kidney biopsy.

Results: C-TMA was diagnosed in 30 patients (coexisting conditions, n=26 [87%]), including 16 (53%) cases with rare complement gene variants; 27 patients had secondary TMA related to autoimmunity (n=13), hypertension (n=10), and other etiologies (n=4). Patients presented with acute kidney injury, while systemic hemolysis was uncommon in both groups (n=14/30 vs. n=6/27; P=0.05). C-TMA was linked to younger age (37 [±14] vs. 46 [±15] years; P=0.04), low plasma C3 (n=16/29 vs. n=3/22; P=0.01), and glomerular thrombosis (n=19/30 vs. n=8/27; P=0.02) as compared to secondary TMA: glomerular thrombosis, however, was common in patients with autoimmunity (n=6/13; P=0.05 vs. C-TMA). These characteristics, when combined, had a specificity and sensitivity for C-TMA of 100% and 33%, respectively. Eculizumab treatment was associated with clinical remission in C-TMA (n=12/14; P<0.01 vs. n=3/16 untreated patients). Morphologic features of chronic damage, i.e., glomerulosclerosis, interstitial fibrosis/tubular atrophy, and arteriosclerosis, did not predict prognosis; 5 out of 6 patients with C-TMA and moderate-to-severe chronicity scores treated with eculizumab recovered and/or improved kidney function.

Conclusion: Patients with TMA, low plasma C3, and glomerular thrombosis who present at younger age (i.e., <45 years) are at high risk for C-TMA. Although a kidney biopsy is often needed to detect the TMA, morphologic features of chronic damage cannot predict prognosis.

PO1466
Limited Therapeutic Arsenal for the Thrombotic Microangiopathy Spectrum
Jesse E. Diaz Correa,1 Joris M. Schuller,2 Harold M. Szerlip,1,2 ‘Baylor University Medical Center at Dallas, Dallas, TX; ‘Dallas Nephrology Associates, Dallas, TX.

Introduction: Thrombotic microangiopathy (TMA) is a common renal pathologic finding with an associated broad spectrum of clinical diseases. Complement-mediated TMA (C-TMA) is a frequently recognized cause of TMA due to uncontrolled complement activation. Terminal complement inhibitors such as Eculizumab have been shown to improve renal function in C-TMA. Multiple case reports have demonstrated a benefit in patients without identifiable complement disorder.

Case Description: 41-year-old Ethiopian female with a history of metastatic ovarian cancer treated with omentectomy, partial hepatectomy, salpingo-oophorectomy, splenectomy one year before admission was admitted for renal biopsy for evaluation of an increasing creatinine and proteinuria. Following her surgery she had been treated initially with paclitaxel and carboplatin and subsequently she had received bevacizumab and doxorubicin; the last doses of these latter agents were six months before admission. Four months prior to admission she developed new onset hypertension and her creatinine began to increase with subsequent development of nephrotic range proteinuria. All serologies were negative. Kidney biopsy demonstrated TMA. Despite the discontinuation of all chemotherapeutic agents and adequate blood pressure control, her creatinine continued to increase, peaking at 6.8 mg/dl 2 months after the biopsy. She was started on Eculizumab with an improvement in creatinine to 3.49 mg/dl 2 months later.

Discussion: There are no randomized trials evaluating terminal complement inhibitors for c-TMA. The indication for these medications becomes even more unclear when we factor in drug-induced TMA, cancer-associated TMA, malignant hypertension, and other TMA with readily identifiable complement disorders. More research on the use of genetic testing and complement inhibition is warranted for the entire spectrum of TMA.

PO1465
Diagnostic and Risk Factors for Deregulated Complement in Thrombotic Microangiopathy
Siorend Timmermans, Pieter van Paassen. Limburg Renal Registry Maastricht Medisch Centrum +, Maastricht, Netherlands.

Background: The syndromes of thrombotic microangiopathy (TMA) are diverse and represent severe endothelial damage caused by various etiologies. The early recognition of complement-mediated (C)-TMA is of utmost importance to select patients for complement inhibition. Whether or not clinicopathologic features at presentation can distinguish C-TMA from secondary TMA was studied. Regression models were used to assess the prognostic value of chronic damage on kidney biopsy.

Results: Of 23 cases, majority were male (65.2%), and the mean age was 49.5 years with 8 cases (34.8%) under 40 years old. At the time of biopsy, 19 cases had proteinuria with a mean 24h urine protein of 3.99g (0.28 to 8.96), 11 of 22 cases had nephrotic syndrome, and 18 of 22 cases had hematuria. The mean serum creatinine was 1.52mg/dl (0.6 to 7.8). 15 cases (65.2%) had eGFR<90 mL/min (CKD-EPI), and 4 cases had eGFR <60mL/min. Eleven of 23 cases (47.8%) showed MPGN, 6 cases showed EGPG, 2 cases showed MesPGN, and 2 cases showed MN. By IF, 21 cases (91.3%) showed mIgG (12 IgG3, 5 IgG1, 1 IgG1A, 1 IgG2, and 2 IgGk without determined subclass) and 2 cases (8.7%) showed mIgA deposits. All cases showed C3 co-deposits, and 6 of 18 cases (33.3%) had a low serum C3 level. EM revealed unorganized and granular deposits in the mesangial area (17 of 17), subendothelial area (15 of 17), and subepithelial area (12 of 17). Three of 4 cases whose eGFR<60 mL/min showed EMG. SIFE showed mIg that matched the renal deposits in 2 of 13 cases (15.3%). After mean follow up of 3 months in 3 cases, 1 patient treated with bortezomib+ CTX+DXM and another patient treated with rituximab both achieved partial renal remission. But the third patient treated with rituximab had a persistent renal dysfunction. Of note, previous or concurrent infections by fungi, HIV, HBV, HPV or other undetermined pathogen, were observed in 5 cases (21.7%). We also found 1 patient with autoimmunity and another with malignancy.

Conclusion: Compared with previous reports, our PGNMID cases showed similar clinical and histological features. EPGN pattern seems to be associated with more severe renal function damage. Previous or concurrent infections, autoimmunity and malignancy were observed in 21.7% of cases.
Hematopoietic Stem Cell Transplant Membranous Nephropathy Is Associated with Protocadherin FAT1
Sanjeev Setlur,1 Benjamin J. Madden,1 Samih H. Nasr,1 Fernando C. Fervenza,1 Mark Haas,2 Mayo Clinic Minnesota, Rochester, MN; 2 Cedars-Sinai Medical Center, Los Angeles, CA.

Background: Membranous nephropathy (MN) is a common cause of proteinuria in patients with a hematopoietic stem cell transplant (HSCT). The antigen(s) responsible for MN in HSCT-associated MN is unknown.

Methods: We performed laser microdissection and mass spectrometry (MS/MS) of glomeruli of 230 cases of PLA2R-negative MN to detect novel proteins/antigens in MN. These included PLA2R-negative MN developing in the setting of HSCT and de-novo MN in the kidney transplant.

Results: We detected a novel protein Protocadherin FAT1 (FAT1) in 9 cases of PLA2R-negative MN. Of the 9 FAT1-associated MN cases, 7 patients followed HSCT and 2 followed kidney transplant (de-novo MN). HSCT was done for treatment of AML (5 cases), MDS (1 case) and essential thrombocytopenia (1 case). All 9 cases were negative for known antigens of MN including PLA2R, THSD7A, NELL1, PCDH7, NCAM1, SEMA3B and HTRA1. Baseline PLA2R spectral counts were detected in 7 of the 9 cases. The FAT1 total spectral counts ranged from 27 to 70 (mean 44.1 ± 13.1). FAT1 was not detected in MS/MS in 115 control cases that included time 0 transplant, minimal change disease, FSGS, diabetes and IgA nephropathy. FAT1 was also not detected in 28 cases of PLA2R-positive MN. No case of FAT1-associated MN was detected in a non-transplant setting. The mean age of patients with FAT1-associated MN was 36 ± 9.7 yrs, 7 patients were females and 2 were males. MN occurred 2.5 ± 0.8 yrs and 7.5 ± 1.2 yrs after HSCT and kidney transplant, respectively. The mean serum creatinine and proteinuria at kidney biopsy was 1.9 ± 1.2 mg/dL and 7.4 ± 5.4 gms/L, respectively. Kidney biopsy showed IgG (2-3+) and minimal C3 (0-1+) along glomerular capillary walls; electron microscopy showed stage II MN in 8 out of 9 cases.

Conclusions: FAT1 appears to be a unique protein found in MN developing in the setting of HSCT and de-novo MN following kidney transplant. Further studies to localize FAT1 on the glomerular basement membranes and detect circulating antibodies are ongoing.

POI1468
Netrin G1 Is a Novel Target Antigen in Membranous Nephropathy
Linda Reinhard, Maya Machera, Theresen Teich, Nicoletta Ferru, Elon Hoxha, Rolf A. Stahl. Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

Background: PLA-R is the main target antigen in membranous nephropathy (MN) representing 70-80% of cases. In the past years a number of confirmed, or potential target antigens, such as THSD7A, NELL1, HTRA1, Semai3B and PCDH7 have been reported, showing that the pathophysiology of PLA-R-antibody (ab) negative MN represents a diverse repertoire of antigens with low frequency.

Methods: Western blot (WB) analysis was used to identify sera of MN patients with IgG4 specific signals binding to antigens in the membrane fraction of human glomerular extracts (HGE). Only sera which were negative for PLA2R- and THSD7A- and PCDH7 were used. Recombinant protein was used to confirm the reactivity of patient sera by WB and identify other patients in a large cohort of MN patients. The deposition of the target antigen in the glomerular immune deposits was confirmed by immunohistochemistry (IHC).

Results: Using this approach, we identified Netrin G1 (NTNG1) as a novel target antigen in MN. NTNG1 is a 50 kDa secreted glycoprotein, which is attached to the cell surface by a GPI anchor (Fig. A, B). We identified NTNG1-1 in two out of 110 PLA-R- and THSD7A-negative MN patients. A follow-up of 5 years was available for the index patient. During this time, both proteinuria and NTNG1 persisted while renal function was stable. Further, a granular positivity for NTNG1 along the glomerular capillary wall was confirmed in the kidney biopsy by IHC (Fig. C), but was undetectable in the negative control (PLA-R- and THSD7A-negative MN).

Conclusions: We report NTNG1 as a novel target antigen in MN, occurring with low frequency and expanding the repertoire of antigens in patients with MN. The prevalence, pathogenic and clinical roles remain to be defined.

PO1470

Epitode Spreading and Immune Complex Rearrangement in Membranous Nephropathy

Olusola Soegbein, Marijan Afrozian, Tina Kochar. The University of Texas Medical Branch at Galveston, Galveston, TX.

Introduction: We present a rare case of ANA and anti-dsDNA negative, anti-GBM positive lupus nephritis (LN) patient with two biopsies demonstrating LN Class III+V with possible immune complex (IC) rearrangement and/or epitope spreading (ES).

Case Description: A 62-year-old white male presented with a year-long history of purpuric rash and hematuria. His hospital admission laboratory data is detailed in Table 1. The first renal biopsy showed crescents in 2/4 glomeruli with mild (+) granular and segmentally linear deposits by immunofluorescence (IF). The patient received cyclophosphamide, corticosteroids and one session of therapeutic plasma exchange due to rapidly worsening renal function and an initial presumptive diagnosis of anti-GBM disease. The second biopsy demonstrated no crescents but features of combined class III + V LN with IF findings suggestive of a full-house pattern with a change in the deposits from segmentally linear to pure granular. He began therapy with mycophenolate mofetil and prednisone resulting in a decrease in his UPCR from 2.3 to 0.3 mg/mg (complete remission) over the next four months and significant improvement in renal function.

Discussion: A link has been reported between anti-GBM histopathology and membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations. ES refers to the molecular conformational changes of secondary, non-membranous nephropathy. Evidence suggests IC rearrangement and/or ES as possible explanations.

We believe our case suggests this possible pathogenic mechanism. More research is needed to improve understanding of the sequential change observed on immunofluorescence microscopy.

Generation of Anti-THSD7A Antibodies Using a Human Antibody Phage Display Library

Sarah Köllner,1 Larissa Seifert,2 Philip A. Heine,2 Michael Hust,2 Nicola M. Tomas.1 1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2Technische Universität Braunschweig, Braunschweig, Germany.

Background: Membranous nephropathy (MN) is an antibody-mediated autoimmune renal disease. In the majority of cases, autoantibodies target podocyte membrane proteins such as PLA2R1 and THSD7A. We could previously demonstrate that autoantibodies in THSD7A-associated MN cause disease and recognize several extracellular domains of the target antigen. However, the clinical relevance of this antibody polyclonality remains unclear as disease pathogenicity. The aim of this study was the generation of anti-THSD7A antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Methods: In the antibody phage display technology, antibody fragments are displayed on the phage particle and the corresponding gene fragment encoding the antibody fragment is packaged in the phage particle. A selection process called panning enables the selection of antibody fragments against virtually any target structure in vitro. In this project, a naïve antibody gene library was used to select binders to the extracellular part of human and mouse THSD7A. Binders were sequenced, cloned into scFv-Fc format - an IgG like format - and produced in HEK293 cells. Binding of scFv-Fc to human and mouse THSD7A was investigated using Western blot, ELISA and indirect immunofluorescence testing (IFT). Epitope regions were mapped using an ELISA.

Results: Four binders (SAK79-B1, SAK78-C12, SAK78-E6, SAK78-F8) could be obtained. While SAK78-F8 exclusively bound human THSD7A, the other binders reacted with both human and murine THSD7A in Western blot, ELISA and IFT. A domain-specific ELISA revealed binding of SAK78-C12, SAK78-E6 and SAK78-F8 to the regions d8, d9, d11, d2 and d6, d7, respectively. SAK79-B1 did not react with any domain combination, but showed strong binding to murine and human d1, d2. We suspect a conformational epitope that was not conserved in the coated domain fragments. SAK78-C12 and SAK78-E6 were successfully cloned into human IgG subclass backbone IgG1-IgG4. We generated recombinant antibodies using a human antibody phage display library for further diagnostic and pathomechanistic studies.

Conclusions: Antibody phage display represents a powerful method to generate recombinant antibodies. The antibodies selected show different binding characteristics in vitro. In vivo binding characteristics, pathogenicity and potential as a diagnostic tool in THSD7A in patient biopsies, need to be determined.

A Comparison of aPLA2Rab Assays on Treatment with Cyclophosphamide and Steroids

Coralien Vink van Setten,1 Anne-Elis van de Logt,1 Alexander Kühnh,2 Jack F. Wetzel.3 1Radboudumc, Nijmegen, Netherlands; 2EUROIMMUN Medizinische Labordiagnostika AG, Lübeck, Germany.

Background: Anti-PLA2R antibodies (aPLA2R) are present in ~75% of patients with primary membranous nephropathy (MN). A qualitative immunofluorescence test (IFT) allows accurate detection of aPLA2R, additionally ELISA and ChLIA provide quantitative analysis. Sensitivity of the two latter methods after start of immunosuppressive therapy is not well studied.

Methods: We retrieved stored samples of patients with aPLA2R associated MN, who were treated with cyclophosphamide and steroids(CP), collected at baseline and 8 weeks after start of therapy. Assays were performed by the EUROIMMUN research lab, Lübeck, Germany. All samples were analysed by IIFT, ELISA and ChLIA. We categorized ELISA results to cut-off values used in literature: 2, 14, and 20 RU/ml resp.

Results: We included baseline samples of 50, and 8 week samples of 51 patients. At baseline, all patients tested IIFT positive; ELISA test was positive in 94% or 98% of samples using cut-off values of 20 RU/ml or 14 RU/ml resp., indicating high sensitivity. Agreement between IIFT and ChLIA was 100%. After 8 weeks on CP, 37/51 patients had immunological remission by IIFT. ELISA test results are given in Table 1. In the IIFT positive samples collected after 8 weeks, ELISA titers were < 20RU/ml or < 14 RU/ml in 9/14 and 5/14 patients respectively, suggesting lower sensitivity. All IIFT negative samples had ELISA titers < 14 RU/ml. When analysing IIFT negative patients with ELISA titer <2 U/ml (N=23) vs. 2-14 U/ml (N=14), persistent immunological and clinical remission was better in the first group (74% vs 58%), however not statistically different. With ChLIA only 4/51 (8%) had different results (2 IIFT-/ChLIA+, 2 IIFT+/ChLIA-); resulting in a sensitivity of 86% and a specificity of 95%, when comparing IIFT.

Conclusions: Using immunological remission as treatment target, as described here after 8 weeks of CP, requires evaluation of the applied assay for this purpose. Of the examined quantitative methods, ChLIA demonstrated the highest agreement with IIFT. ELISA titers below the recommended cut-off for initial diagnosis still show a tendency towards the clinical outcome, which could be investigated by further studies.

PO1473

The Classical Pathway Triggers Pathogenic Complement Activation in Membranous Nephropathy

Larissa Seifert,1 Gunther Zahnner,1 Naemi C. Hickstein,1 Sarah Köllner,1 Catherine Meyer-Schwesinger,2 Dominik Kylies,1 Anna Borodovsky,3 Peter F. Zipfel,4 Victor G. Puuelles,5 Ulf Panzer,6 Tobias B. Huber,7 Thomas Weich,4 Nicola M. Tomas.1 1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2Alylam Pharmaceuticals Inc, Cambridge, MA; 3Leibniz-Institut für Naturstoff-Forschung und Infektionsbiologie eV, Hans-Knohl-Institut, Jena, Germany.

Background: Membranous nephropathy (MN) is characterized by severe proteinuria, circulating autoantibodies against podocyte antigens such as PLA2R1 and THSD7A, and glomerular deposition of IgG and complement components (CCs). However, the pathways triggering the complement cascade (classical, alternative or lectin) and the significance of local glomerular complement action for podocyte damage and proteinuria are poorly understood.

Methods: Complement activation was investigated in 20 biopsies from patients with PLA2R1- and THSD7A-associated MN using immunofluorescence and proximity ligand blotting to visualize the assembly of CCs/convertases. Experimental autoimmune MN (EAMN) was established in 12-week-old BALB/c mice by immunization with THSD7A. Anti-THSD7A antibodies, proteinuria, serum parameters, and histological signs of MN were analyzed. The role of the complement system was studied by induction of EAMN in C3-/- mice. The efficacy of complement-targeted treatment was evaluated by weekly injection of a C3-silencing siRNA after the onset of proteinuria.

Results: The assembly of the classical/lectin convertase was identified in 19/20 MN biopsies, which was accompanied by detection of IgG and C3 in the majority of cases. The alternative convertase and MBL deposits were detected in fewer cases. Upon immunization, mice developed classical and histopathological features of MN. Proteinuria ranged from mild to severe nephrotic syndrome and histopathological features included granular glomerular deposition of IgG and CCs including C1q and C3 as well as loss of the integral podocyte proteins nephrin and nephrin. Strikingly, severe disease with ascites was prevented in C3-/- mice and overall proteinuria was reduced in comparison to WT littermates. Finally, treatment with C3-silencing siRNA after the onset of proteinuria attenuated disease.
Conclusions: The complement system is dominantly activated via the classical path in MN patients. Experimental data in the first author’s membranous model suggests an antigen that is pathogenically relevant in patients suggest complement-targeted treatment as a promising strategy for MN patients with severe disease, but also hint at a role of complement-independent mechanisms in the pathogenesis of MN.

PO1476
Compelent Activation and Suppression Profile Reveals Distinct Subtypes in C3 Glomerulonephritis

Background: The complement pathway is an innate immune defense mechanism, and uncontrolled activation can cause damage to host tissues including the kidney. C3GN is characterized by deposits in the glomerulus made up entirely of complement C3 protein without the presence of immunoglobulins.

Methods: The activity of the alternative complement pathway (ACP) was determined in serum derived from C3GN patients, IgA Nephropathy (IgAN) and Polycystic Kidney Disease (PKD) and healthy controls (HC) by measuring the lysis of rabbit red blood cells (rRBC). Complement factor H (CFH) was added to the serum of C3GN patients to test if CFH is capable of inhibiting the ACP in C3GN patients.

Results: Analysis of the ACP using the serum of C3GN, IgAN, PKD patients and healthy controls can be calculated by the lysis of rRBC. The percent lysis at specified time points (5, 10 and 15 minutes) was calculated using the maximal lysis for each sample. Serum from C3GN patients result in more significant lysis (one way ANOVA, p = 0.01) at 5 and 10 minutes (22.9% ± 11% and 42.7% ± 12%, respectively) compared to HC (7.1% ± 3% and 21.7% ± 6%, respectively), IgAN (10.9% ± 7% and 27.3% ± 15%, respectively) and PKD (8.6% ± 6% and 24.4% ± 12%, respectively). However, at 15 minutes, there were no statistically different differences in the lysis of the rRBC between these groups, suggesting that the ACP is more rapidly activated in C3GN patients, leading to a faster depletion of C3. Addition of CFH to the serum of C3GN patients reduced the ACP activity to control levels in 6 out of 14 patients. We did not detect CFH specific antibodies in the serum of patients who did not respond to CFH, indicating additional mechanisms are involved with the rapid activation of the ACP in C3GN.

Conclusions: The ACP is rapidly activated by the serum of C3GN patients compared to other kidney diseases and HC. Although the addition of CFH to the serum reduced the ACP activation compared to controls in 42% of C3GN patients, not all the serum samples responded to CFH. Future work may elucidate additional mechanisms of the continued ACP activation in C3GN patients and have implications for therapy of these patients.

Preexisting Autoimmune Dysregulation Unmasks a Role for Silica Dust Exposure in Nephrotrophic Autoantibody Production
LaNette Fee1, Robert M. Tighe,2,2 Mary H. Foster.1,2 Duke University, Durham, NC; 1DVMAC, Durham, NC.

Background: Pathogenic autoantibodies (autoAb) promote severe glomerulonephritis in ANCA vasculitis and lupus. Genetic susceptibility and environmental exposures, particularly inhalation of silica (Si) dust, are implicated in dysregulated autoreactivity and are targets for therapeutic intervention. Using a mouse reporter system expressing a regulated nephrotropic autoAb transgene (Tg) targeting basement membrane (BM) and instilling Si by oropharyngeal aspiration (OAP), we demonstrated that central B cell tolerance and anergy to BM are preserved in multiple lupus strains despite induction of lung inflammation and ectopic lymphoid tissue. Nonetheless, Si exposure increased local and systemic anti-DNA Ig levels in wildtype (WT) B6 and lupus mice, suggesting subversion of alternative regulatory checkpoints. Herein we leverage the aberrant M7 anti-BM Tg lineage that demonstrates partial escape from tolerance and evidence of glomerular Ig deposition to study the interaction of Si exposure with preexisting defects in autoreactive cell regulation.

Methods: M7 Tg mice (WT at Ig light chain, or LC, locus) were exposed to Si or vehicle (V) by OAP, organs harvested at 5-6 weeks, and cells cultured aToll-like receptor ligand (TLR-L). To restrict Ig specificity, a subset of mice (TgK) was bred to heterozygosity for the Vκ8.8/κ V8. Ig LC knock-in. Tg autoAb were measured by ELISA; mean OD±SD.

Results: Presence of serum Tg autoAb and induction of high levels of autoAb by TLR-L stimulated splenocytes (OD 2.61±0.49; TLR7/9, v 0.06±0.03; medium, p=0.0001) confirmed Tg phenotype, and bronchoalveolar lavage fluid cell counts confirmed exposure (237.1±130 vs 18±1.7, x1000, Si vs V, p<0.05). Among Tg WT mice, more autoAb were produced by TLR7/9-stimulated lung cells from Si vs V mice (OD 0.13±0.15, Si, vs 0.03±0.01, V, p<0.05), indicating that Tg B cells recruited by Si exposure contribute to local autoAb production. Among Si-exposed mice, Tg autoAb levels were higher in Tg vs Tg/Ki mice: OD 1.23±0.47 for TLR4-L stimulated splenocytes, Tg/Ki vs 0.51±0.43, Tg/Ki, p<0.05. Increased CFH was added to the serum of C3GN patients to test if CFH is capable of inhibiting the ACP in C3GN.

Conclusions: The method is rapid activated by the serum of C3GN patients compared to other kidney diseases and HC. Although the addition of CFH to the serum reduced the ACP activation compared to controls in 42% of C3GN patients, not all the serum samples responded to CFH. Future work may elucidate additional mechanisms of the continued ACP activation in C3GN patients and have implications for therapy of these patients.

**Characteristics of Membranous Nephropathy Patients with IgA and IgA Co-Deposits on Capillary Wall**

**Guan Yi, Qionghong Xie, Ruying Chen, Shaojun Liu, Lingyun Lai. Huashan Hospital Fudan University, Shanghai, China.**

**Background:** Membranous nephropathy (MN) is characterized by immune deposits on glomerular capillary wall, predominantly IgG. There have been several reports of MN combined with IgA nephropathy with features of IgA immunofluorescence staining in the glomerular mesangium. However, we found that IgA can also be deposited on the capillary wall with IgG. This study aimed to investigate the prognostic, clinical and renal histopathological characteristics of adult MN patients with IgA and IgA co-deposits on capillary wall.

**Methods:** A retrospective study was conducted in biopsy-proven MN patients of our renal department during January, 2007 to May, 2020. Clinical data were collected at time of biopsy and the latest followed-up. Pathological parameters included immunofluorescence staining, pla2 staining, membranous Chang’s stages, sclerosis, crescent, focal segmental sclerosis lesion, chronic tubulointerstitial injury and et al. Indirect immunofluorescence experiment was conducted in 293T cells transfected with pla2 plasmid.

**Results:** Out of 531 cases diagnosed with MN, 53 patients have moderate IgA deposit on capillary walls with IgG. 19 cases were determined to be secondary MN, which were 10 cases of autoimmune disease, 4 cases of Hepatitis B, 3 cases of kidney transplantation, 1 case of chemical exposure and 1 case of AL amyloidosis-associated secondary MN. 31 Idiopathic MN patients with both IgA and IgG depositing on capillary wall were followed up for a median interval of 49months (interquartile-range, 17-82) and 3 patients were transferred to stage 3 (6.5%) patients progressed to ESKD or death, 2 (6.5%) patients had their eGFR declined by half, 11 (35.5%) patients had no remission and 15 (53.6%) patients withdrew. 3 (9.8%) patients progressed to ESKD or death, 2 (6.5%) patients had their eGFR declined by half.

**Conclusions:** IgA and IgG could be co-depositing on glomerular capillary wall in MN patients, secondary causes should be screened with cation. IgA and IgG type of autoantibodies linked to MN co-existed in serum of idiopathic MN patients, whose prognosis might be poor.

**Humanistic Burden of Rare Kidney Diseases: Understanding the Impact of FSGS and IgAN on Patients and Caregivers: The HONUS Rationale and Study Design**

**Justyna Szklarzewicz. HONUS Advisory Board Members and HONUS Study Team University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.**

**Background:** While both Immunoglobulin A Nephropathy (IgAN) and Focal Segmental Glomerulosclerosis (FSGS) conditions have been shown to be associated with significant clinical and economic burden to healthcare systems, less is known about the humanistic burden associated with these diseases. Here we describe the Humanistic Burden of Rare Kidney Diseases: Understanding the Impact of FSGS and IgAN on Patients and Caregivers Study (HONUS), which aims to elucidate the impact of these conditions.

**Methods:** HONUS is being designed in consultation with patient and clinical community members at inception of study design, ensuring the right elements are informed decision making. For industry, data supports value assessments and ensures therapeutic options, but also has broader benefits. For patients and care-partners, insights into patient and caregiver burden, particularly in the context of disability or Quality-Adjusted Life Years (DALYS or QALYS), is commonly quantified in population health context as Disability- or Quality-Adjusted Life Years (DALYS or QALYS). Quantifying humanistic burden is foundational for value assessment of new therapeutic options, but also has broader benefits. For patients and care-partners, insights can validate and support individual experiences and coping. For patient advocacy groups, information can be used to raise awareness, facilitate education and develop resources for affected families. For the clinical community, evidence supports patient/ family communication, education of the broader clinical community and contributes to informed decision making. For industry, data supports value assessments and ensures the patient and care-partner voice is heard. This begins with engagement of patient and clinical community members at inception of study design, ensuring the right elements are included in the study, the design fits with the evidence generation goal, and results are disseminated in a comprehensive and useful way.

**Conclusions:** HONUS will provide evidence quantifying the humanistic burden of FSGS and IgAN from patient and care-partner perspectives.

**Funding:** Commercial Support - Travere Therapeutics

**Mystery Cryoglobulinemic Glomerulonephritis Treated with Rituximab**

**Mohamed Hassanein, Hanny Sawaf, Leal C. Herltitz, Michael Lioudis. Cleveland Clinic, Cleveland, OH.**

**Introduction:** Cryoglobulinemic Glomerulonephritis (GN) is characterized by the deposition of immunoglobulins (IG), also known as cryoglobulins (CG), in the kidney. We report a case of idiopathic mixed cryoglobulinic GN treated with rituximab and prednisone.

**Case Description:** A 42-year-old tri-athlete with a history of pediatric meningitis with hydrocephalus requiring placement of a ventriculoperitoneal shunt presented with lower extremity swelling limiting his ability to exercise. He denied non-steroidal anti-inflammatory drug and illicit drug use, and was not on any prescribed medications. Laboratory workup showed serum creatinine: 1.2 mg/dL (normal 0.7 – 1.2), serum albumin: 2.1 mg/dL (normal 3.9 – 4.9), CG: 140 mg/mL (normal 0 – 50), C3: 39 mg/dL (normal 86 – 166), C4: 7 (normal 13 - 46), and a urine protein to creatinine ratio (UPCR) 5.9 g/g. Kidney biopsy showed diffuse proliferative GN with polyclonal IG deposits consistent with mixed cryoglobulinic GN (figure 1). An infectious workup, including human immunodeficiency virus (HIV), viral hepatitis, blood and urine culture, and a lumbar puncture were unremarkable. Computed tomography of the chest, abdomen, and pelvis revealed splenomegaly. Echocardiogram and bone marrow biopsy were non-diagnostic. He was treated with rituximab and prednisone with normalization of CG, C3, and C4, a reduction in UPCR to 0.5 g/g and return to full exercise capacity five months later.

**Discussion:** Mixed cryoglobulinic GN is a rare disorder caused by polyclonal deposition of Ig in the kidney. Autoimmune disease, hematological malignancies, and infectious etiologies such as endocarditis, HIV, and viral hepatitis should be ruled out prior to immunosuppressive therapy. Our patient elected to proceed with treatment due to his poor quality of life and evidence of end-organ involvement. Although workup for hematological malignancies was unremarkable, it is unclear if his splenomegaly could be reflective of an underlying indolent lymphoma, which could have simultaneously responded to rituximab treatment.
Vancymycin-Induced Thrombotic Microangiopathy: A Rare Association
Gaurav Rajashekar, Anuja Java. Washington University in St. Louis Washington University in St. Louis, St Louis, MO.

Introduction: Thrombotic microangiopathies (TMAs) are life-threatening conditions characterized by hemolytic anemia, thrombocytopenia and AKI. Drug-induced TMA (DITMA) is a diagnostic challenge because specific tests to identify a drug etiology are not available.

Case Description: A 40 yr-old female with history of neurofibromatosis type 2 underwent resection of a T10-11 schwannoma. The surgery was complicated by wound dehiscence which was treated with incision and drainage followed by intravenous vancomycin and cefazolin. The next day, she developed fever, altered mental status and a diffuse purpuric rash (Fig 1). Labs showed anemia (Hgb 6.2 g/dl), thrombocytopenia (PLT 15 k/µL), elevated LDH and anuric AKI requiring dialysis. C3 and C4 were low. Coombs test was negative. She subsequently developed disseminated intravascular coagulation and elevated liver enzymes. Skin biopsy revealed a leukocytoclastic vasculitis with IgG and complement deposition within vessel walls. Given the concern for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Treatment with prednisone and plasmapheresis was initiated which led to improvement for DITMA versus thrombotic thrombocytopenic purpura, vancomycin was discontinued. Unfortunately, later during the hospitalization, she developed acute respiratory failure leading to cardiac arrest.

Discussion: This is a rare case of vancomycin-induced TMA. We speculate the mechanism is immune-mediated given the presence of low complement levels (although we did not test for vancomycin-dependent antibodies). Patients with immune-mediated DITMA present with sudden onset of severe systemic symptoms after a short exposure to the implicated drug. Greater awareness with improved methodology for diagnosis of DITMA is critical for clinicians evaluating such patients. Recognition of DITMA and documentation of the drug etiology are essential for patient safety.

Cryoglobulinemic Vasculitis in a Patient with Known Thrombotic Microangiopathy
Sanjay Gadi,1 Eugene P. Rhee,2 Veronica E. Klepeis,3 Janewit Wongboonsin.4
1Harvard Medical School, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA; 4Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Introduction: Acute kidney injury (AKI) is a ubiquitous presentation, but thrombotic microangiopathy (TMA) and cryoglobulinemia are uncommon causes that are not easily diagnosed. We highlight a case of AKI that was found to be cryoglobulinemic vasculitis, an unexpected diagnosis in a patient with history of TMA.

Case Description: A 68-year-old female was diagnosed with giant cell arteritis, with temporal artery biopsy showing inflammation of the adventitia consistent with small vessel vasculitis. She received prednisone and tocilizumab. 6 months later, she was admitted for hypertensive crisis with thrombocytopenia and schistocytes, with creatinine (Cr) elevation to 3.5 from baseline of 1.0. Renal biopsy showed TMA. Tocilizumab was discontinued. She was transitioned to eculizumab, eventually resulting in renal recovery (Cr 1.5) after 1.5 months. However, she continued to feel poorly and returned to the hospital, where she was found to have Cr 4.0. Physical exam was significant for hypertension and tender retiform purpura. Urine studies were consistent with cellular casts. Dermal biopsy showed dermal necrosis but no intravascular thrombi. Renal biopsy ultimately revealed cryoglobulin deposition, resulting in a diagnosis of cryoglobulinemic vasculitis. She was treated with prednisone, rituximab, and cyclophosphamide with good renal response, and discharged with Cr 2.4.

Discussion: The finding of cryoglobulin on this patient’s renal biopsy was subtle, causing a near-miss in her diagnosis. Her history and repeat clinical evidence of TMA further confounded her presentation. Therefore, when TMA is on the differential, workup should also evaluate for cryoglobulinemia. Her prior diagnosis of GCA also acted as a confounder, though absence of panarteritis and large vessel involvement on temporal artery biopsy may have hinted at underlying systemic vasculitis. While eculizumab is a standard therapy for TMA, there is limited evidence for its use in treating cryoglobulinemic vasculitis. This patient’s positive renal response to eculizumab supports the potential role of complement inhibitors in treating cryoglobulinemia. It remains possible that the patient could have had TMA and cryoglobulinemia concurrently, with renal biopsy during this presentation only capturing the latter. Therefore, further research into the role of complement inhibitors for cryoglobulinemia is needed.
POI1485

Minimal Change Disease as a Novel Manifestation of Cytomegalovirus
Andrew Lee, Hsiao L. Lai, Abdullah Thayyil, Reginald I. Obi. ECU Nephrology and Hypertension East Carolina University Division of Health Sciences, Greenville, NC.

Introduction: Cytomegalovirus (CMV) infection is typically asymptomatic among the immunocompetent or can cause a mononucleosis. Among immunosuppressed patients common presentations are colitis, hepatitis, encephalitis, retinitis and even Guillain-Barre syndrome. This case is a rare dissemination of CMV manifesting as acute glomerulonephropathy.

Case Description: A 67 year-old female with past medical history of lupus, rheumatoid arthritis, and Sjogrens syndrome on maintenance steroids presented with a prolonged cough, joint swelling, shortness of breath and rash consistent with livedo reticularis. She developed worsening weakness in the arms and legs. High dose IV steroids were initiated for presumed rheumatoid vasculitis. Nephrology was consulted for worsening renal function with urine protein to creatinine ratio of 42 g, later requiring hemodialysis for volume management. Work up for nephritic range proteinuria including hepatitis B/C, HIV, SLEP, UPEP, and complement screen was unrevealing. Renal ultrasound demonstrated an 11.7 cm right kidney and 14 cm left kidney. Renal biopsy demonstrated diffuse podocyte effacement and large atypical mononuclear cells within the glomerulus. No immune deposits seen on electron microscopy. Immunohistochemical staining confirmed glomerular CMV. Six weeks after starting treatment with ganciclovir and tapering steroids, CMV viral load was undetectable and renal function recovered to baseline.

Discussion: CMV involvement of the kidney is unusual aside from tubulointerstitial nephritis. Rare cases of collapsing glomerulopathy and focal segmental glomerulosclerosis are found in literature. We report a novel presentation of CMV glomerulonephropathy with minimal change disease and renal failure. To prevent tissue invasive CMV in a chronically immune suppressed patient one needs to maintain clinical suspicion for infectious pathogens and perform tissue biopsy.

POI1486

Minimal Change Disease Following the mRNA-1237 Vaccine in a Kidney Transplant Recipient
Juanly N. Rodriguez, Shobana Sivan, Mariella O. Goggins. University of Miami School of Medicine, Miami, FL.

Introduction: Kidney transplant recipients (KTR) are susceptible to post-transplant glomerulopathies. Minimal change disease (MCD) is seen rarely. Few cases have been reported post-immunization, recently with the Pfizer-BioNTech vaccine against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report a case of de novo MCD after mRNA-1237 vaccine in a deceased donor KTR, with a sudden onset nephrotic syndrome (NS) and acute kidney injury (AKI) a week after the first dose.

Case Description: 45-yr-old woman with history of ESKD from lupus nephritis, underwent DDKT on 09/2019 from a 20-yr Caucasian male, kidney donor profile index (KDP) 1. She was a Transplant Recipient (TTR) with mild membranous nephropathy on prior baseline. Her creatinine was 0.9 mg/dL but increased to 1.8 mg/dL within 2 months. She follows with maintenance prednisone. Her creatinine has stabilized to 1.4 mg/dL and urine protein to creatinine ratio (UPCR) 9.6 g/g, albumin 2.1 g/dl consistent with NS.

Discussion: This is a seropositive SARS-CoV-2 KTR from previous COVID-19 pneumonia who developed NS following mRNA-1237 mRNA vaccine. Biopsy consisted of MCD. Immunogenicity to mRNA vaccines in transplant recipients is blunted after the first dose but higher in seropositive patients. Timing from vaccine exposure to development of MCD ranges from days to months, our patient mounted an immune response in 4 days. The acute tubular injury seen in LM is atypical, unclear if this is a cell mediated process from allograft rejection or part of the pathogenesis post-immunization. In cases of AKI with NS, days to weeks following either class of mRNA vaccine a prompt initiation of steroids and further investigation with kidney biopsy is warranted.

POI1487

COVID-19-Associated Collapsing Focal Segmental Glomerulosclerosis During Pregnancy in a Woman with Lupus Nephritis
Ramchandani Santosh, Nye Aoyn, Sharon E. Maynard. Lehigh Valley Health Network, Allentown, PA.

Introduction: Lupus nephritis (LN) is a common clinical entity in patients with systemic lupus erythematosus (SLE). LN is classified on the basis of renal biopsy findings. We present a woman with a history of LN who was diagnosed with COVID and AKI during pregnancy. Kidney biopsy showed collapsing FSGS and class V LN with APOL1 gene mutation.

Case Description: A 32-year-old G4P0012 African American female presented to a multidisciplinary Nephrology Maternal-Fetal Medicine program at 12 weeks gestation for management of LN in pregnancy. She was diagnosed with SLE at age 8, previously treated with rituximab and belimumab for rash, and other extrarenal manifestations. Three years ago she was diagnosed with LN Class 3 + Class V treated with MMF with partial remission. She was switched from MMF to azathioprine at pregnancy diagnosis. She was diagnosed with COVID 4 days prior to the telemedicine office visit with GI symptoms and fever and admitted to the hospital. Her creatinine was 3.9 mg/dL, increased from the prior baseline of 1.3 mg/dl. Urinalysis showed proteurina, and 24-hour urine collection contained 13.6 grams of protein. Her renal function continued to worsen despite intravenous fluid administration. Laboratory results included anti-Ds DNA titer 1:80, C3 61 mg/dl (90-180 mg/dl), and C4 34 mg/dl (10 -40 mg/dl). Kidney biopsy revealed class V LN and FSGS potentially related to COVID. As per biopsy finding and ethnicity, we sent APOL1 genetic analysis which came back positive. Treatment was started with IV steroids. The creatinine peaked at 4.7 mg/dL on hospital day 8 and subsequently improved. She did not require RRT and was continued on her maintenance IS. Unfortunately, she had fetal demise at 18 weeks 3 days of gestation with stable renal function.

Discussion: This is a case of COVID-associated FSGS in a pregnant woman with a history of LN. The initial impression included prerenal azotemia, LN flare, and COVID-associated kidney injury. Serologies were consistent with an LN flare, but renal biopsy showed both class 5 LN and FSGS potentially related to COVID. Kidney biopsy should be considered in pregnant patients with hematuria, proteinuria, to rule out alternative etiologies, even when LN is suspected on clinical grounds. The threshold of RRT is very narrow in pregnancy and requires increasing dialysis frequency for adequate pregnancy outcomes.

POI1488

Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO) Syndrome and IgA Nephropathy
Jaye N. Cho, Grant Oakley,1 Gary DiPerna,2 Michael C. Akom.1 1 Maine Medical Center, Portland, ME, 2 Tufts University School of Medicine, Boston, MA.

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common form of glomerulonephritis (GN). It is characterized by IgA deposits within glomeruli, classically caused by poorly galactosylated immunoglobulin A1 that trigger autoantibodies. Other forms of IgA nephropathy include IgA vasculitis with nephritis (Henoch-Schönlein purpura) and secondary forms arising from chronic lower respiratory disease, chronic infections and neoplasms.

Case Description: Patient is a 50 year old female with anemia, hypothyroidism and chronic joint pain who presented for rising creatinine and hematuria. Baseline creatinine was 0.9 mg/dl, increased to 1.8 mg/dl within 2 months. She follows with maintenance IS. Unfortunately, she had fetal demise at 18 weeks 3 days of gestation with stable renal function.

Discussion: This is a seropositive SARS-CoV-2 KTR from previous COVID-19 pneumonia who developed NS following mRNA-1237 vaccine. Biopsy consisted of MCD. Immunogenicity to mRNA vaccines in transplant recipients is blunted after the first dose but higher in seropositive patients. Timing from vaccine exposure to development of MCD ranges from days to months, our patient mounted an immune response in 4 days. The acute tubular injury seen in LM is atypical, unclear if this is a cell mediated process from allograft rejection or part of the pathogenesis post-immunization. In cases of AKI with NS, days to weeks following either class of mRNA vaccine a prompt initiation of steroids and further investigation with kidney biopsy is warranted.

Kidney biopsy for IgA case depicting membranoproliferative pattern of glomerular injury in patient with SAPHO syndrome

PO1489
Crescentic Pauci-Immune Glomerulonephritis in a Patient with Sickle Cell Anemia and Cocaine Abuse
Marimar Contreras Nieves, Stanford Medicine, Stanford, CA.

Introduction: Levamisole is an anthelminthic agent and a common contaminant found in cocaine. It has been linked to ANCA-associated vasculitis with cutaneous, and more rarely, renal and pulmonary manifestations. This is the case of a patient with sickle cell anemia and cocaine abuse presenting with acute kidney injury (AKI) and nephrotic-range proteinuria in sickle cell anemia, return to baseline, which could have been due to his degree of kidney injury and ongoing crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy. He was evaluated for ANCA vasculitis. Pathology showed pauci-immune necrotizing and crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy. He was treated with pulse dose steroids and rituximab, followed by maintenance prednisone and additional doses of rituximab after discharge. His renal function improved, but did not return to baseline, which could have been due to his degree of kidney injury and ongoing cocaine use after discharge.

Discussion: This case demonstrates the importance of keeping a broad differential diagnosis in the evaluation of AKI and nephritic-range proteinuria in sickle cell anemia, particularly in the setting of cocaine use and its known association with vasculitis. A kidney biopsy was performed, with pathology showing a pauci-immune necrotizing and crescentic glomerulonephritis, transmural arteritis, and sickle cell nephropathy.

PO1490
A Case of Rapid Progressive Glomerulonephritis Associated with Disseminated Gonococcal Infection
Safa Osman, Nihal M. Ali, Pradeep Varilla, Franco H. Cabeza Rivera. The University of Mississippi Medical Center, Jackson, MS.

Introduction: Disseminated gonococcal infection (DGI) results from bacteremic spread of the sexually transmitted pathogen, Neisseria gonorrhoeae. Direct and immunological damage of multiple organs can be seen. We are reporting a case of sterile DGI with RPGN as part of the initial presentation.

Case Description: A 60-year-old male with a 5-year history of seronegative spondyloarthropathy, hypertension, heart failure, poor dentition who presented to the hospital with shortness of breathing, diarrhea, joint pain, and palpable purpura ongoing for several weeks. Work-up revealed severe anemia and rapidly progressive acute renal failure (Baseline creatinine unknown, peaked at 7.2 mg/dL on admission), urine showed 9.3 g of proteinuria, hematuria, and pyuria. Serological work-up showed low C3 with normal C4, ASO, ANA, ANCA and anti-GM. Negative HIV, hepatitis B, C, syphilis serologies, monoclonal and cryoglobulins. Skin biopsy showed leukocytoclastic vasculitis which improved with steroids. Kidney biopsy showed crescentic glomerulonephritis (GN) with 10% IFTA likely due to infectious GN (RPGN). Patient completed 3-day course of ceftriaxone but left before cyclophosphamide could be initiated. A week later he presented with persistent hematuria and oliguria. Echocardiogram showed tricuspid endocarditis and leaflet perforation. Blood cultures were negative. Patient started on vancomycin and Ropeschin for culture negative endocarditis. Extensive infectious disease workup, metagenomics test showed Neisseria gonorrhoeae as the cause of endocarditis. Kidney function improved. Due to disseminated GC and concern for complement deficiency, he was referred to Adult Immunology clinic.

Discussion: DGI is estimated to occur in up to 3 percent of patients infected with N. gonorrhoeae. The probability that a localized gonococcal infection will spread to joints and other tissues depends upon specific host, microbial, and possibly immune factors.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

RPNG is unusual presentation, the immunopathogenesis is uncertain but immunological and hypersensitivity damage is postulated based on the frequent lack of N. gonorrhoeae growth from blood, skin, and synovial fluid cultures during disseminated infection. Congenital or acquired complement deficiencies (C5, C6, C7, or C8) predispose to DGI as a result of decreased complement-mediated killing of N. gonorrhoeae.

PO1491
Proliferative Glomerulonephritis with Monoclonal IgM Deposits in ANCA Vasculitis
Rama Kethninen, Marc Barry, Monica P. Revelo Penafiel, Janame J. Kottey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNMID) is a rare entity of unclear etiology that can be occasionally associated with an underlying hematological malignancy. We report a case of PGNMID in a patient with ANCA vasculitis.

Case Description: A 78 yr old female with hypertension presented with a history of recurrent sinusitis over 6 months that was treated with steroids and antibiotics. She had progressive weight loss, fatigue, cough, and dyspnea. Chest X-ray was normal prompting a CT chest, which showed bilateral pulmonary nodules. Her creatinine was 0.96mg/dL. Urine analysis was notable for hematuria. Antineutrophil cytoplasmic antibodies were positive at 1: 640 with myeloperoxidase Abs IgG of 199. Serum protein electrophoresis showed a normal pattern with no monoclonal spike on immunofixation electrophoresis. Her Kappa/Lambda light chain ratio was normal at 1.04, infections were ruled out, and cryoglobulin was not detected. She was started on prednisone 60 mg and had a renal biopsy. Renal biopsy showed focal segmental necrotizing glomerular lesions, mesangial hypercellularity with deposition of IgM with lambda light chains restriction on immunofluorescence and occasional mesangial and subendothelial granular electron densities on electron microscopy. She was referred to hematology for concern with monoclonal gammopathy of renal significance and had a negative evaluation on serological tests, bone marrow biopsy and PET CT scan. She was treated with Rituximab. Her creatinine had remained stable with resolution of hematuria and respiratory symptoms.

Discussion: PGNMID is an immune complex glomerulonephritis that is occasionally associated with a hematological malignancy. The pathophysiology remains elusive and treatment can be challenging. We present a case of ANCA vasculitis with monoclonal IgM with light lambda chain restriction with an unusual association with ANCA vasculitis.
severe interstitial fibrosis and tubular atrophy indicating MPA. Patient was treated with pulse steroid and plasma pheresis initially, later received Rituximab. Patient improved clinically with therapy. Later, serum creatinine plateaued around 3.6 with eGFR 15.6 indicating patient’s CKD had progressed to advanced CKD stage 4/5.

Discussion: Though the presence of AAV is not common in MCTD, this case illustrates the importance of considering AAV for worsening pulmonary and renal function in overlap syndrome. Microscopic polyangiitis is one of the most common cause of pulmonary-renal syndrome, often manifested as diffuse alveolar hemorrhage and RPGN. Prompt diagnosis and early intervention can dramatically improve the patient outcome.

PO1493
Nephrotic Range Proteinuria due to ANCA-Associated Vasculitis in a Diffuse Systemic Sclerosis Patient: A Rare Presentation
Pranav Sharma, Steve I. Khalil, Jonathan Lebowitz. Rutgers University New Brunswick, New Brunswick, NJ.

Introduction: Scleroderma renal crisis (SRC) is a severe complication of SSC and typically presents with new-onset hypertension and a reduction in renal functioning. Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a rare co-occurrence with SSC. We present a rare case of diffuse systemic sclerosis who presented with features of SRC and AAV with nephrotic range proteinuria without significant renal failure.

Case Description: The patient is a 32-year old woman with diffuse systemic sclerosis complicated by pulmonary fibrosis who had been treated with Mycophenolate mofetil but she discontinued treatment in order to conceive. She reports having an uncomplicated pregnancy without proteinuria or hypertension, but she delivered 7 weeks early. After delivery, she began experiencing weakness of her lower extremities and was diagnosed with myasthenia gravis. She had been treated with intravenous immunoglobulin with partial response and received rituximab with full recovery. Several months later, she developed proteinuria and nephrotic range proteinuria. She was started on mycophenolate mofetil and azathioprine. After 6 months of treatment, she was on the waiting list for a renal transplant. She received a kidney from a deceased donor who developed glomerulonephritis secondary to G-CSF treatment.

Discussion: Clinicians should remain vigilant for concomitant autoimmune disorders in patients with scleroderma. In the background of systemic sclerosis, our patient developed AAV with neurologic and renal manifestations. Thus, renal injury, proteinuria or rapid onset of hypertension should not be assumed to be due to scleroderma renal crisis, particularly when there is nephrotic range proteinuria or an active urine sediment.

PO1494
Filgrastim-Induced ANCA-Associated Glomerulonephritis in the Presence of Membranous “Full House Nephropathy”
Ayial Angel-Korman, Adi Leiba,1 Assuta Ashdod Hospital, Ashdod, Israel; 2Harvard Medical School, Boston, MA.

Introduction: G-CSF is commonly used to stimulate progenitor cell collection for bone marrow transplantation. We present a seemingly healthy altruistic bone marrow donor who developed glomerulonephritis secondary to G-CSF treatment.

Case Description: A 34-year old man presented after altruistic bone marrow donation. During G-CSF treatment he developed headache, epistaxis, painless macrohematuria and AKI (creatinine -2.91mg/dL). Seven years and one year prior to this event he had similar presentations of macrohematuria, AKI and proteinuria. In between episodes he had persistent microhematuria. At this admission, Myeloperoxidase antibodies (MPO) were found to be elevated to 97 IU/ml. all other serologies were unremarkable. A kidney biopsy revealed glomerular inflammatory crescents (Figure 1). Capillary loop “spikes” were seen on silver staining (Figure 2). On immunofluorescence, there was a “full house” granular pattern. PL2AR and IgG4 stains were negative. Electron Microscopy revealed mainly subepithelial electron dense deposits. His current creatinine, without immunosupression, is 1.19 mg/dL.

Discussion: G-CSF induced ANCA associated glomerulonephritis developed on top of silent membranous “full house nephropathy”. Bone marrow donors should be asked about prior glomerulopathies and screened for proteinuria and hematuria before bone marrow donation is authorized.

PO1495
Ivermectin-Induced ANCA Vasculitis
Shuichi Pandey,1 Hemant Magode,1 Ashish Verma,1 Sudhir Perincheri,2 Saint Vincent Hospital, Worcester, MA; 2Yale-New Haven Hospital, New Haven, CT.

Introduction: Ivermectin is an antiparasitic agent that has demonstrated antiviral potential against HIV1, Dengue, Zika viruses and most recently, COVID-19. But the use of self-medication and off-label use for COVID prophylaxis in some countries is cause for concern. Here, we present what may be the first reported case of ANCA- associated vasculitis (AAV) from Ivermectin use.

Case Description: A 56-year male with no significant past medical history presented with dark urine, epistaxis, conjunctival redness, arthralgias, and malaise. His mother was on dialysis for the past few years for ESRD of unknown etiology. For several months, he had been taking Ivermectin imported from Peru for COVID prophylaxis per family advice. He was on no other medications. His creatinine, normal at baseline, was now 4.5mg/dL. He had hematuria, 3g/d proteinuria, dysmorphic RBCs and RBC casts. Serum C3, C4, ANA, anti-dsDNA, anti-GBM, hepatitis B&C screen, SPER&LUPE were negative. Atypical and p-ANCA were negative, but c-ANCA was 1:640. Kidney biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis. He soon developed pulmonary hemorrhages. Ivermectin was discontinued. He received prednisone 1mg/kg, 3 biweekly doses of intravenous cyclophosphamide, 10 doses of plasmapheresis, and was initiated on dialysis. Four weeks later, he has no epistaxis or pulmonary hemorrhages and is off oxygen. He does remain dialysis-dependent. Drug exposure can trigger ANCA formation against myeloperoxidase(MPO) and, less commonly, proteinase 3(P33). Drug-associated AAV can’t be discerned from primary AAV based on clinical and pathological findings. Clues suggesting drug-associated AAV include a temporal relationship of symptom onset with suspected drug, a high ANCA titer, and positive autoantibodies like elastase and lactoferrin. Drug-associated AAV has a better prognosis than its primary counterpart, with symptoms often resolving with drug withdrawal. Though this may not suffice in cases with pulmonary and renal involvement, outcomes in drug-associated AAV remain comparable even with shorter induction and often no maintenance regimens. Commonly implicated drugs are hydralazine, levamisole-contaminated cocaine, propylthiouracil, allopurinol.

PO1496
Presence of Membranous “Full House Nephropathy”
Angel-Korman,1 Adi Leiba.1 Assuta Ashdod Hospital, Ashdod, Israel; 2Harvard Medical School, Boston, MA.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

470
Although no case of Ivermectin-induced AAV has been reported, we recommend a high index of suspicion as prompt cessation of the offending drug can significantly improve prognosis in drug-associated AAV.

**PO1496**

Myeloperoxidase-ANCA and Takayasu Arteritis Overlap Syndrome Presenting as Rapidly Progressive Glomerulonephritis

Introduction: The spectrum of vasculitides is classified according to the size of the vessels involved and the clinical and histopathological findings. The simultaneous involvement of Takayasu arteritis and myeloperoxidase-ANCA vasculitis is extremely rare.

Case Description: A 12-year-old female with no previous medical history. In the last three years the patient developed lower limb claudication and unexplained intermittent fever. In recent weeks she developed edema and oliguria, she was admitted in another hospital where she was started on renal replacement therapy. Large vessel involvement was suspected so a contrast enhanced CT was ordered and was compatible with Takayasu arteritis. The patient was referred to our hospital for evaluation. During nephrology assessment she was found to have acute kidney disease with massive proteinuria (16 g/dL), so work up was directed towards rapidly progressive kidney disease. Percutaneous kidney biopsy was performed, and it revealed pauci-immune crescentic glomerulonephritis. ANCA and glomerular basement membrane antibodies were ordered, with a positive MPO-ANCA result. She was then started on IV methylprednisolone pulses and 5 cycles of plasma exchange therapy. After this, rituximab was started on a weekly basis. The biopsy was performed, and it revealed pauci-immune crescentic glomerulonephritis.

Discussion: This an extremely rare case which highlights the diagnostic and therapeutic difficulties in patients presenting with overlap clinical and serological features of different forms of systemic vasculitis.

**PO1497**

Granulocyte Colony Stimulating Factor-Associated Vasculitis: Adding Fuel to the Fire

Nilam Patel, Ahmed Siddiqui, Pravir V. Baxi. Rush University Medical Center, Chicago, IL.

Introduction: Granulocyte colony-stimulating factor (G-CSF) is commonly used with chemotherapy to stimulate bone marrow production and prevent neutropenia. Although usually well tolerated, G-CSF can exacerbate underlying autoimmune diseases with the development or progression of glomerulonephritis (GN). We present a case of pauci-immune necrotizing GN that developed in a patient with rheumatoid arthritis (RA) after receiving G-CSF therapy.

Case Description: A 61 y/o man with ampullary adenocarcinoma and RA without prior renal involvement presented with AKI. One week prior to admission he had received G-CSF therapy. His creatinine (Cr) was 4.8 mg/dL from a baseline of 0.9 mg/dL. His urinalysis was notable for hematuria and urine protein-creatinine ratio (UPC) of 5.2 g/wk. Workup showed: +p-ANCA (1:320), + anti-histone Ab, + SSA and + ANA (1:1280 speckled pattern). A renal biopsy revealed necrotizing GN with crescents or crescents in 75% of the glomeruli. There was no evidence of immune deposits/c pauci-immune GN. He received steroids and rituximab for induction. His Cr peaked at 6.0 mg/dl but improved down to 1.1 and UPC improved to 0.6 g/wk after 3 months.

Discussion: G-CSF is used to prevent neutropenia and reduce infection risk by activating mature neutrophils and preventing neutrophil apoptosis. G-CSF can also have inflammatory effects including the release of proinflammatory cytokines and tissue infiltration by activated neutrophils with the potential of end-organ damage. In patients with preexisting GN or an autoimmune disease (e.g. RA, SLE), G-CSF administration can exacerbate or even initiate a de-novo GN. Pauci-immune GN is a rare but well established complication of RA. In our case, the almost immediate temporal relationship between the development of the GN and the G-CSF administration supports G-CSF as etiologic. This case demonstrates the importance of considering the possible renal complications and need for close monitoring while giving G-CSF in patients with autoimmune diseases.

Pemphigus Vulgaris and PLA2R-Associated Membranous Nephropathy: Two IgG4-Related Diseases in the Same Patient
Camila L. Costa,1 Matheus R. Correia,2 Luis H. Sette,2 Denise M. Costa,3 Camila B. Oliveira,2 Maria Alina G. Cavalcante,3 Lucila Maria Valente,3 Giselle Vajgel,3 1Hospital dos Servidores do Estado de Pernambuco, Recife, Brazil; 2Hospital Getulio Vargas, Recife, Brazil; 3Universidade Federal de Pernambuco, Recife, Brazil.

Introduction: The relationship between bullous skin diseases and glomerulopathies has been increasingly recognized. Other bullous diseases were previously reported in association with membranous nephropathy (MN), but the association between pemphigus vulgaris (PV) and MN has not been reported in the literature yet.

Case Description: A 39-years-old smoker woman presented with trunk blisters and worsened mouth ulcers after stopping the treatment for MN. One year before, she had nephrotic syndrome and the kidney biopsy was positive for anti-PLA2R and IgG4 (and negative for THSD7A) in the immunohistochemistry (IHQ). Serum anti-PLA2R was negative. Four months earlier she was started on cyclopentone, but stopped it due to mouth ulcers. She had nephrotic range proteinuria, no edema, when the painful blisters spread out on the trunk, back, limbs, scalp as well as ulcers in the oral cavity and esophagus. The diagnosis of PV was confirmed by skin and esophagus biopsy and IHQ showed the presence of IgG4 subclass antibody in the epithelial tissue. She received pulse and oral steroids along with azathioprine for the PV. The skin lesions were slowly healing and no more new blisters have appeared.

Discussion: The humoral auto-immune response in pemphigus produces anti-desmoglein 1 and 3, both IgG4. Desmogleins are responsible for adhesion in stratified squamous epithelia, when damaged produces to the blistering eruptions. There is a genetic predisposition between PV and MN, with HLA-DQA1, HLA-DRB1 and the thrombospondin gene (THSD7A). Environmental factors such as smoking and air pollution could act as a second trigger for the development of auto-immune diseases. PLA2R can be expressed in the bronchiolar tissue and in macrophages of the lung, however there is no evidence of histological damage in the pulmonary tissue. Although we found no description on the expression of PLA2R in the skin, in an attempt to find a common antigen for both diseases, we did search for anti-PLA2R in the skin, but it was negative. In conclusion, this is the first described case of association of pemphigus vulgaris and PLA2R-associated MN, both IgG4-related conditions that involve the production of different autoantibodies directed to skin and kidney antigens.

POI1501

A Case of an Elderly Woman with Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits Whose Renal Biopsy Revealed Renal Cell Carcinoma

Introduction: Membranous-like glomerulopathy with masked monoclonal IgG deposits (MGIMD) is a recently described form of glomerulopathy with a unique histopathology reported by Larsen et al. The pattern is characterized by subepithelial and/or supramembranous deposits that are “masked,” to immunoglobulin staining by routine immunofluorescence but strongly stained for IgG and kappa light chain after protease digestion. Patients with MGIMD are commonly young females and have a vague history of autoimmune diseases such as low titer antinuclear antibodies.

Case Description: A 65-year-old woman was referred to our hospital with urinary protein (0.80 g/gCr) and microscopic hematuria. Serum antinuclear antibody, rheumatoid factor, and M-protein were negative and serum C3 and C4 were normal. Plain CT showed no evidence of hepatic and ymphatic systems. Image 1 shows giant cells on PAS. She was started on prednisone 40 mg daily and azathioprine for PV. The skin lesions were slowly healing and no more new blisters have appeared.

Discussion: The humoral auto-immune response in pemphigus produces anti-desmoglein 1 and 3, both IgG4. Desmogleins are responsible for adhesion in stratified squamous epithelia, when damaged produces to the blistering eruptions. There is a genetic predisposition between PV and MN, with HLA-DQA1, HLA-DRB1 and the thrombospondin gene (THSD7A). Environmental factors such as smoking and air pollution could act as a second trigger for the development of auto-immune diseases. PLA2R can be expressed in the bronchiolar tissue and in macrophages of the lung, however there is no evidence of histological damage in the pulmonary tissue. Although we found no description on the expression of PLA2R in the skin, in an attempt to find a common antigen for both diseases, we did search for anti-PLA2R in the skin, but it was negative. In conclusion, this is the first described case of association of pemphigus vulgaris and PLA2R-associated MN, both IgG4-related conditions that involve the production of different autoantibodies directed to skin and kidney antigens.

polycyclonal increase in gamma globulins. It is likely that in some patients with lupus, B cell regulation becomes impaired in a way that allows a clonal, but not necessarily neoplastic, an expansion that results in increased production of paraproteins, leading to MGUS. This case adds to the literature showing that there indeed may be an association between MGUS and lupus.

**PO1504**

**Bartonella Henselae Infective Endocarditis (BHEIE): A Rare Cause of Pauci-Immune Necrotizing GN (PINGN)**

**Muhammad A. Shahzad, Aji Purohit, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.**

**Introduction:** Bartonella is the commonest cause of culture negative endocarditis. While, infection Related GN (IRGN) can mimic pauci-immune vasculitis, the majority of cases of BHE have been immune complex (IC) mediated. We present a case of BHE related PINGN. Timely recognition of this atypical presentation led to appropriate medical therapy.

**Case Description:** A 33 yo M with HIV on HAART and recent tooth extraction was admitted with a severe headache due to a sub arachnoid hemorrhage from a ruptured right anterior cerebral artery mycotic aneurysm. TEE showed a vegetation on the aortic valve (AV). Blood cultures were negative. Initial SCR was 3.3 mg/dl and urinalysis had 2+ protein, 3+ blood with 29 RBC/hpf and a UPro/Cr ratio was 1.7 g/g. The C4 was low (10.2 mg/dL) and PR3-ANCA elevated-4.0 (NL <3 .5 U/mL). The Bartonella henselae IgG titre was elevated 1.56 (NL <1.320). Renal biopsy revealed pauci-immune necrotizing GN (Figure) with no evidence of IC deposition. BHE associated PINGN was diagnosed and treatment with doxycycline, ceftriaxone and gentamicin initiated. The AV was replaced and was positive for BH by PCR. After a prolonged course of antibiotics the SCR improved to 2.5 mg/dl.

**Discussion:** B henselae associated GN is a rare cause of PR3-ANCA positive GN with only 6 cases previously reported. By immunofluorescence, 4 cases were immune complex deposition involving glomeruli, and arteries. Mass spectrometry performed at Mayo Clinic Laboratories confirmed renal involvement by Amyloidosis, AA (serum amyloid A Abs, meeting criteria for DM. Patient continued eculizumab. Within 7d, LDH decreased to 772, haptoglobin increased to 79 and platelets normalized. Further workup revealed elevated creatine kinase 1,271 U/L, aldolase 17 U/L, AST 566 U/L with normal ALT and positive anti-MDA5 and transcription intermediary factor-1-gamma (TIF-1-γ) Abs, meeting criteria for DM. Patient continued eculizumab and prednisone. Eventually developed invasive aspergillosis and expired.

**Discussion:** We report a case of STE-DM overlap with anti-MDA5 and TIF-1γ Abs complicated by aHUS and severe hypocalcemia in the setting of pancreatitis. The cutaneous manifestations and typical of MDA5-associated DM. Due to the risk of developing intestital lung disease, exemplifying range of variation from case to case. The presence of anti-TIF-1γ confers a 6-fold increased malignancy risk; finding of omental nodularity in this case would warrant further investigation. aHUS as a complication of SLE-DM overlap is rare, with mortality risk up to 52%. AKI, infection and low C3 are associated with highest mortality. Prompt diagnosis, high clinical suspicion and early initiation of eculizumab resulted in a rapid response.

**PO1506**

**Anti-LRP2 Nephropathy in a Patient with Chronic Lymphocytic Leukemia**

**Derek Tran, Chien-Wen Yang, Avantika Israni, Abdollah Sassine Garea, Al J. Lee, St Mary Medical Center, Longhorne, PA; Penn Medicine, Philadelphia, PA.**

**Introduction:** Anti-LRP2/anti-Brush Border nephropathy is a newly identified autoimmune tubulo-interstitial nephritis triggered by circulating antibodies to low-density lipoprotein receptor-related lipoprotein 2 (LRP2). We present a case of anti-LRP2 nephropathy in a patient with chronic lymphocytic leukemia (CLL).

**Case Description:** A 74-year-old Caucasian male patient known to have CLL presented following a fall with a forearm laceration. At presentation, he had acute renal failure (Scr of 5.04 mg/dL) and severe thrombocytopenia (platelets of 11,000/uL).

**Additional Evaluation showed positive ANA and p-ANCA. The patient had proteinuria of 1754 mg/g creatinine. The kidney biopsy showed moderate interstitial fibrosis and tubular atrophy involving 30-40% of the renal cortex. The tubular epithelium showed reactive-appearing nuclei as well as cytoplasmic thinning with loss of the proximal tubular brush border. Immunofluorescence showed IgG (3+ and C3 (3+)) for the glomerular capillary and the TBM. There was focal staining of the brush borders by IgG with positive LRP2 stain in the TBM. Electron microscopy revealed numerous subepithelial electron-dense deposits. The serum anti-LRP2 antibody titer was 1:100. The patient was started on dexamethasone and rituximab with improvement of the thrombocytopenia. Plasmaphenesis was prescribed for 5 sessions, the creatinine continued to worsen (Scr of 7.37 mg/dL), and the anti-LRP2 titer did not improve. The patient is being transitioned to renal replacement therapy.

**Discussion:** The mechanism that links the ABBA disease with lymphoproliferative disease is still unknown. The current reported cases suggest an association between direct lymphoma renal infiltration, progression of the lymphoproliferative disease and the presence of the ABBA disease. However, in our reported case, the patient’s underlying CLL was stable without evidence of renal infiltration. The poor response to treatment in this case is consistent with the poor outcomes of many anti-LRP2 reported cases. The renal biopsy on this patient also showed membranous glomerulonephritis. We presented a case with anti-LRP2 nephropathy/ABBA disease with concurrent CLL without evidence of CLL infiltration which is typical of poorly to immune responsive therapy and the prognosis of ABBA associated paraneoplastic syndrome with underlying CLL warrants future investigation.

**PO1507**

**Black Tar Heroin and AA Amyloidosis**

**Rama Kethineni, Monique E. Cho, Monica P. Revelo Penafiel, Olesya Ilkun, Janame J. Kottee, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.**

**Introduction:** AA amyloidosis due to deposition of serum amyloid A protein occurs as a secondary reaction to chronic inflammatory disease, chronic infections, and familial period fever syndromes. We present a case of AA amyloidosis secondary to chronic black tar heroin use in the Intermountain West.

**Case Description:** A 61 yr. old Caucasian female with a history of Hepatitis C, IV Heroin use presented with bilateral leg pain, swelling, and abdominal distension. Examination was significant for ulceration in lower extremities with purulent discharges. Nebulized lab data include Hemoglobin of 8.2 g/dl, potassium of 10.6 mg/dl, BUN of 90 mg/dl, creatinine of 2.9 mg/dl, serum albumin of 2.1 g/dl, and ESR of 129 mm/hour. She had a urine protein to creatinine ratio of 12.3 g/g. Abdominal US revealed enlarged liver and normal renal echogenicity. The quantification of HCV RNA by polymerase chain reaction was negative, and her complement levels were within normal range. Cryoglobulin was also negative with a kappa/lambda light chain ratio of 1.33. Serum protein electrophoresis showed decreased albumin and immuno fixation electrophoresis showed a faint band in IgG kappa suggestive of a specific immune response. A TBM was obtained and showed non-AL amyloid deposition involving glomeruli, and arterries. Mass spectrometry performed at Mayo Clinic Laboratories confirmed renal involvement by Amyloidosis, AA (serum amyloid A)-type.

**Discussion:** “Black tar heroin” has increasingly been identified as a risk factor for AA Amyloidosis. Impurities in heroin promote vascular sclerosis and lead to the use of injection into muscle and skin. The suppurative infections that follow stimulate
the production of serum amyloid A protein with subsequent deposition in the kidney leading to nephritic syndrome and end stage kidney disease. Greater awareness of this complication may help prevention in areas with increased black tar heroin use. leading to nephrotic syndrome and end stage kidney disease. Greater awareness of this complication may help prevention in areas with increased black tar heroin use.

**Discussion:** Proteinuria is one of the lesser known side effects of statin therapy. It was not well described in the clinical development programme for Rosuvastatin, where it was found that the 80 mg dose caused proteinuria in 12% of patients. Furthermore, a comprehensive review of the renal effects of rosuvastatin, found that 1.2% of patients taking 40 mg of rosuvastatin developed 2+ proteinuria, and 0.3% developed 2+ proteinuria and 1+ hematuria. Our case highlights a rare manifestation of Rosuvastatin induced urinary abnormalities, which improve after stopping the drug. This should be kept in mind for patients on Rosuvastatin with negative workup for proteinuria and hematuria, before a renal biopsy is pursued.

**PO1510**

Rituximab for Membranous Nephropathy in a Patient with Sjögren Syndrome and Mixed-Connective Tissue Disease

**Joshua D. Pollock,** Maurice I. Khayat. Madigan Army Medical Center, Tacoma, WA.

**Introduction:** Membranous nephropathy (MN), a cause of nephrotic syndrome, is characterized by the deposition of immune complexes in the glomerular basement membrane with resultant subepithelial “spikes” visualized under light microscopy. Although often a primary disease process, several secondary etiologies exist, including Sjögren’s syndrome (SS) and mixed-connective tissue disease (MCTD). Treatment typically targets the underlying condition. Despite rituximab’s demonstrated efficacy in MN, MCTD and SS, case reports for specific treatment of MN secondary to these conditions have primarily described regimens of systemic corticosteroids with or without cyclophamide.

**Case Description:** A 54-year-old male was diagnosed with MN on renal biopsy in 2001. Multiple features suggested a secondary etiology (tubulointerstitial, mild to moderate proteinuria, negative ANCA, and circulating cryoglobulins). Rituximab 1000 mg on day 1 and 0 was administered, with partial remission noted 4 months following therapy. Complete remission was achieved 8 months following therapy and has been sustained for 13 months. His extrarenal symptoms of MCTD and SS have also resolved.

**Discussion:** Rituximab is a well-described treatment for primary MN, MCTD and SS. However, there is a paucity of literature evaluating its use in MN as the specific renal manifestation of MCTD and SS. This case illustrates the potential role for rituximab as an effective treatment for membranous nephropathy secondary to SS and MCTD when deciding on immunomodulatory therapy. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

**PO1511**

A Rare Case of Concurrent Glomerulonephritis and Autoimmunity

**Introduction:** We report a rare case of necrotizing and crescentic glomerulonephritis in the setting of Streptococcus mitis bacteremia.

**Case Description:** A sixty-one year old man with a history of hypertension, hyperlipidemia, and non-insulin-dependent diabetes presented to the emergency room with progressive lower extremity edema and dyspnea with tea-colored frothy urine. Hyperlipidemia, and non-insulin-dependent diabetes presented to the emergency room with progressive lower extremity edema and dyspnea with tea-colored frothy urine. Initial workup revealed bilateral pulmonary edema and acute kidney injury with a serum creatinine of 1.84 mg/dL (0.8 mg/dL 6 months prior) with 9.18 grams proteinuria and an active urine sediment. He was initially diuresed for decompensated heart failure but further workup revealed hypocomplementemia and positive ANCA/antineutrophil cytoplasmic antibody (PANCA/ANCA). A kidney biopsy revealed membranous glomerulonephritis (MGN) with focal endocapillary proliferative features and focal crescents with fibrinoid necrosis with positive PLAX2 immunostaining and serum PLAX2 IgG antibody testing revealing a titer of 1:2560. An echocardiogram revealed reduced left ventricular ejection fraction with a new aortic valve vegetation. Blood cultures obtained on admission ultimately grew Streptococcus mitis and he underwent aortic valve repair. Despite completion of a full antibiotic course, his creatinine remained impaired with nephrotic-range proteinuria and elevated serum PLAX2 titers. Repeat renal biopsy revealed membranous glomerulonephritis and he was started on immunosuppression with treatment of PLAX2-associated MGN.

**Discussion:** Peri-infectious PLAX2-associated MGN and ANCA-associated glomerulonephritis appears to be a rare. While its pluriactive ANCA-mediated glomerulonephritis was likely related to the infectious endocarditis, the relationship to the PLAX2-positive MGN remains unclear. We hypothesize that host immune response to infectious agents lead to an autoimmune process resulting in glomerulonephritis. It is possible that in addition to a genetic predisposition (“first hit”), a “second hit” which begins with activation of the innate immune response by an infectious agent leading to autoimmunity through various mechanisms including defective immune regulation, molecular mimicry, epitope spreading, and autoantigen complementarity.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**
Introduction: Deficiencies in the classical complement pathway have been associated with the development of systemic lupus erythematosus (SLE) and lupus-like disease in 10-20% of affected patients. In fact, SLE patients deficient in classical complement present at an earlier age, with severe manifestations and a worse prognosis. Several mechanisms have been described to explain these immune phenomena including impaired clearance of immune complexes, impaired handling of apoptotic cells, or changes in regulation of cytokines. Here, we present a case of a young female with ANA-negative lupus presenting with dyspnea and acute renal failure responsive to immunosuppressive therapy found to have C2 Complement deficiency.

Case Description: A 44-year-old female with sickle cell trait, ANA-negative SLE, ESRD due to biopsy-proven class IV lupus nephritis briefly requiring HD, pulmonary HTN, presented with signs of fluid overload, acute on chronic renal failure in the setting of malignant hypertension. Labs revealed thrombocytopenia of 52 with a creatinine of 2.66 (prior 1.61), hypocoomplementemia and undetectable CH50 levels concerning for acute flare of SLE and an underlying functional complement deficiency. Low C3 and C4 were confirmed. Peripheral smear with schistocytes raised concerns for microangiopathy. Hospital course was complicated by encephalopathy and possible CNS involvement of lupus. Renal biopsy confirmed chronic sclerosing immune complex glomerulonephritis with minimal activity. The patient responded well to high dose corticosteroids, plasma exchange and mycophenolate mofetil. Final serology confirmed persistent C2 complement deficiency.

Discussion: There is a well-studied link between immune-complex mediated disease and complement deficiency. Of these, C2 deficiency is the most common. In our case, a C2 deficiency was found in the setting of ANA-negative SLE with severe clinical manifestations. Our case raises the question of whether testing to exclude underlying complement deficiency is particularly indicated in patients with ANA-negative SLE. It also remains to be seen whether clinical manifestations of microangiopathy are prevalent in these patients, and whether therapeutics targeting complement may be effective in their treatment.

PO1515

Hydralazine-Induced ANCA Vasculitis and Lupus Nephritis

Ankita Ashoka, Golnaz Vahdati, Waseem Albasha, Erika R. Bracomonte, Preethi Subramaniam, Iyad S. Mansour, Amy Yaa. Banner University Medical Center Tucson, Tucson, AZ.

Introduction: Hydralazine is a common antihypertensive drug, but drug induced glomerulonephritis (DI-GN) is observed in 5-10% of the population on hydralazine after three years of therapy. We present a case of rapidly progressive glomerulonephritis due to hydralazine.

Case Description: 65-year-old female with a history of hypertension, diabetes mellitus, and chronic kidney disease presented for altered mental status. Her serum creatinine (SCr) three months and two years prior were 2.3 mg/dL and 0.9 mg/dL respectively. On presentation, her SCr was 12.7 mg/dL, and she was started on hemodialysis. During her hospitalization, she had persistent hemoptysis with worsening dyspnea, skin rash, HTN, and acute renal failure. Kidney biopsies were performed, which revealed lupus nephritis, low complement levels, negative histone antibody and ANCA titers, and negative double stranded DNA antibody (Table 1). Skin biopsy showed small and medium vessel vasculitis. Kidney biopsy revealed class 5 lupus nephritis with full house immunofluorescence staining and active cellular crescents (Fig 3). Review of her medications included hydralazine 25 mg three times a day for three years, and she was diagnosed with hydralazine induced glomerulonephritis and systemic vasculitis. She was given pulse steroids and cyclophosphamide with improvement in extrarenal manifestations, but no renal recovery.

PO1514

Postinfectious Glomerulonephritis Complicated by Complement-Positive Coombs Autoimmune Hemolytic Anemia

Elizabeth A. Armstrong, Christian Hanna, Mary E. Fidler, Cheryl L. Tran. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Postinfectious glomerulonephritis (PIGN) is the most common cause of GN in children. Mild normocytic anemia is often noted during the acute illness and is usually thought to be secondary to hemolysis from fluid overload and/or depressed erythrocyte production. Here, we describe a case of PIGN and autoimmune hemolytic anemia in a pediatric patient.

Case Description: A 3-year-old girl presented with 5 days of gross hematuria, fatigue, and decreased urination. Laboratory evaluation revealed elevated potassium at 5.4 mmol/L (normal range 3.6-5.2 mmol/L), creatinine 3.04 mg/dL (0.19-0.49 mg/dL), and blood urea nitrogen 98 mg/dL (7-20 mg/dL), low hemoglobin (Hb) 8.4 g/dL (11.4-14.3 g/dL) and normal platelet count. Urinalysis showed numerous red blood cells (RBCs) and nphoretic range proteinuria. Bilirubin, lactic dehydrogenase, and haptoglobin were normal. Direct antiglobulin test (DAT) was positive for monospecific C3, and negative for IgG. Peripheral blood smear revealed mild RBC polychromasia and occasional hemolysis and Poikilocytosis. Several hours after admission, her Hb dropped acutely to 6.3 g/dL requiring blood transfusion. Complement proteins C3 and C4 were low at <6 mg/dL (75-175 mg/dL) and 5 mg/dL (14.40 mg/dL), respectively. DNase-B Antibody was normal and dsDNA antibody was negative. A kidney biopsy revealed findings consistent with PIGN (Image 1). She received acute hemodialysis for the first 48 hours after admission for worsening hyperkalemia, uremia, anemia, and edema. Her Hb remained stable and did not require additional blood transfusions.

Discussion: Our case of concurrent PIGN and autoimmune hemolytic anemia is exceptionally rare. This unique association may explain the anemia that is often seen in PIGN. We suggest that PIGN cases with anemia should have a DAT performed.
PO1516

Chicken or the Egg Causality Dilemma: Primary ANCA Vasculitis Complicated by Infective Endocarditis (IE) vs. IE Leading to ANCA Vasculitis

Benjamin P. Catanese, Ayesha Anwar, Shuchi Anand. Stanford Health Care, Stanford, CA.

Introduction: As the cases of infective endocarditis increase in the United States it is important to recognize the associated complications. Glomerulonephritis is a well-recognized but not fully understood consequence. Immune complex deposition is the most common etiology but ANCA-mediated kidney injury is increasingly described and even less understood.

Case Description: A 65 year old male presented with acute onset dysarthria, left facial droop, left sided weakness, and dizziness. 5 months prior he was diagnosed with PR3+ ANCA vasculitis after presenting with 18 lbs weight loss, purpura, anemia, hematuria and sub nephrotic proteinuria. He was treated with methotrexate and a steroid taper, which finished one week prior to the current presentation. Admission vitals were: 145/74 mmHg, heart rate of 90 bpm, afibrile, and 100% oxygen saturation on room air. Lab work revealed: hemoglobin of 10.7 K/uL, creatinine of 1.17 mg/dl (baseline 0.9), low C3: 81 mg/dL, positive PR3 (>8.0), negative c-ANCA (1:128), negative MPO and p-ANCA, and UA: 3+ blood, negative protein, and 11-20 WBC. MRIs of the brain and heart revealed numerous acute and subacute infarcts and severe mitral regurgitation respectively, concerning for small vessel vasculitis, and he was started on high dose steroids. Discovery of streptococcus mutans bacteremia was a surprise. Suspicion was raised that the ANCA vasculitis may have been a consequence of underlying sub-acute endocarditis rather than a primary disease hence a kidney biopsy was planned and he was discharged on steroids and IV antibiotics. Kidney biopsy confirmed the diagnosis of ANCA-mediated endocarditis-associated glomerulonephritis with the presence of glomerulosclerosis with fibrocellular/fibrous crescents, segmental fibrinoid necrosis but no obvious immune deposits on light microscopy. Granular deposits in the mesangial and capillary wall stained for C3, IgM, IgA, kappa and lambda. He underwent 6 weeks of ceftriaxone and mitral valve replacement. His renal function is mildly impaired; he is recovering neurologically.

Discussion: Endocarditis-associated GN typically requires treatment of the underlying infection without immunosuppression, but when the injury is primarily ANCA-mediated, this presents a unique challenge in that end-organ damage from vasculitis may not improve without immunosuppression.

PO1517

Crescentic Glomerulonephritis in Sjögren Syndrome

Jake N. Cho,1,2 Danielle Janison,3 Grant Oakley,1,2 Gary DiPerna.1 1Maine Medical Center, Portland, ME; 2Tufts University School of Medicine, Boston, MA; 3Maine Nephrology Associates PA, Portland, ME.

Introduction: Sjögren’s syndrome (SS) is an inflammatory autoimmune disorder involving the parotid, lacrimal and salivary glands causing sicca syndrome. Kidney involvement is variable and most often results in tubulointerstitial nephritis. Glomerular disease is infrequent with MPGN and membranous nephropathy being most prevalent pathologically.

Case Description: Patient is a 21 year old female with SS, hypothyroidism and asthma who was being evaluated for fever and fatigue. Lab evaluation revealed acute kidney injury (AKI) with creatinine rising from 1.0 to 1.8 mg/dL over several weeks. Echocardiogram was concerning for mobile echodensity at the tricuspid valve, but transesophageal echo showed no abnormalities and evaluation for infection was negative. CT showed extensive prominent lymph nodes in the chest, abdomen, and pelvis but lymph node biopsy showed benign reactive hyperplasia without neoplasm. Renal ultrasound showed normal sized kidneys. Urima persuasive for the presence of granulomatous inflammation and sediment revealed dysmorphic RBCs. She was started on high dose prednisone and hydroxychloroquine for possible lupus nephritis but due to diagnostic uncertainty and unresolved AKI, kidney biopsy was performed.

Discussion: Kidney biopsy demonstrated plasma rich interstitial nephritis with severe tubulitis consistent with SS. Interestingly, the biopsy showed 3 active cellular crescents out of 21 glomeruli with focal crescentic GN. Tubulointerstitial nephritis is the most common renal pathology in primary SS leading to renal tubular acidosis, impaired concentrating ability and proximal tubule defects. GN in SS is rare but has been associated with membranoproliferative GN, membranous nephropathy and cryoglobulinemic GN. Crescentic GN was unexpected and the treatment plan was adapted to taper the prednisone, start on Mycophenolate Mofetil and trial on Rituximab.

Light microscopy for renal biopsy of Sjogren’s case depicting interstitial nephritis and crescentic glomeruli
**PO1519**

**Unmasking a Case of Membranous-Like Glomerulopathy with Masked IgG-κ Deposits**
Alissa Lec, Darren W. Barefield. Louisiana State University Health Sciences Center, Baton Rouge, LA.

**Introduction:** Membranous-like glomerulopathy with masked IgG-κ deposits (MGMID) is a recently described, exceedingly uncommon entity of glomerular immune-complex deposition requiring antigen retrieval on formalin-fixed paraffin-embedded tissue. We report a rare case of MGMID in a young female with newly diagnosed APLA.

**Case Description:** An 18 year old female with no medical history presented with left leg swelling. Vital signs were normal and an enlarged, discolored left lower extremity was appreciated on exam. Initial laboratory results were remarkable for Cr 0.78 mg/dL, albumin 2.3 g/dL, platelets 128,000/µL, PTT 87.1 s, INR 1.02, and hematuria and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PLA2r, complements, hepatitis serologies, ANA, ANCA, A1C, SPEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

**Discussion:** Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.

**Figure 1: Pathology**

Positive SAA staining

---

**PO1520**

**A Case of Secondary Renal Amyloidosis Associated with HIV**

**Introduction:** Secondary amyloidosis is known to be associated with multiple chronic infections and inflammatory conditions including rheumatoid arthritis, inflammatory bowel disease, systemic lupus erythematosus, and tuberculosis. HIV has not yet been established as a known association. We present a case of secondary amyloidosis associated with well-controlled HIV with no history of other potential etiologies.

**Case Description:** A 71-year-old man with hypertension and well-controlled HIV for 40 years (viral load undetectable and last CD4 917) was referred to the renal clinic for acute kidney injury and heavy proteinuria. He had complained of leg swelling and foamy urine. Spot urine protein:creatinine ratio was 10 and albumin was 1.6 mg/dL. The creatinine had slowly risen over several months from 0.9 mg/dL to a plateau of 1.8. Serologic work-up was unrevealing; PLA2r, complements, hepatitis serologies, ANA, ANCA, A1C, SPEP, immunofixation, and free light chains were all normal. Renal biopsy demonstrated amorphous deposits throughout the glomeruli which stained positive for serum amyloid A (SAA) (figure 1). We found no systemic causes to explain secondary amyloidosis. This case demonstrates a possible association of secondary amyloidosis with HIV.

**Discussion:** Only a few case reports have described an association of secondary amyloidosis with HIV. SAA renal amyloidosis has been described in a patient who acquired HIV via intravenous drug use. It was unclear if it was related to the HIV disease or to chronic inflammation from skin infections due to needle use. Renal amyloidosis has also been occasionally described in South African patients with HIV and in non-human primates with HIV-like disease. Elevated levels of amyloid A protein have been found in AIDS patients, suggesting a possible pathogenetic linkage. More studies are needed in this area to determine if there is a causal relationship between the two disorders and what is the best approach for management.

Renal Cell Carcinoma Presenting as Henoch-Schönlein Purpura with AKI and Leukocytoclastic Vasculitis in Adults
Ashton N. Breithaupt, Neeruhika Mettupalli, Stacy A. Johnson, Alice Chedid.
The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Introduction: Henoch-Schönlein purpura (HSP) is a small vessel vasculitis characterized by IgA tissue deposition. HSP presenting in adults is often the result of an underlying malignancy.

Case Description: A 60-year-old man with history of HTN, CVA, DMII, recent COVID-19 infection, presented for 2 week history of petechiae on bilateral upper and lower extremities. Skin biopsy findings were compatible with leukocytoclastic vasculitis (LCV). Patient on admission was also found to have AKI with creatinine 2.1 mg/dl, microscopic hematuria, and sub-nephrotic range proteinuria with urine protein/creatinine ratio of 2.66 g/g. Kidney biopsy findings were consistent with IgA dominant glomerulonephritis. Given multi-system involvement, patient was diagnosed with Henoch-Schönlein Purpura. Given unusual presentation with extreme of age, there was concern for malignancy. CT scan chest abdomen pelvis was performed which revealed a solid and septated 8.3 cm exophytic mass on the superior pole of left kidney. A partial left nephrectomy was performed with pathology report consistent with clear cell renal carcinoma. Patient’s hematuria, proteinuria and skin rash resolved with surgical intervention. Creatinine remained stable in the 1.6-1.8 mg/dl range on discharge.

Discussion: Henoch-Schönlein purpura (HSP) is generally seen in the first decade of life. There have been a few cases of HSP presenting in adults due to underlying solid organ malignancies including renal cell carcinoma (RCC). Our case illustrates the importance of evaluating adults presenting with clinical findings of HSP for underlying malignancy. Treatment of underlying malignancy will improve vasculitis symptoms including renal parameters.

Exophytic and septated mass within superior pole of left kidney (Figure 1).

PO1522
A Case of Necrotizing Crescentic Glomerulonephritis due to ANCA Vasculitis and Fibrillary Glomerulonephritis
Munahal Nasim, 1 Faizan Babar. 1Nishat Medical College and Hospital, Multan, Pakistan; 2Nephrology Associates Lexington, Lexington, KY.

Introduction: Fibrillary Glomerulonephritis is a rare disorder thought to be idiopathic in nature. Cases of fibrillary GN have been associated with malignancy, monoclonal gammopathy, autoimmune disease, or infection. We present a unique case of fibrillary GN with pauc-immune crescentic GN due to Myeloperoxidase antibody (MPO) vasculitis.

Case Description: A 77 year old lady with history of well controlled diabetes, hypertension, congenital deafness, presented with weakness, fatigue & weight loss for four weeks. She was noted to have severe anemia with Hemoglobin of 6.6 g/dl, and presumed acute kidney injury. Her labs on admission were remarkable for creatinine 2.5mg/dl (unclear baseline creatinine), eGFR 25ml/min, potassium 5.3, Bicarbonate 16, Sodium 128. Urinalysis showed large blood and 1+ protein. The serological workup was positive for P ANCA 1:640, C ANCA 1:640, MPO ab and negative for PR-3 ANA, SRFP. Free light chain ratio, HIV, Hepatitis panel. Endoscopy and Colonoscopy was negative for any obvious bleeding. Patient underwent renal biopsy which showed 7 out of 15 glomeruli with early fibrocellular crescents with fibrinoid necrosis, along with healing phase of necrotizing arteritis. Immunofluorescence didn’t show any preferential staining for immunoglobulin, kappa or lambda. Electron microscopy showed mesangial mild non branching randomly arrayed thick fibrils with no immune complex type deposits. EM findings were confirmed by positive DNAJ/B9 stain. Patient received treatment with pulse dose steroids, two doses of rituximab 1 gm 14 days apart and continued on prednisone for slow taper with good renal response. Due to the findings of Fibrillar GN addition workup for lymphoproliferative disorder was done Whole body CT scan was negative but flow cytometry testing still pending.

Discussion: We present a unique case of fibrillary GN and pauci-immune crescentic GN with positive MPO antibodies. The significance of fibrillary deposits in this setting is unclear and usually not seen with pauci-immune crescentic GN. Fibrillary GN is a very rare diagnosis mostly thought to be idiopathic in nature. This unique presentation of fibrillary GN with ANCA vasculitis questions the current pathogenesis fibrillary GN and overall renal prognosis in association with glomerular pathologies like ANCA vasculitis.

PO1523
An Unexpected Clue in the Urinary Space: The Overlap Between IgA Predominant Staphylococcus aureus-Associated Glomerulonephritis and IgA Nephropathy: A Case Report
Luise J. Froessler,1 Luan D. Truong,2 Justin Merszuci.1 Baylor College of Medicine, Houston, TX; 2Houston Methodist Hospital, Houston, TX.

Introduction: There is significant histological overlap between IgA nephropathy (IgANP) and IgA predominant Staphylococcus-aureus associated glomerulonephritis (IgAASAAGN). [1] [1] Satoskar et al., “Staphylococcus Infection-Associated Glomerulonephritis Mimicking IgA Nephropathy,” November 2006.

Case Description: Kidney biopsy was performed in a 60 yo male for an unexpected decline in kidney function. IgAASAAGN was diagnosed on histology and foreign particles that were consistent with staphylococci were noted in the urinary space on electron microscopy. The patient was found to have methicillin-sensitive staphylococcus aureus (MSSA) pneumonia. Two months later, after a second decline in kidney function, IgANP was diagnosed on repeat kidney biopsy.

Discussion: This patient is diagnosed with two distinct conditions on pathology samples that show very similar histological findings. The presence of SA in the urinary space is a previously unreported finding. SA infection is known as the initiating factor for the development of IgAASAAGN. Recent studies have also suggested SA cell envelope antigens as a new candidate for the induction of IgANP and antigens have been colocalized with IgA deposits in the glomeruli of affected patients. [2] SA infection and IgA deposition seem to play an essential role in the pathogenesis of both conditions, and the consideration that they may be two extremes of a disease spectrum could be considered. If the role of SA in the development of IgA nephropathy is confirmed, it may be of interest to explore the role of anti-staphylococcal antibiotics in the treatment regimen of IgANP. [2] Koyama et al., “Staphylococcus Aureus Cell Envelope Antigen Is A New Candidate for the Induction of IgA Nephropathy.”
Diagnostic Dilemma: Glomerular IgG Deposit with Negative Anti-GBM Antibody
Sonali Gupta,1 Meenakshi Sambharia,1 Daniele G. Holanda,1 Elyas Safar,2 Y-Chen Huang,1 1The University of Iowa Hospitals and Clinics, Iowa City, IA; 2Blessing Hospital, Quincy, IL.

Introduction: Linear deposition of IgG along glomerular basement membrane (GBM) is hallmark of anti GBM glomerulonephritis. Subclass IgG 3 deposition is seen predominantly in these cases. Rare atypical anti-GBM cases have been described in literature as rare, indolent, no pulmonary involvement and undetectable antibodies. We describe a case of atypical anti GBM, four days after mRNA COVID vaccine.

Case Description: A 77-year-old male with history of hypertension presented with hypertensive emergency and acute kidney injury 4 days after first COVID vaccine (mRNA). Workup revealed sCr 2.6 mg/dl (1.5 mg/dl 1 month back), 3+ blood and 3+ protein by UA, normal C3, C4, ANA 1: 160, spot urine protein: creatinine- 2.2, serum albumin- 4g/dl, ANCA and anti-GBM antibody was negative so was Hepatitis panel and HIV. Serum electrochemistry was negative for monoclonal protein. He did not have any pulmonary symptoms and CXR was negative for acute pathology. Renal biopsy was performed. LM: mild to moderate nodular mesangial expansion, mildly increased mesangial cellularity and focal segmental nodular mesangial sclerosis. IF showed positive linear global capillary loop staining with IgG (2+), with kappa (1+) and lambda (2+) co-staining. Trace mesangial IgM and granular C3 (trace1+) are also noted in the peripheral capillary loops. EM showed diffuse foot process effacement. Few subepithelial, intramembranous and mesangial electron dense deposits were seen. Additional IgG subclasses IF showed positive linear glomerular staining for IgG1 (3+), IgG2 (1+), IgG4 (1+), negative for IgG3.

Discussion: Although no definitive active glomerular crescents or necrotizing lesions were seen, positive linear IgG staining in the glomerular capillary loops was concerning for atypical anti-GBM disease in setting of negative antibody and negative IgG3A study looking at 20 atypical anti-GBM patients found that 1 year patient and renal survival was 93% and 85% respectively. A few patients in this study had biopsy findings of DFPE and sub-epithelial deposits like ours. There have been few reports of COVID vaccine unmasking glomerulonephritis. However, it needs further investigation.

PO1526
Rapidly Progressive Glomerulonephritis due to Crescentic IgA Nephropathy in the Setting of HIV

Introduction: In patients with HIV-related kidney diseases, the most widely recognized histological abnormality is focal segmental glomerulosclerosis (FSGS). Less commonly found is IgA nephropathy in HIV patients, which tends to have a chronic stable course. We report a case of crescentic IgA nephropathy and FSGS in a patient with rapidly progressive glomerulonephritis and newly diagnosed HIV.

Case Description: A 54-year-old transgender woman with a history of alcohol use disorder presented with a petechial rash and lower extremity edema for 1 week, and was found to have a new diagnosis of HIV with an elevated creatinine. CD4 count was 143 and viral load was 103,774, and she was started on renally-dosed dolutegravir, abacavir and emtricitabine. Creatinine on admission was 1.27 mg/dL (baseline 0.7), and increased over the next several days to 5.3. Urine microscopy revealed dysmorphic RBCs and granular casts, which may help determine the optimal therapy for IgA nephropathy and IgA-induced FSGS.

Features and Outcomes of Patients with C1q Nephropathy in the NEPTUNE and CureGN Cohorts: Comparisons to Minimal Change Disease and Focal Segmental Glomerulosclerosis

Scott E. Wenderker,1,2 Maria Larkin,1 Mir Reza Bekhechmiria,1 Clarissa A. Cassoll,1 Carmen Avila-Cassado,1 Laura Barisoni,3 William E. Smoyer,4,5 Laura H. Mariani,1 Bayley College of Medicine, Houston, TX; Texas Children’s Hospital, Houston, TX; University of Michigan, Ann Arbor, MI; Arkana Laboratories, Little Rock, AR; University Health Network, Toronto, ON, Canada; Duke University, Durham, NC; Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH.

Background: Predominant immunostaining for C1q distinguishes a subset of patients with primary glomerular disease. C1q nephropathy (C1qN) has been proposed but not universally accepted as a distinct glomerular disease. This study describes clinical characteristics and short-term outcomes of patients meeting the provisional CureGN definition of C1qN, including comparisons to patients with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) without C1qN.

Methods: MCD and FSGS patients with C1qN were identified from the Cure Glomerulonephropathy Network (CureGN) and NEPTUNE cohorts. Comparisons were made to MCD and FSGS patients without C1qN, based on age, disease, and time since kidney biopsy, using 5-to-1 matching. We performed cross-sectional analyses of clinical and treatment data at enrollment and a longitudinal analysis of disease course.

Results: A total of 42 patients met the provisional CureGN definition for C1qN (16 adults >18yo, 11 teens 12-18yo, and 15 children <12yo), including 15 with MCD and 27 with FSGS. Those with C1qN were more commonly female (60 vs 49%, p=0.2) and black (34 vs 27%, p=0.4). At enrollment, those with and without C1qN had comparable kidney function (eGFR 90 vs 88 mL/min/1.73m², p=0.8). Individuals with C1qN were equally likely to have been treated with steroids or other immunosuppressive therapy (76 vs 81%, p=0.4) and to have ever achieved complete remission of proteinuria (defined as uPCR <0.3) (54 vs 65%, p=0.2). Median time to last follow-up was 3.1 yrs (IQR 1.9, 4.4) from enrollment and 4.8 yrs (IQR 3.3, 6.5) from biopsy date. While proportions with kidney failure were higher for FSGS compared to MCD (14 vs 1%, p=0.01), they were similar between patients with and without C1qN (7 vs 10%, p=0.6). There was a trend towards steeper GFR slope in C1qN patients (4.8 vs -0.2 mL/min/yr, p=0.06).

Conclusions: FSGS and MCD patients with and without C1qN have comparable demographics and short-term outcomes in CureGN and NEPTUNE. Outcomes do not appear to be biased by differences in immunosuppressive therapies. Further interrogation of genetic and molecular profiles between patients with and without C1q immunostaining on biopsy may be more informative.

Morphologic Descriptors Most Predictive of Clinical Outcomes in Minimal Change Disease and FSGS

Jacey Zee,1 Qian Liu,4 Abigail R. Smith,1 Laura H. Mariani,1 Jeffrey B. Hodgkin,2 Brenda W. Gillespie,2 Laura Barisoni,1,3 Lawrence B. Holmes.1 University of Pennsylvania, Philadelphia, PA; University of Michigan, Ann Arbor, MI; Duke University, Durham, NC; Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Previous studies applying the NEPTUNE Digital Pathology Scoring System (NDPSS) uncovered the value of kidney tissue features for clinically relevant patient subcategorization. This study aims to identify biomarkers in ultrastuctural descriptors most predictive of clinical outcomes in NEPTUNE patients.

Methods: 39 glomerular, 9 tubulointerstitial, 2 vascular, and 20 ultrastructural descriptors were quantified using the NDPSS on 39 MCD, 61 MCD-like, and 124 FSGS NEPTUNE digital kidney biopsies. Outcomes included time from biopsy to disease progression (kidney failure or a ≥40% eGFR decline with eGFR <90) and first complete remission (CR) of proteinuria (uPCR <0.3). Relative importance of descriptors for prediction of outcomes was obtained from random forest models, without adjusting for clinical features.

Results: The mean age, eGFR and UPCR at biopsy for the total 224 participants was 28.8, 85.2, and 5.4, respectively. Model performance was excellent (predictive discrimination 0.902 for disease progression and 0.853 for CR). Most predictive descriptors included conventional (e.g., global sclerosis or segmental sclerosis, and interstitial fibrosis/tubular atrophy) and unconventional features [Fig]. Top 10 predictors included inflammation, podocyte abnormalities, and acute tubular injury for both outcomes; deflation, interstitial foam cells, and collapse for disease progression; and endothelial cell abnormalities, hyalinosis, and periglomerular fibrosis for CR.

Conclusions: Most predictive descriptors of proteinuric glomerulopathies reflected structural changes in various renal compartments. Reporting these descriptors should be standardized to guide the subcategorization of proteinuric glomerular diseases and improve targeted clinical care.

Natural History of Focal Segmental Glomerulosclerosis (FSGS): The UK National RadAr Idiopathic Nephrotic Syndrome Cohort

Mohamed Salem,1,2 Jonathan Barratt,3,4 Fiona E. Braddon,5,6 Kevin Carroll,7,8 Ulysses A. Diva,9 Maryam Afailed,10 Bruce M. Hendry,10 Alex Mercer,10 David Pitcher,1,2,5 Retha D. Steenkamp,1,2,5,11 A. Neil Turner,12 Daniel P. Gale,5,13 University of Bristol, Bristol, United Kingdom; Bristol Royal Hospital for Children, Bristol, United Kingdom; University of Leicester, Leicester, United Kingdom; Leicester General Hospital, Leicester, United Kingdom; UK Renal Registry, Bristol, United Kingdom; Royal Free Hospital, London, United Kingdom; University College London, London, United Kingdom; Traveque Therapeutics Inc, San Diego, CA; University of Edinburgh, Edinburgh, United Kingdom; JAMCO Pharma Consulting, Stockholm, Sweden; KCL Statistics Ltd, Cheshire, United Kingdom; The Renal Association, Bristol, United Kingdom.

Background: Idiopathic FSGS is an important cause of proteinuric renal disease leading to ESKD. Here we describe the natural history of FSGS using the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RadAr-INS) Cohort, including retrospective and prospective data from 3007 patients with nephrotic syndrome (NS) not attributable to glomerulonephritis or systemic disorders recruited from 107 adult and paediatric kidney units across the UK since 2010.

Methods: Participants included those with biopsy-proven or monogenic FSGS and ≥12 mo. observation from baseline. Patients with ESKD (CKD stage 5 or on renal replacement therapy) at or prior to baseline were excluded. Baseline date was defined as first database occurrence of renal biopsy, primary renal diagnosis, NS symptoms, PCR ≥1 g/L, or initiation of immunosuppression. Renal survival was defined as absence of ESKD or death with survival time calculated from baseline to last follow-up.

Results: Of 786 FSGS patients meeting eligibility, median baseline age was 28 yrs (IQR 9-49) with paediatric patients representing 38% of the study population. Median proteinuria at baseline was 5.9 g/L (IQR 3.3-11.0; n=140), while mean eGFR was 163 mL/min/1.73m² (SD 47; n=69) and 71 mL/min/1.73m² (SD 32; n=103) for children and adults, respectively. Median follow-up duration was 9.7 yrs (IQR 5.7-16.1) with ESKD/death events occurring in 46% of patients (1% death). Kaplan-Meier survival curves of children and adults show 50% renal survival probability of 16 years & 12 years, respectively (Figure 1).

Conclusions: The RadAr-INS Cohort represents a large study population with lengthy follow-up data. These analyses indicate rapid progression and poor outcomes, highlighting a need for effective treatments for patients with FSGS.

Funding: Commercial Support - Traveque Therapeutics
Funding: Commercial Support - Traveere Therapeutics

Conclusions: Non-White patients are more frequently diagnosed with FSGS at later CKD stages with advanced GS. Strategies to improve earlier awareness and detection of FSGS are needed to allow effective intervention before severe kidney damage has occurred.

Clinicopathological Characteristics of Adult Patients in the United States with Focal Segmental Glomerulosclerosis (FSGS)

Katherine R. Tuttle,1 Clint Abner,2 Kerime Ararat,2 Patrick D. Walker,2 Amin Yakubu,2 Martin C. Bunke,2 University of Washington, Spokane, WA; 2Arkana Laboratories, Little Rock, AR; 3Genesis Research, LLC, Hoboken, NJ; 4Traveere Therapeutics Inc. San Diego, CA.

Background: Focal segmental glomerulosclerosis (FSGS) is a common histopathologic lesion of glomerular injury in patients with nephrotic syndrome. These analyses characterize clinical and histological features of FSGS in adults at time of kidney biopsy.

Methods: A retrospective study was performed using data from the Arkana Biopsy Database (January 1, 2016 to May 31, 2020) in patients that met study criteria, which included: ≥18 yrs, ≥1 FSGS positive kidney biopsy, and no prior kidney transplant, and available data on race/ethnicity. Outcomes included clinical and histologic characteristics.

eGFR was calculated using CKD-EPI-creatinine equation without race modifier.

Results: Of 64,105 adult kidney biopsies performed during the study period, 2,665 (3.2%) FSGS positive cases were identified and 1,482 pts (71.8%) evaluated met study criteria. Demographic characteristics included: 56.2% male, 55.1% White, 32.1% African American (AA), 7.7% Hispanic and 3.4% Asian. Overall mean (SD) age at biopsy was 49.0 (17.2) years. Outcomes included clinical and histological characteristics. Outcomes included clinical and histological characteristics. Among all FSGS types, “not otherwise specified” (27.2%) was most frequent across all race/ethnicity groups. Asians (17.7%) or Whites (14.7%). Of all FSGS types, “not otherwise specified” was most common across all race/ethnicity groups (range 64.2–75.4%). Among other FSGS types, tip lesion was most frequent in Whites (14.6%) and lowest in Hispanics (12.5%). The highest rates of severe foot process effacement (≥80%), while interstitial fibrosis and tubular atrophy ≥50% was most common in AAs (34.6%) compared to Hispanics (27.2%), Asians (17.7%) or Whites (14.7%). Of all FSGS types, “not otherwise specified” was most common across all race/ethnicity groups (range 64.2–75.4%). Among other FSGS types, tip lesion was most frequent in Whites (21.5%) and collapsing was most frequent in AA patients (12.4%).

Conclusions: Non-White patients are more frequently diagnosed with FSGS at later CKD stages with advanced GS. Strategies to improve earlier awareness and detection of FSGS are needed to allow effective intervention before severe kidney damage has occurred.

PO1532

Long-Term Outcomes of Patients with Focal and Segmental Glomerulosclerosis Treated with Tacrolimus

Mukunthan Srikantanarajah,1 Thomas M. Connor,1 Jeremy B. Levy,1 Stephen P. McAdoo,1 Megan Griffith,1 Imperial College Healthcare NHS Trust, London, United Kingdom; 2Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.

Background: Tacrolimus (TAC) is used to treat Focal and Segmental Glomerulosclerosis (FSGS). Prolonged treatment is often required and there is little data on long-term outcomes.

Methods: This is a retrospective study of 29 patients who received TAC as first line immunosuppression for nephrotic syndrome (NS) secondary to FSGS from December 2007- January 2020 at our institution.

Results: Mean follow up was 59.6 months (12–144). The mean age at diagnosis was 42 years (range 18-85). 52% were Male. 59% were White, 10% Black, 21% Asian, 3% Chinese, 7% Other. Baseline mean eGFR was 64 ml/min (18-90). 23/29 (79%) obtained complete (CR) or partial remission (PR) of NS, at a mean time of 5.09 months (range 1-31 months). 6/29 (21%) did not enter remission with TAC. 2/6 subsequently achieved

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
remission with CyP and prednisolone/rituximab. 7/23 (30%) patients who achieved remission with TAC had at least one relapse, 4/7 after stopping TAC, 1/7 during TAC wean and 2/7 with therapeutic TAC levels. 4/7 were treated by restarting or increasing TAC, 1/7 also had steroids added, 1/7 received rituximab (achieving remission) and 1/7 was not further treated with immunosuppression. 4/4 restated with TAC monotherapy reached remission. 16/23 (70%) patients did not relapse and 7 of these remain off TAC and in remission (mean follow up of 92.6 months). At 1 year, the mean eGFR was 67.4 ml/minute (21-90). 1/29 patient developed end-stage kidney disease (ESKD) at 2 months. This patient did not responded to TAC. 16 patients have 5-year-follow up. The mean eGFR was 66.5 ml/minute (11-90). 1 further patient developed ESKD (this patient had not responded to TAC nor subsequent immunosuppression). 4 patients have 10-year follow-up. The mean eGFR was 80.8 ml/minute (67-90). 3 further patients developed ESKD. 1/3 had achieved PR, 1/3 had achieved CR but had multiple relapses despite re-treatment and 1/3 had CR but defaulted from follow up, presenting with ESKD 6 years later.

Conclusions: The long-term data from this study suggests tacrolimus can be effective in both achieving and maintaining remission of NS in FSGS. CR is associated with good long-term outcomes in most patients although relapse can occur and long term careful follow up is required. Non-responders have a worse outcome, although some patients do respond to alternative immunosuppression.

PO1533
Collapsing FSGS in a Patient with Acute Myeloid Leukemia and Prior COVID-19 Infection
Surya Manivannan, Stephanie S. Pavlovich, Irshadjahane Malek, Koyal Jain. University of North Carolina System, Chapel Hill, NC.

Introduction: Collapsing focal segmental glomerulosclerosis (c-FSGS) has been independently associated with COVID-19 infection, acute myeloid leukemia (AML), and apolipoprotein L1 (APOL1) risk variants. We describe a patient with homozygous APOL1 G1 risk allele and AML who developed renal failure due to c-FSGS and acute tubular injury.

Case Description: A 25-year-old male with a history of mild asthma and COVID-19 infection 1 month prior presented with a 3-week history of severe fatigue, weight loss, persistent dyspnea, and fevers. He was found to have leukopenia, thrombocytopenia, an acute kidney injury, and nephrotic range proteinuria. The patient was diagnosed with AML by bone marrow biopsy (BMBx). At presentation, his serum creatinine was 2.8 mg/dL, which rapidly increased to 6.9 mg/dL over 2 weeks. Urine protein:creatinine ratio (UPCR) by bone marrow biopsy (BMBx). At presentation, his serum creatinine was 2.8 mg/dL, which rapidly increased to 6.9 mg/dL over 2 weeks. Urine protein:creatinine ratio (UPCR) of 11g/g. Renal biopsy demonstrated acute interstitial nephritis (AIN) on light microscopy. Electron microscopy revealed global podocyte activation and foot process effacement, consistent with MCD (Figure). He responded to alternative immunosuppression.

Discussion: COVID-19 is associated with immunologic alterations precipitating c-FSGS, especially in patients with APOL1 high risk alleles. Additionally, FSGS has been reported in AML, but the etiology behind glomerular pathologies in AML is unclear and likely multifactorial. Studies have indicated immunologic dysregulation related to leukemia, as well as viral-related etiologies. The trigger for c-FSGS in our patient is uncertain.

PO1534
Role of LDL-Apheresis in Management of Glucocorticoid-Resistant Minimal Change Disease
Dhakiria P. Shah, Alka A. Tyagi, Jason Prosek, Eshtetu L. Obote. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Minimal Change Disease (MCD) is described as diffuse podocyte foot process effacement on kidney biopsy, resulting in nephrotic proteinuria, ~3 grams/day. Glucocorticoids (GC) are the mainstay of therapy and most patients achieve complete remission in a few months. 7-12% patients, however, have GC-resistance and thus limited treatment options. Often, they are suspected of having focal segmental glomerulosclerosis (FSGS) due to biopsy sampling error. We present a challenging case of GC-resistant MCD, managed with immunosuppression, and ultimately lipid (LDL) apheresis.

Case Description: An otherwise healthy 20-year-old male presented for sudden onset lower extremity swelling and 10-pound weight gain. Work up including ANA, C3, C4, p-ANCA, c-ANCA, serum and urine immunofluorescence and renal ultrasound were unremarkable. Notably, LDL was 390 mg/dL, proteinuria of 9 grams/day and serum creatinine (Scr) of 0.96 mg/dL. Kidney biopsy revealed diffuse podocyte effacement, consistent with MCD. He was treated with oral prednisone 1 mg/kg/day and diuretics for several weeks with minimal symptomatic improvement and had worsening kidney function, Scr 1.5 mg/dL and proteinuria of 36 grams/day. Unfortunately, he also contracted COVID-19 disease prior to second kidney biopsy. Repeat kidney biopsy revealed acute tubular necrosis along with widespread podocyte effacement, without sclerotic lesions, ~10% interstitial fibrosis and tubular atrophy. He was empirically treated with tacrolimus for FSGS. However, proteinuria continued to worsen and peaked at 83 grams/day. Ultimately diagnosed as GC-resistant MCD, he was weaned off steroids, he was referred for LDL-apheresis therapy. He is maintained on tacrolimus and LDL apheresis with symptomatic improvement, still has significant proteinuria of 67 grams/day and advanced chronic kidney disease (CKD).

Discussion: The exact pathophysiology of nephrotic syndromes is unclear, mechanisms of T-cell dysfunction causing production of glomerular permeability factor and nephrotoxic hyperlipidemia have been described. In cases of GC-resistant diseases, immunosuppression has only been partially successful. LDL-apheresis has a role in the management of such nephrotic syndromes, thought to reduce circulating lipid induced disruption of podocyte integrity, and help prevent decline of kidney function and decrease proteinuria as seen in this patient.

PO1535
Infliximab-Associated Minimal Change Disease in an Adult with Ulcerative Colitis

Introduction: Tumor necrosis factor-alpha (TNF-α) inhibitors are increasingly utilized for the treatment of several autoimmune conditions. They have been associated, in rare cases, with renal complications. We report a patient who developed minimal change disease (MCD) and interstitial nephritis while being treated with infliximab (IFX) for ulcerative colitis (UC).

Case Description: A 48-year-old male with a history of primary sclerosing cholangitis, liver transplant 8 years prior, psoriasis, and UC well-controlled on monthly IFX presented with a one-week history of lower extremity swelling, dyspnea, and weight gain. He was found to have rapidly progressive renal failure and nephrotic syndrome. Laboratory data showed a serum creatinine of 11mg/dl up from 1mg/dl 3-weeks prior and urine protein:creatinine ratio (UPCR) of 11g/g. Renal biopsy demonstrated acute interstitial nephritis (AIN) on light microscopy. Electron microscopy revealed global podocyte activation and foot process effacement, consistent with MCD (Figure). He continued to become progressively oliguric despite escalating doses of diuretics and received two days of hemodialysis due to volume overload. After a total of 7 days of high dose steroids, his urine output increased and hemodialysis was stopped. IFX was discontinued due to the association of TNF-α inhibitors with MCD and AIN. After a month of prednisone, his creatine improved to 1.6 mg/dl and UPCR improved to 0.3g/g.

Discussion: This is the first report of IFX associated MCD. Although IFX has been associated with lGA nephropathy, crescentic glomerulonephritis, renal artery occlusion, membranous glomerulopathy, and AIN in patients with spondylarthritides spectrum diseases, no reports exist in the literature regarding MCD. In our patient, infliximab was associated with AIN. Although IFX was not associated with HLA, we could not rule out a role of TNF-α inhibitors in our patient. The mechanism of infliximab associated MCD is unclear, but IFX may exacerbate or induce MCD in patients with inflammatory bowel disease.
PO1536

Anti-Phospholipase A2 Receptor Antibody Levels in Asian Patients with Membranous Nephropathy: A Territory-Wide Study

Desmond Y. Yap, Irene Yam, Michelle Lam, Hemlata Binnsahuthsing, Tak Mao D. Chan. University of Hong Kong, Hong Kong, Hong Kong.

Background: Different cut-offs of values of anti-phospholipase A2 receptor (anti-PLA2R) antibody for determining between primary membranous nephropathy (PMN) and secondary membranous nephropathy have been reported. The optimal anti-PLA2R levels to reflect disease activity states in Asian patients with PMN remain undefined.

Methods: We conducted a territory-wide study in Hong Kong to investigate the serum anti-PLA2R levels in Chinese patients with PMN during 2017-2020. Anti-PLA2R levels were measured by commercial ELISA kits (Euroimmun, Germany) in serum samples collected from biopsy-confirmed PMN patients during active disease or remission, and their predictive values for active PMN were evaluated.

Results: Forty and six serum samples from 320 PMN patients were analysed. 319 samples were obtained during active disease and 87 during disease remission. Anti-PLA2R titres during active diseases were significantly higher than that during remission (95.1±235.0 RU/mL vs. 19.3±9.3 RU/mL respectively, p<0.001). Using 20 RU/mL as cut-off, the sensitivity (SN) and specificity (SP) for predicting active disease were 39% and 98% respectively [AUC 0.68, p<0.001; positive predictive value (PPV) and negative predictive value (NPV) were 98% and 30% respectively]. Using 10 RU/mL as cut-off, the SN and SP for diagnosing active PMN were 46% and 95% respectively [AUC<0.71, p<0.001; PPV and NPV were 97% and 32% respectively]. Anti-PLA2R titres correlated with urine protein-to-creatinine ratio and 24-hr urine protein levels (r=0.32 and 0.37 respectively, p<0.001).

Conclusions: Anti-PLA2R showed good SP and PPV prediction for active PMN in Chinese patients, and correlated with severity of proteinuria. A lower threshold (10 RU/mL) may show improved SN for predicting active PMN in Asian patients.

PO1537

Qualitative and Quantitative Dosage of the Anti M-Type Phospholipase A2 Receptor Autoantibody: One-Year Experience in Quebec's Reference Center

Simon Leclerc,1,2 Karim Benkiran,1,2 Caroline Lamarche,1,2 Jean-Philippe Laurin,1,2,12 Annie-Claire Nadeau-Fredette,1 Virginie Royal,3,12 Vincent Picchett,1,2 Louis-Philippe Laurin,1,2 Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 1Universite de Montreal, Montreal, QC, Canada.

Background: Dosage of the M-type phospholipase A2 receptor antibody (anti-PLA2R) is now an essential tool for diagnosis and management of primary membranous nephropathy (MN). Since October 2018, Hôpital Maisonneuve-Rosemont (HMR) has been designated as Quebec’s reference center for serum anti-PLA2R antibody testing by the Institut National d’Excellence en Santé et Services Sociaux (INESSS), the regulatory body on drugs and tests usage in Quebec.

Methods: All patients who had a serum anti-PLA2R antibody testing performed at HMR from October 1st, 2018 to October 1st, 2019 were included in the study. Serum anti-PLA2R antibodies were screened by a qualitative test, followed by a quantitative test if the results were undetermined or positive. We calculated sensitivity, specificity, predictive value, and likelihood ratio for both tests, using kidney biopsy findings as the gold standard.

Results: In the province of Quebec, a total of 1690 tests were performed among 1025 patients during the study year. A small proportion of these patients (8%) were followed at HMR. Patients tested at HMR and in the rest of Quebec had similar characteristics. Test validity was only characterized for patients tested at HMR. Sensitivity and specificity were respectively, 59% and 100% for the qualitative test, and 71% and 100% for the quantitative test. The combined net sensitivity was 42% and the net specificity, 100%. The net positive and negative predictive value were 100% and 84% respectively, whereas the net negative likelihood ratio was 0.58.

Conclusions: Serum anti-PLA2R antibody testing was widely used in Quebec during its first year of availability. In one of the biggest real life cohort described, the test performed as previously described in the literature. Moreover, the two-step approach that was used at HMR, using a qualitative test before a quantitative test if needed, appeared to be an efficient way to avoid quantitative testing in negative patients and to better characterize undetermined results on immunofluorescence.

PO1538

Clinical Relevance of NELL1 Antibodies in Patients with Membranous Nephropathy

Linda Reinhard, Benedikt Krümpelmann, Thorsten Wiech, Rolf A. Stahl, Elian Hoxa.

Background: NELL1 was identified as a potential novel target antigen in membranous nephropathy (MN). Here, we studied the association of NELL1-antibody (ab) with treatment response and prognosis in a large cohort of MN patients.

Methods: Circulating NELL1-antibodies were detected by Western blot in a prospective cohort of 87 PLA-R- and THSD7A-ab negative MN patients, 130 PLA-R- or THSD7A-ab positive MN patients and 116 control patients with a biopsy-proven GN other than MN. Clinical follow-up included treatment, remission or relapse of proteinuria and development of kidney function.

Results: NELL1-ab were identified in 18 (21%) patients with PLA-R- and THSD7A-ab negative MN but none of the control cohorts’ patients. We identified NELL1-specific IgG1, IgG2, IgG3 and IgG4 subclasses in the serum of 12 (67%), 7 (39%), 11 (61%) and 15 (83%) NELL1-ab positive patients, respectively. NELL1-ab positive patients were significantly (p<0.05) older compared to PLA-R-ab positive patients or MN patients without NELL1-ab (age: 70 vs 58 years). During 6 months of MN diagnosis, a malignant tumor was identified in 2 (11%) NELL1-ab positive, 7 (6%) PLA-R-ab positive, 3 (50%) THSD7A-ab positive and 7 (10%) MN patients without known target antigen. 14 NELL1-ab positive patients were observed over a median follow-up of 75 months. One patient presented with eGFR < 30 ml/min due to severe hypertensive and diabetic kidney damage and developed ESKD after 69 months. All other 13 patients had a remission of proteinuria. 12 (92%) patients had a complete remission, although only 4 patients received an immunosuppressive therapy. Remarkably, of the 9 untreated patients with complete remission of proteinuria, 4 patients had persisting NELL1-ab in the circulation over the whole observation period and 2 patients reached complete remission of proteinuria before NELL1-ab disappeared. Renal function was stable in NELL1-ab positive patients but showed a more pronounced decline in NELL1- ab negative patients.

Conclusions: NELL1-ab positive MN patients had slightly more often a malignant tumor, but also were significantly older compared to PLA-R-ab positive patients. Overall, NELL1-ab positive patients had a good prognosis. The presence of NELL1-ab in the serum did not show a close association with disease outcome.

Non-Pathogenic THSD7A Antibodies in a Patient with No Membranous Nephropathy

Linda Reinhard, Cindy Thomas,2 Maya Machalitzs,1 Erik Lattewin,2 Lothar S. Weil,1 Jan Vitu,2 Thorsten Wiech,1 Rolf A. Stahl,1 Elian Hoxa,1

1Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 2EUROIMMUN Medizinische Labordiagnostika AG, Lübeck, Germany; 3Medizinisches Versorgungszentrum Hamburg-Sinstorf der MVZ gGmbH der PHV, Hamburg, Germany.

Background: PLA-R- and THSD7A-ab (anti-PLA2R) antibodies (ab) are considered to be specific for the diagnosis of membranous nephropathy (MN). There is a controversial discussion whether the detection of circulating PLA-R- or THSD7A-ab is sufficient to diagnose MN, without the need of a kidney biopsy.

Methods: Circulating THSD7A-ab were detected and their specificity evaluated by an indirect immunofluorescence test (IFT), reducing, non-reducing and native Western blot analyses as well as a live cell assay. The kidney biopsy was investigated by immunohistochemistry and electron microscopy.

Results: A patient presented with high level proteinuria and was tested positive for THSD7A-ab using IFT. Except for the diagnosis of diabetes mellitus, the medical history of the patient was unremarkable. Because of persistent proteinuria and a decline of kidney function, a kidney biopsy was performed, showing the diagnosis of diabetic nephropathy and excluding MN. A detailed biochemical characterization of the THSD7A-ab was performed to clarify these discrepancies between the serological and histomorphological findings. The circulating THSD7A-ab from the serum of the patient bound to recombinant THSD7A in the IIFT, co-localizing with THSD7A in co-immunofluorescence staining experiments and reacted with purified THSD7A in reducing WB analyses. However, these antibodies did not bind THSD7A derived from human glomerular tissue in any of the tested conditions. Since the kidney biopsy revealed a diagnosis of type 2 diabetes mellitus, the circulating THSD7A-ab did not recognize recombinant THSD7A under native conditions in the native Western blot or live cell assay. In contrast, THSD7A-ab from MN patients recognized native THSD7A in all experiments.

Conclusions: In the first time the existence of non-pathogenic THSD7A-ab, which are not able to bind THSD7A in vivo and can hence not induce MN. Nevertheless, their presence can be detected by different assays, leading to false-positive results for pathogenic circulating THSD7A-ab. In cases of low THSD7A-ab positivity in IFT, findings from different diagnostic tests such as kidney biopsy, Western blot analyses and live cell assays should be integrated in making a safe diagnosis of THSD7A-ab positive MN.

Urinary NPHS2-mRNA in Relation to Glomerular and Tubular Damage Markers in Patients with Membranous Nephropathy

Bartholomeus T. van den Berge,1,2 Anne-Els van de Logt,1,2 Jitske Jansen,1,2 Bart Sneets,1 Johan Van der vlag,1 Jack F. Wetzels,1 Rutger J. Maas,1,2

1Radbouduime Afdeling Niezerken, Nijmegen, Netherlands; 2Radbouduime Afdeling Pathologie, Nijmegen, Netherlands; 3Radbouduime Afdeling Kindergeneeskunde, Nijmegen, Netherlands.

Background: Measurement of podocyte-specific mRNA in patients’ urine samples has been proposed as a novel tool to monitor podocyte loss in glomerular disease, and may have prognostic value. In our hospital, we routinely measure timed urinary excretion of high- and low-molecular weight proteins as prognostic markers in patients with membranous nephropathy (MN). Here, we investigated the relationship between NPHS2-mRNA and high- and low-molecular weight proteins in patients with MN.

Urine Biomarkers Predict Treatment Response in the MENTOR Study

PO1541

Urine Biomarkers Predict Treatment Response in the MENTOR Study

Methods: We included 35 patients with MN (80% male, median age 67, median eGFR 63). NPHS2-mRNA was measured in urine pellets as described by Wickman et al. (JASN 2013). Normal values of urinary NPHS2-mRNA were obtained in spot urine samples of 19 healthy controls.

Results: Clinical characteristics and results of urinary measurement are shown in Table 1. Mean urinary NPHS2-mRNA/creatinine ratio (UpodCR) was 64 fold higher in patients with MN versus healthy controls. UpodCR showed weak but significant correlations with urinary IgG excretion and proteinuria selectivity index (Figure 1), but not with total proteinuria or gFR (Table 1).

Conclusions: Urinary expression of NPHS2-mRNA correlated significantly with protein markers of glomerular damage in patients with MN. However, correlations were weak. Prospective studies are needed to evaluate if urinary NPHS2-mRNA excretion holds independent prognostic value.

PO1542

Use of Urinary Proteins as Predictors of Response to Immunosuppressive Treatment in Membranous Nephropathy

PO1543

APOL1 High-Risk Genotype Is Associated with Worse Renal Outcomes in Black Patients with Membranous Nephropathy

Methods: We measured the abundance of 55 urinary cytokines, metalloproteases and urinary excretion of NPHS2 mRNA. The primary outcome of interest was achievement of CR/PR at 12 months despite IS with rituximab or cyclosporine. The treatment outcome was defined as patients achieving either complete (CR; <0.3g/24 hours) or partial remission (PR; >0.3-<3.5g/24 hours) of proteinuria at 12 months.

Results: In both cyclosporin and rituximab arm, all urinary proteins exhibited a decline from baseline to 12 months post treatment. However, none of the baseline urinary proteins were found to be significantly associated with treatment response at 12 months (p>0.05 for all). Results were similar when restricted to patients with positive anti-PLA2R at baseline.

Conclusions: Baseline measures of the urinary albumin, uIgM, uIgG, and uα1m are not predictors of patients going into CR or PR at 12 months after treatment with rituximab or cyclosporine.
White patients from CureGN were included for comparison. Data from CureGN or chart abstraction for GDCN patients were used to determine demographics, diagnosis, disease onset, and ESKD (dialysis initiation or transplantation). Fisher’s exact, Wilcoxon rank, and Kaplan-Meier curves with log rank tests were used to evaluate differences between high risk (2 variants) and low risk (0/1 variant) and white population. 

Results: There were 106 African American patients with diagnosis of MN in our study. Of these, 15 patients (14%) were high risk (two risk alleles of APOL1) and the remaining 91 patients (86%) were low risk (0/1 risk alleles of APOL1). Data were available for 493 white patients. Hazard ratio for composite outcome of ESKD/death was 4.21 (95% CI 1.54,11.51) among African Americans (high risk vs. low risk) and 6.37 (95% CI 2.74, 14.80) compared to white population. Time to endpoint was significantly faster in those with high risk APOL1 genotype (Figure), p<0.0001. 

Conclusions: High-risk APOL1 genotype in African Americans is associated with faster time to ESKD/death compared to low-risk AA or white patients with MN.

PO1544
Treatment-Resistant Membranous Nephropathy in a Patient with NPHS2 Mutation
Ioana Ailincăi, Gabriela Lupusor, George C. Costea, Georgiana Fratila, Oana Ion, Gener Ismail. Fundeni Clinical Institute, Bucharest, Romania.

Introduction: Membranous nephropathy (MN) is one of the most frequent causes of nephrotic syndrome (NS) in adults. NPHS2 gene encodes podocin, a protein of the slit diaphragm that is essential for recruitment of nephrin into the lipid rafts and for maintaining the glomerular filtration barrier. Recessively transmitted mutations in NPHS2 cause familial forms of steroid-resistant NS that progress to end-stage renal disease (ESRD).

Description: A 37-year-old male was referred to our clinic with NS and hypertension. Admission labs showed creatinine of 3 mg/dl, serum albumin of 3 g/dl, proteinuria of 2 g/dl and microscopic hematuria (30 cells/hpf). Immunological testing – ANA, ANCA, anti-C1q, anti-GBM – was negative, C3 and C4 were normal. Kidneys appeared normal on ultrasound examination. A renal biopsy was performed. Light microscopy revealed 19/23 glomeruli with global sclerosis and 4/23 glomeruli with thickening of GBM, podocyte hypertrophy and segmental sclerosis; there was also diffuse tubular atrophy, interstitial fibrosis and arteriolar hyalinization. Electron microscopy showed subepithelial electron dense deposits with spike formation, with granular capillary loop staining for IgG4 in immunofluorescence. The histopathological diagnosis was stage II MN associated with diffuse glomerulosclerosis secondary to hypertension. In the meantime, the anti-PLA2R antibodies returned positive (titre 1:320). Therapy was started with Rituximab 1000 mg; a second dose was administered after 14 days. Despite treatment, NS persisted and kidney function worsened; hemodialysis was initiated 6 months after the diagnosis. One year later, the patient’s 16-year-old son was diagnosed with NS, resistant to steroids. Genetic testing identified NPHS2 c.947C>T p.(Pro316Leu), c.3447dup, p.(Val1150Cysfs*39) in KANK1, inherited from the mother.

Discussion: Recent data suggest an important role of genes in the pathogenesis of MN. NPHS1 polymorphisms are associated with low remission rate after treatment and high disease progression. Our patient has a heterozygous mutation in NPHS2, resulting in abnormal signaling through the nephrin-podocin complex and podocyte dysfunction. Therefore, it is very probable that in this case of primary MN genetics played a major role in treatment resistance and progression to ESRD.

PO1545
Primary Membranous Nephropathy Flare After COVID-19 Vaccination
Kelly V. Liang, Elizabeth C. Kurtz, Matthew Pittappily, Syeda B. Ahmad, Marta I. Minervini. University of Pittsburgh, Pittsburgh, PA.

Introduction: Primary membranous nephropathy (MN) is most commonly due to phospholipase A2 receptor antibodies (PLA2R Ab). It is unclear whether the COVID-19 vaccine can trigger flares of glomerular diseases such as primary MN. We present a patient with MN and metastatic breast cancer who developed nephrotic syndrome after receiving her second mRNA-1273 COVID-19 vaccine with positive PLA2R Ab by ELISA suggesting MN flare.

Case Description: A 62 year old female with history of Stage IIIIB T3N3M1 ER/PR positive HER-2 negative metastatic left breast invasive ductal carcinoma, hypertension, breast cancer, and primary MN with histology confirmed with histology confirmed with histopathology and proteinuria 2 weeks after COVID-19 vaccination. She had previous proteinuria of 7029 mg/24hr in August 2018 with PLA2R Ab 128 RU/mL in October 2018. She underwent modified radical mastectomy in September 2018 followed by adjuvant chemotherapy in December 2018, after which PLA2R Ab decreased to <2 RU/mL. In February 2019 and urine protein/creatinine ratio (UPCR) decreased to 1094 mg/g Cr in April 2019. She was diagnosed with metastatic breast cancer and started anastrozole transiently. She received mRNA-1273 COVID-19 vaccines in late January and February 2021. In March 2021, she presented with bilateral leg edema, dyspnea, and bilateral pleural effusions. Urinalysis had >1000 protein, 24hr urine protein 11.2 g, Cr 1.6 mg/dl, and PLA2R Ab 787 RU/mL. Renal biopsy showed immune complex-mediated glomerulopathy with positive PLA2R, consistent with primary MN stage II-H. Glomerular basement membrane deposits were strongly positive for IgG4. Electron microscopy showed numerous subepithelial and occasional intramembranous electron-dense immune-type deposits. She was treated with lisinopril and furosemide followed by rituximab in May 2021. Prior to rituximab PLA2R Ab was 342 RU/mL and UPCR was 8671 mg/g Cr.

Discussion: There is insufficient data on the risk of flare after COVID-19 vaccine in glomerular diseases. There have been few cases reports of primary MN and minimal change disease after COVID-19 vaccine as well as MN after influenza vaccine. Our case of primary MN flare after COVID-19 vaccine adds support to a potential association between SARS-CoV-2 variants and antigen loss to the PLA2R antigen. Close follow-up of patients with primary MN and other glomerular diseases after COVID-19 vaccination is warranted.

PO1546
Primary Membranous Nephropathy Concurrent with ANCA-Positive Crescentic Glomerulopathy in a Hispanic Man
Leonardo Pozo Garcia,1,2 Daniel Varela,1,2 Steffi Sathiyaraj,1,2 Mourad Alsbabh,2 Sergio A. Trevino Manlio,2 John Manolio,3,7 The University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; 3DHR Health, Edinburg, TX; 4South Texas Kidney Specialists, McAllen, TX.

Introduction: Primary membranous nephropathy (MN) is a common cause of glomerular disease in adults usually presenting with nephrotic syndrome. Crescents are an unusual finding in MN; its presence suggests a concomitant disease process, such as pauci-immune anti-neutrophil cytoplasmic antibody-related (ANCA) glomerulonephritis (GN).

Case Description: A 36-year-old Hispanic man presented with a 1-week history of fatigue, weight loss, and lethargy. Examinations revealed an obese Hispanic man with rales on lung auscultation and lower-extremity edema. Laboratory results showed a serum creatinine (sCr) 8.8 mg/dl, BUN of 54 mg/dl. Urinalysis revealed 4+ protein, 25-50 red blood cells per hpf. Spot urine protein creatinine ratio (UPCR) was 19 g/g, p-ANCA titer 1:640. Urine toxicology screen was positive for cocaine. Other serologies and imaging were unremarkable. Renal biopsy showed MN with PLA2R positive staining as well as necrotizing and crescentic glomerulonephritis. Interstitial fibrosis and tubular atrophy were seen only in 10% of the sample. Management was initiated with a pulse of steroids followed by a taper, and renally dosed oral cyclophosphamide. The patient was initiated on hemodialysis due to uremic symptoms and volume overload. Three months after initiation of therapy, urine output significantly improved. Laboratory data showed: a 24 hours urine creatinine clearance of 31 ml/min, sCr 2.9 mg/dl, and UPCR 5.3 g/l. Patient was euolemic. Hemodialysis was discontinued. MN and ANCA GN are distinct manifestations of renal injury with different clinical, laboratory, and pathology findings. Our case highlights an individual with both entities. We hypothesize that the patient’s renal findings of p-ANCA and crescentic GN were likely associated with levamisole adulterated cocaine in the background of primary MN. The patient discontinued cocaine use after our discussions. We decided to treat the patient’s MN with immunosuppressive therapy. Fortunately, the patient has responded favorably to our management with significant improvement in renal function.

PO1547
Clinical-Pathological Features of Podocyte Infolding Glomerulopathy
Ling Hong,1,2 Lin Wang,2 Zhihua Zheng,1 Wenfang Chen.1 Department of Nephrology, The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen, China; 2Department of Pathology,The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3Department of Renal Pathology, Guangzhou Kingmed Diagnostic Laboratory Ltd, Guangzhou, China.

Background: Podocyte infolding glomerulopathy (PIG) is characterized by presence of microstructural aggregates originated from cytoplasmic infoldings of podocytes in the glomerular basement membrane (GBM). Few PIG cases have been reported and the significance of this morphology is still unclear. This study aims to elucidate the incidence, clinical-pathological features and prognosis of PIG.

Methods: Renal biopsies with PIG features from January 2018 to December 2020 in Kingmed Diagnostic Laboratory were reviewed. Patients were divided into three groups according to their clinical and pathological findings.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
PO1548
Baseline Characteristics of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits in the International Kidney Registry Consortium (K-REG)

Ghazal Z. Quinn,1 Sandra Susinbar-Adaniya,1 Stacey Lau,2 Radhakrishna R. Kallem,1 Jonathan Hogan.1 The International Kidney Registry Consortium (K-REG) and the International Kidney and Monoclonal Gammapathy (IKMG) Research Group University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; University of Pennsylvania, Philadelphia, PA.

Background: Proliferative glomerulonephritis with monoclonal Ig deposits (PGNMID) is a monoclonal gammopathy of renal significance-associated lesion unique for low rates of paraprotein and clone detection. Prognosis is poor with 30% of patients progressing to ESKD, but recent data suggest improved outcomes with clone-directed therapy regardless of clone-detection status. Here, we present the baseline kidney and hematologic characteristics of patients with PGNMID from the International Kidney Registry Consortium (K-REG).

Methods: PGNMID cases were identified retrospectively by K-REG sites. Baseline demographic, clinical, kidney biopsy, hematologic and treatment data were analyzed and stratified by presence or absence of clone detected, as well conservative vs. non-specific immunosuppression vs. clone-directed therapy prescribed.

Results: 134 patients from 15 sites in 3 countries with PGNMID were included, 13% of which had been included in previously published studies. The mean age was 57 (SD 17) years, of whom were female and 72% Caucasian. The median baseline eGFR was 35 (IQR 21-52) ml/min/1.73m2 and median proteinuria 3.9 (IQR 1.5-7.2) g/day. IgG kappa was the most common involved paraprotein (61%). 30% of patients had a detectable circulating paraprotein by SPEP or sIFE and 11% by UPEP or uIFE. 75% of patients underwent a bone marrow biopsy. Overall, a clone was detected in 19% of patients. There were no significant differences in age, sex, race, baseline eGFR, or proteinuria based on clone or paraprotein-detection status. Clone-directed therapy was prescribed in 55% of patients, non-specific immunosuppression to 15% of patients and conservative therapy in 40% of patients. Clone-directed therapy was prescribed in 82% of patients with a detectable clone vs. 52% of patients without a detectable clone (p = 0.011).

Conclusions: In this large series of PGNMID, a minority of patients had detectable clone. Baseline demographic and clinical characteristics were not different based on clone detection status but treatment varied significantly depending on clone-detection status. Additional analyses of the K-REG cohort will provide insight into renal and hematologic responses.

PO1549
Kidney Outcomes in Biopsy-Proven Thrombotic Microangiopathy with Eculizumab Therapy

Mohammad A. Sohail,1 John R. Sedor,2 Susana Arrigian,1 Jesse D. Schold,2 Leaf C. Herlitz,2 Ali Mehdi,1 Cleveland Clinic, Cleveland, OH; ‘Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: There are limited long-term data on kidney outcomes in ecuizumab-treated patients with biopsy-proven thrombotic microangiopathy (TMA). We report our experience of using eculizumab in patients with primary (genetic/antibody mediated) TMA, secondary TMA syndromes associated with antiphospholipid syndrome (APS) or systemic lupus erythematosus (SLE), as well as TMA of undetermined etiology.

Methods: We reviewed adult patients with kidney biopsy-proven TMA treated with eculizumab between 2014-2019. Transplant recipients, pregnant patients and those with scleroderma, shiga-toxin related hemolytic uremic syndrome or thrombotic thrombocytopenic purpura were excluded. Kidney response to eculizumab at 26 weeks for patients not on kidney replacement therapy (KRT) and for those requiring KRT at the time of or within 1 week of initiation of eculizumab, was defined as an increase of 15 ml/min/1.73m2 and liberation from KRT respectively.

Results: We collected data on 16 patients (primary TMA [n=3]; secondary TMA including SLE [n=3] and APS [n=4]; TMA of undetermined etiology [n=6]). The median time from biopsy diagnosis to treatment initiation was 3.0 days (IQR: 1.0-10.0) and the median duration of therapy was 303 days (IQR:160,604). 13 patients (81%) required KRT at the time of initiation of eculizumab. 4 patients died during follow up, 2 of whom died within 26 weeks. 6 (37.5%) patients were off KRT at 26 weeks. 2/3 patients who required KRT when therapy was started. 2 of 3 patients who did not need KRT initially eventually progressed to end-stage kidney disease after 1 and 5.5 years from initiation treatment. 3/6 patients (50%) and 3/8 patients (37.5%) with mild and moderate interstitial fibrosis and tubular atrophy (IFTA) (IFTA) on biopsy respectively responded to therapy, whilst those with severe IFTA (n=2) showed no response.

Conclusions: Although eculizumab use has been expanding rapidly for primary and secondary TMA syndromes, our data depicts a suboptimal kidney response, which appears independent of the need for KRT at treatment initiation. Severity of IFTA may be a predictor of kidney response to eculizumab. We suggest that more data is needed on long-term kidney outcomes with eculizumab across TMA syndromes before universally adopting this expensive therapeutic strategy.

PO1550
Recurrence of Atypical Hemolytic Uremic Syndrome After Kidney Transplantation: A Prospective Cohort Study

Caroline Duineved, Romy N. Bouwmeester, Keea L. Wijnssma, Nicole Van De Kar, Jack F. Wetzels. CUREiHUS study group Radboudumc, Nijmegen, Netherlands.

Background: Since 2016, aHUS patients in the Netherlands are treated with a restrictive treatment protocol. Withdrawal of eculizumab is considered after a treatment period of three months. Furthermore, kidney transplantations in aHUS patients are performed without eculizumab prophylaxis, with initiation of eculizumab in case of post-transplant recurrence. This restrictive treatment protocol is monitored in the CUREiHUS study. Here, we present the CUREiHUS study results for kidney transplant patients.

Methods: All kidney transplant patients who received eculizumab therapy for a suspected aHUS recurrence, and who were included in the CUREiHUS study (after informed consent), were evaluated.

Results: In the period from January 2016 until October 2020 we included 15 (F 12, M 3; median age 42y, range 24-66) patients with suspected aHUS recurrence after kidney transplantation. Patients were classified as high (N=8) or moderate (N=7) recurrence risk. The time-interval to recurrence showed a bimodal distribution. Seven patients presented early after transplantation (median 3 m, range 0.3-8.8), with typical aHUS features: rapid GFR loss and laboratory signs of TMA. Eight patients presented late (median 46m, range 18-69) after transplantation. Of these, 3 patients showed typical aHUS features, while in 5 patients no laboratory evidence of TMA was seen, and only a gradual eGFR loss. Treatment with eculizumab resulted in disappearance of TMA and improvement/ stabilization of eGFR in 14 patients. Withdrawal of eculizumab was thus far proposed in 10 patients, and successful in only 5. Median follow-up after recurrence is 29 months (range 3-53 months). At last follow-up median eGFR was 32.0 (ml/min/1.73m2) (range 7-80), considerably less than eGFR before recurrence (54.3 ml/min/1.73m2, range 22-103).

Conclusions: Patients with aHUS who develop recurrence after kidney transplantation do not fully recover kidney function. The major cause is treatment delay due to late recognition of disease recurrence in patients who present with a “creeping creatinine”. Discontinuation of eculizumab is often unsuccessful.

PO1551
A Case of Thrombotic Microangiopathy from an Intra-Abdominal Abscess

Introduction: Infection mediated thrombotic microangiopathy (TMA) has a high mortality with many patients requiring kidney replacement therapy. Recognition of TMA can only occur in the setting where clinical abnormalities can be identified. A rare case of TMA from complicated diverticulitis and polymicrobial intra-abdominal abscess.
Early Recurrence of C3 Glomerulopathy (C3G) in the Allograft

Yonatan Borovitz,1 Hadas Alfandary,2 Amit Dagan,2 Orly Haskin,1 Daniel Landau,2 Miriam Davidovitz,2 Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: C3 glomerulopathy (C3G) has been classified as a glomerular complement mediated disease with predominant C3 deposits for decades. Data regarding clinical course, treatment options and long term prognosis in children and adolescents is still scarce. The aim of the study was to retrospectively describe a single tertiary center’s experience with C3G in the pediatric population, and correlate presentation, pathology, complement findings, response to treatment and disease course.

Methods: A retrospective cohort study. Patients presented with C3G by the age of 18 years comprised the study group. All cases underwent kidney biopsy at presentation. Repeated kidney biopsy was performed on a need basis, in native or transplanted kidneys.

Definition of C3G was based on the 2013 consensus guidelines. Patients underwent complement workup and genetic tests. Treatment regimen was not uniform.

Results: 17 patients were diagnosed with C3 glomerulopathy. Features of Dense deposit disease (DDD) were found in 8 patients, C3 glomerulonephritis in 6 patients. For 1 patient EM was not available. Mean age at diagnosis was 12.7 years (range 1.9 – 17.3). 6 girls and 11 boys. Median follow up 4.4 years (range 1.1-20.9). Treatment modalities ranged from ACE inhibitors and Angiotensin receptor blockers to corticosteroids, rashes (4) (23%) patients reached end stage renal failure and had kidney transplantation. All of them had disease recurrence in the transplanted kidney. Complement workup was positive for C3Nef in 6 patients, C4Nef in 2 patients, C5Nef in 2 patients, factor H antibodies in 2 patients. Genetic testing was positive in one patient. Elevated creatinine at presentation, severe proteinuria, DDD in kidney biopsy– were correlated with worse prognosis.

Conclusions: Understanding the pathophysiology of C3G as a complement mediated disease has progressed during the past years. Still no guidelines exist regarding treatment and prognosis in the pediatric population. Our cohort presented a wide variability in disease course and presentation. Further understanding of the correlation between exact complement abnormality and C3G prognosis is warranted, especially now when new complement system blockers may become available.
PO1555

Utilizing Pharmacokinetic Studies to Optimize Therapy in a Child with C3 Glomerulonephritis and Nephrotic Syndrome: A Precision Medicine Approach
Magdalena Riosl Khursigara, Damien G. Noone, Seetha Radhakrishnan, James A. Tjon, Rose Chami, Rulan S. Parekh, Valerie Langlois, Christoph Licht, Chia Wei Teoh. The Hospital for Sick Children, Toronto, ON, Canada.

Introduction: C3 glomerulonephritis (C3GN) is caused by complement alternative pathway dysregulation, has no definitive treatment and is characterized by progression to ESRD. Terminal complement blockade has successfully been used especially in patients with elevated C5b-9 levels.

Case Description: We describe a 6 year old boy with C3GN, who presented with nephrotic syndrome, severe hypertension (4 anti-hypertensive medications) and acute kidney injury. Complement C3 level was 0.12 g/L (normal 0.8-1.5) with pos C3NeF and elevated C5b-9 levels (2135, normal <239 ng/ml). Despite 6 months of treatment with steroid and MMF, he had ongoing nephrotic syndrome and worsening kidney function. He commenced on standard Eculizumab dosing. Despite 6 months of therapy, he had persistent severe hypertension, nephrotic syndrome requiring weekly albumin/levo-furosemide infusions and worsening kidney function. Complement C3 levels remained low with elevated C5b-9 levels, suggesting sub-optimal terminal complement inhibition due to urinary loss. We confirmed sub-therapeutic plasma concentrations of eculizumab as free plasma eculizumab levels were low on day 7 (9, normal >99 ug/ml) and undetectable on days 10 and 14 post-infusion. Eculizumab frequency was subsequently increased to weekly with MPA-AUC guided adjustment of MMF dosing. Since then, his kidney function, C5b-9 levels (279 ng/ml) and nephrotic syndrome improved significantly, leading to discontinuation of albumin/levo-furosemide and anti-hypertensive medications.

Discussion: Use of pharmacokinetic studies can aid in individualized eculizumab treatment in C3GN patients with ongoing proteinuria and who failed to respond to standard dosing.

PO1556

Remission of C3 Glomerulonephritis with Rituximab
Aki Ilandanavakki Angamuthu, Fatima Batool, Neethu Gopissetti, Imara Dissanayake, Ji Young Shin. Albert Einstein Medical Center, Philadelphia, PA.

Introduction: C3 glomerulonephritis (C3GN) is rare form of glomerulonephritis. It is diagnosed primarily by kidney biopsy with immunofluorescence showing deposits of C3 along the basement membranes. It differs from dense deposit disease with absence of the pathognomonic deposits on electron microscopy (1). There are no randomized trials to guide therapeutic decisions. Spontaneous and treatment-associated complete remissions are rare.

Case Description: 69-year-old female with history of well controlled hypertension on amldipine was sent to hospital with elevated creatinine of 2.52 (unknown baseline) with positive ANA - 1:320 titer. Patient was asymptomatic with negative family history of kidney disease. She denied taking NSAIDs. Serum creatinine on admission was 3.05 mg/dL. Urinalysis showed numerous RBCs with 2 g of proteinuria in the 24-hour urine collection. P-ANCA was positive. All other pertinent serologies were negative including complements, C-ANCA, MPO, PR3. Renal ultrasound revealed medical renal disease. Renal biopsy was performed and preliminary reports showed crescentic glomerulonephritis. Pulse dose steroids was started followed by oral prednisone. In addition, Rituximab was started weekly. Final biopsy confirmed C3GN. Patient did not require dialysis and renal function significantly improved after 4 doses of rituximab to serum creatinine of 1.5 mg/dL.

Discussion: In C3GN with rapidly progressive glomerulonephritis (crescents on biopsy), treatment is not well established. Most patients are treated with steroids in combination with either cyclophosphamide or Mycophenolate mofetil (2). Rituximab was used in some case reports (3). In our patient, since P-ANCA was positive and preliminary biopsy showed crescents, Rituximab was started immediately after pulse dose steroids. Patient did not require dialysis, due to good response and remission. Rituximab is a promising treatment option for C3GN. Remission of C3 glomerulopathy with rituximab as only immunosuppressive therapy. Clin Nephrol. 2015 Jan;83(1):57-60.

PO1557

Myeloperoxidase Immunohistochemical Staining and Response to Eculizumab in a Pediatric Patient with Dense Deposit Disease

Introduction: Previous studies have demonstrated residual complement mediated deposits in repeat renal biopsies of patients with C3 glomerulopathies (Dense deposit disease (DDD) and C3 glomerulonephritis) following eculizumab treatment despite clinical improvement. With the residual complement deposition, it is often difficult to determine whether there is a reduced complement mediated endothelial cell injury. Herein, we report the use of myeloperoxidase (MPO) immunohistochemical staining to show decreased glomerular endothelial cell injury in a pediatric patient with DDD on chronic eculizumab therapy.

Case Description: Our patient was diagnosed with DDD by renal biopsy when he was 5 years old after presenting with a serum creatinine of 5.2 mg/dL, a urine protein to creatinine ratio of 2.5, and a complement C3 level of 50 mg/dL. Functional complement testing showed the presence of C3 and C5 nephritic factors. He was treated with eculizumab (600 mg every 2 weeks) and azathioprine, and over the course of 6 months, his serum creatinine, proteinuria, and complement C3 levels returned to normal. After weaning the frequency of his eculizumab infusions, he experienced a flare of DDD 15 months after initial presentation with a serum creatinine of 3.6 mg/dL, urine protein to creatinine ratio of 7, and complement C3 level of 76 mg/dL. He was re-dosed with eculizumab (600 mg every 2 weeks) with a rapid response to treatment. He had normalization of his serum creatinine to pre-flare levels within 6 months. Since then he has been maintained on eculizumab infusions (600 mg every 4 weeks) along with mycophenolate mofetil. A second kidney biopsy was performed after 3 years of treatment with eculizumab to evaluate response to treatment. The biopsy showed some residual features of dense deposit disease including C3 complement deposition. To evaluate if eculizumab blocked complement mediated injury on glomerular endothelial cells, MPO staining of his initial and repeat biopsy was performed: his initial biopsy revealed diffuse endothelial staining for MPO along glomerular endothelium and the repeat biopsy showed either no MPO staining or weak MPO staining in the glomerular endothelium.

Discussion: In this case, we find that MPO immunohistochemical staining may be useful for monitoring the response to complement blockade in patients with DDD.
PO1558

Pregnancy-Associated Membranoproliferative Glomerulonephritis (MPGN)
Pamela C. Vasquez Buitron,1 Saeed K. Shaffi,1 Zhi Xu,1 Michael B. Kuperman,2 J Pedro Teixeira,1†University of New Mexico School of Medicine, Albuquerque, NM; 2Arkana Laboratories, Little Rock, AR.

Introduction: Nephrotic syndrome (NS) in pregnancy is rare due to MPGN. We present a case of MPGN in pregnancy for which no other cause was found.

Case Description: A 33-year-old G1P0 woman develops hypertension and proteinuria at 12 weeks gestation followed at 21 weeks by NS (75g/24h proteinuria, albumin 1.1 g/dL). AKI with creatinine (Cr) 1.1 mg/dL (up from 0.6), hematuria, and mildly elevated AST and ALT. C4 is low (5.9 mg/dL). SLEP and UPEP detect monoclonal IgG kappa with serum light chain ratio 5.1. ANA, anti-dDNA, cryoglobulins, C3 nephritic factor, and serologies for hepatitis B and C, T. pallidum, and HIV are negative. Renal biopsy reveals MPGN. After counseling, she opts to end the pregnancy. Cr, AST, ALT, and hematuria rapidly normalize, but the proteinuria at first persists. Immunosuppression is offered, but she declines. The proteinuria slowly falls to <0.1 g/dL Cr with supportive care and telmisartan over a year. Apart from low C4, an atypical hemolytic uremic syndrome (aHUS) panel is negative. Genetic testing for aHUS is also negative (heterozygous mutation in DGKE and heterozygous deletion in CFH R1-CFH R3). HLA analysis shows B35 and B51 alleles. C4d staining later performed on the biopsy is strongly positive.

Discussion: As in this case, in NS pregnancy is associated with an increased risk of complications such as superimposed preeclampsia. The etiology of this MPGN case is unknown, with no clear infectious or autoimmune cause. The C4d deposition and negative aHUS testing suggest a defect in the classic complement pathway. The paraprotein may or may not be involved as, though the immune complex deposition was polyclonal, monoclonal IgG-kappa has been rarely reported to activate complement in other autoimmune disorders. Regardless of mechanism, we speculate this MPGN case was triggered by pregnancy as it improved after the pregnancy with supportive care alone.

PO1559

Comparing and Contrasting Glomerular Disease Patients: A Real-World Analysis Showing Demographic, Clinical, and Treatment Differences Across More Than 1,000 Patients

Background: One-half of nephrologists selected glomerular diseases as their leading area of interest in nephrology in 2020. These rare and often-idiopathic disorders are seen as particularly challenging to manage, but an influx of promising pipeline drugs may offer new treatment options in the not-so-distant future.

Methods: 1,112 glomerular disease patient records were collected in collaboration with 290 US nephrologists via HIPAA-compliant, online chart review tool between December 20, 2020 – February 16, 2021.

Results: Chart audits reveal ~8% of nephrologists’ patient populations have a glomerular disorder. Of that group, 26% have IgAN, 26% have FSGS, and 3% have Alport’s Syndrome, among other conditions. IgAN patients are typically middle-aged, white males, in the middle-to-upper class and often present with hypertension, hyperlipidemia, and/or obesity. FSGS patients are mostly middle-aged, black males, in the lower-to-middle class and often present with hypertension, hyperlipidemia, obesity, and/or edema. Alport Syndrome patients tend to be younger (18-49), white males, in the lower-to-middle class and present with hypertension, hearing loss, and sometimes ocular abnormalities. Of the three conditions, FSGS patients are most heavily prescribed steroids and advanced therapeutics like MMs, cyclophosphamide, and Achar Gel and are least likely to be deemed “optimally managed” by their nephrologist. Alport patients are much less likely to receive steroids and are most likely to be seen as optimally managed. Interestingly, despite the value of ACEI/ARB therapy, 42% of IgAN patients were not on therapy at referral, with FSGS and Alport close behind. Nephrologists are trialing SOLITZIs across conditions, with up to one-in-ten patients currently on the drug. A diagnosis for Alport Syndrome may take several months or even years after referral to determine (unlike IgAN and FSGS where it usually takes under four months). Alport is also the least likely of the three diseases to be diagnosed via kidney biopsy. Patient referrals are often deemed “late” by nephrologists, but particularly with the faster-progressive FSGS and IgAN.

Conclusions: Deeper understanding of key comparative differences among rare glomerular diseases may aid physicians in developing strategies for diagnosis and treatment.

PO1560

Glomerular Diseases in Flanders: Overview of the FCGG Biopsy Registry
Dries Deleersnijder,1 Wim Laurens,2 Johan M. De Meester,3 Amelie Dendooven,2 Ben Sprangers.1 Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; 2AZ Nikolaas, Sint-Niklaas, Belgium; 3Universitair Ziekenhuis Gent, Gent, Belgium.

Background: High-quality population-based registries on glomerular diseases are required for epidemiological study and new trial design. The FCGG (Flemish Collaborative Glomerulonephritis Group) database is a population-based registry that has been including data on all native kidney biopsies performed in Flanders since 2017 (Northern part of Belgium) covering a population of approximately 6.5 million inhabitants.

Methods: Clinical data and nephrological diagnosis according to the ERA-EDTA Coding system for Primary Renal Disease are collected together with pathological data including primary and secondary pathological diagnoses according to the Mayo Clinic/ Renal Pathology Society Consensus Guideline 2016. Here, we describe the main results of the first three years of the registry.

Results: From 2017 until 2019, 2,178 biopsies were included, of which 5.7% were performed in the pediatric population. Median age (IQR) was 59 years (42-71). Biopsy incidence proportion was 130 biopsies p.m.p. per year in the adult population. Glomerular disease was present in 54% of the adult biopsies (Fig. 1A). IgA-nephropathy (IgAN) was the most frequently diagnosed disease in adults (17.3% of total, 30.2% of glomerular subcategory). The etiologies of the nephrotic syndrome differed across age categories, with membranous nephropathy (MN) being most frequently diagnosed in the total group of adult nephrotic patients (Fig. 1B). IgAN and pauci-immune glomerulonephritis (AAN) were the two most important causes of the nephritic syndrome in adults. A crescentic pattern of injury was most frequently diagnosed in adults with AAV, lupus nephritis (LN) and IgAN (Fig. 1C, crescents in 82%, 31% and 24% of biopsies, respectively).

Conclusions: The FCGG database is a valuable population-based registry that characterizes the epidemiology of glomerular disease in Flanders. These results are relevant to the clinician, will enable disease subgroup analyses and are useful to set up observational or interventional trials in patients with glomerular disease.
Results: Our analysis indicates specific and unique protein/molecular signatures among patients with GN, MCD, FSGS and LN with respect to disease status and pathological diagnosis. Univariate analysis indicated that at least 62 proteins were significantly different in complete remission vs. proteinuric patients across all pathologies. Multivariate analysis showed significant contributions by several proteins to identify disease state and pathological status of identified protein signatures that are differentially abundant across the 3 distinct glomerulopathies.

Conclusions: Pediatric glomerular disease and disease activity are associated with unique urine proteomes and if confirmed will lead to further identification of important biomarkers. We are currently performing validation of a subset of proteins as biomarkers to determine if they are diagnostic and predictive of treatment response.

PO1562
The Thromboembolism Among Hospitalized Patients with Different Types of Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital

Chaoxiaohong Fan, Jie Ma, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Chronic kidney disease is associated with hypercoagulability and platelet dysfunction. However, data on thromboembolism associating different types of chronic glomerulonephritis (CGN) are less.

Methods: We conducted a retrospective analysis using the database of hospitalization with CGN in Peking Union Medical College Hospital (PUMCH), China from 2000 to 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify types of thromboembolism and etiology of glomerulonephritis (GN), systemic vasculitis (AAV), Henoch-Schönlein purpura nephritis (HSPN), IgA nephritis (IgAN), idiopathic membranous nephropathy (IMN), minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS). Cochran-Armitage trend test and Logistic regression were used for analysis.

Results: Between 2000 and 2017, there were 15,714 hospitalizations with the aforementioned CGN. Their mean age was 51.7 ± 19.8 years and 39.4% were males. The annual prevalence of overall thromboembolism increased steadily from 1.6% in 2000 to 6.6% in 2017 in a dose-response manner (p for trend <0.001). Among all thromboembolism cases, 49.8% had venous thromboembolism and 31.7% had a pulmonary embolism. The prevalence of thromboembolism in IgAN, FSGS, MCD, IMN, HSPN, LN, and AAV were 0.6%, 2.4%, 2.6%, 5.89%, 2.2%, 4.4%, and 5.3%, respectively. The patients with thromboembolism had 2.30-fold increased risk of death (95% CI 1.53-3.46) after adjustment for age and gender. In multivariate analyses adjusted for multiple confounders such as gender, hypertension, diabetes, cardiovascular disease, cerebrovascular disease, heart failure, chronic obstructive pulmonary disease, infection, LN (OR 8.15; 95% CI 5.25-12.65), IMN (OR 6.93; 95% CI 4.39-10.92), AAV (OR 4.53; 95% CI 2.66-7.61), MCD (OR 4.42; 95% CI 2.56-7.61), HSPN (OR 4.05; 95% CI 2.33-7.03), and FSGS (OR 3.18; 95% CI 1.56-6.49) were significantly associated with the increased risk of thromboembolism compared with IgAN.

Conclusions: In the present study, chronic glomerulonephritis, particularly lupus nephritis, idiopathic membranephropathy, and systemic vasculitis were independently associated with an increased risk of thromboembolism.

PO1563
Identification and Validation of Infection-Related Acute Care Events in Patients with Glomerular Disease

Dorey A. Glenn,1 Jarcy Zec,2 Anisha R. Hegde,1 Candace D. Henderson,1 Michelle M. O’Shaughnessy,3 Andrew S. Bombaek,1 Keisha L. Gibson,1 Larry A. Greenbaum,1,4 Sarah Mansfield,5 Yichun Hu,1 Laura H. Mariani,1 Ronald J. Falk,5 Susan L. Hogan,1 Michelle Denburg,1 Amy K. Mottl,1 University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3Columbia University, New York, NY; 4University of Michigan, Ann Arbor, MI; 5Children’s Healthcare of Atlanta Inc, Atlanta, GA; 6Emory University School of Medicine, Atlanta, GA; 7University College Cork, Cork, Ireland; 8Arbor Research Collaborative for Health, Ann Arbor, MI; 9The Children's Hospital of Philadelphia, Philadelphia, PA.

Background: Infections are an important contributor to morbidity and mortality in glomerular disease (GD). Accurate identification of infections using real world clinical data would support the conduct of observational studies examining infection risk, but standard approaches are labor-intensive. We sought to derive and test the validity of diagnosis-code based algorithms to identify infection-related acute care events (ACEs) within a large cohort of children and adults with GD.

Methods: CureGN is a prospective multi-center cohort study of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, or IgA Nephropathy. We describe the sensitivity, specificity, and positive and negative predictive values (PPV/NPV) of four infection diagnosis code lists using manually curated infectious and non-infectious ACEs (hospitalization or emergency department visit) as the gold standard. We then validate the best performing code list within a more contemporary CureGN cohort, using multi-site adjudication of medical records.

Results: In the development phase, the optimal performing combination of diagnosis code lists were used by CureGN coordinators combined with those described by Sahli et al. (PPV 78%, 95% CI 73-83%) (Table 1). Using this code list, 265 infections and 1231 non-infectious ACEs were identified among 2599 CureGN participants in the validation phase (labeled 124 were randomly selected and adjudicated). The PPV and NPV for the final code set were 87% (95% CI 75-90%) and 83% (95% CI 72-93%) respectively.

Conclusions: Diagnosis codes can be used to accurately identify infection-related ACEs among patients with GD. Future studies should validate our findings in other GD cohorts and for specific infection types of high-severity or burden.

Risk Factors for TB in GN

PO1564
Patients with Glomerular Disease Are at Very High Risk of TB Infection Compared to the General Population

Andrew D. Vickers,1,2 Mark A. Dryden,1 Yuyan Zheng,1 Jonathan Hogan,1 Sean Barbour,1,4 BC Provincial Renal Agency, Vancouver, BC, Canada; 2Department of Medicine, University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, ON, Canada; 3Division of Nephrology, University of Pennsylvania, Philadelphia, PA; 4Division of Nephrology, University of British Columbia, Vancouver, BC, Canada.

Background: Advanced kidney disease is a known risk factor for active TB disease; however this risk has not been studied in patients with glomerular disease (GN). We sought to determine the incidence of TB disease in patients with GN and to explore the risk factors associated with immunosuppressed (treatment) and non-immunosuppressed (treatment susceptible) patients with GN.

Methods: A population-level cohort was created using a centralized kidney biopsy registry (2000-2012) of all GN cases in British Columbia, Canada. IgA nephropathy (IgAN) n=857, focal segmental glomerulosclerosis (FSGS) n=564, ANCA-GN n=404, lupus nephritis (LN) n=366, membranous nephropathy (MN) n=398, minimal change disease (MCD) n=191, and other GN (n=305). TB disease was ascertained by linkage to administrative databases. High TB incidence was defined as >30/100,000 person years (PY) consistent with the definition used in first-world countries. Incidence rates were standardized to the general population to generate standardized incidence ratios (SIR, 95% CI). Hazard ratios were calculated using Cox proportional hazards regression.

Results: During a median follow-up 6.2 years, there were 41 cases of TB disease. TB incident rate was 197.4/100,000PY, and was higher in patients with LN vs. other types of GN (403.0/100,000PY, p<0.05). TB incidence in patients with GN was 23-fold higher than the general population (SIR 23.4, 16.8-31.7), and was high in both Canadian and foreign-born patients (range 124.1-579.6/100,000PY). TB incidence was higher during periods of IS use (282.4 vs. 147.8 per 100,000PY, p<0.05), and most cases (80.5%) had IS exposure prior to TB diagnosis. Time from IS to TB disease was highly variable, with median 3.9 years but 24% of TB cases occurred within 1 year. Reduced kidney function and higher proteinuria were also associated with increased TB risk (Table).

Conclusions: Patients with GN have a high risk of TB disease, irrespective of GN type or country of origin. TB disease can occur within months of starting IS, suggesting that all GN patients should be screened for latent TB early in their disease course.

Risk Factors for TB in GN

Poster
The Impact of Obesity on Glomerulonephritis: A Multicenter Cohort Study of Kidney Biopsy over 40 Years

Jennifer Young

Common form of GN. Obesity had significant risks for progression of ESKD in patients with DMN, and HT-N are significantly higher in obese patients although IgAN is the most common form of obesity at time of diagnosis associated with proteinuria in glomerulonephritis (GN) in obese patients.

Methods: A total of 14,833 adult patients who underwent kidney biopsy and had body mass index (BMI) ≥ 30 kg/m² were identified in 18 tertiary hospitals during 1979-2018. Obesity was defined as BMI ≥ 30 kg/m². We analyzed the prevalence of specific forms of glomerulonephritis in obese patients and effect of obesity on mortality and end stage kidney disease (ESKD).

Results: Obese patients in glomerular disease have increased about 12.8-fold over 40 years between 1979-1988 (0.6%) and 2009-2018 (7.7%). In GN patients with obesity, prevalence of IgA nephropathy (IgAN) is the most common (33.7%) followed by FSGS (13.3%), minimal change disease (MCD) (10.8%), membranoproliferative (MN) (6.0%), lupus nephritis (LN) (2.7%), and hypertensive nephropathy (HT-N) (2.6%). The prevalence of FSGS (HR 1.60, 95% CI 1.24-2.06), DMN (HR 1.46, 95% CI 1.01-2.12) and HT-N (HR 2.14, 95% CI 1.29-3.54) were significant higher in obese patients compared than non-obese patients. Obesity had a 1.39-fold increased risk for ESKD progression during 93.8±0.8 months follow up in total patients (95% CI 1.11-1.73). Obesity had higher risks for progression of ESKD in MCD (HR 2.48, 95% CI 1.02-6.04) and LN (HR, 3.28, 95% CI 1.30-8.31). In patients with FSGS, DMN, and HT-N, obesity was not associated with ESKD. Obesity was not associated with mortality in GN patients although obesity was related to mortality only in MCD patients (HR 2.48, 95% CI 1.02-6.04).

Conclusions: Obesity rates are increasing in GN patients. The prevalence of FSGS, DMN, and HT-N are significantly higher in obese patients although IgAN is the most common form of GN. Obesity had significant risks for progression of ESKD in patients with GN, especially MCD and LN patients.

PO1566

Obesity at Time of Diagnosis Associated with Proteinuria in Glomerular Disease

Evon Zeitler, Yichun Hu, Caroline J. Poulton, Lauren N. Blazek, Amy K. Mottl, Jennifer E. Flythe, Susan L. Hogan. UNC Kidney Center, Chapel Hill, NC.

Background: Obesity is an established risk factor for chronic kidney disease (CKD).

Methods: We evaluated a cohort of adult patients with biopsy-proven IgA nephropathy, focal segmental glomerulosclerosis (FSGS), ANCA-associated vasculitis (ANCA), or membranoproliferative (MN) between January 2014 and June 2020, to follow up through April 2021. We categorized body mass index (BMI) at time of biopsy as <25 kg/m², 25 kg/m² ≥ 30 kg/m² or ≥ 30 kg/m². We used Fisher's exact and Kruskal-Wallis tests to compare baseline characteristics between groups and a proportional hazards model to evaluate factors associated with CKD progression to kidney replacement therapy (KRT). We used the sign rank test to compare Kaplan-Meier curves of KRT-free survival.

Results: The cohort included 153 patients: 77 (50%) male with median age 50 (IQR 38-65) years and median BMI 28 (IQR 24-34) kg/m². Compared to patients with lower BMIs, patients with BMI ≥ 25 kg/m² had higher median urine protein to creatinine ratios (uPCR) (p = 0.02, Table 1). In univariate analyses, factors associated with progression to KRT were: blood pressure (p = 0.01), uPCR (<p = 0.01), and lower eGFR (<p = 0.001). BMI at biopsy was not associated with CKD progression, adjusted HRs (95% CIs): BMI ≥ 25 kg/m²-1.09 (0.42-2.83); BMI ≥ 30 kg/m²-1.54 (0.68-3.52). Logrank test for differences (data not shown).

Conclusions: Among glomerular disease patients, BMI was associated with proteinuria, but not with progression to KRT.

Funding: NIDDK Support
The Significance of Hematuria in Primary Proteinuric Glomerular Disease

PO1569

Rulan Saha,1 Damian Fermin,1 Andrew Sampson,4 Howard Mottl,3 Matt Mariani.1
1University of Michigan, Ann Arbor, MI; 2Columbia University, New York, NY; 3University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 4Hospital de Clinicas de Passo Fundo, Passo Fundo, Brazil

Background: Urinary casts identified through microscopic examination of the urinary sediment (MicrExUrSed) constitute clinically useful elements for the diagnosis of acute and chronic kidney pathologies. Granular, waxy and cellular casts are well characterized. However, a unique type of casts containing non-polarizable lipid-like granules immersed within a lightly granular cast matrix is occasionally found. These casts have been labelled as vacuolated denatured casts (VDC). The clinical significance of VDC is not known.

Methods: A total of 1,022-kidney biopsies was performed. The median follow-up time was 67 (IQR 45, 92) months. Age for GN patients was 43.9 ± 16.7 years and 44.8 ± males. The total and average YLL of all GN were 4741.9 years and 4.64 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 ± 2.23 years (p = 0.05). DN (n = 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 1.57. P < 0.05.

Conclusions: The relation between the primary cause of GN and the clinical and histological presentations of GN is not clear. The present study provides useful information on the impact of GN for prioritization of public health policies intervention.

Methods: In this retrospective study, we estimated the average YLL in each glomerular disease. The YLL is the difference between age at death and the standard life expectancy of an individual at the same age. To calculate YLL, we retrieved data from Ramathibodi Hospital Glomerular Registry during January 2011 to December 2020 and national data of standard life expectancy 2020. In both cases, deaths and date of death were recorded. Life table estimator (Newton-Cotes formula) was used to get the average YLL. The total patients in each GN type. GN were categorized into primary GN (IgA nephropathy (IgAN), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MGN) and minimal change disease (MCD)), and secondary GN (tubulointerstitial, ANCA-GN, infection related GN (IGN) or MPGN, and diabetic nephropathy (DN)).

Results: A total of 1,022-kidney biopsies was performed. The median follow-up time was 67 (IQR 45, 92) months. Age for GN patients was 43.9 ± 16.7 years and 44.8 ± males. The total and average YLL of all GN were 4741.9 years and 4.64 years, respectively. The average YLL for secondary GN (n = 391) was higher than primary GN (n = 469) being 7.31 ± 2.23 years (p = 0.05). DN (n = 97) had average YLL at 9.76 years followed by LN (n = 243) at 7.1 years. The average YLL (years) for primary GN were: FSGS (n=125), 2.52 years; MGN (n=106), 2.32; IgAN (n=164), 2.26; and MCD (n=74) 1.57.

Conclusions: GN causes premature mortality with secondary GN being associated with higher premature mortality. The primary GN, DN and IIGN nephritis have the highest YLL. This study provides useful information on the impact of GN for prioritization of public health policies intervention.

Feasibility and Acceptability of Home Urinalysis Monitoring Using a Smartphone Application
Daniella Lev Fere,1,2 Hannah C. Derwick,3,4 Susan L. Furth,5 Lance S. Ballester,5
Jonah Mink,1,2 Stephanie Omumua,1 Michelle Denburg,1 ’The Children’s Hospital of Philadelphia, Philadelphia, PA; 2Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; 3Helen IO, Tel Aviv, Israel; 4Ben Gurion University Faculty of Health Sciences, Beer Sheva, Israel.

Background: Monitoring proteinuria in patients with kidney disease is of crucial importance given its implications for long term disease progression and clinical management. As part of efforts to encourage test adherence, leveraging technology to provide a clinical grade urine analysis result from a home test can greatly enhance the clinical experience for patients, caregivers and providers.

Methods: Children and young adults (5-21 yrs old) at a single pediatric center participated. Caregivers or patients (>12yrs) completed a brief survey and then received a home urinalysis kit by mail. The Healthy.io smartphone app uses advanced computer vision to assess the urine analysis dipstick using the smartphone camera. Families downloaded the app through a text message link and performed a home urine test followed by a survey about their experience. Urine results immediately appeared in the app for patients and accessed by the study team through a secure portal. Patient satisfaction was compared between the new app and current practice (home albumusis or a urine sample brought to clinic) using Wilcoxon rank test with a p value <0.05. Free text responses were analyzed to identify themes related to the app experience.

Results: 103 children, 63 (61%) male, median age 10.9 yrs. (IQR 7.8-14.2) were enrolled. Primary diagnosis included: 47 (46%) glomerular disease, 48 (47%) non-glomerular disease and 8 (8%) kidney transplant recipients. 103(98%) patients were satisfied with the smartphone app compared to 41(40%) patients who were satisfied with the current practice P<0.0001. (Table 1) Patients’ free text comments were divided into themes in table 2.

Conclusions: The Healthy.io home urine testing app received very high rates of satisfaction among patients and caregivers compared to current practice and holds great potential to enhance patient-centered care.

Proliferative Glomerulonephritis in a Patient with NK Cell Lymphocytosis
Hannah Angle, Jia Yi, Koyal Jain. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Introduction: Monoclonal gammapathy of renal significance (MGRS) occurs in patients with non-malignant lymphoproliferative disorders who present with kidney injury secondary to monoclonal immunoglobulin deposition.1 We present a rare case of proliferative glomerulonephritis (PGN) likely due to NK cell lymphocytosis.

Case Description: A 57-year-old male with NK lymphocytosis and HITN presented with progressively worsening oliguric renal failure (creatinine 1.1 to 6.2 mg/dL over 3 months) and elevated lambda free light chains (FLC) with a k/λ ratio of 0.06 (k=5.314, λ=52.58). Urine sediment showed numerous dysmorphic RBCs and granular casts. Renal biopsy (limited specimens) revealed PGN with polyclonal-IgG-dominant deposition and background of moderate interstitial fibrosis and tubular atrophy. Although obvious monoclonal lesions were absent and the PGN may have been coincidental, there was concern for a potential paraneoplastic GN induced by NK cell lymphocytosis or, less likely, MGRS. Thus, patient was treated with Cyclophosphamide-Bortezomib-Dexamethasone (CyBoD). However, due to worsening kidney function patient was started on hemodialysis, hoping for potential renal recovery. Despite significant hematologic response (plasma cell burden <1%), chemotherapy was discontinued after 7 months due to lack of renal improvement and worsening medication side effects.

PO1574
A Sporadic Case of Fibronection Glomerulopathy in Which Mass Spectrometry Was Indispensable for the Diagnosis
Rie Kunitomo, Takahisa Kawakami, Kiyotaka Nagahama, Satoru Hibuino, Kazuhiro Fukuoka, Yoshinori Komagata, Shinya Kaname. Kyorin University, Tokyo, Japan.

Introduction: Fibronection glomerulopathy (FG) is an autosomal-dominant hereditary disease, which is caused by deposition of mutated fibronection (FN). The immunostaining of FN is decisive for the diagnosis. We present a case of FG, in which FN was not detected with immunostaining and the detection of FN with mass spectrometry determined the diagnosis.

Case Description: A 60-year-old female with non-functional right kidney with calcui, 5-year history of proteinuria and 2-year history of hypertension presented with proteinuria and nephrocalcinosis. There was no family history of kidney diseases. Physical examination was significant for blood pressure of 176/98 mmHg and the edema. Laboratory test showed serum creatinine of 2.53 mg/dL, serum albumin of 2.3 g/dL, urinary protein 5.8 g/day, and slight urinary granular RBCs. Anti-nuclear antibody, monoclonal protein, cryoglobulin, HCV, or hypercomplementemia was not detected. Open biopsy was performed. Light microscopy showed lobular glomeruli with mesangial expansion with PAS-positive material. Immunoglobulins, including k and λ, light chains, and complements were not detected. Electron microscopy showed massive mesangial deposits with fibrilary structure. However, Congo red staining and immunostaining of DNAJ9B and fibronection (IST-4 and IST-9) were all negative. Finally, the analysis of microdissected glomeruli with liquid chromatography/mass spectrometry (LC/MS) revealed abundance of FN, demonstrating the diagnosis of solitary FG.

Discussion: FG is caused by deposition of the soluble form of FN from serum, rather than the insoluble form produced by resident cells. Therefore, immunostaining with the monoclonal antibody IST-4, which can detect soluble FN, is usually positive in FG, while that with IST-9, which binds only to cellular FN, is negative. Although IST-4 staining was negative in the reported case, FN was detected with LC/MS. This might be due to a structural change of FN in the deposits, which hindered the binding of IST-4 antibody to FN. Furthermore, it was also confirmed that LC/MS is a powerful method to identify characteristics of unexplained glomerular deposits.

PO1575
To Treat or Not to Treat? Therapeutic Challenges in a Case of Advanced Renal Sarcoi
Catherine Lanned, John S. Thrulow, Maura A. Watson. Walter Reed National Military Medical Center, Bethesda, MD.

Introduction: Use of potentially toxic therapy in patients with low chance of renal recovery is clinically challenging. Kidney biopsy with significant interstitial fibrosis and tubular atrophy (IFTA) and reduced estimated glomerular filtration rate (eGFR) suggests unlikely recovery. We describe a patient with advanced IFTA who recovered substantial kidney function with treatment.

Case Description: A 55-year-old man was diagnosed with pulmonary and renal sarcoidosis. Renal biopsy at diagnosis showed granulomatous interstitial nephritis with non-caseating granulomas and 20% IFTA. Prednisone was discontinued but was continued by the patient for onerous side effects. Serum creatinine (Scr) stabilized at 1.5-1.8 mg/dL. He returned two years later with Scr=5.8 mg/dL (eGFR 12 ml/min/1.73m2). Urinalysis was bland. Serum calcium was 10 mg/dL, phosphorus 4.0 mg/dL and intact PTH 20 pg/mL. He lacked pulmonary or systemic symptoms to merit empiric treatment, and he was resistant to receive steroids due to prior side effects. Given new concurrent diagnosis of a monoclonal gammapathy and sclerotic bone lesions, repeat renal biopsy was performed which revealed agranulomatous interstitial nephritis and 50% IFTA consistent with sarcoid. Despite concern for lack of recoverable kidney function due to high chronicity and reduced eGFR, treatment with high-dose prednisone was started based on the unknown time course of recurrence in a relatively young active patient. Scr improved to 3.0-3.2 mg/dL (eGFR 17 ml/min/1.73m2) and dose of prednisone remained stable. The gammapathy was not renally significant and sclerotic bone lesions were attributed to sarcoidosis.

Discussion: In this patient with active sarcoidosis, presenting with eGFR 12 ml/min/1.73m2 and 50% IFTA on biopsy, it would be reasonable to presume limited benefit and defer steroid treatment, especially given patient reluctance. However, there was significant recovery with treatment. This should prompt reconsideration of the prognostic value of renal pathology in sarcoidosis, especially in view of known heterogeneous involvement. The data presented are those of the authors and do not reflect the official policy of the Department of the Army/Navy/air Force, the Department of Defense, or the United States government.
PO1576

Clinicopathological Characteristics of Adult IgA Nephropathy: A Retrospective Cohort Study

Dawn J. Caster,1 Clint Abner,2 Kerime Ararat,2 Patrick D. Walker,2 Amin Yakubu,2 Martin C. Bunke,1 University of Louisville, Louisville, KY; 1Arkana Laboratories, Little Rock, AR; 2Genesis Research, LLC, Hoboken, NJ; 3Traverse Therapeutics Inc, San Diego, CA.

Background: IgA nephropathy (IgAN) is the most common form of primary glomerular nephropathy and a leading cause of chronic kidney disease (CKD). These analyses characterize clinical and histological features of IgAN in adults at time of kidney biopsy.

Methods: A retrospective study of clinical and histologic characteristics was performed in patients (pts) ≥18 yrs of age with ≥1 IgAN positive kidney biopsy without prior kidney transplant reported from Arkana Laboratories (Jan 1, 2016-May 30, 2020). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-Epi equation without race modifier. All results are at the time of biopsy.

Results: Of 47,262 kidney biopsies performed during the study period, 3,638 (6.5%) IgAN positive cases met the study criteria and were included, of which, 62.7% were male, 49.6% White, 5.1% African American, 5.3% Hispanic, 5.6% Asian and 34.4% Unknown/Other race/ethnicity. Mean (SD) age at biopsy was 47.7 (16.6) yrs. Urine protein to creatinine ratio/24-hour urine protein data were available for 52.4% of pts and the median (Q1-Q3) was 3.0 (1.0 – 5.0) g/g. Additionally, 65.2% of pts had hypertension, 63.1% had existing liver disease were excluded.

Conclusions: The large proportion of pts diagnosed at CKD stage ≥3 and high MEST-C scores for S and T suggest significant disease duration at the time of biopsy. Earlier intervention may be of value to prevent ESKD.

Natural History of IgA Nephropathy: Analysis of a UK National RaDaR IgA Nephropathy Cohort

Jonathan Barratt,1,2 Moin Saleem,3,4 Fiona E. Bradlon,1 Kevin Carroll,1 Ping He,1 Bruce M. Hendry,1 Alex Mercer,12 David Pitcher,12 Retha D. Steenkamp,1,2 A. Neil Turner,1,2 Daniel P. Gale,1,2 1University of Leicester, Leicester, United Kingdom; 2Leicester General Hospital, Leicester, United Kingdom; 3University of Bristol, Bristol, United Kingdom; 4Bristol Royal Hospital for Children, Bristol, United Kingdom; 5UK Renal Registry, Bristol, United Kingdom; 6The Renal Association, Bristol, United Kingdom; 7Royal Free Hospital, London, United Kingdom; 8University College London, London, United Kingdom; 9Traverse Therapeutics Inc, San Diego, CA; 10University of Edinburgh, Edinburgh, United Kingdom; 11JAMCO Pharma Consulting, Stockholm, Sweden; 12KIC Statistics Ltd, Cheshire, United Kingdom.

Background: Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis and a major cause of renal failure. Here we describe the natural history of IgAN using the UK National Registry of Rare Kidney Diseases (RaDaR). Since 2013, patients with biopsy-proven IgAN and eGFR <60 mL/min/1.73m² or proteinuria >1g/24h have been enrolled into RaDaR from 107 adult and paediatric kidney units across the UK, including retrospective and prospective data. Patients with systemic vasculitis or pre-existing liver disease were excluded.

Methods: Baseline date was defined as first occurrence of renal biopsy, primary renal diagnosis or symptom presentation. Patients were grouped into those with ESKD (ESKD group) and those without ESKD at baseline with survival time calculated from baseline to last follow-up for all patients.

Results: In the ESKD group (n=326), median age at first dialysis (56% of patients) and kidney transplant (7%) was 38 yrs (IQR 29-50). In the CKD group (n=1838), median baseline age was 39 yrs (IQR 28-50) with paediatric onset of disease comprising 6%. Baseline median urine PCR was 1.5 g/g (IQR 0.6-3.2; n=356) and mean eGFR was 58 mL/min/1.73m² (SD 32; n=440). Median follow-up was 9.2 years (IQR 5.1-16.3) and ESKD/death occurred in 53% of patients (~1% death). Kaplan-Meier survival curves of paediatric and adult patients show 50% survival probability of 24 & 10 years, respectively (Figure 1).

Conclusions: RaDaR contains a large cohort with long follow up enabling detailed investigation of the natural history of IgAN. These results indicate associations between rapid disease progression and poor outcomes, highlighting a need for effective treatments for patients with IgAN with renal impairment or >1g/24h proteinuria.

PO1578

Symptom Burden Among Immunoglobulin A Nephropathy (IgAN) Patients in a US Real-World Setting

Robert M. Perkins,1 Carolina A. Aldworth,2 Raymond Przybysz,3 Jim P. Doherty,2 Stephen W. Olson,1 Aneshe T. George,3 Jaydeep Das,4 Rachel Studer,1 Novartis Pharmaceuticals Corporation, East Hanover, NJ; 2Novartis Pharmaceuticals Corporation, East Hanover, NJ; 3Novartis Healthcare Pvt. Ltd., Hyderabad, India; 4Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Background: Immunoglobulin A nephropathy (IgAN) is the most prevalent chronic glomerulonephritis and 15-40% of patients will progress to end stage kidney disease (ESKD) within 10-20 years of diagnosis. The symptom burden by eGFR and proteinuria levels has not been well described in IgAN and is presented here.

Methods: This is a retrospective, stratified analysis of adult (≥18 years) patients in de-identified Optum® Electronic Health Records (2007-2019). Pre-processed physician notes were used to select patients with at least two IgAN records without any secondary or negative indication. Patients without a record of renal biopsy, valid eGFR and proteinuria

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
levels, or with a history of ESKD/kidney transplant were excluded. The demographic and clinical characteristics, including symptoms up to 12 months before and up to the 1st record of IgAN are presented here; these symptoms were stratified by eGFR and proteinuria levels.

Results: The final cohort consisted of 846 patients with a mean age of 48.5 years; 57.7% were male and 7.0% Asian. Proteinuria levels of ≥1 g/day were found in 35.7% of patients. The median eGFR was 39.0 ml/min/1.73m², median creatinine was 1.8 mg/dL, and 20.8% of patients had severe deterioration of kidney function (eGFR <15). Overall, more patients in higher chronic kidney disease (CKD) stages experienced any given symptom but this trend was inconsistent for higher proteinuria levels.

Conclusions: Our study found that a considerable proportion of patients experienced pain, fatigue and edema. Except in a few instances, all symptoms increased with lower eGFR levels but this trend was less apparent for proteinuria. Our overall findings suggest that a relatively large proportion of IgAN patients, even those with preserved kidney functions could be experiencing substantial symptomatic burden and this warrants further investigation.

PO1579
Clinical Outcomes of Kidney Diseases Diagnosed in Active Duty Service Members
Trevor W. Tobin, John S. Thurlow, Robert Nee, Christina M. Yuan. Walter Reed National Military Medical Center, Bethesda, MD.

Background: There are no studies that have reported glomerular disease prevalence and looked at the overall healthcare outcomes following renal biopsies in active duty soldiers. We aimed to determine the prevalence of renal diseases amongst the soldiers biopsied at our hospital and determine the outcomes for these individuals as a result of their diagnoses.

Methods: In this retrospective study, we evaluated the results of all native renal biopsies performed at Walter Reed National Military Medical Center from 2005 to 2020. We used this data to determine the prevalence of patients who progressed to have ESKD (End Stage Kidney Disease), renal transplantation, creatinine doubling, proteinuria greater than 3.5 gms/day, medical evaluation board (MEB), and death. The AHTLA and JLV EMR systems were used to collect data on the patients who met our inclusion criteria.

After the data was collected, chi squared tests were performed and Kaplan Meier Curves were created for analysis.

Results: Among 169 patients (mean age =32 years old; 79% male; 48% white; 37% black; 7% Hispanic; 4% Asian; 3% pacific islander; 2% other), the most common indication for renal biopsy was for concomitant hematuria and proteinuria (31%) and the most common histologic diagnosis was IgA Nephropathy (23%). The mean time of follow up was 7.3 years. 11% progressed to ESKD, of whom 87% received a kidney transplant (10% overall). Approximately one third progressed to proteinuria greater than 5.3 gms per day and 5% died.

Conclusions: We identified IgA Nephropathy as the dominant histologic diagnosis in our patients undergoing renal biopsy between 2005 and 2020. Despite our patients being largely young and healthy individuals, renal biopsy identified severe disease with over 10% of patients progressing to ESKD and 5% mortality.

PO1580
Clinicopathological Features, Risk Factors, and Outcomes of Immuno-globulin A Nephropathy Associated with Hepatitis B Virus Infection
Jiachuan Xiong, Xinqiao Hospital, Chongqing, China.

Background: Hepatitis B virus (HBV) infections are associated with an increased risk of kidney diseases. However, the effects of HBV infection on the prognosis of immune-A nephropathy (IgAN) are unclear.

Methods: A total of 838 patients with biopsy-confirmed IgAN were enrolled in this retrospective cohort study. The patients were categorized into either affected by IgAN and HBV infection (HBsAg-IgAN) or by primary IgAN with no sign of HBV infection (P-IgAN). A 1:1 propensity-score matching was performed between the two groups, followed by a Kaplan-Meier survival analysis, to compare the diagnoses, and a Cox regression analysis, to identify factors influencing the HBsAg-IgAN outcomes.

Results: A total of 176 pairs of patients were successfully matched. A significant difference in the systolic blood pressure and ura, serum creatinine, uric acid, and 24-h urine protein levels was observed between the groups. A renal pathological analysis also revealed a significant difference in the mesangial hypercellularity between the groups. During a median follow-up period of 2.4 years, Kaplan-Meier analysis also revealed a significant difference in the renal survival between the groups. Furthermore, multivariate Cox analysis confirmed that HBV infection is an independent risk factor for IgAN progression (hazard ratio [HR] 2.096; 95% confidence interval [CI] 1.091-4.026).

Finally, the HBsAg-IgAN patients who received treatment with renin-angiotensin-aldosterone system inhibitors had a better overall prognosis than those who received immunosuppressive therapy and antiviral treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.

PO1581
Factors Associated with ESKD in Mexican Patients with IgA Nephropathy: A Single-Centre Retrospective Cohort Study
Diana Xavier, Guadalupe Ramos De Jesus, Octavio R. Garcia-Flores, Bernardo Moguel. Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis in the world among patients undergoing renal biopsy. To standardize the histological findings, the Oxford Classification (OC) has allowed clarifying kidney lesions that confer potential risk of progression. The aims are describe the factors associated with ESKD and treatment implemented in Mexican patients with IgAN.

Methods: We conducted a single-center, retrospective cohort study in a tertiary hospital in Mexico City, patients with biopsy-proven IgAN and followed up for at least 2 years and examined the relationship between clinical parameters and OC to predict the risk of ESKD after biopsy. We used age and sex adjusted Cox proportional hazards models to study the association of the predictor variables (MEST-C, global glomerulosclerosis and proteinuria >1g/day) with the incidence of ESKD. The HRs were expressed with 95% confidence intervals (95% CI).

Results: 35 patients were included, mean age 37.2±15.2 years, 60% were female, mean eGFR and proteinuria at biopsy were 60.8±34.6 ml/min/1.73m² and 3.4±4.0 g/day respectively. ESKD or eGFR decline by ≥50% as compared to baseline occurred in 10 patients (28.6%) in a median follow-up of 2 years. The eGFR at 24 months post-biopsy 59.1±39.6 ml/min/1.73m². 18 patients received immunosuppressive treatment and 24 received prednisone. The distribution of MEST-C lesions were: M1-35(100%), E1-20(57.1%), S1-33(94.3%), T1-15(42.9%) and T2-2(7.3%), C1-1(31.4%) and podocytopathic features in 0 (0%) of the MEST-C components. only T2-2(7.3%) were significantly associated with ESKD (HR 4.66, 95% CI 0.8 to 27.1). After adjusting for confounding variables global glomerulosclerosis >50% (HR 1.92 [1.02-3.58], p=0.001) and New Oxford classification system (O-grade III (HR 2.79 [0.89-8.58], p=0.001) were independently associated with ESKD.

Conclusions: There are no reports in Mexico of clinical characteristics and outcomes of IgA nephropathy. This study demonstrates that IgA nephropathy was more common in young adults and women and that the progression to ESKD or the global glomerulosclerosis >50% is similar to the reported in the literature. IFTA >50%, and O-grade III were associated with the development of ESKD in Mexican population.

PO1582
External Validation of Two New IgA Risk-Prediction Tools in a Norwegian Cohort
Yngvar Lunde Haakso1, Njål Lura, Rune Bjorneklett, Lars S. Bostad, Thomas Knoop, Haakelund Universitetssjukehus, Bergen, Norway; Universitetet I Bergen, Bergen, Norway.

Background: Recently two prediction tools for IgA nephropathy (IgAN) have been developed combining clinical and histopathological parameters. Barbour and colleagues developed the International IgAN Prediction Tool, to predict the risk for 50 % decline in estimated glomerular filtration rate (eGFR) or end stage renal disease (ESRD) up to 80 months after diagnosis. Schena and colleagues developed the IgA Nephropathy Clinical Decision Support System (CDSS), using artificial neural networks (ANN) to estimate the risk for ESRD. In the present study we aim to externally validate both prediction tools using a Norwegian cohort with long-term follow-up.

Conclusions: Our results indicate that the clinicopathological features and outcomes of patients with IgAN differ significantly between those with and without HBV infection, and that HBV is an independent risk factor for IgAN progression.

Funding: Government Support - Non-U.S.

PO1583
International IgA Nephropathy Network (IIgANN) Risk Prediction and Longitudinal Outcomes in the First South-Asian Prospective IgA Nephropathy Cohort (GRACE-IgANI)
Suceena Alexander,1 Santosh Varughese,1 Athul Thomas,1 Jeethu J. Eappen,1 Elenjickal E. John,1 Anna T. Valson,1 Vinosi G. David,1 Mohamed R. Daha,2 George John,1,2 John Feehally,3 Jonathan Barratt,4 Christian Medical College Vellore, Vellore, India; 2Université Libre de Bruxelles; 3University of Leicester; 4University of Leicester, Leicester, United Kingdom; 5University of Leicester College of Life Sciences, Leicester, United Kingdom.

Background: The Glomerular Research And Clinical Experiments- IgA Nephropathy in Indians is a prospective longitudinal cohort registered with WHO trial id: ISRCTN36834159. The performance of the IIgANN risk prediction score (Barbour et al.) has not been assessed in South Asian IgAN.

Methods: 201 consenting adult IgAN patients were consecutively recruited post kidney biopsy. 195 patients (97%) completed 3 year longitudinal follow-up. Of these, 180 patients had complete Oxford MEST-C score at baseline. Composite outcome (CO) was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m2 or RRT/death.

Results: The median predicted 3-year risk of a 50% decline in eGFR or ESKD using the IIgANN risk prediction tool was 18.1% (IQR 7.4–31.2) at baseline. The minimum risk was defined as ≥50% fall in eGFR from baseline and/or eGFR <15ml/min/1.73m2 or RRT/death. Concordance index was 0.85 for Barbour, and 0.82 for Schena (p=0.03).

Conclusions: Both prediction tools perform well and could become helpful tools for clinicians to identify patients at risk. Barbour’s tool seems to lose prognostic discriminative value at a faster rate than Schena’s over time.

PO1584
IgA Nephropathy Histopathology and Long-Term Renal Prognosis
Nora C. Maddy, Robert Nee, Sarah M. Gordon, Stephen W. Olson. Walter Reed National Military Medical Center, Bethesda, MD.

Background: The Oxford Classification established the mesangial hypercellularity (M), Endocapillary hypercellularity (E), segmental sclerosis (S), Tubulointerstitial fibrosis (T), and crescents (C) score as an important prognostic tool for IgA nephropathy (IgAN). However, these studies did not investigate the impact of complement 3 (C3) immunofluorescence (IF) staining or interstitial inflammation (iI) on long term renal outcomes, nor evaluate an ethnically diverse population which included African Americans.

Methods: We queried the military health system (MHS) by ICD-9/10 codes to identify potential IgA nephropathy cases. We then reviewed the electronic medical record to find those with biopsy-proven IgA nephropathy. Prespecified clinical data was collected to include MEST-C scores, iI, and C3 IF. Primary outcomes included >50% decline in estimated glomerular filtration rates (eGFR), chronic kidney disease (CKD) with eGFR <60ml/min/1.73m2, and end-stage kidney disease (ESKD).

Results: 172 patients were identified with a mean follow-up of 11 years. Mean age was 32 years; 77.9% male; 64.5% White, 9.9% Black, and 12.2% Asian/Pacific Islanders. C3 IF ≥2+ was significantly associated with ESKD (p=0.03) and >50% decline in eGFR (p=0.02). If ≥15% was significant for ESKD (p=0.003), CKD (p=0.01), and >50% decline in eGFR (p=0.01). T and C scores were significant for ESKD, CKD, and >50% decline in eGFR (all p<0.001). S score was significant for ESKD (p=0.02) and CKD (p<0.001). E score was significant for CKD (p<0.003). M score was not significant for any of the primary outcomes.

Conclusions: We present histopathology associated long term renal outcome data for the most ethnically diverse IgAN cohort with the longest follow up to date in such a population. Our data suggests that degree of C3 staining on IF and amount of interstitial inflammation could augment the prognostic accuracy of the MEST-C score. In addition, it supports the theory that IgA immune complexes activate the alternative complement pathway which drives significant interstitial inflammation ultimately resulting in tubular atrophy and interstitial fibrosis.

Disclaimer: The views expressed are those of the authors and do not reflect official policy of the Department of the Army/Navy/Air Force, Department of Defense, or United States government.
PO1585

Severity of Arterial and Arteriolar Sclerosis in IgA Nephropathy and Effects of Renin-Angiotensin System Inhibitors on Its Prognosis

Naoko Sugiuira, Takahito Moriyama, Yoci Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: IgA nephropathy (IgAN) patients often suffer from renal arterial intimal thickening (AIT) and arteriolar hyaline (AH) however, it is unclear whether these features are associated with a poor prognosis. This study aimed to analyze whether treatment with renin-angiotensin system inhibitors (RASI) improves those patients’ survival.

Methods: This retrospective cohort analysis included total 871 patients with IgAN, grouped according to the absence or presence of AIT (Study 1; AIT0: n=415, AIT1: n=268) or AH (Study 2; AH0: n=405, AH1: n=354). The clinical, laboratory, and histological backgrou nds of the patients were analyzed along with their 20-year renal progression. In the AIT1 and AH1 groups, the effect of renin-angiotensin system inhibitors (RASI) on renal progression after making adjustments for the background was analyzed and risk factors for progression were also analyzed.

Results: IgAN patients with AIT1 or AH1 had significantly higher age, blood pressure, body mass index, total cholesterol, uric acid levels, and proteinuria than patients with AIT0 or AH0. They also had more marked histodiagnostic findings, decreased renal function, and lower survival rates (AIT: 62.2% vs. 83.4%, P<0.0001; AH: 63.5% vs. 85.4%, P<0.0001). Multivariate Cox regression analysis considering with clinical and histological findings and treatments revealed AIT and AH as an independent factor for disease progression (AIT1: hazard ratio (HR), 1.98, 95% confidence interval (CI), 1.98-2.01; AH1: HR, 2.12, 95%CI, 2.04-2.19). The renal survival rate was significantly higher in IgAN patients with AIT0 or AH0 who were treated with RASI than in those who were not treated with RASI after background adjustments (AIT1: 71.1% vs. 50.4%, P=0.023; AH1: 76.4% vs. 39.5%, P=0.006). RASI was found to be an independent factor in the prevention of progression, by multivariate Cox regression analysis (AIT1: HR, 0.40, 95%CI, 0.14-0.84; AH1: HR, 0.42, 95%CI, 0.27-0.67).

Conclusions: AIT and AH are associated with serious clinical, laboratory and histological findings and a poor prognosis. RASI was found to improve renal progression of those patients.

PO1586

Intensity of Glomerular Galactose-Deficient IgA1 Deposition Can Be a Marker of Disease Activity in IgA Nephropathy

Maiko Nakayama,1 Hitoshi Suzuki,1,2 Yusuke Fukao,1 Mingfeng Lee,1 Toshiki Kano,1 Yuki Makita,1 Yusuke Suzuki,1 Department of Nephrology, Juntendo University School of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; 3Department of Nephrology, Juntendo University Nippon Medical School, Tokyo, Japan.

Background: Galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the development of IgA nephropathy (IgAN). Recently, it was reported that Gd-IgA1 specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association of intensity of Gd-IgA1 deposition and clinical parameters and histological severity are not clarified.

Methods: We performed immunostaining with KM55 mAb on paraffin sections of all 141 patients with primary IgAN, glomerular Gd-IgA1 deposition was quantified by Image-J software (low, middle, and high groups). The level of proteinuria in the positive. We divided patients into tertiles according to the amount of Gd-IgA1 deposition with creatinine, serum/urinary level of Gd-IgA1, and proteinuria.

Results: Intensity of glomerular Gd-IgA1 by Image-J software, and analyzed its association with histological findings. We also analyzed the association of intensity of glomerular Gd-IgA1 by Image-J software, and analyzed its association with clinical parameters and histological severity are not clarified.

Conclusions: The intensity of glomerular Gd-IgA1 deposition is associated with histological severity, especially acute lesions. Thus, galactose-deficient IgA1 staining may be a valuable index for therapeutic intervention.

PO1587

Segmental Necrotizing/Crescentic Glomerulonephritis (SGN) in IgA Nephropathy (IgAN): A Single-Center Experience

Nirali B. Ramani, William L. Whittier, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Background: The presence of SNGN on renal biopsy generally portends a poor prognosis, similarly poor prognosis was seen with presentation and course of pts with IgAN to determine if the presence of SNGN portends a poorer prognosis in this pt population.

Methods: Biopsies done at Rush University Medical Center from 1992-2019, found IgAN in 75 pts in whom AIT and SNGN was seen in 21 (28%). Clinical, laboratory, histologic features at biopsy, treatment and outcome data (doubling of SCr and ESKD) were collected prospectively. Pts with and without SNGN were compared. Data is presented a means±SD and a P value of <0.05 was significant.

Results: At biopsy there was no difference in age (42±16 vs 43±17 yrs), gender (54% vs 46% male), race or Scr (1.7±1 vs 1.6±1 mg/dl) in pts with compared to those without SNGN. Pts with SNGN had higher systolic BPs (140±14 vs 131±17 mmHg, P=0.02) and higher UPro/Scr ratio (2.8±2.7 vs 1.7±1.7 g/g, P=0.04). All 15 SNGN pts tested were ANCA negative. The percent of glomeruli with global (GS)+segmental (SS) sclerosis (33±25% vs 38±28%) and interstitial fibrosis/tubular atrophy (IFTA) (22±20 vs 23±22%) was similar for those with vs without SNGN. In pts with SNGN, only 15% had lesions involving >25% of glomeruli. FU was similar on average (76± vs 87± yrs) in pts with and without SNGN and treatment with ACEi/ARBs was similar (88 vs 100%). A larger proportion of pts with SNGN were treated with immunosuppressive agents (69 vs 21%, P=0.003). At FU, doubling of SCr (25 vs 22%), ESKD (19 vs 21%) and renal survival at 10 yrs (80 vs 76%) were similar in pts with and without SNGN. In both groups, pts that progressed to ESKD had a higher proportion of glomeruli with GS+SS (IgAN: 63±16 vs 24±21%, P=0.002 and No SNGN: 64±27 vs 31±24%, P=0.002) and IFTA (IgAN: 47±19 vs 16±16%, P=0.006 and No SNGN: 41±27 vs 17±18%, P=0.01). In pts with SNGN, the proportion of glomeruli with SNGN was similar in those with and without ESKD (16±14 vs 18±17%).

Conclusions: In pts with IgAN, the presence of SNGN is frequently seen but does not alter prognosis. This may be the result of >25% involvement with SNGN lesions in the majority of our pts and more aggressive treatment in pts with SNGN. The presence of advanced GS+SS and IFTA at biopsy were most associated with progressive kidney disease rather than SNGN.

PO1588

Novel Scoring System Based on the Oxford Classification Indicating Steroid Therapy Use for IgA Nephropathy

Takahito Moriyama, Eri Kasama, Yoci Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: The Oxford classification identifies predictors of the renal prognosis for IgA nephropathy (IgAN); however, it has been unclear about usefulness for deciding the management approach. We analyzed the clinical utility of this classification for indicating steroid therapy.

Methods: The effects of steroid therapy on the long-term prognosis for all 858 IgAN patients and patients divided with M0, M1, E0, E1, S0, S1, and C0 scores were analyzed using the Oxford classification (M, mesangial hypercellularity; E, endocapillary hypercellularity; S, segmental sclerosis; T, tubular atrophy/intertstitial fibrosis, and C, crescents) were examined using Kaplan-Meier analysis and Cox regression analysis. The steroid responder score (SRS) and steroid non-responder score (SNRS) were determined using the obtained results. The effects of steroid therapy on renal prognosis according to the combination of the total SRS and SNRS for IgAN were analyzed using Cox regression analysis.

Results: Steroid therapy improved the 20-year renal survival rates in all IgAN patients (steroid (+): 75.5% vs. steroid (-): 61.7%, P=0.025) and patients with M1, E1, S1, and T0 scores. We recognized the total score of M1, E1, S1, and C scores (0-4 points) as the SRS and that of T1 and T2 scores (0-2 points) as the SNRS. Multivariate Cox regression analysis revealed that steroid therapy improved the long-term renal prognosis in IgAN patients with higher SRS and lower SNRS (SRS4/SNRS0: hazard ratio [HR], 0.08 and P<0.008; SRS3/SNRS3: HR, 0.05 and P<0.025; SRS4/SNRS1: HR, 0.11 and P<0.007), but not in IgAN patients with lower SRS (0–3) SNRS1 and any SRS/SNRS2.

Conclusions: Patients with SRS4/SNRS1 or SRS3/SNRS3 who responded to steroid treatment; contrarily, those with T1 and T2 scores did not. A higher SRS was a useful indicator for steroid therapy. Nevertheless, prevention of progression in IgAN patients with SNSR was difficult with steroid therapy.
PO1589

Remission of Hematuria Is Associated with Favorable Prognosis in IgA Nephropathy

Kyoung Ho Lee, Young seung Oh, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang, Byung chul Yu. Soochunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.

Background: Recent studies have shown that remission of hematuria is associated with favorable clinical outcomes in patients with IgA nephropathy (IgAN). The current study was conducted to compare the long-term clinical outcomes between patients with remission of hematuria and those with persistent hematuria using the stricter but intuitive definition of “remission of hematuria” than that used in previous studies.

Methods: This retrospective, multicenter, observational study was conducted using a cohort of patients diagnosed with IgAN through kidney biopsy at three tertiary hospitals. A total of 403 patients who had been followed up for more than 3 years and who underwent regular check-ups at intervals of at least 6 months were enrolled. Hematuria remission was defined as the absence of hematuria for at least 3 months after biopsy for diagnosis but with no RBC per high-power field observed in the urine under the microscope for at least 2 years thereafter.

Results: The mean annual rate of eGFR decline was lower in the remission of hematuria group than in the persistent hematuria group (-1.51 ± 2.86 vs. -2.60 ± 3.18 mL/min/1.73 m²/yr, p = 0.002). In the remission of hematuria group, the mean annual rate of eGFR decline decreased after hematuria disappearance (from -1.28 ± 7.06 to 0.09 ± 0.29 mL/min/1.73 m²/yr; p = 0.016). Multivariable analysis revealed remission of hematuria as an independent predictor of a 50% reduction in kidney function (hazard ratio, 0.55; 95% CI, 0.33 to 0.99). Renal survival, defined as a 50% reduction in kidney function, was better in the remission of hematuria group than in the persistent hematuria group (p = 0.030). However, free of ESRD was not significantly different between the two groups (p = 0.079).

Conclusions: In this study, which used a more rigorous but intuitive definition of hematuria remission than that used in previous studies, patients with remission of hematuria showed favorable kidney prognosis. This new definition for remission of hematuria could be used as a prognostic marker in actual clinical practice.

Comparison of renal outcomes between the two groups

PO1590

Reduction of Urinary Levels of Lectin Pathway Complement Components in an IgA Vasculitis Patient After MASp-2 Inhibition with Narsoplimab

Laura Pérez Álvaro1, Katrin Scionti1, Karen Molyneux2, Jonathan Barratt1,2,3, Peter Garratt1,2.

Rigshospitalet, Copenhagen, Denmark; 1University of Leicester, Leicester, United Kingdom; 2Leicester General Hospital, Leicester; 3United Kingdom.

Background: A young female suffering from IgA vasculitis was treated with 4 mg/kg weekly infusions of narsoplimab (a MASp-2 inhibitor) for 12 weeks. MASp-2 is considered the key activator of the lectin pathway (LP) by cleaving C4 and C2, after the binding of LP pattern recognition molecules to its ligands. Inhibition of MASp-2 is predicted to decrease complement activation in complement-mediated kidney diseases. In this exploratory study we measured the levels of different LP complement components to evaluate the influence of narsoplimab on complement activation.

Methods: Urine levels of complement activation markers (C4c, C3bc and soluble C5b-9) and urinary levels of ficolin-1, -2 and -3, MBL, CL-11, MASp-3, MAC-1 and PTX-3 were measured using sandwich-ELISAs. Urine samples were subjected to LC/MS/MS. Correlations between LC/MS/MS and sandwich-ELISA were conducted using simple linear regression and Spearman’s rank correlation coefficient. Significance: p value < 0.05. Urine proteins were adjusted for creatinine excretion and expressed as specific protein/creatinine ratio.

Results: C4c/creatinine ratio, ficolin-3/creatinine ratio and C3bc/creatinine ratio levels were decreased 75%, 58% and 29% respectively, from baseline to the end of the treatment; while levels of MBL and CL-11 remained stable during the treatment. C4c/creatinine ratio levels were significantly correlated to LC/MS/MS C4 data (R²: 0.5059; Spearman: r = 0.5824, p = 0.0402). Circulating levels of complement components in serum were unaltered during treatment. Soluble C5b-9, ficolin-1, -2, MASp-3 and MAC-1 were undetectable in urine and PTX-3 was undetectable in both urine and serum.

Conclusions: This is the first report describing the effect of narsoplimab on urinary complement levels in a complement-mediated kidney disease. Our data suggest a decrease in local complement activation with narsoplimab treatment. Further studies are ongoing to evaluate the use of urine as a non-invasive, inexpensive and readily accessible resource to monitor responses to complement-directed treatments.

PO1591

Identification of Urinary Diagnostic Biomarker for IgA Nephropathy by Lectin Microarray

Yasuhiro Onishi,1 Koki Mise,2 Haruhiito A. Uchida,1 Hitoshi Sugiyama,1 Jun Wada.1,2 Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; 1The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis and the pathogenic roles of aberrantly glycosylated IgA1 have been reported. The glycan abnormalities are mediated by the alterations of glycan processing enzymes, such as decreased activity of β-1,3-galactosyltransferase (CIGALT1). However, it is unknown whether the detection of urinary glycosylation changes contributes to the diagnosis of IgAN.

Methods: We measured the urinary glycan signals bound to 45 lectins on LeCChip in the 493 patients with renal biopsy-proven kidney diseases at Okayama University Hospital from December 2010 to September 2017. To evaluate the diagnostic performance, we added the urinary glycan signals to the diagnosis model with the reference standard, i.e., the presence of hematuria, 24 hr urinary protein excretion, and concentration of serum IgA.

Results: The inclusion of 6 lectins showed a significant improvement of the models: Amanthus Caudatus (ACA) with the difference of AUC 0.038 [95%Cl, 0.019 - 0.058, P < 0.001], Agaricus Bisporus (ABA) 0.035 [95%Cl, 0.015 - 0.055, P = 0.001], Mawia Amuresis (MAH) 0.035 [95%CI, 0.015 - 0.054, P < 0.001], Mawia Amurensis (MAH) 0.035 [95%CI, 0.015 - 0.054, P < 0.001], Macula Pomifera (MPA) 0.021 [95%CI, 0.000 - 0.047, P = 0.006], Jacalin 0.019 [95%CI, 0.004 - 0.034, P = 0.012], and Lycopersicon Esculentum (LEL) 0.016 [95%CI, 0.0 - 0.032, P = 0.045]. All 6 lectins demonstrated reduced signals in IgAN patients and 3 lectins (ACA, BABA, MAH) showed false discovery rate (FDR) below 0.05. In 3 lectins, each signal plus reference standard showed good model fitting associated with the improvement of AUC. By decision curve analysis, there was a 3.45% net benefit by adding urinary glycan signals to ACA at the pre-defined threshold probability of 40%.

Conclusions: The reduction of Galβ1-3GalNAc (T-antigen), Sia(2-6)Galβ1-3 GalNAc (Sialyl T) and Sia(2-3)Gal(α1-3) GalNAc (disialyl-T) was suggested by binding specificities of 3 lectins. CIGALT1 and COSMC were responsible for the biosynthesis of these glycans, and they were known to be downregulated in IgAN. The urinary glycan profile may be useful for the identification of diagnostic marker for IgA nephropathy.

Urinary Transferin and IgG Are Significant and Early Markers of Tubulo-interstitial Lesions in Patients with IgA Nephropathy

Elena Saganova, Olga Galkina, Vasiliy Sipovskii, Pervyj Sankt-Peterburgskij gosudarstvennyj medicinskij universitet imeni akademika I P Pavlova, Sankt Peterburg, Russian Federation.

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis and is a frequent cause of end-stage renal disease. There is a pressing need to identify suitable noninvasive biomarkers in IgAN, to aid with diagnosis, treatment decisions, prediction of the histological lesions and disease progression. Our aim was to assess diagnostic value of urinary transferrin and IgG excretions in prediction of morphological lesions in patients with IgAN.

Methods: 37 patients [19 female, age Me 33 (25; 48) years] with biopsy proven IgAN and without acute kidney injury, infectious diseases, severe heart failure, respiratory insufficiency, cancer were included in the study. 24-hour urinary excretions of transferrin (uTr), IgG (uIgG) were measured by immunoturbidimetric method. Tubulo-interstitial fibrosis (TIF), tubular atrophy (TA) were assessed semi-quantitatively (0-lesions absent; 1-mild focal tubular and interstitial lesions; 2-moderate tubular and interstitial lesions; 3-diffuse tubular and interstitial lesions). All patients consistently were separated into two groups according to the degree of each morphological lesion (TIF or TA): “mild” (TIF or TA grade 0 or 1) and “severe” (TIF/TA grade 2-3).

Results: uTr, uIgG positively correlated (p<0.05) with TIF (r=0.38, r=0.43) and TA (r=0.38, r=0.43), respectively. We did not find correlations between uTr, uIgG and glomerulosclerosis. Using ROC-analysis all patients were separated in two groups using uTr or uIgG according to the degree of morphological lesions (“mild” or “severe”) (Figure 1). We also found that all cut-off values of uTr, uIgG corresponded to the level of urinary protein excretion not more than 1.25 g/24hour.

Conclusions: Our data shows that uTr and uIgG can be used as markers of early tubulo-interstitial lesions in patients with IgA nephropathy with mild protein excretion (<1,25 g/24hour).

Funding: Government Support - Non-U.S.
GWAS methods. The results were tested for Hardy-Weinberg equilibrium (control group; ± ± ± ± patients (mean age 42,9 ± 14,22 y.; 14 ♂), 39 sex- and age-matched and 35 unmatched.

**Background:** IgA nephropathy (IgAN) is the most common glomerular nephropathy globally, with up to 40% of patients at risk of progressing to ESKD. Endothelin (ET) A receptor activation results in mesangial cell (MC) activation, proteinuria, inflammation, and fibrosis, all considered hallmarks of IgAN progression, suggesting the potential for therapeutic benefit of ETA antagonists. The aim of our study was to identify intrarenal transcriptional signatures of ET-activation to stratify patients at high risk of IgAN progression.

**Methods:** We used two approaches to establish a transcriptional signature of ET-activation. First, using a targeted approach, an ET-activation network was generated using three publicly available datasets, produced a gene set of 60 transcripts to create an activity score which was assessed in kidney biopsy profiles in patients with IgAN (n = 25) from the European Renal CNDA Bank (ERCDB). In addition, an ET-activation signature was also generated via RNASeq profiling of primary human MCs stimulated with ET1 (4nM) +/- the selective ETA antagonist atrasentan (1nM, 25nM, n=3/group). Pairwise differential gene expression and gene set enrichment analysis (GSEA) was performed.

**Results:** The targeted analysis showed that the ET-activity score correlated with increased proteinuria (r=0.42, p<0.05) and decreased eGFR (r=-0.47, p=0.02) in patients with IgAN. The transcript network showed enrichment in endothelial and fibrotic clusters in renal single cell RNASeq profiles. Differential expression analysis identified three publicly available datasets, produced a geneset of 60 transcripts to create an activity score which was assessed in kidney biopsy profiles in patients with IgAN (n = 25) from the European Renal CNDA Bank (ERCDB). In addition, an ET-activation signature was also generated via RNASeq profiling of primary human MCs stimulated with ET1 (4nM) +/- the selective ETA antagonist atrasentan (1nM, 25nM, n=3/group). Pairwise differential gene expression and gene set enrichment analysis (GSEA) was performed.

**Conclusions:** The targeted analysis showed that the ET-activity score correlated with increased proteinuria (r=0.42, p<0.05) and decreased eGFR (r=-0.47, p=0.02) in patients with IgAN. The transcript network showed enrichment in endothelial and mesangial cell clusters in renal single cell RNASeq profiles. Differential expression analysis identified the ET gene network was reversed by atrasentan in MCs (25nM, n=7-8 genes, q<0.05). GSEA in MCs revealed up-regulation of cell proliferation, inflammation and fibrotic networks, with ET1 treatment, which were blocked by atrasentan.

PO1595

**NR3C1 Polymorphisms in Membranous and IgA Nephropathies**

Michal Pac, Natalia Krata, Beata Kalita, Barbara Moszczyk, Aleksandra Wyczalkowska-Tomasik, Julia Prystupa, Krzysztof Krylik, Krzysztof Mucha.

**Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland; Department of Clinical Immunology, Medical University of Warsaw, Warsaw, Poland; Department of Medicine, Columbia University, College of Physicians and Surgeons, New York, NY; Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland.

**Background:** In other diseases (ex. asthma and pemphigus vulgaris) NR3C1 single nucleotide polymorphisms (SNPs) were associated with glucocorticoid (GC) treatment outcomes. The aim of the study was evaluation of the frequency of NR3C1 (SNPs) in adult membranous (MN) and IgA (IgAN) nephropathies biopsy proven patients.

**Methods:** We analyzed NR3C1 SNPs rs6198, rs14123247 and rs17209237 in 39 MN patients (mean age 42,9±14,22 y.; 14 ♂, 39 sex- and age-matched and 35 unmatched IgAN patients (mean age 33,5±12,3 y.; 34 ♂ and 39 sex- and age-matched and 136-unmatched healthy controls (mean age 48,7±17,9 years; 89 ♂) using RT-PCR and GWAS methods. The results were tested for Hardy-Weinberg equilibrium (genotypes p<0,05) and compared between MN, IgAN and controls within MN and IgAN between GC-resistant and -sensitive and GC-dependent and -independent groups using the χ² with Yates’s correction test.

**Results:** The frequency of the minor C allele of rs6198 SNP was significantly increased in MN (p=0,05) and IgAN (p=0,05) compared to controls; and in GC-resistant MN (p=0,05), GC-resistant (p=0,05) and GC-dependent (p=0,05) IgAN. The rs14198 SNP genotypes were unequally distributed among GC-resistant MN and IgAN (p=0,05) and GC-dependent (p=0,05) IgAN. The frequency of the major A allele of rs17209237 was significantly increased in GC-sensitive (p<0,05) and -independent (p<0,05) IgAN. There was a disequilibrium in rs17209237 SNP distribution among GC-sensitive MN (p<0,05). The minor C allele was significantly more frequent among MN (p<0,05) and IgAN (p<0,05) relapse patients and there was rs6198 genotypes distribution inequality for these both groups (p<0,05, p<0,05).

**Conclusions:** Rs6198 and rs17209237 alleles and genotypes have different values between MN and IgAN and controls; and between patients differently responding to the GC treatment. Results indicate that they predict GC treatment outcomes and therefore should be further investigated for their potential prognostic value.

PO1596

**A Rare Case of Paraneoplastic IgA Nephropathy in the Setting of Renal Cell Carcinoma**

Alka A. Tyagi, Mohankumar Doraiswamy, Sethu M. Madhavan. The Ohio State University Wexner Medical Center, Columbus, OH.

**Introduction:** Paraneoplastic nephropathy can present in patients with malignancy. Renal cell carcinoma (RCC) is the most common urologic malignancy; there is a paucity of reported paraneoplastic nephropathies associated with this condition. As such, we present an intriguingly unique case of nephrotic range proteinuria in the setting of recurrent, metastatic renal cell carcinoma.

**Case Description:** An 81-year-old male with history of recurrent metastatic RCC, solitary kidney after a nephrectomy, with stage III chronic kidney disease (CKD) presents with newly worsening renal function. In a 3-month span, his creatinine (Cr) rose from 1.35 mg/dL to 4.6 mg/dL, which prompted further investigation. He had reported taking daily nonsteroidal anti-inflammatory drugs along with his ACE-inhibitor. Urinalysis showed microscopic hematuria with random urine protein/creatinine ratio resulted 16 g/g and renal ultrasound was unremarkable. Other serologic tests at the time were notable for C3 134 mg/dL, C4 32 mg/dL, negative ANA, negative C-ANCA. Of note, he had suffered an E. coli and MRSA UTI, clostridium difficile infection, and was treated for pneumonia with microbials. A renal biopsy was obtained with pathology significant for IgA-dominant mesangial and capillary wall immune complex deposition with only segmental and weak C3 (Oxford score was reported as M1, E1, S1, T0, C9). Because of the weak C3, in spite of the patient’s history of recent infections, a secondary para-neoplastic IgA nephropathy was favored. He was treated with Nivolumab plus Ipilimumab with improvement in serum Cr improved to 2.23 mg/dL in the following 3 months after starting immunotherapy and remained stable in one-year follow up.

**Discussion:** Acutely worsening renal function and nephrotic range proteinuria in the setting of malignancy prompts investigation into a paraneoplastic nephropathy. As in this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is scarce and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.

PO1597

**Circulating and Depositing Glomerular Antibodies: A Concordance or Coexistence**

Deepthi Avanavelli, Dhalakshmi Vurum. ESIC Medical College and Hospital Hyderabad, Hyderabad, India.

**Introduction:** Anti-GBM disease is a systemic autoimmune disorder characterized by circulating IgG antibodies (rarely IgA and IgM), may coexist with pauci-immune membranoproliferative glomerulonephritis and membranous glomerulopathy. The concurrent or sequential presentation of anti-GBM disease with IgA nephropathy has been rarely described.

**Case Description:** We herein report a case of 31-year-old female who had presented with sudden onset of breathlessness, pedal oedema for 15 days and oliguria for 5 days with 1 episode of haematuria. There were no arthralgias, oral ulcers, alopecia, skin rash, sore throat and diarrhoea. Her marital life was of five years with no history of conception or abortions. On examination she had mild pedal edema and her BP was 180/130 mm Hg. Blood investigations revealed haemoglobin 9.5 g/dl, urea 209 mg/dl, serum creatinine of 26 mg/dl, thrombocytopenia, and anemia. She was treated with high dose prednisolone and his ACE-inhibitor. Urinalysis showed 5+ proteinuria and white blood cell casts. Her creatinine improved to 2.23 mg/dL in the following 3 months after starting immunotherapy and remained stable in one-year follow up.

**Discussion:** Acutely worsening renal function and nephrotic range proteinuria in the setting of malignancy prompts investigation into a paraneoplastic nephropathy. As in this case, secondary IgA mesangial nephropathy can rarely present with RCC. This association is scarce and furthermore there is a lack of understanding of the development of this glomerulopathy. Treatment of the underlying malignancy has shown to improve and preserve renal function. Further investigation into the immune-pathophysiology can help drive the development of further treatment strategies.
Discussion: Presentation of IgAN along with anti GBM without linear deposition on renal biopsy but with positive anti GBM titers makes this case interesting. The association of anti GBM disease with IgAN nephropathy could be a coexistence as IgAN is most common glomerular disease or these IgA mesangial deposits might have role in the pathogenesis of triggering GBM antigens and formation of antibodies in this case.

PO1597
Early Predictors for Stable Kidney Function in Lupus Nephritis
Juan M. Mejia-Vilela, Megan Ashley N. Gerrard, Raque A. Comuidad Bonilla, Luis E. Morales-Buenrostro. National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico.

Background: Early prediction of outcomes in LN is essential to adjust LN treatment. The aim of this study was to evaluate the early course of laboratory parameters and their association with long-term stability of kidney function.

Methods: We studied 433 patients from our local LN cohort recruited between 2008 and 2017. All patients had >36 months follow-up and complete evaluation at LN flare, 3-, 6- and 12-months of follow up with hemoglobin, creatinine, 24h-proteinuria, albumin, anti-dsDNA-Ab, complement C3 and C4 fragments. The main outcome was stable kidney function defined as eGFR within 25% of the best eGFR attained in the first 12 months of treatment. Each variable was evaluated individually by ROC curves and in association with other variables. The change in area under the curve (AUC) was analyzed with De Long’s test.

Results: Median follow up was 73 months (IQR 51-101). Kidney survival was 90% and 81% at 3- and 5-years, respectively. Stability of kidney function was 77% and 65% at 3- and 5-years, respectively. The predictive performance of each parameter varied with the timepoint where evaluated (Table). Serum albumin and hemoglobin AUCs improved from baseline to the 3- and 6-month timepoint. Proteinuria and eGFR AUCs improved at each timepoint up to the 12-month timepoint. C3, C4, and anti-dsDNA-Ab level did not improve at any timepoint vs. baseline. The best predictor of 36-month eGFR stability was proteinuria <1g/g by 12 months. The sum of proteinuria plus eGFR provided the best combined AUC at each timepoint (Figure 1).

Conclusions: Early course of albumin, hemoglobin, and serological parameters does not improve prediction for stable kidney function in LN. The predictive performance of each biomarker improves over time. The combination of proteinuria and eGFR remains the best predictor of kidney outcomes.

Table 1. Area under the curve (AUC) of the evaluated parameters to predict stable kidney function by 36 months.

PO1598
Long-Term Outcomes of Lupus Nephritis in a Single Tertiary Care Center in South India
Srinivas N. Kinijarapu, Swamalatha Guditi, Siddharth Herur. Nizam’s Institute of Medical Sciences, Hyderabad, India.

Background: Lupus nephritis (LN) is a frequent and severe manifestation of SLE, a risk factor for chronic kidney injury and end-stage renal disease in SLE we evaluated the clinical presentation and outcome with various treatment regimens in patients with lupus nephritis

Methods: A retrospective study in 50 patients with biopsy proven LN [class III (12), class IV(11), class V(4), class III+V(10), class III+V(7), class IV+V(6)] treated with NMP for 3 days followed by monthly CYC for 6 months and oral corticosteroids 0.5-1mg/kg with tapering to 10mg/day at the end of 6th month as induction protocol. AZA or MMF as maintenance regimen based on clinician discretion. Clinical presentation, histopathological (LM+IP) features, treatment regimen, treatment response and renal relapse and outcome were evaluated.

Results: Patients had a mean follow up of 3.6 years, clinical presentation nephrotic N.S (36%), nephritic Nes (24%), RPGN (16%), nephritic-nephrotic NS-NeN (12%), AKI (12%) patients who had RPGN and AKI presentation had crescentic GN and high chronicity index, 46% attained complete remission(CR), 28% attained partial remission, 26% did not respond to treatment(NR) at the end of induction.15 and 8 patients out of 23 who attained complete remission were initiated on MMF and AZA as maintenance regimen respectively, 13/15 in MMF group and 7/8 in azathioprine.patients continued to have CR or NR at the end of 2 years. In patients who attained partial remission 5 on MMF and 5 on AZA, 4 on quarterly pulse doses of cyclophosphamide, 3/5 patients on MMF had C.R, 2/5 on AZA had C.R, 2/4 on quarterly pulse doses of CYC had C.R. 6 out of 12 patients maintained renal remission progressed to CKD at the end of 6 months. 4/7 patients who did not respond to CYC as induction were treated with MMF, 2 patient were treated with rituximab and one with triple immunosuppression(tacrolimus+MMF+corticosteroids),1 patient who treated with MMF and 1 patient who treated with rituximab attained partial remission, no patient attained complete remission at the end of 2 years.

Conclusions: Induction regimen with cyclophosphamide is non inferior when compared to various other induction regimen in LN. Quarterly pulse dose of CYC has no better outcome when compared to AZA and MMF as maintenance. Non responders at the end of 6 months of induction does not have better outcome at the end of 2 years.

PO1599
The Relationship Between Renal Flares and Continuity of Medical Care in Patients with Lupus Nephritis
Louwla Alsharhan,1 Insa M. Schmidt,2 Ramon Bonegos,2 Michael R. York,2 Christina Lam,2 Monica Crespo-Bosque,2 Sushrut S. Waikar,2 Hanni Menn-Josephy,2 ‘Kuwait Ministry of Health, Safat, Kuwait; ‘Boston University, Boston, MA.

Background: African American and Hispanic patients with lupus nephritis (LN) are known to have worse clinical outcomes compared to those of white patients, with higher prevalence of severe inflammatory nephritis, higher rates of doubling creatinine, End Stage Kidney Disease (ESKD) and death. In this study, we characterized the frequency and severity of renal flares of patients treated in our lupus nephritis clinic.

Methods: Patient demographics are presented as mean ±SD; student t-tests were used when appropriate; Chi-square tests were used to determine differences in the number of renal flares and the number of missed appointments (dischotomized into 0 vs. >1).

Results: Between 2005–2019, a total of 116 patients with Lupus Nephritis treated at the multidisciplinary lupus clinic in a safety net hospital in Boston, MA were enrolled in our study. 23.3% of patients (n=27) self-identified as white and Asian and non-Hispanic (group 1); 76.7% of patients (n=89) self-identified as Black, African American and/ or Hispanic (group 2). Patients’ demographics and disease characteristics were similar between the two groups. Over the duration of the study, 59.5% of patients (n=69) did not experience any flare, and 40.5% of patients (n=47) experienced a flares. Of the patients that experienced ≥1 flares, 89% (n=42) missed one or more appointments over the course of the study. The rate of missed appointments in group 2 was significantly higher than the one observed in group 1 (85.4% vs. 48.1% respectively, p<0.001).

Conclusions: This study represents one of the largest cohorts of patients with lupus nephritis with consistent, longitudinal, long term follow up. We found that in our black, African American and/ or Hispanic population, there is a significant difference in frequency and number of missed appointments between renal flares and missed appointments. In our safety net hospital setting, missed appointments frequently represents patients’ inability to access care due to various challenges including lack of sick days at work, transportation challenges, access to certain technologies and language barriers. When looking to reduce racial and ethnic health care disparities, we should design interventions that are aimed at removing key barrier to health care access.

PO1600
Collapsing Glomerulopathy Can Worsen Prognosis in Lupus Nephritis

Background: Collapsing glomerulopathy (CG) conveys a poor renal prognosis and is characterized by podocyte atrophy with segmental or global collapse of the capillary walls. While it can be idiopathic, it is often seen in association with other viral, drug, and autoimmune conditions including lupus nephritis (LN). This retrospective study describes features and clinical outcomes of 16 patients with SLE and biopsy proven CG.

Methods: Using our Glomerular Disease Collaborative Network registry, we performed retrospective chart review on patients with systemic lupus erythematosus and CG on kidney biopsy with or without an LN lesion from 2000 - 2021. Patients with multiple biopsies, the first biopsy with GC was identified as the incident biopsy. We defined poor renal outcome as reaching a renal endpoint of serum creatinine doubling, chronic dialysis initiation, or renal transplantation. Patients were characterized by baseline demographics, laboratory results, interstitial fibrosis, and medications.

Results: We identified 16 patients with mean age of 33 years at incident biopsy. Most were female (87.5%) and black (87.5%). Mean serum creatinine (S Cr) was 3.1mg/dL and mean proteinuria by 24-hour urine collection or spot urine protein:creatinine ratio was 7.12g. Excluding 2 patients with limited follow-up, 11 of 14 (78.6%) patients had poor renal outcomes. These patients were similar in age (mean 33 years) and were also majority female (90.1%) and black (90.1%). In this group, mean S Cr was 5.35mg/dL and proteinuria was 3.69g. This group had significant interstitial fibrosis and tubular atrophy with 71% grade severe and 28.6% grade moderate. 43% of patients were on IFTA. The renal endpoint was reached in 4.5 years (average). Of 3 patients who did not have a renal end point, mean S Cr was 1.83 mg/dL with less IFTA noted on biopsy. Treatment options varied with most receiving mycophenolate or cyclophosphamide.

Conclusions: This descriptive project confirmed that CG was associated with poor renal prognosis in LN; the majority of the patients required dialysis, proceeded to transplantation, or had doubling of serum creatinine during follow up. Despite treatment with standard of care agents, outcomes remained poor. Patients who had worse S Cr at presentation or severe IFTA had worse outcomes.
PO1601
SEROLOGICAL ACTIVITY IN PURE MEMBRANOUS LUPUS NEPHRITIS IN A PREDOMINANTLY BLACK POPULATION
Levar G. Roberts, Akriti Arora, Hilton Mozzone, Jason Cobb. Emory University, Atlanta, GA.

Background: Clinically significant kidney disease is estimated to occur in nearly 60% of patients with systemic lupus erythematosus (SLE). A majority of these patients develop proliferative disease, however 10-15% develop a non-proliferative form of disease known as membranous lupus nephritis (LN) (Class V lupus nephritis). These patients typically present with significant proteinuria. Austin et al. reported 7% of patients with low complement levels and 21% with elevated anti-dsDNA levels. In this study we assess serological activity (C3, C4, anti-dsDNA) of pure membranous LN in a predominantly black patient population.

Methods: Kidney biopsy log from 2010-2017, and a retrospective chart review was completed. We excluded any patients with proliferative disease (active or chronic). We analyzed serological activity (C3 level, C4 level & anti-dsDNA) at time of renal biopsy and again at 24 weeks. Results: Of the total 101 patients with pure membranous LN, we had 54 patients with sufficient follow-up data. 52 of the 54 were female with an average age of 35.5; 92.5% (50 of 54) were black. At time of kidney biopsy, low C3 and low C4 was found in 54% and 41% of patients respectively. Whereas an elevated anti-dsDNA was identified in 39% with 20% having the classic triad of low C3, low C4 and elevated anti-dsDNA. When compared to 24 weeks (roughly end of induction therapy) low C3 and low C4 was found in 37% and 24% of patients respectively. Whereas an elevated anti-dsDNA was identified in 31% with 13% have the combination of low C3, low C4 and elevated anti-dsDNA

Conclusions: In this predominantly black population of pure membranous LN the majority of patients did not have the classic triad of low complements and elevated anti-dsDNA (20% at time of diagnosis/biopsy). Compared to others looking at pure membranous we did find higher rates of low complements and elevated anti-dsDNA at time of diagnosis (54% with low C3 initially). Possibly due to our unique urban patient population which is >90 percent black, i.e. more severe SLE. Despite the majority of patients not having the classic triad of low C3, low C4, and elevated anti-dsDNA, clinical providers must be diligent in assessing the need for kidney biopsy in SLE; and non-SLE patients as serological activity does not correlate with biopsy findings. Earlier treatment correlates with improved prognosis.

PO1602
Role of Kidney Biopsies in Lupus Erythematosus Patients: Clinico-pathological Correlation
Lorenz Leuprecht, James M. Chevalier, Thanangami Muthukumar, Surya V. Seshan. Weill Cornell Medicine, New York, NY.

Background: Lupus nephritis (LN) affects >50% of the patients with systemic lupus erythematosus (SLE) and is a major cause for morbidity and mortality. The diagnosis of LN as well as the extent and severity of renal involvement are assessed via kidney biopsy. However, appropriate clinical indications for a kidney biopsy are not well defined in adults, nor is the predictability of the clinical presentation. Therefore, a clinico-pathological correlation of patients with SLE and presumed SLE who underwent a kidney biopsy is conducted.

Methods: We evaluated a total of 134 biopsy samples from 123 patients with either SLE or presumed SLE at the time of biopsy that were obtained during a 10-year period at a major medical center in New York City. 11 patients underwent a biopsy twice during that period. Laboratory, and clinical data were also collected retrospectively via chart review.

Results: 86% of the patients were female, 31% African American, 21% White, and 11% Asian. The mean age at the time of the biopsy was 36.2±12.6 years, the mean serum-creatinine 1.4±1±28 mg/dL, and the mean urinary protein excretion 3.8±3.43 g/dL. 97% of the biopsy samples had evidence of LN, with the majority showing either Class IV-V (29%) or Class V (33%). About 13% had findings other than LN, such as TMA, focal collapsing features of the glomeruli, diabetic nephropathy, or possible ANCA vasculitis, with or without evidence of LN. Additionally, in patients of 65% of the biopsy samples, eGFR was <60 mL/min/1.73 m², and 29% (38/132) had a negative urine dipstick for blood. Complement levels were low in 88/128 instances, and anti-dsDNA was positive in 57% of the instances (n=127). When comparing all proliferative forms of LN (n=74) with Class V lupus nephritis, there were significantly higher creatinine, higher proportion of hematuria, anti-dsDNA positivity, low complements, as well as a proteinuria level ≥1 g/d.

Conclusions: We conclude that normal serum-creatinine values may not preclude significant kidney pathology in SLE patients and those with proliferative forms of LN may have a negative urine dipstick for blood (14%), normal complement levels (14%), and/or a negative anti-dsDNA test (29%) around the time of the biopsy. Furthermore, patients with SLE may have other morphologic findings correlating with clinical renal presentation, instead of LN.

PO1603
RITUXIMAB FOR SEVERE RECURRENT PROLIFERATIVE LUPUS NEPHRITIS AFTER KIDNEY TRANSPLANTATION: PONDERING A RARE CASE
Rui Song, Mingyue He, Ilay Rakham, Serban Constantinescu, Iris J. Lee. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Severe histologic recurrence of lupus nephritis (LN) post-kidney transplant (KTX) is extremely rare on standard transplant immunosuppression. Severe recurrence shortens allograft survival, yet treatment guidelines post-KTX are lacking.

Case Description: A 52-year-old African American (AA) man with ESRD secondary to LN underwent a second KTX from a deceased donor. He had a prior living-unrelated KTX with graft failure due to mixed rejection without LN recurrence. For the second KTX, he received Thymoglobulin induction and maintenance immunosuppressive regimens including re-coated mycophenolate sodium (EC-MPS), Tacrolimus, Prednisone, with immediate graft function (nadir creatinine 1.4mg/dL). He developed leukopenia requiring a reduction of EC-MPS to 360mg twice daily. He developed nephrotic range proteinuria 6 months post-KTX but had stable allograft function, bland urine sediment, normal complements, and negative anti-dsDNA antibodies. Despite inactive serologies, allograft biopsy revealed diffuse proliferative sclerosing and crescentic LN (ISN/RPS class IV). Due to persistent leukopenia, Rituximab was chosen over commonly-used Cyclophosphamide (CYC) for therapy. He received intravenous Methylprednisolone (3000 mg) and Rituximab 800mg (375 mg/m²) for 4 doses. Complete B-cell depletion was maintained for 3 months. His proteinuria decreased from 6.9 g/day to 1.2 g/day, and renal allograft function remained stable.

Discussion: Severe recurrent LN post-kidney transplant is rare and can present a diagnostic and therapeutic challenge. Despite rituximab’s efficacy in LN recurrence, the first KTX did not rule out LN recurrence on the second kidney allograft. In our case, the only presence of persistent progressive proteinuria warranted allograft biopsy. AA ethnicity and reduction of EC-MPS were risk factors, which highlights the significance of LN pathogenesis. Rituximab targets CD20+ B cells and has been successfully utilized for refractory LN. It has a more favorable toxicity profile compared to CYC which has been the conventional treatment for clinically significant LN post-KTX. We propose Rituximab as a better treatment option for severe recurrence of LN post-KTX.

PO1604
INFLUENZA VACCINATION IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): EFFECTIVENESS, EFFICACY, SAFETY, UTILIZATION, AND BARRIERS
Fangfang Li, Lin Sing, 1, Cyriel G. Emory University, 2, National University Singapore Yong Loo Lin School of Medicine, Singapore, Singapore, 3, Singapore General Hospital, Singapore, Singapore.

Background: Influenza infections increase morbidity and mortality among immunocompromised individuals with SLE and lupus nephritis. Yet, they are highly preventable through vaccination. We aimed to describe the effectiveness, efficacy, safety, utilization and barriers to influenza vaccination in SLE so that targeted strategies can be implemented to improve vaccination rates.

Methods: We conducted a systematic review and meta-analysis of all published and unpublished studies up to 19 May 2021 via PubMed, Embase, Cochrane, WHO Clinical Trials, and ClinicalTrials.gov, which reported on our desired outcomes relating to influenza vaccination in SLE and lupus nephritis.

Results: Of 726 articles screened, 44 studies (14779 patients) were included. 9 studies reported on effectiveness, 20 studies on efficacy, 24 studies on safety, 12 studies on utilization, and 4 studies on barriers to influenza vaccination. Influenza involvement or lupus nephritis was present in 20%. The majority were female (90.8%). The mean age was 41.3 years (95% CI 36.8-45.7), mean disease duration was 10.91 years (95% CI 7.10-14.72), and mean SLEDAI score was 4.15 (95% CI 3.18-5.12). Individuals who received influenza vaccination were less likely to develop pneumonia (relative risk, RR 0.38, 95% CI 0.08-1.86, p=0.23), acute bronchitis (RR 0.21, 95% CI 0.09-0.48, p=0.0002), and viral respiratory infections (RR 0.36, 95% CI 0.21-0.64, p<0.0005). Pooled seroconversion and seroprotection rates were 56.6% and 68.2% for H1N1, 56.7% and 73.7% for H3N2, and 46.8% and 69.9% for B influenza strains. Mean SLEDAI scores did not change significantly after vaccination. Flares occurred in 20.3%, while local and systemic adverse events occurred in 20.5% and 26.6%, respectively. Only 39.1% of SLE patients were currently vaccinated against influenza. Meta-regression showed that vaccination rates were significantly associated with increasing GDP of the country (p=0.002) and increasing mean years of disease duration (p=0.02). The most common barriers to vaccination were concerns over the safety or efficacy of the vaccine (37.2%), lack of doctor recommend (23%), and having experienced side effects of other vaccines previously (13%).

Conclusions: Influenza vaccination is effective and safe in SLE and lupus nephritis. Targeted strategies are required to overcome barriers to improve influenza vaccination uptake.

PO1605
LUPUS NEPHRITIS IN A PATIENT WITH AUTOIMMUNE HEPATITIS: A CASE REPORT
Sox H. Kug, 1 Erin Lawler, 2 Sankar N. Niranjan. 1 UConn Health, Farmington, CT; 2 Greater Hartford Nephrology, Bloomfield, CT.

Introduction: Overlapping autoimmune hepatitis (AIH) and lupus nephritis (LN) is a rare entity, only occurring in 1-2.6% of AIH cases, and is difficult to diagnose due to the overlap of diagnostic criteria. Over 100 cases have been reported in the literature.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Delayed Clinical Manifestation of Biopsy-Proven Thrombotic Microangiopathy in a Patient with Lupus Nephritis: A Case Report

Najia Idrees,1 Madeline A. Dilorenzo,1 Joshua S. Huddert,2 Jean M. Francis,1 Hann Menni-Joseph.1 1Boston Medical Center, Boston, MA; 2South Shore Hospital, Weymouth, MA.

Introduction: Complement-mediated thrombotic microangiopathy (c-TMA) involves unregulated complement activation due to inherited or acquired mutations in complement regulatory proteins. Immune complex formation, an important component of lupus nephritis (LN) pathogenesis, can over activate the complement system leading to c-TMA in the kidneys. Findings of c-TMA in LN patients have been associated with end-stage kidney disease (ESKD) or death in up to 50% of patients.

Case Description: 32-year-old female, with a history of lupus and ISN/RPS class III LN since 2017 and recent stroke, was evaluated at our lupus clinic for LN flare and baseline eGFR (mean ± SD) at baseline and 6 months follow up were 20.8 ± 13.7. Almost all patients (59/60, 98.3%) presented with hematuria and 17/60 (28.3%) had nephrotic-range proteinuria. Extra renal involvement most commonly pulmonary was seen in 35/60 (58.3%) patients. 44/60 (73.0%) had crescents and nearly all had interstitial fibrosis and tubular atrophy (IFTA) (median, IQR 30%, 56%). Most patients were induced with cyclophosphamide (49/60, 81.7%) and 16/60 (26.7%) received plasma exchange. eGFR (meanSD) at baseline and 6 months follow up were 20.8±19.4 and 43.5±23.0 respectively. 15/60 (25%) patients progressed to ESKD. On multivariate linear regression analysis, age (B = -0.5), IFTA (B = -0.7) and baseline eGFR (B = 0.3) predicted eGFR at 6 months and IFTA (OR, 95% CI, 11.5, 1.1-11907.7) and eGFR at 6 months (OR 0.9, 95% CI 0.8-1.0) were associated with ESKD (P < 0.05) on multivariate logistic regression analysis. Ethnicity, ANCA type or titer, crescents on biopsy and treatment received did not predict ESKD at 6 months.

PO1610

Glomerular Diseases: Clinicopathological Features and Outcomes in IgAN, Lupus Nephritis, and Vasculitis

PO1611

ANCA-Associated Crescentic Glomerulonephritis (AAV-GN) in Patients with Chronic Lymphocytic Leukemia (CLL): A Case Series

Background: Previous case reports have identified an association between CLL and AAV-GN. However, information on the clinical and pathologic characteristics and long-term outcomes of AAV in these patients is limited.

Methods: We queried medical records and research databases of CLL and AAV subjects seen at our institution to identify patients with diagnoses of CLL and AAV-GN from 1990-2020. We analyzed patient demographics, AAV-GN, CLL specific characteristics, treatments, and outcomes. Kidney biopsies were also reviewed.

Results: We identified 12 patients with AAV-GN and CLL. The mean age at diagnosis was 65 years (48, 80) for CLL and 68 years (57, 80) for AAV-GN. 5 patients were diagnosed with CLL prior to AAV-GN, 4 the same month, and 2 developed CLL >3 years after diagnosis of AAV-GN. At the time of first AAV-GN diagnosis, all had acute kidney injury, with a median serum creatinine (SCr) of 1.9 mg/dL (SD 3.2). Other organs involved included lungs (n=3), skin (n=1), and eyes/encephalitis (n=1). 9 patients p-ANCA-MPO and 2 had c-ANCA-PR3 and one with an indeterminate ANCA but had PR3. On light microscopy, all had crescents, no vasculitis of the arteries, but 9 patients had focal lymphoid infiltrates without a formal diagnosis of CLL in the kidneys. On immunofluorescence 6/12 had trace to 1+ of IgA, 5/12 with IgG and 4/12 with C3. 5/12 of the biopsies had mesangial deposits and majority (1 with diffuse and 7 with moderate) had foot process effacement. All patients received treatment for AAV (9 with rituximab, and 3 with cytotoxic drugs). Renal outcomes were favorable with 11 patients showing an improvement or stabilization in Scr. One patient (p-ANCA MPO antibodies) developed end stage kidney disease, and 3 patients died, two from CLL and the other from heart failure.

Conclusions: In this cohort of outcomes, kidney biopsies were informative. AAV and CLL, the vast majority had p-ANCA MPO, suggesting that the two conditions have either a common underlying lymphocyte dysfunction or that CLL is a predisposing factor to the development of AAV. Anti-CD20 monoclonal antibody therapy was most commonly used, and it led to remission of AAV-GN.

PO1609

Predicting Outcomes in ANCA-Associated Vasculitis Using a Complete National Cohort

Dominic P. McGregor, Jennifer S. Lees, Colin C. Geddes, Emily Mcquarrie, Kate I. Stevens. The Scottish Renal Biopsy Registry The Glasgow Renal and Transplant Unit, Glasgow, United Kingdom.

Background: Outcomes in ANCA vasculitis remain difficult to predict & therapeutic decision-making can be challenging. We aimed to establish if a renal risk score (RRS) could predict outcomes.

Methods: The Scottish Renal Biopsy Registry is a complete national dataset of all biopsies performed in Scotland. Those who had a first renal biopsy between 2014 & 2017 with evidence of ANCA vasculitis were included. Demographic data & outcomes were recorded. A new risk score was calculated. Each patient was categorised according to % of normal glomeruli, % of tubular atrophy/interstitial fibrosis & eGFR (CKD-EPI) at time of biopsy. Individual scores were summated & patients defined as low, medium or high risk. Cox proportional hazard models were created for survival to ESKD, relapse & death, stratified for risk group.

Results: Two-hundred & sixty-nine patients with biopsy proven ANCA vasculitis were identified. Fifty percent (n=123), 46% (n=112) & 5% (n=11) were stratified as low, medium & high risk respectively. Fifty-two percent (n=129) were male & mean age at biopsy was 67.7±12.2 years. Mean eGFR was lower in the high-risk category (8.6±1.8) vs. ‘v’ Low risk 45.7±26.0 ml/min/1.73 m2, p<0.001) & proteinuria was higher (405 (170-767) vs. ‘v’ Low risk 81 (QI 41-155) mg/mmol, p<0.001). Thirty-seven percent (n=91) were PR3 antigen positive. Eighteen (7%) patients experienced pulmonary haemorrhage; representation similar across all risk groups. Those categorised as medium or high risk were more likely to receive plasma exchange & haemodialysis at presentation (p<0.001) compared with the low risk category. Overall, 16% (n=40) of patients relapsed with a trend to higher risk of relapse in the low risk group (27% of these patients, p<0.05). Thirty seven (15%) patients developed ESKD. Cox proportional hazard model for development of ESKD shows that those in high risk category were more likely to reach ESKD (adj HR 78.4, 95% CI 14-438.4, p<0.001).

Conclusions: A simple RRS, using routinely reported data, in patients with renal biopsy proven ANCA vasculitis can help to predict development of ESKD. It may also be predictive of future relapse in those with a lower RRS. The RRS could inform monitoring & treatment decisions. A unique strength of this data is that it is based on a complete national dataset making it less susceptible to bias from regional variations in practice.

PO1612

Kidney Biopsy Chronicity Grading in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

Marta I. Casal Moura, Fernando C. Fervenza, Ulrich Specks, Sanjeev Sethi. Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: Kidney biopsy is valuable for prognostic assessment of renal outcomes in antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with glomerulonephritis (AAV-GN) but the impact of chronic changes is not determined.

Methods: A retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV and active renal disease. We applied the Mayo Clinic Chronicity Score (MCCS), validated and evaluated its implications on outcome prediction in AAV-GN.

Results: We analyzed 329 patients with kidney biopsies available to score. The extent of chronicity was graded by MCCS as (i) minimal – 102 (31.0%), (ii) mild – 106 (32.2%), (iii) moderate – 86 (26.1%), and (iv) severe – 35 (10.6%). The MCCS grades correlated with the degree of renal function impairment at presentation (mean eGFR of 48.3 vs. 29.2 vs. 23.7 vs. 18.5 mL/min/1.73 m2, p<0.0001). Higher degrees of the individual components of the MCCS (glomerulosclerosis, interstitial fibrosis, tubular atrophy and arteriosclerosis) were associated with lower median eGFR (p<0.0001) and decreased event free (kidney failure (KF) and death) survival (p=0.002, p<0.001, p<0.001 and p<0.0001 respectively). Patients with a high MCCS grade showed decreased renal function more frequently (p<0.0001). Increasing MCCS grades were associated with decreased renal recovery (p<0.001), more frequent events and shorter time to KF (p=0.0001), KF and death (p<0.0001), and death (p=0.0001) in our cohort. Clinical presentation and treatment used (CYC or RTX). The MCCS stratified renal outcomes for each MCCS grade and can be used in clinical practice as a cut-off for KF prediction (MCC/Sa4).

Conclusions: Chronic changes on kidney histology independently predict renal function, outcomes and response to treatment in AAV-GN.

PO1613

The Effect of Cumulative UVB Dose on ANCA-Associated Vasculitis

Jennifer Scott,1 Enoch Hayvaramanna,2 Albert Navarro-Gallinad,1 Jason Wyse,1 Jos van Geffen,1 Antonia Buettner,1 Tamara Wanigasekera,1 Louis J. Aslett,4 Norman Basu,1 Lina Zgaga,1 Mark A. Logan1,2,3 Trinity Health Kidney Centre, Trinity College Dublin, Ireland; 1The University of Dublin Trinity College, Dublin, Ireland; 2Institute of infection, immunity and inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; 3Royal Netherlands Meteorological Institute (KNMI), De Bilt, Netherlands; 4Department of Mathematical Science, University of Durham, Durham, United Kingdom.

Background: ANCA-associated vasculitis (AAV) has a relapsing-remitting course but the precise triggers of onset and relapse are unknown. The potential effect of ultraviolet B (UVB) radiation on disease phenotype and activity, mediated by vitamin D (vit D), has been proposed, given the marked incidence variation of AAV phenotypes and serotypes with latitude. Using a well-validated vit D proxy (cumulative-weighted

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

503
UVB dose (CW-D-UVB) at wavelengths that induce vitD synthesis, we hypothesized that prolonged periods of low ambient UVB are associated with an increased risk of GPA phenotype and AAV relapse in this subgroup.

Methods: The UKIVAS (n=1994) and Irish Rare Kidney Disease (RKD) (n=439) registries were used (total n=2433). Inclusion criteria: i) definite AAV diagnosis, ii) positive proteinase-3 (PR3) or myeloperoxidase (MPO) serology and/or positive histopathology. Logistic regression was used to investigate the relationship between latitude, CW-D-UVB and AAV phenotype/serotype in the entire cohort. A multi-level model was then applied to examine their effect on AAV relapse risk in the RKD subgroup.

Results: CW-D-UVB varied across seasons and latitudes. There was no relationship between latitude/CW-D-UVB at disease onset and AAV phenotype/serotype. MPA, MPO-ANCA, older age and rituximab maintenance were protective against relapse. There was no association between CW-D-UVB and relapse risk, even when examining phenotype specific risk (table 1).

Conclusions: We found no association between cumulative UVB, a validated vitD proxy, and AAV phenotype, ANCA serotype nor AAV disease activity in a genetically homogeneous cohort. These findings cast doubt on the role of vitD in AAV disease activity.

PO1614
A Severe Presentation of Systemic Lupus Erythematosus (SLE) and ANCA-Associated Vasculitis (AAV) Overlap Syndrome
Jaelyn Khil, Thuy M. Nguyen, Sijie Zheng. Kaiser Permanente Oakland Medical Center, Oakland, CA.

Introduction: An increasingly recognized overlap syndrome (OS) of lupus nephritis and AAV is defined by the presence of aminogram and ANCA positivity. We report a case of a patient presenting with the symptoms and laboratory findings suggestive of both conditions.

Case Description: A 42 y.o. woman with no PMH presented with 3 weeks of cough, dyspnea, fever, malaise, AKI and hypoxia. Her hgb was 6.3 g/dL and creatinine 17.4 mg/dl(normal 1.5 years prior). UA showed large hgb and >182 RBCs and UPCR 5.72 g/g. Cardiolipin ab was elevated but beta 2 glycoprotein ab and lupus anticoagulant ab were negative. Chest CT showed multifocal opacities. She was urgently started on hemodialysis and solumedrol 1g for 3 days then prednisone 60 mg daily. On day 2 of admission she underwent renal biopsy. Her course was complicated by hemoptysis and bronchoalveolar lavage showed diffuse alveolar hemorrhage (DAH). She was initiated on plasmapheresis. Biopsy demonstrated necrotizing crescentic GN with immunofluorescence showing full house pattern and complex deposits with strong ANCA staining of nuclei. Given the biopsy results and serologies the patient was diagnosed with LN/AAV overlap. The patient was started on Cytoxan 750mg monthly administration. She completed 7 daily sessions of plasmapheresis and renal function recovered sufficiently to stop dialysis. Two months after discharge, her renal function continued to improve with her most recent creatinine down to 2 mg/dl.

Discussion: LN and AAV overlap is rare and there are no guidelines regarding management of these patients. This case stresses the importance of having a high suspicion of LN/AAV when a young, female patient presents with new onset renal failure and DAH. The patient benefited from early, aggressive treatment targeting both disease processes including early initiation of high dose steroids. Secondly, plasma exchange should be initiated emergently with severe presentation, including DAH. Plasmapheresis did not reduce incidence of ESKD in PEXIVAS trial, however, we suspect in this case it contributed to the good outcome. Lastly, little is known about outcomes in these patients, but this is an example of a severe presentation with a positive outcome.
PO1617
A Rare Case of Crescentsc Glomerulonephritis, Diffuse Proliferative Class IV Lupus Nephritis, and Collapsing Glomerulopathy in a COVID, P-ANCA, and Myeloperoxidase-Positive Patient

Introduction: An unusual case of Diffuse Class 4 Lupus Nephritis, along with Collapsing Glomerulopathy from asymptomatic COVID infection
Case Description: 42 year old Asian female presented with painless hematuria, anasarca, reduced hearing, and eye redness over a month. She had empiric antibiotics and steroids prior to admission. On admission, she was hypertensive with anasarca. Labs revealed AKI creatinine of 2.5 mg/dl, proteinuria of 11 grams, and serum albumin 1.9 gm/dl. Urine analysis showed dysmorphic RBCs, RBC casts. Ultrasound showed 12 cm kidneys bilaterally. She had normal complements and DS DNA, antinuclear, lupus anticoagulant negative. ANA, antinuclear antibodies, COVID, PANCA, MPO all positive. Kidney biopsy showed crescentsc glomerulonephritis, diffuse proliferative glomerulonephritis Class IV, collapsing glomerulopathy, infarct house pattern on IF. EM showed sub endothelial, mesangial, and para mesangial deposits, diffuse podocyte foot process effacement, corona virions in endothelial cells. The patient did not have any COVID symptoms and was treated with pulse steroids, MIF induction, hydroxychloroquine, and ACE I. Serum creatinine improved to 1.33 mg/dl, proteinuria improved to 5.6 grams. Her eye redness and hearing impairment resolved.
Discussion: This is a rare case of diffuse class IV lupus nephritis with normal complements, DS DNA, and full house pattern on IF. She tested positive for COVID, was asymptomatic, and was able to start treatment. Corona virions and podocytopathy was noted on EM. Improvement in proteinuria, serum creatinine, albumin, and resolution of anasarca were used to monitor response to treatments. Complements and DS DNA could not monitor disease activity. Thus, clinicians should not rely purely on serologies for diagnosis but should pursue kidney biopsy for definitive diagnosis and treatment. Patients may have atypical presentations.
PO1620

Renal Survival in Anti-Glomerular Basement Membrane Disease

Lauren Floyd,1 Anna S. Li,2 Nina Brown,3 Helen Alderson,3 Silke R. Brix,2 Ajay P. Dhayguide,1 1Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 2The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 3Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Background: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Presentation with severe kidney dysfunction in need of renal replacement therapy (RRT) often results in end stage kidney disease (ESKD). Reliable predictors of survival are needed.

Methods: Retrospective analysis of patients with anti-GBM disease from the North West of England.

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for anti-neutrophil cytoplasmatic (ANCA) and GBM antibodies (28.57%). Median age was 64 years (Interquartile range 43 – 76 years). 39 patients were female (55.7%). Median kidney function at presentation was estimated glomerular filtration rate (eGFR) 91.49 – 835.75 ml/min. Fifty six patients required RRT at presentation, and twelve of these patients recovered sufficient kidney function to withdraw RRT (25.5%). Median follow up was 41 months (IQR 11 – 77.5), and during follow up two additional patients developed ESKD (n = 50). The median presenting eGFR was numerically higher but not significantly different in patients that required dialysis initially and recovered residual function compared to patients that remained dialysis dependent, and no cut-off was detected (p=0.25). Patients with presenting eGFR as low as 2 ml/min recovered function.

Conclusions: Timely aggressive therapy to salvage kidney function is crucial. Better predictors of outcome are needed to optimise management in GBM vasculitis.

PO1621

Validation of the Renal Risk Score in Anti-GBM Disease

Anna S. Li,1,4 Lauren Floyd,1 Nina Brown,3 Helen Alderson,3 Ajay P. Dhayguide,3 Graeme T. Reid,3 Silke R. Brix,1,4 1The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 2Salford Royal NHS Foundation Trust, Salford, United Kingdom; 3Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.

Background: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated kidney disease. Risk stratification can on an aggregate nature occur resulting in end stage kidney disease (ESKD). Clinical and histological variables predicting outcome are needed to individualise therapy and improve outcome.

Methods: We performed a retrospective multicentre analysis and investigated the Renal Risk Score (RRS) proposed in anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis for its prognostic value in anti-GBM disease. We used the published cut-offs for percentage of normal glomeruli (N0 > 25%, N1 > 20%, N2 < 10%), estimated glomerular filtration rate (eGFR, G0 > 15 ml/min/1.73 m2, G1 ≥ 15 ml/min/1.73 m2) and a simplified cut off for tubular atrophy and interstitial fibrosis (T0 mild to moderate, T1 severe). We assigned points to each parameter (N1 = 4, N2 = 6, G1 – 3, T1 – 2 points) and patients to risk groups, low (0), intermediate (2 – 7), and high risk (8 – 11 points).

Results: Seventy patients with GBM nephritis were identified, 20 patients presented double positive for ANCA and GBM antibodies (28.57%). Median age was 64 years (Interquartile range, IQR 43 – 76 years). 39 patients were female (55.7%). Median eGFR at presentation was 91.49 ml/min (IQR 41,755 – 835,75 ml/min). Median follow up was 41 months (IQR 11 – 77.5 months), and fifty patients developed ESKD (71.4%). Forty-seven biopsies were available for scoring. Four patients were low risk, and none developed ESKD (0%). Eight patients belonged in the medium risk group, and five of these developed permanent kidney failure (62.5%). Of 35 patients in the high-risk group, 30 patients developed ESKD (85.7%). Three patients had the highest score of 11 points and remained dialysis independent (100%). The risk groups differed in renal survival (p=0.001).

Conclusions: Low percentage of normal glomeruli, higher grade of tubulo-interstitial damage and severe kidney failure are associated with poor outcome in anti-GBM disease. Combining these variables, the Renal Risk Score accurately predicted kidney survival in anti-GBM disease.

PO1622

Anti-Glomerular Basement Membrane Disease in Pregnancy

Anna S. Li,2,3 Shahid Abdullah,2 Iren Szeki,2 Silke R. Brix,2 1The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Introduction: Anti-glomerular basement membrane (GBM) vasculitis is a rare immune mediated inflammation resulting in organ- and life-threatening disease. Presentation during pregnancy presents an additional challenge to preserve organ function and life of the unborn child.

Case Description: We report the case of a 23-year-old woman, 18 weeks pregnant, presenting with haemoptysis and acute kidney injury. Her chest X Ray demonstrated multilobar consolidation with perihilar prominence consistent with pulmonary haemorrhage. Her blood tests detected an anemia (Hb 51 g/L) and kidney failure (eGFR 17 ml/min). Her GBM antibody was 30.3 AI. She received daily plasma exchange (PLEX) for 7 days until her GBM antibody normalised. Additionally, she was commenced on 1 gram of cyclophosphamide, and after following plasma exchange sessions she received 1 gram of rituximab. Her acute kidney injury progressed (eGFR 13 ml/min), and renal replacement therapy was initiated. Intravenous fluid overload was managed with catheter dialysis which was maintained for 8 days in the high dependency unit on high flow oxygen therapy due to respiratory failure due to her diffuse alveolar haemorrhage needing daily transfusions to maintain her haemoglobin. Daily gynaecology reviews were performed. Post rituximab, PLEX was recommenced after 72 hours and continued daily for another week with 13 sessions in total. The patient stabilised, renal replacement therapy was discontinued, and she was discharged after a hospital stay of 27 days. Her baby was delivered via caesarean section due to the development of preeclampsia at week 28 gestation. Twelve months later, patient and baby are healthy with normal development percentile, and patient’s kidney function has recovered with a current eGFR of 86 ml/min.

Discussion: Timely and aggressive therapy is crucial to salvage kidney function in anti-GBM disease. Here, we present a case of a pregnant patient highlighting that a certain amount of cyclophosphamide is acceptable in life-threatening maternal conditions. Additionally, we demonstrate the possibility to significantly reduce cyclophosphamide in anti-GBM disease by adding in rituximab.

PO1623

Itilizumab, a Novel Anti-CD6 Therapy, in Systemic Lupus Erythematous Patients: Interim Safety Results from the Phase 1b EQUILISE Dose-escalation Study

Chaim Putterman,1 Richard Furie,2 Jai Radhakrishnan,3 Vandana S. Mathur,4 Krishna R. P valu,2 Stephen Connolly,2 Joel M. Rothman,2 Cericie T. Ng,2 Leslie Chin,2 Maple M. Fung,2 Dolea Thomas,2 Kenneth Kalunian,3 Yeshua University Department of Internal Medicine, New York, NY; 2Northwell Health, New Hyde Park, NY; 3Columbia University, New York, NY; 4University of California San Diego, La Jolla, CA; 5Equillium, Inc, La Jolla, CA.

Background: CD6 is a co-stimulatory receptor predominantly expressed on T cells. The CD6 ligand, ALCAM, is expressed on antigen presenting cells, epithelial and endothelial cells. Itolizumab (ITO) is a humanized IgG1 monoclonal antibody that binds CD6 and blocks ALCAM interaction to inhibit T cell activation and trafficking.

Methods: EQUILISE is an open-label Phase 1b dose part study evaluating the safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of subcutaneous doses (SC) of ITO (0.4 to 3.2 mg/kg). Part A enrolled adults with active or inactive SLE who received ≥1 SLE treatment. Treated subjects received ITO SC Q2 weeks x 2. Part B, which evaluates ITO in subjects with active proliferative Class III/IV LN for 24 weeks, is currently enrolling (NCT01428579).

Results: Part A enrolled 34 subjects: 0.4 mg/kg (n=6), 0.8 mg/kg (n=7), 1.6 mg/kg (n=7), 2.4 mg/kg (n=6), and 3.2 mg/kg (n=9). Similar baseline characteristics were noted in all cohorts. The mean age was 51, with 94% female, 74% white and ±11 years since SLE diagnosis. C3 and C4 were within normal ranges. Mean eGFR was 98 ml/min/1.73m² and the median UPCR was 91 mg/g (range 48-1505). SC dosing of 0.4 mg/kg to 2.4 mg/kg (n=26) was well tolerated, with 38% reporting an AE, predominantly mild injection site reactions, with no SAEs reported. >85% of 3.2 mg/kg subjects reported an AE, the most common was injection site reactions, with 2 non-treatment related SAEs reported in 1 subject (hypotension, syncope). 4 3.2 mg/kg subjects (50%) discontinued treatment after 1 dose voluntarily. In all cohorts, there were no notable changes in vital signs, or other lab parameters, except for transient elevations in WBC which resolved without clinical sequelae. PK and PD results show dose-proportional increases in ITO exposure and rapid and dose-dependent decreases in CD4 cell surface expression of CD6.

Conclusions: 2 SC doses of ITO up to 2.4 mg/kg SC in SLE subjects were well tolerated with high less tolerability to the 3.2 mg/kg dose, as 50% discontinued after 1 dose. The data support continued evaluation of ITO in SLE/LN. The ongoing EQUILISE Part B assesses ITO safety and efficacy in Class III/IV LN patients.

PO1624
Itolizumab, a Novel Anti-CD6 Antibody, in Systemic Lupus Patients with Proteinuria: An Interim Subgroup Analysis from EQUALISE, a Phase Ib Study
Chaim Patterman,1 Richard Furie,2 Jai Radhakrishnan,3 Vandana S. Mathur,4 Krishna R. Pola,5 Stephen Connolly,6 Joel M. Rothman,7 Leslie Chinin,8 Nuwarawattu Gayawardhana,9 Maple M. Lugs,9 Cherrie T. Ng,9 Dolca Thomas,9 Kenneth Kalunian,10 Yeshiva University Department of Medicine, Bronx, NY; 2Northwell Health, New Hyde Park, NY; 3Columbia University, New York, NY; 4University of California San Diego Health Sciences, La Jolla, CA; 5Equillium
Background: CD6 is a co-stimulatory receptor that is expressed on T cells. The CD6 ligand, ALCAM, is found on antigen presenting cells, as well as epithelial and endothelial cells. Itolizumab (ITO), a humanized IgG1 monoclonal antibody that binds CD6 and inhibits the interaction of CD6 and ALCAM, inhibits T cell activity and trafficking. ITO is being evaluated as a treatment for systemic lupus erythematosus (SLE) and lupus nephritis (LN).
Methods: EQUALISE (NCT04128579) is a Phase 1b US study of ITO in SLE patients with and without active proliferative LN. Part A enrolled SLE patients (N = 34) who had received a ≥1 SLE treatment but did not have active proliferative LN. Patients received 2 open-label doses of 0.4 to 3.2 mg/kg each on Day 1 and Day 15 with follow up through Day 57.
Results: A subgroup analysis of 16 subjects with Baseline (mean of screening and Day 1) urine protein/creatinine ratio (UPCR) > 100 mg/g was performed. Mean age was 55, 94% were female; 81% white and the mean years since SLE diagnosis was approximately 11. Mean baseline eGFR was 95 ml/min/1.73m2 and UPCR was 272 mg/g (range 50-1509). On Day 29, a geometric mean decrease in UPCR of ~45% was observed in these 16 subjects with greater decline seen for subjects with higher Baseline UPCR values. By Day 57, 6 weeks post treatment the decrease was 34% from Baseline (Figure). Notable is one subject (1.6 mg/kg dose) who had significant Baseline UPCR of 1569 and who was declined at Day 29 and at Day 57 reached 857 mg/g. SC treatment was well tolerated. Of the 6 subjects who had a total of 12 treatment-emergent adverse events (AEs), 4 were from the 3.2 mg/kg cohort. All AEs were mild or moderate in severity.
Conclusions: Patients with SLE and mild baseline proteinuria tolerated ITO treatment well. EQUALISE Part B will further explore the safety and efficacy of ITO in LN patients.

PO1625
Adding Low-Dose CYC to RTX Combined with a Tailored RTX Maintenance Regimen Seems to Favor Stable Remission in Severe ANCA Vasculitis
Renate Ysermans, Matthias H. Busch, Joop Aendekerk, Pieter van Paassen, Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.
Background: Rituximab (RTX) and cyclophosphamide (Cyc) are effective remission-induction therapies in ANCA-associated vasculitis (AAV). High dose CYC is however considered toxic, whereas RTX monotherapy may increase the risk of persistent MPO-ANCA seronegative conversion (OR 3.028, [95%CI, 1.262 – 7.268], p=0.048). MPO-ANCA reappearance after seronegative conversion was associated with increased relapse risk at 24 months (HR 3.651, [95%CI, 1.114-11.966], p=0.048). The risk reduction in ESKD, but absolute risk increase in serious infections was higher for CYC compared to RTX. One year risk of end stage kidney disease (ESKD) and serious infections with and without PLEX in AAV were presented across 5 serum creatinine categories: 150, 250, 350, 450 and 600µmol/L. For each scenario, participants were asked: “If they were a patient with a new diagnosis or relapse of AA V would they prefer CYC than PLEX (yes or no) given its absolute risk reduction in ESKD, but absolute risk increase in serious infections?” Multilevel multivariable logistic regression was performed to identify independent predictors of choosing treatment with PLEX.
Results: There were 549 responses. The mean age of respondents was 57.4 (SD 14.5) years, 72.3% were female, and responders were from the United States (58.1%), United Kingdom (23.7%), Canada (14.0%), and other countries (4.2%). The majority had AAV (86.7%). 190/549 (34.6%) would always choose PLEX and 87/549 (15.8%) would always decline PLEX across the baseline risks of ESKD or serious infections presented. Independent predictors for choosing PLEX included age (OR 0.98, 95% CI 0.96-0.99 per 1 year increase), country (United Kingdom OR 2.73, 95% CI 1.20-6.21), diagnosis (individuals with vasculitis other than AAV were more likely), previous dialysis (OR 3.34, 95% CI 1.37-8.16), previous PLEX (OR 5.13, 95% CI 2.50-10.49), and increased baseline risk of ESKD (Cr 350 and 450µmol/L only).
Conclusions: One third of participants would always choose treatment with PLEX across the 5 scenarios presented. The decision to choose PLEX is influenced by age, country and previous dialysis, and the baseline risk of ESKD and serious infections. Patient values and preferences are needed to inform shared decision-making regarding PLEX in AAV.

PO1627
Maintenance of Remission and Risk for Relapse in Myeloperoxidase Positive Antineutrophil Cytoplasmic Antibody-Associated Vasculitis with Kidney Involvement
Marta I. Casal Moura,1 Shahzadur Tehrani,1 Shane A. Bobart,2,3 Ladan Zand,1 Eddie L. Greene,1 Sanjeev Sethi,1 Ulrich Specks,1 Fernando C. Fervenza,7 Mayo Foundation for Medical Education and Research, Rochester, MN; 2Cleveland Clinic, Cleveland, FL.
Background: Optimal time of remission-maintenance therapy in patients with MPO-ANCA associated vasculitis (MPO-AAV) is not established. Defining clinical and laboratory parameters to guide safe withdrawal of maintenance immunosuppression is required in order to mitigate the risk of relapse.
Methods: A retrospective cohort study of all patients followed at the Mayo Clinic with in RTX on MPA (MPA-AAV) and thrice weekly injections, hypoglycemia, eGFR < 60 ml/min/1.73 m², age ≥ 65 years, treated with MPO-ANCA status and remission-maintenance strategy were characterized.
Results: We analyzed 159 MPO-ANCA positive patients with active kidney involvement. A total of 66 (41.5%) patients had at least 1 relapse. MPO-ANCA patients who became and remained seronegative did not relapse (HR 0.03, [95%CI, 0.001-0.970], p=0.048). MPO-ANCA reappearance after seronegative conversion was associated with increased relapse risk at 24 months (HR 3.65, [95%CI, 1.14-11.966], p=0.012). Immunosuppression was withdrawn in 80 (50.3%) and this was predicted by persistent MPO-ANCA seronegative conversion (OR 3.028, [95%CI, 1.262 – 7.268], p=0.031). In patients who withdrew remission-maintenance therapy, 32 (40.0%) relapsed (in comparison with 34 relapses [43.0%] in those who maintained immunosuppression, p=0.097). ENT involvement (OR 6.095 [95%CI, 1.280 – 29.010], p=0.023) and MPO-ANCA reappearance (OR 9.208, [95%CI, 1.282 – 72.376], p<0.0001), were independent predictive factors for relapse after withdrawal.
Conclusions: Our results suggest that patients who seroconverted and remain MPO-ANCA negative are at lower risk of relapse: remission-maintenance treatment might be withdrawn without an additional risk of relapse. MPO-ANCA reappearance after seronegative conversion is a risk factor for relapse at 24 months. Serial MPO-ANCA determinations are useful to guide clinical decisions on remission-maintenance treatment strategies.

Renal Histological Biomarkers and Response to Different Induction Regimens in ANCA-Associated Glomerulonephritis: The REASSESS Study

Maritza Uzzo,1 Jennifer Scott,7 Alice A. Guerini,2 Stefania Affaitato,2 Rosanna Lacereta,1 Andreas Kronbichler,2 Iva Gunnarsson,13 Marco Allinovi,1 Gaetano La Manna,8 Mario Cuzzolino,1 Anna Breuschfeld,11 Federica Mescia,2 Federico Pieruzzi,1 Stephen P. McAdoo,6 Renato A. Sinico,1 Matija Crnogorac,12 Francesco Scolari,1,2 Mark A. Little,2 David R. Jayne,2 Federico Alberici,2
1Department of Medicine and Surgery, University of Milano-Bicocca and ASST Monza, Milan, Italy; 2Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy; 3Nephrology, Dialysis and Transplantation Unit, Careggi University Hospital, Florence, Italy; 4Dialysis and Renal Transplant Unit, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy; 5Department of Health Sciences, Renal Division, ASST San Paolo e Carlo, University of Milan, Milan, Italy; 6Imperial College London, London, United Kingdom; 7The University of Dublin Trinity College, Dublin, Ireland; 8University of Cambridge, Cambridge, United Kingdom; 9Medizinische Universität Innsbruck Department für Operative Medizin, Innsbruck, Austria; 10Karolinska Universitetssjukhuset, Stockholm, Sweden; 11Linköpings universitet, Linköping, Sweden; 12Department of Nephrology and Dialysis, Agram Special Hospital, Zagreb, Croatia.

Background: The role of kidney biopsy on ANCA-associated vasculitis (AAV) is still debated: despite its significant prognostic value, whether it has an impact on the induction regimen choice has not been explored yet.

Methods: 323 AAV patients with biopsy-proven renal involvement were collected retrospectively from eleven centers and stratified according to the histopathological characteristics at the kidney biopsy and the induction regimen employed.

Results: The median follow-up time was 36 months; the eGFR was 19 ml/min/1.73m². 508 AA V patients with biopsy-proven renal involvement were collected and comparable in the different groups. In the unadjusted survival analysis with the K-M classification, 24% biopsies were classified as Focal, 31% as Crescentic, 33% as Mixed and 12% as Sclerotic. Renal remission rate at 6 months and relapse-free survival were 32% in the Focal, 29% in the Crescentic, 25% in the Mixed, and 22% in the Sclerotic group. The difference was significant in favor of the Focal group (P < 0.001).

Conclusions: Renal histology is an important biomarker for disease activity and it may also play a role in the choice of therapy.

POI1629

ANCA Vasculitis Induction Management in the COVID-19 Pandemic: Results of an International Retrospective Cohort Study

Antonio Salas,1 Duvuru Geetha,2 ANCAITCOV 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins University Department of Medicine, Baltimore, MD.

Background: Induction therapy for severe ANCA-associated vasculitis (AAV) combines glucocorticoids (GC) with either rituximab (RTX) or cyclophosphamide (CYC). The coronavirus 2019 disease (COVID-19) pandemic has increased concern around using aggressive immunosuppression; whether this concern has impacted AAV management is unknown. Here, we report treatment regimens and outcomes of patients with active AAV receiving induction immunosuppression during the first wave of the pandemic.

Methods: We retrospectively studied AAV patients with new or relapsing disease receiving remission induction therapy during the first wave of the COVID-19 pandemic across sites in the US, UK and Europe. Primary outcome was achievement of complete remission at 6 months.

Results: Of 191 patients with a mean age of 65 years old, 52% were female and a majority (89%) were Caucasian. Standard induction was deployed across all sites. Out of the US, UK, and European patient populations, the US used higher GC pulses leading to a higher average cumulative GC dose for remission induction (4153 mg, 2174 mg, 3408 mg, respectively, p = 0.001) and had the highest proportion of patients given RTX induction therapy (64%; p < 0.005). Complete remission was achieved in 90% of patients. Improvement in kidney function at 6 months was similar with all treatment regimens (6 ml/min² increase, p = 0.68). Sixteen patients were diagnosed with COVID-19 and had similar exposures to CYC and RTX. There were no differences in remission rates, ESKD or death when stratified by induction therapy type.

Conclusions: Induction immunotherapy practices differ across the world, but specialists continued their standard management during the COVID-19 pandemic. AAV outcomes or rates of COVID-19 infection were not influenced by different induction regimens.

POI1630

Non-Sucrose Containing IV Immunoglobulin in ANCA Vasculitis Has No Adverse Effects on Renal Function

Renee Yaserman,1 Matthias H. Busch, Joop Aarden, Pieter van Paassen, Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands.

Background: Intravenous immunoglobulin (IVIG) has proven to be effective as an immunomodulator in several autoimmune and inflammatory diseases, including antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Moreover, in the era of B cell-depleting therapies, secondary immunodeficiencies are common, urging supplementation by IVIG. Reported adverse effects are generally mild in nature. However, concerns have been raised about the safety profile of IVIG in relation to renal function. IVIG associated kidney injury is proposed to be mainly related to sucrose stabilized products. Non-sucrose containing alternatives are available and increasingly used. We therefore aimed to analyze the safety of non-sucrose containing IVIG with regard to renal function in patients with AAV.

Methods: AAV patients of the Maastricht University Medical Center were retrospectively analyzed for dynamics of serum creatinine levels before and after IVIG using the Wilcoxon signed rank-test. Subanalyses were performed with regard to the presence of ANCA-associated renal disease and IVIG indication. In addition, correlation analysis was conducted to evaluate the relation between serum creatinine change and cumulative IVIG dose during a 1year follow-up.

Results: 36 with 49 courses of IVIG were included in the short-term and 54 patients with 70 courses of IVIG were included in the long-term analysis. No significant differences were found between serum creatinine levels before and after IVIG in the short-term (median [IQR], 132 [88-159] and 125 [86-173] μmol/L, P = 0.380), with a median follow-up of 16 days after the initial IVIG infusion, and the long-term (median [IQR], 104 [66-147] and 110 [90-151] μmol/L, P = 0.077), after 1 year. One patient with active AAV and renal involvement had a reversible serum creatinine increase >30% 6 days after IVIG. Subanalyses showed no significant changes in serum creatinine levels with regard to renal involvement and IVIG indication. There was no association between serum creatinine change and cumulative IVIG dose 1 year after the initial IVIG infusion (P = 0.667).

Conclusions: This study shows no short-term and long-term deleterious effects on renal function in response to treatment with non-sucrose containing IVIG in patients with AAV.
Efficacy and Safety of a Combination Treatment of Mycoprotein Mefoil and Corticosteroid in Advanced IgA Nephropathy: A Multicenter, Prospective Study

Chang-Young Jung,1 Sang Youb Han,2 Beom seok Kim.1 Yongsei University College of Medicine, Seoul, Seoul, Republic of Korea, 1Inje University Ilsan Paik Hospital, Gunpyu, Republic of Korea.

Background: It remains unclear whether immunosuppressive agents are effective in patients with IgA nephropathy (IgAN). We sought to determine the efficacy of mycoprotein mefoil (MMF) and corticosteroid combination therapy in patients with advanced IgAN.

Methods: We conducted a multicenter, randomized, placebo-controlled, parallel group study of a 48-week administration of MMF and corticosteroids in biopsy-proven advanced IgAN patients with an estimated glomerular filtration rate (eGFR) between 20-50 mL/min/1.73m² and a urine protein-to-creatinine ratio (UPCR) greater than 0.75g/day. The primary outcome was complete (UPCR<0.3g/day) or partial remission (reduction of UPCR>50% compared to baseline) at 48 weeks.

Results: Of the 48 randomized patients, complete and partial remission rates were higher in the MMF and corticosteroid combination therapy group (29.1% vs. 5.0%, P=0.05). In contrast to the combination therapy group, eGFR in the control group significantly decreased from 36 weeks onwards, resulting in a final adjusted mean change of -4.39 ± 1.22 mL/min/1.73m² (P=0.002). The adjusted mean changes at 48 weeks were 0.62 ± 1.30 and -5.11 ± 1.30 mL/min/1.73m² (P<0.005) in the treatment and control groups, respectively. The amount of UPCR was also significantly different between the two groups, where the adjusted mean difference was -0.47 ± 0.17 mg/mgCr in the treatment group and 0.07 ± 0.17 mg/mgCr in the control group (P=0.04). Overall adverse events did not differ between the groups.

Conclusions: In patients with advanced IgAN with a high risk for disease progression, combination therapy of MMF and corticosteroid appears to be beneficial in reducing proteinuria and preserving renal function.

Pharmacodynamic and Clinical Responses to BION-1301 in Patients with IgA Nephropathy: Initial Results of a Phase II/III Trial

Jonathan Barratt,1,2 Dr. Brian T. Hour,3 Brian S. Schwartz,2 Bess Sorensen,3 Suzanne F. Roy,4 Colleen L. Stromat,5 Margaret MacDonald,6 Aaron M. Enders,6 Jeannette Lo,6 Alan Glicklich,6 Andrew J. King,6 1University of Lancaster, Lancaster, United Kingdom; 2Chinook Therapeutics Inc, Seattle, WA; 3Certaar LP, Princeton, NJ; 4Amics Research Center, Northridge, CA.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis globally, with up to 45% of patients at risk of progressing to ESKD. The initiating step in IgAN pathogenesis is the excess production of galactose-deficient IgA1 (Gd-IgA1), resulting in the formation of immune complexes that cause kidney inflammation and damage. A proliferation-inducing ligand (APRIL) is elevated in IgAN patients and correlates with higher levels of Gd-IgA1 and proteinuria, and lower eGFR. BION-1301 is a novel monoclonal antibody targeting APRIL. Here we present interim results from Part 3 of a Phase 1/2 study that characterizes the safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary activity of BION-1301 delivered by IV administration in patients with IgAN.

Methods: Part 3 of this Phase 1/2 study (NCT03945318) is an ongoing multicenter, multicohort, open-label study in up to 40 IgAN patients. In Cohort 1, BION-1301 is dosed at 450mg IV every 2 weeks for up to 12 months. Key objectives of the study include safety and the characterization of PK, PD, immunogenicity and changes in proteinuria. Key eligibility criteria include: (1) urine protein ≥0.5 g/24h or baseline UPCR ≥0.5 g/g, (2) stable/optimized dose of ACE-I/ARB or ACE-I/ARB intolerant and (3) biopsy-verified diagnosis of IgAN within the past 10 years.

Results: Preliminary results from the first 5 patients show BION-1301 is well tolerated with no serious adverse events and no adverse events leading to discontinuation to date. BION-1301 drives durable reductions in serum free APRIL, Gd-IgA1, IgA and IgG with a lesser reduction in IgM. A clinically meaningful reduction of 24-hour UPCR was observed within 3 months. Updated data in all 41 treated patients, along with mechanistic response kinetics, will be presented at the meeting.

Conclusions: BION-1301 is a novel anti-APRIL monoclonal antibody being developed as a potential therapy for patients with IgAN. BION-1301 treatment holds modifying potential by directly targeting the pathogenesis of IgAN. Promising early biomarker and clinical activity support the continued development of BION-1301 in IgAN.

Atrasantin Exhibits a Consistent, Predictable Pharmacokinetic Profile Among Healthy Asian Adults

Aniye Rastogi,1 Jicheng Xu,2 David A. Catanzaro,3 Vince Tong.4 1University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 2Peeking University First Hospital, Beijing, China; 3Chinook Therapeutics Inc, Seattle, WA; 4Juntendo Daigaku Igakubu Daigaku Kenkyuka, Bunkyo-ku, Japan.

Background: Atrasantin, a potent and selective endothelin-A receptor antagonist, is under investigation for reducing proteinuria and preserving kidney function in IgA nephropathy and other glomerular diseases. Two phase 1 studies evaluated the pharmacokinetics (PK) and safety of atrasantin in healthy adults of Chinese (Study M11-521) and Japanese (Study M11-522) parentage.

Methods: Study M11-521 was an open-label, randomized (for single-dose regimens), single-center study of single and multiple doses of atrasantin in 36 healthy Chinese adults. Single doses of atrasantin tablets (0.5, 1, or 1.5 mg) were administered in Part I, and multiple daily single doses of atrasantin 1.5 mg were administered in Part II. Study M11-522 was a double-blind, randomized, placebo-controlled, single-center study of single doses of atrasantin (0.5, 0.75, or 1.25 mg) in 36 healthy Japanese adults. Blood samples were collected for analysis of plasma PK parameters, including the area under the plasma concentration-time curve (AUC) and the maximum observed plasma concentration (Cmax).

Results: In Study M11-521, atrasantin AUC increased proportionally with dose in the 0.5 mg to 1.5 mg dose range, and Cmax increased proportionally with dose in the 1 mg to 1.5 mg dose range. No statistically significant differences were observed in either the dose-normalized AUC for the comparison of the 1.5 mg and 0.5 mg dose groups (P = 0.260) or the dose-normalized Cmax for the comparison of the 1.5 mg and the 1 mg dose groups (P = 0.279). In Study M11-522, a linear increase in atrasantin mean AUC was observed across the 0.5 to 1.25 mg dose range; dose-normalized mean Cmax did not show statistically significant differences across the doses (P = 0.735). Atrasantin was generally well tolerated. No clinically significant vital signs, electrocardiogram activity, or laboratory measurements were observed, and no apparent significant differences among the dose regimens were found with respect to safety.

Conclusions: Dose-proportional increases in AUC were observed across the studied range, which includes the 0.75 mg dose being studied in ongoing clinical trials. These data support the safety and tolerability of atrasantin and suggest a consistent and predictable PK profile among patients of Asian descent.

Pharmacodynamic and Clinical Responses to BION-1301 in Patients with IgA Nephropathy: Initial Results of a Phase II/III Trial

Jonathan Barratt,1 Dr. Billy T. Hour,3 Brian S. Schwartz,2 Bess Sorensen,3 Suzanne F. Roy,4 Colleen L. Stromat,5 Margaret MacDonald,6 Aaron M. Enders,6 Jeannette Lo,6 Alan Glicklich,6 Andrew J. King,6 1University of Lancaster, Lancaster, United Kingdom; 2Chinook Therapeutics Inc, Seattle, WA; 3Certaar LP, Princeton, NJ; 4Amics Research Center, Northridge, CA.

Background: IgA nephropathy (IgAN) is the most common biopsy-proven glomerulonephritis in the world. Approximately 40% of IgAN patients reach end-stage kidney disease (ESKD) 20 years after their kidney biopsy. The high prevalence of ESKD shows that IgAN has a high economic impact in the countries because renal replacement therapy is costly. Moreover, the disease’s onset in the second and third decades of life represents a social challenge because young adult patients are very active and highly productive in the workplace. This challenge is one more reason to move from a generalized therapy for all patients to a personalized therapy. Many randomized controlled trials (RCTs) have been conducted, stratifying IgAN patients based on the laboratory findings (serum creatinine, estimated glomerular filtration rate (eGFR) and daily proteinuria). In contrast, data from the kidney biopsy has been used only for clinical diagnosis. Aim. We have designed a RCT to study personalized therapy in biopsy-proven IgAN patients with active and chronic renal lesions.

Methods: Our clinical study of IgAN (CLiGAN) is a multicentre, prospective, controlled and open-label randomized clinical trial based on patient’s stratification at the time of their kidney biopsy. The trial has been registered in ClinicalTrials.gov (NCT 04662723). We will consider, first, the type of renal lesions followed by serum creatinine, estimated glomerular filtration rate (eGFR) and daily proteinuria. Primary and secondary end points have been established. Second, we will determine whether personalized therapy can slow the decline of the renal function and delay the ESKD. Our clinical study of IgAN (CLIgAN) is a multicentre, prospective, controlled and open-label randomized clinical trial based on patient’s stratification at the time of their kidney biopsy. The trial has been registered in ClinicalTrials.gov (NCT 04662723). We will consider, first, the type of renal lesions followed by serum creatinine, estimated glomerular filtration rate (eGFR) and daily proteinuria. Primary and secondary end points have been established. Second, we will determine whether personalized therapy can slow the decline of the renal function and delay the ESKD.

Results: We will enroll 132 IgAN patients with active renal lesions (66 patients per arm) in the first RCT (AClGAn). They will receive corticosteroids combined with renin-angiotensin system blocker (RASB) or RASB alone. Two hundred ninety-four IgAN patients with chronic renal lesions were enrolled in the second RCT (CHRONiGAn) in which they will receive sodium-glucose cotransporter -2 inhibitor (SGLT2-i) combined with RASB or RASB alone.
Conclusions: Using this approach we hypothesize that patients could receive personalized therapy based on renal lesions to ensure that the right drug gets to the right patient at the right time.

POI1635 Enhanced Efficacy of Corticosteroid Therapy by Tonsillectomy in IgA Nephropathy
Keita Hirano,1,2 Tetsuya Kawamura,1 Kentaro Koike,2 Nobuo Tsuibo,2 Takashi Yokoo,3 Yusuke Suzuki,3 1Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 2The Jikei University School of Medicine, Minato-ku, Japan; 3Juntendo University Faculty of Medicine, Bunkyou-ku, Japan.

Background: Efficacy of corticosteroid therapy in IgA nephropathy may vary among countries or races. Nowadays, the strategy to enhance efficacy of corticosteroid therapy is desired. In 2014, our randomized controlled trial demonstrated that corticosteroid therapy combined with tonsillectomy had superior anti-proteinuric effect than that of corticosteroid therapy alone (Nephrol Dial Transplant. 2014). However, the benefit of combining corticosteroid therapy with tonsillectomy for long-term renal survival was uncertain. Therefore, in a Japanese nationwide prospective cohort dataset, we aimed to evaluate whether the benefit of corticosteroid therapy may increase when it was combined with tonsillectomy, or not.

Methods: Patients were registered between April 1, 2005 and August 31, 2015 at 44 facilities throughout Japan. The primary outcome was a 50% increase in serum creatinine from baseline or dialysis initiation. Two interventions were focused in the present study: corticosteroid with or without tonsillectomy. Survival analysis was adjusted with baseline clinicopathological parameters including eGFR, proteinuria, hematuria, RAS inhibitor use and MEST-C score in Oxford classification.

Results: Enrolled 991 patients showed 75.4 ml/min as mean eGFR and 0.58 g/day as median level of proteinuria. Among them, 634 (64.0%) and 425 (42.9%) patients received corticosteroid therapy and tonsillectomy, respectively. During the median follow up of 5.5 years, 87 patients (8.8%) reached primary outcome. Adjusted hazard ratio (HR) of corticosteroid therapy for primary outcome in patients with tonsillectomy was 3-fold favorable than that in those without tonsillectomy (HR 0.18, 95% confidence interval [CI] 0.06-0.65, versus HR 0.59, 95%CI 0.34-1.01; P value for interaction between corticosteroid therapy and tonsillectomy 0.060).

Conclusions: Enhanced efficacy of corticosteroid therapy by tonsillectomy in IgA nephropathy was confirmed in a Japanese nationwide prospective cohort.

POI1636 The Potential Role of Monthly Corticosteroid Pulse in IgA Nephropathy
Arisa Kobayashi,1,2 Keita Hirano,1,2 Nobuo Tsuibo,2 Takashi Yokoo,3 1Japanese Red Cross Ashikaga Hospital, Ashikaga, Japan; 2The Jikei University School of Medicine, Minato-ku, Japan.

Background: The risk of corticosteroid therapy may be underestimated in IgA nephropathy (IgAN). Previous studies provided that a fifth part of patients was older than 60 years and the rate of diabetes mellitus (DM) was increased in IgAN. The novel corticosteroid therapies with not losing benefit and reduced risk of corticosteroid are desired. Here, we aimed to determine whether monthly corticosteroid pulse is non-inferior in proteinuria remission and superior in blood glucose control to standard corticosteroid therapy or not.

Methods: Design: Retrospective, non-inferiority study. Participants: Adult patients with IgAN received intervention described below between 2013 and 2020. Intervention: Monthly corticosteroid pulse alone for 6 months versus standard corticosteroid therapy having oral corticosteroid for 6 months and three times of pulse corticosteroid in the same 6 months (Lancet 1999). Outcomes: The primary outcome was proteinuria remission (<0.3g/day) at 1 year and we prespecified 0.67 in odds ratio (OR) as non-inferiority margin. The secondary outcome was safety of blood glucose care, which was defined by less than 0.3 in change of hemoglobin A1c% between baseline and 6 months.

Results: The enrolled 83 patients (22 patients >60 years old and 11 patients with DM) showed median proteinuria 0.93g/day and mean eGFR 60.5ml/min at baseline. There was no significant difference in proteinuria remission between the two groups but including the non-inferiority margin (16/21[76.2%] versus 38/62[61.3%], adjusted OR 4.10, 95%CI 0.77 to 36.1). The safety of blood glucose care in monthly corticosteroid pulse group was significantly superior to that in standard group in (19/21[90.5%] versus 35/62[56.5%], adjusted OR 14.2, 95%CI 2.02 to 98.9).

Conclusions: Compared to standard corticosteroid therapy, the current study showed that monthly corticosteroid pulse did not reach the statistical requirements for a proven non-inferiority on proteinuria remission, but significantly exhibited safety outcome in the control of blood glucose. Prospective larger studies are needed to determine the role of monthly corticosteroid pulse in IgAN.

POI1637 The Beneficial Effects of Renin-Angiotensin System Inhibitors on IgA Nephropathy with Global Sclerosis
Eri Kasama, Takahito Moriyama, Yoei Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: In IgA nephropathy (IgAN), global sclerosis has been recognized as one of the risk factors for progression, because it induces glomerular hypertension and hyperfiltration in the remained glomeruli. The reno-protective effects of renin-angiotensin system inhibitors (RASI) are considered to decrease glomerular hypertension and hyperfiltration, but their effectiveness in IgAN with global sclerosis has been unknown.

Methods: Of the 871 IgAN patients diagnosed at our institution, we classified them into three grades by the ratio of global sclerosis (G) against whole glomeruli (G0 (n=225); none, G1 (n=445): at least one but <25%, G2 (n=191): ≥25%). We compared each clinical background and 20-year prognosis. Then, we examined the effect of RASI initiated during follow-up period on the long-term prognosis in patients with G1+G2 and in patients with G2 by Kaplan-Meier analysis and Cox regression analysis. To adjust the background characteristics between patients treated with or without RASI, propensity matching score was performed.

Results: The age, blood pressure, proteinuria, renal function, and histological findings were significantly severer with increasing grade in G0, G1, and G2, and 20-year renal survival rate was 83.5%, 75.0% and 54.4% in patients with G0, G1, and G2, respectively (p=0.001). After propensity matching between patients treated with or without RASI, 366 patients in G1+G2 and 90 patients in G2 were eligible for the evaluation. The 20-year renal survival rate was significantly higher in the patients with RASI than in the patients without RASI (G1+G2: 84.5% vs. 50.9%, p=0.001; G2: 63.8% vs. 33.5%, p=0.037). In multivariate Cox regression analysis considering clinical and histological findings and treatment, RASI was an independent factor to prevent progression in patients with G1+G2 and G2 (G1+G2, hazard ratio: 0.39, 95% confidence interval: 0.25-0.62, p<0.001; G2, hazard ratio: 0.35, 95% confidence interval: 0.19-0.66, p=0.001).

Conclusions: In this study, global sclerosis was associated with severer clinical and histological findings, and poor prognosis. However, RASI initiated during follow up period was found to improve renal prognosis in IgAN with at least one global sclerosis.
PO1639
Remission of IgA Nephropathy with Hydroxychloroquine
Hafsa Tariq,1 Jagmeet S. Dhingra,2 1University Hospitals, Cleveland, OH; 2MetroHealth Medical Center, Cleveland, OH.

Introduction: IgA nephropathy is the most common form of glomerulonephritis in the world. Treatment options include blockade of renin-angiotensin-system (RAS) as the first line of therapy. Steroids may be beneficial in refractory cases, however, can result in several adverse effects. Data regarding use of immunosuppression is inconclusive. Combination of RAS inhibition and hydroxychloroquine has shown to reduce proteinuria in recent studies, though, complete remission with long term use has not been described. We report the case of a 46-year-old Asian female with IgA nephropathy, who was treated with maximally tolerated RAS inhibition and hydroxychloroquine for about 24 months resulting in complete remission of proteinuria and hematuria.

Case Description: The patient was referred to nephrology for evaluation of hematuria and proteinuria (1.5 g/g, Serum creatinine 0.9mg/dl). Serological work-up was negative. She was initiated on angiotensin receptor blocker (ARB) and underwent kidney biopsy which confirmed IgA Nephropathy. There were 8 glomeruli with 20-25% sclerosis, mild to moderate chronic tubulointerstitial nephritis and fibrosis, no crescents, mild mesangial proliferation and hypercellularity with IgA staining 3+. She did not have any significant improvement in proteinuria despite maximally tolerated ARB (losartan 100 mg daily) therapy for three months. Her kidney function also declined, creatinine 1.2mg/dl. Hydroxychloroquine 200mg daily was then initiated along with regular eye exams and hepatic function tests. Repeat workup in three months showed improvement in proteinuria to 0.2g/g and creatinine 1.1mg/dl. She was continued on the same regimen for about 24-months with recent work-up showing complete resolution of proteinuria and hematuria.

Discussion: As per our literature review, this is the first reported case of IgA nephropathy treated with RAS inhibition and hydroxychloroquine over a span of almost two years resulting in complete remission. Hydroxychloroquine can be considered, in select cases, as an alternative to steroid therapy in refractory proteinuria.

PO1640
Long-Term Follow-Up Study of Immunosuppressive Therapy in IgAN Patients with CKD Stage 3 and 4
Yuehui Ni. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: The benefits of immunosuppressive therapy in patients with IgAN remain controversial, especially for those with more severe renal pathology and reduced renal function.

Methods: A total of 496 primary IgAN patients were screened between 2012 to 2014. Patients were divided into 4 groups according to CKD stage and the treatment. The primary endpoints were doubling of creatinine, progression to ESRD or death. The secondary endpoint was decrease in eGFR. Subgroup analysis of CKD3 immunosuppressive treatment group was conducted to explore the factors affecting the prognosis after treatment.

Results: 164 patients were enrolled and mean follow-up time was 5.5 years. There were 126 patients in CKD3 stage and 38 patients in CKD4 stage. Immunosuppressive therapy significantly improved prognosis in patients with CKD stage3 (HR 0.435[95% CI 0.296-0.759]; p=0.035), but no difference for CKD stage4(p=0.364). Subgroup analysis showed baseline eGFR(OR 0.909[95%CI 0.834-0.991];p=0.031), serum IgG level(OR 0.809 [95%CI 0.658-0.995];p=0.045) were associated with primary outcome and loop diuretics (OR 0.109[95% CI 0.050-0.709], p=0.014), proportion of crescents (OR 0.200[95% CI 0.100-0.521], p=0.003), interstitial fibrosis>50%(OR 5.490[95% CI 1.323-22.727]) were associated with secondary outcome. Remission within 1 year could be an indicator of good long-term prognosis (HR 0.555[95%CI 0.296-0.759]; p=0.035).

Conclusions: For IgAN patients with CKD stage3, immunosuppressive therapy should be actively applied under the general treatment, but for patients with CKD stage4, it should be carefully. Patients with good renal function, more acute lesions of renal pathology could have a better prognosis after immunosuppressive therapy. Patients who achieved remission within 1 year would have better long-term prognosis.
PO1642
Long-Term Effectiveness of Low-Dose Prednisone Treatment in Relapses of Steroid-Sensitive Minimal Change Disease

Irene Martin Capon,1 Elizabeth R. Viera,1 Eduardo Gutierrez-martinez,2 Milagros Fernandez-Luc,1 Javier Villacorta Perez.1 1Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Madrid, Spain.

Background: Treatment of relapses of steroid-sensitive minimal change disease (SMCD) involves administration of high doses of prednisone for several weeks, implying significant pharmacological toxicity. In a previous pilot study, the efficacy of treatment with low doses of prednisone for the treatment of relapses in these patients was demonstrated.

Methods: Retrospective analysis of SMCD relapses treated with low doses of prednisone in two centers, was performed, and the response to treatment, the time to reach remission and the free-time of relapse was studied, comparing it with previous relapses of the same patients treated with standard doses of steroids.

Results: 85 relapses in 21 patients with SMCD were analyzed. The median age of patients was 35 years (IQR 18-53), with 62% being male. The mean proteinuria at relapse debut was 4.37 ± 4.11 g/day, serum albumin 2.47 ± 0.94 g/dl and creatinine 0.86 ± 0.33 mg/dl. Thirty-six relapses (42.3%) were treated with low doses of prednisone (LDP) and compared with 49 previous relapses (57.6%) of the same patients, treated with high doses of prednisone (HDP). The mean initial prednisone dose in relapses treated with LDP and HDP was 0.45 ± 0.1 mg/kg and 1.00 ± 0.3 mg/kg, respectively (p = 0.001). The mean cumulative dose of prednisone in relapses treated with LDP and HDP was 1771 ± 1303 mg and 3894 ± 2134 mg respectively (p < 0.001). There were no differences in treatment duration between relapses treated with low and high corticosteroids doses (124 days vs 153 respectively; p = 0.2). All patients achieved complete remission after steroid treatment. Mean time to remission was 18.44 days for relapses with LDP and 17.1 days for HDP (p = 0.6). The mean free time to relapse after treatment with low doses was 12.6 months vs 10.9 months for those treated with high doses (p = 0.6).

Conclusions: Among SMCD patients, treatment of relapses with low doses of prednisone (0.5 mg/kg) is effective and safe, allowing to minimize cumulative steroid doses and derived toxicity.

PO1643
DEFINE Physicians: An International Delphi Survey to Identify Consensus in the Care of Patients with FSGS or Idiopathic Nephrotic Syndrome

Marina Vivarelli,1 Keisha L. Gibson,2 Debbie S. Gipson,3 Manuel Praga,4 Heather N. Reich,3 Michiel F. Schruder,1 Vladimir Tesar,5 Marcello Tonelli,6 Jack F. Wetzels,7 Jai Radhakrishnan,8 Jürgen Reitsma,9 Eduardo Floege.10 1School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC; 2University of Michigan, Ann Arbor, MI; 3School of Medicine, Radboud University Nijmegen, Nijmegen, Netherlands; 4University of Toronto, Toronto, ON, Canada; 5Amalia Children’s Hospital, New York, NY; 6Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany.

Background: High consensus regarding clinical decisions and the importance of controlling proteinuria in IgAN was observed in this Delphi survey. Although the level of consensus related to corticosteroid use was lower for adult patients vs pediatric patients, the level of consensus was relatively high for both groups.

Funding: Commercial Support - Travere Therapeutics, Inc.

Methods: DEFINE: Physicians was a 2-round Delphi survey that recruited nephrologists from North America and Europe. A total of 22 FSGS/INS statements were scored using a 1-9 Likert scale (9=strongly agree). Consensus was defined as median and mean score ≥7, and ≥75% of participants scoring agreement (ie, score 7-9). Statements not achieving high consensus (≥80% agreement) in Round 1 were revised and retested in Round 2.

Results: This study involved 207 adult and pediatric nephrologists. Median clinical experience was 18 (range 5-49) years; 103 participants (50%) worked in nonacademic settings. In Round 1, 21 statements met consensus criteria and 7 statements not achieving high consensus were revised or divided into multiple parts, creating 11 revised statements for testing in Round 2. In Round 2, 9 of 11 statements met at least moderate consensus. Round 1 statements with high consensus described prognostic significance of proteinuria and disease management (Figure 1). Controversial statements retested in Round 2 pertained to distinction between primary and secondary FSGS in adults, and to management of frequently relapsing INS in children (Figure 2).

Conclusions: The level of consensus in this Delphi survey was high for statements on treatment decisions and the importance of proteinuria control. The main area where high consensus was not reached pertained to differentiation between primary and secondary FSGS and managing frequently relapsing INS in children, suggesting that these areas require further research.

PO1644
Safety and Efficacy of ANG-3070 in Patients with Primary Proteinuric Kidney Disease: A Phase 2 Study Design

Jai Radhakrishnan,1 Shakil Aslam,2 John F. Neylan,2 Dana Rizk,3 Howard Trachtman,4 1Columbia University Irving Medical Center, New York, NY; 2Angion Biomedica Corp, Uniondale, NY; 3University of Alabama at Birmingham, Birmingham, AL; 4NYU Grossman School of Medicine, New York, NY.

Background: Primary proteinuric kidney diseases (PPKD) are among the leading causes of End-Stage Kidney Disease (ESKD). Receptor tyrosine kinases like PDGFR, DDR1, DDR2 are thought to play a role in the progression of PPKDs to ESKD. ANG-3070, a selective oral tyrosine kinase inhibitor, has demonstrated beneficial effects in chronic kidney disease animal models. Objective: Design the design of a proof-of-concept study of ANG-3070 in the treatment of PPKD patients with persistent proteinuria while on standard of care (SOC).

Methods: A 12-week, randomized, double-blind, placebo-controlled study enrolling 100 patients with biopsy-proven PPKD and persistent proteinuria, ≥1 g/day, while on the SOC including maximum tolerated RAAS inhibitors. Patients will be randomized 1:1:1:1 to 200 mg or 400 mg once-daily or 300 mg twice-daily of ANG-3070 or placebo (Fig. 1).

Results: The primary endpoint is the percentage change in 24-hr urinary protein at Week 12. Key secondary endpoints evaluated at week 12 include percentage change in 24-hr urinary albumin, number of patients with complete remission in proteinuria (24-hr urinary protein < 300 mg), number of patients with partial remissions in proteinuria (24-hr urinary protein reduction of ≥50% from the baseline and a 24-hr urinary protein < 3.5 g/day if the baseline 24-hr urinary protein > 3.5 g), number of patients with ≥50% reduction in 24-hr urinary protein from the baseline, and number of patients with a ≥50% reduction in 24-hr urinary albumin from baseline. An independent data monitoring committee will review safety throughout the study.

Conclusions: This Phase 2 study will provide data about the safety and efficacy of ANG-3070 in PPKD patients that will inform the design of a Phase 3 study.

Funding: Commercial Support - Angion Biomedica, Inc.
POI1645

Transcutaneous Auricular Vagus Nerve Stimulation (taVNS) for the Treatment of Pediatric Nephrotic Syndrome (NS)

Christine B. Sethna,1,2 Kumail Merchant,1 Stavros Zanos,2 Timir Datta-Chaudhuri,1 Pamela Singer,1 Laura J. Castellanos,3 Rachel Frank,1 1Steven and Alexandra Cohen Children’s Medical Center, New Hyde Park, NY; 2Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

Background: Children with NS, especially those with frequent relapses (FRNS) or steroid resistance (SRNS), are exposed to prolonged courses of immunosuppressant medications with side effects and variable efficacy. There is an urgent need to identify novel and safe therapies to treat pediatric NS. taVNS modulates the immune system via the cholinergic anti-inflammatory pathway and has become a therapy of interest for treating immune-mediated illnesses. The objective was to conduct an open-label early feasibility study of taVNS therapy for pediatric NS.

Methods: Children with FRNS (≥2 relapses in previous 6 months) or SRNS (no remission after 4 weeks of steroids) were enrolled. Participants with FRNS were in remission and off immunosuppression (off steroids >14 days and other immunosuppression >3 months). SRNS patients were on a stable regimen of medications for 6 months prior to enrollment. Participants performed taVNS therapy 5 minutes daily for 6 months with a TENS 7000 unit. taVNS was delivered to the auricular branch of the vagus nerve via the left cymba concha. Cytokine levels were compared using the Wilcoxon test.

Results: Seven participants (3 FRNS, 3 SRNS, 1 genetic congenital nephrotic syndrome [CNS]) had a median age of 7 years (range 3-17) and 63% were male. FRNS participants remained relapse-free during the study period (two continued taVNS at 9 and 13 months and remained in remission). SRNS participants had a 25-76% reduction in urine protein to creatinine ratio (upc) compared to baseline (Figure). Upe decreased (13.7%) in the participant with CNS but remained in nephrotic range. All but one participant (non-compliant) had a reduction in TNF-α (7.33 pg/mL vs. 5.46 pg/mL, p=0.03). No adverse effects were reported.

Conclusions: taVNS prevented NS relapses in FRNS, reduced proteinuria in SRNS, and reduced TNF-α levels without any adverse effects, suggesting taVNS as a promising therapy for pediatric NS. A larger, randomized clinical trial is needed to confirm these findings.

A Study Comparing Rituximab and Modified Ponticelli (MP) Regimen in Primary Membranous Nephropathy (PMN)

Abhishek Kumar, Arpita Ray Chaudhury, Saugat D. Gupta, Sriranjak Mukherjee, Moumita Sengupta. IPGIMER Nephrology Institute of Postgraduate Medical Education and Research, Kolkata, India.

Background: The study was designed in December 2018 when the Gemritux trial had established Rituximab as an alternative to MP regimen in the treatment of PMN. So we designed a study comparing Rituximab and MP Regimen.

Methods: We allocated 35 adults with PMN and proteinuria >3.5 gm/day in a 3:2 ratio to MP regimen or Rituximab 375mg/m² on days 1,8,15 and 22. The primary outcome was complete or partial remission (CR+PR) at 6 and 12 months in the 2 groups. The other findings included trends of 24 hr urine protein, albumin, creatine and serious adverse events at 6 and 12 months in both groups.

Results: At 6 months, 12 of 21 patients (57.14%) allocated to MP Regimen and 5 of 14 patients (35.71%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 2.4; 95% CI, 0.596–9.670, p value 0.10). At 12 months, 14 of 21 patients (66.66%) allocated to MP Regimen and 10 of 14 patients (71.43%) allocated to Rituximab experienced remission (CR+PR) (odds ratio [OR], 0.8; 95% CI, 0.184–3.487, p value 0.383). Serious adverse events occurred in 15% of patients receiving Rituximab and in 24% receiving the MP Regimen.

Conclusions: We found No Statistically Significant difference between Rituximab and the Modified Ponticelli Regimen in the treatment of membranous nephropathy. A head-to-head, longer follow up study comparing MP Regimen versus Rituximab is required in terms of duration of remission and side effect profile between the two treatment groups.

Underline represents presenting author.
Methods: M-PLACE (NCT04145440) is an open-label, multi-national Phase IIb/III study of adults with anti-PLA2R+ MN requiring immunosuppressive therapy (IST). Cohort 1 includes de novo and IST-relapsed pts (n=20) and Cohort 2 IST-refractory pts (n=10). Participants receive nine felzartamab infusions (16 mg/kg) over six 28-day cycles (weekly in Cycle 1; monthly thereafter), followed by a 28-week observational follow-up. Concomitant IST use is prohibited. The primary endpoint is the incidence and severity of treatment-emergent adverse events. The key secondary endpoint is the immunologic response rate, as determined by anti-PLA2R Ab reductions. Exploratory endpoints include evaluations of proteinuria and kidney function.

Results: As of April 2021, 12/30 planned pts were enrolled (Cohort 1, n=8; Cohort 2, n=4). Median age was 62.5 years (range 43 to 77 years), 83% were male, and median baseline anti-PLA2R Ab titer was 178 U/mL (18 to 1027 U/mL). Seven pts had received ≥4 weeks of felzartamab therapy. At Week 4, 5/7 pts had a >50% reduction from baseline in anti-PLA2R Ab (Cohort 1, n=3; Cohort 2, n=2); the other 2/7 pts had reductions from baseline of −16.8% and −5.0% (both Cohort 1). Mean % decline in anti-PLA2R Ab from baseline to Week 4 was −53.0% (−92.0% to −5.0%). B-cell counts were not markedly changed from baseline. Felzartamab was well tolerated.

Conclusions: The M-PLACE proof-of-concept study has so far shown that felzartamab rapidly and substantially reduces anti-PLA2R Ab titers in pts with anti-PLA2R+ MN. Longer follow-up is required to assess felzartamab safety and efficacy in this population.

Intravenous Cyclophosphamide vs. Calcineurin Inhibitors as Treatment in High-Risk Idiopathic Membranous Nephropathy: The Benefit in MAKE Is Preserved in the Presentation IV?

Anita M. Cordoba Hurtado,1 L. M. Perez-Navarro,1 Jesus D. Lima-Lucero,2 Virgilia Soto,2 Rafael Valdez-Ortiz.2 1Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; 2Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.

Background: The use of intravenous cyclophosphamide (IV CYC) in high-risk idiopathic membranous nephropathy (IMN) has not been fully evaluated in the making primary endpoints (serum Cr doubling, ESRD, mortality). In our center, the treatment of high-risk IMN is performed with IV CYC or with calcineurin inhibitors (CNI) according to criteria of accessibility and availability of the drug. Our aim was to compare the immunosuppressive treatment scheme with IV CYC vs CNI in primary IMN events in patients with high-risk IMN.

Methods: Retrospective cohort study. Patients with a diagnosis of IMN diagnosed between January 2012 and January 2020 were included. The patients were treated with IV CYC or CNI. With a minimum follow-up of 12 months and MAKE primary events were recorded in addition to complete, partial, composite response and adverse events at the end of the study.

Results: Thirty-seven patients of which 14 (37.8%) were treated with IV CYC and 23 (62.2%) with CNI. The mean age was 46 ± 15.3 years, 54% male, and 27% hypertensive. Average PrU/ CrU 10.4 ± 4.4 gr/dL, mean albumin 1.8 ± 0.68 gr/dL, and GFR by CKD EPI of 75ml/min/1.73m². With a follow-up of 45.91 ± 23.9 months, no baseline differences were observed between the groups. Table 1 shows the comparison between IV CYC vs CNI for high-risk IMN shows similar outcomes focused on MAKE. However, the comparison in complete and partial response shows a result in favor of the use of CNI. This perspective provides clinical evidence about the use of IV CYC, which is why it is suggested that there are possible differences between our findings and those reported so far with oral CYC. Prospective clinical trials are required to have conclusive results.

An 8-Week Course of Cyclophosphamide and Steroids Is Effective Therapy in Patients with Membranous Nephropathy (MN) and Low PLA2Rab Levels

Coralie Vink- van Setten,1 Anne-Elis van de Logt,1 Alexander Kühl,2 Jack F. Wetzel’s.1 Radboudumc, Nijmegen, Netherlands; 2EURIMMUN Medizinische Labordiagnostika AG, Lübeck, Germany.

Background: We introduced individualized therapy in patients with MN and positive anti PL2AR antibodies (aPLA2R) by IIFT test. Treatment (cyclophosphamide combined with steroids) was stopped when the IIFT test (measured at 8, 16, or 24 weeks) became negative. After 8 weeks, 71% of patients were in immunological remission. Unfortunately, 30% of these latter patients needed renewed therapy within 12 months because of immunological and/or clinical relapse. We questioned if quantitative aPLA2R measurement would predict response.

Methods: Available, stored serum samples were retrieved, and aPLA2R levels were measured by ELISA (EURIMMUN Lübeck, Germany). Good outcome was defined as immunological remission at 8 weeks, followed by clinical remission without clinical relapse nor the need for additional immunosuppressive therapy within 12 months. Results: Serum samples of 60 patients were available for analysis. Patients were grouped according tertiles of aPLA2R (Table). Higher aPLA2R levels were associated with more severe proteinuria. Patients in the lowest tertile were more likely to develop immunological remission at 8 weeks (95% vs 65% and 50% in the middle and highest tertiles). Moreover, in the subgroup of patients who were treated for 8 weeks only, fewer patients in the lowest tertile of aPLA2R needed renewed immunosuppressive therapy, although not statistically significant (16% vs 43%, p = 0.054).

Conclusions: Individualized treatment of MN patients with cyclophosphamide and steroids has been recently introduced. In this study we show that baseline aPLA2R levels predict immunological remission at 8 weeks. Furthermore, patients with low aPLA2R levels at baseline seem to be more likely to have a good overall outcome.

Prospective Cohort Study of Antibody-Guided Therapy in Patients with Membranous Nephropathy

Background: Guidelines advise a standard course of 6 months of cyclophosphamide (CP) and steroids in patients with membranous nephropathy (MN). We hypothesized that monitoring of aPLA2R-antibodies (aPLA2R) may enable individualized (and shorter duration of) therapy.

Methods: Patients with MN, with positive aPLA2R and high risk of progression were included. Treatment consisted of CP (1.5 mg/kg/day combined with steroids). aPLA2R were monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If the IFT test was negative, CP was stopped and prednisone tapered. If the IFT test remained positive at 24 weeks, CP was switched to MMF and therapy continued.

Results: Sixty-five patients (48 males) were included; mean age 61 ± 12 yrs, median serum creatinine 136 [IQR 100-161] µmol/l, serum albumin 21 [IQR 16-26] g/l and UPCR 7.7 [IQR 5.4-11.1] g/10 mmol. Follow-up was 37 [IQR 27-58] months. aPLA2R test was negative in 46 patients after 8 weeks (group A), in 10 patients after 16 weeks (group B1), in 1 patient after 24 weeks (group B2) and in 8 patients aPLA2R remained positive after more than 24 weeks (group B3). In group A no clinical remission (PCR <3.0 g/10 mmol) was observed in 26 % (12 patients) compared to 21 % (4 patients) in group B1-B3 (Log-rank p=0.579). Overall 22 patients (34 %) received additional immunosuppressive (IS) therapy because of persistent proteinuria (after aPLA2R disappearance) or clinical relapse. IS free survival was lower in group A compared to group B1-B3 (Figure 1).

Conclusions: Approximately 50% of patients developed long-term clinical remission after 8 weeks of therapy. Our data support aPLA2R-guided therapy. However, in approximately 25% of patients immunological remission was not followed by clinical remission, underlining the need for better biomarkers.

POI1652
Economic Evaluation of the MENTOR Trial Comparing Rituximab and Cyclosporine for the Treatment of Membranous Nephropathy (MN)
Matthew J. Kedatz,1,2 Scott Klarenbach,3 Helen So,1 Fernando C. Fervenza,4 Daniel C. Cattran,1 Sean Barbour.1 On behalf of the MENTOR trial investigators 1The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; 2Vancouver Coastal Health Research Institute, Vancouver, BC, Canada; 3University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; 4Mayo Clinic Minnesota, Rochester, MN; 1University of Toronto, Toronto, ON, Canada.

Background: The MENTOR trial (Membranous Nephropathy Trial Of Rituximab) showed that rituximab (RTX) was noninferior to cyclosporine (CSA) in inducing complete or partial remission of proteinuria and was superior in maintaining proteinuria remission. However, the cost of RTX is high and it’s cost-effectiveness has not been determined.

Methods: A Markov model (Fig 1) was used to determine the incremental cost-effectiveness ratio (ICER) of RTX compared with CSA for the treatment MN from the perspective of a health care payer with a life-time time horizon ($2020 USD). The model outcomes were informed by data from the MENTOR trial and previously published literature. Cost and utility inputs were obtained from the literature.

Results: Based on 1,000 simulations, the mean additional cost of RTX therapy for MN compared with CSA was $168,064 with an improvement in utility of 6.70 QALYs (Fig 2). RTX was cost-effective (assuming a willingness-to-pay threshold of $50,000 / QALY) compared with cyclosporine, with an ICER of $25,071 per additional quality adjusted life year (QALY) over a lifetime time horizon (45 years).

Conclusions: While the initial cost of RTX is high, RTX is a cost-effective option (assuming willingness to pay thresholds of $50,000 or greater) for the treatment of MN when compared with the alternative of CSA. The cost-effectiveness will be further improved with the use of less expensive biosimilars.

A Multicenter, Prospective, Open-Labeled Study of Acthar Gel Alone or with Tacrolimus to Reduce Urinary Proteinuria in Patients with Idiopathic DNA-JB9-Positive Fibrillary Glomerulopathy
James A. Tumlin,1 Richard A. Lafayette,2 Andrew S. Bomback,3 Amber S. Podoll,4 FACT Trial Group 1Emory University, Atlanta, GA; 2Columbia University, New York, NY; 3Stanford University, Stanford, CA; 4University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Fibrillary Glomerulopathy (FGN) is a rare primary glomerular disease characterized by glomerular accumulation of nonbranching, randomly arranged 10-30 nm in diameter fibrils. The resulting podocyte dysfunction and progressive proteinuria leads to ESRD rates of 50% within 4 years. Herein we present data on 15 patients treated with ACTH or ACTH + Tacrolimus completing 12 months of therapy.

Methods: Study Design: Randomized prospective open labeled study of 12 months of SQ ACTH alone or with Tacrolimus in 15 patients with biopsy proven, DNA-B9 + Fibrillary glomerulopathy. Study Drug Dosing: ACTH 80 units SQ 2X/week, Tacrolimus 1.0 mg PO BID. Primary Endpoint: Change in UP/Cr ratio (mg/gm) in patients after 12 months of ACTH+gel alone or in combination with Tacrolimus. Definitions: Responders-Complete-Partial-Clinical response defined at ≤ 300 mg/gm or ≥ 50% reduction or ≥ 30% reduction in UP/Cr from baseline at 12 months.

Results: Of the 15 patients completing 12 months of treatment, 14.3% achieved complete remission (UP/Cr ratio < 300 mg/gm); 26.8% achieved a ≥ 75% reduction from baseline, while 60.0% achieved a ≥ 50% reduction in UP/Cr at 12 months. A total

BCX9930, an Oral Factor D Inhibitor in Development for Treatment of Complement-Mediated Diseases, Inhibits Complement Alternative Pathway (AP) Activity in Healthy Subjects

Xulin Chen1, Fugang Zhu2, Cynthia D. Parker1, Melanie Corropost1, William P. Sheridan2, Matthew Davidson2, Yarladdaga S. Babu2, Biocryst Pharmaceuticals Inc, Birmingham, AL; 2Biocryst Pharmaceuticals Inc, Durham, NC.

Background: Factor D, the rate-limiting enzyme of the AP, is required for the formation of C3 convertase as well as amplification of complement activities initiated by any of the 3 complement pathways. These results support further development of oral BCX9930 for the treatment of complement mediated glomerular diseases.

PO1655

Early Eculizumab Withdrawal in Atypical Hemolytic Uremic Syndrome Is Safe and Cost-Effective

Romy N. Bouwmeester, Caroline Duineveld, Kiao L. Wijnsma, L.P.W.J. Van Den Heuvel, Jack F. Wetzel, Nicole Van De Kar. on behalf of the CUREiHUS study group Radboudumc, Nijmegen, Netherlands.

Background: The introduction of eculizumab has improved outcome in patients with atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy is debated. It is unknown if unbiased withdrawal of eculizumab is a safe strategy. Here we report the results of the CUREiHUS study, a national observational study monitoring eculizumab discontinuation in Dutch aHUS patients after three months of therapy.

Methods: All pediatric and adult aHUS patients with native kidneys and first-time eculizumab treatment (n=21) were evaluated. At last follow-up, there were no clinical sequelae, i.e. no clinically relevant increase in serum creatinine, proteinuria and/or hypertension, in the relapsing patients. No clinically relevant predictors of relapse (including the presence of a pathogenic mutation) could be determined. The total medical expenses, including costs of among others hospital admission and disease recurrence, of our population were only 33% of the fictive expenses made when patients would have received eculizumab every fortnight.

Conclusions: It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.

PO1656

Outcome of Kidney Transplantation in Atypical Hemolytic Uremic Syndrome Without Eculizumab Prophylaxis: A Single-Center Experience

Caroline Duineveld, Romy N. Bouwmeester, Kiao L. Wijnsma, Nicole Van De Kar, Jack F. Wetzel. Radboudumc, Nijmegen, Netherlands.

Background: A high risk of aHUS recurrence (60-80%) is reported after kidney transplantation. Therefore, it is suggested to perform kidney transplantation in aHUS patients with eculizumab prophylaxis. In 2017 we reported a favorable outcome after kidney transplantation in aHUS patients without eculizumab prophylaxis, using kidney donors with absence of aHUS and a known negative aHUS check-up. The aim of this study is to report on a larger cohort of 26 patients.

Methods: All pediatric and adult aHUS patients with native kidneys and first-time kidney transplantation between 2013 and 2020 were evaluated.

Results: We included 26 aHUS patients (M 9; F 17, median age at transplantation 47y, range 22-69). In 22 patients (85%) 24 genetic variants were found: C3 (N=14), CFH (N=8), CFB (N=2). Recurrence risk was considered high in 18 patients and moderate in 8 patients. Nineteen patients received a graft from a living donor (LD) and 7 patients a graft from a deceased donor (DD). All patients showed full recovery of hematological thrombotic microangiopathy (TMA) parameters after start of eculizumab. A renal response was noted in 18 patients. After a treatment duration of 13.6 weeks (range 2.1-43.9), eculizumab was withdrawn in all patients (Figure 1). During follow-up (80.7 weeks (0.0-236.9)), a relapse occurred in four patients (19.0%). Median time to first relapse was 14.3 weeks (7.1-62.0). Eculizumab was re-initiated within 24 hours in all relapsing patients. At last follow-up, there were no chronic sequelae, i.e. no clinically relevant increase in serum creatinine, proteinuria and/or hypertension, in the relapsing patients. No clinically relevant predictors of relapse (including the presence of a pathogenic mutation) could be determined. The total medical expenses, including costs of among others hospital admission and disease recurrence, of our population were only 33% of the fictive expenses made when patients would have received eculizumab every fortnight.

Conclusions: It is safe and (cost-)effective to discontinue eculizumab after three months of therapy in patients with aHUS in native kidneys. Larger data registries are needed to determine factors to predict relapse(s) and short- and long-term outcomes.
PO1657
Podocytes Soften in Proteinuric CKD: A Potential New Mechanism for Proteinuria?
Luisa Ulloa severtino, Xiaolin He, Franciska Lausecker, Rachel Lennon, Mira Krendel, Darren A. Yuen, Yuen Lab "St Michael's Hospital, Toronto, ON, Canada; 2University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; 3State University of New York Upstate Medical University, Syracuse, NY.

Background: Proteinuria is one of the most common manifestations of glomerular injury, and an important predictor of disease progression. Podocytes are a critical component of the glomerular filtration barrier, and as such podocyte injury is a major cause of proteinuria. Historically, investigators have focused on biochemical changes in podocytes that occur following podocyte injury. In contrast, little is known about the changes in the physical properties of the highly specialized epithelial cells.

Methods: 3 different models of proteinuric glomerular disease were studied: (1) Akita Ren-/- mice (a murine model of diabetes and renin-mediated hypertension that we have recently shown develops progressive glomerulosclerosis that mimics human diabetic kidney disease), n = 7; (2) Myo1e-/- mice, a model of genetic FSGS characterized by deficiency of a non-muscle myosin involved in actomyosin contraction, n = 6), and (3) Col4a5-/- mice, a mouse model of Alport’s syndrome (n = 12). The stiffness of glomeruli, glomerular basement membrane (GBM), and podocytes was measured using atomic force microscopy (AFM) and associated histology (picrosirius red, silver, and WT1 staining). Similar stiffness measurements were performed in human FSGS and healthy kidney donor biopsies.

Results: AFM measurements revealed that glomerular stiffness increased in Akita Ren-/- and Col4a5-/- mice, a finding that correlated with the degree of glomerulosclerosis. Glomerular stiffness was not increased in Myo1e-/- mice. GBM stiffness was increased in Akita Ren-/- and Myo1e-/- mice, but not in Col4a5-/- Alport’s mice. In all 3 mouse models, as well as in human FSGS biopsies, podocytes were softer than in healthy control kidneys.

Conclusions: Taken together, these are the first data demonstrating that podocytes soften in proteinuric glomerular disease. Given the major rearrangements in the actomyosin network that occur in podocytes of proteinuric kidneys, our data suggest that softening is solely a consequence of podocyte injury, or if it also contributes to ongoing podocyte damage.

PO1658
Novel Small Molecule Compounds Protect Podocytes from Injury In Vitro and In Vivo
Richard Helmut1, Manuel Noben,1 Ha Won Lee,1 Jean-Michel Saffin,2 Jochen Reiser,1 Susanne Heynen-Genel,1 Vinette Gupta1,1 Gunta lab 'Rush University Medical Center, Chicago, IL; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocyte dysfunction and loss is a key determinant of proteinuria and glomerular injury. Thus, maintaining healthy podocytes is a therapeutic strategy against kidney disease. We previously developed a high-content imaging-based assay and used it to screen a number of small molecule compounds that show protection of podocytes from injury, suggesting it to be a viable strategy for the discovery and development of novel podocyte-protective agents.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates as previously described (Lee et al. JASN, 2015). Cells were exposed to puromycin aminonucleoside (PAN, podocyte inducing agent), with compounds from the screening libraries, or DMSO as control, for 48 hours. Cells were fixed and stained which allowed detection using the Opera High-Content Screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. Drosophila based screening assy were used to determine efficacy of selected hits in vivo.

Results: PAN damage resulted in quantitative reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes in the ultra-miniaturized assay system. Screening of a library of chemical compounds identified ~28 hits that dose-dependently reduced podocyte damage. A set of 9 compounds showed significant protection in a drosophila model of kidney injury, supporting the findings from the high-throughput screening assay.

Conclusions: Our 1536-well plate-based assay system identified a number of small molecule compounds that dose dependently protected podocytes from damage in vitro. A drosophila model of kidney injury validated most of the in vitro data from the podocyte, screening assay, as well as in vivo and in vivo mechanistic studies are underway to elucidate new insights into podocyte pathways that are therapeutically targeted by the selected hits. These agents hold promise as novel therapeutics for kidney disease patients with podocyte pathologies.

PO1659
Characterization of the Direct Effect of Mycophenolic Acid on Murine Podocytes
Seif El Din Abo Zed,1 Agnes Hackl,2 Katrin Bohl,3 Gregor Fink,1 Eva Nüsken,1 Kai D. Nüsken,1 Bernhard Schermer,1 Lutz T. Weber,2 Nephrologisches Forschungslabor 'Children's and Adolescents' Hospital, Faculty of Medicine and University Hospital of Cologne, Cologne, Germany; 2Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 3Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany.

Background: Mycophenolic Acid (MPA) is the active component of Mycophenolate Mofetil, a selective, noncompetitive inhibitor of the inosine monophosphate dehydrogenase. Blockade of the de novo purine synthesis depletes the pool of deoxyguanosine triphosphate, leading to a specific suppression of proliferation of B- and T-lymphocytes. MFM has an established role as a therapeutic agent in nephritic nephropathy syndrome, where it currently serves as a second line option for frequent relapsing and steroid dependent cases. Although its immunological functions are well studied, direct effects of MPA on podocytes remain largely unknown. With first preliminary results showing a protective effect in vivo, the present study aims to examine the direct effect of MPA on murine podocytes and its abilities to alter albumin-induced podocyte injury.

Methods: Cultured murine podocytes were exposed to albumin for 48 hours, with one group receiving treatment with MPA for the second 24 hours. Cells were stained with a Synaptotagmin antibody and additional markers to visualize components of the cytoskeleton. Currently, we are analyzing apoptosis through a TUNEL assay as well as alterations in intracellular Calcium content with Fluo-4 and fura red. In addition, we study podocyte injury under MPA intervention by migration assays. We will also study small GTPases content and activity through a pull-down assay for RhoA and Rac1. In an unbiased approach, podocytes were exposed to either 2 hours of 10 mg/1 MPA or an additional 22 hours of 4 mg/1 MPA. Total RNA was isolated and subjected to gene expression analyses.

Results: Synaptotagmin immunofluorescence shows significant alterations of the actin cytoskeleton through albumin exposure. MPA treated cells reveal a restorative ability of the drug, with a recovery of stress fiber formation and a reduction of albumin-induced vacuole formation. MPA expression data from cultured podocytes were analyzed.

Conclusions: First results show a promising effect of MPA on stress fiber formation. The additional functional assays will be finished by late summer this year and will give an important insight to MPA abilities to influence pathways, known to be affected during the development of proteinic diseases. The RNA seq results will provide an objective and detailed picture of the direct effects of MPA on podocytes.
PO1661
Spatially Resolved Analysis of Glomerular Structures in Alport Syndrome and FSGS

Laura Perin,1 Hasim Soloyan,2 Paolo Cravedi,3 Fadi E. Salem,2 Andrea Angeletti,1 Sargis Sedrakyan.1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Mount Sinai Health System, New York, NY; 3Università di Bologna, Bologna, Italy.

Background: Many transcriptomics studies highlighted the molecular mechanism underlying glomerular phenotypes, but very little is known about interglomerular heterogeneity and how each glomerulus is affected during progressive CKD. Using Spatial transcriptomics, which allows the characterization of the gene expression based on morphological context, we showed important differences between glomeruli of Alport Syndrome (AS) and FSGS patients and defined the interactive gene networks involved in glomerulosclerosis using healthy glomeruli as reference.

Methods: Using the Nanostring GeoMX Spatial Profiling (DSP, Whole Transcriptomic Atlas) we generated spatial maps of gene expression of human AS (COLA4A5 and COLA4A5) and FSGS glomeruli (both males and females) and compared them to age-matched healthy controls. A total of 90 regions of interest were selected. After data QC and Q3 normalization, data were analyzed using different platforms and integrated with histopathology assessment.

Results: Data distinguished genes associated with podocyte, glomerular endothelial and mesangial cell phenotype. Unsupervised clustering and dimensionality reduction analysis showed clear differences between not only diseased and normal glomeruli (which presented homogenous gene expression profile), but also between glomeruli of AS vs FSGS. Though glomeruli of AS and FSGS were histologically similar within each sample, they presented different transcriptomics profiles (for instance, while oxidative phosphorylation, focal adhesions were common to all gloms in AS, Apelin, PK3-Akt, and Hippo signaling were unique to only a few glomeruli). Marked differences between males and females were observed in both AS and FSGS glomeruli (sheer stress and leukocyte transmindedial migration was more typical in AS male than female, while insulin signaling was only present in AS female. Similar heterogeneity patterns were observed in FSGS). In contrast to FSGS, AS were more enriched for genes associated with TCA cycle, protein processing in the ER, and neurotrophin signaling.

Conclusions: DSP revealed significant interglomerular heterogeneity in AS and FSGS regardless of age and gender leading to the discovery of pathways defining disease phenotypes at single glomerular level. These preliminary data using DSP may allow the discovery of potential new therapeutic targets for CKD patients.

EGR1 Is an Injury Marker in Podocytes

Masahiro Okabe,1 Nobuo Tsuboi,1 Taiji Matsusaka,2 Takashi Yokoo.1 1Jikei University School of Medicine, Tokyo, Japan; 2Tokai University School of Medicine, Isehara, Japan.

Background: There is no good marker that depicts injured podocytes in human histology samples as well as deamin staining in rodent samples. EGR1 (Early Growth Response 1) is a transcriptional factor that regulates cell survival, proliferation, and cell death in response to growth factors, DNA damage, and ischemia. We have reported that injured podocytes express EGR1 in the early stages of damage in animal experiments and that EGR1 is expressed on podocytes in human glomeruli. This study aims to explore an association between EGR1 staining in podocytes and podocyte injury that injured podocytes express EGR1 protein in the early stages of damage in animal models.

Methods: DSP revealed significant interglomerular heterogeneity in AS and FSGS regardless of age and gender leading to the discovery of pathways defining disease phenotypes at single glomerular level. These preliminary data using DSP may allow the discovery of potential new therapeutic targets for CKD patients.

The CLVS1 H310Y Variant Associated with Steroid-Responsive Nephrotic Syndrome Affects Podocyte Function and Glomerular Filtration Barrier Integrity

Brandon M. Lane,1,2 Megan Chryst-Stangl,1,2,3 Mohamed A. Shalaby,2,4 Sherif M. El desoky,5 Guanghong Wu,2,5 Liming Wang,2 Elhussein A. Elhassan,3 David N. Howell,2 Peter J. Conlon,2 Robert F. Spurney,2 Rasheed A. Gbadegesin,2,5 1Duke University Department of Pediatrics, Durham, NC; 2Duke University School of Medicine, Durham, NC; 3Duke University Department of Pathology, Durham, NC; 4King Abdullah University Hospital, Jeddah, Saudi Arabia; 5Duke University Hospital, Durham, NC.

Background: We identified a rare homozygous variant, p.H310Y, in the gene encoding clavesin1 (CLVS1) as a novel cause of steroid sensitive nephrotic syndrome (SSNS). We performed a follow-up of the CLVS1 gene in zebrin resulted in edema phenotypes that could be rescued with WT CLVS1 mRNA but not the H310Y variant. CLVS1 knockout in cultured human podocytes decreased endocytosis, increased reactive oxygen species (ROS) accumulation, and increased apoptosis. These aberrant phenotypes were rescued in the presence of glucocorticoids, mimicking the steroid responsive phenotype of CLVS1 H310Y patients. Treatment with ROS inhibitors also rescued the reduced viability phenotype in CLVS1 KO podocytes.

Methods: To better understand the effects of the CLVS1 H310Y variant on podocyte homeostasis, we created human podocyte cell lines with CRISPR-Cas9 mediated heterozygous and homozygous CLVS1 H310Y knock-in (KI) mutations. We evaluated the KO and KI podocytes through automated live-cell imaging. Additionally, we further evaluated the effects of reduced CLVS1 function on podocyte function in vivo in zebrafish.

Results: CLVS1 is functionally required for glomerular filtered in human glomeruli. Additionally, homozygous H310Y KI podocytes displayed similar corticosteroid responsive phenotypes to CLVS1 KO lines, including increased apoptosis that could be rescued with ROS inhibition, while heterozygous KI lines were unaffected. Furthermore, we confirmed that the H310Y variant reduces binding to a critical antioxidant transporter, alpha tocopherol transfer protein (V<0.001), likely contributing to the ROS phenotypes. Electron microscopy analysis and quantification of excreted proteins revealed podocyte effacement and decreased glomerular filtration barrier integrity in zebrafish with knockdown of orthologous CLVS1 when compared to controls (V<0.001).

Conclusions: Our data further demonstrates the importance of clavesin1 in the maintenance of podocyte viability and GFB integrity. It also suggests that oxidative stress may be compromised in patients carrying pathogenic CLVS1 variants and highlights the potential for alternative therapies for NS patients that target ROS accumulation in podocytes.

Rare Variants in RCAN1-3 Genes Are Enriched in Patients with CKD

Brandon M. Lane,1,2 Katherine A. Benson,4 Susan L. Murray,5 Megan Chryst-Stangl,1,2,5 Guanghong Wu,2,5 Liming Wang,2 Elhussein A. Elhassan,3 David N. Howell,2 Peter J. Conlon,2 Robert F. Spurney,2 Rasheed A. Gbadegesin,2,5 1Duke University Department of Pediatrics, Durham, NC; 2Duke Molecular Physiology Institute, Duke University, Durham, NC; 3Beaumont Hospital, Dublin, Ireland; 4Royal College of Surgeons in Ireland, Dublin, Ireland; 5Duke University Hospital, Durham, NC; 6Duke University School of Medicine, Durham, NC; 7Duke University Department of Pathology, Durham, NC.

Background: We recently identified rare variants in the gene encoding Regulator of Calcineurin Type 1 (RCAN1) as a novel cause of FSGS/RRSNS. Cells expressing mutant RCAN1 and human podocytes with reduced RCAN1 displayed increased CN activity that resulted in increased susceptibility to apoptosis compared to WT RCAN1. There are two additional proteins in the RCAN family, RCAN2 and RCAN3, both of which are capable of regulating CN activity. To further elucidate the role of pathogenic variants in RCAN genes in the etiology and pathogenesis of chronic kidney disease, we screened patients with rare variants in RCAN-3 genes. In addition, we performed kinase screening to identify compounds that can rescue the phenotype induced by defective RCAN1.

Methods: In collaboration with the Genome England Consortium, we examined associations between potentially pathogenic variants in RCAN1-3 genes and kidney disease using the large multi-ethnic National Health Service database. We compared the percentage of patients with rare (MAF <0.01), functional RCAN1-3 variants in patients with CKD (renal and urinary tract disorders) and patients with neurological disorders. We also used target kinase inhibition to examine additional potential RCAN1 regulatory kinases.

Results: Of the 4,153 patients in the UK National Health Service data set with CKD, 39 (0.94%) had rare functional RCAN-1 variants compared to 87 (0.57%) of the 15,141 patients with neurological disorders, revealing a significant enrichment of rare pathogenic variants in RCAN1-3 genes in patients with kidney disease compared to those without (V=0.0006). Pharmacological inhibition of additional RCAN regulatory kinases including DYNKL1 (Harmane) or BMK1 (Ax15836 and XMID-85) could rescue the elevated CN activity (p=0.496, 0.398 and 0.0912 respectively) and reduced viability (p=0.05) in disease causing mutant RCAN1 expressing cells compared to WT controls.

Funding: RCAN1-3 genes in patients with kidney disease compared to those without (V=0.0006). Pharmacological inhibition of additional RCAN regulatory kinases including DYNKL1 (Harmane) or BMK1 (Ax15836 and XMID-85) could rescue the elevated CN activity (p=0.496, 0.398 and 0.0912 respectively) and reduced viability (p=0.05) in disease causing mutant RCAN1 expressing cells compared to WT controls.

Spatial Transcriptomic Profiling of Collapsing Glomerulopathy
Shreeram Akilesh,1 Kammi J. Henriksen,2 Roberto F. Nicoisia,1 Charles E. Alpers,1 Kelly D. Smith.1 1University of Washington, Seattle, WA; 2University of Chicago Pritzker School of Medicine, Chicago, IL.

Background: Collapsing glomerulopathy is a histologically distinct variant of focal and segmental glomerulosclerosis that presents with heavy proteinuria and portends a poor prognosis. Collapsing glomerulopathy can be triggered by viral infections such as HIV and SARS-CoV-2. However, it is not known if distinct molecular mechanisms drive histologically indistinguishable lesions of collapsing glomerulopathy in different clinical contexts.

Methods: Transcriptional profiling of collapsing glomerulopathy lesions is difficult since only a few glomeruli may exhibit this histology within a kidney biopsy. Therefore, we used recently developed spatial transcriptional profiling to quantify 1,852 transcripts in individual glomeruli from HIV and SARS-CoV-2 infected patients with biopsy confirmed collapsing glomerulopathy.

Results: We compared transcriptional signatures on the basis of disease or histology and identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy and thrombotic microangiopathy (Figure). Focused validation using downregulated and identified distinct pathways of injury in HIV and SARS-CoV-2 associated collapsing glomerulopathy.

Conclusions: Spatial transcriptional profiling represents a powerful new method to dissect transcriptional programs of pathologically discernible kidney lesions.

Protein Kinase R Inhibition Ameliorates Mitochondrial Dysfunction in the Tg26 HIV-Associated Nephropathy Mouse Model
Teruhiko Yoshida,1 Khan Zaw Latt,1 Avi Z. Rosenberg,2 Shashi Shrivastav,1 Ariyan Weerasinghe,1 Mark Reinhart,17,8,9 Jurgen Heymann,2 Moshe Levi,2 Cheryl A. Winkler,4 Jeffrey B. Kopp,4 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 2Johns Hopkins University, Baltimore, MD; 3Georgetown University, Washington, DC; 4Frederick National Laboratory for Cancer Research, Frederick, MD.

Background: Double-stranded RNA (dsRNA)-activated protein kinase (PKR) is a sensor for dsRNA in response to viral infections, including HIV-1. We previously reported that APOL1 risk alleles damage podocytes through double-stranded RNA-activated protein kinase (PKR) activation (Okamoto, Comm Biol, 2018). Here, we hypothesized that PKR activation could be a mechanistic pathway shared by HIV- and APOL1-mediated nephropathies. Hence, we investigated the effects of PKR inhibition on HIVAN in the well-characterized Tg26 mouse model, which expresses HIV regulatory and accessory genes.

Methods: We evaluated the kidney phenotype of Tg26 mice and wild-type mice treated with the PKR inhibitor (C16) from 6 to 12 weeks of age. We profiled kidney gene expression by RNA-seq and mitochondrial function by the extracellular flux assay using ex vivo glomerular tissues.

Results: Kidney disease manifestations, including albuminuria (mean [IQR]) (668 mg/g Cr [60, 1064] vs 2564 [1785, 5646], p=0.03) and global glomerulosclerosis (0.0% [0.0-0.0] vs 8.1 [2.3, 15.8], p=0.008), were reduced in the C16 treated group compared to the vehicle control group. C16 treatment increased mitochondrial gene expression and restored spare respiratory capacity as measured by extracellular flux assay (Fig.B).

Conclusions: PKR inhibition ameliorated mitochondrial dysfunction associated with the HIVAN phenotype observed in Tg26 mice, suggesting that PKR activation contributes to the development of mitochondrial dysfunction in HIVAN.

Recurrent Nephrotic Plasma Activates Pro-Fibrotic Signalling Pathways Downstream of Protease-Activated Receptor 1
Musleeha Chesar,1,2 Jack P. Tuffin,1 Carl J. May,1 Irene Ghobrial,3 Melissa H. Little,4 Moin Saleem,5 Gavin L. Welsh.1 1University of Bristol, Bristol, United Kingdom; 2Princess of Naradhiwas University, Narathiwat, Thailand; 3Murdoch Childrens Research Institute, Parkville, VIC, Australia; 4University of Melbourne, Melbourne, VIC, Australia.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous work suggests a signaling role for protease-activated receptor-1 (PAR-1), leading to impaired podocyte function. The signaling pathways downstream of PAR-1 in podocytes are unknown and could reveal novel mechanistic insights into the disease.

Methods: Conditionally immortalized human podocytes (ciPods), glomerular-like structure spheroids, and human kidney organoids were treated with PAR-1 agonist peptide or nephrotic plasma (NP), in the absence or presence of four different PAR-1 antagonists.

Results: PAR-1 agonist and patient relapse NP, but not paired remission plasma, induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by PAR-1 inhibitors, but not by TGF-β1 inhibition. Four PAR-1 inhibitors demonstrated specific antagonistic properties. The phosphorylation of VASP and JNK in a 3D spheroid model and from stem-cell derived kidney organoids corroborated the finding from the 2D model. Functionally, relapse NP induced podocyte motility and podocyte loss from spheroids both of which were also selectively rescued by PAR-1 inhibitors. Treatment of kidney organoids with relapse NP induced the same VASP and pro-fibrotic phosphorylation in podocytes and the loss of podocyte-specific markers.

Conclusions: We propose that the circulating factor acts as a pro-fibrotic effector by activating PAR-1. A greater understanding of these signaling pathways will lead to the identification of novel therapeutic targets for this disease.

Molecular and Functional Characterization of Human Urinary APOL1 G2/G2 High-Risk Genotype Podocyte
Oyindamola C. Adebayo,1,2 Pepe M. Eku,2,3 Jean-Paul Decuyper,2 Mohamed A. Elmeniem,4,5 Agathe B. Nkoy,1,6 Djaliha Mekahli,7 Benedetta Buissolat,1 L.P.W.J. Van Den Heuvel,1 Fanny O. Arcolino,1 Elena N. Levtecheko. Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium.1 Center for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium.2 Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium.3 Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); 4Department of Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt; 5Department of Molecular and Biotechnology and Health Sciences, University of Turin, Turin, Italy; 6Department of Pediatric Nephrology, Radboud University Medical Center, Nijmegen, Netherlands.

Background: APolipoprotein L1 (APOL1) risk variants, G1 and G2, increase the risk of various non-diabetic kidney diseases in the African population. To date, the precise mechanisms by which APOL1 risk variants induce injury on podocytes and other kidney cells remain unclear. Trying to unravel these mechanisms, most studies used animal or cell models created by gene editing.

Methods: Conditionally immortalized human podocyte cell lines from urine of a donor carrying APOL1 high-risk genotype, G2/G2, was developed. The APOL1 G2/G2 cell lines were characterized for podocyte markers at both the mRNA and the protein levels, using real-time quantitative PCR, Western blot and immunofluorescence staining. Following induction of APOL1 expression by 50 µg/ml polyinosinic-polycytidylic acid (poly(I:C)), we assessed the functional features of APOL1-induced podocyte dysfunction, such as cell detachment, cell viability, cell death, autophagy, cytokotosis organization and podocyte permeability. As control, APOL1 wild type (G0/G0) podocytes previously generated from a Caucasian donor were used.

Results: We successfully generated human APOL1 G2/G2 urinary podocyte cell lines. Upon exposure to poly(I:C), G2/G2 and G0/G0 podocytes upregulated APOL1 expression resulting in podocytes detachment, decreased cell viability and increased apoptosis rate in a genotype-independent manner. G2/G2 podocyte cell lines exhibited altered features, including upregulation of CD2AP, alteration of cytokotosis, reduction of autophagic flux and increased permeability in an in vitro model under continuous perfusion.

Conclusions: The human APOL1 G2/G2 podocyte cell model is a useful tool for unraveling the mechanisms of APOL1-induced podocyte injury and the cellular functions of APOL1.

PO1669
Topology Mapping of Membrane-Inserted ApoL1
John C. Edwards, Jonathan M. Bruno. Saint Louis University, Saint Louis, MO.

Background: ApoL1 inserts into membranes at pH 6.0 where it has anion permease activity. Titration of the cis compartment to pH 7.5 suppresses the anion permease and activates a cation channel. How ApoL1 is arrayed in the membrane-inserted form at various pH values is unclear.

Methods: Cys was substituted for Ser or Thr at positions throughout ApoL1 and resulting mutants expressed in E. coli. Purified mutants were allowed to insert into phospholipid vesicles at pH 6.0, held at pH 6.0 or titrated to pH 7.5, and reacted with extravesicular membrane-impermeant fluorescent Cys modifying reagent, Alexafluor-568-maleimide. Unreacted reagent was quenched. Non-membrane-inserted protein was removed by chaotropic extraction and Sepharose 4B chromatography. Membrane-associated protein was separated on SDS-PAGE along with ApoL1 standards for quantification. Ratio of fluorescence intensity to mass of ApoL1 protein was normalized to that of protein modified after detergent denaturation to determine relative accessibility of each Cys to the modifying reagent.

Results: Cys substitutions were generated at amino acid positions 40, 80, 149, 180, 200, 204, 226, 247, and 365. We found three patterns of reactivity after membrane insertion. Cys at positions 40, 149, and 365 showed reactivity that was roughly comparable to that in detergent solution with little difference between pH 6.0 and 7.5, consistent with exposure to the aqueous solution on the cis face of the membrane under all conditions. In contrast, Cys at positions 186, 226 and 247 showed decreased reactivity after membrane insertion that was similar at both pH 6.0 and pH 7.5; these positions are not fully accessible from the external solution. Finally, Cys at positions 80, 173, 200, and 204 had decreased reactivity at pH 6.0 with increase in reactivity at pH 7.5, suggesting these positions may be initially buried in the membrane upon insertion at low pH, but titration to neutral pH induces a structural transition that exposes them to the external solution.

Conclusions: Mapping accessibility of individual amino acid positions in ApoL1 support a model in which a substantial structural transition accompanies the pH shift-induced activation of the cation channel.

Deep Learning-Based Segmentation and Quantification of Podocyte Foot Process Morphology
Linus Butt,1 David Unnersjö-Jess,1 Martin Höhne,1 German Sergej,2 Annika Wernerson,3 Anna Witasp,1 Bernhard Schermer,1 Kasia Bozek,2 Thomas Benzing,1,2 1Uniklinik Köln, Köln, Germany; 2University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; 3Karolinska Institutet Enheten for medicinska njursjukdomar, Huddinge, Sweden.

Background: The advent of super-resolution light microscopy enabled imaging of the nanoscale dimensions of podocyte foot processes and the slit diaphragm and subsequent quantification of morphological alterations upon glomerular injury. However, these morphological analyses require manual work, which is time-consuming and investigator-dependent.

Methods: We used novel sample preparation protocols and applied super-resolution STED microscopy and conventional confocal microscopy to image podocyte foot processes in murine and human kidney tissue. Deep learning-based segmentation was utilized to automatically segment both the slit diaphragm pattern as well as several thousands of individual foot processes per sample.

Results: Our algorithm, the automatic morphological analysis of podocytes (AMAP), segmented the FPs and the SD at high accuracy and more effectively as compared to a previously published semi-automatic dataset. The morphological quantifications show a high agreement with our previous analysis, thereby confirming the correlation of albuminuria with certain morphological alterations of podocytes. In addition, we applied AMAP to human patient tissue and found different patterns of effacement in different disease entities.

Conclusions: The combination of three-dimensional optical imaging and deep-learning-based segmentation can be used to perform extensive morphological analyses of podocyte in health and disease. It confirms our previous semi-automatically performed analyses in a mouse model of FSGS and can be applied to patient material in order to assess morphological alterations in glomerular disease while eliminating investigator bias. We believe AMAP can in the future complement the diagnostic algorithms in research and clinical pathology.

Podometric Differences in Different Cortical Zones and Associations with the Number of Non-Sclerotic Glomeruli

Kotaro Haruhara,1,2 Go Kanzaki,2 Takaya Sasaki,2 Saeko Hatanaka,2 Yusuke Okabayashi,2 Akira Shimizu,2 Luise A. Cullen-McEwen,1 Nobuo Tsai,1 Takashi Yoko,2 John F. Bertram,1 1Monash University, Clayton, VIC, Australia; 2Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; 3Nihon Ika Daigaku, Bunkyo-ku, Japan.

Background: Reduced nephron and podocyte number are common features in CKD. While it is well known that glomerular volume and glomerular density (glomerular number per cortical area) differ between cortical zones, zonal differences in podometrics and correlations with nephron number have not previously been explored.

Methods: Non-sclerotic glomerular number per kidney was estimated using the physical disector/fractionator combination. Podocyte density, podocyte number, podocyte volume and volumetric density of podocyte to glomerulus in each cortical zone were estimated using model-based stereology on a single histological section immunostained with two podocyte markers and imaged by confocal microscopy.

Results: Fifty autopsy kidneys were studied. The median age was 68 years ranging from 28 to 85 years. Median eGFR was 74 mL/min/1.73m². The median number of non-sclerotic glomeruli per kidney was 421,547 (IQR, 289,095–548,233). Non-sclerotic glomerular number was directly correlated with podocyte number per tuft, podocyte density and smallest podocyte volume. Podocyte number and volumetric density of podocytes were similar across the cortical zones.

Conclusions: These results demonstrate for the first time that a higher number of non-sclerotic glomeruli is directly associated with three beneficial indices of podocyte health. Podocyte number and volumetric density of podocytes were similar across the cortical zones.

Can Podocyte Number and Density Predict the Response to Therapy in Patients with Primary FSGS?

Natalasha de Zoya,1 Jonathan E. Ling,2 Kotaro Haruhara,1,3 Peter G. Kerr,2 David J. Nikolic-Paterson,1 John F. Bertram,1 Luise A. Cullen-McEwen,1 Nobuo Tsai,1 Takashi Yoko,2 John F. Bertram,1 Luise A. Cullen-McEwen,1 1Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; 2Monash Medical Centre Clayton, Clayton, VIC, Australia; 3Tokyo Jikeikai Iga Daigaku Igakubu Igakuka, Minato-ku, Japan.

Background: Podocyte loss is a key event in primary focal segmental glomerulosclerosis (FSGS). Common first-line therapy for patients with primary FSGS involves steroid therapy with or without blood pressure control; however 40-70% of patients achieve no remission. Animal studies have shown that treatment efficacy is achieved partly through preservation of podocyte number, as well as podocyte protective effects. Animal studies have also determined that podocyte number and density are predictive of FSGS severity. Therefore, this study aimed to determine if podocyte number and density can predict the response to therapy in patients with primary FSGS.

Methods: A retrospective cohort study of renal biopsies was conducted from 2009-2020 in Melbourne, Australia at a tertiary hospital (Monash Medical Centre). Patients diagnosed with primary FSGS were screened (n=84). Patients were excluded for lack of consent for samples to be used for research purposes (n=38), risks of other forms of FSGS (n=13), insufficient clinical data available (n=2), no biopsy tissue available (n=7) or insufficient clinical data available (n=2). Included patients were allocated into groups of treatment responders (n=11) or non-responders (n=8) based on urinary/serum data 6 months following initial diagnosis and commencement of treatment. Biopsies were immunofluorescently stained for podocyte-specific markers. Model-based stereology was used to estimate podometrics. Sections were re-stained with PAS to measure the glomerulosclerotic index (GSI).

Results: Podocyte number per glomerulus in responders (347 (215-606); median (IQR)) was 45% higher than in non-responders (190; 143-263) (P=0.03). Podocyte density in responders (76; 58-142 per 10⁶m² of glomerular volume) was similar to non-responders (66; 44-88 per 10⁶m² of glomerular volume) (P=0.38). GSI was significantly higher in non-responder patients (1.1; 0.6-2.3) than responders (0.6; 0.2-0.9) (P=0.04), and was significantly and negatively correlated with podocyte number (r = -0.64; P=0.003) and podocyte density (r = -0.48; P=0.04).

Conclusions: Podocyte number per glomerulus in diagnostic renal biopsies could be used as a predictor of treatment response for patients with primary FSGS.

PO1673

Nephrotic Syndrome in a Patient with Systemic Lupus Erythematosus: Is it Lupus Podocytopathy?

Nora H. Hernandez Garcilazo,1 Mohamed Hassanein,2 Christopher C. Garces,3 Si Yuan Khor,1 Beenu K.1,2 Cleveland Clinic, Cleveland, OH; 3Sparrow Health System, Lansing, MI.

Introduction: Lupus podocytopathy (LP) is a rare form of lupus nephritis (LN) that clinically mimics minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS). We present a case of LP in a patient with systemic lupus erythematosus (SLE).

Case Description: A 73-year-old female with a history of SLE (on Hydroxychloroquine), and nephrolithiasis presented with left flank pain for 2 weeks. Physical exam was notable for peripheral edema and left costovertebral angle tenderness. Labs showed a creatinine 1.02 mg/dL (baseline 0.7), serum albumin 2.6 mg/dL, and urine microalbumin/creatinine (MA/Cr) ratio of 7.5 g/g. Further workup revealed a positive ANA, negative anti-dsDNA antibodies, and normal complements. Kidney biopsy showed FSGS, tiv variant, and 100% podocyte foot process effacement (PPE). She was started on high-dose prednisone, simvastatin, ACE inhibitor, and furosemide with potassium supplementation for significant pedal edema. Two months later, her MA/Cr ratio improved to 3 g/g. Prednisone was slowly tapered off over a 7-month period during which symptoms were well-controlled and MA/Cr ratio continued to improve.

Discussion: Nephrotic syndrome in patients with SLE raises suspicion for LP, which represents 1% of LN biopsies. Biopsy findings include diffuse PPE (>70%) on electron microscopy, and absence of immune deposits on light, immunofluorescence, and electron microscopy. LP is divided into MCD or FSGS, with the latter having higher rates of hypertension, acute kidney injury on presentation, and overall worse outcomes. Treatment consists of a short course of high-dose glucocorticoids; however high rates of relapse are observed and tend to coincide with SLE activity.
PO1674

Minimal Change Disease as a Sequela of Psoriasis in an Adult
Priya Debnath, Chibuzo C. Okeye, Arham Zia, Samiran Roy Chaudhury, Elena Frolova. New York City Health and Hospitals Coney Island, Brooklyn, NY.

Introduction: Minimal change disease (MCD) is usually found in children but can be an uncommon presentation in adults. Relation to psoriasis has not been significantly established even though the latter has been associated with kidney disease such as IgA nephropathy, focal segmental glomerulosclerosis leading to kidney failure. This is an interesting case given that this is a young patient with psoriasis presenting with a flare in the setting of newly diagnosed MCD.

Case Description: A 34-year-old male with history of psoriasis presented with severe body edema after psoriatic flare two weeks prior admission. He was found to have exceptionally low serum albumin of 1.4g/dl, massive proteinuria with spot urine protein creatinine ratio of 7.6 and significant hyperlipidemia. Protein electrophoresis did not show glomerular pathology or spikes in proteins and extensive serological workup was normal. Kidney biopsy reported MCD. Patient improved quickly with steroids of 1mg/kg/day, IV furosemide and albumin infusion. Six months later, the patient was readmitted with new psoriasis flare and again nephrotic syndrome with 7.2g of proteinuria. His symptoms resolved quickly with same treatment used on the first admission. Follow up in clinic one-month post discharge showed normal renal function with proteinuria now at 100mg/day.

Discussion: While there has been evidence of link between psoriasis and kidney disease, finding of MCD is a unique development. The idea can be postulated that since psoriasis is a disease due to dysfunction of T-cells among other causes, a flare can be the initiating event leading to dysregulation of an otherwise stable immune system. This T-cell dysregulation has also been noted in MCD. The underlying cause of MCD is not clear. However, a lot of studies suggest that T-cell dysfunction is one of the implicated agents, known for cell destruction, causing damage to the glomerular membrane leading to the loss of proteins. The rarity of this case belies the complexity of the immunological process leading to the presentation and further research needs to be done to document and establish this as the pathologic process linking the two diseases.

PO1675

Collapsing FSGS from Acquired Nephrin Antibody
Hsiao L. Lai,1 Abdullah Thayyi,1 Astrid Weins,2 Keith H. Keller,2 1East Carolina University, Greenville, NC; 2Bigham and Women's Hospital, Boston, MA.

Introduction: Deficits in nephrin and other podocyte components are known to result in congenital nephrotic and familial FSGS syndromes. Weins et. al. recently described acquired anti-nephrin antibody localizing in glomerular podocytes of patients with minimal change disease.

Case Description: A 16 year old male referred for new onset nephrotic syndrome progressive over 2 weeks was found to have serum albumin 1.2 gm/dl, UPCR 3.1, and elevated lipids with BP 160/100 mm Hg. Hepatitis B/C, HIV, SLE screens were negative. Renal biopsy demonstrated focal collapsing lesions with diffuse podocyte effacement. Immunofluorescence showed punctate IgG, kappa and lambda light chain staining in podocytes, but no albumin. Anti-human IgG colocalized with nephrin in the granular staining. ParvoB19 and COVID-19 titers were negative. Creatinine rose from 0.65 to 1.65 and UPCR to 10.3 but improved rapidly with high dose prednisone and ACEi. Serology for circulating anti-nephrin 2 weeks into treatment was negative, consistent with previous finding that circulating antibody levels quickly drop to low or undetectable with partial clinical remission.

Discussion: This case strengthens evidence that anti-nephrin antibodies cause disruption of the slit pore diaphragm which appears to be readily responsive to immune therapy. Anti-nephrit mediated podocytopathy may present with a spectrum of glomerular histopathology, which on the background of other susceptibility factors, can lead to more severe presentations such as collapsing FSGS.
slit diaphragms. Confocal imaging of IgG/nephrin IF confirms substantial overlap in the fine podocyte granules (arrows), but not in coarse PRGs (asterisks). A diagnosis of early primary FSGS is made. Sera collected on post-biopsy days 19, 25 and 27 are serologically positive for anti-nephrin. The patient was started on oral glucocorticoids, and on d27 was in partial remission (UPCR 2.6g/gCr, SAld 2.8g/dl). Anti-B cell therapy is considered.

Discussion: Our findings reveal that autoimmune-mediated anti-nephrin podocytopathy can trigger irreversible podocyte injury leading to FSGS, likely in patients with additional predisposing factors. This enhances our understanding of diffuse progressive podocytopathies; accurate and early diagnosis identifies patients who benefit most from B-cell-targeted immunosuppressive therapy.

PO1677

Nephrotic Syndrome Secondary to Minimal Change Disease Following Moderna COVID-19 Vaccine

Shaefiq B. Thappy, Sherin R. Thalappil, Shahem Abbarh, Mohammed Akhtar, Mohammad M. Alkadi. Hamad Medical Corporation, Doha, Qatar.

Introduction: Minimal Change Disease (MCD) has been reported following vaccines against hepatitis, pneumococcus, influenza and measles. In the COVID-19 era, 3 cases of new-onset MCD and one case of MCD relapse have been reported following the Pfizer-BioNTech COVID-19 vaccine. We herein report a case of MCD after receiving the first dose of Moderna COVID-19 vaccine.

Case Description: A 43-year-old Ethiopian man with no significant past medical history presented with progressive bilateral lower limb edema for two weeks. His symptoms started 7 days after receiving the first dose of COVID-19 vaccine. He then developed dyspnea and scrotal swelling over the following 10-14 days. On physical examination, his blood pressure was 150/92 mm Hg. There was decreased air entry at lung bases, significant bilateral lower limb pitting edema extending to above the knees and scrotal swelling. Lab investigations revealed hypoalbuminemia, hyperlipidemia and proteinuria of 15 grams. There was no hematuria and his immunologic and serologic work up was negative. Renal biopsy showed minimal change disease with underlying IgA nephropathy. There was no global or segmental glomerulosclerosis, mesangial or endocapillary proliferation. Patient was started on oral prednisolone and furosemide. His edema resolved, serum albumin doubled and proteinuria decreased within the first week of treatment.

Discussion: Symptoms of MCD have been reported 4 days to 16 weeks after vaccination. Although the pathogenesis of MCD is not fully understood, studies suggest that T-cell dysfunction might play a role. More studies are needed to determine the incidence and pathophysiology of this adverse event post COVID-19 vaccine. It is not clear in this case if or when the second dose of the COVID-19 vaccine should be administered.

PO1678

Antiproteinuric and Podocytoprotective Effects of Direct Oral Anticoagulant Therapy in Glomerular Disease

Amanda P. Waller,1 Katelyn Wolfgang,1 Eman Abdelghani,1 Bryce A. Kerlin,1,2 Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; 2The Ohio State University College of Medicine, Columbus, OH.

Background: Podocyte injury is a key determinant of chronic kidney disease (CKD) progression toward end stage kidney disease. We and others have recently uncovered a putative podocytopathic role for intraglomerular thrombin during proteinuric glomerular disease. Direct oral anticoagulant (DOAC) therapies limit thrombin activity but their ability to improve podocyte health and potentially slow CKD progression remains unknown. Thus, the aim of this study is to determine if DOACs reduce thrombin-mediated podocytopathy during glomerular proteinuria. We hypothesized that DOACs would preserve podocyte health and function in a podocyte-specific model of proteinuric glomerular disease.

Methods: Diphtheria Toxin was used to induce proteinuria in transgenic rats expressing human diphtheria toxin receptor (DTR) in a podocyte-specific manner and was subsequently treated with 1) Dabigatran (20 mg/kg; Dabi), 2) Rivaroxaban (3 mg/kg; Riva), or 3) Sham (saline) and compared to healthy controls (n=7-9/group). Morning spot urine was collected on day 0 and 10 post-DT. Glomeruli were isolated from the kidney, dissociated into single-cell suspensions, and analyzed by flow cytometry after immunofluorescent synaptophysin antibody and TUNEL staining.

Results: Both Dabi and Riva significantly reduced proteinuria (Fig A) and terminal podocyte injury (TUNEL positive podocyte fraction; Fig B). In addition, there was a trend toward in situ podocyte preservation with both DOACs with a significant overall effect of DOAC therapy on podocyte survival (Fig C).

Conclusions: Both Dabi (a direct thrombin inhibitor) and Riva (a direct factor Xa inhibitor) reduce proteinuria and enhance podocyte health in a podocyte-specific model of proteinuric glomerular disease. These data suggest that DOACs may be repurposed as a novel approach to slow or halt proteinuric glomerular disease progression. Because thrombotic disease is a life-threatening co-morbidity of both glomerular disease and CKD, this approach may enable simultaneous thromboprophylaxis and glomerular disease therapy.

A Highly Efficient and Reproducible Differentiation Protocol for Induced Pluripotent Stem Cell-Derived Podocytes

Sergii Kyrychenko, Justin A. Gallagher, Timothy A. Norman, Alyssa Fanelli, Xiang Pan, Eva Fast, Rachel Gallagher, Thomas A. Gustafson, Maria Lalioti. Goldfitch Bio Inc., Cambridge, MA.

Background: Podocyte processes intertwine to create a slit diaphragm, which, when damaged, leads to proteinuria, dysfiltration, and eventually to renal failure. It is critical to be able to study the disease and test therapeutic interventions in patient-derived cells, and assess genetic and environmental aspects. Current protocols for differentiation of iPSCs into podocytes (iPods) suffer from a lack of podocyte maturity or low reproducibility. Our goal was to test and optimize multiple protocols to establish a more translatable, physiologically relevant, and reproducible method.

Methods: We compared two distinct published protocols [Ciampi 2016; Musial 2018]. Additional conditions were tested, including varying the extracellular matrices, media, and length of differentiation. Podocyte signature was evaluated by IF, flow cytometry, and Nanorstring analysis. For models of injury, we utilized prolineamine sulfate (PS) or puromycin aminonucleoside (PAN) treatment. A mouse podocyte cell line was used as a control.

Results: Both protocols generated iPods with similar efficiency, as measured by synaptopodin, nesprin and podocin staining. iPods generated from protocol-1 could be maintained in culture up to 14 days but remained relatively immature, based on the expression of collagen α1α2α1 (IV) and lack of α3α5ε4 (IV). Response to PS and PAN treatment was variable compared to mouse podocytes. Altering the matrix from collagen to laminin-521 did not improve reproducibility. iPods from protocol-2 developed more filopodia and complex cell-cell junctions and appeared more homogeneous, with extended survival up to 4 weeks post-differentiation. PS treatment induced a significant and reproducible dose-time-dependent decrease in synaptopodin expression, and a more robust accumulation of phalloidin aggregation. Both effects were effectively prevented by cyclopasin A, a calcineurin inhibitor, in a similar manner as in mouse podocytes. iPods from protocol-2 also showed a more consistent dose-dependent response to PAN injury.

Conclusions: We achieved a more robust and translatable iPods platform utilizing human iPSC. Patient-derived iPods will be an invaluable tool to validate new therapeutic approaches for podocytopathy-driven kidney disease.

Novel Ex Vivo Culture System Reveals Mechanosensitive “Sarcocere-Like Structures” During Early Podocyte Spreading

Shumeng Jiang, Jeffrey H. Miner, Guy M. Genin, Han Suleiman. Washington University in St Louis, St Louis, MO; Washington University in St Louis School of Medicine, St Louis, MO.

Background: Chronic kidney disease and ESKD are widespread health problems with no cure, in part because the biophysics underlying them are still not clear. A recently discovered feature of injured podocytes includes the de novo assembly of sarcocere-like stress fibers, identified by their alternating myosin and synaptop Sin-a-actin-4. It is not known whether these indicate a transient healing phenotype or are a feature of the cascade leading to foot process effacement.

Methods: To model the early events of podocyte injury, we developed a new in vitro system that enables the study of podocytes outside of their native microenvironment, but with in vivo-like mechanobiological and extracellular matrix (ECM) features. This system includes controllable stiffness, micropatterned substrates for spreading, and the use of primary podocytes as they migrate from freshly isolated glomeruli.

Results: When cultured on micropatterns of physiologically relevant extracellular matrix proteins and appropriate stiffness, myosin- and synaptopodin-positive stress fibers developed within two days of culture, then disappeared after six days, and the appearance of these stress fibers was sensitive to substrate stiffness and could be disrupted by inhibiting actomyosin contraction (blebbistatin), culturing cells with stiffness outside of the physiologic range, or presenting cells with substrates associated with pathology.

Conclusions: These results reveal the role of mechanobiological factors in podocytes represented by the mechanoresponsive sarcocere-like structure and establish a novel system for characterizing this mechanobiology in vitro.

Primary Cilia in Podocyte Health and Disease

Lindsey A. Fitzsimmons,1,2 Kara M. Button,1 Jake N. Cho,1 Michael C. Akom,1,4 Kerry L. Tucker,1,2 Ron Korstanje.1,3 University of Maine at Orono, Graduate New England School of Biomedical Science & Engineering, Orono, ME; University of New England College of Osteopathic Medicine, Biddeford, ME; Maine Medical Center, Portland, ME; Tufts University School of Medicine, Boston, MA;1 The Jackson Laboratory, Bar Harbor, ME.

Background: Primary cilia are highly specialized elaborations of the plasma membrane that direct many of the signaling cascades critical for pre- and post-natal development and disease. While renal primary cilia are recognized as key genetic and cellular targets in polycystic kidney disease, the presence and function of primary cilia within the renal corpuscle and glomerulus have yet to be fully characterized. The purpose of our study was to perform a focused and quantifiable characterization of primary cilia of glomerular cell populations in health and disease.

Methods: Renal biopsy samples were obtained from patients with Minimal Change Disease (MCD; N=6), Focal Segmental Glomerular Sclerosis (FSGS; N=5), and control renal tissue (CON; N=4). Immunofluorescence analyses (IF) were used to quantify primary cilia number and length, as well as the expression of Sonic Hedgehog (SHH) protein, the ligand component of the Hedgehog signaling pathway and one measure of primary cilial function.

Results: Mean percent ciliation was significantly increased in MCD and FSGS when compared to CON. Analysis of individual glomerular primary cilia revealed increased cilary length (μm) in both MCD and FSGS when compared to CON. Further analysis comparing primary cilia length in WT-1-positive nuclei (WT-1+; podocytes) also revealed a pronounced increase in cilia length in MCD and FSGS podocyte primary cilia versus CON. Despite increased length of primary cilia, glomerular SHH expression was significantly decreased in both MCD and FSGS when compared to CON. Glomerular diseases MCD and FSGS are therefore associated with an overall increase in podocyte primary cilia length and ciliation, an effect which corresponded to a decrease in SHH expression.

Conclusions: These data provide evidence in support of a role for primary cilia in glomerular disease pathogenesis. Ongoing and future research is needed to establish a mechanistic explanation for these changes observed in glomerular and podocyte primary cilia number and length. A more thorough understanding of the role(s) of primary cilia in glomerular cells, and specifically in podocytes, remains critical for both our understanding of disease pathogenesis as well as for the pharmacologic treatment of glomerular chronic kidney disease.

Establishing a Podocyte-PEC Cross-Talk Model Using an Open Microfluidic Co-Culture Device

Yuting Zeng, Jeffrey W. Pippin, Stuart J. Shankland, Ashleigh B. Theberge.1 University of Washington Department of Chemistry, Seattle, WA; 2University of Washington Division of Nephrology, Seattle, WA; 3University of Washington Department of Urology, Seattle, WA.

Background: Although focal segmental glomerulosclerosis (FSGS) is initially caused by podocyte injuries, their neighboring parietal epithelial cells (PECs) also undergo molecular changes that further damage the glomerulus. The cross-talk between podocytes and PECs is poorly understood, in part due to a lack of appropriate experimental models for study. Our goal is to establish an in vitro coculture model to induce podocyte injury and determine the mediators and responses of PECs.

Methods: Mouse podocytes labeled with EGFP and PECs labeled with tdTomato were cultured in two neighboring channels of an open microfluidic device that we engineered. The chambers remain separated until more media is added to overflow the half wall in between. To induce injury, podocytes were exposed to increasing concentrations...
of cytotoxic sheep anti-glomerular antibodies (or media alone as control) for 2 hours. The two groups were then washed 4× to remove unbound antibodies. Diffusion calculations suggested moderate sized (10 kDa) signaling molecules take approximately 2 days to reach the other chamber. Immunochemistry characterized podocyte injury and PEC activation and epithelial-mesenchymal transition (EMT).

Background: Podocytes are highly specialized cells that bridge membrane-spanning proteins to cortical actin, shaping the cellular architecture. The loss of podocyte function, which occurs in glomerular diseases, can impair filtration and lead to proteinuria. Recent studies have shown that CLIC5A (clic5a, also known as PIEZO2) is involved in the mechanosensitive ion channel activity of podocytes, which plays a crucial role in the regulation of glomerular filtration. However, the mechanisms underlying the mechanosensitive ion channel activity of podocytes remain unclear.

Methods: First, we confirmed CLIC5A expression and localization at the nephrocyte membrane using immunofluorescence microscopy. Then, we investigated the functional role of the mechanosensitive ion channel Piezo in nephrocyte injury via hypertrophy.

Results: We found that CLIC5A interacts directly with the Ezrin C-terminal domain, but not with other proteins. This suggests that the 16 C-terminal amino acids of Ezrin were necessary for the interaction and Ezrin phosphorylation at T567 increased CLIC5A binding. Expression of a C-terminal ezrin fragment (Ezrin 432-586, phosphomimic T567D), but not C-terminally truncated Ezrin (Ezrin 432-570) effectively blocked CLIC5A-stimulated Rac1 activation. In glomeruli 49±4% of endogenous CLIC5A was in the cytoplasmic, 33±3% in membrane and 18±1% in the cytoskeleton-associated fraction. As expected, PI(4,5)P2 hydrolysis reduced Ezrin phosphorylation and shifted Ezrin from membrane and cytoskeletal fractions into the soluble pool. Similarly, PI(4,5)P2 hydrolysis suggests that CLIC5A localizes to the plasma membrane because of its direct interaction with Ezrin.

The Mechanosensitive Ion Channel Piezo Activates Rho1 in Drosophila Nephrocytes

Sybille Koehler, Barry Denholm. Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Podocytes constantly face biomechanical forces such as shear stress and hydrostatic pressure. Increasing forces result in morphological changes, detachment from the glomerular basement membrane and loss into the primary urine. This highlights a requirement for podocytes to sense changes in their physical environment and induce a reaction to respond to increased biomechanical force.

Methods: Here, we investigated the functional role of the mechanosensitive ion channel Piezo in Drosophila nephrocytes.

Results: First, we confirmed Piezo expression and localisation at the nephrocyte membrane using immunofluorescence microscopy. In vivo analysis revealed that Piezo was necessary for the development of glomerulus and podocytes. In the absence of Piezo, podocytes were sequestered from glomerulus, and glomerulus were not formed. Additionally, we observed a significant increase in podocyte hypertrophy in Drosophila mutants with reduced piezo expression. These results collectively suggest that Piezo-induced Increases in hydrostatic pressure and shear stress are crucial for the maintenance of podocyte function and morphology.

Conclusion: Taken together, our data confirms the functional expression of Piezo in nephrocytes, indicative of its role in regulating Glomerular filtration. This study highlights the importance of Piezo in the mechanosensitive response of podocytes to biomechanical forces.
PO1687
Characterization of a Novel FSGS-Associated ACTN4 Mutation in Drosophila melanogaster
Johanna Odenthal, Bodo B. Beck, Bernhard Schermer, Thomas Benzing, Paul T. Brinkkoetter, Malte P. Bartram.
Unlikink Kohn, Kohn, Germany.

Background: Decisive for podocyte morphology and homeostasis during health and disease is a specialized and highly regulated organization of the actin cytoskeleton. In this context, the actin cross-linking protein Alpha-actinin4 (ACTN4) has been shown to play a crucial role in podocyte architecture and function. Mutations in the ACTN4 gene are associated with focal segmental glomerulosclerosis (FSGS). Here, performing gene panel sequencing in a pediatric patient presenting with steroid resistant nephrotic syndrome and FSGS, a de novo, potentially disease causing variant of ACTN4 was identified, which was previously undescribed and not found in available genome or exome databases. Our aim is to elucidate the pathogenic potential of this variant for podocytes and FSGS progression.

Methods: To elucidate pathogenic effects of the newly identified ACTN4 variant, we employed the genetic toolbox of Drosophila. The fly holds podocyte-equivalent cells called nephrocytes, which are responsible for filtration and detoxification of the hemolymph. Cell-specific genetic manipulation enabled us to analyze RNA-mediated knockdown of Actin in the single fly homog, in nephrocytes and its impact on cell morphology and function. Rescue experiments with the novel human ACTN4 variant will now enable us to most possible pathogenic consequences of the mutation when compared to wildtype as well as previously described disease-associated variants of ACTN4.

Results: Knockdown of Drosophila Actin in nephrocytes leads to severe functional and morphological defects, including a reduction by 50%, morphologically mislocalization of the ZO-1 homolog Polychaetoid as observed as well as overall reduction of nephrocyte diaphragms. First rescue experiments with wildtype human ACTN4 led to partial rescue of functional and morphological phenotypes observed upon Actin knockdowns.

Conclusions: Our results underline the importance of Actin in nephrocyte biology. Capacity of wildtype human ACTN4 in rescuing the knockdown associated phenotypes indicates the model’s suitability. Further experiments will be performed to elucidate the pathogenic consequences of the novel ACTN4 variant also in comparison to previously described pathogenic mutations.

The Calcium-Sensing Receptor Restores Podocyte Function in Proteinuric Humans and Mice
Anne K. Muehlig,1 Johanna Steingroever,1 Wiebke Sachs,1 Catherine Meyer-Schwesinger,2 Hoon Young Choi,3 Nicole Endlich,4 Fabian Braun,2 Tobias B. Huber,2 Victor G. Puelles,2 Claus Peter Schmidt,2 Jun Oh.2
1Department of Pediatric Nephrology, University Children’s Hospital, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Institute of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3Center of Experimental Medicine, Institute of Cellular and Integrative Physiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4Department of Anatomy and Cell Biology, University of Greifswald, Greifswald, Germany; 5Department of Pediatrics, Heidelberg University Hospital, Heidelberg, Germany; 6Insei University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

Background: Calcimimetic agents allosterically increase the calcium (Ca2+) sensitivity of the calcium-sensing receptor (CaSR), which suppresses the secretion of parathyromone in the parathyroid gland and therefore regulates Ca2+-homeostasis. The CaSR is furthermore expressed in the tubular system and to a lesser extend in podocytes. Activation of CaSR reduces glomerular proteinuria and podocyte damage in animals. However, the precise role of the podocyte CaSR is still unclear.

Methods: A CaSR knockdown (KD) in murine podocytes and podocyte-specific CaSR knockout (KO) in BALB/c mice were generated to study its role in proteinuria.

Results: Podocyte CaSR KD abolished the calcimimetic R-568 mediated -influx, reduced the number of actin fibers, cellular attachment and migration velocity in podocytes. In contrast, the activation of the CaSR with R-568 protected podocytes from Adriamycin (ADR)-induced cytoskeletal rearrangement and reduction in adhesion capacity. In vivo ADR-induced proteinuria enhanced glomerular CaSR expression in wild type mice (control vs ADR: 33.5±2.0 vs 75.8±7.8 CaSR positive podocytes (%); p=0.0286). In podocyte-specific CaSR KO ADR treatment resulted in a higher albuminuria (control vs KO: 27.9±3.8 vs 85.9±5.2 g/galbin/creatinine; p=0.023 at day 7), podocyte foot process effacement, podocyte loss (control vs KO: 350±28.3 vs 2969±457.2 p57+cells/mm2; p=0.0238 at day 8) and glomerular sclerosis compared to wild type littermates. In addition, four children with nephrotic syndrome, objecting glucocorticoid therapy, were treated with the calcimimetic cinacalcet for 1 to 33 days. Proteinuria declined transiently by up to 96 %, serum albumin increased and edema resolved.

Conclusions: The activation of CaSR regulates key podocyte functions and protects from ADR induced cellular damage in vitro. The CaSR reduces toxic induced proteinuria, podocyte loss and glomerular damage in mice. Our findings suggest a major role of CaSR signaling in glomerular disease.

Regression of Severe Preexisting Glomerular Pathology in a Mouse FSGS Model in Response to Treatment with Macula Densa-Derived Biologicals

Georgina Gvaryati, Urvi Nikhil Shroff, Audrey Izhara, Janos Peti-Peterdi. University of Southern California Keck School of Medicine, Los Angeles, CA.

Background: Macula densa (MD) cells localized at the glomerular vascular pole synthesize and release numerous vasoactive autacoids and newly identified angiogenic (e.g. CCN1) and glomerulotrophic factors that act in a paracrine fashion to maintain high renal/glomerular blood flow and endogenous tissue remodeling. The present study aimed to test the tissue regenerative therapeutic potential of MD-derived biologicals in vivo in a mouse model of focal segmental glomerulosclerosis (FSGS).

Methods: Balb/C mice with Adenovirus-induced stable, severe FSGS and albuminuria (albumin/creatinine ratio ACR>10,000/g) were randomized into 5 groups and started daily ip injections (150μl each) of saline (S), human recombinant (hr) CCN1 in low-dose (0.3 ng/mouse) (L), hrCCN1 high-dose (2 μg/mouse) (H), DMEM/F12 control (D), and conditioned culture media of the new MD cell line mdD5® (MD) for 4 weeks. Transcutaneous GFR (MediBeacon) and ACR were measured weekly. Terminal histological analysis was performed using PAS and Trichrome staining.

Results: Kidney injury was severe at the onset (GFR 1160±1 μL/min/100 g BW, ACR 1219±637) and was sustained throughout the 4 weeks of treatment in control S and D groups (GFR: 108±143, 992±164, ACR: 1022±786, 3958±1638, respectively). In contrast, a progressive and significant improvement in kidney function was observed in response to both L, H, and MD treatment (ACR reduced to 134±273, 921±173, 113±173, 921±270, 131±1113, 131±1113 in S; 47±2 in L, 57±3 in D based on Picrosirius ± index (67±2 in MD vs 80±3.4 in S; 113±173±2.3 in H vs 0.9 in D), GS index (131±1113±573, 921±270, 113±173±2.3 in H vs 0.9 in D), and GFR: 1080±188, 492±164, 1022±786, 3958±1638, respectively). In response to both L, H, and MD treatment (ACR reduced to 134±273, 921±173, 113±173, 921±270, 113±173±2.3 in H vs 0.9 in D), GS index (131±1113±573, 921±270, 113±173±2.3 in H vs 0.9 in D), and GFR: 1080±188, 492±164, 1022±786, 3958±1638, respectively). Mechanistically we found that Cd44 expression was upregulated at both mRNA and protein levels in response to MD treatment. The effects of MD treatment on kidney function are consistent with previous studies demonstrating the therapeutic potential of MD-derived biologicals in mouse models of FSGS.

Conclusions: MD-derived biologicals have the potential to improve kidney function in a mouse model of FSGS. Treatment with MD-derived biologicals improved significantly in response to treatment with MD biologicals. These findings suggest that MD-derived biologicals have potential therapeutic applications in the treatment of FSGS.

Insulin-Like Growth Factor 1 Receptor (IGF1R) Suppression in the Glomerular Podocyte Has Beneficial and Detrimental Consequences Dependent on the Level of Inhibition

Jenny Harcombe,1 Fern Barrington,1 Virginie M. Betin,1 Abigail C. Lay,1 Luzynia Dayalan,1 Lan Yi,1 Paul T. Brinkkocket,2 Martin Holzenberger,2 Gavin I. Welsh,1 Richard Coward.1 1University of Bristol, Bristol, Bristol, United Kingdom; 2Uniklinik Köln, Köln, Germany. 1INSERM, Paris, France.

Background: Insulin signaling to the glomerular podocyte via the insulin receptor (IR) is known to be critical for normal kidney function. This study aimed to define the physiological importance of the closely related insulin-like growth factor 1 receptor (IGF1R) in podocytes.

Methods: Transgenic mice with conditional inactivation of podocyte IGF1R were generated to determine the effects of IGF1R suppression in vivo. In vitro, conditionally immortalised genetic IGF1R knockout and wild-type podocytes treated with IGF1R inhibitor pircodophyllin (PPP) were characterised using global proteomic analysis.

Results: Transgenic mice with partial podocyte-specific IGF1R knockout, generated using conventional Cre recombinase, had no apparent basal renal phenotype but did not survive past 24 weeks. Transcutaneous GFR (MediBeacon) and ACR were measured weekly. Terminal histological analysis was performed using PAS and Trichrome staining.

Conclusions: In vivo preclinical study confirmed that the supplementation of key MD cell-derived factors in the form of injectable biologicals can augment endogenous kidney tissue repair and restores kidney function in a mouse model of FSGS. Targeting key MD cell-derived factors in the form of injectable biologicals can augment endogenous staining density) improved significantly in response to treatment with MD biologicals.

Calcium/Cammodulin Kinase 4 Induces FSGS by Promoting Apoptosis While Inhibiting Autophagy in Podocytes

Rhea Bhardava, Kayaho Maeda, Abhigyan Satyam, Isaac E. Stillman, George C. Tsokos. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Podocyte injury and death precede the development of focal segmental glomerulosclerosis (FSGS), but the involved mechanisms remain poorly understood. Calcium/calcmodulin kinase 4 (CaM/K4), a serine threonine kinase, is increased in podocytes of people with FSGS and in experimental models of FSGS.

Methods: B6, B6 Camk4/fl/fl.podocyte or Camk4/fl/fl.podocyte mice were created and injected with i.v. adriamycin. Urine was collected on days 0, 3, 7, or 14, and kidney samples were collected on day 7 or 14 after adriamycin injection. Cultured human podocytes in the presence and absence of CAMK4 inhibitor (KN93) were exposed to adriamycin after which immunofluorescence and western blot was performed. Pull down mass-spectrometry and co-immunoprecipitation analysis was performed to identify proteins involved in cell death and those that directly interact with CaM/K4 in FSGS.

Results: We found that lack of Camk4 in podocytes suppressed the development of kidney pathology including the presence of hyaline deposits in glomeruli, podocytopenia and tubulointerstitial damage with intratubular casts in mice injected with adriamycin. Proteinuria in mice lacking Camk4 in podocytes exposed to adriamycin, was reduced at 7 days and remained low through the 14th day when compared to control mice. Mechanistically we found that Camk4 phosphorylates 14-3-3, releasing pro-apoptotic protein BAD which in turn binds to the antiapoptotic protein BCL-2, thereby allowing BAX, to aggregate on mitochondria and induce release of cytochrome c through mitochondrial pore formation, followed by caspase activation and apoptosis. In parallel, CAMK4 inhibits autophagy, a process needed for the renovation of damaged organelles, through the mTOR pathway, by directly phosphorylating AKT and S6 kinase.

Conclusions: We demonstrate that mice lacking Camk4 specifically in podocytes are protected from FSGS-like disease after exposure to adriamycin. These mice also demonstrate markedly reduced proteinuria and podocytopenia. We found that apoptosis leads to cell death while autophagy is protective in FSGS. The characterization of the specific molecular events which lead to podocyte loss and glomerulosclerosis point to putative therapeutic targets and biomarkers for FSGS.

A Noncanonical Role for IRE1α in Podocyte Endoplasmic Reticulum (ER)-Phagy

José R. Navarro-Betancourt,1 Joan Papillon,1 Julie Guillemette,1 Takao Iwawaki,2 Andrey V. Culybusky.1 ’McGill University, Montreal, QC, Canada; 2Kanazawa Medical University, Kaho-ku, Japan.

Background: Glomerular diseases involving podocyte (glomerular epithelial cell; GEC) injury feature endoplasmic reticulum (ER) stress and activation of the unfolded protein response (UPR). Inositol requiring enzyme-1α (IRE1α), a UPR transducer, mediates chaperone production and autophagy in podocytes during ER stress. Selective autophagy of the ER (ERphagy) is dependent on ER-resident adaptors (e.g. RTN3L) and is stimulated by ER stress. ER-derived coat protein complex II (COPII) vesicles may participate in the delivery of ER cargo to autophagosomes; however, regulation and importance of ERphagy in glomerular disease are not understood.

Methods: We employed mice with podocyte-specific deletion of IRE1α and littermate controls. IRE1α knockout (KO) and control GECs were produced from these mice. GECs were incubated with tunicamycin (TM) to induce ER stress.

Results: Mass spectrometry analysis of TM-stimulated control and IRE1α KO GECs showed that in addition to ER chaperones, proteins in the secretory pathway, including the COPII component Sec23B, were increased in an IRE1α-dependent manner. By immunoblottting, TM enhanced Sec23B and RTN3L expression in control, but not IRE1α KO GECs. By immunofluorescence microscopy, in control GECs, TM increased the biogenesis of LC3 and Sec23B particles, as well as colocalization of Sec23B with LC3 and RTN3L with LC3; increases were attenuated in IRE1α KO GECs. Thus, deletion of IRE1α impaired delivery of COPII vesicles and RTN3L-coated ER fragments to autophagosomes. Knockdown of Sec23B with siRNAs abolished the increased LC3 expression in control GECs. By blocking protein synthesis with cycloheximide, TM stimulated degradation of RTN3L in control GECs, consistent with ERphagy flux, but RTN3L degradation was impaired in IRE1α KO cells. Similarly, TM induced degradation of 63/45 kDa collagen IV in control, but not IRE1α KO GECs, suggesting that collagen IV is an IRE1α-dependent ERphagy substrate. In adriamycin nephrosis, where IRE1α activates an adaptive UPR and autophagy, expression of Sec23B and RTN3L was increased in glomeruli of control, but not IRE1α KO mice.

Conclusions: During ER stress, IRE1α redirects a subset of Sec23B-positive COPII vesicles to deliver RTN3L-coated ER fragments to autophagosomes. ERphagy is a novel outcome of the IRE1α pathway in podocytes and may play a cytoprotective role in glomerular diseases.

PO1695
ACE Inhibition Modulates Insulin-Like Growth Factor 1 (IGF-1) Filtration to Regulate Compensatory Kidney and Glomerular Hypertrophy

Background: Modeling suggests that preventing glomerular volume (GV) increase could serve as a therapeutic target to mitigate hypertrophy-associated progressive glomerulosclerosis (GS). We, therefore, evaluated how GV is regulated, and how Angiotensin-Converting Enzyme inhibition (ACEI) could reduce compensatory GV increase.

Methods: Uni-nephrectomized (Uni-Nx) wild-type Fischer344 rats were used to model progressive GV triggered from the single kidney state, and the effect of ACEI was analyzed. ACEI started either before or after Uni-Nx. Urine IGF ELISA assay, computer-assisted morphometry, single-cell, bulk transcriptomics, immunofluorescence, and human databases were analyzed.

Results: ACEI started before, but not after Uni-Nx, reduced short (Panel A) and long-term (Panel B) compensatory GV increase, and the associated 8-fold peak of urine IGF-1 post-nephrectomy (Panel C). An IGF-IR inhibitor (piropodophyllin) also reduced compensatory kidney hypertrophy (Panel D). Post-Uni-Nx, a decrease in both serum IGF-1 and glomerular kidney IGF-1 transcript were noted, and IGFFBP3 (the major blood IGFBP) was present in podocyte cytoplasm in the absence of detectable podocyte IGFFBP3 transcript, suggesting that IGF-1 and IGF-IGFBP complex had come from blood. A model was developed to predict how IGF-1, IGF-2, and IGF-IGFBP protein complexes would interact with the glomerular filter, and its predictions were confirmed in ERCB database. The importance of hypertrophied IGF-1 as a driver of glomerular failure in single kidney states was further supported by human kidney allograft half-life analysis.

Conclusions: Hyperfiltrated IGF-1 drives compensatory GV increase leading to long-term proteinuria and GS. Timing of ACEi in relation to Uni-Nx can reduce both IGF-1 hyperfiltration and GV increase, thereby prolonging single kidney lifespan.

Angiotensin II Induces Oxidative Podocyte Injury via the Upregulation of Nox4
Tae-Sun Ha, Chung-hak Kwak, Sung Uk Oh, Hyun-Jin Kim, Jin Hyuk Lee, Hye Young Park, Jun Hyo Kim, Seung Hoon Kim

Background: Angiotensin II (Ang II) induces glomerular and podocyte injury via systemic and local vasoconstrictive or non-hemodynamic effects including oxidative stress. The release of free radicals from podocytes may participate in the development of glomerular injury and proteinuria. We studied the pathophysiological roles of oxidative stress in Ang II-induced podocyte apoptosis.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times and transfected by Nox4 or AT1R siRNAs or negative control scrambled siRNA for 24 h. The changes of podocyte oxidative stress and apoptosis were observed by confocal imaging, western blotting, realtime PCR, FACS and TUNEL assay according to the presence of Ang II.

Results: Ang II increased the generation of superoxide anions and intracellular reactive oxygen species (ROS) levels but suppressed the podocyte proliferation. Ang II increased Nox4 protein expression and podocyte apoptosis, measured using western blotting and real-time PCR analysis which was also reversed by probucol. Nox4 suppression by small interfering RNA (siRNA) reduced the oxidative stress induced by Ang II. These results suggest that Ang II induced oxidative stress via the upregulation of Nox4 protein in a transcriptional mechanism. Ang II promoted podocyte apoptosis that was reversed significantly by probucol and Nox4 siRNA. Ang II-induced podocyte apoptosis were also recovered by Ang II type 1 receptor (AT1R) siRNA.

Conclusions: Our findings suggest that Ang II induced podocyte oxidative stress and apoptosis through AT1R and Nox4. These findings suggest that Ang II promoted podocyte oxidative stress and apoptosis through AT1R and via the upregulation of Nox4, which could be prevented by Nox4 inhibition and/or antagonizing AT1R as well as antioxidants.

Anillin Serves a Protective Function in a Mouse Model of HIV-Associated Nephropathy
Brandon M. Lane,1,2 Alexis Musick,1 Guanghong Wu,1,3 Megan Chryst-Stangl,1,2 Gentzon Hall,1,2 David N. Howell,1 Rasheed A. Gbadegesin,1,2 Duke University Department of Pediatrics, Durham, NC; 3Duke Molecular Physiology Institute, Duke University, Durham, NC; 4Duke University School of Medicine, Durham, NC; 5Duke University Department of Pathology, Durham, NC; 6Duke University Hospital, Durham, NC.

Background: HIV-associated nephropathy (HIVAN) is characterized by a rapid progression to end stage kidney disease with limited treatment options. We previously demonstrated that mutations in the gene encoding anilin (ANLN) can cause FSGS and showed that ANLN is upregulated in the glomerulitis of HIVAN patients as well as the HIVAN Tg26 mouse model. ANLN is an F-actin binding protein that affects cell proliferation and survival, two cell processes that are predicted to play a key role in the phenotype associated with HIVAN. We hypothesized that ANLN upregulation is one of the drivers of glomerular failure in HIVAN mice, therefore modulating ANLN expression may present an alternative therapeutic strategy for HIVAN.

Methods: To evaluate the therapeutic potential of reduced functional ANLN in a HIVAN mouse model, we created a mouse line using CRISPR Cas9 mediated gene editing that contains an early stop codon in the Anln gene (ANLNx). We then bred heterozygous ANLNx mice with Tg26 HIVAN mice and evaluated proteinuria and mortality over 16 weeks for each genotype. Sclerotic glomeruli from 3 mice in each group were evaluated and quantified at 16 weeks by age pathologists blinded to genotype.

Results: There was no improvement in glomerular disease phenotype associated with the reduction of functional ANLN in the Tg26 HIVAN model. Urine albumin to creatinine ratio at 8, 12, and 16 weeks were similar between ANLNx and Tg26 heterozygotes compared to Tg26 HIVAN mice (p=0.383, 0.0863. 0.0761 for each time-point). Mice heterozygous for both the ANLNx and Tg26 alleles also did not display any increase in survival compared to mice carrying only the Tg26 allele (p=0.361). Evaluation and scoring of PAS stained kidney sections by independent pathologists revealed similar levels of sclerosis between Tg26 HIVAN mice and mice heterozygous for both the ANLNx and Tg26 alleles.

Conclusions: Genetic ablation of ANLN does not improve kidney disease phenotypes in Tg26 HIVAN mice. ANLN upregulation likely represents a survival mechanism in Tg26 HIVAN mice and not a cause of injury.

The Role of LRP1 in Podocytes
Marwin Groener,1,2 Patricia Bolanos-Palmieri,1 Tilman Jobst-Schwan,1 Mario Schiffer1,2. University Hospital Erlangen - Department of Medicine 4 - Nephropathy and Hypertension, Erlangen, Germany; 3Research Center On Rare Kidney Diseases (RECORD), University Hospital Erlangen, Erlangen, Germany.

Background: Recent studies have demonstrated the importance of endocytosis for podocyte health. However, little is known about the function of the internalized cargo proteins. We investigated the role of the low-density lipoprotein receptor-related protein 1 (LRP1), a large endocytic scavenger receptor, in podocytes in vitro and in vivo.

Methods: We used immunoblotting and -fluorescence to determine quantity and localization of LRP1 in cultured human podocytes. siRNA knockdown (KD) of LRP1 and an antagonist were used to investigate potential functional importance in vitro. We used zebrafish morpholino knockdown models of LRP1 homologs to study the function of LRP1 in vivo. LRP1 expression in healthy and diseased human renal tissue was determined by immunohistochemistry.

Results: LRP1 is highly expressed in cultured podocytes where it localizes to the perinuclear and perinuclear region. It colocalizes with early and late endosomes, in line with its role in endocytic trafficking. Interaction with β1-Integrin (ITBI) was confirmed by immunoprecipitation and colocalization. siRNA KD of LRP1 resulted in a reduction of podocyte number and cell size. Morpholino KD of both LRP1 isoforms in zebrafish led to pericardial effusion and generalized edema, hinting at a renal phenotype. Interestingly, LRP1 has nearly absent baseline expression in healthy human glomeruli. Glomerular expression is significantly increased in human biopsies of various podocytopathies. However, LRP1 does not colocalize with the podocyte marker nephrin in human tissue.

Conclusions: LRP1 is a highly expressed endocytic receptor in cultured podocytes. Ablation of LRP1 function caused by siRNA KD or pharmacological inhibition resulted in disarrayment of podocyte shape, implicating a crucial role in adhesion and cytoskeletal regulation in vitro. Colocalization and immunoprecipitation with ITBI suggests interaction with an integrin trafficking. The importance of LRP1 for kidney function is corroborated by our zebrafish experiments where LRP1 silencing led to a renal phenotype. Since glomerular LRP1 expression is increased in proteinuric diseases, it could function as a mediating or compensating factor in glomerular injury. However, its absence from podocytes in vivo makes its function for podocytes outside of the culture environment unclear. Our findings thus exemplify the difference in podocyte adhesion regulation between podocytes in vitro and in vivo.

Dach1 Is Essential for Maintaining Normal Podocytes
Keiko Tanaka,1 Taiji Matsuoka,2 Okayama Daigaiku Daigakusho Ishiyaku-ku Sogo Kenkyuka, Okayama, Japan; 3Tokai Daigaiku Ikaguho Daigaiku Ikagu Kenkyuka, Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We aimed to elucidate the function of Dach1 in podocytes in vitro.

Methods: Because Dach1 null mice die shortly after birth, kidneys were harvested at P0 and histologically examined. To study the role of Dach1 in mature podocytes, podocyte-specific Dach1 deleted mice were generated by mating Dach1fl/fl mice with Nphs1-Cre or Nphs2-CreERT2 mice. Eleven Nphs1-Cre/Dach1fl/fl mice with Nphs2-CreERT2/Dach1fl/fl mice were analyzed at 8-35 weeks of age. 14 indicating inefficient Cre-mediated recombination. Nevertheless, all examined samples showing normal slit membrane, and no abnormal leakage of albumin. Immunostaining for WT1, nephrin, podocin, synaptopodin and nesprin was normal. Only a small number of podocytes lacked Dach1 staining in Nphs1-Cre/Dach1fl/fl and Nphs2-CreERT2/Dach1fl/fl mice, indicating inefficient Cre-mediated recombination. Nevertheless, all Nphs1-Cre/Dach1fl/fl exhibited normal albuminuria (UACR 4.7±1.6 mg/g vs. 0.06±0.007), which increased with age, and seven (65%) mice showed FSGS. Seven (50%) Nphs2-CreERT2/Dach1fl/fl mice exhibited abnormal albuminuria, and three (21%) mice showed early sclerotic lesions. Immunostaining showed that sclerotic lesions lacked Dach1 as well as WT1, synaptopodin and nesprin. Most of Dach1 negative podocytes in non-sclerotic glomeruli had normal staining for podocyte marker proteins.

Results: These results indicate that Dach1 does not determine the fate of differentiation into podocytes but is indispensable for maintaining normal integrity of mature podocytes.

TAZ Is Important for Structural and Functional Integrity of Podocytes
 Jianchun Chen, Raymond C. Harris. Vanderbilt University Medical Center; Nashville, TN.

Background: Podocyte is an important component of the glomerular filtration barrier (GFB). Maintenance of integrity of slit-diaphragm(SD) structure is critical for normal kidney function. Podocytes lost most epithelial cell tight junction components except for Zonula occludens-1 and -2 (ZO-1 and ZO-2). In podocytes, ZO-1 is an important binding partner of nephrin, and mice with podocyte-specific ZO-1 deletion showed significant growth retardation and severe proteinuria starting at 2 weeks of age, but the regulation of ZO-1 expression in podocytes are not clear. TAZ (transcriptional coactivator with PDZ-binding motif) and its paralog Yes-associated protein (YAP) are two crucial effectors of the Hippo signaling pathway. Recent study has shown that TAZ is present in human podocytes both in vitro and in vivo, as its expression domain coincides with glomerular cells labeled with synaptopodin. Additionally, the RI is present in cultured podocytes both before and after the temperature shift used to induce quiescence, and it appears to increase after differentiation. There is also expression modulation of RNH1 in response to PAN to determine if changes in RI expression occur as a response. RNH1 inhibition was performed in a transgenic zebrafish line that allows for the detection of proteinuria via a GFP-tagged protein in the circulation. At 60hpf the severity of the edema phenotype and the fluorescence levels were recorded.

Results: Our preliminary data shows that the RI is present in human podocytes both in vitro and in vivo, as its expression domain coincides with glomerular cells labeled with synaptopodin. Additionally, the RI is present in cultured podocytes both before and after the temperature shift used to induce quiescence, and it appears to increase after differentiation. There is also expression modulation of RNH1 in response to PAN treatment of podocytes. In our zebrafish model, RNH1 knockdown resulted in up to a 40% increase in mild to severe edema and over 30% decrease in fluorescent suggesting that a reduction in RI might compromise the filtration barrier enough to lead to proteinuria. Taken together our initial data show a promising avenue for research where the balance between members of the RNaseA superfamily and their cytoplasmic inhibitor may represent a powerful mechanism that allows the cells to modulate the proteinuria response to stimuli. An imbalance in this relationship might ultimately affect the integrity of the cells in the kidney.

Neurexin1α Containing Splice Site 4 Interacts with Nephrin and Contributes to Maintenance of the Integrity of Podocyte Slit Diaphragm
Yoshiyasu Fukusumi, Hidemori Yasuda, Ying Zhang, Hiroshi Kawachi. Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background: Neurexins (NRXNs) are synaptic cell adhesion molecules having essential roles in the assembly and maturation of synapses. It is known that NRXN1α contains 6 splice sites (SSs), and multiple splicing variants were diffusely expressed in neuronal tissues. We have previously reported that NRXN1α is expressed at slit diaphragm (SD), a cell-cell junction of podocyte, and is downregulated in injured podocytes. The report also showed that NRXN1α expressed in podocytes is a unique variant containing SS1, 3, 4, and 5, which is a rare variant in neural tissues (Am J Physiol, 300:R340, 2011). However, the role of NRXN1α at SD is not well understood yet.

Methods: The interaction of NRXN1α with SD-associated molecules was analyzed by the immunoprecipitation (IP) assay. The function and structure of SD of NRXN1α KO mice were precisely analyzed.

Results: The interaction of NRXN1α with SD molecules such as nephrin and ephrin-B1 was detected by the IP assay with rat glomerular lysates. IP assay with the HEK cell expression systems showed NRXN1α containing SS4 interacted with nephrin, but NRXN1α lacking SS4 did not. The interaction between NRXN1α and nephrin was dissociated, if nephrin was phosphorylated. The interaction of NRXN1α with ephrin-B1 was not detected in the HEK system, suggesting NRXN1α interacts with ephrin-B1 via nephrin. Abnormal proteinuria (92.1 µg/day vs. 23.8 µg/day, p<0.05) and clear proteinuria in urine (12.67 vs 27.86 µg/mg, p<0.05) were observed in NRXN1α KO mice as compared with WT1. We aimed to elucidate the function of Dach1 in podocytes

Atypical Caspase 3-Dependent Death in Podocytes
Kazuyoshi Yamamoto,1,2 Masahiro Okabe,1,2 Taiji Matsusaka,1 Takashi Yokoo,1
Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; 2Tokai Daigaku, Hiratsuka, Japan.

Background: Apoptosis of podocytes has been widely reported in many in vitro studies, but definitive apoptosis has never been documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vivo and in vitro. Methods: Primary mouse podocytes were transiently transfected with ICD25 and EGFP expression plasmids and treated with a ICD25-targeting immunotoxin, LMB2 (1nM), and observed 1 day later. In some experiments, the cultured podocytes were transfected with Bak1 or Bax siRNA before treatment with LMB2. In vivo experiments, podocyte injury was induced by injecting LMB2 (1.25ng/gBW) into NEP25 mice, which express ICD25 in podocytes, and analyzed 7 days later.

Results: In vivo studies, administration of LMB2 caused loss of co-introduced EGFP in 56.8±13.6%, incorporation of propidium iodide in 13.6±2.5%, activation of caspase 3 (Casp3) in 19.6±2.6% and TUNEL staining in 4.5±1.3% without significant increase in LDH activity in the culture medium. These phenomena were not observed in cells without ICD25 or without LMB2. Ac-DEVD-CHO (10uM), a Casp3 inhibitor, attenuated the loss of EGFP by 38.2%. Inhibition of Bak1 and Bax using siRNAs attenuated EGFP loss by 77.6% and 28.4%, respectively. These indicate that LMB2 induced the typical Casp3 dependent intrinsic apoptosis in podocytes in vivo. In in vivo studies, kidneys of NEP25 mice contained podocytes positive for cleaved (c) Casp3 and those for cLaminA, a product of Casp3, but no TUNEL+ podocytes. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. The urinary sediments contained podacyclin-positive podocytes (2.5±0.3%). Among these, 39.3±1.7% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to 5/6 nephrectomy 1 day before sacrifice. The obstructed kidney contained more cLaminA+ podocytes than the contralateral kidney. In addition, detachting podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: Thus, due to physical force of glomerular filtration, podocytes doomed to Casp3 dependent death are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. This accounts for the absence of podocyte apoptosis in vivo.

Glomerular Endothelial Cell-Derived MicroRNA-192 Regulates Podocyte Nephronectin in Membranous Glomerulonephritis
Janina Müller-Deile,1 Nina Sopel, Victoria Rose, Christoph Daniel, Kerstin U. Amann, Mario Schiffer, Friedrich-Alexander-Universität Erlangen-Nurnberg, Erlangen, Germany.

Background: Autoantibodies binding to podocyte antigens cause idiopathic membranous glomerulonephritis (iMGN). It remains elusive how autoantibodies reach the subepithelial space because the glomerular filtration barrier (GFB) is normally size-selective and impermeable for antibodies.

Methods: Kidney biopsies from patients with iMGN, cell culture, zebrafish and mice models were used to investigate the role of nephronectin (NPNT) regulating microRNAs (miRs) for the GFB.

Results: Glomerular endothelial cell (GEC)-derived miR-192-5p and podocyte-derived miR-378a-3p are upregulated in glomeruli of patients with iMGN whereas NPNT expression is reduced. Overexpression miR-192-5p as well as morpholino-mediated npnt knockdown induced edema, proteinuria and podocyte effacement similar to podocyte-derived miR-378a-3p in zebrafish. Moreover, structural changes of the glomerular basement membrane (GMB) with increased lucidity, slicing and lamellation especially of the lamina rara interna similar to ultrastructural findings seen in advanced stages of iMGN were found (Fig. 1). IgG size nanoparticles accumulated in lucidity areas of the lamina rara interna and lamina densa of the GMB in npnt knockdown zebrafish models. Loss of slit diaphragm proteins and severe structural impairment of the GMB were further confirmed in podocyte-specific Npnt knockout mice. GECs downregulate podocyte Npnt by secretion of miR-192-5p containing exosomes in a paracrine manner.

Conclusions: Podocyte NPNT is important for proper GFB function and GFB structure and is regulated by GEC-derived miR-192-5p and podocyte-derived miR-378a-3p. We hypothesize that loss of NPNT in the GFB is part of the pathophysiology of iMGN and enables subepithelial immune complex deposition in iMGN.
PO1706
Identification of the Mechanism Underlying the Toxicity of Systemically Administered miR-145-5p on Podocytes Based on Podocyte Essential Genes
Zhang Sihan, Junnan Wu, Xiaodong Zhu, Hui Song, Lu Ren, Qiaoli Tang, Xu Xiaodong, Jong Zhang, Weixin Hu, Zhihong Liu, Shaoxin Shi. Jinling Hospital National Clinical Research Center for Kidney Diseases, Nanjing, China.

Background: MicroRNAs are emerging as effective therapeutic agents. MiR-145-5p dysregulation has been shown to be involved in kidney injury. To determine whether supplementation of miR-145-5p would alleviate kidney injury in mouse models, we first tested the miR-145-5p enriched extracellular vesicles (miR-145-5p EVs) sample for toxicity or side effects on healthy control mice.

Methods: miR-145-5p EVs were injected to mice intravenously every day for a total of 6 days. A group of mice were simultaneously injected with miR-145-5p inhibitor using TransIT®-EE Delivery Solution. Cultured cells were transfected with RNAiMAX or Fugene.

Results: miR-145-5p EVs resulted in proteinuria and podocyte foot process effacement in normal control mice, and this effect was abolished by miR-145-5p inhibitor. We demonstrated that systemically administered miRNA can enter podocytes. miR-145-5p EVs could enter cultured podocytes and cause F-actin loss. miR-145-5p mimic caused a similar reduction of F-actin in the cells. We speculated that miR-145-5p is toxic to podocytes because it is not normally expressed in podocytes and exogenous miR-145-5p can effectively target genes essential for podocytes. By using the concept that genes commonly expressed in all individual podocytes are likely podocyte essential genes, we predicted that podocyte genes when knocked down with shRNA/RPMK. We found that 32 of them are predicted to be targeted by miR-145-5p. Functional annotation of the 32 genes revealed small GTPase mediated signal transduction as the top function. Among genes associated with the small GTPases pathway, Arhgap24 is known to be responsible for podocyte injury and podocyte hypertrophy activity. We found and miR-145-5p significantly repressed Arhgap24 expression in podocytes in vivo and in vitro. miR-145-5p increased activity of both Rac1 and Cdc42.

Conclusions: MiR-145-5p induced podocyte injury through targeting podocyte essential genes associated with small GTPase mediated pathway. Our study provides a novel approach to investigate how a miRNA affects a given cell type, allowing not only identification of the molecular mechanism underlying an observed side effect of a miRNA drug but also prediction of miRNA drug toxicity on various cell types.

PO1707
Glomerular mRNAs Are Alternatively Spliced and Polyadenylated During Podocyte Injury in Animal Models of Nephrotic Syndrome
Claire L. Moore,1, 2 Shipra Agrawal,1 Abigail Wexor Research Institute at Nationwide Children’s Hospital, Columbus, OH; 1The Ohio State University, Columbus, OH; 1Tufts University School of Medicine, Boston, MA.

Background: Glomerular disease, often manifesting as nephrotic syndrome (NS) with high proteinuria, is characterized by podocyte loss and injury. Furthermore, alternative mRNA processing, such as alternative splicing (AS) and alternative polyadenylation (APA) play important roles in physiology, development, and disease; however, there is very limited knowledge on their roles in glomerular disease. We hypothesized that AS and APA events of glomerular RNAs is associated with podocyte injury and proteinuria in NS.

Methods: Glomerular damage characterized by proteinuria was induced by purumycin aminonucleoside (PAN) or adriamycin (ADR) to mimic human minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS), respectively. Urine and serum chemistries, kidney histology and glomerular RNA-seq analyses were performed. APATrap and JunctionSeq bioinformatics analyses software were used to detect APA and AS glomerular events. Correlation of differentially expressed genes (DEGs) was performed with known glomerular disease genes and polyadenylation and splicing factors.

Results: Robust proteinuria was induced in both PAN-MCD and ADR-FSGS models, accompanied by hypoproteinemia, hypercholerolemia and histological alterations in the kidneys (protein casts and podocyte hypertrophy). Out of 13,265 genes, MCD model resulted in 1033 and FSGS model in 1308 glomerular DEGs with abs(log2FC)>1 and P<0.05. Of 80 analyzed genes with established roles in glomerular disease, 30 were altered in both MCD and FSGS. Significant APA was identified in 71 and 746 genes in MCD and FSGS models, respectively, and of 173 polyadenylation factors analyzed, 21 were altered in MCD and 24 in FSGS. Significant AS was identified in 136 and 1875 genes in MCD and FSGS models, respectively. In accordance, of 50 splicing factors analyzed, 3 were altered in MCD and 5 in FSGS. Specifically, the identified APA and AS events affected genes of the slit diaphragm complex such as Npx1, Npx2, and Tpil1, which are critical determinants of podocyte structure and function.

Conclusions: Association of global glomerular mRNA alteration due to AS and APA with podocyte and glomerular injury is a newly recognized phenomenon, with potential implications for therapy and molecular understanding of the disease.

PO1708
Continuous Non-Mutagenic DNA Damage in Podocytes Activates Inflammatory Response and May Accelerate Kidney Aging
Ran Nakamichi, Akiko Hishikawa, Kaori Hayashi, Hiroshi Itoh. Keio University School of Medicine Department of Internal Medicine, Tokyo, Japan.

Background: Podocytes are suggested to contribute to kidney aging because of their terminal differentiated features. We have previously reported the association of KAT5-mediated DNA damage repair with altered DNA methylation in podocytes (Cell Rep 2019). However, the role of podocyte DNA damage itself on DNA methylation changes and kidney aging has remained to be adequately elucidated.

Methods: To investigate the significance of DNA double-strand breaks (DSBs) in podocytes, we generated podocyte-specific I-Ppol-expressing mice (podocin-Cre ROSA26-STOP- I-Ppol). I-Ppol is a homing endonuclease which causes non-mutagenic DSBs. RNA-seq and MeDIP-seq analysis were performed using isolated podocytes in I-Ppol mice and wildtype controls.

Results: I-Ppol mice showed severe albuminuria (WT 43±3.4 μg/gcr, I-Ppol 2224±7.3 μg/gcr, p<0.01) with diffuse foot process effacement in podocytes but glomerulosclerosis and interstitial fibrosis were not observed at 12 weeks of age. Interestingly, infiltration of CD11b-positive cells was shown in I-Ppol mice, which is a similar finding in 2-year-old aged mice. The aged mice showed increased DNA damage and DNA methylation. In I-Ppol mice, rapid deterioration of renal function with glomerulosclerosis and tubulointerstitial fibrosis developed around the age of 20 weeks. RNA-seq analysis revealed that inflammatory-related genes were upregulated in podocytes of I-Ppol mice. Senessent-associated secretory phenotype (SASP)-related gene expression was also increased. MeDIP-seq analysis revealed that 5219 differentially methylation regions (DMRs) were identified in I-Ppol mice compared with controls. Interestingly, there was no significant correlation between the distance from the I-Ppol cutting site and DMRs. DNA methylation was increased in genes containing I-Ppol cutting sites or podocyte epithelial genes such as nephrin and podocin, whereas it was decreased in inflammatory related genes, suggesting gene-specific DNA methylation changes following DNA damage.

Conclusions: The phenotype of the I-Ppol mice may reflect one aspect of accelerated kidney aging. Repeated DNA damage repair in podocytes may cause altered DNA methylation independent of primary DNA damaged sites with promoted inflammation and podocyte morphological changes.
POI1710

Delayed Treatment with a Novel Highly Selective Small-Molecule Agonist of MC5R Attenuates Podocyte Injury and Proteinuria in Parvinum Aminonucleoside Nephrosis
Bohan Chen, Yan Ge, Lance D. Dworkin, Ruijun Gong. University of Toledo College of Medicine and Life Sciences, Toledo, OH.

Background: Clinical studies indicate that the melanocortin peptide ACTH is effective in inducing remission of nephrotic glomerulopathies like MCD and FSGS, even those resistant to steroids, suggesting that a steroid-independent melanocortinergic mechanism might contribute. However, the type of melanocortin receptor (MCR) that conveys this beneficial effect as well as the underlying mechanisms remains controversial. Recently, burgeoning evidence suggests that MC5R is likely involved in glomerular pathobiology. This study aims to test the effectiveness of a novel highly selective MC5R agonist (MC5RA) in parvinum aminonucleoside (PAN) nephrosis.

Methods: MC5RA was generated by N-terminal modification of the melanocortin core tetrapeptide His-D-Phe-Arg-Trp-NH2 with an aromatic group, resulting in a triphenylpropionyl melanocortin analog with a 100-fold selective agonistic activity on MC5R. Rats were injured with a tail vein injection of PAN, and 5 days later, were randomized to daily MC5RA or vehicle treatment.

Results: Upon PAN injury, rats developed heavy proteinuria on day 5, entailing an established nephrotic glomerulopathy. Following vehicle treatment, proteinuria continued to progress on day 14 and was sustained till day 21, accompanied by evident histologic signs of podocyte damage: marked by ultrastructural lesions of glomeruli, including extensive effacement of podocyte foot processes and podocyte microvillus transformation, and concomitant with loss of podocyte homeostatic markers, such as synaptopodin and nephrin, and de novo expression of proteinuria marker desmin. Rescue treatment with MC5RA significantly attenuated urine albumin excretion and mitigated the loss of podocyte markers proteins, resulting in improved podocyte ultrastructural changes. In vitro in cultured podocytes, MC5RA prevented the PAN-induced disruption of actin cytoskeleton integrity and apoptosis. Mechanistically, MC5RA treatment reinstated inhibitory phosphorylation and thus averted hyperactivity of GSK3β, a central point of multiple podocytopathic pathways, in PAN-injured podocytes in vitro and in vivo.

Conclusions: Pharmacologic targeting of MC5R by using the highly selective small-molecule agonist is likely a promising and feasible therapeutic strategy to improve proteinuria and podocyte injury in glomerular disease.

Tadalafil, a PDE5 inhibitor, Exhibits Renoprotective Effects Preventing Podocyte Damage in an Adriamycin-Induced Nephrotic Syndrome Model
Natsumi Tomita,1 Yuki Hotta,1 Aya Naiki-Ito,2 Tomoya Katoaka,3 Satoru Takahashi,1 Kazumori Kimura.1 1Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; 2Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; 3Department of Clinical Pharmacometrics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

Background: Phosphodiesterase (PDE)-5 inhibitor is reportedly a renoprotective compound. Although PDE5 expression is confirmed in the glomeruli, its relationship with renal dysfunction remains elusive. We have previously investigated the renoprotective effects of tadalafil in a CKD model (Tomita N, et al. Physiol Rep. 2020), suggesting that such an effect would be related to podocyte damage attenuation. In this study, we investigated how tadalafil, a PDE5 inhibitor, could affect a rat nephrotic syndrome model.

Methods: Wistar ST rats were established as nephrotic syndrome models by administrating adriamycin (ADR) injection. The animals were divided into 3 groups: control (n = 6), ADR (n = 5), and ADR + tadalafil (n = 5). Tadalafil was administered 10 mg/kg daily. After 2 weeks of treatment, the urinary protein and serum albumin levels were evaluated, and the kidney tissue was harvested. WT1-positive cells were identified as podocytes by WT1 immunostaining. Moreover, human renal glomerular epithelial cell damage was induced in vitro by ADR supplementation. After 24 h of ADR treatment with or without tadalafil, cell viability was determined by CCK-8.

Results: The ADR injection induced high urinary protein and low serum albumin levels. Two weeks of tadalafil treatment attenuated proteinuria compared to the ADR group (P<0.01). ADR reduced the WT1-positive cell number and the tadalafil treatment prevented the reduction (P<0.05). Moreover, the ADR treatment resulted in reduced cell viability in vitro. The tadalafil treatment improved cell viability compared to the ADR treatment only (P<0.05).

Conclusions: This study suggests that the treatment with tadalafil, a PDE5 inhibitor, could effectively prevent podocyte damage in the case of nephrotic syndrome.

POI1712

Targeting mTOR Signaling Improved Kidney Function in APOL1 Risk Variant Mice with Chronic Exposure to Inflammatory Stimuli
Shrijal Shah, Calum Tattersfield, David Dement, Olivia Donovan, Lena B. Schaller, Gizelle Mccarthy, Martin R. Pollak, David J. Friedman. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Inheriting two copies of APOL1 risk variants significantly increases the likelihood of developing chronic kidney disease in African Americans. Many different pathways of disease have been proposed using cell-based model systems. Here we try to understand risk variant pathophysiology using a transgenic mouse model.

Methods: Transgenic mice with a single copy of human APOL1 G0 and G2 were generated using bacterial artificial chromosome (BAC) on a FVB background. Mice were injected with interleukin gamma (IFN-γ) plasmid via hydrodynamic tail vein injections to induce APOL1 expression. Since mTOR activation has been frequently observed in podocytes during FSGS, we blocked the pathway using rapamycin to see if it could improve disease outcomes. Mice were injected with 2mg/kg of rapamycin every other day (3 days/week, intraperitoneally) for a total of 2 weeks. Paraffin embedded tissue sections were used for immunohistochemistry and Periodic acid–Schiff (PAS) staining. Glomerular isolations were performed using Dynabeads. APOL1 oligomerization was assessed using blue native PAGE.

Results: 7 Days after IFN-γ plasmid injection, the podocytes of G2 mice stained positive for phospho-S6 ribosomal protein indicating mTOR activation accompanied by proteinuria. Blocking mTOR activation using rapamycin reversed ribosomal protein S6 phosphorylation, reduced proteinuria, and improved tissue histology as seen by PAS staining. We hypothesized that rapamycin might be activating autophagy and clearing APOL1 oligomers, but found no evidence for this mechanism of rescue. Instead, we were able to replicate the rescue we had observed with rapamycin using a cell cycle inhibitor, suggesting that rapamycin might be rescuing G2 phenotype by inhibiting podocyte cell cycle entry downregulating risk variant mediated injury.

Conclusions: Persistent expression of APOL1 risk variants pushes podocytes into cell cycle entry. Inhibiting mTOR signaling and subsequent cell cycle entry alleviated injury.

PLIN5 Deficiency in Podocyte Negatively Affects the Communication Between Lipid Droplets and Mitochondria in Alport Syndrome
Jin Ju Kim,1 Sydney S. Wilbon,2 Judith T. Molina David,1 Hazel H. Sesto,1 Jeffrey H. Miner,1 Flavia Fontanesi,1 Sandra M. Merscher,1 Alessia Formenti,1 1University of Miami School of Medicine, Miami, FL; 2Washington University in St Louis, St Louis, MO; 3Social Profit Network, Melno Park, CA; 4The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

Background: Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid droplets (LD) and triglyceride (TG) accumulation in experimental AS (Col4a3KO mice). Excessive FA breakdown and the loss of LD-mitochondrial contact, thus contributing to disease progression. Here we try to understand how these mechanisms of disease have been proposed using cell-based model systems. Here we try to understand risk variant pathophysiology using a transgenic mouse model.

Methods: In vitro, Immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3KO mice (Jackson Laboratory) to B6.Cg-Aij. AS transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in AS podocytes and kidney cortex in AS mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM and electron microscopy.

Results: PLIN5 deficiency was observed in the kidney cortex of Col4a3KO mice when compared to controls (p<0.001). We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes (p<0.01). AS podocytes also showed significantly increased rates of TG lipolysis (p<0.05), intracellular free fatty acids (p<0.05) and apoptosis (p<0.01) when compared to WT podocytes. AS podocytes had reduced number of LD-mitochondrial contacts (p<0.05), implying that and apoptosis. Moreover, Ezetimibe, which restored LD-mitochondrial contact in vitro (P<0.05) and improved kidney function in vivo, was found to restore PLIN5 expression in vitro and in vivo (P<0.05).

Conclusions: Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria, leading to mitochondrial dysfunction and contributing to disease progression.

Podocyte Damage in Chimeric Kidney Organoids
Tatai Matusaka,1 Tomohiro Udagawa,2 Kenji Osafune,1 Toshikazu Araoka,3 1Tokai Daigaku Igukubu Daigakuken Igaku Kenkyuka, Isehara, Japan; 2Tokyo Ika Shiha Daigaku, Bunkyo-ku, Japan; 3Kyoto Daigaku, Kyoto, Japan.

Background: We previously found that when a portion of podocytes are injured, other podocytes are secondarily injured in a mouse model, which may underlie the relentless progression of chronic renal failure. In the present study, we tested whether this phenomenon is observed in kidney organoids.

Methods: Nephrone progerotics cells (NPCs) were established by culture-dependent purification (CDP) method from 12.5 dpc NEP25 and RiboTag mouse kidneys (Cell Stem Cell, 2016, 19, 516-29). Podocytes of NEP25 mice express hcDC25 and can be injured by hcDC25-targeted immunotoxin. LMB2. Podocytes of RiboTag mice express hemagglutinin (HA)-tagged ribosomal protein. Kidney organoids were generated by transient stimulation with FGFI2 and CHIR99021 of NPC aggregates and subsequent 8-day culture. On day 8, LMB2 (20 nM) was added to induce injury in hcDC25+- podocytes.

Results: We confirmed that podocytes in both organoids are stained for nephrin, podocin and WT1. Podocytes derived from NEP25 NPC expressed hcDC25 and were injured by LMB2, and those from RiboTag NPC expressed HA and were resistant to LMB2. When two types of NPCs were mixed at 1:1 ratio, organoids showed a chimeric pattern containing hcDC25+ and HA+ podocytes (Fig). 2 days after LMB2 treatment, hcDC25 staining completely disappeared accompanied by cleaved (c) lamin A staining, a cell death marker. HA staining was retained, but WT1 was diminished and podocin disappeared (Fig 2). Occasionally, c-lamin A was positive in HA+ cells. RNA of Ribotag podocytes can be obtained by immunoprecipitation with anti-HA antibody. qPCR revealed that Nphsl (0.31), Nphs2 (0.04), Wil1 (0.37) were decreased to the indicated fold by LMB2 and that Gadd45β was increased to 4.82-fold.

Conclusions: Thus, podocyte damage damages podocytes in kidney organoids that lack glomerular filtration.

Increased Old Astrocyte Specifically Induced Substance (OASIS) in Podocytes Leads to the Progression of Nephrotic Syndrome
Yoshiaki Miyake,1 Masanori Obana,1 Ayahama Yamamoto,1 Shunsuke Noda,1 Koki Tanaka,1 Shota Tanaka,1 Makiko Maeda,1 Katsuhiko Asanuma,2 Yasushi Fujio.1 1Osaka Daigaku Daigakuken Igaku Kenkyuin Igakubu, Chiba, Japan.

Background: Old astrocyte specifically induced substance (OASIS) is a transcription factor of the CREB/ATF family. Previously, we found that OASIS was expressed in podocytes in murine kidneys. However, the pathophysiological roles of OASIS in podocytes remain unclear. The aim of this study is to elucidate the role of OASIS in podocytes.

Methods: To assess the relevance of OASIS to renal pathology, the expression of OASIS in glomeruli of lipopolysaccharide (LPS)-treated mice or streptozotocin (STZ)-treated diabetic mice was examined by laser capture microdissection, followed by immunoblotting. To further investigate the functional roles of OASIS in podocytes, podocyte-restricted OASIS overexpressing transgenic (OASIS TG) mice were established. Urinary albumin-creatinine ratio (uACR) was measured. Podocyte injury was assessed by electron microscopy. Tubular injury was evaluated by PAS staining and by measuring related genes, and COL1A1 and LCN2 mRNA expression. Masson’s trichrome staining and quantitative PCR for fibrosis-related genes, COL1A1 and FNI, were performed to analyze tubulointerstitial fibrosis. To explore the effect of OASIS on podocyte actin cytoskeleton in vitro, phalloidin staining was performed on lentivirus-induced OASIS overexpressing murine cultured podocytes. The increased OASIS in podocytes contributed to nephrotic progression.

Results: OASIS expression was increased in glomeruli of both LPS-treated and diabetic mice. uACR was significantly increased in OASIS TG mice (uACR (μg/mg)): control; 35.1±8461.4, n=9 for control, n=7 for OASIS TG), and electron microscope analysis showed that OASIS overexpression in podocytes caused foot process effacement. In addition, damaged tubules and LCN2 upregulation were observed in OASIS TG mice. Furthermore, Masson’s trichrome staining showed that OASIS overexpression in podocytes evoked kidney fibrosis, and the expression of COL1A1 and FNI were upregulated in OASIS TG mice. Consistent with in vivo study, OASIS overexpressing podocytes showed the reduction in actin stress fiber formation.

Conclusions: The increased OASIS in podocytes contributes to nephrotic progression.

Podocyte-Derived RARRES1 Aggravates Kidney Disease Progression by Inducing Both Glomerular and Tubular Injury
Ye Feng,1 Bi-Cheng Liu,1 Kyung Lee,1 John C. He.1 Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; 2Southeast University Zhongda Hospital, Nanjing, China.

Background: Our previous study demonstrates that the expression of retinoic acid receptor responder protein 1 (RARRES1) increases in glomeruli of patients with diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS). The glomerular expression of RARRES1 also correlates with cGFR slope and predicts glomerular disease progression. Single-cell RNA-sequencing of the kidney showed that RARRES1 was expressed mostly in podocytes within the kidney. Mechanistically, WT-RARRES1 is cleaved into a soluble form which subsequently induces podocyte apoptosis whereas mutant RARRES1 with cleavage defect failed to induce podocyte apoptosis in vitro. Here, we further determined whether increased expression of WT-RARRES1 in the podocytes aggravated progression of glomerular disease.

Methods: Mice with podocyte-specific overexpression of human WT- RARRES1 or mutant RARRES1 with cleavage defect were generated and then subjected to aging, adriamycin (ADR) administration or streptozotocin (STZ) injection. To identify the role of podocyte-derived soluble RARRES1 in tubular cells, HK2 cells were treated with soluble RARRES1 obtained from podocyte supernatants.

Results: In vivo, podocyte-specific overexpression of WT-RARRES1 resulted in severe proteinuria and marked glomerular injury in mice with aging, adriamycin-induced nephropathy, or STZ-induced diabetic nephropathy as compared to the control mice with overexpression of mutant RARRES1. In vitro, tubular vacuolation and interstitial injury were also observed in these mice with podocyte-specific overexpression of RARRES1. In addition, we showed that soluble RARRES1 collected from podocyte supernatants was endocytosed in HK2 cells to induce cellular injury. Similarly, cleaved forms of human RARRES1 in the mice with podocyte-specific human RARRES1 overexpression was found in the tubular compartments, indicating that soluble RARRES1 generated from podocytes may act on tubular cells through glomeruli-tubule crosstalk.

Conclusions: Our study suggests that RARRES1 is a risk gene for glomerular disease progression through its direct effects in podocytes as well as indirect effects in tubular cells probably via glomeruli to tubules crosstalk.

PO1722
Podocyte-Specific Extracellular Vesicles Yield Novel Insight into Intercellular Signaling in the Glomerulus

Background: Extracellular vesicles (EVs) have been identified to play an essential role in basic pathological processes such as priming of the metastatic niche, autoimmunity and propagation of insulin resistance. Nevertheless, knowledge about their role in kidney health and disease remains scarce. A new group of EVs, shed upon apoptosis with the ability to induce a proliferative effect in neighboring cells, was recently identified in cell culture models as well as experimental glomerulonephritis. This study aimed to characterize these medium-sized EVs and the signaling propagated by them in podocyte damage.

Methods: Using differential centrifugation and filtration we established a protocol to separate medium-sized EVs from cell culture supernatants, kidney tissue and urine samples. We performed scanning and transmission electron microscopy and image flow cytometry, we investigated the release dynamics of podocyte-specific vesicles in different models of murine podocyte damage in vitro and in vivo. Furthermore, cross culture experiments and life microscopy were used to determine the effect of podocyte-specific medium-sized EVs on parietal epithelial cells.

Results: Podocyte-specific medium-sized EVs were detected in baseline podocyte culture supernatant, untreated murine kidney tissue as well as the urine of healthy human volunteers. Vesicle quantification revealed a drastic increase of vesicle release upon podocyte damage both in vitro and in vivo. Interestingly, podocyte-specific EVs exerted different effects on the proliferative and migratory behavior of primary parietal epithelial cells.

Conclusions: Our study represents the first investigation of podocyte-specific medium-sized extracellular vesicles, their release dynamics and functional implications in health and disease. Ongoing analyses aim to characterize their proteomic content and effect other renal epithelial cells. As these vesicles can be separated without advanced equipment such as ultracentrifuges, we believe they could also be a valuable source for biomarker research in various nephropathies.

PO1723
Effects of Varying Mild Tubular Injury on Subsequent Glomerular Injury Janka Babickova,1,2 Haichun Yang,3 Agnes B. Fogo.1 Vanderbilt University Medical Center, Nashville, TN; 2University of Bergen, Bergen, Norway.

Background: Tubular injury predisposes to CKD, including glomerular injury. We analyzed effects of mild tubular injury on subsequent glomerular injury.

Methods: Mice were divided into 5 groups (WT and AS males and female mice) with (human CD25 receptor on podocytes and Diphtheria toxin (DT) receptor on proximal tubules) received DT (25, 50, or 100ng/kg; 2x one week apart, n=5/group) to induce tubular injury, or vehicle (VEH). Uninephrectomy was done 4 wks later, 5 wks later glomerular injury was induced by LMB2 toxin (CD25 ligand) and mice were sacrificed 10 days later.

Results: In males, urinary KIM-1 was significantly higher vs VEH with all DT doses on d3 after DT injections, lowest in DT30 and similar with DT50 and DT100. KIM-1 levels were significantly higher in females; numerically higher in DT50 and DT100 vs VEH by wk 6. Uninephrectomy was significantly increased at d3 only in DT100 vs VEH. NGAL levels normalized in all DT groups by week 6. In females, KIM-1 levels were increased by d3 with highest level with DT100. KIM-1 levels were only numerically higher vs VEH in a dose-dependent manner in males. Urinary NGAL was only nonsignificantly elevated. On d3, NGAL levels were significantly higher vs VEH in females, normalized by wk 6, with numerically highest level in DT100. Males had higher levels of KIM-1 vs females at all timepoints, while NGAL showed similar levels in males and females at DT100 on d3, but higher levels in females at DT100 dose at wk 6. In males, albumin excretion was elevated and sacrificed at d5 after podocyte injury showed numerically higher levels by 67% in DT100 vs VEH. In females, albuminuria gradually increased, with levels lower than in males in all groups. Ultrastructural analysis after podocyte injury showed similar significant foot process effacement, glomerular capillary fenestration loss and increased GBM thickness in all groups.

Conclusions: Sex differences in response to tubular injury and albuminuria were observed. Even very mild tubular injury, recovered by assessment of KIM-1 and NGAL-1 led to numerical increase in albuminuria after second hit glomerular injury in both sexes. The sex-dependent differences in KIM-1 and NGAL-1 further support differential susceptibility of nephron segments to injury in females vs males, which may play a role in glomerular sensitization to injury.

PO1724
Effect of Glomerular Disease on the Podocyte Cell Cycle Laura Perin,1 Camille H. Nicolas Frank,2 Xiaoang Hou,1 Gregory Clair,3 Fadi E. Salem,4 Roger E. De Filippo,5 Paolo Cravedi,6 Kevin V. Lemley.7 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Harvard Medical School, Boston, MA; 3Pacific Northwest National Laboratory Biological Sciences Division, Richland, WA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Progression of glomerulosclerosis is associated with loss of podocytes and subsequent glomerular tuft instability. A decreased number of podocytes may be able to preserve tuft stability through cell hypertrophy associated with cell cycle re-entry. At the same time, re-entry into the cell cycle can lead to podocyte detachment from the glomerular basement membrane, if podocytes cross the G1/S checkpoint and undergo apoptosis.

Methods: To study cell cycle dynamics during CKD development, we used a Fucci mouse model (fluorescence ubiquitination-based cell cycle indicator) affected by X-linked Alport Syndrome (AS). This model has progressive CKD and expresses cell cycle fluorescent reporters exclusively in podocytes. We quantified podocytes cell cycle distribution in WT and AS mice at different ages and collected podocytes in G0 and G1 for proteomics studies.

Results: We showed that with the development of CKD, an increasing fraction of podocytes in vivo are in G1 or later cell cycle stages. A decreased number of podocytes may be able to preserve tuft stability through cell hypertrophy associated with cell cycle re-entry. At the same time, re-entry into the cell cycle can lead to podocyte detachment from the glomerular basement membrane, if podocytes cross the G1/S checkpoint and undergo apoptosis.

Conclusions: Our data showed that, during progressive CKD, the podocyte cell cycle distribution changes dramatically, suggesting that cell cycle manipulation may have a role in the therapy of progressive glomerular diseases characterized by podocyteopathy.

PO1725
Glucocorticoid- and Pioglitazone-Induced Proteinuria Reduction Correlates with Glomerular Extracellular Matrix Remodeling in Experimental Nephrotic Syndrome Sagar Bhavna, Shipra Agrawal, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Peter White, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephrotic Syndrome (NS) is a common glomerular disease in children. While glucocorticoids (GC) are the mainstay of childhood NS treatment, pioglitazone (Pio; an FDA-approved PPARγ agonist to treat type 2 diabetes) has been reported to reduce proteinuria in experimental NS and to directly protect podocytes from injury. Since both GC and Pio activate nuclear receptors (NR3C1 and PPARγ, respectively) we hypothesized that their proteinuria-reducing effects result from overlapping glomerular gene transcriptional patterns.

Methods: We performed transcriptome analyses on glomeruli isolated from GC (immunosuppressive)- and Pio (non-immunosuppressive)-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Unsupervised clustering revealed partial reversibility of PAN-associated mRNA expression changes by treatment with either GC or Pio. IPA analyses identified 29 genes-of-interest common to GC- and Pio-induced proteinuria reduction, which included ECM remodeling, lipid metabolism, DNA-binding and cytoskeletal organization. Based on expression differences using real-time PCR,
29 genes-of-interest were selected for further analysis, which on clinical correlation with a SIF-1 SIFG database (Neuropathy) suggested a direct relevance of glomerular ECM regulation in NS. Also, glomerular cell deconvolution using published single-cell glomerular transcriptome profiles identified podocyte- and mesangial cell-specific perturbations in gene expression during NS and with treatments. Finally, validation of selected genes of interest with PAN-induced injury of human podocytes and mesangial cells confirmed significant upregulation of LGAQLS (primary role in cell adhesion) and MMP2/ACTA2 (primary role in ECM degradation/cell motility or integrity) respectively.

Conclusions: These studies identified podocyte- and mesangial cell-specific transcripts common to both proteinuria-reducing treatments that identify possible targets for future treatment for NS.

PO1726
Alterations of Intestinal Microbiota in Patients with ESRD Undergoing Hemodialysis
Takeo Koshida,1 Tomohito Gohda,2 Takuya Sugimoto,2 Takashi Ashahara,3 Masanori Ishizaka,1 Maki Murakoshi,1 Yusuke Suzuki,11 ‘Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan;’ Yakult Central Institute, Yakult Honsha Co. Ltd, Tokyo, Japan.

Background: The alteration in the intestinal microbiota is reported to be associated with various diseases, indicating that the development and progression of end-stage kidney disease also might be associated with dysbiosis.

Methods: The stool samples were collected from patients with hemodialysis (n = 41, HD group) and those with normal renal function (n = 40, NRF group). Both groups are comprised of patients with (HD_DS, n = 20; NRF_DS, n = 19) and without diabetes (HD_non-DS, n = 21; NRF_non-DS, n = 21). We conducted 16S RNA gene amplicon sequencing using stool samples to analyze the intestinal microbiota.

Results: The reduced abundance of the genera Megamonas and Fusobacteribacter, and the enriched abundance of the genera Family XIII AD3011 group (Anaerovoracaceae family), UBA_1819 (Ruminococcaceae family), and Pseudomonas in the stool samples of HD patients were observed significantly compared with those of NRF patients. Compared with patients with NRF, the relative abundance of the genera Megamonas was decreased and that of Family XIII AD3011 group was increased significantly in patients with HD, although those relative abundance did not alter between NRF_non-DS and HD_non-DS. The relative abundance of the genera Streptobacteria in HD_non-DS was significantly decreased than that in NRF_non-DS, although that relative abundance did not differ between NRF_DS and HD_DS. In the microbial beta diversity, there was no difference between NRF_DS and NRF_non-DS by weighted and unweighted UniFrac analysis, however, there was significant difference between HD_DS and HD_non-DS by weighted UniFrac analysis (p = 0.007). These results suggest that the gut microbiota alters with renal function decline, and varies depending on the presence or absence of diabetes.

Conclusions: The intestinal microbiota might be varied substantially depending on renal function and the presence or absence of diabetes.

PO1727
Nutritional Intervention in Intensive Care Unit Patients Undergoing CRRT
Jihyun Yang, Tae-bum Kim, Hyoeon-Jin Min, Young-Bin Son, Jonghyun Lee, Sewon Oh, Myung-Gyu Kim, Won-Yong Cho, Sang-Kyung Jo. Korea University Anam Hospital, Seoul, Republic of Korea.

Background: Providing adequate calories and protein constitutes an important part of critical care, and inadequate nutrition for critically ill patients is associated with poor prognosis. Therefore, increased loss of amino acids, electrolytes, and water-soluble vitamins during continuous renal replacement therapy (CRRT) could be a therapeutic target. We evaluated whether enforcing protein, trace elements and vitamin supply could improve the prognosis of CRRT patients.

Methods: A nutritional intervention (100 mg/day of Thiamine, 25–30 kcal/kg of energy, 1.8 g/kg of protein, and 50–100 mcg/day of microelement with selenium) was conducted in patients subject to CRRT from May 2020 to December 2020. The primary outcomes were 28-day mortality, CRRT day, ICU stay, and ventilator-free day, and the outcomes before and after the intervention were compared.

Results: Total 88 patients were included during the study period and compared with 88 patients in the previous year. The average age was 68.05 years old, 56 (63.5%) patients were male. At day 1 APACHE-II score was 35.41±2.9, SAPS3 88.1±16.8, SOFA 10.4±2.7. There were 9 (10.2%) patients with ECMO, 78 (88.6%) using ventilator. There were 19 (21.6%) pneumonia with ARDS patient, 18 (20.5%) cardiac disease, 9 (10.2%) UTI sepsis, 11 (12.5%) gastrointestinal bleeding and sepsis, 6 (6.8%) cerebral hemorrhage, and others. The main reason for CRRT was hemodynamic instability. Baseline characteristics including APACHE-II score, SAPS 3, and SOFA were not significantly different between the nutritional intervention and the non-intervention patients. Nutritional intervention did not induce significant changes in 28-day mortality (36 versus 37, p = 0.56) and CRRT days (7.3 ± 6.9 versus 6.3 ± 5.2, p = 0.29). However, nutritional intervention showed minimal improvement in ICU stay (22.1 ± 23.9 vs 20.7 ± 22.1, p = 0.05) and ventilator-free days (17.8 ± 22.3 vs 12.4 ± 14.4, p = 0.05).

Conclusions: This study suggests that support for protein, trace elements, and vitamins may have a positive effect in CRRT patients. Therefore, the nutritional requirements of patients with CRRT should be carefully assessed, individualized, and considered as an important axis of CRRT treatment.
PO1732
Long-Term Safety of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Serum Electrolytes and Albumin
Pablo E. Pergola,1 Jeanene Fogli,2 Yang Yang,2 David M. Spiegel.1 Renal Associates PA, San Antonio, TX; 1Ardeley Inc, Fremont, CA.

Background: Tenapanor, an investigational first-in-class phosphate absorption inhibitor (PAI), blocks the paracellular absorption of phosphate in the gastrointestinal tract by local inhibition of the sodium-hydrogen exchanger (NH3). Tenapanor is being studied as a non-binder approach for the management of hyperphosphatemia in patients on dialysis and it is dosed as one pill (10, 20, or 30 mg) twice daily. Due to its novel mechanism of action, it is important to understand its safety profile, including any potential effects on serum electrolytes and albumin.

Methods: This report evaluates the effects of tenapanor on serum electrolyte and albumin concentrations using data from 3 pivotal trials in which tenapanor met its primary phosphorus-lowering endpoint. Trials included a 12-week monotherapy study (BLOCK), a 52-week monotherapy study (PIREEDOM), and a 4-week tenapanor + phosphate binder combination study (AMPLIFY). Serum electrolytes and albumin were measured per study protocol in central research laboratories.

Results: Tenapanor was generally well tolerated, with diarrhea being the only adverse event reported by >5% of patients. Diarrhea was typically mild to moderate in severity, was transient, and resolved with continued treatment. Data from all 3 trials showed that tenapanor treatment, either alone or in combination with phosphate binders, resulted in no clinically meaningful changes in measured serum electrolytes or albumin at any time point. Data from patients treated with tenapanor continuously for 52 weeks in the longest trial, PIREEDOM, are shown in the table.

Conclusions: In these clinical trials, tenapanor inhibited paracellular absorption of phosphate and decreased serum phosphorus with an acceptable safety profile, with no observed effect on serum electrolytes or albumin in patients on maintenance dialysis with hyperphosphatemia.

Funding: Commercial Support - Ardeley, Inc.

PO1733
Patient-Reported Experience with Tenapanor in the OPTIMIZE Trial
Susan A. Edelstein, Yang Yang, Brett Stephenson, Suling Zhao, Nucia Pagliaro, Jeanene Fogli, Ardeley Inc, Fremont, CA.

Background: Tenapanor (TEN), a first-in-class phosphate absorption inhibitor (PAI) that works via the paracellular pathway, provides a novel approach for hyperphosphatemia management. The primary goal of this study is to evaluate how to optimize the treatment of hyperphosphatemia in patients with chronic kidney disease (CKD) on dialysis with the use of TEN and its novel mechanism of action.

Methods: Patients with serum phosphorus (sP) >5.5 and ≤10.0 mg/dL during stable dialysis treatment, especially as new treatment options are available on the market to help patients.

Results: When thinking generally, nephrologists estimate that nearly one-half of end-stage renal disease patients (3.4% of HD patients and 3.6% of PD patients). On their last visit with their dialysis patients, nephrologists noted that only 4% of patients were diagnosed with a rash, itch, or pruritus (3.7% of HD patients and 5.6% of PD patients). Interestingly, only approximately one-third of those patients were diagnosed with uremic pruritus, indicating there are more patients presenting with a rash or itch who are not actually being diagnosed. Despite the impact on patient treatment, nephrologists report that only 25% of HD patients diagnosed with uremic pruritus are pharmacologically treated; this drops to 17% of PD patients with uremic pruritus. Treatments vary wildly and have varying levels of reported success among physicians. Nephrologists do recognize the impact pruritus can have on a patient’s quality of life, making the high rate of undertreatment especially troubling. On a 1-10 scale rating unmet need for a new therapeutic agent, 62% of nephrologists rated a high unmet need for pruritis in dialysis patients.

Conclusions: While many recognize that itching impacts many dialysis patients, actual diagnoses and treatment are rare, driven by a lack of effective treatment options. Elevating awareness among nephrologists will help with patient identification and treatment, especially as new treatment options are available on the market to help patients.
64.2% of patients (63.8% and 64.8% in Cohort 1 and Cohort 2, respectively) identified an improved perception of their medication regimen as the top reason for the improved perception, and 30.5% of patients (31.3% and 29.6% in Cohort 1 and Cohort 2, respectively) reported an improved perception of the form or frequency of bowel movements as the top reason for improved perception of their treatment routine.

Conclusions: Patients who were switched to TEN or added TEN to a reduced PB therapy regimen reported improved experience with their sP management. The findings from this analysis show that TEN may improve patient experience with sP management regimens. Further research is needed to elucidate what factors affect a patient’s perspective of sP management.

POI1734

Apparent Paradoxical Relations of Serum Phosphate and Albumin Variability with Outcomes Are Explained by the Directional Change

Xiaoling Ye,1 Karlien J. ter Meulen,2 Len A. Usyan,2 Jeroen Kooman,4 Peter Potanova,2,5 Franklin W. Maddux,2,3 Renal Research Institute, New York, NY; 2Fresenius Medical Care North America, Waltham, MA; 3Mount Sinai Hospital Mount Sinai Heart, New York, NY; 4Maastricht Universitair Medisch Centrum", Maastricht, Netherlands.

Background: Evidence indicates that variability of serum phosphate (P) and albumin (Alb) is associated with higher risk of mortality. We aimed to study the variability of P and Alb with all-cause mortality taking into account the interaction with the averaged levels.

Methods: All adult incident HD patients (pts) treated in Fresenius Medical Care NA clinics between 2010&2018 were included. Serum P and Alb levels were averaged from month(mo) 1 to 6 after HD initiation. Variability of P and Alb were described by standard deviation (SD) and directional changes (DR). All-cause mortality was recorded between mo 7 and 18. Cox proportional hazards models with spline terms were applied to explore the association between variability of P & Alb and all-cause mortality. Additionally, tensor product smoothing splines were computed to study the effect of interactions between averaged values of parameters and their variability with outcomes.

Results: We enrolled 353,142 pts. Averaged P was 4.98 mg/dL; median SD and DR were 0.92 and 1.10. Baseline Alb was 3.61 g/dL, median standard deviation (SD) and median DR were 0.21 and 0.40. Across different levels of P, higher SD of P were associated with higher risk of mortality, especially in those pts with lower averaged P. Contrasting, in pts with low Alb, higher SD was associated with reduced mortality. Results from Group 1, an unidirectional relation between DR and outcome was observed, whereas the relation between DR with outcomes was bidirectional for P (Fig1 &2).

Conclusions: The relationship between P variability and mortality was apparent at all levels of P. In well-nourished pts, higher P variability are associated with increased risk of mortality, which is related to the adverse effects of both an increase and a decline of this parameter. In pts with low Alb, the apparently paradoxical association between higher levels Alb variability and better survival due to an improvement of nutritional and inflammatory status, related to a positive DR. Due to possible nonlinear relations between risk factors and outcomes in patients on HD, variability should ideally be explored by various metrics.

POI1735

Restrict Dietary Phosphorus to Decrease Proteinuria and Prevent Decline in Glomerular Filtration Rate in CKD Stages 1 and 2

Anita Saxena. Renal Nutrition Group Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: Though dietary phosphorus restriction is therapeutic for disordered phosphorus homeostasis, restriction of dietary phosphorus is not advised in CKD. Aim: Does early control of dietary phosphorus ameliorates proteinuria, prevent decline in glomerular filtration rate and prevent rise in FGF-23.

Methods: One year longitudinal study on 79 CKD stages 1 and 2 patients. eGFR, serum creatinine, phosphorus, calcium, FGF-23, soluble o-Klotho iPTH FGF 23, blood pressure, were evaluated and compared with 35 controls. 3 days dietary intake was taken using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake: Group 1 (n 42): normal phosphorous intake (1000mg/day) and Group 2 (n=37): high phosphorous intake (>1000mg/d). Patients in Group 2 were educated on high and low phosphorus foods and counselled to adopt a plant-based diet, for low phosphorus absorption with directed diet plan. Data were analysed using SPSS.

Results: At baseline there was no significant difference in the GFR (group 1 53.85±12.58 vs group 2 53.23±16.30 mL/min/1.73 m2), serum creatinine between the groups. In group 2; GFR, sKlotho, serum phosphorus and FGF-23 correlated significantly with dietary phosphorus intake. In group 2, FGF-23, serum phosphorus, dietary protein and phosphorus intake were significantly higher and sKlotho was significantly lower than group 1. There was significant difference in serum phosphorus (p 0.000), iPTH, (p 0.004), FGF23 (p<0.005), Klotho (p<0.000), dietary protein (Group 1 37.57±3.40; Group 248.79±5.86 p 0.000) and phosphorus (Group 1868.96±69.99 mg/d and Group 2 1312.26±137.77 mg/d p<0.000) intake and dietary phosphorus to protein ratio (p<0.000) between groups 1 and 2. On dietary intervention in group 2 GFR increased p 0.0002 from 80.93±15.34 to 84.11±15.38, and to 87.43±18.27 ml/min at 6 and 12 months respectively, Urinary protein declined to 22.0±4.33 mg/mL. FGF 23 declined from 60.67±6.26 to 58.00±7.07 to 53.29±9.48 pg/mL at 12 months. Dietary phosphorus: protein ratio reduced significantly from 27.1±6±4.35 to 24.7±5±4.34 p<0.000 at 12 months (p<0.000). Urinary phosphorus excretion increased from 574.37±21.42 to 624.64±137.67 at 12 months.

Conclusions: Restricting dietary phosphorus in stages 1 and 2 can prevent progression of CKD and for control proteinuria.

POI1736

Understanding Obesity Management in CKD Patients

Background: Obesity is a global epidemic that is directly and indirectly linked to progression of chronic kidney disease (CKD). Nephrologists’ attitude towards obesity management is not understood.

Methods: We surveyed 14 nephrologists practicing in an academic centre in London, Ontario, Canada to investigate their perception and management of obesity. Then we performed a retrospective chart review of patients in a CKD clinic with obesity (BMI >30kg/m2). Ten follow-up visits were randomly selected for each nephrologist between Jan-Dec 2019. Each chart was assessed for documentation of obesity and a management plan such as lifestyle counselling, pharmacologic intervention, or specialist referral.

Results: There were 13 responses (93%). Responses from a 5-point Likert scale, agree and strongly agree, have been combined. All nephrologists agreed that obesity negatively impacts CKD patients. 92% reported that discussing obesity evokes a negative response and 39% thought patients want to discuss obesity. Interestingly, 0% of nephrologists thought patients know that obesity has effective treatments. 85% of nephrologists talked to their patients about obesity, but 0% felt that they had time to treat it. With regards to management, 54% of nephrologists were comfortable with non-pharmacologic treatment, but only one was comfortable with pharmacologic treatments. 85% of respondents felt that patients should be referred to a specialist. A total of 140 charts were reviewed with a mean age 66 years, weight 105 kg, and BMI 37 kg/m2. Only one chart had obesity as a clinic issue and documented a weight loss discussion using non-pharmacologic strategies.

Conclusions: Our results suggest that obesity is rarely managed despite nephrologists’ desire to treat it. This care gap can be addressed using robust Quality Improvement principles. Our centre will improve obesity management by developing a clinical handbook for nephrologists on how to efficiently address obesity with patients as well as a partnership and streamlined referral process to an obesity specialist.

Changes over Time in DASH Diet Accordance by Racial/Ethnic Groups Among US Adults

Tanushree Banerjee,1 Charles E. McCulloch,1 Deidra C. Crews,2 Nilka Rios Burrows,2 Alain Koyama,3 Hal Morgenstern, 4 Rajiv Saran,5 Neil R. Powe.1 1University of California San Francisco, San Francisco, CA; 2Johns Hopkins University, Baltimore, MD; 3Centers for Disease Control and Prevention, Atlanta, GA; 4University of Michigan, Ann Arbor, MI.

Background: Recommendations for healthy dietary patterns may vary for individuals with and without CKD. Racial/ethnic disparities in dietary quality exist, yet there is limited understanding of how dietary patterns have changed over years in different racial/ethnic groups. We examined trends in accordance to a Dietary Approaches to Stop Hypertension (DASH) diet by different racial/ethnic groups in adults with and without CKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
POI738

Food Purchasing Patterns Among Participants of a Dietary Intervention Trial for African Americans with Hypertension and CKD

Background: Financial resources and the surrounding food environment can impact healthy food purchasing patterns and may play a role in disparities in CKD. We examined predictors of healthy food purchases among control group participants of a clinical trial who were assigned to receive a $30 per week grocery allowance for 4 months ($480 total) but received no specific guidance on purchases.

Methods: We examined purchasing patterns of 50 participants using receipts linked to a grocery club card. The primary outcome of interest was the number of fresh or frozen fruit or vegetable items purchased, dichotomized at the median to those purchasing <= 6 and > 6 types of fruits/vegetables. Predictors examined included participant sociodemographic factors and food environment factors (i.e. living in a healthy food priority area). Statistical analyses included descriptive statistics and multiple linear regression.

Results: All participants were African American; median age was 63 yrs; 64% were female. Most (78%) were either unemployed or retired; 58% received a H.S. diploma/GED or less. Half had annual income < $25,000. Purchases made included both food and non-food items and many used other funds beyond those from the study. Adjusting for income, women purchased 2.3 more fruit/vegetable items than men (95% CI 0.2-4.5). However, prevalence of poor accordance did not change in NHB and MA with CKD. For MA, a significant change in prevalence was noted among no-CKD (p trend = 0.008), but not in those with CKD.

Conclusions: Poor accordance to a DASH diet was greater in adults with no-CKD. However, prevalence of poor accordance did not change in NHB and MA with CKD. Efforts to further improve promotion and accordance to DASH diets may help address CKD progression and health disparities in the US.

POI1740

Barriers and Facilitators to DASH Diet Adherence Among Black Adults with CKD: A Qualitative Study

Crystal C. Tyson,1 Laura P. Svetkey,1 Isa Granados,1 Danielle L. Kennedy,2 Travia K. Dunbar,1 Pao-Hwa Lin,3 Gary G. Bennett,3 Cynthia H. Redd,3 L. Ebony Boulware,1 Laura J. Fish,3 Duke University School of Medicine, Durham, NC; 2Duke University, Durham, NC; 3Duke Cancer Institute, Durham, NC.

Background: Black individuals are disproportionately burdened by hypertension and chronic kidney disease (CKD). The Dietary Approaches to Stop Hypertension diet (DASH) improves hypertension in Black individuals and is associated with improved CKD outcomes. Yet, adherence to DASH among Black individuals is low. We conducted a qualitative study to assess barriers and facilitators to DASH adherence in Black adults with CKD.

Methods: We conducted focus groups and individual interviews with Black adults with CKD stages 3 or 4 (n=22). Questions included perceptions of CKD and DASH, barriers and facilitators to adopting DASH. Qualitative content analysis was used to analyze interview transcripts.

Results: Among 22 participants (2 focus groups, 8 individual interviews), 13 (59%) had CKD stage 3, 13 (59%) were female, the median age was 61 years, and 19 (90%) had hypertension. Some participants reported having previously heard of DASH, which they perceived as a healthy diet. Participants perceived DASH as culturally-compatible based on 3 emergent themes: 1) Blacks individuals already eat DASH-recommended foods (“Blacks eat pretty much like this”); 2) traditional (e.g., southern or soul-food) recipes can be modified into healthy versions (“you can come up with decent substitutes to make it just as good”); and 3) DASH is not uniform among Black individuals (“I can’t say that I eat traditional”). Barriers included unfamiliarity or inconvenience measuring portion sizes, inadequate cooking skills, unsupportive household members, and high cost of healthy foods. Eleven (52%) reported “rarely” or “never” having leftover money to
purchase healthy food after paying monthly bills. Facilitators included having local access to healthy food, living alone or with supportive household members, and having will power and internal/external motivation for change.

Conclusions: Black adults with CKD were interested in adopting DASH and viewed it as a healthy, culturally-compatible diet. Recognizing that diet in Black adults is not viewed as a healthy, culturally-compatible diet. Recognizing that diet in Black adults is not

POI741

Priorities for Person-Centered Obesity Management in ESKD

Background: Although obesity is a pervasive kidney transplant barrier, little is known about the social, dietary, and process-of-care challenges to addressing obesity among individuals with ESKD.

Methods: Using purposive sampling we recruited adults with ESKD and obesity (N=40) and ESKD health care professionals (HCPs, N=20) in the United States for semi-structured interviews to elicit perspectives about obesity and barriers and strategies for healthy weight loss. Recorded phone interviews lasting 1.5 hours were transcribed verbatim and analyzed using inductive and deductive thematic analysis.

Results: Median patient age was 55 (interquartile range [IQR] 47,63) years, median dialysis exposure was 5 (IQR 3,10) years, 51% were female, 27% were Black, and median BMI was 37.8 (IQR 33.5, 40.8) kg/m². Greater dietary added sugar, total carbohydrate, and carbohydrate to fiber ratio was associated with higher average daily blood sugar (P=0.001, P=0.006, respectively). Each 1-point greater HEI score (healthier eating) was inversely associated with average daily blood sugar for fatty acid (-1.09 mg/dL; 95% CI -2.11, -0.07), added sugar (-1.76 mg/dL; CI -3.11, -0.4), vegetable (-2.85 mg/dL; CI -5.5, -0.2), and fruit (-2.63 mg/dL; CI -5.03, -0.22). HEI total score did not show significant association with the CGM readings.

Conclusions: Greater added sugar, saturated fats, and dietary carbohydrate to fiber ratio are strongly associated with greater average daily blood sugar. Sugar, carbohydrates, and saturated fats contribute to glycemic variability. Healthy eating centered on low sugar, low fat, and high vegetable and fruit intake may improve glycemic control in both diabetic and non-diabetic CKD patients.

POI743

Late Stage 3 CKD Is an Independent Risk Factor for Sarcopenia, but Not Proteinuria

Yong Seon Choi, Jung Nam An, Jwa-kyung Kim, Sung gyun Kim, Young rim Song. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Most epidemiologic studies assessing the relationship between chronic kidney disease (CKD) and sarcopenia have been performed in dialysis patients. This study aimed to evaluate the relationship between estimated glomerular filtration rate (eGFR), proteinuria, and sarcopenia in patients with non-dialysis-dependent CKD.

Methods: A total of 892 outpatients who did not show any rapid changes in renal function were enrolled in this observational cohort study. We measured the muscle mass using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was found in 28.1% of the patients and its prevalence decreased as body mass index (BMI) increased; however, in patients with BMI ≥ 23 kg/m², the prevalence did not increase with BMI. As eGFR decreased, the lean tissue index and HGS significantly decreased. However, the eGFR did not affect the fat tissue index. The risk of sarcopenia increased approximately 1.6 times in patients with eGFR < 45 mL/min/1.73 m². However, proteinuria was not associated with sarcopenia. With a decrease in eGFR, the lean muscle mass and muscle strength decreased, and the prevalence of sarcopenia increased.

Conclusions: In patients with late stage 3 CKD, further assessment of body composition and screening for sarcopenia may be needed.

POI742

Association of Nutritional Data and Glycemic Variability in CKD Patients

Nandakishor Kapa, Harshanna Badheshha, Tae Youn Kim, Olivia A. Moss, Chenroa R. Vargas, Seung M. Jin, Henning Langer, Usman Rehman, Jennifer E. Norman, Armin Ahmad, Thomas Jue, Maryam Afkarian, Baback Roshanravan. University of California Davis Medical Center, Sacramento, CA.

Background: Insulin resistance is highly prevalent in chronic kidney disease (CKD) and strongly associated with adverse clinical outcomes. Glycemic variability measured by continuous glucose monitoring (CGM) is a clinical measure of insulin resistance. The association of dietary recalls and healthy eating measures with CGM readings in CKD are unknown.

Methods: We recruited diabetic (n=7) and non-diabetic (n=8) participants with eGFR=60mL/min who had CGM performed over 2 weeks. The ASA24 Dietary Assessment Tool was used to perform dietary recalls on 3 random days over the CGM period. The Healthy Eating Index 2015 (HEI-2015) was used to determine how closely an individual’s eating pattern matched Dietary Guidelines for Americans’ recommendations. A linear mixed model adjusting for diabetes status was used to determine association of dietary measures from ASA24, HEI-2015 scores, and CGM readings over 3 days.

Results: Participants had a mean age 59±11years, eGFR 35.5±4.6mL/min/1.73m² and BMI 32±6kg/m². Greater dietary added sugar, total carbohydrate, and carbohydrate to fiber ratio was associated with higher average daily blood sugar (P=0.001, P=0.006, respectively). Each 1-point greater HEI score (healthier eating) was inversely associated with average daily blood sugar for fatty acid (-1.09 mg/dL; 95% CI -2.11, -0.07), added sugar (-1.76 mg/dL; CI -3.11, -0.4), vegetable (-2.85 mg/dL; CI -5.5, -0.2), and fruit (-2.63 mg/dL; CI -5.03, -0.22). HEI total score did not show significant association with the CGM readings.

Conclusions: Greater added sugar, saturated fats, and dietary carbohydrate to fiber ratio are strongly associated with greater average daily blood sugar. Sugar, carbohydrates, and saturated fats contribute to glycemic variability. Healthy eating centered on low sugar, low fat, and high vegetable and fruit intake may improve glycemic control in both diabetic and non-diabetic CKD patients.

Association of Serum Selenium Levels with the Response to Erythropoiesis-Stimulating Agents in Maintenance Hemodialysis Patients

Minoru Yasukawa, Shigeyuki Ariai, Michito Nagura, Daigoro Hirohama, Osamu Yamazaki, Yoshifuru Tamura, Yoshihide Fujigaki, Shigeru Shibata, Teikyo Daigaku Igakuka Daigakuin Igaku Kenkyuka, Ibarashi-ku, Japan.

Background: Reduced response to erythropoiesis-stimulating agent (ESA) has been shown to be associated with poor outcomes in maintenance hemodialysis (MHD) patients. Selenium is a trace element that modulates diverse physiological processes, such as immune responses and cardiovascular function. Previous studies also indicate that selenium and selenoproteins are involved in erythropoiesis. However, its role in the control of anemia in chronic kidney disease patients remains unclear. In this study, we determined serum selenium levels in MHD patients and analyzed their association with hemoglobin levels and the doses of ESA.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: The study included 174 patients who received MHD from four dialysis facilities. We obtained data on demographics, laboratory, comorbidities, hemodialysis prescription and medication by medical record abstraction. Concentration of selenium was measured in serum using ICP-MS.

Results: The mean age was 67.2 years, 77% were male, and 44% of patients received dialysis at least for five years. The average serum selenium concentrations in our cohort were 10.7 ± 2.9 µg/dL, and 88 patients (51%) had a selenium levels of less than 10.5 µg/dL (a lower limit of normal serum selenium levels for adult Japanese population). Patient characteristics, including age, sex, BMI, dialysis vintage, and comorbidities were not significantly different between the low selenium (Low) group and normal selenium (Normal) group. However, the percentage of patients receiving ESA tended to be higher in Low group than in Normal group, whereas hemoglobin levels as well as percentage of patients receiving iron therapy were similar between the groups. In a subgroup analysis involving 146 patients who received ESA, we found a significant negative correlation between serum selenium levels and ESA-resistance index (ERI) (r = -0.25, p = 0.002).

Conclusions: Our study indicates that low levels of serum selenium are associated with poor response to ESA. The relationship between selenium and response to ESA in MHD patients merits further evaluation in larger populations.

PO1745
Serum Irisin and Prediction of Cardiovascular Events in Elderly Patients with CKD Stage 3-5
Teresa Del Mastro, Teresa Arcidiacono, Monica Avino, Arianna Bologna, Nadia Edvige Folligno, Federico Persico, Giuseppe Vezzoli. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Irisin is a circulating myokine released from skeletal muscles after physical exercise. Irisin production decreases during the course of chronic kidney disease (CKD) as a potential consequence of sarcopenia and physical inactivity.

Methods: This observational study explored the relationship of serum irisin with cardiovascular outcome in 79 patients with stage 3-5 CKD.

Results: Serum irisin was significantly higher in healthy subjects (n=20) than CKD patients (7.2 ± 3.1 ± 0.9 µg/ml; p=0.0001) and was higher in patients with CKD stage 3 (3.2 ± 0.2 µg/ml) compared with patients at stage 4 and 5 taken together (n=36, 2.6 ± 0.7 µg/ml; p=0.05). Patients in the lowest serum irisin tertile had lower serum 1,25(OH)D levels (21.6±11.8 pg/ml) than patients in the middle (30.2±13 pg/ml; p=0.005) and the highest tertile (27±14 pg/ml; p=0.047). Patients in the highest irisin tertile had lower Kauppila score (10.6±6.9) than patients in the middle (11.8±5.5; p=0.007) and the lowest tertile (6.9±6.8; p=0.03). Twenty patients suffered from cardiovascular events during a 3-year follow-up. A Cox regression model using age, body weight, presence of diabetes mellitus, gender, Kauppila calcification score, serum values of FGF23 (as logarithm), phosphate, sclerostin, albumin and cholesterol, eGFR and serum irisin tertiles as covariates showed that patients in the highest tertile of serum irisin had a lower cardiovascular risk than patients in the middle tertile (B 1.61, OR 5.1, 95% CI 1.09-22.83; p=0.038).

Conclusions: These findings suggest that serum irisin may be a marker of cardiovascular outcome in CKD patients.

PO1746
Deoxycholic Acid (DCA) and Cognitive Impairment and Decline in the Chronic Renal Insufficiency Cohort (CRIC) Study
Kristen L. Nowak,1 Makoto Miyazaki,2 Michel Chonchol,3 Anand Srivastava,2 Michael J. Fischer,4 Ana C. Ricardo,5 Jiang He,4 Katherine T. Mills,4 Katherine L. Wolfrum,5 Amanda H. Anderson,2 Manjula Kurella Tamura,5 Harold I. Feldman,5 Tamara Isakova,2 Anna Jovanovich,2 1University of Colorado Health, Aurora, CO; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3University of Illinois at Chicago, Chicago, IL; 4Tulane University, New Orleans, LA; 5University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 6Standford University, Palo Alto, CA; 7VA Eastern Colorado Health Care System, Aurora, CO.

Background: Cognitive impairment is common in chronic kidney disease (CKD). The secondary bile acid, DCA, is associated with endothelial dysfunction and oxidative stress, characteristics of cognitive impairment. DCA is also associated with cognitive impairment and risk of Alzheimer’s dementia among older adults without CKD. Whether DCA is associated with cognitive impairment in CKD is unknown.

Methods: We used multivariable-adjusted regression models to cross-sectionally and longitudinally evaluate the association between fasting serum DCA levels measured at visit 5 (considered baseline) and cognitive impairment. Among 2836 CRIC Study participants, cognitive impairment was assessed by the Mini-mental State Exam (MMSE). Among 698 participants enrolled in the CRIC Cognitive (COG) Study, cognitive impairment was further assessed by Trails A&B, Category Fluency, Buschke Recall, and Boston Naming tests. Cognitive impairment was defined by a test score ≥1 standard deviation (SD) worse than the test mean.

Results: Mean age was 59 ± 10 years, 45% were female, and 39% were black. In cross-sectional analyses, there was no association between DCA and cognitive impairment assessed by MMSE in the total cohort after adjustment for demographics and clinical factors (prevalence ratio per 1-SD increase ln DCA: 1.03, 95% CI 0.91-1.17). In longitudinal analyses, DCA was associated with progressive impairment (mean annual % change MMSE per 1-SD increase in DCA: -0.15, 95% CI -0.34 - -0.02), but not with incident impairment. Among CRIC COG Study participants, cross-sectional analyses DCA was associated with cognitive impairment based on Category Fluency (prevalence ratio per 1-SD increase in DCA: 1.36, 95% CI 1.05-1.76) but not with other measures of impairment. In longitudinal analyses among CRIC COG Study participants, DCA was not associated with progressive or incident cognitive impairment.

Conclusions: Among individuals with CKD stages 2-4, higher DCA levels were independently associated with prevalent cognitive impairment in Category Fluency and progressive cognitive impairment assessed by MMSE.

PO1747
The Association of Sodium Intake and Albuminuria According to Cotinine-Verified Smoking Status: Korean National Health Examination Survey (KoNHEs)
Young-Bin Sung, Tae-bum Kim, Hyeon-Jin Min, Jonghyun Lee, Jiyang Yoon, Myung-Gyu Son, Park Hyun-Kyung, Won-Young Cho, Sewon Oh. Division of Nephrology, Department of Internal Medicine, Korea University Annyang Medical Center Korea University Medical Center, Seoul, Republic of Korea.

Background: Smoking and high sodium intake are reported to be associated with chronic kidney disease. Smoking and sodium intake are modifiable risk factors and the implementation of life style changes in the broad population could have a beneficial effect on public health. We assessed the association of sodium intake and smoking on the presence of albuminuria.

Methods: An observational study from the Korean National Health and Nutrition Examination Survey (2008-2011, 2014-2018) was performed. We included 38,161 adults with eGFR≥60 ml/min/1.73m2 and had urine cotinine/creatinine ratio (UCot/Ucrea). Smoking status was assumed by Ucot/Ucrea. 24 hour sodium intake was estimated from spot urine sodium using Kawasaki formula. Albuminuria was defined as urine albumin creatinine ratio a 30mg/g.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only 
Underline represents presenting author.
Results: Ucot/Ucrea level was significantly higher in current smokers than those in ex-smokers or non-smokers (CA: 0.00; 0.01; 0.046; vs. 0.23; 0.01; P = 0.001). Ucot/Ucrea level was significantly associated with sodium intake. Sodium intake of 2nd and 3rd Ucot/Ucrea tertile were significantly higher than that of 1st Ucot/Ucrea tertile (4.15±1.31, 4.13±1.43 vs. 3.73±1.15 mg; P < 0.001). The quartile groups of sodium intake had a linear relationship with albuminuria (5.2, 5.8, 7.5, and 9.7%, P < 0.001). The highest quartile of sodium intake was significantly associated with risk of albuminuria (OR 1.43, 95% CI 1.05-1.93, P = 0.022). We evaluated the association of sodium intake with albuminuria according to smoking status estimated by Ucot/Ucrea. In the group with the highest Ucot/Ucrea level, the highest sodium intake was significantly associated with risk of albuminuria (OR 1.62, 95% CI 1.23-2.14, P = 0.001). The highest quartile of sodium intake was significantly higher than that of other quartiles 2nd, 3rd, and 4th were 0.83 (95% confidence interval [CI], 0.75-0.91), 0.76 (95% CI, 0.68-0.84) and 0.80 (95% CI, 0.72-0.88), respectively. Restricted cubic spline regression also found a U-shaped relationship between total body water and all-cause mortality. In the correlation analysis, as the water intake increased, the total body water amount measured by BIA increased. Additionally, participants showed lower mortality rates as the total amount of water in the body was higher (1st vs. 2nd aHR 0.928 [95% CI, 0.622-1.384] and 1st vs. 3rd aHR 0.542 [95% CI, 0.315-0.933]).

Conclusion: In the general population, too little water in the body and water intake are associated with increased mortality. It is important to maintain adequate hydration status through adequate water consumption.

PO1750

Serum Cystatin C-to-Creatinine Ratio Is a Potential Biomarker for Sarcopenia in Patients with Non-Dialysis-Dependent CKD

Ileen Cho, Yong Seon Choi, Jung Nam An, Sung gun Kim, Young rim Song, HaHyun University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Sarcopenia is a prevalent complication in patients with chronic kidney disease (CKD) and linked with quality of life, morbidity and mortality. Sarcopenia is defined as both a biological, functional and body composition parameters, although several candidate biomarkers for this condition have been evaluated. This study aimed to evaluate serum cystatin C to creatinine (Cr) ratio as a potential biomarker for sarcopenia in patients with non-dialysis-dependent CKD.

Methods: A total of 517 outpatients were enrolled in this observational cohort study. We measured the muscle mass (lean tissue index, LTI) using bioimpedance analysis and handgrip strength (HGS), and sarcopenia was defined as low HGS and low muscle mass.

Results: Sarcopenia was observed in 25.5% patients. The serum cystatin C/Cr ratio was significantly higher in patients with sarcopenia regardless of age, sex, eGFR, and BMI and showed a positive correlation with age and pulse pressure, but LTI, HGS, hemoglobin, and serum albumin level showed a negative correlation with serum cystatin C/Cr ratio. Especially in patients with eGFR ≥ 45 mL/min/1.73 m², serum cystatin C/Cr ratio showed high negative predictive value in predicting sarcopenia (90.5%) and low LTI (90.4%). As the serum cystatin C/Cr ratio increased by 1, the prevalence rate of sarcopenia and low LTI increased by about 5.8 times and about 9.9 times even after adjusting for sex, age, BMI, underlying disease, albumin, Hb, and eGFR. The association between serum cystatin C/Cr ratio and sarcopenia was maximized in patients with eGFR less than 30, resulting in an increased prevalence rate of about 22.7 times, and in the case of low LTI, an independent association was found in patients with eGFR less than 45, and among them, a 43.9-fold increase in risk was identified. However, there was also no significant result for low HGS.

Conclusions: Serum cystatin C/Cr ratio is inexpensive and easily, quickly, and repeatedly measured; therefore, quick screening and management of sarcopenia will be possible, which will be of great help in the treatment of CKD patients.

Prevalence of Inflammation and Associated Healthcare Resource Utilization in Patients with CKD

Rachel Lai,1 Lynda Szczec,1 Sarah Clayton,2 Lewis Harrison,2 Mollie Lowe,2 James Jackson.2 Fibrogen Inc, San Francisco, CA; 2Adelphi Group Ltd, Bollington, United Kingdom.

Background: Many patients with chronic kidney disease (CKD) suffer from inflammation, which often increases as CKD progresses. Inflammation is a risk factor for cardiorenal complications and complications related to treatment of anemia, but CKD inflammation has been associated with reduced red blood cell and erythropoietin production, as well as increased hepcidin levels, which can lead to functional iron deficiency. Because data on the impact of inflammation on healthcare utilization (HCRU) in patients with CKD is limited, we aimed to assess HCRU in these patients.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a point-in-time survey of physicians and their patients with CKD (stage 3–5D) collected in the United States in 2018. Physician and patient reported HCRU-related information, including the mean number of healthcare visits, tests conducted, and payments conducted to diagnose and monitor patients. Inflammation was defined as C-reactive protein ≥ 4 mg/L, ferritin ≥ 700 ng/mL, or albumin ≤ 3.6 g/L. Fisher’s exact and t-tests were conducted to assess differences in HCRU between patients with and without inflammation.

Results: There were 2,536 patients with CKD and of these, inflammation was present in 136/491 (28%) non-dialysis-dependent, and 91/212 (43%) dialysis-dependent patients. HCRU, including the mean number of healthcare visits, tests conducted, and hospitalizations in the last 12 months, number of pills and injections taken per day, and amount of missing data if requiring a carer were greater in patients with inflammation vs those without (all p < 0.05; Table 1).

Key: TH – Thursday; FR – Friday; SA – Saturday; OR – Oral; PO – Poster; PUB – Publication Only

Underline represents presenting author.
Conclusions: We found that inflammation was common in patients with CKD and associated with greater HCRU across multiple measures in a real-world setting. Novel treatment approaches in CKD that are effective in patients with inflammation may help to reduce HCRU.

Methods: We identified patients with diabetes who initiated SGLT2i (n=925), GLP1RA (n=400), dipeptidyl peptidase-4 inhibitors (DPP4i, n=1190), or sulfonylureas (SU, n=3285) between 2015 and 2018 in Geisinger Health System. Outcomes were percent weight change per year among all patients within 1 year after medication initiation and time to first achieving 5% weight loss among patients with overweight/obesity at medication initiation. Inverse probability of treatment weighting (IPTW) based on multinomial propensity scores was used to account for differences in baseline patient characteristics by medication class.

Results: The mean (SD) age of the 6919 patients was 58 (14) years and 3381 (49%) were females. Compared with SU, SGLT2i, GLP1RA, and DPP4i were associated with significant weight loss, with stronger associations for SGLT2i and GLP1RA (Table). Similarly, SGLT2i, GLP1RA, and DPP4i users were more likely to achieve 5% weight loss compared with SU (HR [95% CI]: 1.47 [1.28, 1.69] for SGLT2i; HR: 1.55 [1.32,1.82] for GLP1; HR: 1.31 [1.19,1.44] for DPP4). The associations were consistent across CKD stages.

Conclusions: In patients with and without CKD, SGLT2i and GLP1RA were associated with significant weight loss compared with SU. These results may further motivate uptake of SGLT2i and GLP1RA, two classes of medications with proven renal benefits among patients with overweight or obesity.

Effects of Home BP-Based Behavioral Guidance on Urinary Albumin Excretion in School Workers with Microalbuminuria - Masanori Karoshi

Background: Prevention of work-related cardiovascular events, or Karoshi is an important social issue in Japan. This study aimed to examine if home-BP based behavioral guidance is effective to reduce CV event risk in school staffs associated with microalbuminuria, a marker of endothelial damage.

Methods: Subjects were 3868 Miyagi prefectural school workers. Urinary albumin excretion adjusted for creatinine (UAE) and daily sodium intake based on Tanaka method was examined together with usual annual health check-up in 2019. Among them, 169 were diagnosed as having microalbuminuria (30-299.9mg/gCr). Ninety-one subjects agreed to receive the home-BP based health guidance. Guidance was given according to 5 days mean of home BP measurements, or encouraging medical consultation and lifestyle guidance for subjects with 125-134/80-84mmHg and adequate lifestyle guidance for subjects <125/80mmHg if necessary. Outcomes were UAE and frequency of microalbuminuria in the next year. Data were compared between guided and non-guided subjects. Subjects with menstruation were excluded from analysis. Final analysis number was 48 and 43 for guided and non-guided groups.

Results: Guided group demonstrated similar baseline data as compared with non-guided group for age, male gender, body mass index, cardiovascular risk factors and UAE level. Prescription rate for hypertension and diabetes also was similar between them. LogUAE was significantly and similarly decreased in both groups. One year later, microalbuminuria was present in 31.2% for guided group and 30.2% for non-guided group for age, male gender, body mass index, cardiovascular risk factors and UAE level.

Conclusions: Reduction in UAE did not differ between groups with or without home-BP based behavioral guidance. Our data suggest that notification of microalbuminuria per se have considerable degree of favorable behavioral effects in school workers with microalbuminuria.

Weight Changes Following Diabetes Medication: A Population-Based Study - Beini Lyu

Background: The majority of patients with type 2 diabetes are obese, with greater percentages in those with concomitant CKD. Clinical trials suggest that the newer glucose-lowering medications, including sodium-glucose cotransporter-2 inhibitors (SGLT2i) and glucagon-like peptide-1 receptor antagonists (GLP1), provide an added benefit of weight loss in people with type 2 diabetes. We evaluated the magnitude of weight change associated with diabetes medication prescription in real-world practice in persons with and without CKD (eGFR <60 vs. ≥60 ml/kg/1.73 m²).

Methods: Of a cohort of 111 participants who were randomized, 99 had baseline ccf-mtDNA levels, and 92 completed the study. The median age was 57 years old, 44% were female, and 92% had diabetes. Plasma ccf-mtDNA median concentrations at baseline, two, and four months were 3.62, 3.08, 2.78 pm for the usual activity group, and 2.01, 2.20, 2.67 pm for the aerobic exercise group. There was a 16.1% increase per month in ccf-mtDNA in the aerobic exercise group compared to the usual activity group (p = 0.024), especially with the combination of aerobic exercise and caloric restriction (29.5% increase per month). After four months of intervention, ccf-mtDNA increased in the aerobic exercise group by 81.6% (95% confidence intervals [CI] 8.2-204.8; p = 0.024) compared to the usual activity group, but it was only observed in the aerobic exercise and caloric restriction group (181.7% increase, 95% CI 41.1-462.2; p = 0.003).

Conclusions: Our data suggest that aerobic exercise increases plasma ccf-mtDNA levels in patients with CKD stages 3-4, more profoundly in ones with a combination of caloric restriction.

Effects of Caloric Restriction and Aerobic Exercise on Circulating Cell-Free Mitochondrial DNA in Patients with Moderate-to-Severe CKD: A Pilot Study - Javier Jaramillo Morales

Background: Understanding mechanisms for increased oxidative stress and inflammation in patients with chronic kidney disease (CKD) is vital due to their role in the pathophysiology of this population. Circulating cell-free mitochondrial DNA (ccf-mtDNA) is released to the plasma as a damaged-associated molecular pattern. Previous studies suggested that in patients with kidney disease, ccf-mtDNA increases and may induce inflammation. Past investigations in patients with CKD have found that aerobic exercise decreases inflammation. We hypothesized that in patients with moderate to severe CKD, aerobic exercise would reduce plasma levels of ccf-mtDNA.

Methods: We performed a post hoc analysis of a multi-center pilot randomized trial of aerobic exercise and caloric restriction (NCT01150851). We measured ccf-mtDNA in plasma at baseline and two and four months after four interventions (aerobic exercise (EX), caloric restriction (CR), EX + CR, usual activity and usual diet). A multivariable model adjusted for age, race, sex, systolic BP, BMI, diabetes, and eGFR was done.

Results: Of a cohort of 111 participants who were randomized, 99 had baseline ccf-mtDNA levels, and 92 completed the study. The median age was 57 years old, 44% were female, and 92% had diabetes. Plasma ccf-mtDNA median concentrations at baseline, two, and four months were 3.62, 3.08, 2.78 pm for the usual activity group, and 2.01, 2.20, 2.67 pm for the aerobic exercise group. There was a 16.1% increase per month in ccf-mtDNA in the aerobic exercise group compared to the usual activity group (p = 0.024), especially with the combination of aerobic exercise and caloric restriction (29.5% increase per month). After four months of intervention, ccf-mtDNA increased in the aerobic exercise group by 81.6% (95% confidence intervals [CI] 8.2-204.8; p = 0.024) compared to the usual activity group, but it was only observed in the aerobic exercise and caloric restriction group (181.7% increase, 95% CI 41.1-462.2; p = 0.003).

Conclusions: Our data suggest that aerobic exercise increases plasma ccf-mtDNA levels in patients with CKD stages 3-4, more profoundly in ones with a combination of caloric restriction.

Physical Activity Scores in Hemodialysis Patients with Thyroid Dysfunction: A Substudy of the NIH THYROID-HD Trial
Yuhei Otobe,1,2 Richard Casaburi,1,3 Harry B. Rossiter,3 Shlomit Radom-Aizik,1 Joel D. Kopple,2,3 Matthew J. Budoff,2,3 Rachelle Bross,2 MacKenzie K. Cervantes,3 Gregory Brent,4,5 Csaba P. Kovessy,3 Yalitzi Guerrero,1 Yoko Narasaki,1 Amy S. You,1 Danh V. Nguyen,1 Kamyr Kalantar-Zadeh,1 Connie Rhee.1 1University of California Irvine, Irvine, CA; 2The Lundquist Institute, Torrance, CA; 3Harbor-UCLA Medical Center, Torrance, CA; 4University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 5VA Greater Los Angeles Healthcare System, Los Angeles, CA; 6The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: Low physical activity is common in hemodialysis (HD) patients and is associated with adverse outcomes in this population (poor health-related quality of life, cardiovascular [CV] disease, death). Prior studies show that hypothyroidism is highly prevalent in HD patients, and is associated with worse self-reported physical function.

Methods: In a substudy of the ongoing multi-center NIH THYROID-HD Trial, we examined baseline physical activity scores determined by the Human Activity Profile (HAP), a validated 94-item instrument assessing daily activities across a wide range of energy expenditures, in HD patients with TSH levels in the high-normal (TSH >3-5 mIU/L) and subclinical hypothyroid range (TSH >5-10 mIU/L). The HAP was used to derive the Maximum Activity Score (MAS) and Adjusted Activity Score (AAS), representing greatest and mean estimated energy expenditures, respectively (range 0-94, segmented to low [<52], moderate [54-73], and high [>74] scores).

Results: Among 57 HD patients who underwent baseline HAP assessment, the mean±SD MAS and AAS scores were 52±21 and 26±27, respectively; median (IQR) MAS and AAS scores were 52 (40, 68) and 22 (0, 49), respectively. In the overall cohort, 79% had low, 14% moderate, and 7% high AAS scores. MAS scores were lower in patients who were older (>65 yrs), female, White, Hispanic, of longer (>1 yr) vintage, diabetic, or with underlying CV disease. A similar trend was observed for AAS scores.

Conclusions: In this substudy of the NIH THYROID-HD Trial, HAP scores in HD patients with high-normal and subclinical hypothyroid range TSH levels were lower than observed in prior historical dialysis cohorts that did not have underlying thyroid dysfunction. Further research is needed to determine the impact of thyroid hormone replacement on improving physical activity and function in this population.

In Vivo Muscle Mitochondrial Function Is Associated with Exercise Capacity and Efficiency in CKD
Chenoa R. Vargas,1 Gwenaelle Begue,2 Usman Rehman,2 Armin Ahmadi,2 Tae Youn Kim,2 Seung M. Jin,2 Jorge Gamboa,3 Thomas Jue,2 Baback Roshanravan.1 1University of California Davis Department of Internal Medicine, Sacramento, CA; 2University of California Davis, Davis, CA; 3California State University Sacramento, Sacramento, CA; 4Vanderbilt University, Nashville, TN.

Background: CKD is associated with skeletal muscle dysfunction increasing risk for frailty. Muscle mitochondrial dysfunction may underlie impaired physical performance. The associations of in vivo muscle mitochondrial function with exercise capacity and efficiency in CKD is unknown.

Methods: We recruited 8 diabetic and 6 non-diabetic patients with CKD. Leg muscle mitochondrial oxidative capacity was measured by exercise recovery kinetics of [PCr] using 31P Magnetic Resonance Spectroscopy (31P MRS). Cardiorespiratory fitness (CRF, VO2 peak), total work, and work efficiency (total work/VO2peak) were assessed by cycle ergometry. We tested associations of 31P MRS measures with endpoints using Pearson correlations.

Results: Participants had a mean age was 61±10yrs, eGFR of 35±12ml/min with 43% females. Faster PCr recovery rate correlated with VO2 peak (r=0.58, p=0.03), total work (r=0.70, p=0.03) and work efficiency (r=0.59, p=0.03) (Figure). Associations of PCr recovery with work and work efficiency were independent of age, sex, and weight (both p>0.03).

Conclusions: Muscle mitochondrial oxidative capacity is a major determinant of exercise efficiency and capacity. Therapeutics targeting muscle mitochondrial function in CKD may improve physical performance and CRF.

Comparisons of In-Clinic and Free-Living Measures of Physical Function in Predicting Hospitalization in Patients with CKD
Nikita Abraham,1 Robert E. Boucher,1 Guo Wei,1 Jesse Christensen,2 Sydney E. Hartsell,1 Judy Carle,1 Victoria Gonce,1 Srinivas Beddu,1,2 Kate Lyden.1 1The University of Utah School of Medicine, Salt Lake City, UT; 2Salt Lake City Health Care System, Salt Lake City, UT; 3University of Massachusetts Amherst, Amherst, MA.

Background: Physical function is associated with risk of hospitalization; however, comparisons of in-clinic and free-living measures of physical function and their associations with risk of hospitalization has not been well established.

Methods: In this secondary analysis of the Sit Less, Interact, Move More (SLIMM) pilot study, we compared in clinic and free-living measures using accelerometry data. Participants with CKD were randomized to the SLIMM intervention or standard of care and asked to wear a thigh worn accelerometer 7 days before a visit to capture their physical activity. In clinic measures of physical function like 6-minute walk distance were performed during visits. Free-living measures were determined from accelerometry.

Results: 106 participants were randomized, the mean age was 69 ± 12 and 69 ± 14, baseline eGFR was 44 ± 12 and 45 ± 14, and 48% and 37% were female for the standard of care and SLIMM groups respectively. When adjusted for covariates, both in clinic and free-living 6-minute walk distance and steps respectively were associated with hospitalizations (table). In comparisons between in clinic and free-living measures, in clinic measures were not significantly associated with hospitalizations while free-living measures were (table).

Conclusions: Both in clinic and free-living measures of physical function were predictors of hospitalization in patients with CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

Adjusted cox proportional hazard model for hospitalization in in clinic and free-living 6-minute walk.

PO1759
Blood Pressure Trends in a Cohort of 9- and 10-Year-Old Children in Iceland: A 10-Year Follow-Up Study
Aðúsi H. Sigurðardóttir,1,2 Ólafur S. Indriðason,1 Sigurður S. Stephensen,2 Thordís J. Hrafnsfúkisdóttir,1 Vidar O. Edvardsson.1 1Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavík, Iceland; 2Children’s Medical Center, Landspítali – The National University Hospital of Iceland, Reykjavík, Iceland; 3Division of Nephrology, Landspítali – The National University Hospital of Iceland, Reykjavík, Iceland; 4Division of Cardiology, Landspítali-The National University Hospital of Iceland, Reykjavik, Iceland.

Background: Although there is significant evidence for an association between childhood and adult office blood pressure (BP), data on the correlation of childhood BP and ambulatory BP (ABP) in young adults are missing. The aim of this study was to examine the association between childhood office BP and both ABP and office BP indices in young adults.

Methods: Subjects were recruited from a cohort of 970 young adults aged 20-21 years who participated in a population-based study of BP in 9-10-year-old Icelandic school children. All participants underwent a minimum of 4 resting BP measurements at the childhood BP screening. A total of 121 individuals have completed their participation in the follow-up study, which included office and ambulatory BP measurements. Pearson correlation and linear regression analysis were used to examine the relationship between childhood and follow-up BP.

Results: A significant positive correlation was observed between childhood mean systolic BP (SBP) and systolic office and ambulatory BP at follow-up (r = 0.386, p < 0.001 and r = 0.370, p < 0.001, respectively). The correlation between mean childhood mean systolic office BP and follow-up mean systolic office BP was stronger for males (r = 0.50, p < 0.001) than for females (r = 0.298, p = 0.012), and the same applied for mean systolic ABP (r = 0.491, p < 0.001 and r = 0.323, p = 0.006, respectively). The correlation of mean childhood diastolic office BP and follow-up with mean DBP was insigniﬁcant for males (office DBP: r = 0.278, p = 0.055) but remained signiﬁcant for females (office DBP: r = 0.355, p = 0.0026; ABP: r = 0.449, p = 0.001). In adjusted analysis, childhood mean office SBP signiﬁcantly associated with mean ofﬁce SBP at follow-up in both males (beta = 0.69, p < 0.001) and females (beta = 0.26, p < 0.001). Each mmHg increment in mean childhood SBP predicted an increase of mean ambulatory SBP by 0.52 mmHg (p < 0.001), unaffected by sex. Childhood DBP did not significantly predict office or ambulatory BP at follow-up in adjusted analysis.

Conclusions: These preliminary results indicate that childhood SBP significantly predicts both systolic office and ambulatory SBP in young adults and these associations are stronger in males.

Clinical Event Reductions in Hypertension Patients with and Without CKD Treated with Renal Denervation: A Model-Based Estimate Based on Data from the Global SYMPLECTIC Registry

Rolf E. Schmieder,1 Felix Mahfoud,2 Bryan Williams,3 Giuseppe Mancia,4 Krzysztof Narkiewicz,2 Luis M. Ruizope,4 Markus S. Segal,2 Oliver J. Pittzsch,3 1Universitätsklinikum Erlangen, Erlangen, Germany; 2University des Saarlandes, Saarbrücken, Germany; 3University College London, London, United Kingdom; 4Universita degli Studi di Milano-Bicocca, Milano, Italy; 5Gdansk University Medecyzy, Gdansk, Poland; 6Faculty of Ciencias Medicas 10 de Octubre, La Habana, Cuba; 7The University of Western Australia, Perth, WA, Australia; 8Wing Tech, Inc., Menlo Park, CA.

Background: Estimates of clinical event reductions following renal denervation (RDN) were modelled for patients with and without chronic kidney disease (CKD) based on the RDN study data of the Global SYMPLECTIC Registry (GSR). Methods: GSR had 1,860 patients, 630 of whom had G3a CKD (eGFR<60 ml/min/1.73m²; n=630) and No CKD (eGFR ≥ 60 ml/min/1.73m²; n=1,860) cohorts of the GSR were analyzed. Reductions in office systolic blood pressure (oSBP) at 6, 12, 24, and 36 months follow-up were averaged and relative risks (RR) for death, cardiovascular (CV) death, myocardial infarction (MI), stroke, and new-onset end-stage renal disease (ESRD) were obtained from published meta-regression analysis of randomized trials of blood pressure lowering in hypertensive patients. Using the derived RRs, clinical event estimates for maintained baseline oSBP were calculated, facilitating estimation of 36-month absolute event reductions and resulting numbers needed to treat (NNT) for the individual endpoints. Results: Baseline oSBP and oSBP reductions for the CKD and No CKD cohorts were 163.6 ± 25.7, 11.1 and 166.7 ± 24.6; 135.2 mmHg, respectively. RR from 0.6% for death to 0.9 to 0.9 for death in the CKD cohort. The stroke, a numerically higher absolute reduction in major adverse cardiovascular events (MACE: composite of CV death, MI and stroke) within 3 years of RDN treatment in the CKD vs. No CKD patients (4.0% vs. 3.2%, p=0.12), in part due to higher overall 3-year MACCE rates observed in CKD patients (18.8% vs. 11.7%, p<0.001) (Table).

Conclusions: Model-based projections provide a directional estimate of the potential clinical event reductions following RDN treatment and suggest clinically meaningful risk reduction in patients with and without CKD.

Funding: Commercial Support - Medtronic

Achievement of Blood Pressure Target and Risk of Major Adverse Cardiovascular and Cerebrovascular Events in Patients with Metabolic Syndrome

Jimin Lim,1 Soojin Lee,2 Junghee Kwon,2 Jin Hyuk Paek,3 Woo Yeong Park,4 Kyubok Jin,1 Seung Jin Han,1 Yaerim Kim1 1Kyeungin University School of Medicine, Daegu, Daegu, Republic of Korea; 2Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; 3Kidney Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; 4Eulji University Hospital in Uijeongbu, Uijeongbu-si, Gyeonggi-do, Republic of Korea.

Background: Metabolic syndrome (MetS) is closely related to adversely cardiovascular morbidities and mortality. Among the components of MetS, controlling the hypertension might provide the highest yield in reducing major cerebro- and cardiovascular events (MACCE). Hence, we aimed to investigate the impact of control of hypertension on the development of MACCE and all-cause mortality according to the presence of MetS.

Methods: We performed a nationwide population-based study using the national health insurance database of South Korea. Among 2,998,127 subjects with hypertension who received more than 3 times national health screenings 2003 to 2011, a total of 1,920,601 subjects were included in the study. The study group was divided by the presence of the MetS and the degree of control of blood pressure (BP), 1) intensive well-controlled (well-C) (SBP <120 and DBP <70), 2) standard well-controlled (SBP 120-130 and DBP 80-89), 3) uncontrolled subgroup 1 (U-S1) (SBP 130-159 or DBP 80-99), and 4) uncontrolled subgroup 2 (U-S2) (SBP ≥ 160 or DBP ≥100). The main study outcome was all-cause mortality and composite MACCE. The study outcomes were investigated using multivariable Cox-regression analysis after adjusting for clinical variables.

Results: There were 945,243 (49.2%) subjects with 2 or more components of MetS. Among them, 142,991, 179,041, 562,725, and 60,486 subjects were grouped in the well-C intensive, well-C standard, U-S1, and U-S2, respectively. Compared to the well-C standard group, both intensively controlled group (hazard ratio [HR]: 1.123, 95% confidence interval [95% CI]: 1.062-1.186) and uncontrolled group (HR: 1.106; 95% CI: 1.015-1.216) in U-S2 group was associated with increased risk of composite MACCE. In addition, the risk of all-cause mortality in subjects with MetS was increased in well-C intensive group (HR: 1.197; 95% CI: 1.143-1.254) and U-S2 group (HR: 1.211; 95% CI: 1.121-1.386), compared to the well-C standard group.

Conclusions: Uncontrolled hypertension increased risk for MACCE and all-cause mortality in patients with or without MetS, whereas intensive control of BP also increased risk. Therefore, proper targeting the blood pressure is important to reduce the risk of major clinical outcomes irrespective of the presence of MetS.

Vascular Function Indices Are Strong Predictors of the Severity and Characteristics of Carotid Atherosclerosis

Ashutosh M. Shukla,1 Lena Ly,2 Malea Joyce,2 Tatiana Orozco,5 Alfredo Ruilope,6 Markus Böhm,2 Mancia,4 Böhm,2 Mancia,4 Roland S. Segal,2 1VA North Florida South Georgia Veterans Health System, Gainesville, FL; 2University of Florida, Gainesville, FL; 3University of Utah Health, Salt Lake City, UT; 4University of Arkansas for Medical Sciences, Little Rock, AR.

Background: Vascular functional indices strongly predict adverse cardiac outcomes in CKD. However, few have examined the link between vascular function and the severity and characteristics of carotid atherosclerosis in CKD. Management of Cardiovascular disease in CKD is closely related to adversely vascular dysfunction and carotid atherosclerosis in Veterans with high-CV risk CKD. Analyzing the baseline parameters of enrollees, we aim to evaluate the predictors of carotid atherosclerosis in CKD patients.

Methods: All randomized participants of MaCK study underwent detailed clinical and laboratory evaluations, including evaluation of inflammation (hsCRP), vascular function (central aortic pressure(CAP), augmentation index(AI) and aorta pulse wave velocity(APWV) by sphygmocon® XCEL) and detailed evaluation of carotid atherosclerosis 15 mm around bifurcation (total plaque volume (TPV), lipid-rich necrosis, calcification, fibrous cap, and intraplaque hemorrhage by 3T MRI analyzed with Piaqiview® software).

Results: Initial 17 randomized participants (age 73±4years, all male, 41% with pre-existing CVD and 88% on statins, with eGFR 40±20, median of WC of the total study population.

Conclusions: Non-invasively measured central aortic pressure and aortic pulse wave velocity are strong predictors of carotid atherosclerosis and unstable plaques.

**Framingham Risk Score and ACC/AHA Pooled Cohort Equation for Prediction of Atherosclerotic Cardiovascular Events in CKD**

Benjamin Lidgard,1 Leila R. Zelnick,1 Alan S. Go,2 Kevin D. O’Brien,1 Nisha Bansal.1
1University of Washington, Seattle, WA; 2Kaiser Permanente Southern California, Pasadena, CA.

**Background:** The Framingham Risk Score and the ACC/AHA Pooled Cohort Equation are used clinically to identify patients at high risk for atherosclerotic cardiovascular disease (ASCVD). The performance of these equations (alone or with clinically available cardiac biomarkers) is unclear in patients with chronic kidney disease (CKD), particularly at more advanced stages. We tested the discrimination of these risk scores and cardiac biomarkers to predict ASCVD in CKD.

**Methods:** We studied 1027 participants in the Chronic Renal Insufficiency Cohort without ASCVD who were not taking aspirin or statins. Framingham Risk Score, Pooled Cohort Equation, N-terminal pro-brain type natriuretic peptide (NT-proBNP), and high-sensitivity troponin T (HsTnT) were measured at baseline. Outcomes were the composite of fatal and non-fatal myocardial infarction (MI) and cardiac death, with or without stroke, over 10 years. We estimated internally valid C-indices using 10-fold cross validation for each risk score and cardiac risk marker overall, and across categories of eGFR.

**Results:** Among 1027 participants, the mean age was 52 years, and the mean eGFR was 48 mL/min/1.73 m². The C-index (95% CI) was 0.74 (0.69, 0.79) for the Framingham Risk Score, and 0.72 (0.67, 0.78) for the Pooled Cohort Equation. Both risk scores had better discrimination for predicting ASCVD at eGFR >60 mL/min/1.73 m² compared with lower eGFR. HsTnT had comparable discrimination to both risk scores overall. HsTnT alone had comparable discrimination across the spectrum of CKD severity (difference in C-index for lowest vs highest eGFR category for ASCVD -0.04; 95% CI -0.21, 0.14) (Table).

**Conclusions:** The Framingham Risk Score and Pooled Cohort Equation had moderate discrimination for prediction of ASCVD in CKD and performed better at eGFRs >60 versus <60 mL/min/1.73 m². HsTnT alone had discrimination comparable to each risk score overall, and comparable discrimination across the spectrum of CKD severity. Further work is needed to develop novel risk scores including cardiac biomarkers specifically for use in CKD.

**Nondipping Heart Rate in Patients with CKD**

Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.

**Background:** A decrease in the nocturnal heart rate (HR) decline, nondipping HR (NHR), was reported to be 14% in the general population and related to cardiovascular events and all-cause mortality; however, the clinicopathological features of chronic kidney disease (CKD) patients with NHR is still unclear. Previous studies have reported that interstitial and/or tubular atrophy (IFTA) was significantly associated with both daytime and nighttime hypertrophy observed with ambulatory blood pressure monitoring (ABPM). We aimed to investigate the clinicopathological findings associated with NHR status in patients with CKD.

**Methods:** We retrospectively identified 135 subjects who underwent ABPM and kidney biopsy simultaneously at our institution, from 2016 to 2019. We excluded patients with age <20 years, end-stage kidney disease, less than 5 glomeruli in the kidney biopsy, and patients taking β-blockers. NHR status was defined as (daytime HR – nighttime HR)/daytime HR <0.1. The percentage of global glomerulosclerosis (GS%), IFTA, and the severity of arteriosclerosis were scored semi-quantitatively according to the Mayo Clinic/Renal Pathology Society Chronicity Score (CS).

**Results:** Our median age was 51 years (interquartile range: 35–63), 54.0% of which were male, and the median eGFR was 53.0 [30.0–75.0] mL/min/1.73m². NHR status was found in 39 out of 135 patients (28.9%). Patients with NHR were older and had worse renal function, higher blood pressure, lower hemoglobin level, and a larger amount of urinary protein excretion than patients with dipping HR. In terms of histopathological parameters, patients with NHR had more severe GS%, IFTA, and arteriosclerosis, and higher CS (Table 1). In multivariable analysis, GS% was established as an independent determinant of NHR status after its adjustment according to age, sex, and other statistically significant parameters (β = 1.03 [1.00–1.05], P = 0.02).

**Conclusions:** NHR status was observed in 28.9% of CKD patients. This study indicates that GS% is the most relevant histopathological parameter associated with NHR in this population.

Turning the Page on Page Kidney with Dual RAAS Blockade
William J. Assante,1,2 Jennifer Griffiths,1,2 Aromma Kapoor,1,2 1Westchester Medical Center Health Network, Valhalla, NY; 2New York Medical College, Valhalla, NY.

Introduction: Page kidney is a rare form of secondary hypertension from activation of the renin-angiotensin-aldosterone (RAAS) axis by compression of renal parenchyma. It can occur with blunt abdominal trauma/procedures, but it can occur spontaneously. Initial treatment is an ACE inhibitor (ACE) or angiotensin receptor blocker (ARB). Surgical intervention is usually a last resort after more conservative measures fail. Procedures carry their own intrinsic risk for morbidity and mortality, particularly in the setting of uncontrolled hypertension. This report details the case of a patient with Page kidney responsive to an unconventional conservative management approach: dual RAAS blockade with ACE + ARB to achieve normotensive control.

Case Description: The patient is a 55M with a history of end stage renal disease (ESRD). On admission, he was hypertensive with a blood pressure of 160/110 mmHg. A CT scan of the abdomen showed a 16.5cm right retroperitoneal hematoma adjacent to the right kidney with anterior dislocation of the kidney. A CT angiogram showed active extravasation within the hematoma. Coumadin was held and a dose of Vitamin K was given to reverse the patient's INR. Lisinopril 20mg PO daily was added and increased to maximum tolerated dose. Hemoglobin was stable therafter.

The patient soon developed hypertensive urgency with a rise in blood pressure to 180/120 mmHg. The patient was dyspneic and weak with right flank pain. He denied headaches, visual disturbances, and other symptoms of critical illness. He was hypotensive with systolic blood pressure of 120s, and was immediately admitted to the ICU. The patient was started on 120mmHg target blood pressure. The patient's blood pressure normalized with average in 120s systolic by 72 hrs post admission. No intervention was needed for bleeding control or surgical evacuation of the hematoma. The patient was discharged with lisinopril 40mg PO daily, and was followed with a nephrology consult.

Discussion: Page kidney is a rare but serious form of secondary hypertension from RAAS activation from renal parenchymal compression. Historically, a trial of either an ACE or ARB is indicated, with refractory cases being managed surgically. In this case, dual RAAS blockade was required for blood pressure control, which allowed surgical interventions, and their associated risk of morbidity and mortality, to be avoided.

ESRD Risk Predicting Using Cumulative Hypertension Burden
Chang Seong Ma,1,2 Hong sang Choi,1 Eun Hui Bae,1 Seong Kwon Ma,1 Soo Hwa Park,1 Jeong Ki Kim,1 and Byoung Koo Bae,2 1Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea; 2Chonnam National University Medical School, Gwangju, Republic of Korea.

Background: Hypertension is the leading risk factor for end-stage renal disease (ESRD). However, the association between sustained exposure of increased blood pressure (BP) and ESRD is not well-established. This study investigated whether the cumulative hypertension burden is a substantial risk factor for ESRD.

Methods: The incidence of ESRD among 2,144,801 participants identified from the Korean National Health Insurance Service database, who had documented BP assessments for annual health checkup data between 2006 and 2010, was determined. Over a median follow-up of 7.2 years, ESRD was identified in 1,758 participants. Hypertension burden was defined as the cumulative exposure of hypertension (systolic BP ≥140 mmHg or diastolic BP ≥90 mmHg) during 4 consecutive follow up period, and scaled 0 to 4.

Results: Hypertension burden was as follows: 0 (n = 1,164,488), 77.6%; 1 (n = 292,377), 13.6%; 2 (n = 114,397), 5.3%; 3 (n = 52,671), 2.5%; and 4 (n = 26,886), 1.0%. Compared to the hypertension burden of 0, adjusted hazard ratio for ESRD was increased to 1.43, 1.74, 1.85, and 2.70 in hypertension burden of 1, 2, 3, and 4, respectively. A positive dose-dependent relationship between the hypertension burdens and ESRD was found (P for interaction < 0.001). This association was maintained for the sustained exposure of both systolic and diastolic hypertension burden. In conclusion, hypertension burden increases the risk of ESRD.

Conclusions: Our study underlines the usefulness of a new assessment of the hypertension burden over a certain period for predicting the risk of ESRD from a large population-based cohort.
PO1772
Perseverance of Uncontrolled Hypertension Among Older Women Post Implementation of Hypertension Improvement Program
Emily Walsh,1 Olivia Myers,2 Talar Markossian,2 Holly J. Kramer,2 Katherine Habicht,1 Beatrice D. Probst,1 Loyola University Chicago Stritch School of Medicine, Maywood, IL; 1Parkinson School of Health Sciences & Public Health, Loyola University Chicago, Maywood, IL; 2Loyola University Medical Center, Maywood, IL.

Background: Age-dependent sex differences in hypertension control have been demonstrated in multiple populations. Four large primary care (PC) practices at Loyola adopted the Target:BP hypertension improvement program in 2018; hypertension control rates increased after adoption. Our study evaluated the impact of the Target:BP program on hypertension control by sex and by age group.

Methods: Analysis used data from 21,864 patients age ≥18 years with a hypertension diagnosis and ≥1 outpatient visit in 2019 to a PC clinic enrolled in Target:BP program. Uncontrolled hypertension was defined as blood pressure ≥140/90 mmHg based on last visit. Mixed effects models were used to calculate adjusted odds of uncontrolled hypertension after adjustment for demographics and co-morbidities. Interaction term of sex*age group (≥65, 66-75, >75 years) in fully adjusted mixed effects models was significant (P < 0.001) so adjusted odds of uncontrolled hypertension were calculated by sex and by age group. Adjusted proportion of patients with uncontrolled hypertension by sex and by age group was calculated using marginal effects.

Results: Mean age of patients with hypertension was 64.8 ± 12.7 years; 56.3% were female, 66.6% were White, 21.4% were Black and 11.0% were of Hispanic ethnicity. Among the 5973 (27.3%) with uncontrolled hypertension, 54.7% were female; mean age was 65.2 ± 12.9 years. Adjusted odds of uncontrolled hypertension was significantly higher among women vs. men age 66-75 years (OR 1.33; 95% CI 1.30, 2.28) and age 76+ years (OR 1.73; 95% CI 1.31, 2.28) vs. age ≤65 years. Figure 1 shows the adjusted proportion of patients with uncontrolled hypertension by sex and by age group.

Conclusions: Despite implementation of a hypertension improvement program, sex disparities in hypertension control persist among older adults.

PO1773
Influence of Biological Sex on Brachial Cuff Blood Pressure Accuracy
Yasmine Abbassri,1 Florence Lamarche,1 Annie-Claire Nadeau-Fredette,2 Mohsen Agharazii,3 Francois Madore,3 Remi Goupil,1 Hôpital du Sacré-Cœur de Montréal, Montreal, QC, Canada; 2Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; 3CHU de Quebec-Université Laval, Quebec, QC, Canada.

Background: Females have higher risks of cardiovascular events compared to males with similar BP. Our objective was to assess if the accuracy of brachial cuff and central BP measurements towards intra-aortic BP is influenced by biological sex.

Methods: We enrolled 500 patients undergoing coronary angiography for simultaneous measurements of invasive aortic BP with brachial cuff and central BP (Mobi-o-Graph device). Acceptable accuracy was defined as a mean difference between non-invasive and aortic BPs ≤5 ± 8 mmHg. Linear regression and mediation analyses were used to adjust for potential confounders in the relationship between biological sex and BP accuracy.

Results: Of 500 participants, 145 were females. Several characteristics were different in males and females (Table). Brachial cuff systolic BP (SBP) was identical in both groups whereas aortic SBP was 6.2 mmHg higher in females (p=0.001). As such, the brachial cuff SBP was appreciably underestimated the aortic SBP in females but not in males. Type II central SBP was the most accurate BP in females, whereas it was brachial cuff SBP in males. In an adjusted linear regression model, only height and pulse pressure were independently associated with the accuracy of brachial cuff SBP. This effect of sex on accuracy was mostly mediated by height (3.5 mmHg; 95% CI 1.4 to 5.6; 57% mediation) to an extent that the direct effect of sex became non-significant (2.9 mmHg; 95% CI -0.3 to 6.2).

Conclusions: High potassium intake is associated with lower blood pressure and lower risk of cardiovascular disease. Whether these associations differ between men and women and whether they depend on daily sodium intake is unknown.

Methods: We performed an analysis in 11,267 men and 13,696 women from the Epic-Norfolk cohort. Daily sodium and potassium consumption was estimated from sodium and potassium concentration in spot urine samples by using the Kawasaki formula. Linear and Cox regression were used to explore the association between potassium intake, systolic blood pressure and cardiovascular events (defined as hospitalization or death due to cardiac disease).

Results: After adjustment for confounders, interaction between potassium intake and sex was significantly associated with systolic blood pressure (p=0.001) and cardiovascular events (p=0.035). In women, but not in men, the inverse slope between potassium intake and systolic blood pressure was steeper in those within the highest quintile compared to the lowest quintile of sodium intake (p=0.001 for interaction). In women within the highest quintile of sodium intake, every 1-gram increase in potassium intake was associated with a 2.9 mmHg lower systolic blood pressure. These associations were paralleled with lower risk of cardiovascular disease in women (highest vs. lowest potassium intake tertile: HR 0.88, 95% CI 0.93-0.94). Conversely, in men, the inverse association between potassium intake and cardiovascular disease was not statistically significant (highest vs. lowest potassium intake tertile: HR 0.94, 95% CI 0.88-1.01).

Conclusions: Females have higher aortic SBPs than males with identical brachial SBP, which is mostly mediated by a lower height. This could partly explain why females are at higher risk of cardiovascular diseases than males at similar brachial cuff SBP levels.
Background: Inflammation and oxidative stress contribute to the increased cardiovascular disease (CVD) burden in CKD patients. Altered tryptophan catabolism via the kynurenine pathway associates with CVD, but the ability of these specific metabolites to act as biomarkers of CVD risk in CKD warrants further research.

Methods: We measured tryptophan metabolites using targeted mass spectrometry in moderate to severe CKD patients (n=325; median follow-up 3 years). Vascular calcification at the coronary artery and aorta was measured using a 4-slice LightSpeed QXI and reported as Agatston scores. Incident CVD events included myocardial infarction, coronary revascularization procedures, stroke, transient ischemic attack, new-onset heart failure, sudden cardiac death, and peripheral vascular disease requiring revascularization or amputation. Multiple linear regression and Cox proportional hazard analyses assessed the relationship of tryptophan metabolites to subclinical markers of CVD and CVD events.

Results: We found that lower baseline tryptophan levels predicted increased aortic calcification in a fully adjusted model controlling for demographics, CVD history, traditional risk factors, renal function, CRP, and serum albumin (p<0.006). Higher baseline levels of anthranilic acid and hydroxanthranilic acid predicted increased coronary calcification and higher total Agatston score, respectively, in the fully adjusted model (p=0.03 and p=0.03). One unit decrease in serum tryptophan at baseline is associated with 70% decrease in time to incident CVD event when adjusting for demographics, CVD history, risk factors, and renal function (HR: 0.31, p<0.04). Increased anthranilic acid and quinolinic acid independently reduced time to incident CVD event (HR: 1.88, p=0.02; HR: 0.62, p=0.007, respectively), but were not significant in the fully adjusted model.

Conclusions: Lower tryptophan levels are associated with increased aortic calcification and decreased time to incident CVD events. Higher levels of anthranilic acid, hydroxanthranilic acid, and quinolinic acid are associated with subclinical CVD. Together, these data suggest that catabolism of tryptophan via the kynurenine pathway is associated with subclinical CVD and predicts cardiovascular events in CKD.

High Level of Uromodulin Increases the Risk of Hypertension: A Mendelian Randomization Study
Ruijian You, Lanlan Chen, Lubin Xu, Haitao Li, Xiaoxiao Shi, Yali Zheng, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China; Jilin University, Changchun, China; Ningxia Medical University, Yinchuan, China.

Background: The association of uromodulin and hypertension was clinically observed, but not proved as a causal relationship. We conducted a two-sample Mendelian randomization analysis to investigate the causal relationship between uromodulin and blood pressure based on the public datasets.

Methods: We selected two SNPs for the uUMOD exposure from the Genome-Wide Association Studies (GWAS) meta-analysis study(N=10884) and sixteen SNPs for uUMOD. These data demonstrate that catabolism of uromodulin(uUMOD) in the kidney results in increased blood pressure

Results: We found that lower baseline tryptophan levels predicted increased aortic calcification in a fully adjusted model controlling for demographics, CVD history, traditional risk factors, renal function, CRP, and serum albumin (p<0.006). Higher baseline levels of anthranilic acid and hydroxanthranilic acid predicted increased coronary calcification and higher total Agatston score, respectively, in the fully adjusted model (p=0.03 and p=0.03). One unit decrease in serum tryptophan at baseline is associated with 70% decrease in time to incident CVD event when adjusting for demographics, CVD history, risk factors, and renal function (HR: 0.31, p<0.04). Increased anthranilic acid and quinolinic acid independently reduced time to incident CVD event (HR: 1.88, p=0.02; HR: 0.62, p=0.007, respectively), but were not significant in the fully adjusted model.

Conclusions: Lower tryptophan levels are associated with increased aortic calcification and decreased time to incident CVD events. Higher levels of anthranilic acid, hydroxanthranilic acid, and quinolinic acid are associated with subclinical CVD. Together, these data suggest that catabolism of tryptophan via the kynurenine pathway is associated with subclinical CVD and predicts cardiovascular events in CKD.

PO1778
Follistatin Is a Potential Novel Therapeutic Agent for Essential Hypertension
Ann Kuganathan, Marcos S. Leal, Chao Lu, Bo Gao, Jeffrey G. Dickhout, Joan C. Krepinsky. McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.

Background: Follistatin (FST) is an inhibitor of several members of the proline-rich TGFβ superfamily. It is highly effective at neutralizing activins, without activity against TGFβ itself. Activins are known to induce inflammation, oxidative stress and fibrosis, all of which contribute to the vascular dysfunction characteristic of hypertension (HTN). We previously showed that FST inhibits kidney fibrosis, improves kidney function and lowers blood pressure (BP) in a hypertensive chronic kidney disease mouse model. While this is a model of secondary HTN, here we seek to analyze the efficacy of FST in improving BP and vascular structure and function in a model of essential HTN.

Methods: Telemeters were implanted in the abdominal aorta of spontaneously hypertensive rats (SHR), a model of essential HTN, and normotensive control Wistar Kyoto (WKY) rats for wireless BP monitoring. Rats were treated with 0.075mg/kg FST or vehicle IP every other day from 12-20 weeks of age (8 weeks). BP was recorded weekly. First branch mesenteric arteries were harvested for analysis of vascular function using myography, assessed for oxidative stress by DHE, or formalin fixed for IHC.

Results: By the end of the study, FST significantly lowered both systolic and diastolic BP in SHRs (208 +/- 9 over 132 +/- 4 mmHg in control and 189 +/- 2 over 123 +/- 2 mmHg in FST-treated SHRs, P < 0.04 and P < 0.03 respectively). SHR vessels showed increased contractility with the α1 adrenergic agonist phenylephrine, which was attenuated by FST. Post streptozotocin (STZ) injection-induced relaxation in SHR vessels was also improved by FST. Structurally, FST-treated vessels had less collagen deposition, assessed by Trichrome, which was accompanied by a reduction in medial thickness. Increased oxidative stress seen in SHR vessels was inhibited by FST.

Conclusions: FST lowers BP in SHR with established HTN, at least in part by reducing vascular oxidative stress and medial thickening. This manifests as improved vascular function, with decreased hypersensitivity to contractile agents and improved endothelial function. Future work will identify the effects of FST on inflammation, and the role of specific activins in essential HTN.

Age and Sex Disparities in Hypertension Treatment Inertia After Implementation of Target: BP
Olivia Myers, Talar Markossian, Beatrice D. Probst, Katherine Habich, Holly J. Kramer. Loyola University Chicago, Chicago, IL; Loyola University Health System, Maywood, IL.

Background: Blood pressure (BP) control decreases with advancing age among women but not men, but reasons for sex disparities remain uncertain. Our institution enrolled four large outpatient primary care clinics in the Target:BP hypertension improvement program in 2018. This hypertension improvement program included audit and feedback of physician prescribing practices of BP lowering medications. We examined the adjusted association of medication escalation, a measure of treatment inertia, with age group among adults with uncontrolled hypertension and determined whether this association is modified by sex. We hypothesized that medication escalation for BP control differs by age group and by sex.

Methods: Adults aged 18 years with uncontrolled hypertension (BP ≥ 140/90 mmHg at last visit) receiving primary care at a clinic enrolled in Target:BP and a 1 primary care visit during 2019 were included. Medication escalation was defined as a change in BP lowering medication class or dose during a visit when hypertension was uncontrolled. Mixed effects models were used to calculate adjusted odds of medication escalation by age group (≤ 65, 66-75, ≥ 76 years) after adjustment for demographics and co-morbidities. Interaction term of sex* age group was then fitted in fully adjusted mixed effects models and was significant (P < 0.001). Adjusted odds of medication escalation were then calculated by sex and by age group and adjusted prevalence of medication escalation by age group and by sex was calculated using marginal effects.

Results: Mean age of 5973 adults with uncontrolled hypertension was 65.2 (SD 18) years; 54.7% were women; 64.7% were White, 24.0% were Black and 9.9% were Hispanic ethnicity. Figure (left panel) shows that adjusted prevalence of medication escalation declined with advancing age group among men and women combined. Right panel shows the decline in medication escalation with advancing age group differed by sex until age 76 years.

Conclusions: Medication escalation for uncontrolled hypertension declines with advancing age and this age associated treatment inertia differs by sex.
Oscillometric vs. Auscultatory Blood Pressure Measurements and the Impact of Atrial Fibrillation
Ahmed Aburahma, Christopher B. McFadden. Cooper University Health Care, Camden, NJ.

Background: The Hypertension literature recognizes a difference in Oscillometric Blood pressures compared to Auscultatory Blood pressure measurements. These differences are small but increased in patients with Atrial fibrillation. This difference varies in previous studies. Again this Difference is larger in subjects with atrial fibrillation. Current Blood pressure measurement guidelines emphasize the use of an Auscultatory method or repeated oscillometric measures to measure blood pressure in patient with arrhythmias including atrial fibrillation. This recommendation is not consistently implemented in clinical medicine. We aim to quantify the differences in blood pressure readings between oscillometric and auscultatory method and correlate that to presence or absence of atrial fibrillation.

Methods: This is a retrospective study that involved adult patients seen in the outpatient nephrology clinic by one of the investigators (CM) between January 2016 and January 2020. Data collection included age, sex, BMI, atrial fibrillation (AF), CKD stage, diabetes mellitus, blood pressure readings (by both methods, which were done by the investigator (CM) in all antihypertensive patients) and number of blood pressure medications. Information on a total of 200 patients were collected. 100 of those had hypertension with AF while the other 100 had hypertension but no AF to achieve a power of 80% and P value of 0.05.

Results: After using Unpaired t test, the average difference between two methods in hypotensive patients (259 µmHg) was significantly lower than systolic blood pressure (P value of 0.9 and 95% CI from -5.5 to 6.12) and 5.39 mmHg in diastolic blood pressure (P value of 0.0068 and 95% CI from 1.5 to 9.24). On the other hand, the average difference between two methods in hypertensive patients with atrial fibrillation were 6.8 mmHg in systolic blood pressure (P value of 0.018 and 95% CI from 1.18 to 12.5) and 5.04 mmHg in diastolic blood pressure (P value of 0.002 and 95% CI from 1.87 to 8.21).

Conclusions: This study showed a statistical difference between the two methods in measuring the blood pressure of hypertensive patients with atrial fibrillation. A larger study is needed to show the difference between the two methods. For now we need to encourage the use of auscultatory method in measuring the Blood pressure in this group of patients.

Small Changes in eGFR Are Associated with Different Patterns of 24-Hour Ambulatory Blood Pressure Monitoring in the General Population
Sang Youn Han,1 Sanggon Yoon,2 Seung Ku Lee,2 Chol Shin.3 Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; 3Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

Background: Alteration of circadian blood pressure (BP) rhythm such as non-dipper and reverse-dipper pattern is associated with cardiovascular diseases and chronic kidney disease (CKD). However, most studies did not control for kidney function even though kidney function is an important risk factor. In this study, we tried to show 24-h ambulatory blood pressure monitoring (ABPM) patterns based on an eGFR in patients without CKD.

Methods: This study was a cross-sectional study from the data of the Korean Genome and Epidemiology Study, which is ongoing prospective cohort study. A total of 1733 participants (60.0±7.00 years, 938 women) who had an eGFR > 60 ml/min/1.73m2 were included. Dipping status was stratified as reverse dipper (≥<10%), non-dipper (0% to <<10%), and dipper (≥10%) based on the night to day ratio of mean BP. They were divided into 4 groups based on quartile of an eGFR (Q4, 128.6-101.6 g, Q3, 101.5-95.7, Q2, 95.6-87.4, Q1, 87.3-60.5).

Results: The proportion of dipper was progressively decreased from the highest to the lowest eGFR whereas that of reverse dipper and non-dipper significantly increased. (P<0.001). We analyzed the data using logistic regression model in relation to dipper, non-dipper, reverse dipper, and non-plus reverse dipper according to the quartiles of an eGFR. The highest quartile group (Q4) was fixed as the reference. In univariate analyses, Q1 and Q2 groups were significantly associated with increased odds ratio (OR) with reverse dipper and reverse plus non-dipper plus reverse dipper. After full-adjustment with age, sex, hypertension, diabetes, body mass index, smoking status, exercise, and alcohol consumption, the lowest eGFR group was significantly associated with reverse dippers and non-dipper plus reverse dippers compared to the highest eGFR group (OR=1.689, 95% CI, 1.005-2.840, OR=1.427, 95% CI, 1.027-1.855, respectively). The significant linear trend of non-dipper plus reverse dipper with a decrease in eGFR was confirmed with the test for trend (P=0.024).

Conclusions: Small changes in eGFR are associated with different pattern of 24-h ABPM in general population. ABPM could be useful tool to detect patients with non-dipper in this population.

Small Changes in eGFR Are Associated with Different Patterns of 24-Hour Ambulatory Blood Pressure Monitoring in the General Population
Sang Youn Han,1 Sanggon Yoon,2 Seung Ku Lee,2 Chol Shin.3 Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; 3Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

After full-adjustment with age, sex, hypertension, diabetes, body mass index, smoking status, exercise, and alcohol consumption, the lowest eGFR group was significantly associated with reverse dippers and non-dipper plus reverse dippers compared to the highest eGFR group (OR=1.689, 95% CI, 1.005-2.840, OR=1.427, 95% CI, 1.027-1.855, respectively). The significant linear trend of non-dipper plus reverse dipper with a decrease in eGFR was confirmed with the test for trend (P=0.024).

Conclusions: Small changes in eGFR are associated with different pattern of 24-h ABPM in general population. ABPM could be useful tool to detect patients with non-dipper in this population.
PO1784
Crit-Line Monitoring Effect on Blood Pressure Control in ESRD Patients Undergoing In-Center Hemodialysis
Washington University in St Louis, St Louis, MO.

Background: Patients with end stage renal disease (ESRD) are admitted to the hospital about twice per year, with a 35% readmission rate. Cardiovascular disease (CVD) makes up 28% of admissions; 38% of patients with CVD admissions have pulmonary edema. Fluid overload in ESRD increases morbidity and mortality. Fluid management improvements have potential to positively impact clinic outcomes in dialysis patients.

Methods: This was a prospective cohort study with adult patients at two outpatient dialysis facilities on the Washington University in St Louis Campus. Our inclusion criteria were patients with consistent 3x weekly in-center hemodialysis defined as 80% attendance in the 30 days prior to the study. A Critline protocol was implemented by the treatment team (Figure 1).

Results: Among 58 qualified patients, average age was 59. 77% were African American with male predominance (57%). Average BMI was 29. In the Critline cohort, systolic blood pressure trended down (Figure 2). In the initial 25 weeks, average number of antihypertensive medications per patient decreased from 2.6 to 1.8. The number of admissions for fluid overload stayed stable at 10, however readmissions decreased from 4 to 1.

Conclusions: Implementing a Critline protocol trended improvements in blood pressure and reduced number of antihypertensives medications. Our findings suggest that a protocolized approach to fluid management using critline will improve our patients outcomes.

Methods: We conducted a cross-sectional study of 241 CKD stage 5 patients from the Cardiopulmonary Exercise Testing in Renal Failure (CAPER) cohort. VO2peak (primary endpoint) was assessed by cardiopulmonary exercise testing (CPET) in parallel with transthoracic echocardiography.

Results: Of the 241 patients (mean age [SD] age, 48.9 [14.9] years; 154 [65.9%] males) 105 patients were pre-dialysis (mean eGFR [SD], 14 [3.4] ml/min/1.73m2). Major CVD was in tertile 1 of dialysis vintage (0-17 months), n=69 in tertile 2 (18-50 months) and n=64 in tertile 3 (>51 months). Predialysis patients had an impaired VO2peak of 22.7 [5.2] ml/min/kg, and this significantly declined to 18.5 [5.5] ml/min/kg in tertile 1 dialysis patients compared to the pre-dialysis group, tertile 1 dialysis patients exhibited reduced maximal workload (p=0.003), impaired maximal heart rate (p=0.02), increased LVMi (p=0.001) and markedly elevated FGF23 levels (p=0.01). On assessment of the effects of dialysis vintage, we found an incremental downward trend in VO2peak across the groups (4.5 [2.2] tertile 1, 18.4 [7.1] tertile 2, 16.9 [4.2] ml/min/kg) following exclusion of patients who had prior kidney transplants, however this did not reach statistical significance (p=0.2).

Conclusions: Initiating dialysis in advanced CKD patients is associated with impaired CFC comparable to declines seen in new onset heart failure, making this a critical time for these patients.

PO1786
Major Adverse Limb Events and Mortality After Peripheral Artery Revascularization in Hemodialysis Patients
Ting-yun Lin, Szu-Chun Hung. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Revascularization is important for symptom relief and limb salvage in peripheral artery disease, yet limited information exists on the prognosis of hemodialysis patients who receive the procedure. This study sought to determine the incidence and associated factors of major adverse limb events (MALE) after peripheral artery revascularization among hemodialysis patients.

Methods: Hemodialysis patients undergoing peripheral artery revascularization between July 1, 2005, and December 31, 2019, in the Taipei Tzu Chi Hospital were examined for the primary outcome of MALE, defined as severe limb ischemia leading to an intervention or amputation. The secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality. Multivariable-adjusted Cox proportional hazards models were used to explore risk factors associated with development of MALE.

Results: A total of 402 hemodialysis patients were included in the final analysis. Overall, the mean age was 68 years, 56.5% (n = 227) were male, 83.3% (n = 335) had diabetes, and 58.0% (n = 233) had coronary artery disease. During a median follow-up of 2.2 years, 54.0% (n = 217) experienced a subsequent MALE. 33.6% (n = 136) had a MACE, and 54.5% (n = 219) died. Diabetes, coronary artery disease, current smoking, lower body mass index, and higher platelet count or total cholesterol were significantly associated with increased risk of post-procedure MALE.

Conclusions: A significant proportion of hemodialysis patients undergoing peripheral artery revascularization developed a subsequent MALE and MACE or died. Strategies that address risk factors for MALE should be evaluated to improve the outcomes of revascularized hemodialysis patients.

PO1785
Cardiovascular Functional Changes in Transplant Waitlist Dialysis Patients
Peter E. Ummukoro,1 Tzongshi Lu,2 Sharon M. Moe,1 Ranjani N. Moorthi,3 Gordon Megregor,2 Thomas F. Hiennstra,2 Kenneth Lim.1 Indiana University School of Medicine, Indianapolis, IN; 2Brigham and Women’s Hospital, Boston, MA; 3University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; 4University of Warwick Warwick Medical School, Coventry, United Kingdom.

Background: The transition to dialysis is a crucial time in patients with advanced chronic kidney disease (CKD), conferred an increased risk for cardiovascular death. We recently showed that VO2peak, an index of cardiovascular functional capacity (CFC) significantly declined in advanced CKD patients following 1-year follow-up in the absence of changes in left ventricular mass index (LVMI). Herein, we hypothesized that initiating dialysis and continuing dialysis could worsen an individual’s CFC over time.

Conclusions: A protocolized approach to fluid management using critline will improve outcomes in dialysis patients.

Methods: This was a prospective cohort study with adult patients at two outpatient dialysis facilities on the Washington University in St Louis Campus. Our inclusion criteria were patients with consistent 3x weekly in-center hemodialysis defined as 80% attendance in the 30 days prior to the study. A Critline protocol was implemented by the treatment team (Figure 1).

Results: Among 58 qualified patients, average age was 59. 77% were African American with male predominance (57%). Average BMI was 29. In the Critline cohort, systolic blood pressure trended down (Figure 2). In the initial 25 weeks, average number of antihypertensive medications per patient decreased from 2.6 to 1.8. The number of admissions for fluid overload stayed stable at 10, however readmissions decreased from 4 to 1.

Conclusions: Implementing a Critline protocol trended improvements in blood pressure and reduced number of antihypertensives medications. Our findings suggest that a protocolized approach to fluid management using critline will improve our patients outcomes.

Conclusions: Initiating dialysis in advanced CKD patients is associated with impaired CFC comparable to declines seen in new onset heart failure, making this a critical time for these patients.

Conclusions: A significant proportion of hemodialysis patients undergoing peripheral artery revascularization developed a subsequent MALE and MACE or died. Strategies that address risk factors for MALE should be evaluated to improve the outcomes of revascularized hemodialysis patients.

PO1787
Central Blood Pressure Calibration Method and Cardiovascular Risk Prediction According to Sex
Florence Lamarche,1 Mohsen Agharazii,3 Annie-Claire Nadeau-Fredette,2 Francois Madore,1 Remi Goupil.1 Hôpital du Sacré-Coeur de Montréal, Montreal, QC, Canada; 2Hôpital Maisonneuve-Rosemont, Montréal, QC, Canada; 3CHU de Québec-Universite Laval, Quebec, QC, Canada.

Background: The accuracy of central BP is improved when calibrated on the mean BP and diastolic BP (CBSBP) compared to calibration on the systolic BP and diastolic BP (CBSBP). Furthermore, preliminary data suggest CBSBP may have the best accuracy in females. We aim to assess whether this enhanced accuracy translates into improved cardiovascular (CV) risk prediction when compared to brachial SBP (bsBP) and CBSBP in the general population and stratified by sex.

Methods: 12,927 participants exempt of known CV disease, with prospective follow-up from administrative databases and central BP measurements based on the SphygmoCor device was used to estimate CBSBP. CBSBP was derived from uncompensated radial pressure waveforms extracted from SphygmoCor output data, which was recalibrated with diastolic BP and 40% form factor derived mean BP. Participants with heart rate >60 were excluded due to incomplete waveform. Major CV events (MACE) comprised myocardial infarction, stroke, heart failure with hospitalization and CV death. Multivariable Cox regressions, differences in area under the curve, net reclassification index and integrated discrimination index were calculated comparing CBSBP to bsSBP and to CBSBP.

Results: Over a median follow-up of 10.1 years (IQR 9.9-10.3), there were 2125 MACE (723/7013 females and 860/5934 males). All BP parameters were significantly associated with MACE, regardless of sex. In the overall cohort, risk prediction metrics marginally favored CBSBP compared to bsSBP but were similar to CBSBP. No significant improvement of CV risk prediction was found in sex-stratified analyses (see Table).

Conclusions: CBSBP marginally improved CV risk prediction when compared to bsSBP but not CBSBP in the overall cohort only. All three BP parameters were similarly predictive in both sex, although this analysis possibly lacked power. This may be related to the FF-derived MAP (rather than oscillometric MAP), which is highly dependent on the brachial SBP.

Suppressed Renin Activity in CKD: Are We Missing Primary Hyperaldosteronism?
Mohammad D. D. El Shafie,1,2 Georges Nakhoul,3 Susana Arrigain,3 Jesse D. Schold,3 Jonathan J. Tailerisco,3 George Thomas,2 Ali Mehdi.2 1 Cleveland Clinic, Cleveland, OH; 2 Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.

Background: Primary hyperaldosteronism (PA) is more prevalent than once thought and associated with adverse kidney and cardiovascular outcomes. A prior analysis of the CKD registry at the Cleveland Clinic in patients without a diagnosis of PA showed that the lowest quartile of plasma renin activity (PRA) (PRA ≤20 ng/ml/hr) had severe hypertension and faster eGFR decline. We hypothesized that some of these patients with suppressed PRA may have undiagnosed PA.

Methods: We reviewed patients in the Cleveland Clinic CKD registry with documented PRA and absolute plasma aldosterone concentration (PAC). Patients in the lowest PRA quartile were identified and stratified by PRA/PAC ratio. A cutoff ratio of ≥20 was considered suggestive of PA regardless of the PAC. Characteristics and outcomes of these two subgroups were compared using t-tests, chi-square tests, Kaplan-Meier analyses and Cox models.

Results: 576 patients were identified for this analysis. Median PRA and PAC were 0.5 μg/L/hr and 8.7 ng/dl respectively. 141 (51%) patients had a PAC/PRA ratio of ≥20 with a median PAC of 14.6 ng/dl in this subgroup. Patients with PAC>PRA of a ≥20 vs. <20 had significantly lower eGFR (mean: 50.7 vs. 55.4 mL/min/1.73 m²; p<0.009), more resistant hypertension (63.1% vs. 48.9%; p=0.044), lower serum potassium values (mean: 3.9 vs. 4.2 mmol/L; p<0.001), and higher serum bicarbonate levels (mean: 26.4 vs. 25.3 mmol/L; p=0.0001). With median follow up of 4.2 years, there was no difference in mortality between the two subgroups on adjusted cox model analysis (HR for ≥20 vs.<20: 0.83, 95%CI: 0.47,1.47). No difference in ESKD-free survival at 5 years was noted but the event rate was low (92.6 vs. 91.9 for ≥20 vs.<20; p=0.77).

Conclusions: Our analysis indicates that some CKD patients with suppressed PRA may have underlying PA. More than half of our suppressed PRA cohort had elevated PAC/PRA ratio of ≥20 suggestive of PA. The biochemical profile and severe hypertension further supports this diagnosis. We hypothesize that the diagnosis of PA was possibly ruled out because of the “not very high” PAC. Given the limitations of the spot PAC/PRA screen to diurnal PAC variations, a suppressed PRA should merit an in-depth evaluation for undiagnosed PA regardless of the PAC. Making this diagnosis is critical since it has significant therapeutic implications.

POI1790
Cardiovascular and Renal Outcomes of the New Intensive Blood Pressure Target in a CKD Population in Korea
Kyunghwan Jeong,1 Soo-Yoon Yoon,1 Ji Yoon Kong,2 Daeyoung Kim,1 Jongho Kim,1 Shinyeong Kang,1 Jin sug Kim,1 Heyeon Seok Hwang.1 Kyung Hee University Medical Center, Seoul, Republic of Korea; 2Kyung Hee University, Seoul, Republic of Korea.

Background: Hypertension is one of the most important modifiable risk factors of cardiovascular disease (CVD) including ischemic heart disease (IHD) and stroke. The 2021 kidney disease: improving global outcomes (KDIGO) clinical practice guideline for the management of blood pressure (BP) in CKD recommended a target systolic BP (SBP) <120 mmHg regarding of albuminuria, using standardized office BP measurement. We evaluated the prevalence of cardiovascular events and CVD progression to assess the adequacy of this intensive BP target for CKD patients in Korea.

Methods: The data of 166,397 adults whose baseline estimated glomerular filtration rate (eGFR) <60 mL/min per 1.73 m² were extracted from the Korean national health insurance service database between 2009 and 2011. The data were adjusted for multiple factors such as age, sex, smoking, eGFR, and anti-hypertensive medications in multivariable Cox proportional hazards regression models. All patients were divided into four SBP categories (<120 mmHg, 120-129 mmHg, 130-139 mmHg, ≥140 mmHg). The primary outcome was CVD risk, and the secondary outcome was the risk of progression to end-stage renal disease (ESRD), especially in need of intermittent hemodialysis (HD).

Results: The mean ages of the each group of CKD patients were 45.1±15.7 years in SBP <120 mmHg group and 52.13±16.0 years in SBP 120-129 mmHg group, 11.1% in SBP ≥130 mmHg group and 24.6% in SBP 120-129 mmHg group of the participants were already taking anti-hypertensive medications. 112,012 patients (67.3%) had SBP ≥120 mmHg, and 78,119 patients (46.9%) had SBP ≥130 mmHg. Participants with SBP ≥120-129 mmHg exhibited a significantly high risk for IHD (hazard ratio (HR), 1.29; 95% confidence interval (CI), 1.03-1.61; P = 0.03) and stroke (HR, 1.57; 95% CI, 1.13-2.18; P <0.01) when compared with the participants with SBP <120 mmHg. Also, the risk of progression to ESRD was also higher (HR, 1.67; 95% CI, 1.46-1.91; P<0.001). Similar trend of findings were observed between the group with SBP<120 mmHg and the other groups.

Conclusions: Therefore, the new intensive BP target can be applied to the real clinical practice in CKD population with proper BP monitoring in Korea and it may eventually reduce the risk of CVD and progression to ESRD in a number of CKD patients.

POI1791
Intensive Blood Pressure Control, Age, and All-Cause Mortality in the US Veterans Health Administration
Masaaki Yamada,1,2 Benjamin R. Griffin,3,2 Jason Wachsmuth,2 Meenakshi Sambharia,1 Melissa L. Sweeney,3 Saket R. Girotra,2 Heather Reissinger,3 Brian C. Lund,2 Mary V. Sarrazin,2 Diana J. Jalal.1,2 The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; 2Department of Research as & Development, Iowa City VA Medical Center, Iowa City, IA; 3Institute for Clinical and Translational Science, Iowa City, IA.

Background: Intensive blood pressure (BP) control has been shown to improve survival in large clinical trials. It is unknown if intensive BP control is associated with improved outcomes amongst older adults in the real-world setting. We examined the association of intensive BP control with all-cause mortality in U.S. Veterans.

Methods: This retrospective analysis of Veterans Health Administration (VHA) data included Veterans with ≥2 systolic blood pressure (SBP) readings between January 2016 and December 2017 excluding those with mean SBP <100 mmHg to minimize reverse causation. Prevalent hypertension was defined as diagnostic codes related to hypertension, prescribed antihypertensive drugs, or ≥2 office BP of ≥130/90 mmHg. The following SBP categories were investigated: SBP <120 mmHg, ≥120-129 mmHg, and ≥130 mmHg. A two-way interaction between SBP category and age was examined to assess if the effect of BP control on mortality differed by age category.

Results: We estimated the potential effect of SBP control on all-cause mortality and evaluated the potential interaction with age using a random-effect Cox regression model. Among the 1,959,003 Veterans, 18% had SBP <120 mmHg (n=352,684), 26% had SBP 120-129 mmHg (n=507,907), and 56% had SBP ≥130 mmHg (n=1,098,412). Mean SBP <120 and 120-129 mmHg associated significantly with mortality (the adjusted hazard ratio [aHR] was 1.30; 95% confidence interval [CI] 1.26-1.32 for SBP ≥120 mmHg and 1.03 [95% CI 1.01-1.04] for SBP 120-129 mmHg). There was a significant interaction between SBP category and age (p<0.01). Specifically, we observed a graded association of SBP <120 mmHg with all-cause mortality across increased age categories; this association was significant in the age categories 70 years (Figure 1).

Conclusions: Based on the analysis of real-world data of approximately 1.9 million Veterans, intensive BP control (SBP <120 mmHg) was associated with higher mortality specifically among older Veterans. These data have implications for BP management and suggest that intensive control of SBP may be harmful in older adults.

Markers of Kidney Tubular Secretion and Risk of Cardiovascular Disease and Mortality in Persons with CKD in SPRINT

Simon Ascher,1,2 Ronit Katz,3 Rebecca Scherzer,1 Alexander Bullen,4,5
Cheng-Ta Lee,6 Jesse Stein,7 Simon Malhotra,4 Michelle Estrella,2 Jesse C. Seegmiller,1 Joachim H. Ix,3,7 Michael Shlipak,3 Pranav S. Garimella,1
1Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; 2University of California Davis, Davis, CA; 3University of Washington, Seattle, WA; 4University of California San Diego, La Jolla, CA; 5Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; 6University of Minnesota Academic Health Center, Minneapolis, MN; 7Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion of organic solutes is essential to the clearance of many drugs, metabolites, and toxins. Whether novel measures of tubular secretion have prognostic value for cardiovascular and mortality risk among hypertensive, nondiabetic persons with CKD is uncertain.

Methods: In 2008 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. We used multivariable Cox proportional hazards models to evaluate associations between secretion scores and risk of Cardiovascular disease (CVD) and all-cause mortality.

Results: Mean age at baseline was 73 ± 9 years and mean eGFR was 46 ± 11 ml/min/1.73m2. There were 272 CVD events and 144 deaths during a median follow-up of 3.26 years. Unadjusted analyses, a 1-SD higher secretion score was associated with a lower risk of CVD (hazard ratio [HR] per 1.73m2). There were 272 CVD events and 144 deaths during a median follow-up of 3.26 years. In adjusted analyses, a 1-SD higher secretion score was associated with a lower risk of CVD (HR: 0.87; 95% CI: 0.76, 0.99), but not all-cause mortality (HR: 1.12, 95% CI: 0.95, 1.33).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was not significantly associated with risk of CVD or mortality after adjustment for eGFR and albuminuria.

MARKERS OF KIDNEY TUBULAR SECRETION AND RISK OF ADVERSE EVENTS IN PERSONS WITH CKD IN SPRINT

Simon Ascher,1,2 Rebecca Scherzer,1 Pranav S. Garimella,1 Ronit Katz,4 Stein I. Hallan,5 Vasanthan Jotwani,5 Rakesh Malhotra,5 Michelle M. Estrella,2 Jesse C. Seegmiller,1 Joachim H. Ix,3,7 Michael Shlipak,3 Alexander Bullen,2
1Kidney Health Research Collaborative, Department of Medicine, San Francisco Veterans Affairs Health Care System and University of California San Francisco, San Francisco, CA; 2University of California Davis, Davis, CA; 3University of California San Diego, La Jolla, CA; 4University of California San Francisco, San Francisco, CA; 5Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; 6University of Minnesota Academic Health Center, Minneapolis, MN; 7Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Tubular secretion is an essential mechanism for the elimination of many drugs, metabolites, and toxins. Impaired tubular secretion may contribute to the high burden of adverse events (AEs) in persons with CKD. Whether novel measures of tubular secretion have prognostic value for AEs during hypertension treatment is unknown.

Methods: In 2008 SPRINT (Systolic Blood Pressure Intervention Trial) participants with baseline eGFR <60 ml/min/1.73m2, we created a summary secretion score from 10 tubular secretion biomarkers by averaging across their urine-to-plasma ratios. Multivariable Cox proportional hazards models were used to evaluate associations between secretion scores and risk of a composite of pre-specified serious AEs (hypertension, syncope, bradycardia, acute kidney injury, electrolyte abnormalities, and injurious falls) and two outpatient AEs (hyperkalemia and hypokalemia).

Results: Mean age was 73 ± 9 years and mean eGFR was 46 ± 11 ml/min/1.73m2. Overall, 30% of participants experienced at least one AE during a median follow-up of 3.2 years. The association between secretion score and composite AE risk followed a curvilinear pattern. Compared to the lowest secretion score quartile, the highest quartile was associated with reduced risk of the composite AE in analyses adjusting for demographics and clinical characteristics (hazard ratio [HR]: 0.63; 95% CI: 0.44, 0.91) (Table). After additionally adjusting for baseline eGFR and albuminuria, the association attenuated and was no longer significant (HR: 1.01, 95% CI: 0.67, 1.50). In multivariable analyses of the individual AEs, higher secretion was independently associated with higher risk of syncope or hypotension (HR per 1-SD higher secretion score: 1.30, 95% CI: 1.10, 1.54) and lower risk of ambulatory hyperkalemia (HR: 0.71, 95% CI: 0.54, 0.95).

Conclusions: Among SPRINT participants with CKD, higher tubular secretion was associated with lower AE risk, but this association was not independent of eGFR and albuminuria.

Longitudinal Changes in FGF-23 and High-Sensitivity C-Reactive Protein with Incident CKD in the Accord-BP Trial

Wenjin Liu,1 Yufeng Huang,2 Robert E. Boucher,1 Guo Wei,3 Glenn M. Chertow,2 Srinivasan Beddhu,1,4 1University of Utah School of Medicine, Salt Lake City, UT; 2VA Salt Lake City Health Care System, Salt Lake City, UT; 3Stanford University, Stanford, CA.

Background: In adults over 50 with increased cardiovascular (CV) risk, intensive systolic blood pressure (SBP) lowering reduces the risk of death and major CV events, but increases the risk of incident CKD. Metabolic manifestations of incident CKD related to intensive SBP lowering are unknown. Here we explored the relation between incident CKD and FGF23, an early marker of bone and mineral metabolism, in participants enrolled in the ACCORD-BP trial.

Methods: We included 362 ACCORD BP participants with incident CKD during follow-up along with 359 control participants without any kidney events. Control participants were matched for age, sex, race/ethnicity, SBP intervention and glycemia treatment arms. Incident CKD was defined as a >30% decrease in eGFR to <60 ml/min/1.73m2. Serum concentrations of FGF23 and hs-CRP were measured using Meso Scale Discovery fluorescent immunoassays platform at baseline, month 24 and 48–close out. Differences from baseline were estimated for the average of month 24 and 48–close out using mixed effect models with fixed effects for group and visit.

Results: Mean age was 63±9 years, 55% women, and 30% non-white. Baseline duration of diabetes was 11±8 years; baseline eGFR, FGF23 and hs-CRP in the incident CKD and control groups were 87±17 and 92±19, 76(55,107) and 52(40,76) pg/ml and 3.2 (1.3,7.2) and 3.8(1.3,12.0) µm/ml, respectively. Longitudinal changes in these parameters are summarized in the Table and Figure.
POI1795

Carotid Plaque Characteristics and Incident Cognitive Impairment in Hypertensive Adults

L ParkerGregg,1,2 Srinivasan Beddu,1,2,4 Robert E. Boucher,3,4 Manjula Kurella Tamura,1 Chun Yuan,1 Je Sun,2 Niranjan Balu,2 Nicholas M. Pajewski,7 Jeff D. Williamson,6 Sankar D. Navaneethan,1,2 3,4 Baylor College of Medicine, Houston, TX; 5Michael E DeBakey VA Medical Center, Houston, TX; 6University of Utah Health, Salt Lake City, UT; 7VA Salt Lake City Health Care System, Salt Lake City, UT; 8Stanford Medicine, Stanford, CA; 9University of Washington, Seattle, WA; 10Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Carotid atherosclerosis is associated with cognitive impairment. We investigated associations of plaque characteristics on carotid magnetic resonance imaging (MRI) with the development of mild cognitive impairment (MCI) or probable dementia.

Methods: In an ancillary study to the Systolic Blood Pressure Intervention Trial (SPRINT), carotid plaque was identified by MRI and characterized as having a lipid-rich necrotic core (NC) or calcification. In the parent study, adjudicated MCI and probable dementia were associated with both pre-event (odds ratio [OR], 2.04 [95% CI, 1.52–2.72]; P<0.001) and post-event dementia (hazard ratio [HR], 2.01 [95% CI, 1.65–2.44]; P<0.001) however, these associations attenuated and became non-significant after adjustment for the above covariates (OR=0.92 [0.65–1.31]; P=0.65 and HR=1.09 [0.85–1.39]; P=0.50). The results were similar when a competing risk model was used (subdistribution HR [SHR] =1.74 [1.43–2.12]; P<0.001, attenuating to 1.01 [0.78–1.33]; P=0.92 with complete adjustment). CKD was more strongly associated with late (>1 year) post-event dementia (SHR=2.32, 1.70–3.17; P<0.001), particularly in the minor events subgroup (SHR=3.08, 2.05–4.64; P<0.001), but not significantly so after complete adjustment (SHR=1.53, 0.90–2.60; P=0.12).

Results: Of 465 participants, 137 (29.5%) had NC plaque. Those with NC plaque were older and more likely to have cardiovascular disease than those without NC plaque. There were 38 MCI/probable dementia outcomes in the entire cohort over 2220 person-years of follow-up. The incidence (95% CI) of a composite outcome of MCI or probable dementia at 3 years of follow-up was 12.0% (7.5, 18.9) in the NC group and 7.0% (4.6, 10.4) in the no NC group with an absolute risk difference of 5.1% (95% CI -1.2, 11.3, P=0.11). With further adjustment, the absolute risk difference attenuated but the point estimate remained high (Figure). Results for the presence of any plaque or calcified plaque with MCI/probable dementia are also summarized in the Figure.

Conclusions: We observed large differences in risk for MCI/probable dementia associated with the presence vs. absence of NC plaques, but the significance of this finding was uncertain due to the small number of incident cases of cognitive impairment. Nonetheless, our observations indicate the need to study NC plaque as a novel and potentially more relevant marker of vascular health in future studies of cognitive impairment in hypertensive adults.

POI1796

Associations of CKD with Dementia Before and After Transient Ischemic Attack and Stroke in a Population-Based Cohort Study

Background: Individuals with chronic kidney disease (CKD) appear to have a greater risk of developing cognitive disorders than the general population. Both vascular and neurodegenerative hypotheses have been proposed to underlie this cognitive burden.

To explore the vascular hypothesis further, we investigated the association between CKD and dementia before and after transient ischaemic attack (TIA) and stroke.

Methods: In a prospective, population-based cohort study of TIA and stroke (Oxford Vascular Study, 2002-2012), pre-event and new post-event dementia were ascertained through direct patient assessment and follow-up for 5 years, supplemented by review of hospital/primary care records. Associations between pre-dementia and CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73 m²) were examined using logistic regression, and between post-event dementia and CKD using both Cox and competing risk regression models, adjusted for age, sex, education, cerebrovascular burden (stroke severity, prior stroke, white matter disease), diabetes mellitus, and dyslipidaemia.

Results: Among 2305 TIA/stroke patients (median [IQR] age, 77 [67-84] years, 1174 [51%] male, 688 [30%] TIA), 1174 (50.9%) had CKD. CKD initially appeared to be associated with both pre-event (odds ratio [OR], 2.04 [95% CI, 1.52–2.72]; P<0.001) and post-event dementia (hazard ratio [HR], 2.01 [95% CI, 1.65–2.44]; P<0.001); however, these associations attenuated and became non-significant after adjustment for the above covariates (OR=0.92 [0.65–1.31]; P=0.65 and HR=1.09 [0.85–1.39]; P=0.50). The results were similar when a competing risk model was used (subdistribution HR [SHR] =1.74 [1.43–2.12]; P<0.001, attenuating to 1.01 [0.78–1.33]; P=0.92 with complete adjustment). CKD was more strongly associated with late (>1 year) post-event dementia (SHR=2.32, 1.70–3.17; P<0.001), particularly in the minor events subgroup (SHR=3.08, 2.05–4.64; P<0.001), but not significantly so after complete adjustment (SHR=1.53, 0.90–2.60; P=0.12).

Conclusions: In patients with TIA and stroke, CKD was not independently associated with either pre- or post-event dementia, suggesting that age, sex, education, and cerebrovascular burden may play a more important role in the relationship than renal-specific neurodegenerative mechanisms.

PO1798
Platelet Activity Mediates Enhanced Cardiovascular Risk in Patients with CKD and Peripheral Artery Disease

**Background:** Chronic kidney disease (CKD) is common in patients with peripheral artery disease (PAD), and both are associated with poor cardiovascular (CV) outcomes. Platelets drive PAD pathogenesis and mediate atherosclerosis. Platelet function in CKD and the related CV risk is unclear. We investigated relationships between CKD, platelet activity, and incident CV events in a cohort of patients with PAD.

**Methods:** The Platelet Activity and Cardiovascular Events (PACE) study enrolled 289 patients with PAD undergoing lower extremity revascularization (LER). CKD was defined as eGFR<60 mL/min/1.73m² by the CKD-EPI equation. We measured platelet activity via light transmission aggregometry (LTA) in response to submaximal ADP, collagen, serotonin, epinephrine, and arachidonic acid (AA) prior to LER, and followed patients for a median of 18 months. The primary clinical endpoints were myocardial infarction (MI) and a composite of major adverse CV events (MACE, MI, stroke, death).

**Results:** There were 113 (40%) patients with and 172 (60%) without CKD. Patients with CKD (vs. non-CKD) were older and more likely to be female, Hispanic, have diabetes, heart failure, and critical limb ischemia (P<0.05 for each). There were no significant differences in prevalent coronary artery disease or use of antithrombotic therapy between groups. Platelet aggregation in response to submaximal ADP, serotonin, epinephrine, and AA was elevated in the CKD group (Figure). After multivariable adjustment, patients with CKD were at greater risk of MI (aHR 2.2 [95% CI, 1.02-4.9]; P=0.045) and MACE (1.9 [1.2-3.3]; P=0.01) than those without CKD. Platelet aggregation in response to submaximal agonist stimulation had a 25% and 12% mediating effect on the association of CKD with PAD.

**Conclusions:** In patients with PAD, CKD was associated with increased platelet activity and CV events. Heightened platelet activity is an important mechanism underlying increased CV risk in CKD.

PO1799
Circulating Vascular Adhesion Protein-1 Levels Predict Risk of Cardiovascular Events and Mortality in Hemodialysis Patients
Dae Kyu Kim,1 Yu ho Lee,2 Soo-Young Yoon,1 Jongho Kim,1 Jin sug Kim,1 Yang guyn Kim,1 So-young Lee,1 Shin-young Ahn,2 Shinyeong Kang,1 Dong-Young Lee,1 Kyung hwan Jeong,1 Ju young Moon,1 Hyeon Soek Hwang,1 Sangho Lee,1 Kyung Hee University Medical Center, Seoul, Republic of Korea; 2CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.

**Background:** Vascular adhesion protein-1 (VAP-1) is an oxidative enzyme of primary amnies that facilitates the transmigration of inflammatory cells. The oxidative and inflammatory effects of VAP-1 are prominently increased in pathological conditions such as metabolic, atherosclerotic, and cardiac diseases. However, the clinical significance of circulating VAP-1 levels in hemodialysis (HD) patients is unclear.

**Methods:** A total of 439 HD patients were enrolled from June 2016 to April 2019 as part of a prospective multicenter cohort study. Plasma VAP-1 levels were measured at the time of study data entry, and the primary endpoint was defined as a composite of cardiovascular (CV) events and cardiac events.

**Results:** Circulating VAP-1 levels were positively correlated with plasma levels of circulating VAP-1 levels in hemodialysis patients is unclear. Serum VAP-1 levels were positively correlated with ventricular (LV) mass index, LV end-systolic volume, and LV end-diastolic volume. Multivariate linear regression analysis revealed that VAP-1 levels was negatively correlated with LV ejection fraction (β = −2.14; p = 0.013). The cumulative event rate of the composite of CV events was significantly greater in VAP-1 tertile 3 (p = 0.049). VAP-1 tertile 3 was also associated with an increased cumulative event rate of cardiac events (p = 0.016). In Cox regression analysis, VAP-1 tertile 3 was associated with a 2.61-fold risk for the composite of CV events (95% confidence interval [CI], 1.37–4.97) and a 2.72-fold risk for cardiac events (95% CI, 1.33–5.56) after adjustment for multiple variables.

**Conclusions:** Higher circulating VAP-1 levels independently predicted the composite of CV events and cardiac events in HD patients. The results of this study suggest the importance of future studies on the effect of neprilysin inhibition in reducing CV events.

PO1800
Circulating Neprilysin Level Predicts the Risk of Cardiovascular Events in Hemodialysis Patients
Hyeon Seok Hwang,1 Jin sug Kim,1 Yang guyn Kim,1 Yu ho Lee,2 Dong-Young Lee,1 Shin-young Ahn,2 Ju young Moon,1 Sangho Lee,1 Kyung hwan Jeong,1 Kyung Hee University Medical Center, Seoul, Republic of Korea; 2CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; 3Korea Veterans Health Service, Seoul, Republic of Korea; 4Korea University Medical Center, Seoul, Republic of Korea.

**Background:** Neprilysin inhibition has demonstrated impressive benefits in heart failure treatment, and is the current focus of interest in cardiovascular (CV) and kidney diseases. However, the role of circulating neprilysin as a biomarker for CV events is unclear in hemodialysis (HD) patients.

**Methods:** A total of 439 HD patients from the K-cohort were enrolled from June 2016 to April 2019. The plasma neprilysin level and echocardiographic findings at baseline were examined. The patients were prospectively followed up to assess the primary endpoint (composite of CV events and cardiac events).

**Results:** Plasma neprilysin level was positively correlated with ventricular (LV) mass index, LV end-systolic volume, and LV end-diastolic volume. Multivariate linear regression analysis revealed that neprilysin level was negatively correlated with LV ejection fraction (β = −2.14; p = 0.013). The cumulative event rate of the composite of CV events was significantly greater in neprilysin tertile 3 (p = 0.049). Neprilysin tertile 3 was also associated with an increased cumulative event rate of cardiac events (p = 0.016). In Cox regression analysis, neprilysin tertile 3 was associated with a 2.61-fold risk for the composite of CV events (95% confidence interval [CI], 1.37–4.97) and a 2.72-fold risk for cardiac events (95% CI, 1.33–5.56) after adjustment for multiple variables.

**Conclusions:** Higher circulating neprilysin levels independently predicted the composite of CV events and cardiac events in HD patients. The results of this study suggest the importance of future studies on the effect of neprilysin inhibition in reducing CV events.

PO1801
Serum Cathepsin-S Concentration Is Not Related to Arterial Calcification Severity Among Hemodialysis Patients
Hao-Wei Ma,1 Chih-Ching Lin,2 Szu-Yuan Li. Taipei Veterans General Hospital, Taipei, Taiwan.

**Background:** Vascular calcification is prevalent among hemodialysis patients and is strongly correlated to their cardiovascular and total mortality. Cathepsin S, a lysosomal cysteine protease that is elevated in CKD patients, has shown its critical role of vascular calcification in cell culture experiments and in uremic animal model. To validate the relationship of Cathepsin S and vascular calcification in clinical practice, we conducted the current cross sectional study.

**Methods:** 88 patients on maintenance hemodialysis were enrolled and their serum Cathepsin S and its natural inhibitor Cystatin C were measured. Serum level of vascular calcification was semi-quantified by aortic arch calcification (AAC) score on chest X-rays. Patients were divided into groups according to their AAC score, and the serum Cathepsin S level, Cathepsin S / Cystatin C ratio and other factors were compared between groups.

**Results:** There was no significant difference in the level of Cathepsin S (p=0.778) or Cathepsin S to Cystatin C ratio (p=0.417) between patients with different aortic arch calcification score. Only age was associated with the severity of AAC score (p=0.014).

**Conclusions:** Despite a pre-clinical study supporting the role of Cathepsin S in the development of vascular calcification under uremic and phosphate-rich conditions, serum Cathepsin S was not found to be associated with vascular calcification severity among hemodialysis patients in this study. Serum cathepsin S is the strongest predicting factor for higher Cathepsin S levels in these patients. Further study is needed to confirm these findings using a different grading system.
Mean age and serum Cathepsin S with 95% confidence interval between groups of patients, categorized by their Aortic arch calcification (AAC) grade.

Kidney Function Trajectory Following Left Ventricular Assist Device Implantation

Carl P. Walther, Julia Benoit, Harveen Lamba, Sankar D. Navaneethan.

Background: LVADs have variable effects on kidney function. Identification of distinctive eGFR trajectory groups after LVAD placement, by applying unsupervised techniques to longitudinal eGFR measures, may enable insights into diverse pathophysiology.

Methods: From a national cohort, we identified persons who underwent isolated, primary continuous flow LVAD implantation in the US, 2016-17. eGFR values from pre-LVAD implantation to 12 months post were used. Latent class mixed models using cubic splines were applied to derivation and validation subsets, and models with 2-9 distinct groups were evaluated to find the optimal number.

Results: In the cohort (3,461 in derivation subset, 1,154 in validation), we identified 5 distinct trajectory groups. The 2 largest groups (1,2) are similar to previously reported cohort averages, with early eGFR increase followed by decline, but differed by baseline eGFR. Three smaller groups (3-5, ~15% of the cohort) demonstrated novel trajectories: group 3 had early worsening with sustained low kidney function; 4 had early and sustained eGFR improvement, and 5 had substantial eGFR variation. These groups differed in baseline factors (groups 3 and 4 had the most pre-LVAD acute dialysis, 4 and 5 the most cardiogenic shock) and outcomes (groups 2 and 4 had the highest survival, 3 and 5 had the lowest).

Conclusions: Novel eGFR trajectories after LVAD implantation were identified in a national cohort. Group 4, with early and sustained increase in eGFR, may reflect type 1 cardiorenal syndrome. Group 3 may reflect chronic kidney disease with early complications, and group 5 may reflect intact kidney parenchyma but post-LVAD right ventricular failure. These results demonstrate the feasibility of identifying previously unobserved heterogeneity in kidney outcomes. The novel trajectory groups may reveal potential for tailored care, in addition to pathophysiologic insights.

Which Loop Is Best? Comparing the Effect of Loop Diuretic Prescribing on Mortality and Heart Failure Readmission

Arti V. Virkud, Abhijit V. Kshirsagar, Patricia Chang, Michele Jonsson Funk, Jessica K. Edwards, Michael R. Kosorok, Emily Gower.

Background: Loop diuretics are a mainstay of heart failure (HF) management. While furosemide is most commonly prescribed, torsemide and bumetanide are increasingly being prescribed, possibly due to their superior bioavailability. Few trials or real-world evidence studies have compared the effectiveness of prescribing these loop diuretics while adequately addressing critical study design biases.

Methods: We identified beneficiaries initiating the study loop diuretics by using an active comparator, new-user cohort design and Medicare claims data from 2007-2017. We estimated 1-year risks of death and a composite outcome (HF readmission/death) using inverse probability of treatment weighting to adjust for relevant confounders. We calculated a dose equivalence based on furosemide to adjust for disease severity.

Results: We identified 45,310 furosemide, 1,148 torsemide, and 1,630 bumetanide new users. In the total weighted population, 24.3% had a reduced ejection fraction, 27.1% had CKD (≥ Stage 2), with a mean age of 80.1 years and a mean furosemide dose equivalent of 50.8 mg/mL. The 1-year risk of death across all study loop diuretics was similar (19.9%-20.6%), whereas the risk of the composite outcome was more varied (29.1%-32.0%). The 1-year risk difference (95% CI) of the composite outcome was -2.9% (-6.2, 0.4) for torsemide vs. furosemide and -1.1% (-3.8, 1.6) for bumetanide vs. furosemide.

Conclusions: Among Medicare beneficiaries, the risk of HF readmission/death varies meaningfully with torsemide having a reduced risk compared to other study loop diuretics. This study leverages claims data and causal methodology to generate a less biased and more generalizable estimate than previous studies. While additional trial and real-world evidence studies are needed, this study suggests initial loop diuretic prescription after HF hospitalization may produce long-term differences in risk of death and HF readmission.

POI1804

Diuretic Resistance in Acute Decompensated Heart Failure with Preserved vs. Reduced Ejection Fraction

Akash Sharma, Rahul Patel, Chakradhar Velagapudi, Shweta Bansal.

Background: Loop diuretic resistance (DR) is one of the common causes of inadequate decongestion in patients hospitalized with acute decompensated heart failure (ADHF). However, DR has not been characterized in patients with HF with preserved ejection fraction (HFpEF). We estimate 1-year risks of death and a composite outcome (HF readmission/death) among Medicare beneficiaries with HF hospitalization and initiating a loop diuretic (2007-2017).

Methods: We identified beneficiaries initiating the study loop diuretics by using an active comparator, new-user cohort design and Medicare claims data from 2007-2017. We estimated 1-year risks of death and a composite outcome (HF readmission/death) using inverse probability of treatment weighting to adjust for relevant confounders. We calculated a dose equivalence based on furosemide to adjust for disease severity.

Results: We identified 45,310 furosemide, 1,148 torsemide, and 1,630 bumetanide new users. In the total weighted population, 24.3% had a reduced ejection fraction, 27.1% had CKD (≥ Stage 2), with a mean age of 80.1 years and a mean furosemide dose equivalent of 50.8 mg/mL. The 1-year risk of death across all study loop diuretics was similar (19.9%-20.6%), whereas the risk of the composite outcome was more varied (29.1%-32.0%). The 1-year risk difference (95% CI) of the composite outcome was -2.9% (-6.2, 0.4) for torsemide vs. furosemide and -1.1% (-3.8, 1.6) for bumetanide vs. furosemide.

Conclusions: Among Medicare beneficiaries, the risk of HF readmission/death varies meaningfully with torsemide having a reduced risk compared to other study loop diuretics. This study leverages claims data and causal methodology to generate a less biased and more generalizable estimate than previous studies. While additional trial and real-world evidence studies are needed, this study suggests initial loop diuretic prescription after HF hospitalization may produce long-term differences in risk of death and HF readmission.

Funding: NIDDK Support
**Conclusions:** Although the comparisons were not statistically significant due to small sample size; the results suggest that DR is more prevalent in HFpEF. Despite similar clinical features of congestion and response to high-dose spironolactone, a state of reduced neurohormonal activation points that additional factors might be contributing to DR in HFpEF compared to HFrEF patients.

**Funding:** Commercial Support - Relypsa Education Grant

Renal Outcomes and Safety of Angiotensin Receptor Neprilysin Inhibitors in Patients with Heart Failure: A Meta-Analysis

Rima N. Abou arkoub, Thomas Mavrokanas, Amy Bergeron, Abhinav Sharma, Ahsan Alam. 1McGill University Health Centre, Montreal, QC, Canada; 2McGill University Health Centre Glen Site McConnell Resource Centre Medical Library, Montreal, QC, Canada.

**Background:** Angiotensin receptor neprilysin inhibitors (ARNIs) are an effective treatment for heart failure. However, their safety profile compared with angiotensin converting enzyme-inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) with respect to renal outcomes has not been clearly established.

**Methods:** We conducted a literature search of MEDLINE, Cochrane library, Embase, and clinical trials registries using relevant search terms (last search date May 7, 2021). The primary renal outcome was kidney function decline and the safety outcome was hyperkalemia. Only studies with at least 12 weeks of follow up were included in the renal outcome analysis to better capture CKD.

**Results:** Ten randomized controlled trials were eligible for inclusion (n=22,174 participants). ARNIs were associated with a lower risk of kidney function decline compared with ACEIs or ARBs: RR 0.65 (95% CI 0.53-0.81). The risk of hyperkalemia was similar in both treatment groups: RR 0.96 (95% CI 0.81-1.13).

**Conclusions:** ARNI use in patients with heart failure is associated with a lower risk of kidney function decline and a similar risk of hyperkalemia compared to ACEIs or ARBs.
PO1806
Hydralazine-Isosorbide Dinitrate Associated with Reduced All-Cause and Cardiovascular Mortality in Patients on Dialysis with Heart Failure
Qandeel H. Soomo,1 Thomas Mavrakanas,2,3 David M. Charytan,1,4 1NYU Langone Health, New York, NY; 2McGill University, Montreal, QC, Canada; 3Brigham and Women’s Hospital, Boston, MA

Background: Heart failure (HF) is an important contributor to the increased cardiovascular (CV) mortality incidence in ESKD. Therapies targeting HF’s unique pathophysiology in ESKD are lacking. Hydralazine-isosorbide dinitrate (H-ISDN) targets reduced nitric oxide bioavailability and could improve CV mortality in ESKD

Methods: Adult patients with HF on maintenance dialysis between January 2011 and December 31, 2016 were identified using the United States Renal Data System. There were 6306 patients with at least one prescription for H-ISDN and 75,851 non-users. The primary outcome was death from any cause. Secondary outcomes included cardiovascular death and sudden death. Treatment effects were estimated using stabilized inverse probability weights in Cox proportional hazards regression. Because H-ISDN has been shown to improve outcomes in Black HF patients, we investigated effect modification by race

Results: Age was similar in H-ISDN users (66 ± 13 years) and non-users (69 ± 13 years) with 50% and 51% men, respectively. H-ISDN (51%) users were more likely to be of Black race than non-users (27%). Dialysis vintage was longer in H-ISDN (25 months) users compared with non-users (15 months). All characteristics were well balanced in weighted models. Risks of all-cause mortality, cardiovascular death, and sudden death were significantly reduced in H-ISDN users compared to non-users (Table). We did not identify significant effect modification by race (Figure)

Conclusions: To our knowledge, this is the first analysis of the impact of H-ISDN on mortality in ESKD. Our results suggest that combination H-ISDN improves survival in dialysis patients with HF

PO1807
Long-Term Outcomes After Renal Revascularization for Atherosclerotic Renovascular Disease in the ASTRAL Trial
Philip A. Kalra,1,2 Darren Green,1,2 Natalie Ives.1 The ASTRAL trial investigators 1Salford Royal Hospital, Salford, United Kingdom; 2The University of Manchester, Manchester, United Kingdom; 3University of Birmingham, Birmingham, United Kingdom

Background: The Angioplasty and Stenting for Renal Artery Lesions (ASTRAL) trial randomized 806 patients with atherosclerotic renal artery stenosis (RAS) between 2000-2007, randomised 1:1 to medical therapy with or without renal artery stenting. The initial results were presented in 2009 at median follow-up 34.6 months when no benefit of revascularization to renal functional outcome or cardiovascular events (CVE) was evident. Surviving patients remained under follow up until 2014.

Methods: All available data were analysed to assess whether there was a later impact of revascularization on renal function, CVE and survival, including a composite outcome of renal and CV outcomes and death (as used in the CORAL trial). Pre-specified sub-group analyses of different categories of renal function, renal length, prior rapid deterioration in kidney function, and severity of RAS. Further post-hoc analysis of patients with severe RAS (defined as bilateral 70% or > 70% RAS in a solitary kidney – global renal ischemia), those with/without proteinuria and a per protocol analysis were performed.

Results: The mean age of the entry population was 70.5 years, mean eGFR 40 ml/min/1.73m², with mean RAS 76% and blood pressure 150/76 mmHg. 83% of the revascularization group underwent attempted stenting. Median follow-up was 56.4 months with 108 patients lost to follow up or withdrawn; 50% of the evaluable population had died, 14% had received RRT and 40% had suffered a 1° CVE. No benefit of revascularization was observed for any outcome in the intention to treat and per protocol analyses, either in the whole population or the pre-specified sub-groups. In the severe RAS sub-group (163 patients) revascularization was associated with a hazard ratio (HR) of 0.74 (0.54-1.01; p=0.062) for the composite renal and CV outcome and an HR of 0.70 (0.49-1.0) for death (p=0.051).

Conclusions: The long-term follow-up of the ASTRAL trial population showed no overall benefit of renal revascularization to renal and CV outcomes. It has been highlighted that a proportion of the population had lower risk mild-moderate RAS. The long-term outcomes in patients with severe RAS (global renal ischemia) point to a potential benefit of stenting that may be worthy of further study in a more selected population.

Revascularization in Atherosclerotic Bilateral Renal Artery Stenosis
Sana J. Shaikh, Bilal Al-Khalil, Ling Chen, Anitha Vijayan. Washington University in St Louis, St Louis, MO.

Background: Patients with B/L RAS, if found to have worsening renal failure, refractory HTN or recurrent CHF, are often referred for revascularization despite limited evidence. We hypothesized that revascularization plus medical management prevents adverse outcomes in patients with B/L RAS.

Methods: This was a retrospective single-center cohort study in patients with B/L RAS, RAS in a solitary kidney, U/L RAS with an atrophic or <1cm smaller contralateral kidney or, RAS in a U/L functioning kidney. We excluded patients with non-atherosclerotic RAS, renal artery dissection, atheroembolism and renal transplantation. The primary outcome was Major Adverse Kidney Events (MAKE) at 3 mo. Secondary outcomes were renal events, changes in BP, hospital admissions and all-cause mortality at 1 yr. We used the Chi-square test for the primary outcome and the Chi-square test or two-sample t-tests for the secondary outcomes.

Results: 153 patients were included in the study. There were no differences in the baseline characteristics of the intervention and control groups, except for higher number of smokers in the control cohort (Table 1). There was no difference in MAKE between the 2 groups at 3 mo. At 1 yr, there were fewer admissions for CHF in the intervention group (Table 2). There were no other major differences in secondary outcome measures.

Conclusions: Revascularization for B/L RAS does not improve renal outcomes, BP control or mortality, but may prevent admissions for CHF.

Hypertension in a Young Female: A Common but an Intriguing Anecdote
Bailoo,1 Sohail Sabir.2 1Foundation University Medical College, Rawalpindi, Pakistan; 2National University of Medical Sciences, Rawalpindi, Pakistan

Introduction: Renal artery stenosis accounts for about 1-10% of the 50 million people worldwide with hypertension. All major trials conducted so far on RAS found no benefit with renal artery stenting. Here we report a case of resistant hypertension in a young female who subsequently found to have bilateral renal artery stenosis and ultimately benefited from unilateral stenting.

Case Description: A 35 yrs female, married, with no comorbidities, presented with 03 months history of intermittent episodes of throbbing headache along with dizziness, palpitations, fatigue. Examination revealed BP - 160/100 with no postural drop, and regular pulse with no radio-radial, radio-femoral delays. Her baseline investigations(including blood complete picture, LFTs, RFTs, urine routine examination, PTT:PTK were Normal. Hepatitis B and C serology were negative) USG abdomen showed right shrunken kidney with no renal artery flows on Doppler ultrasound. She was put on four different groups of anti hypertensives including a beta blocker, a calcium channel blocker, thiazide diuretic and an angiotensin receptor blocker but her blood pressure did not settle. Further investigations revealed raised ESR but other tests including autoimmune screening, 2DECHO all negative-CT aortogram revealed a non visualised shrunken right kidney. So based on renal imaging findings, a final diagnosis of bilateral renal artery stenosis was made. Percutaneous transluminal angioplasty with stenting to proximal left renal artery was done. She was given dual antiplatelets along with a statin post operatively and advised monthly follow up. Currently she is normotensive.

Long-Term Safety and Efficacy of Renal Denervation with the Symplicity Spyral Catheter in the Global SYMPLICITY Registry
Markus P. Schlaefer,1 Felix Mahfoud,2 Bryan Williams,3 Luis M. Ruijlope,4 Krzysztof Narkiewicz,2 Martin Faly,2 Giuseppe Mancia,2 Michael Böhnm,2 1The University of Western Australia, Perth, WA, Australia; 2Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany; 3University College London, London, United Kingdom; 4Hospital Universitario 12 de Octubre, Madrid, Spain; 5Gänsis Universitet Medyczny, Gdańsk, Poland; 6Università degli Studi di Milano-Bicocca, Milano, Italy; 7Medtronic Inc, Minneapolis, MN.

Background: Catheter-based renal denervation (RDN) therapy targets overactivity of the sympathetic nervous system to treat hypertension. Results from recent randomized sham-controlled clinical trials have demonstrated the safety and efficacy of RDN, but long-term safety and durability of the procedure in real-world patients is also important.

Methods: The Global SYMPLICITY Registry (GSR) is a prospective, international registry of patients who receive radiofrequency RDN treatment due to uncontrolled hypertension or conditions associated with excessive sympathetic nervous system activation. Office and ambulatory blood pressure (BP) levels were measured at baseline, 3, 6, 12, 24, and 36 months per standard of care. Adverse events were collected out to 3 years. In this analysis, we present safety and efficacy data for patients who received RDN with the multi-electrode Symplicity Spyral catheter in GSR.

Results: Currently there are 641 patients treated with the Symplicity Spyral catheter (baseline office BP 168±25 mmHg, 4.6±1.5 prescribed anti-hypertensive medication classes, mean age 60.5±12.5 years, 56.9% male, 42.5% history of cardiace disease, 37.2% type II diabetes mellitus, and 19.1% renal insuficiency with eGFR<60 ml/min/1.73m²).

At 1 year, there were no cases of new renal artery stenosis >70% or renal artery re-intervention. Rates of other adverse events at 3 years included new onset end stage renal disease (2.4%), cardiovascular death (1.6%) and myocardial infarction (0.8%). Mean change in eGFR from baseline to 3 years was -6.5±15.7 mL/min/1.73m². Changes in mean 24-hour and office BP from baseline to 6, 12, 24 and 36 months are shown in the Figure.

Conclusions: Office and 24-hour BP were significantly reduced from baseline at all follow up time-points after RDN with the Symplicity Spyral catheter, with no instances of renal artery re-intervention.

Funding: Commercial Support - Medtronic

Endovascular Renal Denervation Efficacy in a Five-Year Follow-Up
João Carvalho,1 Patricia Q. Branco,2 Catarina Mateus,2 Pedro Gonçalves,2 Manuel D. Almeida,3 Maria augusta C. Gaspar,2 1Servico de Saúde da Regiao Autonoma da Madeira, Funchal, Portugal; 2Centro Hospitalar de Lisboa Ocidental EPE Hospital da Santa Cruz, Carnaxide, Portugal.

Background: Endovascular renal denervation (ERD) is a minimally invasive procedure that uses radiofrequency ablation to burn the nerves in the renal arteries. Renal sympathetic nerves can modulate sympathetic activity at the whole body level, playing an important role in essential hypertension. This study aims to evaluate ERD efficacy in the treatment of essential hypertension in a five-year follow-up.

Methods: We conducted a prospective study including 41 patients with essential hypertension. ERD was performed using Simplicity Probe or Spyral. Blood pressure (BP) was evaluated using 24-hour ambulatory BP monitoring. Echocardiography was performed using HDI 5000. Clinical and biochemical variables were explored.

Results: A total of 41 patients were included. Overall, 53.7% (n=22) were females with a mean age of 63.6 ± 7.5 years, BMI 30.8 ± 5.2 Kg/m², 17.1% (n=7) had an estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m² and 68.3% (n=28) had diabetes. Proteinuria (>300mg/g) was found in 24.4% (n=10) of the patients. A significant reduction in the number of antihypertensive drugs being taken was found after 5 years’ follow-up (p<0.001). Despite this reduction, a significant reduction in diastolic blood pressure.
(DBP) (p = 0.001) was found, but not in systolic blood pressure (SBP) (p = 0.08). Also left ventricle mass index (LVMi) reduced significantly (p = 0.0001) and a reduction of acute elevation of left ventricle filling pressure (LVFP) was detected using E’/E (p = 0.0001). There was a worsening of eGFR (p = 0.0001) as expected by the progressive worsening of kidney function. We have found a non significant reduction in proteinuria (p = 0.07). In female patients with a reduction in proteinuria, it was not associated with BP and an overall reduction in proteinuria when using multivariate analysis. In a multivariate analysis, the reduction in the number of antihypertensive drugs, of the LVMi, SBP and DBP were not related with age, gender, body mass index and proteinuria.

From our observation, we managed to reduce the number of antihypertensive drugs and still patients DBP with RDN. Also RDN showed benefits in reducing LVMi and LVFP. Reduction of proteinuria, when present, was independent of BP and an overall LVMi. There was a worsening of kidney function as expected in a long term follow-up. RDN has been shown to be an effective mean of treating essential hypertension.

Potential Benefits of Asymptomatic Hyperuricemia Treatment: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Dhir N. Gala,1 Kireillos S. Said,2 Nuala E. El-Shabat,3 Allison Parrill,4 Hader S. Mohamed,4 Nada Abdellahim,4 Mostafa A. Amin,4 Hassan S. Abdalrahim,4 Majid Alahmar,6 Nguyen Tien Huy,5 Mohammed Abdel Gawad,2 ‘American University of the Caribbean School of Medicine BY, Cupecoy, Sint Maarten (Dutch part); ‘Alexandra University Faculty of Medicine, Alexandria, Egypt; ‘Al-Azhar University Faculty of Medicine, Cairo, Egypt; ‘Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; ‘Mansoora University Faculty of Medicine, Mansoora, Egypt; ‘Gawad Nephrology Clinic, Alexandria, Egypt; ‘School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan.

**Background:** Asymptomatic hyperuricemia is strongly associated with an increased risk for chronic kidney disease and cardiovascular conditions. However, many current guidelines suggest no medical treatment for patients with asymptomatic hyperuricemia. We aim to systematically analyze randomized control trials with serum uric acid-lowering medication in the treatment of patients with asymptomatic hyperuricemia.

**Methods:** A literature review of seven medical databases (Scopus, Clinical Gov, Pubmed, Web of Science, Google Scholar, VHL, and GHL) for randomized controlled trials related to the treatment of asymptomatic hyperuricemia was conducted. Bias was evaluated using the Cochrane Risk of Bias 2 tool. Standard differences of means of variables of interest were combined across studies to compare the effects of uric acid lowering treatment versus control. Using the Comprehensive Meta-Analysis Program, fixed-effects and random heterogeneity model, forest plots were created for each variable of interest.

**Results:** Analysis of eleven studies showed significant decreases in creatinine [0.302 (95% CI: -0.599, 0.005)], systolic blood pressure [-0.277 (95% CI: -0.5, -0.055)], and serum uric acid [-1.972 (95% CI: -2.145, -1.800)] in the treatment versus control group. Furthermore, significant increases in estimated glomerular filtration rate (eGFR) after analysis sensitivity [0.228 (95% CI: 0.027, 0.428)], and high sensitivity-C reactive protein [0.588 (95% CI: 0.205, 0.971)] were observed in the treatment versus control group. Lastly, non-significant increases in creatinine [0.087 (95% CI: -0.269, 0.042)], and diastolic blood pressure [-0.312 (95% CI: -0.638, 0.013)], while non-significant increases in hemoglobin A1C [0.394 (95% CI: -0.026, 0.813)] and fasting glucose level [0.117 (95% CI: -0.145, 0.380)] were found in the treatment versus control group.

**Conclusions:** This study showed that uric acid lowering treatment of patients with asymptomatic hyperuricemia may be beneficial in those with elevated creatinine and blood pressure, and decreased eGFR.

Urinary Glycogen Synthase Kinase 3β Level Predicts the Progression of Hypertensive Nephrosclerosis

Limfeng Zeng, Cheuk-Chun Szeto. Department of Medicine & Therapeutics and Li Ka Shing Institute of Health Sciences (LiHSI), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.

**Background:** Hypertensive nephrosclerosis (HTN) is a serious consequence of end-stage kidney disease. Recently, emerging evidence suggests that glycogen synthase kinase (GSK) 3β is a key factor in the progression of diabetic kidney disease (DKD). However, it remains uncertain whether the role of GSK3β is specific for DKD or a generic mediator of renal damage irrespective to the underlying cause. We aim to 1. identify patients with biopsy-confirmed HTN patients. Their GSK3β 3 level in urinary supernatant was measured by conventional ELISA, and GSK3β mRNA level in urinary sediment was measured by quantitative polymerase chain reaction. The results were compared to the baseline kidney function and the subsequent risk of renal function deterioration. 2. The results: average GSK3β 3 level was 212.67 ± 47.74 nL/g by conventional ELISA, which closely correlated with its mRNA level in urinary sediment (r = 0.821, P = 0.0001). Urinary GSK3β level significantly correlated with baseline glomerular filtration rate (GFR) (r = 0.337, P = 0.010) and the slope of GFR decline (r = 0.397, P = 0.033). Patients with a high urinary GSK3β level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level. 3. GSK3β 3 mRNA level also significantly correlated with baseline GFR (r = 0.582, P < 0.0001) and the slope of GFR decline (r = -0.402, P = 0.022). Patients with a high urinary GSK3β mRNA level has a higher risk of developing 40% kidney function loss and progressing to dialysis-dependent kidney failure than those with a low GSK3β level (p = 0.022 and p = 0.004, respectively).

**Conclusions:** These results demonstrated that urinary GSK3β level correlates with the rate of kidney function loss in patients with biopsy-confirmed HTN, and urinary sediment GSK3β level appears to be a better prognostic marker than urinary GSK3β level by ELISA. Our results suggest that GSK3β is a generic mediator for the progression of chronic kidney disease and is not specific for DKD.

**Funding:** Clinical Research Support, Government Support - Non-U.S.
**Conclusions:** These observations are compatible with a sexual dimorphism in the NKA via mechanism of regulation of NHE3 and Na+ transport in the RPT. This study highlights the importance of improving our understanding of the natriuretic mechanism of NKA signaling in the RPT and its potential impact on sex-based differences in renal physiology and pathophysiology.

Sex-Dependent Regulation of the WNK-NCC Pathway via Ubiquitination in Response to Dietary High Salt Intake in Young Sprague-Dawley Rats

Kyoung Kim, Mohammed Z. Ferdaus, Richard D. Wainford. Boston University School of Medicine, Boston, MA.

**Background:** The thiazide-sensitive Na+-Cl–cotransporter (NCC), located in the thick ascending limb of distal convoluted tubule, fine-tunes sodium reabsorption and regulates blood pressure. The NCC is downregulated by high salt intake in normotensive salt resistant rats. These studies investigated the potential mechanistic pathways by which NCC is degraded in response to high salt intake in male and female Sprague-Dawley (SD) rats.

**Methods:** 3-month-old normotensive male and female SD rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days. On day 21, the kidneys were collected and ~200 mg of the renal cortex was used to measure the expression of total NCC, WNK1, WNK4, Nedd4-2, Sortilin, KLHL3, and calcineurin via immunoblotting (N=5–6/group).

**Results:** A 21-day HS diet evokes the suppression of total NCC protein expression in young normotensive male and female SD rats. A HS diet downregulated WNK1 in male but not female SD rats. HS diet suppressed the expression of the full-length and short WNK4 variants in female SD rats only. There was a trend for HS to increase Nedd4-2 expression in male SD rats (P=0.06), in contrast female rats downregulated Nedd4-2 in response to HS. The expression of sortilin, KLHL3, and calcineurin was suppressed by a HS diet in female SD rats.

**Conclusions:** These data suggest that in response to a HS diet young female SD rats exhibit greater ubiquitin-dependent proteolytic and lysosomal degradation of the NCC with young male SD rats to regulate sodium homeostasis and blood pressure via a WNK-dependent signaling pathway.

**Table 1:** NS, 0.6% NaCl; HS, 4% NaCl. *P*<0.05 vs. respective NS Group.
Conclusions: Thus far, we report a shift in the histaminergic tone toward less histamine production and increased NO production, which led to a reduced HS diet. Dahl SS rats are associated with HT2 blocker exhibit lower water consumption, reduced diuresis, and increased urinary osmolality.

PO1820 Salt-Induced Blood Pressure Elevation in Females Is Associated with Increased Arachidonic Acid Metabolites
Jeanne A. Ishimwe, Annet Kirabo, Fernando Elijojich, Jane F. Ferguson.
Vanderbilt University Medical Center, Nashville, TN.

Background: Excess dietary sodium (Na+) intake is a major risk factor for salt-sensitive hypertension and cardiovascular disease. Several clinical trials have found that women are more salt-sensitive than men, but the contributing sex-specific mechanisms are poorly understood. Arachidonic acid (AA) and its metabolites play a role in the pathophysiology of hypertension. We hypothesized that women have greater blood pressure (BP) elevation in response to Na+ intake that is associated with higher AA metabolites than men.

Methods: Plasma AA metabolites were measured via a metabolomics analysis in volunteers who completed a validated 3-day food record to estimate dietary Na+ intake before the study visit where BP was measured. Based on the recommendations by the American Heart Association, we classified daily Na+ intake <2.3g as normal salt, and high salt for subjects consuming a 2.3g Na+. Spearman correlation was used to assess the relationship between AA metabolites and SBP/DBP, and sex differences in BP response.

Results: Women (n=81) displayed a stronger relationship between BP and Na+ intake than men (n=49) (r=0.372; p=0.001 vs. r=0.317; p=0.026). The relationship between Na+ intake and BP was stronger in white (n=46, r=0.4172; p=0.004) than in black (n=22, r=0.338; p=0.124) women and conversely stronger in black (n=7, r=0.70; p=0.034) than white (n=32, r=0.251; p=0.166). We measured plasma levels of palmitate and linoleate, both upstream of AA synthesis, AA, and 12-Hydroxyeicosatetraenoic acid (12-HETE) an AA metabolite. In subjects consuming a high Na+ diet (women 28, men 25) levels of linoleate (1.211 ± 0.330 vs. 0.869 ± 0.170, p<0.001), palmitate (1.155 ± 0.292 vs. 0.924 ± 0.233; p= 0.003), AA (1.119 ± 0.242 vs. 0.965 ± 0.201; p=0.015) and 12-HETE (1.329 ± 0.925 vs. 0.92 ± 0.52; p=0.0469) were higher in women. In contrast, no sex differences in any of these parameters were observed between men and women consuming a normal salt diet.

Conclusions: Our findings suggest that AA and its metabolites may account for sex and perhaps also racial differences in salt sensitivity of BP. Further study of AA and its metabolites may shed light on the mechanisms of the sex differences in salt sensitivity.

PO1821 Gstm1 Genotype Affects Metabolic Response in Hypertension
Yves T. Wang, Nhu Nguyen, Thu H. Le.
University of Rochester Medical Center, Rochester, NY.

Background: Glutathione S-transferases (GSTs) are a family of enzymes that detoxify electrophilic compounds and products of oxidative stress. In humans, GST μ- (GSTM1) has a common null allele variant, GSTM1/0, which has been linked to elevated oxidative stress in pathophysiological conditions and increased risk and/or accelerated progression of a variety of diseases. Recently, we reported that Gstm1 knockout (KO) mice had increased oxidant stress and augmented kidney injury in angiotensin II (Ang II)-induced hypertension (HTN).

Methods: Kidney tissue was obtained from 12-20 week old male wild-type (WT) and Gstm1 knockout (KO) mice at either baseline (no treatment) or following 4 weeks of Ang II- induced HTN via mini-osmotic pump at 1000 ng/kg/min. For each animal, a kidney was excised and snap frozen. For qPCR, mRNA was extracted from an homogenized kidney and used to create cDNA, followed by probing for a panel of 18 Gt genes. For metabolomics, frozen tissue was ground to a fine powder and sent to Metabolon (Morrisville, NC) to obtain a global metabolic profile.

Results: Analysis of qPCR results showed no significant alternations in the expression of Gt genes between WT and KO mice, except for the expected loss of Gstm1 in KO mice. Metabolomics analysis yielded data for 926 metabolites, with expected significant increases in compounds with known pro-inflammatory effects and a further 131 (14%) displayed an interaction between genotype and treatment. Comparing Ang II-treated KO and WT mice, there was a significant increase in metabolite abundance in the methionine and glutathione pathways, including the transulfuration pathway linking them. Furthermore, there was an increase in carnitine and anserine and a decrease in several lipid peroxidation markers.

Conclusions: The loss of GSTM1 in Ang II-induced HTN did not elicit a significant compensatory upregulation of mRNA of other GSTs. It is likely other antioxidant pathways are upregulated based on the altered metabolite abundances. However, based on previous results in treated KO mice, any compensatory mechanism is insufficient to protect against the oxidative stress-induced kidney damage. Further research should be pursued to elucidate the oxidative stress-related specific substrates of GSTM1 that are not detected by other pathways.

PO1822 HMGB-1 Activates Mineralocorticoid Receptor-Dependent Endothelial Cell Injury via Receptor for Advanced Glycation End Products
Tomoyuki Otsuka,1 Seiji Ueda,1 Hajime Nagasawa,1 Teruyuki Okuma,1 Koji Sato,1 Takanori Matsui,1 Sho-ichi Yamagishi,2 Yisuke Suzuki,1 Juntendo University Faculty of Medicine, Bunkyo-ku, Japan;2 Showa University Faculty of Medicine, Shinagawa-ku, Japan;3 Kurume University Faculty of Medicine, Kurume-shi, Japan.

Background: Endothelial dysfunction plays a central role in the pathogenesis of cardio-renal syndrome. High mobility group box-1 (HMGB-1) is a protein with various roles in different cellular compartments, and indirectly regulates the activity of transcription and DNA repair in the nucleus. On the other hand, during tissue damage, it is released into the extracellular environment as damage-associated molecular patterns (DAMPs). HMGB-1 has been shown to be elevated in CKD patients and be involved in endothelial dysfunction through binding to toll like receptor (TLR) and receptor for advanced glycation end products (RAGE). In addition, we recently demonstrated that RAGE-mediated Rac1 activated mineralocorticoid receptor (MR) and resulted in podocytes damage. In the present study, we hypothesized that crosstalk between HMGB-1/ RAGE and Rac1-MR pathways could contribute to endothelial dysfunction in kidney diseases.

Methods: In the present study, we investigated whether HMGB-1 could activate Rac1-MR axis and induce endothelial injury in cultured umbilical vein endothelial cells (HUVECs) by assessing expression levels of genes for MCP-1 and cell adhesion factors (ICAM-1, VCAM-1) with or without administration of RAGE antagonist or MR blocker (exsrenorenne, 1uM).

Results: HMGB-1 supplementation significantly increased GTP-bound Rac1 and enhanced MR transcription into the nucleus in HUVECs. We also found that RAGE expression was enhanced by HMGB-1 and RAGE antagonist completely abolished Rac1 activation and MR translocation observed in HMGB-1 exposed HUVECs. HMGB-1 also upregulated MCP-1, ICAM-1, and VCAM-1 in HUVECs, all of which were significantly blocked by pretreatment of Rac1 antagonist as well as MR blocker.

Conclusions: These results suggest that there may be a close relationship between HMGB-1/ RAGE axis and Rac1/ MR activation, thus contributing endothelial injury. Using RAGE antagonist or MR blocker could be novel therapeutic strategies against endothelial dysfunction in patients with kidney diseases.

PO1824

Effect of Tochu Extract and Its Component Geniposidic Acid on Renal Hemodynamics and Hypertensive Renal Damage
Akihiro Tojo, Hiroshi Satonaka, Toshikio Ishimitsu. Dokkyo Medical University, Mibu, Japan.

Background: Aqueous extract of Eucommia ulmoides (Tochu) leaf is used as Tochu tea in Japan and has the effect of lowering blood pressure. We investigated the effects of Tochu extract and its component geniposidic acid on renal hemodynamics and hypertensive renal damage in Dahl salt-sensitive hypertensive rats (DS).

Methods: DS rats received 1% saline solution from 4 weeks of age. After the blood pressure reached 150 mmHg or higher at 9 weeks of age, the rats were treated with 1% saline solution (DSHS), or 1% saline added 0.5% Tochu extract (DSHS + T) or, 1% saline added 0.2% geniposidic acid (DSHS + G) for another 4 weeks. RS rats fed with tap water were used as controls (DSLS). At 13 weeks, renal plasma flow (RPF) was measured by renal clearance study, and immunostaining and PCR of NADPH oxidase, eNOS, sodium transporters and fibrinectin factors were performed.

Results: Blood pressure was significantly increased in DS rats compared to DSLS rats (196 vs.144 mmHg, p<0.01), which was significantly decreased in DS + T rats (158 mmHg) and DS + G rats (162 mmHg). Vascular resistance of afferent arterioles was significantly increased in DS + G rats compared to DSLS rats, and was decreased in both DS + T and DS + G rats. RPF was significantly higher in DS + T rats than in DSLS rats associated with reduced renal vascular resistance (p <0.05). In DSLS rats, NADPH oxidase expression and superoxide production were increased, with increased TGF-beta, procollagen 1, fibronectin and renal fibrosis. These were suppressed in DS + T and DS + G rats. NO production by eNOS was decreased in DSLS rats, but the treatment groups increased eNOS expression and NO production in the vascular endothelium, resulting in decreased renal vascular resistance and improved renal blood flow. Urinary sodium excretion was significantly higher in DSLS rats than in DS + T rats with increased sodium chloride co-transporter (NCC). However, there was no further change in NCC or other sodium transporters in the treatment groups, and the high urinary Na excretion in the treatment groups was due to the increased RPF.

Conclusions: Tochu and geniposidic acid suppressed NADPH oxidase and increased eNOS in DS rats, resulting in improved blood pressure, renal hemodynamics and renal damage.

PO1825

Effect of Uremia on Endothelial Cell Damage Is Mediated by Excessive Neutrophil Extracellular Trap Formation
Jwa-kyung Kim, Hoi Woul Lee, Sung gun Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

Background: Uremia is a clinical syndrome characterized by accumulation of various uremic toxins and associated metabolic abnormalities in chronic kidney disease (CKD). Patients with CKD are at increased risk for cardiovascular (CV) disease and death, and endothelial dysfunction may be a key uremia-specific risk factor. However, the mechanism by which uremia influences endothelial dysfunction is still unclear. We report a role for excessive neutrophil extracellular trap (NET) formation induced by uremic serum on endothelial cell (EC) injury.

Methods: Plasma nucleosome and myeloperoxidase-DNA, representative markers of in vivo NETs, and the intracellular adhesion molecule (ICAM)-1 level were measured in incident hemodialysis (HD) patients and healthy volunteer (HV), and their prognostic role was evaluated. For in vitro study, we differentiated HL-60 cells into neutrophil-like cells (dHL-60) by applying retinoic acid, and the effect of uremic serum on dHL-60 and ECs were determined.

Results: The amount of in vivo NETs were significantly higher in incident HD patients compared to HV, and the markers were strongly associated with ICAM-1 levels. In particular, nucleosome and ICAM-1 levels were independent predictors of a composite endpoint, all-cause mortality or vascular access failure. In vitro, uremic serum derived from HD patients showed significantly increased NETs formation from dHL-60, and these NETs significantly decreased EC viability and induced apoptosis. In addition, the ICAM-1 level in HUVEC supernatant was significantly increased by uremic serum-induced NETs compared to control serum-induced NETs.

Conclusions: Dysregulated neutrophil activities in the uremic milieu may play a key role in endothelial damage and vascular inflammatory responses.

Contributions of Obesity and Hypertension to Progression of Cardiovascular Disease
Isabel T. Nguyen, Jaap A. Joles, Marianne C. Verhaar. Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands.

Background: Obesity and hypertension are highly prevalent in patients with cardiorenal syndrome (CRS). Insight in how these comorbidities individually contribute to disease progression is required to improve treatment strategy. We dissected the separate contribution of obesity and worsening hypertension by deoxycorticosterone acetate (DOCA) plus high salt diet in the obese female ZSF1 rat, a model of metabolic CRS in the absence of diabetes [Nguyen, PLoS One 2020]. We hypothesize that in obese non-diabetic female ZSF1 rats obesity has a profound effect on functional progression of CRS while hypertension mainly affects fibrosis and inflammation.

Methods: Systolic blood pressure (SBP), renal and cardiac function were assessed biweekly in lean and obese female ZSF1 rats from 12 to 26 weeks of age. From 19 weeks, rats were implanted with either a DOCA pellet and fed a high salt (6% w/w) diet or with a placebo pellet and fed a normal salt diet. At 26 weeks of age, glomerular filtration rate (GFR) and effective renal plasma flow (ERPF) were assessed under isoflurane anesthesia. Subsequently, rats were sacrificed and tissues processed for analysis of renal and cardiac damage and inflammation.

Results: Obese versus lean placebo rats showed elevated E/e' ratio from 12 weeks, indicative of diastolic dysfunction. From 24 weeks obese compared to lean placebo rats developed proteinuria with lower GFR at 26 weeks of age. DOCA-salt markedly increased SBP in obese but not lean rats, despite similarly high natriuresis compared to placebo rats. ERPF was increased by DOCA-salt in lean but not obese rats. DOCA-salt worsened proteinuria and glomerulosclerosis in obese rats. Cardiac fibrosis and glomerular hypertrophy, present in obese rats, were not aggravated by DOCA-salt.

Conclusions: DOCA-salt increased the number of macrophages in heart, but not in glomeruli of obese ZSF1 rats.

Association Between Kidney Function and Lipid Levels in Older Adults
Shreya Srivastava, Josef Coresh, Casey Rebholz, Morgan Grams, Seth S. Martin, Jung-Im Shin. Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; Johns Hopkins Medicine, Baltimore, MD.

Background: The associations between kidney function and lipid levels in older adults have not been well characterized. Moreover, it is unknown whether residual atherosclerotic cardiovascular disease (ASCVD) risk after statin use differs by lipid levels other than total cholesterol (TC) or low-density lipoprotein cholesterol (LDL-C), such as triglyceride (TG).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We conducted a cross-sectional study of older adults (≥65 years) using visit 5 data (2011-2013) of the Atherosclerosis Risk in Communities study. Multivariable linear and logistic regression was used to examine the eGFR-lipid level associations, stratified by statin use. Among statin users without ASCVD who had LDL-C levels ≥100 mg/dL, we predicted 10-year ASCVD risk after statin use by TG levels (<150 mg/dL vs. ≥150 mg/dL) across eGFR levels.

Results: The mean age of the study population (n=4965) was 75 (SD 5) years, 58% were female, and 22% were Black. The mean eGFR was 63 (SD 18) ml/min/1.73 m² and 52% were on statins. In both statin users and non-users, there were no associations between eGFR and total TG or LDL-C. Low eGFR was associated with low high-density lipoprotein cholesterol (HDL-C) and high TG (Figure). Among statin non-users, eGFR <45 (vs. ≥60) was independently associated with low HDL-C (<50 mg/dL) (prevalence 95% CI: 1.86; 96% CI: 1.38-2.51) and high TG (≥150 mg/dL) (31% vs. 20%; 1.15; 1.01-1.30). The results were similar among statin users. Among statin users with LDL-C ≥100 mg/dL, the prevalence of high predicted ASCVD risk (risk ≥20%) was greater among those with vs. without high TG across all eGFR categories (eGFR ≥60, 66% vs. 59%; 45-59, 78% vs. 73%; eGFR <45, 90% vs. 79%).

Conclusions: We found that low eGFR was associated with low HDL-C and high TG levels, regardless of statin use. Among statin users who achieved adequate LDL-C control, ASCVD risk was still higher among those with high TG compared to those without high TG.

Cerebrovascular Dysfunction in CKD
Cortney Steele, Esther Oh, Heather Farmer-Bailey, Rachael L. Reddin, Taylor Strenumo, Michel Chonchol, Kristen L. Nowak. University of Colorado - Anschutz Medical Campus, Aurora, CO.

Background: Cerebrovascular dysfunction, characterized by reduced cerebrovascular reactivity, cerebral hypoperfusion, and increased pulsatile flow within the brain precedes the onset of dementia and is linked to cognitive dysfunction. While large-artery vascular dysfunction is prevalent in chronic kidney disease (CKD), cerebrovascular function has not been well characterized to date in moderate-to-severe CKD.

Methods: Using transcranial Doppler, we compared middle cerebral artery (MCA) blood flow-velocity response to hypercapnia (normalized for blood pressure and end-tidal CO₂) in a measure of cerebrovascular reactivity) and MCA pulsatility (a measure of cerebrovascular stiffness) in patients with stage 3-4 CKD vs. age-matched healthy controls using an independent samples t-test. We also administered the trail making test (parts A and B) as an index of processing speed and measured carotid-femoral pulse-wave velocity (CFPWV) as an index of aortic stiffness.

Results: Seven participants with CKD (2F, 68±3 yrs [means±SEM]), estimated glomerular filtration rate [eGFR]: 38±5 ml/min/1.73m²) were compared to 8 healthy controls (1F, 63±2 yrs, eGFR: 83±5 ml/min/1.73m²). MCA pulsatility index was greater (1.08±0.10 vs. 0.85±0.04 A.U.; p=0.05) and normalized MCA blood flow-velocity response to hypercapnia tended to be lower (6.3±4.0 vs. 11.6±7.3 %; p=0.06) in CKD as compared to healthy controls. Trail making part A time was slower (A: 31.8±3.3 s vs. 20.2±1.6 s; p<0.01); part B time tended to be slower (longer time to complete): 71.7±13.6 s vs. 42.7±6.7 s; p=0.07) and CFPWV was greater (1122±115 vs. 811±88 cm/sec; p=0.05) in CKD vs. control. Greater MCA pulsatility index correlated with worse cerebrovascular reactivity (r = −0.63, p=0.01), greater CFPWV (r = 0.65, p<0.01), slower trail making part B time (r = 0.59, p<0.05), and lower eGFR (r = −0.53, p=0.09).

Conclusions: Impaired cerebrovascular function is evident in patients with moderate-to-severe CKD. Increased cerebrovascular stiffness is associated with reduced kidney function, increased aortic stiffness, impaired processing speed, and worse cerebrovascular reactivity.

POI1830
Circadian Clock Provides Beneficial Effects Against Endothelial Dysfunction by Regulating Heme Synthesis and Heme Oxygenase 1 Expression
Hidemuki Negoro,1,2 Harvard Medical School, Boston, MA; 2The Graduate School of Project Design, Tokyo, Japan.

Background: The circadian clock is a molecular mechanism that confers 24 hours variations in gene expression and function to regulate number of physiological functions in humans. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. 5-Aminolevulinic acid (ALA) is the common precursor of heme. The iron ion is inserted into PPIX to form heme in the mitochondrion and incorporated into hemoproteins. Heme is a ligand of REV-ERBα and REV-ERβ which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 in different cell lines to evaluate the protein levels of HO-1 expression in the knocked down cells. To synchronize circadian rhythms, serum stimulations were performed. Cells were also pre-incubated with or without 1 mM ALA and 0.5 mM sodium ferrous citrate (SFC).

Results: In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to the regulation of key regulators for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. ALA/SFC co-incubation affected the oscillation and phase variation in gene expression and function to regulate number of physiological functions in humans. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. 5-Aminolevulinic acid (ALA) is the common precursor of heme. The iron ion is inserted into PPIX to form heme in the mitochondrion and incorporated into hemoproteins. Heme is a ligand of REV-ERBα and REV-ERβ which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherothrombosis by regulating Heme synthesis and HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Bradykinin Reduces Long-Lasting TRPV1-Mediated Inward Currents in Afferent Nonfiring Renal Neurons
Kristina Rodionova,1 Christina Forray-Strauss,1 Tilmann Ditting,1,2 Karl F. Hilgers,2 Nada Cordasc,2 Peter Linz,2 Christian Ott,2 Roland E. Schmieder,1 Mario Schiffer,1 Kerstin U. Amann,1 Roland Veelken,1
1Universitätsklinikum Erlangen - Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität - Nürnberg, Nürnberg, Germany; 3Universitätsklinikum Erlangen, Abteilung für Nephropathologie, Erlangen, Germany.

Background: Bradykinin has been reported to be sympathoexcitatory via renal afferent nerves. Hence we tested the hypothesis that bradykinin directly stimulates cultivated renal neurons with afferent axons.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were investigated in voltage clamp mode to assess inward currents and current clamp mode to assess action potential (AP) generation [neurons classified as tonic (high AP generation upon stimulation), phasic (AP ≤ 5 upon stimulation) or no firing]. Stimulation of TRPV1 receptors by protons (pH 6) with and without the addition of bradykinin (1, 10, 100 µM). 111 DRG renal neurons retrogradely stained with Dil for investigation.

Results: Bradykinin (BK) alone did not induce inward currents nor APs. Proton stimulation (pH 6) of TRPV1 significantly augmented long-term inward currents (baseline -0.36 ± 0.09 nA vs. -1.39 ± 0.34 nA, p < 0.05, mean±SEM) and increased action potential generation in tonic neurons (0 APs/10s vs. 9.57 ± 1.89 APs/10s, p < 0.05, mean±SEM). However, the co-stimulation of renal neurons with protons and BK had any effect only in one specific subgroup of renal neurons: it significantly decreased long-lasting currents in non firing neurons (AD stimulation with 100µM BK+HCl: -0.12 ± 0.62 nA, 10µM BK+HCl: -0.11 ± 0.07 nA; 1µM BK+HCl: -0.06 ± 0.02 nA versus pH 6: -0.32 ± 0.06 nA*, **p < 0.05, mean±SEM).

Conclusions: Bradykinin was only able to reduce long-lasting, TRPV1 dependent inward currents in non-firing renal neurons. Alterations of inward currents are likely involved in the release of neurogenic proinflammatory peptides (SP, CGRP). Hence, bradykinin might impair the release of neuropetides from intraretal axons of a specific subgroup of renal afferent neurons.

T Lymphocytes in Human Hypertension
Ghalz Z. Quinn,1 Xin Sheng,1 Amin Abedini,1 Lynda Vuong,2 Briania G. Nixon,2 Jonathan Hill,2 Steven S. Pullen,1 Myung Shin,3 Ming Li,4 A. A. Hakimi,1 Katalin Suzsak,1 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3Bristol-Myers Squibb, Inc., Ridgefield, CT; 4Merck & Co Inc, Kenilworth, NJ.

Background: Mouse models have shown that T lymphocytes are required for hypertension (HTN) development and accumulate in the vasculature and kidneys. The role of immune cells, including T lymphocytes, remains poorly understood in patients with HTN. Here, we analyzed immune cells in human kidney tissue samples in patients with HTN.

Methods: Human kidney tissue was obtained from the unaffected portions of 631 tumor nephrectomies and included clinical, histological and follow-up tissue data. Tissue was microdissected into glomerular and tubular compartments for RNA-sequencing. In silico deconvolution of each kidney sample was performed using the CIBERSORTx method to enumerate relative cell type fractions. Flow cytometry was used for validation analyses using cell type specific antibodies in another set of 58 human kidney tissue samples. Regression analyses were used to determine the associations of renal immune cells and clinical parameters. Linear mixed modeling was used to assess longitudinal data.

Results: CD4 and CD8 T-cells were increased in patients with HTN (p=0.05) while T regulatory cells (Tregs) were decreased (0.4% vs. 0.6%, p=0.022). In adjusted models, HTN was associated with older age, Black race, diabetes, decreasing eGFR, and lower Tregs and natural killer T-cells and higher CD4 T-cells were associated with HTN, independent of baseline eGFR or the degree of renal fibrosis (p<0.01). We observed that 3.8mM BGP decreased fibronectin expression (p<0.01), but did not significantly change trimeric collagen I (COL1) expression. Additionally, 3.8mM BGP decreased fibronectin expression (p<0.01), but did not significantly change trimeric collagen I (COL1) expression. In vitro studies involving treatment of human ventricular cardiac fibroblast models were also conducted.

Results: Hearts from HD donors exhibited significant myofibrosis (p<0.01) compared to HTN and control. HD and HTN hearts had higher heart weights (p<0.01) and greater LV wall thickness (p<0.01) compared to control hearts. RNA-sequencing revealed that the focal adhesion pathway was one of the most perturbed pathways in HD hearts compared to control. FAK mRNA and protein expression was significantly upregulated (p<0.05), and major cytoskeletal proteins associated with the focal adhesion pathway, including β-actin (p<0.01), β-tubulin (p<0.01), vinculin (p<0.05), and vimentin (p<0.01) were significantly dysregulated in HD hearts compared to control. Uremic mineral stressors (high phosphate and high calcium) decreased FAK expression as well as β-tubulin (p<0.05) and vimentin, and promoted cleavage of FAK and vimentin, in vitro. Concurrent FAK sRNA transfection and mineral stress significantly decreased both full-length and cleaved FAK expression (p<0.05) and further dysregulated vimentin (p<0.05) and vinculin (p<0.05) expression, in vitro.

Conclusions: FAK and the focal adhesion pathway plays a central role in the development of CKD-associated cardiomyopathy and appears to preserve the dynamic formation and turnover of cytoskeletal HD hearts. These findings suggest a potential therapeutic target for regulating the focal adhesion pathway in the management of cardiac remodeling in CKD.
Plasma Proteins Associated with eGFR and Incident Cardiovascular Events in the Cardiovascular Health Study Cohort

Christine P. Limonte,1 Pranav S. Garimella,2 Robert Gorszet,3 Diana I. Jalal,4 Michelle Odde,5 Michael Shlipak,6 Nisha Bansal,7 Thomas R. Austin,8 Ian H. de Boer,9 University of Washington, Seattle, WA; 10 The University of Iowa Hospitals and Clinics, Iowa City, IA; 11 University of California San Francisco, San Francisco, CA; 12 University of California San Diego, La Jolla, CA; 13 Beth Israel Deaconess Medical Center, Boston, MA; 14 Stanford University, Stanford, CA.

Background: Proteinomics may help identify mechanisms through which low estimated glomerular filtration rate (eGFR) increases risks of heart failure (HF), myocardial infarction (MI), and cardiovascular (CV) death. We investigated the changes in pendrin levels in urinary extravasal (uEV) and intracellular vesicles (eVs) from patients with aldosterone (PA) and in rats with aldosterone-induced hypertension.

Methods: We designed an aptamer-based assay to measure 1300 proteins among 3185 older adults in the Cardiovascular Health Study. Proteins associated with eGFR were identified using linear regression models. A Bonferroni-corrected p-value less than 7.6x10^-8 was used to account for multiple testing. Proteins significantly associated with eGFR were tested for associations with incident HF, MI, and CV death using Cox-proportional hazard regression adjusting for demographic and clinical variables. We evaluated whether proteins mediated associations between eGFR and incident CV events.

Results: The mean baseline eGFR was 70 ml/min/1.73m^2 and over a follow-up median of 13 years, there were 1033 incident HF, 555 incident MI, and 963 CV death events. 797 proteins were significantly associated with eGFR. Of these, 52, 0, and 22 proteins were associated with incident HF, MI, and CV death, respectively. All proteins associated with HF and CV death significantly mediated the effects between eGFR and incident CHF and CV death, respectively. The 10 proteins most strongly associated with both HF and CV are shown in Table.

Conclusions: eGFR is associated with a large number of plasma proteins. A subset of these proteins are also associated with incident HF and CV death and may reflect mechanisms through which reduced eGFR increases the risk of these outcomes.

Funding: Other NIH Support - NIH - NHLBI

Conclusions: This study included 30 patients who were diagnosed as having PA in Yokohama Rosai Hospital or in Teikyo University Hospital. The protocol was approved by the institutional review board. In animal experiments, SD rats received continuous infusion of aldosterone after uninephrectomy. Isolation of uEV was performed by the ultracentrifugation method in accordance with the previous report (Fernandez-Llama et al. JCI 2010).

Results: Western blot analysis revealed that pendrin is detected in dimeric and monomeric forms in uEVs in humans and in rats. In aldosterone-infused rats, pendrin levels in uEVs were highly correlated with the pendrin abundance in the kidney. We also found significant correlation between abundance in uEVs and that in the kidney for Na-CI cotransporter and epithelial Na channel in this model. In PA patients, pendrin levels in uEVs were reduced by 49% from the baseline by adenectomy or pharmacological MR blockade. Correlation analysis revealed that the magnitude of pendrin reduction after treatment significantly correlated with the baseline aldosterone-renin ratio (ARR), and tended to inversely correlate with serum K+ levels. Furthermore, a cross-sectional analysis in PA patients confirmed a significant correlation between ARR and pendrin levels in uEVs.

Conclusions: These data are consistent with experimental studies demonstrating the role of pendrin in aldosterone-induced hypertension, and suggest that pendrin analysis in uEVs may also be useful to understand the pathophysiology of human hypertension.

Correlations of Creatinine with Biomarkers of Tubular Injury and Secretory Function in Patients Admitted with Heart Failure
Alexander J. Kula,1,2 David K. Prince,2 Kevin D. O’Brien,2 Bryan R. Kestenbaum,2 Song Li,2 Nisha Bansal,2 Seattle Children’s Hospital, Seattle, WA;1University of Washington, Seattle, WA.

Background: Serum creatinine values during hospitalization for decompensated heart failure (ADHF) may not comprehensively capture kidney function. The aim of this pilot study was to evaluate correlations of traditional markers of filtration (serum creatinine) with novel measures of tubular injury and tubular secretion in patients admitted with ADHF.

Methods: Biospecimens were obtained within 24 hours of admission in 61 patients admitted with ADHF at a University of Washington hospital. We measured serum creatinine, urine tubular injury markers (urine NGAL, KIM-1, II-18 and TIMP2 standardized to urine creatinine) and proximal tubular secretory function ([urine concentration]/[plasma concentration] normalized to U). We calculated spearman correlations of each kidney measure with each other and admission serum brain natriuretic peptide (BNP).

Results: Serum creatinine poorly correlated to biomarkers of tubular injury (Table 1). Higher serum creatinine was significantly correlated with lower clearance of all secretory biomarkers aside from cinnamoylglycine. Admission BNP did not correlate with serum creatinine or injury biomarkers but had a consistent inverse relationship with secretory biomarkers aside from cinnamoylglycine. Admission BNP poorly correlated to biomarkers of tubular injury (Table 1).

Conclusions: The results from this pilot study demonstrate that serum creatinine poorly correlates with biomarkers of tubular injury and inversely correlates with tubular secretory clearance in patients admitted for ADHF. More research is needed to understand how filtration, tubular injury, and secretory clearance relate to clinical outcomes and response to treatment in patients with ADHF.

PO1844
RAAS vs. COVID: Case of an 18-Year-Old with New-Onset Hypertension
Srikanth Thiruvaresan,1 Arthita Jeyarajasingam,1 Theesitha Srikanth,1 Sichuan University West China Hospital, Chengdu, China;2University of Washington, Seattle, WA.

Introduction: It has been increasingly known that SARS-CoV-2 causes an imbalance in the Renin-Angiotensin-Aldosterone System (RAAS). Here we present an interesting case of a young man, who presented with new onset of HTN and elevated renin and aldosterone levels with a history of COVID-19.

Case Description: An 18-year-old Caucasian man with a remote history of asthma initially presented to his primary care physician with new onset of headaches. He was noted to have an elevated blood pressure, but otherwise a benign physical examination. A workup for secondary HTN revealed an elevated renin (8.7 ng/mL/hr), aldosterone levels (42 ng/dL) and otherwise unremarkable. He was started on Enalapril 5mg daily. A workup including CT and MRI of the brain, were unremarkable. He was referred to nephrology for the new diagnosis of HTN and elevated renin and aldosterone levels with a history of COVID-19.

During the initial renal evaluation, patient was asymptomatic and his BP was well controlled on the Enalapril. Renin and aldosterone levels were repeated, about 8 weeks after the cessation of Enalapril. Patient’s blood pressure remained well controlled and didn’t require any medications. Since the diagnosis of HTN, the patient maintained a strict low salt diet. He always had good fluid intake. At a follow up visit, patient continued to remain asymptomatic and with good blood pressure control without needing medications. Repeat renin (1.9 ng/mL/hr) and aldosterone (16.8 ng/dL), as well as aldosterone/renin levels were resulted within normal limits. Later patient admitted that he was diagnosed with COVID-19 a month prior to his onset of headaches.

Discussion: SARS-CoV-2, which causes COVID-19, is known to hijack the RAAS cascade and use ACE2 enzyme to make human cell entry. Studies have demonstrated the possible correlation between COVID severity and comorbidities such as HTN (potentially involving the RAAS). Current recommendations are to continue the use of ACE Inhibitors (ACEI) and Angiotensin Receptor Blockers (ARB) in COVID-19 patients. Our case, not only supports the above findings, but also demonstrates how RAAS is vulnerable to SARS-CoV-2, can manifest with new onset HTN and other complications. It is also interesting to see, how ACEIs and ARBs should be utilized as first line agents for BP control and to improve outcomes. To much relief, the effect on RAAS by the SARS-CoV-2 seems to be transient and short lived.
Page Kidney and Uncontrolled Hypertension: Rare Complication Post Kidney Biopsy

Navaera Ammad, Marvi M. Bukhari, Blaise W. Abramovitz. University of Pittsburgh Medical Center, Pittsburgh, PA.

Introduction: Page kidney is a rare phenomenon defined as an external compression of the renal parenchyma that can lead to hypertension and acute kidney injury. Compression of the renal parenchyma can occur from the formation of a subcapsular hematoma of traumatic or non-traumatic origin. This phenomenon can be seen as a rare cause of hypoperfusion related to subcapsular hematoma formation following kidney biopsy. We report a case of a 34-year-old male with chronic kidney disease who developed abdominal pain and uncontrolled hypertension within 24 hours of kidney biopsy, found to have imaging findings consistent with Page kidney as a complication of the procedure.

Case Description: A 34-year-old male patient with a history of HTN, CAD, and stage 3B CKD presented to the ER with left flank pain and hypertensive urgency with SBP > 200 mmHg one day following a native kidney biopsy. He underwent a kidney biopsy for evaluation of sub-nephrotic range proteinuria and unclear etiology of CKD. CT abdomen/pelvis with contrast demonstrated a new 3.5 cm left subcapsular hematoma with perinephric and retroperitoneal extension. Abdominal pain worsened and repeat imaging showed expansion of the hematoma up to 24.5 cm. Before, during, and after kidney biopsy, the patient had well-controlled HTN with SBP range in the 130-140 mmHg. The day following the biopsy, SBP had risen to over 200 mmHg. Given his recent biopsy, significant HTN, and expansion of subcapsular hematoma on imaging, Page kidney was identified as the culprit leading to uncontrolled HTN. He was admitted to the ICU and started on a nicardipine drip with improvement in BP. Interventional radiology was consulted, and the patient underwent a left renal angiogram showing active extravasation at the hematoma site, which was then embolized. The patient achieved adequate BP control and the nicardipine drip was successfully weaned off. He was then transitioned back to his home oral antihypertensives.

Discussion: Page kidney refers to a condition in which there is an external force compressing the kidney resulting in decreased kidney perfusion manifesting in a state of ischemia. This activates the RAAS system leading to secondary hypertension. Although many cases have previously been reported, Page kidney remains an uncommon cause, especially over recent years, of uncontrolled secondary hypertension and acute kidney injury.

Non-suppressed Plasma Renin Activity in Primary Aldosteronism with Hypertensive Kidney Disease

Hazem Ayesh. University of Toledo - Health Science Campus, Toledo, OH.

Introduction: Primary aldosteronism (PA) prevalence has been estimated at 4.7–25.5% of all hypertensive patients. Renin aldosterone ratio (ARR) serves as a widely used screening test. Elevated ARR with suppressed plasma renin activity (PRA) is considered a positive screening test which should be followed by confirmatory testing. There are cases when PA is associated with non-suppressed PRA as in our case.

Case Description: A 37-year-old African American female patient with a past medical history of chronic kidney disease stage 4 presented to the hospital with a complaint of severe headache for 2 days associated with nausea and vomiting. Physical exam was remarkable for tachycardia and elevated blood pressure at 190/101 mmHg. Notable labs include low potassium at 3.4 [3.5 – 5.0 mmol/L], elevated creatinine at 4.84 [0.40 – 1.00 mg/dL] with a baseline creatinine of 2.36 mg/dL, urinalysis was positive for proteinuria. Secondary hypertension workup showed unremarkable renal duplex ultrasound, unremarkable thyroid function test, normal free plasma metanephrine, unremarkable urine drug screen. Screening for Cushing’s syndrome wasn’t performed given there were no supporting clinical manifestations. Plasma aldosterone concentration (PAC) elevated at 64.1 [3.1 – 35.4 ng/dL] with normal PRA at 1.7 ng/mL-hour. Calculated ARR was elevated at 37.7 ng/dL per ng/mL-hour, which raised the suspicion for primary aldosteronism (PA). Saline infusion test (SIT) showed elevated post-infusion PAC at 78.1 ng/dL which confirmed the diagnosis of PA.

Discussion: There are reports in literature that PA is more common than initially thought and has adverse effects on cardiovascular and renal systems independent of hypertension. So early diagnosis and management are highly recommended. The initial finding of non-suppressed PRA despite elevated ARR complicated diagnostic process. Multiple case studies reported non-suppressed PRA in patients with PA, especially when associated with hypertensive kidney disease and arteriosclerosis. In our case, kidney biopsy showed glomerulosclerosis with arteriopathy consistent with hypertensive kidney disease. We suggest focusing on ARR as a reliable screening for PA and not solely depend on the fact that PA is associated with suppressed PRA, especially in these cases. Another important point is to consider lowering ARR cutoff for diagnosis of PA since PRA isn’t completely suppressed in these cases.

Abiraterone-Induced Mineralocorticoid Excess Despite Concurrent Prednisone in Setting of Drug-Induced Liver Injury (DILI)

Georges Nakhoul, Jessica Nino, Xin Yee Tan, Ali Mehdi, Roman A. Shinghaver. Cleveland Clinic, Cleveland, OH.

Introduction: Abiraterone, a CYP17A inhibitor used in the treatment of castration-resistant prostate cancer (CRPC), is prescribed with concurrent glucocorticoids (GC) to prevent secondary mineralocorticoid excess (SME). We hereby describe a case of refractory hypokalemia in setting of abiraterone-induced SME despite prophylactic GC.

Case Description: A 70-year-old male with CRPC on abiraterone 1g and prednisone 5mg daily, presented with jaundice, fatigue, and hypertension. Workup revealed hyperbilirubinemia, transaminitis and profound hypokalemia. Liver biopsy demonstrated DILI. Abiraterone was thus discontinued. Hypokalemia persisted despite aggressive repletion with up to 320mEq KCl daily. Deoxycorticosterone elevation confirmed abiraterone-induced SME. Increased dosage of prednisone to 40mg daily and addition of eplerenone led to prompt normalization of potassium and blood pressure. Darolutamide was started after DILI resolution for CRPC treatment.

Discussion: Abiraterone’s antitumor effect lies in reduction of androgen production by CYP17 inhibition. Excessive deoxycorticosterone/corticosterone accumulation, driven by reactive rise in corticotropin, may manifest as hypokalemia, hypertension or fluid retention. GC coadministration serves to mitigate SME. SME in this case may be explained by 1) Liver injury: Pharmacokinetic studies have shown increased systemic abiraterone exposure in liver impairment up to 3.6 folds, necessitating dose reduction or drug discontinuation. Severe liver impairment causing decreased availability of hepatic 11β-hydroxylase (11β-HSD1) may also partially contribute to its active form prednisolone, removing negative feedback to corticotropin. 2) Prednisone 5mg BID or dexamethasone 0.5mg daily has shown superiority to prednisone 5mg daily (in this case) for SME prevention, at expense of greater weight gain and insulin resistance. Eplerenone can be used in addition to GC in SME treatment and may be noninferior to GC as steroid sparing preventive option. Spironolactone should be avoided due to its affinity to androgen receptor. It is prudent to monitor for medication adjustment as SME resolves.

Non-suppressed Plasma Renin Activity in Primary Aldosteronism with Hypertensive Kidney Disease

Suramath Isaranuwatchai. Chulabhorn Hospital, Bangkok, Thailand.

Background: Hypertonatremia is the most common electrolyte disorder in cancer patients and associated with poor prognosis in several types of cancer. Severe hyponatremia (serum sodium less than 120 mmol/L) is linked to increased hospital length. We conducted this retrospective study to evaluate for clinical and laboratory characteristics of cancer patients with severe hyponatremia.

Methods: Medical records from previous 2 years at Chulabhorn hospital were reviewed. Cancer patients who had serum sodium less than 120 mmol/L were included. Clinical data, including symptoms, causes of hyponatremia, treatments, response to treatments and survival rate, were recorded.

Results: A total of 154 patients with cancer and severe hyponatremia were identified. 147 patients (95.5%) had solid malignancy. Only 7 patients (4.5%) had hematologic malignancy, all of which were lymphoma. The most common solid malignancy was hepatocellular carcinoma (14.9%), followed by lung cancer (14.3%) and pancreatic cancer (10.4%). Interestingly, 36.3% of patients were asymptomatic despite severe hyponatremia. Of 98 patients that were diagnosed with symptomatic hyponatremia, the most common symptom was fatigue (30.5%), followed by nausea/vomiting (26.0%) and alteration of consciousness (19.5%). Seizures were present in only 3 patients (1.9%). The most common cause of hyponatremia was volume depletion (83.8%), which was mostly due to poor intake. Syndrome of inappropriate antidiuresis (SIAD) was the cause of severe hyponatremia in only 7 patients (4.5%). Most of our patients (76.0%) were treated with isotonic saline infusion and 83.8% of which responded with significant improvement in serum sodium level. Hypertonic saline infusion was given in only 27 patients (17.5%). Survival rate at 30 days was 46.1% and survival rate at 6 months was 26.4%.

Conclusions: Our data demonstrated that the most common cause of severe hyponatremia in cancer patients was volume depletion from poor intake, in contrast to SIAD which was suggested by other previous studies. In addition, most patients in our cohort responded to isotonic saline infusion. Fluid restriction and diuretic/aquaretic drug administration, presuming that patients have SIAD, may worsen the serum sodium level in these hyponovolemic cancer patients. This study emphasized the importance of clinical evaluation and investigation for cancer patients with severe hyponatremia to achieve the correct diagnosis and provide proper management.
PO1850
Novel Use of Daratumumab for Post-Hematopoietic Cell Transplant Membranous Nephropathy
Stefanie W. Benoit,1,2 Pooja Khandelwal,1,2 Michael S. Grilley,1,2 Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 1University of Cincinnati College of Medicine, Cincinnati, OH.

Introduction: Membranous nephropathy (MN) is the most common cause of glomerulopathy after hematopoietic cell transplantation (HCT), usually seen with graft versus host disease (GVHD). Although remission frequently occurs upon immunosuppression, 20% of patients fail to respond and may progress to end stage renal disease. Here we report the rapid remission of a treatment resistant patient with daratumumab (Dmab).

Case Description: A 16 year old female 1 year post-HCT for beta thalassemia major was started on rituximab for oral GVHD. Three months later, she developed nephrotic syndrome. Renal biopsy showed MN. Serum and renal tissue were negative for PLA2R antibody. Rituximab was changed to rituximab in case MN was medication induced. She was treated with tacrolimus (tough 3 – 8 ng/mL), prednisone, losartan, atorvastatin, and 4 weekly rituximab infusions. Eight months into therapy, she failed to meet criteria for even partial remission. The toxicity of additional steroids and or cyclophosphamide was undesirable. With 0% CD19 cells, rituximab was not indicated. Thus, plasma cell dyscrasia was treated with tacrolimus (trough 3 – 8 ng/mL), prednisone, losartan, atorvastatin, and 4 weekly rituximab infusions. Eight months into therapy, she failed to meet criteria for even partial remission. The toxicity of additional steroids and or cyclophosphamide was undesirable. With 0% CD19 cells, rituximab was not indicated. Thus, plasma cell dyscrasia was started on ruxolitinib for oral GVHD. Three months later, she developed nephrotic syndrome resolved and her serum albumin was greater than 3.0 g/dL by week 10. She weaned off of steroids and tacrolimus by week 16, at which time she had near-complete remission of her renal disease. Trialed off of losartan week 16 – 17, but protein excretion increased, so it was restarted. Time course and biomarkers of MN are in Figure 1.

Discussion: The mechanism of HCT-associated MN is incompletely understood. Its association with GVHD and often successful treatment with rituximab have implicated direct or indirect humoral activation as potential pathogenic mechanisms. The success of CD38 depletion with Dmab may imply omalizumab production by resident plasma cells as a driver of refractory disease. Dmab may be a novel therapeutic option for HCT patients who are not responsive to traditional MN therapy.

Figure 1: Time course and biomarkers of MN after Dmab. *Urinary collection 15 hours

PO1852

Background: the prevalence of chronic kidney disease is high among kidney neoplasm patients because of the overlapping risk factors. We aim to identify risk factors of eGFR decline in kidney cancer survivors post partial nephrectomy (nx).

Methods: All partial nx patients with neoplasm at Northwell Health were included (2018/7-2020/5, n=187). Clinical and histology parameters, including neoplastic and non-neoplastic pathology, were analyzed. Non-neoplastic assessment includes glomerulosclerosis(GS), interstitial fibrosis and tubular atrophy(IFPA), and a semi-quantitative estimate of the severity of arterial and arteriolar sclerosis (AAS). Multivariate linear mixed model was performed. Independent variables included age, sex, hypertension, diabetes, baseline eGFR, tumor diagnosis, proteinuria, G5%, IFTA%, and AAS.

Results: The median follow-up time is 147d. In all patients, independent risk factors of post-nx decreased eGFR were female(p=0.02), age(p<0.01), overweight(p<0.001), eGFR<90 at the time of nephrectomy(p<0.001), severe AAS(p<0.01), and prolonged follow-up. In the ones with baseline eGFR≥90(n=61), proteinuria(p<0.001) and the non-cancer kidney organoids for cancer invasion assay. The CL experiment showed that M2-like macrophage depletion from the IRI-kidney cortex inhibited tumor progression and increased tumor infiltrated CD8 T cell. And CD8 efficacy in reduction or inhibition of the invasion.

Results: Kidney cancer on IRI kidneys (IRI-KC) was more progressive than that on non-cancer kidneys. AAS. (p=0.02), GS%>25%(p=0.02) and overweight (p=0.03) were independent risk factors of decreased post-nx eGFR. eGFR time trend of patients with and without these risk factors is shown in the figure.

Conclusions: We propose a minimum workup for this population to include eGFR, urinalysis, and non-neoplastic pathology evaluation. The time of kidney cancer treatment may be a unique opportunity for these patients to be identified and directed to early interventions, including nephrology consults and patient education on nutrition and weight control.

PO1853
Development of 3D Renal Cell Carcinoma Organoids and Cancer Invasion Assay Nathan Lee,1 Shun-Yang Cheng,1,2 Joseph V. Bonventre.1 1Brigham and Women’s Hospital, Boston, MA; 1University of Southern California, Los Angeles, CA.

Background: Recent advances in in vitro 3D culture technologies, such as organoids, derived from hPSCs, have opened new avenues for development of human disease models. Modeling cancer by utilizing cancer organoids provides advantages as they maintain 3D cell-cell interactions, heterogeneity, microenvironment, and drug response of the sample they originate from. Such preclinical models are essential for more efficient translation of cancer research into novel treatment regimens for patients. 5-year survival rate at advanced stage IV RCC is 17% less than 10%, as RCC is also notorious for resistance to chemotherapy and radiation therapy. Therefore, development of effective tools for better understanding and drug screening for RCC are needed. Kidney cancer organoids and novel assays such as cancer invasion assays can be useful tools to personalize potential therapeutics.

Methods: Primary kidney cancer cell lines were generated from patient biopsy samples. 3D kidney cancer organoids and non-cancer kidney organoids for cancer invasion assay were generated from primary kidney cancer cell lines and hPSCs, respectively, by modifications of our laboratory’s prior published kidney organoids techniques. Organoids were characterized by immunostaining. Upon maturation, organoids were added onto the non-cancer kidney organoids and incubated together for the invasion assay with or without treatment with drugs. Frozen sections and imaging were utilized to examine the cancer invasion. Kidney cancer organoids were treated with various drugs to investigate efficacy in reduction or inhibition of the invasion.

Results: RCC cancer organoids showed significantly better expression of kidney cancer markers such as KIM-1, HIF-1α, HIF-2α, and CAIX compared to 2D primary RCC cells. Addition of the cancer organoids to normal kidney organoids within 3 days. Treatment of the cancer organoids by the receptor tyrosine kinase inhibitor, sunitinib or the histone acetyltransferase inhibitor (A-485) showed reduction in efficacy of cancer invasion.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author. 571
Conclusions: Development and use of cancer invasion assay for renal cell carcinoma utilizing kidney cancer patient derived kidney organoids could lead to better understanding of cancer invasion and provide the capability to screen and profile for identification of potential treatment options in renal cell carcinoma.

Multi-Omics Approach to Uncover Underlying Biology of Low-Risk Clear Cell Renal Cell Carcinoma Patients with Progressive Disease

Philipp Strauss,1 Andreas Scherer,1 Oystein Elkrem,1 Hans-Peter Marti.1 1Universitetet i Bergen, Bergen, Norway; 2spheromics, Helsinki, Finland.

Background: Renal Cell Carcinoma (RCC) constitutes approximately 3 % of all cancers and its incidence is rising worldwide, especially in Western countries. In the last two decades, enormous advances have been made in the development and implementation of medical therapies for metastatic ccRCC, however, surgery still represents the only curative option. One of the issues in developing a curative medical therapy lies in the high degree of inter- and intra tumor heterogeneity. We believe that by applying multi-omics technology to highly specific subgroups and comparing them to closely matched controls we can mitigate the heterogeneity issue and deepen our understanding one step and subgroup at the time.

Methods: We assembled a cohort of ccRCC patients (n=443) and identified all “low-risk” patients which later developed progressing tumours (n=8). Subsequently we performed genome-wide expression profiling, miRNA profiling and proteomics profiling from formalin-fixed samples obtained at initial surgery from these “low-risk” patients and 16 matched patients not progressing to recurrence with metastasis. The patients were matched for Leibovich risk score, age, sex, tumor size and tumor stage.

Results: Pathway analysis yielded differences between progressive and non-progressive patients in categories such as Molecular Mechanisms of Cancer, B Cell Receptor Signaling in mRNA data and Acute Phase Response Signaling and FXR/RXR Activation in proteomics data. By integrating our three -omics analysis we revealed that acute Phase Response Signaling also plays a role on all three levels. Additionally, we developed a 14-component classifier, drawing from both mRNA, miRNA and protein-based data that reliably differentiated the different subgroups. We further examined the correlations between each of the components and uncovered a dense network of interactions.

Conclusions: Multi-omics methods represent an important tool in furthering our understanding renal cancer biology in the pursuit of medical therapies.

PO1855

TME2M7 Expression and Clinical Characteristics and Survival in Clear Cell Renal Cell Carcinoma

Rickinder Grewal,1 Hae Yoon Grace Choung,1 Lisa L. Roberts,1 Timothy J. Beane,1 Luojing Chen,1 Daniel X. Gilroy,2 Thu H. Le.1 1University of Rochester School of Medicine and Dentistry, Rochester, NY; 2Rochester Institute of Technology, Rochester, NY.

Background: Transmembrane protein 27 (TME2M7/collectrin), a glycoprotein and homolog of angiogenic matricellular enzyme 2 (ACE2), is a regulator of renal amino acid uptake in the proximal tubule and may have a protective role in hypertension. Two previous reports have shown that the absence of TME2M7 expression in clear cell renal cell carcinoma (ccRCC) correlates with poorer cancer-related survival. Here we report our findings of TME2M7 expression in ccRCC and clinical outcomes.

Methods: We conducted a retrospective analysis to identify all cases of ccRCC diagnosed between 2010 and 2015 at the University of Rochester Medical Center. The intensity of TME2M7 immunostaining on tumor tissue was semi-quantitatively graded on a scale of 0, 0.5, 1, 1.5, 2, 2.5, and 3 by a single pathologist, and correlated with tumor characteristics and survival.

Results: There were 321 cases of ccRCC. There was evidence of metastasis at time of nephrectomy in 36 (11.2%), and at the latest follow up in 70 (21.8%), and 82 (25.5%) of patients.

Conclusions: The absence of TME2M7 expression is associated with more aggressive tumor characteristics and poorer all-cause mortality in ccRCC. TME2M7 may be a useful biomarker to assess cancer prognosis. Further studies are needed to better assess if TME2M7 is protective in RCC.

Role of miR-23b and miR-133a in Apoptosis Control Induced by TRAIL in Lung Adenocarcinoma and Kidney Carcinoma Cell Lines

Denise Leite, Edgar Maquigussa, Mirian A. Boim. Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil.

Background: Lung and kidney cancer are often diagnosed as advanced disease and frequently become resistant to systemic therapies. Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL) binds to TRAIL receptor 1 and 2 (TRAIL-R1/R2) on the cell surface to stimulate apoptosis, making TRAIL apoptotic pathway a promising target for cancer therapy. Cullin-3 ubiquitination is essential to TRAIL receptors activation. However, resistance to TRAIL is an obstacle to achieve an effective anti-tumoral therapy. One of the mechanisms that lead to TRAIL resistance appears to be dependent on translocation, mediated by clathrin (CLTA), of TRAIL receptors to the nucleus. MicroRNAs (miRs)-23b and -133a may have relevant role in TRAIL resistance.

Methods: A549 and CaKi-2 cell lines and their respective controls (MRC-5 and HK2) were used. mRNA expressions of miR-23b, miR-133a, TRAIL-R1/R2, CLT3, CLAIPaf-1 and KPNA-1 were estimated by RT-qPCR. MTT assay was used to evaluate the effect of TRAIL-induced cytotoxicity. TRAIL receptors cellular distribution was determined by western blot.

Results: Both cell lines were TRAIL resistant on MTT. TRAIL-R1 and TRAIL-R2 were predominantly located in nuclear compartment of A549 cells. TargetScan showed that miR-23b targets CLT3, Apaf-1 and KPNA-1 and miR-133a targets CLTA. MiR-23b expression was upregulated in A549 and CaKi-2 cells. MiR-23b inhibition upregulated CLT3 expression in A549 cells. In contrast, miR-133a was undetectable in both cell lines. TargetScan was used to determine potential mRNA targets for miR-23b and miR-133a.

Conclusions: MiR-23b expression was upregulated in A549 and CaKi-2 cells. However, supposed miR-23a target mRNAs were unchanged suggesting no relationship between miR-23a and those molecules. MiR-23b inhibition upregulated CLT3 expression in A549 cells, which could enhance TRAIL receptors activation and sensitivity- this will be investigated in next step. In contrast, miR-133a was undetectable raising the hypothesis of an increased capacity of cells to translocate TRAIL receptors to the nucleus via clathrin and thus be resistant to TRAIL. The possible miR-133a ability to reduce clathrin expression may represent a novel approach for control of TRAIL apoptotic pathway and must be further investigated as a TRAIL sensitizing mechanism.

PO1857

Recapitulating Kidney Angiomyolipoma with Renal Organoids

Generated from Tuberous Sclerosis Complex Patient-Derived Induced Pluripotent Stem Cells

Dario R. Lemos,1,2 Lemos Lab 1Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA.

Background: Angiomyolipomas (AMLs) constitute 80% of the renal lesions found in patients with Tuberous Sclerosis Complex. AML can cause kidney failure and lead to premature death due to the formation of vascular aneurysms that are prone to spontaneous bleeding. Key aspects of the pathology of AMLs, and most remarkably the cell(s) type(s) and developmental mechanisms that give raise to the lesions, remain unknown. Previous efforts to recapitulate AML experimentally using transgenic mice have failed to produce reliable models of AMLs, precluding our ability to study tumor mechanisms and develop novel therapies.

Methods: We directed the nephric differentiation of a series of TSC patient-derived iPSC lines that included a line carrying a heterozygous microdeletion in the TSC2 locus (TSC2-/-), a TALEN-engineered isogenic cell line carrying microdeletions in both TSC2 alleles (TSC2-/-) and a cell line in which the original mutation present in the patient was corrected using CRISPR-Cas9 (TSC2-/-).

Results: We derived renal organoids from isogenic TSC2-/-, TSC2-/- and TSC2-/- iPSCs. Flow cytometry analysis of kidney organoids derived from TSC2-/- iPSCs but not from isogenic TSC2-/- or TSC2-/- iPSCs were enriched in ACTA2 cells, a percentage of which (~24%) co-expressed melanocytic markers including prelaminar protein (PMEL), melanin A (MLANA) and cathepsin K (CTSK) indicative of a myomelanocytic phenotype that is a hallmark of kidney AMLs. Morphologically, ACTA2 cells found in TSC2-/- organoids had a plump myoid morphology that matched the well-characterized morphology of kidney AML cells. Whole transcriptome RNA sequencing (RNA-seq) of TSC2-/-, TSC2-/- and TSC2-/- organoids identified MLANA, PMEL, GPNMB, MITF, CTSK and ACTA2 as genes that were exclusively upregulated in TSC2-/- organoids, confirming the myomelanocytic phenotype of TSC2-/- AML organoids. Hallmark gene sets enriched in TSC2-/- renal organoids in each comparison included IL-6-JAK-STAT3 signaling, adipogenesis, angiogenesis, fatty acid metabolism, KRAS signaling and estrogen response, as major pathways shared with kidney AMLs.

Conclusions: Collectively, our findings support the notion that AMLs originate from cells of the renal lineage and suggest a central role for TSC2 loss-of-heterozygosity (LOH) genetic mechanisms in the etiology of AML.

**Characterization of Wilms Tumor and Human Fetal Kidney Using Spatial Transcriptomics**

Laura Perin,1 Astigik Petrosyan,1 Valentina Villani,1 Paola Aguiri,1 Matthew E. Thornton,2 Shengmei Zhou,3 Brendan Grubbs,2 Roger E. De Filippo,1 Marie Csete,2 Kevin V. Lemley,3 Sargis Sedrakyan,4 Stefano Da Sarthe5 Children’s Hospital of Los Angeles, Los Angeles, CA; 5University of Southern California, Los Angeles, CA.

**Background:** Growing evidence links Wilms tumor (WT) to aberrant nephrogenesis. Studies highlighted the genetic complexity of WT, but little is known about the molecular mechanisms that regulate WT development. Using Spatial transcriptomics (ST), which allows analysis of the gene expression based on morphological context, we showed important differences between WT subtypes and defined the interactive gene networks involved in WT development using human fetal kidney (hFK) as reference.

**Methods:** Using Visium 10X Genomics, we generated spatial maps of gene expression in human fetal kidney (hFK) and/or unfavorable (stage III) and unfavorable (stage I) WTs. Data were analyzed using Space Ranger software v.1.0. Seurat v.3.2, Panther V14, and Loupe Cell Browser and further analyzed against our previously generated bulk/sc-RNA seq data on the same samples.

**Results:** ST identified specific clusters in hFK that closely recapitulated the developmental stages of normal nephrogenesis (nephrogenic zone, glomeruli, tubules, and stroma). Unfavorable WT and favorable WT clusters showed heterogeneity of the tumor landscape (blastosoma, epithelium, and stroma and non-renal phenotypes). Blastosma in WT favorable vs. WT unfavorable, though histologically identical, presented different transcriptomics profiles. WTs also showed gene expression typical of muscle tissue (or other non-renal phenotypes) rather than mature kidney structures, which correlated with the histologic absence of mature tubules and glomeruli. Comparative RNA-seq analysis identified cells expressing SIX2 and CITED1 as the root cells of the origin of the WT. Unfavorable WT expressed a higher level of CITED1 in blastema foci and higher expression of uncommitted genes and modulation of inductive nephrogenic signals like WNT and FGF. We also identified genes expressed specifically in WT subtypes and performed a preliminary characterization of the immune milieu of WT.

**Conclusions:** The spatiotemporal mapping combined with different transcriptomic data highlighted the heterogeneity of the WT subtypes confirming uncommitted nephron progenitors as driving the development of WT. We identified genes that may allow for better stratification of WT and potential therapeutic targets for distinct WT subtypes.

**Recurrent Renal Cell Carcinoma Post Renal Transplantation**

Ivan Rakie,1 Rujuta R. Patil,1 Anita K. Patel,2 Wayne State University School of Medicine, Detroit, MI; 2Henry Ford Hospital, Detroit, MI.

**Introduction:** Renal Cell Carcinoma (RCC) can occur in renal transplant recipients (RTR). RCC recurrence post nephrectomy occurs in 20-40% of non-transplant (Tx) patients and in less than 15% of RTR. The median survival for patients with metastasis is 6-12 months with 5 year survival less than 10%. We present 3 RTR who developed recurrent RCC post-Tx.

**Case Description:** RTR1 was 61 years old and received a deceased donor kidney Tx (DDKTx) for IgA nephropathy. He was induced with thymoglobulin. Immunosuppression (IS) included Mycophenolate Mofetil (MMF), Tacrolimus (FK), and steroids (S). 8 years pre-Tx, a 2.5cm RCC lesion was found in the R native kidney, and he underwent nephrectomy. 1 year later, he developed BK viremia, and IS was changed to Everolimus and S. 2 years post-Tx, RCC metastasis was detected only in the pancreas head and tail. Treatment involved tyrosine kinase inhibitors (TKI) and VEGF inhibitors without resolution; he died within 2 years of RCC recurrence with a functioning allograft. RTR2 was 56 years old and received a DDKTx, secondary to ADPKD. IS involved MMF, Cyclosporine, and S. History was significant for L nephrectomy 3 years pre-Tx for RCC. Both lesions were small and recently limited. 10 years post-Tx, she presented with recurrent RCC in the pancreas and thyroid. Treatment involved change in IS to Sirolimus and Azathioprine. No other treatment was taken by the patient. She died 4 years later with a functioning allograft. RTR3 is a 54 year-old who received a living related renal Tx for CKD stage 5. IS included MMF, FK, and S. 8 years post-Tx, he was diagnosed with an 8cm RCC lesion of the L native kidney and underwent nephrectomy. After a 6 year tumor free interval, RCC recurred only in the lungs and lymph nodes. He received IS reduction and TKI with progression of disease to bone metastasis. His current treatment involves TKI with Denosumab, and he still has a functioning allograft.

**Discussion:** Our cases demonstrate that RCC recurrence occurs at variable time points post-Tx and can present aggressively in RTR with poor outcomes. We suspect that recurrent disease arises from micrometastatic tumor cells that escape immune surveillance. RTR with a history of RCC prior to Tx should be monitored closely for metastatic recurrence post-Tx.

**Impact of ESKD on Overall and Cancer-Specific Mortality in Patients with Localized Prostate Cancer (PCa): A Retrospective Cohort Study of SEER-Medicare**

Nagaratna Sarabu,1 University Hospitals, Cleveland, OH.

**Background:** Our objective was to compare overall and PCA specific mortality between ESKD and non-ESKD patients with localized PCa.

**Methods:** Study participants were male patients, who were diagnosed with localized PCa between January 1st 2004 and September 30, 2015 (last day of International Classification of Diseases-9-Clinical Modification (ICD-9-CM) use) and were 40 years or older at the time of diagnosis. ESKD status, further stratified into dialysis and kidney transplant (KT) was determined using ICD-9-CM codes. Time to death from any cause was modeled using Cox regression and time to PCA specific death using Fine and Gray competing risk model.

**Results:** At a median follow up of 6.2 years, 3.5 years and 5.0 years for non-ESKD (N=186,482), dialysis (N=970) and KT (N=413), overall mortality rates were 1.8%, 8.5%, and 4.8% at 1-year, 7.7%, 31.5% and 13.5% at 3-years and 15.2%, 50.8% and 27.9% at 5-years respectively (P-Value: <0.001). Figure 1. In multivariate model, dialysis status was associated with 2.9 times higher hazard of death (HR: 2.9, 95% CI: 2.0, 3.0) compared to non-ESKD group. Rates of PCA specific mortality were 0.4%, 1.1%, and 0.7% at 1-year, 1.6%, 3.1%, and 1.5% at 3-years and 3%, 4.8%, and 2.2% at 5-years for non-ESKD, dialysis, and transplant groups respectively (P-value: 0.04). In multivariate model, dialysis status and transplant status were associated with similar risks for PCa specific death to non-ESKD group. Figure 2.

**Conclusions:** ESKD patients have excess relative overall mortality but similar PCa specific mortality compared to non-ESKD patients with localized PCas.

**Case of Spontaneous Tumor Lysis Syndrome in Metastatic Prostate Cancer**

Mohammad Al-Hasan,1 Mauricio Monroy,2 Albany Medical Center, Albany, NY.

**Introduction:** Tumor lysis syndrome has been described in hematological malignancies mainly where there is a large tumor burden that lyse in relatively short period of time causing a large burden of metabolites that causes AKI. In this case, we will present a case of spontaneous tumor lysis syndrome caused by widespread metastatic cancer prostrate which is an unusual cancer to cause such syndrome. That metastasis was mainly to the bone marrow causing a picture of pancytopenia, which also raises the possibility that the tumor lysis syndrome could be due to the breakdown of the cells of the bone marrow rather than the lysis of the prostate cancer cells.

Underline represents presenting author.
Case Description: 65-year-old male patient presented with altered mental status upper quadrant abdominal pain, and fever. He weighed 182.2, severe anemia with hemoglobin of 8.8 gm/dL, a creatinine of 7.32 and BUN of 181, calcium 9.3, phosphorus 7.4, uric acid 41.5, bilirubin of 2.9 and LDH was high at 789, alkaline phosphatase was 345, patient had severe anaemia with hemoglobin of 2.6, white count 12,600 and thrombocytopenia with platelet count of 6600. Urine analysis showed uric acid crystals. Flow cytometry analysis of peripheral blood did not reveal a clonal population of cells or expanded population of blasts. CT scan chest abdomen pelvis suggested diffuse osseous lytic and blastic metastatic lesions. Serum immuno-electrophoresis was negative. PSA level of more than 1400.

Diagnosis: The patient along with severely elevated serum uric acid level, and presence of uric acid crystals in the urine sediment, made it highly likely the diagnosis of TLS. The presence of diffuse osseous lesions and a PSA above the level that can be measured were consistent with metastatic prostate cancer as the underlying malignancy. The new onset of patient's symptoms was TLS in solid malignancies, rare, especially without anti-neoplastic therapy. In this case, the presence of severe anaemia and thrombocytopenia were highly suspicious for bone marrow invasion, and possible contributor to TLS. Regrettfully, a bone marrow biopsy couldn’t be obtained before patient expired. Conclusion: Bone marrow extension with lysis of bone marrow cells may be a contributing factor.

PO1862
Overlooked and Unanticipated: Life-Threatening Hypocalcemia due to Denosumab in a Patient with Prostate Cancer

George Vasquez-Rios, Johnson L. Gomez, Pramodh Chanumolu, Amanda Dijanic, Matthew Abramson. Icahn School of Medicine at Mount Sinai, New York, NY

Introduction: Denosumab is a monoclonal antibody that inhibits osteoclast-mediated bone resorption by binding to receptor activator of NF-kB ligand, which is upregulated by tumor cells. Despite FDA warning, insidious and severe onset hypocalcemia is a known complication in patients treated with this agent.

Case Description: A 77-year-old man with a history of prostate cancer and CKD stage 4 presented to the ED with tremors and numbness in both arms along with perioral dysesthesias. In addition to furousemide and metoprolol, he received his first dose of denosumab 2 weeks prior to presentation, indicated for bone metastasis. Physical examination was remarkable for the Chvostek sign and delayed reflexes in his upper and lower extremities. Lab results were as follows: Na 136 mEq/L, K 4.4 mEq/L, HCO3: 6.4 mEq/L, Cr: 4.8 mg/dL, PO4: 6.1 mg/dL, Ca: 4.8 mg/dL, Mg: 2.6 mg/dL & albumin: 3.5 g/dL. Further testing disclosed 25 hydroxy vitamin D (25(OH)D): 6.5 (<25 ng/mL), iPTH: 988 (10-55 pg/mL). Free FT3 and FT4 was normal, TSH slightly high. C-reactive protein was 167 (40-465 pg/mL), ALP: 243 (44-147 iU/L). Urine calcium-to-creatinine ratio was 0.04, suggestive of minimal calcium excretion. ECG showed prolonged QTc. Given the clinical evidence of severe hypocalcemia and ECG changes, the patient was started on peripheral calcium infusion with hourly iCa2+ measurements to maintain iCa >1 mmol/L and reversal of QTc prolongation. Concomitantly, the patient was treated with calcium carbonate 2500 mg TID, ergocalciferol 50,000 units weekly, and thrombocytopenia were highly suspicious for bone marrow invasion, and possible contributor to TLS. Regrettfully, a bone marrow biopsy couldn’t be obtained before patient expired. Conclusion: Bone marrow extension with lysis of bone marrow cells maybe a contributing factor.

PO1863
Impact of CKD on the Nutritional Status of Patients with Cancer

Micheline T. Souza,1 Luiz A. Gil,1 Thais d. Cardenas,2 Renato A. Caires,2 Elerson Costalonga,1 George B. Coura-Filho,1 Marcelo T. Sapienza,1 Lesley A. Inker,1 Andrew S. Levey,1 Emmanuel A. Burdham,2 Veronica T. Costa e Silva,1,2 1University of Sao Paulo Medical School, Sao Paulo, Brazil; 2Sao Paulo State Cancer Institute, Sao Paulo, Brazil; 3Tufts Medical Center Cancer Center, Boston, MA.

Background: Cancer patients routinely live with impaired nutritional status and other comorbidities. There are few prospective data on the impact of chronic kidney disease (CKD) on the nutritional aspects of patients with cancer.

Methods: Patients with solid cancer, admitted for treatment at a cancer hospital in Brazil (Instituto de Câncer do Estado de Sao Paulo) were prospectively evaluated between April 2015 and October 2017. Patients underwent a nutritional evaluation including subjective global assessment produced by the patient (PG-SGA), anthropometry (Arm Muscle Area-AMB, weight, height) and electrical bioimpedance (BIA). sarcopenia was determined when the sum of three measures of BIA ≤17.4 kg/m2 for KM and ≤15 kg/m2 for FFM. Measurement of the glomerular filtration rate was determined through plasma clearance of 125I-EDTA (mGFR). CKD was classified according to the K/DOQI guidelines based on mGFR indexed for body surface area.

Results: Six hundred and ninety-six pts were enrolled. Patients were 60(51-67) years old, 51.9% male. The most common cancer sites were breast(26.3%), prostate(20%), and gastrointestinal(12.2%). A total of 14.7% had metastatic disease, 94.9% ECOG (0-1), median mGFR was 81(66.7-94.6), with 55.7%, 32.8% and 11.5% presenting mGFR G1, G2 and G3, respectively. When compared to patients with mGFR G1, patients with mGFR G2 and G3 had a higher frequency of malnutrition by PG-SGA and BMI, and higher proportion to AKI compared to AMB. In addition, fat free mass deficit, sarcopenia and lower phase angle values were more frequently observed in mGFR G2 and G3 according to the BIA data(Table1).

Conclusions: In patients with cancer admitted for treatment lower mGFR was associated with worse nutritional status. Therefore, nutritional monitoring in conjunction with the oncology, nephrology and nutritional team is necessary.

PO1864
The Impact of a Nutritional-Nephrological Combined Approach (NNCA) on the Metabolic Profile and Perceived Quality of Life of CKD Patients

Arianna Bettigo, Federico Di marco, Francesco Fiorio, Riccardo Vago, Ugo Papi, Giovanni, Francesco Montorsi, Andrea Salonia, Francesco Trevisani. IRCCS Ospedale San Raffaele, Milano, Italy.

Background: Nutritional therapy (NT) based on controlled protein intake represents a cornerstone of the management of CKD. However there is not a precisely defined an adequate protein intake for onco-nephrological patients. Aim of our study is to investigate the impact of a low-normal protein diet on metabolic profile and quality of life in CKD pts affected (CS) or not (CT) by urological non-metastatic malignancies treated with a NNCA.

Methods: 103 pts were enrolled in the Urological Department at San Raffaele hospital between 2018 and 2020, screened for absence of malnutrition and administered a conventional CKD protein-controlled diet (0,7-1 g/Kg/die, 30-35 kcal/kg/die) including aprotic foods. Anthropometrical outcomes, lab test exams and clinical variables were examined at baseline and after 6 months. To evaluate the impact of the NNCA on perceived quality of life, a QoL-Short Form36 (SF36) questionnaire were administered to pts.

Results: The combined treatment produced eGFR improvement and urea parameters improvements (49% of pts improved eGFR, 65% uremia) without negatively altering the anthropometrical outcomes. The nutritional status was preserved in both groups and all pts had an improvement in BMI (CS: 2.8 kg/h; CT: 1.3 kg/h) PA* (CS: 2.8%; CT: 1.3%); ROH (CS: 1.3%; CT: 0.38) and FFM (h) (CS: 0.1; CT: 2) and a decrease of WC (CS: 1.3cm; CT: -1.65cm), and ECW/ICW (CS: 0.02; CT: 0.03). The SF36 questionnaire highlighted a good perceived quality of life in subjects treated with the NNCA, even if social activities were negatively affected.

Conclusions: Our study suggests that low-normal protein high calories diet ameliorates the nephrological scenario, the metabolic complications and the nutritional perspective in uro-oncological CKD pts. Following NNCA, perceived quality of life has been pushed towards high scores and does not appear to be influenced by physical health or emotional status. Monitoring and food choice limitations may have increased the perception of the pathological condition, thereby increasing the sense of responsibility in adhering to the NT. All this improves the physical health, but also demotivates pts and worsens their social attitudes.

PO1865
A Rare Case of Calcitriol-Mediated Hypercalcemia in Metastatic Gastrointestinal Stromal Tumor (GIST)

Iman S. Khan,1 Victoria Gutgarts,2 Daniel Kirchhoff,2 Lakshmi V. Ramanathan,2 Roman A. Shingarev,3 Weill Cornell Medicine, New York, NY; 3Memorial Sloan Kettering Cancer Center, New York, NY; 4Clinic and Clinic, Cleveland, OH.

Introduction: Hypercalcemia accompanies 10-30% of malignancies. Calcitriol production accounts for <1% cases, usually with lymphoma, but has been reported with solid tumors.

Case Description: A 62 year old male with GIST with liver involvement was admitted for an elevated calcium (Ca) of 13.9 mg/dL & AKI with creatinine (Cr) 2.2 mg/dL. Diagnosed with GIST 3 years prior, he was treated with imatinib & an investigational mitogen-activated protein kinase enzyme inhibitor. Due to disease progression, he was switched to sunitinib 1 week prior to admission and endorsed taking 100,000 IU of OTC vitamin D tablets daily for perceived immunologic benefits. Further workup showed bland urinalysis & fractional sodium excretion of 2.6%. Renal sonogram was normal. AKI was ascribed to hypercalcemia-mediated vasoconstriction & renal blood flow reduction. He had an ionized Calcium 6.6 mg/dL (nl: 4.8-5.3 mg/dL), appropriately low PTH & PTHrP 0.9 pmol/L (nl:4.2 pmol/L). The 25(OH) vitamin D was reported at >156 ng/mL, then quantified at 240 ng/mL. Calcitriol was elevated at 71 pg/mL (nl: 18-64 pg/mL). Echocardiography was thought to be from excess vitamin D intake. Cr & Ca improved with hydration, calcitonin & pamidronate. He was readmitted at >156 ng/mL, then quantified at 240 ng/mL. Calcitriol was elevated at 71 pg/mL (nl: 18-64 pg/mL).
PO1866
Kidney Pathology Findings in Patients with AKI Associated with Tyrosine Kinase Inhibitors
Venkata Kishore R. Mukku,1,2 Omar Mamlouk,2 William F. Glass,3 Amanda Tchakarov,1 Sreedhar A. Mandyam.2 1The University of Texas Medical Branch at Galveston, Galveston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3The University of Texas Health Science Center at Houston, Houston, TX

Background: Tyrosine kinase inhibitors (TKIs) are widely used targeted cancer therapy as they play a critical role in the modulation of growth factor signaling. Nephrotoxicity associated with TKIs can lead to interruption of therapy. However, the literature on the kidney pathology associated with TKIs nephrotoxicity is limited. Here, we present our center observation of tubular and glomerular lesions attributed to possible TKIs.

Methods: We retrospectively reviewed all cancer patients from 2018 to 2020 who were treated with TKIs and underwent a kidney biopsy at the University of Texas MDACC.

Results: We identified 13 cancer patients treated with Sunitinib, Cabozantinib, Lenvatinib, Regorafenib, Erlotinib, Osimertinib and Irinotecan between 2018-2020 and developed acute kidney injury (AKI) attributed to possible TKI nephrotoxicity. The median age was 70 (range, 43 to 80) and the median time to develop AKI was 4 months (range, 1 to 58 months) of starting TKI. AKI was severe (stage ≥3) in 6 patients, among which 4 required hemodialysis. Most of the patients had bland urine (7 out of 13) and proteinuria was observed only in 6 patients. Thrombotic microangiopathy (TMA) was the most common pathological finding followed by acute tubular injury (ATI) as they were observed in 5 and 4 patients, respectively. One patient had proliferative glomerulonephritis, one patient had chronic lymphocytic leukemia infiltration, and one patient had no active lesion. TKIs were discontinued in nine patients, and nine patients had partial kidney recovery. Five patients had disease progression and died within 4 months of AKI.

Conclusions: Our case series has demonstrated that limited type TMA and ATI are common pathology findings in patients with suspected TKI nephrotoxicity. Nonetheless, half of patients with TMA were on concurrent checkpoint inhibitor therapy with TKI and half of the patients with ATI had associated sepsis diagnosis. The mechanism is likely multifactorial and possibly related to mTOR and VEGF inhibition leading to endothelial injury, and inhibition of the downstream signaling pathway of MAPK/ERK1/2 leading to ATI. Urinary analysis was not predictive of the kidney pathology. Treating nephrotoxicity by discontinuation of the offending TKI was associated with partial kidney recovery, however patients had poor overall prognosis.

PO1867
Renal Pathology in Cancer Patients in a New Era of Treatments
Mónica Bofolle,1 Clara García-Carro,1 María Jose Soler.1 On behalf of the GLOSEN/ONCONEFROLOGÍA. 1 Vall Hebron, Barcelona, Spain; 2 Hospital Clínico San Carlos, Madrid, Spain.

Background: Classically patients with metastatic cancer were not submitted to invasive procedures because of their short life expectancy. Kidney biopsy(KB) is an especially useful diagnostic and prognostic tool in these patients when they develop kidney injury. The aim of our study is to assess clinical and histological characteristics of patients with active solid organ malignancy that underwent KB in a multicenter cohort.

Methods: We performed a multicenter collaborative study. Clinical, demographical and pathological data from patients with an active neoplasia or active cancer treatment who underwent KB were collected. We studied the follow-up of the patients in terms of renal function and survival.

Results: 124 patients with cancer who underwent KB during the study period from 2017 to 2020 were included. Sex ratio men/women was 46/78, mean age 60.8 (SD 18.5). The indications of KB were acute renal failure (56.2%), proteinuria (20.2%) and exacerbation of CKD (15.3%). At the time of the KB, 30.6% patients presented diabetes and 63.7% high blood pressure. Malignancies: lung (30.6%), intestinal (27.4%), melanoma (7.3%) and urothelial (7.7%), with a relative metastatic rate of 45%, with 35.5% received chemotherapy, 31.4% immunotherapy (of which 26.3% received more than 1 checkpoint inhibitor), 24.2% specific therapies and 3.2% conservative treatment Baseline renal function before KB,16.1% presented Cr=1.5mg/dL. At the time of KB, mean Cr 2.55mg/dL, [1.7-3.97] [25-75%], protein/Cr ratio 959mg/gCr [585-1050] and 53.2% hematuria kidney diagnosis:35.5% acute interstitial nephritis (AIN), acute tubular necrosis(8.9%) and IgA nephropathy(8.1%),65% of patients received corticosteroids for an average of 4.8 months[SD ± 5.9] 2.0% required kidney replacement therapy and 36.3% presented Cr=1.5mg/dL at 3 months. Average follow-up 16.2±5.5 (IQR 2.5-75%) 31 patients died at 37.9% died at the end of KB, and the moment of KB was identified as an independent risk factor for mortality (p=0.012)

Conclusions: Currently, AIN is the first cause of kidney injury in biopsied patients with active cancer. This is followed by bythombocytopenia, membranoproliferative nephropathy and IgA among others. KB in this group of patients provides valuable diagnostic and prognostic information. More studies are needed to expand the consensus in the diagnosis and treatment of oncological patients with renal injury.
as etiology for above laboratory abnormalities and history of treatments with ICI (nivolumab), while awaiting these lab results, patient was started on fluid restriction and salt tablets for management of hyponatremia based on available labs at that point which pointed to hypotonic hyponatremia with high urine osmolality pointing to ADH release and goal for correction for sodium level maintained 6-8 Meq for 24hours. Both serum sodium function corrected and ACTH levels were found to be low with values of 1.4ug/dl and 3.5pg/ml respectively. Patient was subsequently started on IV fluids and IV Hydrocortisone 100 0.9%L. Serum sodium level improved at an appropriate rate during the course of hospitalization and serum sodium at the time of discharge was in safe range (135mmol/L). Other peripheral hormones including prolactin, GH, TSH, LH and FSH which were normal. MRI Brain was done to rule out Hypothysis which revealed normal sella.

Discussion: Long-term follow-up of endocrine irAEs suggests that on occasions thyroid function may recover, but that dysfunction of the corticosteroid and gonadal axis is likely to be permanent. Patients should be informed of the potential adverse events prior to initiation of immune checkpoint inhibitors. Laboratory findings similar to our patient should raise concern for adrenal insufficiency to allow timely diagnosis and management and thus prevent morbidity and mortality.

PO1870 Immune Checkpoint Inhibitors Associated Distal RTA with and without AKI
David Henderson,1 Kenar D. Jhaveri,2 Rimda Wanchoo,2 Chintan V. Shah,1
1University of Florida College of Medicine, Gainesville, FL; 2Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: As immune checkpoint inhibitors (ICPI) gain popularity as a widely used anti-cancer therapy, unique immune-related adverse events (irAE) are being associated with their use. Hereby, we present two cases that link ICPI therapy to distal RTA, one with and one without AKI.

Case Description: A 73-year-old male with urothelial cancer on pembrolizumab was evaluated for AKI and acidosis. After 5 doses of ICPI therapy, he was noted to have a serum creatinine of 1.8mg/dl (normal baseline) and a serum CO2 of 20mmol/L. Over the next few days, the serum CO2 further decreased to 11mmol/L and serum potassium declined to 3.0mmol/L. Further workup revealed a urine pH of 6.5 with a positive urine anion gap. He was diagnosed with likely ICPI-induced AKI with distal RTA and initiated on sodium bicarbonate, potassium citrate, and prednisone 60mg/day. His ICPI was held. After 2 weeks of treatment, his serum creatinine returned to 1.2mg/dl and serum CO2 to 22mmol/L. A 46-year-old female was diagnosed with metastatic lung cancer and squamous cell cancer colitis. She had a history of renal transplant for which she was initially treated with Carboplatin/Paclitaxel/Pembrolizumab followed by maintenance Pembrolizumab. Almost 3 months after being initiated on ICPI, she was noted to have normal gap metabolic acidosis that gradually worsened to serum CO2 of 15mmol/L along with serum potassium of 2.4meq/L and serum creatinine of 0.6 mg/dl. Further workup showed a urine anion gap of 126, urine osmolar gap of 80, urine pH of 6.0. 24-hour urine citrate was undetectable. Diagnosis of distal RTA secondary to pembrolizumab was made and therapy was held. Steroids were not initiated, as the kidney biopsy, performed within 2 months of holding the therapy, did not reveal any tubulitis or cellular infiltrates. She is being treated with potassium citrate with normalization of acidosis and hypokalemia.

Discussion: We describe two cases of distal RTA presenting as immune related adverse events associated with use of ICPI. AKI presence is not necessary. Prompt recognition and management of hypokalemia as soon as it is noted has been reported. A potential difference in the expression of PD-L1 among the tubular epithelial cells is responsible for isolated distal RTA.

PO1871 Immune Checkpoint Inhibitor-Associated Electrolyte Disorders: Query of the FDA Adverse Event Reporting System
Vipulbhai Sakhija, Rimda Wanchoo, Kenar D. Jhaveri. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Electrolyte disorders with immune checkpoint inhibitors (ICI) therapy are not well characterized. Single center studies have noted hyponatremia as the most common electrolyte disorder associated with ICI. nivolumab. We performed a revised more recent query of the FAERS database with a more detailed look at electrolyte disorders only (search terms: hyponatremia, hypernatremia, hypokalemia, hypercalcemia, hypophosphatemia, hypomagnesemia, acidosis, hyperphosphatemia and renal tubular acidosis) from 2011-2021.

Results: A total of 2556 cases of electrolyte disorders were reported to the FAERS system. The most commonly reported abnormality is hyponatremia (53.7%), followed by hypokalemia (18.71%), hypercalcemia (9.65%), hyperkalemia (5.6%) and hypocalcemia at 4.06%. The remaining abnormalities were <4%. In all three groups of the agents (CTLA4 inhibitors, PD and PDL1 inhibitors), the trend remained similar. Most events were reported at a median age of 64 in all 3 groups analyzed. Among reported events, proportions of events in male were statistically more significant (p<0.01) than females in all 3 drug groups. Nivolumab (n=1130) and ipilimumab (n=676) were the most frequently reported events. In total, 554 cases of hyponatremia, 63 cases of hypernatremia, 275 cases of hypokalemia and 18 cases of hypercalcemia were reported in the literature demonstrates similar incidence of immune-related adverse events in patients with ESKD receiving dialysis as compared to the general population (49%). Grade 3 and 4 adverse events had been seen in fifteen patients (16%). Cancer remission (complete and partial) was seen in close to 30% of patients. Stable disease was seen in 28% and progression of disease in approximately 36% of patients. Overall, 60% of the patients died. Urothelial and RCC represented approximately half of all treated cancers, and accounted for approximately 50% of all deaths reported (Figure). Eighteen of the reported dialysis patients had prior kidney transplant. Of these, 11 (61%) initiated dialysis around 3-4 months after ICI-related rejection of their kidney allograft.

Conclusions: ICI is well tolerated in ESKD patients. Additional data in the dialysis population with use of ICI, and involvement in prospective studies, is needed to better assess outcomes, particularly within specific cancer types.
distress and hemoptysis concerning for diffuse alveolar hemorrhage led to ICU transfer. Kernicterus was ruled out as the patient showed no evidence of kernicterus, intraparenchymal hemorrhage, glomerulosclerosis, interstitial fibrosis or immune complex-deposits. Proximal tubules were focally dilated, suggestive of tubular injury. HLH was subsequently diagnosed and treatment with steroids and intravenous immune globulin was followed by electrolyte normalization and improved clinical status.

Discussion: Immune checkpoint inhibitors are increasingly used for cancer treatment. These medications carry risk of immune-related adverse effects. While secondary HLH has been reported with use of immune checkpoint inhibitors, cases are few and renal involvement even rarer. To date there has been no documented case of HLH with profound electrolyte derangements but normal GFR after receiving bintrafusp alfa. Awareness of these adverse events is necessary as these medications see more widespread use. The views expressed are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. government.

Utility of Liquid Chromatography in Monitoring Methotrexate Levels After Glucarpidase for Methotrexate Toxicity

Vishnupriya Reddi Parvathaneni Venkata Kishore R. Mukku, A. Anuradha S. Polani, 1,2 Sheldon Chen,1,2 Baylor College of Medicine, Houston, TX; 3The University of Texas Medical Branch at Galveston, Galveston, TX; 3The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Methotrexate (MTX) is an anti-metabolite with a 1,000-fold affinity for dihydrofolate reductase, competitively inhibiting the reduction of dihydrofolate to tetrahydrofolate that is needed for DNA/RNA and protein synthesis. High-dose MTX is defined as a dose higher than 500 mg/m² and results in acute kidney injury in 2-12% of patients. Values above 10 µM at 24 h post-infusion confer a high risk for toxicity.

Case Description: A 61 y/o male with newly diagnosed primary CNS diffuse B cell lymphoma was admitted for De Angelis regimen which included MTX 3,500 mg/m². His creatinine increased from 0.9 to 3.1 mg/dL despite concurrent hydration, intravenous corticosteroids, and leucovorin. MTX level was 90 at 24 h, confirming MTX toxicity. He then received a single dose of glucarpidase 50 U/kg IV. Plasma MTX levels remained high at 44, 41, and 14 on post-glucarpidase days 1, 2, and 3. In contrast, high-performance liquid chromatography (HPLC) measurement of MTX was below 0.05 on post-glucarpidase days 2, showing efficacy of glucarpidase in lowering MTX levels.

Discussion: After high-dose MTX, serum levels must be monitored to determine when to administer leucovorin and glucarpidase, a recombinant carboxypeptidase-G2 that cleaves MTX to inactive metabolites. Intrarenal MTX crystallization can 1) obstruct the tubules, 2) damage the tubular epithelium, and 3) vasoconstrict the afferent arterioles. Because volume depletion and acidic urine are major risk factors for glucarpidase, hyperhydration and urine alkalinization are mandatory during high-dose MTX treatment. Early intervention with the combination of leucovorin and glucarpidase is highly effective in patients who develop kidney dysfunction. A single dose of glucarpidase 50 U/kg IV reduces plasma MTX concentration by >97% within 15 mins. Liquid chromatographic measurement of MTX is recommended within 48 hours of glucarpidase administration, as the MTX metabolites 7-hydroxymethotrexate and 4-deoxy-4-amino N10 methylpteroic acid (DAMPA) cross react with standard immunoassays and falsely elevate the level. In our patient, the serum MTX levels were still elevated by immunoassay, while they were undetectable by liquid chromatography. We recommend using HPLC when available to confirm the lowering of MTX by glucarpidase.
However, BNP is produced primarily by myocardial cells of the left ventricle in response to stretching. The two primary natriuretic peptides of the CNS are thought to be C-type natriuretic peptide and D-type natriuretic peptide, which have been shown to induce natriuresis leading to hyponatremia and suppressed ADH levels, as was possibly seen in our patient. We report this case to allow clinicians to be aware of this possible occurrence.

PO1877
Cisplatin-Induced AKI Cancer Mouse Model Refinement
Lauren E. Thompson, Courtney D. McGinnis, Charles L. Edelstein, Melanie S. Joy. University of Colorado Health, Aurora, CO.

Background: Cisplatin (CIS), a common chemotherapeutic, causes acute kidney injury (AKI) in up to one-third of patients. Traditional mouse models use healthy mice and a single, lethal dose of CIS (20-30 mg/kg). This model does not accurately reflect the clinical use of CIS where cancer patients receive 25-100 mg/m² every 3-4 weeks. There is a need for a multi-dose mouse cancer model of CIS-AKI that more closely reflects CIS clinical use.

Methods: C57BL/6 male mice (8 weeks old; n=45) were injected in the right flank with murine lung cancer cells (CMT167; 0-1,500,000 cells). Subcutaneous solid tumors were allowed to grow for ~2 weeks until digital caliper measurement confirmed they were ≥50 mm³. Mice were then dosed with CIS (0, 12.5, 15 mg/kg) or vehicle (saline) 1x/week for up to 4 weeks. Mice were evaluated for outcomes of general health (body weight), survival, cancer progression (tumor volume), and kidney injury (Scr, BUN, KIM-1). Assessments were performed a1x/week until sacrifice after 1-4 weeks of CIS treatment. Analyses for differences from baseline to sacrifice based on both cancer cells injected and CIS dose were assessed by 2-way ANOVA with a Tukey-Kramer post-hoc test; p<0.05 was considered statistically significant.

Results: Groups injected with >1 million CMT167 cells experienced the greatest decline in survival due to rapidly growing tumors and ulceration (0% at 8 d). Cancer-free mice treated with CIS also experienced poor survival due to dehydration and weight loss (60% at 15 d). Mice injected with 50,000 CMT167 cells had the best survival (100% at 13 d). Body weight was significantly decreased as CIS dose increased (p=1.9x10⁻⁸) and increased as number of CMT167 cells increased (p=5.5x10⁻⁹). Tumor volume was significantly increased as number of CMT167 cells increased (p=5.1x10⁻⁸) and somewhat decreased as CIS dose increased (p=0.002). CIS dose did not significantly impact BUN or Scr levels but an increase in KIM-1 was somewhat associated with an increased CIS dose (p=0.105; 12.5 vs 15 mg/kg CIS p=0.191). There were no significant differences in body weight, tumor volume, or survival between the 12.5 and 15 mg/kg CIS treated mice.

Conclusions: The results indicate that the ideal CMT167 mouse cancer model of CIS-AKI should use 50,000 CMT167 cells and 15 mg/kg CIS. This model can be used to better understand CIS-AKI and to test potential protective compounds.

PO1878
Renal Outcomes in High-Dose Cisplatin in Locally Advanced Squamous Cell Carcinoma of the Head and Neck: A New and Interesting Perspective
Francesco Trevisani,1 Giulia Quattrini,1 Daniele Pugno,2 Giulia Pegoraro,2 Alessandro Cinque,1 Vanesa Gregori,1 Aurora Mirabile,1 IRCCS Ospedale San Raffaele, San Raffaele, Milan, Italy; Biorex S.R.L., Milan, Italy.

Background: Three-weekly high-dose cisplatin (100 mg/m²) concomitant to radiation is considered a standard of care with a curative intent in most of locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). Nevertheless, cisplatin is known as a particularly nephrotoxic drug especially at the cumulative dose of 200 mg/m² or more. The aim of this study was to investigate the incidence of AKI in patients with LA-SCCHN during and after treatment with high-dose cisplatin-based CRT to identify risk factors for cisplatin-induced AKI.

Methods: A consecutive cohort of 82 patients treated with cisplatin cumulative dose ≥200mg/m² concomitant to radiotherapy, was enrolled in a tertiary single hospital from 2019 and 2020. Serum creatinine, hemoglobin, lymphocytes and eGFR formulas (CKD-EPI, MDRD, Cockcroft-Gault) were detected at baseline and after each cycle of chemotherapy. AKI and CKD onset were determined according to K-DIGO criteria. Clinical tumor stage as well as comorbidities were also included. Bayesian linear regression model was used to evaluate the impact of the clinical and pathological features on eGFR decay through cycles.

Results: At baseline, 57% of pts were CKD stage 3, 37% CKD II stage, 6.1% CKD III stage A-B. Medium decay of eGFR from the baseline to the end of 3 cycle is reported in table 1 showing CKD different stages. The marked decay appears in day 10 during cycle 2 (Figure 1). Performing a Bayesian linear regression over cycles, hypertension showed a remarkable impact on the eGFR decay through the therapy over time (Figure 2). However, the AKI incidence was very low in all CKD classes; 2.4% in 1 cycle, 4.8% in 2 cycle and 2.4% in 3 cycle.

Conclusions: Surprisingly, from these data high dose of cisplatin seems feasible in different CKD stages with very low rate of renal toxicity events and AKI-CKD onset.

PO1879
Double Hit: A Case of Chromogranin A-Mediated Proximal Tubulopathy That Progressed to Full-Blown Fanconi Syndrome After Treatment with Everolimus
Adnann S. Polani,1 Biruh Workneh,2 Baylor College of Medicine, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Hypophosphatemia is an independent risk factor for poor patient outcomes. We present a rare case of hypophosphatemia from a complication of a neuroendocrine tumor (NET) and the treatment for it.

Case Description: A 54-year-old female with metastatic NET presented with dyspnea. Patient had Pneumonia which was treated but a comprehensive electrolyte panel revealed profound hypophosphatemia (phosphorous levels < 1 mg/dl). Initial suspicion was that poor nutritional status may be the underlying etiology, however despite aggressive intravenous phosphorus supplementation, the hypophosphatemia persisted and progressed. Workup revealed obvious evidence of Fanconi syndrome. Patient had profound glucosuria with normal serum glucose. 24 hours urine phosphorus excretion was markedly elevated at 900 mg. Vitamin D level was borderline low but activated (1,25-vitamin D) levels were markedly low at 1.8 pg/ml. PTH levels were only mildly elevated at 120 pg/ml. A deeper investigation into her course found that patient was diagnosed with a NET 8 months prior to this presentation and had evidence of mild glucosuria with mild-moderate hypophosphatemia at that time. Chromogranin A levels from her NET were substantially elevated at that time. Serial urine analyses during the course of her disease were repeated, and it was evident that the glucosuria became markedly worse after the patient was started on everolimus therapy. We concluded that hypophosphatemia in this patient is from chromogranin A mediated proximal tubulopathy that developed to full blown Fanconi Syndrome after everolimus. We changed phosphorous supplementation to oral only and recommended holding everolimus provided it was appropriate from an oncological standpoint. Follow up of the patient in 4 weeks off everolimus showed continued improvement in phosphorous levels.

Discussion: Both chromogranin-A and mitor inhibitors have shown to cause acute tubular injury in proximal tubules. Our case is unique in the sense that it presented as severe hypophosphatemia from Fanconi syndrome secondary to two uncommon culprit agents that acted in a sequential manner to worsen the proximal tubulopathy. Based on this case we recommend that in NET patients with high chromogranin A levels, we check for signs of proximal tubulopathy before starting mitor inhibitor therapy.
Conclusions: Our study surprisingly highlights that both cisplatin/carboplatin-based CT and immunotherapy display a similar incidence of AKI and eGFR decay over time in NSCLC metastatic patients.

PO1881
AKI with BRAF and MEK Inhibitors May Not Be a Class Effect
Supriya Gerardine,1,2 Surya V. Seshan,3 Ilya Glezerman,2 Weill Cornell Medicine, New York, NY; 1Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: BRAF tyrosine kinase inhibitors are used in the treatment of BRAF mutant metastatic melanoma. Simultaneous MEK inhibition has been shown to provide better response rates and fewer side effects. Renal toxicity has been reported with these agents which can include AIN, ATN and Fanconi syndrome. We report a case of AKI due to biopsy proven AIN from BRAF and MEK inhibitor vemurafenib and cobimetinib.

Case Description: This is a 64-year-old woman with diabetes mellitus type 2, stage IV melanoma with BRAF V600E mutation and baseline serum creatinine (Scr) of 0.8 (0.6-1.1) mg/dL. She has been treated with multiple chemotherapy regimens and immunotherapy (last dose of immunotherapy 28 months prior to presentation). Patient received dabrafenib and trametinib until 8 months prior to presentation but stopped due to development of fever and AKI (Scr 1.7mg/dL). She was started on vemurafenib 480 mg BID every other day and cobimetinib 40mg every other day 6½ months before presentation. Two months later the vemurafenib dose was increased to 960mg BID but patient was noted to have AKI with Scr of 4.5 mg/dL and vemurafenib and cobimetinib were stopped. Her blood pressure was elevated to 154/70 mmHg. Urinalysis showed protein of 100 mg/dL, 0-3 RBC/HPF and 0-6 WBC/HPF. Scr improved to 2.2 mg/dL but remained elevated and renal consult was obtained with subsequent kidney biopsy. It showed active, subacute, and chronic interstitial nephritis with extensive tubular atrophy. Patient was treated with prednisone 50 mg daily and was tapered down to 10 mg daily over two months. Repeat CT scan showed new peritoneal nodules and she was started on a new BRAF/MEK combination of encorafenib and binimetinib. She is followed on a new regimen and her kidney function is improving.

Discussion: This case strengthens the importance of being vigilant for renal toxicity from BRAF and MEK inhibitors. Renal toxicity has been reported in 1% of patients of the phase 2 trial but not in the phase 3 trial. Nectin-4 protein and leads to subsequent cell apoptosis through impaired cell division. Dermatologic disrupting agent monomethyl auristatin E (MMAE). The drug binds to Nectin-4, expressed on tumor cells, with high affinity, which induces the internalization of MMAE and leads to subsequent cell apoptosis through impaired cell division. Dermatologic toxicity occurs from drug binding to Nectin-4 expressed on normal skin cells. AKI was reported in 1% of patients of the phase 2 trial but not in the phase 3 trial. Nectin-4 protein is expressed and can be stained in renal tubular epithelial cells. While DKA may have contributed to our patient’s tubular injury, direct tubular toxicity may be possible and requires further research. Physicians prescribing Enfortumab vedotin should be aware of this potential side effect.

PO1884
An Elevated Serum Creatinine in a Patient Receiving Palbociclib
Marco A. Bonilla, Khawaja A. Bashir, Kenar D. Chaverti. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: Serum Creatinine (Scr) is the most widely used parameter in clinical practice to estimate glomerular filtration rate (GFR). Various drugs have been reported to cause a reversible and transient elevation in Scr without a true reduction in overall kidney function.

Case Description: A 66-year-old woman with a past medical history of metastatic right breast poorly differentiated invasive ductal carcinoma, hormone receptor-positive, and HER2 negative. Who received treatment with fulvestrant and palbociclib, the dose of Palbociclib was 100mg orally a day. Presented for evaluation of elevated serum creatinine with decreased eGFR. On initial evaluation Scr was 1.6mg/dL, blood urea nitrogen of 21mg/dL, eGFR of 33mL/min/1.73m², her baseline eGFR was ranging from 42 to 52 mL/min/1.73m² in the past one year. An estimated glomerular filtration rate by cystatin C was performed and showed a value of 47mL/min with a cystatin-C level of 1.36mg/dL, which was at her baseline kidney function for the past year.

Discussion: Creatinine is freely filtered by the glomerulus and actively secreted by the proximal tubule from the peritubular capillaries, which accounts for 10-40% of creatinine clearance. The organic cation transporter 2 (OCT2), multidrug and toxin extrusion protein (MATE) 1 and MATE2-K, are the solute carrier transporters in the kidney that mediate clearance. Of these, OCT2 has been shown to have a reversible increase in creatinine of about 15-40% over baseline of patients with cancer and healthy subjects. This effect has been seen in about 25% of patients treated with abemaciclib however none of the clinical trials on palbociclib have
reported an increase in serum creatinine. In our case, the difference between eGFR by cystatin C and by serum creatinine demonstrated not a true decrease in kidney function. We have attributed these events to inhibition of the tubular secretion of creatinine by palbociclib and decided to continue treatment with palbociclib. Physicians should be aware that patients undergoing therapy with palbociclib require monitoring of kidney function and an increase in serum creatinine from baseline, might represent an inhibitory effect of the secretion of creatinine and not an actual decrease in kidney function.

**PO1885**

A Case of IgA Nephropathy in the Setting of Sezary Syndrome and Mogamulizumab

Mohankumar Doraiswamy,1 Sergey V. Brodsky,1 John C. Reneau,2 Joshua Leisring.1 The Ohio State University Wexner Medical Center, Columbus, OH; 2The Ohio State University Comprehensive Cancer Center Arthur G James Cancer Hospital and Richard J Solove Research Institute, Columbus, OH.

Introduction: IgA Nephropathy (IgAN) is an autoimmune disease with complex pathogenesis. Sezary syndrome (SS) is a leukemic subtype of cutaneous T cell lymphoma (CTCL). A rare association has previously been reported between IgAN and CTCL. Mogamulizumab (MG) is a monoclonal antibody drug targeting C-C chemokine receptor type 4 (CCR4) and is used in the treatment of CTCL and SS. MG has been associated with drug eruptions and systemic immune-mediated adverse events.

Case Description: A 63 year-old woman with SS was treated with MG. Her skin symptoms improved and circulating Sezary cells cleared. Due to a cutaneous drug eruption, the frequency of MG administration was reduced to monthly after cycle 7. Labs prior to cycle 19 demonstrated serum creatinine (Cr) 1.77 mg/dL from a prior baseline ~0.9-1.0 mg/dL. She received intravenous fluids but Cr worsened to 3.97 mg/dL. Urinalysis (UA) revealed more than 20 red blood cells (RBCs) per high powered field (HPF). 24 hour urine protein to creatinine ratio (UPCR) was 2.03 g/g. Serologies and complement levels were normal except double stranded DNA which was 12 IU/mL (normal <4 IU/mL). Kidney biopsy demonstrated mesangial immune complex deposition with IgA, IgG, and C3 predomiance consistent with IgAN (Oxford M1/0/R/T/I/T/3C). Prednisone was initiated at 1 mg/kg/day and tapered over 6 months. MG was stopped. After 6 months Cr had improved to 1.10 mg/dL. UA showed 3-5 RBCs per HPF with UPCR of 0.122 g/g. Her SS remained well controlled without systemic toxicity.

Discussion: This case reinforces the association between IgAN and CTCL which has been described in prior case series. In patients with CTCL, altered T cell populations and a dysregulated immune response may contribute to the pathogenesis of IgAN. Complicating this case is the use of MG which can deplete normal CCR4-expressing regulatory T cells and thus dysregulate immune response leading to increased renal injury. In the presence of pre-existing renal pathology, MGRS and induced kidney injury should be suspected due to its potential risk for exacerbating pre-existing glomerulonephritis.

**PO1886**

Filgrastim-Induced Crescentic Glomerulonephritis

Danyi Zheng.1 William F. Glass,1 Ala Abudayyeh.2 The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is caused by deposition of monoclonal immunoglobulins in the glomeruli. It is one of renal disorders included in the spectrum of monoclonal gammopathy of renal significance (MGRS). IgG3 kappa light chain is the most common type. Autologous stem cell transplantation (SCT) provides a durable remission and better renal outcomes. Granulocyte colony stimulating factor (GCSF) is a recombinant glycoprotein used for mobilization of bone marrow in SCT. GCSF has been implicated as a cause of crescentic transformation of an acute glomerulonephritis in one prior case with a monoclonal deposits in a kidney transplant patient. In this case, we report the clinical and pathologic findings of GCSF induced exacerbation and crescentic transformation of pre-existing PGNMID with successful treatment and SCT.

Case Description: A 48-year-old male with recent diagnosis of MGRS presenting as MPGN and monoclonal IgG Kappa with C3 deposits on biopsy and treated with Velcade, cyclophosphamide and dexamethasone with a plan for SCT. Patient was admitted after acute increase in creatinine from 2.87 mg/dl to 6.6mg/dl with hematuria and proteinuria after receiving GCSF during stem cell mobilization. Timing of acute renal injury correlated with increase in WBC after GCSF injections with a peak of 69 K/ul. Repeat kidney biopsy was significant for crescentic membranoproliferative (62% crescents) glomerulonephritis with monoclonal IgG/kappa deposits. Patient received 5 sessions of plasmapheresis, one dose of renally adjusted IV Cytosan, and pulse steroids followed with a taper. After a month he undergo an Autologous SCT (creatinine at baseline 1mg/dl). His kidney function continued to improve and after 16 months post SCT his creatinine is at 1.4mg/dl.

Discussion: GCSF enhances neutrophils activation in large counts and induces its endothelial activation. In the presence of pre-existing renal pathology, MGRS and MPGN with IgG kappa and C3 deposits in this case, the localized immunoglobulin and complement deposits in the glomeruli can attract activated neutrophils leading to its infiltration and degranulation in the glomerular microenvironment, and resulting in rupture of glomeruli basement membrane and formation of crescent. Therefore, GCSF induced kidney injury should be suspected due to its potential risk for exacerbating pre-existing glomerulonephritis.

**PO1887**

Creatinine-Cystatin C Ratio and Mortality in Cancer Patients: A Retrospective Cohort Study

Chan-Young Jung,1 Keun Hyung Park,2 Seung Hyeok Han,3 Tae-Hyun Yoo,1 Shin-Wook Kang,4 Jung Tak Park,5 Yonsei University College of Medicine, Seoul, Seoul, Republic of Korea.

Background: Muscle wasting is prevalent in cancer patients, and early recognition of this phenomenon is important for risk stratification. Recent studies have suggested that the creatinine-cystatin C ratio may correlate with muscle mass in several patient populations. The association between creatinine-cystatin C ratio and survival was assessed in cancer patients.

Methods: A total of 3,060 patients who were evaluated for serum creatinine and cystatin C levels at the time of cancer diagnosis were included. The primary outcome was 6-month mortality. The 1-year mortality, and length of intensive care unit (ICU) and hospital stay were also evaluated.

Results: The mean age was 61.6±13.5 years, and 1,409 patients (46.0%) were female. The median creatinine and cystatin C levels were 0.9 (interquartile range [IQR], 0.6-1.3) mg/dL and 1.0 (IQR, 0.8-1.5) mg/L, respectively, with a creatinine-cystatin C ratio range of 0.12-12.54. In the multivariate Cox analysis, an increase in the creatinine-cystatin C ratio was associated with a significant decrease in the 6-month mortality (per 1 creatinine-cystatin C ratio, hazard ratio [HR] 0.35; 95% confidence interval [CI], 0.28-0.44). When stratified into quartiles, the risk of 6-month mortality was significantly lower in the highest quartile (HR 0.30; 95% CI, 0.24-0.37) than in the lowest quartile. Analysis of 1-year mortality outcomes revealed similar findings. The highest quartile was also associated with shorter length of ICU and hospital stay (both P<0.001). These associations were independent of confounding factors.

Conclusions: The creatinine-cystatin C ratio at the time of cancer diagnosis significantly associates with survival and hospitalization in cancer patients.

Poster 580
Methods: We enrolled 181 cancer patients treated at an academic tertiary cancer hospital in Brazil (Instituto do Cáncer do Estado de São Paulo), who had undergone abdominal imaging and measurement of GFR by plasma clearance of 51Cr-EDTA within 60 days. eGFR was determined based on the CKD-EPI equation using Scr (eGFRcr) and Scr combined with Scys (eGFRcr-cys). eGFR and mGFR were non indexed for body surface area. Total kidney volume (TKV) was measured using a semi-automatic segmentation program, excluding non-functional tissues. The correlations between mGFR and TKV as well as mGFR and eGFR were calculated using the Pearson correlation coefficient. Linear regression models for mGFR having TKV and eGFR equations as predictors were built.

Results: Patients were 55 (14.0) y, 50.3% male. Most common cancer sites were breast (22.7%), male genital (21.8%) and gastrointestinal (20.9%). ECOG levels 0/1 corresponded to 95% of patients. Mean (SD) Body mass index was 27.18 (5.18). Mean (SD) mGFR, eGFRcr and eGFRcr-cys were 84.0 (27.23), 90.4 (24.9), and 83.8 (25.9), ml/min, respectively. Mean (SD) TKV for both kidneys was 302.2 (77.9) cm3. PCC for mGFR-TKV, mGFR-eGFRcr and mGFR-eGFRcr-cys were 0.76, 0.78 and 0.85, respectively. TKV improved the coefficient of determination of the linear regression models when added to both eGFRcr and eGFRcr-cys, in overall and assessed subgroups (Table 1).

Conclusions: In conclusion, our results suggest that measurement of TKV is a reliable predictor of mGFR in cancer patients with the potential to be incorporated to the current eGFR equations used in clinical practice.

Table 1: Linear regression models for measured glomerular filtration rate (mGFR) and estimated glomerular filtration rate (eGFR).

POI1890
Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits: Searching for the Underlying Clone

Vincent Lavauzelle1,2, Virginie Pascal1, Sébastien Bender1, Jean-Michel Goujon1, Guy Touchard1, Christophe Sirac2, Frank Bridoux1,2. Centre national de référence amylose AL et autres maladies par dépôts d’Ig monoclonales Centre Hospitalier Universitaire de Poitiers, Poitiers, France; 2Centre National de la Recherche Scientifique, Limoges, France; 3Centre Hospitalier Universitaire de Limoges, Limoges, France.

Background: The pathophysiological mechanisms of proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) are still largely unknown. Only 30% of PGNMID cases have a detectable circulating monoclonal immunoglobulin (Ig) and a bone marrow corresponding clone.

Methods: We reviewed a French cohort of PGNMID with particular focus on hematological characteristics. A high-throughput sequencing assay from bone marrow and/or blood mRNA encoding immunoglobulins (RACE-RepSeq) was used to detect the underlying clone.

Results: Seventy-one patients (M/F ratio=1.6, median age 59 years) were included. At diagnosis, 73% had renal insufficiency (median serum creatinine=1.7 mg/dL). All patients had proteinuria, with nephrotic syndrome in 59% and microscopic hematuria in 85% of cases. No patient had extra-renal manifestations. Light microscopy, kidney biopsy, revealed mesangial proliferation and mesangial glomerulonephritis in 69% cases. By immunofluorescence (IF), deposits were revealed in 18/26 cases (mostly IgG3, IgM in 7 cases, IgA in 4 cases or light chain (LC) only in 5 cases. Serum and/or urine immunofixation was positive in 26 cases (37%). An underlying clone was found in 21 cases (30%) using bone marrow or blood flow cytometry analysis. The clonal detection rate was particularly low in IgG3-PGNMID (9%). The nature of the clone differs with PGNMID subtype: lymphoplasmacytic in IgM-PGNMID, and plasmacytic in IgA-LC-PGNMID. RACE-RepSeq analysis failed to detect a bone marrow or blood clone in 18/26 cases (IgG3-PGNMID, n=17; IgGAK-PGNMID, n=1). IF analysis of kidney samples using anti-Vκ antibodies showed positive staining for Vκ in 26 cases and Vλ in 3/3 tested IgG3k-PGNMID patients without a detectable clone, whereas deposits stained only for Vκ in one IgG1k-PGNMID patient who had a bone marrow Vκ clone by RACE-RepSeq analysis.

Conclusions: These results suggest that PGNMID is a heterogeneous medical condition and that some cases might involve oligoclonal production of nephrotoxic Ig restricted to the IgG3k isotype. Such cases should no longer be classified as MGUS.

POI1891
Rituximab-Associated Flare of Cryoglobulinemic Vasculitis

Background: Patients with cryoglobulinemic vasculitis (CV) can develop disease flare after rituximab administration. The pathogenesis is hypothesized to be from immune complex deposition in the microvasculature, wherein the immune complex consists of the involved cryoglobulin and an antigenic portion of rituximab. Our objective was to describe the prevalence, clinical characteristics, predisposing factors, and outcomes of rituximab-associated flare of CV.
Methods: We conducted a retrospective study in a tertiary referral center. We defined renal deterioration within two days following rituximab administration, including onset of new organ involvement or worsening of the underlying CV not clearly explained by disease progression alone - with or without laboratory evidence.

Results: Among 64 patients with known CV who received rituximab therapy in our center, 14 (22%) developed disease flare. Median age was 67.5 years. Seven patients (50%) had type II CV while the other half had either type I (n=6) or type III (n=1). Twelve patients (86%) had IgM-mediated CV flare. Twelve patients (86%) had an underlying B-cell lymphoproliferative disorder as the cause of their CV flare occurred after a median time of 5.5 days (range: 2-8 days). The organ systems most involved were the skin (n=10), kidneys (n=5), and peripheral nerves (n=3). Nearly all patients received treatment directed against their underlying diseases, including chemotherapy, corticosteroids, and/or immunosuppressives, with or without correlation to monoclonal IgG deposits (MGMID) is a recently described entity characterized by a membranous pattern of injury with monoclonal IgG-kappa restriction, unmasked by pronase digestion on deposits (MGMID). The aim of this study was to characterize the clinicopathologic features of MGMID and compare the differences between drug-induced TMA and other causes of TMA from our academic center with biopsy proven TMA, describe their clinical characteristics of response to treatment. Clinicians should be cognizant of its existence and have a high index of suspicion for this phenomenon.

PO1892 Membranous-Like Glomerulopathy with Masked Monoclonal IgG Deposits
Kumail Merchant,1 Christine B. Setina,1 Malachandra,2 Vana Bajol,2 Kenar D. Jhaveri,2 Steven and Alexandra Cohen Children’s Medical Center, New Hyde Park, NY; Northwell Health, New Hyde Park, NY.

Introduction: Membranous-like glomerulopathy with masked monoclonal IgG (MGMID) is a recently described entity characterized by a membranous pattern of injury with monoclonal IgG-kappa restriction, unmasked by pronase digestion on formalin-fixed paraffin-embedded (FFPE) tissue by immunofluorescence microscopy (IF). Retrospective pathology and chart review was performed within a large health system in the USA between 2019-2021 identifying 5 patients.

Case Description: All 5 patients were Caucasian females with median age 17 years (range 12-40). On presentation, 4 patients had elevated urine protein to creatinine ratio (UPC), 3 had microscopic hematuria, and 1 patient had an eGFR <90ml/min/1.73m². Low C3 and C4 levels were noted on presentation along with a normal COMP and CH50 suggesting a hypocomplementemic, anti-thrombotic complement mediated mechanism of injury. Two patients had complement C3 levels of <50 mg/dl at diagnosis. Electron microscopy revealed subepithelial/intramembranous deposits without substructural organization. On FFPE after pronase digestion, all cases revealed glomerular capillary wall staining for gamma-1 (4 cases) or gamma-3 (1 case) and kappa light chains; lambda light chains were negative. Extensive hemotologic workup was negative for monoclonal bands or lytic lytic processes. All patients were treated with angiotensin converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) therapy, and 2 patients were also treated with Rituximab. Eight patients had an improvement in UPC. None of the patients remained dialysis dependent on discharge from the hospital as opposed to 33% at presentation, and 15/33 had MAHA. In those in which a cause was able to be determined, 12/33 had drug induced TMA with the most common medication being VEGF inhibitors and Tyrosine kinase inhibitors with anti-VEGF properties (8/12). Three patients had TMA secondary to calcineurin inhibitors and one patient had cocaine induced TMA. 3/33 had complement mediated TMA, diagnosed by confirming activation of the alternative complement cascade. In patients with drug induced TMA, 6/12 patients had delayed proteinuria and kidney function after withdrawal of the drug. 3 remained dialysis dependent and 2 were transitioned to home hospice. In the drug induced TMA category, 33% patients were dialysis dependent on discharge from the hospital as opposed to 43% in the non-drug induced TMA category.

Conclusions: Every patient with biopsy proven TMA should undergo a thorough history including medication use and work up, so optimal management can be initiated. In our series, 50% of the patients with drug induced TMA improved after withdrawal of the culprit medication.

PO1894 TAFRO: A New Cause for Thrombotic Microangiopathy Mimicking Atypical Hemolytic Uremic Syndrome Successfully Treated with Anakinra and Eculizumab

Introduction: atTAFRO is syndrome of Castleman’s disease with thrombocytopenia, anaasarca, myelofibrosis, AKI & organomegaly. We present a 17 yr old girl with abdominal lymph nodes who rapidly developed anaasarca, splenomegaly, AKI requiring dialysis, & respiratory failure requiring mechanical ventilation. After a lymph node bx 2 months later showed multicentric Castleman’s, plasma cell variant, we realized she early on had TAFRO.

Case Description: She rapidly developed anaasarca, an 18 cm spleen, & abdominal nodes to 1.9 cm. Bacterial cultures, spinal tap, viral resp panel, mono, HIV, HIV-1 levels were normal (NLM). Hgb dropped to 6.7 g/dl without hemolysis, platelets 57,000 & WBC,15,500. CRP was 32.5 & sed rate 130. Oliguria ensued & creatinine rose to 3.6 mg/dl. Urea was 18,930 pg/ml, CXCL9 107 pg/ml but Il-6 was only 11.3 pg/ml. Bone marrow showed increased megakaryocytes & no hemoglobinosis. aHUS testing was negative for all genetic causes & no abs were found to any complements(C) but both, C3, 65 mg/dl & C4, 4 mg/dl were low & the membrane attack complex C5-C9, markedly elevated at > 50 mg/dl. Renal bx showed endothelial swelling & thrombotic microangiopathy (TM) confirmed on EM with negative IF. 3 pulses of solomedrol daily, dialysis, 2 plasmaphereses before the aHUS panel returned were started along with 2 doses of Anakinra, an anti-IL-1 drug, 4mg/kg sub q separated by 3 days & 1 dose of Eculizumab, 1200 mg iv. She rapidly improved, was extubated & was discharged off dialysis with a NL creatinine & no edema.

Discussion: We conclude: 1) TAFRO can mimic aHUS & present with markedly elevated IL-2R levels rather than IL-6 levels which can fix complement by the classic pathway leading to high membrane attack complexes adding to capillary leak, anaasarca and TM. 2) An Anti IL-1 drug, Anakinra, & a drug inhibiting C5 cleavage to C5a & C5b, Eculizumab can be combined to successfully treat TAFRO 3) TAFRO must now be added to all reviews and textbooks as a new cause for TM & aHUS with classic complement pathway activation.

Large Abdominal Mass: An Unusual Presentation of Multiple Myeloma
Naseer Khan,1,2 Rama Nadella,1,2 Gregory W. Proctor,1,2 Paul L. Cespedes,1,2 Irfan Agha.1,2 Medical City Dallas Hospital, Dallas, TX; Medical City Dallas Hospital, Dallas, TX; Dallas Renal Group, Dallas, TX.

Introduction: Extramedullary Soft Tissue Mass (ESTM) is an infrequent presentation of Multiple Myeloma. We present a unique case of Multiple Myeloma with very large bulky tumor masses.

Case Description: A 69 year old AA female presented with severe abdominal distention. CT Scan showed a 17 x 10 x 10 cm mass originating in the retroperitoneal region, a 12.5 cm mass in the pelvis and a 4.3 x 2.7 cm mass in the liver as shown in the image. Further testing showed anemia and renal failure. Biopsy of the mass revealed multiple myeloma, driving a monoclonal IgG lambda clone. FISH panel was positive for 17p/TP53 deletion which is very unfavorable. Patient was treated initially with dexamethasone/cyclophosphamide/Velcade and later with Daratumumab/Carfilzomib/dexamethasone without any response and remained on dialysis ultimately succumbing within 6 weeks of diagnosis.

Discussion: Initial Extramedullary Soft Tissue Mass (ESTM) manifestations in Multiple Myeloma occur in about 3% of the cases. In a large majority (93.5%) these lesions are solitary. Our patient had large, multiple masses with high tumor burden and unfavorable cytogenetic signature. She did not respond to therapy despite utilization of aggressive regimens. This is a very unique presentation of myeloma and with the unfavorable characteristics, had a dismal prognosis despite aggressive therapy.

Fibrillary Glomerulonephritis and Graft vs. Host Disease
Omar S. Elbita, Gunjan Garg. University of Louisville, Louisville, KY.

Introduction: Fibrillary Glomerulonephritis (FGN) is rare and seen in 1% of kidney biopsies. Etiology is unknown. It is associated with malignancy, monoclonal gammopathy, autoimmune disorders and infections. There has not been FGN case reported in a pt with Graft Versus Host Disease (GVHD). We present a case AKI seen to FGN with h/o Acute Lymphocytic Leukemia, status post Allogeneic Stem Cell Transplant complicated by Gastrointestinal GVHD.

Case Description: 67 yo African American female with DM, HTN, ALL s/p ASCT in remission, recently diagnosed with GI GVHD, presented with nausea, vomiting & diarrhea. Labs: BP 140/70, Temp 37.4°C, HR 109. Exam showed 3+ LEs edema. Labs: Cr 3.5 mg/dL, baseline of 1.1mg/dL. Urinalysis showed hematuria and 14.6g/g protein. Histology showed C3 crescentic GN. DNAJB9 stain returned positive and EM findings confirmed FGN. Patient received Solumedrol, followed by Rituximab and then Cyclophosphamide. She was dialysis dependent within 6 mos of diagnosis.

Discussion: FGN may have an undescribed association with GVHD. It is understudied because of rarity. It can present with AKI and kidney Biopsies. Etiology is unknown. It is associated with malignancy, monoclonal gammopathy, autoimmune disorders and infections. There has not been FGN case reported in a pt with Graft Versus Host Disease (GVHD). We present a case AKI seen to FGN with h/o Acute Lymphocytic Leukemia, status post Allogeneic Stem Cell Transplant complicated by Gastrointestinal GVHD.

Underline represents presenting author.
He remained in remission for four years. In 2020 he had relapse of his nephrotic syndrome and eGFR dropped to 17 ml/min. Further imaging suggested progression of the CTLL. He had further renal biopsy which again confirmed recurrent Fibrillar GN. He was started on the Tyrosine kinase inhibitor (TKI) Ibrutinib in December 2020 and within 3 months his renal function had improved to an eGFR of 33 ml/min and reduction in proteinuria.

TKIs have mostly been linked with kidney injury secondary to the potential deleterious effects on the renal endothelium. This is the first reported case of the use of a TKI as a treatment for Fibrillar GN secondary to C. L. In addition, there is scarcity of experience with relapse of Fibrillar GN as it is usually a progressive disease and with little prospect of recovery. This case highlights the following: If there is an identifiable cause driving Fibrillar GN, treatment can be associated with remission of proteinuria and improvement in renal function. Monitoring of the underlying disease is important as recurrence can result in subsequent relapse of nephrotic syndrome. TKIs used with caution can be beneficial in the setting of MGRS.

Ruxolitinib for Graft vs. Host Disease-Associated Nephrotic Syndrome: A Case Report

**Introduction:** Graft-versus-host disease (GVHD) is a serious complication of allogeneic stem cell transplant in which donor T-cells attack the host antigens. We report a case in which ruxolitinib successfully treated GVHD-related nephrotic syndrome.

**Case Description:** A 48-years-old male known to have myelodysplastic syndrome (MDS) was referred for evaluation of proteinuria. He was diagnosed with MDS four years previously. A 1-year history of this disease was consistent with azacitidine, he received allogeneic stem cell transplant (SCT) about a year after the MDS diagnosis and he achieved complete remission. However, the post-transplant course was complicated by chronic GVHD which manifested mainly as non-specific interstitial pneumonia (NSIP) about three and a half-year post-transplant. NSIP was treated with high-dose oral steroid therapy, which was slowly tapered down to a maintenance dose of 10 mg daily, and Mycophenolate Mofetil. During his course of GVHD, he had persistent mild proteinuria (UPCR less than 1 g/g of creatinine) without active urine sediment. This proteinuria was noted initially prior to NSIP diagnosis, improved while on high-dose prednisone but progressively worsened after the prednisone was tapered to 10 mg once daily. The proteinuria peaked at 2.4 g/g of creatinine with hypoalbuminemia of 2.6 g/dL at which point it was investigated with a renal biopsy. Renal biopsy showed Membranous Nephropathy with negative staining for anti-PLA2R antibody. The patient was started on ruxolitinib at a dose of 10 mg twice a day. Subsequent follow-up showed dramatic reduction in proteinuria. UPCR (g/g of creatinine) of 0.96, 0.4 and 0.09 was noted at 12- and 5-months post-therapy initiation respectively.

**Discussion:** Nephrotic syndrome is a rare manifestation of GVHD with membranous nephropathy histology seen in almost two thirds of patients. Traditionally treated with high-dose steroid with variable efficacy, we decided against it due to the patient-reported adverse effects from prior high-dose steroid therapy. Recent studies such as REACH2 and REACH3 trials have demonstrated that ruxolitinib, a selective Janus Kinase (JAK) 1 and 2 inhibitor, has superior efficacy than other second-line therapy options available. Hence, ruxolitinib can be considered in GVHD-associated nephrotic syndrome especially if a steroid-sparing approach is needed.

Clonal Hematopoiesis of Indeterminate Potential Is Associated with Worse Kidney Function and Anemia in a Cohort of Patients with Advanced CKD

Caitlyn Vlaschectaer,1 Amy J. McNaughton,2 Wilma M. Hopman,3 Bryan R. Kestenbaum,2 Cassianne Robinson-Cohen,1 Sarah M. Moran,1 Jocelyn S. Garland,1 Rachel M. Holden,1 Matthew B. Lanktree,1,4 Michael J. Rauh,1 ‘Queen’s University, Kingston, ON, Canada; 2University of Washington, Seattle, WA; 3Vanderbilt University, Nashville, TN; 4McMaster University, Hamilton, ON, Canada.

**Background:** Clonal hematopoiesis of indeterminate potential (CHIP) is an inflammatory premalignant disorder resulting from acquired genetic mutations in hematopoietic stem cells. CHIP is common in aging populations and associated with cardiovascular morbidity and overall mortality, but its role in chronic kidney disease (CKD) has not been investigated.

**Methods:** We performed targeted sequencing to detect CHIP mutations in a cohort of 87 adults with advanced CKD (eGFR < 60 ml/min/1.73 m2). Kidney function, hematologic, and mineral bone disease parameters were assessed cross-sectionally at baseline, and a total of 2,091 creatinine measurements and 3,382 hemoglobin measurements were retrospectively collected over the following 12-year period.

**Results:** At baseline, 26 of 87 (23%) cohort participants had CHIP detected. Those with CHIP had lower baseline eGFR (22.2 ± 2.5 vs. 28.2 ± 1.4 ml/min/1.73 m2, P = 0.04) in age- and sex-adjusted regression models. Individuals with CHIP had a 2.5-fold increased risk of a 50% decline in eGFR or ESKD in a Cox proportional hazard model adjusted for age and sex (95% confidence interval, 1.3–4.7). Further, those with CHIP had lower hemoglobin at baseline (11.6 ± 0.3 vs. 12.8 ± 0.2 g/dL, P = 0.0003) and throughout the follow-up period despite a greater use of erythropoiesis-stimulating agents. Mean cell volume was associated with variant allele fraction, suggesting CHIP may contribute to defective erythropoiesis in CKD.
