KIDNEY WEEK EDITION

Journal of the American  
Society of Nephrology

## Abstract Supplement

# KIDNEY WEEK 2022

## Abstract Supplement

### Abstract Publication

More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type\*\*, then by presentation date\* for orals, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

\* TH = Thursday, FR = Friday, SA = Saturday

\*\* OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.

### Abstract Author Index

The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

### Abstract Keyword Index

The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

### Abstract Reference Format

To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 33, 2022: Page(s).

### Abstract Disclaimer and Copyright

This abstract issue of JASN® contains proprietary information belonging to the American Society of Nephrology. It is published as a service for the personal, noncommercial, and informational use only of the kidney community. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such materials within Kidney Week and other ASN publications or online postings does not constitute endorsement by ASN.

### Abstract Experts

Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

### ASN General Information

#### Kidney Week Program and Presentations

The Kidney Week program, which can be found on the ASN website, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

#### Disclosure Statement

ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

## TH-OR01

## Clonal Hematopoiesis of Indeterminate Potential Is Associated With a Higher Risk of Incident AKI

Caitlyn Vlasschaert,<sup>1</sup> Alexander Bick,<sup>2</sup> Michael J. Rauh,<sup>1</sup> Matthew B. Lanktree,<sup>3</sup> Morgan Grams,<sup>5</sup> Bruce M. Psaty,<sup>4</sup> Anna Kottgen,<sup>6</sup> Nora Franceschini,<sup>8</sup> Holly J. Kramer,<sup>7</sup> Bryan R. Kestenbaum,<sup>4</sup> Cassianne Robinson-Cohen.<sup>2</sup> TOPMed Kidney Working Group <sup>1</sup>Queen's University, Kingston, ON, Canada; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>McMaster University, Hamilton, ON, Canada; <sup>4</sup>University of Washington, Seattle, WA; <sup>5</sup>Johns Hopkins University, Baltimore, MD; <sup>6</sup>Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, Germany; <sup>7</sup>Loyola University Chicago, Chicago, IL; <sup>8</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Background:** Clonal hematopoiesis of indeterminate potential (CHIP) is a common, age-related process wherein an acquired driver mutation in a hematopoietic stem cell produces a resilient clonal leukocyte population with dysregulated inflammatory signaling. The presence of CHIP has been associated with the progression of chronic kidney disease. We tested whether CHIP is a novel risk factor for acute kidney injury (AKI) in two community-based cohorts.

**Methods:** We evaluated participants from the Atherosclerosis Risk in Community (ARIC; N = 10,570) and Cardiovascular Health Study (CHS; N = 2,792). We identified somatic DNA mutations in peripheral leukocytes that met established criteria for CHIP using whole exome and whole genome data. AKI events were previously ascertained in both cohorts based on hospitalization codes with additional validation by manual chart review in CHS. We used proportional hazards regression to test associations of CHIP with AKI after adjustment for relevant confounders.

**Results:** CHIP was identified in 7.6% of ARIC participants (median age: 58) and 14.5% of CHS participants (median age: 72). The incidence rate of AKI was higher among persons with CHIP in both cohorts: 12.6 vs. 10.4 events per 1000 person-years in ARIC and 6.6 vs. 4.4 events per 1000 person-years in CHS. In a fixed-effects meta-analysis adjusted for age, age<sup>2</sup>, sex, and baseline eGFR, the presence of CHIP was associated with an estimated 18% greater risk of AKI (HR 1.18, 95% CI: 1.02 – 1.37). The risk for AKI was greatest for mutations in driver genes other than DNMT3A (non-DNMT3A CHIP; HR 1.29, 95% CI: 1.07 – 1.55).

**Conclusions:** CHIP is associated with a greater risk of incident AKI in two large community-based cohorts. Non-DNMT3A CHIP mutations demonstrate the strongest associations with incident AKI. CHIP may therefore be a novel risk factor for AKI that could partially explain the strong age dependency of this condition. Future studies will elucidate which subtypes of CHIP pose the highest risk of kidney sequelae and in which scenarios emerging treatments for CHIP would be beneficial.

**Funding:** Other NIH Support - NHLBI Trans-Omics for Precision Medicine

## TH-OR02

## Leveraging AKI Recovery Patterns Reveals a Genome-Wide Significant Variant Associated With a Higher Risk of Non-Resolving AKI

Pavan K. Bhatraju,<sup>1</sup> Ian B. Stanaway,<sup>1</sup> Rajasree Menon,<sup>2</sup> Jennifer A. Schaub,<sup>2</sup> Matthias Kretzler,<sup>2</sup> Talat Alp Ikizler,<sup>3</sup> Edward D. Siew,<sup>3</sup> Vernon M. Chinchilli,<sup>4</sup> Amit X. Garg,<sup>5</sup> Steven G. Coca,<sup>6</sup> Alan S. Go,<sup>7</sup> James S. Kaufman,<sup>8</sup> Paul L. Kimmel,<sup>9</sup> Chirag R. Parikh,<sup>10</sup> Mark M. Wurfel,<sup>1</sup> Jonathan Himmelfarb.<sup>1</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Vanderbilt University, Nashville, TN; <sup>4</sup>The Pennsylvania State University, University Park, PA; <sup>5</sup>Western University, London, ON, Canada; <sup>6</sup>Mount Sinai Health System, New York, NY; <sup>7</sup>University of California San Francisco, San Francisco, CA; <sup>8</sup>New York University, New York, NY; <sup>9</sup>The George Washington University, Washington, DC; <sup>10</sup>Johns Hopkins University, Baltimore, MD.

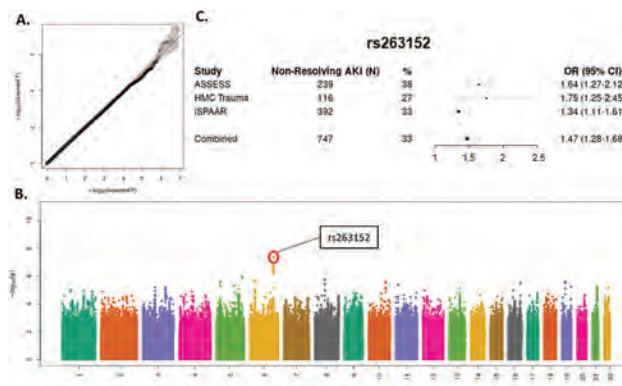

**Background:** Genetic studies have focused on associations between genetic variants and the risk for AKI compared to controls, but this framework may be limited because AKI is highly heterogeneous. We hypothesized that a GWAS for distinct AKI recovery patterns (resolving versus non-resolving AKI) would identify novel and robust genetic risks for AKI.

**Methods:** We included 2,271 patients with AKI previously enrolled in three different studies of hospitalized patients (ASSESS-AKI, iSPAAR and HMC Trauma). Resolving AKI was a  $\geq 0.3$  mg/dL or  $\geq 25\%$  decrease in serum creatinine within the first 72 hours after AKI onset (n=1524) and non-resolving AKI was the absence of resolving (n=747). Array-based genome-wide genotypes were obtained from each dataset and imputed with Haplotype Reference Consortium v 1.1. We pooled results from all three studies and used an additive genetic model adjusting for site, age, sex, and the first 10 principal components (significance was  $p < 5 \times 10^{-8}$ ).

**Results:** We identified one variant (rs263152, C>T, frequency 29%) on chromosome 6 that achieved genome-wide significance with the T allele associated with a greater risk of non-resolving AKI (OR=1.47, 95% CI: 1.28-1.68,  $p=4.28 \times 10^{-8}$ ) (Figure 1). rs263152 is intronic to LOC153910, a long non-coding RNA. In each cohort, the minor allele of rs263152 was consistently associated with a greater risk of non-resolving AKI. Query of the NephQTL database revealed that rs263152 is a cis eQTL for *AIG1* (Androgen Induced Gene-1) in tubulointerstitial cells ( $p=0.007$ ). *AIG1* has been implicated in albuminuria in the Framingham Heart Study.

**Conclusions:** Identification of genetic risks for AKI may be facilitated by a focus on less heterogeneous sub-phenotypes, such as non-resolving AKI. Our findings suggest that genetic variation that alters expression of *AIG1* confers greater risk of non-resolving AKI.

**Funding:** NIDDK Support

**Figure 1.** Genome wide significant variant is associated with non-resolving AKI compared to resolving AKI. A. Quantile-quantile plot showing overall adherence to expected p values. The genomic inflation factor based on a median chi-square was estimated at 0.997, indicating negligible variation in population structure between cases and controls. B. Manhattan plot demonstrates rs263152, an intronic SNP in chromosome 6, is significantly associated with a greater risk of non-resolving AKI (OR=1.47, 95% CI: 1.28-1.68,  $p=4.28 \times 10^{-8}$ ). C. Forest plot demonstrates a consistent direction of effect with the minor allele of rs263152 associated with a greater risk of non-resolving AKI in all three studies. The size of the boxes represents the sample size of each study.

## TH-OR03

## Associations of Blood Mitochondrial DNA Copy Number With Risk of AKI After Cardiac Surgery

Vasanth Jotwani,<sup>1</sup> Heather Thiessen Philbrook,<sup>2</sup> Ronit Katz,<sup>3</sup> Dan Arking,<sup>2</sup> Joachim H. Ix,<sup>4</sup> Gregory J. Tranah,<sup>8</sup> Sushrut S. Waikar,<sup>5</sup> Samir M. Parikh,<sup>7</sup> Mark J. Sarnak,<sup>6</sup> Michael Shlipak,<sup>1</sup> Chirag R. Parikh,<sup>2</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>Johns Hopkins University, Baltimore, MD; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>University of California San Diego, La Jolla, CA; <sup>5</sup>Boston University, Boston, MA; <sup>6</sup>Tufts University, Medford, MA; <sup>7</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>8</sup>California Pacific Medical Center, San Francisco, CA.

**Background:** Mitochondria are necessary for recovery from ischemia-reperfusion injury due to their critical roles in oxidative phosphorylation. Mitochondrial DNA copy number (mtDNA-CN) is an indirect marker of mitochondrial abundance that has been used to quantify the number of mitochondrial genomes per cell. Prior epidemiologic studies have associated higher blood mtDNA-CN with reduced risks of chronic kidney disease and mortality, but to our knowledge no study has examined risk of acute kidney injury (AKI).

**Methods:** Among 628 adults undergoing cardiac surgery, mtDNA-CN was quantified in pre-operative blood buffy coat specimens using multiplexed SYBR Green-based qPCR. AKI was defined as  $>50\%$  increase in serum creatinine or need for dialysis following surgery. Subclinical AKI was defined by the highest quintiles of urine interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), monocyte chemoattractant protein-1 (MCP-1), and chitinase-3-like-protein-1 (YKL-40) on the first post-operative day among those without clinical AKI. Multivariable logistic regression models were used to evaluate associations of mtDNA-CN with clinical and subclinical AKI.

**Results:** The mean age was  $73 \pm 9$  years and mean pre-operative eGFR was  $72 \pm 18$  mL/min/1.73m<sup>2</sup>. Each SD higher mtDNA-CN was associated with about a 38% lower risk of AKI (Table) in both unadjusted and multivariable adjusted models. There were no significant associations of mtDNA-CN with subclinical AKI, as defined by urinary levels of IL-18, KIM-1, MCP-1, or YKL-40.

**Conclusions:** Among adults undergoing cardiac surgery, higher pre-operative mtDNA-CN was associated with reduced risk of AKI but not with urinary biomarkers of tubular injury. MtDNA-CN may reflect kidney energetic reserve that promotes defense against acute ischemic stress.

**Funding:** NIDDK Support, Other NIH Support - NIA 2R01AG027002

**Table:** Association of pre-operative mtDNA copy number with risk of AKI after cardiac surgery among TRIBE participants

mtDNA-CN	AKI <sup>1</sup>	Odds Ratio (95% CI)	
		Unadjusted	Multivariable adjusted <sup>2</sup>
per SD higher <sup>3</sup> (N=628)	70 (11%)	0.64 (0.49, 0.84)	0.62 (0.47, 0.82)
T1 (N=209)	33 (16%)	1.0 (ref)	1.0 (ref)
T2 (N=210)	24 (11%)	0.69 (0.39, 1.21)	0.69 (0.39, 1.22)
T3 (N=209)	13 (6%)	0.35 (0.16, 0.69)	0.34 (0.17, 0.67)

Abbreviations: AKI, acute kidney injury; SD, standard deviation

<sup>1</sup>AKI defined as  $>50\%$  increase in serum creatinine or need for dialysis

<sup>2</sup>Multivariable model adjusts for age, sex, pre-operative estimated glomerular filtration rate, diabetes mellitus, and heart failure

Oral Anticoagulant Therapy and Risk of Kidney Disease: A Nationwide Cohort Study

Ane Emilie F. Vestergaard,<sup>1</sup> Simon K. Jensen,<sup>1</sup> Uffe Heide-Jørgensen,<sup>1</sup> Kasper Adelborg,<sup>1</sup> Henrik Birn,<sup>3,4</sup> Juan J. Carrero,<sup>2</sup> Christian F. Christiansen.<sup>1</sup>  
<sup>1</sup>Aarhus Universitet Klinisk Epidemiologisk Afdeling, Aarhus, Denmark; <sup>2</sup>Karolinska Institutet Institutionen för medicinsk epidemiologi och biostatistik, Stockholm, Sweden; <sup>3</sup>Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark; <sup>4</sup>Aarhus Universitetshospital Nyremedicinsk Afdeling C, Aarhus, Denmark.

**Background:** Oral anticoagulant therapy may be associated with kidney complications. Emerging evidence from observational studies suggest lower risks associated with direct oral anticoagulants (DOACs) compared to vitamin K-antagonists (VKAs). However, these studies suffer from methodological limitations, which we aimed to address using the unique Danish setting of population-based medical databases.

**Methods:** We conducted a new user active comparator cohort study in patients who started oral anticoagulant drug use within three months after an incident atrial fibrillation diagnosis during 2012 to 2018. Using routinely collected creatinine measurements from laboratory databases, we followed patients in an intension-to-treat approach for acute kidney injury (AKI) and chronic kidney disease (CKD) progression. AKI was defined according to the KDIGO criteria; CKD progression was a composite of >30% decline in estimated glomerular filtration rate (eGFR) or kidney failure. Propensity-score weighting was used to balance baseline confounders; we reported weighted absolute risks using the Aalen-Johansen estimator and weighted hazard ratios (HRs) using Cox regression. Consistency was checked within prespecified subgroups.

**Results:** We included 33,670 persons with atrial fibrillation initiating oral anticoagulation with 77% in the DOAC cohort. The median age was 75 years, 48% were women, and 25% had a baseline eGFR <60 ml/min/1.73 m<sup>2</sup>. The median follow-up was 2.3 years. Absolute risks of kidney complications were high: During the first year of treatment the cumulative risk of AKI was 13.9% in the DOAC group and 15.5% in the VKA group; the 5-year risk of CKD progression was 14.0% in DOAC users and 15.4% in VKA users. Compared to VKA initiation, DOAC treated patients had lower rates of both AKI and CKD progression with HRs of 0.85 (95% CI [0.81; 0.89]) and 0.84 (95% CI [0.78; 0.91]) respectively. Results were similar across subgroups of age, sex, baseline eGFR, and diabetes.

**Conclusions:** Kidney complications were common among atrial fibrillation patients initiating oral anticoagulant drugs. DOAC initiators had lower absolute risks and corresponding lower rates of AKI and CKD progression than initiators of VKAs.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

TH-OR05

Urine NGAL for AKI Screening Following Triggering of Baby NINJA (Nephrotoxic Injury Negated by Just-in-Time Action)

Cara L. Slagle,<sup>1,2</sup> Trina S. Hemmelgarn,<sup>1,2</sup> Hailey W. Gavigan,<sup>3</sup> Kelli A. Krallman,<sup>1</sup> Stuart Goldstein.<sup>1,2</sup> <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>University of Cincinnati, Cincinnati, OH; <sup>3</sup>Levine Children's Hospital, Charlotte, NC.

**Background:** Nephrotoxic medication (NTM) exposure is a cause of neonatal Acute Kidney Injury (AKI). Baby NINJA (Nephrotoxic Injury Negated by Just-in-time Action) is a screening process aimed to reduce NTM exposure and AKI in the neonatal intensive care unit, but requires daily serum creatinine (sCr) screening. Urine neutrophil gelatinase-associated lipocalin (uNGAL) has been associated with AKI and offers a less invasive screening mechanism.

**Methods:** This single center study observed use of an alternative pathway for daily screening following patient triggering of Baby NINJA starting June 2021. Following triggering, providers were prompted daily for selection of sCr or uNGAL monitoring. If uNGAL was >150 ng/mL, screening was transitioned to daily sCr only. Screening compliance was tracked for quality metrics and calculated by daily sCr or uNGAL obtained divided by NTM exposure days plus 2 days. Process control methods determined trends from baseline. Statistical analysis included Mann-Whitney U Test.

**Results:** Daily screening compliance increased following implementation of the alternative pathway (*pre* 78% vs. *post* 84%, *p*= 0.006)(Figure 1). 37% of screening occurred by uNGAL with conversion to daily sCr in 21%(21/99) of new exposures. Rates of high NTM exposure per 1000 patient days decreased (8% to 5%, *p*=0.0002). AKI rates did not differ between *pre* and *post* implementation eras. Median uNGAL that triggered conversion was 263 ng/mL (IQR 195-825 ng/mL). Median birth gestational age of those that converted was 30 wks (IQR 25-35 wks). Following implementation, 7 subjects experienced a total of 16 days of AKI. 5 patients had AKI at the time of baby NINJA trigger and continued with daily sCr, while 2 patients uNGALs triggered conversion (859 & 2835 ng/mL). Of the 7 patients with AKI, 4 experienced death within 48 hours of trigger. Clinical uNGAL was obtained with sCr in subjects with AKI with a median uNGAL of 946 ng/mL (IQR 594–2724 ng/mL).

**Conclusions:** Urine NGAL offers a less invasive screening pathway for AKI from nephrotoxic medication exposure.

TH-OR06

Development of a Machine Learning Algorithm to Predict Major Adverse Kidney Events (MAKE) After Hospitalization

Jay L. Koyner,<sup>1</sup> Kyle Carey,<sup>1</sup> Matthew M. Churpek.<sup>2</sup> <sup>1</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>2</sup>University of Wisconsin-Madison, Madison, WI.

**Background:** MAKE are common after inpatient stays and are associated with increased morbidity, mortality, and costs. We seek to develop a machine learning (ML) risk score to identify patients at high risk for MAKE following hospitalization.

**Methods:** All patients discharged alive following admission to the University of Chicago between November 2008 and June 2020 were eligible for inclusion, and patients with a history of dialysis and/or chronic kidney disease ((CKD) stage 4 or 5 based on ICD codes or admission creatinine (SCr) ≥3) prior to admission were excluded. An ML-gradient boosted algorithm was developed using demographics, inpatient vital signs, and laboratory results to identify patients at risk for MAKE within 90 of discharge (primary outcome). MAKE was defined as a composite of new CKD (defined by ICD codes for CKD4 or 5 or an SCr > 3.0 mg/dl), recurrent AKI (defined by KDIGO SCr criteria or ICD codes), ESRD / need for dialysis, or mortality. The algorithm was developed in 70% of the admissions and areas under the receiver operating characteristic curve (AUCs) were calculated for the MAKE composite endpoint and the individual components at day 90 and 365 in the held-out 30% test data.

**Results:** Of the 50,448 included patients, 9,931 (19.7%) developed a MAKE outcome within 90 days of discharge. The ML model provided an AUC(95%CI) of 0.74(0.73,0.75) for the detection of MAKE90 in the test set. The model performed best at identifying those patients who developed post-hospitalization CKD at both 90 and 365 days (Table).

**Conclusions:** We developed and validated a post-hospital discharge ML risk algorithm to predict the future development of MAKE90. Our model can be used to identify the discharged patients most in need of follow-up with nephrology.

**Funding:** NIDDK Support

AUC for MAKE Outcomes

Outcome	Timing	AUC (95% CI)
Major Adverse Kidney Event	90 Days	0.74 (0.73, 0.75)
	365 Days	0.73 (0.72, 0.73)
CKD Progression	90 Days	0.94 (0.93, 0.95)
	365 Days	0.92 (0.91, 0.93)
Recurrent AKI	90 Days	0.74 (0.73, 0.74)
	365 Days	0.72 (0.72, 0.73)
Need for New Dialysis	90 Days	0.87 (0.83, 0.91)
	365 Days	0.85 (0.82, 0.87)
Death	90 Days	0.76 (0.74, 0.78)
	365 Days	0.75 (0.74, 0.76)

## TH-OR07

**Machine Learning Models Uncover Subphenotypes of AKI With Unique Signatures That Associate With Differing Clinical Outcomes**

George Vasquez-Rios,<sup>1</sup> Wonsuk Oh,<sup>1</sup> Samuel Lee,<sup>1</sup> Pavan K. Bhatraju,<sup>2</sup> Sherry Mansour,<sup>3</sup> Dennis G. Moledina,<sup>3</sup> Edward D. Siew,<sup>4</sup> Amit X. Garg,<sup>5</sup> Vernon M. Chinchilli,<sup>6</sup> James S. Kaufman,<sup>7</sup> Chi-yuan Hsu,<sup>8</sup> Kathleen D. Liu,<sup>8</sup> Paul L. Kimmel,<sup>9</sup> Alan S. Go,<sup>8</sup> Mark M. Wurfel,<sup>2</sup> Jonathan Himmelfarb,<sup>2</sup> Chirag R. Parikh,<sup>10</sup> Steven G. Coca,<sup>1</sup> Girish N. Nadkarni.<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Yale University, New Haven, CT; <sup>4</sup>Vanderbilt University, Nashville, TN; <sup>5</sup>Western University, London, ON, Canada; <sup>6</sup>The Pennsylvania State University, University Park, PA; <sup>7</sup>New York University, New York, NY; <sup>8</sup>University of California San Francisco, San Francisco, CA; <sup>9</sup>National Institutes of Health, Bethesda, MD; <sup>10</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Acute kidney injury (AKI) is defined through serum creatinine and urine output metrics. However, these markers do not capture the complexity of AKI and do not fully inform on the future risk of kidney and clinical events.

**Methods:** We evaluated clinical and biomarker data from AKI patients during the acute hospitalization from ASSESS-AKI via three machine learning algorithms to uncover different AKI composites. We compared key characteristics within each subphenotype via classic statistics and then examined the time to event for kidney events (CKD incidence and progression), cardiovascular events, and death by subphenotype.

**Results:** We included 748 AKI patients. The mean age ( $\pm$  SD) was 64 (13) years, 67.9% were men, and the median follow-up was 4.8 years. Patients with AKI subphenotype 1 ('cardiorenal injury', N=181) were characterized by prevalent CVD (78%,  $P<0.001$ ) and the highest levels of KIM-1, urinary IL-18, and Troponin T. Subphenotype 2 ('benign', N=250) was comprised of individuals with a low prevalence of comorbid conditions and high uromodulin levels, a marker of tubular repair. AKI subphenotype 3 ('cardiorenal inflammation', N=159) comprised patients with markedly high levels of pro-BNP, TNFRs and low kidney injury (KIM-1, NGAL). Finally, patients subphenotype 4 ('sepsis-AKI', N=158) had high rates of infections and dialysis-requiring AKI. These patients had the highest levels of vascular/kidney (YKL-40, MCP-1), and injury activity. AKI subphenotype 3 and 4 were independently associated with a higher risk of death: adjusted hazard ratios (aHR) of 2.9 (95% CI: 1.8 – 4.6,  $p<0.001$ ) and 1.6 (1.01 – 2.6,  $p=0.04$ ), respectively. Subphenotype 3 was also independently associated with triple the risk of CKD outcomes (aHR: 2.6, CI: 1.6 – 4.2) and CVD events (aHR: 2.6, CI: 1.6 – 4.1).

**Conclusions:** We discovered four novel and clinically meaningful AKI subphenotypes that inform on potential pathway abnormalities that associate with differing risks for long-term events. We found a new role for biomarkers when they are evaluated in an agnostic fashion, which can serve to advance precision medicine in AKI care.

**Funding:** NIDDK Support

## TH-OR08

**Machine Learning for Development of a Real Time AKI Risk Prediction Model in ICU With External Validation and Federated Learning at Five Medical Centers: From Model Development to Clinical Application**

Chun-Te Huang. Taichung Veterans General Hospital, Taichung, Taiwan.

**Background:** Early prediction of AKI ahead of 24 to 48 hours window has now been proposed as a possible strategy to prevent or alleviate AKI by providing clinicians sufficient time for timely intervention. We aim to develop a parsimonious AKI prediction model and build a platform using federated learning for easy data transport and integration of the model between different hospitals.

**Methods:** All adult ICU admissions from 2015-2020 in Taichung Veterans General Hospital (TCVGH) were used as the derivation cohort. Adult ICU admissions from 2018-2020 in four other medical centers were used as external validation cohort. AKI labelling is based on 2012 KDIGO AKI definition. A parsimonious prediction model was selected by LASSO and deployed to the 2018-2020 external validation cohort at 4 other medical centers. A federated learning platform is built retrain and tune the AKI prediction model.

**Results:** A total of 16785 adult ICU admissions were included in the derivation cohort with median age of 68, 62% male, and 30.8% AKI incidence. Total of 60 predictors were included in the model. The machine learning algorithm for AKI prediction revealed XGBoost with better performance metrics in terms of sensitivity:0.795, specificity:0.866, AUROC:0.911, precision:0.726, and accuracy:0.844, and decision curve analysis. After applying LASSO for parsimonious prediction model for external validation at these 4 hospitals showed the prediction performance with AUROC ranging from 0.785 to 0.864. Federated learning using neuron network algorithm improved the prediction performance.

**Conclusions:** AKI is common in ICU with poor prognosis. Early prediction ahead of 24-48 hours may help clinicians for timely intervention to prevent it from happening. We demonstrate the concept of artificial intelligence as medical assistance to clinicians in a feasible way.

**Funding:** Government Support - Non-U.S.

## TH-OR09

**AKI Flagger: A Standardized AKI Definition Tool for Electronic Health Record (EHR) Research**

Abinet M. Aklilu, Ishan Saran, Francis P. Wilson. CTRA (Clinical and Translational Research Accelerator) Yale School of Medicine, New Haven, CT.

**Background:** EHR data is increasingly utilized in large studies investigating in-hospital AKI. Although such studies often attempt to use guideline criteria to diagnose AKI, there is often variability in the methodologies. We have hence developed the AKI Flagger-an open-source tool to help standardize the definition of AKI in large database studies.

**Methods:** The AKI Flagger tool employs three techniques to operationalize the definition of AKI using the KDIGO serum creatinine (SCr) criteria for AKI: Rolling Minimum Window (RMW, using 48hour and 7day windows), Historical Baseline Trumping (HBT, median SCr within 7-365days pre-AKI) and Baseline Creatinine Imputation (BCI, imputed from eGFR 75mL/min/1.73m<sup>2</sup>). The flagger was internally validated in a cohort of 40,106 adult inpatients at 6 hospitals. We determined the sensitivity and specificity of various AKI definitions in predicting stage 2 AKI, dialysis, and death.

**Results:** The incidence of AKI was higher using BCI(40.0%) compared to the HBT(31.1%) and RMW(26.1%) techniques. AKI was detected earlier with BCI (median 0.9d, IQR:0.0-5.7), followed by HBT (median 2.7d, IQR:0.0-8.1), and RMW (median 4.2d, IQR:1.6-10.3). AKI diagnosed using RMW was associated with the highest percentage of dialysis (3.2 vs 2.7 vs 2.1%) and mortality (8.0 vs 7.3 vs 6.2%), and the longest hospital stay (9.01 vs 8.31 vs 8.03 days) compared to HBT and BCI, respectively. BCI had the highest sensitivity (0.93) and lowest specificity (0.69) for AKI progression with an AUC of 0.81. RMW had the lowest sensitivity (0.87) and highest specificity (0.83) for predicting AKI progression with an AUC of 0.85.

**Conclusions:** The incidence of AKI and related outcomes vary according to the definition and timeframe used. The AKI Flagger can be a useful tool to promote consistent reporting and reproducibility in AKI research. It is available for use without permission in R and Python.

Performance of the AKI Flagger tool in predicting AKI outcomes

Technique	Sensitivity/Specificity	AUC
AKI progression*		
BCI	0.93 / 0.67	0.81
HBT	0.89 / 0.77	0.83
RMW	0.87 / 0.83	0.85
Dialysis		
BCI	1.00 / 0.61	0.80
HBT	0.99 / 0.70	0.84
RMW	0.98 / 0.75	0.86

## Novel Urinary Proteins Differentiate Sub-Phenotypes in Patients With Sepsis-Induced AKI

Ian B. Stanaway, Matthew R. Thau, Leila R. Zelnick, Eric D. Morrell, Bryan R. Kestenbaum, Mark M. Wurfel, Pavan K. Bhattraju. *University of Washington School of Medicine, Seattle, WA.*

**Background:** Patients with sepsis-induced AKI can be classified into distinct sub-phenotypes (AKI-SP1 and AKI-SP2) using biomarkers of inflammation and endothelial dysfunction. These sub-phenotypes differ in clinical outcomes and treatment response, though biologic mechanisms underlying these sub-phenotypes remain unknown.

**Methods:** We prospectively enrolled 120 ICU patients with suspected infection (including COVID-19), both with AKI (n=62) and without (n=58), collecting matched blood and urine within 24 hours of ICU admission. We classified patients with AKI as AKI-SP1 (n=45) or AKI-SP2 (n=17) using three plasma biomarkers: angiopoietin-1, angiopoietin-2 and soluble tumor necrosis factor receptor 1. Using the SomaScan® platform to measure 5,212 urinary proteins, we compared urinary proteins in patients with and without AKI and between patients with AKI-SP1 and AKI-SP2, adjusting for age, sex, BMI, and COVID infection using a false discovery rate (FDR) < 0.05.

**Results:** AKI-SP2 had higher risk for new dialysis (OR=12.2; 95% CI: 2.0-73.1;  $p=0.006$ ) compared to AKI-SP1, adjusting for age, sex, BMI, and COVID infection. No urinary proteins were differentially expressed in patients with and without AKI (Figure 1A). In patients with AKI, 194 proteins were significantly higher in the urine in AKI-SP2, and 296 proteins were higher in AKI-SP1 (Figure 1B). Proteins involved in inflammation, chemotaxis of neutrophils and monocytes (CXCL1 and CCL14) and oxidative stress (SOD2) were associated with AKI-SP2, while proteins involved in collagen deposition (GP6), podocyte derived (SPOCK2), and mesenchymal cell proliferation (IL11RA) were associated with AKI-SP1.

**Conclusions:** In patients with sepsis-induced AKI, we identified 490 urinary proteins that differed significantly between two AKI sub-phenotypes. The alternative functions of these proteins suggest heterogeneity in the pathophysiology that drives AKI in sepsis and supports the value of AKI sub-phenotypes for the identification of novel pathways in AKI development.

**Funding:** NIDDK Support, Other U.S. Government Support

Figure 1. Comparison of urinary proteomic profile between patients with and without AKI and between patients with AKI-SP1 and AKI-SP2. Figure legend: (a) Volcano plot showing no proteins are differentially expressed between patients with and without AKI adjusted for age, sex, body mass index and COVID status. (b) Volcano plot showing that limiting the analysis to only patients with AKI demonstrates that 194 proteins were significantly more abundant in the urine in AKI-SP2, while 296 proteins were higher in AKI-SP1. Dotted line indicates a false discovery rate (FDR) 0.05 significant threshold. Urinary proteins to the right of 0 are higher in patients with AKI-SP2 and proteins to the left of 0 are higher in patients with AKI-SP1.

## TH-OR11

## Role of the Pre-Hemodialysis Lung Ultrasound for Dry-Weight Assessment and Intradialytic Hypotension Risk Prediction

Giulia Palazzini,<sup>1,2</sup> Gianmarco Lugli,<sup>1,3</sup> Iacopo Gianassi,<sup>2</sup> Egrina Dervishi,<sup>2</sup> Lino C. Cirami,<sup>2</sup> Marco Allinovi.<sup>2</sup> <sup>1</sup>Università degli Studi di Firenze, Firenze, Italy; <sup>2</sup>Azienda Ospedaliero Universitaria Careggi, Firenze, Italy; <sup>3</sup>Azienda Ospedaliero Universitaria Meyer, Firenze, Italy.

**Background:** Intradialytic hypotension (IDH) is a frequent complication of hemodialysis, occurring in about one-third of patients. The importance of IDH is given by its association with potential severe clinical outcomes. Nevertheless, IDH prediction and dry-weight determination may be difficult by using conventional parameters and techniques.

**Methods:** In this prospective observational study, 91 chronic hemodialytic patients underwent a multiparametric evaluation of fluid status, through lung ultrasound (LUS) with quantification of B-lines, physical examination, blood pressure, NT-proBNP and chest X-rays, immediately before and at the end of the dialysis session. The patients were divided into IDH or no-IDH group.

**Results:** A pre-dialysis B-line number  $\geq 15$  showed a high sensitivity in fluid overload diagnosis (90%), even higher than chest X-ray and physical examination. On the other hand, a pre-dialysis number of B-lines  $\leq 8$  was predictive of IDH episode with a sensibility of 61.7% and a specificity of 74.2% (ROC curve was 0.704). A single increase in B-lines number gave a 5.083 times higher odds to exhibit fluid overload and a 0.957 times higher odds to exhibit IDH, thus indicating that decreasing B-lines was associated with an increasing likelihood of IDH. At the multivariable analysis, NYHA class, blood-albumin low level, low pre-dialysis systolic BP and a low pre-dialysis B-line number resulted as independent risk factors for IDH.

**Conclusions:** LUS is a valuable and reliable method for evaluating fluid status in dialysis patients. B-lines quantification at the beginning of dialysis showed a high sensitivity in fluid overload diagnosis and IDH prediction. Thus, LUS can help individualized ultrafiltrative profile prescription through an integrated bedside approach.

	Multivariable Analysis		
	OR	95% CI	p
NYHA Class	2.149	0.998 - 4.627	0.051
SBP before dialysis (mmHg)	0.971	0.943 - 0.999	0.043
Hypoalbuminemia (yes/no)	3.245	1.045 - 10.075	0.042
B-Lines before dialysis (n)	0.931	0.880 - 0.973	0.001

Multivariable analysis on different risk factors for predicting an intradialytic hypotension episode

## TH-OR12

## Application of Intradialytic Magnetic Resonance Imaging and Spectroscopy Demonstrates Hemodialysis-Related Acute Brain Injury

Dickson Y. Wong,<sup>1</sup> Uduanna C. Anazodo,<sup>4,2</sup> Jean Théberge,<sup>4,2</sup> Madeleine T. Dacey,<sup>2</sup> Janice Gomes,<sup>5,3</sup> Jarrin D. Penny,<sup>2,3</sup> Michael J. Van Ginkel,<sup>1</sup> Stefan E. Poirier,<sup>2,4</sup> Christopher W. McIntyre.<sup>4,3</sup> <sup>1</sup>Western University Schulich School of Medicine & Dentistry, London, ON, Canada; <sup>2</sup>Western University Department of Medical Biophysics, London, ON, Canada; <sup>3</sup>London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada; <sup>4</sup>Lawson Health Research Institute, London, ON, Canada; <sup>5</sup>Western University Department of Pathology and Laboratory Medicine, London, ON, Canada.

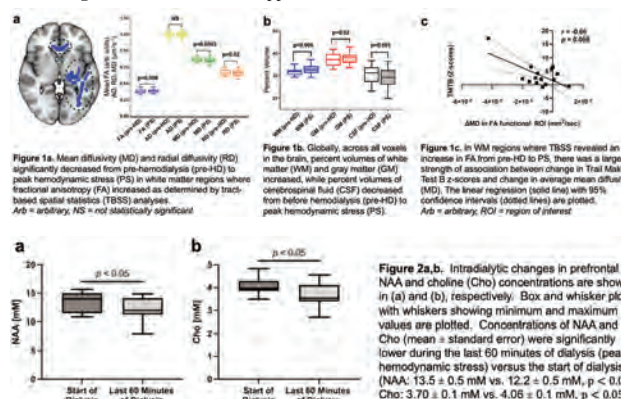

**Background:** Hemodialysis (HD) provides lifesaving treatment for patients with end stage kidney disease. However, treatment related hemodynamic stress results in recurrent ischemic injury to vulnerable organs, such as the heart. Short term reduction in brain blood flow and long-term white matter (WM) changes have been reported. However, the basis of HD-induced brain injury is neither well recognized nor understood even though progressive cognitive impairment is common.

**Methods:** 21 patients (age:  $63 \pm 13$  years, male: 58.8%) were recruited. Study procedures included neurocognitive assessments, intradialytic anatomical magnetic resonance imaging (MRI), diffusion tensor imaging (DTI), and magnetic resonance spectroscopy (H-MRS). Data acquired before HD and during the last 60 minutes of HD (during peak hemodynamic stress) were analyzed to assess the acute impact of HD on the brain.

**Results:** HD resulted in the development of multiple regions of white matter (WM) intradialytic fractional anisotropy (FA) increase with associated mean diffusivity (MD) and radial diffusivity (RD) decreases (Fig. 1a), characteristic features of cytotoxic edema (with increase in global brain volumes, Fig. 1b). Decreases in H-MRS measured NAA and choline concentrations during HD were also observed (Fig. 2), indicative of regional ischemia. Severity of WM changes were associated with reduced cognitive function performance, particularly relating to executive functioning (Fig. 1c).

**Conclusions:** This study demonstrates, for the first time, that functionally significant intradialytic changes in brain tissue volume, diffusion metrics, and brain metabolite concentrations consistent with ischemic injury occurs. Preventing HD-induced brain injury requires urgent additional investigation to improve subjective tolerability of treatment and maintenance of independence and cognitive vitality for patients.

## TH-OR13

**Intradialytic Exercise Is Associated With Lower Mortality Risk in Hemodialysis Patients**

Pedro M. Martins,<sup>1,2</sup> Diogo V. Leal,<sup>1</sup> Kenneth R. Wilund,<sup>3</sup> Manuel A. Ferreira,<sup>2,4</sup> Joao L. Viana.<sup>1</sup> <sup>1</sup>Research Center in Sports Sciences, Health Sciences and Human Development (CIDESD), University of Maia, Maia, Portugal; <sup>2</sup>Nephrocare Portugal SA, Lisboa, Portugal; <sup>3</sup>University of Illinois Urbana-Champaign Department of Kinesiology and Community Health, Champaign, IL; <sup>4</sup>Universidade Nova de Lisboa Comprehensive Health Research Centre, Lisboa, Portugal.

**Background:** HD patients have an increased mortality risk that may be minimized with physical activity (PA). Intradialytic exercise (IDE) is very convenient, potentially increasing adherence to PA and making use of otherwise sedentary time. However, it is not known whether this potential protective role of PA can be achieved through IDE. Thus, the aim of this study was to analyze the association of IDE with mortality in HD patients.

**Methods:** Multicenter prospective cohort study in adult HD patients eligible to IDE (3 times/week cycling and lower body resistance exercises using ankle weights) from 21 HD units in Portugal. After 1-year of IDE implementation, patients were followed for up to 3 years. Three groups were created based on IDE exposure (exercise minutes/week): no-exercise (patients who refused IDE); low-exercise (<87 min/week); high-exercise (≥87 min/week). Kaplan-Meier (unadjusted analysis) and cox proportional hazard models (adjusted for age, dialysis vintage, vascular access, comorbidity index, cardiovascular disease, lean tissue, overhydration and hospitalizations) were used with no-exercise group as reference. Further, sub-analysis restricted to IDE participants were performed with exposure as a continuous variable.

**Results:** 741 patients (no-exercise: 394; low-exercise: 174; high-exercise: 173) were followed for a median of 33.2 (IQR 11.5) months. Unadjusted mortality incidence was different between the three groups: (no-exercise: 21.6%; low-exercise: 19.0%; high-exercise: 6.4%;  $p<0.001$ ). In adjusted analysis, the high-exercise group had a lower mortality risk than the no-exercise group (HR=0.38, 95% CI 0.20-0.75,  $p=0.005$ ), whilst this was not observed in the low-exercise group (HR=1.18, 95% CI 0.77-1.79,  $p=0.453$ ). Moreover, the mortality risk was reduced for each 50 min of exercise/week in unadjusted (HR=0.43, 95% CI 0.26-0.71,  $p=0.001$ ) and adjusted analysis (HR=0.47, 95% CI 0.27-0.82,  $p=0.008$ ).

**Conclusions:** Our data shows that IDE is associated with a reduction in mortality risk in HD patients, but considerable exercise volume is required. Therefore, patients achieving low-exercise doses may need out-of-clinic PA/exercise approaches to complement IDE.

## TH-OR14

**0.075% Capsaicin Lotion for the Treatment of Peripheral Neuropathy in ESRD Patients: A Multicenter Randomized Double-Blind Placebo-Controlled, Cross-Over Trial**

Parinada Kittidanairuk,<sup>1</sup> Narittaya Varothai,<sup>1</sup> Veerapatr Nimkietkajorn.<sup>2</sup> <sup>1</sup>Phramongkutklao Hospital, Bangkok, Thailand; <sup>2</sup>Buddhachinaraj Phitsanulok Hospital, Phitsanulok, Thailand.

**Background:** Neuropathic pain is one of the common symptom in chronic kidney disease (CKD) patients leads to problems in physical, mental and quality of life. Pain medications are also limited in CKD. This study aims to evaluate the effect of 0.075% capsaicin lotion in neuropathic pain, quality of life and side effect of End Stage Renal Disease (ESRD) patient required Renal Replacement Therapy (RRT).

**Methods:** We conducted a multicenter randomized, double-blinded, crossover, placebo controlled trial included 60 ESRD patients required RRT who had peripheral neuropathy in dialysis units in Bangkok and Phitsanulok province. The participants were randomized to received 0.075% capsaicin/placebo for 8 weeks, then crossing over to the other treatment for 8 weeks after a 2-weeks washout period. Primary outcome was the change in visual analog scale (VAS) score of pain severity. Secondary outcomes were changes in neuropathic pain scale, short-form McGill Pain questionnaire, quality of life in kidney disease using KDQOL-36 and adverse event.

**Results:** A total of 55 participants were enrolled, baseline VAS pain score was 6.05. After 8 weeks of capsaicin lotion, VAS score decrease 1.75 ( $p=0.615$ ) after 8 weeks. Proportions of patients with pain score reductions of 50% significantly decreased in capsaicin group 23 (41%) and 14 (25.45%) in control group ( $p=0.022$ ). From subgroup analysis, VAS in patients with severe pain score at start decreased significantly ( $p=0.021$ ), compare to those with moderate pain score at start ( $p=1.000$ ). KDQOL-36, the mean score in daily activity trend to decrease 0.25 in capsaicin group compare to 0.05 in control group ( $p=0.094$ ). Capsaicin lotion was well tolerated with some local skin reactions.

**Conclusions:** In ESRD patients with peripheral neuropathy, 0.075% capsaicin lotion can significantly decrease pain score 50% and trend to improve daily activity aspect of quality of life in kidney disease.

**Funding:** Commercial Support - Bangkok Drug Company

## TH-OR15

**Preferences for End-of-Life Care Among Dialysis Patients: A Discrete Choice Experiment**

Ania Filus, Katie T. Harmeyer, Steven M. Brunelli, Francesca Tentori, Davita Clinical Research, Minneapolis, MN.

**Background:** Given the high symptom and morbidity burden related to kidney failure, there is an urgent need to deliver care that aligns with patient wishes and priorities at each stage of their disease, including as they approach End of life (EoL). However, there is a knowledge gap of patients' specific preferences for their EoL care. We leveraged a discrete choice experiment approach to identify factors that are important to dialysis patients.

**Methods:** In August-September 2021, we deployed an online survey that assessed the importance of the three aspects of EoL care: degree of pain management (well vs. poorly controlled), frequency of hospitalizations (sometimes vs. often), and place of death (home vs. hospital). We utilized a block fraction factorial design with 2 blocks and 4 questions within each block (Figure 1). Patients were asked to choose between two alternative scenarios of EoL care for each question.

**Results:** Surveys were collected from 796 patients, including home dialysis (2.2%) and in-center (97.8%) dialysis patients. The median age was 54 years and 40% were female. The race composition was 37% White, 35% Black, 16% Hispanic, and 5% Asian. The majority of surveyed patients (70%) reported being on dialysis from 1 to 7 years and most rated their subjective health as average (49%) or better (33%) than other dialysis patients. Results from the discrete choice experiment indicate that patients were 3.7 times more likely to choose a scenario with well-managed pain over poor pain management. The frequency of hospital visits [OR 1.3 (95% CI 1.21-1.47)] at the EoL was the least important attribute of quality of care at the end of life (Table 1). Patients were 1.5 times more likely to choose dying at home vs the hospital.

**Conclusions:** The level of pain management was the most important attribute of quality of care at the end of life, over frequency of hospital visits and place of death.

	Coefficient	Odds Ratio	SE (Coefficient)	Statistical Significance
Well managed pain vs. not well managed pain	1.31	3.7	0.05	$p<0.001$
Occasional hospitalization vs. frequent hospitalization	0.29	1.3	0.05	$p<0.001$
Dying at home vs. dying in the hospital	0.40	1.5	0.05	$p<0.001$

Read carefully the description of two hypothetical options for care at the end of life. Which option (A or B) would you prefer? Select one choice.

## TH-OR16

**DIALIZE China: A Phase 3b Study to Reduce Pre-Dialysis Hyperkalemia With Sodium Zirconium Cyclosilicate in Chinese Subjects**

June Zhao,<sup>1</sup> Zhaohui Ni,<sup>2</sup> Renhua Lu,<sup>2</sup> Xudong Xu,<sup>3</sup> Xueyan Bian,<sup>4</sup> Zhou Zhihong,<sup>5</sup> Junwei Yang,<sup>6</sup> Qun Luo,<sup>7</sup> Chen M. Hua,<sup>8</sup> Chaosheng Chen,<sup>9</sup> Xiuli Sun,<sup>10</sup> Lei Yu,<sup>11</sup> Qiang He,<sup>12</sup> Hong Jiang,<sup>13</sup> Wei jie Yuan,<sup>14</sup> Yi Li,<sup>15</sup> Rong Zhou,<sup>16</sup> Wang Jianqin,<sup>17</sup> Xinzhou Zhang,<sup>18</sup> Li Zuo,<sup>19</sup> Haijiao Jin,<sup>2</sup> Xiangwen Meng,<sup>20</sup> Zhiren Chang.<sup>20</sup> For the DIALIZE China Study Group. <sup>1</sup>AstraZeneca, Wilmington, DE; <sup>2</sup>Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; <sup>3</sup>Central Hospital of Minhang District, Shanghai, China; <sup>4</sup>Ningbo First Hospital, Ningbo, China; <sup>5</sup>The Second Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; <sup>6</sup>The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; <sup>7</sup>Ningbo Huamei Hospital, University of Chinese Academy of Sciences, Ningbo, China; <sup>8</sup>General Hospital of Ningxia Medical University, Yinchuan, China; <sup>9</sup>The First Affiliated Hospital of Wenzhou College, Wenzhou, China; <sup>10</sup>Baotou City Central Hospital, Baotou, China; <sup>11</sup>Inner Mongolia People's Hospital, Hohhot, China; <sup>12</sup>Zhejiang Traditional Chinese Medicine Hospital, Hangzhou, China; <sup>13</sup>People's Hospital of Xinjiang Uygur Autonomous Region, Xinjiang, China; <sup>14</sup>Shanghai General Hospital, Shanghai, China; <sup>15</sup>Dongguan People's Hospital, Dongguan, China; <sup>16</sup>Shanghai Yangpu District Central Hospital, Shanghai, China; <sup>17</sup>Lanzhou University Second Hospital, Lanzhou, China; <sup>18</sup>Shenzhen People's Hospital, Shenzhen, China; <sup>19</sup>Peking University People's Hospital, Beijing, China; <sup>20</sup>AstraZeneca, Shanghai, China.

**Background:** Sodium zirconium cyclosilicate (SZC) is an anti-hyperkalemia (HK) therapy (oral potassium binder) indicated in adults. DIALIZE China (NCT04217590) evaluated the safety and efficacy of SZC in individuals receiving hemodialysis (HD) in China.

**Methods:** DIALIZE China was a randomized, double-blind, placebo (PBO)-controlled, multicenter, phase 3b study of adults receiving HD 3-times weekly for kidney failure with pre-dialysis HK (serum potassium [sK<sup>+</sup>] >5.4 mmol/L after the long interdialytic interval [LIDI] and >5.0 mmol/L after 1 short interdialytic interval). Following a 1-week screening period, subjects were randomized 1:1 to SZC or PBO (5 g/day on non-dialysis days), titrated over 4 weeks up to 15 g/day as required to achieve normokalemia (NK; pre-dialysis sK<sup>+</sup> 3.5–5.5 mmol/L), prior to a 4-week evaluation and 2-week follow-up. The primary outcome was the proportion of responders (pre-dialysis sK<sup>+</sup> 4.0–5.0 mmol/L for ≥3 of 4 HD visits following the LIDI, without any rescue therapy during evaluation). Secondary outcomes included assessment of pre-dialysis sK<sup>+</sup> values; safety outcomes included adverse events (AEs).

**Results:** Overall, 134 adults from China were randomized to SZC or PBO (each n=67); mean (SD) age was 54.7 (11.3) years, 49% were male and mean weight was 60 kg. There was a significantly higher proportion of responders in the SZC arm (37.3%) vs PBO arm (10.4%) (estimated odds ratio [OR]: 5.10, 95% CI: 1.90–15.12, *P*<0.001). A greater proportion of subjects achieved NK on ≥3 of 4 LIDI visits during evaluation with SZC (73%) than with PBO (30%). The probability of all pre-dialysis sK<sup>+</sup> values being between ≥3.5 to ≤5.5 mmol/L was significantly higher with SZC vs PBO (estimated OR: 6.41, 95% CI: 2.71–15.12, *P*<0.001). AEs and serious AEs, respectively, occurred in 64% and 9% of subjects in the SZC arm, and 66% and 12% of subjects in the PBO arm, with no new safety concerns identified.

**Conclusions:** SZC is an effective and well-tolerated treatment for HK in Chinese individuals receiving HD.

**Funding:** Commercial Support - AstraZeneca

## TH-OR17

### Effect of ESRD Treatment Choices (ETC) on Home Dialysis Utilization Among Incident Dialysis Patients

Kirsten L. Johansen,<sup>1,2</sup> Shuling Li,<sup>3</sup> David T. Gilbertson,<sup>1,2</sup> Eric D. Weinhandl,<sup>3,1</sup> Chuanyu Kou,<sup>1</sup> Christopher D. Knapp,<sup>1</sup> James B. Wetmore,<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>3</sup>Satellite Healthcare, San Jose, CA.

**Background:** The Advancing American Kidney Health Executive Order set ambitious targets for home dialysis in the US. CMS introduced payment models to incentivize home dialysis, including ETC, which launched in January 2021. Although ETC applies only to Medicare fee-for-service (FFS) beneficiaries, it has the potential to change provider behavior for all patients. We examined changes in use of home dialysis among all incident dialysis patients in the US according to provider ETC assignment.

**Methods:** ESRD providers were randomly assigned to ETC participation at the Hospital Referral Region (HRR) level. Using USRDS data, we analyzed adult patients with incident ESRD who initiated dialysis from January 1, 2016 to March 31, 2022. We excluded patients dialyzing in a SNF or long-term care facility, prior transplant, or missing provider ZIP code. We examined the percentage of patients on home dialysis by ETC participation from first quarter (Q1) 2016 to Q1 2022 and used a changepoint method to assess whether there was a change in the differences between ETC and non-ETC markets during this period.

**Results:** In total, 766,055 patients were studied (31% ETC participants). Before the assignment of ETC markets in late Q3 2020, the proportion of patients started on home dialysis was increasing steadily but was slightly lower among patients in ETC markets than among those in non-ETC markets (Figure). A changepoint was found just prior to Q4 2020 (*p*=0.004 for before-after Q4 2020). After this time, home dialysis use increased among patients in ETC markets but not among those in non-ETC markets. After the launch of ETC, a higher percentage started home dialysis in ETC markets (15.4% vs. 14.5%).

**Conclusions:** The ETC payment model for Medicare FFS beneficiaries appears to have affected practice patterns for all incident dialysis patients. After its introduction, the proportion of patients starting home dialysis continued to increase in ETC markets and flattened in non-ETC markets.

**Funding:** NIDDK Support

## TH-OR18

### The Effects of Implementing a Home Dialysis Project ECHO

Christopher T. Chan,<sup>1</sup> Rajnish Mehrotra,<sup>2</sup> Matthew B. Rivara,<sup>2</sup> Danilo Concepcion,<sup>3</sup> Karen Crampton,<sup>4</sup> Renin Cassidy,<sup>6</sup> Nancy Pierce,<sup>7</sup> Katy G. Wilkens,<sup>6</sup> Stephanie Hutchinson,<sup>5</sup> Barbara Dommert-Breckler,<sup>5</sup> Jessica Joseph,<sup>8</sup> Elizabeth Montgomery,<sup>8</sup> Home Dialysis Echo HUB group <sup>1</sup>University of Toronto, Toronto, ON, Canada; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Providence St Joseph Health, Renton, WA; <sup>4</sup>University of Michigan, Ann Arbor, MI; <sup>5</sup>Comagine Health, Seattle, WA; <sup>6</sup>Northwest Kidney Centers, Seattle, WA; <sup>7</sup>ESRD Network 16, Seattle, WA; <sup>8</sup>National Kidney Foundation, New York, NY.

**Background:** Insufficient home dialysis education and mentorship are suggested barriers contributing to the under utilization of home therapies in the U.S. The National Kidney Foundation KDOQI Home Dialysis task force hypothesized that the use of a Project ECHO (Extension for Community Healthcare Outcome) program may enhance home dialysis uptake.

**Methods:** In partnership with Comagine Health, the NKF home dialysis ECHO project delivered 20 interprofessional education sessions virtually to 108 registrants from 19 dialysis centers derived from 2 ESRD network regions over 1 year. Our home dialysis curriculum has previously been published. Sessions were divided into case discussion and didactic teaching moderated by the home dialysis hub team. Using a mixed method before and after approach, we described the differences in home dialysis rate and knowledge utilization.

**Results:** 108 healthcare workers registered for our home dialysis ECHO project. The median number of participated sessions was 1.5 (range = 16). The registrants represented a diverse background (including: dietitian [n = 15], facility administrator [n = 20], nurse [n=36] and social worker [n=18]). Using exit questionnaires, the registrants consistently recommended ECHO sessions to their peers with the top sessions saturating amongst the themes of “establishing home dialysis culture”, “modality education” and “psychosocial adjustment”. At baseline, the participating centers’ median home dialysis rate was 9.28% (0.00 – 18.52%) [25–75%] which increased to 12.8% (0.00 – 24.6%) [Wilcoxon Signed Rank Test, *p* = 0.004] after the program.

**Conclusions:** We demonstrated that home dialysis ECHO project was a feasible strategy that was associated with a modest increase in home dialysis rates. A prospective examination of national adoption of such a strategy to physicians and dialysis clinic staff is warranted.

Home Dialysis Rate Before and After Virtual ECHO project

## TH-OR19

### High-Flow Arteriovenous Fistula and Myocardial Fibrosis in Hemodialysis Patients With Non-Contrast Cardiac Magnetic Resonance Imaging

Jwa-kyung Kim,<sup>1</sup> Sung Jin Moon,<sup>2</sup> Sungmin Kim,<sup>1</sup> Dong Hee Lee,<sup>1</sup> Sung Gyun Kim,<sup>1</sup> <sup>1</sup>Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; <sup>2</sup>Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea.

**Background:** Myocardial fibrosis is a critical part of maladaptive cardiac remodeling that leads to heart failure (HF). In patients with chronic kidney disease, diffuse myocardial fibrosis is a typical uremic cardiomyopathy characteristic unrelated to ischemic heart disease. The role of high-flow arteriovenous fistula (AVF) in myocardial fibrosis in hemodialysis (HD) patients is very likely under-recognized.

**Methods:** Markers of myocardial damage, galectin-3 and N-terminal pro B-type natriuretic peptide (NT-proBNP), were measured in 101 HD patients who underwent regular monitoring of intra-access Qa. AVF with Qa >2 L/min was considered a high-flow AVF. The degree of myocardial fibrosis according to intra-access Qa was assessed by native T1 relaxation times on cardiac MRI and serum galectin-3.

**Results:** Compared to HV, HD patients showed a significantly higher galectin-3 value and increased T1 relaxation time, suggesting increased myocardial fibrosis in uremic conditions. In HD patients, 20 (19.8%) had a  $Q_a > 2$  L/min, and they had significantly higher cardiac output, cardiac index, left ventricular mass, as well as increased T1 relaxation times than those with a  $Q_a \leq 2$  L/min. Also, galectin-3 value and NT-proBNP levels were much higher in these patients with a high  $Q_a$ , indicating a close relationship between increased  $Q_a$ , myocardial fibrosis, and increased risk of HF. Notably, the association between higher  $Q_a$  and myocardial fibrosis was independent of traditional risk factors as well as serum NT-proBNP and inflammatory marker, monocyte chemoattractant protein-1.

**Conclusions:** A supra-physiologically high  $Q_a$  can be related to increased myocardial fibrosis and remodeling in HD patients. Regular  $Q_a$  monitoring and early detection of myocardial fibrosis could be helpful for preventing further cardiac damage.

## TH-OR20

### Biofunctionalized Vascular Access Graft Enhanced Patency and Endothelialization in a Pig Arteriovenous (AV) Model

Prakash Parthiban Selvakumar,<sup>1</sup> Unimunkh Uriyanghai,<sup>2</sup> Richard D. Johnson,<sup>1</sup> Christine Wai,<sup>2</sup> Prabir Roy-Chaudhury,<sup>2</sup> Wei Tan.<sup>1</sup> <sup>1</sup>University of Colorado Boulder, Boulder, CO; <sup>2</sup>University of North Carolina System, Chapel, NC.

**Background:** Dialysis vascular access is currently both the “lifeline” and the “Achilles heel” of dialysis vascular access. Dialysis access grafts suffer from clinical complications such as kinking, thrombosis, restenosis, and lack of rapid endothelialization. An anti-kinkable vascular access graft which promotes rapid endothelialization, thus restricting thrombosis and restenosis is a clinical necessity. Previously, we have successfully developed an acellular vascular graft which showed promising results in small animals. Here, we have reinforced the same graft to provide anti-kinking properties, and examined its effectiveness in a large animal model of AV stenosis.

**Methods:** 6 mm graft comprising poly-ε-caprolactone (PCL) and polyethylene glycol norbornene (PEG-NB) was coaxially electrospun with PCL as the core and PEG-NB as the sheath and conjugated with various biomolecules. Biodegradable polydioxane sutures were spirally wound for anti-kinkability. These grafts were implanted in a loop configuration between the femoral artery and vein of pigs. Computer tomography (CT; weeks 1 and 4) and Doppler ultrasound examination (a week for 4 weeks) was performed. The grafts were removed after 28d for histological examination.

**Results:** We observed no kinking of the grafts during the test period. The CT scan showed a patent lumen with continuous blood flow. Ultrasounds documented patency and an average volume flow of 756.3 ml/min (Fig. 1a-c). Histology revealed active cellular integration, ECM synthesis and the formation of a luminal endothelial layer (Fig. 1d).

**Conclusions:** Our electrospun grafts with precision engineered biomolecules, promoted rapid endothelialization and cellular integration with good flow, in an arteriovenous configuration. This approach will reduce the huge morbidity, mortality and economic cost currently associated with dialysis vascular access dysfunction.

### Hyperaldosteronism Screening Among a Large Diverse Resistant Hypertension Population Within an Integrated Healthcare System

Victor D. Kim,<sup>1</sup> Jiaxiao Shi,<sup>2</sup> Jaecin An,<sup>2,3</sup> John J. Sim,<sup>1,3</sup> Kaiser Permanente Los Angeles Nephrology <sup>1</sup>Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; <sup>2</sup>KPSC Research and Evaluation, Pasadena, CA; <sup>3</sup>Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA.

**Background:** Hyperaldosteronism (HA) is one of the most common causes of resistant hypertension (RH), and screening for HA is recommended. HA is potentially treatable with more targeted therapy and interventions such as mineralocorticoid receptor antagonists (MRAs). We sought to determine the rate of screening for HA and use of MRAs among a large diverse RH population from an integrated health system.

**Methods:** A cross-sectional study was performed within Kaiser Permanente Southern California using electronic health records. We identified patients with RH between 7/1/2014 and 6/30/2015 using a criteria of systolic blood pressure  $>130$  mm Hg on 3 or more antihypertensive medicines or requiring 4 or more medicines regardless of BP. We evaluated the rate of serological screening for HA among those with RH. Screening captured as closest date before or after 5 years of RH index date. Positive screen for HA was defined as aldosterone renin ratio  $\geq 20$  or aldosterone level  $\geq 15$  ng/dl. We evaluated patient demographic and clinical characteristics, and MRA use among RH and HA patients.

**Results:** Among 102,480 RH patients (Hispanic = 24.5%, black = 19.5%, white = 44.4%, Asian = 8.6%), a total of 2,824 (2.8%) patients were screened for HA and among them, 1,170 (41.4%) patients met criteria for HA. HA patients were more likely to be male, black, and had lower potassium levels (3.9 vs 4.1 mEq/L). MRA use was 6.5% among all RH, 14.7% among all screened, and 31.7% among patients with HA.

**Conclusions:** Among a large diverse RH population, we observed a low rate of screening for HA while the positivity rate was high among those screened. MRA use was low in the RH population but higher among HA patients. Understanding potential barriers to HA screening and empiric use of MRA among the RH population warrant further investigation.

## TH-OR23

**Influence of Baseline Diastolic BP (DBP) on the Effects of BP Lowering on Cardiovascular (CV) Outcomes: A Meta-Analysis of NIH BP Trials**

Amara Sarwal,<sup>1</sup> Robert E. Boucher,<sup>1</sup> Sydney E. Hartsell,<sup>1</sup> Guo Wei,<sup>1</sup> Xiangyang Ye,<sup>1</sup> Jincheng Shen,<sup>1</sup> Glenn Chertow,<sup>2</sup> Paul K. Whelton,<sup>3</sup> Alfred K. Cheung,<sup>1</sup> Tom Greene,<sup>1</sup> Srinivasan Beddhu.<sup>1</sup> <sup>1</sup>University of Utah Health, Salt Lake City, UT; <sup>2</sup>Stanford University School of Medicine, Stanford, CA; <sup>3</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

**Background:** Lowering systolic BP (SBP) in persons with low DBP might affect tissue perfusion and thereby, increase risk for CV events.

**Methods:** We conducted a meta-analysis of 4 NIH BP trials that examined the effects of BP goals on CV outcomes; SPRINT, N = 9247, SBP goal < 120 vs. < 140, ACCORD BP standard glycemia arm (N = 2361, SBP goal < 120 vs. < 140), SPS3 (N = 3008, SBP goal < 130 vs. < 140) and AASK (N = 1094, goal MAP < 92 mmHg vs. 102-107). We used DerSimonian-Laird random-effects models in Stata version 15.1 to conduct meta-analyses of the interaction between baseline DBP and the BP intervention on CV outcomes.

**Results:** Mean baseline DBP in SPRINT, ACCORD BP, SPS-3 and AASK were 78 ± 12, 76 ± 10, 78 ± 11, 96 ± 14 mmHg, respectively with evidence of heterogeneity. In the 15,710 participants included, there were 1614 CV events over 59,925 person-years of follow-up. Intensive BP control resulted in overall lower hazard of CV events, (HR 0.79, CI 0.72, 0.87) (Table). Lower baseline DBP was associated with increased risk of CV events in SPRINT and ACCORD BP but not in SPS3 and AASK with a non-significant association of lower DBP with CV events (HR 1.10, CI 0.97, 1.24) (Table). The interaction term of baseline DBP and the BP intervention on CV events was non-significant in each of the studies and pooled overall (Figure).

**Conclusions:** In this meta-analysis of large, multicenter NIH-funded trials, BP intervention was beneficial for improving CV outcomes, but there was no evidence that these beneficial effects were modified by baseline DBP.

**Funding:** NIDDK Support, Other NIH Support - NIA, Veterans Affairs Support

Effects of BP intervention on and the associations of baseline DBP with CV events

	Intensive vs Standard BP (HR, CI)	HR per 10 mmHg ↓ in baseline DBP (HR, CI)
SPRINT	0.76 (0.65, 0.88)	1.20 (1.12, 1.28)
ACCORD-BP	0.76 (0.62, 0.94)	1.24 (1.11, 1.37)
SPS3	0.86 (0.70, 1.06)	1.02 (0.92, 1.12)
AASK	0.90 (0.65, 1.24)	0.95 (0.85, 1.06)
Overall	0.79 (0.72, 0.87)	1.10 (0.97, 1.24)

## TH-OR24

**Sex Difference in Cardiovascular Risk in Non-CKD and CKD: NHANES 1999-2018**

Ester Oh,<sup>1</sup> Zhiying You,<sup>1</sup> Kristen L. Nowak,<sup>1</sup> Anna Jovanovich,<sup>1,2</sup> <sup>1</sup>University of Colorado - Anschutz Medical Campus, Aurora, CO; <sup>2</sup>VA Eastern Colorado Health Care System, Aurora, CO.

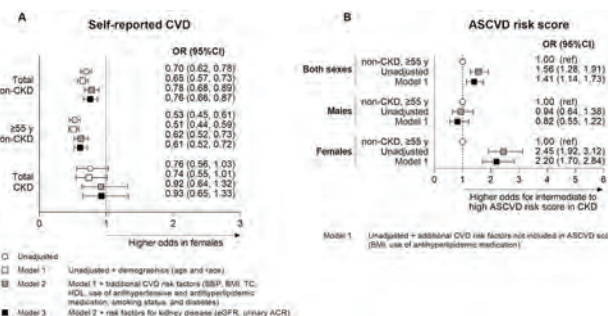

**Background:** In the general population, females (vs. males) have a lower risk for cardiovascular disease (CVD). However, little is known whether this sex-specific risk pattern of CVD translates to individuals with chronic kidney disease (CKD). The purpose of this study was to examine if there was a sex-specific risk of CVD in adults who participated in the National Health and Nutrition Examination Survey (NHANES), both with CKD and without CKD.

**Methods:** Multivariable logistic regression models were used to examine the odds ratio (OR) for 1) self-reported CVD, including myocardial infarction, stroke, angina pectoris, and congestive heart failure, in females vs. males in non-CKD (18-75 y and ≥55 y) and stage 3-4 CKD sub-groups (18-75 y and ≥55 y) 2) Atherosclerotic Cardiovascular Disease (ASCVD) risk score in non-CKD (18-75 y and ≥55 y) vs. CKD (18-75 y), separately for males and females.

**Results:** Adults with CKD (n=1,347; 52% F; 64±9 y; estimated glomerular filtration rate [eGFR] 47±10 ml/min/1.73m<sup>2</sup>) and without CKD (n=38,858; 51% F; 43±16 y; eGFR 102±18 ml/min/1.73m<sup>2</sup>) were included in the study. In order to better match the mean age between the non-CKD and CKD sub-groups, adults without CKD were further sub-grouped into those ≥55 y (n=11,117; 50% F; 64±5 y; eGFR 87±13 ml/min/1.73m<sup>2</sup>). Females had a lower fully adjusted odds for CVD than males in the 18-75 y and ≥55 y non-CKD (Fig. 1A). However, in adults 18-75 y with CKD, there was no sex difference in fully adjusted odds for CVD. As compared to females ≥55 y without CKD, females 18-75 y with CKD had a higher odds of intermediate-high vs. low-borderline ASCVD risk score in the fully adjusted model (Fig. 1B). No difference was observed in the OR of a higher ASCVD score between CKD males 18-75 y vs. non-CKD males ≥55 y.

**Conclusions:** Our findings suggest that CKD abolishes the cardiovascular protection observed in females without CKD. In addition, CKD may be a stronger risk factor for CVD in females than males.

**Funding:** NIDDK Support, Veterans Affairs Support

## TH-OR25

**Associations of Impaired Kidney Function With Cerebral Small Vessel Disease and Cognitive Disorders: Findings From the Framingham Heart Study**

Dearbhla M. Kelly,<sup>1</sup> Adlin Pinheiro,<sup>3,2</sup> Christopher D. Anderson,<sup>4,5</sup> Hugo J. Aparicio,<sup>3,6</sup> Charles S. Decarli,<sup>7</sup> Shih-Jen Hwang,<sup>3</sup> A. Viswanathan,<sup>1</sup> Jose R. Romero,<sup>3,6</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Boston University School of Public Health, Boston, MA; <sup>3</sup>Framingham Heart Study, Framingham, MA; <sup>4</sup>Brigham and Women's Hospital, Boston, MA; <sup>5</sup>Broad Institute, Cambridge, MA; <sup>6</sup>Boston University School of Medicine, Boston, MA; <sup>7</sup>University of California Davis School of Medicine, Sacramento, CA.

**Background:** CKD has been associated with cognitive dysfunction in epidemiological studies, but it is unclear if this association is independent of blood pressure (BP) and related to cerebral small vessel disease (CSVD). Using the Framingham Heart Study, a population-based longitudinal cohort study with detailed cognitive phenotyping and neuroimaging, we evaluated baseline kidney function in relation to subsequent BP measurements and CSVD, and to mild cognitive impairment (MCI) and dementia.

**Methods:** We included Framingham Offspring participants free of dementia, attending an examination during midlife for ascertainment of kidney function status, with brain MRI late in life, cognitive outcome data and available interim BP assessments. We related CKD (eGFR < 60 ml/min/1.73m<sup>2</sup>) and albuminuria (UACR ≥ 30 mg/g) to CSVD markers (enlarged perivascular spaces [ePVS] and covert brain infarcts [CBI]) using multivariate logistic regression, and to incident MCI or dementia using Cox proportional hazards regression. Models for CSVD markers adjusted for age, sex, mean pre-morbid systolic BP, and time interval between MRI date and exam 8. Models for incident MCI/dementia adjusted for age, sex, education, and mean pre-morbid systolic BP.

**Results:** Among 2738 participants (mean age 67.4 (SD=9.2), 187 (7%) had CKD and 251 (9%) albuminuria. Albuminuria was associated with both high burden of ePVS in mixed brain regions (adjusted OR=1.56 [1.06-2.31] p=0.026), particularly in the basal ganglia (adjusted OR=1.64 [1.13-2.38] p=0.010), and CBI (OR=1.65 [95% CI: 1.09-2.49] p=0.017). Albuminuria was also independently associated with incident MCI and dementia (adjusted HR=1.65 [1.23-2.23] p=0.001). CKD was not associated with CSVD markers but was associated with higher risk of incident dementia (adjusted HR=1.51 [1.01-2.27] p=0.046), mainly the vascular subtype (adjusted HR=2.39 [1.01-5.67] p=0.048).

**Conclusions:** Albuminuria was associated with both CSVD markers and cognitive disorders independent of pre-morbid BP, indicating that 1) hypertensive cerebral vascular injury (reflected on CSVD markers) may not be reflected by BP measurements alone, or 2) other shared pathobiology may exist between the kidney and the brain, for instance with mechanisms such as endothelial dysfunction.

## TH-OR26

**Nutritional Status and Cardiorenal Syndrome: Associations of Protein-Energy Wasting and Abdominal Obesity With the Risk of Heart Failure in CKD**

Tejita Agarwal,<sup>1</sup> Sydney E. Hartsell,<sup>1,2</sup> Robert E. Boucher,<sup>1,2</sup> Farahnaz A. Moghaddam,<sup>1</sup> Stephen R. Sammons,<sup>1,2</sup> Amara Sarwal,<sup>1,2</sup> Adhish Agarwal,<sup>1,2</sup> Guo Wei,<sup>1,2</sup> Srinivasan Beddhu.<sup>1,2</sup> <sup>1</sup>The University of Utah School of Medicine, Salt Lake City, UT; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** The term malnutrition is defined as faulty nutrition due to inadequate or unbalanced intake of nutrients or their impaired assimilation or utilization. In that context, both Protein-Energy Wasting (PEW) syndrome and abdominal obesity are two extremes of this disorder. We examined the hypothesis that both of these extremes are risk factors for heart failure (HF) in CKD and thus might play a role in cardiorenal syndrome.

**Methods:** We used data from the Chronic Renal Insufficiency Cohort Study (CRIC), a NIH-funded observational study of participants with CKD. We used a previously published, modified definition of PEW syndrome categories (low serum chemistry, low body mass and low muscle mass). Presence of at least one criteria (albumin < 3.5 g/dl or cholesterol < 100 mg/dl for serum chemistry, BMI < 23 kg/m<sup>2</sup> for body mass and sex specific < 25th percentile of 24-hour urinary creatinine for low muscle mass) within each

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

category was considered to meet the presence of that category. Abdominal obesity was defined by waist circumference. We used separate Cox regression models to relate baseline PEW and abdominal obesity with the time to subsequent adjudicated HF outcomes.

**Results:** 3745 CRIC participants were included. Mean baseline age was  $58 \pm 11$  yrs and eGFR  $44 \pm 15$  ml/min/1.73 m<sup>2</sup>. At baseline, 1094 patients (29.2%) met 1 PEW criterion, 320 (8.5%) met  $\geq 2$  criteria and 2486 (67%) had abdominal obesity. There were 630 HF events over 32,877 years of follow-up. As shown in table, adjusted for baseline demographics, smoking, alcohol use, income, comorbid conditions, BP levels, and eGFR, both PEW and abdominal obesity were associated with higher risk of HF events.

**Conclusions:** Abdominal obesity is much more common than PEW in CKD. Both abdominal obesity and PEW are risk factors for HF in CKD. The underlying mechanisms by which PEW might play a role in cardiorenal syndrome needs further study.

**Funding:** NIDDK Support, Other NIH Support - NHLBI, NIA, Veterans Affairs Support

HR (95% CI) for CHF

	Unadjusted	+Demographics, alcohol, smoking, income	+Comorbidities, BP, eGFR

## TH-OR27

### Role of Human T Cells in Hypertension and Hypertensive Organ Damage

Masudur Rahman, Johannes Stegbauer, Mina Yakoub, Denada Arifaj, Lydia Hering, Lars C. Rump. *Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.*

**Background:** Inflammation seems to influence hypertension and hypertensive organ damage. Animal studies suggest that adaptive immunity, in particular T cells contribute to the development hypertension. Due to the complex pathophysiological interactions *in vivo*, the impact of human T cells in the development of hypertension and hypertensive organ damage is still unknown.

**Methods:** To investigate the impact of human T cells in hypertension, we transferred T cells from treatment resistant hypertensive patients (TRH) and healthy controls (controls) into immunodeficient NOD.Cg-Prkdcscid H2-K1tm1Bpe H2-D1tm1Bpe Il2rgtm1Wjl/SzJ (NSG-(KbDb) null) mice to establish a humanized mouse model. Hypertension was induced by angiotensin (AngII) (500ng/kg/min) infusion for 14 days.

**Results:** PBMCs from RHT or controls were transferred to NSG-(KbDb) null mice. After ensuring T cell engraftment, blood pressure (BP) was measured by radiotelemetry. At baseline, systolic BP did not differ, however, systolic BP in response to AngII was increased in NSG-(KbDb) null mice receiving PBMCs from TRH compared to controls (week 1:  $133 \pm 6$  vs.  $162 \pm 3$  mmHg,  $p < 0.01$ ; week 2:  $141 \pm 6$  vs.  $158 \pm 7$  mmHg,  $n = 5-6$ ,  $p < 0.05$ ). Moreover, endothelial-dependent vasorelaxation was significantly impaired in isolated perfused kidneys of NSG-(KbDb) null mice receiving PBMCs from TRH compared to controls. Proportions of effector memory CD4 and Th17 CD4 cells in the spleens and kidneys of NSG-(KbDb) null mice engrafted with PBMCs from TRH were significantly higher compare to controls. Furthermore, renal mRNA expression of TNF $\alpha$  derived from human T cells ( $p < 0.05$ ) and renal perivascular T cell infiltration were significantly higher in NSG-(KbDb) null mice engrafted with PBMCs from TRH compared to controls. Overnight incubation of aortic rings with human TNF $\alpha$  impaired endothelial-dependent vasorelaxation compared to untreated aortic rings ( $p < 0.01$ ). Finally, NSG-(KbDb) null mice engrafted with PBMC from TRH were treated with the TNF $\alpha$  inhibitor etanercept. TNF $\alpha$  inhibition attenuated the systolic BP response to AngII compared to untreated mice ( $132 \pm 1$  vs.  $160 \pm 2$  mmHg,  $n = 6$ ,  $p < 0.01$ ).

**Conclusions:** The present results suggest that pro-inflammatory cytokines released by T cells from patients with TRH directly influence the development of hypertension and therefore may have a pathophysiological relevance in the genesis of human hypertension.

## TH-OR28

### HLA-DR/DQ Single Molecule Eplet Mismatch and Formation of De Novo Donor-Specific Anti-HLA Antibodies After Kidney Transplantation in Children

Vaka K. Sigurjonsdottir,<sup>1,2</sup> Kim H. Piburn,<sup>2</sup> Paul C. Grimm.<sup>2</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Stanford University School of Medicine, Stanford, CA.

**Background:** Eplet mismatches in HLA at the single-molecule level, have been identified as a prognostic biomarker for primary alloimmunity. Limited evidence exists on the optimal risk stratification cut-offs in racially diverse pediatric patients receiving kidney transplantation

**Methods:** Children transplanted from 1/1/2010-3/1/2018 at Stanford, with  $>12$ -month follow-up, were included. High-resolution HLA typing was performed using next-generation sequencing. Outcome: time to de novo donor specific antibody (dnDSA) formation. dnDSA were screened at the time of transplant, 1, 2, 3, 6, and 12 months following, at least annually thereafter, and as clinically indicated. ROC analysis at the DR and DQ loci was performed to determine risk categories based on total and single-molecule eplet mismatch thresholds. Survival analysis was performed by the Kaplan-Meier method using the log-rank test for significance

**Results:** A total of 233 patients were identified. Our preliminary results include high-resolution typing for 174. Of those, median age was 13 (IQR 9), 23.6% had living donor transplant and 48.3% were female. The Median follow-up time was 36.5 months (IQR 36). 46.0% formed Anti-HLA class II dnDSA. Patients with an eplet mismatch sum of HLA DR  $> 6$  and/or DQ  $> 4$  ( $n = 161$ ) had increased risk of HLA-DR/DQ dnDSA formation,  $p = 0.006$ . Similarly, patients with single-molecule HLA-DR  $> 5$  and/or DQ  $> 4$  had an increased risk of HLA-DR/DQ dnDSA development. [Figure]

**Conclusions:** Single-molecule eplet mismatch and total eplet mismatch are associated with an increased risk of dnDSA formation. Assessing a patient's individual risk based on donor/recipient HLA-DR/DQ eplet mismatches may guide immunosuppression regimen in the post-transplant period and predict adverse outcomes.

**Funding:** Private Foundation Support

## TH-OR29

### A Multi-Population Polygenic Risk Score for Pediatric Steroid Sensitive Nephrotic Syndrome Is Correlated With Disease Age at Onset

China Nagano,<sup>1,2</sup> Alexandra Barry,<sup>1</sup> Michelle McNulty,<sup>1</sup> Matt G. Sampson.<sup>1</sup> NEPTUNE <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Kobe University Graduate School of Medicine, Kobe, Japan.

**Background:** Genome wide association studies (GWAS) have implicated thousands of single nucleotide polymorphisms (SNPs) in common complex diseases and traits. These SNPs can be combined to generate polygenic risk scores (PRS) that can be used for subsequent predictions and clinical association studies. There are no known PRSs of nephrotic syndrome (NS). In this study, we created a multi-population PRS of pediatric steroid sensitive nephrotic syndrome (SSNS) from the largest GWAS of this disease ever conducted and examined its relationship with clinical phenotypes in two independent cohorts.

**Methods:** The PRS for SSNS was constructed using PRS-CSx, which improves PRS prediction by integrating GWAS from multiple populations. We used GWAS summary statistics derived from European (361 cases and 4309 controls) and Asian (1364 cases and 7954 controls) datasets to generate population-specific PRSs. We used an independent European pediatric SSNS cohort (313 cases and 2508 controls) to identify the optimal parameters based on predictive performance. We then tested the association between SSNS PRS and multiple clinical covariates in the independent European cohort. We then assessed PRS associations in the more clinically heterogeneous Nephrotic Syndrome Study Network (NEPTUNE) cohort.

**Results:** 239 children with SSNS from the independent European cohort also had clinical information. There was a significant negative correlation between PRS and age of onset ( $P = 0.002$ ) adjusting for sex and genetic principal components. There were no significant differences in the PRS between sexes or relapse patterns. We then generated PRS for 353 patients with focal segmental glomerulosclerosis or minimal change disease from NEPTUNE. The PRS was associated with age of onset ( $P = 7.90 \times 10^{-10}$ ) after adjustment for genetic ancestry, sex, and histology. Increasing PRS was significantly associated with increased odds of being child- vs adult- onset (adult onset  $\geq 19$  yrs;  $P = 7.21 \times 10^{-3}$ ).

**Conclusions:** This is the first study to create a PRS of NS. We used it to assess the relationship between PRS and NS phenotypes in two independent cohorts. Results suggest that individuals with increased genetic risk of disease have earlier onset. Future studies are needed to replicate our results and examine its predictive power.

## TH-OR30

## Prevalence and Persistence of CKD and Hypertension 36 Months Post-Cisplatin in Children

Kelly McMahon,<sup>1</sup> Yajur Iyengar,<sup>2</sup> Asaf Lebel,<sup>3</sup> Vedran Cockovski,<sup>3</sup> Stella Q. Wang,<sup>3</sup> Michael Zappitelli,<sup>3</sup> ABLE Nephrotoxicity Group <sup>1</sup>Research Institute of the McGill University Health Centre, Montreal, QC, Canada; <sup>2</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>3</sup>SickKids Research Institute, Toronto, ON, Canada.

**Background:** Long-term kidney outcomes in children treated with Cisplatin(CisP) are unclear. We 1) estimated low eGFR and elevated BP or hypertension(eBP-HT) prevalence 36 months(m) post- pediatric CisP therapy; 2) determined if a)AKI during CisP and b)3m and 12 m kidney and BP status were associated with 36m low eGFR and eBP-HT.

**Methods:** 12 Canadian-site 36m prospective cohort study of CisP-treated children. Exposures: a) AKI during CisP therapy (KDIGO serum creatinine criteria); b) 3m and 12m low eGFR (<90ml/min/1.73m<sup>2</sup>) and eBP-HT. 36m outcomes: a) low eGFR; eBP-HTN. Univariate tests and logistic regression (odds ratios [OR], 95% CI) were used to evaluate exposure-outcome associations.

**Results:** 101 participants (51.5% girls, median[IQR] age 4.4[2.4-9.2]) included. 36m post CisP: 16/85(18.8%) had low eGFR; 26/88(29.6%) had eBP-HT; 38/79 patients(48.1%) had low eGFR or eBP-HT. Table 1 shows characteristics by outcomes. AKI was associated with 36m composite low eGFR or eBP-HTN (AKI: 23/38[60.5%]; no AKI: 15/38[39.5%], p<0.05). Low eGFR at 3m and 12m post-CisP were associated with 36m low eGFR (OR[95% CI]: 17.5[1.7-183]; 16[1.5-167], respectively, Table 1). 12m eBP-HT was associated with 36m eBP-HT (OR [95% CI] 4[1.4-11.8], Table 1). 12m low eGFR or eBP-HT was associated with 36m low eGFR or eBP-HT (OR [95% CI] 3.0 [1.1-8.3]).

**Conclusions:** Low eGFR and high BP are common after CisP and persist from 3m and 12m to 36m. Clear post-CisP kidney health follow-up guidelines must be developed. AKI during therapy may portend worse long-term CisP kidney health.

Table 1. Characteristics by low eGFR and by eBP-HT status at 36 months post CisP therapy

	Low eGFR		eBP or HT

## Rapid Correction of Hypernatremia Is Not Associated With Mortality or Neurological Morbidity in Children: The Correcting Hypernatremia in Children Study

Madeleine Didsbury,<sup>1</sup> Emily See,<sup>1,2</sup> Daryl R. Cheng,<sup>1,3</sup> Joshua Y. Kausman,<sup>1,3</sup> Catherine Quinlan,<sup>1,3</sup> <sup>1</sup>The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; <sup>2</sup>The Royal Melbourne Hospital, Parkville, VIC, Australia; <sup>3</sup>Murdoch Children's Research Institute, Parkville, VIC, Australia.

**Background:** In patients with hypernatremia current guidelines recommend reducing sodium by <0.5mmol/L per hour to avoid cerebral edema, however there are no large-scale studies in the pediatric population. This study aimed to examine the rate of correction of hypernatremia, neurological outcomes, and mortality in children.

**Methods:** A retrospective review was conducted using the electronic medical record at a quaternary pediatric hospital to capture all children with at least one sodium level of ≥150mmol/L from 2016-2019. Electroencephalogram results, neuroimaging and medical records were reviewed manually for seizures and cerebral edema. Correction rates over the first 24 hours and overall were calculated from the peak sodium and defined as rapid (>0.5mmol/L) or slow (<0.5mmol/L per hour). Binary, univariable and multivariable analyses were used to examine the association between the rate of correction and need for neurological investigation and death.

**Results:** There were 402 episodes of hypernatremia amongst 358 children over three years. 179 were community-acquired and 223 developed during admission. 28 patients (7%) died during admission. Compared to those with community-acquired hypernatremia, patients with hospital-acquired hypernatremia had higher mortality (10% vs 4%, p=0.02), more intensive care unit (ICU) admissions (63% vs 51%, p=0.01), and a longer length of stay (20.7 vs 7.2 days, p<0.001). Rapid correction occurred in 200 children and was not associated with increased mortality (OR 0.54, 95% CI 0.24 to 1.2, p=0.13) or neurological investigation (OR 0.89, 95% CI 0.55 to 1.46, p=0.65) compared to slow correction. Findings were consistent when examined with the correction rate as a continuous variable and by age subgroups. Both hospital and ICU length of stay were longer in children who received slow correction (median days in hospital 24.9 vs 15.9, p=0.009; median days in ICU 11.3 vs 8.5, p=0.03).

**Conclusions:** We did not find any evidence that rapid sodium correction was associated with neurological morbidity or mortality; however slow correction was associated with a longer length of stay. Further prospective studies are needed to confirm the safety and advantages of rapid correction in children.

## TH-OR32

## Intradialytic Hypotension and Mortality in Children and Young Adults

Xixi Zhao,<sup>1</sup> Tara I. Chang,<sup>1</sup> Wolfgang C. Winkelmayer,<sup>2</sup> Olivera Marseanic.<sup>1</sup> <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>Baylor College of Medicine, Houston, TX.

**Background:** Intradialytic hypotension (IDH) is associated with mortality in adult patients requiring hemodialysis (HD), however large-scale pediatric studies are lacking. Moreover, there is no evidence-based consensus definition of IDH in the pediatric literature. We aimed to test whether a similar relationship between IDH and mortality existed in children and young adult patients, and if so, which IDH definition captured that association best.

**Methods:** We studied 1,581 patients (ages 1-21 years old) receiving HD at a large dialysis organization to investigate the associations of commonly used IDH definitions with mortality. IDH definitions were selected *a priori* based on a literature review (Table 1). Patients were classified as having IDH if they experienced IDH in at least 30% of HD treatments.

**Results:** IDH did not associate with mortality in any of the commonly used IDH definitions after adjusting for age, race, cause of end-stage kidney disease, predialysis systolic blood pressure (SBP), and ultrafiltration rate (Figure 1). Subgroup analysis by age (≤18 and 19-21 years old) and predialysis SBP (<120, 120-150, >150 mmHg) did not demonstrate an association with mortality either. We then examined the occurrence of IDH in <5%, 5-29%, 30-50%, and >50% of baseline treatments, and did not find a dose-response association of IDH with mortality.

**Conclusions:** IDH was not independently associated with mortality in children and young adults, contrary to the findings in adults. Future studies will examine the association of IDH with outcomes other than death, and mechanisms that may allow this population to better tolerate IDH.

## IDH definitions

Term	Definition
5th percentile	70 + (2 × age)
50th percentile	90 + (2 × age)
20 drop	(Predialysis SBP – nadir intradialytic SBP) > 20 mmHg
30 drop	(Predialysis SBP – nadir intradialytic SBP) > 30 mmHg
SBP<90	Nadir intradialytic SBP<90 mmHg
SBP<100	Nadir intradialytic SBP<100 mmHg
20 drop + SBP<90	(Predialysis SBP – nadir intradialytic SBP) > 20 mmHg and nadir intradialytic SBP<90 mmHg
30 drop + SBP<90	(Predialysis SBP – nadir intradialytic SBP) > 30 mmHg and nadir intradialytic SBP<90 mmHg

## TH-OR33

### Urinary DKK3 Predicts Short-Term eGFR Decline and Nephroprotective Efficacy of Antihypertensive Therapy in Children With CKD: Findings From the 4C Study and ESCAPE Trial

Franz S. Schaefer,<sup>1</sup> Thimoteus Speer,<sup>2</sup> Stefan J. Schunk,<sup>2</sup> Danilo Fliser.<sup>2</sup> 4C trial and ESCAPE study investigators <sup>1</sup>Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; <sup>2</sup>Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany.

**Background:** Childhood-onset chronic kidney disease (CKD) is a progressive condition with major impact on life expectancy and quality. We evaluated the usefulness of the kidney tubular cell stress marker urinary Dickkopf-3 (uDKK3) in determining the short-term risk of CKD progression in children and identifying those who will benefit from specific nephroprotective interventions.

**Methods:** We assessed the association between uDKK3 and kidney endpoints, and its interaction with intensified blood pressure reduction in the randomized-controlled ESCAPE trial. Estimated glomerular filtration rate (eGFR) and uDKK3 were quantified in 659 children with CKD enrolled in the prospective multicenter ESCAPE and 4C studies at baseline and at 6-monthly follow-up visits, yielding 3,935 semi-annual evaluation blocks.

**Results:** In ESCAPE, the effect of intensified blood pressure control on the kidney survival endpoint and the need for kidney replacement therapy was limited to children with uDKK3 above the median, i.e.  $>1,689$  pg/mg (HR 0.33, 95%CI:0.17-0.64; NNT 4.1 vs. 25.0 and HR 0.27, 95%CI:0.11-0.66; NNT 6.7 vs. 55.6). In 4C, inhibition of the renin-angiotensin-system resulted in lower uDKK3 levels (12,235 vs. 6,861 pg/mg,  $P=4.7 \times 10^{-6}$ ). In both cohorts, uDKK3  $>1,689$  pg/mg creatinine was associated with significantly greater 6-month eGFR decline (ESCAPE: -6.3%, 95%CI:-7.8—-4.9% vs. 0.2%, 95%CI:-1.1—1.6%,  $P=4.2 \times 10^{-10}$ ; 4C: -6.5%, 95%CI:-13.4—0.4 vs. -1.7%, 95%CI:-8.6—5.2,  $P=2.4 \times 10^{-10}$ ), independently of kidney diagnosis, eGFR, and albuminuria.

**Conclusions:** uDKK3 is associated with a greater short-term risk of declining kidney function and may allow a personalized medicine approach to pharmacological nephroprotection by identifying children who benefit from intensified blood pressure lowering.

## TH-OR34

### Nedosiran in Patients With Primary Hyperoxaluria 1: Interim Results From an Extension Trial (PHYOX3)

John C. Lieske,<sup>1</sup> Gema Ariceta,<sup>2</sup> Michelle A. Baum,<sup>3</sup> Vladimir Belostotsky,<sup>4</sup> Andrea Cappoli,<sup>5</sup> Pierre Cochat,<sup>6</sup> Thomas A. Forbes,<sup>7</sup> Jaap Grothoff,<sup>8</sup> Shuzo Hamamoto,<sup>9</sup> Bernd Hoppe,<sup>10,11</sup> Andrew J. Mallett,<sup>12</sup> Armando Torres,<sup>13</sup> Hiroyuki Satoh,<sup>14</sup> Burkhard Toenshoff,<sup>15</sup> John Karafilidis,<sup>11</sup> Shabbir H. Moochhala.<sup>16</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>3</sup>Boston Children's Hospital, Boston, MA; <sup>4</sup>McMaster Children's Hospital, Hamilton, ON, Canada; <sup>5</sup>Ospedale Pediatrico Bambino Gesù, Roma, Italy; <sup>6</sup>Hospices Civils de Lyon, Lyon, France; <sup>7</sup>The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; <sup>8</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>9</sup>Nagoya Shiritsu Daigaku, Nagoya, Japan; <sup>10</sup>Universitätsklinikum Bonn, Bonn, Germany; <sup>11</sup>Dicerna Pharmaceuticals, Inc. A wholly owned subsidiary of Novo Nordisk A/S, Lexington, MA; <sup>12</sup>Royal Brisbane and Women's Hospital, Herston, QLD, Australia; <sup>13</sup>Hospital Universitario de Canarias, La Laguna, Spain; <sup>14</sup>Tokyo Toritsu Shoni Iryo Center, Fuchu, Japan; <sup>15</sup>Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; <sup>16</sup>Royal Free Hospital, London, United Kingdom.

**Background:** Primary hyperoxaluria (PH) is a family of genetic disorders leading to oxalate overproduction, causing calcium oxalate stones and kidney damage, which may result in kidney failure. Nedosiran—an investigational RNA interference (RNAi) therapy in development for treatment of PH—silences hepatic LDH expression encoded by the LDHA gene, which reduces oxalate production. In a 6-month (mo) placebo-controlled pivotal trial (PHYOX2), monthly nedosiran resulted in significantly lower urinary (Uox) and plasma oxalate in PH1 patients.

**Methods:** PHYOX3 (NCT04042402) is an open-label extension trial evaluating long-term safety and efficacy of monthly SC nedosiran in patients with genetically confirmed PH and eGFR  $\geq 30$  mL/min/1.73 m<sup>2</sup> who completed a previous nedosiran trial. This is a 9-mo analysis of PH1 patients from PHYOX2 nedosiran (NEDO|NEDO) and placebo (PLBO|NEDO) arms who rolled into PHYOX3.

**Results:** Both NEDO|NEDO and PLBO|NEDO groups showed substantial reduction in 24-hr Uox, regardless of baseline Uox entering PHYOX2 or PHYOX3 (Figure). The mean Uox reduction was 64.9% and 68.1% for NEDO|NEDO and 55.1% and 60.8% for PLBO|NEDO at the 6-mo and 9-mo visits, respectively. Among the NEDO|NEDO patients, 11 of 13 (85%) and 7 of 7 (100%) achieved normal or near-normal Uox ( $< 0.6$  mmol/24-hr;  $< 1.3 \times$  ULN) at the 6-mo and 9-mo visits, respectively. Most common drug-related AEs were administration site events; injection site reactions were observed in 3 patients. There were no drug-related SAEs or study discontinuations, or deaths.

**Conclusions:** Nedosiran administration to PH1 patients resulted in significant and persistent reduction of Uox and showed an acceptable safety profile. Analysis of long-term effects on kidney function is ongoing.

**Funding:** Commercial Support - Dicerna Pharmaceuticals, Inc. (A wholly owned subsidiary of Novo Nordisk A/S)

## TH-OR35

### Ciliary ARL13B Is a Major Driver of Kidney Cystogenesis

Robert E. Van Sciver,<sup>1</sup> Eduardo Gigante,<sup>2</sup> Tamara Caspary.<sup>1</sup> <sup>1</sup>Emory University, Atlanta, GA; <sup>2</sup>Georgia Institute of Technology, Atlanta, GA.

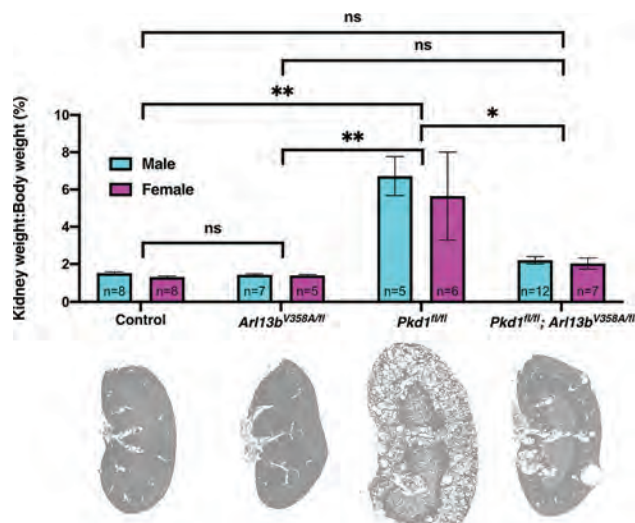

**Background:** Polycystic kidney disease (PKD) is intricately linked to the primary cilium. *PKD1* and *PKD2* encode for polycystin proteins which localize to cilia, and mutations in these genes are causative for PKD. Mouse models predict the presence of a cilia-dependent cyst activating (CDCA) pathway that functions in cilia to drive cystogenesis. Despite the central importance of this organelle to renal cystic diseases, the ciliary driver(s) of cyst pathogenesis remain unknown. Mouse models have implicated that the ciliary GTPase ARL13B may be a major regulator of the CDCA pathway.

**Methods:** To directly test ARL13B's role in the CDCA pathway, we engineered mice with an amino acid point mutation in ARL13B's cilia-localization motif so the mice express cilia-excluded ARL13B from the endogenous locus. The resulting protein retains all known ARL13B biochemical functions, is stably expressed and is undetectable in cilia. Combining this mouse model with the kidney-specific loss *Pkd1* allowed us to directly test ARL13B's ciliary role in kidney cystogenesis.

**Results:** At 18-weeks, control kidneys had a kidney weight to body weight ratio (KW:BW) of  $1.41 \pm 0.05$ . In adult induction mouse models, loss of ciliary ARL13B did not lead to cysts with a KW:BW of  $1.40 \pm 0.03$ , while loss of *Pkd1* led to severe cystic kidneys with KW:BW of  $6.13 \pm 1.33$ . Loss of *Pkd1* and ciliary exclusion of ARL13B suppressed the cystic phenotype caused by loss of *Pkd1* alone with KW:BW of  $2.13 \pm 0.16$ .

**Conclusions:** In adult induction models, loss of ciliary ARL13B suppresses the severe cystic kidney phenotype caused by loss of *Pkd1* alone. These results directly implicate ciliary ARL13B as a major regulator of the CDCA pathway. Our findings indicate that ARL13B plays a critical role within the cilium in regulating kidney cystogenesis, with ciliary ARL13B activating a pro-cystogenic pathway.

**Funding:** NIDDK Support, Other NIH Support - NIGMS

Ciliary exclusion of ARL13B suppresses the severe cystic phenotype caused by loss of *Pkd1*.

### TH-OR36

#### Arginine Metabolism Has a Pivotal Role in Cystogenesis of Tuberous Sclerosis Complex (TSC) and Its Inhibition Alleviates TSC Cyst Overload

Morris Nechama, Athar Amleh, Iddo Z. Ben-Dov, Oded Volovelsky. *Hadassah University Medical Center, Jerusalem, Israel.*

**Background:** Kidney disease affects most patients with tuberous sclerosis complex disease (TSC) and is a leading cause of death in adulthood. Mutations in *Tsc1* or *Tsc2* in TSC induce mTOR activation, resulting in cell growth manifested by cystic kidney disease. However, the exact mechanisms leading to tubular cell damage and cyst formation remain poorly understood. Metabolic reprogramming is an essential mechanism by which cells rewire their activity to promote cell proliferation and growth. Here, we show that TSC kidneys exhibit major metabolic alterations, mainly the arginine biosynthesis pathway and that arginine pathway inhibition alleviates the TSC cyst overload.

**Methods:** Metabolites were extracted and analyzed from kidneys of vehicle or rapamycin-treated *Six2 Cre<sup>+/tg</sup> Tsc1<sup>-/-</sup>*, and control mice using liquid chromatography/inline tandem mass spectrometry. Kidneys were also used for histology, RNA/protein extraction, and immunofluorescence.

**Results:** Metabolome analysis of whole kidneys and proximal tubular cells (PTCs) from TSC mice showed major perturbation in several metabolic pathways, mainly the arginine biosynthesis pathway. These trends were associated with an increase in urea cycle metabolites and the rate-limiting enzyme, argininosuccinate synthase 1 (ASS1), expression levels. High ASS1 level was specifically localized in cyst lining cells in the TSC kidney. Rapamycin treatment reversed the increase in ASS1 expression in *Tsc1* Knockout HK2 cell, emphasizing the contribution of the *Tsc1*-mTORC1 pathway to ASS1 expression. Finally, arginine depletion *in vivo* and *in vitro* reduced the mTOR signaling pathway, cell proliferation, and kidney cyst overload.

**Conclusions:** TSC kidneys exhibit significant perturbations in the arginine biosynthesis pathway. Based on our results, we suggest that dysregulated mTOR pathway in TSC PTCs induces the arginine biosynthesis pathway by overexpression of ASS1 to support the high arginine demand in PTCs. Arginine depletion ameliorates PTC signaling and cell proliferation which are significant contributors to cyst development in TSC. Our studies highlight potential targets for immediate translational and clinical implications.

#### Transdermal Glomerular Filtration Rate Measurement: Clinical Results From a Pilot Multicenter Study Establishing Feasibility and Efficacy

Richard B. Dorshow, Martin Debreczeny, Jeng-Jong Shieh. *MediBeacon Inc., Saint Louis, MO.*

**Background:** Point-of-care measured (not estimated) glomerular filtration rate has been a goal of nephrologists for the last 30 years. To this end, a fluorescent GFR tracer agent, relmapirizin, has been rationally designed and 24 standard nonclinical assays as required by the FDA have been performed. Fluorescent detection instrumentation to acquire and process the emission signal from the agent through the skin has been developed. The pilot clinical study objectives were to: *Demonstrate relmapirizin is a*

*GFR agent in humans by comparison to iohexol, Establish that the GFR as measured by the transdermal fluorescence excretion rate matches the plasma GFR.* This combination product was evaluated on 120 subjects covering three clinical sites.

**Methods:** Subjects were enrolled with GFR values from normal to Stage 4 CKD values, and for all six skin colors on the Fitzpatrick Skin Scale (FSS). Relmapirizin and iohexol were administered IV in consecutive boluses, and blood samples were taken periodically over the subsequent 12 hours. Prior to agent dosing, the transdermal sensor was placed on the chest of each subject and fluorescent readings were initiated. Urine was collected post-dosing.

**Results:** The plasma-derived GFR measured from relmapirizin matched the plasma-derived GFR measured from iohexol. An algorithm was developed to convert the transdermal fluorescence measurement directly into an indexed GFR, applicable to the entire GFR range and for all skin colors (Figure 1). The % administered relmapirizin dose recovered in the urine matched that of iohexol. No serious nor significant adverse events were reported.

**Conclusions:** Clinically amenable point-of-care measured GFR has been demonstrated for subjects with a range of GFR values and for all skin colors, thus validating this methodology. Data and fits will be shown in this oral presentation.

**Funding:** Commercial Support - MediBeacon Inc.

The transdermal GFR (tGFR) correlates to the indexed plasma GFR (nGFR).

### TH-OR39

#### Evaluation of Renal Blood Flow Using <sup>64</sup>Cu-ATSM PET

Naoki Takahashi, Yudai Nishikawa, Sho Nishikawa, Yuki Shimamoto, Kazuhisa Nishimori, Sachiko Fukushima, Sayu Morita, Mamiko Kobayashi, Hideki Kimura, Kenji Kasuno, Masamichi Ikawa, Tetsuya Tujikawa, Hidehiko Okazawa, Masayuki Iwano. *Fukui Daigaku Igakubu, Yoshida-gun, Japan.*

**Background:** In patients with CKD, it is important to evaluate renal blood flow (RBF). RBF can be obtained by the clearance method, estimation from eGFR or measurement using nuclear medicine test, but all have their advantages and disadvantages. For this reason, a method to assess RBF with ASL-MRI has recently been investigated and has been shown to be reliable. Cu(II)-diacetyl-bis(4-methylthiosemicarbazone) (<sup>64</sup>Cu-ATSM) is a tracer developed for hypoxia imaging and has been reported to be able to quantify cerebral blood flow. Therefore, in this study, we performed ASL-MRI and PET imaging simultaneously and obtained the actual RBF values. Furthermore, we compared the estimated RBF (eRBF) obtained from clinical parameters with the measured RBF of both imaging methods and investigated the usefulness of PET for the evaluation of RBF.

**Methods:** The study consisted of 15 subjects, including 5 healthy subjects and 10 patients with various CKD. A single dose of 300-400 MBq <sup>64</sup>Cu-ATSM was administered, the abdomen was imaged for PET, and then ASL images were taken. Circular ROIs were placed on the upper to lower poles of the kidney cortex for PET/MRI imaging. To obtain an RBF, the mean of the 20 ROI values was calculated. eGFR was calculated from serum creatinine (sCr) and cystatin C (sCys), respectively, and eRBF was calculated using the eGFR, hematocrit and FF values. Furthermore, renal volume was calculated by integrating MRI and eRBF per 100 g of kidney weight was calculated.

**Results:** The RBF measured with MRI-ASL was positively correlated with eRBF by sCr ( $r=0.596$ ,  $p<0.05$ ) and sCys ( $r=0.669$ ,  $p<0.01$ ), respectively. The RBF measured with <sup>64</sup>Cu-ATSM was positively correlated with the RBF estimated by sCr ( $r=0.621$ ,  $p<0.05$ ) and sCys ( $r=0.591$ ,  $p=0.02$ ), respectively. The RBF measured with MRI-ASL was positively correlated with the RBF measured with <sup>64</sup>Cu-ATSM ( $r=0.714$ ,  $p=0.003$ ). The linear regression line had a slope close to 1 (0.88) and the intercept (14.1) also approximated the origin. The Bland-Altman analysis showed agreement with the RBF measured by ASL imaging and <sup>64</sup>Cu-ATSM imaging (Bias=-2.4, SD=24.9).

**Conclusions:** We report for the first time that <sup>64</sup>Cu-ATSM PET is useful for assessing RBF in healthy subjects and patients with various renal diseases, as well as ASL-MRI.

**Funding:** Government Support - Non-U.S.

## TH-OR40

## Targeted Isolation of Urine-Derived Renal Tubular Cells for Personalised Medicine

Chutong Zhong, Stephen B. Walsh, Keith Siew. *University College London, London, United Kingdom.*

**Background:** The kidney achieves homeostasis through the complex actions of the nephron; a heterogenous structure made up of 14+ segments. Rare monogenic tubular diseases are often characterised by impairment of specific tubular segments. Isolation and characterisation of patient-specific urine-derived renal tubular epithelial cells (uRTEC) from disease-relevant segments can assist diagnosis and treatment planning.

**Methods:** Urine samples collected from healthy volunteers and patients with genetic tubular disease were pelleted by centrifugation at 400 RCF for 10min at RT, and the cell pellet was washed with a 50:50 mixture of DMEM:F12 (supplemented with 10% FBS, 100U/ml penicillin, 100µg/ml streptomycin, 1X insulin-transferrin-selenium, 2.5µg/ml nicotinamide, 500µg/ml hydrocortisone). Targeted isolation and enrichment of segment-specific cells was performed using a magnetic beads conjugated to target-specific antibodies/lectins. Primary urine-derived cells were either fixed using 4% w/v formaldehyde-PBS for 15min at RT at 60% confluency, or lysed with TRI reagent at 90% confluency for RNA isolation. Cell types were validated by staining with fluorescently-tagged marker antibodies/lectins and qPCR of segment specific mRNAs.

**Results:** Primary urinary cells successfully cultured from patients' urine samples with different morphologies presented and can be maintained to the third passage. As can be seen in **Figure 1**, cells from several patients stained positively with *Dolichos Biflorus Agglutinin* indicating the presence of distal convoluted tubule cells. These was validated by confirmation of expression of NCC.

**Conclusions:** uRTEC can be routinely isolated from patient's urine, targeted for enrichment, and successfully subcultured for several passages. Future work, would aim to utilise these cells in 3D "Organ-on-a-Chip" systems, where we could potentially artificially reconstruct patient's tubules from primary urinary cells and conduct individualised pharmacological experiments to optimize treatments, thereby bringing true personalised medicine to nephrology.

## TH-OR41

## CODEX Multiplex Imaging Uncovers Unique Cell Types, States, and Niches in Health and Disease

Daria Barwinska,<sup>1</sup> Angela R. Sabo,<sup>1</sup> Seth Winfree,<sup>2</sup> Connor J. Gulbranson,<sup>1</sup> Michael T. Eadon,<sup>1</sup> James C. Williams,<sup>1</sup> Tarek M. El-Achkar.<sup>1</sup> *KPMF<sup>1</sup> Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>University of Nebraska Medical Center, Omaha, NE.*

**Background:** Co-Detection by indEXing (CODEX) multiplex imaging is a new and powerful tool for imaging many protein markers on one tissue specimen. A challenge in applying this technology on human kidney tissue is to establish a robust analytical pipeline to analyze the resultant multidimensional large-scale data and compare multiple datasets.

**Methods:** We imaged human cortical tissue from healthy reference and renal disease (AKI, Lupus, CKD, IgA) specimens with 38 different antibodies, including epithelial, immune, and injury markers. Segmentation of nuclei and unsupervised analysis, classification and visualization were performed using a customized open-source software tool: Volumetric Tissue Exploration and Analysis (VTEA). Additional analysis to combine datasets in a single analytical space was performed using R and visualized in VTEA. We also performed cell centric neighborhood analysis to define spatially relevant cell niches.

**Results:** In healthy tissue, unsupervised clustering and classification of cell types not only identified the major structures in the renal cortex, but also unique subsets of both proximal tubules (PTs) and thick ascending limbs (TALs). PTs were consistently found to have a unique subset that was positive for THY1 (CD90), which is a marker of cell differentiation. PT and TALs cells also showed a subset that was positive for PROM1 (CD133), which is a marker associated with repair. Immune cell clusters were defined using various markers such as CD45, CD68, CD11C, CD206, CD20 and CD3. In kidney disease, we observed a marked alteration in the abundance and distribution of epithelial

and immune cell subtypes. Neighborhood analysis showed unique cell niches that were altered in disease. Specifically, cell niches enriched in THY1+ PTs were markedly diminished, whereas immune-rich niches expanded with disease.

**Conclusions:** We established a unique analytical pipeline for CODEX multiplexed imaging data that can be utilized to define various cell types in the human kidney in health and disease and compare between specimens. Our findings highlight unique cell niches and uncover alteration of specialized epithelial and immune cell types with disease, thereby identifying potential novel targets for therapy.

**Funding:** NIDDK Support

## TH-OR42

## Super-Resolution Microscopy in Clinical Specimens Using Conventional Widefield Microscopes

Dominik Kyllies,<sup>1</sup> Marina Zimmermann,<sup>1</sup> Fabian Haas,<sup>1</sup> Malte B. Kuehl,<sup>1</sup> Jan Czogalla,<sup>1</sup> Oliver Kretz,<sup>1</sup> Nicola M. Tomas,<sup>1</sup> Thorsten Wiech,<sup>1</sup> Christoph Kuppe,<sup>2</sup> Rafael Kramann,<sup>2</sup> Milagros N. Wong,<sup>1</sup> Tobias B. Huber,<sup>1</sup> Victor G. Puelles.<sup>1</sup> *<sup>1</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany.*

**Background:** Super-resolution microscopy (SRM) enables nanoscale molecular characterization of tissues, but the access to SRM systems is limited, hindering their applicability in the scientific and clinical pathology community. Expansion microscopy and computational image enhancement algorithms like "super-resolution radial fluctuations" (SRRF) are promising alternatives, but do not achieve sufficient resolution when combined with LED-based widefield microscopy (WFM). Here, we introduce expansion-enhanced super-resolution radial fluctuations (ExSRRF), enabling nanoscale molecular SRM in clinical pathology samples using WFM.

**Methods:** We performed immunofluorescence labeling of tissues, followed by hydrogel embedding, tissue expansion and time-stacked image acquisition with WFM. Subsequent computational processing using the SRRF algorithm yielded super-resolved images. To define the resolution range, nanorulers (synthetic molecules containing two fluorescent dyes at precisely predefined distances) were expanded and imaged in a similar fashion to tissues. Automated image analysis of the slit diaphragm (SD) was performed using a multi-step process including region of interest- and ridge-detection, followed by SD-density and dilatation measurements using both, custom and open-source tools.

**Results:** In a set of nanorulers, ExSRRF displayed non-overlapping point-spread functions at distances between 120nm and 25nm, thus providing a resolution of at least 25nm. ExSRRF was applied across a broad range of formalin-fixed paraffin-embedded clinical and experimental tissues. In an experimental model of renal ischemia-re-perfusion injury, ExSRRF resolved endoplasmic reticular dilatation. In human kidney biopsies, ExSRRF resolved normal foot processes (FP) and detected FP effacement as a diagnostic feature of minimal change disease (MCD). In a small case series, ExSRRF resolved the SD and provided quantitative changes and a morphological disease signature of MCD.

**Conclusions:** ExSRRF is a flexible, scalable, inexpensive, and robust method for the molecular characterization of experimental and clinical specimens and thus has the potential to bridge SRM and both clinical and experimental pathology, enabling universal access to molecular nanopathology.

## TH-OR43

## Analyzing Cell Type-Specific Dynamics of Metabolism in Kidney Repair

Ton J. Rabelink,<sup>1</sup> Gangqi Wang,<sup>1</sup> Bram Heijs,<sup>1</sup> Sarantos Kostidis,<sup>1</sup> Ahmed Mahfouz,<sup>1</sup> Rosalie Rietjens,<sup>1</sup> Roel Bijkerk,<sup>1</sup> Angela Koudijs,<sup>1</sup> Lois van der Pluijm,<sup>1</sup> Cathelijne W. Van den Berg,<sup>1</sup> Sébastien J. Dumas,<sup>2</sup> Peter Carmeliet,<sup>2</sup> Martin Giera,<sup>1</sup> Bernard van den Berg.<sup>1</sup> *<sup>1</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands; <sup>2</sup>Vlaams Instituut voor Biotechnologie KU Leuven Center for Cancer Biology, Leuven, Belgium.*

**Background:** Conventional single-cell metabolomics approaches such as MALDI based mass spectrometry imaging (MALDI-MSI) generate biochemical snapshots, neglecting the inherent dynamic nature of metabolism. Here we describe a platform based on isotope tracing and MALDI-MSI that allows *in-situ* dynamic measurements of cell type-specific metabolism at single-cell resolution, and thus unravel cell metabolism within its tissue architecture.

**Methods:** We applied different <sup>13</sup>C-isotope-labeled nutrients on vibratome slices of fresh mouse kidney. MALDI-MSI at single-cell resolution (i.e. pixel size of 5 × 5 µm<sup>2</sup>) was then applied to detect metabolites and lipids from the harvested tissues. Following MALDI-MSI analysis, post-MSI-analyzed sections were stained and subsequently imaged using multiplexed immunofluorescence (IF) microscopy for cell-type identification.

**Results:** We show that this method can map cell type-specific dynamic changes in the central carbon metabolism, as well as the contribution of different nutrients to energy metabolism in a complex heterogenous tissue architecture such as the kidney. Combined with multiplexed immunofluorescence staining, we can detect metabolic changes and nutrient partitioning in targeted cell types as demonstrated in a bilateral renal ischemia/reperfusion injury (bIRI) model. At baseline, we identified a marked heterogeneity in respect to TCA metabolite consumption and glycolysis in the outer stripe outer medullary proximal tubular segments (PT-S3) when compared to the cortical PT-S1/S2 segments. After bIRI, PT cells that failed to repair remained in a hyperglycolytic state. Meanwhile, PT cells with an apparent normal phenotype in the recovery phase still display a striking difference in tricarboxylic acid (TCA) cycle substrate use when compared to those in sham kidneys. As TCA metabolites serve biosynthesis as well as gene regulation this may be of relevance to the homeostatic capacity of the kidney microenvironment.

**Conclusions:** In sum, this method allows to achieve single-cell resolution *in situ* and hence interpret cell type-specific metabolic dynamics in the context of kidney structure and metabolism of neighboring cells.

## TH-OR44

### High Resolution Spatially Resolved Transcriptomic Atlas of Kidney Injury and Repair With Direct RNA Hybridization-Based In Situ Sequencing

Haojia Wu,<sup>1</sup> Eryn E. Dixon,<sup>1</sup> Juanru Guo,<sup>1</sup> Debashish Chitnis,<sup>2</sup> Anezka Niesnerova,<sup>2</sup> Hao Xu,<sup>2</sup> Morgane Rouault,<sup>2</sup> Benjamin D. Humphreys.<sup>1,3</sup> The Humphreys Lab <sup>1</sup>Division of Nephrology, Department of Medicine, Washington University in St. Louis, St Louis, MO; <sup>2</sup>10X Genomics, Pleasanton, CA; <sup>3</sup>Department of Developmental Biology, Washington University in St. Louis, St Louis, MO.

**Background:** Understanding how different kidney cell types contribute to acute kidney injury (AKI) requires knowledge of their spatial organization and connectivity, information that is lost in single cell techniques that rely on cell dissociation. Recent advances in spatial transcriptomic technologies enable visualization of multiplexed transcripts at cellular resolution.

**Methods:** We performed highly multiplexed direct RNA hybridization based in situ sequencing (dRNA-HyBIS) (CARTANA, part of 10X Genomics) on the mouse kidneys from sham, 4h, 12h, 2d, and 6w after bilateral ischemia-reperfusion injury (IRI).

**Results:** We achieved sub-cellular transcript resolution and were able to map cell type specific markers precisely to their respective cell types (Fig 1). As expected, spatial expression of the injury marker Haver1 was confined to the PT-S3 segment at 4h, 12h and 2d, and was absent in sham and 6w. We segmented ~400,000 cells from all time points of IRI. Unsupervised clustering revealed 10 major kidney cell types including rare cell types such as podocytes and JGA cells. We were able to reconstruct glomerular cell type organization with podocyte, EC and JGA. We revealed dynamic changes in spatial distribution of immune cell subsets across IRI time course. For example, Cd14+ monocytes were increased in early time points of IRI whereas the Ptpcr+ macrophages accumulated only in later time point. Integration with snRNA-seq data increased resolution of our spatial map to 26 kidney cell types, including different PT injury states. We also compare these results to Visium analysis of the same time course, revealing that dRNA-HyBIS provided much higher cell resolution including classification of individual rare cell types.

**Conclusions:** dRNA-HyBIS enables in situ identification and spatial mapping of cell types in the kidney. When applying this technique to IRI, we reveal the dynamics of immune cell migration both in time and region during kidney injury and repair.

## TH-OR45

### Genome-Wide CRISPR Screen Reveals That Elamipretide (SS-31) Mediated PLSCR3 Activation Mitigates Mitochondrial Dysfunction During AKI

Josie A. Silvaroli,<sup>1</sup> Bijay Bisunke,<sup>2</sup> Ji Young Kim,<sup>1</sup> Navjot Singh P. Pabla,<sup>1</sup> Amandeep Bajwa.<sup>2</sup> <sup>1</sup>The Ohio State University, Columbus, OH; <sup>2</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

**Background:** Mitochondrial dysfunction is a hallmark of several human disorders, including acute kidney injury (AKI). SS-31 a cell-permeable mitochondrial-targeted peptide restores healthy mitochondrial function and is currently undergoing clinical trials. SS-31 interacts with cardiolipin in the inner mitochondrial membrane; however, the pharmacological basis of its protective effects remains obscure. Importantly, the role of phospholipid scramblase 3 (PLSCR3), a mitochondrial cardiolipin binding protein, in SS-31 and renal biology is unknown.

**Methods:** We performed a genome-wide CRISPR screen in a nephrotoxic model of tubular epithelial cell-death with SS-31. The primary and secondary screens in BUMPT and HK-2 cells showed that PLSCR3 is essential for the protective effects of SS-31. Seahorse based analysis of mitochondrial function was also carried out in WT and PLSCR3 KO HK-2 cells. Conditional KO mice were generated by crossing PLSCR3-floxed with GGT1-Cre mice (Fig. 1). Next *in vivo* KO of PLSCR3 through hydrodynamic intravenous

RNAi injections was done. The severity of renal injury (IRI and cisplatin) was monitored in control and KO littermates or in mice injected with control and PLSCR3 siRNA through measurement of BUN, serum creatinine, histological analysis, and biomarker analysis.

**Results:** In cell culture models of cisplatin nephrotoxicity, cell survival and mitochondrial protection provided by SS-31 is abrogated by PLSCR3 knockdown or knockout. *In vivo*, PLSCR3 gene ablation or knockdown in RTECs suppresses the protective effects of SS-31 in cisplatin and ischemia-reperfusion associated models of AKI (Fig.1). Using liposome-based assays, we also found that SS-31 activates PLSCR3 scramblase activity.

**Conclusions:** Our studies have discovered phospholipid scramblase 3 as the crucial mediator of the cell protective effects of SS-31. We propose that SS-31 activates PLSCR3 phospholipid scramblase activity resulting in mitochondrial protection under stress conditions associated with AKI.

**Funding:** NIDDK Support

**Figure 1: Tubular PLSCR3 gene ablation abrogates the renal protective effects of SS-31 during cisplatin nephrotoxicity.** RTEC-specific PLSCR3 knockout mice were generated by crossing Ggt1-Cre mice with PLSCR3-floxed mice. 8-12-week-old littermate control and PLSCR3 conditional knockout mice (indicated by PLSCR3<sup>PT/-</sup>) were then challenged with cisplatin (50 mg/kg, single intraperitoneal injection) in the presence or absence of SS-31 (5 mg/kg, intraperitoneal, 2 hours before cisplatin) followed by examination of renal structure and function at 72 hours. (a-b) Blood urea nitrogen and serum creatinine analysis showed that tubular epithelial-specific PLSCR3 deficiency results in suppression of the renal protective effects of SS-31. (c) H&E staining and histological analysis of tubular damage confirmed that SS-31 mediated renal protection is abrogated in the PLSCR3 conditional knockout mice. One-way ANOVA followed by Tukey's multiple-comparison test was carried out (n=5 biologically independent samples), and statistical significance is indicated by \*p < 0.05, \*\*p < 0.01, \*\*\*p < 0.001.

## TH-OR46

### Downregulation of Syndecan-1 and Alternative Complement in Renal Proximal Tubular Epithelial Cells by Crotamine/Sirna Complexes

Jacob van den Born,<sup>1</sup> Joana D. Campeiro,<sup>1</sup> Wendy Dam,<sup>1</sup> Miriani A. Hayashii.<sup>2</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Universidade Federal de Sao Paulo, Sao Paulo, Brazil.

**Background:** In proteinuria, syndecan-1, an epithelial heparan sulfate proteoglycan, serves as a docking platform for filtrated urinary properdin in the apical membranes of proximal tubular epithelial cells (PTEC) activating the complement system via alternative pathway. Targeting PTEC aiming to reduce syndecan-1 expression might be useful to slow down the alternative complement activation during proteinuria. Crotamine is a non-viral cell-penetrating peptide which after *ip* injection accumulates in PTEC via apical endocytosis. We now tested crotamine-siRNA complexes for *in vitro* and *in vivo* targeting of PTEC.

**Methods:** The complexes formed by crotamine and syndecan-1 siRNA were characterized by biophysical methods. After the *in vitro* transfection of HK2 cells with crotamine-siRNA complexes, the efficiency to downregulate the syndecan-1 expression, properdin binding, and subsequently, complement deposition was assessed by FACS and qRT-PCR. The targeted internalization into PTEC *in vivo* was evaluated by confocal microscopy of kidney sections from mice injected with fluorescently-labeled crotamine-siRNA complexes.

**Results:** We demonstrated that the efficient complex formation is time- and crotamine-siRNA ratio-dependent and that crotamine is able to protect siRNA against degradation by endonucleases. After 48 h, the transfection with the complex reduced ~50% of syndecan-1 expression at both mRNA and protein levels (both p<0.01) *in vitro*. Subsequently, properdin binding was also comparably reduced (p<0.001) and the alternative pathway activation declined ~60% (p<0.001). Moreover, *ip* injection of the fluorescently-labeled crotamine-siRNA complexes in mice showed siRNA presence in the cell membranes of proximal tubular cells, followed by internalization into these tubular cells.

**Conclusions:** We show for the first time the use of crotamine as a non-viral nanocarrier for PTEC-specific delivery of siRNA both *in vitro* and *in vivo*. Successful reduction of the expression of syndecan-1 was accompanied by down modulation of alternative complement activation by PTECs *in vitro*. We suggest crotamine as a prototypic next generation kidney-specific non-viral vector to modulate aberrant gene expression in kidney PTECs, for instance, in proteinuric renal diseases.

## TH-OR47

**#AskRenal: Use of an Automated Twitter Account to Crowdsourcing Nephrology Queries**

Jade M. Teakell,<sup>1</sup> Alicja Rosolowska,<sup>2</sup> Swapnil Hiremath,<sup>3</sup> Matthew A. Sparks,<sup>4</sup> Edgar V. Lerma,<sup>5</sup> Joel M. Topf,<sup>6</sup> Nikhil A. Shah.<sup>7</sup> *#NephJC 'The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; <sup>2</sup>Uniwersytet Medyczny w Białymstoku, Białystok, Poland; <sup>3</sup>University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; <sup>4</sup>Duke University, Durham, NC; <sup>5</sup>University of Illinois Chicago, Chicago, IL; <sup>6</sup>Oakland University William Beaumont School of Medicine, Rochester, MI; <sup>7</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

**Background:** Social media platforms are used in contemporary crowdsourcing, and Twitter is apt for reaching a large number of people with a common interest. Users, especially those with a small follower count may find it challenging to reach a large audience. #AskRenal was developed as a Twitter crowdsourcing tool to help users get answers to nephrology questions. We hypothesized that the #AskRenal hashtag could be used by anyone to receive helpful and timely responses to simple or complex nephrology questions posed on the social media platform.

**Methods:** A Twitter account @AskRenal, and an online Twitter bot that automatically retweeted any new tweets containing the hashtag #AskRenal were created. Using the Symplr Healthcare Hashtag tool, we extracted and analyzed public Twitter content containing the hashtag #AskRenal posted between Dec 2016 to Aug 2020. Tweets were excluded if they were duplicates, retweets, or if the tweet content was not the form of an original question. A group of 15 medical professionals reviewed #AskRenal tweets individually and a 10-question survey was completed for each one.

**Results:** During the study period, there were 17,704 tweets containing the hashtag #AskRenal and 3099 were included in the survey analysis. We found that 40% (1228/3099) of #AskRenal questions were posed by users with < 1000 followers and 9% (270/3099) were from students and trainees. The questions were spread across a wide range of nephrology topics. Over 75% (2386/3099) of the #AskRenal questions garnered a response, and answers came quickly with 69% (1644/2386) receiving a reply within 6 hours of posting. The reviewers found these responses to be helpful in answering the original questions 83% (1978/2386) of the time. The inclusion of hyperlinks and images in the reply was associated with a helpful answer ( $p < 0.001$ ) and a higher follower count was not significantly associated with the probability of obtaining a helpful answer.

**Conclusions:** We demonstrated that a targeted hashtag and a dedicated Twitter account that retweets the hashtag automatically can be used to garner timely and helpful responses by a wide range of individuals, irrespective of follower count, seeking answers to nephrology questions.

## TH-OR48

**Using Three-Dimensional Imaging and Single-Cell Transcriptomics to Interrogate Human Kidney Lymphatics in Transplant Rejection**

Daniyal J. Jafree,<sup>1,2</sup> Benjamin J. Stewart,<sup>4</sup> Maria K. Joannou,<sup>1</sup> Lauren G. Russell,<sup>1</sup> Gideon Pomeranz,<sup>1</sup> Peter Scambler,<sup>1</sup> Menna R. Clatworthy,<sup>4</sup> Reza Motalebzadeh,<sup>3</sup> David A. Long.<sup>1</sup> *UCL ICH Kidney Development & Disease Group <sup>1</sup>UCL Great Ormond Street Institute of Child Health, London, United Kingdom; <sup>2</sup>UCL MB/PhD Programme, London, United Kingdom; <sup>3</sup>UCL Division of Surgery and Interventional Science, London, United Kingdom; <sup>4</sup>University of Cambridge, Cambridge, United Kingdom.*

**Background:** Lymphatics participate in immune homeostasis and their dysfunction has been linked to autoimmunity and cancer. There is a need to enhance our understanding of the spatial and molecular features of lymphatics in human kidney health and transplant rejection.

**Methods:** Wholmount immunolabelling, tissue clearing and 3D microscopy were used to visualise lymphatics in non-transplanted donor kidney and allografts with chronic transplant rejection (CKTR). Furthermore, we integrated multiple human kidney single-cell RNA sequencing (scRNA-seq) datasets, including samples with distinct aetiologies of CKTR.

**Results:** In donor kidneys, lymphatics reside hierarchically within the cortex, form terminal branches along cortical nephron segments and possess a unique capillary phenotype, which is distinct from other organ lymphatics due to their low expression of LYVE1. In CKTR, lymphatics undergo expansion, lose structural hierarchy and infiltrate the medulla (Fig.1). Allograft lymphatics are predominantly donor-derived, express HLA-DR, and exhibit C4d immunoreactivity; indicative of targeting by anti-allograft antibodies. Additionally, kidney lymphatics are T cell-rich conduits which interconnect tertiary lymphoid structures. Using scRNA-seq, we identify putative crosstalk between lymphatics and T cells, featuring co-inhibitory immune checkpoints.

**Conclusions:** Utilising 3D imaging and scRNA-seq, we uncovered the spatial and molecular profile of human kidney lymphatics. We have revealed fundamentals of these vessels to inform future studies into renal biology, as well as identifying lymphatic phenomena and molecular candidates involved in CKTR.

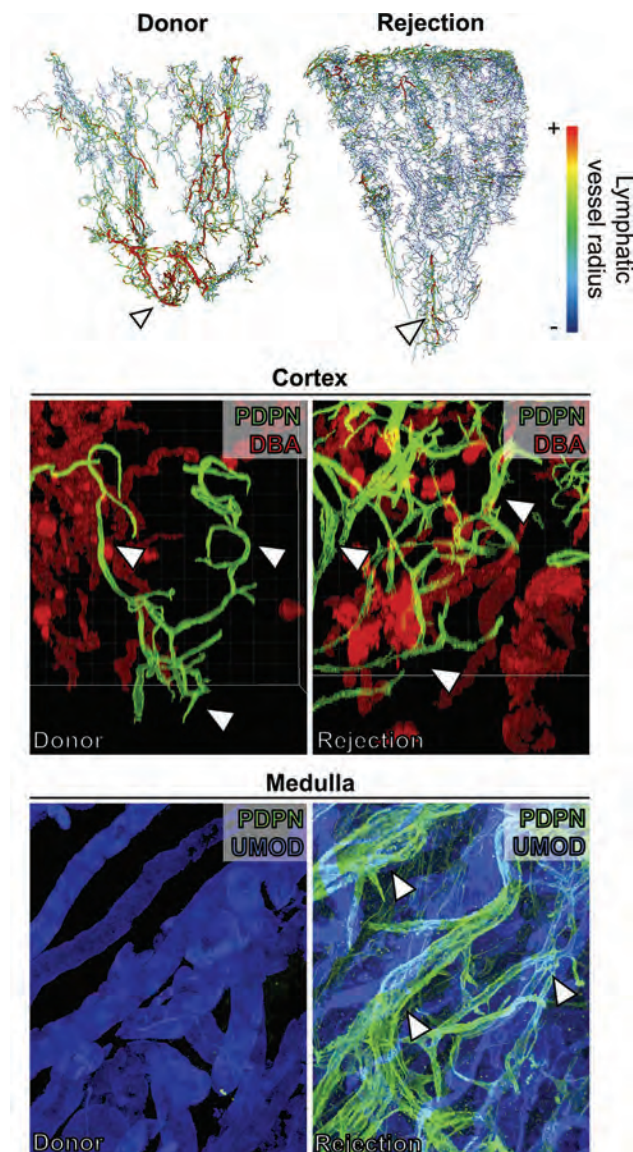

Fig.1. The lymphatic phenotype in transplant rejection

## TH-OR49

**Critical Role of CD74 in Immune Regulation and Allograft Tolerance**

Zhabiz Solhjoui,<sup>1</sup> Nour K. Younis,<sup>1</sup> Hengcheng Zhang,<sup>1</sup> John Y. Choi,<sup>1</sup> Anis J. Saad,<sup>1</sup> Christa A. Deban,<sup>1</sup> Ahmad Halawi,<sup>1</sup> Richard Bucala,<sup>2</sup> Jamil R. Azzi.<sup>1</sup> *Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Yale School of Medicine, New Haven, CT.*

**Background:** While known as the receptor for Microphage Inhibitory Factor (MIF) and MHC class II chaperone, the role of CD74 remains elusive in alloimmunity. We identified enriched CD74 transcriptome in urinary exosome of kidney allograft rejection, thus we explored the role of CD74 in alloimmune response in a mice transplant model.

**Methods:** We generated universal and conditional CD74KO mice and used as recipients of murine heart allograft in a full HLA mismatch model. Graft survival assessed; with Immunophenotyping of allograft and proliferation and functional assays performed.

**Results:** We observed indefinite survival heart allografts in CD74KO recipients compared to WT (MST >100 vs 7 days,  $p=0.0008$ ); Treg depletion resulted in allograft rejection (Fig 1,2). At day 7 post-transplantation, 5 times increase in Tregs infiltrating allograft as compared to WT noted, similar pattern with smaller magnitude observed in draining lymph node. To our surprise, higher frequency of activated effector CD4 cells (CD44+) observed in allograft of CD74KO recipients. In-vitro, activated effector CD4 cells harvested from CD74KO mice revealed decreased proliferation compared to WT. In contrast, CD74KO Tregs showed higher proliferation and suppressive function in-vitro. Naive CD4 cells show minimal CD74 expression. CD74 expression significantly increased in Tregs upon stimulation at both protein and RNA level (up to 30 times), with minimal MIF expression. Effector CD4 cells show 8 times increase in MIF expression. MIF is involved in activation of CD4 cells and we are currently studying its role in suppression of Treg activity and function.

**Conclusions:** Our data identifies a differential role of CD74 on regulatory and effector T cells function towards stronger regulatory and defective effector function. This contrasting cell-type specific phenotype could be at least partly due to MIF dependent CD74 inhibitory signaling of Tregs.

**Funding:** NIDDK Support

## TH-OR50

### Single Nuclei RNA-Sequencing Identifies Distinct Immune Profiles in Interstitial Fibrosis and Tubular Atrophy Human Allografts Following 15 Months Post-Transplantation

Thomas Rousselle,<sup>1</sup> Jennifer M. McDaniels,<sup>1</sup> Amol C. Shetty,<sup>1</sup> Elissa Bardhi,<sup>1</sup> Cem Kusecu,<sup>2</sup> Canan Kusecu,<sup>2</sup> Manish Talwar,<sup>2</sup> Thangamani Muthukumar,<sup>3</sup> James D. Eason,<sup>2</sup> Daniel G. Maluf,<sup>1</sup> Valeria R. Mas.<sup>1</sup> <sup>1</sup>University of Maryland Baltimore, Baltimore, MD; <sup>2</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>3</sup>Cornell University, Ithaca, NY.

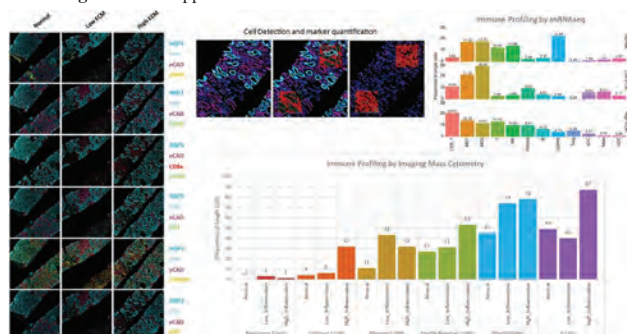

**Background:** The cellular immune response associated with interstitial fibrosis and tubular atrophy (IFTA) following kidney transplantation is unclear. This study utilized snRNAseq to uncover the immune landscape between normal and IFTA human allografts after 15-months post-transplantation (PT). Immune profiling is validated using imaging mass cytometry (IMC).

**Methods:** snRNAseq was performed for normal (n=3) and IFTA (n=5) human kidney allografts. Differences in ECM production and immune cell distribution led to the division of two IFTA groups: low vs high ECM (L-ECM vs H-ECM). Ligand receptor analysis was performed using the LRdb package in R and an interaction score was computed. IMC detected immune cells and spatial distribution. IMC images were processed in QuPath using Ir192 nuclei stain to detect cells. Antibody expression per cell was quantified by an artificial neural network and significant values ( $p \leq 0.05$ ) used to annotate cellular identity.

**Results:** snRNAseq revealed 12 distinct immune subclusters. Higher proportions of monocytes (MO1/MO2), dendritic, and mast cells were detected in L-ECM whereas B- and T-cells were more abundant in H-ECM. Congruent with snRNAseq results, B- and T-cells were largely detected in H-ECM. However, memory T-cells (CD3+CD4+CD45RO+) were more abundant in L-ECM than H-ECM. In addition, IMC revealed a distinct subpopulation of double negative T-cells (CD3+CD4-CD8-) that was not previously explored in snRNAseq. Significant proportions of macrophages (CD68+) were found to be increased in L- and H-ECM, indicating its key role in pathogenesis.

**Conclusions:** Defining the immune cell landscape will uncover novel immune to kidney cell interactions to target fibrogenesis and improve long-term outcomes.

**Funding:** NIDDK Support

## TH-OR51

### A Single-Nucleus RNA-Sequencing of Human Kidney Transplant Biopsies Identifies a Novel Role of Pericytes and Endothelium in Cellular Rejection

Ahmad Halawi,<sup>1</sup> Abdullah B. El Kurdi,<sup>2</sup> Katherine A. Vernon,<sup>3</sup> Zhabiz Solhjoui,<sup>1</sup> John Y. Choi,<sup>1</sup> Anis J. Saad,<sup>1</sup> Nour K. Younis,<sup>1</sup> Christa A. Deban,<sup>1</sup> Pierre Khoeiry,<sup>2</sup> Anna Greka,<sup>4,5</sup> Jamil R. Azzi.<sup>5,1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>American University of Beirut, Beirut, Lebanon; <sup>3</sup>Q32 BIO, Cambridge, MA; <sup>4</sup>Broad Institute, Cambridge, MA; <sup>5</sup>Harvard Medical School, Boston, MA.

**Background:** Immunosuppressive therapies in kidney transplantation were developed based on their effect on T-cell activation rather than alloimmunity mechanisms. Thus, understanding the role of different cells during rejection is essential to identifying directed therapies.

**Methods:** Single nucleus RNA sequencing was done on non-rejecting allograft, borderline, and T-cell mediated rejection (TCMR) samples. Data analysis was done using RStudio and Seurat. Pathway analysis was performed using Enrichr and Gene Sets Enrichment Analysis. Ligand-Receptor (LR) analysis was performed using SingleCellSignalR.

**Results:** Pathway analysis of T-cells in borderline and TCMR samples showed enrichment for allograft rejection and IFN-gamma response pathways, suggesting that our borderline sample reflects an early rejection. Hence, this allows for studying the early stages of cellular rejection. Pathway analysis of endothelial cells (ECs) of borderline and non-rejecting samples showed that focal adhesion and IFN-gamma pathways were significantly enriched compared to TCMR. Furthermore, LR analysis found that in borderline rejection, ECs increase NOTCH4 response to JAG1, among others. These interactions potentiate pericytes' ability to stabilize ECs and protect the allograft from lymphocyte invasion in the borderline rejection, but not in TCMR. Furthermore, ECs upregulate TLR4 in borderline rejection and not TCMR, which interacts with T-cells' HMGB1 suggesting a role for TLR4 in early rejection. To support our findings, we performed biopsy staining from borderline and TCMR and in vitro analysis of HUVEC exposed to IFN-gamma and T-cells.

**Conclusions:** ECs are involved in the early rejection process by upregulating IFN-gamma response, focal adhesion pathway, and TLR4 interacting with HMGB1 secreted by T-cells.

## TH-OR52

**IL-2/Anti-IL-2 Immune Complex Attenuates Cold Ischemia-Reperfusion Injury in Kidney Transplantation by Expanding Regulatory T Cells**

Ga Young Heo,<sup>1</sup> Joon Young Jang,<sup>1</sup> Tai yeon Koo,<sup>2</sup> Hee Byung Koh,<sup>1</sup> Hyo Jeong Kim,<sup>1</sup> Beom Seok Kim,<sup>1</sup> Jaeseok Yang,<sup>1</sup> <sup>1</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; <sup>2</sup>Korea University Medical Center, Seoul, Republic of Korea.

**Background:** Renal cold ischemia-reperfusion injury (IRI) is an inevitable complication after kidney transplantation and a more severe inflammatory response than renal warm IRI. We investigated role of regulatory T cells (Tregs) in cold renal IRI and whether Treg-expanding IL-2/anti-IL-2 complex (IL-2C) can attenuate renal cold IRI.

**Methods:** We used a mouse cold IRI model based on kidney transplantation along with Foxp3-DTR mouse to deplete Tregs. We investigated impact of IL-2C on acute, subacute, and chronic phase of cold IRI as well as role of Tregs.

**Results:** Cold IRI induced more severe renal functional deterioration, renal tissue damage and fibrosis than warm IRI. Mortality after cold IRI increased as cold ischemic time became longer than 6hr. Adoptive transfer of Tregs successfully attenuated cold IRI. In parallel, administration of IL-2C, a Treg expander before cold IRI, attenuated acute renal functional deterioration, renal tissue injury and apoptosis, and suppressed renal infiltration of effector cells along with expression of pro-inflammatory cytokines. IL-2C also attenuated subacute renal injury and facilitated renal regeneration on day 7 after cold IRI. Furthermore, IL-2C suppressed chronic fibrosis and epithelial mesenchymal transition along with renal infiltration of SMA<sup>+</sup>F4/80<sup>+</sup>CD11b<sup>+</sup> profibrotic macrophages on day 28 after cold IRI. ROS injury was also attenuated by IL-2C, as expression levels of Nox2, 8-OHG, MDA, and nitrotyrosine were decreased with increased expression of SOD and GSH. On the other hand, depletion of Tregs using diphtheria toxin in the presence of IL-2C, abrogated the beneficial effects of IL-2C on cold IRI.

**Conclusions:** Tregs play protective roles in renal cold IRI. IL-2C attenuated acute injury, facilitated subacute recovery, and suppressed chronic fibrosis in renal cold IRI through expansion of renal Tregs, suggesting the therapeutic potential of IL-2C in kidney transplantation-associated cold IRI.

## TH-OR53

**Mobilizing MHC Class Ib-Restricted Regulatory CD8 T Cells (CD8 Treg) With a Peptide Agonist Promotes Allograft Tolerance in a Fully Mismatched Mouse Kidney Transplant Model**

John Y. Choi,<sup>1,2</sup> Hengcheng Zhang,<sup>1</sup> Anis J. Saad,<sup>1</sup> Zhabiz Solhjoui,<sup>1,2</sup> Christa A. Deban,<sup>1</sup> Hye-jung Kim,<sup>3,2</sup> Harvey Cantor,<sup>3,2</sup> Jamil R. Azzi,<sup>3,2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Dana-Farber Cancer Institute, Boston, MA.

**Background:** A subset of CD8 T cells that express TCR restricted to Qa-1 - a Class-Ib MHC molecule - plays a critical regulatory function. CD8 Tregs kill activated CD4 T cells, which significantly upregulate Qa-1 during allograft rejection. We previously showed that allograft recipients with dysfunctional CD8 Treg undergo severe antibody-mediated rejection. We have engineered a Qa-1-binding 9-mer peptide superagonist (FL9-SA) that strongly activates CD8 Treg. We hypothesized that vaccinating hosts with FL9-SA may mobilize CD8 Treg and promote allograft tolerance by suppressing alloreactive CD4 T cells in the kidney transplant model.

**Methods:** The kidney of BALB/c mice (H-2<sup>d</sup>) was recovered with a full-length ureter and transplanted into B6 hosts (H-2<sup>b</sup>). The ureter of the remaining native kidneys was then ligated to inhibit native kidney function. Transplanted B6 hosts were treated intraperitoneally FL9-SA, or PBS emulsified in Adjuvant, once a week, starting POD2. Rapamycin was provided to certain groups on POD 0-4.

**Results:** Hosts treated with FL9-SA showed prolonged allograft survival compared to the control group (40 days vs 20.5 days). We also observed the indefinite survival of the kidney allograft when FL9-SA is combined with an mTOR inhibitor compared to the mTOR inhibitor only (38.5 days). Mechanistic analysis showed a diminished germinal center response and suppressed DSA level in hosts treated with FL9-SA compared to the control group. The allograft retrieved from the FL9-SA treated group showed a significant reduction in C4d deposit and cellular infiltrate. The overall memory CD4 T cells between the two groups remained similar; however, CD4 T cells from hosts treated with FL9-SA showed less proliferative capacity when co-cultured with irradiated donor splenocytes.

**Conclusions:** Our study suggests that mobilizing CD8 Tregs with a tolerogenic peptide vaccine is a novel method to promote kidney allograft tolerance. CD8 Treg-specific superagonist showed a synergistic effect with an mTOR inhibitor. Finally, mobilized CD8 Treg specifically suppresses alloreactive CD4 T cells while sparing the rest of the memory CD4 T cells that may play important role in host defense against pathogens.

## TH-OR54

**Targeting the Archetypal Innate Immune Receptor Integrin CD11b Prolongs Kidney Allograft Survival in Nonhuman Primates (NHPs)**

Abbas Dehnadi,<sup>1,2</sup> Grace Lassiter,<sup>1</sup> Takayuki Hirose,<sup>1,2</sup> Tatsuo Kawai,<sup>1,2</sup> Anthony B. Cosimi,<sup>1,2</sup> M. Amin Arnaout,<sup>1,2</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Peri-transplant IRI activates innate immunity leading to delayed graft function, inferior long-term transplant outcomes, and interferes with tolerance induction. mAb107 is a first-in-class orthosteric antagonist of CD11b that blocks on-target

conformational activation and proinflammatory outside-in signaling in an NHP model of IRI (*Nature Comm*, 2017). We have now evaluated the effect of mAb107 on allograft survival in NHPs receiving subtherapeutic tacrolimus (Tac) in our well-studied transplant model.

**Methods:** The donor's kidney from each of 8 NHPs was subjected to a 20-min WIT, followed by a 2-hour CIT before transplanting into each of 8 right nephrectomized MHC-mismatched recipients (half receiving IV mAb107 before allograft reperfusion and the other half receiving saline). The left native ureter was ligated on day 8 post-transplant (Tx). Recipients were followed by blood tests, transabdominal ultrasound, and Tac trough levels (adjusted to <10ng/ml, previously determined to result in acute rejection within 4-5 weeks in controls). Protocol biopsies were performed on days 8-10 and 30 post-Tx and all surviving animals were to be sacrificed on day 60 post-Tx.

**Results:** Following revascularization, immediate uniform reperfusion was observed only in mAb107-treated allografts, suggesting rapid termination of the maladaptive responses to ischemia. mAb107 induced significant prolongation of allograft survival in recipients (Fig. 1), with sustained vascular perfusion on day 20 post-Tx, reduced C4d staining, and ACR.

**Conclusions:** Suppressing the peri-transplant inflammatory response significantly prolonged NHP allograft survival, suggesting the potential of mAb107 in preventing/mitigating delayed graft function and enhancing tolerance.

**Funding:** NIDDK Support

## TH-OR55

**Molecular and Cellular Mechanisms of Lipocalin-2-Mediated Renoprotection in Kidney Transplantation**

Anna M. Pfeifferkorn,<sup>1</sup> Liang Zhao,<sup>2,3</sup> Minze Xu,<sup>3</sup> Angelika Kusch,<sup>4</sup> Raphaela Fritsche,<sup>5</sup> Cem Erdogan,<sup>3</sup> Hubert G. Schwelberger,<sup>7</sup> Felix Aigner,<sup>6</sup> Andreas Patzak,<sup>3</sup> Igor M. Sauer,<sup>1</sup> Muhammad Imtiaz Ashraf,<sup>1</sup> <sup>1</sup>Department of Surgery, Experimental Surgery, Charité – Universitätsmedizin, Berlin, Germany; <sup>2</sup>Department of Nephrology, the Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China; <sup>3</sup>Institute of Translational Physiology, Charité-Universitätsmedizin, Berlin, Germany; <sup>4</sup>Berlin Institute of Health at Charité - Universitätsmedizin, Berlin, Germany; <sup>5</sup>Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Metabolomics Platform, Berlin, Germany; <sup>6</sup>Department of Surgery, Krankenhaus der Barmherzigen Brüder, Graz, Austria; <sup>7</sup>Department of Visceral, Transplant and Thoracic Surgery, Medical University Innsbruck, Innsbruck, Austria.

**Background:** While Lipocalin-2 (Lcn2) is an early marker of acute kidney injury, delayed graft function and acute rejection, our previous studies have outlined a protective effect of recombinant Lcn2:Siderophore:Fe (rLcn2) in a mouse kidney transplantation (KTx) model. The underlying mechanism of renoprotection has not yet been fully investigated, elucidating which forms the primary focus of this study.

**Methods:** Kidneys were transplanted from Balb/c to C57Bl/6 mice ( $\pm$ rLcn2, 250mg/kg). Phenotyping of the immune cells, isolated from graft, spleen, lymph nodes and blood was performed by flow cytometry at post-KTx day 3 and 7. For analyses of stress, inflammation and survival signaling in the mouse kidney multiplex signaling analysis was performed following syngeneic KTx (cold ischemia (CI): 5.5h, reperfusion (R): 24h  $\pm$ rLcn2, 250mg/kg) and in mouse primary proximal tubular epithelial cells, subjected to hypoxia/reoxygenation (H: 24h/ R: 30min, 6h, 12h, 24h  $\pm$ rLcn2, 1 $\mu$ g/ml). To determine the effect of rLcn2 on physiology of renal microvessels, dilatation function of BAY 58-2667 (soluble guanylyl cyclase activator) on angiotensin II-precontracted murine afferent arterioles (AA) was examined following H/R (H:30min/ R:10min) and syngeneic KTx (CI: 5.5h, R: 20h)  $\pm$ rLcn2, apo-rLcn2 and deferoxamine (DFO).

**Results:** Analysis of the leukocytes revealed no general immunosuppressive or regulatory effect of rLcn2. However, rLcn2 treatment curtailed intra graft accumulation of total and in particular of activated (NKG2D<sup>+</sup>) CD8<sup>+</sup> T cells. Degranulation capacity and frequency of interferon gamma<sup>+</sup> and perforin<sup>+</sup> CD8<sup>+</sup> T cells was significantly attenuated. No clear effect of rLcn2 was observed on candidate stress, inflammation and survival signaling molecules in the mouse kidney epithelia during H/R and KTx. Interestingly, rLcn2 not only circumvented H/R-induced loss in dilatation of isolated renal AA but also substantially improved CI-impaired vasodilatation. While Fe free apo-rLcn2 could not ameliorate loss of vasodilatation, DFO reversed the protective effect of rLcn2, validating the iron-dependent effect.

**Conclusions:** rLcn2 protects mouse renal allografts from CD8<sup>+</sup>T cell mediated alloimmune response and abates loss in dilatation of renal AA both *in vitro* (H/R) and *in vivo* (KTx).

### Phascolarctobacterium-Producing Propionate and Acute Rejection Among Kidney Transplant Recipients

Hyunjeong Cho,<sup>1</sup> Ji Eun Kim,<sup>2</sup> Jangwook Lee,<sup>3</sup> Yong Chul Kim,<sup>4</sup> Ji In Park,<sup>5</sup> Jung Pyo Lee,<sup>6</sup> Dong Ki Kim,<sup>4</sup> Yon Su Kim,<sup>4</sup> Hajeong Lee.<sup>4</sup> <sup>1</sup>Chungbuk National University Hospital, Cheongju, Republic of Korea; <sup>2</sup>Korea University Guro Hospital, Seoul, Republic of Korea; <sup>3</sup>Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; <sup>4</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>5</sup>Kangwon National University Hospital, Chuncheon, Gangwon, Republic of Korea; <sup>6</sup>Seoul National University Hospital, Biomedical Research Institute, Seoul, Republic of Korea.

**Background:** Acute rejection (AR) is associated with worse long-term allograft survival. Therefore, identifying and regulating the potential risk factors of AR is very important. Recent studies have shown that gut microbiota regulates host immune response, although the association between gut microbiota and AR in kidney transplant (KT) recipients is poorly understood. Here, we aimed to evaluate the gut microbiota and its metabolites could predict AR after kidney transplantation (KT).

**Methods:** We prospectively collected 98 KT recipients' stool samples at pretransplant (n=97), posttransplant 3 months (n=66), and 12 months (n=33). Metagenomic DNA from feces was sequenced using by Illumina MiSeq system. Stool metabolites were measured by a 1H nuclear magnetic resonance spectroscopy. We obtained various clinical factors including biopsy-proven AR within 1 year after KT.

**Results:** Within the 1<sup>st</sup> year of the transplantation, 33 (34%) patients developed AR. Bacterial richness (observed ASVs) and diversity of the microbial communities (Shannon diversity index) were lower in the AR group than in the non-rejection group ( $P_{FDR}=0.07$ ,  $P_{FDR}=0.02$ , Wilcoxon rank-sum test with FDR). In ALDEx2 analysis, at the genus level, the *Escherichia-Shigella* had significantly increased abundance in the AR group compared to that in the non-rejection group ( $P_{FDR} < 0.25$ ), while the *Phascolarctobacterium* was significantly decreased ( $P_{FDR} < 0.25$ ) in the AR group compared to in the non-rejection group. In ROC analysis, two bacteria adding clinical values significantly predict AR (AUC: 0.897). In LEFSe analysis based on the PICRUST2 results, we found 83 differentially abundant metaCyc pathways in the AR group than in the non-rejection group (LDA score  $> 2.0$  and  $P < 0.05$ ). In particular, pathways of homolactic fermentation and mixed acid fermentation were enriched in the AR group. And finally, fecal propionate, a key metabolite of short-chain fatty acid was 12% lower in the AR group than in the non-rejection group ( $p=0.05$ ).

**Conclusions:** In this study, we found that pre-transplant decreased relative abundance of *Phascolarctobacterium* was associated with AR after KT. In addition, its fecal propionic acid which was known to be produced by *Phascolarctobacterium* was decreased in the AR group.

## TH-OR57

### Cytomegalovirus-Responsive CD4 T Cells Exhibit a Stable, Cytotoxic Phenotype During the First Year After Solid Organ Transplant

Ayah Ahmad,<sup>1</sup> Lauren Higdon,<sup>2</sup> Jonathan S. Maltzman.<sup>2,3</sup> <sup>1</sup>Hunter College, New York, NY; <sup>2</sup>Stanford University, Stanford, CA; <sup>3</sup>VA Palo Alto Health Care System, Palo Alto, CA.

**Background:** Cytomegalovirus (CMV) can cause serious disease in humans after solid organ transplant. In healthy individuals, immune surveillance typically controls primary infection of CMV. However, the latent virus remains dormant with the potential to reactivate periodically, causing deleterious effects on immune-compromised individuals. The anti-viral immune response to CMV in transplant recipients is hindered by associated

immunosuppressive therapies. Antiviral CD4 T cells are an important component of viral control through production of inflammatory cytokines as well as lysis of infected cells. We sought to understand the homeostasis of this critical population in transplant recipients.

**Methods:** We characterized the phenotype and repertoire of protective CD4 T cells in six recipients of kidney or heart transplant within the first year after transplant. We analyzed peripheral blood samples from the recipients pre-, 3-, and 12-months post-transplant by both flow cytometry and targeted single cell sequencing. To analyze the phenotype of CMV-responsive CD4 T cells, we isolated CD4 T cells producing interferon gamma in response to CMV peptide stimulation and used targeted single cell RNA sequencing of T cells producing cytokine in response to CMV peptide stimulation to measure gene expression as well as T-cell receptors (TCR) to measure clonal expansion.

**Results:** By flow cytometry, we found that pre-transplant exposure to CMV was associated with elevated aging of CD4 T cells in comparison to recipients with no pre-transplant exposure. CD4 T cells maintained phenotypic stability over time. Our sequencing data also indicate that CMV-responsive CD4 T cells are largely anti-viral and cytotoxic, and phenotypically stable during the first year after transplant. We found that clonally expanded CMV-responsive CD4 T cells were primarily of an aged, cytotoxic phenotype as well.

**Conclusions:** Overall, these data indicate that in contrast to CD8 cells, transplantation and immunosuppression do not have a significant impact on CMV-responsive CD4 T cells within the first year post-transplant. Furthermore, the cytotoxic phenotype of the CD4 T cells suggests that these cells play an important role in control of CMV. Future studies are required to determine the impact of CMV-responsive CD4 T cells on control of CMV and post-transplant outcomes.

## FR-OR01

### The Effect of a Fermentable Dietary Fiber Inulin on a Rat Model of CKD-MBD

Neal X. Chen,<sup>1</sup> Kalisha O'Neill,<sup>1</sup> Shruthi Srinivasan,<sup>1</sup> Corinne E. Metzger,<sup>1</sup> Paul B. Fallen,<sup>1</sup> Annabel Birute,<sup>1</sup> Pieter Evenepoel,<sup>2</sup> Matthew R. Allen,<sup>1</sup> Sharon M. Moe.<sup>1</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Nephrology and Renal Transplantation Research Group, Leuven, Belgium.

**Background:** Human studies have suggested that a diet rich in fermentable dietary fiber may prevent the progression of chronic kidney disease and its associated complications by altering gut microbiome and decreasing uremic toxins. The goal of this study is to investigate if the fermentable fiber inulin supplement will improve CKD-MBD.

**Methods:** We treated a naturally occurring model of CKD-MBD, the Cy/+ rat, with a casein-based diet supplemented with or without the fermentable fiber 10% inulin for 10 weeks, starting at 22 weeks (~CKD stage 3b) with euthanization at 32 wk (~15% of normal GFR). Normal littermates (NL) were used as control. Blood biochemistry, cardiovascular parameters and bone quantity and turnover were assessed.

**Results:** CKD rats had the expected elevations of blood creatinine, phosphorus, PTH, fibroblast growth factor 23 (FGF23) and oxidative stress marker 8-OHdG compared to NL. The CKD with inulin treatment compared to CKD without inulin had similar kidney function, but reduced levels of plasma phosphorus by 23% ( $p<0.001$ ), PTH by 65% ( $p<0.003$ ) and 8-OHdG by 22% ( $p<0.01$ ). CKD rats had elevated serum levels of uremic toxin indoxyl sulfate (IS) and p-cresyl sulfate (PS) and inulin treatment significantly decreased IS levels by 54% ( $p<0.001$ ) and PS levels by 80% ( $p<0.02$ ). Inulin treatment also improved cardiovascular parameters in CKD rats by reducing aorta calcification by 28%, heart calcification by 80% and left ventricular mass by 17%. In the skeleton, CKD rats had increased cortical porosity and reduced cortical thickness and area compared to NL and inulin treatment in CKD rats normalized these parameters ( $P<0.01$ ). Furthermore, inulin treatment decreased trabecular osteoclast surfaces by 37% in CKD rats. However, inulin treatment did not improve bone mechanics in CKD rats.

**Conclusions:** These results suggested that the fermentable dietary fiber inulin had a beneficial effect on CKD-MBD by reducing cardiovascular disease, cortical porosity, and osteoclasts although there was no effect on bone mechanics. These data suggest that changes in gut microbiota and/or uremic toxins may play a role in the severity of CKD-MBD and may justify a concerted effort to increase fermentable fiber in the diet of patients.

## FR-OR02

### Estrogen Protects Female Mice With CKD From Developing FGF23-Induced Left Ventricular Hypertrophy

Dominik Kentrup, Guillaume Courbon, Xueyan Wang, Bridget Hunt-Tobey, Valentin David, Aline Martin. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Elevated levels of serum fibroblast growth factor 23 (FGF23) directly contribute to the development of left ventricular hypertrophy (LVH) and mortality in patients with chronic kidney disease (CKD). Although the risk of cardiovascular events and mortality is significantly higher in men than in women, the sex-specific differences in FGF23-induced LVH are unclear.

**Methods:** We studied age-matched C57BL/6J wild-type (WT) and Col4a3 knockout (CKD) male and female littermate mice with progressive CKD at 4, 8, 12, 16, and 20 weeks of age. We analyzed kidney and heart morphology and function and circulating markers of mineral metabolism in all mice. We performed RNAseq analyses on hearts isolated from 20 week-old mice. We assessed lifespan in a separate set of mice. In vitro, we isolated primary cardiomyocytes (NMCs) from mouse neonates separated by sex, and cultured them in presence of FGF23, estradiol (E2), both or none.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**  
Underline represents presenting author.

**Results:** Compared to WT, CKD males showed elevated blood urea nitrogen (BUN) levels starting at 16 weeks of age indicating onset of CKD. Concomitant with CKD progression, serum levels of FGF23 also started to increase at 16 weeks. At 20 weeks, CKD males showed overt LVH and died at 22 weeks. In contrast, CKD females showed an earlier decline in kidney function and increase in FGF23 levels at 12 weeks of age. At all timepoints, CKD females displayed higher FGF23 levels than CKD males. However, CKD females did not develop LVH and lived until 24 weeks. Heart transcriptomics analyses showed that differentially regulated LVH-related genes were downstream targets of estrogen receptor 1. In culture, E2 alone slightly reduced the size of female NCMCs, but had no effect on male cells. In contrast, FGF23 induced similar hypertrophic growth in male and female NCMCs. E2 co-treatment partially reduced the dose-dependent FGF23 hypertrophic effects in male cells and fully prevented them in female cells.

**Conclusions:** CKD female mice do not develop LVH and live longer than CKD males, despite an earlier CKD onset and higher FGF23, indicating that the mechanisms leading to LVH in CKD are sex-dependent. This study shows that estradiol cancels the direct hypertrophic effects of FGF23 on female cardiomyocytes, suggesting the presence of common molecular targets of FGF23 and E2 signaling in the heart.

## FR-OR03

### Vitamin D Receptor Regulates Furin-Mediated FGF23 Cleavage

**Petra Simic**, Isinsu Bastepe, Wen Zhou, Birol Ay, Eugene P. Rhee, Murat Bastepe. *Massachusetts General Hospital, Boston, MA.*

**Background:** Fibroblast growth factor 23 (FGF23) is a bone-derived hormone that decreases serum phosphate. The full-length protein, intact FGF23 (iFGF23), is cleaved by furin protease at an Arg-XX-Arg site into inactive N-terminal (aa 25-179) and C-terminal (aa 180-251) fragments. Several studies have proposed a putative role of vitamin D in the regulation of furin in the context of infections. Therefore, we investigated the effect of vitamin D (1,25(OH)<sub>2</sub>D) and vitamin D receptor (VDR) on furin-mediated cleavage of FGF23.

**Methods:** In *Vdr* knock out (*Vdr*<sup>-/-</sup>) mice, we first quantitated the relative abundance of FGF23 and its fragments in circulation, utilizing ELISA assays that specifically detect only iFGF23, or a combination of iFGF23 and C-terminal cleavage fragments (cFGF23). We further evaluated gene expression and protein levels of furin in bone marrow and plasma and furin activity in plasma. We administered a furin inhibitor, decanoyl-RVKR-CMK, *i.p.* to test if furin mediates cleavage in *Vdr*<sup>-/-</sup> animals. Conversely, we administered recombinant furin protein to wild type mice to test if its effect on FGF23 cleavage can be blocked by 1,25(OH)<sub>2</sub>D administration. All experiments were repeated *in vitro* in the osteocyte-like Ocy454 cells in which *Vdr* was knocked out using CRISPR/Cas9.

**Results:** Mice lacking VDR had a 25-fold increase in FGF23 cleavage, judged by the cFGF23-to-iFGF23 ratio, and elevated furin gene expression, protein levels and activity compared to wild type (WT) littermates. Inhibition of furin activity by decanoyl-RVKR-CMK fully blocked increased FGF23 cleavage in *Vdr*<sup>-/-</sup> animals, and decreased cFGF23 to levels comparable to WT mice. This effect was recapitulated in a cell-autonomous manner in *Vdr* deficient Ocy454 cells. Moreover, 1,25(OH)<sub>2</sub>D injection increased total FGF23 without an increase in FGF23 cleavage, with cFGF23/iFGF23 ratio being comparable to vehicle injected animals. When administered with furin recombinant protein, 1,25(OH)<sub>2</sub>D fully blocked furin's effect on increased FGF23 cleavage.

**Conclusions:** In summary, 1,25(OH)<sub>2</sub>D and VDR suppress furin-induced FGF23 cleavage, providing a mechanism by which vitamin D signaling can augment biologically active FGF23 levels.

### Skeletal Muscle Is a Novel Source of FGF23 in Mouse Models of CKD and Skeletal Muscle Atrophy

**Kylie Heitman**, Isaac D. Campos, Christopher Yanucil, David G. Westbrook, Madison Thomas, Abul Fajol, Christian Faul. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

**Background:** Chronic Kidney Disease (CKD) affects various tissues and is associated with elevated serum levels of fibroblast growth factor 23 (FGF23) and phosphate (Pi). FGF23 is a hormone that is produced by the bone and targets the kidney to regulate Pi homeostasis. Since Pi is a potent inducer of FGF23 expression in bone, we studied whether Pi can induce FGF23 production in skeletal muscle (SM), and potentially contribute to atrophy. We analyzed SM on a functional, histological and molecular level in four models of hyperphosphatemia – two CKD models, i.e. mice with global deletion of collagen 4a3 and wildtype mice receiving an adenine-rich diet, as well as wildtype mice on a high Pi diet with normal kidney function, and *kltho* deficient mice. Finally, we determined the effect of a low Pi diet on SM in Col4a3<sup>-/-</sup> mice.

**Methods:** C2C12 myotubes were treated with 1-5 mM Pi for 24 hours, followed by qPCR expression analysis of FGF23 and atrophy genes. We studied Col4a3<sup>-/-</sup> mice receiving normal chow or a 0.2% phosphate diet at 10 weeks age; C57Bl/6 mice receiving an adenine-rich (0.2%) diet for 14 weeks or 3% phosphate diet for 6 months, and *kltho* deficient mice. We analyzed grip strength, hindlimb area by MRI, muscle mass, cross-sectional area of muscle fibers, and expression levels of atrogenes by qPCR and of FGF23 by qPCR, ELISA, and immunofluorescence microscopy.

**Results:** Pi treatments increased the expression levels of atrogenes and FGF23 in C2C12 myotubes. In the four mouse models, grip strength was significantly reduced. In CKD and *kltho* deficient mice, muscle mass, cross-sectional area of myofibers was reduced, and the expression levels of atrogenes were elevated when compared to

respective controls. Furthermore, we detected elevations in the mRNA and protein levels of FGF23 in the hindlimb muscles of all models. Administration of a low Pi diet protected Col4a3<sup>-/-</sup> mice from developing SM atrophy.

**Conclusions:** Elevated Pi induces myotube atrophy and FGF23 expression *in vitro*. Mouse models with hyperphosphatemia develop SM atrophy and produce FGF23 in SM tissue in the presence and absence of CKD. Administration of a low Pi diet protects the SM in CKD mice. Future studies need to determine whether SM-derived FGF23 contributes to tissue injury or is protective against phosphate-induced damage.

## FR-OR05

### Parathyroidectomy Decreases Muscle Expression of TGF-β1 and Improves Muscle Function

**Eduardo J. Duque**<sup>1</sup>, Shirley F. Crispilho<sup>3</sup>, Andre Kakinoki Teng<sup>1</sup>, Ivone B. Oliveira<sup>1</sup>, Luzia N. Furukawa<sup>1</sup>, Vanda Jorgetti<sup>1</sup>, Samuel K. Shinjo<sup>1</sup>, Carla M. Avesani<sup>2</sup>, Rosilene M. Elias<sup>1,3</sup>, Rosa M. Moyses<sup>1</sup>. <sup>1</sup>Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Universidade Nove de Julho, Sao Paulo, Brazil.

**Background:** Secondary hyperparathyroidism (SHPT) is commonly associated with muscle dysfunction in patients with chronic kidney disease (CKD). PTH and TGF-β are known to operate together to exert their biological activities, and pathological TGF-β release from bones was shown to mediate muscle weakness. We sought to investigate the relationship between changes in mineral and bone metabolism (MBD) in patients with SHPT pre- and post-parathyroidectomy (PTX), and muscle expression of TGF-β, FNDC5 (the irisin precursor), and RANKL, which has been recently recognized as an inducer of sarcopenia.

**Methods:** We prospectively enrolled 29 patients on dialysis (39 ys, 62% female) referred for PTX. Muscle phenotyping involved histological analysis by immunohistochemistry and gene expression; body composition by DXA; functional and strength tests analysis by using Actigraph GT3X accelerometer, handgrip (HGS), supine (SP) and leg press (LP). Muscle biopsies were obtained from the vastus lateralis at baseline and 6 months after PTX, and from healthy controls. Biochemical parameters were also collected.

**Results:** MBD, DXA and physical evaluation parameters are shown in Table 1. TGF-β1 expression decreased (21 vs 7%, p < 0.01) and vitamin-D receptor increased (31 vs. 68 +cells/mm<sup>2</sup>, p<0.01) after PTX. At baseline, muscle RANKL and FGF21 genes were upregulated (16-fold, p=0.002; and 6-fold, p=0.06, respectively), when compared to controls, with no effect of PTX. Conversely, FNDC5 was downregulated (3.2-fold, p=0.034), and PTX led to its increase (2-fold, p < 0.01).

**Conclusions:** Patients with SHPT on dialysis submitted to PTX experienced a marked improvement in bone mass and muscular function, but not in muscle mass. Our findings suggest that muscle TGF-β1 and RANKL might play a role in CKD-associated sarcopenia. We also propose that SHPT impairs muscular strength through changes in Irisin and TGF-β synthesis, which were reverted by PTX.

**Funding:** Government Support - Non-U.S.

## FR-OR06

### Early Changes in Bone Turnover Markers Predict Bone Loss After Kidney Transplantation

**Hanne S. Joergensen**<sup>1,2</sup>, Patrick D'Haese<sup>5</sup>, Etienne Cavalier<sup>3</sup>, Pieter Evenepoel<sup>1,4</sup>. <sup>1</sup>Katholieke Universiteit Leuven, Leuven, Belgium; <sup>2</sup>Aarhus Universitetshospital, Aarhus, Denmark; <sup>3</sup>Universite de Liege, Liege, Belgium; <sup>4</sup>Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; <sup>5</sup>Universiteit Antwerpen, Antwerpen, Belgium.

**Background:** Bone mineral density (BMD) changes are highly variable after kidney transplantation (TX) with subgroups of patients gaining or losing BMD in the first post-TX year. We investigated whether early changes in bone turnover markers (BTMs) could predict the BMD trajectory, which could enable targeted therapy.

**Methods:** BMD was measured at TX and 1 yr and parathyroid hormone (PTH) and BTMs at TX, 3 mo, and 1 yr (n=230). Paired transiliac bone biopsies were available in a subset (n=49).

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Results:** Lumbar spine BMD loss at 1 yr was associated with higher PTH and BTMs at TX, with greater decreases in BTMs at 3 and 12 mo (Table). Trajectories of BTMs differed for patients gaining and losing BMD (Figure). By bone biopsy, patients with lumbar spine BMD gain vs loss had greater decreases in osteoid volume (-1.7 vs +2.2%, p=0.01) and surface (-9.09 vs +8.97uM, p=0.01). Changes in cortical porosity and thickness by micro-CT (n=19) were minimal and unrelated to changes in BMD.

**Conclusions:** Rapid mineralization of osteoid results in substantial BMD gain post-TX in a subset of patients. Changes in bone turnover markers during the first 3 mo can be used to predict the trajectory of BMD in the first post-TX yr.

FR-OR07

**Hepatocyte Nuclear Factor 4 Alpha 2 Is a Novel Osteoblast Transcription Factor That Plays a Role in CKD-MBD**  
Marta Martinez-Calle,<sup>1</sup> Guillaume Courbon,<sup>1</sup> Bridget Hunt-Tobey,<sup>1</sup> Jadeah J. Spindler,<sup>1</sup> Xueyan Wang,<sup>1</sup> Luciene dos Reis,<sup>2</sup> Carolina S. Martins,<sup>2</sup> Rosa M. Moyses,<sup>2</sup> Aline Martin,<sup>1</sup> Valentin David.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Hospital das Clinicas da Faculdade de Medicina de Botucatu, Botucatu, Brazil.

**Background:** Renal osteodystrophy (ROD) is a poorly understood disorder of bone metabolism that affects virtually all patients with chronic kidney disease (CKD), and is associated with adverse clinical outcomes including fractures, cardiovascular events and death. Using RNA (RNAseq) and Chromatin Immunoprecipitation (ChIPseq) sequencing approaches and complementary mouse models, we aimed to identify novel bone-derived factors that contribute to the onset and progression of ROD.

**Methods:** We first performed RNAseq in bone biopsies isolated from patients and mice with and without CKD and identified hepatocyte nuclear factor (HNF) 4 alpha as one of the top regulated genes with reduced expression in CKD. Next, we generated mice harboring a conditional deletion of *Hnf4a* in osteoblasts and osteocytes (*Hnf4a*<sup>oc-KO</sup>) and studied their bone phenotype at 6 and 12 weeks of age. In parallel, we characterized the transcriptome and HNF4a cistrome of MC3T3 and osteoblast cultures lacking (*Hnf4a*<sup>KO</sup>) or overexpressing *Hnf4a* (*Hnf4a*<sup>Tg</sup>). Finally, we evaluated the impact of restoring osteoblastic *Hnf4a* expression in mice with CKD.

**Results:** Osteoblast deletion of *Hnf4a* resulted in impaired osteogenesis in cells and mice. *Hnf4a*<sup>oc-KO</sup> mice showed reduced bone formation and increased bone resorption, resulting in a ~50% loss of trabecular bone volume at 12 weeks of age compared to

wild-type (WT) littermates. In addition, osteoblast cultures isolated from *Hnf4a*<sup>oc-KO</sup> mice showed altered differentiation and mineralization compared to WT cells. In sharp contrast, *Hnf4a*<sup>Tg</sup> cells showed increased expression of osteoblastic markers, such as *Runx2*, *Sp7* (Osterix) and *Bglap* (Osteocalcin), and ChIPseq analysis demonstrated that HNF4a is a master regulator of osteogenic genes. As a consequence, osteoblast specific overexpression of *Hnf4a* in mice with CKD delayed the onset of ROD and resulted in a 2-fold increase in trabecular bone volume and ~40% reduction of cortical porosity compared to CKD mice.

**Conclusions:** Our results establish the direct role of HNF4a in the regulation of osteogenesis, suggest that osseous HNF4a deficiency contributes to the pathogenesis of ROD and propose a novel mechanism to explain intrinsic bone defects in patients with CKD.

**Encalceret Normalized Mineral Homeostasis in Autosomal Dominant Hypocalcemia Type 1 (ADH1) in a Phase 2 Study**  
Kelly Roszko,<sup>1</sup> Rachel Gafni,<sup>1</sup> Iris R. Hartley,<sup>1</sup> Edward F. Nemeth,<sup>2</sup> Karen A. Pozo,<sup>1</sup> Ed Lombardi,<sup>3</sup> Mary S. Roberts,<sup>3</sup> Scott H. Adler,<sup>3</sup> Michael Collins.<sup>1</sup> <sup>1</sup>National Institute of Dental and Craniofacial Research, Bethesda, MD; <sup>2</sup>MetisMedica, Toronto, ON, Canada; <sup>3</sup>Calcilytix Therapeutics, San Francisco, CA.

**Background:** Gain-of-function variants in the calcium-sensing receptor (CaSR) cause ADH1, a disorder of low PTH, hypocalcemia, hypercalciuria, & hyperphosphatemia. Therapy with calcium and active vitamin D worsens hypercalciuria and can lead to renal morbidity. Calcilytics (negative allosteric modulators of the CaSR) decrease the CaSR's sensitivity to extracellular calcium and correct biochemical abnormalities in rodent models. Encalceret is an oral calcilytic under investigation as a potential treatment for ADH1.

**Methods:** Thirteen adults with ADH1 participated in a Phase 2b open-label dose-ranging study. Mean (range) therapy at screening was: calcium 2120mg/day (750-4800); calcitriol 0.7µg/day (0.2-2.0). These and thiazides were stopped before encalceret initiation. Periods 1 and 2 evaluated safety/tolerability and dose-finding. Period 3 (P3) was a 24-week (W24) outpatient period to optimize dosing and assess safety and efficacy. Encalceret doses were individually titrated to normalize corrected blood calcium (cCa).

**Results:** P3W24 mean±SD encalceret sulfate dose was 86±70mg BID (5-190 BID). Encalceret was well-tolerated with no serious adverse events reported; there were no treatment or study discontinuations. Encalceret resulted in dose-dependent increases in iPTH and normalization of mineral homeostasis (table):

**Conclusions:** This study represents a molecularly-targeted, precision medicine approach to ADH1 treatment. The consistent and sustained normalization of cCa and 24-hr UCa are clinically meaningful and support Phase 3 evaluation of the efficacy and safety of encalceret as a potential treatment for ADH1.

**A Spatially Anchored Transcriptomic Atlas of the Human Kidney Papilla Identifies Significant Immune Injury and Matrix Remodeling in Stone Disease Patients**  
Angela R. Sabo,<sup>1</sup> Victor Hugo Canela,<sup>1</sup> William S. Bowen,<sup>1</sup> Ricardo Melo ferreira,<sup>1</sup> Daria Barwinska,<sup>1</sup> Seth Winfree,<sup>2</sup> Blue Lake,<sup>4</sup> Ying-Hua Cheng,<sup>1</sup> Kaice A. LaFavers,<sup>1</sup> Kun Zhang,<sup>4</sup> Fredric L. Coe,<sup>6</sup> Elaine M. Worcester,<sup>6</sup> Sanjay Jain,<sup>3</sup> Michael T. Eadon,<sup>1</sup> James C. Williams,<sup>1</sup> Tarek M. El-Achkar.<sup>1,5</sup> <sup>1</sup>KPMP <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>University of Nebraska Medical Center, Omaha, NE; <sup>3</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>4</sup>University of California San Diego Department of Bioengineering, San Diego, CA; <sup>5</sup>Richard L Roudebush VA Medical Center, Indianapolis, IN; <sup>6</sup>University of Chicago Department of Medicine, Chicago, IL.

**Background:** Kidney stone disease causes significant morbidity and health care utilization. The pathogenesis of this disease is incompletely understood. This is partly due to the poor characterization of the cellular and molecular makeup of the human papilla and its alteration with disease.

**Methods:** We utilized renal papillary biopsies obtained from calcium oxalate stone formers and non-stone formers. Specimens underwent single nuclear RNA sequencing (snRNAseq), spatial transcriptomics and/or high-resolution large-scale multiplexed 3D and Co-detection by indexing (CODEX) imaging. snRNAseq data from the Kidney Precision Medicine Project was used for comparison. A cohort including 58 patients and healthy volunteers was used for urine studies.

**Results:** We define and localize a complete landscape of papillary cells, which include surface epithelial cells, stromal and immune cells, unique subtypes of principal cells, and an undifferentiated epithelial cell type that was enriched in specimens from stone patients. Despite the focal nature of mineral deposition, we show that injury pathways such as immune activation, oxidative stress and matrix remodeling are globally upregulated across multiple cell types within the papilla of stone patients. We also characterize Randall's plaque as an active immune zone with inflammatory macrophages and T cells and demonstrate the presence of an immune lifespan around mineral deposition ranging from inflammation to fibrosis. Finally, we show that two matrix metalloproteinase, MMP7 and MMP9, are linked to active stone disease and mineralization within the papilla, and that their levels in the urine correlate with disease activity.

**Conclusions:** Our integrated multimomics approach reveals the complexity of the human kidney papilla and provides insights into the role of immune system activation and matrix remodeling in mineral deposition and stone disease. We also identify MMP7 and MMP9 as potential noninvasive markers of kidney stone disease course and activity.

## FR-OR10

### Crystalluria Impairs Macrophage Function During Kidney Stone Formation

Tanecia Mitchell, Emma Laurence, Parveen Kumar. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

**Background:** Approximately 10% of the United States population will form a kidney stone in their lifetime. Increased consumption of oxalate-rich meals is positively associated with urinary oxalate levels and stone formation. Macrophages are essential for removing crystals, which are the precursors to kidney stones, and rely on mitochondria and lysosomes to carry out their function. Interleukin-10 (IL-10) is an anti-inflammatory cytokine that regulates mitochondrial function in macrophages. The purpose of this study was to determine whether urinary nanocrystals reduce macrophage metabolism, signaling, and mitochondrial/lysosomal function. We hypothesize human urinary nanocrystals impair macrophage metabolism, IL-10 signaling, and mitochondrial quality control.

**Methods:** Ten adult healthy subjects and CaOx stone formers consumed controlled high oxalate diets for 4 days. Urine was collected 24 hours before and after the dietary regimen. Urinary nanocrystals were characterized using nanoparticle tracking analysis and subsequently exposed to macrophages (human and THP-1 monocyte-derived macrophages) with or without exogenous IL-10 (40 ng/ml) for 24 hours. Cell viability was measured using the MTT assay and metabolism was assessed using the Seahorse XF Analyzer. Mitochondrial and lysosomal gene expression and protein levels were determined using real-time quantitative reverse transcription-PCR, western blotting, or confocal microscopy. Mitochondrial reactive oxygen species (ROS) levels, mitochondrial membrane potential, and lysosomal activity were assessed using fluorescent-based plate reader assays.

**Results:** Our results show that high oxalate diets stimulate urinary nanocrystals and these crystals impair macrophage viability, metabolism, IL-10 and ROS signaling, mitochondrial and lysosomal gene expression and protein levels, and mitochondrial quality control. Further, we determined that exogenous IL-10 treatment prevented these outcomes.

**Conclusions:** These findings suggest that urinary nanocrystals impact macrophage function and this may reduce their ability to prevent kidney stone formation and growth. Future studies will determine mechanisms contributing to IL-10 signaling impairment in macrophages following oxalate exposure and test potential therapies to improve macrophage function during kidney stone formation.

## FR-OR11

### Intracellular Magnesium Trafficking: A Novel Target to Prevent Ischemic Kidney Injury

William B. Reeves, Weiwei Wang, Kang Li, Serena J. Kim, Manigandan Venkatesan, Neelanjan Vishnu, Karthik Ramachandran, Muniswamy Madesh. *The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX.*

**Background:** Mitochondrial dysfunction is a hallmark of AKI. We recently reported that intracellular lactate triggers the release of  $Mg^{2+}$  from endoplasmic reticulum with subsequent  $Mg^{2+}$  uptake by mitochondria via the mitochondrial  $Mg^{2+}$  channel Mrs2 (Daw et al Cell 2020). High mitochondrial  $Mg^{2+}$  uptake resulted in impaired mitochondrial function. Since lactate accumulation occurs in conditions of impaired oxidative phosphorylation, we explored the role of mitochondrial  $Mg^{2+}$  uptake in ischemic AKI.

**Methods:** We induced ischemic AKI via bilateral clamping of the renal pedicle for 26 minutes in male WT mice and in mice lacking Mrs2 (Mrs2 KO). Kidney function was assessed by measurement of blood urea nitrogen (BUN) and creatinine. Kidney histology was assessed by PAS staining and Ly6G staining for neutrophils.

**Results:** WT mice developed severe loss of renal function (24 hr BUN=99±16 mg/dl, Cr=1.13±.19 mg/dl, n=9), along with elevated KIM1 and NGAL, histologic tubular injury and leukocyte infiltration. In contrast, Mrs2 KO mice had preserved renal function

(BUN=27±7 mg/dl, creatinine=0.48±0.09 mg/dl, n=9, P<0.01 vs WT) and less histologic damage and inflammation. Studies in bone marrow chimeric mice demonstrated that the presence or absence of parenchymal Mrs2, rather than hematopoietic Mrs2, accounted for these differences. CPACC, a novel inhibitor of Mrs2, administered 2 hours prior to ischemia largely prevented ischemic kidney injury (Cr: CPACC 0.35±0.06 mg/dl vs saline 1.47±0.30, P=0.006, n=5). To explore the potential role of lactate in mediating these effects, we administered oxamate, an inhibitor of LDH, which catalyzes the conversion of pyruvate to lactate, prior to ischemia. Mice which received oxamate, sustained significantly less renal dysfunction (BUN 34±5 mg/dl; Cr 0.37±.06 mg/dl), histologic injury and inflammation than saline treated mice (BUN 148±25 mg/dl, Cr 0.93±0.12 mg/dl, P=0.0001). Administration of oxamate 6 hours after ischemia had no protective effect.

**Conclusions:** These results support the view that lactate-triggered  $Mg^{2+}$  uptake into mitochondria is a critical mediator of ischemic AKI and that targeting this pathway may prevent ischemic kidney injury.

**Funding:** NIDDK Support

## FR-OR12

### Proximal Tubule Pannexin 1 Channel Regulates Cell Death and Inflammation During AKI

Nabin Poudel, Shuqiu Zheng, Nataliya Skrypnik, Eibhlín S. Goggins, Christopher B. Medina, Diane L. Rosin, Mark D. Okusa. *University of Virginia, Charlottesville, VA.*

**Background:** Pannexin 1 (Panx1) serves as a conduit for release of small metabolites during cellular stress and injury. Pharmacological inhibition or genetic deletion of *Panx1* in mice is protective against renal ischemia-reperfusion injury (IRI). We hypothesized that proximal tubule Panx1 mediated metabolite release exacerbates AKI by inducing proximal tubule cell death and by increasing inflammatory cell recruitment to the injured kidney.

**Methods:** We performed bilateral IRI or cisplatin-induced AKI (cis-AKI) in a transgenic mouse that overexpresses the human isoform of PANX1 globally (*PANX1<sup>tg</sup>*), specifically in proximal tubules (*PTEC<sup>Ptg</sup>*), or endothelium (*EC<sup>Ptg</sup>*) and evaluated extent of kidney injury. *PANX1* overexpressing proximal tubule epithelial cells (OX) were treated with cisplatin *in vitro* to assess cell death and mitochondrial damage. Flow cytometry was performed to measure leukocyte infiltration in the kidneys after cis-AKI.

**Results:** *PANX1<sup>tg</sup>* mice had significant rise in plasma creatinine and expression of kidney injury marker, *Ngal*, in the kidneys in both models of AKI compared to their littermate controls. *PTEC<sup>Ptg</sup>* mice also had significantly higher injury compared to their littermates in both cis-AKI or IRI-AKI. *In vitro* studies showed that OX cells had higher cisplatin-induced cell death than wildtype (WT) cells. Furthermore, in a co-culture model in which both WT and OX cells were cultured together, OX cells had higher cisplatin-induced cell death. Conditioned media from cisplatin treated OX cells induced higher cell death compared to conditioned media from cisplatin treated WT cells. The higher cisplatin-induced cell death was associated with reduced mitochondrial function and increased mitochondrial ROS production. Assessment of mitochondria in kidneys showed a significant reduction in Drp1 levels in *PANX1<sup>tg</sup>* kidneys compared to WT controls. Cisplatin induced a higher infiltration of neutrophils, CD8-positive T cells, and CD11b-positive dendritic cells in the kidneys of *PTEC<sup>Ptg</sup>* animals compared to WT.

**Conclusions:** We showed that PANX1 overexpression resulted in overt renal injury during AKI that is in part mediated by reduced mitochondrial function, increased cell death, and inflammation. Selective strategies to inhibit Panx1 could help prevent or treat AKI.

## FR-OR13

### Proteomic Analysis Reveals Proteins Associated Exclusively With Urinary Muddy Brown Granular Casts

Michael G. Janech,<sup>1</sup> Elizabeth A. Fongheiser,<sup>1</sup> Noah F. Compton,<sup>1</sup> Alison Bland,<sup>1</sup> Benjamin A. Neely,<sup>3</sup> Vipin Varghese,<sup>2,4</sup> Juan Carlos Q. Velez,<sup>2,4</sup> Ochsner Nephrology <sup>1</sup>College of Charleston, Charleston, SC; <sup>2</sup>Ochsner Medical Center, New Orleans, LA; <sup>3</sup>National Institute of Standards and Technology Material Measurement Laboratory, Charleston, SC; <sup>4</sup>The University of Queensland Ochsner Clinical School - New Orleans, New Orleans, LA.

**Background:** The presence of “muddy” brown granular casts (MBGC) in the urinary sediment is pathognomonic for acute tubular injury (ATI), but the composition of MBGC remains understudied and no proteomic studies have been reported. Because MBGC are only visualized via manual inspection by microscopy, a diagnostic test to identify MBGC without microscopic inspection of the urine could be clinically useful. Unlike most acute kidney injury (AKI) biomarker discovery approaches, we hypothesized that MBGC-enriched urinary sediment (MBGC-sedi) contains unique proteins that could serve as biomarkers of ATI.

**Methods:** MBGC were enriched from 12 patients with AKI using a series of cell strainers (mesh size: 40 - 100µm). Enriched MBGC, matching urine supernatant samples, and urine sediments controls without MBGC (N=6) were proteolytically digested using S-traps and analyzed using tandem mass spectrometry. Proteins were identified by MASCOT and accepted at 1% false discovery. Identified proteins were quantified by weighted spectral count and ranked using exponentially modified protein abundance index (emPAI). ANOVA was utilized to filter proteins that were enriched in MBGC samples versus sediment lacking MBGC or urine supernatant.

**Results:** A total of 3367 proteins were identified across all MBGC samples (mean $\pm$ SD = 1976 $\pm$ 243 proteins/sample). The most abundant proteins in MBGC samples were Ig kappa constant region and retinol-binding protein 4. Although abundant, uromodulin had a mean rank of 15 across all MBGC samples. A total of 272 proteins were higher in MBGC compared to urine supernatant or control sediment without MBGC. Only one protein was exclusive to all MBGC samples, adrenodoxin, a small 19 kDa iron-binding mitochondrial protein known to be expressed in kidney tubules. A second protein, PDZ/LIM domain protein 1 was exclusive to 11 out of 12 MBGC samples and is involved in cytoskeletal stress fiber assembly in fibroblasts.

**Conclusions:** Mitochondrial adrenodoxin (ferredoxin) and PDZ/LIM domain protein 1 may constitute a biomarker of MBGC presence and serve an alternative method to urine microscopy for identifying the presence of MBGC. We conclude that urinary adrenodoxin and PDZ/LIM domain protein 1 are potential target proteins for ATI diagnosis.

## FR-OR14

### Ketone Body Metabolism in Renal Endothelium Triggers PPAR Signaling, Reduces Immune Cell Recruitment, and Preserves Kidney Function Upon Ischemia/Reperfusion Injury

Mila Borri,<sup>1</sup> Sébastien J. Dumas,<sup>1</sup> Elda Meta,<sup>1</sup> Ann Bouché,<sup>1</sup> Pepijn Saraber,<sup>1</sup> Melissa García-Caballero,<sup>1,3</sup> Nuphar Veiga,<sup>1</sup> Joanna Kalucka,<sup>1,2</sup> Guy Eelen,<sup>1</sup> Peter Carmeliet.<sup>1,2</sup> <sup>1</sup>Vlaams Instituut voor Biotechnologie KU Leuven Center for Cancer Biology, Leuven, Belgium; <sup>2</sup>Aarhus Universitet, Aarhus, Denmark; <sup>3</sup>Universidad de Malaga, Malaga, Spain.

**Background:** Renal ischemia/reperfusion injury (IRI), a major cause of acute kidney injury (AKI), affects cellular energy state, induces oxidative stress and immune cell recruitment, ultimately impairing kidney function. Targeting renal endothelial cells (ECs) could prevent kidney dysfunction and improve the outcome for patients with IRI-related AKI. Ketone body supplementation protects against IRI. Renal ECs are directly exposed to circulating ketone bodies but their contribution to the protective effect and possible underlying mechanisms remain unknown.

**Methods:** *Oxct1*<sup>WT</sup> and *Oxct1*<sup>NECKO</sup> mice (lacking the rate-limiting enzyme of ketolysis in ECs) were fed a chow or ketogenic diet (KD) and exposed to sham surgery or bilateral clamping of renal pedicles. Kidney function (plasma markers) and injury (histology) were assessed 24h after reperfusion. Renal ECs were freshly isolated and submitted to bulk RNA-seq. Immune cell populations in kidneys were analyzed by flow cytometry. Gene expression was assessed in *OXCT1*-silenced HUVECs by qPCR.

**Results:** KD improved kidney function, decreased tubule injury and immune cell infiltration in kidneys of mice exposed to renal IRI. These effects were partly impaired in *Oxct1*<sup>NECKO</sup> mice, highlighting the role of EC ketolysis. Transcriptomics analysis of renal ECs upon IRI showed upregulation of immune activation genes and downregulation of metabolic genes involved in fatty acid, arachidonic acid, and glutathione metabolism, among others. KD partially reverted this gene signature in *Oxct1*<sup>WT</sup> ECs, but only to a limited extent in *Oxct1*<sup>KO</sup> ECs. Geneset enrichment analysis identified PPAR signaling as a potential hub downstream of ketolysis, since oppositely regulated by KD and *Oxct1* knockout. *OXCT1*-silenced HUVECs upregulated immune activation genes, suggesting an anti-inflammatory role of ketolysis in ECs.

**Conclusions:** EC ketolysis partly mediated the KD protective effect in a mouse model of renal IRI, by preventing renal EC activation, reducing immune cell recruitment, maintaining a metabolic homeostasis in ECs, and preventing kidney function impairment. Activation of the metabolic regulator PPAR in ECs appears to contribute to this protective mechanism in IRI.

**Funding:** Government Support - Non-U.S.

## FR-OR15

### Kidney Injury Molecule-1 (KIM-1) Shapes the Kidney Immune Microenvironment via Lymphotoxin Beta Receptor (LTbR) Signaling

Naoka Murakami, Shun Kawashima, Yutaro Mori, Samuel Mon-Wei Yu, Takaharu Ichimura, Joseph V. Bonventre. *Brigham and Women's Hospital, Boston, MA.*

**Background:** Tertiary lymphoid tissues (TLTs) are inducible ectopic lymphoid tissues which are found in chronic inflammatory conditions and in various pathologic kidney diseases. However, the mechanisms of TLT formation in kidney and its implication in acute kidney injury are poorly understood.

**Methods:** In an aristolochic acid (AA)-induced kidney injury mouse model, we analyzed the resultant immune microenvironment in KIM-1 wild type (WT) and KIM-1 mutant (delta mucin, functional knockout of KIM-1) animals. Gene expression was examined in kidneys harvested on day 14 after AA treatment (5 mg/kg, intraperitoneal injection, once). Primary mouse kidney tubular epithelial cells (TEC), derived from WT and KIM-1 mutant kidneys were treated with AA and assessed cytokine production. In addition, immune-related gene expression profiles were examined using human kidney biopsy samples.

**Results:** AA treatment induced more prominent TLTs in kidney interstitium in KIM-1 WT animals, associated with higher levels of lymphotoxin beta (LTb) and its receptor (LTbR) expression in the kidneys when compared to results in KIM-1 mutant animals, suggesting that the expression of KIM-1 plays a role in lymphocyte trafficking. Gene expression of chemokine ligand/receptor pairs such as CXCL13/CXCR5, CCL21/CCR7, were also higher in KIM-1 WT compared to KIM-1<sup>delta-mucin</sup> mutants. Primary tubule epithelial cells (TECs) co-cultured with endothelial cells revealed that AA treatment in vitro induced higher CXCL13 and CCL21 secretion in cells derived from WT animals

as compared to TECs isolated from KIM-1<sup>Dmucin</sup> animals, and greater endothelial activation evident by increased PNA<sup>d</sup>. Human kidney biopsy samples from patients with drug-induced AKI confirmed expression of LTb, CXCL13 and CCL21, suggesting the relevance of these molecules in human AKI.

**Conclusions:** KIM-1 expression plays a crucial role on lymphocyte trafficking via inducing expression of LTb/LTbR and chemokines in kidneys. Our data provide novel information to suggest epithelial-endothelial-immune crosstalk and may lead to identification of novel therapeutic targets.

**Funding:** NIDDK Support, Private Foundation Support

## FR-OR16

### Kidney Resident Macrophages Alter MHC II Expression and Location in Response to Acute and Chronic Injury

Elise Erman,<sup>1,2</sup> Kyle H. Moore,<sup>1,2</sup> Matthew D. Cheung,<sup>1,2</sup> Anupam Agarwal,<sup>2</sup> James F. George.<sup>1</sup> <sup>1</sup>The University of Alabama at Birmingham Department of Surgery, Birmingham, AL; <sup>2</sup>The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL.

**Background:** Patients remain at increased risk for developing chronic kidney disease (CKD) after recovery from AKI. The cause of this increased risk is unknown and biomarkers for it are severely lacking. We have identified a subpopulation of kidney injury-associated macrophages (KIA) that appear after AKI and lack MHC II expression. We hypothesize that KIA cells are uniquely involved in the pathogenesis of injury and may be a key to an AKI to CKD transition.

**Methods:** C57BL/6J mice (n=6/grp) were subjected to a bilateral ischemia-reperfusion injury (AKI) or aristolochic acid treatment at doses of 2 mg/kg BW (CKD) or 3 mg/kg BW (severe CKD). KIA cells were localized within the tissue using Visium Spatial Transcriptomics and single-cell RNA sequencing (scRNAseq). The phenotype was validated by flow cytometry. Kidney function was determined using serum creatinine and glomerular filtration rate (GFR).

**Results:** Following AKI, KIA cells are detectable at 24 hours by flow cytometry and at 12 hours by scRNAseq. Spatial transcriptomics shows that KIA cells localize to the cortico-medullary region contiguous with the proximal tubule S3 segments. Differentially expressed genes include those associated with platelets and wound healing. As kidney function recovers, KIA cells decrease in number and return to quiescent levels by 14 days post-injury (p < 0.0001). In contrast, in the severe CKD model, KIA cells persist for up to six weeks, composing approximately 20% of the total kidney resident macrophage population (p = 0.0035). A less severe version of CKD results in fewer KIA cells but similar persistence, suggesting the appearance of KIA cells directly correlates with injury severity. Following a low dose of LPS, KIA cells represent up to 90% of the resident compartment without a significant increase in serum creatinine (p < 0.0001).

**Conclusions:** We conclude that KIA cells may locate at damage sites and may be involved in the AKI to CKD transition. Therefore, targeting KIA cells could potentially reduce CKD risk following AKI.

## FR-OR17

### Tubular Epithelium-Specific Deletion of Megalin Aggravates Ischemia/Reperfusion Kidney Injury and Accelerates the Progression to CKD

Qingtian Li,<sup>1</sup> Michael Holliday,<sup>1,2</sup> Jenny S. Pan,<sup>1,2</sup> David (Daud) Sheikh-Hamad.<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Michael E DeBakey VA Medical Center, Houston, TX.

**Background:** Ischemic AKI may accelerate the progression to ESKD. We have shown stanniocalcin-1 (STC1) activates AMPK and promotes mitochondrial antioxidant defenses through upregulation of uncoupling protein 2 and SIRT3. Transgenic overexpression of STC1 confers resistance to ischemia/reperfusion (I/R) kidney injury. We have shown STC1 is shuttled by megalin from the cell surface to the mitochondria through retrograde-early endosomes-to-Golgi- and Rab32-mediated pathway; knockout of megalin in cultured cells impairs glycolysis and mitochondrial respiration. In the current experiments, we sought to determine kidney phenotype after I/R kidney injury in mice with tubular epithelium-specific deletion of megalin.

**Methods:** We generated mice (on C57B/6 background) with tubular epithelium-specific KO of megalin (Lrp2f/f;Pax8rtTA;LC1-Cre; referred to as tLrp2KO) and combined tubular epithelium-specific KO of megalin and overexpression of STC1 (Lrp2f/f;tetOhSTC1;Pax8rtTA;LC1-Cre; referred to as tLrp2KO;ISTC1O), upon treatment with Doxycycline. Eight -12 weeks old mice were subjected to 30 min ischemia (clamping both renal pedicles) followed by reperfusion. Mice were euthanized after 1, 3, 10 and 45 days, blood was collected for creatinine measurement, and kidneys were harvested for analyses.

**Results:** Compared with I/R in control mice, I/R in tLrp2KO mice was associated with more severe AKI (higher NGAL and serum creatinine), greater inflammation and fibrosis. Kidney injury was less severe in female mice; but, the injury was greater in female tLrp2KO mice. Kidney injury was not rescued in tLrp2KO;ISTC1O mice, consistent with megalin-dependent STC1-mediated renal protection from I/R. I/R in tLrp2KO mice was associated with exaggerated inflammatory response that persisted through day 45, diminished tubular epithelial cell proliferation, upregulation of TGF- $\beta$  signaling and fibrosis, and accelerated CKD progression. CRISPR-Cas-mediated knockout of megalin in cultured proximal tubular epithelial cells (BUMPT) upregulates TGF- $\beta$  signaling, induces cell cycle arrest, impairs mitogenesis and diminishes autophagosome clearance.

**Conclusions:** Tubular epithelium-specific deletion of megalin aggravates I/R kidney injury and accelerates the progression to CKD.

**Funding:** Veterans Affairs Support

## FR-OR18

**The Role of the Circadian Clock System in the Transition From AKI to CKD**

Yina Fang, Ko Yoon Sook, Lee Hee Young, Sewon Oh, Young Eun Choi, Suk Min Chung, Sungyeon Kim, Sang-Kyung Jo, Myung-Gyu Kim. *Korea University Anam Hospital, Seoul, Republic of Korea.*

**Background:** Recent studies suggest that circadian rhythms are an important factor in maintaining healthy kidney functions; however, its role in acute kidney injury (AKI) remains unclear.

**Methods:** To investigate the role of tubule-specific clock gene disturbance in hypoxic tubular injury, we created human proximal tubule-specific *BMAL1* KO cells using CRISPR-Cas9 gene editing. In mice, we also determined whether time-restricted feeding (TRF), a dietary strategy to enhance circadian rhythm, can have beneficial effect on recovery of ischemia reperfusion injury (IRI) or its progression to chronic kidney disease (CKD).

**Results:** *BMAL1* loss in tubule cells resulted in the upregulation of cell cycle regulatory gene (p21) and inflammatory genes (TNF- $\alpha$  and CCL4) mRNA expression, suggesting that *BMAL1* is a critical regulator of these genes. Exposure to hypoxia for 48 h resulted in more increased expressions of p21 in *BMAL1* KO cells than in WT HK-2 cells, leading to higher expression of TGF- $\beta$ . In addition, loss of *BMAL1* led to significantly increased vimentin and decreased E-cadherin expression upon TGF- $\beta$  stimulation, suggesting an aggravated epithelial-mesenchymal transition upon *BMAL1* deletion. To clarify the role of clock system in AKI, we also tested whether TRF can have a beneficial effect during recovery phase after IRI. Despite limited access to food, TRF for 4 weeks after IRI had no effect on the total intake or weight of mice. However, we observed that TRF significantly improved renal function on day21 and reduced renal fibrosis on day28, which suggests that enhancing clock gene oscillations through restoring fasting/feeding cycle has a protective effect in the AKI to CKD transition.

**Conclusions:** We identified an important role of clock system in hypoxic tubular injury and the effects of treatment targeting circadian rhythm in AKI. Our results can provide a new perspective for developing novel therapeutic strategies for AKI.

## FR-OR19

**TIGIT Modulates Kidney T Cell Memory Phenotype and Metabolic Profile and Mediates Both Ischemic and Nephrotoxic AKI in Mice**

Sanjeev Noel, Kyungho Lee, Sepideh Gharaie, Johanna T. Kurzhagen, Lois J. Arend, Patrick Cahan, Hamid Rabb. *Johns Hopkins University, Baltimore, MD.*

**Background:** T cells play pathogenic and reparative roles in acute kidney injury (AKI) but mechanisms regulating their functions are poorly understood. We found upregulated expression of the novel immune checkpoint molecule T cell immunoreceptor with Ig and ITIM domains (TIGIT) on kidney CD4 T cells after ischemia reperfusion (IR) using RNA-Seq. We explored TIGIT effect on kidney T cells, AKI outcomes and mechanisms.

**Methods:** TIGIT effect on murine kidney T cells was assessed at baseline and after ischemic AKI by flow cytometry and single cell RNA sequencing (scRNA-Seq). B6 wild type (WT) and TIGIT knockout (KO) mice were studied during ischemic and cisplatin-induced AKI. TIGIT expression was assessed in AKI patients using the Kidney Precision Medicine Project (KPMP) scRNA-Seq dataset.

**Results:** Ischemic AKI in WT mice led to an increase in kidney CD4+TIGIT+ effector memory (EM; 79.4 $\pm$ 3.9 vs 65.4 $\pm$ 5.4%, p=0.05) and central memory (CM; 10.0 $\pm$ 2.3 vs 0.9 $\pm$ 0.1%, p=0.001) cells compared to CD4+TIGIT- cells. CD4+TIGIT+ T cells had increased mean fluorescent intensity (MFI) of CD44 and reduced MFI of CD62L at baseline and after IR injury. TIGIT KO mice had significantly reduced serum creatinine (Scr) after IR (24h Scr, 1.1 $\pm$ 0.2 vs 2.7 $\pm$ 0.1 mg/dL; p $\leq$ 0.001) and cisplatin (72h Scr, 0.8 $\pm$ 0.1 vs 1.4 $\pm$ 0.1 mg/dL; p=0.0002) injury compared to WT mice. TIGIT KO kidneys had significantly reduced necrotic tubules in outer medulla after IR (48.8 $\pm$ 4.7% vs 73.0 $\pm$ 1.5%; p=0.001) and cisplatin (11.5 $\pm$ 3.0% vs 31.3 $\pm$ 4.0%; p=0.008) injury than WT kidneys. scRNA-Seq analysis showed enrichment of inflammatory genes in Th1 and Th17 cells from WT kidney. Th1 and Th17 cells from TIGIT KO kidney had an enrichment of oxidative phosphorylation and mTORC1 signaling related genes. Human KPMP data demonstrated increased TIGIT expression in kidney T/NK cells of AKI patients compared to controls (p $\leq$ 0.0001).

**Conclusions:** TIGIT is a direct pathophysiologic mediator of both experimental ischemic and nephrotoxic AKI. Kidney CD4 TIGIT expression correlated with effector and central memory phenotype, and distinct inflammatory/metabolic transcriptional profiles. TIGIT expression also increased in kidney T cells from AKI patients. TIGIT is a promising novel therapeutic target for AKI, and also relevant due to increasing use of TIGIT blockade to treat cancer.

**Proximal Tubular Epithelial Cell States in KPMP Protocol Kidney Biopsies Are Linked to Short-Term AKI Patient Outcomes**

Jennifer A. Schaub,<sup>1</sup> Rajasree Menon,<sup>1</sup> Pavan K. Bhatraju,<sup>2</sup> Ricardo Melo ferreira,<sup>3</sup> Blue Lake,<sup>8</sup> Edgar A. Otto,<sup>1</sup> Rachel S. Sealfon,<sup>3</sup> Olga Troyanskaya,<sup>3</sup> Jeffrey B. Hodgin,<sup>1</sup> Laura Barisoni,<sup>4</sup> Michael T. Eadon,<sup>5</sup> Kun Zhang,<sup>8</sup> Angela M. Victoria Castro,<sup>6</sup> Francis P. Wilson,<sup>6</sup> Raghavan Murugan,<sup>7</sup> Matthew R. Rosengart,<sup>7</sup> Paul M. Palevsky,<sup>7</sup> Sanjay Jain,<sup>2</sup> Jonathan Himmelfarb,<sup>2</sup> Matthias Kretzler.<sup>1</sup> KPMP <sup>1</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>2</sup>Washington University in St Louis, St Louis, MO; <sup>3</sup>Princeton University, Princeton, NJ; <sup>4</sup>Duke University School of Medicine, Durham, NC; <sup>5</sup>Indiana University, Bloomington, IN; <sup>6</sup>Yale School of Medicine, New Haven, CT; <sup>7</sup>University of Pittsburgh, Pittsburgh, PA; <sup>8</sup>University of California San Diego, La Jolla, CA.

**Background:** Acute Kidney Injury (AKI) is a heterogeneous syndrome making it challenging to identify biological underpinnings for poor outcomes. Linking sub-phenotypes, such as resolving and non-resolving AKI, with single cell RNA sequencing data may help identify relevant biologic signatures. As part of Kidney Precision Medicine Project (KPMP), we performed an integrated tissue level analysis from 19 participating AKI patients.

**Methods:** Clinical assessment of AKI resolution 72 hours post diagnosis was performed on the AKI patients, classified as ‘resolving’ versus ‘non-resolving’. Resolving AKI was defined as “decrease in the concentration of sCr of 0.3 mg/dl or more or 25% or more from maximum in the first 72 hours after AKI diagnosis” (PMC7154800). Single cell and single nucleus analyses (sc/sn) (10x Chromium) and spatial transcriptomic data (visium) were performed on biopsy samples from AKI patients. Cell clusters were annotated using the integrated analysis of AKI sc/sn datasets per KPMP atlas (bioRxiv 2021.07.28.454201).

**Results:** 107,119 sc/sn post QC from the 19 AKI samples clustered to 71 cell types/states. A global differential expression analysis across all cell types/states between resolving (n=6) and non-resolving (n=13) samples resulted in 231 genes that were significantly differentially expressed (adj p value < 0.05). Majority of these genes were enriched in the degenerative (5,990 sc, 4,177 sn) and adaptive (6,134 sc, 13,237 sn) states of the proximal tubular epithelial cell; Immune-related processes were enriched for these genes. Ligand receptor analysis indicated multiple potential interactions between T cells and these two proximal tubular cell states. Moreover, we were able to identify a similar adaptive proximal cell state using spatial transcriptomic technology in resolving AKI kidney biopsy tissue.

**Conclusions:** Using integrated analysis of single cell expression data with a clinical assessment variable, we identified a molecular signature enriched in adaptive and degenerative cell states of proximal epithelial cells linked to short term outcomes in AKI.

## FR-OR21

**Air Pollution, Genetic Factors, and the Risk of Incident CKD: A Prospective Study of Polygenic Risk Score Analysis in the UK Biobank**

Boram Weon,<sup>1</sup> Jeonghwan Lee,<sup>2,1</sup> Jung Pyo Lee,<sup>2,1</sup> Chun Soo Lim.<sup>2,1</sup> <sup>1</sup>Seoul National University Boramae Medical Center, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Both genetic and environmental factors contribute to chronic kidney disease (CKD), but the degree to which air pollution modifies the impact of genetic susceptibility on CKD remains unknown. We aimed to investigate the effects and their interaction of air pollution and genetic factors on incident CKD.

**Methods:** We analyzed data from 350,994 participants (53% women) without previous CKD at baseline in the UK Biobank. The concentrations of particulate matter (PM) <2.5 mm in aerodynamic diameter [PM<sub>2.5</sub>], coarse PM between 2.5 mm and 10 mm in aerodynamic diameter [PM<sub>coarse</sub>], and PM <10 mm in aerodynamic diameter [PM<sub>10</sub>], nitrogen dioxide (NO<sub>2</sub>), and nitrogen oxides (NO<sub>x</sub>) were estimated by using land-use regression models, and the association between air pollutants and incident CKD was investigated by using a Cox proportional hazard model. Furthermore, we constructed a polygenic risk score and evaluated whether air pollutants modified the effect of genetic susceptibility on the development of CKD.

**Results:** The results showed significant associations between the risk of CKD and PM<sub>2.5</sub> (hazard ratio [HR], 1.21; 95% confidence interval [CI], 1.06–1.37) and NO<sub>x</sub> (HR, 1.19; 95% CI, 1.05–1.35). There were additive interactions between air pollutants and the genetic risk in PM<sub>10</sub> and PM<sub>coarse</sub>. Compared with participants with high genetic risk score groups, those with high air pollution exposure and low genetic risk showed significantly increased hazards for incident CKD (PM<sub>2.5</sub>: HR, 1.21; 95% CI, 1.06–1.37; NO<sub>x</sub>: HR, 1.19; 95% CI, 1.05–1.35).

**Conclusions:** Long-term exposure to air pollution may increase the risk of CKD, especially in those with low genetic risk.

Fig.1. The effect of PM2.5 exposure on hazard ratio (HR) for CKD according to the polygenic risk score (PRS) tertiles (Restrictive Cubic Spline curves).

Fig.2. The effect of NOx exposure on hazard ratio (HR) for CKD according to the polygenic risk score (PRS) tertiles (Restrictive Cubic Spline curves).

FR-OR22

Time-Dependent Risk Differences in Kidney Failure and Death Between Black and White Veterans Following Incident CKD

Guofen Yan,<sup>1</sup> Robert Nee,<sup>2</sup> Julia J. Scialla,<sup>1</sup> Wei Yu,<sup>1</sup> Tom Greene,<sup>3</sup> Alfred K. Cheung,<sup>3,4</sup> Keith C. Norris.<sup>5</sup> <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>Walter Reed National Military Medical Center, Bethesda, MD; <sup>3</sup>University of Utah Health, Salt Lake City, UT; <sup>4</sup>VA Salt Lake City Health Care System, Salt Lake City, UT; <sup>5</sup>University of California Los Angeles, Los Angeles, CA.

**Background:** Recent research indicates that among US veterans with incident CKD defined using the new 2021 CKD-EPI creatinine equation, Black patients had 27-37% higher adjusted rates of kidney failure (KF) than White patients. We examined whether this higher rate persisted in the entire course of CKD or only within a certain time period following incident CKD.

**Methods:** The study included 180,881 non-Hispanic White and 32,187 non-Hispanic Black veterans, aged 18-90 years, with incident CKD from 2003-2008 in the US Veterans Health Administration, followed through 2018. Incident CKD was defined by the first time when two eGFR values >3 months apart were both <60 mL/min/1.73 m<sup>2</sup> using the 2021 CKD-EPI equation. We calculated cause-specific hazard ratios (HR) of KF, censoring on death, and HRs of death (including death after KF) for Blacks versus Whites in five consecutive 2-year intervals for a total of 10 years, adjusting for demographics, clinical factors, and comorbidities.

**Results:** At incident CKD, Black veterans were on average younger than White veterans (66 and 74 years, respectively) with similar mean eGFR (50-51 mL/min/1.73 m<sup>2</sup>). Over 10 years of follow-up, the adjusted risk of KF was 30% greater in Blacks than in Whites (Table), but this difference was more pronounced over the early years of CKD onset (e.g., 38% greater risk in years 0-2) than at later years (only 8% greater risk, p>0.05 in years 8-10). Despite the overall similar adjusted mortality risks after adjusting for major confounding of age along with other covariates, the difference evolved over time, with a greater adjusted risk of death for Blacks during the first 4 years of CKD onset, followed by a lower risk thereafter. These risk differences over time were consistent across subgroups such as those with and without specific comorbidities (e.g., hypertension, diabetes, or cardiovascular diseases).

**Conclusions:** Black individuals are particularly susceptible to adverse outcomes during the first several years of CKD onset, which demands a stronger urgency for close evaluation in the earlier years of CKD to improve outcomes.

**Funding:** NIDDK Support

Adjusted HRs (95% CIs) for Black versus White veterans in years after incident CKD

Outcome	The entire 10-year period	Years after CKD onset				
		0-2	2-4	4-6	6-8	8-10
Kidney failure	1.30 (1.24-1.37)	1.38 (1.26-1.52)	1.44 (1.31-1.57)	1.32 (1.20-1.45)	1.23 (1.11-1.36)	1.08 (0.96-1.21)
Death	1.01 (0.99-1.03)	1.27 (1.23-1.32)	1.07 (1.03-1.11)	0.95 (0.91-0.99)	0.94 (0.91-0.98)	0.83 (0.82-0.89)

FR-OR23

Protein Carbamylation and the Risk of CKD Progression

Sahir Kalim,<sup>1,2</sup> Sophia Zhao,<sup>3</sup> Mengyao Tang,<sup>1</sup> Eugene P. Rhee,<sup>1,2</sup> Andrew S. Allegretti,<sup>1,2</sup> Sagar U. Nigwekar,<sup>1,2</sup> James P. Lash.<sup>4</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Analytica Now, Brookline, MA; <sup>4</sup>University of Illinois Chicago, Chicago, IL.

**Background:** Protein carbamylation, a post-translational protein modification driven by urea, associates with mortality and adverse outcomes in ESKD, but less is known about its relationship to clinical outcomes in earlier stages of CKD.

**Methods:** In 3,111 patients with CKD stages 2 through 4 enrolled in the Chronic Renal Insufficiency Cohort study, we evaluated an established protein carbamylation marker (carbamylated albumin, C-Alb) as a risk factor for ESKD (primary); the composite ESKD or 50% decline in eGFR; and death.

**Results:** Participant demographics included mean [SD] age 59 [10.8] years; 1358 (43.7%) female; 1334 (42.9%) white. The mean [SD] eGFR at the time of C-Alb assessment was 41.8 [16.4] mL/min/1.73m<sup>2</sup> and the median [IQR] C-Alb value was 7.8 mmol/mol [5.8 - 10.7]. During an average of 7.9 [4.1] years of follow up, 981 (31.5%) individuals reached the outcome of ESKD, and 1175 (37.8%) individuals reached the composite end point of ESKD or a 50% decline in eGFR. In multivariable adjusted Cox models, on a continuous scale or in quartiles, higher C-Alb levels independently associated with a monotonically increasing risk of both ESKD and the composite endpoint. Compared with quartile 1 (C-Alb ≤ 5.80 mmol/mol) those in quartile 4 (C-Alb > 10.71 mmol/mol) had a greater risk for ESKD (adjusted hazard ratio [HR], 2.29; 95% confidence interval [CI] 1.75-2.99), as well as a greater risk for the composite endpoint (HR 2.01; CI 1.59-2.53). Moreover, the top C-Alb quartile had a 1.58 (95% CI, 1.25 - 2.01) times increased risk of death compared to the bottom quartile. The results remained significant across numerous sub-group analyses, when treating death as a competing event in CKD progression analyses, using different assessments of eGFR, and after adjustment for blood urea nitrogen levels. Measures of risk discrimination showed significant improvement when C-Alb was added to fully adjusted models.

**Conclusions:** These results reflect the largest study of carbamylation in humans to date. Higher levels of protein carbamylation as measured by circulating C-Alb levels were an independent risk factor for CKD progression, ESKD, and death in individuals with CKD stages 2 to 4. Future studies should evaluate whether therapeutic interventions to prevent or lower carbamylation can improve CKD outcomes.

FR-OR24

Changes in CKD Prevalence in the United States Using the Age-Adapted CKD Classification System

Maria Clarissa Tio,<sup>1</sup> Aliba Syed,<sup>2</sup> Elani Streja,<sup>2</sup> Rajesh Talluri,<sup>1</sup> Yoshitsugu Obi,<sup>1</sup> Tariq Shafi,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>2</sup> <sup>1</sup>University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>University of California Irvine, Irvine, CA.

**Background:** Current eGFR criteria for diagnosing CKD (eGFR<60 mL/min/1.73m<sup>2</sup>) do not take an individual's age into consideration. An age-adapted CKD definition was recently proposed (JASN 2019). We determined the changes in CKD prevalence in the US, comparing the current KDIGO classification system (CKD-KDIGO) to an age-adapted CKD classification system (CKD-Age).

**Methods:** We analyzed data from the 2017-2020 National Health and Nutrition Examination Survey (NHANES; N=8,016). CKD-KDIGO was defined as having a CKD-EPI 2021 eGFR <60 mL/min/1.73m<sup>2</sup> or ACR ≥30 mg/g. CKD-Age was defined as proposed: eGFR <75 mL/min/1.73m<sup>2</sup> for ages 18 to <40 years, eGFR <60 mL/min/1.73m<sup>2</sup> for ages 40 to 65 years, eGFR <45 mL/min/1.73m<sup>2</sup> for ages >65 years, or ACR ≥30 mg/g. We used reclassification tables to determine changes in CKD prevalence.

**Results:** The US CKD population has a mean age of 60 years. Among the 31 million persons with CKD-KDIGO, 39.4% were 18 to <40 years old, 43.4% were 40-65 years, and 17.2% were >65 years. Median age is 71 years for CKD-KDIGO G3A, 76 years for G3B, 78 years for G4, and 63 years for G5. Using the CKD-Age classification, 5.2 million (16.7%) of those with CKD-KDIGO were reclassified to being CKD-free (Table 1). 1.2 million (0.6%) of those without CKD were reclassified to having CKD-Age and all of these individuals were 40-65 years old.

**Conclusions:** Age-based CKD classification may prevent overdiagnosis of CKD in older individuals and identify younger individuals with low eGFR at risk for kidney failure, allowing prioritization of care.

**Funding:** Other NIH Support - NIGMS

Table 1: Changes in CKD Prevalence Using the Current KDIGO Classification (CKD-KDIGO) vs. the Age-Adapted CKD Classification System (CKD-Age)

CKD-KDIGO	Total	CKD-Age	
		Not CKD	CKD
Not CKD	195.2 million (99.4%)	195.2 million (99.4%)	1.2 million (0.6%)
CKD	5.2 million (16.7%)	5.2 million (16.7%)	26 million (83.3%)
Total	200.4 million (88.1%)	200.4 million (88.1%)	27.1 million (11.9%)

## FR-OR25

**Dipstick Urinalysis Protein and Specific Gravity Can Identify Patients With Early CKD Who Lack a Quantified Proteinuria Measurement**

Meredith C. McAdams, Michael M. Li, Pin Xu, Duwayne L. Willett, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Urine albumin-to-creatinine ratio (UACR) >30 mg/g or protein-to-creatinine ratio (UPCR) >0.15 g/g are the gold standard cutoffs for diagnosing early stages of CKD for patients with preserved estimated glomerular filtration rates (eGFR) >60 mL/min, but these tests are not commonly obtained. Dipstick urinalysis protein (DSP) is a widely-available and routinely obtained test that provides a semi-qualitative measurement of albuminuria but is affected by urine specific gravity (SG).

**Methods:** We conducted an analysis using the EPIC electronic health records of 11,229 patients with a UPCR or UACR value obtained on the same day as a urinalysis. Prognostic utility of various DSP cutoffs (negative/trace, 30, 100, 300, and ≥500 mg/dL) were compared to clinically significant proteinuria (UACR >30 mg/g or UPCR >0.15 g/g). Predictive models for proteinuria were built using DSP, adjusted for SG and assessed with receiver operating characteristic (ROC) curves comparing areas under the curve (AUC). 10-fold cross-validation was performed.

**Results:** Of 11,229 included, 4073 (36%) had clinically significant proteinuria based on gold standard definitions. 54.0% were female, 27.5% had diabetes mellitus, 51.3% hypertension, and 11.9% cardiovascular disease. A DSP of 30 mg/dL had an odds ratio (OR) (95% CI) of 5.84 (5.22, 6.52) and 9.92 (8.73, 11.27), when adjusted for SG, to predict proteinuria. A DSP of 100 mg/dL had an OR of 44.63 (95% CI 36.11, 55.15) and 77.66 (95% CI 61.67, 97.80), when adjusted for SG. A DSP value ≥300 mg/dL had an OR of 278.37 (95% CI 115.00, 673.81) and 495.91 (95% CI 202.03, 1, 217.26) in the SG adjusted model. Addition of SG to DSP improved the AUC to 0.824 (95% CI 0.815, 0.833) from 0.765 (95% CI, 0.756, 0.773) for DSP alone, P<.001. The final model including SG had a specificity of 93%, positive predictive value of 83%, negative predictive value of 80%, and positive and negative likelihood ratios of 9.52 and 0.43. Optimal predicted SG cutoffs to use for each DSP value were negative/trace=1.001; 30 mg/dL=1.024; 100 mg/dL=1.044; ≥300 mg/dL=1.063.

**Conclusions:** Combining DSP and SG from dipstick urinalysis can accurately determine clinically significant proteinuria to identify patients with early stages of CKD in clinical practice.

## FR-OR26

**Dapagliflozin Effect on Hospital Admissions in Patients With CKD: A Post Hoc Analysis of the DAPA-CKD Trial**

Meir Schechter,<sup>1,7</sup> Niels Jongs,<sup>1</sup> Glenn Chertow,<sup>2</sup> Ofri Mosenzon,<sup>7,11</sup> John McMurray,<sup>3</sup> Ricardo Correa-Rotter,<sup>4</sup> Peter Rossing,<sup>5</sup> Anna Maria Langkilde,<sup>6</sup> David Sjöström,<sup>6</sup> Robert D. Toto,<sup>8</sup> David C. Wheeler,<sup>9</sup> Hiddo J. L. Heerspink.<sup>1,10</sup>  
<sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Stanford University School of Medicine, Stanford, CA; <sup>3</sup>University of Glasgow, Glasgow, United Kingdom; <sup>4</sup>National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; <sup>5</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>6</sup>AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; <sup>7</sup>Hadassah University Medical Center, Jerusalem, Israel; <sup>8</sup>UT Southwestern Medical Center, Department of Internal Medicine, Dallas, TX; <sup>9</sup>University College London Faculty of Medical Sciences, London, United Kingdom; <sup>10</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>11</sup>Hebrew University of Jerusalem Faculty of Medicine, Jerusalem, Israel.

**Background:** The DAPA-CKD trial demonstrated that the sodium glucose co-transporter 2 inhibitor dapagliflozin improves kidney and cardiovascular outcomes in patients with chronic kidney disease (CKD) with or without type 2 diabetes (T2D). In a post-hoc analysis, we investigated the effect of dapagliflozin on all-cause hospital admissions (ACHA).

**Methods:** We randomized 4304 adults with estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73m<sup>2</sup> and urinary albumin-to-creatinine ratio (UACR) 200–5000 mg/g to either dapagliflozin 10 mg or placebo once daily (1:1). Treatment effects on first and all (first and recurrent) ACHA were assessed in the whole population and in the prespecified eGFR (<45 or ≥45 mL/min/1.73m<sup>2</sup>) and UACR (≤1000 or >1000 mg/g) subgroups. We used the system organ class classification as reported by investigators to evaluate the effects of dapagliflozin on different causes of admission. Admissions were analyzed using Cox-proportional hazards regression models (first ACHA), the Lin-Wei-Ying-Yang method (all ACHA), and negative binomial models (all admissions related to specific causes).

**Results:** Over a median follow-up of 2.4 years, ACHA occurred in 566 (26.3%) patients in the dapagliflozin group and 658 (30.6%) in the placebo group. Compared to placebo, dapagliflozin reduced the risk of first ACHA (HR 0.84 [95% CI 0.75–0.94]; P<0.001; number needed to treat over the study period of 23 [95% CI 14–63]) and all ACHA (RR 0.79 [95% CI 0.70–0.89]; P=0.002). The effect of treatment was consistent across the eGFR and UACR subgroups (P-interaction ≥0.215). Compared to placebo, dapagliflozin reduced the rate of admissions due to cardiac disorders (438 events; RR 0.67 [95% CI 0.53–0.86]), renal and urinary disorders (313 events; RR 0.61 [95% CI 0.46–0.79]), metabolism and nutrition disorders (134 events; RR 0.61 [95% CI 0.41–0.91]), and neoplasms (84 events; RR 0.62 [95% CI 0.39–0.96]; all P≤0.033).

**Conclusions:** Dapagliflozin reduced the risk of ACHA among patients with CKD, with or without T2D. These findings may have significant implications for quality of life in individual patients and the overall healthcare burden and expenditure attributed to CKD.

**Funding:** Commercial Support - AstraZeneca

## FR-OR27

**Notch Blockade Specifically in FSP-1-Positive Cells Ameliorates Renal Fibrosis by Attenuating Inflammation**

Jizhong Cheng,<sup>1</sup> Ming Liang,<sup>1,2</sup> Yongdong Wu,<sup>1</sup> Tae Hoon Lee,<sup>1</sup> William E. Mitch,<sup>1</sup> Luan D. Truong,<sup>3</sup> *<sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>South China University of Technology, Guangzhou, China; <sup>3</sup>Houston Methodist, Houston, TX.*

**Background:** The infiltration of inflammatory cells during kidney injury stimulates myofibroblast activation leading to kidney fibrosis. Fibroblast specific protein 1 (FSP-1) positive cells have been reported as myofibroblast and monocytes during tissue fibrosis. The function and regulation of the FSP-1<sup>+</sup> cells have not been well investigated.

**Methods:** In current study, the FSP-1<sup>+</sup> cells were characterized and the role of Notch signaling in activation of these cells was determined during kidney fibrosis.

**Results:** After creating unilateral ureteral obstruction (UUO), the FSP-1<sup>+</sup> cells were significantly accumulated in the tubulointerstitial area. Only few FSP-1<sup>+</sup> cells (< 5%) expressed markers of myofibroblasts, in contrast, most of the FSP-1<sup>+</sup> cells costained with inflammatory cell markers (CD45, F4/80). This observation was further confirmed obstructed kidneys in FSP-1 reporter mice (FSP-1-GFP). Most of GFP<sup>+</sup> cells (FSP-1<sup>+</sup> cells, > 90%) were positive for myeloid cell marker. Moreover, these GFP<sup>+</sup> cells were found in obstructed kidneys in WT mice that were transplanted with bone marrow from FSP-1-GFP reporter mice. These results indicate that FSP-1<sup>+</sup> cells represent a bone marrow-derived specific inflammatory cell population. Notably, the levels of Notch targets were increased in UUO, and activated Notch1 co-expressed with FSP-1 in cells in tubulointerstitium. *In vitro*, the isolated bone marrow FSP-1<sup>+</sup> cells were differentiated into functional type I and type II macrophage after treatment with LPS or IL-4, respectively. Inhibition of Notch signaling blocked activation and cytokine secretion of FSP-1<sup>+</sup> cells that were induced by LPS, but not by IL-4. In mice, specific KO of RBP-Jk in bone marrow FSP-1<sup>+</sup> cells suppressed UUO-induced ECM deposition, inflammatory cell accumulation, cytokine production, and interstitial fibrosis. Furthermore, inducible expression of dominant negative mastermind1, the co-activator of Notch signaling, in FSP-1<sup>+</sup> cells ameliorated myofibroblast activation and renal fibrosis in obstructed kidneys.

**Conclusions:** In conclusion, our study reveals that most of FSP-1<sup>+</sup> cells in obstructed kidneys are activated macrophage that are derived from bone marrow, Notch signaling activates the production of M1 cytokines in FSP-1<sup>+</sup> monocytes/macrophage, which is important for renal inflammation and fibrosis.

## FR-OR28

**Cyclin G1 Promotes Proximal Tubule Cell Maladaptive Dedifferentiation and Fibrosis in CKD**

Bertha C. Elias, Kensei Taguchi, Sho Sugahara, Craig R. Brooks. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Acute Kidney Injury (AKI) frequently occurs in hospitalized patients and predisposes them to developing chronic kidney disease (CKD). This AKI-to-CKD transition promotes irreversible fibrosis, loss of kidney function, and ultimately organ failure. Though the exact molecular mechanisms that are involved in this process are unclear, we and others have shown that maladaptive repair of proximal tubule cells (PTC), G2-M cell cycle arrest, PTC dedifferentiation, upregulation of senescence markers, and secretion of profibrotic cytokines are features of the AKI-to-CKD transition. Here we directly test whether cyclin G1 promotes fibrosis through G2-M arrest of PTCs.

**Methods:** Male BL57Bl/6 (WT) and cyclin G1 knockout (CG1KO) littermates age 8-12 weeks were subjected to 3 different kidney injury models: aristolochic acid nephropathy (AAN), repeat low-dose cisplatin, and unilateral ureter obstruction (UUO) models. Paclitaxel was used to induce G2/M arrest. The expression of cyclin G1, fibrotic markers, and dedifferentiation markers were measured by immunofluorescence, protein expression and/or mRNA levels.

**Results:** Kidney fibrosis, G2-M arrest and the expression of dedifferentiation markers were all reduced in CG1KO mice when compared to wild-types in all three injury models tested. Treatment with paclitaxel increased G2-M arrest in AAN injured CG1KO mice to similar levels to AAN + paclitaxel treated wild-type mice; however, wild-type mice showed significantly lower kidney function and increased kidney fibrosis compared to CG1KO mice following treatment. While deletion of cyclin G1 did not reduce the number of dedifferentiated cells in the acute phase of injury, the number of dedifferentiated cells in the chronic phase of injury were greatly reduced in all three models tested. Paclitaxel/G2-M arrest did not induce dedifferentiation in CG1KO mice. CG1KO primary PTCs were resistant to AAN and/or paclitaxel induced dedifferentiation and did not develop senescence markers or profibrotic cytokine secretion.

**Conclusions:** Cyclin G1 regulates G2-M arrest but G2-M arrest in the absence of dedifferentiation does not affect AKI-to-CKD transition. CG1 promotes maladaptive dedifferentiation possibly by activation of CDK5. Inhibition of CG1 and/or CDK5 may be a promising therapeutic strategy to prevent AKI to CKD transition.

## FR-OR29

**PRDM16 Protected Tubular Mitochondrial Function and Attenuated Renal Fibrosis by Upregulating PGC-1 $\alpha$** 

Qian Yuan, Ben Tang, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

**Background:** The kidney is a high oxygen consumption organ with abundant mitochondria. However, in the kidney of chronic kidney disease (CKD) patients or animals, mitochondria in tubules were decreased and destroyed. Similarly, brown adipocytes with rich mitochondria converted into white adipocytes with rare mitochondria due to loss of PRDM16. Thus, we proposed that PRDM16 preserved tubular mitochondria and attenuated renal fibrosis.

**Methods:** Male C57BL/6J mice with 8 weeks were operated with unilateral ureteral obstruction (UUO) and unilateral ischemia-reperfusion (UIRI) surgery. Kidneys and blood were collected. Western Blot, qPCR, and immunohistochemical staining (IHC) were used to test the expression of PRDM16 in injured kidneys. Lentivirus was used to overexpress PRDM16 in HK2 cells, and UUO and UIRI models. RNA-sequencing, Western Blot, qPCR, IHC, ATP detecting, Oil-red staining, mito-tracker staining, Masson's staining, renal function detecting, and electron microscope were used to verify the renal protected role of PRDM16 in vivo and in vitro. Tubular-specific PRDM16 knockout mice were generated. PGC-1 $\alpha$  agonist ZLN-005, p-Smad3 inhibitor SIS3, DNA-pull down, ChIP, Co-IP, and luciferase assay were used to verify the mechanism of PRDM16.

**Results:** The results showed PRDM16 was largely expressed by tubular epithelial cells of healthy kidneys, but decreased greatly in injured kidneys. TGF- $\beta$  mediated the depression of PRDM16 in Smad3 dependent way. PRDM16 overexpression inhibited TGF- $\beta$  induced mitochondrial dysfunction and restored PGC-1 $\alpha$  levels in vitro. And PRDM16 attenuated renal fibrosis, and preserved mitochondrial function and PGC-1 $\alpha$  levels in UUO and UIRI models. However, the kidney injury was worse in PRDM16 tubular-specific knockout mice who suffered from UUO and UIRI surgery, and the effects can be attenuated by the PGC-1 $\alpha$  agonist, ZLN-005. Mechanistically, PRDM16 upregulated the expression of PGC-1 $\alpha$  by directly binding to the promoter of PGC-1 $\alpha$ .

**Conclusions:** PRDM16 was highly expressed by normal tubular epithelial cells but decreased greatly in injured kidneys. The downregulation of PRDM16 was mediated by TGF- $\beta$  in Smad3 dependent way. PRDM16 overexpression attenuated renal fibrosis and protected tubular mitochondrial function. Mechanistically, PRDM16 upregulated the expression of PGC-1 $\alpha$  by directly binding to the promoter of PGC-1 $\alpha$ .

## FR-OR30

**Unbiased Human and Mouse Kidney Metabolomics Identifies the Key Role of NAD Metabolism in Kidney Disease Development**

Tomohito Doke, Katalin Susztak. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

**Background:** The kidney is a highly metabolically active organ and plays a key role in organismal metabolism. Changes in human kidney metabolism have been analyzed in an unbiased manner.

**Methods:** Here we collected 50 human kidney samples from healthy and chronic kidney disease subjects. We obtained clinical information, and histological analysis, and performed untargeted metabolomics (900 metabolites) and gene expression studies by RNA sequencing. Metabolites data was analyzed using Metaboanalyst. Gene expression analysis and untargeted metabolomic studies have also been performed for the cisplatin-induced mouse kidney injury model. Wild type and RIG-I knock-out mice were injected with cisplatin. We used the primary culture of mouse kidney tubule cells. Human snATAC and in situ hybridization were employed for validation.

**Results:** Untargeted metabolomics identified 153 metabolites showing differences in human CKD kidneys and 687 in mice. Pathway enrichment analysis indicated NAD metabolism pathway was commonly enriched in both human and mice metabolomics data. Treating mice with NAD precursor NR (Nicotinamide riboside) and NMN (Nicotinamide mononucleotide) ameliorated cisplatin-induced kidney disease severity. Unbiased gene expression analysis showed significant normalization of genes associated with cytosolic RNA sensing, and immune and mitochondrial pathways. In vitro cell culture studies indicated NAD precursor treatment protected from mitochondrial depolarization, ROS release, cell death, and proinflammatory gene expression. Molecular analysis showed that cisplatin treatment led to the cytosolic leakage of mitochondrial RNA and activation of the cytosolic RNA sensor RIG-I. Kidney damage, (BUN level, structural changes) was lower in cisplatin-treated RIG-I KO mice compared to wild-type animals. Increased RIG-I expression in renal tubules was confirmed in human disease kidneys. Kidney NAD levels negatively correlated with RIG-I, Isg15, and Irf7 expression in human kidneys.

**Conclusions:** Unbiased metabolomics of human kidneys highlighted changes in NAD metabolism. NAD precursor treatment protected from mitochondrial damage and improved kidney function in mice by preventing the activation of the cytosolic nucleotide sensors.

**The Single-Cell Landscape of Kidney Immune Cells Reveals Transcriptional Heterogeneity in Late Diabetic Kidney Disease**

Jia Fu, Zeguo Sun, Weijia Zhang, Kyung Lee, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Mounting evidence supports the involvement of renal inflammation is the key driver in diabetic kidney disease (DKD) pathogenesis and it contributes significantly to the progression of DKD. Many studies have demonstrated that macrophages are a major inflammatory cell type infiltrating the kidney in both patient and experimental animal models of DKD. Our preliminary data revealed relatively mild alteration in molecular and phenotype shift in macrophage subpopulation in early DKD, but the dynamic shift and transcriptional signature of these subpopulations in later stages of DKD remain largely unknown.

**Methods:** Fluorescence-activated cell sorting was used to isolate CD45+ cells from control and OVE26 diabetic mice at 28 weeks. To uncover the gene expression changes in specific immune cell subsets in late DKD, we employed single-cell RNA sequencing using the 10x Genomics platform. We generated single cell transcriptome profiles and performed comprehensive bioinformatics analysis and gene expression validation. Cell Ranger, R and Seurat, Macspectrum were used to make gene-cell matrices and for downstream analyses.

**Results:** Gene ontology enrichment analysis showed pronounced activation of immune pathways shared across MNPs in late DKD, whereas oxidative phosphorylation and cellular respiration were enriched in early DKD. Compared to early DKD, there's a significant accumulation of infiltrating macrophage (IM) in late DKD, particularly anti-inflammatory Ly6c<sup>low</sup> Ace<sup>hi</sup> IMs and a novel population M2-like macrophage, which highly expressed alternatively activated macrophage markers (*Retnla*, *Fcna*, *Cd163*). After injury, go terms show Ly6c<sup>low</sup> IM played more roles in tissue repair, regulation of cell matrix adhesion, and cellular response to laminar fluid shear stress upon injury. Interestingly, M2-like macrophages were well distinguished by expressing genes enriched in TGF- $\beta$  signaling, a key pathway that leads to renal fibrosis.

**Conclusions:** We revealed recruitment of alternatively activated macrophage and reparative macrophage phenotype Ly6c<sup>low</sup> Ace<sup>hi</sup> IMs in late DKD, suggesting the dynamic plasticity of macrophage functions in kidney during disease progression. This highlights the value of potential therapeutic target of immunotherapy as a means of preventing the progression of DKD are discussed.

**Human Kidney Multimodal Single Cell and Spatial Transcriptomics Atlas Identify Key Cell Types and Pathways for Diabetic Kidney Disease**

Amin Abedini,<sup>1</sup> Ziyuan Ma,<sup>1</sup> Julia Frederick,<sup>1</sup> Kishor B. Devalaraja-Narashimha,<sup>2</sup> Lori Morton,<sup>2</sup> Gurmanna Kalra,<sup>3</sup> Erding Hu,<sup>3</sup> Lea Sarov-Blat,<sup>3</sup> Carine Boustany,<sup>4</sup> Paolo Guarnieri,<sup>4</sup> John T. Liles,<sup>5</sup> Anil K. Karihaloo,<sup>6</sup> Hanying Yan,<sup>1</sup> Kyle P. Coleman,<sup>1</sup> Jian Hu,<sup>1</sup> Qihuang Zhang,<sup>1</sup> Matthew Palmer,<sup>1</sup> Mingyao Li,<sup>1</sup> Katalin Susztak.<sup>1</sup> <sup>1</sup>University of Pennsylvania, Philadelphia, PA; <sup>2</sup>Cardiovascular, Renal and Fibrosis Research, Regeneron Pharmaceuticals Inc, Tarrytown, NY; <sup>3</sup>Research and Development, GSK, Collegeville, PA; <sup>4</sup>Department of Cardiometaabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT; <sup>5</sup>Department of Biology, Gilead Sciences, Foster City, CA; <sup>6</sup>Novo Nordisk Research Center Seattle, Inc, Seattle, WA.

**Background:** Diabetic kidney disease (DKD) is responsible for more than half of all end stage renal disease in the US, yet disease driving cell types and pathways are poorly defined. Innovative single cell tools can define transcriptomics, gene regulation or even spatial gene expression at single cell resolution.

**Methods:** We generated single cell and single nuclear gene expression (scRNA-seq, snRNA-seq) and single nuclear assay of open chromatin (snATAC-seq) datasets for 66 (34 healthy and 32 CKD/DKD) samples capturing 0.5 million cells. Furthermore, we generated high-quality spatial gene expression datasets for healthy and DKD kidneys. The data was complemented with bulk RNA-seq, clinical and histological information available for 298 human kidney samples.

**Results:** Our high-quality kidney single cell atlas captured 40 main and more than 100 cell subtypes or cell states, including epithelial, endothelial, immune and stromal cells. Using a combination of snRNA and spatial transcriptomics analyses, we successfully mapped all cell types and states back to their spatial location in healthy and diseased kidneys. Our results highlighted the key role of proximal tubule, immune, and stromal cells in disease development. We identified different localization patterns of different cell types, including a novel interaction between stromal, immune cells and injured tubule cells in fibrosis. Our analyses defined a gene signature pattern for injury niches, which could also accurately classify a cohort of 298 tubule bulk RNA-seq into subsets based on eGFR and renal fibrosis.

**Conclusions:** Our comprehensive human kidney single cell and spatial atlas define new pathways and gene signatures for DKD, and a valuable resource for the community to identify potential new therapeutic targets, pathways and cell types in kidney diseases.

## FR-OR33

**Multi-Omic Analysis Identifies a New Class of Proximal Tubular Cell With Metabolic Alterations in Diabetic Kidney Disease**

Hiroshi Maekawa, Yalu Zhou, Margaret E. Fain, Dorian Kaminski, Navdeep S. Chandel, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Therapeutic inhibition of the sodium glucose cotransporter 2 (SGLT2) protects the kidney although underlying mechanisms are incompletely known. We tested the hypothesis that cell-specific metabolic pathways activated by SGLT2 inhibition in diabetic kidney disease (DKD) underly benefits.

**Methods:** Kidneys from 10-week-old male SglT2 mutant (MT) and wildtype (WT) mice, fed with normal or high fat diet (HFD) for eight or eighteen weeks, were analyzed. Changes in body weight, food intake, insulin and glucose tolerance were determined. Single cell RNA sequence (scRNA seq) analysis was performed on libraries prepared from whole kidneys. Metabolomic analysis of renal cortex was conducted by Metabolon, Inc. Human proximal tubular cells (HK-2), were exposed to 50 mM of D-glucose with/without 1μM of Methionine Adenosyltransferase 2A inhibitor (MAT2Ai) and treated with SGLT2 siRNA or S-Adenosyl methionine (SAM) for 48hr.

**Results:** HFD-induced obesity was similar in both MT and WT while compensatory hyperphagia was observed in MT. Glucose intolerance occurred in mice fed HFD (WT>MT). Molecular and functional markers of kidney injury including KIM-1, number of apoptotic cells and albuminuria were higher in WT>MT. Analysis of scRNAseq data showed emergence of a new class of proximal tubular cells (New-PTC), predominantly found in HFD-fed WT. New-PTC showed increased expression of genes related to epithelial-mesenchymal transition (EMT), apoptosis and inflammation. Pathway enrichment analysis of metabolomic data uncovered differences in WT vs MT renal cortex; metabolites of methionine cycle including SAM were preferentially increased in HFD-fed MT. High glucose treatment of HK-2 recapitulated molecular changes observed in New-PTC of HFD-WT mice, including markers of EMT (elevated fibronectin, reduced E-cadherin) and inflammation (increased IL-6, IL-8, TNF) which could be inhibited by SGLT2 knock down or SAM supplementation, which enhances methionine metabolism. Conversely, an inhibitor of the methionine cycle, MAT2Ai, exacerbated EMT and inflammation.

**Conclusions:** Multi-omic analysis identified a New-PTC type and an association between methionine cycle pathway and renal-protection in a model of DKD. SGLT2 inhibition suppressed the emergence of this New-PTC, which can be replicated in vitro by modulation of methionine cycle.

## FR-OR34

**Combination of Transcriptional Signatures and 3D Images of Epithelial Nuclei in Kidney Biopsies Using a Deep-Learning Outlier Detection Model Uncovers Signatures of Injury in Diabetic Kidney Disease**

Seth Winfree,<sup>1</sup> Daria Barwinska,<sup>3</sup> Jun Zhuang,<sup>2</sup> Niloy Talukder,<sup>2</sup> Michael T. Eadon,<sup>3</sup> Pierre C. Dagher,<sup>3</sup> Mohammad A. Hasan,<sup>2</sup> Tarek M. El-Achkar.<sup>3</sup> Kidney Precision Medicine Project <sup>1</sup>University of Nebraska Medical Center College of Medicine, Omaha, NE; <sup>2</sup>Indiana University Purdue University Indianapolis, Indianapolis, IN; <sup>3</sup>Indiana University School of Medicine, Indianapolis, IN.

**Background:** Epithelial cell states in renal health and disease have become an area of intense research focus. By integrating multiomics and imaging from samples collected by large consortia (e.g. Kidney Precision Medicine Project) epithelial cell states of injury, maladaptive and adaptive repair, cycling and degeneration have been identified. Recently, we demonstrated the sufficiency of nuclei labeled with a common nuclear stain in classifying the epithelia of the nephron in the human renal cortex. To expand this approach and identify signatures of injury in diabetes, we implemented a deep learning model for outlier detection combining transcriptional profile of cell states with images of renal epithelial nuclei.

**Methods:** To identify injury classes of epithelia in imaging data we first trained a deep learning encoder with 3D images of nuclei of proximal tubule (PT) and thick ascending limb (TAL) generated by Volumetric Tissue Exploration and Analysis. In parallel, a side-information encoder was trained with transcriptional signatures of normal PT or TAL based on genes previously defined. Lastly, the two encoders were trained jointly to minimize the embedding distance between an image of a given label and its corresponding transcriptional signature for classification.

**Results:** Our outlier detection model was used to classify 3D nuclei of PT and TAL cells in biopsies from patients with diabetic kidney disease collected by the Kidney Precision Medicine Project. PT and TAL cells were either classified as normal or injured based on an outlier score. The putative injured PT and TAL were shown to positively correlate ( $p < 0.05$  by Pearson) with areas of injury by neighborhood analysis in the original image volumes.

**Conclusions:** Using a deep learning approach that integrates 3D images of nuclei and transcriptomics we identify a putative signature of injury in biopsies of patients with diabetic kidney disease. Our approach has implications for unbiased assessment of the landscape of cellular injury based only on the morphology and textures of nuclei, leading to a better characterization of the severity of disease and its prognosis.

## FR-OR35

**Identification of Early Diabetes-Induced Renal Changes Using Spatial Metabolomics**

Rosalie Rietjens,<sup>1</sup> Gangqi Wang,<sup>1</sup> Bram Heijs,<sup>2</sup> Bernard van den Berg,<sup>1</sup> Ton J. Rabelink,<sup>1</sup> <sup>1</sup>Leids Universitair Medisch Centrum Niercentrum, Leiden, Netherlands; <sup>2</sup>Leids Universitair Medisch Centrum Center for Proteomics and Metabolomics, Leiden, Netherlands.

**Background:** Diabetic nephropathy usually presents itself with irreversible kidney damage. Clearly, there is a need to better understand early renal cell type specific diabetes-induced changes before occurrence of overt renal histopathology. The metabolism is a very dynamic process which is expected to change upon diabetes, preceding morphological changes. Mass spectrometry imaging (MSI) offers a label-free method to study metabolism in the context of tissue histology, giving us the opportunity to investigate renal cell type specific metabolic changes.

**Methods:** Apolipoprotein E-knockout mice were treated with streptozotocin (STZ) and put on an enriched cholesterol diet to induce diabetes. After 12 weeks, both control (n=4) and diabetic (n=4) mice were sacrificed and kidneys were harvested for immunohistochemistry and MSI. Post-MSI immunofluorescent microscopy (IF)-assisted annotation was used to identify various renal cell types. Metabolome-driven segmentation and subsequent multivariate analysis allowed us to find cell type specific metabolic changes in the diabetic kidney.

**Results:** Two weeks after STZ induction, blood glucose levels of diabetic mice were significantly elevated compared to control. Besides small glomerular changes, we could not find further histological signs of diabetic tubular injury. Metabolome-driven spatial segmentation analysis of the MSI data revealed that in both groups different renal cell types could be distinguished based on their metabolic profile. Using IF-assisted cell type annotation, we found various metabolites and lipids being reduced in glomeruli of the diabetic kidney. Furthermore, we found considerable changes in the metabolic profile of the proximal tubular cells in the S3 segment (PT-S3). Using a multivariate ROC analysis, we established metabolites and lipids that could distinguish PT-S3 between healthy and diabetic kidneys. Membrane lipid metabolism and protein homeostasis in these PT-S3 cells already appeared to be affected by diabetes, before showing signs of histological changes.

**Conclusions:** Using a spatial metabolomics approach, we were able to identify renal cell type specific diabetes-induced early changes in the diabetic kidney compared to the healthy control. Already finding such changes in molecular phenotype would allow to assess therapeutics for treatment before irreversible damage occurs in the kidney.

## FR-OR36

**Multi-Omics Integration Links Angiopoietin-Tie Signaling Pathway Activation With Diabetic Kidney Disease Progression**

Viji Nair,<sup>1</sup> Jiahao Liu,<sup>3</sup> Yiyang Zhao,<sup>4</sup> Dongyuan Chang,<sup>4</sup> Christine P. Limonte,<sup>2</sup> Nisha Bansal,<sup>2</sup> Ian H. de Boer,<sup>2</sup> Min Chen,<sup>4</sup> Markus Bitzer,<sup>1</sup> Matthias Kretzler,<sup>1</sup> Wenjun Ju.<sup>1</sup> KPMP <sup>1</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Central South University, Changsha, China; <sup>4</sup>Peking University First Hospital, Beijing, China.

**Background:** Identification of prognostic biomarkers and pathways reflective of underlying molecular mechanisms are critical for effective management of diabetes and chronic kidney disease. Our study aims to establish this link by integrating circulating biomarker and kidney transcriptomic profiles with disease progression

**Methods:** A marker panel of circulating proteins measured in SOMASCAN platform predicting composite outcome of ESRD or 40% baseline GFR reduction from the C-PROBE cohort was identified using a machine learning method. Validations were performed in Cardiovascular Health Study, CHS (N=3183) and a Chinese Cohort Study of Chronic Kidney Disease participants with DKD (N=210). An Angiopoietin/Tie (ANG-TIE) pathway score was generated using expression of ANG-TIE signaling mediators using transcriptomic data. Cell specific regulation of the pathway and receptors were evaluated using single cell RNAseq profiles of DKD participants from the Kidney Precision Medicine Project.

**Results:** The three-plasma marker panel (ANGPT2, CLEC4M, EGFR) significantly improved prediction of composite outcome in discovery (N=58) and validation group (N=68) over the clinical parameters, LR test  $p=0.003$  and  $0.0004$ , respectively. Plasma ANGPT2 remained significant in CHS (HR=1.50, 1.18:1.92) and Chinese cohort (HR=2.07, 1.39:3.09) with higher levels associated with increased risk of progression after adjusting for confounding factors including age, gender, race, diabetic history, GFR, and ACR. The glomerular ANG-TIE pathway activation scores were elevated in progressors/advanced DKD in C-PROBE ( $p=0.02$ ) and in an external cohort ( $p<0.01$ ). This was further supported by higher Tyrosine-Protein Kinase Receptor TEK level in glomeruli and higher ANG-TIE activation scores in endothelial cells in DKD by scRNASeq data. ANG-TIE pathway activation also showed positive correlation with plasma ANGPT2 levels ( $r=0.43$ ,  $P=0.01$ ).

**Conclusions:** Our work suggests that activation of ANG-TIE signaling in the kidneys underlies the association of plasma ANGPT2 with disease progression, thereby providing potential targets to prevent DKD progression.

**Funding:** NIDDK Support, Other NIH Support - a grant from the University of Michigan Health System and Peking University Health Sciences Center Joint Institute for Translational and Clinical Research.

## FR-OR37

**A Prospective Study of Urinary Complement Proteins in Early Diabetic Kidney Disease in Type 1 Diabetes**

Zaipul I Md Dom,<sup>1,2</sup> Salina Moon,<sup>1</sup> Sara D. Pickett,<sup>1</sup> Andrzej Galecki,<sup>3</sup> Michael Mauer,<sup>4</sup> Alessandro Doria,<sup>1,2</sup> Monika A. Niewczas,<sup>1,2</sup> *Joslin Diabetes Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>University of Michigan, Ann Arbor, MI; <sup>4</sup>University of Minnesota Twin Cities, Minneapolis, MN.*

**Background:** We identified robust urinary Complement-enriched proteomics profiles that were associated with 10-year ESKD risk in a prospective Joslin Kidney Study cohort with overt diabetic kidney disease (DKD). The role of the Complement pathway in early stages of the disease process remains unknown. This study evaluated the associations of Complement proteins and early DKD in T1D.

**Methods:** This prospective study included 207 participants followed for 3 years from the Preventing Early Renal Function Loss (PERL) study with T1D and baseline albuminuria (AER  $\geq 20$   $\mu\text{g}/\text{min}$ ) and CKD stages 1-3 (median AER: 127  $\mu\text{g}/\text{min}$ ; mean eGFR: 74 mL/min/1.73m<sup>2</sup>). Two dozen Complement proteins were measured in baseline spot urines using low-multiplex immunoassays. The kidney outcomes of interest included binary eGFR decline  $\geq 3$  (43% of subjects) or 5 (23%) mL/min/1.73m<sup>2</sup>/year, and a continuous eGFR slope. Model accuracy was evaluated with biostatistical and machine learning approaches.

**Results:** In the univariable logistic models, more than a dozen Complement proteins were associated with eGFR decline. Odds of developing eGFR decline per one tertile increase in the distribution of CFP the top Complement protein was: OR (95%CI): 2.5 (1.8, 3.6);  $p < 10^{-6}$ . The proteins represented all major components of the Complement pathway. Most of the proteins remained significant after adjustment for select clinical covariates. Albuminuria substantially impacted the Complement associations (changes in beta estimates: from 23-40%). The effect size in the principal component (PCA)-based model was larger in comparison with other models using individual proteins (Fig.1).

**Conclusions:** Our study of subjects with T1D and mild to moderate DKD demonstrated that Complement proteins are associated with kidney function decline over a 3-year period. These new findings suggest that the Complement pathway may play a role at earlier stages of disease process than previously assumed.

**Funding:** Other NIH Support - NIH R01 DK123459, Private Foundation Support

3-year Kidney Outcome		
	OR (95%CI)	P

**Endogenous Retroviruses Contribute to Kidney Fibrosis Development by Triggering the Innate Immune Response**

Poonam Dhillon, Kelly A. Mulholland, Hailong Hu, Xin Sheng, Jihwan Park, Amin Abedini, Allison Vassalotti, Hongbo Liu, Junnan Wu, Katalin Susztak. *Susztak Lab University of Pennsylvania, Philadelphia, PA.*

**Background:** Inflammation is a common feature of diabetic kidney disease (DKD); however, underlying mechanisms triggering inflammation remain poorly understood. Endogenous retroviruses (ERVs) are transposable elements (TEs) that were fixed in the genome by cumulative exogenous retroviral infection over millions of years. ERVs constitute 10% of the human and mouse genome. ERVs are dynamically silenced in the genome by cytosine methylation or other repressive epigenetic modifications. The aim of this study was to characterize ERV expression and to understand its role in kidney disease development.

**Methods:** We performed RNA-seq and genome-wide methylation analysis on 485 human kidney samples and mouse kidney fibrosis models induced by folic acid injection (FAN) or unilateral ureteral obstruction (UUO) and quantified TEs using RepeatMasker and full-length ERVs by HERVQuant. Mouse models with kidney tubule-specific deletion of DNA methyltransferase 1 (DNMT1) and nucleotide sensors (STING and RIG-I) were generated. For *in-vitro* experiments, primary cultures of mouse kidney tubule cells were analyzed.

**Results:** Our analysis identified 1925 TEs and 74 ERVs levels that were increased and correlated with kidney disease severity in patients. We detected increased expression of 560 TEs in UUO and 130 TEs in FAN mice kidneys. The strong correlation between ERVs and cytosolic demethylation suggested that epigenetic derepression likely contributes

to increased TE/ERV levels in diseased kidneys. Kidney-specific genetic deletion or pharmacological inhibition of DNMT1 resulted in increased TE/ERV levels leading to renal inflammation and fibrosis. The ectopic expression of ERV in cultured kidney tubule cells triggered the activation of cytosolic nucleotide sensors such as RIG-I, MDA5, and STING and the expression of IFN-stimulated genes (ISGs). TE/ERV expression in human and mice kidney tissue samples correlated with RIG-I/STING pathway gene expression and with kidney immune cell fractions. Genetic deletion of RIG-I or STING or treatment mice with reverse transcriptase inhibitor ameliorated kidney fibroinflammation.

**Conclusions:** Epigenetic derepression mediated increased ERV levels contribute to the sterile inflammation in DKD by activating the cytosolic nucleotide sensing pathways (RIG-I/STING).

**Funding:** NIDDK Support

## FR-OR39

**A Phase 2b Randomized Controlled Trial of Selonsertib in Moderate to Severe Diabetic Kidney Disease (MOSAIC)**

Vlado Perkovic,<sup>1</sup> Katherine R. Tuttle,<sup>2</sup> Pablo E. Pergola,<sup>3</sup> Kenneth W. Mahaffey,<sup>8</sup> Uptal D. Patel,<sup>4</sup> Julie H. Ishida,<sup>4</sup> Fang Chen,<sup>4</sup> Gerald Crans,<sup>4</sup> Robert Kustra,<sup>4</sup> Mona Trivedi,<sup>4</sup> Hiddo J. L. Heerspink,<sup>5</sup> Peter Rossing,<sup>6</sup> Naoki Kashihara,<sup>7</sup> Glenn Chertow.<sup>8</sup> *<sup>1</sup>University of New South Wales, Sydney, NSW, Australia; <sup>2</sup>University of Washington and Providence Health Care, Spokane, WA; <sup>3</sup>Renal Associates PA, San Antonio, TX; <sup>4</sup>Gilead Sciences Inc, Foster City, CA; <sup>5</sup>University Medical Center, University of Groningen, Groningen, Netherlands; <sup>6</sup>Kobenhavns Universitet, Kobenhavn, Denmark; <sup>7</sup>Kawasaki Ika Daigaku, Kurashiki, Japan; <sup>8</sup>Stanford Center for Clinical Research, Stanford University, Stanford, CA.*

**Background:** Selonsertib (SEL) is an apoptosis signal-regulating kinase 1 inhibitor that reduces inflammation, fibrosis, and apoptosis. The MOSAIC study evaluated whether SEL could slow decline in kidney function in patients with diabetic kidney disease (DKD).

**Methods:** We conducted a Phase 2b study in adults with type 2 diabetes mellitus and eGFR 20- $<60$  mL/min/1.73m<sup>2</sup> with UACR 150-5000 mg/g on an ACEi or ARB. To account for the acute decrease in eGFR<sub>cr</sub> associated with SEL initiation, following placebo (PBO), all patients entered a 4-week SEL run-in period to establish treatment-specific baseline eGFRs (Fig 1). Patients were randomized 1:1 to SEL 18 mg or PBO once daily for  $\geq 48$  weeks. The primary efficacy endpoint was eGFR<sub>cr</sub> slope from treatment-specific baselines to Week 84, evaluated at a 2-sided significance level of 0.30. Kidney clinical events (KCE; eGFR<sub>cr</sub>  $\geq 40\%$  decline from pre-run-in baseline, kidney failure, or death due to kidney disease) and adverse events (AEs) were evaluated.

**Results:** Overall, 310 patients were randomized (SEL n=154, PBO n=156; 68% male, 52% white, mean age 65 years, 18% SGLT-2i use at randomization, and mean baseline eGFR<sub>cr</sub> 35.0 mL/min/1.73m<sup>2</sup>). The mean difference in eGFR<sub>cr</sub> slope at Week 84 between arms was 1.20 mL/min/1.73m<sup>2</sup>/year (95% CI, -0.41, 2.81;  $p=0.14$ ) (Fig 2). KCEs occurred in 17% (26/154) of the SEL arm and 12% (19/156) in PBO (difference, 5%; 95% CI, -6%, 16%;  $p=0.19$ ). The most common AE was acute kidney injury (AKI) (SEL, 11.0/100 patient-years [PY]; PBO, 5.9/100 PY).

**Conclusions:** The study met the primary efficacy endpoint, suggesting that SEL may slow kidney function decline in diabetic kidney disease, although a potential safety concern for AKI was identified.

**Funding:** Commercial Support - Gilead Sciences

# Safety and Preliminary Efficacy Results of a Novel Mesenchymal Stromal Cell Therapy in Diabetic Kidney Disease: The Multicenter, Randomized, Placebo-Controlled, Phase-1b/2a NEPHSTROM Clinical Trial

Matthew D. Griffin,<sup>1</sup> Giuseppe Remuzzi,<sup>2</sup> Paul Cockwell,<sup>3,4</sup> Alexander P. Maxwell,<sup>9</sup> Norberto Perico,<sup>2</sup> Piero L. Ruggenenti,<sup>5,2</sup> Martino Intronà,<sup>5</sup> Andrew A. Finnerty,<sup>6</sup> Jon Smythe,<sup>10</sup> Willem E. Fibbe,<sup>7</sup> Stephen J. Elliman,<sup>8</sup> Timothy O'Brien.<sup>1</sup> The NEPHSTROM Trial Consortium  
<sup>1</sup>Regenerative Medicine Institute (REMEDI), School of Medicine, NUI, Galway, Ireland; <sup>2</sup>Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy; <sup>3</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; <sup>4</sup>Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; <sup>5</sup>Aziende Socio Sanitarie Territoriali Papa Giovanni XXIII, Bergamo, Italy; <sup>6</sup>National University of Ireland Galway (NUIG), Galway, Ireland; <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands; <sup>8</sup>Orbsen Therapeutics Ltd, Galway, Ireland; <sup>9</sup>Queen's University Belfast Centre for Public Health, Belfast, United Kingdom; <sup>10</sup>National Head of Cellular and Molecular Therapies, Oxford, United Kingdom.

**Background:** Mesenchymal stromal cells (MSC), by targeting individual or combined effects of renoprotective processes, are candidates for treatment of diabetic kidney disease (DKD).

**Methods:** NEPHSTROM is a randomized, placebo-controlled, double blind, dose-escalation phase 1b/2a clinical trial of next-generation bone marrow-derived, antibody-purified allo-CD362<sup>+</sup> MSC (ORBCEL-M) in adults with type 2 diabetes, DKD and eGFR 25-55 ml/min/1.73 m<sup>2</sup> with evidence of or risk of progressive eGFR decline. We report the experience with the first dose cohort, consisting of 16 subjects [single i.v. infusion of ORBCEL-M 80x10<sup>6</sup> cell (n=12, group A) or placebo (n=4, group B)], enrolled at 3 sites in Italy, Ireland and UK, and followed-up for 18 months.

**Results:** All randomized patients were negative for anti-HLA antibodies at study entry. Mean baseline measured GFR (mGFR, iothexol clearance) and estimated GFR (eGFR, CKD-EPI equation) were comparable between the two groups. The trial intervention was well tolerated and safe (primary outcome), with one quickly-resolved infusion reaction (in the placebo group) and no subsequent SAEs ascribed to trial product. Two patients in group A died of cell product unrelated causes between 12 and 18 months. Serial serum assays for anti-HLA antibodies indicated low-level allo-immune sensitization in a patient from month 3. The median annual rate of renal function decline by mGFR (secondary outcome) was numerically lower in group A than group B; by eGFR this was statistically significant (Table). Blood pressure, glycemic and lipid profiles and spot morning urinary albumin creatinine ratio were comparable in the two groups during the 18 month follow-up.

**Conclusions:** In summary, for subjects enrolled into the first (low-dose) cohort of the NEPHSTROM trial, the safety and tolerability of ORBCEL-M was established. Over 18 months rate of decline of eGFR was less for recipients of cells compared to placebo.

	ORBCEL-M	Placebo	P value*
mGFR (ml/min/1.73m <sup>2</sup> per year)	-3.8 [-5.7, -2.1]	-7.5 [-13.9, +1.0]	0.467
eGFR - CKD-EPI (ml/min/1.73m <sup>2</sup> per year)	-2.6 [-4.2, -0.3]	-8.7 [-11.4, -4.6]	0.034

Values are median [IQR]. \*Wilcoxon rank sum ORBCEL-M vs Placebo

## FR-OR41

# The Impact of Microgravity on Kidney Function During Spaceflight

Keith Siew, Stephen B. Walsh. University College London, London, United Kingdom.

**Background:** The impact of microgravity (MG) on deep space travellers has mainly focused on cardiovascular, musculoskeletal, neurological and ocular health. However, MG exposed astronauts have an unusually high rate of kidney stone formation which poses a mission critical risk. In fact, over 30 incidents have been reported and previous missions have almost been aborted due renal stone formation

**Methods:** To investigate this, we studied kidneys and biofluids from mice aboard the Rodent Research-10 (RR-10) Mission that launched with SpaceX-21 to the International Space Station and spent ~30 days in MG. These were compared to ground controls (n=10 per all groups) and underwent spatial transcriptomics and miRNA analysis, quantitative proteomics/phosphoproteomics, urine/plasma electrolyte analysis and 3D imaging of immunostained optically cleared tissues for histomorphometry.

**Results:** Thus far, our network analysis of the data supports evidence of mitochondrial damage, extracellular matrix dysfunction and decreased lomerular filtration rate. Interestingly, there are also marked dysregulation in gene products relating to lipid metabolism, SLC membrane transporter superfamily and phosphorylation status.

**Conclusions:** Our data suggest that there are detrimental changes in the abundance and activity of key transporters/channels that either directly or indirectly regulate calcium homeostasis, and that these may be primary changes in the kidney that drive renal stone formation on the backdrop of milieu of increased renal stone risk factors (e.g. bone resorption, dehydration, enhance crystal formation in MG).

**FIGURE 1:** Lightsheet microscopy of SHIELD cleared renal tissue stained for total SLC12A3 (Magenta) and T53 Phospho-SLC12A3 (A) Representative slide of distal convoluted tubule from animal not exposed to MG (A) and animal exposed to MG (B).

## FR-OR42

# Dietary Anion Controls Potassium Excretion: It's More Than a Poorly Absorbable Anion Effect

Lama Al-Qusairi,<sup>1</sup> Rick Grimm,<sup>1</sup> Ava M. Zapf,<sup>1</sup> Seyedmohammadebrahim Tahaei,<sup>1</sup> Delaney C. Abood,<sup>2</sup> Susan M. Wall,<sup>2</sup> Paul A. Welling.<sup>1</sup> <sup>1</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>2</sup>Emory University, Atlanta, GA.

**Background:** Aldosterone-dependent and -independent mechanisms are known to orchestrate potassium excretion in the distal nephron (DN). In the latter, potassium secretion, mediated by ROMK and BK channels, is dependent on lumen-negative transepithelial potential established by ENaC. Poorly absorbable anions, including HCO<sub>3</sub><sup>-</sup>, are thought to increase K<sup>+</sup> secretion by hyperpolarizing the membrane potential, but accumulating data indicate luminal anions may also directly influence the expression of the potassium secretory machinery.

**Methods:** Here we characterize the anion effect in wild-type mice randomized to control, or high KCl or high KHCO<sub>3</sub> diets, and explore mechanisms in knockout mice, lacking aldosterone synthase (AS-KO) or the chloride-bicarbonate exchanger, pendrin (Pds-KO).

**Results:** Consumption of the high KHCO<sub>3</sub> diet increased urinary potassium K<sup>+</sup> excretion and the trans-tubular K<sup>+</sup> gradient (TTKG) significantly more than high KCl diet. Although both diets increased ENaC expression and proteolytic activation and increased ROMK protein abundance and apical membrane expression in the early connecting tubule (CNT), the responses were significantly more pronounced with consumption of the high KHCO<sub>3</sub> diet, despite elevating aldosterone to similar levels. Compared to the more restricted response in the early CNT with the high KCl diet, the high KHCO<sub>3</sub> diet increased apical membrane ROMK along the entire CNT. In addition, the high KHCO<sub>3</sub> diet uniquely increased the abundance of the BK potassium channel b4 subunit, which stabilizes BKA channel membrane localization. Studies in AS-KO mice revealed the stimulatory effects of high KHCO<sub>3</sub> diet on ROMK are not dependent on aldosterone. The KHCO<sub>3</sub> diet also uniquely upregulated the Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger, pendrin, and studies in pendrin KO mice revealed that pendrin deletion blunted the increase in the TTKG specific to the KHCO<sub>3</sub> condition.

**Conclusions:** In summary, bicarbonate stimulates potassium excretion beyond a non-absorbable anion effect, increasing ENaC cleavage, and apical membrane expression of ROMK and pendrin. The latter plays a significant role in K<sup>+</sup> secretion by providing the luminal HCO<sub>3</sub><sup>-</sup>. The response provides an adaptive mechanism to prevent hyperkalemia and alkalosis while consuming alkaline-ash rich diets.

## FR-OR43

# Wearable Device for Continuous, Non-Invasive Monitoring of Serum Potassium in Hemodialysis Patients

Forrest Miller, Alio, San Francisco, CA.

**Background:** Maintenance of healthy serum potassium levels is critical for the approximately 500,000 patients undergoing dialysis in the United States. Hypo- and hyperkalemia are serious conditions that can result in extreme adverse outcomes including sudden cardiac death. The SmartPatch system (SP) offers a wearable, remote monitoring system for serum potassium.

**Methods:** This study evaluated the ability of the SP system to identify hemodialysis patients with hypo- or hyperkalemia. Hemodialysis patients (n=96) with a functional arteriovenous fistula were prospectively enrolled in an IRB-approved study. During one dialysis session per month for four months, a wearable SP was applied over the fistula by a nurse or the patient, neither with prior experience placing the device. Venous blood samples were tested before and after dialysis to measure serum potassium (K<sup>+</sup>) levels. SP data was remotely collected throughout dialysis and analyzed for hematocrit (Hct) and K<sup>+</sup>. A classification model was trained and tested, using nested cross-validation, to classify data points according to potassium level. Hypokalemia was defined as K<sup>+</sup> < 3.5 mEq/L and hyperkalemia was defined as K<sup>+</sup> > 5.2 mEq/L.

**Results:** A combined set of 1229 data recordings were collected and used in this analysis, and all parameter tuning and performance evaluation was performed using nested k-fold cross validation. Reference serum potassium values ranged from 2.5 to 6.4 mEq/L. The median value was 4.2 mEq/L. Reference Hct values ranged from 18 to 48 percentage points. The median value was 34 percentage points. The SP dyskalemia algorithm identified dyskalemia-defined as either hypokalemia (K<sup>+</sup> < 3.5 mEq/L) or

hyperkalemia ( $K^+ > 5.2$  mEq/L)—with a total weighted recall of 86%. The precision—also known as the positive predictive value—of the model was 86%, indicating that the model achieved both high sensitivity and a low rate of false positives.

**Conclusions:** The results of this study demonstrate a novel proof-of-concept for a noninvasive PPG-based assessment of  $K^+$  status in hemodialysis patients using the Alio system. Future studies will include patients who present with hypokalemia at the start of dialysis, as the safety benefit from at-home surveillance is likely greatest for these patients, compared to those who only present with post-dialysis hypokalemia, as was the case in this study.

## FR-OR44

### KCC3a, a Pathway for Potassium Loss in Alkalemia

Mohammed Z. Ferdaus, Andrew S. Terker, Rainelli Koumangoye, Eric J. Delpire. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Loss-of-function mutations in the human potassium chloride cotransporter-3 (KCC3) cause a hereditary motor sensory neuropathy associated with agenesis of the corpus callosum. While recapitulating the neuropathy, KCC3 knockout (KCC3-KO) mice also exhibit high blood pressure. This phenotype is believed to have neurogenic and/or vascular origins. The role of KCC3 in the kidney is poorly understood. KCC3 is encoded by two major isoforms originating from alternative promoters: KCC3a and KCC3b, with KCC3b being the predominant transcript in kidney. Although the transporter has previously been localized to the proximal tubule, the localization and function of renal KCC3a isoform is unknown.

**Methods:** Using KCC3-KO mice, we validated a KCC3a-specific polyclonal antibody for both immunofluorescence and immunoblotting studies. Wild-type mice were subjected to dietary manipulation, water restriction, or 7 days of diuretic administration. Immunofluorescence was used to study protein localization and Western blotting was used for quantification.

**Results:** We observed intense KCC3a signal restricted to cortical intercalated cells. No overlap was detected between KCC3a and sodium chloride cotransporter (NCC), a distal convoluted tubule (DCT) marker; or between KCC3a and ENaC or calbindin, which are both principal cell markers. KCC3a signal was observed in cells expressing the apical V-ATPase and pendrin, establishing a unique expression pattern characteristic of intercalated cells of type B or type non-A/non-B. We further show that treatment of wild-type mice with hydrochlorothiazide, amiloride, or fed a  $K^+$  deficient diet up-regulated KCC3a levels, suggesting that volume depletion increases KCC3a abundance. This hypothesis was confirmed by showing higher abundance of KCC3a protein after 23-hrs water restriction or after placing the mice on a low salt diet. More importantly, abundance of the  $Cl^-/HCO_3^-$  exchanger, pendrin, which is known to secrete bicarbonate in alkalotic conditions, was significantly diminished in KCC3 knockout mice. In addition, KCC3a abundance increased significantly alongside pendrin abundance in bicarbonate-treated alkalotic mice, providing a credible mechanism for  $K^+$  loss in metabolic alkalosis.

**Conclusions:** We showed that KCC3a is expressed in pendrin-expressing intercalated cells and propose a possible mechanism for  $K^+$  loss in metabolic alkalemia.

**Funding:** NIDDK Support, Private Foundation Support

## FR-OR45

### Complications and Treatment of Hypercalciuria in Familial Hyperkalaemic Hypertension (FHHt)

Viola D'Ambrosio, Keith Siew, Stephen B. Walsh. *University College London, London, United Kingdom.*

**Background:** Hypertension is frequently associated with hypercalciuria<sup>1,2</sup>, nephrolithiasis<sup>3</sup> and low bone mineral density<sup>4</sup>. Familial Hyperkalaemic Hypertension (FHHt) causes hypercalciuria<sup>5</sup>, although complications of this are not reported.

**Methods:** We examined a cohort of 9 patients with genetically confirmed FHHt. Biochemical, radiological, and clinical data was obtained in patients before and after thiazide treatment. All patients gave informed consent. The study had ethics committee approval (REC 05/Q0508/6). Data were compared using paired t tests or Wilcoxon paired rank tests.

**Results:** 5 of the 9 patients were female (median age 41.7 years). The genetic diagnosis was confirmed in all patients, 5 patients had variants in KLHL3, 3 patients had variants of WNK4, and one had a variant of WNK1. Pre-treatment potassium was high (median 5.6 IQR 5.2-6.2 mmol/L). Pre-treatment calcium was in the normal range (2.34 IQR 2.29-2.38 mmol/L). There was significant hypercalciuria with a raised urinary calcium/creatinine ratio (0.69 IQR 0.41-1.13). However, PTH (4 IQR 3.95-4.35 pmol/L), phosphate (1.15 IQR 1.25mmol/L) and alkaline phosphatase (57 IQR 45-84 mmol/L) were all in the normal range. Thiazide treatment significantly reduced hypercalciuria (calcium/creatinine ratio 0.15 IQR 0.05-0.29  $p=0.04$ ) as well as the serum potassium (3.9 IQR 3.5-4.4 mmol/L  $p=0.0167$ ). Patients also developed complications of hypercalciuria. 3 patients had kidney stones demonstrated on cross-sectional imaging. One of these patients (male, 30 years old) had DXA criteria for osteoporosis (T score Femoral neck -1.5, lumbar spine -2.4).

**Conclusions:** This is the first case series to demonstrate complications of hypercalciuria (i.e. kidney stones) in patients with FHHt. We demonstrate that thiazide treatment normalises urinary calcium excretion. Thiazide treatment may have clinical utility in FHHt even if hypertension or hyperkalaemia are not problematic in order to avoid the complications of hypercalciuria.

## FR-OR46

### Insulin Receptor Substrate 4 (IRS4) Contributes to Hypomagnesemia by Mediating the Insulin Effect on the Renal Magnesium Channel TRPM6

Matthias T. Wolf,<sup>1</sup> Jing Zhang,<sup>1</sup> Sudha Neeam,<sup>1</sup> Anuja Bhatta,<sup>1</sup> Femke Latta,<sup>2</sup> Joost Hoenderop,<sup>2</sup> Michel G. Baum,<sup>1</sup> Sung wan An.<sup>1</sup> *<sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>Radboud Universiteit, Nijmegen, Netherlands.*

**Background:** The kidney is the key regulator of magnesium ( $Mg^{2+}$ ) homeostasis in the human body. In the distal convoluted tubule (DCT), the apical epithelial  $Mg^{2+}$  channel TRPM6, determines how much  $Mg^{2+}$  is excreted. To better understand the regulation of human renal  $Mg^{2+}$  absorption we screened for novel TRPM6 interaction partners. We identified insulin receptor substrate 4 (IRS4) as a new TRPM6 modifier mediating the insulin effect on TRPM6.

**Methods:** After a TRPM6-GST pulldown assay we pursued liquid chromatography/tandem mass spectrometry (LC/MS MS) sequencing and confirmed the TRPM6-IRS4 protein interaction by co-immunoprecipitation. For tubular *Irs4* gene expression we performed microdissection of wild-type (WT) C57BL/6 mouse tubules. Gene expression of *Irs4* and magnesiotropic genes (in kidneys of WT and *Irs4* knockout (*Irs4*<sup>-/-</sup>) mice) was studied with qRT-PCR. 24 h urinary  $Mg^{2+}$  excretion and serum  $Mg^{2+}$  levels were tested in *Irs4*<sup>-/-</sup> and WT mice using metabolic cages. Glucose tolerance tests were performed. The IRS4 effect on TRPM6 was examined with whole-cell patch-clamp studies.

**Results:** With LC/MS MS sequencing, we found IRS4 enriched with TRPM6-GST but not with GST control. We confirmed physical interaction between IRS4 and TRPM6 by co-immunoprecipitation. Micro-dissecting mouse tubules, we detected IRS4 mRNA expression mostly in the DCT and to a lower degree in the proximal tubule and thick ascending limb. Given the overall low abundance of IRS4 mRNA along the tubule, we investigated the phenotype of *Irs4*<sup>-/-</sup> mice. The *Irs4*<sup>-/-</sup> mice displayed significantly higher urinary  $Mg^{2+}$  losses at 3, 6, and 12 months and lower blood  $Mg^{2+}$  levels at 6 and 12 months than WT mice. Claudin-16, claudin-19, and Hnf1b mRNA and Claudin-16 and Trpm6 protein expression was significantly higher in kidneys of 3 month old *Irs4*<sup>-/-</sup> mice consistent with a compensatory mechanism to conserve  $Mg^{2+}$  in the body. Applying whole-cell patch clamp recording we confirmed the stimulatory role of insulin on TRPM6 and showed that IRS4 targets the two TRPM6 phosphorylation sites T1391 and S1583 to enhance TRPM6 current density. Glucose tolerance was mildly abnormal in 6 month old *Irs4*<sup>-/-</sup> mice.

**Conclusions:** We show that IRS4 mediates insulin signaling towards TRPM6 by phosphorylating the TRPM6 residues T1391 and S1583.

## FR-OR47

### Salt-Sensitive Blood Pressure Response in CKD Is Not Volume Mediated

Jetta J. Oppelaar, Emma H. van Schijndel, Bert-Jan Van den born, Rik H. Olde Engberink, Liffert Vogt. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

**Background:** Chronic kidney disease (CKD) patients are advised to limit salt intake, because of blood pressure (BP) and albuminuria lowering effects. The salt-sensitive BP response in CKD is classically attributed to the renal incapacity to excrete sodium ( $Na^+$ ) resulting in fluid overload. In non-kidney patients BP sensitivity to salt has been shown to be fluid independent and might be linked to vasodysfunction. We aimed to investigate which factor contributes to BP sensitivity to salt in CKD.

**Methods:** We performed a randomized cross-over study in CKD patients (stage 2a-3, proteinuria  $>50$  mg/d) and healthy controls (HC). All subjects followed both an 8-day low sodium diet (LSD,  $<50$  mmol/d) and high sodium diet (HSD,  $>200$  mmol/d). After each diet, assessment of the hemodynamic profile included 24-hour BP measurements (Mobil-O-Graph) and cardiac output (using Nexfin™), by which SVR was calculated accordingly. Body fluid volume was assessed with multi-frequency body impedance spectroscopy (Fresenius).

**Results:** We included 13 HC (median age 27 yrs) and 6 CKD patients (median age 49 yrs, proteinuria 1.2 (SD 1.1) grams/day). After HSD, patients with CKD showed a mean daytime systolic BP increase (LSD vs HSD (118.2 (SD 10.6) mmHg vs. 130.8 (SD 7.8) mmHg,  $p=0.04$ ) while systolic BP in HC did not increase. After HSD, we observed a comparable extracellular fluid (ECV) expansion in CKD and HC subjects (Fig 1A), but no effect on cardiac output (Fig 1B). Delta SVR showed a distinct response in CKD and HC (respectively, 67.6 (SD 313.3) vs -67.5 (SD 106.6) dyn/s/cm<sup>5</sup>,  $p=0.07$ ). The difference in BP response was not accompanied by differences in urinary  $Na^+$  excretion after HSD (259 mmol/day vs 247 mmol/day,  $p=0.73$ ).

**Conclusions:** Salt sensitivity in CKD is characterized by systolic BP increase. In these patients, this BP increase may not be explained by increased volume expansion due to the renal incapacity to excrete  $Na^+$ . However, in CKD the salt sensitive BP response might coincide with incapacity for vasodilation.

**Figure 1 A.**  $\text{Na}^+$  induced effects on extracellular fluid volume (ECV) were equal in CKD and HC (1.7 vs 1.5,  $p=0.74$ ). **B.** Cardiac output was not affected by  $\text{Na}^+$  in CKD (6.1 vs 6.4,  $p=0.70$ ) and HC (5.8 vs 6.0,  $p=0.62$ )

## FR-OR48

**In Vivo and In Vitro Effects of Hypoxia on NKCC2: Role of MAGE-D2**  
Kamel Laghmani,<sup>1,2</sup> Dalal Bakhos Al Douaihy,<sup>2</sup> Thibaut Charlemagne,<sup>1,2</sup> Stefan Rudloff,<sup>3</sup> Elie Seaayfan,<sup>4</sup> Sylvie Demaretz,<sup>1,2</sup> Uyen Huynh-do,<sup>3</sup> Martin Kömhoff.<sup>4</sup> <sup>1</sup>Inserm, CNRS-ERL8228, Sorbonne Université, Paris, France; <sup>2</sup>Centre de Recherche des Cordeliers, Paris, France; <sup>3</sup>Universität Bern, Bern, Switzerland; <sup>4</sup>Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany.

**Background:** We previously reported that MAGE-D2 mutations cause a severe but a transient form of antenatal Bartter syndrome (tBS) associated with impaired expression of the sodium-chloride cotransporters NKCC2 and NCC. However, the transient nature of the disease remained unclear. In this regard, hypoxia was of particular interest because we considered it as the major difference between the antenatal symptomatic stage of MAGE-D2 related tBS and the post-natal asymptomatic stage. Consequently, the aim of the present study was to investigate the effect of chronic hypoxia induced *in vivo* and *in vitro*, on NKCC2 biogenesis and explore the potential role of MAGE-D2 in this process.

**Methods:** To model chronic fetal hypoxia, timed-mated pregnant mice were exposed to 10% oxygen from E14.5 to E18.5 as previously described (Rudloff et al, Nat Commun 2021; 12:549). NKCC2 subcellular distribution was assessed using immunohistochemistry. *In vitro* hypoxia was induced, in HEK cells transiently or stably transfected with NKCC2, physically (1%  $\text{O}_2$ ) or chemically using cobalt chloride for 16-24 hours. NKCC2 stability was assessed by cycloheximide chase assay.

**Results:** Chronic fetal hypoxia induced ER stress conditions as illustrated by the increase in the expression of GRP78/BIP. Importantly, this was associated with a reduction of NKCC2 surface expression in hypoxic fetal kidneys as judged by enhanced ER retention and colocalization with the ER marker BIP. Physically or chemically induced cellular hypoxia in HEK cells, marked by the stabilization of HIF-1  $\alpha$ , was correlated also with an elevation of this ER stress marker. Under these hypoxic conditions, total NKCC2 protein expression was significantly decreased. Moreover, cycloheximide chase assay revealed that in cells submitted to cellular hypoxia, NKCC2 stability and maturation are decreased. Interestingly, the detrimental effect of hypoxia on NKCC2 maturation was more profound in MAGE-D2 depleted cells.

**Conclusions:** Our data indicate that cellular hypoxia induces ER stress and impairs NKCC2 maturation and cell surface expression. Most importantly, our findings strongly suggest that MAGE-D2 protects NKCC2 against ER associated degradation induced by ER stress under cellular hypoxia, which could explain, at least in part, the transient nature of BS in carriers of MAGE-D2 mutations.

## FR-OR49

### One Size Does Not Fit All: Real World Data on the Safety of Bolus Hypertonic Saline for Symptomatic Hyponatremia

Anissa Pelouto, Adrienne A. Zandbergen, Ewout J. Hoorn. Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

**Background:** Symptomatic hyponatremia is a medical emergency that warrants prompt correction. The European and American guidelines recommend rapid bolus-wise infusion of hypertonic saline with fixed volumes of 150 and 100ml regardless of body weight. However, this approach may lead to overcorrection, which may be harmful in patients with “acute on chronic” or chronic hyponatremia with symptoms. Here, our aim was to assess the safety of the current “one size fits all” approach in clinical practice. We hypothesized that lower BMI results in more overcorrection.

**Methods:** We retrospectively assessed biochemical and clinical outcomes in patients treated with fixed bolus hypertonic saline (150 or 100ml) for hyponatremia at Erasmus Medical Center between July 2017 and July 2021. The cut-off for low BMI was  $21 \text{ kg/m}^2$ , based on the lowest quartile of the cohort. Primary outcome was overcorrection, defined as an increase in plasma sodium ( $\text{pNa}$ )  $>10 \text{ mmol/L/24 hours}$ ,  $>18 \text{ mmol/L/48 hours}$ , or need for  $\text{pNa}$  lowering (use of hypotonic fluids and/or desmopressin). We performed multivariable logistic regression analyses to identify predictors for the primary outcome, adjusting for known risk factors including baseline  $\text{pNa}$  level, volume depletion and hypokalemia.

**Results:** A total of 183 patients were included for analysis (median age 63, IQR 55-7; 44% males, median baseline  $\text{pNa}$  120 mmol/L, IQR 116-122). Overcorrection occurred in 20% of patients. The overcorrection rate was significantly higher in patients with low BMI compared to patients without low BMI (37% versus 14%,  $P<0.001$ ). In addition, BMI was independently associated with overcorrection both when analyzed continuously (aOR 0.86, 95%CI 0.76-0.96) and when categorized as low BMI (aOR 4.24, 95%CI 1.67-10.80). Furthermore, we confirm that lower baseline  $\text{pNa}$  (aOR 0.87, 95%CI 0.80-0.94), volume depletion (aOR 5.81, 95%CI 2.11-16.00) and hypokalemia (aOR 5.62, 95%CI 1.89-16.91) are independent risk factors of overcorrection.

**Conclusions:** We show that the current “one size fits all” approach – bolus infusion of hypertonic saline with fixed volumes – exposes patients with low BMI to a significantly higher risk of overcorrection. Therefore, we recommend volume adjustments in patients with low BMI. Future prospective studies should test whether a weight-based approach is indeed safer.

## FR-OR50

### Thiazides Induce Glucose Intolerance Through Inhibition of Mitochondrial Carbonic Anhydrase 5b in $\beta$ -Cells

Patrycja Kucharczyk,<sup>1,2</sup> Giuseppe Albano,<sup>1,2</sup> Daniel G. Fuster.<sup>1,2</sup> <sup>1</sup>Inselspital Universitätsspital Bern Universitätsklinik für Nephrologie und Hypertonie, Bern, Switzerland; <sup>2</sup>Department for BioMedical Research (DBMR), University of Bern, Bern, Switzerland.

**Background:** Thiazide and thiazide-like diuretics (thiazides) have been the cornerstone for the treatment of arterial hypertension and pharmacologic recurrence prevention of kidney stones for more than 50 years. Hence, not surprisingly, thiazides belong to the most widely prescribed drugs worldwide. Since their introduction into clinical medicine, thiazides are known to be associated with glucose intolerance and new onset diabetes, but the molecular mechanisms remain elusive. The aim of this study was to decipher the molecular basis of thiazide-induced glucose intolerance.

**Methods:** We employed wild-type and genetically modified mice, primary pancreatic  $\beta$ -cells and murine MIN6 cells to study the impact of thiazides on systemic glucose homeostasis, insulin sensitivity and insulin secretion.

**Results:** In mice, hydrochlorothiazide induced a pathological glucose tolerance, characterized by reduced first phase insulin secretion but normal insulin sensitivity. *In vitro*, thiazides inhibited glucose- and sulfonylurea-stimulated insulin secretion in islets and the murine  $\beta$ -cell line Min6 at pharmacologically relevant concentrations. Inhibition of insulin secretion by thiazides was  $\text{CO}_2/\text{HCO}_3^-$ -dependent, not additive to unselective carbonic anhydrase (CA) inhibition with acetazolamide and independent of extracellular potassium. In contrast, insulin secretion was unaltered in islets of mice lacking the known molecular thiazide targets NCC (SLC12A3) or NDCBE (SLC4A8). CA expression profiling with subsequent knock-down of individual CA isoforms suggested mitochondrial CA5b as molecular target. In support of these findings, thiazides significantly attenuated Krebs cycle anaplerosis through reduction of mitochondrial oxalacetate synthesis. CA5b KO mice were resistant to thiazide-induced glucose intolerance, and insulin secretion of islets isolated from CA5b KO mice was unaffected by thiazides.

**Conclusions:** Our study reveals attenuated insulin secretion due to inhibition of the mitochondrial CA5b isoform in  $\beta$ -cells as molecular mechanism of thiazide-induced glucose intolerance.

**Funding:** Government Support - Non-U.S.

## FR-OR51

### The Predictive and Prognostic Value of Antigen-Specific Memory B Cell Levels in PLA2R-Associated Primary Membranous Nephropathy

Quansheng Zhu,<sup>1</sup> Meryl A. Waldman,<sup>2</sup> Richard Zhu,<sup>1</sup> Hong Tang.<sup>1</sup> <sup>1</sup>ImmunoWork, Monrovia, CA; <sup>2</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

**Background:** B lymphocytes play a critical role in developing autoimmunity in patients through antigen-presentation, cytokine release, and antibody production. Antigen stimulation of the cognate memory B cells triggers their rapid differentiation into plasma cells, producing massive amounts of pathogenic antibodies in a short period. In idiopathic nephrotic syndrome, rheumatoid arthritis, systemic lupus erythematosus, and IgG4-related disease, an early recovery of memory B cells in patients post-Rituximab therapy is the only reliable parameter that strongly predicts disease relapse. The phospholipase A2 receptor (PLA2R) is the dominant autoantigen in primary membranous nephropathy (PMN), associated with ~80% of clinical cases. Considering that memory B cells are a heterogeneous pool of antigen-experienced B cells, we developed a sensitive and reliable method to detect and quantify the PLA2R antigen-specific memory B cells (PLA2R-MB) in patients diagnosed with PLA2R-associated PMN.

**Methods:** The PLA2R antigen was expressed in the HEK 293 cells and affinity purified. The purified antigens were then conjugated to a fluorochrome. Peripheral blood mononuclear cells (PBMCs) from biopsy-proven PMN patients and healthy volunteers were isolated using the BD Vacutainer® CPT™ mononuclear cell preparation tubes, stained with the PLA2R fluorescent probe, anti-CD19, and anti-CD27 monoclonal antibodies, and subsequently analyzed by the flow cytometry.

**Results:** The PBMCs isolated from healthy volunteers or patients with non-PLA2R-associated PMN had little PLA2R fluorescent probe staining in the memory B cell repertoire, less than 2%, whereas the PBMCs isolated from patients with PLA2R-associated PMN had up to 70% of positive staining that correlated to the disease status. Importantly, patients with early signs of relapse, while possessing undetectable

anti-PLA2R antibodies, showed at least a one-fold increase in the PLA2R-MB level. Moreover, patients with partial remission showed a sustained high level of PLA2R-MBs, which fluctuated with the immunosuppressive therapy.

**Conclusions:** Our data indicate that the PLA2R antigen-specific memory B cell levels in patients have a substantial value in serving as a new biomarker to assess the patient response to immunosuppressive therapies for treatment adjustment and predict the pre-clinical signs of PMN relapse.

## FR-OR52

### APOL1 Promotes Endothelial Cell Activation Beyond the Glomerulus

Miguel Carracedo,<sup>1</sup> Elke Ericson,<sup>1</sup> Rasmus Ågren,<sup>1</sup> Anna Forslöv,<sup>1</sup> Katja Madeyski-Bengtson,<sup>1</sup> Rebecca B. Riddle,<sup>2</sup> Jonas Christoffersson,<sup>1</sup> Hernán González-King Garibotti,<sup>1</sup> Bojana Lazovic,<sup>1</sup> Peter J. Greasley,<sup>1</sup> Mark Lal.<sup>1</sup> *<sup>1</sup>AstraZeneca PLC, Gothenburg, Sweden; <sup>2</sup>University of Cambridge, Cambridge, United Kingdom.*

**Background:** Apolipoprotein-L1 (APOL1) high-risk genotypes are associated with increased risk of chronic kidney disease (CKD) in people of African ancestry. APOL1 is endogenously expressed in the kidney by podocytes, and endothelial cells (ECs). Interestingly, despite the abundant APOL1 expression in the endothelium little attention has been given to this cell type. Given the importance of ECs in the development and progression of CKD we hypothesized that APOL1 high-risk genotypes may promote EC activation and dysfunction.

**Methods:** To test our hypothesis we performed bioinformatic analysis of publicly available transcriptomics datasets from human and transgenic mice. *In vitro*, we expressed APOL1 in ECs derived from genetically modified induced pluripotent stem cells (iPSCs) as well as in transfected primary glomerular ECs.

**Results:** In this study, we show the high expression of endogenous APOL1 and its inducibility in various vascular beds of the kidney. Utilizing two datasets of glomeruli from patients with nephrotic syndrome and focal segmental glomerulosclerosis, we identified an increase in intercellular adhesion molecule-1 (ICAM-1) expression and an enrichment in leukocyte migration pathways in patients carrying APOL1 high-risk genotypes. This signature of EC activation was confirmed by analyzing publicly available RNA-seq data from podocyte-specific APOL1 transgenic mice, which presented a 4.9 and 2.8-fold increase in VCAM-1 and ICAM-1, respectively. In both ECs derived from genetically modified iPSCs and primary human glomerular ECs we show that APOL1 expression induced EC activation in a non-phlogistic manner. Specifically, APOL1 overexpression promoted changes in adhesion molecules, endothelial junctional proteins, inflammatory receptors, and intracellular complexity leading to an increase in monocyte attachment.

**Conclusions:** Overall, our data support the involvement of APOL1 as an inducer of EC activation and dysfunction, both *in vivo* and *in vitro*, in multiple vascular beds with effects beyond the glomerular vasculature.

## FR-OR53

### Identification of Glomerular and Plasma APOM as Novel Biomarkers in Glomerular Disease

Yelena Drexler,<sup>1</sup> Makoto Kurano,<sup>3</sup> Judith T. Molina David,<sup>1</sup> Tali Elfassy,<sup>1</sup> Ruijuan Ma,<sup>1</sup> Christina Christoffersen,<sup>4</sup> Yutaka Yatomi,<sup>3</sup> Laura H. Mariani,<sup>2</sup> Gabriel Contreras,<sup>1</sup> Sandra M. Merscher,<sup>1</sup> Alessia Fornoni.<sup>1</sup> *<sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>3</sup>Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu Seirigaku, Bunkyo-ku, Japan; <sup>4</sup>Rigshospitalet, Kobenhavn, Denmark.*

**Background:** Lipid-induced kidney injury is a highly relevant pathway in experimental models of glomerular disease (GD). Apolipoprotein M (APOM) has a crucial role in the mobilization of cellular cholesterol and modulation of the bioactive sphingolipid sphingosine-1-phosphate (S1P). APOM expression is decreased in glomeruli of patients with focal segmental glomerulosclerosis. We hypothesized that GD represents a state of glomerular APOM deficiency and that altered APOM expression and plasma APOM correlate with clinical outcomes.

**Methods:** GD patients from the NEPTUNE study with proteinuria >1 g/g and available microarray gene expression data were included in the analysis (n=84). Glomerular mRNA expression levels of APOM, sphingosine kinase 1 (SPHK1), and S1P receptors 1-5 (S1P1-5) were obtained from microdissected kidney tissue in GD patients and living kidney donor controls (n=6). From baseline samples, plasma APOM (pAPOM) was measured by ELISA and log<sub>2</sub>-transformed. Plasma S1P (pS1P) and other bioactive lipids were measured by LC-MS/MS. We used Welch's t-test to compare gene expression in GD and controls. We used correlation analyses to determine associations between glomerular APOM expression with pAPOM levels. We used linear regression to determine whether glomerular APOM, pAPOM, pS1P, and bioactive lipids were associated with baseline eGFR. Using Cox models, we determined whether glomerular APOM and pAPOM were associated with time to complete remission (CR).

**Results:** In GD patients compared to controls, APOM expression was reduced (P<0.01) and SPHK1 and S1P1-5 expression was increased (P<0.05), suggesting modulation of APOM/S1P signaling. APOM expression was positively correlated with pAPOM levels (R<sup>2</sup>=0.12, P<0.01). Every unit decrease in APOM expression and pAPOM was associated with a 10.17 (95% CI, 4.35–16.00) and 14.95 (95% CI, 5.29–24.61) lower eGFR, respectively (P<0.01). pS1P was not associated with eGFR. From Cox models adjusted for age, sex, and race, pAPOM was a significant predictor of CR (HR 1.85; 95% CI, 1.06–3.23).

**Conclusions:** Plasma APOM is a non-invasive biomarker of glomerular APOM deficiency and is strongly associated with clinical outcomes in GD. We also found evidence supporting APOM/S1P pathway modulation, warranting further study.

**Funding:** Other NIH Support - The project is supported by Grant Number KL2TR002737, Miami Clinical and Translational Science Institute, from the National Center for Advancing Translational Sciences and the National Institute on Minority Health and Health Disparities.

## FR-OR54

### Urinary CD4+ T Cell Quantification Identifies ANCA Patients at Risk for Subsequent Renal Flares: Results of the Prospective, Multicenter Pre-Flared Study

Luka Prskalo,<sup>1</sup> Christopher Skopnik,<sup>1</sup> Janis Sonnemann,<sup>1</sup> Emil Grothgar,<sup>1</sup> Jan Klocke,<sup>1</sup> Udo Schneider,<sup>1</sup> Alan D. Salama,<sup>2</sup> Markus Bieringer,<sup>3</sup> Adrian Schreiber,<sup>1</sup> Philipp Enghard.<sup>1</sup> *<sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>University College London Medical School, London, United Kingdom; <sup>3</sup>Helios Kliniken GmbH, Berlin, Germany.*

**Background:** Patients with ANCA-associated vasculitis (AAV) are at risk for recurrent renal flares. Presently, there are no reliable biomarkers for flare prediction. Urinary CD4+ T cells have previously been reported to distinguish active renal involvement in AAV from AAV in stable remission, but it is currently unknown if they may predict future flares in quiescent disease.

**Methods:** We prospectively collected urine samples from 112 AAV patients in remission (BVAS=0) at three AAV clinics in two hospitals (NCT04428398). 10 patients met the exclusion criteria; 102 patient samples were analyzed. Renal flares were defined as an increase in BVAS >0 and at least one element of the renal BVAS or alternatively as new initiation of induction treatment. Using flow cytometry, urinary CD4+ and CD8+ T cell subsets were quantified. The primary end point was the prediction of renal relapse after six months using the initial CD4+ count.

**Results:** Of the 102 analyzed patients 10 developed a renal flare, 2 developed a non-renal flare and 90 remained in stable remission. The number of urinary CD4+ T cells predicted renal flares with an Receiver-Operator Characteristic (ROC) area under the curve (AUC) of 0.88. Urinary CD4+ T cells outperformed traditional biomarkers such as ANCA titers, hematuria, and proteinuria in renal flare prediction. Applying a cut-off of 490 CD4+ T cells per 100ml urine yielded a sensitivity of 60% and specificity of 97.8% in identifying patients with future renal flares. A combination of urinary CD4+ T cells (>50/100ml) and PR3 ANCA levels (>40IU/ml) increased the predictive value to the sensitivity of 100% and specificity of 92%. Furthermore, in the complete patient cohort (n=102), the number of urinary CD4+ T cells correlated with loss of GFR (p<0.01) and increase in proteinuria (p<0.05) in the subsequent 6 months.

**Conclusions:** Urinary CD4+ T cell numbers identify AAV patients at risk for renal flares. Combining urinary CD4+ T cell numbers with ANCA levels may further improve flare prediction.

## FR-OR55

### Explainability of a Deep Learning Based Classification Model for ANCA-Associated Glomerulonephritis

Maria Wester Trejo,<sup>1</sup> Maryam Sadeghi,<sup>2</sup> Shivam Singh,<sup>2</sup> Andreas Kronbichler,<sup>3</sup> Vladimir Tesar,<sup>4</sup> Xavier Puéchal,<sup>5</sup> Georg Goebel,<sup>2</sup> Ingeborg M. Bajema.<sup>1</sup> *<sup>1</sup>Leiden University Medical Center, Department of Pathology, Leiden, Netherlands; <sup>2</sup>Medical University of Innsbruck, Department of Medical Statistics, Informatics and Health Economics, Innsbruck, Austria; <sup>3</sup>University of Cambridge, Department of Medicine, Cambridge, United Kingdom; <sup>4</sup>Charles University and General University Hospital, Department of Nephrology, Prague, Czechia; <sup>5</sup>Hôpital Cochin, Department of Internal Medicine, Paris, France.*

**Background:** The histopathological classification for ANCA-associated glomerulonephritis (ANCA-GN) is a well-established tool to reflect the variety of patterns and severity of lesions that can occur in renal biopsies of patients with ANCA-associated vasculitis. As with many fields, medicine saw a rapid emergence of Artificial Intelligence (AI) and Deep Learning (DL) approaches. In the field of digital pathology, AI can now serve as decision-support for pathologists, with the potential for gains in productivity and time-saving. It was demonstrated previously that AI can aid in identifying histopathological classes of renal diseases, e.g. of diabetic nephropathy. Although these models reach high prediction accuracies, their black box structure makes them very non-transparent. The disadvantage is that the networks' decisions are not easily interpretable by humans and it is not clear what information in the input data underlies their decisions. This necessitates the use of Explainable AI (XAI), so that decisions made by AI models become accessible for validation by a human expert.

**Methods:** Renal biopsy slides of 80 patients with ANCA-GN from 3 European centers, who underwent a diagnostic renal biopsy between 1991 and 2011, were included. On the scanned slides glomeruli were labelled as 'normal', 'sclerotic', 'crescentic' or 'abnormal - other'. We developed a DL-based computational pipeline, which detects and classifies the glomeruli. We investigated the explainability of our model, using XAI techniques to shed light on the decision-making criteria of our trained DL classifier, using saliency maps. These maps were analyzed by pathologists to compare the decision-making criteria of humans and the DL model.

**Results:** Our DL model shows a prediction accuracy of 93% for classifying glomeruli. The saliency maps from our trained DL models help us to better understand the decision-making criteria of the DL black box.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** AI and DL play an increasingly important role in (nephro) pathology. To ultimately enable safe implementation of these models in clinical practice, validation of their decisions is needed. To achieve this, we used XAI techniques, which showed great potential for illuminating the decision-making criteria of the DL black box.

## FR-OR56

### Sparsentan Improves Glomerular Endothelial and Podocyte Functions and Augments Protective Tissue Repair in a Mouse Model of Focal Segmental Glomerulosclerosis (FSGS)

Georgina Gyarmati,<sup>1</sup> Sachin K. Deepak,<sup>1</sup> Urvi Nikhil Shroff,<sup>1</sup> Audrey Izuhara,<sup>1</sup> Radko Komers,<sup>2</sup> Patricia W. Bedard,<sup>2</sup> Janos Peti-Peterdi.<sup>1</sup> <sup>1</sup>University of Southern California Keck School of Medicine, Los Angeles, CA; <sup>2</sup>Travere Therapeutics Inc, San Diego, CA.

**Background:** Emerging evidence indicates strong nephroprotection by dual antagonism of the endothelin (ET) type A (ETAR) and angiotensin (AngII) type 1 (AT1R) receptors with sparsentan (SP). Previously, we reported antiproteinuric and protective hemodynamic effects of SP in both FSGS and normal mouse kidneys and differences between SP and AT1R inhibition alone. This study investigated the glomerular cell and molecular mechanisms of SP's protective effects in experimental FSGS.

**Methods:** Multiphoton microscopy (MPM) of the kidney in vivo was combined with urinalysis and histology. Glomerular endothelial surface layer (glycocalyx) thickness (FITC-WGA labeling), podocyte mitochondrial metabolism (MitoTracker-Red intensity), and endothelial and renin lineage single-cell fate-tracking using Confetti mice were measured in 6 months-old FSGS mice (TRPC6 overexpression) received either no drug, losartan (Los; 10 mg/kg/day), or SP (120 mg/kg/day) in custom rodent chow for 6 weeks.

**Results:** The heterogeneous segmental increase in glomerular endothelial glycocalyx observed in FSGS mice was fully restored by SP compared to the intermediate effects of Los. Similarly, MPM found clear elevation of mitochondrial membrane potential indicating oxidative stress in podocytes in FSGS, which was attenuated by both Los and SP. Moreover, compared to Los, SP resulted in a more robust increase in the number of Confetti+ cells of both renin and endothelial lineages, clones, and individual cells/clone in both the glomeruli and tubules of FSGS mice indicating active tissue remodeling in response to SP.

**Conclusions:** MPM imaging directly visualized the pleiotropic protective effects of SP in the intact living kidney of FSGS mice including restoration of glomerular endothelial surface layer and podocyte metabolic functions and enhanced endogenous tissue repair, in addition to the previously identified hemodynamic improvements. Compared to Los, SP was more effective in the long-term preservation of kidney structure and function and in augmenting endogenous tissue repair in experimental FSGS, which further underscores the importance of ET component in the nephroprotective actions of SP.

**Funding:** Commercial Support - Travere Therapeutics

## FR-OR57

### Long-Term Efficacy and Safety of Sparsentan in FSGS: 240-Week Analysis of the DUET Open-Label Extension (OLE)

Tarak Srivastava,<sup>1</sup> Vladimir Tesar,<sup>2</sup> Kirk N. Campbell,<sup>3</sup> Michelle N. Rheault,<sup>4</sup> Radko Komers,<sup>5</sup> Edward Murphy,<sup>5</sup> Howard Trachtman,<sup>6</sup> Loreto Gesualdo.<sup>7</sup> <sup>1</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>2</sup>Charles University, General University Hospital, Prague, Czechia; <sup>3</sup>Ichan School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>5</sup>Travere Therapeutics Inc, San Diego, CA; <sup>6</sup>University of Michigan, Ann Arbor, MI; <sup>7</sup>University of Bari Aldo Moro, Bari, Italy.

**Background:** Sparsentan (SPAR) is a novel, orally active, single molecule Dual Endothelin Angiotensin Receptor Antagonist (DEARA) being investigated for focal segmental glomerulosclerosis (FSGS) and immunoglobulin A nephropathy. In the 8-week double-blind period of the phase 2 DUET trial in patients with FSGS (excluding secondary FSGS), SPAR (200, 400, and 800 mg/day) resulted in greater proteinuria reduction vs irbesartan 300 mg/day. The 240-week analysis of the DUET OLE reports the on-treatment long-term efficacy and safety of SPAR.

**Methods:** Patients (n=108 who received  $\geq 1$  SPAR dose) were examined from first SPAR dose (double-blind or OLE) through 240 weeks (4.6 years). Urinary protein/creatinine ratio (UP/C), eGFR, and blood pressure (BP) were assessed every ~12 weeks. Treatment-emergent adverse events (TEAEs) and treatment-related TEAEs were summarized as cases per 100 patient-years.

**Results:** At OLE data cutoff (February 5, 2021), 45/108 patients (41.7%) had ongoing SPAR treatment. Total patient years with SPAR were 366. Median years to treatment discontinuation was 3.9. At Week 240 vs baseline, median (IQR) UP/C was 0.80 g/g (0.33, 2.55; n=41) vs 2.7 g/g (1.5, 4.2; n=107) and eGFR was 57.8 mL/min/1.73m<sup>2</sup> (34.3, 71.4; n=45) vs 69.4 mL/min/1.73m<sup>2</sup> (44.1, 92.0; n=108). Systolic/diastolic BP (mean $\pm$ SD) was 122.9 $\pm$ 15.0/76.1 $\pm$ 9.6 mmHg (n=47) vs 129.0 $\pm$ 12.4/81.6 $\pm$ 8.8 mmHg (n=108). **Table** shows the most common TEAEs and the cases considered treatment-related.

**Conclusions:** Sustained proteinuria reduction was observed over 240 weeks in patients who continued SPAR in the OLE. No new or unexpected TEAEs vs the double-blind period were observed with long-term SPAR treatment.

**Funding:** Commercial Support - Travere Therapeutics, Inc., San Diego, CA

Table. Incidence of the Most Common TEAEs and TR-TEAEs by Cases Per 100 Patient-Years (PY)

Preferred Term	TEAE $\geq 7$ cases/100 PY	TR-TEAE cases/100 PY
Headache	11.74	3.82
Edema peripheral	11.19	2.46
URTI	10.64	0
Hyperkalemia	10.37	9.28
Hypotension	9.28	7.92
Nausea	8.46	3.55
Hypertension	7.64	0.55
Vomiting	7.64	2.46
Diarrhea	7.10	1.09

PY, patient years; TR-TEAE, treatment-related treatment emergent adverse events; URTI, upper respiratory tract infection.

## FR-OR58

### Efficacy and Safety of Voclosporin Over 3 Years in Patients With Severe Lupus Nephritis

Hanni Menn-Josephy,<sup>1</sup> Matt Truman,<sup>2</sup> Mary Palmen,<sup>2</sup> Henry Leher.<sup>2</sup> <sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

**Background:** The AURORA 1 study demonstrated that addition of voclosporin, a novel calcineurin inhibitor, to mycophenolate mofetil (MMF) and low-dose steroids significantly increased rates of complete renal response (CRR) at 52 weeks in patients with lupus nephritis, with efficacy maintained for an additional 24 months in those who continued treatment in the AURORA 2 study. Here we report on a post hoc analysis evaluating voclosporin use in patients with severe lupus nephritis using pooled data from the AURORA 1 and AURORA 2 studies.

**Methods:** Patients who completed AURORA 1 were eligible to enter AURORA 2 to continue the same blinded therapy of voclosporin or placebo; all patients received MMF and low-dose steroids. In this post hoc analysis, the definition of severe lupus nephritis included patients with Class III or IV ( $\pm$  Class V) disease with active lesions and urine protein creatinine ratio (UPCR)  $\geq 3$  mg/mg at AURORA 1 baseline. CRR was defined as UPCR  $\leq 0.5$  mg/mg with stable renal function, use of low-dose steroids, and no use of rescue medication and was assessed over the three-year treatment period of AURORA 1 and AURORA 2.

**Results:** Of the 116 patients in the voclosporin arm and 100 patients in the control arm who continued treatment in AURORA 2, 47 and 37 patients in each arm, respectively, had severe disease. Mean (SD) UPCR at pre-treatment AURORA 1 baseline was 6.02 (2.29) mg/mg in the voclosporin arm and 6.08 (2.46) mg/mg in the control arm. Rates of CRR in the voclosporin and control arms were 46.8% and 21.6%, respectively, at one year (OR 4.41, 95% CI 1.47, 13.26; p=0.008), 57.4% and 35.1% at two years (OR 3.08, 95% CI 1.17, 8.10; p=0.022), and 53.2% and 35.1% at three years (OR 2.92, 95% CI 1.07, 7.94; p=0.036). The rates of serious adverse events were similar in the voclosporin (21.3%) and control (27.0%) arms, with one death occurring in a control-treated patient.

**Conclusions:** In patients with severe lupus nephritis, adding voclosporin to MMF and low-dose steroids results in significantly higher CRR rates and a similar safety profile to that of control. This is clinically meaningful given that patients with severe disease are at higher risk of worse long-term outcomes and development of end stage kidney disease.

**Funding:** Commercial Support - Aurinia Pharmaceuticals Inc.

## FR-OR59

### Effect of Iptacopan on Proteinuria and Complement Biomarkers Over Time in IgA Nephropathy

Brad H. Rovin,<sup>1</sup> Jonathan Barratt,<sup>2,3</sup> Hong Zhang,<sup>4</sup> Dana Rizk,<sup>5</sup> Naoki Kashiwara,<sup>6</sup> Bart D. Maes,<sup>7</sup> Hernan Trimarchi,<sup>8</sup> Ben Sprangers,<sup>9</sup> Matthias Meier,<sup>10</sup> Dmitriy Kollins,<sup>10</sup> Annabel R. Magirr,<sup>10</sup> Guido Junge,<sup>11</sup> Vlado Perkovic.<sup>12</sup> <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; <sup>3</sup>University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; <sup>4</sup>Peking University First Hospital Department of Nephrology Renal Division, Beijing, China; <sup>5</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL; <sup>6</sup>Kawasaki Ika Daigaku Jinzo Koketsuatsu Naikagaku Kyoshitsu, Kurashiki, Japan; <sup>7</sup>AZ Delta vzw, Roeselare, Belgium; <sup>8</sup>Hospital Britanico de Buenos Aires, Buenos Aires, Argentina; <sup>9</sup>Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; <sup>10</sup>Novartis Pharma AG, Basel, Switzerland; <sup>11</sup>Novartis Institutes for BioMedical Research Basel Department of Translational Medicine, Basel, Switzerland; <sup>12</sup>University of New South Wales, Sydney, NSW, Australia.

**Background:** The alternative complement pathway (AP) plays a key role in the pathogenesis of IgA nephropathy (IgAN). Iptacopan (LNP023) is an oral, first in class, highly-potent, selective inhibitor of factor B (FB). In a Phase 2 study, iptacopan treatment led to a dose dependent reduction in proteinuria and inhibition of AP in patients with IgAN.

**Methods:** This parallel-group adaptive design Phase 2 study (NCT03373461) randomized biopsy-confirmed IgAN patients to one of the four iptacopan doses (10, 50, 100, or 200 mg bid) or placebo for either a 3-month (m) (Part 1; N=46) or 6-m (Part 2; N=66) treatment period. In this analysis, we report changes in proteinuria (ratio to baseline

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in UPCR), and biomarkers of complement activity (plasma Bb, FB, properdin, C3 and C4, and serum Wieslab activity) with iptacopan 200 mg bid (n=26) vs placebo (n=25) at 3 m (pooled part 1 and 2 data) and 6 m (part 2).

**Results:** UPCR fell by 31% (80% CI: 23%, 39%) and 41% (31%, 49%) from baseline to 3- and 6-m (post-hoc analysis of part 1 and 2) in the iptacopan arm vs 12% (0%, 20%) and 2% (-20%, 23%) in the placebo arm (Figure 1A). Iptacopan selectively inhibited AP as demonstrated by changes in Wieslab activity, Bb, FB, properdin levels (Figure 1B) and small increases in C3; C4 levels remained largely unchanged indicating that iptacopan does not inhibit classical/lectin pathway (Figure 1B).

**Conclusions:** In accordance with its mechanism of action, iptacopan 200 mg bid attenuates activation of AP and results in clinically meaningful reductions in proteinuria in patients with IgAN.

**Funding:** Commercial Support - Novartis Pharma AG

Effect of iptacopan on proteinuria and complement biomarkers

## FR-OR60

### A Multi-Omics Approach to IgA Nephropathy Characterization in the NURTURE Cohort Enables Precision-Based Treatment Approaches

N. E. Olson,<sup>1</sup> Jennifer H. Cox,<sup>1</sup> I-Ju Lo,<sup>2</sup> Seamus Ragan,<sup>1</sup> Niklas Michel,<sup>2</sup> Johannes Pospiech,<sup>2</sup> Michaela Bayerlová,<sup>2</sup> Simone Romoli,<sup>1</sup> Taher Sathaliya,<sup>1</sup> Tobias Bohnenpoll,<sup>2</sup> Nikolas Stroth,<sup>2</sup> Olivier Radresa,<sup>2</sup> Andrew J. King,<sup>1</sup> Uwe Andag.<sup>2</sup> <sup>1</sup>Chinook Therapeutics Inc, Seattle, WA; <sup>2</sup>Evotec International GmbH, Göttingen, Germany.

**Background:** IgA nephropathy (IgAN) is the most commonly reported primary glomerulonephritis, yet risk stratification and prediction of treatment response remain a challenge. Systems biology approaches integrating multiple data types have the potential to identify patient subsets that could benefit from precise treatment approaches. Here we describe a multi-omics analysis of the NURTURE IgAN patient cohort to generate an integrated understanding of disease pathogenesis and patient stratification.

**Methods:** Data collected from 205 patients with IgAN in the NURTURE cohort included clinical characteristics, MEST-C scores for glomerular and tubular injury, serum proteomics using the Olink Explore panel of 3072 analytes and blood and kidney transcriptomes (Table). Relationships between serum proteins, kidney function, kidney and blood gene expression and histopathology were determined using Spearman correlation, ANOVA and Kruskal-Wallis tests.

**Results:** Serum protein levels of TNFSRF1A, B2M, LCN2, APRIL and TNFSRF17 were inversely correlated with eGFR. Analysis by MEST-C score identified proteins significantly associated with the tubular atrophy/interstitial fibrosis (T) score, including LCN2 and B2M, which are increased in patients with T1 or T2. Analysis of kidney biopsy gene expression by MEST-C score showed that scores for an inflammatory response gene signature were significantly higher in kidney biopsies from patients with T1 or T2.

**Conclusions:** A multi-omics approach to the characterization of IgAN in the NURTURE cohort was performed, integrating clinical, histological, transcriptomic and serum proteomic data to gain deeper insights into patient stratification and disease

biology. These learnings will be applied to clinical studies evaluating atrasentan, an endothelin receptor A antagonist, and BION-1301, an anti-APRIL antibody, for the treatment of IgAN.

## SA-OR01

### Long-Term Renal Outcomes of COVID-19-Associated Nephropathy (COVAN)

Gabriel A. Giannini,<sup>1</sup> Tiffany Caza,<sup>1</sup> Rebecca May,<sup>1</sup> Muner Mohamed,<sup>2</sup> Clarissa A. Cassol,<sup>1</sup> Shree G. Sharma,<sup>1</sup> Christopher P. Larsen,<sup>1</sup> Juan Carlos Q. Velez,<sup>3</sup> <sup>1</sup>Arkana Laboratories, Little Rock, AR; <sup>2</sup>Stamford Hospital, Stamford, CT; <sup>3</sup>Ochsner Health Network LLC, New Orleans, LA.

**Background:** COVID-19-associated nephropathy (COVAN) is a type of collapsing glomerulopathy that leads to acute kidney injury (AKI) and overt proteinuria in individuals with apolipoprotein L1 (APOL1) polymorphism infected with SARS-CoV-2. Although the severity of the acute presentation of COVAN is well described, the long-term renal prognosis has not been clearly established.

**Methods:** We retrospectively identified native kidney biopsies from patients with diagnosis of COVAN discharged alive between January 2020 and March 2021. Time of biopsy pathological and clinical data were collected. We performed APOL1 genotyping for G1/G2 risk alleles. We examined the rate of end-stage kidney disease (ESKD), *de novo* or progressive chronic kidney disease (CKD) and death. Factors associated with those outcomes were assessed by logistic regression.

**Results:** A total of 43 patients with COVAN with median follow-up at 244 days were included. Mean age was 53 ± 12 years (range 30-78), 49% women, and 85% were of African descent. High-risk APOL1 genotypes were found in 86%. Most presented with AKI (91%) and nephrotic-range proteinuria (81%). Sixteen patients required dialysis at presentation (AKI-RRT), 8 of which reached ESKD and dialysis dependence at follow-up. Additionally, 6 patients without AKI-RRT developed ESKD and required dialysis at follow-up. Forty patients (93%) either developed *de novo* CKD or progressed to advanced stage of CKD [mean serum creatinine (sCr) 3.1 ± 1.9 mg/dL]. Overall, 35% reached the combined endpoint of ESKD, progressive CKD or death. Predictive factors of ESKD included older age (59.1 ± 13.9 vs. 50.4 ± 10.7 years, p=0.03), increased sCr at time of biopsy (9.4 ± 3.2 vs. 6.0 ± 4.9, p=0.03), increased glomerular obsolescence (52.8 ± 21.3 vs. 25.0 ± 23.2%, p=0.0005), and IFTA [moderate-severe vs. mild, OR 9.8 (CI: 1.1-85.2), p=0.03]. AKI-RRT, sex, proteinuria at the time of biopsy, and absence vs. presence of an APOL1 high-risk genotype were not predictive of ESKD.

**Conclusions:** COVAN is associated with ominous long-term renal sequelae. Serum creatinine at time of biopsy, patient age, glomerular obsolescence, and IFTA are associated with greater risk of ESKD.

## SA-OR02

### Renal Pathology of Fatal Cases of COVID-19: A Study of 94 Autopsies

Arian Pourmehdi Lahiji, Rachel A. Gietzen, David D. Walker, Judith Aronson, Marjan Afrouzan. The University of Texas Medical Branch at Galveston, Galveston, TX.

**Background:** Acute kidney injury (AKI) is a serious complication of infection with SARS-CoV-2 and it associated with high mortality. Post-mortem examination of kidney & lung of these patients allows a logistical assessment of the glomerular & vascular events. This is one of the largest North American autopsy series with details on renal lesions correlated with lung microthrombi.

**Methods:** From April 2020 to July 2021, a total of 94 autopsy cases were examined: 82 COVID-19 cases examined prospectively, & 12 control cases with similar comorbidities, retrospectively from the pre-COVID-19 era. Demographics, clinical presentation, cause of death, laboratory results were collected & pathologic findings, focusing on the following pathological lesions were studied: 1- collapsing glomerulopathy (CG), 2- evidence of thrombotic microangiopathy (TMA), i.e., presence of any glomerular microthrombi +/- thrombi in arteries/arterioles & acute tubular injury & necrosis (ATI-ATN); 3- topography

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

of the lesions in cortex; 4- presence of pulmonary microthrombi. Beside routine stains used in renal pathology, Martius-scarlet-blue (MSB) stain and immunohistochemistry for fibrin were performed on 54 cases to detect microthrombi.

**Results:** In the COVID-19 group composed of 82 cases, CG was observed in 40 (49%) cases, of whom only 14 (35%) were of African descent; TMA in 32 (39%); combined CG + TMA in 16 (19%) & ATI-ATN in 29 (35%). In the control group composed of 12 cases, TMA was observed in 3 (25%), ATI-ATN in 6 (50%) and no CG was found. Lung microthrombi examined in 35 cases were found in 19 cases (54%), 14 (40%) cases having TMA in the kidney. Statistical analysis of Variance showed a p-value of 0.0847, reflecting trending correlation between presence of TMA and CG.

**Conclusions:** TMA, CG, and ATI-ATN were the main renal pathologic findings in our study. Wedge-shaped areas of cortical scarring suggesting a vascular pattern were observed. Co-incidence of TMA & CG was observed in half of the cases, suggesting an association between TMA & CG. Only a percentage of cases with CG were of African descent suggesting a second pathogenesis (other than podocyte injury related to APOL-1) for CG: In patients of non-African descent, TMA may be the pathogenesis behind the development of CG.

## SA-OR03

### Incidence and Clinical Course of Gross Hematuria Following COVID-19 Vaccination Among Patients With IgA Nephropathy

Hitomi Kimura, Hiroko Beppu, Tomoko Kawanishi, Hina Ogawa, Ayumi Ishiwatari, Minami Toda, Yuiko Kamei, Toshie Ogawa, Yasutomo Abe, Mariko Endo, Sachiko Wakai. *Okubo Byoin, Shinjuku-ku, Japan.*

**Background:** IgA nephropathy (IgAN) flares with gross hematuria after COVID-19 vaccination have been recently reported as adverse events of immunization, but no study to date has examined the incidence and clinical course of IgAN patients with gross hematuria following vaccination.

**Methods:** A single-center retrospective observational study included 301 patients with biopsy-proven IgAN and followed-up for more than 6 months with therapeutic intervention and received at least one dose of COVID-19 vaccination. We examined from medical records the incidence of gross hematuria following vaccination and also evaluated the clinical course of eGFR, spot urine protein/Cr ratio (UPCR), urinary erythrocyte count (URBC) /hpf among IgAN patients with gross hematuria following COVID-19 vaccination.

**Results:** We identified 7 (3.0 %) patients with gross hematuria following COVID-19 vaccination. 6 patients were female. The median age was 42 (range, 33 to 48). Median time to develop gross hematuria after vaccination was 1 (range, 0 to 4) day and gross hematuria resolved within 3 (range, 1 to 7) days. 6 patients presented gross hematuria after the second dose. Mean baseline eGFR and UPCR before vaccination were 73.7 (IQR, 61.3 to 86.0) ml/min/1.73m<sup>2</sup> and 0.23 (range, 0.01 to 0.70) g/g Cr, respectively, and median grade of hematuria was URBC 10-19/hpf. With mean follow up of 238.7 (range, 184 to 282) days after the onset of gross hematuria, 4 patients were introduced steroid therapy. Within one month after the onset of gross hematuria, mean eGFR decreased -13 (range, -29.2 to -5.2) % and UPCR increased +0.70 (range, +0.02 to +2.59) g/gCr from baseline, and median grade of hematuria increased to URBC 50-99/hpf as compared to baseline. At 6 months, mean eGFR and UPCR improved to 73.9 (IQR, 60.2 to 88.0) ml/min/1.73m<sup>2</sup> and 0.30 (range, 0.06 to 0.74) g/g Cr, respectively, and median grade of hematuria decreased to URBC 5-9/hpf.

**Conclusions:** Our study revealed the incidence of gross hematuria following vaccination in IgAN patients and also suggested that eGFR, proteinuria and hematuria may transiently worsen but improve almost to baseline with appropriate therapeutic intervention or careful follow-up.

## SA-OR04

### Urinary Transcriptomics Identified Inflammatory Signals Associated With COVID-19-Related AKI

Sean Eddy,<sup>1</sup> Rajasree Menon,<sup>1</sup> Edgar A. Otto,<sup>1</sup> Jennifer A. Schaub,<sup>1</sup> Chrysta C. Lienczewski,<sup>1</sup> Yuan O. Zhu,<sup>2</sup> Anita Boyapati,<sup>2</sup> Kishor B. Devalaraja-Narashimha,<sup>2</sup> Nikhil Singh,<sup>2</sup> Gabor Halasz,<sup>2</sup> Lori Morton,<sup>2</sup> Abhijit S. Naik,<sup>1</sup> Matthias Kretzler.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Regeneron Pharmaceuticals Inc, Tarrytown, NY.

**Background:** SARS-CoV-2, associated with COVID-19, can include dysfunction in many organs including the kidney. Early in the pandemic, a high incidence of acute kidney injury (AKI), with an associated increase in mortality, was observed, particularly in those with severe respiratory failure. Given the effect on the kidney and limited availability of biopsied tissue, we designed a non-invasive protocol to isolate and sequence renal cells from the urine of patients with COVID-19 to identify the cellular and molecular mechanisms of COVID-19-related AKI, and the impact of immunomodulatory treatment.

**Methods:** Three groups of hospitalized patients, AKI with and without COVID-19 and COVID-19 without AKI, were recruited at Michigan Medicine (N=48). We documented >90 clinical parameters, including serum creatinine trends, treatment exposure to IL-6 inhibitors, and patient outcomes. Urine samples near peak AKI were collected and immediately processed for single cell RNA sequencing (scRNAseq); profiles were generated on the 10x Genomics platform and clustered using Seurat. Differentially expressed gene profiles were generated in a cell type selective manner.

**Results:** Urine scRNAseq profiles from 44,440 cells clustered into 5 major cell-types, based on cell marker assignment. Renal cells comprised 12% of the recovered cells. Comparing renal cells from COVID-19-related AKI group to either of the two other groups identified 129 up-regulated and 89 down-regulated genes in common (q<0.05).

The COVID-19-related AKI renal cell profile was consistent with activation of one or more inflammatory cytokines including IFN- $\gamma$ , IL-6, and IL-1 $\beta$ . Conversely, patients exposed to IL-6 inhibitors had a reduced expression of inflammatory marker genes.

**Conclusions:** This study demonstrates the successful isolation and generation of cell type transcriptional profiles of renal cells in the urine of patients with COVID-19, with or without AKI, and non-COVID-19 AKI. Expression profiles in renal cells were consistent with intra-renal inflammatory activation in COVID-19-related AKI. Association of profiles with renal function and patient outcomes may identify predictive markers of COVID-19-related AKI and potential targets for therapeutic modulation.

## SA-OR05

### Single Nucleus RNA-Sequencing in Diagnostic Biopsy Cores of COVID-AKI Patients Reveals Robust Modelling, Injury, and Profibrotic Markers

Reetika R. Ghag,<sup>1</sup> Madhurima Kaushal,<sup>1</sup> James C. Williams,<sup>2</sup> Lois J. Arend,<sup>3</sup> Avi Z. Rosenberg,<sup>3</sup> Tarek M. El-Achkar,<sup>2</sup> Chirag R. Parikh,<sup>3</sup> Sanjay Jain.<sup>1</sup> <sup>1</sup>Washington University in St Louis, St Louis, MO; <sup>2</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>3</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Renal (acute kidney injury, AKI) involvement in COVID-19 patients is associated with high mortality and morbidity. Critically ill COVID-19 patients are at twice the risk of in hospital mortality compared to nonCOVID AKI patients. The cell types that succumb to direct or indirect damage and the associated abnormal biological responses are unclear. New generation single cell technologies have the potential to provide insights into physiological states and molecular mechanisms in COVID-AKI. One of the key limitations is that biopsies are not routinely performed and the risks of procuring an additional research core is indeterminate making it difficult to get direct insights into the landscape of COVID-AKI disease in the kidney at genome wide and cellular scale.

**Methods:** We developed an innovative method that used remnant kidney biopsy tissue from OCT-embedded frozen diagnostic pathology biopsy core and generated single nucleus transcriptome (snRNAseq) of COVID-AKI from as little as 1 mm<sup>2</sup> of tissue. Comparative analysis of snRNAseq of 4 COVID-AKI and 4 control cortical biopsies was done in conjunction with urine transcriptomics to find overlapping genes in these two datasets representing COVID-AKI-enriched genes and the corresponding cell types in the kidney.

**Results:** snRNAseq of COVID-AKI remnant or control frozen kidney biopsies (15659 and 15604 nuclei passing QC, respectively) identified all major and minor cell types. Differential expression analysis of COVID-AKI biopsies showed pathways enriched in viral response, kidney regeneration, WNT signaling, cancer, kidney development and cytokines in several nephron epithelial cells including kidney injury markers and fibrosis indicating robust remodelling in various cell types. Ten genes were also detected in urine cells of COVID-AKI patients as potential biomarkers. Two of these genes, LRP1B and PDE3A, have been recently implicated in driving fibrosis in COVID-AKI model systems.

**Conclusions:** snRNAseq is feasible on leftover kidney biopsy tissue using minimum amount of sample and enabled identification of altered kidney cell types and states with several novel genes associated with tissue injury, remodelling and fibrosis.

**Funding:** Other NIH Support - Common Fund (NHLBI)

## SA-OR06

### Kidney Disease and COVID-19 Outcomes in the Temporal Analysis of Pandemic Waves

Ning Shang, Krzysztof Kiryluk. *Columbia University, New York, NY.*

**Background:** COVID-19 continues to spread worldwide with considerable morbidity and mortality. CKD is among the most prevalent diseases related to COVID-19 mortality. AKI is a common COVID-19 complication. Distinct pandemic waves were observed as a function of specific COVID-19 variants, public health policies and vaccination status. Studies reported changing patient characteristics and outcomes by different waves. However, changes in the effect of clinical risk factors as a function of each wave have not been well studied. Here, we examine the temporal effects of pre-existing CKD (also KDIGO A and G stages) on COVID-19 outcomes by waves.

**Methods:** We used estimated effective reproduction numbers with US data to define distinct waves. We designed a COVID-19 algorithm based on WHO guidelines, N3C COVID-19 V2.2 and local data characteristics as having  $\geq 1$  positive SARS-CoV-2 RT-PCR or antibody test, or  $\geq 3$  diagnosis or problem codes if no relevant tests. Comorbidities and outcomes were captured electronically using published algorithms. We used logistic regression and survival analysis to identify predictors of COVID-19 outcomes for each wave.

**Results:** Five national waves were identified and mapped to 4 distinct NYC waves observed at Columbia University Medical Center (CUMC). We identified 64246 COVID-19 cases at CUMC, 8% were severe, 18% were hospitalized. The risk of severe COVID-19 was associated with pre-existing CKD, heart disease, diabetes and hypertension in most waves; and lung disease, obesity and cancer in at least one wave. AKI occurred in 49% of severe cases and 35% of hospitalized ones. The risk of AKI was associated with heart failure, obesity, diabetes and cancer in most waves; and CKD, CAD, hypertension and stroke in one or two waves. The risk of AKI was not associated with pre-existing lung disease. A and G stages independently predicted severe COVID-19 and COVID-19 related AKI across all waves. Pre-existing albuminuria significantly predicted COVID-19 mortality independent of G-stage, diabetes, obesity, hypertension, cancer or cardiovascular disease throughout the entire pandemic.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** Pre-existing kidney disease was among the strongest and most consistent clinical predictors of poor COVID-19 outcomes regardless of the pandemic wave. Even in the pandemic late phase, patients with decreased kidney function or albuminuria were at a higher risk of severe COVID-19, AKI and death.

**Funding:** NIDDK Support

## SA-OR07

### COVID-19 Pandemic Effect on Mortality of Hemodialysis Patients

Yan Zhang,<sup>1</sup> Luca Neri,<sup>2</sup> Paola Carioni,<sup>2</sup> Otto Arkossy,<sup>1</sup> Manuela Stauss-Grabo,<sup>1</sup> Frank M. Laukhuf,<sup>1</sup> Len A. Usvyat,<sup>3</sup> Stefano Stuard,<sup>1</sup> Anke Winter.<sup>1</sup>  
<sup>1</sup>Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany;  
<sup>2</sup>Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; <sup>3</sup>Fresenius Medical Care North America, Waltham, MA.

**Background:** COVID-19 was associated with significant excess mortality among dialysis patients. We aimed to assess mortality risk of patients with confirmed COVID-19 infection (COVID-19+) versus other hemodialysis (HD) patients, and its relation to COVID-19 pandemic in general population (GP).

**Methods:** We included 63,216 HD patients treated in 2019-2020 at NephroCare centers of 23 countries from European Clinical Database (EuCliD®). Mortality risk per calendar month in 2020 was estimated separately for COVID-19+ and other HD patients using Cox regression models, with COVID-19 status as a time-varying covariate and patients per month in 2019 as reference. The correlation between monthly mortality risk and numbers of COVID-19 cases and deaths in GP were evaluated.

**Results:** Monthly treated patients were 42,000-43,000 (Fig1). In line with two waves of pandemic in GP, two fluctuations of mortality risk were observed for both COVID-19+ and other HD patients (Fig1). Mortality risk of COVID-19+ patients persisted at much higher levels across 2020, with adjusted hazard ratios (HR)>6.5, whereas mortality risk of other HD patients elevated slightly (HRs<1.5) and mainly during the pandemic peak period (Fig1). Correlation of mortality risk with pandemic in GP were higher for other HD patients (spearman correlation coefficients [ρ] of HRs with the numbers of COVID-19 cases/deaths in GP, 0.77/0.44) than for COVID-19+ HD patients (ρ, -0.10/0.42).

**Conclusions:** COVID-19 pandemic had direct and indirect impact on mortality of HD patients. Potential reasons of increased mortality in patients without confirmed COVID-19 diagnosis could be underestimating or healthcare system capacity constraints. Quantifying the magnitude of pandemics on patients with/without confirmed disease may benefit dialysis clinics to manage patients during critical events.

**Funding:** Commercial Support - Fresenius Medical Care

Figure 1. Mortality risk of HD patients in 2020 and incident COVID-19 cases/deaths in general population (GP)

## SA-OR08

### Vaccine Effectiveness of One, Two, or Three Doses of SARS-CoV-2 mRNA Vaccines in Maintenance Dialysis Patients

Harold J. Manley,<sup>1</sup> Nien Chen Li,<sup>1</sup> Antonia Harford,<sup>1</sup> Jill M. Frament,<sup>1</sup> Margaret McNamara,<sup>1</sup> Gideon N. Aweh,<sup>1</sup> Karen M. Majchrzak,<sup>1</sup> Dana Miskulin,<sup>2</sup> Daniel E. Weiner,<sup>2</sup> Caroline M. Hsu,<sup>2</sup> Doug Johnson,<sup>1</sup> Eduardo K. Lacson.<sup>1,2</sup>  
<sup>1</sup>Dialysis Clinic Inc, Nashville, TN; <sup>2</sup>Tufts Medical Center, Boston, MA.

**Background:** Preventing COVID-19 infection or its consequences through SARS-CoV-2 vaccination in maintenance dialysis patients, a high risk population, is imperative. We determined relative vaccine effectiveness (VE) of 1, 2, or 3 doses of an mRNA vaccine in preventing SARS-CoV-2 infection, hospitalization, and death.

**Methods:** All adult maintenance dialysis patients at Dialysis Clinic, Inc. offered an mRNA vaccine between 12/15/20 and 2/28/22 were included, with follow up time through 3/31/22. Using a multivariable logistic regression model, we calculated adjusted odds ratios (OR) for COVID-19 infection and associated hospitalization and death

within 30 days during pre-Delta (12/15/20-6/19/21), Delta (6/20-12/18/21) and Omicron (12/19/21-2/28/22) periods. VE was calculated as (1-adjusted OR) x 100%. Patients were censored at infection, death, or transplantation.

**Results:** The 17,309 maintenance dialysis patients included had mean age of 63±15 years, 58% male, 35% Black, 47% White, 87% HD and mean vintage 42±55 months. Across all three COVID-19 variant periods, VE increased with each successive mRNA dose received, improving protection against infection, hospitalization and death (Table). VE was highest among patients vaccinated with homologous mRNA-1273 regimens.

**Conclusions:** Two or more SARS-CoV-2 mRNA vaccine doses exhibited VE protecting against COVID-19 related associated hospitalization and death in maintenance dialysis patients irrespective of variant era. At least 3 doses maximizes protection and may be necessary due to uremia-related mild to moderate immunodeficiency.

### SARS-CoV-2 mRNA vaccine effectiveness

Period	# mRNA doses	# Patients	Vaccine Effectiveness, % (95% Confidence Interval)		
			Infection	Hospitalization	Death
Pre-Delta	Unvaccinated	3,651			
	One dose	544	NR	NR	78 (39, 92)
	Two doses	9,444	59 (52, 65)	70 (61, 77)	99 (97, 100)
Delta Dominant	Unvaccinated	2,572			
	One dose	384	NR	NR	NR
	Two doses	4,816	24 (12, 33)	44 (29, 56)	64 (47, 76)
Omicron Dominant	Unvaccinated	2,415			
	One dose	390	NR	NR	NR
	Two doses	3,771	NR	40 (18, 55)	64 (34, 81)
	Three doses	6,896	33 (22, 42)	66 (54, 75)	93 (83, 97)

Ref = reference group; NR = not reported as effect and/or confidence interval crosses zero

## SA-OR09

### Clinical Efficacy of the Fourth Dose of the BNT162b2 Vaccine in Chronic Dialysis Patients

Moshe Shashar,<sup>1</sup> Ayelet Grupper,<sup>3,4</sup> Tzipi Hornik-Lurie,<sup>2,3</sup> Sydney Benchetrit,<sup>2,3</sup> Yael Einbinder,<sup>2,3</sup> Naomi Nacasch,<sup>2,3</sup> Keren Cohen - Hagai,<sup>2,3</sup> <sup>1</sup>Laniado Hospital, Netanya, Israel; <sup>2</sup>Meir Medical Center, Kfar Saba, Israel; <sup>3</sup>Tel Aviv University, Tel Aviv, Israel; <sup>4</sup>Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

**Background:** Following the emergence of the Omicron B.1.1.529 variant of SARS-CoV-2, Israel began on January 2, 2022, to administer a fourth dose of the BNT162b2 vaccine to people 60 years and older and to at-risk populations. Chronic dialysis patients were among the first to receive the fourth dose. Given the scarcity of evidence regarding the efficacy or necessity of a fourth dose, we assessed the clinical efficacy regarding infectivity and all-cause mortality of the fourth dose of the BNT162b2 vaccine among chronic dialysis patients.

**Methods:** This study was conducted using the electronic database of Clalit HMO in Israel. Chronic dialysis patients receiving hemodialysis and peritoneal dialysis during the COVID-19 pandemic were included. The control group was matched in a 4 to 1 ratio to the dialysis group. The study included the pre-vaccination and post-vaccination periods.

**Results:** Included in this analysis were 14,230 patients of whom 2,846 were chronic dialysis patients with a mean age of 66.2±14.3 (range 18-97) years and 62.5% (1,779) were males. Mortality among unvaccinated chronic dialysis patients who tested positive for COVID-19 was 18.4%, as compared to 10.8% among similar patients who did not test positive for COVID-19 during the same period (OR 1.9, 95%CI 1.3-2.7; p=0.001). A total of 1,908 chronic dialysis patients had information available regarding vaccine status and were alive when vaccinations began in December 2020. Among them, 159 (8.3%) were unvaccinated, 113 (5.9%) were vaccinated with 1 dose, 270 (14.2%) with 2 doses, 703 (36.8%) with 3 doses, 663 (34.7%) with 4 doses. During 2022, which was dominated by the Omicron variant, 34.7% of chronic dialysis patients vaccinated with 3-doses were infected with SARS-CoV2 vs. 24.3% of 4-dose patients. Odds ratio for SARS-CoV2 infection after fourth dose was 0.6, (95%CI 0.5-0.8; p<0.001). Odds ratio for all-cause mortality in chronic dialysis patients who received 4 vs. 3 doses was 0.6 (0.4-0.9, 6.3% vs. 10.1%; p<0.001).

**Conclusions:** As seen in the general population, and previous vaccine boosters, the fourth dose of the BNT162b2 vaccine reduced COVID-19 infections, as well as mortality among chronic dialysis patients. Additional studies are needed to establish the exact dose and schedule of the COVID-19 vaccine in patients treated with chronic maintenance dialysis.

## SA-OR10

### BOOST KIDNEY: A Randomized Controlled Trial of Third Dose BNT162b2 vs. mRNA-1273 COVID-19 Vaccination in CKD and Dialysis Patients

Kevin Yau,<sup>1</sup> Christopher T. Chan,<sup>1</sup> Kento T. Abe,<sup>2</sup> Matthew J. Oliver,<sup>1</sup> Adeera Levin,<sup>3</sup> Anne-Claude Gingras,<sup>2</sup> Michelle A. Hladunewich.<sup>1</sup> <sup>1</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>2</sup>Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; <sup>3</sup>BC Provincial Renal Agency, Vancouver, BC, Canada.

**Background:** Due to waning humoral immunity, a third COVID-19 vaccine dose is recommended but there is a lack of evidence regarding whether there is benefit to homologous versus heterologous mRNA vaccination.

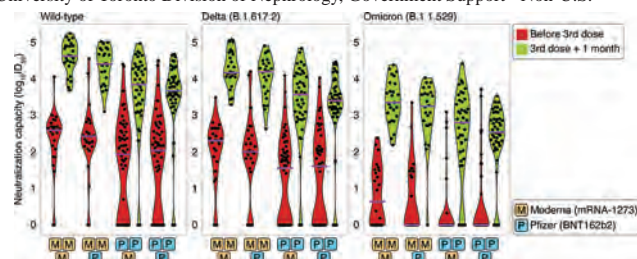

**Methods:** This was a multi-centre parallel group randomized controlled trial in Toronto, Ontario from September 30, 2021 to May 13, 2022 which enrolled participants with stage 3B-5 chronic kidney disease with prior homologous mRNA two dose vaccination. Overall 273 participants were randomized 1:1 to either 30µg BNT162b2 (n=137) or 100 µg mRNA-1273 (n=136) third dose stratified by initial vaccine type. Neutralizing antibodies against the B.1.1.529 (Omicron) variant of concern as well as binding SARS-CoV-2 IgG antibodies to the spike protein, receptor binding domain, and nucleocapsid protein were measured.

**Results:** Participants had a median age of 67 years, 94% were on dialysis, 3% had prior COVID-19, and 59% had received BNT162b2 for initial two dose vaccination. Prior to the third vaccine dose, detectable Omicron neutralizing antibodies were present in 2% with BNT162b2 and 54% with mRNA-1273 two dose vaccination. At 1 month post third dose, among those with baseline BNT162b2, Omicron-specific neutralizing antibodies were detectable in 84% with third dose BNT162b2 in comparison to 83% with third dose mRNA-1273 ( $p=0.70$ ). In those with baseline mRNA-1273, 100% receiving third dose mRNA-1273 had Omicron-specific neutralizing antibodies in comparison to 96% with third dose BNT162b2 ( $p=0.75$ ). During the study period, 9.3% of participants (n=25) contracted COVID-19 and two died from COVID-19 with no difference in infection based on vaccine type ( $p=0.26$ ).

**Conclusions:** In this randomized controlled trial of third dose COVID-19 vaccination, both homologous and heterologous vaccination elicited robust SARS-CoV-2 neutralizing antibody response.

**Funding:** Commercial Support - Oreopoulos/Baxter Home Dialysis Grant from the University of Toronto Division of Nephrology, Government Support - Non-U.S.

Viral neutralization against wild-type, Delta, and Omicron variants of concern prior to third dose and 1 month following third dose BNT162b2 or mRNA-1273 vaccination.

## SA-OR11

### Genome-Wide Association Studies of a Composite Renal Phenotype Reveal Pleiotropic Effects and a Novel Locus

Moumita Barua,<sup>1</sup> Sarah A. Gagliano Talion,<sup>2</sup> Andrew Paterson,<sup>3</sup> <sup>1</sup>Toronto General Hospital, Toronto, ON, Canada; <sup>2</sup>Université de Montreal, Montreal, QC, Canada; <sup>3</sup>The Hospital for Sick Children, Toronto, ON, Canada.

**Background:** Our previous genome-wide association study (GWAS) of hematuria using ICD codes in the UK Biobank identified 6 loci, some of which overlap with loci for albuminuria suggesting pleiotropy. Hematuria cases had higher systolic blood pressure, higher urine albumin:creatinine (uACR) ratios and lower eGFR compared to controls, supporting enrichment for hematuria due to glomerular pathologies. Although most GWAS analyze one trait at a time, many clinical syndromes are defined by combinations of outcomes. Therefore, generating a combined phenotype may improve power to detect loci influencing multiple traits.

**Methods:** The composite outcome of hematuria and albuminuria was chosen to enrich for glomerular disease. We performed a case-control GWAS in the white British subset of the UK Biobank. Cases had both hematuria defined by ICD codes and albuminuria defined as uACR >3 mg/mmol. Controls did not have either an ICD code for hematuria nor a uACR >3 mg/mmol.

**Results:** 2,429 cases and 343,509 controls were included. eGFR was significantly lower in cases (F: 88.6±16.5 mL/min/1.72m<sup>2</sup>, M: 82.2±20.1 mL/min/1.72m<sup>2</sup> by CKD EPI) compared to controls (F: 90.6±13.1 mL/min/1.72m<sup>2</sup>, M: 90.6±12.6 mL/min/1.72m<sup>2</sup>) in both sexes. Variants at 4 loci met genome-wide significance ( $p<5\times 10^{-8}$ ) with the following nearest genes: *COL4A4-COL4A3*, *TRIM27*, *ETV1* and *CUBN*. *TRIM27* is part of the extended *MHC* locus. Our previous GWAS of hematuria reported *COL4A3-COL4A3* variants and *HLA-B\*0801* within *MHC*, but the latter is not in linkage disequilibrium (LD) with the *TRIM27* variant. Additional loci are identified for the composite outcome including *CUBN* (previously associated with albuminuria) and a novel signal at chromosome 7 (*ETV1*, (nearest gene), rs146676616,  $p=1.3\times 10^{-8}$ , alternate allele (G) frequency in cases versus controls: 1.77% versus 0.91%, OR=2.61, 95% CI=1.87-3.63).

**Conclusions:** GWAS for the composite outcome of hematuria and albuminuria identifies 4 loci. Three were not identified in our previous GWAS of hematuria enriched for glomerular causes. These include variants with closest genes *TRIM27*, within the extended *MHC* locus but not in LD with *HLA-B\*0801* reported previously, *CUBN* and a novel signal at chromosome 7. Analysis of composite phenotypes has the potential to identify novel loci which have pleiotropic effects.

**Funding:** Government Support - Non-U.S.

## SA-OR12

### Gene Surgery: A Potential CRISPR/Cas-Based Treatment Option for Nephropathic Cystinosis In Vitro

Elena Sendino Garvía,<sup>1</sup> Mert Öktem,<sup>1</sup> Rosalinde Masereeuw,<sup>1</sup> Patrick T. Harrison,<sup>2</sup> Enrico Mastrobattista,<sup>1</sup> Manoe J. Janssen.<sup>1</sup> Pharmacology Group <sup>1</sup>Universiteit Utrecht Utrechts Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands; <sup>2</sup>University College Cork, Cork, Ireland.

**Background:** Nephropathic cystinosis is a rare monogenetic kidney disease caused by mutations in the *CTNS* gene, which encodes for the lysosomal cystine transporter, cystinosin. Mutations in the *CTNS* gene lead to the loss of the cystinosin transporter, resulting in intralysosomal cystine accumulation. There is no curative treatment for cystinosis to date, therefore, we aim to develop a novel gene repair strategy for the most predominant 57 kb deletion of *CTNS* using CRISPR-Cas9 technology, which allows for the delivery of a *CTNS* repair template into a specific location in the genome.

**Methods:** For this study, we used two conditionally immortalized proximal tubule epithelial cells (ciPTEC): a cystinotic patient-derived and a *CTNS*<sup>-/-</sup> knock-out. For the delivery of the repair complex, we used a novel non-viral peptide-mediated delivery system. The repair construct for *CTNS* (3.2 kb) contains the *CTNS* promoter and the first 10 exons of the *CTNS* gene, as well as a fluorescent reporter gene (*mCherry*). Additionally, a second repair construct was designed (1.7 Kb), excluding the *mCherry* gene, to study a more therapeutic-like construct.

**Results:** After transfection of the repair construct, the large and small repair templates achieved 5% and 20% insertion efficiency ( $N=3$ ), respectively, indicating that the cells had successfully inserted the repair template into their DNA. Further analysis of individual clonal cells showed restoration of lysosomal cystine levels in 60% of the clones transfected with the big template (3.2 Kb), showing cystine values between 1-2nmol/mg protein ( $N=12$ ;  $p<0.001$ ). Strikingly, more than 70% of the clones transfected with the therapeutic-like template (1.7 kb), which were blind sorted, show cystine values between 0.5-2nmol/mg protein ( $N=15$ ;  $p<0.001$ ) thus, indicating that in most of the cells the repair template was inserted, consequently restoring the *CTNS* function.

**Conclusions:** In conclusion, these data show that the *CTNS* repair template can be precisely inserted into the genome, leading to the translation of a functional cystinosin transporter, which consequently restores the lysosomal cystine accumulation. Eventually, this gene repair system may offer a potential curative therapy for cystinosis, as well as a system for the *in vitro* restoration of several other genes involved in monogenic diseases.

**Funding:** Government Support - Non-U.S.

## SA-OR13

### Channel Function of Polycystin-2 in Endoplasmic Reticulum Protects Against Polycystic Kidney Disease

Biswajit Padhy, Jian Xie, Rumping Wang, Fang Lin, Chou-Long Huang, Huang Lab University of Iowa Carver College of Medicine, Iowa City, IA.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is among the most common monogenic inherited disease in humans leading to end-stage renal disease. Mutations in PKD2 gene that encodes PC2 protein are responsible for ~15% of the ADPKD cases. The prevailing view is that altered Ca<sup>2+</sup> influx by mutated PC2 in the primary cilia is the cause for ADPKD pathogenesis. Yet, most of PC2 is localized to endoplasmic reticulum (ER) and more permeable to K<sup>+</sup> than Ca<sup>2+</sup>. In the cilia-centric view, ER-localized PC2 mainly facilitates ciliary targeting of PC1-PC2 complexes.

**Methods:** The trimeric intracellular channel-B (TricB), aka TMEM38B, is an ER resident K<sup>+</sup> channel that mediates K<sup>+</sup>-Ca<sup>2+</sup> counterion exchange for inositol trisphosphate-mediated Ca<sup>2+</sup> release. Using TricB as experimental tool, we explored the function of ER-localized PC2 and its role in ADPKD pathogenesis by using cultured cells, zebrafish, and mouse models.

**Results:** ATP-induced ER Ca<sup>2+</sup> release was defective in PC2-null renal epithelial cells, which was reversed by exogenous expression of TricB. Likewise, exogenous PC2 reversed ER Ca<sup>2+</sup> release defect in TricB-null HEK293 cells. Microinjection of wildtype but not non-functional TricB mRNA into PC2-morphant zebrafish embryos ameliorated pronephric cysts. Similarly, ER targeting of ROMK K<sup>+</sup> channel normally expresses on the plasma membrane suppressed the cystic phenotypes. R6G mutant of PC2 that fails to localize to cilia was still capable of reversing ER Ca<sup>2+</sup> release defect in PC2-null cultured cells and PC2-deficient zebrafish phenotypes. Transgenic expression of TricB reversed cystic phenotypes in conditional Pkd2-inactivated mice. TricB deletion enhanced cystogenesis in Pkd2-heterozygous kidneys.

**Conclusions:** ER-localized PC2 plays an important role in the pathogenesis of ADPKD. It acts as a K<sup>+</sup> channel to facilitate K<sup>+</sup>-Ca<sup>2+</sup> counterion exchange for inositol trisphosphate-mediated Ca<sup>2+</sup> release. The results challenge the current cilia-centric dogma providing insights for understanding ADPKD pathogenesis and proof-of-principle for pharmacotherapy by TricB activators.

## SA-OR14

**Downregulation of O-GlcNAc Reduces Ciliary Length and Attenuates Renal Cystic Disease in PKD Mice**

Matthew A. Kavanaugh,<sup>1,2</sup> Wei Wang,<sup>1,2</sup> Henry Wang,<sup>1,2</sup> Brittany M. Hufft-Martinez,<sup>1,2</sup> Chad Slawson,<sup>2,3</sup> Stephen C. Parnell,<sup>2,3</sup> Darren P. Wallace,<sup>2,4</sup> Pamela V. Tran.<sup>1,2</sup> <sup>1</sup>University of Kansas Medical Center Department of Anatomy and Cell Biology, Kansas City, KS; <sup>2</sup>The Jared Grantham Kidney Institute, Kansas City, KS; <sup>3</sup>University of Kansas Medical Center Department of Biochemistry and Molecular Biology, Kansas City, KS; <sup>4</sup>University of Kansas Medical Center Department of Physiology, Kansas City, KS.

**Background:** Renal cysts occur in both ciliopathies and mitochondrial diseases, and primary cilia and cellular metabolism are important modifiers of autosomal dominant polycystic kidney disease (ADPKD). The nutrient sensor, O-linked N-acetylglucosamine (O-GlcNAc), regulates mitochondrial function as well as ciliary homeostasis. Thus, we hypothesized that O-GlcNAc signaling is misregulated in ADPKD and contributes to renal cystogenesis.

**Methods:** Immunostaining and Western blot analysis were performed to examine O-GlcNAc levels in mouse and human ADPKD tissues. Using the HoxB7-Cre in mice, *Pkd1* was deleted in collecting ducts, alone and together with O-GlcNAc transferase (*Ogt*), which transfers O-GlcNAc onto protein substrates. Mouse kidneys were analyzed on postnatal days 14 and 21. ADPKD patient cells were treated with pharmacological inhibitors of OGT and ciliogenesis, and effects on cilia lengths and *in vitro* cyst formation were examined. Co-immunoprecipitation in mouse renal tissue was performed to determine endogenous targets of OGT.

**Results:** O-GlcNAc levels were elevated in mouse and human ADPKD renal cyst-lining cells compared to normal tissues. *Ogt* deletion in juvenile *Pkd1* conditional knock-out mice reduced ciliary length, renal cystogenesis and kidney weight/body weight, improved kidney function, and increased survival of the mice. Similarly, OGT inhibition in cultured ADPKD patient renal epithelial cells shortened primary cilia and reduced *in vitro* cyst formation. Additionally, combined treatment of ADPKD cells with OGT and ciliogenesis inhibitors reduced cyst formation to a greater extent than treatment with either inhibitor alone. Co-immunoprecipitation data revealed that OGT interacts with intraflagellar transport protein IFT81, which is important for cilia synthesis and maintenance.

**Conclusions:** O-GlcNAc is elevated in ADPKD kidneys, and its downregulation reduces ciliary length and renal cystogenesis. OGT binds to IFT81, which may present a novel mechanism of ciliary length control. We propose that O-GlcNAc links the metabolic and ciliary defects in ADPKD and may present new avenues for designing therapeutic strategies.

## SA-OR15

**The Methionine-Mettl3-RNA Methylation Axis Is Essential for Nephrogenesis**

Harini Ramalingam, Jesus A. Alvarez, Elyse D. Grilli, Thomas J. Carroll, Vishal Patel. *The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX.*

**Background:** RNAs undergo dynamic chemical changes, which can impact their processing, stability, or translational efficiency, a phenomenon termed 'epitranscriptomics'. N6-methyladenosine (m<sup>6</sup>A) is the most abundant eukaryotic RNA chemical modification. Mettl3, an mRNA methyltransferase, mediates the m<sup>6</sup>A reaction by transferring an activated methyl group from S-adenosyl methionine (SAM) to adenosine. A major contributor of renal failure is low 'nephron endowment', which chiefly occurs due to defects in the self-renewal or the differentiation of the nephron progenitors (NPs). Here, we studied whether the methionine-RNA methylation pathway plays a role in the renewal and differentiation of NPs.

**Methods:** We examined Mettl3 expression in the NP lineage of developing kidneys. We generated mice to conditionally ablate or overexpress Mettl3 in the NP lineage. We used a Mettl3-specific inhibitor or activator to pharmacologically modulate the m<sup>6</sup>A pathway in *ex vivo* kidney cultures and isolated primary NP cultures. We also tested whether methionine and SAM impact NP fate.

**Results:** We find that the Mettl3-m<sup>6</sup>A pathway expression is higher in differentiated NPs compared to renewing NPs. Six2/cre-mediated Mettl3 deletion blocks NP differentiation leading to the accumulation of renewing NPs and a markedly lower nephron count. In contrast, deleting Mettl3 subsequent to NP differentiation, using Wnt4/cre, has no impact on kidney development. Conversely, Six2/cre-mediated Mettl3 overexpression results in precocious and ectopic differentiation leading to the premature depletion of renewing NPs. Similarly, acute pharmacological Mettl3 inhibition or methionine depletion blocks NP differentiation whereas acute Mettl3 activation or higher SAM availability has an opposite effect in cultures. Moreover, methionine/SAM promotes Mettl3 expression in NPs, and regulates NP fate through Mettl3. Finally, subthreshold activity of the Mettl3-m<sup>6</sup>A pathway appears to induce both NP renewal and differentiation leading to enhanced nephrogenesis in *ex vivo* kidney cultures and in kidney organoids.

**Conclusions:** Our work uncovers RNA methylation as a novel stem cell pathway in metanephros development and links methionine utilization to m<sup>6</sup>A chemical modification in NP fate commitment.

## SA-OR16

**Estrogen Signaling Is an Essential Regulator of Nephron Segmentation**

Hannah M. Wesselman, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

**Background:** Despite many significant advances in understanding nephron segment patterning, numerous questions remain about the underlying genes and signaling pathways that orchestrate cell fate and regulate differentiation. In an effort to identify novel regulators of nephron segmentation, our lab conducted a high throughput drug screen using a bioactive chemical library and developing zebrafish, which are a conserved vertebrate model and particularly conducive to large-scale screening approaches. 17 $\beta$ -Estradiol (E2), which is the dominant form of estrogen in vertebrates, was a particularly interesting hit from this screen. While E2 has been extensively studied in the context of gonad development, the mechanism of E2 action in nephron development and segmentation remains poorly understood.

**Methods:** We evaluated the effects of E2 on segmentation using high throughput chemical screens and analyzed segmentation phenotypes using whole mount *in situ* hybridization (WISH). Knockdown of estrogen receptors was achieved via morpholino injection and CRISPR-Cas9 mutagenesis. Changes in cell dynamics (e.g. cell death and proliferation) were also analyzed via immunofluorescence.

**Results:** Exogenous estrogen treatments revealed changes in distal segment composition. Interestingly, xenoestrogens ethinylestradiol and genistein yielded the same changes in distal segments. Upon treatment with an Esr2 antagonist, PHTPP, we observed the opposite phenotypes. Similarly, genetic knockdown of Esr2 analogs revealed phenotypes consistent with that of PHTPP treatment. Inhibition of E2 signaling also resulted in decreased expression of essential distal transcription factors.

**Conclusions:** Taken together, these data suggest that estrogenic compounds are essential for distal segment fate during nephrogenesis, and add to our understanding of hormone function during kidney organogenesis. Considering the presence of sex differences observed in kidney morphology and renal disease, exploring the influence of sex hormones in the kidney is of utmost importance.

## SA-OR17

**Human Ureteric Bud Organoids Derived From Pluripotent Stem Cells Recapitulate Embryonic Development and Differentiate Into Collecting Duct Cell Types With Functional Ion Transport**

Kyle McCracken,<sup>1,2</sup> Ankit B. Patel,<sup>2</sup> Joseph V. Bonventre.<sup>2</sup> <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** The ability to derive functional ureteric and collecting duct epithelia from human pluripotent stem cells (hPSCs) will be an essential component of kidney regenerative medicine. Here we describe highly efficient methods to guide the differentiation of ureteric bud (UB) organoids and derive functional collecting duct (CD) cells from these organoids.

**Methods:** Directed differentiation of hPSCs was performed using sequential growth factor manipulations to recapitulate normal developmental stages including pronephric intermediate mesoderm (IM), nephric duct (ND), and UB. At day 3 IM cells were aggregated into spheroids, which at day 7 were then embedded into a 3D matrix to support branching morphogenesis. Cells from the organoids were functionally interrogated using 2D transwell culture and Ussing chambers.

**Results:** hPSCs were induced into PAX2/GATA3<sup>+</sup> pronephric IM progenitor cells at 90% efficiency, which then generated spheroids that underwent spontaneous organization and adopted a molecular phenotype consistent with the ND. In 3D culture, the spheres developed into UB organoids that exhibited branching morphogenesis and spatial organization comparable to the fetal UB. At later stages the UB organoids differentiated into CD organoids, which contained >95% CD cell types as estimated by scRNA-seq. Cells isolated from the organoids generated robust ENaC-mediated vectorial Na<sup>+</sup> transport that was further induced by stimulation with mineralocorticoid signaling. We also showed that ectopic FOX11 induced formation of intercalated cells (ICs), which in 2D exhibited V-type ATPase-mediated H<sup>+</sup> secretion that produced a transepithelial pH gradient.

**Conclusions:** These methods result in efficient and consistent differentiation of UB organoids, making them accessible to the kidney research community. The organoids exhibit developmental properties including branching morphogenesis, which will enable their use in catalyzing novel regenerative medicine approaches. The derivation of both functional principal cells and ICs that exhibit Na<sup>+</sup> and H<sup>+</sup> transport, respectively, is the first demonstration of renal cells derived from hPSCs with advanced ion transport and electrophysiologic properties and presents an unprecedented model for interrogating CD physiology and disease.

## SA-OR18

**ASH2L Is Essential for the Ureteric Bud Lineage Development**

Ziyi Zhao,<sup>1</sup> Fujun Lin,<sup>1,2</sup> Gengru Jiang.<sup>1,2</sup> <sup>1</sup>Xin Hua Hospital of Shanghai Jiao Tong University School of Medicine, Shanghai, China; <sup>2</sup>Centre for Rare Disease, Shanghai, China.

**Background:** Ureteric bud (UB) induction/branching morphogenesis are the fundamental processes during kidney development, of which GDNF-RET/GFRA1 signaling pathway occupies a central place. Histone modifications have a crucial role in kidney development by placing active/silencing histone marks at different gene regions to fine-tune genes expression. Given that ASH2L, a core subunit in KMT2 enzymes which

mediate H3K4 methylation, is widely expressed in UB derivatives, we examined the role of ASH2L in UB lineage morphogenesis during mouse kidney development.

**Methods:** We inactivated *Ash2l* expression in the UB lineage using the Cre/loxP system by crossing transgenic Hoxb7creEGFP mice to *Ash2l<sup>fl/fl</sup>* mice and analyzed the phenotype of the *Ash2l* mutants and their littermate controls. Kidney histology and UB branching morphogenesis were studied in *Ash2l* mutants. E16.5 metanephroi were digested and the UB lineage cells were sorted by FACS and processed for RNA-seq or CUT&Tag-seq. Differentially expressed genes were validated by RT-qPCR and RNA-scope.

**Results:** Conditional inactivation of *Ash2l* in the UB lineage results in malformed kidneys at birth. The budding/branching events of the UB is severely delayed both *in vivo* and *in vitro*. Molecularly, inactivation of *Ash2l* leads to downregulated expression of GDNF-RET/GFRA1 signaling pathway components via repression of H3K4 tri-methylation on promoter regions, resulting in eventually UB cell cycle arrest.

**Conclusions:** Our study uncovers the novel role of ASH2L during the UB lineage development and H3K4 methylation as the upstream epigenetic regulator of GDNF-RET/GFRA1 signaling pathway. Our study also offers new insights into the role of active histone marks in the molecular pathogenesis of CAKUT.

**Funding:** Government Support - Non-U.S.

The mutants show malformed kidneys at birth (a). The budding/branching events of the UB is severely delayed both *in vivo* (b) and *in vitro* (c).

## SA-OR19

### Establishing the Spatiotemporal Organization and Function of Renal Nerves Throughout Nephrogenesis

Pierre-Emmanuel N'Guetta, Lori L. O'Brien. O'Brien Lab The University of North Carolina at Chapel Hill Department of Cell Biology and Physiology, Chapel Hill, NC.

**Background:** Essential kidney functions are regulated by intrinsic cellular mechanisms including signaling through renal nerves. Despite their significance to renal physiology, we still lack a fundamental understanding of the establishment, organization, and function of kidney innervation during organogenesis. Our goal is to spatially and temporally map renal sensory and sympathetic innervation throughout development to identify cellular targets and elucidate functional crosstalk.

**Methods:** To assess the process of kidney innervation across development, we generated 3D anatomical maps of renal nerves using light-sheet fluorescent microscopy and confocal microscopy.

**Results:** Our analyses show that renal innervation initiates at E13.5 as these nerves track closely with the smooth muscle-coated arterial tree. We find that sensory and sympathetic nerves innervate the kidney concomitantly, and that innervation continues via branching events as axons track with the developing vasculature. After the establishment of the renal neurovascular main branches, we observed subsequent interstitial branching by E17.5 as renal nerves grow until axonal projections reach their targets. Further, we uncovered that renal nerves synapse with the vasculature as early as E16.5, suggesting the establishment of functional crosstalk. We also observed synapses near glomeruli and tubules by E18.5. To assess functional roles for nerves during kidney development, we genetically ablated neurons innervating the kidney utilizing a *TrkA* knockout mouse. Postnatal *TrkA* knockout kidneys had a significant reduction in renal innervation and presented with reduced glomerular number and dilated proximal tubules, suggesting renal nerves mediate proper nephrogenesis and/or early function.

**Conclusions:** Taken together our findings provide novel insights into the establishment of renal innervation and the role renal nerves play during development. Future efforts will aim to conditionally delete sensory or sympathetic renal nerves independently and investigate the developmental and functional phenotypes.

## SA-OR20

### Deciphering the Origins of Kidney Lymphatics

Daniyal J. Jafree,<sup>1,2</sup> Christopher Rowan,<sup>3</sup> Maria K. Joannou,<sup>1</sup> Lauren G. Russell,<sup>1</sup> Julie A Siegenthaler,<sup>4</sup> Adrian S. Woolf,<sup>5</sup> Norman D. Rosenblum,<sup>3</sup> Peter Scambler,<sup>1</sup> David A. Long.<sup>1</sup> UCL ICH Kidney Development and Disease <sup>1</sup>UCL Great Ormond Street Institute of Child Health, London, United Kingdom; <sup>2</sup>UCL MB/PhD Programme, London, United Kingdom; <sup>3</sup>SickKids Research Institute, Toronto, ON, Canada; <sup>4</sup>University of Colorado, Denver, CO; <sup>5</sup>The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom.

**Background:** Lymphatics clear excess tissue fluid, cells and macromolecules from organs, and are emerging as players in kidney diseases and transplant rejection. Lymphatics were thought to solely originate by sprouting from veins. More recently, we showed that kidney lymphatics can arise using a distinct cellular mechanism featuring the formation of lymphatic 'clusters', akin to a *de novo* vasculogenic process. In this study, we designed experiments to decipher where kidney lymphatics come from.

**Methods:** To identify kidney lymphatics origins, we utilised Cre recombinase-dependent expression of tdTomato for lineage tracing in mouse embryos. We used the following Cre lines to determine the contribution of different cell lineages to lymphatics: (i) *Tie2-Cre* for endothelial precursors; (ii) *Osr1-CreER<sup>TR</sup>* for posterior intermediate mesoderm and (iii) *Six2-Cre*, *Tbx18-CreER<sup>TR</sup>* and *Foxd1-Cre* for nephron epithelial, ureteral mesenchyme and renal stroma, respectively. Intact, lineage traced kidneys were subject to wholemount immunolabelling for tdTomato and the lymphatic markers, PROX1 and PDPN, before tissue clearing and confocal microscopy. From the resulting high-resolution 3D images, we quantitatively assessed contributions from each origin to kidney lymphatics.

**Results:** We found 85% of kidney lymphatics to derive from endothelial precursors, as assessed by labelling *Tie2<sup>+</sup>* cells and their progeny. Conversely, 15% of kidney lymphatics arose from an *Osr1<sup>+</sup>* cell lineage, whereas lymphatics in the heart, skin and lung did not originate from *Osr1<sup>+</sup>* progenitors. We found that kidney lymphatics did not originate from *Six2<sup>+</sup>* cells, or from *Tbx18<sup>+</sup>* ureteral mesenchyme, both which derive from *Osr1<sup>+</sup>* cells. However, we provide evidence that the *Foxd1<sup>+</sup>* renal stroma is a source of progenitor cells giving rise to kidney lymphatics. No single lineage was exclusive for lymphatic clusters.

**Conclusions:** Our study emphasises the early colonisation of the mammalian kidney by lymphatics. It also points to an unexpected variety of lineages giving rise to kidney lymphatics, including a novel non-endothelial origin specific to the kidney. These insights challenge the paradigm that lymphatics from different origins form through distinct cellular mechanisms. Further, they critically inform future studies of the roles of lymphatics in kidney development and disease.

## SA-OR21

### Tenascin-C Promotes Migration and Proliferation of Parietal Epithelial Cells and Participates in the Pathogenesis of FSGS

Ke Sun, Chuanming Hao. Fudan University, Shanghai, China.

**Background:** The parietal epithelial cells (PECs) have been suggested to play an important role in FSGS. Our previous study shows that extracellular matrix Tenascin-C (TNC) is expressed in the PECs. The present study examined the role of TNC expressing PECs and TNC in the pathogenesis of FSGS.

**Methods:** Experimental FSGS was induced on 8-week-old male BalbC mice by i.v. of 10.5 mg/kg body weight of adriamycin. A TNC promoter driven tamoxifen inducible CreER2-IRES-EGFP knock-in mouse line (BalbC) was generated to examine the role of TNC in FSGS. TNC-CreER-tdTomato mice were used for a TNC reporter and cell lineage tracing experiment.

**Results:** TNC reporter mice showed that TNC was selectively expressed in the PECs. The TNC expression was induced in the kidney of adriamycin-induced FSGS as shown by immunoblot. Immunohistochemistry revealed that the expression of TNC was localized to the sclerotic area in the glomeruli and in the adhesion between the glomerular tuft and Bowman's capsule of sclerotic lesions. Importantly the expression of TNC in the PECs was also observed in human kidney by *in situ* hybridization. To examine the role of TNC expressing parietal epithelial cells in sclerosis lesion in FSGS, we did a cell lineage tracing study. Following adriamycin injection, the daughter cells of the TNC expressing PEC lineage appeared in glomerular tufts, suggesting the migration and invasion of the PECs into the glomerular tufts. To further examine the role of TNC in the sclerotic damage in FSGS, we generated TNC knockout mice. BUN was significantly increased in mice following adriamycin treatment ((6.71±0.73) vs(18.38±2.93) mmol/l, p<0.01). TNC deletion significantly attenuated the elevation of BUN ((15.42±2.09) mmol/l, p<0.05). TNC deletion also significantly attenuated the proteinuria following adriamycin treatment (p<0.05). Cell culture studies showed that TNC promoted PEC proliferation and migration, EGFR/ERK cascade and integrin β1 signaling mediated the effect of TNC on PEC.

**Conclusions:** TNC plays an important role in promoting the migration of parietal epithelial cells into the sclerotic area of the glomeruli and participates in the pathogenesis of FSGS.

## SA-OR22

**Cell-Specific Role of STAT3 Signaling in Podocytes vs. Parietal Epithelial Cells in Proliferative Glomerulopathy**

Yogesh Gowthaman,<sup>1</sup> Yiqing Guo,<sup>1</sup> Jesse A. Pace,<sup>1</sup> Robert Bronstein,<sup>1</sup> John C. He,<sup>2</sup> David J. Salant,<sup>3</sup> Sandeep K. Mallipattu.<sup>1,4</sup> <sup>1</sup>*Stony Brook Medicine, Stony Brook, NY*; <sup>2</sup>*Icahn School of Medicine at Mount Sinai, New York, NY*; <sup>3</sup>*Boston University School of Medicine, Boston, MA*; <sup>4</sup>*Northport VA Medical Center, Northport, NY*.

**Background:** Podocyte-specific loss of an essential zinc finger transcription factor Krüppel-like factor 4 (KLF4) triggers the activation of STAT3 in both podocytes and neighboring parietal epithelial cells (PECs), leading to podocyte loss, PEC activation and proliferation, and eventual FSGS. STAT3 is also activated in podocytes and PECs post-nephrotoxic serum (NTS) treatment, a model of proliferative glomerulopathy. Podocyte-specific loss of *Stat3* preserves podocyte markers and attenuates PEC activation post-NTS treatment. However, the role of *Stat3* in PECs has not previously been studied. The aim of this study is to investigate the cell-context-dependent role of STAT3 in inducing podocyte loss, but contributing to PEC activation and proliferation.

**Methods:** *Podocin-Cre Klf4<sup>fl/fl</sup>;Stat3<sup>fl/fl</sup> (Klf4/Stat3-PODKO)* mice were generated to test whether the loss of *Stat3* prevents podocyte loss and subsequent PEC activation and FSGS in *Klf4-PODKO* mice, a model of proliferative glomerulopathy. Inducible and conditional loss of *Stat3* was achieved in PECs by generating *PEC-rtTA;TRE-Cre;Stat3<sup>fl/fl</sup> (Stat3-PECKO)* after 2 weeks of doxycycline (DOX) treatment. *Stat3-PECKO* and wild-type mice were treated with nephrotoxic serum (NTS). STAT3-specific inhibitor, S31-201, (control-DMSO) was administered in mice after NTS treatment to assess the effects of simultaneous pharmacological inhibition of STAT3 activation in podocytes and PECs.

**Results:** *Klf4/Stat3-PODKO* mice showed improved albuminuria, %FSGS lesion, preservation of podocyte markers (WT1 and synaptopodin) with a reduction in glomerular CD44 expression, indicating improvement in PEC activation as compared to *Klf4-PODKO* mice. *Stat3-PECKO* exhibited less PEC activation and proliferation, albuminuria, crescent formation, and FSGS compared to wild-type mice after NTS treatment. S31-201 attenuated albuminuria, loss of podocyte markers (WT1, synaptopodin, podocin, and podocalyxin), PEC activation and proliferation (CD44), and FSGS lesions compared to DMSO post-NTS treatment.

**Conclusions:** STAT3 activation in podocytes induces podocyte loss, but in PECs contributes to PEC activation and proliferation in proliferative glomerulopathy.

**Funding:** NIDDK Support, Veterans Affairs Support

## SA-OR23

**Continuous Non-Mutagenic DNA Damage in Podocytes Activates Pathogenic Memory T Cells Through Altered DNA Methylation**

Ran Nakamichi, Kaori Hayashi, Akihito Hishikawa, Hiroshi Itoh. *Keio Gijuku Daigaku Igakubu Daigakuin Igaku Kenkyuka Naikagaku Kyoshitsu, Shinjuku-ku, Japan*.

**Background:** We have previously reported the association of KAT5-mediated DNA damage repair with altered DNA methylation in podocytes (Cell Rep 2019). Recent epigenome-wide studies suggested the association of altered DNA methylation in blood cells with kidney function. However, the mechanism and pathological significance has remained to be adequately elucidated.

**Methods:** To investigate the significance of DNA double-strand breaks (DSBs) in podocytes, we generated podocyte-specific I-PpoI-expressing mice. I-PpoI is a homing endonuclease which causes non-mutagenic DSBs.

**Results:** I-PpoI-mice developed nephrotic syndrome at 6 weeks of age and died because of renal failure around 24 weeks of age following rapid deterioration of renal function. Single-cell RNA seq analysis using renal cortex revealed a marked expansion of immune cells, especially CD8+ T cells exhibited a KLRG1low IL-7Rhigh memory precursor effector cell phenotype, with high expression of NKG2D receptors in I-PpoI-mice. The expression of murine NKG2D ligands, which are upregulated by DNA damage, increased in I-PpoI-mice podocytes. Upregulation of human NKG2D ligands in glomeruli was also observed in patients with various kidney diseases. NKG2D blocking prevented exacerbation of albuminuria and attenuated glomerulosclerosis and fibrosis in I-PpoI mice. Me-DIP seq analysis using peripheral blood cells revealed hypermethylated regions in I-PpoI mice, were enriched in binding sites for a transcription factor STAT1. I-PpoI-mice showed a significant increase in CD44high memory phenotype cells of peripheral CD8+ T cell populations, which was similar phenotype of STAT1 knockout mice. The chimeric WT mice with bone marrow (BM) cells of I-PpoI-mice exhibited an increase in albuminuria temporarily, whereas the chimeric I-PpoI-mice with BM cells of WT mice prevented renal fibrosis and renal death.

**Conclusions:** Continuous non-mutagenic DSBs in podocytes altered methylation of blood cells, including CD8+ T cells, leading sustained changes in immune microenvironment of the kidney and also BM. These results suggest the altered immune microenvironment in the kidney may be a therapeutic target preventing exacerbating glomerulosclerosis and renal fibrosis following podocyte DNA damage in CKD.

## SA-OR24

**γ Isoform of Phosphoinositide 3 Kinase Plays a Critical Role in Propagation of Podocyte Injury in a Genetic Podocytopathy**

Xiaoyan Liang,<sup>1,2</sup> Vidhi Dalal,<sup>1,2</sup> Tomoko Hayashida.<sup>1,2</sup> <sup>1</sup>*Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL*; <sup>2</sup>*Northwestern University Feinberg School of Medicine, Chicago, IL*.

**Background:** Injury to podocytes is a hallmark of primary glomerular diseases. We previously showed that pharmacological inhibition of γ isoform of phosphoinositide 3 kinase (PIK3CG) abrogates podocyte injury in a mouse model of chemically induced podocytopathy. Here, we show that genetic ablation of PIK3CG prevents podocyte injury in a mouse model of genetic glomerular disease.

**Methods:** NPHS2 deletion was induced by podocyte-specific inducible Cre (NPHS2-rtTA, Tet-o-Cre) in NPHS2f/f, PIK3CG<sup>-/-</sup> mice or their wild type littermates PIK3CG<sup>+/+</sup> by doxycycline starting at 4 weeks of age for 2 weeks. Kidney, urine and serum samples were harvested 2 and 4 weeks after the completion of Cre induction. Urine albumin and creatinine levels were measured by ELISA. Podocytes were isolated by flow sorting with anti-NPHS1 antibody and subjected to RNA sequencing. Specificity for the effect of PIK3CG deletion in podocytes was validated with inducible PIK3CG knockout mice (PIK3CG cKO-podo) treated with intravenous administration of Adriamycin, a chemically-induced model of podocytopathy.

**Results:** Proteinuria became apparent after 2 weeks and peaked at 4 weeks after the completion of doxycycline administration in NPHS2f/f; NPHS2-rtTA Tet-o-Cre; PIK3CG<sup>+/+</sup> mice. In contrast, NPHS2f/f; NPHS2-rtTA Tet-o-Cre; PIK3CG<sup>-/-</sup> mice, proteinuria was minimal at 2 weeks and significantly less compared to PIK3CG<sup>+/+</sup> mice at 4 weeks after Cre recombinase activation. Electron microscope evaluation confirmed that foot processes were preserved in the PIK3CG<sup>-/-</sup> mice. While PIK3CG is also expressed in leukocytes, PIK3CG cKO-podo mice showed significantly less proteinuria in response to Adriamycin compared to their wild-type littermates, suggesting that the protective effect of PIK3CG deletion is specific to podocytes. RNA sequencing is being performed with RNAs isolated from podocytes of NPHS2f/f, NPHS2-rtTA Tet-o-Cre, PIK3CG<sup>-/-</sup> or <sup>+/+</sup> mice with and without disease induction.

**Conclusions:** Together, our data suggest that PIK3CG mediates podocyte injury and could be a novel therapeutic target for children with genetic mutation causing steroid resistant nephrotic syndrome. However, previous studies found that systemic inhibition of PIK3CG increases severe infection due to suppression of its activity in leukocytes. Genes we find by RNA sequencing in this study could be an alternative target.

**Funding:** NIDDK Support

## SA-OR25

**A Possible Role of Anti-Nephrin Autoantibody in Endocytosis of Nephrin in Patients With Post-Transplant Focal Segmental Glomerulosclerosis Recurrence and Minimal Change Disease**

Yoko Shirai,<sup>1</sup> Kenichiro Miura,<sup>1</sup> Shoichiro Kanda,<sup>2</sup> Kiyonobu Ishizuka,<sup>1</sup> Taro Ando,<sup>1</sup> Misako Nakamura,<sup>1</sup> Ryo Nakatani,<sup>1</sup> Aya Kato,<sup>1</sup> Makoto Eguchi,<sup>1</sup> Kazuho Honda,<sup>3</sup> Yutaka Yamaguchi,<sup>4</sup> Motoshi Hattori.<sup>1</sup> <sup>1</sup>*Department of Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan*; <sup>2</sup>*Department of Pediatrics, Tokyo University, Tokyo, Japan*; <sup>3</sup>*Department of Anatomy, Showa University School of Medicine, Tokyo, Japan*; <sup>4</sup>*Yamaguchi Pathology Laboratory, Chiba, Japan*.

**Background:** Recently, we have found that in a case with post-transplant focal segmental glomerulosclerosis recurrence (rFSGS), circulating nephrin autoantibody was present in the patient's serum and altered localization of nephrin, which merged with IgG, was observed in the kidney tissue specimens of postperfusion (1 h) (Hattori, et al. Am J Transplant 2022). To investigate the mechanism of altered localizations of nephrin in rFSGS, we examined whether phosphorylation of nephrin and endocytosis are involved in very early phases of rFSGS using immunofluorescence study.

**Methods:** 1h biopsy specimens obtained from four patients with rFSGS and native kidney biopsy specimens obtained from four patients with minimal change disease (MCD) relapse were analyzed. Double immunostaining of nephrin or phosphorylated nephrin (p-nephrin) (tyr1176) and IgG were performed using structured illumination microscopy. In addition, double immunostaining of nephrin and ShcA, an adapter protein of p-nephrin, or cholera enterotoxin subunit B (CTxB), a marker of raft-mediated endocytosis (RME), were performed using confocal microscope.

**Results:** Punctate IgG depositions were co-localized with nephrin and p-nephrin (tyr1176) in all patients with rFSGS and three of four patients with MCD relapse. In these seven cases with rFSGS and MCD whose specimens showed punctate IgG deposition co-localizing with nephrin, altered localization of nephrin was observed and the expressions of ShcA were upregulated co-localizing with nephrin. CTxB was colocalized with nephrin in all rFSGS patients, while almost no expression was observed in MCD patients.

**Conclusions:** Anti-nephrin autoantibodies and phosphorylation of nephrin which is associated with ShcA might be involved in the pathogenesis of very early phases of rFSGS and partly contribute to relapse in a subset of MCD patients. Notably, Our study may also suggest that CTxB relating RME altered localizations of nephrin in rFSGS, but not in MCD.

## SA-OR26

**Podocyte-Specific Loss of Klf4 Induces the Formation of Extracellular Matrix Extensions**

Nina Cintron Pregosin, Robert Bronstein, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

**Background:** Podocyte loss is characteristic of multiple glomerular diseases, including focal segmental glomerulosclerosis (FSGS) and rapidly progressive glomerulonephritis (RPGN). In these diseases, podocyte loss triggers the activation and proliferation of neighboring parietal epithelial cells (PECs), leading to crescent formation in the Bowman's space and eventual glomerular injury. We previously identified potential key ligand-receptor interactions between injured podocytes that trigger the activation and proliferation of quiescent PECs in the setting of podocyte-specific knockdown of the pro-differentiation transcription factor, Krüppel-like factor 4 (KLF4). Recent evidence also suggests that injured podocytes might be capable of physically interacting with neighboring cells by extending their extracellular matrices to form bridges between cells. These physical extensions are unique from foot processes and filopodia of podocytes, yet their function is not known.

**Methods:** We investigated bridge formation in two models of proliferative glomerulopathy: mice with podocyte podocyte-specific loss of Klf4 (*Klf4<sup>ΔPod</sup>*) and dual reporter (RFP labeling podocytes, eGFP labeling PECs) mice treated with nephrotic serum (NTS). Immunohistochemistry, immunofluorescence staining, and electron microscopy was used to identify extracellular matrix extensions in glomeruli. Single nucleus (sn)RNA-seq was performed on both injury models.

**Results:** Periodic-acid schiff staining and electron microscopy revealed de novo bridges in mice with podocyte-specific loss of *Klf4* and in mice treated with NTS. Staining NTS-treated dual reporter mice for CD44, a marker of activated PECs, revealed both RFP+ and CD44+ extensions. We also observed colocalization of RFP and CD44, suggesting that both podocytes and PECs are capable of forming bridges. Enrichment analysis of differentially expressed genes between wild type and *Klf4<sup>ΔPod</sup>* mice and IgG and NTS treatment showed common upregulated pathways including focal adhesion (ACTN1, ITGA6, BIRC3), axon guidance (ROCK2, MYL12A, MYL21B), and actin cytoskeleton regulation (ACTN1, FGFR2, MYH9, MSN) in the podocyte and PEC clusters.

**Conclusions:** This is the first study to demonstrate that glomerular bridges in proliferative glomerulopathy originate from both injured podocytes and activated PECs.

## SA-OR27

**RCAN1 I162T Variant Disrupts Calcineurin Regulation and Reduces Viability in Patient-Derived Podocytes**

Kinsie Huggins,<sup>1,4</sup> Somenath Datta,<sup>3,4</sup> Karen Soldano,<sup>3,4</sup> Daniel P. Silas,<sup>3,4</sup> Elhussein A. Elhassan,<sup>2</sup> Megan Chryst-Stangl,<sup>3,4</sup> Guanghong Wu,<sup>3,4</sup> Opeyemi A. Olabisi,<sup>3,4</sup> Peter J. Conlon,<sup>2</sup> Rasheed A. Gbadegesin,<sup>3,4</sup> Brandon M. Lane,<sup>3,4</sup> <sup>1</sup>*Duke University, Durham, NC;* <sup>2</sup>*Beaumont Hospital, Dublin, Ireland;* <sup>3</sup>*Duke University School of Medicine, Durham, NC;* <sup>4</sup>*Duke Molecular Physiology Institute, Durham, NC.*

**Background:** We have previously shown that deleterious mutations in RCAN1 are a cause of familial FSGS. One of these mutations, I162T resulted in dysregulated calcineurin (CN) activity and reduced viability in HEK293 cells overexpressing the variant compared to WT expressing cells. Deficits in I162T cell viability was rescued by treatment with calcineurin inhibitors as well as inhibitors of GSK-3β. Knockdown of RCAN1 also produced similar disruptions in podocyte viability in conditionally immortalized human podocytes. However the phenotype of podocytes derived from patients with RCAN1 I162T mutation is unknown.

**Methods:** Using PBMCs collected from a patient carrying the RCAN1 I162T mutation as well as an unaffected family member, we generated induced pluripotent stem cells (iPSCs). After differentiating iPSCs into podocytes, the cells were examined for changes in CN regulation and viability.

**Results:** Differentiated podocytes from both affected and unaffected individuals displayed podocyte specific markers including Nephlin, WT1 and Synaptopodin as confirmed by both RT-PCR and immunofluorescence. Automated live-cell imaging over 72 hours using a fluorescent reporter of caspase 3 activity revealed an increase in serum starvation induced apoptosis in the podocytes carrying the mutant I162T compared to podocytes from the control unaffected family member (p<0.0001).

**Conclusions:** We have now confirmed that the RCAN1 I162T allele causes decreased podocyte viability due to defects in calcineurin regulation using cells derived from affected family. These patient iPSC derived podocytes set the stage for a better understanding of RCAN1-mediated regulation of CN activity and evaluation of therapeutic alternatives to calcineurin inhibitors in the treatment of FSGS.

## SA-OR28

**C3a/C3aR1 Signaling as a Crucial Pathogenic Mechanism in Membranous Nephropathy**

Stefano Da Sacco,<sup>1</sup> Qi Zhang,<sup>1</sup> Sofia Bin,<sup>2</sup> Astgik Petrosyan,<sup>1</sup> Luis F. Sanchez Russo,<sup>2</sup> Valentina Villani,<sup>1</sup> Micaela Gentile,<sup>2</sup> Roger E. De Filippo,<sup>1</sup> Kevin V. Lemley,<sup>1</sup> Laura Perin,<sup>1</sup> Paolo Cravedi.<sup>2</sup> <sup>1</sup>*Children's Hospital of Los Angeles, Los Angeles, CA;* <sup>2</sup>*Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide caused by the deposition of anti-podocyte-antibodies in the glomerular subepithelial space. While complement deposition is thought to play a crucial pathogenic role, the exact effector mechanism of complement in MN is unclear due to the lack of in vitro and in vivo systems that can faithfully recapitulate human disease. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and glomerular endothelial cells (GEC) and assessed functional response to human MN serum, role of membrane-attack-complex (MAC) formation and C3a/C3aR1 signaling in MN pathogenesis.

**Methods:** GOACs were exposed to anti-PLA2R+ sera from MN patients; sera from healthy individuals were used as control. Functional response was assessed by albumin permeability assay to evaluate permselectivity. Role of PLA2R1, IgGs, complement, MAC and C3a/C3aR1 signaling pathway were assessed by immunofluorescence, western blotting and functional analysis while mechanisms of action were explored by PCR arrays, proteomics and immunostaining. Results were confirmed in vitro using podocytes on which C3aR1 was silenced and in vivo using THSD7A induced MN in balb/c mice.

**Results:** Following exposure to sera from MN patients, we confirmed IgG deposition, complement activation and MAC formation accompanied by albumin leakage. PLA2R silencing on podocytes, IgG neutralization as well as complement inactivation successfully prevented injury while leakage still occurred following MAC inhibition. GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes in which C3aR1 was silenced were able to counteract glomerular filtration damage and prevent albumin leakage and lessen oxidative stress in podocytes. Efficacy of C3aR1 antagonists in preventing proteinuria was confirmed in vivo, substantiating our findings.

**Conclusions:** We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying renal regenerative and disease mechanisms in proteinuric diseases. Using a combination of in vitro and in vivo models, we showed that C3a/C3aR signaling plays a dominant role in complement-mediated MN pathogenesis.

## SA-OR29

**Targeting the Integrated Stress Response Pathway in T Cells Ameliorates Crescentic Glomerulonephritis in Mice**

Nariaki Asada, Pauline Ginsberg, Anna Kaffke, Anett Peters, Hans-Joachim Paust, Christian F. Krebs, Hans-willi Mittrücker, Ulf Panzer. *Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** CD4<sup>+</sup> T cells play a central role in immunity by producing cytokines. After infection, some T cells remain in organs and become tissue-resident memory T (Trm) cells, which contribute to efficient host defense by immediate production of cytokines. Recently, it was demonstrated that Trm cells are also associated with autoimmune disease development and relapse. Therefore, tight regulation of cytokine production by Trm cells is of great importance to achieve efficient host defense without excessive inflammation. However, the underlying mechanisms of cytokine production by Trm cells are not well characterized.

**Methods:** Human and murine T cells in the kidney were analyzed by single cell RNA sequencing (scRNAseq), polysome profiling, RT-PCR, flow-cytometry, immunocytochemistry, and mRNA FISH. Mouse models for *Staphylococcus aureus* infection and crescentic glomerulonephritis were used to induce and study Trm cells *in vivo*.

**Results:** scRNAseq analysis of T cells from human healthy kidney revealed that Trm cells express high mRNA levels of proinflammatory cytokines such as *IL17A*, *INFG*, and *CSF2*. However, flow-cytometry, tissue signature analysis, and polysome profiling showed that Trm cells do not translate cytokine mRNA into protein without re-stimulation. Mechanistically, we demonstrated that the phosphorylation of eIF2α, a key feature of the integrated stress response (ISR) activation, results in recruitment of cytokine mRNA into stress granules, which are organelles crucial for regulating mRNA translation during ISR. Re-stimulation of Trm cells resulted in eIF2α dephosphorylation, leading to rapid translation of cytokine mRNA into protein. Moreover, we found that blocking eIF2α phosphatase by Raphin1 efficiently suppresses eIF2α dephosphorylation and cytokine production from Trm cells. *In vivo* administration of Raphin1 improved crescent formation and albuminuria in immune-mediated kidney injury in mice.

**Conclusions:** CD4<sup>+</sup> Trm cells express high level cytokine mRNA but regulate translation through ISR under homeostatic conditions. Targeting ISR by Raphin1 suppresses cytokine production from activated Trm cells and autoimmune kidney disease progression in mice. Our study identifies a novel mechanism of how ISR regulates rapid cytokine production of poised Trm cells in health and disease.

## SA-OR31

**Linked by Love: Relatability and Cultural Appropriateness of an Edutainment Series About CKD in an African American Family**

LaShara A. Davis,<sup>1</sup> Nicole D. Mendez,<sup>2</sup> Susanne B. Nicholas,<sup>3</sup> Amy D. Waterman.<sup>1</sup> <sup>1</sup>Houston Methodist Hospital, Houston, TX; <sup>2</sup>Mendez National Institute of Transplantation Foundation, Los Angeles, CA; <sup>3</sup>Ronald Reagan UCLA Medical Center, Los Angeles, CA.

**Background:** African Americans (AA) are 3.1 times more likely than Whites to have chronic kidney disease (CKD) and progress to kidney failure, but less likely to receive living donor kidney transplants (LDKTs), in part, due to poorer transplant knowledge and motivation to learn more. We examined whether the scripts for the CKD edutainment series, *Linked by Love*, were engaging and culturally sensitive to the AA community and determine recommendations for improvement.

**Methods:** We recruited AA patients to watch a script read of one of six scripts and provide feedback on the cultural sensitivity of their engagement with the storyline prior to filming. We conducted 13 focus groups (FG) with 2-6 participants (Median: 4) per group. Participants also provided recommendations about how to make the series more authentic to the experiences of CKD patients and families. FGs were transcribed verbatim and thematically coded for reactions to the scripts and recommendations for improvements. Themes were generated using inductive and deductive coding.

**Results:** FG participants (N=32) reported that the series was authentic (55.3%), engaging (42.1%), and enjoyable (42.1%) in a response to a brief survey on engagement. Themes emerged around the lack of awareness of common causes of CKD and limited depictions of AA health stories on television. Script elements depicting the main character as a superwoman and health secrecy within AA families were seen as culturally sensitive and caused curiosity about improving kidney health. Most stated that they would share the series with others. After viewing the series, several participants shared that they now planned to check their creatinine levels. Suggested improvements included earlier distinction of CKD symptoms, more family involvement in the evaluation process, and discussion of nutrition as a factor in health and illness.

**Conclusions:** Fictionalized stories about CKD and transplant challenges in AA families are well received by AA audiences when they include realistic family portrayals, depictions of strong female characters, and highlight AA family secrecy around health and illness. Edutainment is a promising technique to connect with and educate AA families. Further research is needed to assess whether this strategy can improve CKD knowledge, prevention, and behaviors.

## SA-OR32

**A Randomized Controlled Pilot Study of a Patient Decision Aid About Conservative Kidney Management**

Susan P. Wong, Taryn Oestreich, David K. Prince, Bridgett A. Chandler, J. Randall Curtis. *University of Washington Department of Medicine, Seattle, WA.*

**Background:** Conservative kidney management (CKM) is an important treatment option for patients who do not wish to receive maintenance dialysis. However, most patient decision aids do not present information on this treatment approach.

**Methods:** We conducted a randomized controlled pilot study (NCT04919941) to assess the feasibility and acceptability of a new decision aid about CKM with patients aged  $\geq 75$  years with stage 4 or 5 CKD and family members between August 2020-December 2021. After completing an initial study visit (T1), participants were randomized to receive the aid or to usual care. Acceptability was assessed based on attrition rates in each study arm between (T1) and 3-month follow-up (T3). Our primary outcome measure and measure of feasibility was the proportion who discussed CKM with a healthcare provider at T3. We also explored changes in patients' decisional uncertainty (Decision Conflict Scale [DCS] scores) about treatment options for their CKD (dialysis, CKM, or unsure) at T3.

**Results:** We randomized 92 patients of which 86 patients (55.8% male; age 82 $\pm$ 6 years; 82.6% White) completed T1—42 in the usual care arm and 44 in the intervention arm—and 56 family members of which 53 (18.9% male; age 71 $\pm$ 11 years; 86.8% White) completed T1—20 in usual care arm and 33 in the intervention arm. Attrition rates were low in the usual care and intervention groups for patients (21% vs. 21%,  $p=1.0$ ) and family members (10% vs. 18%,  $p=0.46$ ). The intervention was associated with greater discussion of CKM with a healthcare provider for patients (26.4% vs. 3.0%,  $p=0.007$ ) and family members (26.9% vs. 0%,  $p=0.02$ ). Patients who were unsure about which treatment option they preferred decreased by 20.0% in the intervention group and by 12.1% in the control group ( $p=0.27$ ). Patients' decisional uncertainty about their options also decreased for the intervention (DCS -15.7 $\pm$ 21.2) and control (DCS -9.1 $\pm$ 20.6) groups ( $p=0.06$ ).

**Conclusions:** Our decision aid on CKM was feasible, acceptable, and promoted discussion of this treatment option with healthcare providers. The aid may show promise as a useful adjunct to currently available educational tools on treatments for advanced CKD.

## SA-OR33

**Impact of Race/Ethnicity and Age on Hospitalization Outcomes in Advanced CKD Patients Treated With Conservative Management vs. Dialysis**

Connie Rhee,<sup>1</sup> Amy S. You,<sup>1</sup> Yoko Narasaki,<sup>1</sup> Dana B. Mukamel,<sup>1</sup> Susan T. Crowley,<sup>2</sup> Ji Hoon Yoon,<sup>1</sup> Csaba P. Kovacs,<sup>3</sup> Danh V. Nguyen,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

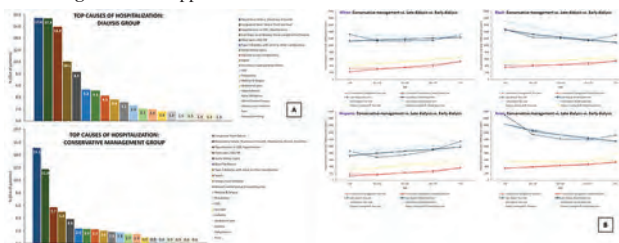

**Background:** Given evidence that dialysis results in greater healthcare utilization and morbidity among certain subgroups, there is rising interest in conservative management (CM) as an alternative patient-centered treatment strategy for advanced CKD. Little is known about the comparative effectiveness of CM vs. dialysis on hospitalization outcomes across different races/ethnicities.

**Methods:** We compared hospitalization rates in advanced CKD patients treated with CM vs. dialysis over 1/07-6/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as EHR data. Patients were categorized according to receipt of CM, defined as those who did not receive dialysis within 2-yr of the index eGFR (1<sup>st</sup> eGFR $<25$ ), vs. receipt of dialysis parsed as late vs. early dialysis transition (eGFRs  $<15$  vs.  $\geq 15$  at dialysis initiation). We used Poisson regression to compare raw and model-based hospitalization rates in CM vs. dialysis patients across race/ethnicity and age.

**Results:** Among 309,188 advanced CKD patients who met eligibility, 55% of patients had  $\geq 1$  hospitalization(s) within 2-yr of the index eGFR; the most common causes of hospitalization in both the CM and dialysis groups were CHF, respiratory, or HTN-related (Fig A). In Non-Hispanic (NH) White, NH Black, and Hispanic patients, late and early dialysis had higher hospitalization rates than CM, in which early dialysis demonstrated the highest rates across all age groups (Fig B). Among Asian patients, whereas late and early dialysis also had higher hospitalization rates than CM, late dialysis had higher model-based rates than early dialysis, particular in older age groups.

**Conclusions:** We observed differential relationships between CM vs. dialysis on hospitalization rates across race/ethnicity and age. Further research is needed to determine which patients are optimal candidates for CM vs. dialysis using a personalized approach.

**Funding:** NIDDK Support

## SA-OR34

**Prevalence of CKD Among Asian Adults in the United States, 2011-2018**

Sophie E. Claudel, Insa M. Schmidt, Sushrut S. Waikar, Ashish Verma. *Boston Medical Center, Boston, MA.*

**Background:** Chronic kidney disease (CKD) is a leading risk factor for cardiovascular disease (CVD). Asian adults in the United States (US) have high rates of CVD. We hypothesized that Asian adults have a higher burden of CKD and associated conditions than White individuals, and risk may vary across Asian ethnicities.

**Methods:** Using cross-sectional data from NHANES 2011-2018 (N=21,566), we calculated weighted, age-adjusted prevalence of CKD and associated conditions (hypertension (HTN), diabetes (DM), obesity, metabolic acidosis, albuminuria, CVD) among non-Hispanic adults. CKD was defined as an estimated GFR $<60$ ml/min per 1.73m<sup>2</sup> or albuminuria  $\geq 30$ mg/g. Using the National Health Interview Survey (NHIS; N=14,194), we explored heterogeneity in self-reported prevalence across Asian ethnicities.

**Results:** The NHANES population was 37% White, 23% Black, 13% Asian, and 28% other race, with a mean age of 48 years. Overall CKD prevalence was 12.7% (95%CI 12.1, 13.4). Asians had a 1.5- and 1.3-fold higher prevalence of CKD compared to White and Black participants, respectively. Among Asians, the prevalence of HTN and obesity increased over time ( $p$ -trend=0.001 for both) and remained significantly greater than among White and Black participants throughout the study period. In the NHIS, there was higher prevalence of HTN and obesity among Filipino participants and lower prevalence of HTN, DM, and obesity among Chinese participants.

**Conclusions:** Analysis of nationally representative data from the US demonstrates a disproportionately high prevalence of CKD and associated conditions among Asian adults, with prevalence rates for some conditions exceeding those of Black and White participants.

## SA-OR35

### Comparison of Clinical Outcomes Between Twice- vs. Thrice-Weekly Hemodialysis in Thai Elderly Patients: A Single-Center Study

Prapa Patrapornpisut,<sup>1</sup> Kittiphon Khruawang,<sup>1</sup> Darunee Buddeewong,<sup>1</sup> Inthira Srichaichana,<sup>1</sup> Kanyapa Srila,<sup>1</sup> Picha Yincharoen,<sup>1</sup> Tanyarat Teerapornlertratt,<sup>1</sup> Kriang Tungsanga.<sup>1,2</sup> <sup>1</sup>Bhumirajanagarindra Kidney Institute Hospital, Bangkok, Thailand; <sup>2</sup>King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

**Background:** Hemodialysis (HD) in the elderly is a complex process, given the physiologic changes and comorbidities. Although studies, which included patients aged  $\geq 18$ , suggested twice-weekly HD (BWD) may not be inferior to thrice-weekly HD (TWD), there are scarce studies in the elderly.

**Methods:** We conducted a single-center, prospective cohort study to observe whether BWD and TWD would result in different outcomes in the elderly. All end-stage kidney disease patients, aged  $\geq 65$ , who had received HD for  $>3$  months at our center, were enrolled. Those who had received kidney transplantation, peritoneal dialysis or refused to give informed consent were excluded. Patients were allocated into 2 groups: BWD and TWD. The decision about HD frequency was shared between treating nephrologists and a patient. The primary outcome was the composite endpoint of all-cause mortality, cardiovascular (CVS) events, and hospitalization from any cause over 36 months.

**Results:** 210 patients were enrolled: 94 in the BWD group and 116 in the TWD group. The overall mean age was 77.4 ( $\pm 7.8$ ) years old, 38% aged over 80. Comparing with the TWD group, the BWD group had shorter dialysis vintage (692 IQR 332, 1207 vs 1324 IQR 884, 1790 days,  $p < 0.001$ ) and a higher proportion of cases with  $K_{tV} \geq 2$  mL/min (36.7% vs 6%,  $p < 0.001$ ). There was no difference in the proportion of cases who reached the primary outcome between the 2 groups [62 (66%) vs 88 (76%) cases, long-rank  $p = 0.25$ ]. There was also no difference in each component of the primary outcome.

**Conclusions:** In summary, over 36 months, elderly patients on BWD did not differ from those on TWD with respect to a composite endpoint of all-cause mortality, CVS events and hospitalization from any cause. This study provides information on outcomes exclusively in the elderly on HD and suggests TWD might not be necessary for this age group. Nevertheless, a RCT is needed to confirm this finding.

**Funding:** Private Foundation Support

Kaplan-Meier showing the cumulative primary outcome

### Effects of Dapagliflozin on Anemia in Patients With CKD With or Without Type 2 Diabetes: A Pre-Specified Analysis of the DAPA-CKD Trial

Hiddo J. L. Heerspink,<sup>1,2</sup> Akihiko Koshino,<sup>1,3</sup> Meir Schechter,<sup>1,4</sup> Priya Vart,<sup>1</sup> Niels Jongs,<sup>1</sup> Glenn Chertow,<sup>5</sup> Robert D. Toto,<sup>6</sup> Peter Rossing,<sup>7,8</sup> Ricardo Correa-Rotter,<sup>9</sup> John McMurray,<sup>10</sup> Anna Maria Langkilde,<sup>11</sup> David C. Wheeler.<sup>12</sup> <sup>1</sup>Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands; <sup>2</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>3</sup>Kanazawa Daigaku Daigakuin Iyaku Hokengaku Sogo Kenkyuka Iyaku Hoken Gakuiki Igakurui, Kanazawa, Japan; <sup>4</sup>Hadassah University Medical Center, Jerusalem, Israel; <sup>5</sup>Stanford Medicine, Stanford, CA; <sup>6</sup>UT Southwestern Medical Center, Department of Internal Medicine, Dallas, TX; <sup>7</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>8</sup>Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Kobenhavn, Denmark; <sup>9</sup>National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; <sup>10</sup>University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; <sup>11</sup>AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; <sup>12</sup>University College London Faculty of Medical Sciences, London, United Kingdom.

**Background:** Anemia is a common complication of chronic kidney disease (CKD) and is associated with worse outcomes. The sodium-glucose cotransporter 2 inhibitor dapagliflozin increased erythropoietin and hematocrit (Hct) and corrected anemia in patients with heart failure. We examined the effect of dapagliflozin in preventing and correcting anemia in patients with CKD with or without type 2 diabetes (T2D).

**Methods:** The DAPA-CKD study randomized patients with eGFR 25-75 mL/min/1.73m<sup>2</sup> and UACR 200-5000 mg/g to dapagliflozin 10mg or placebo. Hct was measured at baseline, 14 days, 2 and 4 months, and every 4 months thereafter. Anemia was defined as Hct levels  $<39\%$  in males or  $<36\%$  in females. Investigators' reporting was used to define anemia-related adverse events. The effect of dapagliflozin on Hct was assessed using mixed effect model for repeated measures. Treatment effect in preventing and reversing anemia was assessed by Cox proportional hazard regression models.

**Results:** Of patients with Hct levels at baseline (N=4292 [99.7%]; mean Hct 38.9%), 1549 (36.1%) had anemia. Patients with anemia had lower mean eGFR (40 vs 45 mL/min/1.73m<sup>2</sup>) and higher median UACR (1124 vs 877 mg/g) compared to those without anemia. Over 2.4 years' median follow-up, dapagliflozin increased absolute Hct levels vs placebo by 2.3% (95%CI 2.1-2.5;  $p < 0.001$ ). In patients without anemia at baseline, 134 (9.7%) developed anemia with dapagliflozin vs 228 (17.0%) with placebo (HR 0.53; 95%CI 0.43-0.66;  $p < 0.001$ ). Dapagliflozin reduced the risk of anemia-related adverse events compared to placebo (HR 0.46; 95%CI 0.23-0.95;  $p = 0.04$ ). In patients with anemia at baseline, anemia was corrected in 343 patients (47.5%) receiving dapagliflozin and 192 (24.8%) receiving placebo (HR 2.27; 95%CI 1.90-2.71;  $p < 0.001$ ). The effects of dapagliflozin in preventing and correcting anemia were consistent in patients with and without T2D ( $p$  interaction  $\geq 0.83$ ).

**Conclusions:** The effects of dapagliflozin on Hct may support its role in prevention and treatment of anemia in patients with CKD with or without T2D.

## Time-Dependent Covariate Analysis of Hemoglobin Values on Risk of Major Adverse Cardiovascular Events in the ASCEND Trials

Gregorio T. Obrador,<sup>1</sup> Kirsten L. Johansen,<sup>2</sup> Sushrut S. Waikar,<sup>3</sup> Vivekanand Jha,<sup>4</sup> Ricardo Correa-Rotter,<sup>5</sup> Lucia Del Vecchio,<sup>6</sup> Aleix Cases,<sup>7</sup> Michele Robertson,<sup>8</sup> Stephen Mallett,<sup>9</sup> Christine K. Bailey,<sup>10</sup> Alexander R. Cobitz,<sup>10</sup> Ajay K. Singh.<sup>11</sup> <sup>1</sup>Universidad Panamericana School of Medicine, Mexico City, Mexico; <sup>2</sup>Hennepin Healthcare, Minneapolis, MN; <sup>3</sup>Boston University School of Medicine and Boston Medical Center, Boston, MA; <sup>4</sup>George Institute for Global Health, New Delhi, India; <sup>5</sup>Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; <sup>6</sup>Azienda Socio Sanitaria Territoriale Lariana, Como, Italy; <sup>7</sup>Universitat de Barcelona, Barcelona, Spain; <sup>8</sup>Robertson Centre for Biostatistics, University of Glasgow, Glasgow, United Kingdom; <sup>9</sup>R&D, GSK, Brentford, United Kingdom; <sup>10</sup>R&D, GSK, Collegeville, PA; <sup>11</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

**Background:** The evidence supporting an association between rapid changes in hemoglobin (Hb) and cardiovascular (CV) outcomes is limited. We performed a time-dependent covariate analysis in patients with chronic kidney disease on dialysis (ASCEND-D, NCT02879305) or not on dialysis (ASCEND-ND, NCT02876835) treated with daprodustat or erythropoiesis-stimulating agent (ESA).

**Methods:** ASCEND-D and ASCEND-ND were event-driven CV outcomes trials, enrolling 2694 and 3872 patients, respectively. Major adverse CV events (MACE) were a composite of death from any cause, non-fatal myocardial infarction, and non-fatal stroke. In this post-hoc analysis, two Hb-related time-dependent covariates were constructed based on 12-weekly intervals for each patient: most recent 4-week Hb change ( $>1$ ,  $\geq 0$  to  $\leq 1$ ,  $\geq -1$  to  $<0$ ,  $<-1$  g/dL) and most recent Hb level (low  $<10$ , medium 10 to 11.5, high  $>11.5$  g/dL). Associations between time-varying Hb and change in Hb and risk of adjudicated first MACE were explored using a piece-wise exponential model adjusted for baseline and other covariates (Figure). Odds ratios and 95% confidence intervals are reported.

**Results:** Results were consistent between daprodustat and ESA treatment arms in ASCEND-D and ASCEND-ND. A most recent 4-week Hb change  $>1$ g/dL and most recent 4-week Hb change  $<-1$ g/dL vs an Hb change  $\geq 0$  to  $\leq 1$ g/dL, and low Hb vs medium Hb, were associated with higher MACE risk (Figure). No increased risk was seen with Hb changes  $\geq -1$  to  $<0$ g/dL or with high Hb.

**Conclusions:** Our data suggest that rapid Hb changes and low absolute Hb values may be associated with higher MACE risk in patients treated with daprodustat or ESA. Additional analyses are needed to delineate these associations further.

**Funding:** Commercial Support - This study was funded by GSK.

**Figure.** Hb-related time-dependent covariate analyses for ASCEND-D (A) and ASCEND-ND (B)

## Change in Albuminuria and GFR Slope as Joint Surrogate Endpoints for Kidney Failure: Implications for Phase 2 Trials

Tom Greene,<sup>1</sup> Lesley A. Inker,<sup>2</sup> Hiddo J. L. Heerspink,<sup>3</sup> Hocine Tighiouart,<sup>4</sup> Willem H. Collier,<sup>1</sup> Benjamin Haaland.<sup>1</sup> Chronic Kidney Disease-Epidemiology Collaboration <sup>1</sup>University of Utah Health, Salt Lake City, UT; <sup>2</sup>Tufts Medical Center, Boston, MA; <sup>3</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>4</sup>Tufts Clinical and Translational Science Institute, Boston, MA.

**Background:** Change in urinary albumin:creatinine ratio (UACR) and GFR slope are individually used as surrogate endpoints in clinical trials of CKD progression. We developed a strategy that combined both endpoints to improve prediction of drug effects on clinical outcomes.

**Methods:** We used data from 43 randomized controlled trials of CKD progression and fitted trial-level Bayesian meta-regression models to characterize the joint relationship between the treatment effects on the clinical endpoint (sustained doubling of serum creatinine, GFR  $< 15$  mL/min per 1.73m<sup>2</sup>, or end-stage kidney disease) and those on UACR change and chronic GFR slope. We applied the results of the meta-regression to the design of a phase 2 trial to assess design implications (sample size, follow-up time) for using UACR change and GFR slope individually or in combination. For each design we calculated the positive predicted value (PPV) for inferring clinical benefit based on observed treatment effects on UACR and GFR slope.

**Results:** The median R<sup>2</sup> of the model was 0.926. The PPV of both surrogates on the clinical endpoint was almost exclusively determined by estimated treatment effects on UACR when the sample size was small (~60 patients per arm) and follow-up short (~1 year; fig1A), with the importance of GFR slope increasing when the sample size and

follow-up increased (fig1B/C). At large sample sizes ( $>600$  per group) or long follow-up ( $\geq 2$  year), clinical benefit was solely determined by GFR slope (fig1D).

**Conclusions:** In phase 2 clinical trials with sample sizes of 100 to 200 patients per arm or follow-up times ranging between 1 and 2 years combining the information from treatment effects on UACR change and GFR slope improved prediction of treatment effects on clinical endpoints.

**Funding:** Private Foundation Support

## Design A: 60 per group, 1.25 years of follow-up, quarterly GFRs

Est. effect on chronic slope ml/min/1.73m <sup>2</sup> /yr	1.00	0.95	0.90	0.85	0.80	0.75	0.70	0.65

PPV from observed treatment effects on ACR and GFR Slope in phase 2 studies to infer clinical benefit defined as HR  $< 1$ . Light gray: PPV $>0.8$ ; dark gray: PPV $>0.9$ . The relationship between joint treatment effects on UACR change and GFR slope with treatment effects on clinical endpoint showed a posterior median meta-regression coefficient of -0.429 (2.5% - 97.5% P: 0.660 to -0.192) for the treatment effect on the GFR slope and -0.113 (-0.839 to 0.631) for that on log UACR.

## SA-OR39

## Effect of a Nutritional Supplement of Probiotics and/or Prebiotics vs. Placebo on Nutritional Status in Automated Peritoneal Dialysis (APD) Patients

Fabiola Martin del Campo,<sup>1</sup> Alfonso M. Cueto-Manzano,<sup>1</sup> Carmen Sanchez-Ramirez,<sup>3</sup> Natali Vega,<sup>4</sup> Marcela Peña Rodríguez,<sup>2</sup> Laura Cortes-Sanabria,<sup>1</sup> Enrique Rojas-Campos,<sup>1</sup> Mariana Villanas Ballesteros.<sup>1</sup> <sup>1</sup>Unidad de Investigación Médica en Enfermedades Renales 'Hospital de Especialidades del Centro Medico Nacional de Occidente IMSS, Guadalajara, Mexico; <sup>2</sup>Universidad de Guadalajara Departamento de Biología Molecular y Genómica, Guadalajara, Mexico; <sup>3</sup>Universidad de Colima Facultad de Medicina, Colima, Mexico; <sup>4</sup>Departamento de Microbiología y Patología, Universidad de Guadalajara, Guadalajara, Mexico.

**Background:** Prebiotics and probiotics may improve nutritional status in dialysis patients by decreasing inflammation and intestinal production of uremic toxins; however, no study has been performed comparing these interventions altogether and separately. Aim: to evaluate the effect of a supplement of probiotics and/or prebiotics vs placebo on nutritional status in APD.

**Methods:** Randomized, triple blinded, controlled, clinical trial in 64 clinically stable APD patients, assigned to: Probiotic (2x10<sup>8</sup> CFU probiotics+placebo); Prebiotic (20g inulin+placebo); Simbiotic (2x10<sup>8</sup> CFU probiotics+20g inulin); or Placebo (placebo+placebo) during 3 months. Nutritional status determined by subjective global assessment (SGA). Intestinal microbiota was evaluated with 16S rRNA gene sequencing.

**Results:** Nutritional status results shown in Figure. Prebiotic group increased SGA score (5.1 $\pm$ 1.1 vs 5.9 $\pm$ 0.7,  $p=0.02$ ), dietary intake of energy (1121 $\pm$ 373 vs 1508 $\pm$ 637,  $p=0.02$ ) and marginally fiber (17 $\pm$ 7 vs 24 $\pm$ 12,  $p=0.08$ ); Probiotic marginally increase SGA (5.6 $\pm$ 1.0 vs 6.1 $\pm$ 0.7,  $p=0.06$ ); no statistical differences were observed in Simbiotic and Placebo groups. At the end of the study, Prebiotic significantly increased relative abundance of Blautia, Ruminococcaceae and Faecalibacterium prausnitzii bacteria and decreased Clostridiales; compared to placebo, Prebiotic showed higher predominance of Succinivibrio, Aeromonadales, Bifidobacterium, Bifidobacteriales and SMB53 at final evaluation. Adherence to treatment was  $>90\%$  in all groups during the study; main adverse effects were mild gastrointestinal symptoms (not significantly different between groups).

**Conclusions:** Prebiotic improve nutritional status and intestinal microbiota in APD patients; this could be an easy and inexpensive intervention for this patients.

## SA-OR40

## Obesity Weight Loss Phenotypes in CKD: Data From the Chronic Renal Insufficiency Cohort Study (CRIC)

Meera N. Harhay,<sup>1,2</sup> Lucy Robinson,<sup>2</sup> Yuna Kim,<sup>2</sup> Brandy-Joe Milliron.<sup>3</sup>  
<sup>1</sup>Drexel University College of Medicine, Philadelphia, PA; <sup>2</sup>Drexel University Dornsife School of Public Health, Philadelphia, PA; <sup>3</sup>Drexel University College of Nursing and Health Professions, Philadelphia, PA.

**Background:** Although adults with chronic kidney disease (CKD) and obesity are often advised to lose weight, weight loss may also signal a decrease in physiologic reserve and higher mortality risk. The aim of this study was to identify features of high-risk weight loss among individuals with obesity and CKD.

**Methods:** We identified CRIC participants with a BMI of  $\geq 30$  kg/m<sup>2</sup> at baseline. We estimated a multivariate latent class model to identify distinct trajectories of change from baseline BMI, mean arterial pressure (MAP), and % fat free mass (FFM) using nonlinear trends over time for each variable and subject-level random effects. We fit a Cox model for death using estimated latent classes and adjusted for race/ethnicity, sex, and baseline age, BMI, %FFM, MAP, diabetes, and estimated glomerular filtration rate (eGFR).

**Results:** Among 2,909 CRIC participants (median baseline BMI 35.5 (IQR 32.4-39.9) kg/m<sup>2</sup>, median follow-up time was 6.4 years, median age was 61 (interquartile range [IQR] 54-67) years, 53% were male, 37% were non-Hispanic White, and 82% were trying to lose weight. Median BMI was 35.5 (IQR 32.4-39.9) kg/m<sup>2</sup>. We observed six distinct latent classes in the study cohort, defined by similar patterns of changes over time in BMI, MAP, and %FFM (Figure). Latent classes were independently and significantly associated with mortality risk ( $p=0.009$ ); class 6 had the lowest unadjusted mortality. Relative to class 6, those in class 1 were younger (58 vs 62 years) more likely to be female (65% vs 46%), have diabetes (70% vs 57%), have higher initial BMI (42 vs 35 kg/m<sup>2</sup>) and MAP (88 vs 85 mm Hg), and lower eGFR (36.9 vs 47.3 ml/min/1.73m<sup>2</sup>) and %FFM (56 vs 62%) at baseline. After multivariable adjustment, class 1 was associated with a nearly 2-fold higher death risk relative to class 6 (adjusted Hazard Ratio 1.9, 95% Confidence Interval 1.18-2.41,  $p=0.004$ ).

**Conclusions:** Among individuals with CKD and obesity, the pattern characterized by steep initial BMI loss, increase in %FFM, and stable MAP was associated with the highest risk of death.

**Funding:** NIDDK Support

Figure. Figure depicts six class-specific mean predicted trajectories of changes in body mass index (BMI), mean arterial pressure (MAP), and % fat free mass (FFM) from baseline among 2,909 CRIC participants with obesity at baseline. Line thickness corresponds to the % of the cohort in each class.

## SA-OR41

## Utilization of SARS-CoV-2 (COVID-19)-Positive Donor Kidneys

Warren T. McKinney,<sup>1,2</sup> David P. Schladt,<sup>3</sup> Ajay K. Israni.<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>Scientific Registry of Transplant Recipients, Minneapolis, MN; <sup>3</sup>Chronic Disease Research Group, Minneapolis, MN.

**Background:** The Organ Procurement and Transplantation Network requires documentation of SARS-CoV-2 (COVID) testing status for each potential donor and lower respiratory specimen testing with nucleic acid tests for all donor lungs. In the absence of guidelines for the use of COVID-positive donor kidneys, we sought to examine the clinical characteristics of COVID-positive donors and trends in the utilization of COVID-positive donor kidneys.

**Methods:** This study used Scientific Registry of Transplant Recipients data and included all deceased donors ( $n=24,940$ ) and recipients ( $n=29,478$ ) from June 1, 2020, through April 2, 2022. Variation in donor and recipient characteristics were considered significant at  $P<.05$ .

**Results:** 1,310 (5.35%) of donors during the observation period had a positive test for COVID-19 with 1,731 (67.70%) kidneys transplanted, 108 (4.22%) not recovered, and 714 (27.92%) recovered but not transplanted. COVID-positive donors differed from COVID-negative or untested donors in terms of race, ethnicity, cause of death, and donation after circulatory death status (all  $P<.05$ ). 813 recipients (2.76%) received COVID-positive deceased donor kidneys. Recipients of COVID-positive donor kidneys were more likely to be White, not have received a previous transplant, and had greater cold ischemic times (all  $P<.05$ ). The number of transplants with COVID-positive donors peaked in early 2022 (Figure 1). Adjusted hazard ratios for all-cause graft failure with COVID-positive donors and death were 0.89 (95% CI, 0.62-1.28) and 0.87 (95% CI, 0.52-1.46), respectively.

**Conclusions:** Transplant with COVID-positive donor kidneys increased during the study period and is not associated with increased risks for recipients. However, high discard rates for COVID-positive donors and greater cold ischemic times may suggest that such donor kidneys remain difficult to place. Patient- and transplant program-level interventions targeting decision support and risk aversion may be necessary to reduce discard rates for COVID-positive donor kidneys.

**Funding:** Other NIH Support - This material is based in part upon work supported by the Agency for Healthcare Research and Quality (AHRQ) and the Patient-Centered Outcomes Research Institute (PCORI) grant K12HS026379 (W.T.M.).

## Viro-Immunological Monitoring as a Predictor for Complicative Events in the First Year After Kidney Transplantation: The VIRENO Study

Patrick Affeldt,<sup>1</sup> Katharina Burkert,<sup>1</sup> Georg Dieplinger,<sup>6</sup> Christopher Holzmann-Littig,<sup>2</sup> Katharina Tuschen,<sup>3,4</sup> Martin Kann,<sup>1</sup> Franziska Grundmann,<sup>1</sup> Vanessa A. Ditt,<sup>8</sup> Benjamin Wilde,<sup>5</sup> Lutz Renders,<sup>2</sup> Dirk L. Stippel,<sup>6</sup> Christine E. Kurschat,<sup>1</sup> Veronica Di Cristanziano,<sup>7</sup> Roman-Ulrich Mueller.<sup>1</sup>  
 VIRENO Team <sup>1</sup>Department II of Internal Medicine and Center for Molecular Medicine Cologne, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany; <sup>2</sup>Department of Nephrology, Klinikum rechts der Isar, Faculty of Medicine, Technical University Munich, Munich, Germany; <sup>3</sup>Medical Clinic III - Nephrology and Dialysis, St. Vincenz Hospital Paderborn, Paderborn, Germany; <sup>4</sup>Department of Medicine I - Nephrology, Transplantation & Medical Intensive Care, University Witten/Herdecke, Medical Center Cologne-Merheim, Cologne, Germany; <sup>5</sup>Department of Nephrology, University Hospital Essen, University Duisburg-Essen, Essen, Germany; <sup>6</sup>Department of General, Visceral, Cancer and Transplant Surgery, Faculty of Medicine, University Hospital Cologne, University of Cologne, Cologne, Germany; <sup>7</sup>Institute of Virology, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne, Germany; <sup>8</sup>Institute for Clinical Transfusion Medicine, Transplant Center Cologne, Merheim Medical Center, Cologne General Hospital, Cologne, Germany.

**Background:** VIRENO is an interdisciplinary, multicenter study aiming at identifying immunological parameters that predict major infectious and immunological adverse events after kidney transplantation (KTX).

**Methods:** Viro-immunological monitoring of the cohort was performed pre-KTX, 3 weeks and 6 months post-KTX. To address humoral immunity, anti-polyomavirus BK (BKPyV) and anti-cytomegalovirus (CMV) IgG were assessed in living donor and recipients. Cellular immunity to CMV was investigated by QuantiFERON-CMV (Qiagen) and T-SPOT®CMV by Oxford Immunotec. In addition, Torque Teno Virus (TTV) viremia was surveyed in all recipients. Clinical parameters were recorded for 12 months after transplantation focusing on infection- and rejection-related endpoints. As part of a first ad hoc evaluation, forward selection (Wald) binary logistic regression was used to determine the variables most suitable for predicting major events after transplantation.

**Results:** In total, 196 patients were followed up for one year after transplantation. Concerning the two primary endpoints, there were 113 infectious events (CMV n= 52, EBV n= 17, BKPvV n= 40, infection with hospitalization n= 59) and 34 immunological events (rejection n= 30, de novo DSA n= 8). A binary logistic regression model was suitable for predicting infectious complications with high sensitivity (87,1%) but low specificity (50,8%). Concerning prediction of immunological events after transplantation, a binary logistic regression model revealed a high sensitivity (91,7 %) and specificity (93,5%)(Table 1).

**Conclusions:** First results indicate that viro-immunological monitoring is a promising tool to predict infectious and immunological complications after kidney transplantation.

Binary logistic regression models for immunological and infectious events in the first year after kidney Transplantation (KTx)

	Accuracy (%)	Sensitivity (%)	Specificity (%)	clinical parameters included	baseline viro-immunological monitoring included	3 weeks post Tx viro-immunological monitoring included
Infectious events	71,9	86,9	49,1	Age <sup>1</sup> , Donor Sex <sup>2</sup> , preoperative Donor <sup>3</sup> , non immunological kidney disease <sup>4</sup> , deceased kidney donation.	TTV (plasma), TTV per MHOCells, Baseline <sup>5</sup> , BKPyV IgG.	TTV (plasma and blood), TTV (urine), BKPyV IgG.
Immunological events	93,1	91,7	93,5	genetic kidney disease	ELISPOT IE1 <sup>6</sup> , Donor BKPvV IgG.	ELISPOT positive-control, CMV Quantiferon-PPMC <sup>7</sup> , ELISPOT IE1 <sup>8</sup> .

### A Randomized Phase 2 Study of MAU868 vs. Placebo to Treat BK Viremia in Kidney Transplant Recipients

Stanley C. Jordan,<sup>1</sup> Ajit Limaye,<sup>2</sup> Bernard V. Fischbach,<sup>3</sup> Puneet Sood,<sup>4</sup> Suzon Collette,<sup>5</sup> Leanne Gasink,<sup>6</sup> Amy Patlick,<sup>7</sup> Marshall W. Fordyce,<sup>9</sup> Celia J. Lin,<sup>9</sup> Daniel C. Brennan,<sup>8</sup> <sup>1</sup>Cedars-Sinai Medical Center, Los Angeles, CA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Dallas Nephrology Associates, Dallas, TX; <sup>4</sup>UPMC, Pittsburgh, PA; <sup>5</sup>Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; <sup>6</sup>LBG Consulting, San Diego, CA; <sup>7</sup>Amplix Pharmaceuticals Inc, San Diego, CA; <sup>8</sup>Johns Hopkins University, Baltimore, MD; <sup>9</sup>Vera Therapeutics, Brisbane, CA.

**Background:** Reactivation of BK virus (BKV) infection can cause significant kidney disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein with potent *in vitro* neutralizing activity against the 4 major BKV genotypes.

**Methods:** This is a Phase 2, randomized, placebo-controlled, double-blind study in patients (pts) who received a kidney transplant within one year. Pts had BK viremia; either  $\geq 10^4$  copies/ml within 10 days of randomization or  $\geq 10^3$  copies/ml in 2 consecutive samples 1-3 wks apart with most recent value measured within 10 days of randomization. Pts were randomized (2:1) to MAU868 or placebo intravenously (IV) every 28 days for 12 wks, with 24 wks follow-up. This analysis reports efficacy results at 16 and 36 wks for 2 cohorts: Cohort 1: MAU868 1350 mg IV X4 doses, and Cohort 2: MAU868 6750 mg IV followed by 1350 mg IV X3 doses. The primary endpoint was safety; BKV viral load (VL) response to treatment was assessed as secondary endpoints and post-hoc analyses.

**Results:** 20 pts received MAU868 and 8 pts received placebo; all completed 12 wks of treatment and 24 wks of follow-up. Baseline characteristics were comparable between groups. Median baseline VL was 16,700 log<sub>10</sub> BKV DNA copies/ml (range 1,200-1,800,000). MAU868 was well tolerated, with a comparable frequency of adverse events and serious adverse events between groups through wk 36. There were 2 deaths in the MAU868 group due to COVID-19 infection deemed unrelated to study drug. The antiviral effect was greater in the MAU868 group than in the placebo group at wk 16 and sustained through wk 36 (Table).

**Conclusions:** MAU868 was well tolerated and demonstrated clinically meaningful BK antiviral activity in kidney transplant recipients with BK viremia. These results support the further development of MAU868 as a therapy for BK viremia.

**Funding:** Commercial Support - Amplix Pharmaceuticals/Vera Therapeutics

	Week 16		Week 36	
	MAU868 (N=20)	Placebo (N=8)	MAU868 (N=20)	Placebo (N=8)
Patients VL decreased by $\geq 1$ log <sub>10</sub> BKV DNA copies/ml vs baseline	8 (40%)	1 (12%)	15 (75%)	4 (50%)
Patients with VL < lower limit of detection (LOD)	3 (15%)	0	6 (30%)	0
Patients with VL $\leq 10^4$ log <sub>10</sub> BKV DNA copies/ml	13 (65%)	3 (38%)	15 (75%)	5 (63%)
BKV VL reduction - median log <sub>10</sub> BKV DNA copies/ml [interquartile range (IQR)]	-0.97 (-2.6, 0.8)	-0.38 (-2.3, 0.5)	-1.31 (-3.3, 0.6)	-0.85 (-2.3, 1.3)

## SA-OR44

### Spatial mRNA Analysis of Human Allograft Endothelium Shows Distinct Structure-Specific Endothelial Transcripts in Chronic Antibody-Mediated Rejection

Ira Doressa Anne L. How,<sup>1</sup> Kristen Tomaszewski,<sup>2</sup> Andrea Rios,<sup>1</sup> Samantha M. Morales,<sup>1</sup> Prajan Divakar,<sup>3</sup> Rex N. Smith,<sup>1</sup> Robert B. Colvin,<sup>1</sup> Ivy A. Rosales,<sup>1</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Cleveland Clinic, Cleveland, OH; <sup>3</sup>NanoString Technologies Inc, Seattle, WA.

**Background:** Bulk tissue mRNA analysis has shown the importance of endothelium-associated transcripts, but structure-specific transcript differences remain unexplored. We used the NanoString GeoMx Digital Spatial Profiler (DSP) to spatially analyze transcripts in glomerular (Ge) and peritubular capillary (PTC) endothelium in human renal allografts with and without T cell-mediated (TCMR) and chronic antibody-mediated (CAMR) rejection.

**Methods:** Five micron-thick formalin-fixed paraffin-embedded (FFPE) sections from 12 CAMR, 13 TCMR, 15 no rejection (NER), and 9 native (control) biopsies were hybridized with an 84-gene Immune Pathways and 10-gene custom panel attached to photocleavable oligonucleotide tags, and incubated with fluorophore-labeled antibodies (DNA, CD10, CD45, CD31). Using GeoMx DSP, Ge and PTCe areas of interest (AOIs, n=210) were segmented by CD31 expression. Oligonucleotide tags from AOIs were quantified using the NanoString nCounter MAX instrument. Data analysis was done using GeoMx DSP software.

**Results:** In controls, *VEGFA*, *KDR* and *EHD3* are enriched in Ge while *PLVAP* is enriched in PTCe. Ge in CAMR with transplant glomerulopathy (TG) shows enrichment of *CD59* (p=0.00005), *PECAM1* (p=0.0005), *COL4A1* (p=0.007), *CD74* (p=0.006), *HLA-DQ* (p=0.02), *CCND1* (p=0.005) and *CXCL9* (p=0.03), while *LAG3* (p=0.00005), *EHD3* (p=0.003) and *VEGFA* (p=0.02) are decreased when compared to TCMR (Figure 1), indicating loss of *VEGFA*, endothelial dedifferentiation, and GBM remodelling with ectopic *COL4A1*. PTCe in CAMR showed IFNG-associated PTCe injury with increased *IFNGR1* (p=0.001), *PRF1* (p=0.005), *ICAM1* (p=0.04), *CD59* (p=0.02) and decreased *PLVAP* (p=0.001). *STAT1* (p=0.05) and *ITGB2* (p=0.005) are enriched in TCMR PTCe.

**Conclusions:** Spatial mRNA analysis identified distinct endothelial transcript expression that are potentially relevant to pathogenesis and therapeutic targets.

**Funding:** Other NIH Support - NIH training grant (5T32AI007529) for Dr. Tomaszewski

## SA-OR45

### Acute Tubular Injury and Necrosis Do Not Lead to Meaningful Elevations in Donor-Derived Cell-Free DNA (dd-cfDNA)

Sridhar Reddy Allam,<sup>1</sup> Alexander C. Wiseman,<sup>2</sup> Matthew Cooper,<sup>3</sup> Dhiren Kumar,<sup>4</sup> Nikhil Agrawal,<sup>5</sup> Thin Thin Maw,<sup>6</sup> <sup>1</sup>Medical City Fort Worth, Fort Worth, TX; <sup>2</sup>Centura Health, Englewood, CO; <sup>3</sup>MedStar Georgetown University Hospital, Washington, DC; <sup>4</sup>Virginia Commonwealth University, Richmond, VA; <sup>5</sup>CareDx Inc, Brisbane, CA; <sup>6</sup>University of Southern California, Los Angeles, CA.

**Background:** Associations between non-rejection histologic diagnoses and dd-cfDNA have not been extensively characterized. We explored these associations in kidney transplant recipients in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** For-cause and surveillance biopsies with no rejection or other abnormalities (NR) or acute tubular injury/necrosis (ATI/ATN), and paired dd-cfDNA were included. The incidence of a composite outcome (eGFR decline > 25%, rejection, and de novo DSA detection) at 12 months after biopsy was also assessed.

**Results:** 166 biopsies (141 patients) with NR and 70 biopsies (64 patients) with ATI/ATN were included; compared to patients with ATI/ATN, patients with NR had lower KDPI (49% vs 64%, p<0.05) and shorter cold ischemia time (13 vs 18 hours, p<0.01). ATI/ATN biopsies were more likely to be for-cause (91.4% vs 59.6%, p<0.001), earlier post-transplant (83.0 vs 116.5 days, p<0.001), and occur at lower eGFRs (43 vs 32 mL/min, p<0.001) [Table 1]. There was no significant difference in median dd-cfDNA between NR (0.23%, IQR: 0.11 - 0.53) and ATI/ATN (0.21%, IQR: 0.13 - 0.55) biopsies (p = 0.993). When patients were stratified by dd-cfDNA at the time of their first biopsy (< 0.5% vs  $\geq$  0.5%), there was a non-significant trend towards a higher incidence of the 12-month clinical composite among those with dd-cfDNA  $\geq$  0.5% (27.5% vs 12.9%, p=0.53), with eGFR decline being most common (78.5% of events).

**Conclusions:** Our findings suggest that acute tubular injury/necrosis is not associated with substantial elevations in dd-cfDNA. The use of dd-cfDNA to identify patients with non-actionable histologic findings may allow more nuanced clinical decision-making and reduce the number of unnecessary biopsies.

**Validation of a Urinary Exosome mRNA Signature for the Diagnosis of Human Kidney Transplant Rejection**  
Rania El Fekih,<sup>1</sup> Brian C. Haynes,<sup>2</sup> Areej saud alghamdi,<sup>2</sup> John Y. Choi,<sup>1</sup> James Hurley,<sup>4</sup> Helmut G. Rennke,<sup>1</sup> Astrid Weins,<sup>1</sup> Christa A. Deban,<sup>1</sup> Anis J. Saad,<sup>1</sup> Ahmad Halawi,<sup>1</sup> Nour K. Younis,<sup>1</sup> Zhabiz Solhjoui,<sup>1</sup> Camila Macedo,<sup>3</sup> Johan Skog,<sup>4</sup> Jamil R. Azzi.<sup>1</sup> Transplant Research Center, Brigham and Women's Hospital <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Boston Children's Hospital, Boston, MA; <sup>3</sup>UPMC, Pittsburgh, PA; <sup>4</sup>Exosome Diagnostics, Waltham, MA; <sup>5</sup>Bio-Techne, Austin, TX.

**Background:** Traditional biomarkers currently used to monitor kidney allograft rejection are late markers of injury, and lack sensitivity and specificity. Biopsies are invasive and costly. Urinary exosomes are nanoscale extracellular vesicles. They are released from kidney cells, and contain a payload of proteins and nucleic acids that reflect the physiology of the parent cells. Their potential to serve as a liquid biopsy and biomarker for post-transplant rejection has recently been investigated.

**Methods:** We collected 411 urine samples from 366 patients undergoing for cause or management transplant kidney biopsy. Using a clinically validated platform for exosome isolation and analysis, a transcript of 17 gene targets, previously determined by us to be associated with kidney rejection, were pre-amplified and evaluated by RT-qPCR. Machine learning was applied to the training cohort data to determine an optimal algorithm for detecting kidney rejection.

**Results:** The prevalence of any-cause rejection among the for-cause and the management biopsy group were 36.3% and 22.2%, respectively. In the for-cause biopsy group, we identified a linear SVM classifier of 3 mRNA features (*IL32*, *B2M*, and *CXCL11*) that distinguishes any-cause rejection from no rejection, achieving an AUC of 0.731, with a sensitivity and an NPV of 93%. This shows the potential to save 43% of unnecessary biopsies. In the management-biopsy group, we identified a classifier that distinguishes any-cause rejection from no rejection, achieving an AUC of 0.781, with a sensitivity of 93% and an NPV of 97%. We are further evaluating the role of significant underlying inflammation determined by biopsy, such as moderate to significant lymphocytic infiltration, interstitial nephritis (BKV nephritis or AIN), glomerulopathy or immune complex deposition, in the classification of samples that are rejection negative by biopsy.

**Conclusions:** mRNA signatures derived from urinary exosomes represent a powerful and non-invasive tool to assess kidney allograft rejection, detect early renal allograft rejection and support clinicians in therapeutic decisions. This signature holds strong potential for diagnostic use, to be further demonstrated in a prospective clinical setting.

SA-OR47

**Five-Year Follow-Up of a Phase 1 Trial of Donor-Derived Modified Immune Cell Infusion in Kidney Transplantation**  
Matthias Schaefer,<sup>1</sup> Christian Morath,<sup>1</sup> Lei Wang,<sup>1</sup> Christian Kleist,<sup>1</sup> Gerhard Opelz,<sup>1</sup> Thuong H. Tran,<sup>1</sup> Sabine Scherer,<sup>1</sup> Caner Süsal,<sup>1</sup> Eman H. Ibrahim,<sup>1</sup> Mostafa G. Aly,<sup>1</sup> Cristian M. Alvarez,<sup>1</sup> Angela Hückelhoven-Krauss,<sup>1</sup> David Czock,<sup>1</sup> Arianeb Mehrabi,<sup>1</sup> Constantin Schwab,<sup>1</sup> Ruediger Waldherr,<sup>1</sup> Paul Schnitzler,<sup>1</sup> Uta Merle,<sup>1</sup> Georg Bohmig,<sup>2</sup> Jochen Reiser,<sup>3</sup> Martin G. Zeier,<sup>1</sup> Michael Schmitt,<sup>1</sup> Peter Terness,<sup>1</sup> Anita Schmitt,<sup>1</sup> Volker Daniel.<sup>1</sup> TOL-1 Study group at Nierenzentrum Heidelberg <sup>1</sup>Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; <sup>2</sup>Medizinische Universität Wien Universitätsklinik für Innere Medizin III, Wien, Austria; <sup>3</sup>Rush University Rush Medical College, Chicago, IL.

**Background:** The administration of modified immune cells (MIC) prior to kidney transplantation led to specific immunosuppression against the allogeneic donor and a significant increase in regulatory B lymphocytes (Breg) (Morath et al., J Clin Invest 2020). We now wanted to investigate how this approach affects the clinical course of treated patients.

**Methods:** Clinical results of ten patients from a phase I clinical trial who had received MIC infusions before kidney transplantation were compared to results of 15 matched standard-risk recipients. Follow-up was until year five after surgery.

**Results:** The 10 MIC patients had an excellent clinical course with stable kidney graft function and showed no donor-specific human leukocyte antigen antibodies (DSA) or acute rejections during follow-up. In contrast, 1 of 15 controls died and 5 of 15 controls developed DSA (log rank  $P = 0.046$ ) (Figure 1 A, B). While the number of patients with a non-opportunistic infection did not differ significantly between groups ( $P = 0.36$ ), opportunistic infections were reported more frequently in controls (log rank  $P = 0.033$ ) (Figure 1 C). Compared to controls, MIC patients were found to have a trend towards a higher COVID-19 anti-S1 IgG index after vaccination with a median of 53 vs. 2 ( $P = 0.16$ ). Importantly, the four MIC patients who had received the highest MIC cell dose 7 days before surgery and were on low immunosuppression during follow-up, continued to show absent anti-donor T lymphocyte reactivity in vitro and high CD19<sup>+</sup>CD24<sup>hi</sup>CD38<sup>hi</sup> transitional Breg as well as CD19<sup>+</sup>CD24<sup>hi</sup>CD27<sup>+</sup> memory Breg.

**Conclusions:** MIC infusions together with reduced conventional immunosuppression were associated with lower de novo DSA development and lower rates of opportunistic infections. In the future, MIC infusions could contribute to graft protection while reducing the side effects of immunosuppressive therapy.

SA-OR48

**A Regimen of Nonmyeloablative Conditioning and CD8+/TCR- Facilitating Cells Tips the Balance Towards Immune Downregulation and Away From Cytopathic Activity in Kidney Allograft Recipients**  
John R. Lee,<sup>1</sup> Joseph Leventhal,<sup>2</sup> Carol Y. Li,<sup>1</sup> Suzanne Ildstad,<sup>3</sup> Manikkam Suthanthiran.<sup>1</sup> <sup>1</sup>Weill Cornell Medicine, New York, NY; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>Talaris Therapeutics, Inc., Louisville, KY.

**Background:** We tested the hypothesis that tolerance induced with a regimen of nonmyeloablative conditioning and CD8+/TCR- facilitating cells (FCR001) is associated with immune down regulation and away from cytopathic activity.

**Methods:** Blinded to clinical status and biopsy diagnosis, the Laboratory quantified urinary cell mRNA levels in 28 urines from 14 FCR001-tolerant patients with durable chimerism and off immunosuppression per protocol(FCR DC off IS); 23 urines from 12 FCR001-tolerant patients with DC and on immunosuppression per protocol(FCR DC on IS); 43 biopsy-matched urines from 34 kidney allograft recipients from the Clinical Trials in Organ Transplantation-04(CTOT-04) study and TCMR biopsies (TCMR Cohort); and 161 biopsy-matched urines from 124 recipients from CTOT-04 study with No Rejection biopsies (NR Cohort).

**Results:** In accord with negative immune regulation in tolerant patients, urinary cell mRNA levels of CTLA-4 were significantly higher in the FCR DC off or on IS than the TCMR cohort or the NR Cohort ( $P < 0.05$ , Wilcoxon rank sum test, Table 1). In accord with lack of cytopathic activity in tolerant patients, levels of Granzyme B and Perforin were significantly lower or no different in the FCR DC off or on IS compared to the NR cohort (Table 1). Levels of additional mRNAs in the FCR DC on or off IS were significantly lower than the TCMR Cohort and mostly similar to that in the NR Cohort (Table 1).

**Conclusions:** Tolerance induced with a nonmyeloablative conditioning regimen and CD8+/TCR- facilitating cells is characterized by tipping of the balance towards immune down regulation and away from cytopathic activity.

Clinical Performance Validation of Tuteva Biomarker

Oriol Bestard,<sup>1</sup> Joshua J. Augustine,<sup>2</sup> Lorenzo G. Gallon,<sup>3</sup> Mohammed Javed Ansari,<sup>4</sup> Gaetano La Manna,<sup>5</sup> Milagros R. Samaniego-Picota,<sup>6</sup> Roslyn B. Mannon.<sup>7</sup> <sup>1</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>2</sup>Cleveland Clinic, Cleveland, OH; <sup>3</sup>Northwestern University, Evanston, IL; <sup>4</sup>Northwestern Memorial HealthCare Corp, Chicago, IL; <sup>5</sup>Universita degli Studi di Bologna, Bologna, Italy; <sup>6</sup>Henry Ford Health System, Detroit, MI; <sup>7</sup>University of Nebraska System, Lincoln, NE.

**Background:** Identification of kidney allograft rejection relies mainly on monitoring methods such as proteinuria and serum creatinine. These measures may lead to assessment by biopsy. Biomarkers which correlate to or predict the presence of acute rejection are needed to support clinical management in a sensitive and less invasive manner. As a priority, biomarkers require validation in a prospective study that is reflective of the complex transplant population and for which correlation to a gold reference standard is measured. Herein we report on the validation of the Tuteva test for predictive risk of the presence of clinical / sub-clinical acute rejection in a global clinical trial.

**Methods:** Tuteva is a blood-RNA expression next-generation sequencing assay which interrogates the gene expression profile (GEP) of kidney transplant recipients using a signature derived in an independent cohort of transplant patients. By applying machine learning algorithm (MLA) to a discrete gene set, the assay generates a risk score interpreted by an MLA derived cut-off to predict a patients' risk of the presence of acute rejection. The test is performed and analytically validated in a CLIA laboratory. All GEP Tuteva results were calculated in a blinded manner. The clinical study was conducted at 13 centers in the USA, Spain, Italy, France and Australia from which 151 unique kidney transplant participants were included. Each patient had blood collected at the time of surveillance or indication biopsy. All biopsies were evaluated by central pathology in blinded manner based on current BANFF criteria; borderline rejections were included in the analysis, and biopsy findings served as the outcome of ABMR, TCMR, or mixed as case definition. The event rate was 30%.

**Results:** Tuteva results were reported as a continuous risk score from 1-100 with a cutpoint at 50 for separating high from low risk. This cutpoint resulted in 26% of patients in high-risk group, of which 60% showed evidence of rejection on biopsy; of the 74% of patients in the low-risk group, 80% had negative biopsy for rejection. Seven biopsies were positive for BK; 6/7 (86%) were low risk in Tuteva.

**Conclusions:** Tuteva represents an advancement in biomarker transplant biology to better inform medical management of all kidney transplant patients in a more personalized and predictive manner.

**Funding:** Commercial Support - Verici Dx Inc

SA-OR50

Immune Cell Transcriptome in Living-Donor Kidney Transplant Patients Tolerized With Allogeneic Hematopoietic Stem Cell Transplantation Therapy

Jennifer M. McDaniels,<sup>1</sup> Amol C. Shetty,<sup>1</sup> Thomas Rousselle,<sup>1</sup> Joseph Leventhal,<sup>2</sup> Suzanne Ildstad,<sup>3</sup> Valeria R. Mas.<sup>1</sup> <sup>1</sup>University of Maryland Baltimore, Baltimore, MD; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>Talaris Therapeutics Inc, Louisville, KY.

**Background:** Long-term outcomes in living donor kidney transplant (LDKT) patients are suboptimal due to lifelong chronic immunosuppression complications. FREEDOM-1 is a randomized, controlled, open-label Phase 3 study of FCR001 in adult LDKT patients. The mechanisms underlying immune tolerance after HSCT are poorly understood. This study deciphered the immune landscape associated with tolerance at single cell resolution.

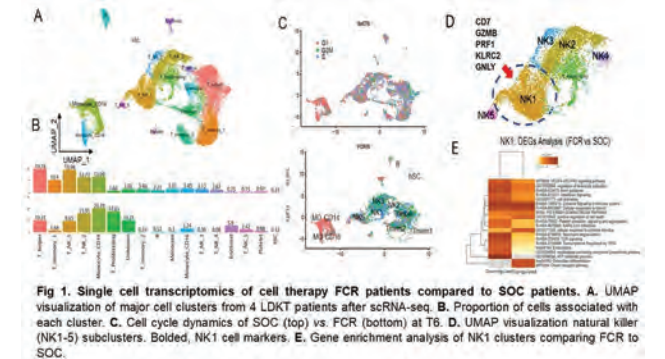

**Methods:** Peripheral blood mononuclear cells (PBMCs) from 4 LDKT patients (3 in the FCR001 group and 1 with standard of care (SOC) immunosuppression) were studied at 4 timepoints (T0-, T1-, T3-, and T6-month(s)). Cross-sectional and longitudinal evaluations were done. Analysis was done using CellRanger software and visualized with UMAP. DEGs (FDR $\leq$ 0.05) identified enriched GO terms and pathways.

**Results:** Unsupervised PBMCs clustering (>100,000 cells) identified 17 unique cell clusters, including monocytes, natural killer (NK) and T cell subclusters (Fig 1A). At T6, FCR was characterized by decreased NK1, T helper, and T memory cells, while CD14+

monocytes, NK2, and T proliferating cell clusters were increased compared to SOC. A mixed immune cluster was increased in FCR (Fig 1B) and characterized by PD-L1 checkpoint and T cell receptor signaling pathways. There was a higher proportion of cells in S phase from FCR, indicating early alterations in transcriptional activity (Fig 1C). High heterogeneity in NK clusters was observed; NK1 was reduced in FCR (Fig 1D). DEGs showed that NK1 cells were less transcriptionally active in FCR at T6 (Fig 1E).

**Conclusions:** This study represents the first longitudinal evaluation of PBMCs from LDKT patients underlying mechanisms of tolerance at single cell resolution. Unique patterns of immune cell types, cell states, and transcriptional activity were identified with NK cell subclusters playing a critical role.

**Funding:** Commercial Support - Talaris Therapeutics

TH-PO001

Quality Improvement in CKD Management in a Resident Primary Care Clinic

Nicole Wyatt, Phillip Madonia. Brookwood Baptist Health, Birmingham, AL.

**Background:** Primary care physicians (PCPs) are in a unique position to identify and manage CKD early in the disease process, preventing disease progression. Given the recent increased emphasis on providing resources and education for PCPs, we identified a need to implement an educational protocol to train internal medicine residents on the diagnosis and management of CKD in the primary care clinic. We present preliminary data evaluating the impact of this educational training.

**Methods:** A retrospective electronic medical record (EMR) search included all patients in the resident clinic diagnosed with CKD stage 3 from June 2019 to October 2021. Each chart was evaluated for urinary albumin creatinine (ACR), blood pressure and glycemic control, therapy with ACEi/ARB and SGLT2i, and referral status to nephrology. Then, an educational presentation and informational handout was given to the residents. A repeat EMR search was made 6 months post-education to re-evaluate the above parameters.

**Results:** Pre-intervention data showed 71 clinic patients diagnosed with CKD3. Blood pressure was controlled in 31% and glucose controlled in 66% with HbA1c ordered (n=59). ACR was ordered at least once in 50.7% and annually in 15.5%. Of those without contraindications (n=65), 84.6% had ACEi/ARB therapy. SGLT2i therapy had been initiated in 2.8%. Referrals to nephrology were made in 42.3%. Review performed 6 months post-intervention revealed 45 patients with CKD3, including those that returned or were newly diagnosed. Blood pressure was controlled in 48.9% and glucose controlled in 67.6% with HbA1c ordered (n=34). Annual ACR had been ordered in 60%, ACEi/ARB therapy was ordered in 78.9% without contraindications (n=38), and SGLT2is were prescribed to 20.9%. Referrals were made in 46.7%. One-year post-intervention data is still being collected.

**Conclusions:** Preliminary results at 6-months post educational training show a promising trend in improvement in the management of CKD stage 3 patients in the resident clinic population. Importantly, there has been an increase in annual ACR orders and SGLT2 inhibitor initiation. We expect this trend to continue with our 12-month interval data collection. Given the importance of PCPs in the identification and management of CKD patients, as well as an overall shift to value-based care, it is integral to improve graduate medical education on this topic.

TH-PO002

A CKD Awareness Campaign and mHealth Education to Improve Knowledge and Quality of Life Among CKD Patients in Bangladesh: A Randomized Controlled Trial

Mohammad H. Sarker. International Centre for Diarrhoeal Disease Research Bangladesh, Dhaka, Bangladesh.

**Background:** Chronic kidney disease (CKD) is linked to major health consequences and a poor quality of life. Despite the fact that CKD is becoming more prevalent, public knowledge of the disease remains low. We aimed to evaluate the outcome of a health education intervention designed to enhance knowledge, health-related quality of life (QOL), and healthy lifestyle among CKD adults.

**Methods:** This was a parallel-group (1:1) randomized controlled trial in Bangladesh that compared two groups of CKD patients. Adults individual with CKD (stages 1-3) were enrolled in November 2020 and randomly assigned to intervention or control group. The intervention group received health education through a CKD awareness campaign and

mHealth technologies, whereas the control group received usual care, and was observed for six months. Primary Outcome was improved scores on the CKD knowledge questionnaire and secondary outcomes were improved QOL and changes in the level of blood pressure (BP), BMI, fasting blood sugar (FBS), cholesterol, triglyceride and serum uric acid.

**Results:** We enrolled 126 patients (control, n=63, intervention, n=63) in the study and performed intention to treat analysis. The analyses included repeated measures ANOVA and results were observed to be significantly different in case of within-group ( $P<.001$ ), between groups ( $P<.001$ ) and interaction of group  $\times$  time factor ( $P<.001$ ) in terms of knowledge score. Diastolic BP and BMI showed significant differences arising from within groups ( $P<.001$ ,  $P=.01$  respectively) and in interaction of group  $\times$  time factor ( $P=.001$ ,  $P=.02$  respectively); hip circumferences showed significant difference arising from within groups ( $P=.03$  respectively) and between groups ( $P=.02$ ). Moreover, systolic BP and waist circumference showed significant differences within groups ( $P<.001$ ,  $P=.003$  respectively). Regarding laboratory findings, from baseline to six months, the mean ( $\pm$ SD) FBS decreased by  $0.51 \pm 3.77$  mg/dl in the intervention group and by  $0.10 \pm 1.44$  g/dl in the control group ( $P=.03$ ).

**Conclusions:** The health education strategy, which included a campaign and mHealth, showed promise for enhancing CKD knowledge and controlling their FBS and BP among CKD patients. The combined health education initiatives give evidence for scaling them up in Bangladesh and possibly other low- and middle-income countries.

**Funding:** Other NIH Support - Grants-in-Aid for Scientific Research Program (KAKENHI)

## TH-PO003

### Advancing Treatments for CKD: Trends and Opportunities

Andrew M. Bevan,<sup>1</sup> Davide Garrisi,<sup>2</sup> Carmichael Angeles,<sup>2</sup> <sup>1</sup>Evidera, a business of PPD, part of Thermo Fisher Scientific, London, United Kingdom; <sup>2</sup>PPD, part of Thermo Fisher Scientific, Morrisville, NC.

**Background:** Several factors, including high unmet need, ongoing evolution of endpoints and faster approval tracks make nephrology an interesting development opportunity, which has contributed to a renewed interest in clinical development. We undertook an analysis of metadata from Clinicaltrials.gov (CT.gov) to characterize trends over the last 20 years and what this may tell us about the future trajectory for treatment development.

**Methods:** CT.gov was searched for studies of drugs or biologicals containing the terms "Chronic Renal Failure", "Chronic Renal Disease", "Chronic Kidney Disease" or "Chronic Renal Insufficiency" posted from 01-Jan-2002 and 31-Dec-2021. 1038 records were returned and 194 were excluded due to the study intervention being either behavioral, procedural, diagnostic, dietary supplement or "other". 844 studies in the analysis were divided into 2 time periods: P1 - 2002 to 2011, and P2 - 2012 to 2021, and analyzed by study phase, population type, type of intervention and funding.

**Results:** There was a 54% increase studies in P2 vs P1 with the most marked increase in early phase studies, which increased by 132%. Most studies were in adults (P1 88%, P2 91%). The number of industry funded studies increased by 32% in P2 vs P1; however, the increase was a more marked in non-industry funded studies, which doubled. In terms of intervention type, there was a 19-fold increase in the number of studies investigating biological interventions in P2 (39) vs P1 (2). Hemoglobin (Hb) was the most frequently assessed primary endpoint in industry sponsored studies, increasing by 55% in P2 vs P1.

**Conclusions:** Our data provides evidence of increased clinical research activity in CKD in the last 10 years and more focus on biologicals that are best designed to precisely target complex biological pathways in disease pathophysiology. Targeted therapies have the potential to transform the treatment of CKD in children, where the level of unmet medical need is high. However, our results did not reveal an increase in research activity in pediatrics. The marked growth in studies investigating the effect of therapies on Hb reflects the surge in interest in the study of CKD-anemia. The marked rise in non-industry funded studies may indicate a growth in basic science that may translate into further increases in industry sponsored research in the future.

**Funding:** Commercial Support - PPD, Part of ThermoFisher Scientific

## TH-PO004

### Online Patient Education on Polycystic Kidney Disease Prompts Real Life Changes

Amy Larkin, Steven Smith. Medscape LLC, New York, NY.

**Background:** We sought to measure the impact of online education for patients on knowledge and confidence as well as on prompting change in daily life.

**Methods:** The educational activity was available online, and comprised of text and integrated visuals as well as a patient video. Demographic questions were asked prior to starting the education. A knowledge question was asked both before and after the activity to assess learning gains, as well as intent to change and confidence questions at the end. Absolute improvements were calculated for pre/post questions. The activity launched December 8, 2021, and preliminary data collected through April 26, 2022.

**Results:** To date, 19,600 learners have participated in the patient/caregiver activity, "Polycystic Kidney Disease: What Do You Need to Know?" Completers of all questions (included in outcomes analysis): 4,765 Demographics: 70% female; 67% white, non-Hispanic; 63% over the age of 54; 19% have polycystic kidney disease, 13% are caregivers or family of someone with polycystic kidney disease, 69% were interested in learning more about polycystic kidney disease Knowledge Changes: 12% increase in learners who recognized that sticking to your PKD treatment is important even if you're feeling ok (55% pre, 67% post) Intent-to-act: 74% plan to talk to their HCP about ways to manage their PKD Confidence: 78% reported being confident in talking to my doctor or healthcare provider about PKD and what it means for me

**Conclusions:** The metrics and outcomes gathered in this assessment are a strong indicator that these patient-focused online educational activities improved knowledge and confidence and prompted intent to act by patients related to polycystic kidney disease.

## TH-PO005

### Nephrologists as Internal Medicine Residency Program Directors: Trends From a National Survey

Patricia F. Kao,<sup>1</sup> Michael Kisieleski,<sup>2</sup> <sup>1</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>2</sup>Alliance for Academic Internal Medicine, Alexandria, VA.

**Background:** Internal medicine (IM) resident interest in nephrology careers peaked in 2008, declined in subsequent years, and has remained low over the last decade. Studies cite a lack of nephrology role models and lack of exposure to nephrology as contributing factors (Beck, 2020). IM program directors (PDs) are important stakeholders and role models who influence nephrology exposure and education during residency training. The number of nephrologists in IM residency leadership roles is currently unknown. The objective of this study was to quantify the number of IM residency PDs who are nephrologists, and to explore historical trends.

**Methods:** The Association of Program Directors in Internal Medicine (APDIM) Annual Survey queries IM PDs from ACGME-accredited ("Continued" or "Initial" status) about their sub-specialty training. The 2021 Annual Survey included PDs from 439 APDIM member programs, representing 80.4% of the 546 accredited U.S./U.S. territory-based IM training programs. To assess historical trends, we performed a multivariate regression and a multivariate test of means with survey data collected using a similar methodology from 2008 to 2021.

**Results:** Of the 267/439 (61.0%) PDs who completed the 2021 Annual Survey, only 10/267 (3.7%) reported specializing in nephrology. From 2008 to 2021, the modal percentage of IM PDs who reported being nephrologists occurred in 2008 (6.0%; 16/268), reaching a nadir in 2020 (1.5%; 4/260). The reported percentage of IM PDs who are nephrologists decreased from 2008 to 2021 ( $p<0.01$ ). (Figure 1)

**Conclusions:** The percentage of IM residency PDs who are nephrologists is low and has declined over the past 14 years. This may represent a missed opportunity for nephrologists to serve as role models to medicine residents and to advocate for more exposure to nephrology during residency training. Attracting more trainees to the field of nephrology may require encouraging more nephrologists to pursue key stakeholder leadership roles in residency education.

Percentage of IM Residency Program Directors Who Are Nephrologists: 2008 to 2021

## TH-PO006

### Impact of a Simulation Dialysis Access Ultrasound Tutorial for Nephrology Fellows

Alexander S. Hawkins,<sup>1</sup> Sarah F. Sanghavi,<sup>1</sup> Ryan Wong,<sup>1,2</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>Banner University Medical Center South, Tucson, AZ.

**Background:** Bedside ultrasound imaging has grown in importance across a variety of specialties, but few Nephrology programs have any formal ultrasound teaching. We developed a tutorial for dialysis access ultrasound assessment using a simulation model, and evaluated the tutorial with a knowledge assessment and a survey on clinical ultrasound use.

**Methods:** We randomly assigned three first year Nephrology fellows to receive a hands-on ultrasound tutorial along with a didactic lecture about dialysis access, with two fellows receiving the didactic only. The tutorial presented several cases with simulation fistulas which could be physically examined with a mock ultrasound probe. Participants were prompted to measure a variety of parameters in evaluating the fistula and calculate blood flow. Cases included outflow stenosis, evaluation of fistula maturity, and pseudoaneurysm. The tutorial was led by a second year fellow. Six months later we sent a knowledge assessment (validated by several Nephrology faculty members), and a survey, which included qualitative measures of each fellow's practical experience with ultrasound, and confidence with vascular access issues.

**Results:** The survey had a 100% response rate. Fellows who completed the tutorial scored an average of 6 of 7 points on the knowledge assessment, while those who did not scored an average of 3.5/7 points. The tutorial group rated their conceptual exposure to dialysis access ultrasound at 43.3/100 points (100 being highest exposure), compared with 29.5 points in the non-tutorial group. When asked about confidence in speaking with Radiology or Vascular Surgery about dialysis access issues on a 5-point scale, the tutorial

group had an average response of 3 (Neutral), versus 2 (Slightly less confident) in the other group. In both groups, clinical use of ultrasound for dialysis access issues was low, with lack of time on rounds and lack of experience with ultrasound being selected as the main barriers.

**Conclusions:** Our hands-on simulation improved knowledge and confidence in assessing dialysis access issues among first year Nephrology fellows when compared with a didactic lecture alone. Barriers to clinical use of ultrasound for dialysis access issues include lack of time and experience. Though limited by small sample size, these results encourage further study and formal implementation into the curriculum.

#### TH-PO007

### Conducting an Ultrasound Guided Kidney Biopsy Workshop in Leon, Nicaragua

Sreedhar A. Mandayam,<sup>1</sup> Biruh Workeneh,<sup>1</sup> Alexei V. Mikhailov,<sup>2</sup> Michael H. Carstens,<sup>2</sup> <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Wake Forest Baptist Medical Center, Winston-Salem, NC.

**Background:** Investigations into the etiology of CKDu are hampered by very limited renal pathology specimens from patients due to multiple constraints like lack of training of nephrologists in bedside ultrasound guided renal biopsy, lack of renal pathologists. We describe our experience on conducting an Ultrasound Guided Renal Biopsy Workshop at the Hospital Escuela Oscar Danilo Rosales Argüello, Leon, Nicaragua

**Methods:** Nephrologists at Hospital Escuela Oscar Danilo Rosales Argüello, Leon and Hospital Espana Chinandega, participated. Patients provided informed consent. Local and Ministry of Health, Nicaragua (MINSa) IRB approval was obtained. 2 nephrologists from MD Anderson Cancer Center with experience performing ultrasound guided renal biopsies conducted the workshop. Phillips Lumify Ultrasound Transducers, Samsung S 6 tablets used scanning and CIVICO brackets used to act as needle guides. Scout scan to ensure 2 kidneys of normal size, lower pole of the kidney identified, depth of cortex measured, CIVICO bracket-needle guide system used to direct the angle of needle placement and depth of needle

**Results:** All biopsies were conducted in the operating room at the hospital. Conscious sedation provided in addition to local anesthesia. CBC and BMP measured 24 hours prior to biopsy. 18 kidney biopsies were performed over 2 days. Initial 2 biopsies performed by faculty and the remaining 16 biopsies by the local doctors with the guidance from the faculty. 3 subjects were not biopsied (kidney size less than 8 cm and 1 uncontrolled HTN). 3 cores were obtained on all the 18 subjects. All cores deemed adequate by bedside cytopathologist. Post biopsy ultrasound scans performed on all 18 subjects showed no significant post biopsy bleeding. All patients had labs drawn at 24 hours and evaluation by nephrologist as safety follow up. None of the 18 subjects had clinically significant bleeding and no complications were noted at 24 hours post biopsy. All attendees affirmed a significant increase in comfort level about performing ultrasound guided renal biopsies and multiple renal biopsies have been performed independently subsequently

**Conclusions:** Ultrasound guided percutaneous renal biopsy can be performed safely in resource limited settings in Leon Nicaragua and the training workshop has significantly increased the ability of local nephrologists to perform renal biopsies

#### TH-PO008

### Impact of Structured Kidney Transplant Patient Education Program on Kidney Transplant Referrals and Pre-Transplant Work-up Within the Northern California Veterans Affairs Health Care System

Michael Joshua G. Morales, Monique L. Parker, Melissa Marston, Inderpreet S. Sekhon, Pratik B. Shah. VA Northern California Health Care System, Mather, CA.

**Background:** Kidney transplantation (KT) is the treatment of choice in patients with end-stage renal disease (ESRD). VA medical centers completing kidney transplant education and pre-transplant work-up submits referral using a standardized electronic process (TRACER) to one of the nine VA kidney transplant centers in the US. The VA Northern California Health Care System (VANCHCS) has been offering KT referral to ESRD patients from its two sites (Sacramento Valley and East Bay). Patient education and timely completion of pre-transplant work-up were noted as barriers in timely referral to KT and potential dropouts in the evaluation process.

**Methods:** Structured KT patient education program was started in VANCHCS in 2020 to address barriers in the pre-transplant work-up. The program involved creation of education clinic, KT education written material and videos, patient engagement, and tracking of pre-transplant work-up and addressing delays in real time. The program was run by nephrology RN at the two sites.

**Results:** *Kidney Transplant Referrals* The annual KT referrals were tallied between the two sites from 2019 to 2021. In 2021, the Sacramento Valley referral numbers are 21 which is a 320% increase compared to 2019 and 133.33% increase compared to 2020. The East Bay's 2021 referrals totaled to 9 which is 125% increase compared to 2019 and 200% increase compared to 2020. *Pre-transplant work-up time* The Sacramento Valley median pre-transplant work-up completion time decreased from 228 to 108. The East Bay median pre-transplant work-up completion time decreased from 248 days to 116 days.

**Conclusions:** Structured kidney transplant education program and tracking resulted in improvement in kidney transplant referral within Northern California VA Health Care System.

Figure 1: Kidney Transplant Referrals

Figure 2: Median Days for completion of pre-transplant work-up

#### TH-PO009

### Qualitative Assessment of a 3-Dimensional (3D) Virtual Reality (VR) Educational Tool

Georges Nakhoul, Jonathan J. Taliercio, Bryce Montane, Susana Arrigain, Jesse D. Schold, Joseph V. Nally, Richard M. Wardrop, John F. O'Toole, S. beth Bierer, John R. Sedor, Ali Mehdi. Cleveland Clinic, Cleveland, OH.

**Background:** Leveraging technological advances in learning platforms has led to creative innovations in the development of interactive tools. Using funding from the ASN, we developed a 3D VR renal physiology course, on which we present a qualitative analysis.

**Methods:** Internal medicine PGY1 residents were randomly assigned into 2 groups: a VR group (exposed to the VR session) and a traditional group (received a printed script of the VR learning course). The VR session consisted of a 3D review of the mechanism of action of diuretics. Within a week of being exposed to the VR vs. traditional material, both groups underwent a 2-hour seminar on diuretics. The VR group was asked to rate their VR experience. Assessment of the VR platform was performed using a Redcap-based survey consisting of a 4-point Likert scale, and focused on the following parameters: interface, clarity, educational value, engagement, likability, and dissemination. Residents randomized to the VR group were also asked to participate in a focus group. Sessions were recorded and transcribed verbatim. Data was analyzed through the content analysis approach by 2 independent reviewers who met to compare coding and reach consensus on emerging themes.

**Results:** 42 residents assigned to VR session attended the seminar and completed the platform assessment. Overall, > 90% of the residents rated the platform positively in all parameters (Table 1A). Two focus groups met for one hour. Several recurring themes emerged in our analysis and were classified as presented in Table 1B. Follow the QR code to see a YouTube video of the 3D application.

**Conclusions:** The feedback of the VR course was overwhelmingly positive and was perceived to be a helpful educational adjunct. Educational institutions should consider supporting the development of interactive educational tools to enhance learner experience.

Survey question	N	Agree or Strongly Agree N (%)
The response time of the program is adequate	41	40(97.6)
I was absorbed in the activity of the simulation	42	42(100.0)
The delivered material was clear	42	40(95.2)
The Oculus Quest made it easy to understand the learning objectives	42	40(95.2)
The Oculus Quest is a useful learning aid	42	40(95.2)
Oculus Quest enhanced my understanding of nephrology concepts during this activity	42	40(95.2)
I found the Oculus Quest enjoyable to use while learning	42	41(97.6)
I preferred using the Oculus Quest to the standard teaching method	42	35(83.3)
I would like the Oculus Quest to be utilized for more topics in nephrology	42	41(97.6)
I would like the simulation to be applied for topics other than nephrology	42	40(95.2)

Table 1A. Survey evaluating the VR platform

POSITIVE THEMES	NEGATIVE THEMES
Recall: memory Anchor	Lack of immediate clinical relevance
Attention span: great hook	More interaction: somewhat passive experience despite interactive format
Interaction: engaging and powerful	Organization: integrate the VR and lesson
Spatiality: improves understanding of structures	Technical / logistical challenges: motion sickness, lag, teleportation feature
Enjoyable: cool / fun / graphically appealing	
Great supplemental resource	

Table 1B. Focus group themes. Note that the QR code will link you to a YouTube video displaying the content of the animation.

## Assessment of a 3-Dimensional (3D) Virtual Reality (VR) Educational Tool

Georges Nakhoul,<sup>1</sup> Ali Mehdi, Alejandro Duran Crane, Jesse D. Schold, Susana Arrigain, Richard M. Wardrop, Joseph V. Nally, S. Beth Bierer, John R. Sedor, John F. O'Toole, Jonathan J. Talierto, Cleveland Clinic, Cleveland, OH.

**Background:** Improving student engagement with information technology has led to the proliferation of innovative teaching tools. Using funding provided by the ASN, we developed a 3D VR kidney physiology course. Our goal was to objectively assess its efficacy as a teaching tool on knowledge gain.

**Methods:** Internal medicine PGY1 residents were randomly assigned into 2 groups: a VR group (exposed to the VR session) and a traditional group (received a printed script of the VR learning course). The VR session consisted of a 3D review of water and electrolyte transport and of the mechanism of action of diuretics. Within a week of being exposed to the VR vs. traditional material, both groups underwent a 2-hour seminar on diuretics. Knowledge acquisition and retention were assessed with a test administered immediately after the seminar and again within 6-12 weeks. The 40-question test was issued using the platform RedCap. Tests were anonymous and it was not possible to link results from both test administrations. We used t-tests to compare the number of correct answers and the percent correct between the VR and traditional groups. Initial and follow-up tests were evaluated separately.

**Results:** Of the 133 PGY1 residents scheduled and randomized to participate, 71 completed the courses and initial testing (41 VR group vs. 30 traditional group). 53.5% of participants were males. Average age was 27.2±2.0. Results of the initial test showed higher scores among VR vs. traditional group (77.6% correct vs. 70.7%, Table 1). 36 PGY1s participated in the follow-up testing (23 VR group vs. 13 traditional group). Results of the follow-up test showed no significant difference in test results (Table 1). Follow the QR code to see a video of our application.

**Conclusions:** The 3D VR platform is a useful supplemental educational tool with improved short-term resident learning. To understand the long-term impact on transfer of learning, a larger student cohort with longer-term follow-up is needed.

Table 1. Test results by group participation

	Overall (N=71)	VR (N=41)	Traditional (N=30)	t-test p-value
<b>Initial Test Score Results</b>				
Score out of 40 questions, Mean ± SD	29.9±4.9	31.0±4.1	28.3±5.6	0.018
Percent correct, Mean ± SD	74.7±12.4	77.6±10.3	70.7±13.9	0.018
<b>Follow up Test Score Results</b>				
Score out of 40 questions, Mean ± SD	26.1±4.7	26.0±4.9	26.2±4.4	0.95
Percent correct, Mean ± SD	65.2±11.7	65.1±12.3	65.4±11.0	0.95

Note: Follow the QR code to see a YouTube video of our 3D application.

## TH-PO011

## Utilizing Virtual Reality Tools in Dialysis Modality Education

Sijie Zheng,<sup>1</sup> Ritchie M. Nabong-Salem,<sup>1</sup> Neelam M. Bhalla,<sup>1</sup> Lierisa D. Villafior,<sup>1</sup> Thomas G. Eppenberger,<sup>2</sup> George Lai.<sup>1</sup> <sup>1</sup>The Permanente Medical Groups, Oakland, CA; <sup>2</sup>Kaiser Permanente, Oakland, CA.

**Background:** In US, only 12% of ESRD patients utilize PD as his/her RRT modality. Part of the reason is lack of effective education tool. Kaiser Permanente Northern California is an integrated health care system providing health care to 4.6 million members in greater San Francisco Bay area. We piloted a proof-of-concept study to test if utilizing virtual reality can improve patient dialysis modality education.

**Methods:** Nephrologists, PD nurses and technology-centered team from KPNC met regularly in 2019 to find out the gaps in dialysis modality educations. After several meetings and reviewing the current educational material, we decided to produce a 360 immersive video with 3 separate segments using a GoPro Camera. Google cardboard is used as the VR tool. We then tested on 9 patients during their patient education section.

**Results:** Three segments showing nursing home visit, patient performing PD at home and patient sleeping during PD were produced. They can be assessed on YouTube: <https://www.youtube.com/watch?v=BayBNoZbNbA>. We tested this VR tool for 9 patients. This number was limited due to in person trainings being curtailed during the COVID-19 pandemic. Most patients felt that the first-person nature of the video (without VR) helped because the content was so helpful. However, there were some challenges: some patient became confused due to too much movement needed, not able to focus. Overall, patients appreciated the content but felt the 360 VR was not needed. They hoped if the video could be steadied, they would have a better experience. Table one listed the demographics and feedbacks.

**Conclusions:** VR is a viable option for better patient education if it can be improved with better ease of use. Further studies with improved technology and larger numbers of patients are warranted to improve patient dialysis modality education.

## Feedback from Patients

Patient Number	Age	Gender	Comments
#1	55	Female	easy but does not serve the purpose; got irritated trying to find focus, make it more user friendly
#2	63	Male	Good content, will be better if steady video
#3	51	Male	Just okay, more on listening, content is good
#4	62	Male	too much movement needed, somewhat helped by listening. Got dizzy w/ movement
#5	58	Female	Confused, poor quality, regular video is sufficient
#6	46	Male	got lost when started to move, content is good, better to just watch steady
#7	60	Male	tried to engage, like the loudness of the conversation, cannot get the full effect, hard to focus
#8	72	Female	it is okay, no comment w/ the video
#9	63	Female	initially got dizzy, went well afterwards, requested steady video

## TH-PO012

## Case-Based Online Education Significantly Improved Nephrologists' Knowledge and Confidence in Managing CKD-aP

Elaine Bell,<sup>1</sup> Joy Marko,<sup>2</sup> James Burton.<sup>3</sup> <sup>1</sup>Medscape Education Global, London, United Kingdom; <sup>2</sup>Medscape LLC, New York, NY; <sup>3</sup>Dept of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is a common and distressing condition that affects ≥60% of people undergoing haemodialysis, with 20-40% reporting moderate-to-severe pruritus. Intense itching can lead to poor sleep quality, depression, reduced quality of life, increased risk of infection, and an increased risk of death. However, there are limited options for controlling CKD-aP, making it a challenging condition to manage effectively.

**Methods:** Nephrologists participated in an online case-based activity entitled 'Patient Case Challenges in CKD-aP' (launched 17 May 2021, data collection by 17 Sept. 2021). Educational effect was assessed using a repeated-pair design, pre-/post-assessment. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating. Cohen's d estimated the effect size of the education on number of correct responses (<.20 modest, .20-.49 small, .50-.79 moderate, ≥.80 large). A series of McNemar's tests were conducted at the question level (5% significance level,  $P < .05$ ).

**Results:** Nephrologists (n=107) significantly improved their knowledge regarding diagnosis & severity assessment of CKD-aP (55% correct answer at baseline, 97% post-assessment), novel therapies for CKD-aP (59% correct answer at baseline, 95% post-assessment), and optimizing outcomes for people with CKD-aP (60% correct answer at baseline, 97% post-assessment) (all  $P < .001$ ) 64% of nephrologists reported improved confidence in understanding treatment options for CKD-aP 98% of nephrologists reported that the education would improve their performance, leading to better patient outcomes

**Conclusions:** These results highlight the benefits of case-based education in helping nephrologists understand how to better manage CKD-aP. Further education would be beneficial to support nephrologists to translate knowledge of novel treatment strategies into clinical practice in order to optimize outcomes.

**Funding:** Commercial Support - Supported by an independent educational grant from Vifor Pharma

## TH-PO013

## A Curriculum of Online Education Significantly Improved Nephrologists' Knowledge and Confidence in Managing CKD-aP

Elaine Bell,<sup>1</sup> Joy Marko,<sup>2</sup> James Burton.<sup>3</sup> <sup>1</sup>Medscape Education Global, London, United Kingdom; <sup>2</sup>Medscape LLC, New York, NY; <sup>3</sup>Dept of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is a common and distressing condition that affects ≥60% of people undergoing hemodialysis. Intense itching is associated with poor quality of life and an increased risk of death. However, there are limited options for controlling CKD-aP, making it a challenging condition to manage effectively.

**Methods:** A curriculum of 6 activities was developed on CKD-aP, including a panel discussion, video lecture and interactive case-based education. Data were collected 2020 to 2021 with n numbers ranging from 56 to 178 completing pre- and post-activity questions. For each activity, educational effect was assessed with a repeated-pairs pre-/post-assessment; 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Data were subsequently combined and analyzed by theme to provide a summative overview of the effect of the education across the combined activities. A McNemar's test was conducted to assess statistical significance of changes from pre- to post-assessment.

**Results:** Nephrologists demonstrated a statistically significant improvement in knowledge or competence across 6 of the 7 learning themes (pathogenesis of itch; impact of itch; diagnosis & severity assessment; mode of action of difelikefalin; treatment/clinical data; all  $P < .001$ ) There was a numerical improvement in knowledge regarding the prevalence of CKD-aP The relative improvements in % of correct responses for each learning theme ranged from 10%-121% Pre-education, 19% of nephrologists felt confident or very confident in managing people with CKD-aP, but this rose to 48% post-education

**Conclusions:** These results highlight the benefits of a curriculum of education in helping nephrologists understand how to better manage pruritus associated with CKD. However, the results suggest that nephrologists would benefit from further education on the prevalence and impact of CKD-aP and to support them in translating knowledge of novel treatment strategies into clinical practice in order to optimize outcomes.

**Funding:** Commercial Support - Supported by an independent educational grant from Vifor Pharma

## TH-PO014

### Nephrology Program Director Protected Time for Program Administration: A National Survey

Christina M. Yuan,<sup>1</sup> Brian Y. Young,<sup>3</sup> Maura A. Watson,<sup>1</sup> Amy N. Sussman.<sup>2</sup>  
<sup>1</sup>Walter Reed National Military Medical Center, Bethesda, MD; <sup>2</sup>Banner University Medical Center Tucson, Tucson, AZ; <sup>3</sup>University of California Davis Health System, Sacramento, CA.

**Background:** In July 2019, the Accreditation Council for Graduate Medical Education (ACGME) reduced protected time for training program administration from 20 to 10-20 hours/week for nephrology program directors (PDs). No minimum time was specified for core faculty, where it had been 10 hours/week. In July 2022, it will be reduced to 8 hours/week for the majority of PDs. Program administration is defined as “non-clinical teaching and administration”.

**Methods:** Anonymous survey of all US adult nephrology PDs, administered from 3/31-4/30/2022, regarding protected time received for program administration, how much they think necessary, and division of their professional time overall. The 20-question, anonymous, on-line survey link was delivered by email to 151 PDs (ACGME Public List of Nephrology Specialty Programs 2021-22).

**Results:** Response rate was 66% (99/151). Geographic distribution and approved clinical fellow positions were similar to the entire population. Median approved clinical fellow positions was 6 (IQR 4,8); 59% had <7 approved positions. Median protected time was 10 hours/week (IQR 5,10), but only 8 hours/week (IQR 5,10) for those with <7 positions. Overall, PDs estimated they required a median 12 hours/week (IQR 10,16) protected time to effectively administer their programs, as did those with <7 approved positions (12 hours/week (IQR 10,15)). PDs reported core clinical faculty receive a median 2 hours/week (IQR 0,5); 39% of PDs reported 0 hours. Of PDs devoting <10 hours/week to program administration (median 8 hours/week (IQR 4,10) protected time), 62% provided >20 hours of direct patient care.

**Conclusions:** Approximately half of US nephrology programs are not in compliance with the ACGME-stipulated 10 hour/week minimum protected time for PDs. The majority estimate at least 12 hours/week are needed to effectively educate fellows and manage their programs. In view of our results and historically low board examination pass rates, the ACGME should track effects and reassess the 2022 decrease in PD protected time, as it does not align with PD-reported needs for education and administration. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy the Department of Defense or the U.S. government.

## TH-PO015

### Educational Efficacy of Mobile Platform in Improving Patient Understanding of Kidney Disease

Jamie E. Cronin,<sup>1</sup> Chang Huei Chen,<sup>2</sup> Ernesto Salcedo.<sup>1</sup> <sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>University of Colorado Health, Aurora, CO.

**Background:** Chronic kidney disease (CKD) is a leading cause of mortality internationally and has very low rates of treatment compliance. Preventing disease progression and minimizing complications is essential in CKD management. Patients' active participation in their treatment plan is critical. However, participation may be limited due to the complex nature of the disease and lack of understanding. Educational intervention of any kind has been demonstrated to improve both patient and clinically reported outcomes. We aimed to evaluate the efficacy of a free, concise mobile application in educating CKD patients and in promoting participation in decision-making for their treatment.

**Methods:** The app has eleven sections covering all aspects of chronic kidney disease. Built in pre- and post-surveys utilize a Likert-type psychometric scale where patients indicate their level of agreement with the statement. The same eleven questions are presented in each survey and are designed to determine the efficacy of the app in educating participants on the urinary system, causes of CKD, stages, lifestyle management, comorbidities, complications, and various treatment methods. Participants first interact with the pre-survey, proceed through the modules, then complete the post-survey. The individual questions are compared between the pre- and post-surveys and a single-tail T-test is used to analyze significance (p-value less than or equal 0.05).

**Results:** Participant recruitment (goal of N=50) and data collection is still ongoing and will conclude by 7/1/2022. Preliminary data has found the app to be significantly effective in helping patients understand the causes of kidney disease ( $P < 0.05$ ), lab values ( $P < 0.05$ ), disease management ( $P < 0.05$ ), and in contributing to patient confidence in discussing their options with a provider ( $P < 0.05$ ).

**Conclusions:** Providing a free, easily accessible, concise application on chronic kidney disease significantly improves health literacy in CKD patients and helps them feel more confident in the decision-making process of their treatment plan.

## TH-PO016

### Virtual NephroTalk: Teaching Communication Skills During the COVID-19 Pandemic

Alexandra E. Bursic, Amar D. Bansal, Jane O. Schell. *University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

**Background:** Nephrologists engage in advance care planning with their patients less often than other specialists caring for patients with similarly life-limiting illnesses, and many patients with kidney disease receive invasive care that may not be consistent with their wishes. The UPMC NephroTalk curriculum has previously been shown to increase both self-rated preparedness and objective performance of essential communication skills to help prepare nephrology fellows to discuss goals of care with patients and families. The COVID-19 pandemic has necessitated innovation in teaching communication skills. We adapted the NephroTalk curriculum to provide the opportunity to acquire and practice communication skills while learning remotely.

**Methods:** Nephrology fellows from 4 ACGME-accredited nephrology programs, as well as other renal healthcare professionals participated in a three-day virtual course with synchronous and asynchronous components including 1) self-paced modules explaining and demonstrating communication skills; 2) small group drills to promote deliberate practice of core skills led by experienced facilitators; and 3) small group practice with simulated patients incorporating peer and facilitator feedback. Surveys measured participants' self-perceived communication preparedness pre- and post-curriculum and satisfaction with the program.

**Results:** Twenty-two healthcare professionals participated in the virtual NephroTalk curriculum over two years. Prior to the course, most learners described feeling “not prepared” or “somewhat prepared” on a 5-point Likert scale to perform 12 key communication skills including discussing prognosis, eliciting patient values, discussing conservative kidney management, and recommending a treatment plan. After completing the program, 100% of participants reported feeling “prepared” or “very prepared” to perform all 12 communication skills. Respondents expressed a high degree of satisfaction with the course overall.

**Conclusions:** The COVID-19 pandemic has resulted in a shift toward virtual learning within medical education. Nephrology fellows and clinicians participating in the virtual NephroTalk curriculum expressed high levels of satisfaction and preparedness to utilize the skills demonstrated in the course. Future research should evaluate the impact of virtual communication skills training on sustained skill maintenance over time and patient outcomes.

## TH-PO017

### Tweeting a Path to Communication Success: What Nephrology Training Programs Are Sharing on Twitter

Laura J. Maursetter,<sup>1</sup> Hector M. Madariaga,<sup>2</sup> Tejas Desai.<sup>3</sup> <sup>1</sup>University of Wisconsin-Madison, Madison, WI; <sup>2</sup>Lahey Hospital and Medical Center, Burlington, MA; <sup>3</sup>Vifor Pharma Ltd, Glatfbrugg, Switzerland.

**Background:** Twitter is an important tool for communication by nephrology training programs. Using Twitter impacts recruitment and programs increasingly rely on this platform to reach a generation of learners who are connected on social media. Effective use of Twitter takes time and dedication and little is known about the patterns of its use. In this study, we collected tweets from US nephrology training programs to provide information on patterns and subjects of Twitter use.

**Methods:** Over a period of 40 months, we collected tweets from nephrology training programs known to have Twitter accounts. We manually reviewed a small corpus of tweets to establish the 5 most common themes. Subsequently, we developed a code book that provided a taxonomy system for the tweets. Excel was programmed to read each tweet and categorize into any of the 5 themes. Tweets could be classified into more than one domain to capture the richness of the tweet.

**Results:** We analyzed 33,112 tweets from 78 of the 149 domestic adult nephrology training programs between 8/2018 and 12/2021. The range of Twitter activity was 2 to 2,265 tweets per program and 4 programs authored 25% of the tweets. Only 42% of tweets contained original content; 58% were retweets. Our thematic analysis categorized each tweet into any combination of the 5 themes: Advocacy/DEI (12%), Work-Life Balance (2%), Professional Development (22%), Promotion (self or program) (45%), and/or Medical Knowledge (42%). Programs interacted with AJKOnline, ASNKidney, CJASN, ASNKidney360, and KidneyMed the most often.

**Conclusions:** Twitter is an increasingly common communication tool used by US nephrology training programs. We analyzed a large numbers of tweets from over 50% of programs with active accounts. The most frequent themes were Medical Knowledge and Promotion. Even though using Twitter can take a significant amount of time and might be challenging, more than half of the activity comes from retweets which can provide a reprieve to busy clinicians. Our next step is to determine if Twitter activity and/or specific themes have made a difference in match outcomes.

## TH-PO018

### Early Recognition of CKD in Primary Care Setting

Alexandra M. Johnston, Mary Lynn Sealey, Lauren Mathos, Mrudula Gadani. *Allegheny Health Network, Pittsburgh, PA.*

**Background:** Chronic kidney disease (CKD) affects 37 million people in the US but 10% are aware they have CKD. Recognizing CKD early in the disease has shown to improve outcomes while failure to do so can lead to increased morbidity and mortality. In the 2020-2021 academic year, there were 28,569 Internal Medicine Residents in the US and this group is of critical importance in identifying patients with CKD.

**Methods:** We aimed to identify and increase screening of CKD in patients in our residency clinic by implementing a small group case-based didactic on recognizing and screening for CKD along with management once diagnosed. We also conducted a pre/post-test to determine the effectiveness of the didactic. Residents were encouraged to utilize a smartphrase created in EPIC to identify patients with risk factors that should be routinely screened for CKD. Baseline data of patients with a diagnosis of CKD was collected and again at 6 months.

**Results:** Ninety five residents participated in didactics with an average pre-test of 2.9/8(36.2%) which improved to 5.7/8(70.7%) post-test. At baseline, a total of 235 patients had a diagnosis of CKD out of 3900 patients (6.0%). 6 months after didactic and implementation of SmartPhrase, a total of 286 out of 4050 patients had a diagnosis of CKD (7.1%). There was an overall increase in patients screened and diagnosed with CKD. Most notable change was in patients over age 65 years and black patients with an increase from 16.7% (149/892) to 19.7% (187/949) and 9.7% (139/1433) to 11.4% (163/1435) respectively.

**Conclusions:** Kirkpatrick evaluation model was utilized to assess our CKD focused small group case-based didactic and QI intervention. Learning was evaluated with pre/post-test showing an increase in scores by 34%. In addition, behavioral change was noted by utilization of SmartPhrase and subsequently resulted in an increase in identification of patients with CKD with largest increase in patients over age 65 years and black patients. Use of a similar hybrid intervention in Internal Medicine Training programs may be beneficial to increase CKD recognition across the country. Future measurement of treatment parameters including blood pressure control and medication use are planned.

### Love and Breakup Letters to an Online Nephrology Learning Tool

Samira S. Farouk,<sup>1</sup> Layla Fattah,<sup>1</sup> Matthew A. Sparks,<sup>2</sup> David C. Thomas.<sup>1</sup>  
<sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Duke University School of Medicine, Durham, NC.

**Background:** NephSIM is a free, open access medical education (FOAMed) tool that aims to teach nephrology to a wide group of learners. It is not known how learners feel about FOAMed as they progress through their training from medical school to fellowship. Love & Breakup Letter Methodology (LBM), while relatively new in medical education, is a technique that has been used extensively in user experience technology-based research. LBM asks participants to creatively write a “love” or “breakup” letter to a product under study to capture their thoughts & emotions when engaging with it. We hypothesized that LBM would allow us to understand reactions towards NephSIM among distinct groups of trainees.

**Methods:** Three 90-min. virtual, recorded focus groups (FG) were conducted with 2nd year medical students (MS), internal medicine residents (IMR), & nephrology fellows (NF). Participants were asked to review selected portions of NephSIM prior to the FG. At the start of the FG, they composed & read their love/breakup letter. Semi-structured FG discussions were led by facilitator-driven questions & peer comments (Fig.1). After FG transcription, analysis was conducted using Braun & Clarke’s 6-step thematic analysis.

**Results:** Inductive thematic analysis revealed reactions varied by trainee experience & perceived situated learning needs. Differences were identified between groups in terms of learning motivation, perceived application, required effort, & resulting benefit to practice. All 8 MS wrote love letters that highlighted the benefits of NephSIM in developing problem solving, critical thinking, & clinical reasoning skills. In contrast, reactions from 7 IMR & 5 NF were mixed: 6/12 & 6/12 wrote love & breakup letters, respectively. IMR were interested in brevity & speed of learning, preferring algorithms & succinct learning to meet their practice-based learning needs. Nephrology fellows’ learning needs were driven by a desire to prepare for the nephrology board examination & review uncommonly seen cases.

**Conclusions:** LBM provided a valuable methodology through which to identify trainee reactions to a FOAMed tool & highlighted the challenges of meeting learning needs of a continuum of trainees with a single learning platform.

## TH-PO020

### Assessing the Value of “A Family Journey” Community Program for Supporting Pursuit of Preemptive Living Kidney Transplantation

Bethany Cruz, Ahmed O. Gaber, Joseph D. Sharp, Vernell Bosie, Julie Corkrean, Edward A. Graviss, Duc T. Nguyen, Alexis Bobu, Amy D. Waterman. *Houston Methodist Hospital, Houston, TX.*

**Background:** Outreach to patients not yet in kidney failure and their support network may result in more preemptive living donor transplants (PLDT). We examined characteristics of kidney patients who participated in an education program, “A Family Journey,” and its impact on PLDT.

**Methods:** Kidney patients not yet on dialysis were invited to attend “A Family Journey,” a 1.5-hour education program at the onset of transplant evaluation. Educational topics discussed included the advantages of having a living donor kidney transplant and PLDT, training on how to seek donors, and available financial resources. Using EMR data and living donor pre-screening portals, we tracked demographic data, the number of living donor inquiries, and PLDT- actions taken by patients attending and not attending the class.

**Results:** Between 2019-2022, 11 in-person and 25 virtual sessions occurred. Of the 466 patients referred to “A Family Journey” class, 333 (71%) attended the class, with those attending being more likely to be White (39.6% vs. 36.8%, p=0.71), African American (26.4% vs. 22.5%, p=0.74), have commercial insurance (62.7% vs. 41.3%, p=0.003), and have incomes over \$75,000 (24.9% vs. 18.0%, p=0.006) (Table). Compared to others, attendees were more likely to finish evaluation (81% vs. 65%, p<0.001), have a living donor inquiry (52% vs. 32%, p<0.001), and receive a PLDT (14% vs. 0.07%, p<0.001).

**Conclusions:** This PDKT-focused community education class was well attended with patients having more living donor inquiries and PLDTs compared to those who didn’t attend. Further randomized controlled trials needed to determine how best to reach disparate communities with less access to PLDT.

Table. Participant Characteristics

TH-PO021

**National Survey: Point-of-Care Ultrasound Use Among Nephrology Program Directors, Fellows, and Graduates**  
David L. Cook<sup>1</sup>, Christina M. Yuan,<sup>1</sup> Robert Nee,<sup>1,3</sup> Samir S. Patel,<sup>2</sup> Scott D. Cohen,<sup>2</sup> Dustin J. Little.<sup>1</sup> <sup>1</sup>Walter Reed National Military Medical Center, Bethesda, MD; <sup>2</sup>Washington DC VA Medical Center, Washington, DC; <sup>3</sup>Uniformed Services University of the Health Sciences, Bethesda, MD.

**Background:** Nephrologists have been slow to adopt Point-of-Care Ultrasound (POCUS). We surveyed all US nephrology program directors (PDs), their fellows, and our program graduates regarding nephrology-specific POCUS training and use.  
**Methods:** Anonymous, online survey of US nephrology PDs and their fellows (academic year 2021-2022), and 90 graduates (1986-2021) of the Walter Reed nephrology program (POCUS curriculum began 2019). We inquired about current/planned POCUS training, training type, and barriers to training and use.  
**Results:** PD response rate (n=151) was 46%. 361 fellows were forwarded the survey link; 33% responded. Of 89 graduates, 62% responded. 51% of programs offered POCUS training, most commonly via bedside training in non-POCUS oriented rotations (71%), didactic lectures (68%), and simulation (43%). 46% of current fellows reported fellowship POCUS training; but approximately half reported not being sufficiently trained or not being confident in kidney (56%), bladder (50%), and IVC assessment (46%). Common barriers to training cited by PDs were: not enough trained faculty (78%), PDs themselves not being sufficiently trained (55%), and equipment expense (51%). 63% of PDs and 56% of fellows reported <10% of faculty were POCUS-trained. 64% of fellows reported too little training. 72% of PDs agreed that POCUS should be part of the curriculum. Among our graduates, 15% perform POCUS in clinical practice, but 50% of those with <5 years of practice experience do so. 77% of graduates agreed that POCUS should be part of the curriculum. The majority of fellows (59%) and graduates (61%) preferred hands-on POCUS training over didactic lectures or simulation.  
**Conclusions:** The majority of fellows, PDs, and fellowship graduates surveyed agreed that POCUS should be incorporated into the nephrology curriculum. The majority did not feel sufficiently trained to confidently perform POCUS, and the greatest barrier to training was lack of sufficiently trained faculty. This highlights the need to “train the trainers” before POCUS can be fully integrated into the curriculum and commonly used in nephrology practice. *Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy the Department of Defense or the U.S. government.*

TH-PO022

**Comparison of Outcomes in Prospective and Retrospective Studies of Biomarker for AKI Risk**  
Ashley La, Samantha Gunning, Jay L. Koyner. *The University of Chicago Medicine, Chicago, IL.*

**Background:** Novel urinary biomarkers, including Tissue Injury Metallo-protease-2 and Insulin-like Growth Factor Binding Protein 7 ([TIMP-2]\*[IGFBP7] or T2\*I7), have been developed to predict patients at risk for developing severe AKI. While T2\*I7 has been approved as an AKI risk stratification tool, “real world” data on its clinical utility in preventing AKI is minimal.  
**Methods:** We conducted a single-center quality improvement study of University of Chicago ICU patients at risk for severe (KDIGO stage 2 or 3) AKI by comparing patients previously enrolled in retrospective clinical trials of T2\*I7 in which clinical teams were not aware of biomarker values (n=59) with a prospective cohort of at-risk and stage 1 AKI patients. In the prospective cohort (n=105), ICU providers were given the biomarker values with KDIGO-based care guidelines based on biomarker values. We analyzed the patients’ charts for data on the use of these guidelines and clinical outcomes.  
**Results:** More patients in the prospective cohort had stage 1 AKI at the time of biomarker measurement (66(63.5%) vs 10(17.0%), p < 0.001). The peak change in serum creatinine (SCr, mean(SD)) within 7 days of ICU admission was lower in the prospective study compared to the retrospective studies among the entire cohort (0.27(0.78) vs 0.93(1.50), p < 0.001) as well as only in those at higher risk for AKI (T2\*I7 >0.3) (0.34(0.87) vs 1.02(1.41), p = 0.004). AUC(SE) for T2\*I7 as a predictor of severe AKI in 48 hours was 0.644(0.40), p=0.057, in the prospective cohort and 0.720(0.66), p=0.077, in the retrospective cohort.  
**Conclusions:** The use of T2\*I7 coupled with practice guidelines is associated with a smaller increase in SCr in ICU patients at high risk for AKI despite more baseline AKI. Given these findings, the impact of T2\*I7 reporting on clinical care warrants continued investigation.

Outcomes of ICU patients with urinary [TIMP-2]\*[IGFBP7] >0.3 by study cohort

	Prospective (n = 78)	Retrospective (n = 37)	p-value
Nephrology consults	22 (28.2%)	2 (5.4%)	0.006
Net intake/output (mL) (SD)	-1044 (8190)	-1343 (8403)	0.85
Incidence of nephrotoxin exposure (SD)	4.99 (4.14)	4.32 (3.54)	0.44
Peak change in SCr in 7 days (mg/dL) (SD)	0.34 (0.87)	1.02 (1.41)	0.004
Inpatient mortality	8 (10.3%)	9 (24.3%)	0.09
Inpatient dialysis	8 (10.3%)	3 (8.1%)	>0.99

TH-PO023

**Impact of Practice Guidelines in Critically Ill Patients at Risk for AKI**  
Ashley La, Samantha Gunning, Jay L. Koyner. *The University of Chicago Medicine, Chicago, IL.*

**Background:** Novel urinary biomarkers, including Tissue Injury Metallo-protease-2 and Insulin-like Growth Factor Binding Protein 7 ([TIMP-2]\*[IGFBP7] or T2\*I7), have been developed to predict which ICU patients are at risk for severe AKI (stage 2/3). While T2\*I7 has been validated as a risk stratification tool, data on its “real-world” impact on patient care outside of clinical trials is lacking.  
**Methods:** We conducted a single-center prospective quality improvement study of ICU patients at risk for AKI or with KDIGO serum creatinine (SCr) stage 1 AKI at the University of Chicago. T2\*I7 measurements were made via the hospital lab at the discretion of the ICU team. ICU providers were given KDIGO AKI-guideline-based practice recommendations based on T2\*I7 results. The use of these guidelines and clinical outcomes were compared amongst patients with T2\*I7 of <0.3, 0.3-2, and >2.  
**Results:** Of 105 ICU patients included in our analysis, 66(63%) had stage 1 AKI at time of biomarker measurement. A higher proportion of patients with T2\*I7 >2 had stage 1 AKI compared with T2\*I7 ≤2 (25(78.1%) vs 41(56.9%), p = 0.038). There was no significant difference in peak change in SCr (mean(SD)) within 7 days of biomarker measurement between T2\*I7 >2 (0.48(1.09)) and T2\*I7 ≤2 (0.17(0.58)) (p = 0.24). There was also no difference in proportions of patients who progressed to severe AKI in 7 days (10(31.3%) vs 14(19.2%), p = 0.5). Across the entire cohort, AUC(SE) for T2\*I7 as a predictor of severe AKI in 48 hours was 0.65(0.11), p=0.06.  
**Conclusions:** Despite having higher T2\*I7 levels and more stage 1 AKI, those ICU patients with values >2 did not progress to have significantly more stage 2 or 3 AKI. When used in conjunction with guideline-based care, T2\*I7 can improve the outcomes of ICU patients.

Outcomes of ICU Patients by Urinary [TIMP-2]\*[IGFBP7]

	[TIMP-2]*[IGFBP7] ≤2 (n = 73)	[TIMP-2]*[IGFBP7] >2 (n = 32)	p-value
Nephrology consults	12 (16.4%)	13 (40.6%)	0.01
Pharmacy consults	34 (46.6%)	17 (53.1%)	0.67
Net intake/output (mL) (SD)	-2776 (6224)	1033 (10590)	0.07
Incidence of nephrotoxin exposure (SD)	5.53 (4.9)	4.19 (3.0)	0.25
Peak change in SCr in 7 days (mg/dL) (SD)	0.17 (0.58)	0.48 (1.09)	0.24
Inpatient mortality	4 (5.5%)	5 (15.6%)	0.13
Inpatient dialysis	4 (5.5%)	5 (15.6%)	0.13

TH-PO024

**Urinary DcR2/Cr Is Associated With Adverse Outcomes in Patients With AKI**  
Xiangling Yi, Jia Chen, Yani He. *Army Medical University, Chongqing, China.*

**Background:** Acute kidney injury (AKI) is now considered a major public health problem affecting millions of people worldwide, and AKI is a significant risk of chronic kidney disease and end-stage renal disease. However, there is currently a lack of biomarkers for the prognosis of AKI. Decoy receptor 2 (DcR2), a senescent marker, is expressed exclusively in senescent tubular epithelia and urinary DcR2 (uDcR2) is associated with renal fibrosis in CKD. The aim of study is to investigate the relationship of uDcR2 with kidney injury and renal prognosis in patients with AKI.  
**Methods:** 130 biopsy-proven AKI patients were included from our hospital from January 2018 to February 2022. A composite renal endpoint included creatinine more than 50% higher than the baseline or ESRD after 90 days. All patients were divided into positive endpoints (n=63) and negative endpoints (n=64). The clinical characteristics were collected, and the pathological injury was scored. uDcR2 levels were measured using enzyme-linked immunosorbent assay and normalized to urinary cre (uDcR2/Cr). The correlation of uDcR2/Cr levels with renal function and renal pathological scores were analyzed. The logistic regression analysis was used to investigate the association of uDcR2/Cr with endpoints. The association of uDcR2/Cr with the composite renal endpoint using Kaplan-Meier curves were calculated.  
**Results:** The level of uDcR2/Cr was positively correlated with cystatin C, and negatively correlated with estimated glomerular filtration rate (eGFR). And uDcR2/Cr was positively associated with renal pathological scores, including acute and chronic kidney injury. The risk factors for endpoint positive were uDcR2/Cr, pathological scores, male, and CKD history. Compared with endpoint-negative group, the uDcR2/Cr level of endpoint-positive patients was significantly higher. Among the patients with uDcR2/Cr < 433ng/g, the percentage of endpoint-negative AKI patients was the higher. And patients with uDcR2/Cr > 433ng/g are more likely to reach the renal end point.  
**Conclusions:** Urinary DcR2/Cr is closely associated to kidney injury and renal prognosis of AKI, suggesting that uDcR2/Cr could sever as a novel biomarker for predicting adverse outcomes in patients with AKI.

**Funding:** Other U.S. Government Support

## TH-PO025

## Urinary Uromodulin Level Reflects Tubular Recovery in Patients With AKI

Takatsugu Iwashita,<sup>1</sup> Izumi Nagayama,<sup>1</sup> Kazutoshi Ono,<sup>2</sup> Daisuke Nagata,<sup>2</sup> Hajime Hasegawa,<sup>1</sup> Akito Maeshima.<sup>1</sup> <sup>1</sup>Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; <sup>2</sup>Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan.

**Background:** Uromodulin is the most abundant protein excreted in the urine under physiological conditions. It is exclusively produced by the thick ascending limb of Henle and secreted into the urine via proteolytic cleavage. Uromodulin plays an important role in preventing urinary tract infections and kidney stones. However, it remains unknown whether urinary uromodulin level is correlated with the severity and prognosis of acute kidney injury (AKI). In this study, we investigated whether urinary uromodulin is useful as a biomarker for AKI.

**Methods:** AKI patients (n=91) who were treated at Jichi Medical University (December 2018 to January 2020) and Saitama Medical Center Saitama Medical University (December 2020 to September 2021) were enrolled. Written consent was obtained from all patients. Serum and urinary uromodulin were measured by ELISA. Correlations of urinary uromodulin level and various clinical parameters were analyzed. This study was approved by the Ethics Committee on Human Research of our institutions (Approval number A18-081, A18-089, No.2472).

**Results:** Urinary uromodulin level was significantly decreased in AKI patients, compared to that in healthy control ( $974.9 \pm 792.3$  vs.  $2251.0 \pm 942.6$  ng/mL,  $p < 0.001$ ). Urinary uromodulin was not correlated with urine protein level, NAG, alpha1-microglobulin, L-FABP, and kidney injury molecule-1. No significant correlation between serum and urinary uromodulin was observed, suggesting that urinary uromodulin is derived from kidney but not from blood. In patient with drug-induced AKI, urinary uromodulin level returned to normal level consistent with improvement of renal function ( $463.5$  to  $1974.6$  ng/mL). No recovery of urinary uromodulin was observed in AKI patients who required renal replacement therapy and progressed to end stage renal disease. In case of kidney transplantation recipient, urinary uromodulin was undetectable at 1 day after transplantation, but was markedly increased thereafter (day 42,  $558.3$  ng/mL).

**Conclusions:** Urinary uromodulin reflects the quantity of normally functioning renal tubules and may be useful for monitoring the recovery of damaged renal tubules in AKI.

## TH-PO026

## Urinary Biomarkers and Kidney Injury in the VA NEPHRON-D Trial

Elizabeth Kiernan,<sup>1</sup> David G. Hu,<sup>1</sup> Heather Thiessen Philbrook,<sup>1</sup> Joachim H. Ix,<sup>2</sup> Steven G. Coca,<sup>3</sup> Michael Shlipak,<sup>4</sup> Dennis G. Moledina,<sup>5</sup> Joseph V. Bonventre,<sup>7</sup> Linda F. Fried,<sup>6</sup> Chirag R. Parikh.<sup>1</sup> <sup>1</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>2</sup>University of California San Diego, La Jolla, CA; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>5</sup>Yale School of Medicine, New Haven, CT; <sup>6</sup>UPMC, Pittsburgh, PA; <sup>7</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** Clinical trials evaluating interventions that modify systemic or intraglomerular pressure lead to elevations in serum creatinine, which may or may not reflect true kidney injury. Urine biomarkers could help phenotype injury patterns in these trial participants.

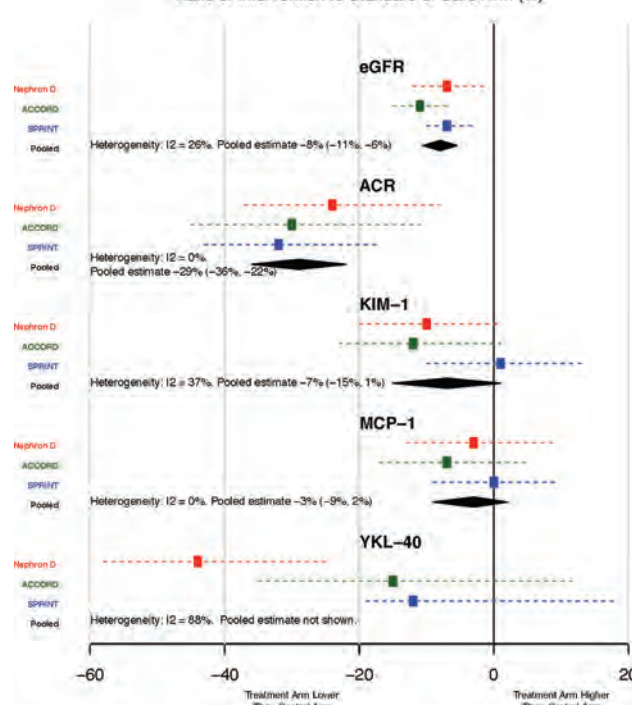

**Methods:** A subset of participants in the VA NEPHRON-D trial had urinary biomarkers including Albumin: Creatinine ratio (ACR), YKL-40, KIM-1, MCP-1 and EGF measured at baseline and at 12-months. Urinary biomarkers were compared between treatment groups (combination vs monotherapy) and by Acute Kidney Injury (AKI) status. Biomarker results from NEPHRON-D were included in a meta-analysis with other large CKD trials (ACCORD and SPRINT) to assess global trends.

**Results:** In 703 participants, with 2.2 years of follow-up, the incidence of AKI was higher (20.7%) in the combination therapy group as compared to the monotherapy group (12.7%) (RR 1.64 (1.2, 2.3)). Urine biomarkers at 12 months were either the same [MCP-1 -3% (-13%, 9%), KIM-1 -10% (-20%, 1%)] or lower [Albuminuria, -24% (-37%, -8%), YKL-40 -44% (-58%, -25%), EGF -7% (-12, -1%)] in the combination arm compared to monotherapy arm. Meta-analysis demonstrated reduction in albuminuria across 3 trials (pooled estimate -29% 95% CI (-36%, -22%)). No trial showed higher biomarkers in the intervention arm which induced rise in serum creatinine.

**Conclusions:** Treatment with combination ACE-i/ARB therapy was associated with a favorable decrease in urinary biomarkers, suggesting improved tubular health, despite higher risk of serum creatinine defined-AKI. This supports use of kidney injury biomarkers in phenotyping of renal injury.

## Prognostic Value of Urinary Liver-Type Fatty Acid-Binding Protein (uL-FABP) for Major Adverse Kidney Outcomes Among Critically Ill Adult Septic Patients

Carlo Antonio Boado, Jeanne B. Bayaca, Armin N. Masbang. *St. Luke's Medical Center, Quezon City, Philippines.*

**Background:** Urinary L-FABP is predominantly located in the proximal tubule and is excreted into the tubular lumen bound to toxic peroxisomal products which accumulate during tubular injury. uL-FABP is detected by a urine test for the early diagnosis of AKI however, its evidence for prognostication remains unclear. This study aimed to determine the utility of uL-FABP to predict the development of major adverse kidney outcomes: critical AKI, initiation of kidney replacement therapy (KRT), and AKI-related mortality over 30 days among critically ill septic patients in an academic medical center.

**Methods:** Urinary L-FABP was tested among critically ill septic patients upon arrival at the emergency department. Patients were then classified according to the uL-FABP test. Patients were then followed up for 30-day major adverse kidney outcomes which include - critical AKI, initiation of KRT, and AKI-related mortality. We also analyzed independent clinical variables that increase the risk for adverse kidney outcomes.

**Results:** A total of 118 septic patients were included in the study. AKI was diagnosed among 87.2% of the subjects. Patients positive for uL-FABP (48) had severe organ dysfunction and the proportion of those with critical AKI (85.42% vs. 40.00%,  $p = 0.001$ ), KRT initiation (75.00% vs. 20.00%,  $p = 0.001$ ) and mortality (72.92% vs. 21.43%,  $p = 0.001$ ) were all significantly higher among those who tested positive for the uL-FABP test. Cox proportional-hazard regression analyses showed that uL-FABP was able to predict major adverse kidney outcomes among septic patients - critical AKI (HR 3.26 (2-5.3)  $p = 0.0001$ , KRT initiation (HR 3.13 (3.29-11.43)  $p = 0.0001$  and AKI-related mortality (HR 3.13 (3.29-11.43)  $p = 0.0001$  over 30 days of observation. Independent variables such as diabetes and chronic kidney disease and dipstick proteinuria correlated were associated with increased risk for adverse kidney outcomes.

**Conclusions:** Urinary L-FABP test is a readily available biomarker for prognostication as it was able to predict 30-day major adverse kidney outcomes among critically ill septic patients. Independent variables like diabetes and chronic kidney disease and an increasing level of proteinuria from the dipstick test are correlated with increased risk for major adverse kidney outcomes.

Kimmel,<sup>6</sup> Jonathan Himmelfarb,<sup>7</sup> Steven G. Coca,<sup>8</sup> Chirag R. Parikh.<sup>1</sup> ASSESS-AKI Consortium <sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Western University, London, ON, Canada; <sup>4</sup>Kaiser Permanente Northern California, Oakland, CA; <sup>5</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>6</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>7</sup>University of Washington School of Medicine, Seattle, WA; <sup>8</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>9</sup>Penn State College of Medicine, Hershey, PA; <sup>10</sup>NYU Langone Health, New York, NY.

**Background:** Acute kidney injury (AKI) and chronic kidney disease (CKD) are interconnected syndromes with AKI recognized as a clear risk factor for CKD incidence or progression. However, biomarkers of repair and epithelial cell integrity of the distal tubule, such as urinary epidermal growth factor (uEGF), may help better inform this risk, given the limitations of serum creatinine (sCr) in the setting of AKI.

**Methods:** We enrolled 1,538 hospitalized patients prospectively in the multi-center Assessment, Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI) Study. We measured uEGF from samples collected during hospitalization and at 3 months post-discharge. The primary outcome was a composite of major adverse kidney events (MAKE) consisting of CKD incidence, progression, or development of end-stage kidney disease.

**Results:** 299 (20%) patients developed the primary outcome at a median of 4.3 years follow-up. In fully adjusted models, each 1-standard deviation increase in uEGF from hospitalization to 3 months was associated with a significantly decreased risk of the composite outcome (aHR 0.71; 95% CI: 0.54-0.94; **Table 1**). Patients in tertile 3 (increase in uEGF) had a significantly lower risk of MAKE (aHR 0.53; 95% CI: 0.36-0.78) compared to those in tertile 2, which included patients who had no improvement in uEGF. Similar results were seen in stratified analysis by AKI status at the time of hospitalization, suggesting subclinical disease in patients without AKI.

**Conclusions:** Urinary EGF is a marker of healthy repair after kidney injury, and increases in uEGF from hospitalization to discharge are associated with a decreased risk of MAKE in patients both with and without AKI.

**Funding:** NIDDK Support

Serum Myo-Inositol Oxygenase Levels at Hospital Discharge Predict Progression to CKD in Community-Acquired AKI

Ashok K. Yadav,<sup>1</sup> Jaskiran Kaur,<sup>1</sup> Kajal Kamboj,<sup>1</sup> Prabhjot K. Johal,<sup>1</sup> Monica Kundu,<sup>2</sup> Arpita Ghosh,<sup>2</sup> Jasmine Sethi,<sup>1</sup> Vivek Kumar,<sup>1</sup> Vivekanand Jha.<sup>2</sup> <sup>1</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>The George Institute for Global Health India, New Delhi, India.

**Background:** Acute kidney injury (AKI) increases the risk of morbidity, mortality, and progression to chronic kidney disease (CKD). There are few data on the risk of CKD following community-acquired AKI (CA-AKI) and its predictors from developing countries. We evaluated the association of a panel of serum and urine biomarkers at the time of hospital discharge with 4-month renal outcome in CA-AKI.

**Methods:** Patients of either sex, aged between 18-70 years, with no underlying CKD, and with CA-AKI were recruited at the time of discharge from hospital. Levels of serum and urine biomarkers were analyzed and association between these markers and development of CKD, defined as eGFR <60 ml/min/1.73 m<sup>2</sup> or dialysis dependence at 4 month after discharge, were analyzed using multivariate logistic regression analysis and penalized least absolute shrinkage and selection operator logistic regression.

**Results:** Out of a total 126 patients followed up for 4 months, 25 developed CKD. Those who developed CKD were older (p=0.008). Adjusted logistic regression showed that each 10% increase in standardized serum myo-inositol oxygenase (MIOX) level increased the odds of progression to CKD by 13.5%. With 10% increase in standardized urine Neutrophil gelatinase-associated lipocalin (NGAL), serum creatinine and urine protein creatinine ratio (uPCR), increase in the odds of progression to CKD was 10.5%, 9.6% and 8%, respectively. Multivariable logistic model including serum MIOX, discharge serum creatinine and discharge uPCR, was able to predict the progression of CKD (Figure 1).

**Conclusions:** High level serum MIOX levels at the time of discharge from hospital are associated with progression to CKD in patients with CA-AKI.

**Funding:** Government Support - Non-U.S.

Insights Into Urinary Renin in AKI

Alexander H. Flannery,<sup>1</sup> Victor M. Ortiz-Soriano,<sup>2</sup> Prasad Devarajan,<sup>3</sup> Javier A. Neyra.<sup>4</sup> <sup>1</sup>University of Kentucky College of Pharmacy, Lexington, KY; <sup>2</sup>University of Kentucky College of Medicine, Lexington, KY; <sup>3</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>4</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** An activated intra-renal renin-angiotensin system (RAS), reflected by urinary markers including renin, is hypothesized to contribute to and serve as a biomarker of AKI. However, methodologic limitations with urinary renin immunoassay have been noted, including whether the standard is prorenin and not renin. Furthermore, it is unknown if urine renin is elevated simply due to elevations in plasma concentrations. Using a validated direct renin assay with a low cross-reactivity for prorenin, we sought to evaluate concurrent concentrations of urinary and serum renin in patients with and without AKI.

**Methods:** Biospecimens for this study were obtained from a previous cohort study investigating serum renin in critically ill patients. We identified 19 patients with AKI (KDIGO stage 2 or higher) due to sepsis and 19 matched control patients (i.e. critical illness without AKI). The biospecimens under study were obtained within the first 3 days of intensive care unit admission. Urine and serum renin were measured in duplicate with renin (active) ELISA and normalized to urine creatinine (Cr).

**Results:** Patients were well-matched with demographics, although AKI patients were more critically ill. Urine renin and urine renin normalized to Cr were significantly (p<0.001 for both) higher in AKI patients versus controls (**Fig. 1A-B**). Serum renin was higher in AKI patients than controls (p=0.014). Urine renin: serum and urine renin (normalized to urine Cr): serum renin ratios were numerically higher in AKI patients versus controls (**Fig. 1C-D**): p=0.300 and 0.226, respectively. Scatterplots (**Fig. 1E-F**) support the concept of a differential relationship of urine to serum renin in AKI and that an elevated serum renin is not a requirement for elevated urinary renin.

**Conclusions:** Urine renin is higher in AKI patients vs. controls, is not solely explained by high circulatory concentrations, and may represent a biomarker of intra-renal RAS activation in AKI.

**Funding:** NIDDK Support

**Galectin-3 and EGF Are the Only Cardiorenal Biomarkers to Predict AKI Progression in the Setting of Acute Heart Failure**

Stephen Duff,<sup>1</sup> Nicholas Wettersten,<sup>2</sup> Yu Horiuchi,<sup>3</sup> Sagar Raturi,<sup>1</sup> Ruairi Irwin,<sup>1</sup> Patrick T. Murray.<sup>1</sup> The AKINESIS Investigators <sup>1</sup>University College Dublin College of Health Sciences, Dublin, Ireland; <sup>2</sup>VA San Diego Healthcare System, San Diego, CA; <sup>3</sup>Shakai Fukushi Hojin Mitsui Kinen Byoin, Chiyoda-ku, Japan.

**Background:** Acute Kidney Injury (AKI) is common in hospitalized patients and is associated with high morbidity and mortality. Acute Kidney Injury Neutrophil gelatinase-associated lipocalin Evaluation of Symptomatic heart failure Study (AKINESIS) was a prospective, international, multicentre cohort which enrolled 927 patients presenting with acute heart failure (AHF). We hypothesised that novel urinary and plasma cardiorenal biomarkers would predict progression of AKI and associated outcomes in the setting of AHF.

**Methods:** The primary analysis assessed if biomarkers measured at the time of developing Stage 1 or 2 AKI within 72 hours of admission predicted progression to a higher AKI Stage, RRT or death within 30 days. Twenty-four novel urinary and plasma biomarkers were analysed using commercially available ELISAs and the architect platform.

**Results:** In total, 175 patients had Stage 1–2 AKI within 72 hours of hospital admission and were included in the study. Of the 24 biomarkers studied, plasma Galectin-3 and EGF improved prediction of AKI progression. None of the other biomarkers were associated with the outcome.

**Conclusions:** AKI progression in AHF occurred in the absence of tubular damage as assessed by a panel of urinary plasma biomarkers, consistent with the functional mechanism of AKI in AHF. Systemic inflammatory and fibrotic processes may contribute to progression.

**Funding:** Government Support - Non-U.S.

**Urine TIMP-2\*IGFBP7 Compared With Traditional Parameters for Predicting Hemodialysis Termination in AKI: A Prospective Observational Study**

Teeraporn Suttayamook, Pongsathorn Gojaseni, Bhumibol Adulyadej Hospital, Bangkok, Thailand.

**Background:** Currently, there is no official guideline or protocol for when to stop intermittent kidney replacement therapy (IKRT) in acute kidney injury (AKI). The decision to stop IKRT was based on clinical perspectives and nephrologists' experiences. The urinary cell cycle arrest biomarkers tissue inhibitor of metalloproteinase-2 (TIMP2) and insulin-like growth factor binding protein-7 (IGFBP7) have good performance in risk prediction of AKI and there is some evidence for predicting renal recovery. Thus, this study aimed to explore the association between successful IKRT discontinuation and urinary TIMP2\*IGFBP7, compared with other traditional parameters.

**Methods:** We prospectively enrolled medical and surgical patients who were diagnosed with AKI based on KDIGO 2012 criteria and required IKRT at Bhumibol Adulyadej Hospital, Bangkok, Thailand from July 2021 to January 2022. TIMP2\*IGFBP7 and other clinical parameters were collected before each IKRT which potential to be the last session. The primary outcome was successful IKRT discontinuation for 14 days.

**Results:** Seventeen patients (age  $68.35 \pm 17.60$ ) with thirty-nine AKI sessions were enrolled in the study. Of 39 IKRT sessions, 8 (20.51%) were able to terminate from IKRT for 14 days. We have found a non-significant association between urinary TIMP2\*IGFBP7 and successful IKRT discontinuation with an area under the receiver operating characteristic curve (AUC) 0.55 [95% confidential interval (CI) 0.32-0.77,  $P=0.66$ ]. On the other hand, 24-hour pre-IKRT urine volume showed the fair performance to predict an ability for successful IKRT discontinuation with an AUC of 0.76 [95% CI 0.56-0.96,  $P=0.023$ ] with optimal cut point  $>1,478$  ml/day (Youden's index 0.49).

**Conclusions:** We have found no association between pre-IKRT urine TIMP2\*IGFBP7 and successful IKRT discontinuation at 14 days, while 24 hours pre-IKRT urine output showed a fair predictive performance. Thus, clinical perspectives still play an important role in deciding to stop IKRT.

## TH-PO033

**Urine Mass Spectrometry Can Distinguish Prerenal and Intrarenal AKI**  
Reece B. Mitchell, Luke T. James, Christian Herzog, Joseph H. Holthoff, John M. Arthur. *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Postrenal causes of acute kidney injury (AKI) are often determined by imaging, but differentiation of prerenal (PR) from intrinsic renal (IR) can be challenging. A point of care method for differentiating these two entities would be useful. Mass spectrometry (MS) can visualize small molecules in urine. We utilized a portable, single quadrupole mass spectrometer with a simple ionization interface to measure small molecules in urine. The interface allows for direct analysis of samples without the need for time-consuming preparation. The goal was to distinguish PR and IR AKI by urine analyte profiles.

**Methods:** Inpatients with AKI were eligible for enrollment. COVID-19 patients were excluded. Informed consent was obtained under an approved UAMS IRB protocol. Patients were categorized as either PR (n=15) or IR (n=19) AKI etiology using the diagnosis by the on-service nephrology attending. Two microliter aliquots of urine were dispensed onto a stainless steel probe without prior processing and analyzed by MS with an Advion Expression CMS Mass Spectrometer. Peaks were recorded within the 20 to 500 m/z range. MS spectra were processed and binned in 1 m/z increments for peak clustering using MATLAB. The frequency of binned peaks in the PR AKI group were compared to the IR group and marked as a PR peak of interest if the difference in peak occurrence was eight or more. IR peaks of interest were identified similarly.

**Results:** Fifteen peaks met our initial criteria for difference in frequency between intrinsic and prerenal cases. From the fifteen, two were PR peaks and thirteen were IR peaks of interest. Mann-Whitney-U testing identified two peaks of significant variation between the PR and IR population: a PR peak with a m/z of 233 (p=0.0027) and an IR peak with a m/z of 372 (p=0.0027).

**Conclusions:** Point of care MS has the potential to rapidly differentiate PR from IR and potentially to further phenotype causes of AKI. Based on previous studies, the peaks we identified are likely small molecule metabolites. Additional sampling will enable the use of machine learning algorithms to classify the kidney disease that is present. Further correlation of the different analytes in prerenal and intrarenal AKIs is needed, however this study shows the potential utility of mass spectrometry to rapidly phenotype AKI in the clinical setting.

## TH-PO034

**Initiation of Terlipressin at Lower Serum Creatinine Levels Is Associated With Avoidance of Dialysis in Patients With Hepatorenal Syndrome Type 1**  
Juan Carlos Q. Velez,<sup>1</sup> Ira Kurtz,<sup>2,3</sup> John M. Vierling,<sup>4</sup> Stevan A. Gonzalez,<sup>5</sup> Khurram Jamil.<sup>6</sup> <sup>1</sup>Ochsner Health Network LLC, New Orleans, LA; <sup>2</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>3</sup>UCLA Brain Research Institution, Los Angeles, CA; <sup>4</sup>Baylor College of Medicine, Houston, TX; <sup>5</sup>Baylor Scott & White Health, Fort Worth, TX; <sup>6</sup>Mallinckrodt LLC, Clinton, NJ.

**Background:** Results from 3 North American, randomized, placebo (PBO)-controlled trials (RCTs [OT-0401, REVERSE, and CONFIRM]) demonstrated that terlipressin (TERLI) effectively reversed acute kidney injury (AKI) due to hepatorenal syndrome type 1 (HRS-1), and reduced the cumulative need for renal replacement therapy (RRT). However, factors associated with avoidance of RRT have not been formally examined.

**Methods:** A pooled analysis of the 3 RCTs in patients with HRS-1 (OT-0401, REVERSE, and CONFIRM) was conducted to compare the efficacy of TERLI + albumin vs. PBO + albumin. Logistic regression analysis was used to evaluate baseline characteristics associated with avoidance of RRT by Day 90. Numerical values were used as continuous variables. Patients who died without undergoing RRT were excluded to eliminate death as a potential confounder.

**Results:** In the pooled cohort, the following factors were significantly associated with a lower odds of avoidance of RRT by Day 90: a higher serum creatinine (SCr) level at study entry ([n=412], odds ratio [OR], 0.55; 95% CI: 0.44–0.68; P<.001) and higher scores for liver disease severity (Child Pugh score [n=393]; OR, 0.89; 95% CI: 0.80–0.99, P=.037; and MELD score [n=361]; OR, 0.96; 95% CI: 0.93–0.99; P=.010). Randomization to TERLI (n=412) was significantly associated with a greater odds of avoidance of RRT (OR, 1.57; 95% CI: 1.06–2.33; P=.025). In contrast, age, male sex, race, alcoholic hepatitis, baseline mean arterial pressure (MAP), serum sodium, serum albumin, total bilirubin, INR, prior albumin use, presence of precipitating factors for HRS, or prior use of midodrine/octreotide were not associated with avoidance of RRT. Among TERLI-treated patients, a higher SCr level (n=241; P<.001) and MELD score (n=213; P=.01) were significantly associated with a lower odds of avoidance of RRT. Among PBO-treated patients (n=171), a higher SCr level (P<.001) and lower MAP (P=.008) were associated with a lower odds of avoidance of RRT.

**Conclusions:** TERLI treatment at a lower SCr level and MELD score was associated with a greater probability of avoiding RRT by Day 90 in patients with HRS-1. Thus, initiation of TERLI in patients with a lower SCr may reduce the need for RRT in patients with AKI due to HRS-1.

## TH-PO035

**Impact of Terlipressin on Serum Sodium Levels in Patients With Hepatorenal Syndrome (HRS): The North American Experience**  
Shehzad N. Merwat,<sup>1</sup> Aftab Karim,<sup>3</sup> Muhammad W. Khattak,<sup>4</sup> Muhammad A. Mujtaba,<sup>1</sup> Zunaira Zafar,<sup>5</sup> Khurram Jamil.<sup>2</sup> <sup>1</sup>The University of Texas Medical Branch at Galveston Development Office, Galveston, TX; <sup>2</sup>Mallinckrodt Pharmaceuticals, Clinton, NJ; <sup>3</sup>Texas Health Presbyterian Hospital Dallas, Dallas, TX; <sup>4</sup>University of Illinois Chicago College of Medicine, Peoria, IL; <sup>5</sup>St. Mary Medical Center, Langhorne, PA.

**Background:** Hyponatremia is an electrolyte abnormality commonly observed in patients (pts) with advanced cirrhosis and is associated with a poor prognosis. HRS—a rapid kidney failure—occurs in pts with decompensated cirrhosis and ascites. In some pts with HRS, terlipressin (Terli) treatment successfully reversed HRS and improved renal function. However, hyponatremia has been previously reported as a common adverse event associated with Terli administration.

**Methods:** Data from the 3 largest (N=608), prospective, randomized, placebo-controlled, clinical studies in HRS (OT-0401, REVERSE, and CONFIRM) were pooled in a database and assessed in a subgroup analysis. Pts with HRS were randomly assigned to receive Terli or placebo (Pbo), both plus albumin. Overall and treatment-response-dependent changes in serum sodium levels were evaluated from baseline to end of treatment (EOT). Response (ie, HRS reversal) was defined as at least 1 serum creatinine (SCr) value of ≤1.5 mg/dL while on treatment. EOT was defined as the last date/time of treatment + 24 hours.

**Results:** Baseline characteristics were similar across treatment groups and were characteristic of advanced liver disease: in the Terli and Pbo groups, mean MELD (SD) scores were 33.0 (6.4) and 33.1 (5.9) and mean (SD) serum sodium levels were almost identical: 132.5 (6.1) mmol/L and 132.7 (6.0) mmol/L, respectively. By EOT, serum sodium levels increased significantly more in the Terli group vs the Pbo group, in general, and in all clinical response categories defined by changes in SCr (P≤.001; **Table**).

**Conclusions:** This subgroup analysis utilized the largest prospective database to evaluate the effects of Terli vs Pbo on serum sodium concentrations. In contrast to previous observations, by EOT, hyponatremia in pts with HRS improved to a significantly greater degree when treated with Terli vs Pbo. The improvement in serum sodium was greater in subjects who had a complete response vs a partial response.

**Funding:** Commercial Support - Mallinckrodt Pharmaceuticals

Group	Change in serum sodium level (mmol/L)		P-value
	Terli (n=338)	Pbo (n=246)	
All	Mean (SD) 4.3 (5.7)	2.0 (5.3)	<.001
Complete response <sup>a</sup>	n 116	42

## TH-PO036

**Impact of Fluid Overload on Patients Receiving Continuous Dialysis for AKI**

Samantha Gunning, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

**Background:** Fluid overload at the time of dialysis initiation for acute kidney injury (AKI) has been associated with dialysis dependence and mortality. This observation supports the view that there is a survival benefit associated with large fluid removal with dialysis (e.g. >10% of body weight); however, this has not been fully explored in the literature.

**Methods:** We conducted a single-center retrospective cohort study among adult patients admitted to the intensive care unit (ICU) at University of Chicago Medical Center with AKI treated with continuous veno-venous hemodialysis (CVVHD) from April 1, 2016 to March 31, 2020. We collected patient demographics, severity of illness, daily fluid balance in the 72 hours prior to and 7 days subsequent to CVVHD initiation, and ICU outcomes (duration of mechanical ventilation, length of stay, dialysis dependence, and mortality). Percent fluid overload was defined as total documented inputs minus outputs divided by weight on ICU admission.

**Results:** Cohort size was 1382 patients who were 42% female, 58% black, with an average age of 60 years. Average SOFA score was 8.5 at the time of ICU admission. In the 72 hours prior to CVVHD there was no association between percent fluid overload and 30-day mortality. In the 72 hour and 7 days after CVVHD start, there was a linear association between percent fluid overload and 30-day mortality with the lowest 30-day mortality among patients achieving greater than -10% fluid overload and highest among patient achieving greater than 10% fluid overload [Table].

**Conclusions:** Percent fluid overload at 72 hours and 7 days after starting CVVHD is associated with 30-day mortality. Those achieving the most substantial fluid removal had the highest 30 day survival.

**Funding:** Commercial Support - Fresenius Medical Care

Percent Fluid Overload at 72 hours prior to CVVHD, 72 hours after CVVHD, and 7 days after CVVHD

% Fluid Overload	72H Pre (%)	30-Day Mortality (%)	72H Post (%)	30-Day Mortality (%)	7D Post (%)	30-Day Mortality (%)

TH-PO037

**Impact of Hepatorenal Syndrome (HRS) Reversal on the Need for Renal Replacement Therapy (RRT): Analysis From 3 Phase 3 Terlipressin Studies**  
Muhammad A. Mujtaba,<sup>1</sup> Ann Kathleen N. Gamilla-Crudo,<sup>1</sup> Shehzad N. Mervat,<sup>1</sup> Michael Kueht,<sup>1</sup> Aftab Karim,<sup>3</sup> Muhammad W. Khattak,<sup>3</sup> Zunaira Zafar,<sup>4</sup> Khurram Jamil.<sup>2</sup> <sup>1</sup>The University of Texas Medical Branch at Galveston Development Office, Galveston, TX; <sup>2</sup>Mallinckrodt LLC, Clinton, NJ; <sup>3</sup>University of Illinois Chicago College of Medicine, Chicago, IL; <sup>4</sup>St. Mary Medical Center, Langhorne, PA.

**Background:** HRS is a progressive but potentially reversible kidney failure in patients (pts) with advanced cirrhosis. RRT is offered if pts fail pharmacotherapy; however, it is an invasive and costly intervention associated with increased morbidity in some pts. Terlipressin (Terli) is the standard-of-care treatment for pts with HRS based on the current US and European guidelines.

**Methods:** Data from 3 Phase 3, placebo (Pbo)-controlled clinical studies (OT-0401, REVERSE, and CONFIRM) were pooled (N=608) for subgroup analyses. Associations between HRS reversal—defined as at least 1 serum creatinine (SCr) value of  $\leq 1.5$  mg/dL while on treatment—and the need for RRT, overall and per treatment, were examined up to 90 days.

**Results:** By Day 90, 209 pts had received RRT (Terli, n=111; Pbo, n=98). Baseline characteristics were similar between treatment groups and typical of pts with advanced cirrhosis: mean (SD) MELD scores were 33.6 (6.4) and 33.2 (6.0) in the Terli and Pbo groups, respectively. Overall, HRS reversal was associated with a reduced need for RRT (Table). In pts who achieved HRS reversal, RRT incidence was similar between treatment groups. Yet, among nonresponders (ie, no HRS reversal), there was still a lower incidence of RRT in pts treated with Terli vs Pbo (Table). Mean (SD) changes in SCr from baseline to end of treatment among nonresponders were 0.1 (1.3) mg/dL in the Terli group vs 0.6 (1.4) in the Pbo group;  $P<.001$ .

**Conclusions:** This analysis evaluated the largest database of pts with HRS treated with Terli. Improved renal function resulted in a decreased need for RRT. Even among nonresponders, changes in renal function were significantly better in the Terli group vs the Pbo group and, therefore, Terli reduced the need for RRT in these pts vs Pbo.

**Porto-Pulmonary Hypertension and Decongestion in Norepinephrine-Treated Hepatorenal Syndrome Type 1**  
Terrance J. Wickman,<sup>1</sup> Adil Yousuf,<sup>1</sup> Muner Mohamed,<sup>1</sup> Juan Carlos Q. Velez.<sup>1,2</sup> <sup>1</sup>Ochsner Nephrology <sup>1</sup>Ochsner Medical Center, New Orleans, LA; <sup>2</sup>The University of Queensland Ochsner Clinical School, Brisbane, QLD, Australia.

**Background:** Porto-pulmonary hypertension (PoPHTN) is a complication of cirrhosis that can lead to venous congestion. Contrary to traditional dogma, we previously reported that in patients with acute kidney injury (AKI) due to hepatorenal syndrome type 1 (HRS-1), addition of IV furosemide (FURO) to vasoconstrictor therapy with norepinephrine (NE) results in enhanced diuresis without worsening the course of AKI. We aimed to examine the relationship between PoPHTN and AKI course and response to FURO in NE-treated HRS-1.

**Methods:** We searched records of patients with HRS-1 treated with NE as a vasoconstrictor who during the course of AKI underwent echocardiography with an estimate of pulmonary artery systolic pressure (PASP) over a 3-year period. PoPHTN was defined as echo-based PASP > 35 mmHg and absence of reduced left ventricular ejection fraction (rLVEF) or left ventricular diastolic dysfunction (LVDD). Outcomes examined were association of PoPHTN with need for dialysis (AKI-RRT) and influence of PoPHTN on the correlation between NE-induced MAP rise and FURO-enhanced diuresis.

**Results:** Among 39 patients with HRS-1 treated with NE, 26 had echo-based PASP, 9 (35%) had PoPHTN (5 confirmed by right heart catheterization); 4 had reduced right ventricular systolic function, 1 rLVEF and 1 LVDD. Five of 9 (55%) of those with PoPHTN reached AKI-RRT compared to 4 of 17 (24%) without PoPHTN ( $p=0.11$ ). Of the 26 patients, 19 received FURO [median 160 (80-240) mg q 12 (8-24) hrs] for decongestion. Urine output (UOP) response correlated with NE-induced MAP rise ( $r=0.62$ ,  $p=0.004$ ). The correlation between UOP and MAP rise among those with PoPHTN ( $n=9$ , median PASP 45,  $r=0.84$ ,  $p=0.009$ ) was stronger than that observed in those without PoPHTN ( $n=10$ , median PASP 27,  $r=0.53$ ,  $p=0.09$ ). Furthermore, PoPHTN with concomitant estimated central venous pressure (CVP) 8-15 mmHg ( $n=4$ ) was associated with greater UOP response to MAP rise compared to absence of PoPHTN with CVP 3 mmHg ( $n=4$ ) (252 vs 101 ml/mmHg,  $p=0.0008$ ).

**Conclusions:** PoPHTN may be present in 1/3 of patients with HRS-1 and it is associated with greater dependence of the UOP response to FURO to the NE-induced MAP rise. Presence of PoPHTN should be assessed to guide decongestive strategies in the management of AKI due to HRS-1.

TH-PO039

**Multi-Center Study to Assess the Safety of a Selective Cytopheretic Device (SCD) for Treatment of Immunomodulatory Dysregulation due to AKI in Children  $\geq 10$  and  $\leq 20$  kg: Report From the First 4 Patients**  
Kelli A. Krallman,<sup>1</sup> Xavier French,<sup>1</sup> H. David Humes,<sup>2</sup> David J. Askenazi,<sup>3</sup> Lenar T. Yessayan,<sup>2</sup> Michaela Collins,<sup>1</sup> Jessica Potts,<sup>3</sup> Stuart Goldstein.<sup>1</sup> <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>University of Michigan Medical School, Ann Arbor, MI; <sup>3</sup>Benjamin Russell Hospital for Children, Birmingham, AL.

**Background:** Acute kidney injury (AKI) that requires continuous kidney replacement therapy (CKRT) is a highly lethal condition in critically ill patients. Despite improvements in acute care and dialysis therapies, the mortality rate from the past four decades has not improved. In a previous single treatment arm study of children on CKRT treated with SCD > 20 kg, 12/16 subjects survived to ICU discharge, all of whom were dialysis independent by day 60. We now report outcomes in findings the first 4 treated patients < 20 kg.

**Methods:** 4 center US study of SCD in children that weigh between  $\geq 10$  and  $\leq 20$ kg, have a clinical diagnosis of AKI requiring CKRT and at least one non-renal organ failure. With these subjects the SCD was integrated post CKRT membrane, changed daily, and circuit ionized calcium (iCa) maintained <0.4 mmol/L. Subjects received SCD treatment for up to 10 days or CKRT discontinuation, whichever came first.

**Results:** 5 patients (2F/3M) have been enrolled since 07/2021. Four patients (Age 1.6 - 10.4 years. PRISM-2 Score range = 14-27) received SCD therapy. Three of these patients received SCD on a PRISMAFLEX™ one on a PRISMAX™ machine. Circuit iCa has been maintained at <0.4 mmol/L during 81% of therapy. Three of the four patients demonstrated renal recovery after SCD therapy, coming off all forms of KRT within 5 days post SCD therapy. Of the patients that have reached day 60, both were dialysis independent. The fourth patient died after SCD therapy had ended but before ICU discharge. An additional patient was enrolled but did not continue with SCD because their iCa was not in range due to citrate intolerance. No SCD-related serious adverse events have been reported.

**Conclusions:** Our initial findings suggest that SCD is safe in critically ill pediatric patients weighing between 10-20kg.

Patient Information

Patient Number	Age (yrs)	Weight (kg)	Diagnosis	Final Outcome
1	1.9	14.1	Shock and pancytopenia	Alive with renal recovery
2	1.7	12	Necrotizing pneumonia	Deceased
3	10.4	16.5	Status epilepticus	Alive with renal recovery
4	3.5	14.3	Bowel perforation and septic shock	Ongoing but off KRT

TH-PO040

**Delay in Renal Replacement Therapy Initiation in Critically Ill Patients With AKI: A Secondary Analysis of the STARRT-AKI Trial**  
Rachel Jeong,<sup>1,2</sup> Andrea K. Harvey,<sup>3</sup> Brian Kirkham,<sup>4</sup> Sean M. Bagshaw,<sup>5</sup> Ron Wald.<sup>6,7</sup> The STARRT-AKI Investigators <sup>1</sup>Department of Critical Care Medicine, University of Calgary, Calgary, AB, Canada; <sup>2</sup>Division of Nephrology, University of Calgary, Calgary, AB, Canada; <sup>3</sup>Department of Medicine, University of Toronto, Toronto, ON, Canada; <sup>4</sup>Applied Health Research Centre, St. Michael's Hospital, Toronto, ON, Canada; <sup>5</sup>Department of Critical Care Medicine, University of Alberta, Edmonton, AB, Canada; <sup>6</sup>Division of Nephrology, St. Michael's Hospital and the University of Toronto, Toronto, AB, Canada; <sup>7</sup>Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, AB, Canada.

**Background:** The STARRT-AKI trial demonstrated that earlier initiation of renal-replacement therapy (RRT) does not lead to improved outcomes as compared to a strategy of watchful waiting until a conventional indication arises. However, in patients with persistent acute kidney injury (AKI), the safety of prolonged delay in RRT initiation is unclear. We hypothesized that protracted delays in RRT initiation would be associated with excess mortality. Our objective was to determine the association between relative delay to RRT initiation and outcomes among patients randomized to the standard-strategy in STARRT-AKI.

**Methods:** We conducted a post-hoc secondary analysis of the standard-strategy group in STARTR-AKI. The exposure was time from randomization to RRT initiation, in quartiles. The primary outcome was all-cause mortality at 90 days after randomization. The association between time to RRT initiation and the outcomes were described as adjusted odds ratios (aOR) or adjusted mean differences (aMD), as appropriate.

**Results:** There were 1462 patients in the standard-strategy group, of whom 903 (62%) received RRT. Median time (IQR) to RRT initiation was 12.1 (8.3-13.8), 24.5 (21.8-26.5), 46.8 (35.2-52.1), and 96.1 (76.7-139.2) hours across quartiles 1 through 4, respectively. Compared to patients in quartile 1, longer delay to RRT initiation was associated with lower 90-day mortality in quartiles 3 and 4 (aOR [95% CI] 0.52 [0.35-0.77] and 0.63 [0.42-0.94], respectively). There were no significant differences in RRT dependence, number of RRT-free or hospitalization-free days at 90 days. Patients in quartile 4 had longer durations of ICU and hospital stay (aMD [95% CI] 8.26 [5.77-10.74] and 12.42 [7.59-17.25] days, respectively), relative to quartile 1.

**Conclusions:** Among patients with persistent AKI, delay in RRT initiation was not associated with excess mortality, however, was associated with longer durations of ICU and hospital stay.

**Funding:** Government Support - Non-U.S.

## TH-PO041

### Endotoxin Removal Therapy With Polymyxin B Immobilized Fiber Column as a Flowchart Protocol Strategy for Endotoxic Shock

Silvia De Rosa,<sup>1,2</sup> Anna Lorenzin,<sup>1,2</sup> Massimo de Cal,<sup>1,2</sup> Marta Proglia,<sup>1</sup> Nicola Marchionna,<sup>1</sup> Claudio Ronco,<sup>2,1</sup> Monica Zanella.<sup>1,2</sup> <sup>1</sup>*Ospedale San Bortolo di Vicenza, Vicenza, Italy;* <sup>2</sup>*International Renal Research Institute of Vicenza, Vicenza, Italy.*

**Background:** Endotoxin-induced sepsis is a leading cause of ICU mortality. From 1994 to present, Polymyxin B-hemoperfusion (PMX-HP) is available as an adjuvant therapeutic option. PMX-HP is also an immunomodulatory blood purification. The aim of this study was to evaluate the role of diagnostic-therapeutic flowchart for the use of endotoxin neutralization by Polymyxin B Hemoperfusion.

**Methods:** We conducted a prospective, observational web-based database analysis (EUPHAS2 registry), single centre basis, of critically ill patients admitted to the ICU between January 2016 until to May 2021 who were affected by endotoxic shock caused by proved or suspected infection related to Gram negative bacteria and received PMX-HP as per clinical indication of the attending physician. Patients were divided based on the use of diagnostic-therapeutic flowchart in two groups: Pre-Flowchart (Pre-F) and Post-Flowchart (Post-F).

**Results:** 61 patients were treated with PMX-HP out of 531 who received diagnosis of septic shock. The most common source of infection was secondary peritonitis (36.0%) followed by community acquired pneumonia (29.0%). We identified gram negative bacteria in most of the microbiological culture (N=59, 51%), followed by gram positive bacteria in (N=31, 27%), fungi (N=11, 9%) and no growth (N=15, 13%). In both groups, SOFA score progressively improved over the next 120h following PMX-HP and it was associated with endotoxin activity levels (EA) decrease. Particularly, in the Post-F Group EA decreased from 0.71 [0.64-0.80] at T0 to 0.56 [0.45-0.66] at T120. Particularly, in Post-F group a lower 28-day mortality [21%], ICU [29%] and lower 90-day mortality [29%] compared to Pre-F group [30%] were observed.

**Conclusions:** In critically ill patients with endotoxic shock, PMX-HP was associated with organ function recovery, hemodynamic improvement and contemporary EA level reduction.

Trend of EAA and PCT in Pre-F and Post-F groups.

## TH-PO042

### Safety and Clinical Efficacy of Plasma-Saving Membrane-Based Therapeutic Plasma Exchange (mTPE) in the Critically Ill Patients Undergoing Continuous Renal Replacement Therapy

Jae Sung Ahn, Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.

**Background:** The mTPE eliminating endotoxin, cytokine and abnormal antibody could be beneficial. To minimize adverse reaction caused by fresh frozen plasma (FFP) and bleeding risk, we used 5-20% albumin, crystalloid fluid and 8 units of FFP as replacement solution. We investigated bleeding event, the changes of platelet count, prothrombin time (PT), activated partial thromboplastin time (aPTT) and 28-Day mortality rate as primary outcome.

**Methods:** In this retrospective study, 118 mTPE sessions were performed in 60 patients (age 59.6±14.4 years, M:F=34:26) undergoing CRRT and receiving antibiotics and vasopressors for severe sepsis/shock (n=43), inflammatory disease (n=12) and others (n=5). Our subjects were divided into four groups according to the SOFA score: I (0-9, predicted mortality rate <10%), II (10-12, 10-30%), III (13-14, 40-60%), and IV (15-24, > 75%). mTPE was repeated with the interval of 24-48 hours up to 10 times, if needed.

**Results:** There was no significant difference in SOFA scores, mean arterial pressure, vasopressor index score and PT. The hemoglobin (8.8±2.0 vs. 8.4±2.0 g/dL, p=0.021) and platelet count (96K±101K vs. 80K±86K /mm<sup>3</sup>, p=0.001) were significantly decreased after 1st mTPE. aPTT was significantly increased from 62.7±38.6 to 74.5±41.2 seconds (p=0.037). The similar changes persisted after 2nd mTPE. However, there was no bleeding event within 24 hours from the end of mTPE sessions. The 28-Day mortality rates were 22.2%, 12.5%, 0% and 67.6% in the 4 groups, respectively. Analyzing survival according to the number of mTPE application, 14 patients survived among 29 who received only one time of mTPE and 4 among 20, two times of mTPE. Only 2 patients survived among 11 who received three time or more of mTPE.

**Conclusions:** Despite aPTT prolongation and decreased hemoglobin and platelet count, no bleeding events and lower-than-expected mortality suggest that mTPE could be safe and beneficial in these patients.

## TH-PO043

### Reduction of Intra-Operative Nephrotoxic Antimicrobial Exposure Can Improve Renal Recovery in Patients Undergoing Heart Transplantation

Syed M. Quadri, Ashley Golbus, Blaithin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

**Background:** Acute Kidney Injury (AKI) is very common complication after orthotopic heart transplant (OHT) with reported incidence of approximately 40-70%. Antibiotics, particularly Piperacillin-tazobactam and vancomycin (VPT) combination has been associated with 3-fold increased hazard ratio for AKI. We hypothesized that reducing the exposure of intra-operative nephrotoxic antimicrobial medication exposure may result in lower rates of AKI after OHT.

**Methods:** Single-center, prospective, non-randomized, open-label observation study was performed at Medical University of South Carolina (MUSC) between 04/2015 to 04/2021. We introduced an intra-operative protocol change from VPT to cefepime and vancomycin (VC) use. 48 patients undergoing adult OHT received intra-operative VPT between 04/2015-05/2019, labelled as pre-intervention arm. 72 patients undergoing OHT between 05/2019-04/2021 received intra-operative VC, labelled as post-intervention arm. AKI was defined as per KDIGO 2012 criteria. Renal recovery was defined as 25% improvement in serum creatinine within 7 days of surgery without kidney replacement therapy (KRT) or KRT cessation in those requiring KRT. Major adverse kidney events (MAKE) were assessed at hospital discharge and 12-months. A p-value of less than 0.05 was considered significant.

**Results:** Rates of all stages of KDIGO AKI and rates of RRT remained the same after the intervention. The rates of renal recovery prior to hospital discharge improved 3.8-fold in the post-intervention group (79.3% vs 44.4%, P<0.05). All patients who required KRT in pre-intervention group did not recover at one-week post-OHT (0% vs 31.25%, P < 0.05). MAKE were less in post-intervention group at hospital discharge (p<0.05). 27% of blood cultures were positive in pre-interventional arm compared to 22% in post-interventional arm (p=0.66). There was no positive enterococcal blood culture in post-interventional arm.

**Conclusions:** Our results suggest that high doses of VPT combination lead to poor AKI recovery rates and significant MAKE at hospital discharge in OHT patients as compared to VC. Though this results in loss of enterococcal coverage, none of the patients grew enterococcal species in blood cultures. The mechanism by which the combination VPT contributes to poor renal recovery requires further research.

## TH-PO044

### Efficacy of Regional Citrate vs. Heparin Anticoagulation in Patients With AKI Requiring Continuous Renal Replacement Therapy: A Randomized Study

Anil Bhalla, Gaurav M. Bhandari, Vaibhav Tiwari, Vinant Bhargava, Anurag Gupta, Manish Malik, Ashwani Gupta, Devinder S. Rana. *Sir Ganga Ram Hospital, New Delhi, India.*

**Background:** For the functioning of any Renal replacement treatment (RRT) and adequate hemoperfusion, it needs anticoagulation to prevent the extracorporeal circuit from clotting. Although heparin is cheap and easy monitoring can be done, bleeding risks are high. Regional citrate anticoagulation (RCA) acts only in the extracorporeal circuit and thus appears safe.

**Methods:** A RCT was conducted in the Intensive Care Unit of this hospital. AKI patients requiring CRRT were randomized into 2 groups based on anticoagulation used. Group 1 - RCA as anticoagulation while group 2 was the heparin group. A total of 52 patients were taken, equally divided into two groups. Efficacy and safety parameters were analyzed in both groups. **Outcome measures:** Filter lifespan, effective delivered RRT dose, number of bleeding episodes, hypocalcemia, citrate toxicity (ratio of total calcium to ionized calcium), and metabolic complications.

**Results:** Demographic data were comparable amongst both the groups. Sepsis was the most common cause of hospital admission in both groups (38.5% vs 50%). Oliguria was the most common indication for CRRT (53.8% in the RCA group and 61.5% in the heparin group). Mean filter lifespan in the RCA group was 45.11 hours while in the heparin group was 26.11 hours and it was clinically significant (P <0.001). The mean effective delivered RRT dose was higher in the RCA group (26 ml/kg/hour) compared to

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

the heparin group (24.23 ml/kg/hour) and was clinically significant ( $P < 0.001$ ). Bleeding was higher in the heparin group than RCA group (42.3% vs 11.5%) and it was clinically significant ( $P = 0.027$ ). 4 patients (15.4%) experienced hypocalcemia in the RCA group but were corrected with calcium and decreasing RCA dose. Zero cases of citrate toxicity were seen and only two patients (7.7%) were found to have metabolic alkalosis which was also corrected by reducing the RCA dose and stopping bicarbonate infusion if going on.

**Conclusions:** In critically ill patients with AKI on CRRT, regional citrate anticoagulation, when compared to systemic heparin, is safe and more effective than heparin. Heparin was associated with significant bleeding complications and increased heparin-induced thrombocytopenia episodes.

## TH-PO045

### Urea Reduction in AKI and Mortality

Jonathan Chavez,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>2</sup> Pablo Maggiani,<sup>1</sup> José David G. Barajas,<sup>1,2</sup> Miguel Ángel P. Venegas,<sup>1,2</sup> Ramon Medina,<sup>1,2</sup> María de la luz Alcantar Vallín,<sup>1,2</sup> Alexa N. Oseguera Gonzalez,<sup>1,2</sup> César Murguía Soto,<sup>1,2</sup> Karina Renoirte,<sup>1,2</sup> Guillermo García-García,<sup>1</sup> <sup>1</sup>Universidad de Guadalajara, Guadalajara, Mexico; <sup>2</sup>Hospital Civil de Guadalajara, Guadalajara, Mexico.

**Background:** Urea is a toxin present in AKI. It is reasonable to think that its decrease could be associated with better clinical evolution. We explore the association between urea reduction and mortality in patients with AKI

**Methods:** In this prospective cohort in AKI patients. We create 4 groups of urea reduction (UrR) by their percentage decrease magnitude: 0, 1-25, 26-50 and >50. The objectives was to assess the association of UrR and mortality within 10 days of admission; find the characteristics of patients with UrR >50% and identify which KRT modality (hemodialysis, peritoneal dialysis and conservative) achieved this goal

**Results:** A total of 651 AKI patients were included. AKI stage 3 was present in 58.5%, sepsis in 45.9%, the mean urea value was 154 mg/dL, kidney replacement therapy (KRT) started in 32.4%, and 18.9% died. 50% did not reduce urea (UrR 0%). A trend to decrease risk of death was observed with the magnitude of UrR. The best survival (94.3%) was observed in those with UrR >50%, and worst (72.1%) in those with UrR 0%. After adjusting for confounders, 10-day hospital mortality was higher in groups that did not achieve a UrR of at least 25% with an OR of 1.20. Subgroups of patients who achieved UrR >50% were those with uremic and obstructive nephropathy.

**Conclusions:** In our prospective cohort 50% with AKI did not reduce urea, and this was associated with an increased risk of death. Achieving UrR of at least 25% decreased the risk, and a greater magnitude of UrR with any treatment was associated with better survival.

Urea reduction in AKI and mortality risk

Subgroup analysis of patients with urea reduction >50% with kidney replacement therapy, conservative management and mortality

## TH-PO046

### Serum Potassium Trajectory During AKI and Mortality

Jonathan Chavez,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>2,1</sup> Pablo Maggiani,<sup>1</sup> Bladimir Diaz Villavicencio,<sup>1,2</sup> Ana E. Oliva,<sup>1,2</sup> Frida Margarita de la Vega Méndez,<sup>1,2</sup> Guillermo García-García,<sup>1</sup> Clementina Elizabeth Calderon García,<sup>1,2</sup> Manuel L. Prieto Magallanes,<sup>1,2</sup> Alejandro Martínez Gallardo González,<sup>1,2</sup> Alexia Romero,<sup>1,2</sup> <sup>1</sup>Universidad de Guadalajara, Guadalajara, Mexico; <sup>2</sup>Hospital Civil de Guadalajara, Guadalajara, Mexico.

**Background:** The association between potassium (sK) trajectory and mortality or the need for kidney replacement therapy (KRT) during acute kidney injury (AKI) has not been explored

**Methods:** In this prospective cohort study, AKI patients were divided in 8 groups based on sK (mEq/L) trajectories, (1) normoK, sK between 3.5-5.5; (2) corrected hyperK, sK > 5.5 to normoK; (3) corrected hypoK, sK < 3.5 to normoK; (4) fluctuating potassium, sK increased / decreased in and out of normoK; (5) uncorrected hypoK, sK < 3.5; (6) normoK to hypoK, sK normal and decreased to hypoK; (7) normoK to hyperK, (8) uncorrected hyperK, sK > 5.5. We assessed the association of sK trajectories with mortality and the need for KRT

**Results:** In 311 AKI patients. AKI 3 was present in 63.9%. KRT started in 36%, and 21.2% died. After adjusting for confounders, 10-day hospital mortality was higher in group 7 and 8 (OR, 1.37 and 1.63  $p < 0.05$ , respectively), and KRT initiation was higher in group 8 (OR 1.40  $p < 0.05$ ) compared with group 1. Mortality in different subgroups of patients did not change the primary results

**Conclusions:** In our prospective cohort, most patients with AKI had dyskalemia. NormoK to hyperK and Uncorrected hyperK were associated with death, while only uncorrected hyperK was correlated with the need for KRT

Potassium trajectories	Model 1 <sup>a</sup> OR (95% CI)	P value	Model 2 <sup>b</sup> OR (95% CI)	P value

### Serum Sodium Trajectory During AKI and Mortality Risk

Jonathan Chavez,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>1,2</sup> Edgar J. Carmona,<sup>1,2</sup> Manuel Arizaga Napoles,<sup>1,2</sup> Karla Hernandez Morales,<sup>1,2</sup> Guillermo García-García,<sup>1</sup> Alejandro Martínez Gallardo González,<sup>1,2</sup> Marcela Plascencia Cruz,<sup>1,2</sup> Fidel Ramos Avellaneda,<sup>2,1</sup> <sup>1</sup>Universidad de Guadalajara, Guadalajara, Mexico; <sup>2</sup>Hospital Civil de Guadalajara, Guadalajara, Mexico.

**Background:** The association between serum sodium (sNa) level and mortality or the need for kidney replacement therapy (KRT) during acute kidney injury has not been explored

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only  
Underline represents presenting author.

**Methods:** In this prospective cohort, we enrolled AKI patients and divided them into 5 groups based on the sNa level trajectories up to 10 days, 1) stable Na (135-145), 2) fluctuating Na levels (increased/decreased in and out of normonatremia), 3) uncorrected hyponatremia, 4) corrected hyponatremia, and 5) uncorrected hypernatremia. We assessed the association of sNa trajectories with mortality and the need for KRT

**Results:** A total of 288 patients were included. AKI3 was present in 50.4%. KRT started in 25% patients, and 15.6% died. After adjusting for confounders, 10-day hospital mortality was higher in group 5 (HR 3.12,  $p = 0.03$ ), and KRT initiation was higher in group 3 (HR, 2.44;  $p = 0.03$ ) compared with group 1

**Conclusions:** In our cohort, most patients with AKI had alterations in sNa. Uncorrected hypernatremia was associated with death, and uncorrected hyponatremia was correlated with the need for KRT

HRs unadjusted for 10-day mortality in different patient subgroups with uncorrected hypernatremia and KRT initiation HRs unadjusted need for KRT initiation in different subgroups of patients with uncorrected hyponatremia

### Temporal and External Validation of the Prediction Model for Successful Discontinuation of Continuous Renal Replacement Therapy

Minsuk Seo, Sehun Lee, Sung Bin Yoon, Junseok Jeon, Jung eun Lee, WooSeong Huh, Yoon-Goo Kim, Hye Ryoung Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

**Background:** Continuous renal replacement therapy (CRRT) is widely used as a preferred modality of renal replacement therapy (RRT) in critically ill patients with acute kidney injury (AKI). However, there is no consensus criterion for discontinuing CRRT. We evaluated the usefulness of the prediction model developed in our previous study through one temporal cohort and four external cohorts.

**Methods:** A total of 1517 critically ill patients with AKI who underwent CRRT from 2018 to 2020 in five medical centers were included in the validation. Patients who underwent CRRT for more than 2 days and survived for 7 or more days after CRRT discontinuation were selected. Successful discontinuation of CRRT was defined as not restarting RRT for 7 days after CRRT discontinuation. The prediction model was composed of four variables: urine output ( $\geq 300$  mL/day, score 4) on the day before discontinuation and blood urea nitrogen (BUN  $< 35$  mg/dL, score 2), serum potassium ( $< 4.1$  mmol/L, score 1), and mean arterial blood pressure (50-78 mmHg, score 1) on the discontinuation day.

**Results:** The prediction model showed area under the curve of the receiver-operating characteristic (AUC-ROC) curve 0.74 (95% CI 0.71-0.76) in pooled analysis of all cohorts. Overall differences between observed and predicted incidence rates were 3.0% (17.7% observed and 16.9% predicted probability), 3.6% (35.2% and 34.8%), and 2.0% (69.3% and 70.3%) in the low- (0-2 points), intermediate- (3-5 points), and high-score (6-8 points) groups, respectively. In an analysis of each cohort, four cohorts including one temporal cohort showed similar good discriminatory power (AUC-ROC 0.770, 0.731, 0.735, and 0.725, respectively), while one cohort showed poor discriminatory power (AUC-ROC 0.556).

**Conclusions:** Our prediction model for successful discontinuation of CRRT in critically ill patients showed good performance in one temporal and three external cohorts, with poor performance in one external cohort. Our results support the need of an appropriate protocol for the discontinuation of CRRT.

## TH-PO049

### A Comparison Among Adult Patients Receiving Extracorporeal Membrane Oxygenation With and Without Continuous Renal Replacement Therapy at an Integrated Healthcare System

Waleed Zafar, Evan Gajkowski, Kaushal V. Solanki, Alex R. Chang, Maria Bermudez. *Geisinger Health, Danville, PA.*

**Background:** Extracorporeal Membrane Oxygenation (ECMO) is being increasingly used among critically ill patients some of whom have multiple organ failure and need concurrent use of continuous renal replacement therapy (CRRT). Limited data are available regarding outcomes among such patients.

**Methods:** We report retrospective data on patients who were treated with ECMO with or without CRRT over a period of 36 months (Jan 2019 – Mar 2022) at hospitals within a single integrated healthcare system in Pennsylvania. Patients with end stage renal disease were not eligible to receive ECMO within this system.

**Results:** 166 patients were treated with ECMO of whom 50 (30.1%) received CRRT during the course of their treatment. Mean age of patients on ECMO was 52.1 years (interquartile range 43-64), 68.1% were male; and 23.5% had Covid-19. Reasons for ECMO included cardiac arrest (43%), post cardiac surgery (18%), acute respiratory distress syndrome (38%) and transcatheter aortic valve placement (2%). Patients received either Venoarterial (VA) ECMO (45.8% patients; mean age 60.0) and its variant extracorporeal cardiopulmonary resuscitation (eCPR) (9.6%; mean age 50.9) or Venovenous (VV) ECMO (44.6%; mean age 44.4). A comparison among patients who needed CRRT versus those who did not is provided in figure 1. 38% patients who received CRRT survived to discharge compared to 62.9% who did not receive CRRT ( $p=0.003$ )

**Conclusions:** Nearly 1 in 3 patients treated with ECMO needed CRRT at some point during their care. Patients who needed CRRT on ECMO were significantly less likely to survive to discharge. Nephrology service was involved in the care of ECMO patients from the beginning in some cases. However, there remains a need for early multi-disciplinary care for critically ill patients requiring ECMO therapy.

Table 1: Characteristics and outcomes among all patient on ECMO who were also on CRRT versus those who never received CRRT

	Received CRRT along with ECMO (50 patients)	Did not need CRRT while on ECMO (116 patients)
Male, n (%)	39 (78.0)	74 (63.8)
Age, years mean (minimum; maximum)	55.0 (20; 82)	50.9 (18; 82)
Age above 65 years, n (%)	16 (32.0)	24 (20.7)
Type of ECMO, n (%)		
VA	33 (66)	43 (37.1)
eCPR	6 (12)	10 (8.6)
VV	11 (22)	63 (54.3)
Covid-19 positive, n (%)	5 (10)	34 (29.3)
Time on ECMO, days; mean (95% confidence interval)	8.27 (6.57 – 9.97)	9.36 (7.47 – 11.25)
Survived ECMO, n (%)	30 (60.0)	80 (69.0)
Survived to discharge, n (%)	19 (38.0)	73 (62.9)
Alive at the time of data extraction	17 (34.0)	70 (60.3)

CRRT: Continuous renal replacement therapy; ECMO: Extra corporeal membrane oxygenation; VV: Venovenous; VA: Venoarterial; eCPR (extracorporeal cardiopulmonary resuscitation) a version of VA ECMO.

## TH-PO050

### Point of Care Creatinine for Community-Acquired AKI in Africa: Study Design

Dimitrios J. Poulidakos,<sup>1</sup> Ibi Erekosima,<sup>1</sup> Prelador E. Fakrogha,<sup>2</sup> David M. Lewis,<sup>1</sup> Agiriye Agba M. Harry,<sup>3</sup> Pedro C. Emem-Chioma.<sup>2</sup>  
<sup>1</sup>Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom;  
<sup>2</sup>University of Port Harcourt, Choba, Nigeria; <sup>3</sup>Rivers State of Nigeria Government, Port Harcourt, Nigeria.

**Background:** Community acquired Acute kidney injury (AKI) is associated with adverse outcomes in low and middle-income countries due to delayed diagnosis and lack of universal health care coverage. Supported by the International Society of Nephrology, in a collaborative project between a UK renal centre and a renal centre and the primary care health board in Port Harcourt Nigeria, we evaluated point of care creatinine (POC Cr) technology using capillary samples (<https://doi.org/10.1016/j.ekir.2022.03.022>).

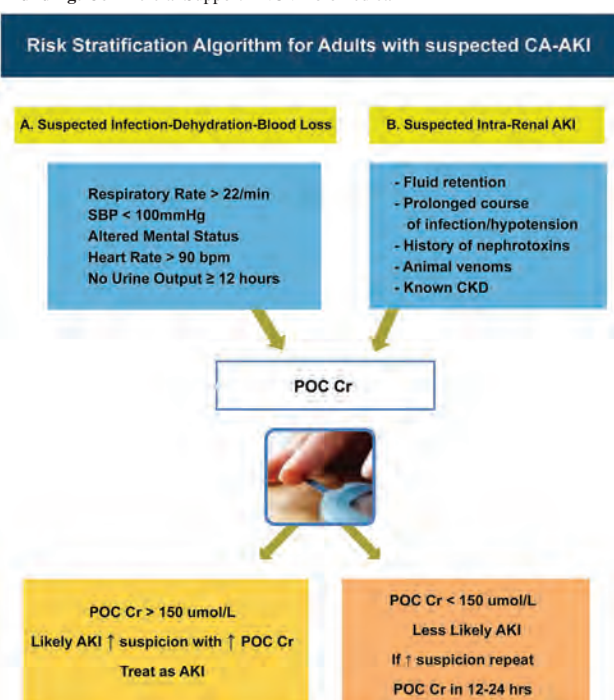

This phase of the project is designed to evaluate the use of POC Cr in conjunction with a minimum bundle of AKI care in a large primary care health centre in Nigeria that does not provide renal function tests.

**Methods:** Attendances data for March 2022 were obtained from the Ozuoba Comprehensive Health Centre in Nigeria. A 2 stage, modified delphi process, will be used to reach consensus amongst primary and secondary care clinicians on clinical algorithm and minimum AKI bundle. We plan to screen with POC Cr 500 patients at risk (Figure 1) with the aim to detect > 100 AKI cases.

**Results:** Out of 4148 recorded patient attendances, (20.3% medical, 18.8% obstetrics and 60.8% paediatrics), 464 (11.1%) were acute requiring short admission and 19 patients were referred to the hospital. The first stage of the consensus process concluded that the minimum AKI bundle will include renal function testing, urine dipstick, IV fluids and/or antibiotics for 48 hours if required. The second stage will be performed at a workshop in Port Harcourt in 2022.

**Conclusions:** This study will assess the cost-effectiveness and clinical impact on outcomes of POC Cr as a triage screening tool in acute presentations in this low-resource primary setting in conjunction with a minimum care bundle.

## TH-PO051

### Multidisciplinary Care Improves Follow-Up for AKI Survivors

Heather P. May, Diana J. Schreier, Joseph Herges, Kianoush Kashani, Andrea G. Kattah, Rozalina G. McCoy, Brenda K. Anderson, Laurie A. Meade, Angeliki G. Tinaglia, Kristin C. Mara, Andrew D. Rule, Erin F. Barreto. The ACT Study Group *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Innovative models are needed to address significant gaps in kidney care follow-up for AKI survivors.

**Methods:** The AKI in Care Transitions (ACT) pilot included adults with stage 3 AKI, discharged to home without dialysis. ACT included pre-discharge education and care coordination and post-discharge follow-up in primary care with a clinician and pharmacist within 14 days (Figure 1). ACT was implemented in phases (Usual Care, Education, ACT) for group comparisons. The primary outcome was feasibility, measured by the proportion of participants who received the phase-appropriate intervention components. Secondary outcomes at 14 and 30 days were compared across groups using the Fisher's exact or Kruskal-Wallis tests.

**Results:** 46 of 110 (42%) eligible adults were enrolled (Table 1). Education was completed in 18/18 and 14/15 participants in the Education and ACT groups, respectively. The cumulative incidence of provider and laboratory follow-up at 14 and 30 days was significantly different across groups [14 days: Usual care 0%, Education 11%, ACT 73% ( $p < 0.01$ ); 30 days: 0%, 22%, and 73% ( $p < 0.01$ )].

**Conclusions:** Multidisciplinary post-AKI care improved timely laboratory and provider follow-up in the primary care setting. This was driven by compliance with best-practice recommendations for urine protein evaluation, a key indicator of prognosis and therapeutic needs.

**Funding:** NIDDK Support, Other NIH Support - National Institute of Allergy and Infectious Diseases (K23 AI143882, PI: E.F.B.), the Agency for Healthcare Research and Quality (HS028060-01, PI: E.F.B.), Private Foundation Support

### Improving Patient-Centered Care in Pediatric AKI

Anna E. Williams, Rasheed A. Gbadegesin, Clarissa J. Diamantidis. *Duke University School of Medicine, Durham, NC.*

**Background:** Acute kidney injury (AKI) is the sudden loss of kidney function and is a common complication of pediatric hospitalizations, affecting approximately 5-10% of all children admitted to the hospital. Despite a persistent risk of adverse outcomes following hospital discharge, providers infrequently provide education to patients or families on how best to manage AKI once they return home. We sought to identify providers' perceived challenges to pediatric AKI care in order to inform optimal patient-centered AKI care strategies.

**Methods:** Physician stakeholders experienced with pediatric AKI were recruited from a single academic center in Durham, North Carolina in June and July 2020 to participate in semi-structured interviews via phone. Interviews assessed perceived barriers and facilitators to post-AKI care for pediatric survivors. The interview guide was developed by the study team using adult learning theory and included open-ended questions. All interviews were recorded and transcribed prior to analysis by the study team for theme identification.

**Results:** Ten physician interviews—4 of outpatient pediatricians and 6 of pediatric nephrologists—were conducted in summer 2020. Providers relayed several themes related to post-AKI care: patient awareness of AKI diagnosis is low, family concerns (e.g. child's prognosis, underlying cause of AKI) often arise during AKI discussions, gaps exist in non-subspecialists AKI knowledge, pediatricians rely on subspecialists for co-management of AKI, and pediatric nephrologists readily offer AKI education. Of these themes, low AKI diagnosis awareness and provider knowledge gaps were considered barriers to optimal post-AKI care. Participants also expressed that these barriers were particularly evident when reflecting on AKI care in the neonatal intensive care unit (NICU).

**Conclusions:** Both pediatric nephrologists and general pediatricians identified patient lack of awareness of diagnosis as a barrier to optimal post-AKI care. Patient-centered educational tools promoting AKI awareness and self-management may improve long-term outcomes for pediatric AKI survivors.

**Funding:** Other NIH Support - NHLBI R38HL143612

## TH-PO053

### Four-Year Report on Renal Outcomes Following Elective Withdrawal of Long-Term RAAS Blockade in a Cohort of Patients With Otherwise Inexplicable New-Onset and Progressive AKI

Macaulay A. Onuigbo.<sup>1,2</sup> <sup>1</sup>University of Vermont College of Medicine, Burlington, VT; <sup>2</sup>University of Vermont Medical Center, Burlington, VT.

**Background:** RAAS blockade is renoprotective for both diabetic and non-diabetic CKD. There have been discordant reports on renal and cardiovascular outcomes following RAAS blockade discontinuation in advanced CKD. To the contrary, a few prospective cohort studies have demonstrated reversal of otherwise inexplicable AKI in patients after discontinuation of RAAS blockade. This is a 4-year report of such a cohort.

**Methods:** Prospective Cohort Analysis, enrolled between February 2018 – May 2021. Kidney function was monitored after elective withdrawal of long-term RAAS blockade in CKD patients presenting with new-onset otherwise inexplicable progressive AKI as defined by a >25% increase in baseline serum creatinine.

**Results:** By February 2022, 12 patients had died, and 8 patients were on hemodialysis for ESRD. The remaining 51 patients, with a baseline serum creatinine of  $1.30 \pm 0.42$  (0.66 - 2.70) mg/dL, have been followed up for 706 (40-1478) days. Peak serum creatinine at study entry was  $2.17 \pm 1.06$  (1.1 - 8.3) mg/dL,  $n=51$ ,  $P < 0.0001$ ,  $t=6.4872$ ,  $df=135$ . Serum creatinine, 48 months later, was  $1.58 \pm 0.54$  (0.84 - 3.3) mg/dL,  $n=50$ ,  $p < 0.0001$ ,  $t=5.1805$ ,  $df=119$ . Death in 7 of 8 (87.5%) patients were from non-renal causes; most deaths occurred despite improved kidney function.

**Conclusions:** Our results support the elective withdrawal of long-term RAAS blockade in CKD patients with new-onset progressive yet otherwise inexplicable AKI. Significant sustainable renal salvage is common - Such self-selected patients generally exhibit clearly improved renal outcomes without increased mortality. (Figure). This is testament to the syndrome of late onset renal failure from angiotensin blockade (LORFAB) which we first described in 2005 from the Mayo Clinic Health System in Northwestern Wisconsin.

Serum creatinine trajectory from February 2020 - February 2022 after the elective withdrawal of Losartan 100 mg/d in December 2020

## TH-PO054

### Patterns of Healthcare Resource Utilization and Goals of Care Discussions in Patients With Cirrhosis and AKI

**Romela Petrosyan,<sup>1</sup>** Paul Endres,<sup>1,2</sup> Nneka Ufere,<sup>3</sup> Shelsea A. St. Hillien,<sup>1</sup> Scott Krinsky,<sup>1</sup> Sahir Kalim,<sup>1</sup> Sagar U. Nigwekar,<sup>1</sup> Andrew S. Allegretti,<sup>1</sup> <sup>1</sup>Massachusetts General Hospital Division of Nephrology, Boston, MA; <sup>2</sup>Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA; <sup>3</sup>Massachusetts General Hospital, Liver Center and Gastrointestinal Division, Boston, MA.

**Background:** Patients with cirrhosis and acute kidney injury (AKI) are critically ill and have high health care resource utilization (HCRU) during hospitalizations. The timing and impact of goals of care discussions on code status changes and rates of HCRU are not well described.

**Methods:** Medical records of 221 patients who previously enrolled in a prospective cohort study of patients hospitalized with AKI and cirrhosis at the Massachusetts General Hospital were reviewed. Documentation and timing of goals of care discussions were analyzed as predictors of high HCRU, defined as a composite outcome of either intubation, initiation of renal replacement therapy, or admission to the ICU.

**Results:** Median MELD score was 26 [IQR 19, 33]. 63/221 (29%) patients were listed for liver transplant and 41/221 (18.5%) patients later received liver transplant. 90-day mortality was 61%. 51% patients had at least one high HCRU episode. For all patients, code status on admission was 91% full code, 7% do not resuscitate, 0% comfort measures. By discharge, this changed to 68% full code, 14% do not resuscitate, 18% comfort measures ( $p < 0.001$ ). 28% patients underwent goals of care discussions, with change in code status at a median of 16 [9,22] days into their admission. However, only 18% of these discussions were prior to a high HCRU episode. Being listed for liver transplant was not associated with whether goals of care discussions occurred (23% listed vs. 31% non-listed,  $p = 0.24$ ) but was associated with higher HCRU (69% vs. 43%;  $p < 0.001$ ).

**Conclusions:** Goals of care discussions occurred late into the hospital course, generally after an episode of high HCRU. Efforts to engage in these discussions earlier in a hospital stay, may decrease HCRU in this critically ill population and provide more goal-concordant care.

## TH-PO055

## Urinary Sediment Microscopy as a Diagnostic Tool in Patients With End-Stage Liver Disease With AKI

Yipin Varghese,<sup>1,2</sup> Mohammad T. Sultan,<sup>1</sup> Dustin Chalmers,<sup>3</sup> Paula A. Cacioppo,<sup>1</sup> Durin Y. Uddin,<sup>1</sup> Juan Carlos Q. Velez,<sup>3,2</sup> Ochsner Nephrology,<sup>1</sup> *Department of Internal Medicine, Ochsner Clinic Foundation, New Orleans, LA;* <sup>2</sup>*The University of Queensland Ochsner Clinical School, New Orleans, LA;* <sup>3</sup>*Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

**Background:** Microscopic examination of the urinary sediment (MicrExUrSed) is a useful diagnostic tool in acute kidney injury (AKI). MicrExUrSed findings in patients with end-stage liver disease (ESLD) with AKI have not been well characterized. Hepatorenal syndrome type 1 (HRS-1), a type of AKI in ESLD, is difficult to diagnose despite the International Club of Ascites (ICA) criteria. Thus, we hypothesized that MicrExUrSed findings in ESLD differ from those in the absence of ESLD, and that they may aid in diagnosis of AKI specifically to distinguish HRS-1 from acute tubular injury (ATI).

**Methods:** MicrEXUrSed was performed in patients with AKI stage  $\geq 2$  with or without ESLD over a 3-year period. Data were collected prospectively. The percentage of low power fields (LPF) containing hyaline casts (HC), waxy casts (WxC), renal tubular epithelial cell casts (RTECC), granular casts (GC), and muddy brown granular casts (MBGC) was assessed. HRS-1 was defined by the ICA criteria and urine Na (uNa)  $< 20$  mEq/L. The presence of GC was used to determine the diagnosis of ATI.

**Results:** Distribution of casts by percentage of LPF containing casts differed between the ESLD (n=185) and non-ESLD (n=421) groups. HC, RTECC, and GC were identified more often in ESLD compared to non-ESLD [42 vs 7% ( $p<0.0001$ ); 30 vs 9% ( $p<0.0001$ ) and 54 vs 26% ( $p<0.0001$ ) for HC, RTECC and GC, respectively]. No difference in frequency of Wx (22 vs 19%,  $p=0.39$ ) or MBGC (21 vs 24%,  $p=0.42$ ) was found. In the ESLD group, total bilirubin level was significantly higher for those with RTECC [24.9 vs. 9.4 mg/dL ( $p<0.0001$ )] suggesting potential pathogenesis of bile cast tubulopathy. A diagnosis of HRS-I (based on ICA + uNa) was assigned to 51/185 (27%) of patients with ESLD and AKI. Among them, 27/51 (53%) were converted to ATI based on the presence of GC.

**Conclusions:** MicrExUrSed can aid in the diagnosis of AKI in ESLD by identifying those with evidence of ATL, i.e., not consistent with HRS-1. Additionally, the spectrum of MicrExUrSed findings in patients with ESLD differs from that of patients without ESLD. Higher frequency of HC in ESLD may reflect more frequent tubular stasis consistent with their disease state. More studies are needed to examine the clinical implications of RTECC seen in those with higher total bilirubin.

## TH-PO056

### Bile Cast Nephropathy-Retrospective Cohort of Hyperbilirubinemia Associated Nephropathy

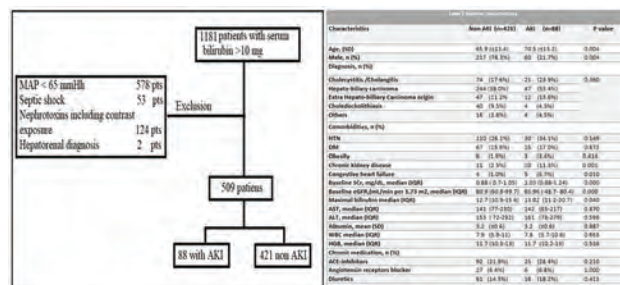

Nabil Abu Amer, Orit Erman, Lesya Kukuy, Margarita Kunin, Sharon Mini-Golddberger, Pazit Beckerman. *Chaim Sheba Medical Center, Rmat Gan, Israel.*

**Background:** Bile cast nephropathy (BCN) represents kidney dysfunction in the setting of severe hyperbilirubinemia. The proposed pathogenesis includes direct bile toxicity and obstructive tubular cast formation. BCN remains controversial despite typical findings on kidney pathology. The aim of this study is clinical characterization and risk factor identification of hyperbilirubinemia associated nephropathy.

**Methods:** A retrospective cohort study of patients admitted to surgery departments between January 2007 and January 2020 with total bilirubin above 10 mg/dL. Hyperbilirubinemia associated acute kidney injury (AKI) were identified, after carefully excluding all other etiologies of AKI. Data collected included demographic parameters, medical background, etiology of hyperbilirubinemia, lab tests, vital signs and nephrotoxic agents given during the hospitalization period.

**Results:** A total of 1,181 patients with serum bilirubin above 10 mg/dl were enrolled. 672 patients with other known kidney insults were excluded. The remaining 509 patients had a mean maximal bilirubin of 14.7 mg/d (SD±5.8). Of which, eighty-eight patients (17%) developed AKI, defined as bile cast nephropathy. They were mostly female (78%) and had a lower baseline estimated glomerular filtration rate compared to patients with hyperbilirubinemia who did not develop AKI (66 mL/min per 1.73 m<sup>2</sup> (IQR 60.8-99.7) and 81 mL/min per 1.73 m<sup>2</sup> (IQR 48.7- 80.4), respectively). Most of the patients (63%) had AKI stage 1 and there was no linear correlation between bilirubin level and AKI event. Renal recovery occurred after a decrease in serum bilirubin to a nadir of 4.19 mg/dl (IQR 1.4-6.8).

**Conclusions:** The diagnosis of bile cast nephropathy should be considered in patients with hyperbilirubinemia who develop AKI. In most cases AKI is mild and resolves following a decrease in bilirubin levels. This finding suggests that reduction in bilirubin levels may be beneficial among patients who develop AKI, even when no definitive treatment of hyperbilirubinemia is available.

## TH-PO057

## Pre-Hospitalization Characteristics Confound AKI Associations With Cardiovascular Outcomes: Findings From the CRIC Study

Ian McCoy,<sup>1</sup> Jesse Y. Hsu,<sup>10</sup> Xiaoming Zhang,<sup>10</sup> Clarissa J. Diamantidis,<sup>5</sup> Jonathan J. Taliercio,<sup>6</sup> Alan S. Go,<sup>7</sup> Kathleen D. Liu,<sup>1</sup> Paul E. Drawz,<sup>11</sup> Anand Srivastava,<sup>4</sup> Edward J. Horwitz,<sup>8</sup> Jiang He,<sup>9</sup> Jing Chen,<sup>9</sup> James P. Lash,<sup>2</sup> Matthew R. Weir,<sup>3</sup> Chi-yuan Hsu,<sup>1,7</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>University of Illinois Chicago College of Medicine, Chicago, IL; <sup>3</sup>University of Maryland School of Medicine, Baltimore, MD; <sup>4</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>5</sup>Duke University School of Medicine, Durham, NC; <sup>6</sup>Cleveland Clinic, Cleveland, OH; <sup>7</sup>Kaiser Permanente, Oakland, CA; <sup>8</sup>Case Western Reserve University, Cleveland, OH; <sup>9</sup>Tulane University, New Orleans, LA; <sup>10</sup>University of Pennsylvania, Philadelphia, PA; <sup>11</sup>Regents of the University of Minnesota, Minneapolis, MN.

**Background:** AKI during hospitalization has been associated with increased risks of cardiovascular events, but these associations may be confounded by differences in pre-hospitalization characteristics, including the pre-hospitalization rate of kidney function decline and pre-hospitalization proteinuria level.

**Methods:** Among 1,630 participants hospitalized in 2013-2019 in the Chronic Renal Insufficiency Cohort (CRIC) study who survived until the next post-hospitalization study visit, we examined associations between AKI and subsequent cardiovascular outcomes: time to first heart failure hospitalization and time to first atherosclerotic event (ASCVD: encompassing myocardial infarction, ischemic stroke, or peripheral arterial disease). AKI-outcome associations (adjusted for demographics, BMI, diabetes mellitus, coronary artery disease, heart failure, smoking status, dyslipidemia, family history of coronary disease) were assessed using cause-specific hazard models before and after adjusting for pre-hospitalization variables (eGFR, eGFR slope, proteinuria, blood pressure, and antihypertensive use).

**Results:** As compared to patients who did not experience AKI (n=1317), patients who experienced AKI during their hospitalizations (n=313) had not only worse kidney function pre-hospitalization (eGFR 44 vs 50 mL/min/1.73m<sup>2</sup>) but also faster chronic loss of kidney function pre-hospitalization (eGFR slope -0.68 vs -0.43 mL/min/1.73m<sup>2</sup>/yr), and more proteinuria pre-hospitalization (UPCR 0.24 vs 0.15 g/g); they also had higher pre-hospitalization systolic blood pressure (130 vs 127 mmHg) despite more antihypertensive medications (p<0.001 for all comparisons). AKI associations with heart failure and ASCVD were attenuated and lost significance after adjustment for pre-AKI variables.

**Conclusions:** Pre-hospitalization variables including eGFR slope and proteinuria confound associations between AKI and cardiovascular outcomes.

**Funding:** NIDDK Support

Adjusted hazard ratios (95% confidence intervals) of AKI for cardiovascular outcomes

Model	Heart Failure (HF)	ASCVD (MI, Stroke, PAD)
AKI (adjusted as per methods section)	1.51 (1.13-2.03)	1.44 (1.03-2.02)
AKI (additionally adjusted for pre-hospitalization variables)	1.30 (0.97-1.75)	1.27 (0.90-1.80)

MI: myocardial infarction; PAD: peripheral arterial disease

## TH-PO058

## Actionable Forecasting of Kidney Function and Serum Potassium in Hospitalized Adults

Carl P. Walther, Jamie Philp, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

**Background:** Derangements in kidney function and electrolytes are common in hospitalizations. Preemptive risk identification for these derangements could enable intervention. We developed forecasting models to inform risk identification using deep learning.

**Methods:** We obtained data for all adults hospitalized at an academic hospital 1/1/20-1/20/22. We divided hospitalizations into training (70%), validation (15%), and test (15%) sets. From each hospitalization, multiple input/target pairs were created, from which all prior information was used to predict each subsequent day's creatinine and potassium. For initial modeling, 12 laboratory tests were used. Long short term memory (LSTM) layers were used, and multiple architectures and hyperparameters were assessed with training/validation data. The best performing model was evaluated using test data. Results were compared to naïve baseline predictions (last value carry forward and linear regression).

**Results:** A total of 219,087 input/target pairs were available. The final model used 4 LSTM layers (64 nodes each), followed by 4 densely connected layers (32 nodes each), a linear layer, and dropout regularization. On test data, the mean absolute error for creatinine was 0.24 mg/dl and for potassium was 0.29 mEq/L. Both outperformed naïve baseline predictions. Interrogation of modeling results in individual hospitalizations from the test set revealed possible patterns that the model learned in forecasting values.

**Conclusions:** A deep learning model outperformed baseline predictions in forecasting creatinine and potassium levels in hospitalized adults. Next steps will incorporate additional predictive variables and translate the predicted levels to risk estimates for clinically actionable derangements.

**Funding:** NIDDK Support

A. Example hospitalization from test set: patient with DKA

B. Example hospitalization from test set: patient with sepsis

Forecasting models to applied to two examples from test set. Predicted values for each day (starting the day after admission) were calculated using all available lab values from all prior days.

## TH-PO059

## Association of Mild-to-Moderate AKI With Decline in eGFRcys vs. eGFRcr Among Individuals With CKD: The CRIC Study

Anthony N. Muir,<sup>1</sup> Jesse Y. Hsu,<sup>2</sup> Xiaoming Zhang,<sup>2</sup> Jonathan J. Taliercio,<sup>3</sup> James H. Sondheimer,<sup>4</sup> Ana C. Ricardo,<sup>5</sup> Ian McCoy,<sup>1</sup> Kathleen D. Liu,<sup>1</sup> James P. Lash,<sup>5</sup> Edward J. Horwitz,<sup>6</sup> Jiang He,<sup>7</sup> Alan S. Go,<sup>8</sup> Barry I. Freedman,<sup>9</sup> Paul E. Drawz,<sup>10</sup> Jing Chen,<sup>7</sup> Lawrence J. Appel,<sup>11</sup> Chi-yuan Hsu,<sup>1</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>University of Pennsylvania, Philadelphia, PA; <sup>3</sup>Cleveland Clinic, Cleveland, OH; <sup>4</sup>Wayne State University, Detroit, MI; <sup>5</sup>University of Illinois Chicago, Chicago, IL; <sup>6</sup>Case Western Reserve University, Cleveland, OH; <sup>7</sup>Tulane University, New Orleans, LA; <sup>8</sup>Kaiser Permanente, Oakland, CA; <sup>9</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>10</sup>Regents of the University of Minnesota, Minneapolis, MN; <sup>11</sup>Johns Hopkins University, Baltimore, MD.

**Background:** We reported that after accounting for key potential confounders such as pre-AKI proteinuria and pre-AKI eGFR slope, mild-moderate AKI was not independently associated with an absolute decline in eGFR creatinine (eGFRcr) after AKI. However, analyses based on eGFRcr may underestimate CKD progression due to loss of muscle mass and reduced creatinine generation after hospitalized AKI. Therefore, we examined the decline in cystatin C based eGFR (eGFRcys) after hospitalized AKI.

**Methods:** In the prospective Chronic Renal Insufficiency Cohort (CRIC), we used multivariable mixed effects models to quantify the independent association between an episode of hospitalized mild-to-moderate AKI with change in absolute eGFR value and change in eGFR slope before vs. after an episode of hospitalized AKI, using eGFRcys (CKD-EPI 2012) and eGFRcr (CKD-EPI 2021).

**Results:** We included a total of 3,150 participants with mean age of 65 years. Mean baseline eGFRcys and eGFRcr were 51 mL/min/1.73m<sup>2</sup> and 52 mL/min/1.73m<sup>2</sup>, respectively. We observed 612 episodes of AKI among 433 CRIC study participants during a median follow-up of 3.9 years. As shown in the table an episode of AKI at 1.9 years was significantly associated with eGFRcys absolute drop (-2.2 mL/min/1.73 m<sup>2</sup>, p=0.02), but not eGFRcr (-0.8 mL/min/1.73 m<sup>2</sup>, p=0.09). There was no detectable change in eGFRcys nor eGFRcr slopes from before to after AKI (see table).

**Conclusions:** Mild-moderate AKI was associated with a modest drop in absolute eGFR after AKI, but only when using cystatin C as the filtration marker. Our findings suggest that cystatin C should be considered as part of routine post-AKI follow-up to evaluate risk for CKD progression after an episode of AKI.

**Funding:** NIDDK Support

	Change in eGFR value after each AKI (95% CI)	p-value	Difference in eGFR slopes, before and after each AKI episode per year (95% CI)	p-value
eGFRcys	-2.2 (-3.9, -0.4)	0.02	0.2 (-0.8, 1.1)	0.74
eGFRcr	-0.8 (-1.7, 0.1)	0.09	0.2 (-0.2, 0.7)	0.35

Linear mixed effect models adjusted for clinical center and demographic characteristics (age, sex, and race), time-updated diabetes mellitus, heart failure, systolic blood pressure, receipt of ACEi and ARBs, and proteinuria

## TH-PO060

### Comparison of Diagnostic Criteria for AKI in Critically Ill Children: A Multicenter Cohort Study

Yuxian Kuai, Hui Huang, Yanhong Li. *Children's Hospital of Soochow University, Suzhou, China.*

**Background:** Substantial interstudy heterogeneity exists in defining acute kidney injury (AKI) and baseline serum creatinine (SCr). This study assessed AKI incidence and its association with pediatric intensive care unit (PICU) mortality under different AKI and baseline SCr definitions to determine the preferable approach for diagnosing pediatric AKI.

**Methods:** This multicenter prospective cohort study was conducted in the PICUs of four tertiary hospitals in China. AKI was defined and staged according to the definitions of the KDIGO, modified KDIGO (SCr increase should reach a concentration of at least 0.5 mg/dL when the KDIGO criterion with SCr is applied to define AKI), and the pROCK (pediatric reference change value optimized for AKI: SCr rise  $\geq 0.2$  mg/dL and  $\geq 1.3$  times the baseline SCr within 7 days). The baseline SCr was calculated based on the Schwartz formula or estimated as the upper normative value (NormsMax), admission SCr (AdmSCr) and modified AdmSCr. The impacts of different AKI definitions and baseline SCr estimation methods on AKI incidence, severity distribution and AKI outcome were evaluated.

**Results:** Different AKI definitions and baseline SCr estimates led to differences in AKI incidence, from 6.8% to 25.7%; patients with AKI across all definitions had higher PICU mortality ranged from 19.0% to 35.4%. A higher AKI incidence (25.7%) but lower mortality (19.0%) was observed based on the Schwartz according to the KDIGO, which however was overcome by modified KDIGO (AKI incidence: 16.3%, PICU mortality: 26.1%). For the modified KDIGO, the consistencies of AKI stages between different baseline SCr estimation methods were all strong with the concordance rates  $>90.0\%$  and weighted kappa values  $>0.8$ , and PICU mortality increased pursuant to staging based on the Schwartz. For the pROCK, PICU mortality did not increase pursuant to staging and AKI stage 3 was not associated with mortality after adjustment for confounders.

**Conclusions:** The AKI incidence and staging vary depending on the definition and baseline SCr estimation method used. The KDIGO definition is sensitive, identifying a great number of mild AKI. The modified KDIGO based on the Schwartz method is more strongly associated with related mortality and may be the preferable approach for the diagnosis of pediatric AKI, which shows promise for improving clinicians' ability to diagnose AKI in children.

## TH-PO061

### Relationship Between the Rate of Fluid Resuscitation and AKI

Swetha Reddy, Kianoush Kashani. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

**Background:** Septic shock is the leading cause of acute kidney injury (AKI) in critically ill patients. While fluid resuscitation has become the cornerstone of early septic shock management, the association between fluid resuscitation rates and kidney outcomes remains unclear. This investigation examines the relationship between fluid resuscitation rate and AKI resolution

**Methods:** We retrospectively studied adult ( $\geq 18$  years) patients with AKI and septic shock, defined based on sepsis III definition, from January 1, 2006, through May 31, 2018, in the medical intensive care unit (MICU) of Mayo Clinic Rochester. The fluid resuscitation time was defined as the time required to infuse the initial fluid bolus of 30 ml/kg, based on the recommendations of the surviving sepsis campaign. The cohort was divided into three groups based on the average fluid resuscitation time ( $<1$ hr, 1.1-2hr,  $>3$ hr) and the corresponding fluid rate  $\geq 0.5$ , 0.25-0.49, and  $<0.17$  ml/kg/min, respectively. The primary outcome was the recovery of AKI on day 7

**Results:** 597 patients met eligibility criteria and were included in the analysis. The AKI recovery was significantly different among the groups ( $P=0.006$ ). Patients in groups 1 and 2 who received fluid resuscitation faster had a higher rate of AKI recovery (53% and 50%) when compared with group 3 (37.8%)

**Conclusions:** In septic shock patients with AKI, an initial fluid resuscitation rate of 0.25-0.50 ml/kg/min (i.e., completion of the initial 30 ml/kg IV fluid resuscitation within the first two hours) is associated with higher AKI recovery compared with slower infusion rates

Figure: AKI recovery with different initial fluid resuscitation rates

## TH-PO062

### Systolic Blood Pressure and Mortality Among Veterans Following AKI

Benjamin R. Griffin, Masaaki Yamada, Meenakshi Sambharia, Melissa L. Swee, Heather Reisinger, Diana I. Jalal. *The University of Iowa Hospitals and Clinics, Iowa City, IA; <sup>2</sup>Veterans Health Administration Center for Access & Delivery Research and Evaluation, Iowa City, IA.*

**Background:** Acute kidney injury (AKI) complicates 20-25% of hospitalizations and is associated with increased long-term mortality. Recommended target blood pressures (BP) have been reduced in the last 5 years, but whether lower targets should be applied in the post-AKI population is unknown. We evaluated the impact of different systolic BP (SBP) categories on mortality among post-AKI Veterans.

**Methods:** In this retrospective cohort analysis, we included all adult VA patients admitted from 2013 to 2018 with in-hospital AKI who were discharged alive and had at least 1 blood pressure within 30 days of discharge. SBP was assessed for up to 2 years after discharge and categorized as 100-120, 120-130, and  $>130$  mmHg (SBP  $<100$  mmHg were excluded). The primary outcome was 2-year mortality. We used Cox Proportional Hazards regression to adjust for baseline age, race, sex, chronic lung disease, unexplained weight loss, dementia, congestive heart failure (CHF), hematocrit, blood urea nitrogen, bilirubin, and albumin, while allowing SBP to vary over the follow-up period. Because angiotensin-converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) are associated with decreased mortality, we stratified the analysis based on whether the patient was on an ACEI/ARB within 90 days of discharge.

**Results:** A total of 97,376 patients met inclusion criteria, of which 25,600 (26%) died within 2 years of discharge. The cohort had high rates of hypertension (85%), CHF (28%), and diabetes mellitus (19%). Within 30 days of discharge, 32%, 25%, and 43% had SBP  $<120$ , 120-130, or  $>130$ , respectively. Compared to follow-up months with SBP  $>130$  mmHg, SBP 120-130 and  $<120$  mmHg had adjusted hazard ratios (HR) for mortality of 0.870 (95% CI 0.865-0.876) and 0.968 (95% CI 0.964-0.971), respectively. Within 90 days, 41,147 (42%) were treated with ACEI/ARB, and these patients had 20.6% 2-year mortality compared to 30.5% in those not treated with ACEI/ARB (unadjusted OR 0.59 (95% CI 0.57-0.61)). When stratified for ACEI/ARB use, HRs for SBP 100-120 and 120-130, relative to SBP  $>130$  were similar to the full cohort.

**Conclusions:** In a post-AKI cohort, SBP of 120-130 mmHg was associated with a lower HR for 2-year mortality than 100-120 mmHg, and both were superior to  $>130$  mmHg. This association was independent of the use of ACEI/ARB.

## TH-PO063

### Mortality and AKI Severity in Cirrhosis: Model for End-Stage Liver Disease Score and Bilirubin Predictive, HRS-1 as AKI Etiology Not Predictive

Mohammad T. Sultan, Vipin Varghese, Dustin Chalmers, Paula A. Cacioppo, Juan Carlos Q. Velez. *Ochsner Nephrology Ochsner Medical Center, New Orleans, LA.*

**Background:** End-stage liver disease (ESLD) carries high morbidity and mortality, particularly among those who develop acute kidney injury (AKI). There is conflicting data regarding factors associated with poor outcomes, including studies examining etiology of AKI [hepatorenal syndrome type 1 (HRS-1) vs acute tubular injury (ATI)] as factor. Moreover, prognostic value of findings from microscopic examination of urinary sediment (MicroExUrSed) in patients with ESLD with AKI has not been examined. We hypothesized that illness severity factors (rather than type of injury) are associated with worse outcomes in this patient population.

**Methods:** We established prospective data collection in patients with ESLD with AKI stage  $\geq 2$  (AKIN) over 3-years. Demographic and clinical data including Model for End-stage Liver Disease (MELD) score were collected. Each patient completed

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

MicroExUrSed. Presence of hyaline casts (HC), waxy casts (WxC), renal tubular epithelial cell casts (RTECC), granular casts (GC), and muddy brown granular casts (MBGC) were recorded. All parameters were assessed for the relative risk (RR) of reaching a composite endpoint (CP) of death/hospice at discharge or need for renal replacement therapy (RRT). Analysis was repeated for RRT alone as secondary end point.

**Results:** We included 185 patients [37% women, 75% white, 16% black, median age 57 (25-87)]. Higher MELD score was associated with greater RR of reaching the CP, RR 1.24 (1.04-1.50),  $p=0.01$ . Total bilirubin level was also associated with greater RR of reaching the CP, RR 1.23 (1.01-1.50),  $p=0.03$ . Neither age, sex nor race were predictive. HRS-1 was not associated with higher mortality compared to ATI (1.09,  $p=0.36$ ). Neither HC, WxC, RTECC, GC nor MBGC were independently associated with higher risk for the CP. Regarding RRT as sole endpoint, only total bilirubin level trended towards an increased risk, RR 1.37 (0.98-1.91),  $p=0.06$ .

**Conclusions:** Higher MELD score and total bilirubin levels were associated with greater risk for poor clinical outcomes in patients with ESKD with AKI, whereas HRS-1 as the etiology of AKI did not confer greater risk of mortality or need for RRT compared to ATI. Altogether, these data suggest that in ESKD, severity of illness is the main driver for ominous outcomes rather than the type of AKI.

#### TH-PO064

##### Persistent AKI Risk Index to Predict Risk of Persistent AKI in Critically Ill Adult Patients: A Validation Cohort Study

Blessa Marie H. Pelayo, Maria Kristina Alolod. *St. Luke's Medical Center - Quezon City, Quezon City, Philippines.*

**Background:** The persistent AKI risk index(PARI) scoring tool is designed as a simple calculator using changes in serum creatinine and only three clinical risk factors such as hyperbilirubinemia, sepsis, ventilation or use of inotropic support. It is an effective bedside tool to exclude low risk patients and detect high risk patients to develop persistent AKI. This risk assessment tool can provide real-time clinical decision to prevent persistent AKI and help clinicians decide on aggressive management such as kidney replacement therapy. The PARI has not been externally validated to detect the potential population of patients at high risk for persistent AKI.

**Methods:** A total of 2560 critically ill adult patients age  $\geq 19$  years were screened for the study from 2015 to 2019 at the critical care units of St. Luke's Medical Center – Quezon City. The mean age of participants were 63.8 years and 59.3% of which were male. Primary outcome is to predict risk of developing persistent AKI using PARI were score of 8 is considered positive. Secondary outcomes includes risk for kidney replacement therapy(KRT), mortality and length of hospital stay. Discrimination using logistic regression C testing and calibration using Hosmer & Lemeshow test were used to evaluate the predictive ability of the scoring system.

**Results:** A total of 386 patients were eligible after exclusion evaluation. The PARI was statistically significant in predicting risk of persistent AKI and need for KRT with an OR of 15.13 (CI 9.1 to 25.0),  $p$  value 0.0001 and OR 11.35 (CI 6.7 to 19.2),  $p$  value 0.0001, respectively and provides acceptable discrimination with C statistics of 0.79 and 0.70. Patients with positive PARI score showed HR of 3.94 (CI 2.6 to 6.1),  $p$  value 0.0001 for mortality with acceptable performance in discriminating patients risk for mortality. No statistical significance in length of hospital stay,  $p$  value 0.83. The calibration study showed  $p$  values of  $<0.05$  indicating poor goodness to fit for all outcomes.

**Conclusions:** PARI is a convenient and cost-effective bedside tool that can be used to predict persistent AKI with an impact in management of critically ill adult patients. This will provide as an add on tool to biomarkers for early intervention and goal-directed therapies for better prognosis.

#### TH-PO065

##### Risk of Ventricular Tachycardia and Its Outcomes in Patients Undergoing Continuous Renal Replacement Therapy due to AKI

Seong Geun Kim, Donghwan Yun, Jinwoo Lee, Min woo Kang, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Seung Seok Han. *Seoul National University College of Medicine, Seoul, Republic of Korea.*

**Background:** Despite the best efforts to treat critically ill patients requiring continuous renal replacement therapy (CRRT) due to acute kidney injury, their mortality risk remains high. This worse condition may be attributable to complications of CRRT, such as arrhythmias. Here, we addressed the occurrence of ventricular tachycardia (VT) and its relationship with patient outcomes after starting CRRT due to acute kidney injury.

**Methods:** A total of 2,397 patients who started CRRT due to severe acute kidney injury were retrospectively enrolled from 2010 to 2020 at Seoul National University Hospital, Korea. The occurrence of VT was evaluated from starting to weaning from CRRT. The odds ratios (ORs) of mortality outcomes were measured using logistic regression models after adjustment for multiple variables.

**Results:** VT occurred in 150 (6.3%) patients after starting CRRT. Among them, 95 cases were defined as sustained VT (i.e., lasting  $\geq 30$  sec), and the other 55 cases were defined as nonsustained VT (i.e., lasting  $< 30$  sec). The occurrence of sustained VT was associated with a higher mortality rate than nonoccurrence (OR, 1.99 [1.17-3.37] for 7-day mortality; OR, 2.04 [1.23-3.39] for 30-day mortality; and OR, 4.06 [2.04-8.08] for 90-day mortality). The mortality rates did not differ between patients with nonsustained VT and nonoccurrence. The use of  $\geq 3$  vasopressors and certain trends of blood laboratory findings such as acidosis and hyperkalemia were associated with the subsequent risk of sustained VT for patients on CRRT.

**Conclusions:** Sustained VT occurrence after starting CRRT is associated with patient mortality. The monitoring of electrolytes and acid-base status during CRRT is essential because of its relationship with the risk of VT.

#### TH-PO066

##### Hyperlactatemia Is a Predictor of Mortality in Patients Undergoing Continuous Renal Replacement Therapy for AKI

Seong Geun Kim, Jinwoo Lee, Min woo Kang, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Seung Seok Han. *Seoul National University College of Medicine, Seoul, Republic of Korea.*

**Background:** Hyperlactatemia occurs frequently in critically ill patients, and this pathologic condition leads to worse outcomes in several disease subsets. Herein, we addressed whether hyperlactatemia is associated with the risk of mortality in patients undergoing continuous renal replacement therapy (CRRT) due to AKI.

**Methods:** A total of 1,661 patients who underwent CRRT for severe AKI were retrospectively reviewed between 2010 and 2020. The patients were categorized according to their serum lactate levels, such as high ( $\geq 7.6$  mmol/l), moderate (2.1-7.5 mmol/l) and low ( $\leq 2$  mmol/l), at the time of CRRT initiation. The hazard ratios (HRs) for in-hospital mortality were calculated with adjustment of multiple variables. The increase in the area under the receiver operating characteristic curve (AUROC) for the mortality risk was evaluated after adding serum lactate levels to the Sequential Organ Failure Assessment (SOFA) and the Acute Physiology and Chronic Health Evaluation (APACHE) II score-based models.

**Results:** The moderate and high lactate groups had a higher risk of mortality than the low lactate group, with HRs of 1.64 (1.22-2.20) and 4.18 (2.99-5.85), respectively. The lactate-enhanced models had higher AUROCs than the models without lactates (0.764 vs. 0.702 for SOFA score; 0.737 vs. 0.678 for APACHE II score).

**Conclusions:** Hyperlactatemia is associated with mortality outcomes in patients undergoing CRRT for AKI. Serum lactate levels may need to be monitored in this patient subset.

## TH-PO067

### U-Shaped Association Between Platelet-to-Lymphocyte Ratio and In-Hospital Mortality in Critically Ill Patients With AKI Requiring Continuous Renal Replacement Therapy

Hee Won Noh, Soojee Jeon, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jeong-Hoon Lim, Jang-Hee Cho. *Kyungpook National University, Daegu, Republic of Korea.*

**Background:** The platelet-to-lymphocyte ratio (PLR) is a marker of inflammation and predictor of mortality in a variety of diseases. However, the effectiveness of PLR as a predictor of mortality in patients with severe acute kidney injury (AKI) is uncertain. We evaluated the association between PLR and mortality in critically ill patients with severe AKI who underwent continuous renal replacement therapy (CRRT).

**Methods:** This is a retrospective observational cohort study, and a total of 1044 patients with AKI who underwent CRRT in Kyungpook National University Hospital from 2017 to 2021 were analyzed. The study subjects were divided into quintiles according to the PLR at CRRT initiation. A Cox proportional hazards model was used to investigate the association between PLR and mortality.

**Results:** PLR was associated with in-hospital mortality in a non-linear manner, showing a higher mortality rate at both ends of the PLR. The Kaplan-Meier curve analysis revealed the highest mortality rates with the first and fifth quintiles, while the lowest mortality rate occurred with the third quintile. Compared with the third quintile (the lowest mortality rate group), the first (adjusted hazard ratio [aHR] = 1.94, 95% confidence interval [CI] = 1.44–2.62,  $P < 0.001$ ) and fifth (aHR = 1.60, 95% CI = 1.18–2.18,  $P = 0.002$ ) quintiles of PLR had significantly higher in-hospital mortality. The first and fifth quintiles showed a consistently increased risk of 30-day and 90-day mortality compared with the third quintile. In the subgroup analysis, lower and higher PLRs were predictors of in-hospital mortality in patients with older age, female sex, hypertension, diabetes, and higher Sequential Organ Failure Assessment score.

**Conclusions:** Both the lower and higher PLRs were independent predictors of in-hospital mortality in critically ill patients with AKI who underwent CRRT. Thus, the PLR may be a useful and easily accessible prognostic indicator for patients with severe AKI.

### AKI Among Patients With Multi-Drug Resistant Infection: A Study From Jordan

Ashraf O. Oweis,<sup>1</sup> Sameeha A. Alshelleh,<sup>2</sup> <sup>1</sup>Jordan University of Science and Technology Faculty of Medicine, Irbid, Jordan; <sup>2</sup>The University of Jordan, Amman, Jordan.

**Background:** Acute kidney injury (AKI) is a well-known complication for hospitalized patients especially in the intensive care unit. Sepsis and various infections play major role in increasing the incidence of AKI. In our study we are evaluating the risk for Multidrug resistant (MDR) infections and its effect on incidence of AKI, hospitalization, need for dialysis and mortality.

**Methods:** In a retrospective study design, data was collected from all adult patients with a positive multi-drug resistant culture who were admitted to King Abdullah University Hospital (KAUH). Records of 436 patients who were admitted to general floors or the intensive care units (ICU) between January 2017 – December 2018 with at least one year follow up and had infection with positive multidrug resistant cultures were reviewed

**Results:** The mean age for the patients was 57.3 years (SD± 23.1) and 58.5% were males. The most common source of positive culture was sputum culture 50%, followed by wound culture 22.2%. The incidence of AKI was 59.2% and most cases were in stage 3 AKI (41%). The most isolated microorganism was *Acinetobacter baumannii* 76.8% followed by *Pseudomonas aeruginosa* 14.9% (picture 2). On multivariate analysis, age (OR 1.1, 95% CI 1.1–1.2,  $P=0.001$ ), HTN (OR 1.8, 95% CI 1.0–3.3,  $P=0.02$ ), DM (OR 1.1, 95% CI 0.6–1.9,  $P=0.69$ ) and the use of foley catheter on chronic bases (OR 4.3, 95% CI 2.6–6.8,  $P<0.0001$ ) were a strong predictors of AKI. Among patients with AKI; 74.4% died in comparison to 44.4% ( $p<0.001$ ).

**Conclusions:** In patients with MDR incidence for AKI, hospitalization, and mortality is high. Early detection and addressing of the problem may decrease bad outcomes, health education for decreasing antibiotic abuse is needed to decrease MDR.

## TH-PO069

### Assessment of the Nature of AKI Post Adult Orthotopic Heart Transplantation: A Single Tertiary Referral Center Experience

Ashley Golbus,<sup>1</sup> Syed M. Quadri,<sup>2</sup> Blaithin A. McMahon,<sup>2</sup> <sup>1</sup>Medical University of South Carolina College of Medicine, Charleston, SC; <sup>2</sup>Medical University of South Carolina Department of Medicine, Charleston, SC.

**Background:** AKI is common following adult orthotopic heart transplantation (OHT) with rates ranging from 40.3% to 72.3%. AKI worsens 12-month survival with a subset of patients requiring kidney replacement therapy (KRT), developing ESRD, worsening CKD, or death. The purpose of our study was to assess the nature of AKI occurring post-adult OHT at the Medical University of South Carolina and to serve as a metric of how to best improve renal outcomes in this cohort of patients.

**Methods:** We analyzed AKI rates and renal outcomes in a cohort of 120 adult patients undergoing OHT at MUSC from 04/2015 to 04/2021. We investigated AKI incidence, severity, and timing; the effect of hemodilution on AKI I criteria; and KRT indication and initiation in a sub-cohort of AKI patients who required KRT (AKI-D patients). We investigated major adverse kidney events (MAKE) outcomes at 12-months post-OHT. We identified several risk factors for AKI and AKI-D and performed a univariate logistic regression analysis of risk factors.

**Results:** 90% of patients met AKI criteria within 7 days post-OHT; 10% had no AKI, 48.3% had stage I AKI, 15.8% stage II, and 25.8% stage III. 31% of AKI stage I patients met criteria due to hemodilution. AKI criteria diagnosis was on median day 1 post-OHT. Median initiation of KRT was POD2 for the predominant indication of volume overload. Of AKI-D patients, MAKE criteria was assessed at 12 months post-OHT and showed 74.2% (n=23) of patients had doubling SCr, 16.2% (n=5) were ESRD, and 19.4% (n=6) died. Significant risk factors for AKI included CPB time (OR: 1.007, 95% CI: 1.001–1.013;  $P=0.015$ ), VIS score (OR: 1.041, 95% CI: 1.011–1.072;  $P=0.007$ ), preoperative SCr (OR: 5.61, 95% CI: 2.397–13.133;  $P<0.001$ ), primary graft dysfunction (OR: 8.546, 95% CI: 2.705–26.994;  $P<0.001$ ), and RV failure (OR: 5.548, 95% CI: 2.263–12.606;  $P<0.001$ ).

**Conclusions:** AKI is a common finding post-OHT, however the majority of the AKI in this cohort of patients was AKI stage I. We identified that any AKI was associated with poor renal outcomes such as MAKE-12 months. Timing of all stages of AKI suggests etiologies such as RV failure and graft dysfunction as major risk factors for AKI.

## TH-PO070

### Seeing Is Believing: Imaging Tests in Acute Renal Failure and Acute-on-Chronic Kidney Disease and Their Influence on Outcomes

Maria Isabel Acosta-Ochoa, Armando Coca, Arturo Lorenzo, Alicia Mendiluce. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

**Background:** Imaging techniques allow the diagnosis of abnormalities of renal structure; patients with structural abnormalities have CKD if persist >3 months. We evaluated if an abnormal imaging test influenced outcomes in patients with acute renal failure (ARF) or Acute on Chronic Kidney Disease (AoCKD).

**Methods:** Retrospective study of in-patients with AKI. We excluded individuals without image tests. We divided the cohort in normal and abnormal imaging, and in acute renal failure (ARF basal GFR >60) and Acute on Chronic Kidney Disease (AoCKD basal GFR <59). We compared clinical features, and tested the incidence of need for HD and in-hospital mortality.

**Results:** We included 616 individuals. Patients with AoCKD in both groups were older and had higher Charlson's Index (ChI); they were hospitalized less frequently in ICU, and more frequently in medical wards compared to ARF individuals. Besides comorbidities, AKI severity and hard renal and clinical outcomes showed no statistically significant differences between groups; except for higher hospital stay in the AoCKD group with normal imaging tests.

**Conclusions:** We found that an abnormal imaging test does not confer worse prognosis in ARF neither AoCKD. It is noteworthy that 52% of patients didn't have an image test during hospitalization. Although individuals with AoCKD are older and

have higher ChI, the hard outcomes rates were not affected by an abnormal imaging test. Future studies with more accurate techniques that measure and evaluate kidney volume, in combination with functional imaging and/or elastography could shed light over ARF and AoCKD diagnosis and prognosis.

Risk Factors for Post-Contrast AKI in Patients Administered Both Iodine- and Gadolinium-Based Contrast Media on the Same Visit to the Emergency Department

Suyeon Han,<sup>1</sup> Hojoon Ko,<sup>1</sup> Moo Jun Kim,<sup>1</sup> Eu Jin Lee,<sup>1</sup> Jae wan Jeon,<sup>3</sup> Youngrok Ham,<sup>2,1</sup> Dae Eun Choi,<sup>2,1</sup> Kiryang Na,<sup>2,1</sup> Kang Wook Lee.<sup>2,1</sup>  
<sup>1</sup>Chungnam National University Hospital, Daejeon, Republic of Korea; <sup>2</sup>Chungnam National University, Daejeon, Republic of Korea; <sup>3</sup>Chungnam National University Sejong Hospital, Sejong, Republic of Korea.

**Background:** This study aimed to investigate the incidence of post-contrast acute kidney injury (PC-AKI) and its risk factor in patients administered iodine-based contrast media (ICM) alone and mixed use of ICM and gadolinium-based contrast media.

**Methods:** This retrospective study analyzed the data from 2016 to 2021. Patients who had end-stage of renal disease or missing data for estimating renal function were excluded. The primary outcome was the development of PC-AKI, i.e., an increase in creatinine of ≥25% or 0.5 mg/dL over the baseline or reduction in eGFR of ≥25% within 72 h. We compared the primary outcomes between the ICM alone and Mixed groups using a propensity score matching (PSM) analysis, and its risk factors were assessed from multivariable logistic regression.

**Results:** Of the 29,635 patients administrated ICM, 6,318 were included. There were 139 patients who mixedly administered ICM and GBCA. Mixed group showed significant higher rate of development of PC-AKI compared with ICM alone group in total cohort (adjusted OR, 3.09 [95% CI, 2.09 – 4.58]) and PSM cohort (adjusted OR, 2.38 [95% CI, 1.25 – 4.55]). On multivariate analysis to investigate risk factors in Mixed group, osmolality (adjusted aOR, 1.05 [95% CI, 1.01–1.10]) and eGFR (adjusted OR, 0.931; 95% CI, 0.883–0.983) were associated with PC-AKI.

**Conclusions:** Mixed administration of ICM and GBCA on same day at ED visit may be a risk factor for PC-AKI compared with single administration of ICM alone. Osmolality and eGFR may be independently associated with PC-AKI after mixed administration of ICM and GBCA

TH-PO072

Evaluation of Nephrotoxicity of Liposomal Amphotericin in Three Administration Regimens for the Treatment of Disseminated Histoplasmosis in AIDS Patients  
Marilia Rodovalho Guimaraes,<sup>1</sup> Renata B. Soares,<sup>3</sup> Talita R. Sanches,<sup>1</sup> Cássia S. Godoy,<sup>3</sup> Diego R. Falci,<sup>4</sup> Alessandro C. Pasqualotto,<sup>2</sup> Lucia Andrade.<sup>1</sup>  
<sup>1</sup>University of São Paulo School of Medicine, Sao Paulo, Brazil; <sup>2</sup>Universidade Federal de Ciências da Saude de Porto Alegre Faculdade de Medicina, Porto Alegre, Brazil; <sup>3</sup>Pontificia Universidade Catolica de Goias, Goiania, Brazil; <sup>4</sup>Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil.

**Background:** HIV infection is now endemic, and disseminated histoplasmosis (DH) is an AIDS-defining disease. One common treatment for DH is liposomal amphotericin B (LAmB), the main side effect of which is nephrotoxicity.

**Methods:** The main objective of this study was to compare different L-AmB regimens, in terms of their nephrotoxicity, in patients with HIV/AIDS undergoing induction therapy for the treatment of DH. We conducted a prospective exploratory cohort study, nested within a prospective, multicenter, open phase II experimental study, to analyze the nephrotoxicity of induction therapies for DH in HIV/AIDS, followed by oral therapy with itraconazole. Patients were randomized into 3 arms of LAmB administration: 10 mg/kg, single dose (arm 1); 10 mg/kg on day 1, followed by 5 mg/kg on day 3 (arm 2); and 3 mg/kg for 14 days (arm 3). Before and after treatment, we measured levels of cystatin C (cys-C) and fractional excretion of sodium, as well as fractional excretions of potassium and magnesium (FENa, FEK and FEMg, respectively). Means, standard deviations and odds ratios were calculated.

**Results:** We selected 90 hospitalized patients, each of whom were randomly assigned to one of the three arms (n = 30/arm). There were no statistical differences among the arms regarding patient sex, age, CD4 count or viral load (VL). The mean age was 42 years, and 80% of the patients were men. Of the 90 patients evaluated, 18 (20%) died during hospitalization. The mean VL was 776,243 copies/mm<sup>3</sup>, and the mean CD4 count was 89±120 cells/mm<sup>3</sup>. Tubular toxicity was greatest in arm 3, FENa and FEMg being increased in 100% of the patients, whereas FEK was increased in 66%. The values of cys-C were higher than were the creatinine values and correlated more strongly with tubular dysfunction (p<0.001). In arm 1, the increases in FENa and FEMg presented an OR of 12.1 for AKI over a 7-day interval.

**Conclusions:** The 14-day LAmB infusion regimen proved to be more toxic to the renal tubule than did the two other regimens evaluated. Tubular dysfunction with increased FENa and FEMg appears to correlate well with AKI, and cys-C appears to more sensitive than creatinine for predicting AKI.

TH-PO073

Precipitous AKI due to Vancomycin: Risk Factors and Clinical Outcomes  
Danielle N. Aliano,<sup>1</sup> Swetha Rani Kanduri,<sup>1,2</sup> Ardem Elmayan,<sup>1</sup> Juan Carlos Q. Velez.<sup>1,2</sup> Ochsner Nephrology <sup>1</sup>Ochsner Medical Center, New Orleans, LA; <sup>2</sup>The University of Queensland Ochsner Clinical School - New Orleans, New Orleans, LA.

**Background:** A distinct form of AKI due to vancomycin (VA-AKI) characterized by a steep rise in serum creatinine (sCr) has been described, known as vancomycin-associated precipitous-AKI (VA-pAKI). However, its incidence, risk factors and associated outcomes are unknown.

**Methods:** We searched records of hospitalized adults ≥18 yrs who received ≥ 2 consecutive doses of IV vancomycin (2012-2021). We defined AKI by KDIGO. VA-pAKI was defined as AKI with a rise in sCr ≥1.6 mg/dL within 24 +/- 2 hrs. To eliminate confounders, we excluded those with pre-existing CKD stages 3-5, ESKD, kidney transplant, shock requiring vasopressors, rhabdomyolysis, and those with concomitant exposure to trimethoprim (blocks creatinine secretion) or to a nephrotoxin (eg, NSAIDs, aminoglycosides, etc.). We compared variables among 3 groups: no AKI, control non-precipitous VA-AKI (VA-npAKI) and VA-pAKI by ANOVA or chi square, as appropriate.

**Results:** A total of 36,768 patients were included. Among them, 2,428 had AKI (7%), 403 (17%) of them stage 3 AKI. Of those, 129 had VA-pAKI (overall incidence 0.4%, 5% of VA-AKI, 30% of stage 3 VA-AKI), averaging 1 VA-pAKI case per month. Median peak rise in sCr for the VA-pAKI cases was 2.0 (1.6-3.5) mg/dL/day. Median age were 58, 60 and 46 yrs for no AKI, VA-npAKI and VA-pAKI, respectively (p<0.0001). No difference in sex or race were found. Median body weight were 177, 192 and 216 lbs. for no AKI, VA-npAKI and VA-pAKI, respectively (p<0.0001). Median cumulative dose were 3.7, 4.2 and 4.8 g for no AKI, VA-npAKI and VA-pAKI, respectively (p<0.0001). Median vancomycin level were 13, 19 and 25 mcg/mL for no AKI, VA-npAKI and VA-pAKI, respectively (p<0.0001). Regarding outcomes, 2% of VA-npAKI needed dialysis compared to 12% of the VA-pAKI group (p<0.0001). Median length of hospital stay (LOS) were 8, 12 and 14 days for no AKI, VA-npAKI and VA-pAKI, respectively (p<0.0001).

**Conclusions:** VA-pAKI is a distinct subtype of VA-AKI associated with younger age, greater body weight, greater cumulative dose of vancomycin and higher vancomycin level. Furthermore, VA-pAKI is associated with prolonged LOS and greater need for dialysis. Mechanistic studies are required to better understand this clinical entity.

TH-PO074

AKI May Be Underdiagnosed in Children Receiving High-Dose Methotrexate  
Brenda Mendoza Flores, Amanda J. Clark, Marie Christelle Saade, Samir M. Parikh. The University of Texas Southwestern Medical Center, Dallas, TX.

**Background:** High-dose methotrexate (HDMTX) is a nephrotoxic therapy given to children with cancer. It is known that every episode of acute kidney injury (AKI) increases the risk of developing chronic kidney disease, making it particularly impactful for children. Current protocols for reducing AKI incidence with HDMTX include hyperhydration, urine monitoring, and serial serum creatinine measurements. It is not well known how hydration affects creatinine interpretation or AKI diagnosis during HDMTX therapy.

**Methods:** All children admitted to a children's hospital receiving HDMTX as part of routine care in a six month period were enrolled under an IRB approved protocol. Clinical and demographic data were collected from patients' charts. For each patient, serum creatinine at admission was recorded along with the hyperhydration creatinine nadir. The nadir was determined as the point in which serial urinalyses showed a specific gravity < 1.010 but before HDMTX was given. AKI was defined as a 50% increase above admission creatinine or hydration nadir creatinine based on KDIGO criteria. Data were analyzed using Chi-square and paired t-tests.

**Results:** In total, 58 admissions for HDMTX were studied representing 19 children aged 2-19. The hydrated nadir creatinine was 15.8% ± 12.6 lower than admission creatinine (Fig1A, p < 0.0001). Based on admission creatinine, 3.45% of HDMTX admissions resulted in AKI. After reclassification using the hydrated nadir, AKI incidence rose to 13.8% (Fig1B-C, p=0.004).

**Conclusions:** These data highlight the difficulties in using serum creatinine as a marker for renal function, especially in children where modest changes in creatinine imply significant changes in estimated function. Serum creatinine fluctuates with fluid

status; fluid augmentation with chemotherapy accentuates this limitation. Our data show that children receiving HDMTX may be underdiagnosed with AKI. This could prevent renal protective medication adjustments and limit access to renal-specific follow-up. These data highlight the ongoing need for more sensitive, specific, and timely markers of renal function, specifically in children.

### AKI and Acute Kidney Disease After Radical Cystectomy for Muscle Invasive Bladder Cancer: A Hidden Uro-Nephrological Affair

Francesco Trevisani,<sup>1,3</sup> Alessandra Cinque,<sup>3</sup> Matteo Floris,<sup>2</sup> Mattia Longoni,<sup>1</sup> Roberto Minnei,<sup>2</sup> Camilla Maria Ester Bonzi,<sup>1</sup> Maria Rita Rota,<sup>1</sup> Andrea Salonia,<sup>1</sup> Alberto Briganti,<sup>1</sup> Francesco Montorsi,<sup>1</sup> Marco Moschini,<sup>1</sup> <sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Azienda Ospedaliera Brotzu, Cagliari, Italy; <sup>3</sup>Biorek s.r.l., Milano, Italy.

**Background:** Radical cystectomy (RC) represents the first line surgical treatment for muscle-invasive bladder cancer (MIBC). RC is a complex surgical procedure characterized by significant morbidity and mortality. The incidence of significant complications following RC is a well-recognized issue however still paucity of data exists regarding postoperative renal function. Aim of the study was to evaluate the incidence of acute kidney injury (AKI) and Acute kidney disease (AKD) after RC, evaluating the impact of surgery and comorbidities.

**Methods:** In this study, we collected a consecutive cohort of 280 patients who underwent RC for MIBC in a single tertiary institution. All clinical variables and comorbidities were reported pre and after surgery. Serum creatinine with subsequently eGFR using CKD-EPI formula were collected at baseline pre-operative and in the acute setting at 24h, 48, 72h, 6 days for the AKI onset, and after 9,12,15,18,21,24,27,30,45, 60, 75, 90 days for the AKD establishment. Fisher's exact test; Wilcoxon rank sum test; Pearson's Chi-squared test were used for the statistical analysis.

**Results:** Clinical data are present in table 1. Surprisingly, the 51.4% of patients experience AKI and 37.5% of pts AKD. The unique risk factor using univariate analysis was the presence of hypertension at baseline. The surgical techniques did not have any influence. 23.6% of patients experience both AKI and AKD, while 13.9% of patients experience AKD, but not AKI.

**Conclusions:** AKI and AKD are very frequent side effects in the RC for MIBC and require the nephrological counseling immediately after the surgery to monitor the onset of AKI and AKD. Hypertension represents the main risk factor.

### Pregnancy Associated AKI: An 8-Year Study From South India

Devidas S. Bantewad, Manjusha Yadla. *Gandhi Hospital, Secunderabad, India.*

**Background:** Pregnancy-related acute kidney injury (PRAKI) is a major cause of maternal and fetal morbidity and mortality in developing countries. With improvement in antenatal and postnatal care, the incidence of PRAKI in India has steadily declined from 22% in 1960s to 9% in 1980s, and further down to 3–7% in 2000s.

**Methods:** **Aim :** To study the clinical characteristics and outcomes of patients with PRAKI **Design :** Prospective observational study **Setting :** Tertiary Care Government Hospital in Telangana **Period of study :** Jan 2014 to May 2022 **Methodology :** Data collected prospectively from All admitted pregnant and postpartum patients who developed a PRAKI. **Inclusion criteria :** All pregnant and postpartum patients who developed a PRAKI. **Exclusion criteria :** 1. Evidence of renal disease prior to pregnancy 2. Elevated serum creatinine prior to gestation

**Results:** A total of 311 patients satisfied inclusion criteria. Pregnancy related Acute Kidney Injury was 0.32% of total pregnancies in our institute. The Institutional incidence of pregnancy related Acute Kidney Injury in context of all cases of AKI was 5.88%, out of which dialysis requiring PRAKI incidence was 4.22% at our institute.

**Conclusions:** 1. Incidence of pregnancy related Acute kidney injury in context of overall AKI was 5.88% 2. Most common cause of PRAKI in our study was preeclampsia (43.4%) 3. Sepsis and multisystem involvement was in 74.27 and 21.86% patients respectively. 4. In our institute Maternal mortality was 21.54% and fetal mortality was 47.58%. 5. Total patients receiving RRT was 223 (71.70%) while 88 (28.29%) patients was managed conservatively.

### AKI in Critically Ill Patients Presenting With Gastrointestinal Hemorrhage

Mythri Anil Kumar,<sup>1</sup> Dheera Grover,<sup>1</sup> Niala Moallem,<sup>1</sup> Tara McLaughlin,<sup>2</sup> Raj Parikh,<sup>2</sup> <sup>1</sup>UConn Health, Farmington, CT; <sup>2</sup>Hartford Hospital, Hartford, CT.

**Background:** Acute gastrointestinal bleeding (GIB) is associated with a high mortality and morbidity rate. Acute kidney injury (AKI) in critically ill patients admitted with GIB as their primary diagnosis is scarcely studied. We aimed to determine the incidence, risk factors and significance of acute kidney injury (AKI) in this cohort.

**Methods:** This was a single center retrospective study of patients admitted to the IU and ICU from the ED with GIB as their primary diagnosis from March 1, 2015 to March 1, 2021. Baseline characteristics, laboratory values and therapeutic interventions performed were extracted. AKI was defined according to the KDIGO criteria. Groups with and without AKI were compared. Chi square test was and Wilcoxon rank sum test were performed for categorical and continuous variables respectively.

**Results:** Among 300 patients, 46.3% developed an AKI. Diabetes mellitus (DM), heart failure (HF), atrial fibrillation (Afib), chronic kidney disease (CKD) were more frequently present in GIB patients who developed AKI. Mean arterial pressure (MAP) and heart rate (HR) at admission were lower in the AKI group [75 (interquartile range (IQR) 67,88) vs 80 (IQR 71,93) and 82 (IQR 72,100) vs 92 (IQR 76.5,108) respectively]. Vasopressor use and mechanical ventilation rates were higher in the AKI group. 14.7% of the GIB patients who developed AKI were transitioned to comfort care only (CMO) compared to 4.9% patients without AKI. While 90-day readmission rate with GIB and 30-day mortality rate were not significantly different between the groups, both the hospital and ICU/IU LOS were longer in patients with AKI [6 (IQR 4,10.25) vs 5 (IQR 3,7); p value <0.001 and 3.5 (IQR 2,5) vs 3 (IQR 2,4); p value 0.015 respectively].

**Conclusions:** In critically ill GIB patients, comorbid conditions such as DM, HF, Afib, CKD are risk factors for the development of AKI. They tended to present with a lower MAP, lower HR and higher lactic acid (LA). Risk stratification scores including Glasgow-Blatchford Bleeding Score (GBS) and AIMS 65 were worse. These patients were sicker and had higher vasopressor and mechanical ventilation needs. Consequently, they had longer hospital and ICU/IU LOS and were more likely to be made CMO. The development of AKI in critically ill GIB patients is associated with greater morbidity.

## TH-PO078

### A Retrospective Analysis of Fluid Balance in Patients With AKI and Respiratory Failure due to COVID-19

Pranav Sharma, Amar M. Bhagat, Chioma Madu, Jonathan Lebowitz, Lilian Saro-Nunez, Steve I. Khalil. *Robert Wood Johnson University Hospital, New Brunswick, NJ.*

**Background:** The optimal amount of hydration for patients with severe COVID-19 infection and AKI is unknown. This study aims to investigate the impact of fluid management strategy and outcomes in patients with AKI and respiratory failure due to COVID-19.

**Methods:** Data was gathered from a retrospective chart review of patients with hypoxia due to COVID-19 infection and stage 2 or greater AKI. Primary outcome was the difference in net fluid balance between patients who were successfully weaned to lower levels of oxygen support and discharged compared to those who died or remained ventilator dependent.

**Results:** Of 58 cases, 41 died, 3 remained ventilator-dependent, and 14 were discharged without supplemental oxygen. The groups differed in net fluid balance (-10,065 cc vs +7,980 cc, p<0.001) and daily fluid balance (-367 vs. 515 cc/day, p<0.001) with a substantially lower mean fluid balance in patients who survived with minimal requirement for supplemental oxygen. Patients who maintained a positive fluid balance were significantly more likely to become ventilator dependent or die (OR: 40.7, 95% CI: 5.3 - 312.9). A fluid restrictive strategy did not reduce the likelihood of recovery from AKI or increase the need for renal replacement therapy.

**Conclusions:** In our cohort, patients with COVID-19 and AKI who survived with minimal or no oxygen requirements tended to have negative fluid balance in contrast to those who died or remained ventilator-dependent. A fluid restrictive strategy with judicious volume removal using diuretics or dialysis may lead to improved outcomes in COVID-19 patients with AKI.

## TH-PO079

### A Tertiary Care Centre Experience of COVID-19-Associated AKI During the First and Second Waves of the Pandemic

Maithrayie Kumaresan,<sup>1,2</sup> Phanidhar Mogga,<sup>2</sup> Georgi Abraham,<sup>2</sup> Urjitha Rajagopalan.<sup>2</sup> <sup>1</sup>University Hospital Lewisham, London, United Kingdom; <sup>2</sup>MGM Healthcare, Chennai, India.

**Background:** There is a scarcity of information on the incidence and outcomes of acute kidney injury in COVID-19 patients in India. Therefore, we analysed the correlation of AKI risk factors and compared the outcomes of the first and second COVID-19 waves in a tertiary care centre.

**Methods:** •Single centre retrospective analysis •Patients who tested positive for COVID-19 between July 2020 and May 2021, with serum creatinine levels measured on admission (n= 1260). •AKI was defined according to the KDIGO clinical practice guidelines. •Multivariate binomial logistic regression yielded odds ratios for risk variables of AKI. •Age-adjusted odds ratios(OR) were used to compare COVID-19 outcomes between the first and second waves.

**Results: Baseline characteristics:** •Median Age= 56 (IQR 47-66) •Population with diabetes-55.2% •Population with hypertension-42.11% **All AKI** (n=86) •Stage 1 (n=57) •Stage 2 (n=20) •Stage 3 (n=9) **Risk factors for AKI:** •Diabetes OR 1.9 (1.2 - 3.1) •Hypertension OR 3.2 (2.0 - 5.2) •C-reactive protein ≥ 10 mg/dl, OR 3.6 (1.6 - 8.0). •D-dimer ≥ 250 pg/ml, OR 4.2 (2.5 - 6.8). •Need for ventilation OR 3.06 (1.8 - 4.9) **Comparison of COVID -19 outcomes:** Compared to the first wave, the second wave cohort had lower risk for: •Acute kidney injury (adj OR: 0.4; CI: 0.2-0.7) •Mortality (adj OR: 0.2; CI: 0.09-0.7) •Invasive mechanical ventilation (adj OR: 0.2; CI: 0.06 - 0.8) •Length of ICU stay > 5days (adj OR: 0.4; CI: 0.2 - 0.7)

**Conclusions:** In our retrospective study, AKI prevalence was 6.8%, and the mortality rate of 2.9%. Our analysis shows that the second wave of COVID -19 exhibits improved clinical outcomes compared to the first wave

### Urine Proteomic Analysis Identifies Interferon Gamma Downstream Chemokine CXCL-9 as a Biomarker for Diagnosis of Acute Interstitial Nephritis

Dennis G. Moledina,<sup>1</sup> Wassim Obeid,<sup>3</sup> Meghan E. Sise,<sup>2</sup> Ivy A. Rosales,<sup>2</sup> Rex N. Smith,<sup>2</sup> Robert B. Colvin,<sup>2</sup> Michael B. Kuperman,<sup>4</sup> Michael Kashgarian,<sup>1</sup> Gilbert W. Moeckel,<sup>1</sup> Francis P. Wilson,<sup>1</sup> Chirag R. Parikh.<sup>3</sup> <sup>1</sup>Yale School of Medicine, New Haven, CT; <sup>2</sup>Massachusetts General Hospital, Boston, MA; <sup>3</sup>Johns Hopkins University, Baltimore, MD; <sup>4</sup>Arkana Laboratories, Little Rock, AR.

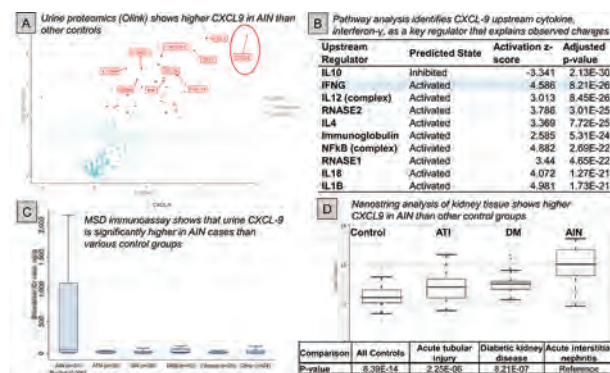

**Background:** Targeted analyses have identified TNF-α and IL-9 as diagnostic biomarkers of AIN. However, unbiased analysis may reveal more accurate biomarkers for AIN diagnosis.

**Methods:** In a prospectively enrolled cohort of participants who underwent a kidney biopsy for evaluation of acute kidney disease with adjudicated histological diagnosis, we performed urine proteomics via Olink assay. We validated proteomics findings by developing a sandwich immunoassay in urine, and by examining gene expression in kidney tissue using Nanostring.

**Results:** We observed that 32 (17%) of 184 proteins were significantly different between AIN cases (n=31) and non-AIN controls (n=57). Of these differentially expressed proteins, CXCL-9 had the highest strength of association (**Figure**). Pathway analysis showed that activation of interferon-γ, the key upstream regulator of CXCL9, explained observed changes in the urine proteome. Using a sandwich immunoassay, we showed that CXCL-9 was 6-fold higher in AIN cases (n=32) than non-AIN controls (n=186). Participants in the top quartile of CXCL-9 had higher odds of AIN than those in the bottom quartile after controlling for a diagnostic model for AIN (adj. OR, 5.9 (95% CI, 1.8, 20)) with an AUC of 0.82 (0.74, 0.89). Finally, CXCL-9 expression was higher in kidney tissue from patients with drug-induced AIN as compared to those with diabetes, acute tubular injury, or healthy kidney donors.

**Conclusions:** Using urine proteomics, we identified CXCL-9 as a novel biomarker for AIN diagnosis. We validated the association of CXCL-9 using immunoassay and kidney tissue expression data.

### Olfactomedin 4 as a Loop of Henle-Specific AKI Biomarker That Predicts Furosemide Response

Denise C. Hasson,<sup>1</sup> Kelli A. Krallman,<sup>1</sup> Bin Zhang,<sup>1</sup> Katherine A. Vandenheuvell,<sup>1</sup> Shina Menon,<sup>2</sup> Kristalynn M. Kempton,<sup>1</sup> Prasad Devarajan,<sup>1</sup> Stuart Goldstein,<sup>1</sup> Matthew N. Alder.<sup>1</sup> <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>Seattle Children's Hospital, Seattle, WA.

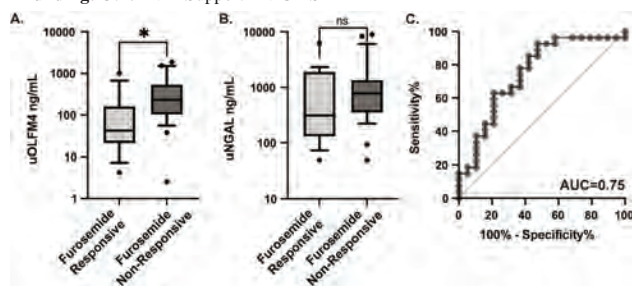

**Background:** Acute kidney injury (AKI) is associated with bad outcomes. Olfactomedin 4 (OLFM4) is a glycoprotein expressed in neutrophils and stressed epithelial cells. In septic animals, OLFM4 expression localized to the loop of Henle (LOH). OLFM4 null septic murine pups had higher renal cell apoptosis and plasma creatinine. We hypothesized urine OLFM4 (uOLFM4) will increase in patients with AKI, and if localized to the LOH in humans, predict furosemide response.

**Methods:** A retrospective study used urine samples based on AKI and sepsis status from day 1 of intensive care unit (ICU) admission from a single center repository. A prospective validation study used convenience urine from ICU patients (pts). uOLFM4 was tested with a custom bead based Luminex immunoassay. Demographic, lab data (NGAL), were collected from the medical record. AKI was defined by KDIGO stage 2-3 (severe) creatinine criteria. Immunofluorescence on biopsies from pts with kidney injury was performed with antibodies for uromodulin, OLFM4. Furosemide response was >3 mL/kg/hr of urine made in 4 hrs after 1mL/kg IV furosemide given for clinical need. Mann Whitney U, Kruskal Wallis tests were performed, and linear mixed modeling accounted for lack of independence.

**Results:** Pts with severe AKI had higher uOLFM4 (retrospective, n=36, p=0.04; prospective, n=178, p=0.007). Although uOLFM4 and urine NGAL correlated (r 0.40, p<0.0001), some pts had high uOLFM4 and low NGAL and vice-versa. On biopsy, OLFM4 signal colocalized with uromodulin, suggesting OLFM4 localizes to human LOH. uOLFM4 was higher in pts who were unresponsive to furosemide (p=0.04), AUC 0.75 (95% CI, 0.60-0.90); NGAL was not.

**Conclusions:** Severe AKI is associated with increased uOLFM4. OLFM4 colocalized to human LOH; higher uOLFM4 associated with furosemide resistance. OLFM4 may be a novel LOH-specific AKI biomarker that warrants further testing to determine whether it may enhance identification of pts likely to benefit from early kidney replacement therapy.

### Carcinoid Tumor Causing Cardiorenal Syndrome

Zachary A. Hansen, Adrian J. Baudy. Tulane University, New Orleans, LA.

**Introduction:** Carcinoid tumors are a rare condition that most commonly occurs in the gastrointestinal tract and presents as flushing, diarrhea, and hypotension. Occasionally, it can develop into carcinoid heart disease causing heart failure. This places patients at risk of developing cardiorenal syndrome (CRS) where dysfunction in the heart causes dysfunction in the kidney. CRS has traditionally been attributed to decreased renal perfusion from left heart failure (LHF) but there is now evidence that venous

congestion from right heart failure (RHF) is a major cause and has been termed congestive nephropathy. Here, we describe a previously unreported case of carcinoid heart disease causing right sided cardiorenal syndrome.

**Case Description:** 70 year old male with heart failure (EF 60-65%), tricuspid regurgitation, carcinoid tumor with liver and mesenteric metastases presented with worsening upper and lower extremity edema, abdominal swelling and dyspnea for 1 week. On exam, he was hypotensive and hypoxic with Jugular venous distention, ascites and +3 lower extremity edema. Labs showed creatinine of 3.4 and BUN 144, from a baseline of 1.4 and 40 respectively. Chest x-ray showed bilateral pleural effusions. He was admitted to the ICU and diagnosed with CRS. He was treated with Milrinone, dobutamine and furosemide and initially had good urine output but it decreased over the next two days. Intrarenal venous doppler showed discontinuous waveforms consistent with congestive nephropathy. Diuretics were increased to a maximum daily dose of 320mg furosemide, 10mg metolazone and 500mg acetazolamide as well as norepinephrine, dobutamine and milrinone with minimal improvement in urine output. He was started on CRRT for volume removal, but his clinical condition deteriorated, and he died a few days later.

**Discussion:** To our knowledge, this is the first reported case of right heart failure causing cardiorenal syndrome as a direct result of carcinoid heart disease. Carcinoid tumors are an uncommon neuroendocrine disorder that rarely affects the heart. Cardiorenal syndrome is a familiar condition but is typically attributed to left rather than right heart failure. This case demonstrates a previously unreported combination of cardiorenal syndrome due to right heart failure caused by carcinoid heart disease. It also emphasizes the difficulty in management and the need for further studies regarding congestive nephropathy from right heart failure.

TH-PO083

### AKI in Patients With SARS-CoV-2 Is Significantly Associated With Mitochondrial Dysfunction and ER Stress

Pushkala Jayaraman,<sup>1</sup> Ishan Paranjpe,<sup>1</sup> George Vasquez-Rios,<sup>1,2</sup> Sergio Dellepiane,<sup>1,2</sup> Girish N. Nadkarni.<sup>1,2</sup> Augmented Intelligence in Medicine at Mount Sinai Group (AIMS group at D3M, MSSM) <sup>1</sup>Cahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Department of Medicine, Mount Sinai, New York, NY.

**Background:** AKI is a common complication of COVID-19. The peripheral blood molecular signatures are unknown and could unveil potential therapeutic targets.

**Methods:** We enrolled a prospective patient cohort of 283 patients with COVID-19 (Mar 24-Aug 26, 2020), with blood samples from Mount Sinai Biobank. We determined AKI severity using KDIGO criteria on admission parameters. 31 patients with severe AKI (AKI 2-3) were defined as cases. We then performed bulk peripheral RNA sequencing and fit a multivariate linear regression model adjusting for key covariates. We also performed cell-type deconvolution following to adjust for neutrophils, and whole blood cells. We considered a significant p-value (0.05) after Bonferroni correction and then used ingenuity pathway analysis (IPA) to analyze differentially expressed genes.

**Results:** Patients who developed AKI were significantly older (67 vs. 60 yrs.) and had a greater prevalence of type 2 diabetes (37% vs 20%), and chronic kidney disease (20% vs 4%) vs. controls. Of the 18539 genes in the analysis, 1597 were upregulated and 267 were downregulated after Bonferroni correction. Top canonical pathways (Fig 1) showed significantly downregulated genes including EIF2, eIF4, and p70S6K via activation of ATF6, a marker of ER stress. Potential mechanisms displayed by our analyses include upregulation of the NF-KB inhibitor and IL6 pathways. Genes involved in oxidative Phosphorylation and mitochondrial dysfunction were heavily downregulated and there was upregulation of markers of kidney cell necrosis. In contrast, upregulated genes CRK and TIMP2 have been previously implicated in kidney injury and progression. Downregulated mTOR pathway is responsible for the activation of the ER stress response via the eIF2/4 complex which is also supported by our finding of upregulated NRF2-transcriptional pathway.

**Conclusions:** Transcriptomic analysis of AKI in COVID-19 revealed evidence of mitochondrial dysfunction driven by ER stress and immune-mediated pathways. Addressing these pathways could aid development of targeted therapies.

**Funding:** NIDDK Support

TH-PO084

### Potential Regulator of KIM-1 Mediated Autophagy

Yilong Li,<sup>1</sup> Elena Tutunea-Fatan,<sup>1,2</sup> Lakshman Gunaratnam.<sup>1,2</sup> <sup>1</sup>Western University, London, ON, Canada; <sup>2</sup>Lawson Health Research Institute, London, ON, Canada.

**Background:** Kidney injury molecule 1 (KIM-1) is a phosphatidylserine receptor expressed on injured proximal tubule epithelial cells (PTECs) during acute kidney injury (AKI). KIM-1 mediates the phagocytic clearance of apoptotic cells by PTECs and targets the engulfed apoptotic corpses to autophagosomes by triggering autophagy. However, the detailed signaling mechanisms are poorly understood. This study aims to uncover KIM-1-interacting proteins that regulate autophagy in PTECs.

**Methods:** KIM-1 immunoprecipitates from human PTECs (HK-2), which endogenously express KIM-1, stimulated with apoptotic cells were separated using SDS-PAGE. The bands of putative KIM-1 interacting proteins were visualized using Coomassie blue staining and analyzed using liquid chromatography with tandem mass spectrometry. Proteins were identified using PEAKS DB proteomics software, which uses *de novo* sequencing assisted database searching. Protein-protein interactions were confirmed using western blot analysis.

**Results:** The immunoprecipitation of KIM-1 was confirmed by both western blot and mass spectrometry analyses, in which KIM-1 was only present in the anti-KIM-1 group and absent in the IgG control. We identified the phosphoinositide-3-kinase regulatory subunit 4 (PIK3R4) with a PEAKS peptide score of 99.1 (minimum threshold at 26.7) and a sequence coverage of 6%. Western blot analysis showed that PIK3R4 co-immunoprecipitated with KIM-1 in both apoptotic cells-stimulated and unstimulated HK-2 cells.

**Conclusions:** PIK3R4 interacts with KIM-1 constitutively in PTECs. It has previously been implicated in the regulation of autophagy including autophagosome formation and endocytic trafficking but not in PTECs. Further investigation will elucidate whether PIK3R4 is required for KIM-1 mediated autophagy.

**Figure 1.** Co-immunoprecipitation of KIM-1 and PIK3R4 from HK-2 cells.

## TH-PO085

### Prerenal Azotemia Triggers the Hepatic Acute Response in a Novel, Clinically Defined Murine Model

Kayo Okamura, Sizhao Lu, Zhibin He, John R. Montford, Mary C. Weiser-Evans, Sarah Faubel. *University of Colorado, Denver, CO.*

**Background:** Prerenal azotemia (PRA) is uncommonly studied in murine models and is thought to be systemically inert. We developed a novel murine model of PRA that met the current clinical definition in humans: Decreased GFR that returns to baseline with restoration of hemodynamics. Since plasma IL-6 is elevated during AKI, in part due to reduced GFR and is the major mediator of the hepatic acute phase response, we hypothesized that PRA would result in elevated plasma levels of IL-6 and hepatic production of acute phase proteins.

**Methods:** Mice: C57Bl/6J. Interventions: 4 mg of furosemide IP (PRA) or vehicle (Veh) at time 0 hours and 3 hours in wild type (WT) and *IL-6*<sup>-/-</sup> mice; at 6 hours, resuscitation was started with 1 mL IP saline x 4 over 36 hours. Measurements: transdermal measured glomerular filtration rate (tGFR) at baseline, 6 and 48 hours; all other measurements at 6 hours that included: plasma IL-6, NGAL, CXCL1, and haptoglobin, and hepatic tissue RNAseq.

**Results:** tGFR was 30% of normal at 6 hours and returned to baseline at 48 hours. At 6 hours, plasma IL-6 was significantly increased, renal and liver histology were normal, renal and liver lactate were normal, and renal KIM-1 IF was normal. By RNAseq, 587 differentially regulated genes were significantly changed in the liver in WT PRA versus WT Veh; 327 genes were significantly upregulated and 260 were significantly suppressed; the acute phase response was the most significantly upregulated pathway. 25% of upregulated genes in the liver were reduced in *IL-6*<sup>-/-</sup> PRA, and the acute phase response was the most significantly downregulated pathway. Hepatic gene expression and protein levels were determined for 3 of the significantly upregulated genes: NGAL, CXCL1, and haptoglobin; gene expression and plasma protein levels were all increased in WT PRA versus WT Veh and were all reduced in *IL-6*<sup>-/-</sup> PRA versus WT PRA.

**Conclusions:** These data demonstrate previously unknown systemic effects of PRA, demonstrating that significant consequences may occur with the sudden loss of GFR in the absence of tubular injury. Since it is widely thought that the systemic consequences of AKI are predominantly associated with tubular injury, these data change the paradigm by which the consequences of PRA should be considered.

## TH-PO086

### Mechanisms of Difference in AKI-CKD Transition due to Acute Cardiorenal Syndrome and Ischemia-Reperfusion Injury

Yoshio Funahashi,<sup>1,2</sup> Jessica F. Hebert,<sup>1,2</sup> Adam C. Munhall,<sup>1,2</sup> Megan N. Nickerson,<sup>1,2</sup> Michael Hutchens,<sup>1,2</sup> <sup>1</sup>Oregon Health & Science University, Portland, OR; <sup>2</sup>Portland VA Medical Center, Portland, OR.

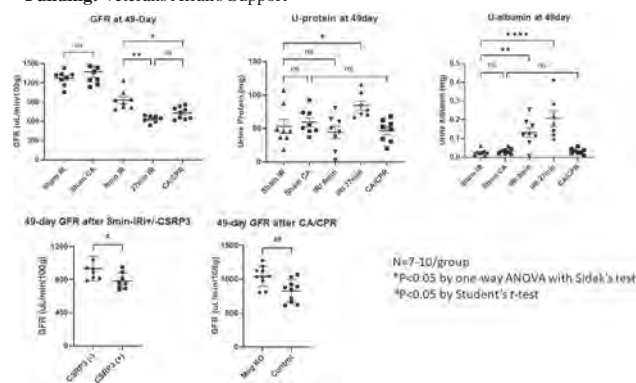

**Background:** Cardiorenal syndrome type 1 (CRS1) is acute kidney injury (AKI) due to acute heart failure. Heart-specific cardiac LIM protein (CSRP3) is released into the plasma after cardiac arrest and is differentially endocytosed in the proximal tubule depending on megalin. We hypothesized that the phenotype of AKI-CKD transition differs between cardiac arrest and cardiopulmonary resuscitation (CA/CPR) and kidney-only ischemia due to renal uptake of heart-specific CSRP3.

**Methods:** 8 to 12 weeks old C57BL/6J male mice and inducible proximal tubule-specific megalin knockout (iMegKO) mice (with littermate controls) were subjected to 8-minute CA/CPR or bilateral renal pedicle occlusion (IRI) with multiple durations. Glomerular filtration rate (GFR) and other outcomes were measured 24h and 49 days later.

**Results:** 24h GFR was equivalent between 27-minute IRI and 8-minute CA/CPR. 8-minute IRI, the same ischemia duration as CA/CPR, resulted in higher 24h GFR than CA/CPR. 49 days after surgery, CA/CPR induced GFR was lower, and blood urea nitrogen (BUN) and cystatin-C (Cys-C) were higher than 8min IRI, suggesting milder chronic injury from 8min IRI. GFR, BUN and Cys-C were not different between CA/CPR and 27min IRI although survival. IRI induced late albuminuria and proteinuria, but CA/CPR did not. Cardiac CSRP3 was elevated after CA/CPR but not after IRI. Injection of recombinant CSRP3 after 8min IRI reduced the GFR 49 days following injection compared with 8min IRI. CA/CPR-exposed iMegKO mice demonstrated increased GFR compared to controls identical to that of 8min IRI compared with 8min CA/CPR. Inducible, cardiac-specific CSRP3 knockout (iCSRP3 KO) mice exhibited cre-recombinase expression and floxed *Csrp3* genotype.

**Conclusions:** Cardiorenal AKI and focal ischemia (IRI)-induced AKI demonstrated different phenotypes in AKI-CKD transition, with different degrees of chronic filtration loss and albuminuria. CSRP3 may mediate this different phenotype. iCSRP3 KO mice are expected to delineate this important mechanism.

## TH-PO087

### Casual Association of Oxidative Stress With Cardiorenal Syndrome in Pulmonary Hypertension: An Experimental Investigation and Its Clinical Implications

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

**Background:** AKI due to pulmonary hypertension (PH) has been associated with an increase in mortality. Studies have shown 36% of the patients with AKI and PH died in the hospital compared with 5% in the PH group who did not develop AKI and retrospective study of hospitalized patients and PH registries shows AKI and CKD in 4%–50% of patients and renal insufficiency associates with poor prognosis. However, there is hardly any data available regarding pathogenesis of complex interplay of kidney, lung and the heart. To investigate experimental model of PH without left ventricular failure is essential to develop novel therapeutic targets.

**Methods:** In a chemically induced experimental model of PH with right ventricle (RV) dysfunction and AKI in rats we investigated whether antioxidant has cardiorenal protective effect & would this treatment modify oxidative stress in kidney & heart. Rats were divided into 3 groups; control, CRS and CRS+ Antioxidant Prob (treated 1 wk pre & 1 wk post chemical injection). Rats were assessed with serial doppler echo for 3 wk to monitor PH via Pulmonary Artery Acceleration (PAAT), ejection fraction (EF) & RV hypertrophy (RVH). At 3 wk heart & kidney tissue and plasma were used to analyze antioxidant enzymes; superoxide dismutase (SOD) and glutathione peroxidase (GSHPx), as well as lipid peroxidation to assess oxidative stress. After sacrificing animals, hearts and kidneys were removed for histopathology. To assess congestion, pieces of tissue from the lung, kidney and the RV were removed to obtain the wet/dry weight ratio.

**Results:** In 3 wk, CRS group showed signs of progressive respiratory distress & doppler Echo demonstrated decrease in PAAT an indication of pulmonary hypertension, increase RVSP & normal EF. Oxidative stress in kidney and the RV was associated with decrease in antioxidant enzyme activities of SOD and GSHPx. Light and electron

microscopy of the Kidney showed ATN. Wet/dry weight showed mild congestion in the lung but not in the kidney and the heart. In CRS+ antioxidant PROB these changes were not observed.

**Conclusions:** Cardiorenal protective effect of antioxidant and absence of renal congestion- a potential contributor in CRS- suggest a cause-effect relationship between oxidative stress and CRS in PH. Targeting oxidative stress may lead to novel therapeutic strategies to improve outcome.

##### Diabetes and Obesity Increase the Severity of Ischemia-Reperfusion Induced AKI in ZSF1 Rats

Li-Jun Ma,<sup>1</sup> Fuyong Du,<sup>1</sup> Kamal Albarazani,<sup>1</sup> Jianying Liu,<sup>1</sup> Qiu Li,<sup>1</sup> Lili Guo,<sup>1</sup> Jenson Qi,<sup>1</sup> George Ho,<sup>1</sup> Rong Meng,<sup>1</sup> Tao Chen,<sup>2</sup> Raul Camacho,<sup>1</sup> Andrea R. Nawrocki.<sup>1</sup> <sup>1</sup>Cardiovascular, Metabolism, and Retina at The Janssen Pharmaceutical Companies of Johnson & Johnson, Spring House, PA; <sup>2</sup>Preclinical Sciences and Translational Safety at Janssen, Johnson & Johnson, Spring House, PA.

**Background:** Acute kidney injury (AKI) is a multifactorial disease with various etiologies including cardiac surgery and sepsis. Preclinical AKI is typically induced in young and healthy rodents and the predictive value of preclinical AKI models for drug discovery is unclear. Obese, diabetic ZSF1 rats display multiple preexisting metabolic complications including kidney dysfunction. We show that obese, diabetic ZSF1 rats are more susceptible to ischemia reperfusion injury (IRI) induced-renal function decline and tubular injury compared to lean, non-diabetic ZSF1 rats.

**Methods:** AKI was induced in male, obese, diabetic ZSF1 (CRL) or age-matched, lean ZSF1 rats at age of 17-18 weeks by unilateral IRI with uninephrectomy (Unx) and followed for 1 or 7 days. Renal function was assessed by transcutaneous glomerular filtration rate (tGFR, FITC-labeled sinistrin, Medibeacon) and plasma creatinine (LC/MS). Urinary Nephrocheck, gene expression and kidney histology were assessed.

**Results:** 24 hrs post IRI surgery, glomerular filtration rate (tGFR) was dramatically decreased in both obese ZSF1 Unx/IRI and lean ZSF1 Unx/IRI groups compared to controls. Further, IRI in obese ZSF1 rats caused significantly greater renal function decline indicated by plasma creatinine, and more severe tubular necrosis. Tubular injury marker genes (Kim1, NGAL) were upregulated in kidney, while mitochondrial genes (mdufa2, ucrs1, ATP5g1, PPARgc1) and tubular integrity marker genes (AQP1, rGT1) were downregulated to a greater extent in obese vs lean ZSF1 IRI kidneys. Urinary Nephrocheck levels were higher in obese vs lean ZSF1 rat IRI. The decline in kidney function persisted in obese ZSF1 IRI rats but recovered in lean ZSF1 IRI rats from day 3 to 7. Overall, we observed 25% mortality in obese ZSF1 rats with Unx/IRI while the moderate AKI was reversed in lean rats after IRI surgery without progression to kidney failure.

**Conclusions:** Our data indicate that obese and diabetic ZSF1 rats with underlying metabolic disease and albuminuria exhibit severe renal function decline after a single, moderate ischemic episode relative to non-diabetic, lean counterparts. Our data suggest that typically used rodent IRI models for AKI do not represent the full spectrum of the human disease.

##### Blue Kidney With Repaired Valve

Kanza Haq, Alana Dasgupta, S.M. Bagnasco, Samir C. Gautam. Johns Hopkins University, Baltimore, MD.

**Introduction:** Renal hemosiderosis has been reported in diseases characterized by chronic intravascular hemolysis but it is a relatively rare finding following cardiac valve repair

**Case Description:** 70-year-old male with a history of CKD stage IIIB2 presented for evaluation of worsening renal function. Pertinent past medical history includes hypertension and mitral valve annuloplasty performed 20 years prior. Serum creatinine had gradually increased from 1.6 mg/dL to 2.3 mg/dL. Urinalysis was consistently notable for hemoglobin pigment with intermittent microscopic hematuria. Serological workup was negative. Laboratory studies were also notable for anemia (hemoglobin 10.7 g/dL), elevated reticulocyte count (4.9%), elevated LDH (1174 U/L), and low haptoglobin (< 3mg/dL). Echocardiogram showed moderate to severe mitral valve regurgitation. Percutaneous renal biopsy revealed proximal tubule epithelial cells containing brown, granular pigment within the cytoplasm (Fig 1), which stains blue with the Prussian blue iron stain (Fig 2). He was ultimately referred to cardiac surgery for consideration of mitral valve replacement.

**Discussion:** Intravascular hemolysis is a well-recognized complication after prosthetic cardiac valve replacement or repair. Recurrent, or residual valvular regurgitation can cause serious mechanical hemolysis as regurgitant flow creates high shear stress that results in fragmentation of red blood cells. The chemically active iron in hemosiderin can cause tubular damage through various mechanisms.

##### Double-Stranded DNA-Induced AIM2 Pyroptosis Limits Excessive Inflammation During Rhabdomyolysis-Induced AKI

Chintogtokh Baatarjav, Takanori Komada, Masafumi Takahashi. Jichi Ika Daigaku, Shimotsuke, Japan.

**Background:** Rhabdomyolysis-induced acute kidney injury (RIAKI) is a severe complication of rhabdomyolysis, reportedly in part via double-stranded DNA (dsDNA) released from necrotic muscle. A dsDNA-sensor absent in melanoma 2 (AIM2) engages inflammasome activation, leading to maturation of IL-1 $\beta$  and gasdermin D (GSDMD)-dependent pro-inflammatory cell death called pyroptosis. The role of AIM2-mediated pyroptosis during RIAKI remains unknown.

**Methods:** C57BL/6J-background wild type (WT) and Aim2-knockout (Aim2-KO) mice underwent intramuscular glycerol injection to induce RIAKI. Isolated kidney macrophages and bone marrow-derived macrophages were subjected to dsDNA-induced pyroptosis assays in vitro.

**Results:** A specific endonuclease for dsDNA, DNase-I, effectively ameliorated tubular injury and inflammation during RIAKI, corroborating that dsDNA is a critical danger molecule of RIAKI. TUNEL staining and immunoblotting for GSDMD in RIAKI kidneys demonstrated massive macrophage pyroptosis in WT, and Aim2-KO diminished this response. While pyroptosis was suppressed, Aim2-KO kidneys displayed abnormally more macrophage accumulation than WT. Aim2-KO promoted RIAKI by TANK-binding kinase 1 (TBK1)-NF- $\kappa$ B signalling and recruited more CD206<sup>+</sup>CXCR3<sup>+</sup> macrophages, resulting in excessive kidney inflammation, fibrosis, and sustained kidney dysfunction. In vitro study, dsDNA induced swift pyroptotic cell death in kidney macrophages without releasing IL-1 $\beta$ . Aim2-KO macrophages were devoid of pyroptosis in response to dsDNA. These surviving Aim2-KO macrophages alternatively developed STING-TBK1-IRF3/NF- $\kappa$ B activation, and secreted IFN $\beta$  and TNF $\alpha$ . Conditioned medium of dsDNA-treated Aim2-KO macrophages, not WT macrophages, upregulated pro-inflammatory genes on macrophages and kidney tubular epithelial cells. These results indicate pro-inflammatory functions of Aim2-deficient macrophages escaped from pyroptosis.

**Conclusions:** Aim2 deficiency worsens inflammation and fibrosis of RIAKI despite reduced macrophage pyroptosis. Macrophage survivors lacking Aim2 potentiate

inflammation on surrounding cells. dsDNA-induced, AIM2-dependent macrophage pyroptosis potentially provides a resolution of inflammation and determines the healing process of RIAKI.

### Magnetic Resonance Imaging (MRI) Contrast Agent Safety: Speciating Intracellular Gadolinium-Rich Nanoparticles in Human and Rodent Kidneys

**Brent Wagner**,<sup>1,2</sup> G. P. Escobar,<sup>1,2</sup> Joshua Deaguero,<sup>1,2</sup> Karol Dokladny,<sup>1,2</sup> Tamara A. Howard,<sup>1</sup> James H. Degnan,<sup>5,2</sup> John D. Watt,<sup>3,4</sup> Adrian Brearley,<sup>6</sup> Kidney Institute of New Mexico <sup>1</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>2</sup>New Mexico VA Health Care System, Albuquerque, NM; <sup>3</sup>Center for Integrated Nanotechnologies, Albuquerque, NM; <sup>4</sup>Los Alamos National Laboratory, Los Alamos, NM; <sup>5</sup>University of New Mexico Department of Mathematics and Statistics, Albuquerque, NM; <sup>6</sup>University of New Mexico Department of Earth & Planetary Sciences, Albuquerque, NM.

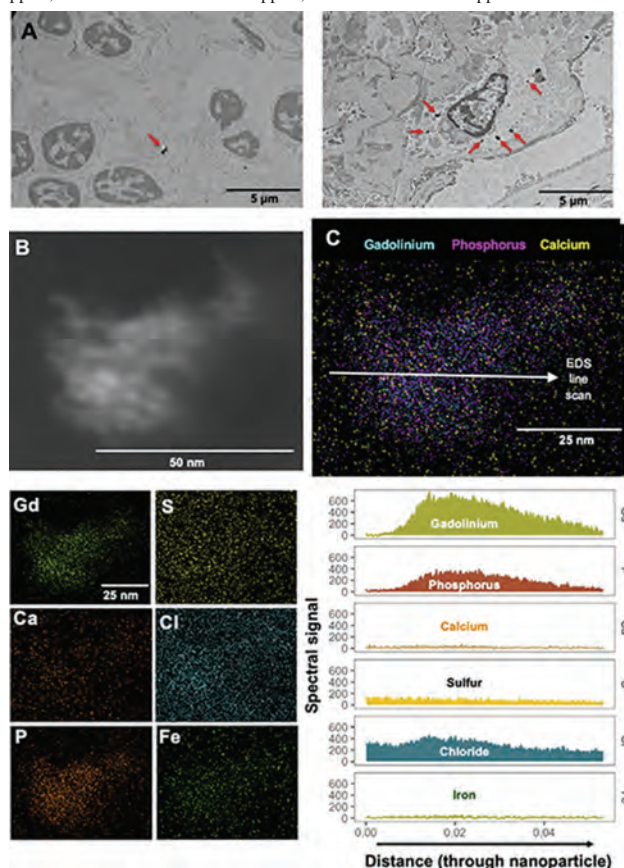

**Background:** The leitmotifs of MRI contrast agent-induced complications are kidney injury, symptoms associated with gadolinium (Gd) exposure (SAGE), Gd encephalopathy, and 'nephrogenic' systemic fibrosis. Despite evidence that Gd is retained intracellularly, disinterested patients flock to unproven therapies (e.g. chelation).

**Methods:** Patient kidneys ( $n = 5/5$  contrast-exposed and naïve) were obtained from the University of New Mexico Health Sciences Center Human Tissue Repository. Inductively-coupled plasma mass spectroscopy was performed with a NexION 300D (PerkinElmer). Energy-dispersive x-ray spectroscopy was performed using a JEOL NEOARM 200 kV aberration correction scanning transmission electron microscope (human).

**Results:** Gd mineralized into nanoparticles throughout the renal cortex, particularly intralysosomal in the proximal tubular epithelia. By multivariable linear regression, gadolinium was positively correlated with phosphorus (P), oxygen (O), and magnesium (P < 0.001). Gd as a function of P and O was the optimal model based on Akaike information criterion (AIC) reduction.

**Conclusions:** Gd mineralizes intracellularly in kidneys. This has ramifications for all MRI contrast agents and purported SAGE therapies such as chelation.

### Detecting the Metabolism of Gadolinium-Based Contrast Agents Using Electron Paramagnetic Resonance (EPR) Spectroscopy

**Brent Wagner**,<sup>1,2</sup> Emily Hong,<sup>2,4</sup> Jing Yang,<sup>3</sup> Karol Dokladny,<sup>2,1</sup> Joshua Deaguero,<sup>2,1</sup> G. P. Escobar,<sup>2,1</sup> Kidney Institute of New Mexico <sup>1</sup>New Mexico VA Health Care System, Albuquerque, NM; <sup>2</sup>Kidney Institute of New Mexico, Albuquerque, NM; <sup>3</sup>University of New Mexico Department of Chemistry and Chemical Biology, Albuquerque, NM; <sup>4</sup>University of New Mexico School of Medicine, Albuquerque, NM.

**Background:** Magnetic resonance imaging (MRI) contrast agents cause kidney injury, symptoms associated with gadolinium (Gd) exposure (SAGE), and 'nephrogenic' systemic fibrosis. Contrast agents are multidentate complexes designed to chelate Gd to 1) reduce free ion toxicity and 2) enhance renal elimination. Whether liberation of Gd from these complexes is a mechanistic step of disease has yet to be proven.

**Methods:** Mice were administered MRI contrast agent as per routine in our laboratory. Room temperature solution EPR spectroscopy was performed using a Bruker EMX spectrometer with associated Bruker magnetic control electronics and microwave bridges. The microwave frequency was ~9.4 GHz, field attenuation 20-25 dB, modulation amplitudes 6 - 10G,  $3.17 \times 10^5$  gain, and up to 16 scans.

**Results:** The  $g$  values for Dotarem (macrocyclic) and Omniscan (open-chained) were  $1.9791 \pm 0.0025$  (mean, S.D.) and  $1.9374 \pm 0.0040$ , respectively. The  $g$  values for Omniscan and Dotarem did not change significantly regardless of freezing/thawing. Concentrated HCl altered the EPR spectra of gadolinium-based contrast agent regardless of class. The EPR spectra remained unchanged in mouse urine days after last administration.

**Conclusions:** The healthcare system largely disinterests individuals with gadolinium-induced complications, many of whom seek off-label therapies such as metal chelation. The affinities of proprietary chelates for gadolinium will not govern equilibrium (chelate-bound metal) as gadolinium precipitates into insoluble minerals according to Le Chatelier's principle. These discoveries provide the foundation for developing rational therapies and improving the safety of magnetic resonance imaging contrast agents.

**Funding:** NIDDK Support, Other NIH Support - UL1TR001449, Veterans Affairs Support, Other U.S. Government Support, Clinical Revenue Support

### Cold Storage-Mediated Global (Phospho)Proteome Changes Following Kidney Transplantation

**Nirmala Parajuli**, Parajuli Research Team *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Extended cold storage (CS) of deceased donor kidney is associated with poor long-term outcome following transplantation. Previously, we showed impaired protein homeostasis and graft dysfunction following 18-hr CS combined with transplantation. However, the precise mechanisms responsible for this CS-mediated renal

graft damage are largely unknown. We hypothesize that CS contributes to covalent post-translational modification of renal proteins leading to impaired protein homeostasis after transplantation.

**Methods:** Isolated donor rat kidneys were cold-stored for 0- or 18-hr followed by transplantation to recipient rats. Kidney transplant homogenates were digested and the resulting peptides were labeled using a tandem mass tag 10-plex isobaric label reagent set and enriched using phosphopeptide enrichment kits. Both enriched and un-enriched isobaric labeled peptides were employed for mass spectrometric analysis. Differential expression and enrichment analyses were performed on (phospho) proteomics data individually followed by integrative analysis.

**Results:** Quantitative proteomics data revealed that 18-hr CS plus transplantation (CS+transplant) resulted in the significant dysregulation of 378 or 256 renal proteins ( $\log_2$  FC =1, Adjusted p value = 0.05) when compared to sham or autotransplantation (ATx; transplant with 0-hr CS), respectively. Gene set enrichment analysis of renal proteomes showed activation of 12 pathways (e.g., complement and coagulation) and suppression of 15 pathways (e.g., glutathione) in the CS+transplant group when compared to sham or ATx groups. Differential abundance analysis with phosphoproteomics data showed that 232 or 143 proteins were differentially phosphorylated in the CS+transplant group when compared to the sham or ATx group, respectively. Integrated analysis of differentially regulated global proteomes (N=378 or N=256) and phosphoproteomes (N=232 or N=143) identified only 8 or 2 renal proteins that were differentially phosphorylated when comparing CS+transplant with the sham or ATx groups, respectively.

**Conclusions:** These data suggest, for the first time, that CS contributes to altered renal (phospho) proteomes, which may lead to disrupted protein homeostasis and graft dysfunction. New studies designed to target the affected renal phosphoproteomes during CS may have promising therapeutic implications for prolonging outcome after renal transplantation.

## TH-PO094

### Gut Microbiota Derived D-Alanine Ameliorates Kidney Damage via Protection of Mitochondria in Murine AKI

Yasunori Iwata, Yusuke Nakade, Takashi Wada. *Kanazawa Daigaku, Kanazawa, Japan.*

**Background:** We have previously reported that the gut microbiota produces various D-amino acids including D-Serine (Ser) and D-Alanine (Ala) in a murine acute kidney injury (AKI) model. D-Ser showed the renoprotective effect on ischemia-reperfusion (I/R) induced kidney injury. Here, we further explored the pathophysiological role of D-Ala in AKI.

**Methods:** We analyzed transcripts of the N-methyl-D-aspartate (NMDA) receptor, a receptor for D-Ala, in tubular epithelial cells (TECs). The therapeutic effect of D-Ala was then assessed in vivo and in vitro. Finally, the plasma level of D-Ala was evaluated in patients with AKI.

**Results:** The *Grin* genes encoding NMDA receptor subtypes were expressed in TECs. D-Ala protected TECs from hypoxia-related cell injury and induced proliferation after hypoxia. D-Ala inhibits reactive oxygen species (ROS) production and improves mitochondrial membrane potential, through NMDA receptor signaling. The ratio of D-Ala to L-Ala was increased in feces, plasma, and urine after the induction of I/R. Moreover, Enterobacteriaceae produce D-Ala. Oral administration of D-Ala ameliorated kidney injury after the induction of I/R in mice. Deficiency of NMDA subunit NR1 in tubular cells worsened kidney damage in AKI. In addition, the plasma level of D-Ala was increased and reflected the level of renal function in patients with AKI.

**Conclusions:** D-Ala ameliorates I/R-induced kidney injury via protection of mitochondria. The plasma level of D-Ala reflects the estimated glomerular filtration rate in patients with AKI. D-Ala could be a promising therapeutic target and potential biomarker for AKI.

## TH-PO095

### Dietary Modification of Fat and Protein Composition and Its Effects on the Repair of Ischemic AKI

Junseok Jeon,<sup>1</sup> Yunsoo Lee,<sup>1</sup> Minsuk Seo,<sup>1</sup> Kyungho Lee,<sup>2</sup> Jung eun Lee,<sup>1</sup> Woosong Huh,<sup>1</sup> Yoon-Goo Kim,<sup>1</sup> Hye Ryoung Jang,<sup>1</sup> <sup>1</sup>*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*; <sup>2</sup>*Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** The effects of dietary composition on the repair after ischemic acute kidney injury (AKI) are not well established. The effects of dietary modification of fat and protein composition on intrarenal immunologic microenvironment and the repair of tubular damage after ischemic AKI were investigated using murine ischemic AKI and human kidney-2 (HK-2) cell hypoxia model.

**Methods:** Three different diet regimen were provided to mice (9-week-old male C57BL/6) from day 3 after bilateral or unilateral ischemia-reperfusion injury (BIRI or UIRI) operation: control diet, high-fat with high-protein (HF+HP) diet, and low-fat with low protein (LF+LP) diet. HK-2 cells were treated with additional lipid or amino acid after hypoxic insult.

**Results:** Body weight was greater and total cholesterol concentration was higher in the HF+HP group, and body weight was lesser and blood pressure and BUN were lower in the LF+LP group compared to the control diet group, while there was no difference in plasma creatinine between groups. In the expression of intrarenal cytokines/chemokines, RANTES was increased in the HF+HP group, and IFN- $\gamma$ , IL-4, IL-10, IL-6, TNF- $\alpha$  were increased and VEGF was decreased in the LF+LP group than in the control group after BIRI. IFN- $\gamma$ , IL-4, and IL-6 were decreased in the HF+HP group and IL-6 was increased

in the LF+LP group than in the control group after UIRI. The fibrosis of postischemic kidney was more extensive in the LF+LP group compared to the control group after UIRI, while comparable between groups after BIRI. In HK-2 cell hypoxia model, addition of amino acid suppressed, but addition of lipid promoted proliferation of HK-2 cells after hypoxic insult.

**Conclusions:** Excessive restriction of protein and fat during the healing phase of ischemic AKI can be detrimental. Further studies are needed to clarify the optimal dietary compositions and the individual effects of protein and lipid during the recovery of ischemic AKI.

**Funding:** Government Support - Non-U.S.

## TH-PO096

### Expression of Urine Cytokines in Patients With Severe Pneumonia by SARS-CoV-2

Gustavo A. Casas-Aparicio. Departamento de Investigación en Enfermedades Infecciosas *Instituto Nacional de Enfermedades Respiratorias, Ciudad de Mexico, Mexico.*

**Background:** Cytokines are involved in the pathogenesis of AKI. The aim of this study was to investigate the urine cytokine profile in patients with severe Pneumonia by SARS-CoV-2 and AKI.

**Methods:** This prospective, longitudinal cohort study was conducted at the National Institute of Respiratory Diseases. We included individuals with Severe pneumonia caused by SARS-CoV-2, >18 years of age; without chronic kidney disease (CKD). AKI was defined as creatinine elevation >0.3 mg/dL in 48 hours or level of TIMP2xIGFBP7 >0.3 ng/ml. Urine samples were collected in critical areas and frozen at -80, urinary concentrations of TIMP-2 and IGFBP7, NGAL and a panel of 27 cytokines were analyzed. **Statistical Analysis:** We first explored whether cytokine patterns between AKI and NO-AKI groups using the Mann-Whitney test, because of a high level of correlation between our panel of urine cytokines and kidney damage biomarkers we performed Principal Component Analysis (PCA). Statistical significance was set at p<0.05.

**Results:** We included 51 patients, 30 were male (58.8%); the median age was 53 years (IQR, 40-61); 14 had hypertension (27.5%); 16 had diabetes (31.4%); and 21 were obese 41.2%. Significant characteristics as well as serum biochemical laboratories, urine kidney stress biomarkers and cytokines are shown in Table 1. We used Principal Component Analysis to built dimensions associated to AKI outcome. After adjustment by Age and Sex, Dimension 2 composed by IL-5, IP 10 (CXCL10), IGFBP7, MIG (CXCL9) was associated with AKI [aHR 95% CI 19.84 (1.00-399) p=0.050] as well as Dimension 3 composed by N-GAL, RANTES, IL 8, INF-gamma [aHR 95% CI 21.52 (1.91-242) p=0.013].

**Conclusions:** In our study, some cytokines and biomarkers of kidney damage, such as IGFBP7 and N-Gal, were involved in the development of AKI.

**Funding:** Government Support - Non-U.S.

## TH-PO097

### IL33 Mediates Cardiomyopathy After AKI by Directly Signaling to Myocytes

Nans Florens, Allen J. York, Jeffery D. Molkenin. Heart Institute - Molecular Cardiovascular Biology *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

**Background:** Acute kidney injury (AKI) is a major cardiovascular risk factor. However, few direct molecular mechanisms have been identified that show how AKI leads to cardiac disease. The aims of this project are to assess the role of IL33 in cardiac damage after AKI.

**Methods:** AKI was induced in mice by ischemia-reperfusion injury of both kidneys by 30 min of reversible artery occlusion in WT, IL33 null and mice in which the IL33-receptor was deleted in cardiomyocytes. We also generated AAV9 carrying the IL33 cDNA (AAV-IL33) or an empty vector (AAV-EV) under a CMV promoter and injected 10<sup>12</sup> viral particles intrathoracically in 6 to 9 days-old pups. Mice containing an insertion of a MerCreMer cDNA driven by the alpha-MHC ( $\alpha$ MHC<sup>CMV</sup>, cardiomyocyte specific) promoter were crossed with a Il1rl1-loxP(f)-targeted mouse (Il1rl1<sup>fl/fl</sup>, IL33-receptor) and recombination was obtained by intraperitoneal tamoxifen injections. Echocardiography was performed at 28 days after AKI surgery. Hearts were analyzed for fibrosis, cardiomyocyte area measurement, capillary content and myocardial ischemia with 2-nitroimidazole (EF5).

**Results:** AKI induced cardiac dysfunction after 28 days, measured with echocardiography (mean ejection fraction (EF): 58 in shams and 46% with AKI, p<0.05). We observed increased fibrosis area in hearts from WT mice after AKI compared to Sham (2.3 vs 4.5% area, p<0.05) and increased cardiomyocyte surface areas indicative

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

of hypertrophy (333 vs 597  $\mu\text{m}^2$ ,  $p<0.05$ ). Compared to Sham, WT AKI mice exhibited a capillary rarefaction (CD31 staining) along with increased myocardial EF5 staining, suggesting ongoing ischemia. However, cardiac function and architecture were preserved after 28 days of AKI in IL33 null mice. Moreover, WT mice injected with AAV9-IL33 showed impaired cardiac function compared to AAV9-EV injected ones after 8 weeks (EF 58 vs 42%,  $p<0.05$ ). After AKI, targeted deletion of the IL33-receptor gene in cardiomyocytes ( $\alpha\text{MHC}^{\text{MCM}}$   $\text{IL1r1}^{\text{fl/fl}}$  mice), preserved cardiac function and architecture with no significant increase in fibrosis, hypertrophy and no significant capillary rarefaction compared to Sham-operated mice ( $\alpha\text{MHC}^{\text{MCM}}$  only mice).

**Conclusions:** Secreted during AKI, IL33 has a direct toxic effect on the heart. Our observations are in contrast to some previous reports in the literature where IL33 was suggested to function as a cardioprotective factor.

TH-PO098

Warm Ischemia Time During Pediatric Kidney Transplant Does Not Correlate With Urine AKI Biomarkers

Kyle Merrill,<sup>1</sup> Cassie L. Kirby,<sup>1</sup> Lakhmir S. Chawla,<sup>3</sup> David K. Hooper,<sup>1,2</sup> Stuart Goldstein.<sup>1,2</sup> <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>University of Cincinnati, Cincinnati, OH; <sup>3</sup>VA San Diego Healthcare System, San Diego, CA.

**Background:** Ischemia-reperfusion injury (IRI) is a mechanism of acute kidney injury (AKI). Like cardiopulmonary bypass, kidney transplantation is a form of controlled IRI resulting in acute tubular necrosis and possibly delayed graft function (DGF). Therefore, we sought to investigate kidney transplantation in pediatric patients as a clinical model of AKI, focusing on warm ischemia time (WIT) and novel AKI urine biomarkers.

**Methods:** Prospective study of patients aged 3 months to 26 years who received a kidney transplant from 7/2020 and 11/2021. Urine was collected daily for 7 days post-transplant. Biomarkers tested were neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule 1 (KIM-1), interleukin 18 (IL-18), and hepcidin. DGF was defined as receiving kidney replacement therapy within 7 days post-transplant. Wilcoxon rank sum test was used to compare cohorts. Linear regression was used to compare biomarker concentrations to WIT on post-operative days 0-2. The optimal cutoff for NGAL to predict lack of DGF was determined using negative predictive value (NPV) and a Youden's index.

**Results:** 4/30 patients developed DGF with a longer WIT of 55 minutes (IQR 52-57) vs. 38 minutes (IQR 32-45). Thus, we compared biomarker concentrations in patients with WIT <45 vs.  $\geq 45$  minutes. NGAL, KIM-1 and Hepcidin did not differ between cohorts. IL-18 was higher on day 1 in the  $\geq 45$ -minute WIT cohort. A positive linear relationship was noted between WIT and NGAL on day 2 and a negative relationship with hepcidin on day 0. The optimal Youden's index was 0.6 for an NGAL cutoff of 150 ng/mL on either day 0 or 1 post-transplant with an NPV of 95.7% (95% CI 80-99%).

**Conclusions:** We found no consistent correlation between WIT and biomarkers suggesting that AKI may be more complex than simply IRI. NGAL <150 ng/mL on post-operative day 0 or 1 correlated to a high NPV for development of DGF.

Distant Organ Effects of Renal Injury

Katherine J. Kelly,<sup>1,2</sup> Jesus H. Dominguez.<sup>1</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Richard L Roudebush VA Medical Center, Indianapolis, IN.

**Background:** Acute kidney injury (AKI) results in immense human and economic cost. The cause of death in AKI is often not kidney failure per se. An enlarging body of data supports the systemic harmful effects of AKI. Understanding the linkage of renal injury with distant organ effects is critical in evaluating potential therapies and preventing/reducing morbidity and mortality.

**Methods:** We employed a well characterized model of renal ischemia/reperfusion injury to examine the effect on distant organs (heart, dura, small intestine, mesentery, liver and spleen) both short term (48 h) and longer term (10 wk) after renal injury. We have previously shown the beneficial effect of renal exosomes, given after renal failure is established, on the kidney. In the present work, we examine the effect of this potential therapy systemically. Controls included sham surgery, unilateral ischemia and nephrectomy (48 hours only).

**Results:** We found leukocyte infiltration following renal ischemia in the heart, dura, small intestine, mesentery, liver and spleen, 2-5 fold the levels following nephrectomy. Tumor necrosis factor alpha was significantly increased in heart, lung and spleen 48 hours after renal ischemia, 2-90 fold. In the heart, significantly altered transcripts included inflammatory (C3, C4), fibrotic (collagen 1, 5, TIMP), angiogenic (VEGF), oxidant (superoxide dismutase, catalase) and apoptosis (bak, bcl2) related, examples in table. Although renal exosomes were not found in large numbers in remote organs, leukocyte infiltration was significantly decreased in these organs in the exosome-treated postischemia group. In longer term studies, we found increased heart and liver weights (1.7 and 1.2 fold increased vs sham surgery, respectively,  $p<0.03$ ), which was ameliorated (1.2 and 1.0 fold,  $p<0.04$ ) after treatment with renal exosomes. More importantly, longer term mortality in the post-renal ischemia group (50%) was eliminated (0%) in the exosome treated group,  $p<0.04$ .

**Conclusions:** Significant remote organ alterations after found after renal ischemia and these can be improved with exosome treatment after renal failure is established.

Complement-Mediated Hemolytic Uremic Syndrome Presenting With Nephrotic Range Proteinuria

Aditi Singh, Stephen N. Simeone, Duha A. Jweeha, Mamta Shah. *UConn Health, Farmington, CT.*

**Introduction:** Complement-mediated hemolytic uremic syndrome (CM-HUS) has a varied clinical presentation and diagnosis remains one of exclusion. We present a case of thrombotic microangiopathy (TMA) secondary to CM-HUS presenting with hematuria and nephrotic range proteinuria without underlying glomerulonephritis (GN).

**Case Description:** A 45-year-old male presented with a three-day history of dark brown urine. Work-up revealed acute kidney injury (AKI) with a serum creatinine of 1.6 mg/dL from a baseline of 0.9 mg/dL, hemoglobin of 10.1 g/dL and a platelet count of 19,000 platelets/ $\mu\text{L}$ . Haptoglobin was <8 mg/dL and peripheral blood smear showed 7 schistocytes per high-power field. Urinalysis depicted large hemoglobin with 10-15 red blood cells and 24-hour urine protein collection had nephrotic range proteinuria at 3 grams. Given suspicion for thrombotic thrombocytopenic purpura, plasma exchange (PEX) was initiated however this was discontinued after ADAMTS13 was found to be 63%. Despite improvement in his hemoglobin and platelet counts, proteinuria persisted and extensive evaluation for an autoimmune, infectious or hematologic etiology was negative. Renal biopsy findings were consistent with glomerular TMA (Figure 1) without evidence of underlying GN or IgA nephropathy. High dose steroids were administered with resolution of his AKI and proteinuria. Genetic testing demonstrated heterozygosity for CD46 and PLG variants of CM-HUS.

**Discussion:** TMA with proteinuria is associated with comorbid GN or systemic vascular diseases such as systemic lupus erythematosus. This case of CM-HUS is unique in its presentation of proteinuria without associated GN. There are few such reported cases of CM-HUS in children and they describe a resolution of proteinuria following PEX and eculizumab treatment. The mechanism of proteinuria in CM-HUS is poorly defined however endothelial injury or podocytopathy could be suspected.

Capillary loop with endothelial cell lift off of glomerular basement membrane with fluffy amorphous deposit in subendothelium

Kidney-Protective Vagus Nerve Stimulation Modulates Splenic Immune Populations and Reduces IFN $\gamma$  Production in Response to Toll-like Receptor Agonists

William Nash,<sup>1</sup> Shinji Tanaka,<sup>2</sup> Mark D. Okusa.<sup>1</sup> <sup>1</sup>University of Virginia School of Medicine, Charlottesville, VA; <sup>2</sup>University of Tokyo Graduate School of Medicine, Bunkyo City, Japan.

**Background:** Vagus nerve stimulation (VNS) prior to injury is able to reduce inflammation and protect mice from acute kidney injury (AKI). This protection requires an intact spleen since splenectomy prior to VNS and AKI removes the protection. Since the immune system and spleen are closely intertwined, we sought to identify alterations in splenic immune cells post-VNS to gain insight into the potential anti-inflammatory and kidney-protective effects of VNS.

**Methods:** Mice underwent VNS or sham surgery. The vagus nerve was exposed at the neck and electrodes placed on it. Electrical pulses were delivered for 10 minutes, sham mice did not receive pulses. After 48 hours, spleens were processed into single cell suspensions. An aliquot was assessed via flow cytometry to quantify immune cell populations. The rest was used to seed 96-well plates for ex vivo stimulation. 7.5x10<sup>5</sup> cells were plated per well and incubated with agonists for toll-like receptors (TLR). Each well received either vehicle control or an agonist to TLR3, 4, or 9. After 20-24 hours, media from each well was collected for cytokine concentration analysis via 32-plex Luminex assay.

**Results:** Spleens from VNS-treated mice weighed less (sham avg=0.064±0.01 g; VNS avg=0.046±0.01 g) and exhibited reduced abundance of most splenic immune cell populations. The most significantly impacted were T cells ( $p=0.007$ ), B cells ( $p=0.01$ ), NK cells ( $p=0.01$ ), dendritic cells ( $p=0.01$ ), and basophils ( $p=0.02$ ). Monocytes and eosinophils also showed trends toward lower numbers, but NKT cells, macrophages, and neutrophils exhibited no reduction. Ex vivo cytokine production was also depressed. The profile of cytokines affected varied depending on TLR agonist, but a subset exhibited common regulation across multiple TLR-stimulation conditions (IFN $\gamma$ , CCL2, CXCL9, VEGF, CCL3, CXCL10, GM-CSF, CCL4, IL-10, and IL-9). In particular, IFN $\gamma$  production was decreased in all conditions tested.

**Conclusions:** VNS modulates immune cell abundance and suppresses cytokine production profiles in response to TLR agonists, which may contribute to establishing an anti-inflammatory state. Our results indicate VNS can dynamically control the inflammatory capacity of immune cells and the apparent ubiquitous impact on IFN $\gamma$  provides a good candidate for further mechanistic investigation into the kidney-protective effects of VNS.

Cytokines and Urinary Biomarkers Predict Adverse Renal Impacts of Propranolol in Biliary Cirrhotic Rats

Chiao-Lin Chuang,<sup>1,2</sup> Hui-Chun Huang.<sup>1,2</sup> <sup>1</sup>Taipei Veterans General Hospital, Taipei, Taiwan; <sup>2</sup>National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.

**Background:** Non-selective beta-blockers (NSBBs) are the mainstay of treatment for variceal bleeding in cirrhotic patients. However, the advantage of NSBBs must be weighed against the potential risk of acute kidney injury (AKI).

**Methods:** Secondary biliary cirrhosis was induced by common bile duct ligation (CBDL). We used propranolol-treated CBDL rats to delineate the thorough hemodynamics, urinary biomarkers, and inflammatory cytokines.

**Results:** Propranolol treatment led to significant decreases in mean arterial pressure (MAP), portal pressure (PP), and renal blood flow (RBF) in CBDL rats ( $p < 0.05$ ). Both MAP and PP significantly correlated with RBF, while RBF inversely correlated with urinary liver-type fatty acid-binding protein (L-FABP) and the combination of tissue inhibitor of metalloproteinase-2 and insulin-like growth factor binding protein-7 ([TIMP-2]x[IGFBP7]) levels in propranolol-treated CBDL rats ( $p < 0.05$ ). Propranolol-treated CBDL rats with severe hypotension (MAP < 65 mmHg) showed higher IL-1 $\beta$ , but lower IL-6 levels than those with MAP  $\geq$  65 mmHg ( $p < 0.05$ ).

**Conclusions:** NSBBs treatment in cirrhosis may need to be individualized accompanied by careful monitoring of blood pressure and inflammatory condition. Urinary L-FABP and [TIMP-2]x[IGFBP7] serve as promising candidates for detecting renal hypoperfusion following NSBBs. The changes in serum IL-1 $\beta$  and IL-6 over time might allow physicians to predict the possibility of NSBBs-induced AKI in cirrhosis.

Hemodynamic and biochemistry data of CBDL rats

	Control (n = 10)	Propranolol + MAP $\geq$ 65 mmHg (n = 13)	Propranolol + MAP < 65 mmHg (n = 6)

TH-PO103

Cancer-Derived Extracellular Vesicles Worsen Sepsis-Induced AKI

Takayuki Tsuji, Naoko Tsuji, Yoshitaka Naito, Naoki Hayase, Xuzhen Hu, Peter S. Yuen, Robert A. Star. National Institutes of Health, Bethesda, MD.

**Background:** Patients with hematological malignancies are at high risk for acute kidney injury (AKI). We established a mouse xenograft model of acute myeloid leukemia (AML)-associated sepsis AKI. We found that AML worsened sepsis AKI (ASN 2020). However, it is not known what leukemia-associated factors contribute to the deterioration of AKI. It has been reported that cancer-derived extracellular vesicles (EVs) have various effects on host immune cells and hematopoiesis. We hypothesized that AML cell-derived EVs worsen sepsis AKI.

**Methods:** AML cells (Human Leukemia HL60 cells) were incubated in serum free medium for 48 h to obtain AML cell-derived EVs. Large and small EVs were isolated by a differential centrifugation procedure (14K x g and 200K x g) and quantitated by Zetaview. To examine the effect of EVs on sepsis-induced AKI, cecal ligation and puncture (CLP) was performed to induce sepsis in male CD-1 mice (n=8-10 per group), and EVs or PBS were injected intravenously at the time of CLP surgery. Multiple organ damage, splenic apoptosis and mouse systemic cytokines were evaluated at 24 h after CLP or sham surgery.

**Results:** EVs obtained from 14K x g pellet (EVs(14K)) intensified sepsis-induced organ damage including AKI. BUN, LDH, AST and ALT were significantly higher in EVs(14K)+CLP than both EVs(200K)+CLP and PBS+CLP. EVs(14K)+CLP, EVs(200K)+CLP, PBS+CLP. BUN; 127.0±13.8, 59.4±33.3, 67.0±43.6 mg/dl, LDH; 4,007±1,378, 2,221±1,040, 3,111±714 U/l, AST; 817±268, 487±147, 514±137 U/l p<0.05). Kidney histological damage and splenic apoptosis were significantly worse in EVs(14K)+CLP compared to either EVs(200K)+CLP or PBS+CLP. Systemic cytokines at 24 h after CLP were significantly higher in EVs(14K)+CLP than either EVs(200K)+CLP or PBS+CLP (TNF $\alpha$ ; 628±220, 149±107, 281±195 pg/ml, IL-6; 119±61, 41±29, 56±59 ng/ml, IL-10; 4,810±1,494, 1,470±913, 2,607±805 pg/ml, p<0.05).

**Conclusions:** We found that AML cell-derived EVs obtained from 14K x g pellet, but not 200K x g pellet worsened sepsis AKI. Therefore, the impact of leukemia can be largely recapitulated by administration of EVs. Further study is needed to determine what components within EVs are responsible for this worsening of sepsis AKI. Additionally, mechanistic insights may inform how to therapeutically target these EVs during septic episodes in leukemia patients.

Acute Oxalate Nephropathy due to Transthyretin (ATTR) Amyloidosis Causing Autonomic Neuropathy and Enteric Hyperoxaluria

Phoenix Xu,<sup>1</sup> Jennine Michaud,<sup>2</sup> Harshad Chaudhari,<sup>1</sup> Smita Mahendrakar,<sup>1</sup> Anjella Manoharan,<sup>1</sup> Michael Yudd.<sup>2</sup> <sup>1</sup>Rutgers New Jersey Medical School, Newark, NJ; <sup>2</sup>VA New Jersey Health Care System, East Orange, NJ.

**Introduction:** Acute oxalate nephropathy (AON) is an uncommon renal biopsy finding. There are 3 pathophysiologic mechanisms leading to AON: genetic mutations causing excessive hepatic production (primary hyperoxaluria, PH); increased bowel absorption of oxalate in malabsorptive states (enteric hyperoxaluria, EH); intake of food or substances that are metabolized to excessive oxalate (e.g., starfruit, ethylene glycol).

**Case Description:** 86 year-old non-diabetic man was admitted with severe acute kidney injury requiring dialysis. Serum creatinine was 0.9 mg/dl 3 months earlier. He had a history of congestive heart failure with reduced ejection fraction and atrial fibrillation. He described a distinct change in bowel habits over the last 6 months, going from regularity to new onset of alternating weekly loose bowel movements and constipation, and weight loss of 60 lbs. Ten years earlier he was diagnosed with peripheral neuropathy when he developed numbness and tingling in hands and feet. Most of his food came from Meals on Wheels. He denied drinking antifreeze, or eating foods with high oxalate content. He weighed 145 lbs and had a BMI of 19.7 kg/m<sup>2</sup>. He appeared weak and cachectic. He had vibratory loss in glove/stocking pattern and somatosensory loss in stocking pattern. Pertinent findings: - Renal biopsy: diffuse tubular oxalate deposits. Congo red (-). - Cardiac: pyrophosphate scan highly suspicious for ATTR amyloid. - Fat pad biopsy: Congo red (+); on mass spectrometry ATTR was most likely wild type. - Gastrointestinal (GI): chronic non-specific inflammation on upper and lower endoscopy, congo red (-). Negative fecal fat. - Genetic testing: negative for both PH and hereditary ATTR.

**Discussion:** EH appeared to be the cause of AON. PH was ruled out by genetic testing, and ingestions appeared very unlikely. The patient was cachectic with marked weight loss, and clearly had a change in his bowel habits. This along with urinary frequency and lightheadedness on standing, suggested the presence of an autonomic neuropathy. The GI work-up ruled out a classic malabsorptive state. ATTR amyloid typically involves the heart and can cause severe peripheral and autonomic neuropathies. We suspect that severe GI autonomic dysfunction lead to marked weight loss and altered absorption, causing EH and subsequently AON.

## TH-PO105

### suPAR Inflames Kidneys With T Cells and Aggravates Septic AKI

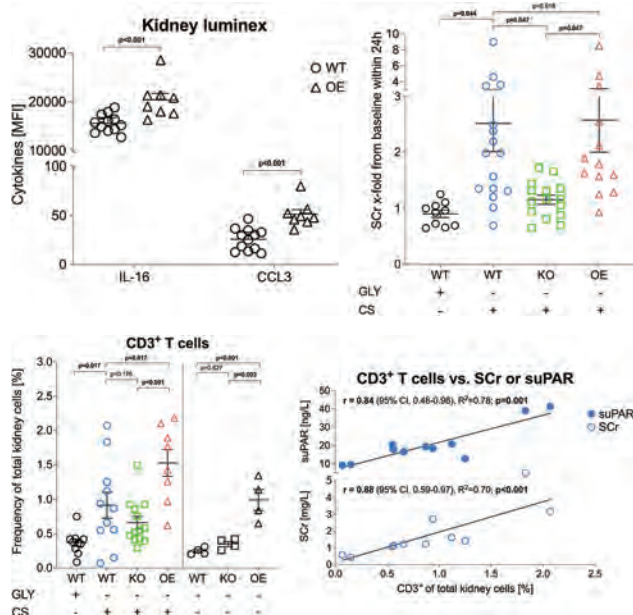

Christian Nussbag,<sup>1,5</sup> David C. Wei,<sup>5</sup> Eunsil Hahm,<sup>5</sup> Salim Hayek,<sup>2</sup> Jing Li,<sup>5</sup> Florian Kälble,<sup>1</sup> Claudius Speer,<sup>1</sup> Jesper Eugen-Olsen,<sup>3</sup> Ellen Krautkrämer,<sup>1</sup> Martin G. Zeier,<sup>1</sup> Christian Morath,<sup>1</sup> Thorsten Brenner,<sup>4</sup> Jochen Reiser.<sup>5</sup>  
<sup>1</sup>Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; <sup>4</sup>Universitätsklinikum Essen, Essen, Germany; <sup>5</sup>Rush University Medical Center, Chicago, IL.

**Background:** The soluble urokinase plasminogen activator receptor (suPAR) is an immune-derived glycoprotein implicated in the pathogenesis of acute kidney injury (AKI). Sepsis is a strong inducer of plasma suPAR levels and a known contributor to the development of AKI. We hypothesized that suPAR is involved in the pathophysiology of sepsis-related AKI.

**Methods:** We used a polymicrobial model of sepsis (Cecal Slurry [CS] vs. Glycerol [GLY]) in wild-type (WT), uPAR knockout (KO), suPAR deficient, and transgenic suPAR-overexpressing (OE) mice. We compared measures of kidney function, tissue damage, and tissue inflammation in septic and untreated mice. Kidney tissue inflammation was quantified by kidney flow cytometry, immunohistochemistry, and kidney luminex assay.

**Results:** Kidneys from untreated OE mice expressed high levels of interleukin-16 (IL-16) and C-C motif chemokine ligand 3 (CCL3); both involved in cell-mediated kidney injury and potent chemo-attractants for T and NK cells. Consistent with this expression pattern, we found significantly increased numbers of kidney T and NK cells in untreated OE mice, equaling numbers observed in septic WT mice. Further, high plasma suPAR aggravated sepsis-induced ultrastructural kidney damage, cellular apoptosis and kidney function impairment after 24h of sepsis. In contrast, KO mice showed a strong protective effect against AKI. Kaplan-Meier analysis revealed a survival benefit of KO over OE mice (87% vs. 50%,  $p=0.033$ ). The composition of kidney immune cells in sepsis was strongly influenced by varying suPAR plasma levels. Especially, numbers of kidney T cells were strongly linked to the extent of systemic suPAR elevation and kidney function impairment, with significant higher numbers in septic OE mice compared to septic WT and KO mice.

**Conclusions:** suPAR inflames the kidney with T cells potentially via local upregulation of IL-16 and CCL3. "SuPAR inflamed" kidneys react with increased kidney injury in sepsis which can potentially be improved by delecting suPAR. These findings hold great potential for new therapeutic strategies.

## TH-PO106

### Calciophylaxis in a Patient With Tumor Lysis Syndrome due to T-Cell Lymphoma

Mahmoud Ali,<sup>1</sup> Mariela Navarro Torres,<sup>2</sup> Molly Fisher.<sup>2</sup> <sup>1</sup>Saint Barnabas Hospital, Bronx, NY; <sup>2</sup>Montefiore Medical Center, Bronx, NY.

**Introduction:** Calciophylaxis is characterized by skin ischemia and necrosis and is most often observed in end-stage kidney disease (ESKD) or transplant patients. Non-ESKD associated calciophylaxis is uncommon but has been reported in patients with primary hyperparathyroidism, alcoholic liver cirrhosis, connective tissue disease and malignancy. We report an unusual presentation of calciophylaxis in the context of severe acute kidney injury (AKI) with tumor lysis syndrome (TLS) from T-cell lymphoma.

**Case Description:** A 46-year-old man with history of colon cancer treated with right hemicolectomy and chemotherapy and untreated T-cell lymphoma presented with respiratory distress. Laboratory results revealed a serum creatinine of 21.8 mg/dL compared to a baseline of 1.1 mg/dL seven months prior, potassium of 6.5 mEq/L, bicarbonate of <10 mEq/L, phosphorus of 15mg/dL, calcium of 7.6 mg/dL, uric acid of 8.9 mg/dL, lactate dehydrogenase of 542 U/L and severe pancytopenia. Spontaneous TLS in the setting of untreated lymphoma was suspected as the cause of his AKI. He was admitted to the intensive care unit and underwent emergent hemodialysis. Two days after admission, he was found to have a firm and tender lesion on the right medial thigh described as an ecchymosis with surrounding ulceration. A CT was negative for necrotizing fasciitis and the skin lesion was treated as a soft tissue infection. However, the lesion progressed, developing eschar. A punch skin biopsy was performed which confirmed a diagnosis of calciophylaxis. Intact parathyroid hormone was 228 pg/mL. Treatment included sodium thiosulfate, phosphorus control and hemodialysis. He was initiated on chemotherapy for his lymphoma and unfortunately, remained dialysis dependent.

**Discussion:** Malignancy is a known risk factor for calciophylaxis but to our knowledge, this is only the second reported case of calciophylaxis in the setting of TLS. We hypothesize that our patient's late presentation of TLS with fulminant AKI and severe metabolic derangements led to vascular calcium chelation and deposition. This case highlights the importance of calcium and phosphorus control in patients with TLS and risk factors for calciophylaxis.

## TH-PO107

### Role of Kynurenine/Tryptophan Ratio in Kidney-Lung Cross-Talk in Two Porcine Trauma-Induced Multi-Organ Injury Models

Pragya Singh,<sup>1</sup> Daniel Montemayor,<sup>1</sup> Annapurna Pamreddy,<sup>1</sup> Viktor Drel,<sup>1,2</sup> Hongping Ye,<sup>1</sup> Anthony J. Franzone,<sup>1</sup> Yanyi Zang,<sup>3</sup> Teryn R. Roberts,<sup>3</sup> Kevin K. Chung,<sup>4</sup> Andriy Batchinsky,<sup>3,4</sup> Kumar Sharma.<sup>1,2</sup> <sup>1</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>2</sup>South Texas Veterans Health Care System, San Antonio, TX; <sup>3</sup>Autonomous Reanimation and Evacuation Research Program, San Antonio, TX; <sup>4</sup>Uniformed Services University of the Health Sciences, Bethesda, MD.

**Background:** Multiple Organ Failure (MOF), often precipitated by Acute Respiratory Distress Syndrome (ARDS) brought on by trauma-induced injury, is a significant cause of death in military and civilian life. In ARDS, Acute Kidney Injury (AKI) is the most common organ failure, affecting nearly half of all patients and having twice the mortality rate than those with ARDS alone. Thus, understanding the molecular differences between survivors and non-survivors can significantly reduce the mortality burden.

**Methods:** A 24-hour unilateral pulmonary contusion porcine model (pneumonecctomy) of trauma-induced MOF model (n=17) and separate 48-hour polytrauma injury of bilateral pulmonary contusion, traumatic brain injury, and hemorrhage (polytrauma) MOF model (n=26) was developed at Dr. Batchinsky's AREVA laboratory. Serum was assayed at baseline and 3h or 6h post-trauma for amino acid metabolites using the Zip-Chip platform for mass spectrometry. The IDO1 enzyme activity assay kit (ab235936) was used to measure IDO1 enzyme activity in the tissue.

**Results:** In the pneumonecctomy model, 10 survived and 7 died and in the polytrauma group, 13 survived and 13 died. In the pneumonecctomy model, there was a significant increase in the serum kynurenine/tryptophan (KYN/TRP) ratio in the non-survivors 3h post-injury. A similar pattern was found in the validation group, which showed a significant increase in the KYN/TRP ratio at 6h post-trauma in non-survivors from the polytrauma model. There was a significant increase in IDO1 enzyme activity in non-survivor kidney tissues and no changes in the lungs in the pneumonecctomy model.

**Conclusions:** In two separate ARDS multi-organ injury trauma porcine models, an increase in the KYN/TRP ratio post-trauma identified the pigs that suffered early mortality. The increase in kidney IDO1 activity could contribute to the reduction in serum tryptophan and increase in kynurenine in the non-survivors. As a result, focusing on therapeutics targeting the kynurenine pathway to reduce the incidence and severity of MOF was warranted.

**Funding:** Other U.S. Government Support

## TH-PO108

## Acute Interstitial Nephritis Secondary to Brentuximab

Nour Hammad, Meghan Kapp, Arash Rashidi. *University Hospitals, Cleveland, OH.*

**Introduction:** Emerging of new treatments such as immune checkpoint inhibitors and targeted therapies have changed treatment of cancer patients. All these new treatments can cause different side effects, including renal complications. Brentuximab vedotin is a CD30-directed antibody drug conjugate, which is used to treat relapsed or refractory Hodgkin lymphoma and systemic anaplastic large cell lymphoma. Here we present a case of acute interstitial nephritis (AIN) in a 65 years old woman with T-cell lymphoma on Brentuximab vedotin (trade name: Adcetris) therapy.

**Case Description:** A 64 year-old female was diagnosed initially with cutaneous T-cell Lymphoma with subsequent metastasis to the liver despite multiple therapies. She was started on Brentuximab vedotin. She had normal kidney function at baseline and after two doses of Brentuximab vedotin her kidney function started declining with peak serum creatinine at 3.75 mg/dl. Urinalysis showed 1+ proteinuria, WBC 4, and RBC 4. A renal biopsy was performed and showed diffuse acute interstitial nephritis (Image 1, PAS, 200x). Subsequently, Brentuximab was discontinued and the patient was started on oral steroid taper with improving kidney function back to baseline creatinine of 1 mg/dl.

**Discussion:** To the best of our knowledge this is the second case of TIN following Brentuximab vedotin. Karyomegalic interstitial nephritis (KIN) was previously described as a potential side effect with Brentuximab. KIN is characterized by enlarged hyperchromatic tubular epithelial cell nuclei which was not seen in our patient's renal biopsy. The timing of AKI has coincided after the second cycle of Brentuximab in our patient making it the major contributor for the AIN. High suspicion for AIN is important as early recognition and treatment have better prognosis. The key prognosticating factor for renal recovery is the extend of renal fibrosis.

A renal biopsy showing interstitial edema, inflammatory infiltrate comprised of lymphocytes, occasional eosinophils, and rare neutrophils, and tubulitis.

## TH-PO109

## Adipose-Derived Mesenchymal Stem Cells Cultured in Serum-Free Medium Attenuate Acute Contrast-Induced Nephropathy by Exerting Anti-Apoptotic Effects

Mitsuki Kadono, Naoki Ishiuchi, Ayumu Nakashima, Kensuke Sasaki, Takao Masaki. *Hiroshima Daigaku Byoin, Hiroshima, Japan.*

**Background:** Contrast-induced nephropathy (CIN) is a major clinical problem associated with acute kidney injury during hospitalization, however therapeutic methods for CIN have made little progress. We previously showed that culturing mesenchymal stem cells (MSCs) in serum-free medium enhanced their anti-inflammatory effects. In this study, we investigated the therapeutic effects of human adipose-derived MSCs cultured in serum-free medium (SF-MSCs) on a mouse model of CIN.

**Methods:** C57BL/6 mice (8 weeks of age) underwent right nephrectomy. One week later, the left renal artery was clamped for 30 min to cause ischemia-reperfusion injury, and mice were injected with iohexol using a retro-orbital injection method. The bodies of mice were shielded using a lead plate, except for the left kidney, which received 10 Gy of X-ray irradiation. MSCs cultured in Dulbecco's Modified Eagle Medium containing 10% fetal bovine serum (S-MSCs) or SF-MSCs were then injected through the tail vein. We also investigated the ability of conditioned medium from S-MSCs or SF-MSCs to suppress apoptosis of X-ray-irradiated HEK293 cells.

**Results:** Serum creatinine and blood urea nitrogen levels were remarkably increased in CIN mice injected with phosphate-buffered saline (control), but suppressed in CIN mice injected with SF-MSCs compared with S-MSCs. Similarly, cleaved caspase 3 protein levels and numbers of TUNEL-positive cells were increased in CIN mice, but suppressed in CIN mice injected with SF-MSCs compared with S-MSCs. In addition, protein levels of  $\gamma$ H2AX, a marker of chromosomal damage, were upregulated in CIN mice, but reduced by S-MSCs

treatment and further reduced by SF-MSCs. In vitro experiments showed that the increase in cleaved caspase 3 protein level induced by radiation of HEK293 cells was more strongly suppressed by conditioned medium from SF-MSCs compared with that from S-MSCs.

**Conclusions:** Adipose-derived SF-MSCs attenuate CIN by exerting anti-apoptotic effects, indicating that SF-MSCs may be a potential therapy for CIN.

## TH-PO110

## Non-Pharmacological Interventions in Chronic Non-Communicable Diseases: The Impact of Moderate Physical Exercise in Rats

Maria de Fatima F. Vattimo,<sup>1,2</sup> Eloiza O. Silva,<sup>1,2</sup> Sara Ventura,<sup>1,2</sup> Brenner K. Oliveira,<sup>3,1</sup> Carla d. Victoria.<sup>1,2</sup> Research Group on Experimental Acute Kidney Injury <sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>School of Nursing, Sao Paulo, Brazil; <sup>3</sup>Universidade Federal do Amazonas, Manaus, Brazil.

**Background:** Chronic non-communicable diseases (NCDs) are the most relevant cause of premature deaths and morbidities. The goal of the World Health Organization is to reduce NCDs by 25% by 2025. Among the complications of NCDs, chronic kidney disease (CKD) and acute kidney injury (AKI) stand out. The physical exercise (E) is a non-pharmacological intervention that suppress the morbidity of CKD and DM. This study aims to evaluate the effect of the moderate aerobic exercise in DM and CKD rats submitted to the nephrotoxicity of the iodinated contrast.

**Methods:** Wistar rats were divided in groups: SHAM; CKD (nephrectomized animals, 5/6 renal mass); CKD+E (CKD submitted to swimming training, 60 min, 5 days, 4 weeks); aCKD (CKD received meglumine sodium ioxithalamate, contrast medium, 6 mL/kg, iv; once); aCKD+E (aCKD trained as described); Citrate (streptozotocin-STZ vehicle, 0.4 mL; ip; once); Citrate+E (Citrate trained as described); DM (STZ, 60 mg/kg, iv, once); DM+E (DM subjected to E as described); aDM+E (aDM trained as described). Renal function (inulin clearance, serum creatinine and microalbuminuria), hemodynamics (renal vascular flow and resistance) and oxidative profile (urinary peroxides, TBARS, nitric oxide and thiols) were evaluated.

**Results:** [Figure 1] [Figure 2].

**Conclusions:** Exercise was confirmed as a non-pharmacological therapy by reducing the progression of CKD and the diabetic kidney disease aggravated by the use of contrast, demonstrating improvement in renal function, renal hemodynamics and oxidative stress.

**Funding:** Government Support - Non-U.S.

## TH-PO111

**Normal Renal Function in a Patient With Elevated Serum Creatinine**

Janelle Muuse, Alexander Pennekamp, John Hergenrother. *Christ Hospital, Cincinnati, OH.*

**Introduction:** Creatinine is an imperfect marker to estimate GFR, and awareness of situations where it will not accurately reflect kidney function is crucial. Creatinine is affected not only by states that increase or decrease its production (i.e. rhabdomyolysis, sarcopenia) but also by factors that affect its reabsorption in the tubule (or within the body).

**Case Description:** A 65 year old male with a history significant for prostate cancer was admitted to the hospital for abdominal pain and distention four days after undergoing a radical prostatectomy. Initial pertinent labs included a serum creatinine of 1.5mg/dL (baseline 1.0 mg/dL) and an eGFR of 47 (CKD-EPI 2009). He had a JP drain in place with large amounts of serosanguinous fluid. Imaging revealed postoperative ileus. On subsequent days, his creatinine continued to rise and was refractory to intravenous fluids. The patient became increasingly distended to the extent that abdominal compartment syndrome was a concern. A decompressing colonoscopy failed to relieve the patient's symptoms. Lasix and albumin were given and caused his JP drain output to increase significantly. The abdominal fluid was found to have a creatinine of 9.7, signifying a possible urine leak. By day 3, his serum creatinine rose to 4.10. Urinalysis was bland. A cystogram was then performed and demonstrated a moderate vesicourethral anastomotic leak. Due to the patient's large urine output and lack of other markers of renal dysfunction such as fluid overload and electrolyte abnormalities, it was determined that both his ileus and elevated creatinine were caused by uroperitoneum. This was later confirmed by a cystatin c level. His urine leak was treated conservatively and his serum creatinine returned to normal in the following days.

**Discussion:** This was an unusual case of uroperitoneum post prostatectomy, as urine leaks most commonly present in the retroperitoneum. Creatinine absorbed into the peritoneum caused an elevated serum creatinine due to reabsorption of creatinine from the peritoneal space back into the blood. The utility of measuring cystatin c is highlighted here—his eGFR using cystatin c was found to be 52 (compared to 14 using the creatinine equation)—showing a much more accurate indicator of renal function. Identifying pseudo-acute renal failure was imperative in this case to avoid unnecessary interventions such as dialysis.

## TH-PO112

**Cilastatin in the Prevention and Treatment of Rhabdomyolysis-Induced Acute Renal Failure**

Maria Angeles Gonzalez-Nicolas Gonzalez,<sup>1</sup> Blanca Humanes Sanchez,<sup>1</sup> Alberto Lazaro Fernandez.<sup>2,1</sup> <sup>1</sup>*Instituto de Investigacion Sanitaria Gregorio Maranon, Madrid, Spain;* <sup>2</sup>*Universidad Complutense de Madrid, Madrid, Spain.*

**Background:** Rhabdomyolysis (RM) is a clinical and biochemical syndrome characterized by skeletal muscle rupture and massive release of cellular components including myoglobin (MG). MG directly damages the kidneys by activation of apoptotic, oxidative and inflammatory pathways in addition to tubular obstruction due to precipitation causing acute renal failure (ARF), one of its most serious complications. In fact, 50% of patients with RM will develop ARF with mortality rate can reach to 60%. Cilastatin, a renal dehydropeptidase-I inhibitor, has demonstrated its usefulness in the protection of ARF induced by nephrotoxic drugs due to interference with lipid rafts. Here, we evaluate the utility of cilastatin as a protector against RM-induced ARF.

**Methods:** RM was induced in Wistar rats by administering in the hind legs with 50% glycerol (or vehicle to the control group). Cilastatin (150 mg/kg) or its vehicle, was administered immediately and every 24 hours after RM induction. Renal damage was assessed 48h after glycerol/vehicle administration by measuring serum creatinine, blood urea nitrogen (BUN), glomerular filtration rate (GFR), renal damage biomarker KIM-1, renal tissue morphology and iron accumulation, as well as apoptotic, oxidative and inflammatory parameters such as caspase 3, CD68, 4-HNE and TGFβ among others.

**Results:** RM increased serum creatinine, BUN and decreased GFR compared to the control group. These renal effects were confirmed by an increase in the KIM-1 and the presence of severe morphological changes. Iron accumulation in tubular cells was observed, as well as a statistically significant increase in apoptotic, inflammatory and oxidative biomarkers. Cilastatin treatment completely prevented renal dysfunction and restored significantly all other parameters to levels found in the control groups. It also reduced many of the histological symptoms of renal damage.

**Conclusions:** Our findings support the potential use of cilastatin as a useful drug in the prevention and treatment of RM, ameliorating RM-induced ARF. Therefore, cilastatin may be a very beneficial therapeutic strategy in clinical practice for patients with some type of trauma or susceptible to renal damage due to RM.

## TH-PO113

**The NADPH Oxidase (NOX2) Is Required to Control Urinary Tract Infections**

Juan de Dios Ruiz-Rosado, Israel Cotzomi Ortega, Rachel Han, Gregory Ballash, Yuriko I. Sanchez-Zamora, Hanna H. Cortado, Birong Li, Brian Becknell. *Nationwide Children's Hospital, Columbus, OH.*

**Background:** Urinary tract infections (UTIs) account for 7 million office visits and \$1.6 billion dollars in health care spending annually in the United States. Uropathogenic *Escherichia coli* (UPEC) is the primary etiological pathogen causing over 80% of UTI. Currently, there is a critical need for innovative and effective strategies to treat UTI. The NADPH oxidase complex 2 (NOX2) is one of the major sources of reactive oxygen species (ROS) in immune phagocytes and has a central role in the antimicrobial response against many bacterial and fungal infections, but its role during UTIs remains unknown. In this study, we elucidated the role of NOX2 during experimental UTI.

**Methods:** Female wild-type (WT) C57BL/6 mice, NOX2 knockout (NOX2 KO) mice, and WT mice treated with a NOX2 inhibitor (GSK) were transurethrally infected with UPEC (CFT073 strain). NOX2 protein expression was analyzed by Western blotting. Cellular sources of NOX2 were identified by immunofluorescence. The bacterial burden (UPEC) in the urinary tract was measured by enumerating colony forming units (CFU). Histopathological analysis of the infected bladder was conducted using the Hopkins score. Bone marrow Neutrophils from uninfected WT, NOX2 KO mice or peripheral blood neutrophils from healthy human donors were infected with UPEC *in vitro*. Neutrophil ROS production was determined using the Amplex Red kit.

**Results:** Knockdown or pharmaceutical inhibition of NOX2 in mice led to an increased bacterial burden in the bladder and kidney during UPEC-induced UTI. The increased susceptibility in infected NOX2 KO mice was associated with augmented bladder pathology, characterized by mucosal lesions and lamina propria edema, compared to infected WT mice. NOX2 expression significantly correlated with bacterial burden in the bladder from infected WT mice. Immunofluorescence microscopy localized NOX2 primarily in infiltrating neutrophils in the infected urinary tract. NOX2 KO neutrophils exhibited impaired extracellular ROS production and increased intracellular bacteria compared to WT neutrophils following UPEC infection *in vitro*. Similar effects occurred in primary human neutrophils following chemical inhibition of NOX2 *in vitro*.

**Conclusions:** NOX2-derived ROS serves a critical antimicrobial role during experimental UTI.

**Funding:** NIDDK Support

## TH-PO114

**Sjogren Syndrome Manifesting as Thrombotic Microangiopathy and Cryoglobulinemic Vasculitis**

Reshma J. Kariyil, Kanza Haq, Alana Dasgupta, S.M. Bagnasco, Samir C. Gautam. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Introduction:** Cryoglobulinemic vasculitis is an immune complex mediated small vessel vasculitis with significant morbidity and mortality. Renal manifestations are generally MPGN pattern but less commonly membranoproliferative glomerulopathy and intraglomerular thrombi.

**Case Description:** We present the case of a 49-year-old Palestinian female with history of SLE on hydroxychloroquine, hypertension, and chronic kidney disease with prior biopsy proven chronic thrombotic microangiopathy. She presented with dyspnea on exertion, lower extremity purpuric rash and edema, and new left foot weakness and numbness. Laboratory testing showed severe acute kidney injury, proteinuria as well as predominantly low C4 hypocomplementemia, positive ANA, RF, and anti-Ro52 and Ro62 antibodies. Renal biopsy showed rare glomeruli with thickened capillary walls and PAS-positive intracapillary coagula. Similar coagula were seen to fill the lumens of several small arteries (Fig 1, PAS 400x). These coagula stained brightly for IgM, IgG, C3, kappa, and lambda on immunofluorescence. On electron microscopy, rare cellular interpositioning with scattered paramesangial and intracapillary electron dense deposits were seen (Fig 2). These deposits were comprised of haphazardly arranged tubulocylinders with an average diameter of 27 nm. Additional laboratory testing revealed circulating type II cryoglobulin with high cryocrit > 40%. She was eventually diagnosed with cryoglobulinemic vasculitis and TMA from Sjogren's syndrome. She was given steroids, rituximab, and ultimately required dialysis.

**Discussion:** Cryoglobulinemic vasculitis with renal involvement is most commonly seen with hepatitis C infection. Among renal manifestations, membranoproliferative pattern is common. Though our patient had fibrinoid necrosis of small arteries, glomerular thrombi were not present. Although association with Sjogren's syndrome is rare, it is associated with higher risk of lymphoma and high systemic disease activity.

## TH-PO115

### Renal Dysfunction in Bartonella Endocarditis With ANCA Positive Titers: A Management Dilemma

Tharika S. Rajmohan,<sup>1</sup> Harsha Sai Sreemantula,<sup>1</sup> O'Neil P. Chaudhry,<sup>1</sup> Muhammad O. Hanif,<sup>1</sup> Charles P. McClure.<sup>2</sup> <sup>1</sup>Mercy Fitzgerald Hospital, Darby, PA; <sup>2</sup>Hospital of the University of Pennsylvania, Philadelphia, PA.

**Introduction:** Bartonella endocarditis is the common cause of culture-negative endocarditis. Renal dysfunction is common in infective endocarditis with immune complex mediated Glomerulonephritis (GN). Here we discuss a case of acute kidney injury in Bartonella endocarditis with elevated anti neutrophil cytoplasmic antibodies (ANCA) which makes the management complex.

**Case Description:** 60-year-old homeless male with history of recurrent upper gastrointestinal (GI) bleeds from arteriovenous malformation, anemia of chronic disease, ischemic cardiomyopathy (ejection fraction of 45%) with defibrillator placement, mitral regurgitation, hypertension, chronic hepatitis B treated, pulmonary embolism not on any anticoagulation due to GI bleed, polysubstance abuse from cocaine and alcohol, presented with complaints of malaise, fatigue and shortness of breath on exertion. Physical examination was remarkable for pale conjunctiva, and holosystolic murmur heard at the apex. Vitals were unremarkable. Labs were remarkable for hemoglobin of 6.9 mg/dL, platelet count of 30,000 and creatinine (Cr) of 6.10 mg/dL (baseline creatinine of 1 mg/dL, 3 months ago). Urinalysis was suggestive of significant proteinuria of >300 mg/dL, Blood +ve with RBC and a normal renal scan. Renal panel showed low complements with positive ANCA titers with proteinase 3 (PR3) along with positive Rheumatoid Factor. Echocardiogram showed vegetation with Bartonella serology positive. Renal Biopsy was placed on hold due to thrombocytopenia and antibiotics was started (Doxycycline and Rifampin). He required hemodialysis due to worsening acidosis and significant uremia and later died due to disseminated intravascular coagulation and septic shock.

**Discussion:** Presence of ANCA positive titers in a culture negative Bartonella endocarditis renal dysfunction is an interesting and challenging at the same time as ANCA vasculitis traditionally is Pauci immune on immunofluorescence with normal complements. Renal dysfunction with hypocomplementemia in an immune complex glomerulonephritis (GN) and positive ANCA titers creates confusion as management can be challenging with antibiotics as the mainstay for the treatment of endocarditis, while immunosuppression is for ANCA vasculitis. Few case reports have been reported where renal biopsy plays a major role in terms of management.

## TH-PO116

### Mathematical Representation of Drug Induced Crystal Nephropathy Using a Quantitative Systems Toxicology Approach

Shailendra Tallapaka,<sup>1</sup> Pallavi Bhargava,<sup>1</sup> Bhabuk Koirala,<sup>2</sup> Jeffrey L. Woodhead.<sup>1</sup> <sup>1</sup>Simulations Plus Inc, Research Triangle Park, NC; <sup>2</sup>Janssen Research and Development LLC, Springhouse, PA.

**Background:** Drugs may cause crystal nephropathy by precipitating within kidney tubules or inducing the precipitation of endogenous compounds. A mechanistic mathematical model of drug induced crystal nephropathy was developed within the context of RENAsym® to help de-risk drug development programs by predicting the potential of a drug to cause crystal nephropathy. RENAsym is a quantitative systems toxicology model of acute kidney injury that includes representation of proximal tubule cells, drug-induced cell death, and resultant biomarker responses. The crystal nephropathy model comprises of formation, aggregation, distribution and elimination of crystals within the kidney and the subsequent toxic effects on kidney function.

**Methods:** The crystal nephropathy model was developed using ethylene glycol (EG)-induced calcium oxalate (CaOx) crystal formation as an exemplar due to the amount of literature data available to inform model parameterization. The model is designed to use the physicochemical properties of a drug in combination with tubular drug concentrations to predict crystal formation. A PBPK model representing EG and its metabolites glycolic acid, glyoxylic acid, and oxalic acid was constructed using GastroPlus 9.8 to inform oxalate concentrations in the kidney tubule. Precipitation of CaOx, crystal disposition, crystal uptake by tubular cells, cell death due to crystal induced oxidative stress, and crystal clearance was then parameterized using published data in mouse and rats.

**Results:** The kidney tubule concentrations predicted by the PBPK model are well above the solubility limit and therefore result in crystal formation at all simulated doses. The RENAsym crystal nephropathy submodel has been parameterized to induce mild PTC injury when EG is administered at a 0.75% (w/v) in drinking water to rats. Simulations did not predict a serum creatinine increase greater than 1.5X baseline, which aligns with the data as the simulated protocol is not expected to have an appreciable effect on creatinine clearance.

**Conclusions:** The crystal nephropathy model in RENAsym does a reasonable job of representing EG-induced CaOx crystal formation and its nephrotoxic effects. The model shows promise in its ability to predict kidney injury due to other compounds that can precipitate in the kidney tubule, such as indinavir.

### Multi-Omics Conjoint Analysis Identified pglyrp1 as a Potential Biomarker and Target for Sepsis-Induced AKI

Ruilian You, Lubin Xu, Jiatong Xu, Yixin Ma, Jianfeng Lin, Huadong Zhu, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

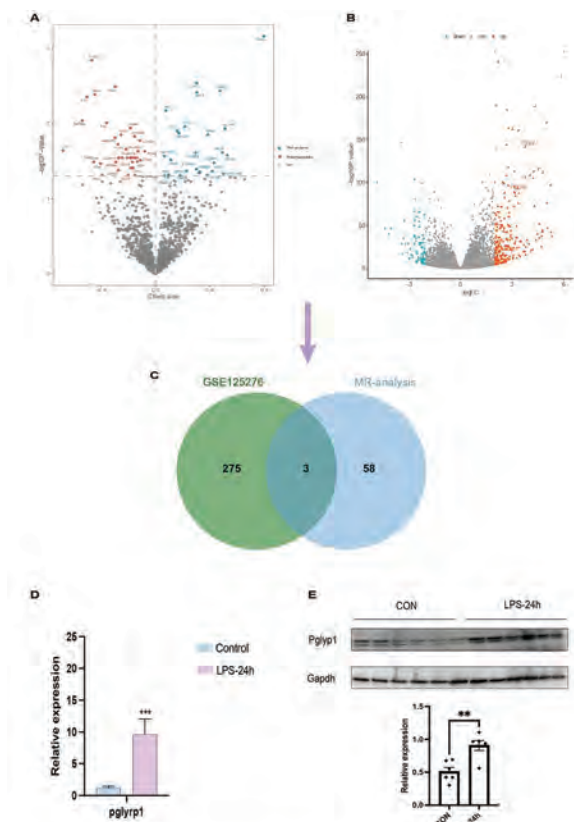

**Background:** Sepsis-induced acute kidney injury (SI-AKI) is a frequent complication of critical patients leading to high morbidity and mortality without a satisfactory prognosis. Further studies are needed to unveil the SI-AKI mechanisms for detecting new biomarkers and treatment targets.

**Methods:** We conducted the genome-wide Mendelian randomization (MR-PheWAS) using the 2116 instruments for 1699 proteins from the open protein quantitative trait loci (pQTLs) data published by the Jie Zheng et al. and the genome-wide association studies (GWAS) of the acute kidney failure including 456348 European. Adjusted  $P < 3 \times 10^{-5}$  was considered significant and  $P < 0.05$  was considered suggestive of an association. We selected the expression profile GSE125276 from the Gene Expression Omnibus (GEO) database to analyze the differentially expressed genes (DEGs) of the SI-AKI. Animal model of SI-AKI was established with lipopolysaccharides (LPS). Common gene identified based on the genome and the transcriptome was validated by the quantitative real-time PCR (qRT-PCR) and western blot.

**Results:** A total of 61 proteins were considered suggestive of an association by the MR-PheWAS, including 34 protective genes and 27 risk proteins. The 316 DEGs were identified from the GSE125276. Csf2rb, pglyrp1, and slurrp1 were common genes of the multi-omics analysis. Pglyrp1 was included in the top hub module extracted from the molecular complex detection (MCODE). The RNA and protein expression levels of the pglyrp1 are all significantly elevated in the nephron tissue of the SI-AKI mice compared to control group.

**Conclusions:** Our study first combined the MR-PheWAS method using genome data and expression data in SI-AKI, validated that pglyrp1 upregulated as a potential causal risk molecular of the SI-AKI.

**Figure 1. Multi-omics conjoint analysis identified pglrp1 as a potential biomarker and target for Sepsis induced Acute Kidney Injury (SI-AKI).** A: Volcano plot of the effect size from MR analysis of 1669 proteins with risk of AKI. B: Volcano plot showed significant DEGs in GSE125276. C: Venn diagram presents the two analysis methods' common genes/proteins. D: The mRNA expression of the pglrp1 in kidney of SI-AKI and control groups. E: Western blot analysis of the protein pglrp1 in SI-AKI and control groups.

## TH-PO118

### Bilateral Hydronephrosis due to Rosai-Dorfman Disease

Olesya Ilkun,<sup>1,2</sup> Rama Kethineni,<sup>1,2</sup> Monique E. Cho,<sup>1,2</sup> Josephine Abraham.<sup>1,2</sup>  
 Utah <sup>1</sup>University of Utah Health Hospitals and Clinics, Salt Lake City, UT; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Introduction:** Rosai-Dorfman Disease (RDD) is a rare histiocytic proliferative disorder, with approximately 100 cases diagnosed each year in the United States. Typically it presents as nodal and cutaneous disease, but kidneys can be affected in 4% of cases.

**Case Description:** We present a case of a 78-year-old man who was admitted with osteomyelitis and acute kidney injury. His serum creatinine was elevated to 2.62 mg/dL from baseline of 0.67 mg/dL ten weeks earlier. Retroperitoneal ultrasound showed bilateral hydronephrosis. Further imaging showed obstruction at the level of ureteropelvic junction due to bilateral masses: left 7.0 x 6.1 cm and right 5.7 x 5.2 cm, that were solely enhancing on PET-CT (Figure 1). Biopsy of the right parapelvic mass showed atypical histiocytic and paraplasmic infiltrate consistent with Rosai-Dorfman Disease. Bone culture showed *Enterobacter cloacae* and patient was started on antibiotics. ANA was detected at 1:320 but C3, C4, and dsDNA were normal and there were no other manifestations to indicate lupus or lupus nephritis. Work-up for other infectious or autoimmune secondary causes was negative. Treatment strategies of this heterogeneous disease vary from surgical resection or debulking, corticosteroids to chemotherapy or radiotherapy. Given ongoing osteomyelitis and further indolent course of his RDD, this patient was managed conservatively with bilateral ureteral stents, and his creatinine improved to 1.4 mg/dL.

**Discussion:** This is a very rare case of Rosai-Dorfman Disease isolated to bilateral kidneys. Ongoing infection hindered use immunosuppression in this patient. This case brings to light a rare disorder and underscores the importance of renal imaging when evaluating acute kidney injury.

A. MRI with contrast showing bilateral peripelvic masses.

B. PET-CT.

## TH-PO119

### Anti-Glomerular Basement Membrane Disease Sans Kidney Involvement

Olesya Ilkun, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

**Introduction:** Anti-Glomerular Basement Membrane (anti-GBM) is an autoimmune disease involving glomerular and pulmonary capillaries diagnosed in 1 patient per million per year. Predominant lung involvement can be seen in 6% of patients most of which still demonstrate microscopic hematuria and biopsy with typical linear IgG immunofluorescence (99%).

**Case Description:** We report a case of a 57-year-old man who presented with several weeks of dyspnea and myalgia, and was found to have acute kidney injury and multifocal tree-in-bud groundglass opacities throughout both lungs (Figure 1). His serum creatinine was elevated to 4.5 mg/dL from baseline of 0.8 mg/dL three months earlier but no proteinuria or hematuria. COVID19 was negative. Bronchoscopy showed blood throughout the tracheobronchial tree. Anti-GBM was elevated at 80 AU/mL. CRP was elevated at 17 mg/dL. Further work-up for other infectious or autoimmune causes was unremarkable. Kidney biopsy showed acute tubular necrosis (ATN), mixed interstitial inflammatory infiltrate, and one isolated fibrous cellular crescent. Immunofluorescence was negative. Due to the concern for progression of untreated anti-GBM disease, the patient was given high dose steroids, plasma exchange, and oral cyclophosphamide. His anti-GBM titer decreased to an undetectable level. Creatinine improved to 2.33 mg/dL.

**Discussion:** This case brings to light a rare variant of anti-GBM with no detectable kidney involvement and presents a therapeutic dilemma. Two independent pathologists reviewed kidney biopsy and felt that crescent was a non-specific result of prior glomerular injury or pauci-immune focal glomerulonephritis. ANCA serologies were negative, and there were no other systemic manifestations. ATN was attributed to poor intake and Naproxen use. The patient received a typical anti-GBM treatment but more data are needed to support this approach in mild cases.

## TH-PO120

### Newly Diagnosed Sickle Cell Disease Complicated by AKI With Bone Marrow Necrosis and Fat Embolism Syndrome Successfully Treated With Plasma Exchange

Jun Li,<sup>1,2</sup> Michel Terzibachi,<sup>1,2</sup> Deep Sharma,<sup>1,2</sup> Jyotsana Thakkar,<sup>1,2</sup> Laurene Tuidar,<sup>3</sup> Molly Fisher.<sup>1,2</sup> <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>2</sup>Montefiore Medical Center, Bronx, NY; <sup>3</sup>United Health Service Medical Center, Johnson City, NY.

**Introduction:** Bone marrow necrosis with fat embolism syndrome (FES) is a devastating complication of sickle cell disease (SCD) that is associated with high mortality. We report an unusual case of an elderly female who presented with severe acute kidney injury (AKI) and features suggestive of thrombotic microangiopathy (TMA) who was found to have hemoglobin SC disease (HbSC) with FES, which was successfully treated with plasma exchange.

**Case Description:** A 76-year-old African American female with diabetes, hypertension, rheumatoid arthritis presented with altered mental status, hypoxic respiratory failure and septic shock due to pneumonia requiring intubation and vasopressors. Upon admission, she was found to have an elevated serum creatinine of 3.6mg/dl as well as severe anemia (hemoglobin 6.7 g/dL), thrombocytopenia (platelet count 66 k/μL) and elevated transaminases. Additional workup revealed a lactate dehydrogenase of 2553 U/L, haptoglobin <10mg/dl, ADAMTS 13 activity 0.52 IU/mL. Peripheral smear revealed schistocytes, sickle cells and findings of bone marrow necrosis. She was also found to have bilateral femoral head avascular necrosis on CT. Hemoglobin electrophoresis was performed and showed elevated hemoglobin S and hemoglobin C, consistent with HbSC disease. The patient received emergent exchange transfusion for FES in the context of sickle cell crisis. She subsequently received plasma exchange for 5 days and supportive hemodialysis. After treatment, her mental status improved as well as her hematologic parameters and kidney function leading to discontinuation of hemodialysis.

**Discussion:** Bone marrow necrosis with FES is a rare complication of SCD that can mimic TMA. Interestingly, this syndrome is most often described in HbSC disease, a mild variant of SCD. The present case highlights the importance of not overlooking this diagnosis in patients with SCD who present with TMA-like features and AKI and also shows that plasma exchange is an effective therapeutic strategy.

## TH-PO121

### High Oxygen Exposure Activates the Renal Endothelin System and Induces Extracellular Matrix Deposition

Abigail Kraus, Sara Biswal, Carmen De Miguel. *University of Alabama at Birmingham, Birmingham, AL.*

**Background:** High oxygen supplementation is abundantly used in the clinical setting. Despite increasing evidence of excessive O<sub>2</sub> increasing mortality and morbidity in ICU patients, the exact molecular mechanisms involved remain obscure. Of note, acute kidney injury and acute lung injury often occur in tandem in critical care and are both associated with elevated levels of endothelin-1 (ET-1) and ET<sub>A</sub> receptor overactivation. However, if the ET-1 system plays a role in kidney injury during exposure to elevated O<sub>2</sub> levels remains unknown. These studies aimed to define the role of the ET-1 system in hyperoxia-induced kidney damage.

**Methods:** Male and female adult C57Bl/6N mice were exposed to room air (RA) or hyperoxia (HA, >95% O<sub>2</sub>) for 72 hours. Kidneys were collected for assessment of extracellular matrix deposition (ECM) via Picrosirius staining as well as mRNA expression of ET-1, and ET<sub>A</sub> and ET<sub>B</sub> receptors and ECM deposition markers in different kidney regions.

**Results:** Kidneys from mice exposed to high O<sub>2</sub> expressed significantly greater ET-1 levels compared to room air littermates. In response to HA, the outer and inner medulla showed a 2.3- and 5-fold upregulation of ET-1 mRNA expression, respectively (RA vs. HA, outer medulla: 1±0.23 vs. 2.3±0.35, p=0.02, n=6-8/group; inner medulla: 1±0.19 vs. 5.2±0.71, p=0.001), but no difference was observed in cortex (p=0.37). No differences in renal expression of ET<sub>A</sub> or ET<sub>B</sub> receptors were detected with HA. The HA-induced changes in the ET-1 system were accompanied by prominent ECM deposition in all areas of the kidney when visualized under bright-field and polarized light microscopy. Further, the inner medulla revealed a 4.5 fold increase in collagen IV gene expression when exposed to HA (1±0.40 vs. 4.01±1.00, p=0.02). No sex differences in the effects of HA on the kidney ET-1 system were detected.

**Conclusions:** In conclusion, high O<sub>2</sub> exposure induces ECM deposition in the kidney and upregulates the ET-1 system, specifically in the renal medulla. Our findings strongly suggest that high O<sub>2</sub> supplementation results in ET-1-mediated kidney injury. A better understanding of the renal ET-1 system response in high O<sub>2</sub> states will help designing better pharmaceutical or O<sub>2</sub> management interventions to limit the detrimental effects of high O<sub>2</sub> supplementation and improve patient care.

## TH-PO122

### Hydralazine-Induced ANCA Vasculitis: The Fault in Our Drugs

Neha Siddiqui, Jay G. Shastri, Lorraine Alcantara, Areej Lalani, Anum S. Khan, Ram Sinha. *AtlanticCare Regional Medical Center, Atlantic City, NJ.*

**Introduction:** Hydralazine is a vasodilator used in the management of high blood pressure. It is not a first-line agent and is usually given to patients who can not tolerate ACE/ARB or as an additional therapy in patients who have residual hypertension. Hydralazine

is known to cause a drug-induced lupus-like syndrome but rarely, Hydralazine can cause antineutrophil cytoplasmic antibody-associated (ANCA) vasculitis, it commonly presents as multi-organ related vasculitis with skin and pulmonary-renal manifestations. In this case study, we present a rare case of renal limited hydralazine induced ANCA vasculitis.

**Case Description:** An 89-year-old female presented to the emergency department due to acutely worsening kidney function in outpatient labs. Urine analysis was positive for hematuria and proteinuria. Ultrasound of the kidneys showed no signs of obstruction. Creatinine continued to rise despite the discontinuation of ACE inhibitors. The patient was positive for p-ANCA/MPO, ANA, and double-stranded DNA antibodies. C3 level was normal and C4 was at the low end of normal. The patient was recently started on hydralazine 100mg TID eleven months before presentation. She denied joint discomfort, visible hematuria, rashes, hemoptysis, shortness of breath, or signs of purpura. She received pulse dose steroids and hydralazine was discontinued. Creatinine responded to discontinuation of hydralazine supporting the diagnosis of hydralazine-associated vasculitis. The patient refused to undergo a biopsy hence immunosuppressive therapy could not be initiated.

**Discussion:** Hydralazine-induced ANCA vasculitis has an incidence of 5.4% in patients receiving 100mg/day of hydralazine and 10.4% in patients receiving 200mg/day for more than 3 years. It mostly presents with multi-organ system disease, there are only four reported cases of hydralazine induced vasculitis limited to the kidney. In a large study comprising 80 cases of hydralazine associated ANCA-GN, 98% of the subjects were P-ANCA/MPO positive and 39% had dual positivity with P-ANCA and C-ANCA. There are few reported cases of asymptomatic, renal limited, hydralazine induced ANCA vasculitis which makes it challenging to diagnose and, therefore, can be easily missed. Increasing awareness amongst the health care workers can lead to timely diagnosis and prompt initiation of treatment resulting in a better outcome.

## TH-PO123

### Cefoxitin-Induced Pseudo-AKI

Jeanette M. Atencio, J. Pedro Teixeira, Sara Combs. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

**Introduction:** Drug toxicity is a common cause of hospital-acquired acute kidney injury (AKI), but drug-induced pseudo-AKI is rare. We present a case of pseudo-AKI from cefoxitin.

**Case Description:** A 57-year-old man with opiate use disorder was transferred for a *Mycobacterium abscessus* prosthetic left hip infection. He had previously been treated for >1 month with amikacin, cefoxitin, and tigecycline with normal serum creatinine (Cr) throughout. On admission to our hospital, blood urea nitrogen (BUN) was 20 mg/dL and Cr was 0.87 mg/dL, he was continued on the same antibiotics. On hospital day (HD) 8, when Cr was 0.94 and BUN was 20, the cefoxitin was switched from 3 times daily dosing to a continuous infusion. On HD 10 his Cr jumped to 10.1 with BUN 17. When redrawn 2h later, Cr was 15.0 and BUN was 16. Nephrology was consulted and cefoxitin was stopped. Renal ultrasound and urinalysis were normal. Infectious disease suspected lab interference from cefoxitin and recommended redrawing labs from a site away from the site of cefoxitin infusion. On HD 11 his Cr returned to 0.86 and cefoxitin was resumed. Cystatin C drawn the afternoon of HD 10 eventually resulted at 0.9 mg/dL.

**Discussion:** Most labs measure serum Cr using the kinetic alkaline picrate (Jaffe) method, which can rarely be subject to interference from other chromogens, leading to spurious elevation. Compounds known to interfere include cefoxitin, flucytosine, dexamethasone, acetacetate (in DKA), and bilirubin (when extremely elevated). When diagnosing pseudo-AKI, the timing of drug administration and lab draw and the venipuncture site relative to the drug infusion site are important factors. Additional clues include non-physiologic rise in Cr and lack of change in other markers of renal function. With intermittently dosed cefoxitin, pseudo-AKI can be confirmed with a lab redraw after cefoxitin is eliminated (i.e., after 2-4h in normal kidney function, 6-8h in mild-to-moderate renal failure, and variable interval in severe renal failure). Though rare, this case illustrates the importance of considering pseudo-AKI in the differential diagnosis of unexplained AKI.

## TH-PO124

### Postpartum Complement Mediated Thrombotic Microangiopathy: A Case Report

Christian Anderson, Iiro Honkanen, Sarat C. Kuppachi. *The University of Iowa Hospitals and Clinics, Iowa City, IA.*

**Introduction:** Complement mediated thrombotic microangiopathy (TMA) can be associated with a high risk of progression to ESRD if it is unrecognized early in its course. Frequently, a trigger in a genetically susceptible individual initiates aberrant activity of the complement cascade causing microangiopathic hemolytic anemia. Herein, we present the case of a 26-year-old who presented with TMA at the time of her delivery and subsequently found to have a mutation in the Wilms' tumor 1 (WT1) gene.

**Case Description:** A 26-year-old nulliparous woman was admitted to the hospital on post-partum day (PPD) 1. Delivery was complicated by profuse bleeding requiring transfusion of RBCs, platelets, and FFP. She was referred to the Nephrology service on PPD2 with anuria, acute kidney injury (AKI) with a creatinine of 3.6 mg/dL, thrombocytopenia (nadir 14,000), hemolytic anemia, and low complement levels. Urinalysis showed hematuria, protein creatinine ratio of 1.55, and muddy brown casts. Given progression of her kidney injury despite plasmapheresis and a normal ADAMTS-13 level, she was started on eculizumab 900 mg every 14 days with improvement in her platelet count. She required three hemodialysis treatments for volume overload, before her kidney function eventually normalized. Her eculizumab was then discontinued. Genetic testing revealed a heterozygous mutation in WT1 variant NM\_024426.6:c.662-6C>A, which is a variant of unknown significance.

**Discussion:** Pregnancy is a well-established trigger for TMA which must be included in the differential diagnosis of peri- and post-partum patients with AKI. Once TMA is identified, it is important to pursue genetic testing to better understand the genetic variants implicated in the disease. This has implications for treatment, prognosis, and further research. To the best of our knowledge there is only one reported case of WT1 mutation presenting as complement mediated hemolytic syndrome. WT1 encoded proteins are necessary to regulate cell growth and maintain normal function of renal podocytes and the glomerular filtration barrier. We hypothesize that reduced WT1 expression, leading to podocytopathy could be one of the pathogenic factors contributing to the occurrence of TMA. Based on this experience, and successful treatment with eculizumab, we want to raise awareness to the to the possibility of WT1 mutations triggering TMA in susceptible patients.

## TH-PO125

### A Case of Streptococcal Toxic Shock Syndrome With Acute Renal Failure

Renuka Tolani, *Palmetto General Hospital, Hialeah, FL.*

**Introduction:** Elderly patients with skin lesions and risk factors such as diabetes, can develop streptococcal toxic shock syndrome (STSS) with multiorgan involvement. Certain patients present with acute kidney injury (AKI), and later progress to renal failure requiring renal replacement therapy.

**Case Description:** Patient is an 86 year old male with past medical history of CKD stage 3b and diabetes (on Ozempic and insulin) who presents to the ED for weakness, chills, and fever after injuring his right arm on a car door the week prior. Physical exam was significant for tenderness and diffuse bullae, with sharp margin of erythema and desquamation in the right upper extremity. Patient was in septic shock with increasing lactic acidosis. Multiple pressors, IV fluids, and broad spectrum antibiotics were administered. Patient became tachypneic and required intubation. Initial labs were significant for leukocytosis of 15 with left shift, bicarb 20, anion gap 13, lactic acid 5.9, and creatinine 2.6 with GFR 23. ABG on 3 L NC showed metabolic acidosis with pH 7.131, pCO2 25, bicarb 8, pO2 98. Repeat labs showed bicarb level dropped from 20 to 9, with anion gap of 22 and lactic acid 17. Ph decreased to 7.057. Cr was 1.6 and GFR was 41 on labs the year prior, AKI on CKD stage 3b. Transaminitis more than 2 times the upper limit of normal also developed. Glucose was 200 without ketones or glucose noted in urine. A foley catheter was placed. Urgent exploratory surgery and biopsy were done. The patient grew strep pyogenes in both blood and wound cultures. Pathology report showed extensive coagulative necrosis with cocci like bacteria, without evidence of necrotizing fasciitis. Despite administration of bicarb drip and pushes, the patient's acidosis did not improve. The patient had less than 500 ccs of urine production in 24 hours, and there was an increase of potassium to 6.3 from 4.6. The creatinine also increased to 4.3 from 2.6. Decision was made to begin Continuous Renal Replacement Therapy (CRRT). Urinalysis was negative for leukocyte esterase or nitrite, but showed WBC > 50 and RBC > 20. His family was offered the choice of right upper extremity amputation, but opted for comfort care.

**Discussion:** Clinicians should recognize the life-threatening process involved in STSS. Hypotension and toxin-induced hemolysis with myoglobinuria and hemoglobinuria, may contribute to acute renal failure and ATN for which CRRT plays a major role.

## TH-PO126

### Kidneys, Windows to the Liver: A Case of Autoimmune Hepatitis With Lupus Nephritis

Leanne Brown, Aditi Singh. *UConn Health, Farmington, CT.*

**Introduction:** Systemic lupus erythematosus (SLE) is an autoimmune disease with a wide range of systemic manifestations. However, primary involvement of the liver is rare and is not part of the diagnostic criterion. We present a case of biopsy proven primary biliary cholangitis (PBC), later diagnosed as lupus nephritis with suspected autoimmune hepatitis (AIH) given remission with immunosuppressive therapy.

**Case Description:** An Asian-American 51 year-old male presented to the hospital with worsening lower extremity edema. Laboratory investigations revealed normal renal function, persistently elevated liver enzymes and equivocal antimitochondrial antibody (AMA) titers. PBC was diagnosed two years prior to presentation with liver biopsy demonstrating interface hepatitis with chronic inflammatory infiltrates and bile duct injury. He was started on ursodiol without significant improvement in his liver dysfunction. He subsequently developed an acute kidney injury (AKI) and was found to have both hematuria and proteinuria. Further work up demonstrated positive antinuclear antibodies in high titres and positive double stranded DNA antibodies with renal biopsy consistent with Class IV Lupus nephritis. He was induced with pulse dose steroids followed by maintenance with cyclophosphamide with later transitioned to mycophenolate mofetil. He achieved clinical and serological remission with improvement in his renal function and complete resolution of liver dysfunction on immunosuppressive regimen for SLE.

**Discussion:** Although the liver is not a major target for damage in SLE, clinical and biochemical evidence of liver dysfunction is common. This can pose great diagnostic challenges given a considerable degree of overlap in the presentation of lupus hepatitis, AIH and PBC. In our case a diagnosis of AIH was made after lupus nephritis was detected on renal biopsy and its response to immunosuppressive therapy. A high degree of clinical suspicion is required, especially in patients of Asian descent where AIH is more prevalent.

## TH-PO127

### A Case of AKI due to Oxalate Toxicity Following an Over-the-Counter 3-Day Cleanse

Louis Damian, Shilpa Sannapaneni, Christopher Hebert, Akinwande A. Akinfolarin. *Baylor Scott & White Health, Dallas, TX.*

**Introduction:** Oxalate toxicity is a rare but serious disorder that can result in crystal induced Acute Kidney Injury. Calcium oxalate deposition in the kidney can be caused by excessive intake of oxalate in food, fat malabsorption following Roux-en-Y gastric bypass causing increased enteric absorption of oxalate, and primary hyperoxaluria due to hepatic enzyme defects. With the increasing use of "juice cleanses", it is important to recognize the potential risk of excessive ingestion of oxalates in juices made from these over the counter products included in "juicing" protocols.

**Case Description:** A 46-year-old male with past medical history significant for chronic alcohol abuse complicated by alcoholic liver disease was admitted to our hospital with worsening jaundice, fatigue, dyspnea at rest, and generalized weakness. He had noticed a reduction in his urine output but had no hematuria or skin rash. He had no significant medication history but on further questioning reported taking the over-the-counter "Renew-Life 3-Day liver cleanse" approximately one week before onset of symptoms. **This cleanse contained extracts from Rhubarb and Cape aloe.** Laboratory findings from his renal panel were significant for a Creatinine of 13.66 mg/dL (his baseline was 0.8), sodium 123 meq/L, potassium 5.6 meq/L. His Liver panel revealed a total bilirubin 36.0 mg/dL, alkaline phosphatase 437 U/L, AST 70 U/L, ALT 60 U/L, INR 1.8. Serum osmolality was 318 mosm/kg (calculated osmolality 301 mosm/kg). Ethylene glycol was absent on serum toxic alcohol screen. **Serum oxalate level was 9.0 mg.** His clinical course was complicated by anuria and electrolyte derangements. His clinical condition deteriorated with acute respiratory failure and therapy with renal replacement was initiated. He has remained anuric and dialysis dependent.

**Discussion:** Over the counter "cleanse" products may have high oxalate content and predispose to crystal induced kidney injury. This may be more so in patients with concurrent liver disease who can develop fulminant liver failure. A high index of suspicion is required in patients presenting with anuric renal failure after a "cleanse", in order to provide appropriate and timely renal therapy. More advocacy should be paid to warning kidney patients of the potential risk of "cleanses".

## TH-PO128

### Renal Limited Sarcoidosis Presenting as Granulomatous Interstitial Nephritis

Shilpa Sannapaneni, Louis Damian, Wesley Hiser, Akinwande A. Akinfolarin. *Baylor University Medical Center at Dallas, Dallas, TX.*

**Introduction:** Sarcoidosis is a multisystem disorder which primarily involves the lung. Although, renal involvement can be seen in up to 35-50% of sarcoidosis patients, renal limited sarcoidosis without any extra renal manifestations is extremely rare. Here we present a unique case of renal limited sarcoidosis presenting with granulomatous interstitial nephritis (GIN).

**Case Description:** A 69-year-old female with a past medical history of type 2 diabetes, hypothyroidism, chronic obstructive pulmonary disease, chronic kidney disease with baseline creatinine of 1.1 mg/dL was referred to Nephrology with generalized weakness, nausea, vomiting. She had no skin rash, lymphadenopathy, hematuria, no recent history of systemic infections, or antibiotic use. Home medications included sitagliptin, levothyroxine, vitamin D and calcium supplements which were all started two years prior to referral. On presentation, her vital signs were normal and physical examination was unremarkable. Laboratory studies revealed Creatinine 4.77 mg/dL, Calcium 15 mg/dL, Vitamin D 82 ng/ml; 1, 25 dihydroxy vitamin D 114 pg/ml, Parathyroid hormone (PTH) 16.9 pg/mL, PTH related peptide 18 pg/ml, Angiotensin converting enzyme level: 74 U/L, urine protein creatinine ratio: 0.3 mg/mg. Extensive infectious work-up was negative. Renal ultrasonography was unremarkable. A kidney biopsy was performed which was significant for acute interstitial nephritis, small granulomas with multinucleated giant cells concerning for granulomatous interstitial nephritis. Computed tomography scan of chest and abdomen showed no evidence of extra renal sarcoidosis. She was started on steroids and her creatinine trended down to 2.4 mg/dL at the time of discharge.

**Discussion:** Renal manifestations of sarcoid include nephrolithiasis, GIN, nephrocalcinosis, non-granulomatous interstitial nephritis and glomerular disease. GIN can be also seen with medications, infections, crystal deposition, paraproteinemias and vasculitis. GIN is a rare pathological diagnosis which may be seen in about 0.5-0.9% of native kidney biopsies and about 6% biopsies with interstitial nephritis. It is extremely rare to find GIN in sarcoidosis without extra renal involvement. A review of literature revealed about 100 cases of renal sarcoid associated GIN but majority had extra renal manifestations. The mainstay of therapy for sarcoidosis with GIN is steroids.

#### TH-PO129

##### If in Doubt, Biopsy: Unexpected Renal Pathology Proves Critical to Patient Management in Two Interesting Cases

Michelle Madden,<sup>1</sup> Mairead Hamill,<sup>1</sup> Blathnaid O'Connell,<sup>1</sup> Robert W. Casey,<sup>1</sup> Brendan Doyle,<sup>2</sup> Catherine M. Brown,<sup>1</sup> Sean F. Leavey.<sup>1</sup> <sup>1</sup>University Hospital Waterford, Waterford, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland.

**Introduction:** We describe two patients who presented with an unexplained elevation in serum creatinine, inconclusive urinalysis and an unexpected rate of eGFR decline leading to kidney biopsy.

**Case Description:** A seventy year-old man presented with several days of severe nausea, vomiting and diarrhoea. Creatinine was 8.92mg/dL, eGFR 6ml/min, a decline from a normal estimate when last checked one year prior. With intravenous fluids, creatinine fell to 4.03mg/dL but failed to improve further. Urinalysis was bland and urine ACR 3 mg/mmol. Kidney biopsy showed oxalate crystal deposition in the tubules and secondary acute tubular injury. The patient subsequently reported commencing a daily supplement of 550mg Vitamin C, more than five times the recommended allowance, eighteen months previously. Supplementation was discontinued and dietary counselling provided; twenty-four hour urine collection two weeks later showed a normal oxalate excretion of 27 mg/24 hour. Kidney function improved to stable stage 4, most recent creatinine 2.38mg/dL, nineteen months post biopsy. An eighty year-old lady was referred by her GP for an eGFR that had fallen from >60 to 33ml/min. Serum creatinine at referral was noted to be 1.45mg/dL, compared to 1.1mg/dL twelve months prior and 0.68mg/dL eighteen months prior. She had no microalbuminuria or hematuria. She was on apixaban for paroxysmal atrial fibrillation. New medications introduced eighteen months prior were pantoprazole and amiodarone. Obstruction and myeloma were ruled out and pantoprazole ceased, but creatinine rose further to 1.72mg/dL over three months and kidney biopsy was arranged. The biopsy revealed acute tubular injury with vacuolization of cells. This pattern of drug-induced injury is associated with amiodarone-related phospholipidosis and toxicity in the literature. Amiodarone was discontinued. The patient's serum creatinine improved and is 1.43mg/dL, eGFR 35ml/min, eighteen months later.

**Discussion:** In each of these cases, an unexpected kidney biopsy result critically and favourably altered management. Had these patients been left untreated, there was a significant likelihood of progression to end-stage kidney disease. Whether amiodarone may be an under-appreciated nephrotoxin deserves further research.

#### TH-PO130

##### Contrast Nephropathy: Associated or Induced?

Ramandeep Kaur,<sup>1</sup> Clay A. Block,<sup>1,2</sup> Jason R. Pettus.<sup>1,2</sup> <sup>1</sup>Dartmouth-Hitchcock Medical Center, Lebanon, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Introduction:** Acute Kidney Injury (AKI) secondary to radiographic contrast exposure has been challenged in recent years. Contrast Associated Nephropathy (CAN) often occurs in the presence of other risk factors for AKI. We report a case in which AKI developed following radiocontrast exposure but also in the presence of other risk factors for AKI. A kidney biopsy established the diagnosis.

**Case Description:** A 64-year-old woman presented with acute confusion and falls suspicious for CNS vasculitis. She was admitted and treated with pulse methylprednisolone and intravenous vancomycin, ampicillin, ceftriaxone, acyclovir and omeprazole while performing studies for infection and autoimmunity. The creatinine rose from 0.6 mg/dL on day 1 to 2.3 mg/dL on day 3. The urine protein - creatinine ratio was 0.55 g/g. UPEP, SPEP, serum free light chains, and immunological studies including C-ANCA, P-ANCA, MPO Ab, ANA, PR3 Ab, C3 and C4 complements, Cryoglobulins, anti-ds DNA, anti-CCP antibodies were negative. A kidney biopsy was done. It demonstrated severe, diffuse tubular isometric vacuolization compatible with osmotic nephrosis. There was no evidence of acyclovir toxicity, AIN, or conventional ATN. With supportive care, the renal function normalized by day 6.

**Discussion:** Radiocontrast is commonly used in hospitalized patients and has a strong potential for nephrotoxicity. CAN is considered when the patient receives a radiocontrast either intravenously or intra-arterially with a subsequent elevation of serum creatinine of either 0.5 mg/dL or 25% increase above the baseline over the next 24-72 hours. In AKI following radiocontrast exposure and competing explanations, kidney biopsy may point to a specific diagnosis.

#### TH-PO131

##### Lamotrigine Causing Drug-Induced Acute Interstitial Nephritis With Granulomas

Mal P. Homan, Brian J. Holahan, Breanna S. Goldner, Margaret Duffy. *Lehigh Valley Health Network, Allentown, PA.*

**Introduction:** Lamotrigine is used for its antiepileptic and mood stabilization properties. Serious complications can include Steven-Johnson Syndrome or aseptic meningitis. A lesser-known adverse reaction from lamotrigine is acute interstitial nephritis (AIN) with granulomas.

**Case Description:** A 25-year-old man presented to the emergency department with fever, bilateral flank pain, and decreased urination. Medical history was remarkable for bipolar II disorder for which lamotrigine was started a few months prior. Upon arrival, his oral temperature was 100.6°F with otherwise unremarkable vitals. Serum creatinine was 2.0 mg/dL (baseline 0.8-0.9 mg/dL) and there were 10% eosinophils on labs. Urine microscopy revealed 11-20 WBC/hpf, 6-10 RBC/hpf, 1+ bacteria, and >10 hyaline casts; urine protein-creatinine ratio was 2.4 g/g. Imaging revealed bilateral renal enlargement, loss of cortical medullary differentiation, and perinephric stranding suspicious for pyelonephritis. He was initiated on antibiotics and admitted. The creatinine progressively worsened up to 9.56 mg/dL with oliguria and hemodialysis was started. He also developed a diffuse maculopapular rash. Infectious work up was negative, and he was given pulse dose steroids for possible drug-related eosinophilic systemic symptoms (DRESS) or AIN. A kidney biopsy revealed severe interstitial nephritis with granulomatous features in a vasculocentric distribution. The lamotrigine was discontinued, and his renal function and diffuse rash subsequently improved. After discharge, he had full renal recovery after a four-week taper of oral prednisone.

**Discussion:** We describe a rare and severe case of acute granulomatous interstitial nephritis attributed to lamotrigine. AIN can occur days to several months after initiation of an offending agent. Non-renal manifestations such as fever, rash, or eosinophilia can also develop. Although AIN is typically associated with medications such as non-steroidal anti-inflammatory drugs, proton-pump inhibitors, or antibiotics, lamotrigine-related AIN has been reported.<sup>1,3</sup> Interstitial nephritis with granulomas on biopsy should prompt a thorough review of a patient's medications, as this pattern of injury is usually due to a drug-related AIN.<sup>4</sup> In patients with new-onset renal failure in the setting of lamotrigine use, AIN should be considered so that early and appropriate intervention can be initiated.

## TH-PO132

**An Unusual Complication of IgG4-Related Interstitial Nephritis as Resistant Hypertension**

Hubert Wang,<sup>1</sup> Monica P. Revelo Penafiel,<sup>2</sup> Sobia N. Khan.<sup>1</sup> <sup>1</sup>*Stony Brook University Renaissance School of Medicine, Stony Brook, NY;* <sup>2</sup>*University of Utah Health, Salt Lake City, UT.*

**Introduction:** IgG4-related disease is immune-mediated, can affect multiple organ systems, and is characterized by tissue biopsy with dense lymphoplasmacytic infiltrate, high numbers of IgG4-positive plasma cells, and varying degrees of tissue fibrosis in a storiform pattern. We present a unique case of resistant hypertension (HTN) as a prominent manifestation in IgG4-related interstitial nephritis.

**Case Description:** A 64-year-old male with history of HTN and livedoid vasculopathy presented for acute kidney injury with no prior kidney disease. He finished 10 days of Bactrim DS 2 weeks before admission. Home medications included bisoprolol-HCTZ 5mg-6.25mg daily. BP 187/94. Labs: Na 129 mmol/L, K 3.2 mmol/L, BUN 41 mg/dL, SCr 3.2 mg/dL. Urinalysis showed + protein. ANA positive, C3/C4 normal, and SPEP/UPEP with Kappa chain elevation and M-spike. Immunofixation showed IgG Kappa monoclonal antibody. Bone marrow biopsy showed 10-15% CD138 positive plasma cells, diagnosed with smoldering multiple myeloma. Renal ultrasound unremarkable. Renal biopsy consistent with acute interstitial nephritis and mild interstitial fibrosis and tubular atrophy. He was treated with prednisone. HTN controlled on amlodipine, labetalol, and hydralazine. Electrolyte abnormalities prevented diuretic use. He developed AKI on CKD 8 months later. Repeat renal biopsy showed mixed interstitial inflammatory infiltrate with IgG4-positive plasma cells and obliterative arteriopathy consistent with IgG4-mediated interstitial nephritis. He was treated with prednisone taper and rituximab. He presented for hypertensive emergency 2 months later, treated with nicardipine infusion, oral minoxidil added, but complicated by bilateral pleural effusions. Secondary HTN workup negative. Final HTN regimen: clonidine patch 0.6 mg weekly, oral clonidine 0.2 mg in AM and 0.3 mg at noon and PM, hydralazine 100 mg TID, imdur 30 mg BID, labetalol 800 mg TID, nifedipine 60 mg BID, and aldactone 12.5 mg daily.

**Discussion:** The prominent characteristic of our patient's IgG4-related interstitial nephritis was resistant hypertension. He had negative renal artery duplex, unremarkable abdominal MRI, and plasma renin activity and serum aldosterone concentration inadequate to conclude on hyperaldosteronism. No prior case report describes resistant HTN as a prominent manifestation in IgG4-related interstitial nephritis.

## TH-PO133

**Stage 3 AKI, Rhabdomyolysis, and Hyponatremia Developing Within 48 Hours of Transurethral Resection of Bladder Tumor (TURBT)**

Harshil Fichadiya,<sup>1</sup> Poorva P. Bhide,<sup>1</sup> Hardik Fichadiya,<sup>2</sup> Raghu Tiperneni,<sup>1</sup> Farah Heis,<sup>1</sup> Ahmad S. Al-Alwan.<sup>1</sup> <sup>1</sup>*Monmouth Medical Center, Long Branch, NJ;* <sup>2</sup>*Trinitas Regional Medical Center, Elizabeth, NJ.*

**Introduction:** 1/3 AKI associated with urologic procedures are seen following elective procedures while 2/3 are seen in patients admitted from the emergency department with the need of a urological intervention. Among elective procedures nephrectomy is the most common etiology of AKI, while sepsis and urinary obstruction are major culprits of AKI for patients requiring emergent urological intervention. TURBT is rarely associated with AKI with most reported cases from pre-renal and post-renal etiology.

**Case Description:** 62 year old male developed sudden onset renal failure with 8 fold rise in serum creatine within 48 hour of TURBT procedure that was complicated by extra-peritoneal rupture of bladder. Euvolemic moderate hyponatremia and mild rhabdomyolysis were seen. His bladder injury was managed conservatively with foley catheter and regular monitoring of urine output. His serum creatinine urine output started to improve on post op day 5 and hyponatremia improved with fluid restriction.

**Discussion:** The following mechanisms lead to development of AKI in our patient: 1) Extraperitoneal rupture of bladder causing leak and systemic absorption of irrigating fluid from systemic veins-> free fluid excess in plasma-> hyponatremia-> muscle swelling and rupture-> rhabdomyolysis-> ATN 2) Reflux of heme and saline from the bladder to renal tubules via the renal collecting system-> toxic damage to renal tubules ->ATN 3) Hemodynamic changes during TURBT procedure cause decreased renal blood flow->pre-renal injury and tubular damage->AKI We recommend restricting the use of irrigating fluid, avoiding hemodynamic changes, careful post-operative monitoring of renal function, electrolytes, CPK post TURBT, and ruling out obstructive etiology with renal imaging.

## TH-PO134

**Dimensions of Muddy Brown Granular Casts and Anthropometrics in Patients With Acute Tubular Injury**

McKinley H. Antley,<sup>1</sup> Dustin Chalmers,<sup>2,3</sup> Akanksh Ramanand,<sup>2,3</sup> Juan Carlos Q. Velez,<sup>2,3</sup> Michael G. Janech.<sup>1</sup> Ochsner Nephrology <sup>1</sup>*College of Charleston, Charleston, SC;* <sup>2</sup>*The University of Queensland Ochsner Clinical School - New Orleans, New Orleans, LA;* <sup>3</sup>*Ochsner Medical Center, New Orleans, LA.*

**Background:** "Muddy" brown granular casts (MBGC) are identifiable by microscopic examination of the urinary sediment (MicrExUrSed). The presence of MBGC is pathognomonic for acute tubular injury (ATI). Although, MBGC have been noted for years, there are no reports regarding their length nor width. The objective of this study was to measure MBGC using images obtained by light microscopy and correlate them to patient anthropometric and urine chemistry values.

**Methods:** At Ochsner Medical Center, data from patients seen in nephrology consultation who had a urine specimen subjected to MicrExUrSed is prospectively collected. Representative images from each case are routinely stored. A subset of patients with diagnosis of ATI as evidenced by visualization of abundant MBGC (>30% low power fields) were sampled. Images were obtained under bright field microscopy at 400x magnification with an accompanying stage micrometer for external calibration and were measured using ImageJ. Length was measured at 3 sections parallel to the longitudinal axis. Width was measured in 6 sections parallel to the transverse axis. A minimum of 15 MBGC were measured per specimen. Spearman rank test was performed to examine correlations between MBGC width and demographics, anthropometrics, and urine chemistry.

**Results:** height 1.70 ± 0.1 m, mean BMI 32 ± 7. Mean MBGC length was 98.1 ± 42.1 (range 39–72) µm. Mean width was 33.5 ± 12.3 (range 9–110) µm. Based on a previous report of cortical tubular diameters, MBGC width corresponded well with the median reported range of 30–40 µm. MBGC width did not correlate with age, race, sex, BMI or weight. Height was positively correlated with mean MBGC width (rho = 0.48, p<0.05). There was no significant correlation between mean MBGC width and urine sodium, potassium, chloride, creatinine, urea nitrogen, pH, specific gravity or total protein.

**Conclusions:** This is the 1<sup>st</sup> study reporting dimensions of MBGC from patients with ATI. MBGC length is highly variable compared to width. Because kidney size is known to correlate with height, the correlation of MBGC with height suggests that nephron size influences MBGC width. Clinical implications of these observations require further study.

**Funding:** NIDDK Support

## TH-PO135

**Hepcidin Deficiency Exacerbates Renal Pathology in Disseminating Candidiasis**

Sadat Kasem,<sup>1</sup> Annanya Agarwal,<sup>1</sup> Dhruv N. Desai,<sup>1</sup> Michail Lionakis,<sup>2</sup> Borna Mehrad,<sup>1</sup> Yogesh M. Scindia.<sup>1</sup> <sup>1</sup>*University of Florida, Gainesville, FL;* <sup>2</sup>*National Institutes of Health, Bethesda, MD.*

**Background:** *Candida albicans* is a human fungal pathogen and accounts for more than 50% of all invasive fungal infections. Fungal growth within the kidney and consequent kidney failure are the major cause of mortality during disseminating candidiasis. *C. albicans* utilizes a range of iron acquisition mechanisms that contribute to its virulence. Patients with fungal infection have substantially increased transferrin saturation and serum iron concentrations independent of underlying hematological disorder. Thus, host iron handling may be critical checkpoint to the outcome of the infection. Using a murine model of systemic iron overload, we investigated whether *C. albicans*-induced pathology is influenced by iron availability.

**Methods:** Iron overloaded hepcidin knockout (Hamp<sup>-/-</sup>) and wild type (WT) litter mates were infected with *C. albicans* SC5314 and outcomes of infection were evaluated.

**Results:** Compared to WT mice, Hamp<sup>-/-</sup> mice displayed increased kidney fungal burden, pathology and had higher mortality. *C. albicans* was in yeast form in the WT kidneys but had transformed into hyphae in the iron rich renal tubular region of Hamp<sup>-/-</sup> mice.

The greater fungal burden was associated with loss of parenchyma and increased infiltration of p21 positive neutrophils in the kidneys of Hamp<sup>-/-</sup> mice, whereas the bone marrow neutrophil output in these mice had decreased.

**Conclusions:** Our data identify systemic iron overload as a susceptibility factor to *C. albicans* induced kidney failure. Hepcidin deficiency-induced kidney iron burden was associated transformation of yeast into hyphae, suggesting increased virulence. Increased p21 expression in neutrophils suggests impaired NETosis and may possibly explain increased fungal burden. Our data highlight importance of host iron metabolism in susceptibility to disseminating candidiasis.

## TH-PO136

### Autotomy of Primary Cilia in Ischemia-Reperfusion Injury: An Electron Microscopic Study

Kyu Youn Ahn,<sup>1</sup> Kwon Moo Park,<sup>2</sup> Ki-Hwan Han,<sup>3</sup> <sup>1</sup>Chonnam National University, Gwangju, Jeollanam-do, Republic of Korea; <sup>2</sup>Kyungpook National University, Daegu, Republic of Korea; <sup>3</sup>Ewha Womans University, Seoul, Republic of Korea.

**Background:** Primary cilia are present in renal tubular cells and can change in length under certain conditions. Acute renal ischemia-reperfusion injury (I/R injury) can shorten primary cilia. It has been proposed that cilia may be rapidly fragmented and excreted into the urine. The purpose of this study was to examine the process of cilia fragmentation under high-resolution microscopy.

**Methods:** Sprague-Dawley rats were subjected to 30 minutes of ischemia by clamping bilateral renal pedicles and 6 hours of reperfusion. Kidney tissues and urine samples were processed for light and electron microscopy. Acetylated  $\alpha$ -tubulin antibodies were used to label the primary cilia, and specific marker proteins were used to differentiate the tubule segments.

**Results:** I/R injury resulted in cell damage mainly in the proximal tubule and collecting duct cells of the outer medulla, and significantly reduced the length of the primary cilia. In the proximal tubule, ciliary labeling was often located within the lumen. Some cilia remained on the surface of detached aquaporin 1-positive cells, while others were disconnected from the tubular cells. On the other hand, in the collecting duct, most of the cilia detected in the lumen were independently labeled regardless of the detached cells. Field emission scanning electron microscope (FE-SEM) revealed that the cilia fragmentation was related to the 'bulging', in which a portion of the cilia sprouts. The bulging of the cilia was not limited to the tip end and appeared as a single or multiple. Most of the sprouting parts were spherical or oval, and the size varied from about 90 to 280 nm.

**Conclusions:** These results demonstrate that the cilia fragments induced by I/R injury can originate from several different tubules. The autotomy of primary cilia may be specifically related to partial sprouting and regulated by dynamic physiological processes. This work was supported by funds from the National Research Foundation of Korea (NRF-2017R1D1A1B03030573 & 2020R1A2C1100184).

## TH-PO137

### A Rare Case of PR3-ANCA Vasculitis in the Setting of Mycobacterium Avium Complex (MAC) Infection

Gurpreet Kaur, Manasi Bapat. Alameda Health System, Oakland, CA.

**Introduction:** Anti-neutrophilic cytoplasmic antibody (ANCA) associated vasculitis is the most common systemic small vessel vasculitis to occur in adults. While the etiology is not always known, a variety of possible associations between infection and vasculitis have been reported. We present a case of PR3-ANCA vasculitis in the setting of Mycobacterium Avium Complex (MAC) infection.

**Case Description:** A 66-year-old man with history of Parkinson's disease and well controlled childhood asthma was admitted to the intensive care unit with acute dyspnea, fever and cough and was found to have ground-glass opacities throughout the right lung on CT chest. Given pulmonary infiltrates and history of sinusitis, ANCA titers were sent. Titers showed elevated c-ANCA titers 1:640 (normal <1:20). Proteinase 3 Ab > 100U/ml (normal 0 to 3.5 U/ml) and negative Myeloperoxidase. During hospitalization, he developed an AKI with creatinine increasing from 0.95 to 1.45 mg/dL (normal 0.50-1.30mg/dL) and microscopic hematuria. Kidney biopsy showed pauci-immune crescentic glomerulonephritis. Given kidney biopsy findings in the setting of elevated c-ANCA, the diagnosis of granulomatosis with polyangiitis (GPA) was made. Patient was started on induction therapy with Rituximab and high-dose steroids. Cultures obtained from bronchoscopy later returned positive for Mycobacterium Avium Complex (MAC). Given that the patient's respiratory symptoms had completely resolved, antimicrobial therapy for MAC was not initiated and patient was subsequently initiated on Rituximab based maintenance therapy for ANCA vasculitis. Patient achieved remission of hematuria as well as improvement in lung radiological findings with normalization of ANCA titers.

**Discussion:** Pulmonary infection may trigger vasculitis through induction on ANCA antigen expression on the surface of neutrophils. ANCA associated vasculitis (AAV) secondary to MAC is very rare and only a few cases have been reported so far. Kidney involvement in AAV is typically with rapidly progressive glomerulonephritis (RPGN) however our patient only had transiently elevated creatinine with hematuria without RPGN. Our case highlights the importance of considering AAV and testing for ANCA in a patient with hematuria and pulmonary symptoms even in the absence of characteristic RPGN.

### Ultrasound Reduces Kidney Injury via a Postsynaptic P2X4-Dependent Mechanism in Sepsis-Associated AKI

Shuqiu Zheng, Junlan Yao, William Nash, Nabin Poudel, Eibhlin S. Goggins, Shuheh Kuwabara, Mark D. Okusa. University of Virginia, Charlottesville, VA.

**Background:** Purinergic X receptor (P2X) receptor subunits are present both in pre- and postsynaptic sites (Gordon, G.R.J et al. 2015). P2X4, one of the most sensitive purinergic ATP receptors, has been reported to exacerbate ischemic acute kidney injury (S.J. Han et al. 2020). We previously showed that pulsed ultrasound (pUS) reduced inflammation and acute kidney injury. However, the exact mechanism has not yet been well defined. Here, we utilized a mouse model of sepsis-associated acute kidney injury (SA-AKI) by injecting lipopolysaccharide (LPS) to investigate the effects of pUS on the expression and trafficking of P2X4 receptor during pathogenesis of SA-AKI.

**Methods:** C57/BL/6 mice received pUS 24 hours before LPS (5 mg/kg, ip) treatment. The parameters of pUS therapy followed the protocol previously published by us (PMID: 23907510). The expression of P2X4 was measured by immunofluorescence and RT-PCR respectively. ATP levels in the mouse kidney were determined by CellTiter-Glo Luminescent Cell Viability Assay Kit (G7571, Promega, Madison, WI), and the luminescence signal was normalized to the protein concentration of the homogenate. The measured luminescence signal is proportional to the amount of ATP.

**Results:** In vehicle treated animals, co-labeling with P2X4 and postsynaptic density 95 protein (PSD-95) showed that P2X4 is located mainly in lysosomes and partially colocalized with PSD-95. However, LPS induced injury upregulated P2X4 expression and translocated to the brush border and plasma membrane of proximal tubules, and whereas those issues were decreased in mice pretreated with pUS. In addition, the temporal changes observed with P2X4 mRNA overexpression correlated with a higher ATP release, pUS attenuated the release of ATP and the overexpression of P2X4 mRNA.

**Conclusions:** Our data suggest that LPS heightened brush border and membrane expression of P2X4 is temporally related to the release of ATP. ATP ligation of P2X4 in proximal tubules may lead to calcium influx and cell death. We believe that the protective mechanism of pUS in response to LPS appears to be associated with attenuated P2X4 receptor expression and signaling in proximal tubules.

## TH-PO139

### Kynu Mediated Sex Dimorphism of AKI Through an NAD<sup>+</sup> Dependent Manner

Weiyan Gong, Chuanming Hao. Fudan University, Shanghai, China.

**Background:** AKI is a disorder that is associated with high mortality and a high risk for development of CKD. It is well documented that female gender is associated with enhanced tolerance to kidney injury, the underlying mechanism is incompletely understood. Mounting evidence suggests that NAD<sup>+</sup> levels are associated with kidney tolerance to injury. The present study examined NAD<sup>+</sup> synthetic pathways and their association with gender related susceptibility to AKI.

**Methods:** IRI induced AKI was performed at 8-week-old C57BL/6J mice, bilateral renal pedicles were clamped for 22min(26min for 12-week-old female KYN<sup>U-/-</sup> and wt mice). The animals were euthanized 48 hours later. Prepubertal female/male mice were ovariectomized or castrated respectively, and euthanized after 5 weeks. The enzymes expression was examined using Immunoblot, qPCR. The metabolites of NAD<sup>+</sup> de novo pathway were examined using HPLC.

**Results:** Following IRI, male mice exhibited severe renal injury compared to female mice, manifested as higher BUN and Scr levels. Further investigation revealed that male kidney express lower levels of kynureninase (KYN<sup>U</sup>), one of the enzymes of the NAD<sup>+</sup> de novo pathway, at adult age and prepubertal castration significantly increase renal Kynu expression but not ovariectomy, demonstrating that the expression of KYN<sup>U</sup> is regulated by testosterone but not estrogen. We next measured the metabolites concentration in kidney and urine. Result showed no difference in the metabolite under physiological condition, however, with the insult of IRI, we observed elevated levels of intermediate metabolites and NAD<sup>+</sup> in female kidney compare to male, suggesting the NAD<sup>+</sup> de novo pathway was more activated in the female kidney, which may contribute to the NAD<sup>+</sup> synthesis and improve AKI. Thus, we generated KYN<sup>U</sup> knockout mice and found that genetic ablation of KYN<sup>U</sup> significantly decreased urinary and kidney metabolites and inhibited the NAD<sup>+</sup> de novo synthetic pathway, accompanied by sharpening kidney damage compared to wt mice following IRI, while supplementation with nicotinamide mononucleotide (NMN), an NAD<sup>+</sup> precursor, restored NAD<sup>+</sup> levels and significantly alleviated kidney injury in KYN<sup>U-/-</sup> mice.

**Conclusions:** We propose a KYN<sup>U</sup>-dependent mechanism, which contributes to the relative renoprotection of female after IRI by regulating NAD<sup>+</sup> levels. NAD<sup>+</sup> de novo pathway may be a potential target for IRI-AKI treatment.

## TH-PO140

## Lineage Tracing and Single Cell Multiomics Reveal Long-Term Effects of Adaptive and Maladaptive Repair After AKI

Louisa M. Gerhardt,<sup>1</sup> Kari A. Koppitch, Sam Cho, Andrew P. McMahon. McMahon Lab, USC Stem Cell Keck School of Medicine of the University of Southern California, Los Angeles, CA.

**Background:** Acute kidney injury (AKI) triggers a proliferative response as part of the intrinsic repair program that can result in adaptive or maladaptive repair of proximal tubule cells (PTCs). Maladaptive PTCs contribute to disease progression from AKI to chronic kidney disease (CKD), but the cellular and molecular understanding underlying the adaptive and maladaptive repair trajectories is limited.

**Methods:** We used genetic fate-mapping to label and trace proliferating (*Ki67*<sup>+</sup>) cells after ischemia-reperfusion injury. Combined snRNA- and ATAC-seq of lineage-traced cells isolated by FACS at 4 weeks and 6 months after AKI and controls was performed to generate a final dataset of 83,315 high-quality nuclei (after quality control and doublet removal). Published snRNA-seq data was used to assess transcriptomic changes early after AKI.

**Results:** Labeling *Ki67*<sup>+</sup> cells early after AKI revealed a broad proliferative response in kidney epithelial and non-epithelial cells, which was preceded by cell type-specific and global gene expression changes, such as downregulation of genes involved in transmembrane transport processes and upregulation of immediate early response genes. A heterogeneous population of maladaptive PTCs derived from all proximal tubule segments persisted until 6 months after AKI, although decreasing in abundance in time post AKI. Combined profiling of gene expression and chromatin accessibility in the same cell showed a specific activation of the transcription factors Rbpj, Klf6, Runx1 and Creb5 as well as of members of the NF- $\kappa$ B and the AP-1 family in maladaptive PTCs, accompanied by corresponding changes in target gene expression. Regulatory factors of adaptively repaired PTCs, such as Maf and Hnf4a, were downregulated in maladaptive PTCs. Comparison of adaptively repaired PTCs with control PTCs suggested long-term effects of AKI on the transcriptional state of PTCs, including reduced expression of genes encoding critical transmembrane transport proteins.

**Conclusions:** This study provides the first combined snRNA- and snATAC-seq atlas of healthy and injured kidney tissue, defines the regulatory landscape of PTCs after adaptive and maladaptive repair and reveals long-term effects of AKI on PTCs even following adaptive repair.

## TH-PO141

## Tubular Cell Polyploidization Leads to a Senescent Profibrotic Phenotype and Is a Trigger of CKD

Elena Lazzeri,<sup>1</sup> Letizia De Chiara,<sup>1</sup> Paola Romagnani,<sup>1,2</sup> <sup>1</sup>Università degli Studi di Firenze, Firenze, Italy; <sup>2</sup>Meyer Children's University Hospital, Florence, Italy.

**Background:** The occurrence of polyploidization in tubular epithelial cells (TC) is a process that increases the DNA content in TC in response to acute kidney injury (AKI). Evolutionary, polyploidy appears to be developed to tolerate conditions of high metabolic demand, sustaining a temporary functional recovery that is not accompanied by structural recovery leading over time to tissue fibrosis. The association of tissue polyploidization, senescence, and fibrosis has been demonstrated in other organs but in the kidney is currently unknown. In this study, we aimed to 1) characterize TC undergoing polyploidy, 2) investigate whether post-AKI fibrosis and senescence could be a consequence of TC polyploidization and 3) whether the latter is a driver of chronic kidney disease (CKD) development.

**Methods:** We performed single cell RNA-sequencing (scRNA-seq) on mouse kidneys after unilateral ischemia reperfusion injury to identify polyploid TC signature. In addition, we employed a conditional transgenic mouse model of increased polyploidization (Pax8/SAV1ko mice) and a treatment with senolytics was used followed by FACS and confocal microscopy analysis.

**Results:** scRNA-seq analysis revealed clusters of proximal TC enriched in genes associated with endoreplication-mediated polyploidy. A trajectory analysis suggested that TC polyploidization started with increased ribosome biogenesis, followed by YAP1 activation and culminated with a pro-fibrotic and senescent signature, suggesting polyploid TC may acquire a senescent phenotype. Indeed, polyploid TC progressively accumulate in the kidney as the mice aged and correlated with GFR decline and senescence. Importantly, sustained TC polyploidization in Pax8/SAV1ko mice was accompanied by increased senescence, fibrosis and a progressive kidney function decline, i.e. CKD. Isolation of polyploid TC proved that they actively transcribe and secrete pro-fibrotic and senescent factors. However, senolytic treatment demonstrated that removal of senescent polyploid TC in Pax8/SAV1ko mice was sufficient to halt CKD progression.

**Conclusions:** We have shown that: 1) polyploid TC exhibits a pro-fibrotic and senescent signature; 2) TC polyploidization leads to senescence, fibrosis and progression of CKD; 3) senolytics can block further ongoing polyploidization of TC, abolishing their senescent profibrotic phenotype and preventing CKD.

## TH-PO142

## Chronotherapy With Cinacalcet Has a Striking Effect on Inhibition of Parathyroid Gland Proliferation in Rats With Secondary Hyperparathyroidism

Søren Egstrand,<sup>1,2</sup> Maria L. Mace,<sup>2</sup> Marya Morevati,<sup>2</sup> Klaus Olgaard,<sup>2</sup> Ewa Lewin.<sup>1,2</sup> <sup>1</sup>Dept. of Nephrology, Herlev Hospital, Copenhagen, Denmark; <sup>2</sup>Dept. of Nephrology, Rigshospitalet, Copenhagen, Denmark.

**Background:** Secondary hyperparathyroidism (sHPT) is associated with parathyroid hyperplasia, bone and vascular disease. Cinacalcet is a modulator of the calcium-sensing receptor used to treat sHPT. Aim was to examine whether taking the circadian rhythm into account might improve treatment response.

**Methods:** CKD was induced by 5/6-nephrectomy in 40 rats. After 4 weeks, 20 CKD rats had Cinacalcet 2.5mg/d by oral gavage either morning (early inactive phase: *Cina1*, N=10) or evening (early active phase: *Cina2*, N=10). After 3 weeks, parathyroid glands, aorta and femur were harvested from Cinacalcet treated rats either morning or evening, 24 h since treatment, and compared to untreated CKD rats (*PNX1* and *PNX2*) and healthy rats. Parathyroid proliferation was assessed by Ki-67 immunostaining, aortic calcium content by the o-cresolphthalein method and bone by  $\mu$ CT.

**Results:** Ki-67 index was significantly decreased in *Cina1* ( $0.92 \pm 0.14\%$ ) compared to *Cina2* ( $2.46 \pm 0.37\%$ ,  $p=0.006$ ) and to the two untreated CKD groups ( $3.45 \pm 0.47\%$  and  $4.14 \pm 0.47\%$ ,  $p=0.0002$  and  $p=0.0001$ ). In healthy control groups:  $1.53 \pm 0.17\%$  and  $1.45 \pm 0.19\%$  (Fig.1). Plasma PTH was decreased by 55% in *Cina1* compared to *PNX1* ( $2279 \pm 447$  pg/ml vs  $5076 \pm 1740$  pg/ml) and by 29% in *Cina2* compared to *PNX2* ( $2667 \pm 594$  pg/ml vs  $3756 \pm 911$  pg/ml). Aortic calcium content and bone porosity were similarly increased in all CKD groups.

**Conclusions:** Administration of Cinacalcet early in the inactive period markedly decreased the proliferation of the parathyroid glands in sHPT compared to dosing early in the active period indicating an advantage of chronotherapy in a translational model of sHPT.

## TH-PO143

## Effect of Evocalcet on Parathyroid Calcium-Sensing Receptor and Vitamin D Receptor Expressions in Uremic Rats

Tomohiro Saito,<sup>1</sup> Masahide Mizobuchi,<sup>1</sup> Mariko Sakai,<sup>2</sup> Takehisa Kawata,<sup>2</sup> Tetsuya Kitayama,<sup>2</sup> Tadashi Kato,<sup>1</sup> Taihei Suzuki,<sup>1</sup> Hiroaki Ogata,<sup>3</sup> Fumihiko Koiwa,<sup>4</sup> Hirokazu Honda.<sup>1</sup> <sup>1</sup>Showa Daigaku, Shinagawa-ku, Japan; <sup>2</sup>Kyowa Kirin Kabushiki Kaisha, Chiyoda-ku, Japan; <sup>3</sup>Showa Daigaku Yokohama-shi Hokubu Byoin, Yokohama, Japan; <sup>4</sup>Showa Daigaku Fujigaoka Byoin, Yokohama, Japan.

**Background:** Little is known about the effect of recently developed calcimimetics evocalcet on the parathyroid calcium-sensing receptor (CaSR) and vitamin D receptor (VDR) expressions.

**Methods:** We examined the effect of evocalcet and cinacalcet on the CaSR and VDR expressions in 5/6 nephrectomized Sprague-Dawley rats fed a high-phosphate diet for 4 weeks to develop secondary hyperparathyroidism. These rats were divided into groups: baseline control (Nx4W), treated with vehicle (V), evocalcet (E), or cinacalcet (C). After 2 weeks of treatment, blood chemistries and parathyroid tissues were analyzed. CaSR and VDR expression were determined by immunohistochemistry. Normal rats were used as normal control (NC).

**Results:** The degree of kidney injury and hyperphosphatemia was similar in the uremic groups (Nx4W, V, E, and C). Serum iPTH levels were significantly higher in Nx4W (2424 pg/ml,  $p<0.01$ ) and V (2098 pg/ml,  $p<0.01$ ) than in NC (103 pg/ml). This increase was significantly suppressed in E (29 pg/ml,  $p<0.01$ ) and C (395 pg/ml,  $p<0.01$ ) compared with V. Serum calcium levels were significantly and equally lower in E (4.7mg/dl,  $p<0.01$ ) and C (5.7 mg/dl,  $p<0.01$ ) than in V (8.1 mg/dl). CaSR expression was significantly decreased in Nx4W (16.9 %,  $p<0.01$ ) and V (16.5 %,  $p<0.01$ ) compared with NC (45.0 %). The decreased expression was significantly and equally up-regulated in E (46.0 %,  $p<0.01$ ) and C (40.7 %,  $p<0.01$ ). A similar trend was observed in VDR expression (62.6% in NC, 16.2 % in Nx4W, 20.2 % in V, 62.2 % in E, and 83.6 % in C).

**Conclusions:** These results indicate that evocalcet can up-regulate the decreased parathyroid CaSR and VDR expressions in uremic rats, which could contribute to its suppressive effect on PTH.

### Antibody Production Requires Neither Vitamin D nor the Vitamin D Receptor

Lori A. Plum, William J. Blaser, Hector F. Deluca. *University of Wisconsin System, Madison, WI.*

**Background:** The idea that vitamin D plays a significant role in immunity, especially in fighting infectious disease, has been proposed repeatedly for many years. Because antibody production is of central importance to an organism's defense against infection, studies were conducted to determine if vitamin D functions in this area of immunity.

**Methods:** Two animal models were utilized: mice depleted of vitamin D and mice devoid of the vitamin D receptor. Vitamin D-deficient mice were generated from parents fed D-deficient diets and housed in rooms with UV-blocked light bulbs. The mice deficient in vitamin D were either given a low (0.235%) or high (0.87%) calcium diet lacking vitamin D. A third group of D-deficient mice was given diet containing vitamin D prior to the antigen challenge. All D-deficient mice were compared to mice that were never depleted of vitamin D. Male VDR knockout mice and wild-type littermates were generated in our vivarium from breeder stock obtained from JAX labs (Stock No. 006133). They were fed either a low (0.235%) or high (0.87%) calcium diet. All mice were challenged with the very antigenic protein, Keyhole Limpet Hemocyanin (KLH). Blood was collected at multiple time points after the KLH was injected intraperitoneally. A booster injection of KLH was administered 30-37 days after the first one to assess the impact of low vitamin D or ablated receptor on the secondary response. The amount of various classes and subclasses of antibodies was assessed using enzyme-linked immunoassays. Statistical analyses were developed and performed under the guidance of the University of Wisconsin-Madison CALS Statistical Consulting Group.

**Results:** Only a few statistically significant differences across dietary groups or between genotypes during the primary or secondary responses were noted. However, none of the differences were present in both animal models; and in some cases, the differences were present in a dietary group that would dictate a change also be present in another group, but there wasn't. Neither the absence of vitamin D or the vitamin D receptor nor hypocalcemia significantly altered the amount of total IgG, IgG1, IG3, IgA, or IgM antibodies.

**Conclusions:** Neither vitamin D nor its receptor are required to successfully mount an antibody response.

**Funding:** Other U.S. Government Support

## TH-PO145

### CKD Alters Parathyroid Pin1 Phosphorylation and Hence PTH mRNA Binding Proteins Leading to Secondary Hyperparathyroidism

Alia Hassan, Morris Nechama, Justin Silver, Iddo Z. Ben-Dov, Tally Naveh-Many. *Hadassah University Medical Center, Jerusalem, Israel.*

**Background:** Secondary hyperparathyroidism (SHP) is a common complication of CKD that increases morbidity and mortality. In experimental models of CKD and SHP, the increased PTH gene expression is due to enhanced PTH mRNA stability, mediated by changes in PTH mRNA interaction with stabilizing AUF1 and destabilizing KSRP. The isomerase Pin1 leads to KSRP dephosphorylation, but in SHP, parathyroid Pin1 activity is decreased and hence phosphorylated KSRP fails to bind PTH mRNA resulting in high PTH mRNA stability and levels. Here we aim to identify the up- and down-stream mechanisms by which CKD stimulates the parathyroid in SHP.

**Methods:** CKD and SHP were induced in rats and mice by adenine-rich high phosphorus diets. Parathyroid organ cultures and transfected cells were incubated with Pin1 inhibitors for their effect on PTH expression. Mass-spectrometry was performed on both parathyroid and PTH mRNA pulled down proteins.

**Results:** We characterized, for the first time, the global changes in protein expression and phosphorylation induced by kidney failure in the minute rat parathyroid glands. CKD led to changes in rat parathyroid proteome and phosphoproteome profiles, including KSRP phosphorylation at Pin1 target sites. Furthermore, both acute and chronic kidney failure led to parathyroid-specific Pin1 Ser16 and Ser71 phosphorylation, which disrupts Pin1 activity. Pharmacologic Pin1 inhibition, that mimics the decreased Pin1 activity in SHP, increased PTH expression ex-vivo in parathyroid glands in culture and in transfected cells, through the PTH mRNA protein-interacting element and KSRP phosphorylation. We also characterized the effect of Pin1 inhibition on global PTH mRNA interacting proteins.

**Conclusions:** Kidney failure leads to loss of parathyroid Pin1 activity by inducing Pin1 phosphorylation. This predisposes parathyroids to increase PTH production through impaired PTH mRNA decay that is dependent on KSRP phosphorylation at Pin1-target motifs. Pin1 and KSRP phosphorylation and the Pin1-KSRP-PTH mRNA axis thus drive SHP.

## TH-PO146

### The Effect of Carnitine Supplementation in a Rat Model of CKD-MBD

Keith G. Avin,<sup>1,2</sup> Ashley D. Troutman,<sup>1</sup> Neal X. Chen,<sup>2</sup> Shruthi Srinivasan,<sup>2</sup> Kalisha O'Neill,<sup>2</sup> Annabel Biruete,<sup>1,2</sup> Sharon M. Moe.<sup>2</sup> *<sup>1</sup>Indiana University–Purdue University Indianapolis, Indianapolis, IN; <sup>2</sup>Indiana University School of Medicine, Indianapolis, IN.*

**Background:** Carnitine affects the musculoskeletal system by shuttling fatty acids into the mitochondria for  $\beta$ -oxidation and adenosine triphosphate production. Lower carnitine levels are seen with primary and secondary CKD carnitine deficiency and are associated with impaired musculoskeletal health. We sought to determine if carnitine treatment can benefit CKD-MBD outcomes in CKD.

**Methods:** We used a slowly, progressive, naturally occurring, CKD rat model (Cy/+ rat) in these groups (n=12/gr): 1) normal littermates (NL), 2) CKD rats, 3) CKD + carnitine (250mg/kg, I.P. daily). Carnitine treatments began at 22 weeks and continued through 32 weeks of age (i.e., mild to severe CKD, respectively). At 32 weeks, the animals were terminated followed by tissue and blood collection. Data analysis included one-way ANOVA with Tukey's test.

**Results:** CKD rats had lower carnitine plasma levels compared to NL ( $p<0.05$ ). Carnitine-treated CKD rats had higher plasma carnitine levels when compared to CKD alone ( $56\pm25$  mM vs.  $20\pm3.5$  mM;  $p<0.0001$ ). Compared to NL, CKD increased blood urea nitrogen, serum creatinine, phosphorous, parathyroid hormone, intact FGF23, c-terminal FGF23 and vascular calcification (all comparisons  $p<0.04$ ). CKD bone volume and tibial number were lower, while tibial spacing was higher compared to NL (all comparisons  $p<0.04$ ). 10 weeks of carnitine treatment increased plasma levels of creatinine, phosphorus, PTH, intact FGF23 and c-terminal FGF23 in CKD rats (all comparisons  $p<0.04$ ). Carnitine treatment had no effect on vascular calcification, but increased cortical porosity in carnitine-treated CKD rats compared to CKD alone ( $p<0.04$ ).

**Conclusions:** Carnitine supplementation did not alter vascular calcification but negatively impacted bone-related outcomes and worsened biochemistries of CKD-MBD. The change in porosity is likely due to the increase in PTH that occurred in the CKD + carnitine animals. In summary, carnitine treatment for 10 weeks that achieved supraphysiologic levels had adverse effects on CKD-MBD, despite dosing that was tested at earlier time point in CKD, and was modest compared to other studies. Whether lower doses or shorter treatment has different effect is unknown. However, this study raises caution about the wide use of supplements containing carnitine by individuals with CKD.

**Funding:** NIDDK Support

## TH-PO147

### mTOR Activity Is Essential for Intact Parathyroid Gland Structure

Nareman Khalaily, Alia Hassan, Justin Silver, Morris Nechama, Oded Volovelsky, Tally Naveh-Many. *Hadassah University Medical Center, Jerusalem, Israel.*

**Background:** mTOR signaling links nutritional status and cell metabolism and is negatively regulated by tuberous sclerosis complex 1 (TSC1). mTOR is a significant regulator of parathyroid cell proliferation in CKD-induced secondary hyperparathyroidism (SHP). CKD leads to parathyroid mTOR pathway activation and the mTOR inhibitor rapamycin decreases parathyroid cell proliferation in vivo and in organ cultures. We now show that in addition to its roles in SHP-induced parathyroid cell proliferation, the mTOR pathway is central to maintaining intact parathyroid glands in mice with normal renal function.

**Methods:** We generated by cre-lox recombination mice with parathyroid-specific mTOR deletion or mTOR activation by TSC1 knockout (KO), combined with red fluorescent protein expression, to monitor the parathyroid glands and allow fluorescent guided microdissection. CKD was induced by an adenine high phosphorus diet. Serum PTH, calcium, phosphate, and urea were measured at different time points after birth. Microdissected parathyroid sections were analyzed by immunofluorescent staining.

**Results:** Parathyroid-specific mTOR KO mice had smaller, punctuated parathyroid glands, from early after birth, with low to normal serum PTH levels. Surprisingly, dietary-induced CKD increased serum PTH to similar levels in both mTOR KO and control mice, despite much smaller still disrupted parathyroid glands in KO mice. In contrast, ablation of the negative mTOR regulator TSC1 led to ~10-fold larger parathyroid glands compared to control mice at 1 month of age. However, serum PTH levels were similar, suggesting that more cells are needed to produce normal serum PTH in TSC1 KO mice. From the age of 2 month, the TSC1 KO mice had ~4-fold higher serum PTH levels and only ~5-fold larger glands compared to controls. CKD similarly increased serum PTH levels in TSC1 KO and control mice, with a reduced fold increase in the KO mice. Immunofluorescent staining for PTH, CaSR, GCM2, phosphorylated ribosomal protein S6, and proliferation markers further supported the phenotype of the mTOR and TSC1 KO mice.

**Conclusions:** This is the first demonstration that mTOR is central to parathyroid gland morphology and maintaining intact glands in the adult.

## TH-PO148

**Fibroblast Growth Factor 23 Induces Endothelial Glycocalyx Collapse and Cortex Stiffening in Patients on Hemodialysis: A Major Role for the C-Terminal Fragment**

Josephine Koch,<sup>1</sup> Tamara Kunze,<sup>2</sup> Carl Vahldieck,<sup>2</sup> Benedikt Fels,<sup>2</sup> Wendy Dam,<sup>1</sup> Casper F. Franssen,<sup>1</sup> Jacob van den Born,<sup>1</sup> Kristina Kusche-Vihrog,<sup>2</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Universitat zu Lubeck, Lubeck, Germany.

**Background:** Cardiovascular disease and endothelial dysfunction (ED) are common in patients with chronic kidney disease (CKD). CKD patients have elevated plasma fibroblast growth factor 23 (FGF23) which associates with higher incidence of cardiovascular events. Hallmarks of ED are damage of the endothelial glycocalyx (eGC) and cortex stiffening. Here we evaluated whether FGF23 directly induces changes in eGC and underlying endothelial cortex.

**Methods:** Human umbilical vein endothelial cells were incubated with uremic sera from hemodialysis patients with low ( $\leq 2,000$  RU/mL; n=6) or high ( $\geq 30,000$  RU/mL; n=6) FGF23, and with recombinant intact FGF23 and c-terminal FGF23 (each 30 ng/mL). Height of the eGC and stiffness of the eGC and cortex were assessed by atomic force microscopy. eGC components and cortical F-actin were quantified by immunofluorescence stainings.

**Results:** Patient sera with high FGF23 reduced eGC height (-12%;  $P<0.0001$ ), increased eGC stiffness (+63%;  $P<0.0001$ ) and enhanced cortical stiffening (+16%;  $P<0.0001$ ) compared to patient sera containing low FGF23. Recombinant c-terminal FGF23 but not intact FGF23 induced similar effects compared to unstimulated controls (eGC height: -37%;  $P<0.0001$ ; eGC stiffness: +69%;  $P<0.0001$ ; cortical stiffness: +32%;  $P<0.0001$ ). Quantification of three eGC glyco-epitopes revealed no differences upon intact FGF23 or c-terminal FGF23 incubation. F-actin increased by 36% after c-terminal FGF23 stimulation ( $P<0.0001$ ), whereas intact FGF23 did not affect F-actin. Specificity was demonstrated by FGF23 blocking antibodies.

**Conclusions:** Our results indicate that c-terminal FGF23 and not intact FGF23 induces collapse of the eGC and stiffens the cortex. Our findings suggest c-terminal FGF23 having a pathophysiological role in the development of ED in hemodialysis patients.

## TH-PO149

**Differential Regulation of FGF23 Production and Cleavage by Iron and EPO in Anemic Mice**

Bridget Hunt-Tobey, Marta Martinez-Calle, Guillaume Courbon, Jadeah J. Spindler, John C. Von Drasek, Xueyan Wang, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Anemia affects over 2 billion people worldwide. In patients and animals, anemia leads to high circulating fibroblast growth factor (FGF)23 cleavage peptides due to simultaneous production and cleavage of intact (i)FGF23. Both iron deficiency and erythropoietin (EPO), which is secreted in response to anemia, independently increase FGF23 production and cleavage. However, their contribution to excess FGF23 in anemia is unknown.

**Methods:** To determine the contribution of iron deficiency and EPO to excess FGF23, we fed C57BL/6J mice from 3 to 6 weeks of age either control (Ctr), iron deficient (ID) or high iron (HI) diets to induce iron deficiency or iron overload anemia, respectively. In all mice, we measured hematological and iron metabolism parameters and circulating EPO and FGF23 levels.

**Results:** Both ID and HI mice developed anemia, as shown by similar and significant reductions of hemoglobin and red blood cell number. As a result, EPO levels increased in both ID and HI mice by 7 fold compared to Ctr mice. As expected, ID mice showed a reduction in iron, transferrin saturation (TSAT) and ferritin levels, as opposed to HI animals which showed higher iron, TSAT and ferritin compared to Ctr mice. As previously shown, ID triggered a 200% increase in total cFGF23 and a milder 20% increase in iFGF23 levels. In sharp contrast, anemic HI mice showed a 50% reduction in iFGF23 compared to Ctr mice, and only a 2 fold increase in total cFGF23 levels, suggesting that FGF23 cleavage increased despite normal FGF23 expression. In all mice, circulating total cFGF23 positively correlated with serum EPO levels. iFGF23 negatively correlated with serum iron, TSAT and ferritin only, but did not correlate with EPO levels.

**Conclusions:** In aggregate, these results suggest that iron deficiency, but not EPO, increases FGF23 production and that in anemia, elevated circulating EPO levels stimulate FGF23 cleavage independently of iron status.

**Funding:** NIDDK Support

## TH-PO150

**Endothelial Cell Dysfunction Promotes Phosphate-Induced Vascular Smooth Muscle Cell Calcification**

Wei Chen,<sup>1,2</sup> Dario F. Riascos-Bernal,<sup>1</sup> Shari J. Zaslowsky,<sup>1</sup> Michael J. Ross,<sup>1</sup> Wenzhu Mowrey,<sup>1</sup> Yabing Chen,<sup>3</sup> Nicholas Sibinga.<sup>1</sup> <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>2</sup>University of Rochester, Rochester, NY; <sup>3</sup>The University of Alabama at Birmingham Department of Pathology, Birmingham, AL.

**Background:** The study objective was to understand interactions between two major vascular cell types – endothelial cells (ECs) and vascular smooth muscle cells (SMCs) – in the pathogenesis of phosphate-induced vascular calcification. Since vascular calcification

greatly resembles bone formation, understanding cellular interactions that are unique to the vasculature may help identify therapies that inhibit vascular calcification without adversely impacting bone health. Here, we tested the hypothesis that high phosphate (P) promotes EC dysfunction, which in turn enhances calcification of SMCs in culture.

**Methods:** To model distinct aspects of complex *in vivo* environment, we established an *in vitro* insert co-culture system of primary human aortic ECs and SMCs. We compared calcification of SMCs co-cultured with and without ECs. Calcification of SMCs was induced by high P media (2 mM calcium, 3 mM P), assessed by Alizarin Red staining, and quantified by calcium content. EC proliferation and viability were measured using a resazurin assay.

**Results:** After 7 days of incubation, SMCs co-cultured with ECs in regular media (1.6 mM calcium, 0.5 mM P) had minimal calcification ( $10 \pm 8$   $\mu$ g calcium/mg protein). In contrast, SMCs co-cultured with ECs and high P media showed overt calcification. SMC calcium content was significantly greater when co-cultured with ECs ( $102 \pm 18$   $\mu$ g calcium/mg protein) than without ECs ( $59 \pm 17$   $\mu$ g calcium/mg protein,  $p=0.001$ ; Figure). Compared to regular media, high P decreased EC proliferation ( $p=0.01$ ), but did not change EC viability ( $p=0.56$ ), suggesting P-induced EC dysfunction.

**Conclusions:** Using a physiological model of co-cultured primary human cells, we found that high P induced EC dysfunction, which in turn worsened P-induced SMC calcification. These findings support the significance of cellular interactions in the pathogenesis of vascular calcification. Further studies are needed to elucidate the molecular mechanisms underlying these interactions.

**Funding:** NIDDK Support, Other NIH Support - NHLBI

Human aortic ECs (HAECs) enhanced P-induced calcification of human aortic SMCs (HASMCs) in a co-culture system.

## TH-PO151

**FGF23 Drives Transcriptional and Genomic Accessibility Reprogramming as Identified in the KL-KO Mouse at the Single Cell Level**

Emmanuel Solis, Rafiou Agoro, Sheng Liu, Jun Wan, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN.*

**Background:** The high affinity FGF23/Klotho(KL)/FGFR receptor complex is critical for controlling 1,25D and phosphate utilization. However, KL is expressed in multiple nephron cell types thus the full spectrum and mechanisms dictating the spatial modes of FGF23-mediated actions remain undefined.

**Methods:** 10X Multiome (single cell RNAseq (scRNAseq) and the Assay for Transposase-Accessible Chromatin (scATACseq)) was used to test KL-dependent FGF23 activity. Kidneys from male KL-KO and wild-type (WT) littermates underwent nuclei isolation/library preparation. Nephron segment-specific RNA expression and chromatin accessibility clustering analysis was performed and alterations of key signaling pathways tested using Ingenuity Pathway Analysis (IPA).

**Results:** High quality sequencing was obtained from libraries of ~10,000 cells, and integrative scRNAseq and scATACseq analysis identified 26 UMAP clusters distinctly comprised of epithelial, endothelial, and immune cells. With the deletion of KL, Cyp24a1 was reduced in proximal tubule (PT) cells, consistent with lack of FGF23 activity in this model, validating our approach. Using cluster enriched markers, the PT was sub-segmented into S1, S2, S3 cells. IPA analyses on these populations demonstrated that in the KL-null vitamin D receptor (VDR) and PTEN signaling were upregulated in PT S1-S3, whereas phagosome formation, involved in protein maturation was down-regulated. Further, with loss of FGF23-mediated activity, genes associated with VDR and PPAR signaling were upregulated in PT S1-S2. However, transcripts associated with xenobiotic metabolism were increased specifically in PT-S3, suggesting a novel role of FGF23 in this segment. Distal convoluted tubule and connecting tubule exhibited decreases in mRNAs controlling Autophagy and CLEAR pathways, but increased AMPK-mediated signaling. Finally, scATACseq revealed increased accessibility of both the VDR and Osteopontin (Spp1) genes in the PT-S1.

**Conclusions:** Our studies pinpoint transcriptional and genomic accessibility reprogramming for specific kidney cell types due to loss of KL-mediated FGF23 bioactivity and show that FGF23/KL interactions control nephron segment-unique and -general mechanisms that regulate mineral metabolism. Identification of these pathways is critical for isolating novel FGF23-related disease targets.

## TH-PO152

**Increased Cardiac Fibroblast Growth Factor 23 in Physiologic Hypertrophy Does Not Change Kidney Sodium Dependent Phosphate Transporter Expression**

Isaac D. Campos,<sup>1</sup> Beatrice Richter,<sup>2</sup> Kylie Heitman,<sup>2</sup> Christopher Yanucil,<sup>2</sup> Madison Thomas,<sup>2</sup> David G. Westbrook,<sup>2</sup> Christian Faul.<sup>2</sup> <sup>1</sup>The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; <sup>2</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone primarily produced by the bone that is elevated over the course of chronic kidney disease (CKD). In animal models of CKD, increased serum FGF23 levels cause *pathologic* cardiac hypertrophy via klotho-independent activation of FGF receptor 4 (FGFR4) and subsequent calcineurin/NFAT signaling in cardiomyocytes. Whether FGF23/FGFR4 also plays a role in *physiologic* cardiac hypertrophy, which is reversible and does not result in tissue damage, has previously been unknown. In mammals, physiologic cardiac hypertrophy is induced during pregnancy to ensure increased cardiac output. The same phenomenon is observed in intermediate feeding snakes, such as the Burmese python, where multiple organs, including the heart, undergo significant hypertrophic growth to meet the sudden increase in metabolic demands after feeding.

**Methods:** To investigate the role of FGFR4 signaling in physiologic cardiac hypertrophy we used virgin C57BL/6J wildtype and global FGFR4 knockout (KO) mice mated with male breeders. We investigate the effect of FGFR4 deletion on the process of adaptive cardiovascular hypertrophy at different time points during and after pregnancy. Virgin littermates served as controls. RTqPCR was used to measure gene expression.

**Results:** We found that mice in late pregnancy had significantly higher heart weight to tibia length ratios, regardless of the genotype. However, the area of individual cardiomyocytes was only significantly increased in wildtype mice. Serum FGF23 levels increased during pregnancy and quickly dropped after delivery and did not reduce kidney expression of NaPi 2a or 2c. We also treated neonatal rat ventricular myocytes (NRVMs) with serum from fasted and previously fed *P. bivittatus* in the absence and presence of an FGFR4-specific blocking antibody. We found that serum from snakes taken 12-hours and 3-days post-feeding significantly increased NRVM area, while serum from fasted snakes did not. This effect was abrogated in NRVM cultures co-treated with anti-FGFR4.

**Conclusions:** Our data suggests a significant role of FGFR4 in the induction of reversible physiologic cardiac hypertrophy in mice and snakes without the induced reduction of phosphate transporters in the kidney.

**Comparative Effectiveness of Alternative Treatment Approaches to Secondary Hyperparathyroidism (SHPT) in Patients on Maintenance Hemodialysis (HD)**

Alyssa C. Platt,<sup>1</sup> Jonathan A. Wilson,<sup>1</sup> Rasheeda K. Hall,<sup>1</sup> Patti Ephraim,<sup>5</sup> Sarah N. Morton,<sup>1</sup> Tariq Shafi,<sup>3</sup> Daniel E. Weiner,<sup>4</sup> L. Ebony Boulware,<sup>1</sup> Jane F. Pendergast,<sup>1</sup> Julia J. Scialla.<sup>2</sup> <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>University of Virginia, Charlottesville, VA; <sup>3</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>4</sup>Tufts Medical Center, Boston, MA; <sup>5</sup>Northwell Health, New Hyde Park, NY.

**Background:** Optimal approaches to treat SHPT in patients on HD are not established in randomized controlled trials (RCTs). Using observational data, we emulate RCTs of different parathyroid hormone (PTH) targets (Trial 1) and different primary agents (Trial 2) for treatment of HD-related SHPT.

**Methods:** Adults with kidney failure on HD at centers affiliated with a moderate-sized, not-for-profit, national dialysis provider were eligible for Trial 1 if they had new onset SHPT between 2009-2014. They were eligible for Trial 2 if they had SHPT and were using low to moderate dose vitamin D sterol, but were cinacalcet naïve. In both trials, patients had ≥180 days of Medicare primary payer before eligibility, and did not have contraindications to either arm or health status likely to limit follow-up. After eligibility, patients were observed for 30 days to define the treatment arm and then for 24 months for outcomes. In Trial 1, upward titration of either vitamin D sterols or cinacalcet in the 30 day period after new SHPT defined a proactive approach targeting lower PTH. Lack of upward titration defined a reactive approach. In Trial 2, the first upward titration defined a vitamin D-favoring (vitamin D first), cinacalcet-favoring (cinacalcet first), or undefined approach (no upward titration; excluded). The primary outcome was all-cause death; secondary outcomes include cardiovascular (CV) hospitalization or the composite of CV hospitalization or death.

**Results:** 1,152 patients were included in Trial 1 (635 proactive, 517 reactive). 3,001 patients were included in Trial 2 including multiple trials if eligible (6,268 vitamin D-favoring, 459 cinacalcet-favoring). The proactive approach associated with lower adjusted hazard of death (HR 0.71; 95% CI 0.52, 0.93), CV hospitalization (HR 0.78; 95% CI 0.63, 0.98), and their composite (HR 0.74; 95% CI 0.61, 0.89). Cinacalcet vs. vitamin D-favoring approach demonstrated modestly lower adjusted risk of death (HR 0.79; 95% CI 0.62, 0.99), but not CV hospitalization or the composite.

**Conclusions:** Proactive SHPT care is associated with better outcomes. A RCT of lower vs. higher PTH targets to prevent death and cardiovascular disease in patients with secondary hyperparathyroidism is justified.

**Funding:** NIDDK Support

## TH-PO154

**Rise in Serum Phosphate Levels Over the Past Decade Among US Hemodialysis Patients: Global Results From The DOPPS Practice Monitor**

Murilo H. Guedes,<sup>1</sup> Brian Bieber,<sup>2</sup> Almudena Vega,<sup>7</sup> Indranil Dasgupta,<sup>6</sup> John Hartman,<sup>8</sup> Kosaku Nitta,<sup>4</sup> Steven M. Brunelli,<sup>5</sup> Jochen G. Raimann,<sup>3</sup> Ronald L. Pisoni,<sup>2</sup> Bruce M. Robinson.<sup>2</sup> <sup>1</sup>Pontificia Universidade Catolica do Parana, Curitiba, Brazil; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>Renal Research Institute, New York, NY; <sup>4</sup>Tokyo Women's Medical University, Dept of Medicine, Tokyo, Japan; <sup>5</sup>Davita Clinical Research, Minneapolis, MN; <sup>6</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; <sup>7</sup>La Fundacion para la Investigacion Biomedica del Hospital Gregorio Maranon, Madrid, Spain; <sup>8</sup>Visonex, Green Bay, WI.

**Background:** KDIGO Guidelines (2009 and 2017) recommended lowering phosphate levels (PO) toward the normal range among dialysis patients. We describe trends over two decades in serum phosphate levels among in-center hemodialysis (ICHD) patients in the US, Japan, and 7 European countries

**Methods:** The Dialysis Outcomes and Practice Patterns Study (DOPPS) is prospective study of ICHD patients. A national sample is constructed in each country by stratified random sampling of dialysis centers, refreshed at 3-year intervals. This analysis includes annual mean serum phosphate levels from DOPPS 2-7 (2002-2021).

**Results:** In 2002, mean PO was 5.5 (Europe), 5.6 (Japan), and 5.7 (US) mg/dL. Levels declined in each region from 2002 to 2012 (-0.6 Europe, -0.4 Japan, -0.7 US). Since then, levels rose in US (to mean 5.6, 2021), were stable in Japan (5.3), and declined in Europe (4.8). In 2021, 52% (US), 27% (Europe), and 39% (Japan) had PO >5.5 mg/dL. In the US, overall phosphate binder PB use was stable (84-80% over 2015-2021), and PTH levels rose only modestly.

**Conclusions:** Among ICHD patients, phosphate trends over the past decade differ in the US (rising) than Japan (stable) and Europe (lower). The US trend contrasts with KDIGO recommendations and may reflect PB titration to higher targets along with more permissive dietary counseling. Hemodiafiltration use (none in US, common elsewhere) may also contribute. Optimal phosphate targets have yet to be ascertained by clinical trials, and effects on patient outcomes are uncertain.

**Funding:** Commercial Support - Global support for the ongoing DOPPS Programs is provided without restriction on publications by a variety of funders. For details see <https://www.dopps.org/AboutUs/Support.aspx>

**Figure.** Serum phosphate trends among ICHD patients, from 2002 to 2021.

[DOPPS phases 2-7 included facilities from the US, Japan, and 7 European countries (Belgium, France, Germany, Italy, Spain, Sweden, United Kingdom). The period covers 123,997 patient-months from the US, 23,789 from Japan and 34,208 from Europe.]

## TH-PO155

**Target Serum Phosphate and Calcium Levels in Patients With CKD Undergoing Hemodialysis Receiving Prescriptions for Phosphate Binders: A Post Hoc Analysis of the LANDMARK Study**

Kiryu Yoshida,<sup>1,2</sup> Takuya Mizukami,<sup>1</sup> Masafumi Fukagawa,<sup>3</sup> Tadao Akizawa,<sup>1</sup> Hokuto Morohoshi,<sup>1</sup> Takehiko Sambe,<sup>1</sup> Hiroaki Ogata,<sup>2</sup> Naoki Uchida.<sup>1</sup> <sup>1</sup>Showa Daigaku, Shinagawa, Japan; <sup>2</sup>Showa Daigaku Yokohama-shi Hokubu Byoin, Yokohama, Japan; <sup>3</sup>Tokai Daigaku, Isehara, Japan.

**Background:** In contemporary CKD-MBD management, there is a need to reexamine optimal target values for phosphate (P) and calcium (Ca) to reduce cardiovascular event risk in patients on hemodialysis.

**Methods:** We performed a post-hoc analysis of the LANDMARK study. The outcomes were defined as cardiovascular events and all-cause death. 2135 patients on hemodialysis at risk for vascular calcification were analyzed using the time-dependent Cox proportional hazards model.

**Results:** In stratified analysis, there was no difference in cardiovascular events between the lower half of the target range (3.5 - 4.8 mg/dL) and the higher half (4.8 - 6.0 mg/dL) for P (adjusted HR 1.18 (95% CI 0.86 - 1.63; p = 0.309)). For corrected Ca, the risk was higher in the higher half of the target range (9.2 - 10.0 mg/dL) than in the lower half (8.4 - 9.2 mg/dL) (adjusted HR 1.84 (95% CI 1.38 - 2.45; p < 0.001)). There was no difference in all-cause mortality between the lower half and the higher half of the target range for P or corrected Ca.

**Conclusions:** Stricter management of P alone was not associated with cardiovascular events in patients on hemodialysis. On the other hand, stricter management of Ca may reduce cardiovascular risk.

#### Results of Time-Dependent Cox Proportional Hazards Model

Outcome	Variables	Number of observation points	Hazard Ratio (95% Confidence Interval)	P-value
Cardiovascular events	Phosphate (mg/dL)			
	3.5 - 4.8	2920	1.00 (reference)	
	4.8 - 6.0	3716	1.18 (0.86 - 1.63)	0.309
	Corrected Calcium (mg/dL)

	8.4 - 9.2	4379	1.00 (reference)	
	9.2 - 10.0	3771	1.24 (0.94 - 1.63)	0.133

#### TH-PO156

#### Etelcalcetide Improves Cardiac Dysfunction in Mice on a High Phosphate Diet

Maren Leifheit-Nestler, Isabel Vogt, Andrea Grund, Beatrice Richter, Dieter Haffner. *Hannover Medical School, Hannover, Germany.*

**Background:** High phosphate levels stimulate the synthesis of the phosphaturic hormone parathyroid hormone (PTH) and fibroblast growth factor (FGF) 23 and are associated with increased cardiovascular morbidity and mortality. In the secondary analysis of the EVOLVE trial, cinacalcet significantly reduced levels of PTH and FGF23 in patients on hemodialysis, and the latter was associated with a lower rate of cardiovascular events and death. Intravenous administration of etelcalcetide reduced FGF23 and improved the progression of left ventricular (LV) hypertrophy in hemodialysis patients. In the present study, we examined the specific cardiac effects of etelcalcetide in mice on a high phosphate diet (HPD).

**Methods:** After four months on a 2% HPD, male C57BL/6N mice were additionally treated with 1 mg/kg body weight/day etelcalcetide (KP-2326) via osmotic minipumps for two more months and compared to mice receiving HPD with vehicle or a 0.8% normal phosphate diet (NPD). The heart function was examined by echocardiography and parameters of the mineral metabolism were determined.

**Results:** Compared to the NPD group, mice on HPD had significantly higher serum phosphate, FGF23 and PTH levels and increased phosphaturia, which was associated with progressive kidney injury. Mice on HPD show a dilated left ventricle with decreased anterior and posterior wall thickness and increased LV end-systolic and end-diastolic diameters and volumes. Ejection fraction and fractional shortening were reduced in mice on HPD, indicating impaired systolic function. Etelcalcetide reduced HPD-induced FGF23 and PTH levels by 80% and 75%, respectively, and resulted in a significant reduction in serum calcium levels, but had no effect on persistent hyperphosphatemia and phosphaturia. Etelcalcetide effectively ameliorated the HPD-induced LV dilatation and systolic dysfunction.

**Conclusions:** In mice, HPD leads to hyperphosphatemia and high plasma FGF23 and PTH concentrations with subsequent LV dilatation and systolic dysfunction. Administration of etelcalcetide effectively prevents the HPD-induced pathological cardiac phenotype despite the presence of hyperphosphatemia, which is at least partly due to the normalization of the high plasma FGF23 and PTH levels.

#### TH-PO157

#### ORCHESTRA Trial: Head-to-Head Comparison of Oral Calcimimetics Evocalcet and Cinacalcet in East Asian Hemodialysis Patients With Secondary Hyperparathyroidism

Xinling Liang,<sup>1</sup> Zhaohui Ni,<sup>2</sup> Chia-Chao Wu,<sup>3</sup> Kyubok Jin,<sup>4</sup> Yong-Lim Kim,<sup>5</sup> Kuo-Cheng Lu,<sup>6</sup> Tak Mao D. Chan,<sup>7</sup> Masafumi Fukagawa,<sup>8</sup> Jun Kinoshita,<sup>9</sup> Chisato Nagai,<sup>9</sup> Masahiro Kojima,<sup>9</sup> Xueqing Yu.<sup>1</sup> The Orchestra Study Group <sup>1</sup>Guangdong Provincial People's Hospital, Guangzhou, China; <sup>2</sup>Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; <sup>3</sup>Tri-Service General Hospital, Taipei, Taiwan; <sup>4</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>5</sup>Kyungpook National University Hospital, Daegu, Republic of Korea; <sup>6</sup>Taipei Tzu Chi Hospital, Taipei, Taiwan; <sup>7</sup>The University of Hong Kong, Hong Kong, Hong Kong; <sup>8</sup>Tokai University School of Medicine, Isehara, Japan; <sup>9</sup>Kyowa Kirin Co., Ltd., Chiyoda-ku, Japan.

**Background:** Cinacalcet is widely used to control secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients, but its upper gastrointestinal (GI) side effects may lead to lower adherence and thus suboptimal efficacy. Evocalcet (KHK7580) is a new oral calcimimetic which can suppress intact parathyroid hormone (iPTH) while inducing fewer upper GI side effects. To date, the experience with evocalcet is only limited to Japanese patients. To compare its efficacy and safety against cinacalcet in SHPT patients of other Asian ethnicities, we conducted a Phase 3 study in Mainland China, Taiwan, Hong Kong and South Korea. (NCT03822507)

**Methods:** In this multicenter, randomized and double-blind trial, HD patients with SHPT and iPTH level >300 pg/mL were randomized to receive evocalcet (n=203) or cinacalcet treatment (n=201) for 52 weeks, at daily dose range of 1-12 mg and 25-100 mg respectively. The primary endpoint was the mean % change in iPTH level from baseline in Week 50-52. Incidence of pre-specified GIAEs (abdominal discomfort, nausea, vomiting, abdominal distension, and decreased appetite) was also evaluated.

**Results:** Evocalcet showed non-inferiority to cinacalcet. The difference in mean % change in iPTH level from baseline in evocalcet (-34.7%) and cinacalcet (-30.2%) was -4.4% (95% CI [-13.1, 4.3]; non-inferiority margin, +15%). The difference in proportion of participants with ≥30% decrease in iPTH from baseline between evocalcet (67.3%) and cinacalcet (58.7%) was 8.6% (95% CI [-1.8, 19.1]). Effective iPTH reduction from baseline was also observed in subjects with high baseline iPTH of ≥1000 pg/mL (-46.1% in evocalcet, -37.1% in cinacalcet). Upper GIAEs occurred in 33.5% of patients receiving evocalcet, which is significantly lower than 50.5% for cinacalcet (p=0.001). Meanwhile, incidences of pre-defined Calcium decrease-related AEs were similar in two groups (61.6% in evocalcet, 61.0% in cinacalcet).

**Conclusions:** In East Asian HD patients with SHPT, the efficacy of evocalcet in reducing serum iPTH is non-inferior to cinacalcet, and evocalcet showed significantly reduced GI side effects compared with cinacalcet. Evocalcet therefore presents a preferable treatment alternative to cinacalcet for SHPT.

#### TH-PO158

#### Calcium Sensing Receptor and Klotho Expression of Advanced Dialysis-Dependent Hyperparathyroidism

Tetsuhiko Sato,<sup>1</sup> Yamato Kikkawa,<sup>2</sup> Manabu Okada,<sup>1</sup> Masafumi Fukagawa.<sup>3</sup> <sup>1</sup>JRC Aichi Medical Center, Nagoya Daini Hospital, Nagoya, Japan; <sup>2</sup>Tokyo University of Pharmacy and Life Sciences, Hachioji, Japan; <sup>3</sup>Tokai University, School of Medicine, Isehara, Japan.

**Background:** Advanced parathyroid hyperplasia is often caused by long-term dialysis-dependent chronic kidney disease, resulted in more aggressive pathological pattern called nodular formation. Each intra-parathyroid gland nodule is thought to have monoclonal proliferation. Calcimimetics are expected to upregulate calcium sensing receptor (CaSR) expression and inhibit PTH synthesis and secretion. However, our surgical center has experienced over 20 parathyroidectomies in each year, although second-generation calcimimetics (intravenous and/or oral) are voluntarily used to control systemic PTH levels. The question remains how enlarged parathyroid glands develop calcimimetics-resistant phenotype, and eventually need surgical resection during this recent calcimimetics-era.

**Methods:** We hypothesized that Klotho expression in each parathyroid nodule may play a key role of advanced hyperparathyroidism, conducted the study of immunofluorescence of CaSR and Klotho expression, and examined the relation of enlarged parathyroid gland weight with immunoreactivity of CaSR and Klotho. We utilized surgically resected enlarged parathyroid glands to perform immunohistochemistry using primary antibodies to CaSR and Klotho.

**Results:** Presurgical PTH levels and total glandular weight on surgery was 520+/-278 pg/mL and 2307+/-1140 mg, respectively (mean+/-SD). Interestingly, parathyroid gland, ranging from 100 to 1000 mg weight possessed heterogenous CaSR (3+ positive to negative) and Klotho expression pattern. Each intra-gland nodule had a wide spectrum of immunoreactivity of CaSR with relatively weaker Klotho expression. In contrast, enlarged single-nodular parathyroid gland, ranging 1000 mg or greater did not harbor remarkable CaSR and Klotho expression.

**Conclusions:** In conclusion, profound use of "second-generation" calcimimetics may enhance CaSR in earlier phase of hyperplastic parathyroid glands, followed by Klotho downregulation, suggesting that multiple nodules of parathyroid hyperplasia have diverse CaSR response to calcimimetics. Aggressively progressed parathyroid glands ended up with overwhelmingly marked downregulation of both CaSR and Klotho. CaSR and Klotho interaction may play a key role of advanced dialysis-dependent hyperparathyroidism.

#### TH-PO159

#### Development of a Yeast-Based Assay to Identify Inhibitors of PiT-1 Phosphate Transporter

Joseph M. Sweeney, Myles Akabas. *Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Advanced chronic kidney disease causes hyperphosphatemia, which may induce vascular calcification. Vascular calcification results from the extracellular precipitation of phosphate and calcium into the arterial walls. This process is actively driven by vascular smooth muscle cells and is dependent on PiT-1, a sodium-phosphate co-transporter. Vascular calcification may cause cardiovascular disease and increased mortality, yet no pharmaceuticals are available to directly attenuate vascular calcification. As PiT-1 plays a key role in the pathogenesis of vascular calcification, it is a promising drug target.

**Methods:** We obtained an *S. cerevisiae* yeast strain with one endogenous yeast phosphate transporter remaining. Using CRISPR/Cas9, we inserted the human PiT-1 gene into this yeast strain and knocked out the remaining endogenous phosphate transporter. The resulting yeast strain expressed PiT-1 as its sole phosphate transporter, confirmed with PCR and western blot. Since phosphate is vital for cellular functions, the proliferation rate of our strain is dependent upon PiT-1 phosphate transport activity. Yeast proliferation rates were measured using the Bioscreen C, which maintains yeast growth with continuous shaking, while periodically measuring turbidity at OD<sub>600</sub> over a period of days.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Results:** We determined the optimal media, pH, and sodium compositions for reproducible proliferation rates of our PiT-1 strain. We determined that media with 20 mM phosphate would provide the most sensitive threshold for identifying potential PiT-1 inhibitors. We identified several low-affinity PiT-1 inhibitors, including potassium sulfate ( $K_2SO_4$ ) and 2-(N-morpholino) ethane sulfonic acid (MES). The proliferation rate of our PiT-1 strain was more sensitive to increasing concentrations of these inhibitors compared to its parent strain.

**Conclusions:** We have developed an *S. cerevisiae* yeast strain expressing PiT-1 as its sole phosphate transporter. We have also determined proliferation conditions optimal for identifying inhibitors of PiT-1 phosphate transport. This method can be used to screen a small molecule library to identify more potent PiT-1 inhibitors. Our method may potentially be used to develop a high throughput screen for inhibitors of other phosphate transporters implicated in human pathophysiology.

**Funding:** Other NIH Support - MSTP Training grant, T32GM007288

## TH-PO160

### Efficacy and Safety of Tenapanor on Hyperphosphatemia in Japanese Hemodialysis Patients: Results of a Randomized Phase 3 Trial

Masafumi Fukagawa,<sup>1</sup> Kazuaki Ikejiri,<sup>2</sup> Jun Kinoshita,<sup>2</sup> Kaoru Nakanishi,<sup>2</sup> Tadao Akizawa,<sup>3</sup> <sup>1</sup>Tokai University School of Medicine, Isehara, Japan; <sup>2</sup>Kyowa Kirin Co., Ltd., Tokyo, Japan; <sup>3</sup>Showa University School of Medicine, Tokyo, Japan.

**Background:** Phosphate binders (PB) are commonly used for hyperphosphatemia in hemodialysis (HD) patients, although some patients do not have sufficient phosphorus control. Poor adherence to PB due to adverse events and heavy pill burden often plays significant roles in such patients. Tenapanor (TEN) is a novel potent treatment for hyperphosphatemia that reduces serum phosphorus (sP) level through selective inhibition of sodium/hydrogen exchanger 3 antiporter and the reduction in paracellular phosphorus absorption. The purpose of this trial was to confirm the efficacy and safety of TEN on hyperphosphatemia in Japanese HD patients.

**Methods:** This was a multicenter, randomized, double-blind, placebo-controlled, parallel-group, phase 3 trial in Japanese HD patients. The trial comprised three periods (screening, up to 3-week washout, 8-week treatment). Patients in screening were enrolled when the sP level at the first dialysis session of the week was 3.5–6.0 mg/dL (the target range by Japanese Society for Dialysis Therapy) and increased by  $\geq 1.0$  mg/dL to 6.1–9.9 mg/dL after washout of PB. Enrolled patients were randomized 1:1 to the placebo or TEN groups. TEN 5 mg was administered twice/day as the starting dose and titrated in a stepwise manner within the range of 5, 10, 20 and 30 mg twice/day based on the sP level. The primary endpoint was the mean change in sP level at week 8 from baseline.

**Results:** One-hundred and sixty-four subjects were enrolled (82 subjects per group). The week 8 sP (primary endpoint) decreased 1.89 mg/dL in the TEN group and increased 0.05 mg/dL in the placebo group (difference  $-1.95$  mg/dL [95%CI  $-2.37$  mg/dL,  $-1.53$  mg/dL],  $p < 0.0001$ ). In the TEN group, the percentage of subjects achieving the target sP (3.5–6.0 mg/dL) gradually increased to 69.2% as the mean dose of TEN was up-titrated to 18.1 mg at the end. In each group, the major adverse event was diarrhea (TEN group: 74.4%, placebo group: 19.5%). In most of the patients, diarrhea was mild in severity and only two subjects withdrew for diarrhea in the TEN group.

**Conclusions:** TEN significantly decreased sP compared with placebo and was well tolerated in Japanese HD patients. These results suggest that TEN can be a new option for the hyperphosphatemia treatment.

**Funding:** Commercial Support - Kyowa Kirin Co., Ltd.

## TH-PO161

### Efficacy and Safety of Tenapanor Added to Phosphate Binders for Hemodialysis Patients Who Have Poorly Controlled Hyperphosphatemia on Existing Phosphate Binders: Results of a Randomized Phase 3 Trial

Junichiro J. Kazama,<sup>1</sup> Miho Kusakabe,<sup>2</sup> Jun Kinoshita,<sup>2</sup> Kaoru Nakanishi,<sup>2</sup> Masafumi Fukagawa,<sup>3</sup> Tadao Akizawa,<sup>4</sup> <sup>1</sup>Fukushima Medical University, Fukushima, Japan; <sup>2</sup>Kyowa Kirin Co., Ltd., Tokyo, Japan; <sup>3</sup>Tokai University School of Medicine, Isehara, Japan; <sup>4</sup>Showa University School of Medicine, Tokyo, Japan.

**Background:** Despite the use of conventional phosphate binders (PB), phosphate management still remains a difficult issue among patients undergoing maintenance hemodialysis (HD) therapy. Tenapanor (TEN) selectively inhibits the intestinal sodium/hydrogen exchanger 3 and decreases paracellular phosphate absorption, which has a potential to improve phosphate management among those HD patients displaying hyperphosphatemia refractory to conventional PB. In this study, we evaluated the efficacy and safety of TEN added to PB for refractory hyperphosphatemia in Japanese HD patients.

**Methods:** This was a phase 3, randomized, multicenter, double-blind, placebo-controlled, parallel-group study. Patients whose serum phosphorus level was out of target range; 6.1–9.9 mg/dL on conventional PBs were eligible for this study. After a 2 weeks observation period, patients were randomized to TEN+PB or placebo + PB in 1:1 ratio. TEN was administered at initial dose of 5 mg twice a day and titrated within the range of 5, 10, 20, and 30 mg twice a day based on serum phosphorus levels, while the PB dosage was unchanged. The primary endpoint was the change in serum phosphorus level from baseline to week 8 after the start of TEN.

**Results:** One-hundred and sixty-nine subjects were randomized. The mean change in the serum phosphorus level from baseline to week 8 was  $-2.00$  mg/dL in the TEN group and  $-0.24$  mg/dL in the placebo group. The difference in the mean change

from baseline in serum phosphorus levels between the TEN and placebo groups was  $-1.76$  mg/dL (95%CI  $[-2.16, -1.37$  mg/dL],  $p < 0.0001$ ). The percentage achieving the target serum phosphorus level (3.5–6.0 mg/dL) after 8 weeks of treatment was 72.6% in the TEN group and 28.9% in the placebo group. Diarrhea was the most frequent adverse event (TEN=63.1%; placebo=14.1%), and all were of mild to moderate in severity.

**Conclusions:** TEN achieved a significant reduction in serum phosphorus levels compared with the placebo when added to PB therapy. This result suggests that TEN combined with PB could be a promising treatment option for hyperphosphatemia refractory to conventional PBs among HD patients.

### Reduction of Serum Phosphorus (sP) With Tenapanor (TEN) in Patients With CKD on Dialysis With Severe Hyperphosphatemia

Stuart M. Sprague,<sup>1</sup> Yang Yang,<sup>2</sup> David M. Spiegel,<sup>2</sup> David P. Rosenbaum.<sup>2</sup> <sup>1</sup>NorthShore University HealthSystem-University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>2</sup>Ardelyx, Inc., Waltham, MA.

**Background:** TEN is a first-in-class, investigational phosphate absorption inhibitor (PAI) that blocks paracellular phosphate absorption in the gastrointestinal tract by local inhibition of intestinal NHE3, providing a novel approach to managing hyperphosphatemia. TEN met the primary sP-lowering endpoint in 2 phase 3 monotherapy trials (BLOCK [NCT02675998], PHREEDOM [NCT03427125]) and was generally well tolerated. In patients with CKD, the risk of cardiovascular (CV) morbidity and mortality increases as sP levels increase. We evaluated the effect of TEN in patients with CKD on dialysis with severe hyperphosphatemia ( $\geq 7.5$  mg/dL) from BLOCK and PHREEDOM.

**Methods:** BLOCK had an 8-week open-label randomized treatment period (RTP; 3, 10, or 30 mg TEN twice a day [bid] dose titration), followed by a 4-week placebo-controlled randomized withdrawal period (RWP). PHREEDOM had a 26-week open-label RTP (30 mg TEN bid dose titration), followed by a placebo-controlled RWP of up to 12 weeks and a 14-week open-label safety extension. Both studies enrolled patients on maintenance dialysis with sP  $\geq 6.0$  and  $\leq 10.0$  mg/dL and an sP increase  $\geq 1.5$  mg/dL after phosphate binder washout. During the RTP of each study, we evaluated sP reduction (to last assessment during RTP) in patients with baseline sP  $\geq 7.5$  mg/dL.

**Results:** In BLOCK, 107/215 patients in the intent-to-treat (ITT) analysis set had a baseline sP  $\geq 7.5$  mg/dL across the 3 dose groups; these patients had a mean sP  $\pm$ SD reduction of  $1.78 \pm 1.73$  mg/dL from baseline to the end of the RTP, and the 37 patients from the 30 mg dose group had a  $1.91 \pm 1.83$  mg/dL sP reduction. In PHREEDOM, 204/407 patients in the ITT analysis sets had a baseline sP  $\geq 7.5$  mg/dL; these patients had a mean sP  $\pm$ SD reduction of  $1.94 \pm 1.86$  mg/dL. During the RTPs of both studies, the only adverse event reported in  $>10\%$  of patients with severe hyperphosphatemia in the safety analysis sets was diarrhea (BLOCK, 43.1%; PHREEDOM, 51.2%), which led to study drug discontinuation in 6.4% and 17.7%, respectively.

**Conclusions:** Tenapanor, a novel investigational PAI dosed as a single twice-daily tablet, provides a clinically meaningful sP reduction with an acceptable safety profile for patients with severe hyperphosphatemia on dialysis who are at high risk of CV morbidity and mortality.

## TH-PO163

### The Predictive Value of Early Response to Tenapanor for the Treatment of Hyperphosphatemia in Patients Receiving Maintenance Dialysis

Daniel E. Weiner,<sup>1</sup> David M. Spiegel,<sup>2</sup> Yang Yang,<sup>2</sup> David P. Rosenbaum.<sup>2</sup> <sup>1</sup>Tufts University School of Medicine, Boston, MA; <sup>2</sup>Ardelyx, Inc., Waltham, MA.

**Background:** Serum phosphorus (sP) control remains challenging for patients receiving maintenance dialysis. Despite adequate dialysis, dietary counseling, and use of phosphate binders, many patients fail to achieve and maintain target sP. Tenapanor is an investigational phosphate absorption inhibitor (PAI) dosed twice a day that blocks the paracellular absorption of dietary phosphate in the intestine. This post hoc analysis of the phase 3 PHREEDOM (NCT03427125) study evaluated whether an early sP reduction predicts continued sP control at week 12 and end of treatment.

**Methods:** In PHREEDOM, patients receiving maintenance dialysis with hyperphosphatemia were randomized 3:1 to tenapanor 30 mg twice a day or sevelamer. Early responders were defined as those with  $\geq 2$  of 3 sP measurements with a reduction of  $\geq 1.2$  mg/dL from baseline at weeks 1, 2, and 4. Early responders were assessed for continued response at week 12 (single measurement) and weeks 17, 22, and 26 defined as having sP  $\geq 1.2$  mg/dL lower than baseline at week 12 or  $\geq 1.2$  mg/dL lower than baseline for  $\geq 2$  of 3 sP measurements at weeks 17, 22, and 26 (end of treatment). Continued response rates were estimated using 2 approaches: Conservative – early responders who missed sP measurement at week 12 or missed  $\geq 2$  of 3 sP measurements at weeks 17, 22, and 26 were considered late non-responders; Observed Case – only the early responders who remained on treatment with sP measurement at week 12 or with  $\geq 2$  of 3 sP measurements at weeks 17, 22, and 26 were included in analysis.

**Results:** In PHREEDOM, 46.4% (189/407) of tenapanor-treated patients achieved an early response. The Table shows the proportion of early responders who remained responders at week 12 and end of treatment. Most early non-responders remained non-responders throughout the study.

**Conclusions:** Among patients receiving maintenance dialysis with an early response to tenapanor who remained on treatment,  $\approx 70\%$  maintained their response at week 12 and  $\approx 80\%$  continued to have a clinically meaningful therapeutic response at the end of treatment. This approach could help guide real-world clinical practice.

**Funding:** Commercial Support - Ardelyx, Inc.

Early Responders Who Achieved a Decrease in sP of ≥1.2 mg/dL at Week 12 and ≥2 of 3 Visits at the End of the 26-Week Treatment Period		
	Week 12	End of treatment
Conservative approach	57.1% (108/189)	58.2% (110/189)
Observed case approach	68.8% (108/157)	79.1% (110/139)

TH-PO164

Changes in Serum Phosphorus Among In-Center Hemodialysis (HD) Patients Initiating Sucroferric Oxyhydroxide (SO) as Part of Routine Care After Kidney Transplant Failure: A 6-Month Follow-Up Study  
Meijiao Zhou, Linda Ficociello, Claudy Mullon, Michael S. Anger. *Fresenius Medical Care, Waltham, MA.*

**Background:** Information on serum phosphorus (sP) management in patients who experience kidney transplant failure (KTF) and initiate dialysis is scarce. This retrospective database analysis aims to assess sP management with sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in post-KTF HD patients (pts) over a 6-month period.

**Methods:** Eligible pts were adult post-KTF HD pts from Fresenius Kidney Care first prescribed SO monotherapy during 5/2018- 12/2019 who had sP measured in the month before SO start (baseline; BL). Included in the analysis were pts who initiated SO within 12 months from start of post-KTF HD. Comparisons were made between BL and the monthly follow up (FU; M1 through M6). Monthly or quarterly means were calculated using mixed effects linear regression for PB pill burden and lab measurements. A subgroup analysis was performed in pts with post-KTF HD < 3 months.

**Results:** At BL, pts (n=100) had mean age of 49 years and were on HD for an average of 5 months post-KTF. No PB prescriptions were recorded for 35% overall and 30% for pts with HD <3 months post-transplant. For the overall pts prescribed PB, most were prescribed sevelamer (45%) or calcium acetate (31%). Among pts with HD <3 months post-KTF, fewer patients were on calcium acetate (15%) and more on ferric citrate (19%, compared to 8% overall). After switching to SO, % of pts with sP ≤ 5.5 mg/dL increased from 20% to 26%- 35% during SO FU, with fewer PB pills per day in all pts; the trends were similar in pts with post-KTF HD < 3 months (Table). Significant decreases of serum calcium (sCa) and iPTH were also observed.

**Conclusions:** During a 6-month follow-up, significant reductions in sP, PB pills/day, serum calcium and iPTH were observed after pts switched to sucroferric oxyhydroxide within 1 year of returning to HD after kidney transplant failure.

TH-PO165

Phosphate Removal During Conventional Hemodialysis Is Continuous and Depends on Pre-Dialysis Serum Levels and Bone Remodeling  
Carolina M. Lima, Patricia T. Goldenstein, Luciene dos Reis, Vanda Jorgetti, Rosilene M. Elias, Rosa M. Moyses. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

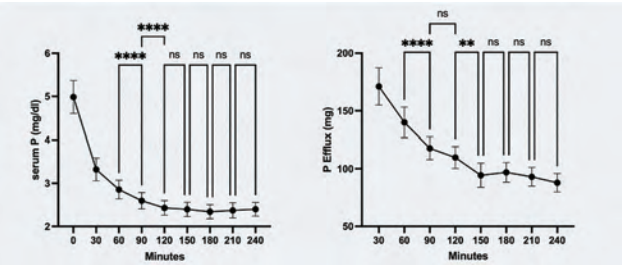

**Background:** Removal of phosphate (P) in conventional hemodialysis (HD) remains a cornerstone for CKD-MBD management. There is a disseminated belief that P removal after the first 90 minutes of HD is irrelevant. In addition, the main determinants of an intradialytic P balance are still a matter of debate.

**Methods:** We measured serum and dialysate P each 30 minduring a HDsession in 10 patients with severe hyperparathyroidism in 3 different periods: before parathyroidectomy (Pre-PTX), during hungry bone syndrome (HBS), and after stabilization of clinical status (Late-PTX). In each period, all patientswere dialyzed 3 times, using a d[Ca] of 1.25, 1.5 or 1.75 mmol/L.

**Results:** P removalwas higher in Pre-PTXthan in HBS and Late-PTX (1098± 313 vs. 744 ±195 and 842 ± 348 mg, respectively, p = 0.04), with no difference among d[Ca]. P removal correlated with pre-dialysis serum P (r = 0.421, p =0.0001) and ultrafiltrationvolume (UF; r=0.259, p =0.014). Percentual serum P reduction in 90 minutes was 52.0%. From this point forward there was no significant change during HD. P removal in 90 minutes was 45.9%. However, despite serum P stabilization, after this point there was a continuous efflux of P, in any study period or d[Ca], of at least 10% every 30 minutes (Figure). GLM revealed that P removal was dependent, in order of importance, on the pre-dialysisserum P, UF and bone remodeling, explaining together 66.8% of P removal.

**Conclusions:** P removal during conventional HD is higher during the first 90 of therapy, achieving a smaller, but stable flux until the 240 minutes. An intradialytic negative P balance depends not only on the pre-dialysis serum P and UF but also on bone remodeling, which may change the P disposal on the bone surface.

Associations Between Serum Phosphate, Kt/V, and Creatinine Clearance Among Peritoneal Dialysis Patients: Preliminary Analysis From the PD-MONDO Initiative  
Murilo H. Guedes,<sup>1</sup> Maria Ines Diaz Bessone,<sup>6</sup> Lili Chan,<sup>2</sup> Ariella E. Mermelstein,<sup>3</sup> Andres E. De la torre quiroga,<sup>4</sup> Douglas R. Farrell,<sup>2</sup> Vincent Peters,<sup>5</sup> Constantijn Konings,<sup>5</sup> Guillermo Garcia-Garcia,<sup>4</sup> Jochen G. Raimann,<sup>3</sup> Adrian M. Guinsburg,<sup>6</sup> Thyago P. Moraes,<sup>1</sup> Peter Kotanko,<sup>3</sup> Jaime Uribarri.<sup>2</sup> *<sup>1</sup>Pontificia Universidade Catolica do Parana, Curitiba, Brazil; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Renal Research Institute, New York, NY; <sup>4</sup>Hospital Civil de Guadalajara, Guadalajara, Mexico; <sup>5</sup>Catharina Hospital Eindhoven, Eindhoven, Netherlands; <sup>6</sup>Fresenius Medical Care, Buenos Aires, Argentina.*

**Background:** Serum phosphate (PO) control requires adequate dialysis, yet commonly used biomarkers of dialysis adequacy (Kt/V) may underestimate PO removal in peritoneal dialysis (PD) patients. We sought to explore if creatinine clearance (CrCl), in addition to Kt/V, yields a better prediction of PO in PD patients.

**Methods:** We performed a cross-sectional analysis of multiple cohorts of incident PD patients – Fresenius Medical Care Latin America (FMC-LATAM), Renal Research Institute (RRI), Mount Sinai Hospital, Hospital Civil Guadalajara, and the BRAZPD cohort. We extracted the first available PO, Kt/V, and CrCl after 90 days of PD start. We fit separate linear regression models between PO, CrCl, and Kt/V, adjusting for predictors of PO. We computed log-likelihood ratio tests (LRT) for the models with and without CrCl. Pooled estimates between datasets were summarized by conducting a meta-analysis using random effects.

**Results:** 16,814 patients were included. Across data sets, median age (max,min) was 56 (60,45), 55% male (50,62); Kt/V and CrCl were 2.1 (1.7,2.5) and 77 (57,96) L/week, respectively. Phosphate binder use was 70% across datasets. In most datasets, Kt/V and CrCl were inversely associated with PO in the models adjusted for age, sex, PO binder use, and normalized protein catabolic rate (nPCR) (Figure) The pooled results confirmed the findings, despite high heterogeneity. Adding CrCl to the Kt/V provided additional information for PO prediction in the largest datasets (LRT p<0.01 for FMC-LATAM and RRI).

**Conclusions:** In this international study of incident PD patients, Kt/V and CrCl were inversely associated with PO. CrCl provided extra information for PO prediction, suggesting that both CrCL and Kt/V could be used to monitor dialysis adequacy in PD patients.

Random effects meta-analysis of the associations between PO, CrCl, and Kt/V. Models adjusted for age, sex, PO binder use, and nPCR.

TH-PO167

Serum Phosphorus and Kidney Disease Quality of Life (KDQoL) Among Maintenance Hemodialysis (HD) Patients  
Kamyar Kalantar-Zadeh,<sup>1</sup> Meijiao Zhou,<sup>2</sup> Linda Ficociello,<sup>2</sup> Claudy Mullon,<sup>2</sup> Michael S. Anger.<sup>2</sup> *<sup>1</sup>University of California Irvine, Orange, CA; <sup>2</sup>Fresenius Medical Care, Waltham, MA.*

**Background:** Dialysis patients experience lower health-related quality of life (QoL) compared to the general population. Previous studies have shown both high and low serum phosphorus (sP) concentrations were associated with lower physical component score of KDQoL among incident dialysis patients; however, the findings were not consistent. The aim of this study was to evaluate the associations between sP and KDQoL among HD patients on phosphate binders (PB).

**Methods:** Eligible patients were adults receiving in-center HD from Fresenius Kidney Care (FKC) facilities who filled out KDQoL-SF 36 during the year of 2019 and had available information on sP within 30 days prior to/on KDQoL survey completion date. Stratified random sampling were applied on 17,757 patients to select the analysis cohort defined by sP levels (<3.5 mg/dL, 3.5 to 5.5 mg/dL, >5.5 to 6.5 mg/dL, >6.5 to 7.5 mg/dL, >7.5 to 8.5 mg/dL, and >8.5 mg/dL), with 100 patients matched on age for each sP category. ANOVA and linear regression were used to examine the associations between sP and KDQoL. Higher scores represented better QoL. Age, gender, race, ethnicity, diabetes, CHF, cinacalcet use, BMI, vintage, Charlson Comorbidity Index (CCI), albumin, hemoglobin, calcium, iPTH, PB pills per day, total pills, TSAT, and spKt/V were considered in the multivariable analysis.

**Results:** Higher sP levels were associated with lower scores in KDQoL scales of symptoms/problems, burden of kidney disease, effects of kidney disease, and mental health (p<0.05; figure). After controlling for respective covariates, sP levels remained associated with symptoms/problems, burden of kidney disease, and effects of kidney disease.

**Conclusions:** Among HD patients who were prescribed PB monotherapy, higher serum phosphorus was associated with lower scores of KDQoL scales of symptoms/problems, burden of kidney disease, and effects of kidney disease. Prospective studies may be warranted to determine whether or to what extent QoL may improve with measures to lower sP.

**Funding:** Commercial Support - Fresenius Medical Care

TH-PO168

**Associations Between Pill Burden and Kidney Disease Quality of Life (KDQoL) Among Patients on Maintenance Hemodialysis (HD) and the Impact of More Potent Phosphorus Binding Therapy**  
Kamyar Kalantar-Zadeh,<sup>1</sup> Linda Ficociello,<sup>2</sup> Meijiao Zhou,<sup>2</sup> Claudy Mullan,<sup>2</sup> Michael S. Anger.<sup>2</sup> <sup>1</sup>University of California Irvine, Orange, CA; <sup>2</sup>Fresenius Medical Care, Waltham, MA.

**Background:** Patients who receive maintenance HD therapy have a high pill burden, which has been associated with lower health-related quality of life (HRQoL). We hypothesize that phosphate binder (PB) pill burden is associated with HRQoL in HD patients. Prior studies were conducted before more potent PB with lower pill burdens were frequently used.

**Methods:** This was a cross-sectional study of adult, in-center HD patients from Fresenius Kidney Care (FKC) facilities who filled out KDQoL-SF 36 in 2019, were prescribed PB monotherapy, with pill burden recorded within 30 days prior to/on KDQoL survey completion date (n=17,757). Stratified random sampling was used to select the study cohort (n=500) defined by PB pills/day (≤3, >3 to 6, >6 to 9, >9 to 12, and >12) and matched for age. As a sensitivity analysis, we examined the association between total pill burden (quartiles of total pills/day: ≤13, >13 to 18, >18 to 24, and >24) and KDQoL. Higher scores are indicative of higher quality of life. ANOVA, chi square, linear regression and logistic regression were utilized.

**Results:** PB pill burden was not significantly associated with KDQoL summary scores but was significantly associated with the *bothered by fluid restriction* question (Table). Total pill burden was associated with symptoms/problems (score of 84.1 to 78.2 from Q1 to Q4 of total pills), effects of kidney disease (80.0 to 75.6), physical health (41.4 to 36.1) and mental health (54.3 to 51.6), as well as the *bothered by fluid restriction* question (74.6 to 65.5).

**Conclusions:** Among HD patients, both higher PB pill burden and total daily pills were associated with higher likelihood to be bothered with fluid restriction. The additional fluid consumption needed to consume pills may need to be examined among patients who struggle with fluid restrictions.

**Funding:** Commercial Support - Fresenius Medical Care

**Phosphate Homeostasis and Apparent Treatment Resistant Hypertension in CKD: The CRIC Study**  
Jing Chen,<sup>1,2</sup> Arnold B. Alper,<sup>1</sup> Halil K. Erol,<sup>1</sup> Siyi Geng,<sup>3,2</sup> Hua He,<sup>3,2</sup> Moh'd Sharshir,<sup>1</sup> Ismail Abubakar Ibrahim,<sup>1</sup> Suayp Oygen,<sup>1</sup> Joshua D. Bundy,<sup>3,2</sup> L. Lee Hamm,<sup>1,2</sup> Jiang He.<sup>3,2</sup> <sup>1</sup>Tulane University School of Medicine, New Orleans, LA; <sup>2</sup>Tulane University Translational Science Institute, New Orleans, LA; <sup>3</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

**Background:** Abnormal phosphate (Pi) homeostasis is associated with vascular dysfunction. We studied the associations of Pi indices with apparent treatment resistant hypertension (ATRH) in CKD.

**Methods:** The CRIC Study enrolled 3939 CKD patients. 3556 without missing data were included in this analysis. ATRH was defined as SBP ≥140 or DBP ≥90 mm Hg while taking ≥3 BP medications or BP <140/90 mm Hg while taking ≥4 medications. Novel Pi overload index was calculated as [serum Pi x (urine Pi/Cr ratio) x alkaline phosphatase (a marker reflecting bone turnover)] to synergistically reflect the effect of high Pi intake on serum Pi, kidneys, and bones. Logistic regression models were used to examine the associations of baseline Pi overload index, serum Pi, FGF23, and PTH with ATRH.

**Results:** The Pi indices are significantly associated with ATRH (Table). The associations remain similar after adjusting for FGF23.

**Conclusions:** These data suggest that Pi overload is independently associated with ATRH. Maintaining normal Pi homeostasis may improve BP control.

**Funding:** NIDDK Support, Other NIH Support - National Institute of General Medical Sciences (NIGMS)

**The Binder That Got Us in a Bind, Sevelamer Crystal Associated Bowel Necrosis: A Case Report**  
Sarah Hryzak, Arun Janakiraman, Sidney M. Kobrin, Abdallah Sassine Geara, Sandeep Aggarwal. *University of Pennsylvania, Philadelphia, PA.*

**Introduction:** Crystal associated colonic necrosis is a rare iatrogenic complication most reported with kayexalate/sorbitol complex use. Sevelamer is a commonly prescribed and well tolerated phosphate binder used in patient's with advanced chronic kidney disease (CKD) for hyperphosphatemia. We report a case of biopsy proven colonic necrosis associated with sevelamer crystals.

**Case Description:** A 67-year-old male with history of IgA nephropathy now end stage renal disease (ESRD) status post failed cadaveric kidney transplant, atrial fibrillation, AAA s/p endovascular repair admitted with abdominal pain, nausea and vomiting found to be in septic shock. Imaging revealed pneumoperitoneum and sigmoid colon perforation. Work up for bowel perforation included evaluation of cardiac/embolic source with transthoracic echocardiogram with no intracardiac thrombi/vegetations. Abdominal vascular imaging showed intact AAA endograft without any endoleaks, dissection or mural thrombi. Work up for infectious, hypercoagulable and autoimmune causes for colitis were unrevealing. Patient underwent exploratory laparotomy with left hemi-colectomy. Anatomical pathology revealed crystalline resin within lumen and stoma ulceration (figure 1) compatible with sevelamer crystals, no evidence of viral inclusions and viable proximal resection margins.

**Discussion:** Colonic necrosis is more commonly known to be associated with various etiologies including cardio-embolic sources, underlying vascular disease, infectious processes and autoimmune conditions. Crystal associated colonic necrosis is a rarely reported cause. Our case report reveals a possible association between sevelamer administration and colonic injury. Large scale correlation studies need to be done to further explore the clinical pathological relationship between sevelamer and colonic necrosis.

Figure 1. Colonic mucosal ulceration with an associated sevelamer crystal

### Identification and Characterization of Mineralization Mediators Derived From Adrenal Glands

Shruti Bhargava,<sup>1,2</sup> Vera Jankowski,<sup>1</sup> Jonas Laget,<sup>3</sup> Bernard Jover,<sup>3</sup> Joachim Jankowski,<sup>1,2</sup> <sup>1</sup>Universitätsklinikum Aachen Institut für Molekulare Herz Kreislauf Forschung, Aachen, Germany; <sup>2</sup>Universiteit Maastricht Cardiovascular Research Institute Maastricht, Maastricht, Netherlands; <sup>3</sup>RD Nephrologie, Montpellier, France.

**Background:** Mineralization of vascular tissue is a common symptom of chronic kidney disease and is accompanied by a reduction in bone mineralization and density. In the current study, we investigated a novel systemic regulation of vascular mineralization processes by adrenal glands.

**Methods:** Bovine adrenal gland were homogenized and separated by chromatographic fractionation. The resulting fractions were assessed in cells, thoracic aortic rings and vitamin D3-nicotine renal failure rat model to study their effects on vascular and bone mineralization processes. Potential mediators were identified by mass spectrometry in complement with pertinent databases.

**Results:** We identified a novel peptide from bovine adrenal glands that inhibits transdifferentiation of aortic smooth muscle cells into osteoblast like cells, thereby hindering vascular mineralization. This peptide named 'Calcification Blocking Factor' (CBF) based on its protective effects against vascular mineralization is released from chromogranin A through enzymatic cleavage by calpain 1 and kallikrein. CBF reduced calcium content of aortic smooth muscle cells and thoracic aortic rings treated under calcifying culture conditions and in aortas from vitamin D3-nicotine (VDN) animals. CBF prevented aortic smooth muscle cell transdifferentiation into osteoblast-like cells in the vessel wall via the PIT-1 sodium-dependent phosphate transporter, inhibiting NF- $\kappa$ B activation and its downstream BMP2/p-SMAD signaling. CBF treated VDN animals showed a significantly lower pulse pressure which is a marker of arterial stiffness. Consistent with our preclinical results, concentration of CBF was found to be significantly reduced in patients with chronic kidney disease who are predisposed to vascular mineralization. Smaller fragments of the 19 aa peptide were analyzed to identify the active site of CBF.

**Conclusions:** In conclusion, we identified a novel peptide derived from adrenal glands which modulates vascular mineralization. Additionally, we identified smaller peptides that reduces vascular calcification by inhibiting smooth muscle cell transdifferentiation. These findings suggest a novel function of adrenal glands in calcium mineralization.

**Funding:** Government Support - Non-U.S.

### Phosphate Inhibits Calcium-Sensing Receptor Expressed Endogenously in TT Cells

Khaleda A. Alghamdi, Sheherzad Salman, Donald T. Ward. *The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom.*

**Background:** Calcium-sensing receptor (CaR) is the key controller of parathyroid hormone (PTH) secretion and extracellular calcium homeostasis. Hyperphosphataemia increases PTH secretion and we reported recently that pathophysiologic phosphate (Pi) concentrations can attenuate CaR activity directly in transfected HEK-293 cells and can increase PTH secretion from human and murine parathyroid cells (Centeno *et al.*, 2019, Nature Communications).

**Methods:** This was investigated further using thyroidal C cell-derived TT cells (ATCC), which express CaR endogenously. Intracellular  $\text{Ca}^{2+}$  ( $\text{Ca}^{2+}_i$ ) mobilisation was assayed by epifluorescence microscopy, protein expression by immunoblotting and calcitonin secretion by ELISA.

**Results:** Co-stimulation of TT cells with the (CaR-activating) calcimimetic R568 (1 $\mu$ M) and spermine (1mM) elicited robust  $\text{Ca}^{2+}_i$  mobilisation, that was inhibited 33 $\pm$ 4% ( $P<0.001$ ) by 2mM (pathophysiologic) Pi-containing buffer vs 0.8mM Pi control. In contrast, raising Pi concentration was without effect on carbachol-induced  $\text{Ca}^{2+}_i$  mobilisation (acting via muscarinic receptors). Also, 1.2mM (high) sulphate elicited a similar CaR inhibition as for Pi (-28 $\pm$ 16%;  $P<0.05$  vs 0.3mM control). Next it was found that CaR-mediated stimulation of the TT cells with 1 $\mu$ M R568 & 1mM spermine (in 2mM  $\text{Ca}^{2+}$  and 0.8mM Pi) increased calcitonin secretion, as expected, whereas the same stimulation in 2mM Pi (in the presence of 2.2mM  $\text{Ca}^{2+}$  to correct for any reduction in free  $\text{Ca}^{2+}$ ) significantly blunted this response ( $P<0.05$ ). CaR protein expression was confirmed in the TT cells by immunoblotting. However, CaR abundance was unaffected by overnight culture in media containing 2mM Pi (vs 0.8mM control) whereas CaR stimulation with 1 $\mu$ M R568 & 1mM spermine (in 0.8mM Pi) decreased CaR abundance by 20 $\pm$ 4% ( $P<0.05$ ). Therefore, sustained exposure to high Pi did not produce CaR downregulation at least in the thyroid-derived TT cells.

**Conclusions:** Therefore, pathophysiologic Pi treatment inhibits endogenous CaR-induced signalling and calcitonin secretion from thyroidal TT cells but without affecting CaR abundance. These results further support the idea that the CaR represents a mineral sensor, at which Pi acts directly as a non-competitive antagonist to limit CaR-induced suppression of PTH secretion.

**Funding:** Government Support - Non-U.S.

## TH-PO173

### PTH Independent Hypercalcemia, Easily Missed Diagnosis: Case Report of Vitamin A Toxicity

Uzma Malik, Abhinaya Sridhar, Sanjeev Gupta, Savneek S. Chugh, Amol Mittal, Shruti Kore. *Westchester Medical Center, Valhalla, NY.*

**Introduction:** The first step in the evaluation of hypercalcemia is establishing the role of PTH in its pathogenesis. There are many causes of PTH independent hypercalcemia; Vitamin A toxicity is a rare cause of PTH-independent hypercalcemia.

**Case Description:** 51 years old male with history of well controlled diabetes, HIV with a suppressed viral load and CKD stage 2 was found to have hypercalcemia at a routine nephrology clinic visit. Patient reported no symptoms of hypercalcemia or decreased urine output. He also denied any weight loss, night sweats, decreased appetite. His vital signs and physical exam were unremarkable. Routine blood work was notable for hypercalcemia 10.5 mg/dL. Repeat testing 2 months later showed persistent hypercalcemia to 10.8 mg/dL. Initial work up revealed 25OH vitamin D 34; PTH 30pg/ml and phosphorus 3.3 mg/dL suggestive of PTH-independent hypercalcemia. Urinalysis was notable for 2+ glucose, no proteinuria. Urine protein to creatinine ratio was 62 mg/g. Given unclear cause of PTH independent hypercalcemia at this time, Vitamin A level was checked which was elevated to 94.6 mg/dL. However, patient denied excessive intake of vitamin A containing food. Patient was encouraged to hydrate well and was provided list of food items high in vitamin A and advised to avoid them. Repeat testing 3 months later showed Cr 1.34, Ca 9.9 and Vitamin A levels within normal limits.

**Discussion:** The tolerable upper daily intake level of vitamin A is approximately 3,000  $\mu$ g RAE. However, Vitamin A toxicity can occur at what is considered to be "safe doses" (700 to 900  $\mu$ g RAE) from dietary sources and supplementation. The mechanism of vitamin A-induced hypercalcemia is poorly understood. It is hypothesized to be secondary to increased osteoclastic activity, suppression of osteoblastic activity, and hormonal dysregulation of calcium homeostasis of parathyroid hormone and vitamin D. In setting of hypercalcemia and suppressed PTH, Vitamin A toxicity should be considered in the diagnostic workup along with malignancy, bone metastasis, vitamin D toxicity, granulomatous disease and immobility. A thorough dietary history and serum retinol levels should be checked. Treatment involves withdrawal of vitamin A sources and supportive care.

## TH-PO175

### Successful Story of Conversion of Cinacalcet to Etelcalcetide During the COVID-19 Pandemic

Tarek A. Fouda, Abdullah I. Hamad, Tarek A. Ghonimi, Anees J. Alomari, Sahar Aly, Rania A. Ibrahim, Asma Abdelmagid, Mohed Y. Taha, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

**Background:** Hamad general Hospital is the main provider of (HD) in Qatar with 932 patients. We established a team from dialysis nurses under direct nephrologist supervision for management of (MBD). We introduced Etelcalcetide in Qatar in May 2021 for HD patients unable to tolerate oral cinacalcet (GIT symptoms) especially during the COVID-19 pandemic where patients had difficulties dispensing medicine and have proper follow up

**Methods:** Our study followed patients from May 2021 till March 2022. We included HD for >6 months patients with (HPT) despite being on cinacalcet therapy. Patients recruited from all HD centers (4) in Qatar. Data collected through electronic medical records.

**Results:** 50 patients fulfilled inclusion criteria and were included in study period. Median (PTH) on cinacalcet was 946 pg/ml (Mean 1123pg/ml). After conversion to Etelcalcetide, PTH median level had significant improvement to 623 pg/ml (mean 749 pg/ml). Average improvement in PTH level was 46% (36% of patients with 50% improvement and 48% of patients with >50% improvement). The Median dose for Etelcalcetide was 21.5mg/week. (Patients with within our PTH target range (150-500pg/ml) improved from 8% in May 2021 (on cinacalcet) to 38% in March 2022 (on Etelcalcetide)  $p=0.0003$  while patients with PTH above 800 decreased from 50% to 20% for the same period ( $p=0.001$ ).

Reasons for conversion from Cinacalcet to Etelcalcetide were noncompliance due to GIT side effects (with resistant elevation of PTH despite optimal dose (90% of patients) also due to the COVID-19 pandemic and its effect in following medication in the face of shortage of our nurses and physician.

**Conclusions:** Our project to optimize MBD management in HD patients with uncontrolled HPT not tolerating Cinacalcet by utilizing Etelcalcetide showed significant improvement in PTH outcomes. It was well tolerated with no reported significant side effects. Utilizing MBD team proven to be a wise decision during the peak of the COVID-19 pandemic with physician shortage and service disturbances.

## TH-PO176

### A Rare Case of Hypercalcemia in Primary Hypoparathyroidism due to Multiple Myeloma

**Muhammad Khalid Tahir**, Arun U. Mahtani, Angela Grigos, Farhang Ebrahimi. *Richmond University Medical Center, Staten Island, NY.*

**Introduction:** - Incidence and prevalence of primary hypoparathyroidism (PHPT) in the United States: 0.08 and 37 per 100,000 person-years, respectively.<sup>1</sup> Seen in females above 45 years. - The most common cause of PHPT is iatrogenic.<sup>2</sup> - Hypercalcemia can also occur iatrogenically due to supplementation.<sup>3</sup> - Several cases linking primary hyperparathyroidism and multiple myeloma (MM) have been reported.<sup>4</sup> - To the author's knowledge, this is the first case of a patient having PHPT with concomitant MM.

**Case Description:** - A 50-year-old-male with a history of chronic kidney disease stage 3 (CKD stage 3), primary hypoparathyroidism since 1997 on calcium and calcitriol supplementation, and gastroesophageal reflux disease (GERD) presented with: lower back pain (LBP), increased urinary frequency, and chronic cough for 1 month. - Physical examination: LBP exacerbated with movement. - Labs: serum calcium of 17.5 mg/dL, serum sodium of 129 mmol/L, serum potassium of 5.2 mmol/L, total protein of 10.4 g/dL, albumin of 4 g/dL, and intact PTH of < 6.3 pg/mL. - Free Kappa/Lambda light chains: 9.4/1369.7. Elevated IgA levels: 3138.4. - SPECT showed no suspicious areas of MM. - Bone marrow biopsy: 41% of monoclonal intracellular lambda positive plasma cell (kappa to lambda ratio: < 0.01). Positive for cytoplasmic heavy chain IgA, partially positive for cluster of differentiation (CD)117, aberrantly positive for CD27, and negative for CD56. - Treatment: intravenous fluids, calcitonin, pamidronate, and chemotherapy.

**Discussion:** - 28% of patients with MM are hypercalcemic.<sup>5</sup> - PTH may be an inducer of MM through signaling pathways involving IL-6.<sup>6</sup> - First reported case of primary hypoparathyroidism in a patient with concomitant MM. - Large-scale studies needed to understand the relationship between PTH and MM. - Etiology of hypercalcemia in primary hypoparathyroidism should always be investigated.

Bone marrow biopsy showing plasma cells

## TH-PO177

### Klotho Protects Diabetic Nephropathy via Inhibiting Orai1 and TRPC5/6 Channels in Podocytes

**Ji-Hee Kim**,<sup>1,3</sup> Bao T. Dang,<sup>1,3</sup> Kyu-Hee Hwang,<sup>1,3</sup> Nghia T. Pham,<sup>1,3</sup> Minseob Eom,<sup>2</sup> Seung-Kuy Cha.<sup>1,3</sup> <sup>1</sup>Department of Physiology, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; <sup>2</sup>Department of Pathology, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; <sup>3</sup>Mitohormesis Research Center, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.

**Background:** Klotho protein is predominantly produced in the kidney, where it regulates multiple renal ion channels to protect the kidney filter and renal diseases. Podocytes play a vital role in kidney filter function and are primary pathologic target for diabetic nephropathy (DN). Perturbation of Ca<sup>2+</sup> signaling has been implicated in podocyte dysfunction leading to DN. Here we demonstrated that Klotho ameliorates podocyte injury by stabilizing Orai1 and TRPC5/6 channel-mediated Ca<sup>2+</sup> signaling to prevent DN.

**Methods:** Type 2 diabetic db/db mice received *i.p.* injections of Klotho protein three times a week. The albumin/creatinine ratio, proteins & mRNA levels were analyzed at 11, 15 and 19-week-old db/db mice and db/m was used as a control group. Live-cell imaging and immunocytochemistry were performed in immortalized mouse podocytes.

**Results:** In a type 2 diabetic db/db mouse model, Klotho and synaptopodin were downregulated, while Orai1, TRPC5, and TRPC6 were overexpressed in early and late periods, respectively. Soluble Klotho suppressed Orai1- and TRPC5/6-mediated Ca<sup>2+</sup> entry in mouse cultured podocytes via inhibiting growth factors and/or insulin signaling. Mechanistically, soluble Klotho reduced cell surface abundance of Orai1 and TRPC5/6, but not TRPC3 by suppressing phosphoinositide-3-kinase-dependent trafficking of these channels. In addition, soluble Klotho downregulated protein expression of Orai1 and TRPC6 by inhibiting growth factor-driven SGK1 activation. Functionally exaggerated actin remodeling by Orai1 and TRPC6 activation was ameliorated by soluble Klotho. Notably, administration of Klotho protein in db/db mice suppressed phosphorylation of SGK1 and rescued dissolution of synaptopodin and WT-1. Finally, Klotho ameliorated podocyte foot process disruption and proteinuria in db/db mice.

**Conclusions:** Taken together, our results suggest that Klotho protects proteinuria and podocyte actin cytoskeletal remodeling through stabilizing Ca<sup>2+</sup> signaling mediated by Orai1 and TRPC5/6, which provides a new potential therapeutic strategy for the treatment of DN.

**Funding:** Government Support - Non-U.S.

## TH-PO178

### The Combination of Empagliflozin and Atrasentan on Top of RAS Blockade Ameliorates Cardiorenal Syndrome in the db/db Type 2 Diabetes Mouse Model

**Under Vergara**,<sup>1,2</sup> Conxita Jacobs Cachá,<sup>1</sup> Carmen Llorens Cebrià,<sup>1</sup> Pamela Domínguez Báez,<sup>1</sup> Nerea Martos,<sup>1</sup> Irene Martínez Díaz,<sup>1</sup> Sheila Bermejo,<sup>1,2</sup> Michael P. Pieper,<sup>3</sup> Begoña Benito,<sup>1,2</sup> Maria Jose Soler.<sup>1,2</sup> <sup>1</sup>Nephrology and Renal Transplant Research Group <sup>1</sup>Vall d'Hebron Institut de Recerca, Barcelona, Spain; <sup>2</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>3</sup>Boehringer Ingelheim Pharma GmbH & Co KG, Biberach an der Riß, Germany.

**Background:** Sodium-glucose cotransporter 2 inhibitors (SGLT2i) prevent cardiovascular events in diabetic patients. Moreover, their diuretic effect could attenuate the adverse events of endothelin receptor antagonists (ERAs), which have also shown beneficial effects in diabetes. The present study aimed to evaluate the cardiorenal protective effects of the SGLT2i, ERAs and ramipril combination vs treatment with ramipril alone in the db/db mouse.

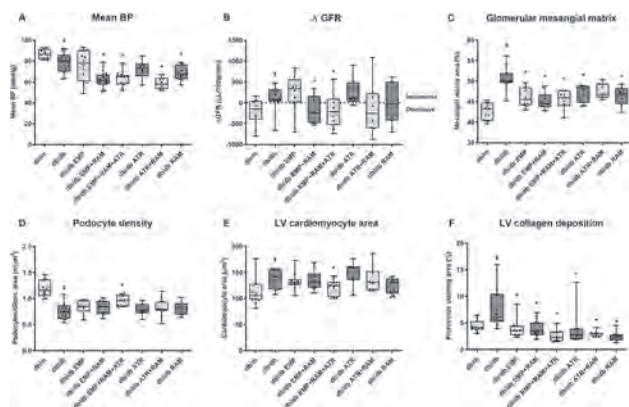

**Methods:** Twelve weeks old db/db mice were treated for 8 weeks with different combinations of an SGLT2i (empagliflozin, 10 mg/Kg/day), an ERA (atrasentan, 7 mg/Kg/day) and a renin-angiotensin system (RAS) blocker (ramipril, 8 mg/Kg/day). Vehicle-treated diabetic and non-diabetic mice were included as controls. During the experiment, blood pressure (BP), glomerular filtration rate (GFR) and echocardiographic parameters were measured. Kidney and heart were collected at the end for histological studies.

**Results:** The triple therapy with empagliflozin, atrasentan and ramipril was superior to ramipril alone in reducing BP, preventing diabetic hyperfiltration (214 µL/100g/min reduction in GFR vs 96 µL/100g/min increase in non-treated db/db, *p*=0.040) and improving echocardiographic parameters of diastolic dysfunction, including left atrium diameter and isovolumetric relaxation time (Figure 1). Moreover, the combined therapy offered protection against diabetic injury in the kidney and heart, decreasing glomerular mesangial matrix, restoring podocyte density, and reducing both left ventricle (LV) cardiomyocyte hypertrophy (125 µm<sup>2</sup> area vs 142 µm<sup>2</sup> in non-treated db/db, *p*=0.032) and LV collagen deposition (Figure 1).

**Conclusions:** In experimental diabetes, combined therapy of ramipril, empagliflozin and atrasentan promotes both heart and kidney protective effects that outweigh the beneficial effects of ramipril alone.

**Funding:** Commercial Support - Boehringer Ingelheim, Government Support - Non-U.S.

## TH-PO179

## The Characteristics and Mechanism of Cell Senescence in Patients With Diabetic Kidney Disease

Ying Zhang,<sup>1,2</sup> Xiaodong Zhu,<sup>1,2</sup> Xiaoliang Zhang,<sup>1,2</sup> Yu Zhao,<sup>1,2</sup> <sup>1</sup>Southeast University Zhongda Hospital, Nanjing, China; <sup>2</sup>Southeast University Medical College, Nanjing, China.

**Background:** Cellular senescence commonly occurs in renal innate cells of diabetic kidney disease (DKD) and autophagy may be involved. However, the features of senescent cells in different pathological stages of DKD, as well as the driving force behind cell senescence remain unknown. The study aims to investigate the characteristics of cell senescence in renal tissue during different pathological stages of DKD and their relationship with renal function and the role of autophagy in it.

**Methods:** Fifty DKD patients diagnosed by renal biopsy were divided into I IIa IIb III IV classes according to the pathologic typing. The other six normal kidney specimens taken from patients with renal trauma or tumor were as the control group. Serum creatinine and proteinuria were collected. Pathological changes in kidney were detected by PAS staining, and the expression of senescence marker p21 was demonstrated by immunohistochemistry. DKD rats were established by intraperitoneal injection with streptozotocin (STZ) and sacrificed respectively at 14w. HK-2 cells were cultured with 25mM glucose with or without autophagy inhibitor (chloroquine (CQ)) and activator (rapamycin). The expressions of LC3, p62 (autophagy proteins) and p53, p21 (senescence markers) were detected by immunohistochemistry and Western Blot.

**Results:** In kidney biopsies, the p21 expression was increased in interstitium and tubules and tightly associated with disease progression ( $p < 0.05$ ), which was proportional to the degree of deterioration of renal function. Similar trends were also observed in the levels of p21, p53, p62 and LC3 in DKD groups ( $p < 0.05$ ). Electronic microscope showed an increase in autophagosomes in the renal tubules of DKD rats. HK-2 cells treated with high glucose exhibited increased expression of p21, p53, p62 and LC3 ( $p < 0.05$ ). CQ elevated p21 and p53 compared to the high glucose group, whereas opposite trend was observed in the rapamycin treatment ( $p < 0.05$ ).

**Conclusions:** Our study demonstrated a positive correlation between cell senescence and progression of DKD, and autophagy attenuated the high-glucose-mediated renal tubule senescence.

Fig 1. The expression of p21 and its association with renal function in DKD patients. A: Immunohistochemistry of p21 (red arrows) ( $\times 400$ , bar = 50  $\mu$ m). B-D: Quantification of p21 and measurement of serum creatinine or proteinuria at different pathological stages in DKD. E-F: Analysis of the correlation between p21 and serum creatinine or proteinuria. The data are presented as the mean  $\pm$  SD (n = 6 per group). a = 0.05 vs. control, b = 0.05 vs. I = IIa = IIb.

## TH-PO180

## Senolytics, Dasatinib Plus Quercetin, Improve Kidney Function and Reduce Inflammation in Murine Diabetic Kidney Disease

Xiaohui Bian,<sup>2</sup> Zachary K. Snow,<sup>2</sup> Anastasia L. Smith,<sup>2</sup> Caroline J. Skaff,<sup>2</sup> Khaled Mosaad Elhusseiny,<sup>2</sup> Yi Zhu,<sup>3</sup> Tamara Tchkonja,<sup>3</sup> Seo Rin Kim,<sup>3</sup> James L. Kirkland,<sup>3</sup> Lilach O. Lerman,<sup>3</sup> LaTonya J. Hickson,<sup>1</sup> Mayo Translational and Regenerative Nephrology Research Laboratory <sup>1</sup>Mayo Clinic in Florida, Jacksonville, FL; <sup>2</sup>Shengjing Hospital of China Medical University Department of Nephrology, Shenyang, China; <sup>3</sup>Mayo Clinic Minnesota, Rochester, MN.

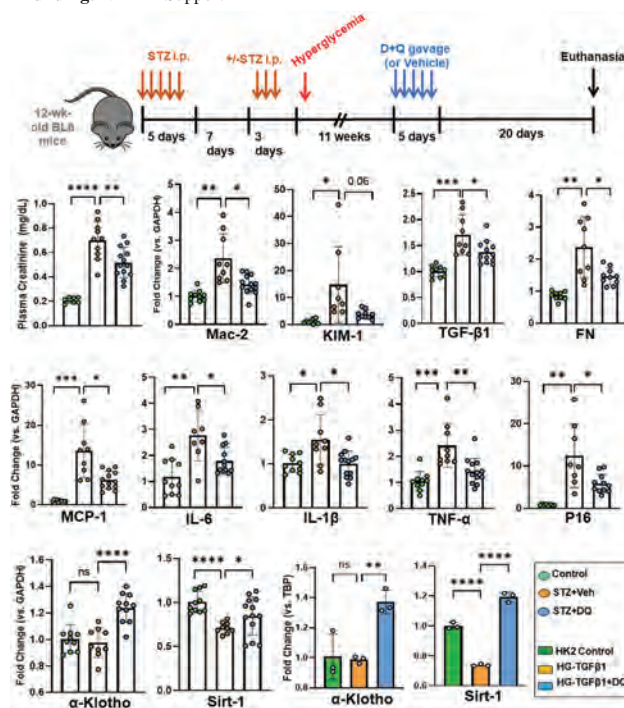

**Background:** Senolytic agents, dasatinib plus quercetin (D+Q), reduced systemic inflammation, macrophage infiltration, and senescent cell burden in adipose tissue in our pilot study of human participants with diabetic kidney disease (DKD). We hypothesized that D+Q would attenuate kidney injury and inflammation in a murine model of DKD.

**Methods:** Twelve-week-old male C57BL/6 mice were injected with 50 mg/kg/d STZ i.p. for 5 (+3) consecutive days (Figure). Mice with fasting glucose  $> 250$  mg/dL at day 100 were randomized to either D+Q (5 and 50 mg/kg, respectively) or vehicle gavage daily for 5 days and euthanized 20 days later. Kidney injury (Mac-2, KIM-1), inflammation (MCP-1, IL-6, IL-1 $\beta$ , TNF $\alpha$ ), profibrotic markers (TGF $\beta$ 1, fibronectin), cellular senescence (p16), and geroprotective factors ( $\alpha$ -Klotho, Sirt-1) were examined by qPCR, and kidney function by serum creatinine. In vitro, we assessed the response to D+Q in renal tubular epithelial cells (HK2) injured by high glucose and TGF- $\beta$ 1.

**Results:** Oral D+Q improved kidney function and decreased kidney injury, profibrotic factors, and senescence marker p16 vs. vehicle-treated mice. In addition, pro-inflammatory (senescence-associated secretory proteins) kidney makers were reduced following D+Q. Finally, both  $\alpha$ -Klotho and Sirt-1 increased in DKD tissue *in vivo* and HK2 cells *in vitro* after D+Q.

**Conclusions:** A "hit and run" treatment with D+Q can attenuate murine DKD injury by altering the inflammatory landscape, reducing senescent cell abundance, and restoring geroprotective factors. D+Q might represent a novel therapeutic strategy in DKD.

**Funding:** NIDDK Support

## TH-PO181

**Kidney Tubule Specific AMPK  $\alpha$ 1 Knockout Abolishes Female Protection From Diabetes and Affects Amino Acid Metabolism in Diabetic Mice**  
Hak Joo Lee,<sup>1,2</sup> Jingli Gao,<sup>1</sup> Liang Min,<sup>1</sup> Hongping Ye,<sup>1</sup> Anthony J. Franzoni,<sup>1</sup> Goutam Ghosh-Choudhury,<sup>1,2</sup> Balakuntalam S. Kasinath,<sup>1,2</sup> Kumar Sharma,<sup>1,2</sup> Center for Precision Medicine <sup>1</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>2</sup>South Texas Veterans Health Care System, San Antonio, TX.

**Background:** Reduced kidney AMPK activity is associated with progression of chronic kidney disease (CKD) which is ameliorated by AMPK stimulation in male mice, whereas female mice resist CKD from obesity and diabetes. Amino acids have been implicated in CKD but their mechanistic role is unclear. We hypothesized that kidney tubule specific deletion of AMPK catalytic  $\alpha$ 1 subunit abolishes female protection and dysregulates amino acid metabolism in diabetic mice.

**Methods:** 3-4 month old kidney specific AMPK  $\alpha 1$  knockout (KO) male and female mice (n=6-9 per group) were placed on normal fat diet or high fat diet (HFD) for 1 month, after which HFD groups received a low dose of streptozotocin. Urinary amino acids were measured by a targeted mass spectrometry platform.

**Results:** AMPK  $\alpha 1$  expression was significantly reduced in the kidney of AMPK  $\alpha 1$  KO mice without compensation by AMPK  $\alpha 2$ . Diabetes induced similar degree of hypertension and albuminuria in male WT and AMPK  $\alpha 1$  KO mice. Female WT mice resisted diabetes-induced hypertension and albuminuria. In contrast, albuminuria and systolic blood pressure were elevated in female diabetic AMPK  $\alpha 1$  KO mice. Diabetes increased urinary lysine level in male WT and AMPK  $\alpha 1$  KO mice. Diabetes-increased urinary lysine level was not observed in female WT mice, but it was increased in female diabetic AMPK  $\alpha 1$  KO mice. Urinary lysine level correlated with diabetes-induced albuminuria in male (p<0.001) and female (p<0.05) mice.

**Conclusions:** Female protection against diabetes is abolished in kidney tubule specific AMPK  $\alpha 1$  KO mice. Our data indicate that AMPK plays a pivotal role in female protection and regulates lysine metabolism in diabetic mice. AMPK could be used for a therapeutic target of diabetes-induced kidney injury and dysfunction of lysine homeostasis.

## TH-PO182

### Insulin Resistance Deregulates Immune Functions in the Collecting Duct That May Increase Urinary Tract Infection Risk

Laura Schwartz,<sup>1</sup> Vidhi Tyagi,<sup>1</sup> Kristin Bender,<sup>1</sup> John D. Spencer.<sup>1,2</sup> <sup>1</sup>*Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH;* <sup>2</sup>*The Ohio State University College of Medicine, Columbus, OH.*

**Background:** Type 2 diabetes affects 10% of the population. Among comorbidities linked to diabetes is increased urinary tract infection (UTI) risk. The factors that increase UTI susceptibility remain unknown. Previously, we showed insulin resistance and disrupted insulin receptor signaling in kidney collecting ducts (CD) and intercalated cells (IC) increases UTI risk. Here, we assess how adipose-derived cytokines impact CD insulin sensitivity, uropathogenic *E.coli* (UPEC) susceptibility, and UTI defenses *in vitro*. To validate these effects *in vivo*, we profile the transcriptomes of IC and principal cells (PC) from obese, insulin resistant male and female mice.

**Methods:** To induce insulin resistance (IR) *in vitro*, mouse and human CD cells were cultured with adipokines or in hypoxic conditions followed by a 1-hour treatment with insulin. Western blotting evaluated insulin signaling and UTI defense targets. To determine if IR effects UTI susceptibility, UPEC attachment and invasion assays assessed were performed on CD cells cultured in IR conditions. To assess the effects of IR on CD immune defenses *in vivo*, we placed female and male C57BL/6 mice on a high-fat diet (HFD) or low-fat diet (LFD) for 8 weeks. We then enriched IC and PC populations from HFD and LFD mice using fluorescence activated cell sorting and performed RNA-seq analysis.

**Results:** TNF $\alpha$ , IL-1 $\beta$  and culturing CD cells in hypoxic conditions increased IR *in vitro*, as shown by decreased insulin receptor and PI3K/AKT activation following insulin treatment. Culturing cells in these conditions deregulated immune targets, including NFkB, MAP kinase, and integrated stress responses. They also resulted in greater UPEC attachment to and invasion of CD cells. Gene expression profiles between HFD- and LFD-fed murine IC and PC populations also revealed altered expression in innate immune pathways, including NFkB signaling and the integrated stress response.

**Conclusions:** These results suggest insulin resistance may directly impact immune mechanisms that shield the kidneys from UPEC. In part, this may be due to the production of adipose-derived circulating cytokines that dysregulate immune mechanisms like NFkB signaling and the integrated stress response. A deeper understanding of these mechanisms may provide insight into why people with insulin resistance or diabetes have increased UTI susceptibility.

**Funding:** NIDDK Support

## TH-PO183

### Spatial Mapping of Mesangial Cell Proliferative Signatures in the Diabetic Kidney

Ricardo Melo ferreira,<sup>1</sup> Mahla Asghari,<sup>1</sup> Carrie L. Phillips,<sup>1</sup> Samir V. Parikh,<sup>2</sup> Daria Barwinska,<sup>1</sup> Michael J. Ferkowicz,<sup>1</sup> Angela R. Sabo,<sup>1</sup> Timothy A. Sutton,<sup>1</sup> Ying-Hua Cheng,<sup>1</sup> Brad H. Rovin,<sup>2</sup> Tarek M. El-Achkar,<sup>1</sup> Pierre C. Dagher,<sup>1</sup> Katherine J. Kelly,<sup>1</sup> Michael T. Eadon.<sup>1</sup> KPMP <sup>1</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>2</sup>*The Ohio State University Wexner Medical Center, Columbus, OH.*

**Background:** The renal mesangium undergoes adaptations in diabetic kidney disease (DKD). These changes include proliferation, hypertrophy, and mesangiolysis that ultimately lead to Kimmelstein-Wilson nodule formation. Using human reference nephrectomy and diabetic biopsy tissue, we sought to define the molecular transition of the mesangial cell (MC) as it undergoes these processes, including the coordinated signals arising from nearby degenerative podocytes and maladaptive glomerular capillary endothelial cells (GCECs).

**Methods:** We delineated the mRNA signature of renal mesangial cell adaptations in a merged KPMP / HubMAP snRNAseq atlas of reference and DKD specimens (>200,000 nuclei). The related signatures and cell neighborhoods in which they are expressed were localized with Seurat 3.2.3 to specific glomeruli within reference (N=6) and diabetic (N=10) kidney specimens using spatial transcriptomics. Spatial transcriptomic spots were selected based on glomerular cell type composition, and clustered based on the proportion of cell type signature, defining neighborhoods. Differential expression and pathway analysis further defined the signature of the neighborhoods.

**Results:** Transcriptome analysis revealed genes associated with MC fate in DKD. With the clustering analysis, we identified MC neighborhoods which included injured podocytes and maladaptive endothelial cells, more abundant in diabetic samples (p<0.05). Pathways enriched for those clusters are associated with morphology and development, and response to hypoxia. The trajectory of these molecular features was compared to histopathologic features (mesangial expansion, nodularity) within the specimens.

**Conclusions:** These studies suggest the existence of a temporal and spatial trajectory for mesangial cells in the progression of DKD, and describe the unique milieu of the diabetic glomeruli.

**Funding:** NIDDK Support

## TH-PO184

### Agnostic Mass Spectrometry Proteomics Identifies Glomerular Adipocyte Enhancer Binding Protein 1 (AEBP1) as a Novel Marker of Diabetic Kidney Disease

Sethu M. Madhavan,<sup>1</sup> John P. Shapiro,<sup>1</sup> Salem Almaani,<sup>1</sup> Anjali A. Satoskar,<sup>1</sup> Michael T. Eadon,<sup>2</sup> Tarek M. El-Achkar,<sup>2</sup> Pierre C. Dagher,<sup>2</sup> Brad H. Rovin,<sup>1</sup> Samir V. Parikh.<sup>1</sup> KPMP <sup>1</sup>*The Ohio State University Wexner Medical Center, Columbus, OH;* <sup>2</sup>*Indiana University School of Medicine, Indianapolis, IN.*

**Background:** Diabetic kidney disease (DKD) results from progressive glomerular inflammation and fibrosis frequently resulting in ESKD. Agnostic mass spectrometry (LC-MS/MS) proteomics was performed on kidney biopsies obtained from the Kidney Precision Medicine Project (KPMP) and potential biomarkers and molecular mediators of DKD were explored.

**Methods:** Frozen kidney biopsies with DKD (n=9) from the KPMP consortium and nephrectomy controls from OSU biorepository (n=4) were included. Biopsies were obtained from recruitment sites in the KPMP and histopathologic diagnoses were adjudicated by an expert committee in KPMP. Glomeruli and tubulointerstitium were isolated by laser capture microdissection and extracted protein was submitted for LC-MS/MS proteomics. Global normalization was performed by spectral counting. The glomerular proteome of DKD was compared to controls. Immunofluorescence microscopy and immunoperoxidase staining were performed in another cohort of DKD (n=5) from OSU biorepository. To determine specificity, proteomics comparison from other glomerular diseases (FSGS and MCD, n=13) was done.

**Results:** Glomerular AEBP1 was one of the most upregulated proteins in glomeruli of DKD compared to controls (4-fold, p=0.0008). AEBP1 was minimally expressed in healthy glomeruli but strongly stained by immunoperoxidase in DKD glomeruli. AEBP1 co-localized with nephrin and CD31 suggesting podocyte and endothelial expression in another cohort of diabetic glomeruli compared to controls. AEBP1 expression was similar to controls in FSGS and MCD.

**Conclusions:** We identified glomerular AEBP1 as a potential novel marker of DKD. AEBP1 has previously been shown to be induced by glucose, activates inflammatory mediators and associated with liver fibrosis in non-steatohepatitis. It has not been previously studied in kidney disease. Glomerular upregulation of AEBP1 in DKD and localization in podocytes and glomerular endothelial cells suggests its role in mediating glomerular inflammation and fibrosis in DKD. AEBP1 upregulation may be specific for DKD. The causal role of AEBP1 in the pathogenesis and progression of DKD will be further investigated within the KPMP consortium utilizing clinical and histology data and a multi-omic interrogation.

### The Evolving Role of the LXR/mTOR Signaling Axis in Diabetes-Induced Autophagy Alteration and Diabetic Kidney Disease

Sahar Alkhansa, Rachel Njeim, Foad N. Ziyadeh, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

**Background:** Diabetes is a metabolic disease that induces kidney injury and is considered the most common cause of end-stage kidney disease. It is well recognized that kidney cells depend on basal autophagy for survival and for conserving overall kidney integrity. New lines of research indicate that diabetes induces renal autophagy deregulation leading to kidney injury, yet the underlying mechanisms are not well elucidated. The mTOR complexes along with oxidative stress have emerged as potentially key players in mediating diabetes-induced autophagy imbalance. Alongside, the role of the Liver-X-Receptor (LXR), which is a nuclear receptor, has been also highlighted in diabetic kidney diseases (DKD). Nevertheless, the role of LXR in autophagy and its crosstalk with key mechanistic pathways in DKD remain to be identified. Herein, we investigate the role of the LXR/mTOR/Akt axis in autophagy and its possible link to podocyte injury in type 1 diabetes mellitus (T1DM).

**Methods:** T1DM was induced in 8-week-old C57BL/6J or FVB/NJ mice by streptozotocin (STZ) injection. Mice were treated with either LXR activator T0, mTORC1 inhibitor Rapamycin, mTORC2 inhibitor JR, or mTORC1/2 inhibitor PP242. Functional, histological, biochemical, and molecular parameters of the kidneys were assessed.

**Results:** Results show that T1DM induces autophagy deregulation which is accompanied by an increase in both mTORC1 and mTORC2 activity, a decrease in LXR expression, and an increase in the levels of superoxide anion generation through the NADPH oxidase 4 (Nox4) pathway. Inhibition of mTORC2 or mTORC1/2 restores the homeostatic functional renal levels by reducing proteinuria, restoring histological and phenotypic changes to near-normal levels, and inhibiting Nox4 expression. Of interest, these treatments ameliorate diabetes-induced autophagy homeostatic deregulation by

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

restoring the expression of LC3 and p62. Furthermore, activating LXR by T0 corrects the observed changes seen in the mTOR complexes, restores autophagy, and reverses diabetes-induced renal injury.

**Conclusions:** To our knowledge, this is the first study to provide evidence for a novel function of LXR/mTOR complexes in regulating autophagy in the onset of kidney disease in diabetes.

## TH-PO186

### Assessing the Influence of Sex on the CD1 Nephrectomized Streptozotocin-Induced Diabetic Kidney Disease Model

Ifeanyi K. Nmecha, Jackie Trink, Dan Zhang, Bo Gao, Melissa Macdonald, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

**Background:** Diabetic kidney disease (DKD) is the leading cause of kidney failure in North America. DKD is characterized by a progressive increase in albuminuria, glomerular hypertrophy, expansion of the glomerular mesangium, thickening of the glomerular basement membrane, and tubulointerstitial fibrosis and atrophy. Recent studies have shown that sex and sex hormones are important factors to consider in the development and progression of DKD. Presently, the hallmarks of this disease have primarily been studied in male rodent models. Here we explored the influence of sex in the CD1 nephrectomized streptozotocin (STZ)-induced murine model.

**Methods:** To induce DKD, 8-week-old CD1 mice underwent a right nephrectomy. After 1 week of recovery, they were injected IP with 200mg/kg STZ and followed for 12 weeks. Outcomes included urinary albumin-to-creatinine ratio (ACR), blood pressure (BP), weight, kidney and glomerular hypertrophy and kidney pathology.

**Results:** STZ dose required reduction in females to 150mg/kg due to high initial mortality. However, females often required reinjection after 2 weeks at 100mg/kg to induce hyperglycemia. Males had a greater decrease in endpoint weight and increase in BP. Both sexes developed comparable hyperglycemia, kidney hypertrophy and albuminuria, although ACR was more variable in females. Glomerular hypertrophy was more pronounced in male diabetics, as was basement membrane thickening. Serum TGFβ1 levels were increased only in females, which may be related to their known greater TGFβ1 production after puberty compared to male mice. However, urine TGFβ1 increased comparably in both sexes. Accumulation of profibrotic proteins fibronectin and collagens I, III, IV, and markers of T-cell and macrophage infiltration were also similar between sexes.

**Conclusions:** Female mice required a modification of the STZ protocol to maintain survival, but induce hyperglycemia. While somewhat more pronounced in male mice, both sexes developed typical characteristics of DKD. Future studies evaluating the potential of therapeutic interventions can thus be assessed in both sexes in this model of DKD.

## TH-PO187

### Investigating the Role of Early B Cell Factor 1 (EBF1) in Maintaining the Integrity of the Glomerular Filtration Barrier

Darrell C. Andrews, Jessica L. Davis, Eoin Brennan, John Crean, Catherine Godson. *University College Dublin, Dublin, Ireland.*

**Background:** Diabetic kidney disease (DKD) is the leading cause of end stage renal disease (ESRD) and organ failure worldwide. Current therapies are inadequate. Proteinuria is a hallmark of DKD and the onset of progressive proteinuria is associated with disease progression and reflects loss of glomerular filtration barrier (GFB) integrity. Defining the underlying mechanisms that lead to a compromised GFB during the progression of DKD is key to developing effective therapeutic strategies. EBF1 was previously identified by our GWAS analysis in a case (individuals with T1DM) vs. control (individuals with T1DM and no evidence of renal disease 15 years post-diagnosis) approach as associated with macroalbuminuria and ESRD (DOI: 10.1681/ASN.2019030218), however the precise mechanisms underlying the function of this gene in the kidney remain elusive.

**Methods:** In order to investigate the functional role of EBF1 in the kidney we utilised primary human mesangial cells and iPSC derived organoid cultures.

**Results:** Our previous investigations in Tg(l-fabp:DBP:EGFP) zebrafish demonstrated that morpholino mediated knockdown of EBF1 resulted in the loss of an albumin-like fluorescent tracer protein from the circulation and the development of generalised edema in zebrafish larvae, suggesting compromised glomerular barrier integrity in the absence of EBF1 and supporting a role for this gene in kidney function. EBF1 expression was investigated during iPSC derived organoid development. EBF1 was found to be most highly expressed in stromal cell populations. To investigate the precise molecular mechanisms underlying the functional role of EBF1 in such populations bulk RNA sequencing analysis was used to map deregulated transcripts in EBF1 knockdown human primary mesangial cells vs control. EBF1 target genes were inferred using motif enrichment analysis.

**Conclusions:** These findings further support a role for EBF1 in maintaining the integrity of the glomerular barrier integrity.

**Funding:** Government Support - Non-U.S.

## TH-PO188

### Ferroptotic Tubular Cell Death Is Facilitated in Diabetic Nephropathy in Mice

Francesca Maremonti,<sup>1</sup> Wulf Tonnus,<sup>1</sup> Anne M. Brucker,<sup>1</sup> Nina Himmerkus,<sup>2</sup> Florian Gembardt,<sup>1</sup> Christian Hugo,<sup>1</sup> Andreas Linkermann.<sup>1</sup> <sup>1</sup>*Technical University Dresden, Dresden, Germany;* <sup>2</sup>*Christian-Albrechts-Universität zu Kiel, Kiel, Germany.*

**Background:** Glycaemic dysregulation associated with diabetes mellitus is the cause of diabetic nephropathy (DN). DN progression involves renal tubular necrosis and glomerulosclerosis. Our previous data suggest that tubular damage involves a regulated form of iron-catalyzed necrosis referred to as ferroptosis. GIP (glucose-dependent insulintropic polypeptide) is an endogenous polypeptide hormone secreted by enteroendocrine K cells of the lower gut. Its receptor, GIPR (GIP receptor) is a G-coupled transmembrane receptor placed on the surface of pancreatic β-cells. GIPR dominant-negative transgenic mice (GIPR<sup>dn</sup>) are the first murine model that exhibits typical late complications of diabetes such as DN and atherosclerosis.

**Methods:** We employed GIPR<sup>dn</sup> mice to study the mechanisms and progression of DKD. Besides histological assessment, we detected serum urea and serum creatinine concentrations over the first year of age at 7, 10, 25, 40, and 50 weeks of age. At all time points, kidney tubules were freshly prepared to assess spontaneous tubular death patterns and LDH release assays over 6 hours following isolation. We monitored cell death propagation by live tubular fluorescence microscopy using Sytox Green and performed Fluorescence Lifetime Microscopy (FLIM). We investigated two models of acute kidney injury (AKI) such as ischemia-reperfusion injury (IRI) and cisplatin-induced AKI.

**Results:** Blood glucose levels and serum concentrations of urea and creatinine of GIPR<sup>dn</sup> transgenic mice were significantly increased in comparison to littermate controls. The difference reached statistical significance from 7 weeks of age. LDH release assays alongside with fluorescence live tubular imaging indicated sensitization to ferroptosis of GIPR<sup>dn</sup> tubules. In the live imaging and in FLIM analysis of freshly isolated tubules, we detected synchronized regulated necrosis and accelerated cell death propagation between tubular cells in the GIPR<sup>dn</sup> transgenic mice. In keeping with these observations, we detected strongly increased sensitivity to all AKI models tested.

**Conclusions:** First, we identify the renal tubule as a primary site of injury in diabetic nephropathy. Second, we conclude that GIPR<sup>dn</sup> mice and diabetic renal tubules are particularly sensitive to ferroptosis. Third, we identify ferroptosis as a novel drug target for AKI in DN.

## TH-PO189

### Role of Toll-like Receptors in Hyperglycemia Induced Injury in Proximal Tubules and Podocytes

Rohit Upadhyay,<sup>1</sup> Rhea Bhargava,<sup>1,2</sup> Vecihi Batuman.<sup>1</sup> <sup>1</sup>*Tulane University School of Medicine, New Orleans, LA;* <sup>2</sup>*Harvard Medical School, Boston, MA.*

**Background:** Diabetic kidney disease (DKD) is a progressive microvascular complication of diabetes mellitus where hyperglycemia induces injury in proximal tubules as well as podocytes and eventually develops in to end-stage renal disease (ESRD). The dysregulated metabolic environment mimicking hyperglycemia initiates DKD. Toll like receptors (TLRs) are first line of defense in innate immunity; however, the role of TLRs in hyperglycemia induced injury in proximal tubules and podocytes has not been well understood.

**Methods:** Human kidney proximal tubule cells (PTCs; HK2 cell line) and human podocytes were exposed to high glucose media at different time points *in vitro*. Cell proliferation, ROS generation, NO production, m-RNA/ protein expressions and mitochondrial dysfunction was checked in the cells after treating them with high glucose.

**Results:** We identified a differential role of TLRs in PTCs and podocytes. TLRs 2, 3, 4, 6 and 9 were activated in PTCs and podocytes cultured in high glucose media. SIRT1 downregulation was correlated with expression of cell specific injury markers (LCN2 for PTCs and SYNPO for podocytes). NLRP3 was activated at late time points; however, TNFA was identified as most prominent upregulated cytokine in time dependent manner for both cell types.

**Conclusions:** TLRs-TNFA-NLRP3 axis mediated injury to PTCs and podocytes could be a novel mechanism and promising target to treat DKD.

## TH-PO190

### Protein-Bound Uremic Toxins as Biomarkers of Kidney Tubular Function in Murine Long-Term Diabetic Nephropathy

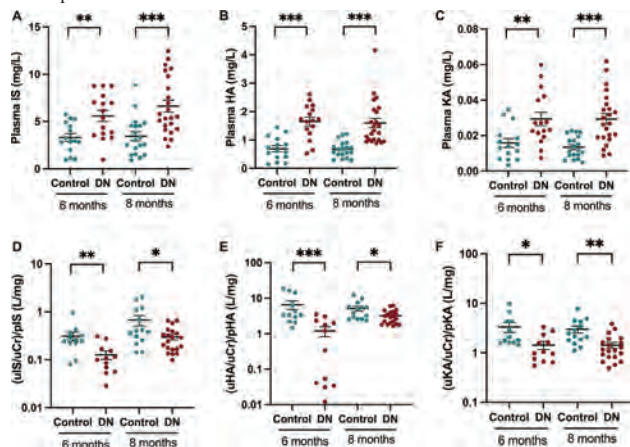

Sabbir Ahmed,<sup>1</sup> Rolf Sparidans,<sup>1</sup> Silvia M. Mihaila,<sup>1,2</sup> Roel Broekhuizen,<sup>2</sup> Roel Goldschmeding,<sup>2</sup> Tri Q. Nguyen,<sup>2</sup> Rosalinde Masereeuw,<sup>1</sup> Karin G. Gerritsen.<sup>2</sup> Prof. Roos' group, Pharmacology <sup>1</sup>*Universiteit Utrecht Utrechts Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands;* <sup>2</sup>*Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

**Background:** Kidney tubular damage is an important prognostic determinant in diabetic nephropathy (DN). A vital homeostatic function of the proximal tubule is the excretion of waste products, including protein-bound uremic toxins (PBUTs) that are actively being secreted via organic anion transporters (OATs), but accumulate in plasma in kidney dysfunction. We hypothesize that plasma concentration and renal clearance of PBUTs may be sensitive tubular function markers.

**Methods:** Diabetes mellitus was induced in C57Bl/6 mice by streptozotocin, which resulted in histopathological and functional kidney tubular damage after 6 and 8 months. PBTUs in plasma, 24h urine and kidney tissue were measured by LC-MS/MS.

**Results:** Among the PBTUs with the highest OAT affinity (*viz.* IS, HA and KA), plasma concentrations were 1.7-, 2.4- and 1.9-fold higher ( $p=0.005$ ,  $<0.001$ ,  $0.006$ ) after 6 months and 1.9-, 2.4- and 2.2-fold higher ( $p<0.001$ ,  $<0.001$ ,  $<0.001$ ) after 8 months in DN (Fig 1A-C), respectively. Their urinary excretions, normalized for plasma concentrations (i.e. a surrogate for clearance), were 2.4-, 5.4- and 2.3-fold lower ( $p=0.005$ ,  $<0.001$ ,  $0.01$ ) after 6 months and 2.3-, 1.6-, 2.1-fold lower ( $p=0.032$ ,  $0.017$ ,  $0.002$ ) after 8 months in DN (Fig 1D-F) respectively. The plasma concentration and clearance of these PBTUs correlated stronger with tubular atrophy, f4/80 scores and tubular injury markers than conventional filtration markers.

**Conclusions:** Tubular function is compromised in murine long-term DN, and plasma concentration and clearance of IS, HA and KA may represent biomarkers of kidney tubular function in DN. Future studies should focus on validation of the novel biomarkers in other species and forms of CKD.

Plasma concentration of IS, HA and KA elevated (A-C), and clearance reduced in DN mice after 6 and 8 months (mean  $\pm$  SEM). DN: diabetic nephropathy; IS: indoxyl sulfate; HA: hippuric acid; KA: kynurenic acid.

## TH-PO191

### Nicotinamide Riboside Ameliorates a Depressive Phenotype in Diabetic Kidney Disease

Katelyn Dial, Komuraiah Myakala, Xiaoxin Wang, Bryce A. Jones, Olga C. Rodriguez, Brent T. Harris, Chris Albanese, Moshe Levi. Levi Lab Georgetown University, Washington, DC.

**Background:** Diabetic kidney disease (DKD) is a risk factor for depression. Decreased NAD<sup>+</sup> is correlated with the pathogenesis of DKD, and nicotinamide riboside (NR) supplementation restores kidney function in DKD. However, NR has never been investigated in models of DKD for its potential in treating the depressive phenotype.

**Methods:** Ten week-old db/m or db/db mice were administered 500 mg/kg NR either in the diet or drinking water for 20 weeks. At 18 weeks of treatment, mice underwent single-voxel 1H-MR-Spectroscopy (MRS) and behavioral evaluation such as the Open Field Test (OFT) and assessment of nesting behavior. After euthanasia, PAS staining, MALDI-guided SpatialOMx, IHC, ELISA, RT-qPCR and Western Blot analysis were performed on the mouse brain and kidneys.

**Results:** PAS staining showed mesangial expansion in db/db mouse kidneys, which was reduced with NR treatment. Urinary KIM-1 and albumin were increased in db/db mice and reduced with NR. NAD<sup>+</sup> levels were significantly decreased in the brain frontal cortex (FC) of db/db mice compared to control mice, and NR treatment restored NAD<sup>+</sup> levels to normal levels. db/db mice exhibited anxiety behavior in the OFT and built significantly less quality nests compared to db/m mice. Interestingly, NR significantly improved db/db mouse behavior in the OFT. MALDI showed reductions in FC N-acetylaspartate, lysophosphatidylcholine and adenosine monophosphate, and increases in FC and hippocampal (HPC) taurine and lysophosphatidylethanolamine in db/db mice compared to db/m. MRS of the FC showed increases in the relative concentrations of taurine, myo-inositol and glutamate to glutamine ratio in db/db mice compared to db/m. NR treatment of db/db mice reduced hippocampal expression of Iba1, GFAP, and STING and FC expression of MCP1. In addition, p-GSK3B and PGC1 $\alpha$  protein levels were significantly increased in the HPC of db/db mice and reduced by NR treatment.

**Conclusions:** Improvements in kidney function with NR treatment coincided with improvements in depressive behavior, reduced brain inflammation, enhanced expression of mitochondrial regulators, and changes in brain metabolites in the FC and HPC. This suggests that NR has potential benefits in the treatment of depression comorbid to DKD.

## TH-PO192

### MDM2 Promotes Diabetic Nephropathy by Targeting Integrin $\beta$ 8 for Ubiquitin Degradation in Renal Pericytes

Yiling Cao, Jieyu Zeng, Xie Yaru, Chun Zhang. Department of Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.

**Background:** Diabetic nephropathy (DN) is one of the most frequent diabetic chronic microvascular complications. Renal pericytes play a critical role in maintaining vascular homeostasis and are the major source of interstitial myofibroblasts in the fibrotic kidney. We previously reported that murine double minute 2 (MDM2), an E3 ubiquitin ligase, is essential in mediating mesangial cell proliferation and extracellular matrix accumulation. However, the mechanism of MDM2 in renal pericytes injury remains to be unknown. Transforming growth factor beta 1 (TGF- $\beta$ 1) is a pivotal profibrotic mediator and integrin  $\beta$ 8 sequesters latent TGF- $\beta$ 1 to prevent its activation in mesangial cells. The present study sought to determine whether MDM2 could induce the activation of TGF- $\beta$ 1 through integrin  $\beta$ 8 ubiquitination, and lead to pericytes differentiation and endothelial cell damage.

**Methods:** We established STZ-induced DN mice model. Primary cultured pericytes and HBZY-1 were stimulated with high glucose (30 mM). The expressions of MDM2, Integrin  $\beta$ 8, TGF- $\beta$ 1, relative fibrotic markers and injury markers were measured by western blot and immunofluorescence. Inflammatory cytokines in culture medium were detected by Elisa kits.

**Results:** MDM2 and TGF- $\beta$ 1 elevated, while integrin  $\beta$ 8 decreased in pericytes of DN mice. After inhibiting MDM2 in pericytes and HBZY-1, the expression of integrin  $\beta$ 8 increased. Silenced MDM2 or overexpressed integrin  $\beta$ 8 could alleviate high glucose-induced TGF- $\beta$ 1 expression and fibrosis and inflammatory response. Meanwhile, the levels of TNF- $\alpha$ , IL-6, TGF- $\beta$ 1 in HBZY-1 culture medium were reduced after MDM2 knockdown or integrin  $\beta$ 8 overexpression. GECs were cultured with the aforementioned medium. The injuries of GECs were reversed in the MDM2 knockdown or integrin  $\beta$ 8 overexpression medium. MG132 prevented the decline of integrin  $\beta$ 8 and immunoprecipitation showed integrin  $\beta$ 8 ubiquitination was increased under high-glucose conditions. *In vivo*, immunofluorescence staining indicated pericytes differentiation into myofibroblasts and the microvascular rarefaction in DN mice.

**Conclusions:** These data indicated that the release of TGF- $\beta$ 1 by ubiquitination-mediated integrin  $\beta$ 8 degradation in pericytes is one of the downstream mechanisms of MDM2 profibrotic property, which contributes to pericytes differentiation into myofibroblasts and endothelial cell damage.

**Funding:** Government Support - Non-U.S.

## TH-PO193

### ACE Inhibition and GLP1 Receptor Agonism Have Direct Effects on the Glomerular Capillary Wall to Reduce Glomerular Albumin Permeability in Diabetes

Michael Crompton,<sup>1</sup> Matthew J. Butler,<sup>1</sup> Gavin I. Welsh,<sup>1</sup> Sagar Bhayana,<sup>2</sup> Rebecca R. Foster,<sup>1</sup> Agnes M. Benardeau,<sup>2</sup> Simon C. Satchell.<sup>1</sup> Bristol Renal <sup>1</sup>University of Bristol, Bristol, United Kingdom; <sup>2</sup>Novo Nordisk AS, Bagsvaerd, Denmark.

**Background:** The mainstay of therapeutics to protect from diabetic kidney disease are anti-hypertensive and anti-glycaemic agents, yet they seem to have additional protective effects on albuminuria. Our validated glomerular permeability assay was developed to directly measure the albumin permeability ( $Ps'_{alb}$ ) of capillary loops within individually trapped glomeruli. This *ex vivo* assay is independent of haemodynamic factors and tubular albumin handling – factors known to affect urine protein concentrations. Using our glomerular  $Ps'_{alb}$  assay, we aimed to understand whether renoprotective standard of care and new compounds could target the cells of the glomerular filtration barrier (GFB) directly.

**Methods:** A rat model of type 1 diabetes was utilised, whereby male Wistar rats were injected with streptozotocin (STZ, 50mg/kg I.P.). Rat glomeruli were isolated from perfused kidneys at week 4 and received a 1-hour treatment in 10% plasma with semaglutide (a glucagon-like peptide-1 receptor agonist), enalapril (an angiotensin-converting enzyme inhibitor), empagliflozin (a sodium-glucose co-transporter 2 inhibitor), angiotensin-1 (a positive control) or vehicle. Our glomerular  $Ps'_{alb}$  assay was used to measure changes in albumin permeability.

**Results:** Rats given STZ were significantly hyperglycaemic at week 1, which was sustained, confirming diabetes ( $P<0.001$ ). Diabetic rats developed albuminuria, with a significant increase in urine albumin:creatinine ratio at week 4 ( $P=0.0014$ ). Diabetes also induced a significant increase in  $Ps'_{alb}$  ( $P=0.005$ ), which was ameliorated by both semaglutide and enalapril to a level comparable with nondiabetic glomeruli. Empagliflozin had no significant effect on the diabetes-induced increase in  $Ps'_{alb}$ . In control glomeruli, semaglutide and enalapril alone had no effect compared with vehicle, suggesting no effect on otherwise healthy capillaries.

**Conclusions:** Semaglutide and enalapril both ameliorate the diabetes-induced increase in  $Ps'_{alb}$ , demonstrating a direct effect on the cells of the GFB in diabetes. Thus, a greater understanding of the mechanisms of glomerular protection mediated by these renoprotective compounds is needed to identify novel therapeutic strategies.

## TH-PO194

**Tenascin C: A Pathogenic Factor in Diabetic Nephropathy?**

Sharma S, Prabhakar, Hemalata Deshmukh. *Texas Tech University Health Sciences Center, Lubbock, TX.*

**Background:** Diabetic nephropathy (DN) is the most common cause of end stage renal disease in most parts of the world. The exact pathogenesis of DN is still unclear but renal fibrosis is a common end-result of all pathogenic mechanisms in DN. Tenascin C (TC) is an extra cellular matrix glycoprotein with pleiotropic effects. TC was shown to interact with several growth factors such as VEGF, IGF, EGF, and TGF  $\beta$ , suggesting its potential role in fibrotic process. While Tenascin C has been incriminated in the progression of CKD, the role of TC in DN has not been studied. We hypothesize that given the potential biological effects of TC, it may be involved in the pathogenesis of DN.

**Methods:** To test our hypothesis we used ZSF rats, an established murine model of DN to examine the expression of TC in the kidneys. Both male and female rats were used and CD rats were used as non-diabetic controls. Rats were studied from 8<sup>th</sup> week to 40<sup>th</sup> week. The ZSF rats were provided a high fat high calorie diet (Purina 5008) to maintain hyperglycemia while control rats were given standard rat chow. All animals were euthanized at 40<sup>th</sup> week and kidneys harvested to prepare tissue homogenates. Urine samples were drawn at the start and end of the study period. Western blots were performed using TC specific antibody on the kidney homogenates to find the expression of TC.

**Results:** ZSF rats developed obesity, diabetes, hypertriglyceridemia, hypertension and proteinuric renal failure while CD rats remained nondiabetic without hypertension, obesity or kidney involvement. Male ZSF rats were heavier (650 gm vs 510 gm) and more hyperglycemic (295 mg/dl vs 210 mg/dl) than females while proteinuria and decreased kidney function were more severe in males versus female ZSF rats. Expression of TC was significantly increased in the kidneys of ZSF rats (males more than females) compared to CD rats.

**Conclusions:** We conclude that ZSF rats exhibit severe metabolic syndrome with stronger phenotypic characteristics in male vs. female ZSF rats. The increased renal expression of TC the ZSF kidneys suggests that they could be biomarkers of DN and may potentially have a pathogenic role.

## TH-PO195

**L-Carnitine Ameliorates Diabetic Kidney Disease by Alleviating Mitochondrial Dysfunction in Spontaneously Diabetic Torii (SDT)-Fatty Rats**

Sakuya Ito, Kensei Taguchi, Yusuke Kaida, Goh Kodama, Tomofumi Moriyama, Yunosuke Yokota, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan.*

**Background:** Abnormal fatty acid metabolism is associated with the progression of diabetic kidney disease (DKD). Carnitine plays a central role in fatty acid  $\beta$ -oxidation by transporting long-chain fatty acids from the cytoplasm to the mitochondria. Juvenile visceral steatosis (jvs) mice, described as an animal model for systemic carnitine deficiency, introduce a marked ectopic fat accumulation in the kidney. These findings suggest that abnormal carnitine dynamics in DKD cause ectopic fat accumulation due to abnormality of the fatty acid metabolism. However, the association between abnormalities of carnitine metabolism and the progression of DKD is unknown.

**Methods:** Spontaneously Diabetic Torii (SDT) fatty rat, an obese type 2 diabetic model was used. Unilateral nephrectomy was performed and 0.3% salt water was administered at 6 weeks of age, and created a renal dysfunction model in SDT fatty rat (DKD model). Age-matched male Sprague-Dawley (SD) rat was used as a control. Experiment 1: We compared 3 groups; SD rats (n=8), SDT fatty rats (n=8), DKD rats (n=8). Experiment 2: We compared 3 groups; SD rats with sham operation (n=8), DKD rats (n=7), DKD rats treated with L-carnitine administration (0.75% L-carnitine diet) for 10 weeks (n=6). All rats were sacrificed at 17 weeks old. Carnitine was measured by the tandem-mass spectrometry.

**Results:** Plasma and renal free carnitine levels and short/middle-long chain acylcarnitine ratio were significantly decreased in DKD rats compared with those in SD and SDT fatty rats. The renal expression levels of OCTN2, CPT1a, CPT2 and CrAT were significantly decreased in DKD rats. Similarly, PGC1 $\alpha$  activity were decreased in DKD rats. L-carnitine administration significantly improved renal function, urinary albumin excretion, interstitial fibrosis and renal ectopic fat accumulation in DKD model rats. L-carnitine administration ameliorated the decrease of renal OCTN2, CPT1a, CPT2 and CrAT protein expression, and significantly improved PGC1 $\alpha$  activity in DKD model rats. Furthermore, L-carnitine administration mitigated oxidative stress and mitochondrial dysfunction in DKD rats.

**Conclusions:** L-carnitine administration might be a promising therapeutic strategy for improving renal function by alleviating mitochondrial dysfunction in DKD rat model.

## TH-PO196

**Differential Expression of Myo-Inositol Oxygenase (MIOX) Modulates Severity of Obesity-Associated Diabetic Nephropathy in Mice**

Isha Sharma, Susan E. Quaggin, Yashpal S. Kanwar. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Myo-inositol oxygenase (MIOX) is predominantly expressed in renal proximal tubules. Overexpression of MIOX in the setting of diabetes leads to exacerbation of renal injury; conversely genetic ablation of MIOX lessens the progression of nephropathy.

**Methods:** Six-weeks-old, wild type (WT), MIOX overexpressing (MIOX-TG) and MIOX-knockout (MIOX-KO) mice were fed with high fat diet (HFD) for 16 weeks. In addition, ob/ob mice were bred with MIOX-KO to generate ob/KO mice.

**Results:** We observed that MIOX deletion had no effect on obesity-driven phenotypes including body weight, triacylglycerol, cholesterol or insulin levels. Interestingly, MIOX-KO and ob/KO had reduced HFD-induced renal damage, as assessed in H & E and PAS-stained kidney sections. Obese WT and MIOX overexpressing mice showed proteinuria assessed by SDS-PAGE, which was reduced in mice with MIOX deletion. In addition, tubular injury, as assessed by increased NGAL and Kim-1 expression was reduced after MIOX deletion. No significant change was observed in serum creatinine or urea levels among various strains of mice. MIOX expression and activity increased following HFD administration, which was accompanied by increased ROS generation and perturbed redox potential in kidney. The Reactive oxygen species-mediated damage caused by lipid peroxidation and lipoprotein toxicity was reduced in mice with MIOX genetic deletion. In addition, we observed MIOX overexpression increased O-GlcNacetylation of renal proteins, which was substantially less in MIOX-KO mice. Interestingly, MIOX-TG mice showed increased SREBP-1 expression. Results of co-immunoprecipitation suggested that SREBP-1 is stabilized by O-GlcNacetylation. SREBP-1 transient knockdown in Palmitate BSA treated HK-2 cells attenuated fibronectin deposition. Results of immunofluorescence studies suggested that MIOX-KO and ob/KO mice had considerably decreased expression of fibronectin compared to WT or MIOX-overexpressor mice.

**Conclusions:** Together, our results suggest that some of the renal damage observed in the setting of obesity are ameliorated following MIOX gene disruption, and support pharmacologic downregulation of MIOX activity as a candidate therapy.

**Funding:** NIDDK Support

## TH-PO197

**A Signaling Module Linking DJ-1, PTEN, and PDGF Receptor  $\beta$  (PDGFR) Governs Activation of mTORC1 to Induce Proximal Tubular Epithelial Cell (PTEC) Injury in Diabetic Nephropathy (DN)**

Falguni Das, Nandini Ghosh-choudhury, Balakuntalam S. Kasinath, Goutam Ghosh-Choudhury. *UTHSCSA, San Antonio, TX.*

**Background:** PTEN inactivation and PDGFR tyrosine kinase-mediated mTORC1 activation have emerged as the centerpiece in pathogenesis of DN and tumorigenesis. The familial Parkinson's disease protein DJ-1 causes cancer. We investigated the hypothesis that DJ-1 acts as a driver of PDGFR-mediated mTORC1 activation in the progression of DN.

**Methods:** Human PTECs, OVE26 and db/db mice, and activation-specific antibodies, immunoblotting, plasmid-derived expression vector, siRNAs and promoter-reporter transfections were employed.

**Results:** In PTECs, 25 mM glucose (HG) increased expression of DJ-1. In determining its role in PTEC pathology, we showed that siRNAs against DJ-1 inhibited HG-induced PTEC hypertrophy and fibronectin and collagen I ( $\alpha$ 2) protein expression and their transcription, while forced expression of FLAG-DJ-1 increased these phenomena. As Akt/mTORC1 signaling regulates these effects of HG, we tested involvement of DJ-1. siDJ-1 inhibited HG-stimulated phosphorylation of Akt, its substrates GSK3 $\beta$ , tuberlin and PRAS40, and phosphorylation of S6 kinase, 4EBP-1 and mTOR. In contrast, FLAG-DJ-1 increased these phosphorylation events similar to HG. We have shown previously that HG-stimulated PTEC injury requires PDGFR stimulation of mTORC1 activity. Crucially, we showed that siDJ-1 decreased HG-stimulated phosphorylation of PDGFR at its docking sites of PI 3 kinase, whose function is known to be inactivated by PTEN, a dual specificity tyrosine and lipid phosphatase. Furthermore, we showed that HG increased association of DJ-1 with PTEN. We hypothesized that DJ-1-bound and inactivated PTEN lead to PDGFR phosphorylation. Interestingly, we showed that plasmid-derived expression of PTEN decreased HG-induced tyrosine phosphorylation of PDGFR and its substrate PI 3 kinase. In addressing the *in vivo* relevance of our results, in the renal cortex of OVE26 and db/db mice models of type 1 and type 2 diabetes, we found increased expression of DJ-1, PDGFR phosphorylation, mTORC1 activation and fibronectin and collagen I ( $\alpha$ 2) expression.

**Conclusions:** Together our results uncover a novel three layered molecular circuitry where PDGFR serves as a substrate of PTEN that is quenched by DJ-1 in PTEC injury in DN.

## TH-PO198

Cell Surface GRP78 and Integrin  $\beta 1$  Regulate TGF $\beta 1$ -Mediated Profibrotic Responses in Diabetic Kidney Disease

Jackie Trink, Renzhong Li, Evan J. Squire, Kian S. O'Neil, Bo Gao, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

**Background:** Diabetic kidney disease (DKD) is the leading cause of kidney failure in North America, characterized by glomerular accumulation of extracellular matrix proteins. High glucose (HG) induction of glomerular mesangial cell (MC) profibrotic responses play a central role in DKD pathogenesis. We recently showed that the endoplasmic reticulum resident protein GRP78 translocates to the cell surface (csGRP78) in response to HG. Here, with integrin  $\beta 1$  (Int $\beta 1$ ) as its coreceptor, it mediates PI3K/Akt activation and downstream profibrotic responses in MC. Transforming growth factor- $\beta 1$  (TGF $\beta 1$ ) is recognized as a central mediator of HG-induced profibrotic responses, but its inhibition is not feasible due to adverse effects. Here, we test whether csGRP78/Int $\beta 1$  can regulate TGF $\beta 1$  synthesis and activation by HG.

**Methods:** Primary MC were treated with 30mM HG. Standard molecular biology techniques were used for assessment.

**Results:** HG-induced TGF $\beta 1$  transcript upregulation and protein secretion were attenuated by specific inhibitory antibodies of either csGRP78 or Int $\beta 1$  and with siRNA knockdown of Int $\beta 1$ . The general integrin activator manganese (Mn) induced TGF $\beta 1$  upregulation and interestingly also induced translocation of GRP78 to the cell surface. Mn-induced TGF $\beta 1$  synthesis was attenuated by csGRP78 or Int $\beta 1$  inhibition. Once secreted, TGF $\beta 1$  resides in a latent state. We thus tested whether csGRP78/Int $\beta 1$  facilitated its activation. Inhibition of csGRP78 or Int $\beta 1$  as above prevented HG- and Mn-induced TGF $\beta 1$  signaling as assessed by activating phosphorylation of its downstream mediator Smad3. Conversely, the Int $\beta 1$ -activating antibody P4G11 induced both GRP78 cell surface translocation and TGF $\beta 1$  signaling. To confirm functionality of TGF $\beta 1$  signaling, MC were cocultured with the TGF $\beta 1$ -responsive mink lung epithelial cells (MLEC) stably expressing a PA1 promoter luciferase plasmid. HG-induced luciferase activity was attenuated by antibody inhibition of either csGRP78 or Int $\beta 1$ .

**Conclusions:** These data strongly support a role for csGRP78/Int $\beta 1$  in mediating HG-induced TGF $\beta 1$  upregulation, activation and profibrotic signaling in MC. Inhibition of csGRP78/Int $\beta 1$  signaling thus represents a novel target for attenuating fibrosis in DKD.

## TH-PO199

## Combination of Systemic ATRAP Deletion With Angiotensin II Stimulation Exacerbates Diabetic Nephropathy in Streptozotocin-Induced Diabetic Mice

Shinya Taguchi, Kengo Azushima, Hiromichi Wakui, Toru Suzuki, Shingo Urate, Eriko Abe, Shohei Tanaka, Shunichiro Tsukamoto, Kouichi Tamura. *Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

**Background:** One of the obstacles to understanding the pathophysiology of diabetic nephropathy (DN) has been the lack of reliable animal models that replicate features of human DN. Angiotensin II (Ang II) type 1 receptor (AT1R)-associated protein (ATRAP) promotes internalization of AT1R from the cell surface into the cytoplasm, resulting in the suppression of the AT1R signaling pathway. We have recently reported that systemic ATRAP deletion exaggerates streptozotocin (STZ)-induced DN via activation of the renal renin-angiotensin system (Haruhara K, et al. *Kidney Int* 2022). However, the increase in albuminuria in STZ-induced diabetic ATRAP knockout mice is still modest with limited pathological changes in glomerulus. To establish more robust DN models, we examined the effect of Ang II stimulation on the development of DN in STZ-treated ATRAP knockout mice.

**Methods:** Eight-week-old male C57BL/6 mice (Ctrl) and systemic ATRAP-knockout mice (KO) were divided into three groups: 1) Ctrl-STZ, 2) Ctrl-STZ-Ang II, and 3) KO-STZ-Ang II. Hyperglycemia was induced by intraperitoneal injection of 55 mg/kg STZ for consecutive 5 days. From 4 weeks after STZ, Ang II (1000 ng/kg/min) was continuously administered for 6 weeks. During the experimental period, body weight (BW) and blood glucose (BG) were measured every 2 weeks. At the end of the experimental period, 24-hour urine samples were collected, and mice were euthanized to evaluate renal pathological changes.

**Results:** During the experimental period, BW gain and BG were not significantly different between the three groups. Nonetheless, the KO-STZ-Ang II group exhibited a remarkable increase in the urinary albumin excretion levels compared to the Ctrl-STZ and Ctrl-STZ-Ang II groups at the end of the experimental period (679.1 $\pm$ 583.7 vs 69.9 $\pm$ 10.0 vs 61.3 $\pm$ 8.2  $\mu$ g/day, respectively). Furthermore, the histopathological analysis revealed a worsening of DN, an exacerbation of mesangial expansion and interstitial fibrosis, in the KO-STZ-Ang II group.

**Conclusions:** The results of present study showed that systemic ATRAP deletion in combination with Ang II stimulation accelerated the development of DN in STZ-induced diabetic mice, suggesting a potential to become a promising mouse model replicating key features of human DN.

## TH-PO200

## IL-34 Mediate the Development of Diabetic Nephropathy by Promoting Macrophage Infiltration

Wang Y. Ning, Ke Zheng, Gangan Wang, Li X. Mei. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

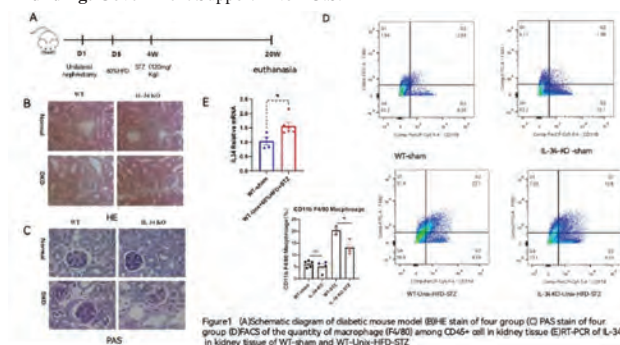

**Background:** Diabetic nephropathy (DN) is the leading cause of end-stage renal disease around the world. Macrophages contribute to the development of renal injury and sclerosis. IL-34, expressed by tubular epithelial cells (TECs), promotes macrophage survival and proliferation by binding to the cFMS receptor and PTPRZ receptor on macrophages in SLE and AKI. The role of IL-34 in diabetic nephropathy and its effect on the quantification and polarization of macrophages have not been elucidated.

**Methods:** To validate the role of IL-34 in diabetes kidney disease, we established progressive diabetes nephropathy by unilateral nephrectomy combined with a 60% high-fat diet and STZ (120mg/kg) injection(Unx+60%HFD+STZ) based on WT and IL-34 KO mice respectively. Meanwhile, the sham operation group was used as the experimental control group. After 16 weeks of injection with STZ, we collected the kidney samples to evaluate the injury extent of the kidney, and flow cytometry was used to evaluate the quantification and polarization direction of macrophages.

**Results:** In vivo, compared with the sham group, the mRNA level of IL-34 in kidney tissue was significantly up-regulated in WT-Unx+60%HFD+STZ. The result of HE staining and PAS staining showed that under the circumstance of unilateral nephrectomy model of high fat, IL-34 KO mice present less renal tissue pathological injury than WT mice. IL-34 KO-Unx+60%HFD+STZ mice had less infiltration of macrophages than WT - Unx+60%HFD+STZ renal tissue.

**Conclusions:** IL-34 accelerates the progression of diabetes by promoting macrophage infiltration, targeting IL-34 knockout can delay the progression of diabetic nephropathy.

## TH-PO201

## Xanthine Oxidase Inhibition Ameliorates High Glucose-Induced Oxidative Stress by Activating AMPK Through the Purine Salvage Pathway in Glomerular Endothelial Cells

Yu Ah Hong,<sup>1,2</sup> Keum-Jin Yang,<sup>2</sup> Wonjung Choi,<sup>1,2</sup> Yoon-Kyung Chang,<sup>1,2</sup> Suk young Kim,<sup>1,2</sup> Cheol Whee Park.<sup>1</sup> *<sup>1</sup>Catholic University of Korea School of Medicine, Seoul, Republic of Korea; <sup>2</sup>Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

**Background:** Oxidative stress plays a crucial role in the pathogenesis of diabetic kidney disease. Xanthine oxidase (XO) contribute to reactive oxygen species (ROS) production, and XO inhibitors have been reported to the protection of kidney diseases. We investigated the cytoprotective mechanism associated with activated AMP-activated protein kinase (AMPK) by XO inhibition in high glucose (HG) condition.

**Methods:** Glomerular endothelial cells (GENCs) exposed to HG were treated with or without febuxostat for 48 hours, and then the phosphorylation of AMPK and its related signaling pathway were evaluated.

**Results:** Febuxostat enhanced cell survival in a dose-dependent manner and decreased ROS in HG-treated GENCs. Febuxostat enhanced phosphorylation of AMPK, and activation of peroxisome proliferator-activated receptor (PPAR)-gamma coactivator (PGC)-1 $\alpha$  and PPAR- $\alpha$ , and dephosphorylation of the Forkhead box O (FoxO)3a in HG-treated GENCs. Febuxostat also suppressed NADPH oxidase expressions and enhanced SOD activity in HG-treated GENCs. The expressions of xanthine/hypoxanthine were significantly reduced, and the levels of xanthine oxidoreductase were increased in HG-treated GENCs, and these findings were attenuated by febuxostat. The intracellular AMP/ATP ratio was inhibited in HG-treated GENCs and enhanced by febuxostat. AMPK inhibition using small interfering RNA suppressed HPRT1 activity and suppressed PGC-1 $\alpha$ -FoxO3a signaling and finally abolished the antioxidant effects by febuxostat in HG-treated GENCs.

**Conclusions:** XO inhibition attenuates HG-induced oxidative stress through the activation of AMPK-PGC-1 $\alpha$ -FoxO3a-NADPH oxidase signaling via purine salvage pathway.

## TH-PO202

**The HIV Protease Inhibitor Darunavir Restores Autophagy in Kidneys of Diabetic Mice**

Michael J. Ross, Heidi Karttunen, Xiaobo Gao. *Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Despite the success of antiretroviral therapy (ART) in improving mortality, persons with HIV have increased risk of death, and kidney disease and diabetes are important contributors to their excess mortality. Data from our laboratory demonstrate that the HIV protease inhibitor darunavir (DRV) prevents kidney disease in HIV-transgenic mice via mechanisms independent of HIV protease and also reduces albuminuria and molecular markers of kidney injury in mice with diabetic kidney disease (DKD). Since autophagy is cytoprotective against HIV and diabetes-induced kidney injury, and autophagy is reduced in the kidneys of patients with DKD, we studied the effect of DRV upon autophagy in a murine model of DKD.

**Methods:** eNOS<sup>-/-</sup> 9 week-old C57BL/6 mice, which develop more severe nephropathy than wild-type C57BL/6 mice, underwent induction of diabetes by administration of 5 daily 50mg/kg doses of streptozotocin (STZ) injection. 14 weeks after diabetes induction, mice were treated with either DRV (100mg/kg) or control by daily oral gavage for 4 weeks. Urinary albumin creatinine ratio (ACR) assay, immunocytochemistry, western blotting and real-time PCR were performed with routine protocols in our laboratory.

**Results:** STZ induced severe sustained hyperglycemia and kidney injury in eNOS<sup>-/-</sup> mice, which resulted in marked increase urine ACR, which was reduced by DRV. Western blotting and immunofluorescence studies demonstrated marked accumulation of lipidated LC3 (LC3-II) and p62 in kidneys of diabetic eNOS<sup>-/-</sup> mice, indicating reduced autophagic flux. Accumulation of LC3-II and p62 in diabetic eNOS<sup>-/-</sup> kidneys was most apparent in tubular cells. DRV treatment reduced LC3-II and p62 in diabetic eNOS<sup>-/-</sup> mice to levels that were similar to non-diabetic mice.

**Conclusions:** Kidneys of diabetic eNOS<sup>-/-</sup> mice had reduced autophagic flux (accumulated LC3-II and p62) compared to non-diabetic mice, which was reversed by DRV. Our previous studies demonstrated that DRV reduced albuminuria and molecular markers of glomerular and tubular injury in mice with DKD. Our data suggest that DRV may protect against DKD via normalization of autophagic flux. Since reducing albuminuria may affect autophagy in tubular cells, future studies will determine whether the effect of DRV upon autophagy is independent of its effects on albuminuria.

## TH-PO203

**PGC1 $\alpha$  Modulates Mitochondrial Homeostasis in Tubular Cells of Diabetic Kidney Disease**

Siyang Ye,<sup>1,2</sup> Bin Li,<sup>1,2</sup> Yuting Fan,<sup>1,2</sup> Yi Lin,<sup>1,2</sup> Suchun Li,<sup>1,2</sup> Huajing Peng,<sup>1,2</sup> Hui Diao,<sup>1,2</sup> Wei Chen.<sup>1,2</sup> <sup>1</sup>*Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China;* <sup>2</sup>*NHC Key Laboratory of Clinical Nephrology (Sun Yat-sen University) and Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China.*

**Background:** Tubular injury and dysregulated mitochondrial dynamics play pivotal roles in the pathogenesis of diabetic kidney disease (DKD). However, the potential mechanism by which mitochondrial dysfunction-initiated tubulopathy triggers intrarenal signaling and mediates DKD progression remains elusive. Our current study aims to investigate the effect of PGC1 $\alpha$ -modulated mitochondrial homeostasis on kidney tubular cells of DKD and to explore the underlying mechanisms.

**Methods:** Human renal proximal tubule epithelial cells (HK-2) were cultured in the presence of palmitic acid (PA, 500  $\mu$ M) plus high glucose (HG, 40 mM) to imitate the diabetic microenvironment. PGC1 $\alpha$  was overexpressed in cultured HK-2 cells through plasmid transfection to perform functional experiments. Mitochondrial status and the related molecular patterns were assessed using multiple standard molecular biology techniques.

**Results:** The transcript and protein expression profile of PGC1 $\alpha$  were significantly inhibited when HK-2 cells were exposed to PA plus HG. In parallel, transcription factor A (TFAM), the important mediator of mitochondrial biogenesis, as well as PTEN-induced kinase 1 (PINK1) and Parkin (parkin RBR E3 ubiquitin protein ligase), the key regulators of mitophagy, were significantly suppressed at both transcriptional and protein level, which resulted in obviously blunted mitochondrial biogenesis and mitophagy, as evidenced by reduced mitochondrial content including mitochondrial marker TOM20 (translocase of outer mitochondrial membrane 20), mitochondrial volume and mitochondrial DNA. Moreover, mitochondrial dysfunction led to dramatically elevated proinflammatory mediators including IL6, IL8, and ICAM1 (intercellular adhesion molecule 1) in cultured HK-2 cells. More importantly, PA plus HG-initiated perturbation of intracellular mitochondrial dynamics and inflammation were prevented by overexpression of PGC1 $\alpha$  in cultured HK-2 cells.

**Conclusions:** Findings from our study support an important role for PGC1 $\alpha$  in preventing DKD-induced mitochondrial dysfunction in tubular cells via maintaining the activation of TFAM and PINK1/Parkin signaling. Functionally, this enables the mitochondrial homeostasis and diminishes the consequent inflammation in the microenvironment of DKD. Means of targeting PGC1 $\alpha$ -regulated mitochondrial homeostasis represents a promising target for the treatment of DKD.

## TH-PO204

**The Genetic Background Predicts the Kind of Renal Damage and Fibrosis Progression in Diabetic Patients**

Paola Pontrelli, Claudia Cinefra, Francesca Conserva, M. Rossini, Francesco Pesce, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

**Background:** Diabetic Nephropathy (DN) is the major causes of end-stage renal failure; renal damage in the diabetic patient can be real DN or non-diabetic renal disease (NDRD). We demonstrated that a characteristic feature only of real DN is an increase in Lys63-ubiquitination (PMID: 27881486; 29806072; 31388051; 34068941). The goal of this project was to identify single nucleotide polymorphisms (SNPs), associated to genes involved in Lys63 ubiquitination, able to predict the different kind of renal damage and the progression of kidney disease in diabetic patients.

**Methods:** We selected 10 HapMap SNPs within coding and regulatory sequences both of miR27b-3p and miR1228-3p, all involved in Lys63 ubiquitination, in order to evaluate their diagnostic and prognostic potential. 203 patients were enrolled in this study, in particular we included: diabetic patients with: i) DN, ii) NDRD, iii) without clinical signs of impaired renal function (T2D), iv) with coexistence of both conditions (ND+NDRD); non-diabetic patients with glomerulonephritis (CKD) or without renal damage (CTRL).

**Results:** The analyzed SNPs showed a different genotype frequency among all the patients classes. Interestingly, SNPs rs47, rs475, rs474, rs38 showed a statistically significant difference in genotypes frequency comparing DN patients with CEU Population ( $p < 0.04$ , 0.05, 0.002, 0.001 respectively) and a control cohort enclosing CTRL and T2D ( $p < 0.02$ , 0.05, 0.001, 0.04 respectively). SNPs rs76, rs107, rs23 genotypes frequency was statistically different among DN patients and the control cohort ( $p < 0.001$ ). The genotype frequencies of the SNPs rs107 ( $p < 0.01$ ) and rs78 ( $p < 0.04$ ) resulted significantly related to tubular fibrosis in DN patients, while the SNPs rs47 ( $p < 0.03$ ) and rs76 ( $p < 0.02$ ) to the glomerular one. In order to evaluate the diagnostic power of the identified SNPs, we used a logistic regression model, and we observed that the SNP rs107, adjusted for age, sex, eGFR and glycaemic index, discriminate DN from NDRD ( $p < 0.05$ ; OR=1.002-1.008; 95% CI).

**Conclusions:** Our data demonstrated that the allelic forms of the analyzed SNPs are related to the different kind of renal damage in diabetic patients. Their prognostic and diagnostic potential could represent the starting point to create a new non-invasive diagnosis system based on clinical and genotyping data.

## TH-PO205

**Lipoxins Protect Against Diabetic Kidney Disease by Attenuating the Expression of Inflammatory Genes**

Phillip Kantharidis,<sup>1</sup> Madhura Bose,<sup>1</sup> Victoria Priori,<sup>2,1</sup> Muthukumar Mohan,<sup>1</sup> Eoin Brennan,<sup>3</sup> Catherine Godson,<sup>3</sup> Mark E. Cooper.<sup>1</sup> <sup>1</sup>*Monash University Department of Diabetes, Melbourne, VIC, Australia;* <sup>2</sup>*Ecole de Biologie Industrielle, Cergy, France;* <sup>3</sup>*School of Medicine and Conway Institute, University College Dublin, Dublin, Ireland.*

**Background:** Many factors contribute to the pathology observed in diabetic kidney disease (DKD) with chronic hyperglycaemia driving the increased generation of ROS and AGEs, ultimately leading to inflammation and kidney fibrosis. In recent years, there has been growing appreciation that the failure of effective resolution of inflammation may underpin DKD. In this context the efficacy of lipoxins [LXs], lipid mediators that promote the resolution of inflammation and suppress fibrosis has been proposed. Here we examined the efficacy of LXs and novel synthetic LX mimetics in experimental DKD compared to candesartan, the current standard of care.

**Methods:** Six-week-old male ApoE KO mice were rendered diabetic by five daily intra-peritoneal (IP) injections of streptozotocin (55mg/kg). Blood glucose and HbA1c were measured to determine diabetes status. Control and diabetic mice were randomly selected to receive vehicle (0.02% ethanol), LX<sub>4</sub> (5 $\mu$ g/kg), or two mimetics, AT-02-CT (1.7 $\mu$ g/kg) or AT-01-KG (3 $\mu$ g/kg) via IP (n=24/gp), twice weekly. At endpoint, mice were culled and kidneys collected for gene expression, immunohistochemistry and histology.

**Results:** Diabetic mice displayed elevated blood glucose, HbA1c and albuminuria compared to control. These changes were accompanied with significantly increased fibrotic (fibronectin, Col 1), inflammatory (TNF $\alpha$ , MCP1, IL-6) and adhesion markers (VCAM-1, ICAM-1). Administration of candesartan, LX<sub>4</sub> or the mimetics significantly reduced inflammatory and adhesion marker expression in diabetic kidney. LX<sub>4</sub> and the mimetics also resulted in significantly decreased albuminuria (~40%) and reduced mesangial expansion. LX<sub>4</sub> and the mimetics were equally effective against fibronectin, collagen 1 and inflammatory markers compared to candesartan alone. However, when compared to the combination treatment with candesartan, Lipoxins alone provide superior protection.

**Conclusions:** Our findings demonstrated that LX and synthetic LX mimetics protect against DKD by attenuating fibrotic and inflammatory signalling and improving kidney function. For some parameters, Lipoxins provided superior protection compared to candesartan, including the combination treatments with candesartan. These results support the use of Lipoxins as a novel pro-resolving approach for the treatment of DKD.

TH-PO206

**Small Molecule Screening Identifies TW-37 as a KIM-1 Inhibitor and Potential Anti-Fibrotic Molecule**  
Amrendra K. Ajay,<sup>1,2</sup> Yutaro Mori,<sup>1</sup> Venkata Sabbiseti,<sup>1</sup> Joseph V. Bonventre.<sup>1,2</sup>  
<sup>1</sup>Brigham and Women's Hospital Department of Medicine, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Kidney Injury Molecule-1 (KIM-1) is a glycosylated protein upregulated following proximal tubular injury. With acute and chronic injury, KIM-1 mediates the uptake of apoptotic cells, oxidized lipids, advanced glycation end products (AGEs), and albumin bound to long chain fatty acids. Overexpression of KIM-1 causes chronic kidney disease (CKD) in mice.  
**Methods:** We developed a high throughput cell-based functional assay for KIM-1 mediated uptake of ox-LDL, and screened 14,414 unique small molecules. After setting up a histological score based on the potential to inhibit cellular ox-LDL uptake for each compound, 240 potential hits were cherry-picked from the primary screening. Raman spectroscopy was employed to investigate the binding of KIM-1 to TW-37. The effectiveness of the selected compound was evaluated in a mouse model of kidney fibrosis.

**Results:** TW-37, a second-generation benzenesulfonyl derivative of gossypol, had the greatest inhibitory effect on ox-LDL uptake. TW-37 is known to have Bcl2 inhibitory activity; however, Bcl-2 blockade with another specific Bcl-2 inhibitor, ABT-263, did not inhibit KIM-1 dependent ox-LDL uptake. TW-37 is not toxic to cells at concentrations up to 11µM. TW-37 neither cleaves KIM-1 nor quenches the fluorophores in our assay systems. Our *in silico* docking revealed a putative TW-37 binding pocket which spans from residues 37 to 52 of KIM-1. TW-37 specifically binds to recombinant KIM-1 and not to the BSA as determined by Raman spectroscopy. We observed a drop in the loops and turn content (44 to 34.5 percent) and an enhanced beta sheet content (42 to 53.5 percent) in the KIM-1+TW-37 sample compared to native KIM-1 spectrum. TW-37 significantly inhibits the uptake of BODIPY-labeled palmitic acid bound to albumin. TW-37 reduces kidney fibrosis induced by palmitic acid-albumin (0.5 mmol/kg PA and 2.5 g/kg BSA) administration daily from days 7 to 14 after aristolochic acid (5 mg/kg) administration.

**Conclusions:** We have identified and characterized TW-37 as an inhibitor of KIM-1 binding. TW-37 protects mice from kidney fibrosis. Thus, TW-37 has potential use as a therapeutic for the treatment of kidney disease where chronic KIM-1 mediated uptake of luminal contents into the proximal tubule contributes to chronic injury and maladaptive repair.

TH-PO207

**ABCA1 Deficiency Primes Inflammasome via APE1/IRF1 Axis in Podocytes**  
Marie Ito, Javier T. Varona Santos, Margaret Z. Gurumani, Alexis J. Sloan, Sandra M. Merscher, Alessia Fornoni. *University of Miami School of Medicine, Miami, FL.*

**Background:** Decreased ATP Binding Cassette Transporter A1 (ABCA1) expression and Caspase-4-mediated noncanonical inflammasome have been described in diabetic kidney disease (DKD). However, a direct link between these two pathways as not been established.

**Methods:** To investigate the role of ABCA1 deficiency in inflammasome, we stably transfected human podocytes with scrambled siRNA as a negative control (siCO) and siABCA1 RNA (siABCA1). Podocytes with transient siRNA knockdown of Interferon regulatory factor 1 (IRF1) were used to study the role of IRF1 in inflammasome. Podocytes were treated with TAK-242 (TLR4 inhibitor) or APX3330 (APE1 redox inhibitor) to investigate the role of toll-like receptor 4 (TLR4) and Apurinic/aprimidinic endonuclease 1 (APE1) in IRF1 regulation. The nuclear fractions of siCO and siABCA1 podocytes were isolated using the ab109719 cell fractionation kit and protein levels of APE1 were evaluated by Western blot analysis. mRNA and protein levels of IRF1 and inflammasome-related genes (NLR family pyrin domain containing 3 (NLRP3), Caspase-4, Gasdermin D, Caspase-1 and Interleukin 1β (IL1β)) were quantified by Western blot analysis and real-time PCR.

**Results:** In siABCA1 podocytes, mRNA levels of IRF1, Caspase-4, GSDMD, Caspase-1 and IL1β but not of NLRP3 and protein levels of Caspase-4, GSDMD and IL1β were significantly increased compared to siCO podocytes. Since IRF1 regulates the expression of Caspase-4, GSDMD and/or Caspase-1 in macrophages, we conducted siRNA knockdown of IRF1 and find that IRF1 knockdown in siABCA1 podocytes prevented increases in Caspase-4, GSDMD and IL1β expression. As candidate mechanism in siABCA1-mediated IRF1 regulation, we next investigated the role of TLR4, which was shown by others to mediate NLRP3 activation in ABCA1 deficient proximal tubular cells, and of APE1, which is excreted from cells via ABCA1. Whereas TAK-242, did not decrease mRNA levels of IRF1 and Caspase-4, APX3330 abrogated siABCA1-induced expression of IRF1 and Caspase-4. APE1 protein expression was also increased in the nuclear fraction of siABCA1 podocytes compared to siCO.

**Conclusions:** These data indicate that ABCA1 deficiency in podocytes caused nuclear APE1 accumulation, which reduces transcription factors to increase the expression of IRF1 and IRF1 target inflammasome-related genes, leading to proptosis priming.

TH-PO208

**CXCL5 Inhibition Attenuates Diabetic Kidney Disease in a Mouse Model of Type 2 Diabetes Mellitus**  
Ting-Ting Chang,<sup>1</sup> Ching Chen,<sup>1</sup> Jaw-Wen Chen.<sup>2</sup> <sup>1</sup>National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan; <sup>2</sup>Taipei Veterans General Hospital, Taipei, Taiwan.

**Background:** Diabetic kidney disease (DKD) is typically characterized by progressive proteinuria and decreasing glomerular filtration rate, which might finally progress to end stage renal disease. Chemokines are critically involved in the inflammatory progression in the development of DN. CXC motif chemokine ligand 5 (CXCL5), a CXC type chemokine, is found upregulated in clinical and experimental diabetes mellitus (DM). Given the potential involvement of CXCL5 in the development or progression of DKD, this study sought to investigate the direct impacts of CXCL5 inhibition on DKD in experimental type 2 DM.

**Methods:** *Lepr<sup>db</sup>/J*Narl type 2 DM mice were used for a mouse model of DKD. Mice were randomly assigned to receive an anti-CXCL5 neutralizing monoclonal antibody or a control antibody for 4 weeks. Serum blood urea nitrogen (BUN), creatinine (Cre), and uric acid levels were examined before and after the treatment. Urinary albumin-to-creatinine ratio (UACR) and kidney-to-body weight ratio were measured. Renal glomerulosclerosis and fibrosis were also evaluated by Periodic acid-Schiff staining and Masson's trichrome staining after the treatment.

**Results:** Serum CXCL5 concentrations, body weight, and blood glucose levels were upregulated in the DKD mice. Serum BUN, Cre, and uric acid levels that were enhanced in DKD mice with a control antibody were decreased in mice treated with an anti-CXCL5 antibody. The UACR and kidney-to-body weight ratio were attenuated by the treatment of anti-CXCL5 antibodies compared to that of control antibodies. Furthermore, glomerular hypertrophy, glomerulosclerosis, and renal fibrosis were also reduced in DKD mice that received the anti-CXCL5 antibody.

**Conclusions:** Our pilot findings suggested that *in vivo* CXCL5 inhibition could improve renal function and reduce urinary albumin-to-creatinine ratios, glomerular hypertrophy, glomerulosclerosis, and renal fibrosis in DKD mice. The molecular mechanistic insights may be further explored to provide a novel theoretical basis for CXCL5 as a potential therapeutic target in DKD.

TH-PO209

**Repeated Doses of Cisplatin (Cis)-Induced Renal Failure Is Associated With Increased Intestinal Permeability and Glucose Intolerance**  
Siddhartha S. Ghosh, Sarah Bu, Graham T. Gipson, Todd W. Gehr. *Virginia Commonwealth University, Richmond, VA.*

**Background:** Repeated doses of Cis have been shown to cause CKD. We show that Cis-induced renal failure can also cause glucose and insulin intolerance, and increased intestinal permeability, in addition to inflammation. We further show that sodium butyrate (NaB), a protector of the intestinal barrier improved renal function, glucose tolerance, and inflammation.

**Methods:** FVBn mice (n=5) were divided into Control (saline), Cis group (7 mg/kg cisplatin ip) every week for 4 weeks. Cis+NaB (7 mg/kg Cis+ NaB 400 mg/kg/day). Euthanized 8 weeks after the last Cisplatin injection. Glucose and insulin tolerance tests (GTT & ITT) were done 2 weeks and 1 week before sacrifice. Oral FITC dextran was used to assess intestinal permeability, 2 hours before sacrifice collected blood was analyzed for FITC and for renal function. Urine, kidney and colon were also harvested. Inflammatory cytokines TNFα, IL6, and ILβ of the kidney and colon were measured by QPCR and the results were further confirmed by western blots in the kidney. Colonic mucin was stained.

**Results:** As shown in the table there was deterioration of renal function, glucose tolerance, and intestinal permeability with Cis that was corrected by NaB. TNFα, IL6 and IL1β in the colon of cisplatin group were 2 to 3fold higher than control (p<0.05) that was significantly lowered by butyrate. Both qPCR and western showed increased cytokines in the kidney (3 to 7fold p<0.050). Butyrate reduced TNFα and IL6 but not IL-1β. A significant loss of mucin was observed in the colon of cisplatin treated mice which was abrogated with butyrate.

**Conclusions:** Cis-mediated inflammation and loss of colonic mucin likely changed intestinal permeability and caused hyperglycemia and renal dysfunction. Butyrate, a colonic nutrient, and HDAC inhibitor prevented intestinal permeability and inflammation resulting in improved renal function, GTT, and ITT.

	Control (C)	Cis	Cis+NaB

### Role of Exosome-Mediated Intraglomerular Cross-Talk Between Mesangial Cells and Macrophages in the Progression of Diabetic Kidney Disease

Daisuke Fujimoto, Shuro Umemoto, Takashige Kuwabara, Ryosuke Date, Yusuke Hata, Teruhiko Mizumoto, Yuichiro Izumi, Masashi Mukoyama. *Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto City, Japan.*

**Background:** Extracellular vesicles (EVs) are important mediators of intercellular communication in the regulation of physiological and pathophysiological processes. Particularly, exosome-mediated intercellular crosstalk has been addressed in several disorders such as cancer and lifestyle-related diseases. In diabetic kidney disease (DKD), it has been reported that macrophages infiltrating the mesangial region may play an important role through inducing local inflammation in glomeruli. However, mechanisms for DKD progression and roles of exosome-mediated processes remain elusive.

**Methods:** We focused on exosomes as possible key factors acting in a paracrine manner in glomeruli and examined the effects of mesangial cell (MC)-derived exosomes on macrophages in culture. In order to identify new therapeutic agents, we screened a validated compound library that can efficiently inhibit this mechanism and also studied their effects on DKD.

**Results:** Exosomes derived from MCs induced inflammation in macrophages, demonstrated by the NFκB transcriptional activity, and TNFα and IL-1β expressions. The effect was significantly enhanced in exosomes from MCs cultured under high-glucose conditions compared to low-glucose conditions. We observed that fluorescent-labeled exosomes were endocytosed by macrophages *in vitro* and *in vivo*. Next, we conducted drug screening using a compound library to find candidates that could specifically and effectively inhibit the inflammation process induced by exosomes. The screening was divided into four steps, and we succeeded in narrowing down the list to 30 candidate compounds from a total of 1,364 compounds. Finally, an HSP90 inhibitor, alvespimycin, was identified as a compound with strong inhibitory effects on both exosome uptake and the NFκB transcriptional activity. Treatment of a diabetic rat model with alvespimycin significantly reduced proteinuria and tended to suppress mesangial expansion.

**Conclusions:** Local inflammation by exosome-mediated crosstalk between MCs and macrophages could be involved in DKD progression. Furthermore, alvespimycin, one of the HSP90 inhibitors obtained by drug screening, can effectively ameliorate this process, suggesting that such mechanism could become a novel therapeutic strategy for DKD.

### SGLT2 Inhibitors Enhance Metallothionein Expression in Kidney Proximal Tubules of Adolescents With Type 2 Diabetes

Fadhl Alakwaa,<sup>1</sup> Phillip J. McCown,<sup>1</sup> Abhijit S. Naik,<sup>1</sup> Jennifer A. Schaub,<sup>1</sup> Rajasree Menon,<sup>1</sup> Edgar A. Otto,<sup>1</sup> Viji Nair,<sup>1</sup> Sean Eddy,<sup>1</sup> Laura Pyle,<sup>4</sup> Roger K. Harned,<sup>4</sup> Patricia E. Ladd,<sup>4</sup> Felix H. Eichinger,<sup>1</sup> Damian Fermin,<sup>1</sup> Wenjun Ju,<sup>1</sup> Jeffrey B. Hodgins,<sup>1</sup> Robert G. Nelson,<sup>3</sup> Frank C. Brosius,<sup>2</sup> Matthias Kretzler,<sup>1</sup> Petter Bjornstad.<sup>4</sup> Kidney Precision Medicine Project <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>University of Arizona, Tucson, AZ; <sup>3</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; <sup>4</sup>University of Colorado School of Medicine, Aurora, CO.

**Background:** Oxidative stress is a main contributor to diabetic kidney disease (DKD), and SGLT2 inhibitors (SGLT2i) mitigate DKD onset in type 2 diabetes (T2D). An investigation of cell-type specific molecular reprogramming in the kidney with SGLT2i treatment was undertaken in young persons with T2D.

**Methods:** Single-cell RNA sequencing (scRNAseq) profiles of young persons (17±2 years) with T2D, treated with SGLT2i (N=10, T2Di+) or not (N=6, T2Di-), and healthy controls (N=6, HC) were obtained from protocol kidney biopsies. Similarly derived scRNAseq data were available for living donors (N=20, LD), T2D Pima Indians with DKD (N=42), and Kidney Precision Medicine Project (N=12) cohorts. Analysis of scRNAseq data identified differentially expressed genes (DEGs). enrichR enabled pathway enrichment analysis of DEGs.

**Results:** All participants had normal to elevated GFR by iothelox clearance (185-224 ml/min). Similar occurrence of microalbuminuria (~20%) but lower HbA1c (6.1% vs. 7.3%) were observed in T2Di- compared to T2Di+ at screening. In the proximal tubular (PT) cluster (10,032 cells), 1003 genes elevated in T2Di- vs. HC were suppressed by SGLT2i (T2Di+ vs. T2Di-) while 176 repressed transcripts in T2Di+ were recovered with SGLT2i. Most metabolic pathways increased in T2Di- were suppressed in PT by SGLT2i, except metallothionein and insulin receptor signaling pathways, which were enhanced with SGLT2i exposure (p<0.05). Repression of metallothioneins in PT could be validated in two independent DKD cohorts (Fig.1).

**Conclusions:** SGLT2i treatment may rescue metallothionein expression in PT, consistent with a more favorable redox state.

**Funding:** NIDDK Support

Fig. 1: Diabetes-associated down-regulation of MT genes in three cohorts (T2D, Pima Indians, KPMP). Treatment with SGLT2i (T2Di) in the youth onset T2D cohort, showed enhanced expression of MT genes relative to T2D. Abbreviations: MT-metallothionein, T2D-type 2 diabetes; LD-living donors; KPMP- Kidney Precision Medicine Project; SGLT2i- sodium-glucose cotransporter-2 inhibitors; logFC-log2 fold change.

## TH-PO212

### Platelets and Neutrophil Extracellular Traps Promote Glomerular Endothelial Dysfunction and Barrier Disruption in Diabetic Kidney Disease

Anubhuti Gupta, Kunal Singh, Khurram Shahzad, Berend H. Isermann, Shrey Kohli. *Universitätsklinikum Leipzig, Leipzig, Germany.*

**Background:** Diabetic kidney disease (DKD) is a major cause of end-stage renal failure contributing to morbidity and mortality worldwide. Therapies to prevent or reverse DKD progression are limited or lacking, respectively. Endothelial dysfunction, platelet-hyperactivity, immune cell infiltration and glomerular filtration barrier (GFB) disruption are associated with DKD. Mechanistic insights concerning the interplay between platelets and neutrophil extracellular traps (NETs) and ensuing endothelial dysfunction for DKD progression limited.

**Methods:** Renal function, platelet activation and NETs formation was evaluated in a mouse diabetes model. Therapeutic interventions (Aspirin, Anakinra, Solulin, GSK484) were performed after establishment of DKD to study disease reversal. *In vitro* studies were performed using glomerular endothelial cells (GENC), platelets and neutrophils exposed to high glucose (HG) in static and flow conditions.

**Results:** Experimental DKD in C57Bl6 mice resulted in albuminuria and increased fractional mesangial area that correlated with activated platelets (CD62P), NETs (H3Cit, NE, PAD4) within glomeruli and plasma NETs markers. In parallel, increased expression of inflammasome markers (NLRP3, IL1β) and reduced expression of thrombomodulin (TM) was observed. *In vitro*, platelets and NETs exacerbate inflammasome markers (IL1β, NLRP3), reduce endothelial function markers (p-eNOS, KLF2, KLF4 and TM) in GENC and disrupted GFB (enhanced FITC-dextran leakage, disoriented VE cadherin) in HG conditions. Under flow condition, platelets enhanced NETs formation on GENC monolayers exposed to HG. Inhibition of platelet activation (Aspirin), amelioration of NETs (GSK484), targeting P-selectin mediated platelet-neutrophil interactions, IL-1 receptor inhibition (anakinra) or restoring TM expression (solulin) ameliorated these effects *in vitro* and *in vivo*. Further experiments evaluating the clinical relevance in diabetic patient cohorts are under progress.

**Conclusions:** Hyperglycemia promotes platelet-neutrophil interactions resulting in intraglomerular NETs formation, sterile inflammation, glomerular endothelial dysfunction and GFB disruption. This results in aggravated disease course and impaired renal health in DKD. Inhibition of platelets or NETs is a promising therapeutic strategy for DKD.

## TH-PO213

### miR-34a as a Potential Marker in Diabetic Kidney Disease

Anil K. Karihaloo,<sup>1</sup> Vivek Das,<sup>1</sup> Shuya Liu,<sup>2</sup> Wenjun Ju,<sup>3</sup> Viji Nair,<sup>3</sup> Laura Goea,<sup>4</sup> Markus Bitzer,<sup>3</sup> Christopher L. O'Connor,<sup>5</sup> Matthias Kretzler,<sup>3</sup> Tobias B. Huber.<sup>2</sup> <sup>1</sup>Novo Nordisk AS, Seattle, WA; <sup>2</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>3</sup>University of Michigan Medical School, Ann Arbor, MI; <sup>4</sup>Bayer CropScience AG, Monheim, Germany; <sup>5</sup>Swiss Institute of Bioinformatics, Lausanne, Switzerland.

**Background:** Diabetic kidney disease (DKD) is the most common complication of diabetes. Various rodent models recapitulate human DKD only partially. Literature evidence suggests role of short non-coding microRNAs in DKD [1]. Through BEAT-DKD we have interrogated the transcriptional and post-transcriptional networks associated with DKD in BTBR Ob/Ob [2] mice in a multi-parametric design spanning across Genotype, Sex differences and course of the disease trajectory.

**Methods:** NanoString microRNA panel (n = 600) was used to profile 200 samples comprising of kidney, urine and serum. We used NACHO for quality control, quantification and limma for multivariable regression to identify microRNAs associating with the phenotypic differences between Ob/Ob vs WT, male vs female, and correlated with disease progression. Quantitative imaging assessment was used to identify kidney phenotypic differences in Ob/Ob vs WT. A support vector machines (SVMs)-based tool miRDB was used to predict functional microRNA-gene targets that are conserved between mice and human with confidence score ≥ 60 and significantly changed in DKD.

**Results:** miR-34a emerged as one of the strongest candidates up-regulated in Ob/Ob kidney and urine (adj.p-value < 0.05). miRDB identified 20 gene targets of miR-34a that are conserved between mice and human, differentially regulated (adj.p-value < 0.05) in human DKD Glomerular RNAseq data and mouse DKD bulk RNAseq data. These miR-34a gene targets included AMAD12, AXL, PDGFRA, PROM-1, etc that enriched for pathways involved in DKD pathogenesis like cell adhesion, podocyte injury, hypoxia inducible factor (HIF)/vascular endothelial growth factor signalling.

**Conclusions:** Our integrative analysis, identified miR-34a and its conserved gene targets significantly changed in both DKD mice and human datasets, revealed molecular networks and pathways with underlying association with disease, thus indicating its potential role in DKD. ### Diabetes Promotes Nitric Oxide Synthase Remodeling in Glomerular Podocytes

Mariia Stefanenko,<sup>1</sup> Marharyta Semenikhina,<sup>1</sup> Mykhailo Fedoriuk,<sup>1</sup> Joshua H. Lipschutz,<sup>1,3</sup> Alexander Staruschenko,<sup>2</sup> Oleg Palygin.<sup>1</sup> <sup>1</sup>*Medical University of South Carolina, Charleston, SC;* <sup>2</sup>*University of South Florida, Tampa, FL;* <sup>3</sup>*VA Medical Center Ralph H Johnson, Charleston, SC.*

**Background:** The release of nitric oxide (NO) by glomerular cells, together with the renin-angiotensin system (RAS), regulate glomerular filtration. Several reports indicate that NO levels in glomeruli are decreased during renal pathology development while restoring NO levels can benefit glomerular function. However, expression of NOS subunits in podocytes, especially under diseased conditions, was not established.

**Methods:** To detect NO production and NOS distribution in control and diabetes, we used confocal imaging of podocytes loaded with DAF-FM fluorescent marker. Freshly isolated glomeruli from the Type 2 Diabetic Nephropathy (T2DN) and control Wistar rats, and conditionally immortalized human podocyte cell line exposed to high glucose conditions (12 hrs) were used in the studies. NO production was detected in response to Ang II stimulation, and NOS distribution was determined using NOS1 and NOS2 commercially available inhibitors (Nω-Propyl-L-arginine hydrochloride and L-NIL, respectively).

**Results:** Under normal conditions, in response to Ang II application, rapid NO production was observed in cultured and Wistar rats isolated glomeruli podocytes. NO release was blocked by preincubation with corresponding NOS inhibitors. Our data indicate that NOS1 is predominant signaling in healthy podocytes (69±5% of total NO response). The rest of the RAS-mediated NO production was attributed to NOS2 (39±5%). Under diabetic conditions, NO release in response to Ang II has slightly decreased with the maximal amplitude of 78±10% of control. Moreover, high glucose drastically changes NOS distribution in cultured podocytes, where NOS2 signaling becomes predominant (89±7 % of total NO response), and NOS1 becomes less significant.

**Conclusions:** The changes in the distribution of NO sources due to shifts in NOS subunit expression activity may be linked to an increase in oxidative and nitrosative stress. Here we demonstrated that under the condition of diabetes NOS2 activity becomes predominant and may be directly related to the rapid development of the pathological processes in podocytes. Further understanding this fundamental pathway in the glomerulus is essential for efficient treatment and prevention of the development of diabetic kidney disease.

## TH-PO215

### Truncated suPAR Simultaneously Causes Kidney Disease and Diabetes Mellitus

Ke Zhu,<sup>1</sup> Kamalika Mukherjee,<sup>2</sup> David C. Wei,<sup>1</sup> Salim Hayek,<sup>3</sup> Agnieszka Collins,<sup>2</sup> Kristin M. Corapi,<sup>2</sup> Mehmet M. Altintas,<sup>1</sup> Sushrut S. Waikar,<sup>4</sup> Antonio C. Bianco,<sup>5</sup> Sanja Sever,<sup>2</sup> Jochen Reiser.<sup>1</sup> <sup>1</sup>*Rush University Medical Center, Chicago, IL;* <sup>2</sup>*Harvard Medical School, Boston, MA;* <sup>3</sup>*University of Michigan, Ann Arbor, MI;* <sup>4</sup>*Boston University, Boston, MA;* <sup>5</sup>*University of Chicago Division of the Biological Sciences, Chicago, IL.*

**Background:** suPAR is an innate-immune derived circulating kidney disease risk factor, elevated plasma levels of which have been associated with diabetic nephropathy. Enzymatic cleavage of domain 1 (D1) from suPAR generates D2D3 fragment. The biological consequence of this fragment is unclear.

**Methods:** 1) we used an immunoprecipitation-mass spectrometry to determine the presence of D2D3 fragment in diabetic nephropathy patients with insulin dependence; 2) we generated a transgenic mouse model that drives D2D3 expression from adipocytes with consequent release into circulation. To stimulate D2D3 expression, we treated the control and D2D3 mice with high fat diet (HFD) for 6 months to measure proteinuria monthly. We analyzed the phenotypes of control and D2D3 mice by glucose tolerance test (GTT), glucose stimulated insulin secretion assay (GSIS) *in vivo* and *in vitro*; 3) we treated both mouse and human islets with recombinant D2D3 proteins purified from HEK293 cells, and performed *in vitro* GSIS to determine islet function; 4) we performed immunohistochemical staining using the control and D2D3 pancreas to explore if D2D3 influences the β-cell mass.

**Results:** Compared to controls, D2D3 mice with HFD developed significantly increased proteinuria and presented with reduced serum insulin levels. Under chow diet, both *in vivo* and *in vitro* GSIS were compromised in D2D3 mice and GTT of these mice was impaired as well. In consistence, isolated islets from WT mice or human pancreas treated with recombinant D2D3 protein displayed impaired response to high dose glucose,

as compared to the BSA-treated islets. α-/β-cells distribution pattern was dramatically altered in the D2D3 mice, with glucagon-positive α-cells being randomly dispersed among insulin-positive β-cells. β-cell mass in D2D3 mice was reduced to half of control levels, assessed by the decreased β-cell population in D2D3 islets. Moreover, treatment of mouse β-cell line (MIN6 cells) with D2D3 displayed reduced insulin secretion upon high glucose stimulation and impaired glycolysis and mitochondrial respiration.

**Conclusions:** Mouse D2D3 fragment regulates glucose homeostasis by playing a direct role in β-cell function. It also impairs podocyte function. Generation of D2D3 represents an inciting event in the immune-derived diabetic kidney disease.

### Diabetes Activates Dynein Mediated Trafficking and Degradation of Nephron via AMPK/SP-1 Regulated Transcription

Hua Sun, Jillian Weidner. *The University of Iowa, Iowa City, IA.*

**Background:** Diabetic podocytopathy is the most prevalent acquired human podocytopathy. Diabetic podocyte injury initiates before the onset of microalbuminuria and eventually leads to 50% of renal failure in the US. We recognized an enhanced dynein-mediated trafficking of nephrin in diabetic podocyte injury, but the mechanism by which diabetes activates the dynein-drive pathogenesis remains unclear. Bioinformatic analysis predicts that dynein genes are under the regulation of specificity protein 1 (SP-1), a transcriptional factor that is modulated by AMP-activated protein kinase (AMPK) under diabetic condition. Therefore, we hypothesize that AMPK/SP-1 guided dynein transcription plays a key role in the early stage of diabetic podocytopathy.

**Methods:** Dynein expression was examined by real time PCR in podocytes growing under hyperglycemic or normoglycemic conditions, with or without manipulations of AMPK activity (by Compound C or AICAR), or knockdown of SP1 (using siRNA). AMPK activity was reflected by measuring Thr 172 phosphorylation. Live cell imaging and trajectory analysis were performed to study the dynein-dependent trafficking of nephrin to lysosomes or recycling endosomes. Dynein expression, as well as its correlations with AMPK activity and nephrin degradation were investigated in glomeruli isolated from Streptozotocin (STZ)-induced diabetic mice.

**Results:** 1. Upregulated expression of dynein was demonstrated in podocytes with prolonged exposure to high glucose, in which AMPK activity was found to be suppressed. This change could be rescued by the activation of AMPK using AICAR, or knockout of SP1. 2. Knockdown of dynein components that were upregulated by hyperglycemia attenuated the sorting of nephrin from recycling endosome to lysosomal system. 3. The increased expression of dynein and dynein-mediated trafficking of nephrin were verified in STZ-induced diabetic glomerulopathy in mice. These changes correlated with the inhibition of AMPK, ubiquitination degradation and depletion of nephrin, especially the surface nephrin.

**Conclusions:** Hyperglycemia suppresses AMPK, which in turn disinhibits SP-1 guided transcription of dynein. The increased expression of dynein in diabetes promotes the trafficking of nephrin from recycling pathway to lysosomal degradation system, depletes the surface nephrin, impairs the slit diaphragm and causes diabetic podocytopathy.

### Podocyte-Mediated Proximal Tubule Preconditioning Is Protective in Diabetic Kidney Disease

Bismark Owusu Frimpong, Nehaben A. Gujarati, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

**Background:** Diabetic kidney disease (DKD) is a glomerulopathy, with inciting events occurring in cells that comprise the glomerulus. However, recent findings have implicated proximal tubule (PT) injury in the progression of DKD. Potential mechanisms by which PT can be preconditioned to prevent the progression of DKD remain poorly understood. The aim of this study is to demonstrate that podocyte-specific induction of a zinc finger transcription factor, Krüppel-like factor 6 (KLF6), attenuates DKD by preconditioning the PT against DKD progression.

**Methods:** Podocyte-specific induction of KLF6 (*hKLF6<sup>POD</sup>*) were generated using *NPHS2-rtTA* and *TRE-KLF6* mice, under doxycycline treatment. Diabetes was induced with UNX-STZ, with SHAM-Veh serving as the control. Single nucleus (sn)RNA-seq was conducted from kidney cortex of all mice. Conditioned media (CM) from podocytes isolated from *hKLF6<sup>POD</sup>* and control mice were collected. *CAMK1d* was knocked down in HK2 cells (*sh-CAMK1d*). CAMK1D signaling was pharmacologically inhibited using STO-609, an inhibitor of the upstream kinase CAMKK, in primary (1°) PT cells. Oxygen consumption rate (OCR) was measured with Seahorse Analyzer.

**Results:** Diabetic *hKLF6<sup>POD</sup>* mice exhibited less albuminuria, podocyte injury, glomerulosclerosis, and tubulointerstitial injury compared to diabetic controls. Clustering of the snRNA-seq data identified a subpopulation of PTs predominant in the *hKLF6<sup>POD</sup>* groups. Gene Set Enrichment Analysis of this subpopulation showed an enrichment for mitochondrial respiration pathways and upregulation in *Camk1d* gene expression and signaling. In assessing the role of CAMK1D in PTs, we found that *sh-CAMK1d* cells exhibited slower growth and lower cell viability with a larger proportion in s-phase of cell cycle compared to control cells. 1° PT cells treated with STO-609 validated this decrease in cell viability and OCR. Additionally, 1° PT cells primed with CM from *hKLF6<sup>POD</sup>* podocytes had preserved OCR compared to PT treated with CM from control podocytes in high glucose conditions.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** These data suggest that podocyte-specific induction of *KLF6* preconditions the proximal tubules against DKD progression by upregulating CAMK1 $\delta$  signaling.

## TH-PO218

### Developing hPSC-Derived Kidney Organoid Model for Emulating Key Pathological Features of Diabetic Nephropathy

Angelysia Cardilla, Tian Zhang, Mihir Y. Naik, Yun Xia. *Lee Kong Chian School of Medicine, Singapore, Singapore.*

**Background:** Diabetic nephropathy (DN) represents one of the leading causes of end-stage renal disease (ESRD). Current treatment of DN focuses primarily on controlling physiological symptoms without retarding or reversing disease progression. To date, most DN studies are based on animal models, though there is a major concern on how closely the animal models mimic human pathophysiology. A new DN model that presents higher relevance with human physiology is urgently needed to better understand the disease mechanisms of DN and to discover effective therapeutics.

**Methods:** In the past decades, organoids have become a powerful tool for modeling human diseases due to their ability to recapitulate the complexity of human organs. Here, we used state-of-the-art kidney organoid technology to emulate pathogenesis of diabetic nephropathy. Kidney organoids are derived *in vitro* from human pluripotent stem cells (hPSCs), harboring segmentally patterned nephron-like structures and stroma, as well as a vascular network. To emulate DN phenotypes, we exposed hPSC-derived kidney organoids to stress paradigms that are presented in pre-diabetic and diabetic states. We performed histopathological and functional analysis to evaluate organoid pathology under these conditions.

**Results:** Within diabetic kidney organoids, we observed multiple phenotypes that are characteristic of DN, including altered tissue architecture and compromised functionality. Particularly, the existence of an intrinsic vascular network enabled us to interrogate the deterioration of renal vasculature during the development of DN.

**Conclusions:** The new human stem cell-based kidney organoid model will allow us to study DN pathogenesis *in vitro* as well as *in vivo*, leading to identification of novel therapeutic agents with higher clinical potential.

## TH-PO219

### Cytochrome P450: Protagonists in the Story of Diabetic Kidney Disease

Batoul Dia, Elias Shamieh, Mohamad Noureldin, Hilda E. Ghadieh, Fuad N. Ziyadeh, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

**Background:** Diabetic kidney disease (DKD) is a debilitating complication and a major contributor to all-cause mortality in patients with diabetes. Cytochrome P450 (CYPs) epoxigenases metabolize arachidonic acid into the vasoactive and renal-active HETEs and EETs. Our group, among others, described the implication of CYPs and their metabolites in the pathogenesis of DKD by activating reactive oxygen species (ROS) production. More importantly, CYPs-encoding genes possess different polymorphisms that can alter the expression of these key enzymes, affecting the prognosis of patients with DKD. Besides, miRNAs that can be involved in DKD are recently gaining high interest. To our knowledge, the regulatory effect of miRNAs on the expression of different CYPs in DKD is not yet established. Herein, we hypothesize that in patients with diabetes, genetic variants in CYP enzymes known to be implicated in AA metabolism potentiate the development of DKD.

**Methods:** Blood and urine were collected from healthy volunteers, patients with type 2 diabetes (T2DM) with or without clinical manifestation of DKD. Urinary and circulating levels of 20-HETE and EETs were assessed and correlated with the expression of CYPs in the kidney biopsies. Furthermore, miRNA analysis was performed to study CYP enzymes regulation.

**Results:** Circulating levels of 20-HETE were increased in patients with DKD when compared to T2DM patients with no clinical signs of DKD, which in turn had higher levels of 20-HETE in comparison to the healthy volunteers. This was associated with an increased expression of CYP4A11 and CYP4F8 in the human kidney biopsies. In parallel, EETs levels were decreased in patients with T2DM and DKD as compared to patients with T2DM only and this was positively correlated with the decreased CYP2B6 expression in kidney biopsies. Of interest patients with DKD carry CYPs polymorph affecting their enzymatic activity and subsequently leading to increased 20-HETE and decreased EETs. The same may be concluded when it comes to our miRNA study.

**Conclusions:** This study may yield crucial findings about novel genetic and epigenetic pathways involved in diabetes-induced renal injury and may identify novel prognostic and diagnostic biomarkers associated to CYPs pathways alteration in DKD.

## TH-PO220

### $\beta_2$ Adrenergic Receptor Agonists as a Novel Treatment for CKD

Ehtesham Arif,<sup>1</sup> Danira Medunjanin,<sup>2</sup> Ashish K. Solanki,<sup>1</sup> Xiaofeng Zuo,<sup>1</sup> Yanhui Su,<sup>1</sup> Brennan Winkler,<sup>1</sup> Oleg Palygin,<sup>1</sup> Marc-Andre Cornier,<sup>1</sup> Bethany Wolf,<sup>3</sup> Kelly J. Hunt,<sup>3,2</sup> Joshua H. Lipschutz.<sup>1,4</sup> <sup>1</sup>Medical University of South Carolina Division of Nephrology, Charleston, SC; <sup>2</sup>Medical University of South Carolina Department of Public Health Sciences, Charleston, SC; <sup>3</sup>Department of Biostatistics, Medical University of South Carolina, Charleston, SC; <sup>4</sup>VA Medical Center Ralph H Johnson, Charleston, SC.

**Background:** We recently showed that formoterol, a long-acting beta 2 adrenergic receptor ( $\beta_2$ -AR) agonist, induced recovery from kidney injury in mice.

**Methods:** To determine the effect of formoterol on renal function in humans, we performed a competing risk regression in Veterans, aged 65 and over, with incident chronic kidney disease (CKD) stage 4 to compare the rate of end stage kidney disease (ESKD) progression in Veterans without and with chronic obstructive pulmonary disease (COPD), who use  $\beta_2$ -AR agonists. Additionally, we used a high fat diet (HFD), a murine model of type 2 diabetes, and streptozotocin, a murine model of type 1 diabetes, to examine the role of formoterol in diabetic nephropathy, the most common cause of ESKD.

**Results:** We found that COPD, by means of  $\beta_2$ -AR agonist intake, was protective against progression to ESKD. A 39.4% [HR:0.61 (95% CI: 0.51-0.72)] reduction in the rate of ESKD in Veterans with COPD compared to those without was observed after adjusting for age, diabetes, sex, and race-ethnicity. Animal studies indicate that there was a marked recovery from and reversal of diabetic kidney disease in HFD mice treated with formoterol compared to those treated with vehicle alone at the ultrastructural, histological, and functional levels. Similar results were seen after formoterol treatment in mice receiving streptozotocin. The mechanism of action appeared to be improvement in mitochondrial function.

**Conclusions:** Together these data indicate that  $\beta_2$ -AR agonists, especially formoterol, may be a novel treatment for diabetic nephropathy and perhaps other forms of CKD. If confirmed in a prospective randomized clinical trial this would be the first treatment able to reverse diabetic nephropathy.

### Long Noncoding RNA ENST00000436340 Promotes Podocyte Injury of Diabetic Kidney Disease by Facilitating the Association of PTBP1 With RAB3B

Zhimei Lv,<sup>1,2</sup> Jinxiu Hu,<sup>2</sup> Rong Wang.<sup>1,2</sup> <sup>1</sup>Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; <sup>2</sup>Department of Nephrology, Shandong Provincial Hospital, Shandong University, Jinan, China.

**Background:** Dysfunction and injury of podocytes has been regarded as an early pathologic characteristic of diabetic kidney disease (DKD), but the role of long noncoding RNAs in this process remains largely unknown. By performing RNA sequencing, we identified ENST00000436340 was significantly upregulated in DKD. However, its function and detailed molecular mechanisms are undefined.

**Methods:** real-time PCR was performed to verify ENST00000436340 expression in DKD. Spearman correlation analysis were used to evaluate the correlation between ENST00000436340 and kidney function. real-time PCR, WB, Immunofluorescence, and FITC-phalloidin staining were performed to assess the lesion of podocyte. MeRIP was performed to investigate the underlying mechanism of ENST00000436340 upregulation. FISH and subcellular fractionation assays were conducted to identify the localization of ENST00000436340 in podocytes. RNA pulldown, RIP and serial deletions assay were performed to explore the interaction between ENST00000436340, RAB3B and PTBP1.

**Results:** We discovered ENST00000436340 was upregulated in DKD, and we showed a correlation between upregulated ENST00000436340 and the severity of kidney injury. Function experiments showed that silencing of ENST00000436340 alleviated high glucose-induced podocyte injury and cytoskeleton rearrangement. Mechanistically, we showed that FTO-mediated m6A induced the upregulation of ENST00000436340, which interacted with PTBP1 and augmented PTBP1 binding to RAB3B mRNA, promoted RAB3B mRNA degradation, and thereby caused cytoskeleton rearrangement and inhibition of GLUT4 translocation, leading to podocyte injury.

**Conclusions:** We identified an ENST00000436340-PTBP1-RAB3B axis in regulating cytoskeleton rearrangement and GLUT4 translocation, leading to podocyte injury, which will provide insights into the prevent and treatment of DKD in the future.

### Significant Differential Methylation of Telomere-Related Genes in Diabetic Kidney Disease and Its Potential Role in Regulating Gene Expression and Wnt Signalling

Claire Hill,<sup>1</sup> Niina Sandholm,<sup>3,4</sup> Jill Kilner,<sup>1</sup> Peter Rossing,<sup>2</sup> Maria Lajer,<sup>2</sup> Per-Henrik Groop,<sup>3,4</sup> Alexander P. Maxwell,<sup>1</sup> A.J. Mcknight.<sup>1</sup> <sup>1</sup>Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom; <sup>2</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>3</sup>Folkhälsan Institute of Genetics, Folkhälsan Research Center, Biomedicum Helsinki, Helsinki, Finland; <sup>4</sup>Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

**Background:** Diabetic kidney disease (DKD) significantly impacts patients, families and health service globally. Accelerated cellular senescence has previously been suggested as a key target for therapeutic development within DKD. The telomereprotective chromosome end structures undergo shortening with advancing age and senescence.

**Methods:** Genotype data in telomere-related genes was extracted from genome-wide case-control association data (n=1,830) while telomere length was calculated relative to a single copy gene and established using quantitative polymerase chain reaction. Cases were defined as individuals with Type 1 Diabetes (T1D) with persistent proteinuria, hypertension, and retinopathy. Controls were individuals with T1D for at least 15 years, normoalbuminuric and not taking antihypertensive medication or ACE inhibitors. Quantitative CpG methylation values for telomere-related genes were extracted from epigenome-wide case-control association data (n=250).

**Results:** Telomere length was significantly shorter in DKD patients vs. controls (P=0.002); however, not sustained following covariate adjustment or replication. DKD and ESKD were nominally associated with telomere-related genetic variation, with Mendelian Randomisation highlighting no significant association between genetically-predicted telomere length and disease outcomes. Investigating 1,091 CpG sites in 378 telomere-related genes, 496 sites in 212 genes reached epigenome-wide significance (P≤10<sup>-8</sup>) for DKD association, and 412 sites in 193 unique genes for ESKD. Functional prediction via gene ontology analysis of differentially methylated genes revealed enriched processes such as developmental regulation and Wnt signalling. Harnessing previously published RNA-sequencing datasets, differential methylation was correlated with gene expression changes during DKD, highlighting prospective targets where epigenetic regulation may result in altered gene expression, potentially influencing disease outcomes.

**Conclusions:** This study utilised multiple telomere focused omic datasets to provide insights into the genomic landscape of DKD, highlighting genes and molecular pathways for downstream analysis to aid the development of diagnostic and therapeutic interventions for CKD.

### Comparative Transcriptomics of Human and Mouse Diabetic Kidney Disease

Frederikke E. Sembach,<sup>1</sup> Mette V. Østergaard,<sup>1</sup> Jens Christian Nielsen,<sup>1</sup> Mikkel Christensen-Dalsgaard,<sup>1</sup> Martin R. Madsen,<sup>1</sup> Bo Feldt-Rasmussen,<sup>2</sup> Esteban Porrini,<sup>3</sup> Mads Hornum,<sup>2</sup> Lisbeth N. Fink.<sup>1</sup> <sup>1</sup>Gubra ApS, Hørsholm, Denmark; <sup>2</sup>Rigshospitalet, Copenhagen, Denmark; <sup>3</sup>Hospital Universitario de Canarias, La Laguna, Spain.

**Background:** Transcriptome profiling is instrumental for investigating molecular mechanisms driving disease progression in diabetic kidney disease (DKD). However, a major impediment in DKD research is the scarcity of frozen kidney tissue specimens from patients with DKD. To overcome this challenge, the present study applied RNA sequencing of formalin-fixed paraffin-embedded (FFPE) kidney samples from an ongoing study in patients with DKD. The clinical translatability of an advanced DKD mouse model was assessed by comparison to the human transcriptome profile.

**Methods:** RNA sequencing was performed on FFPE kidney samples from patients undergoing nephrectomy as part of the European Nephrectomy BioBank project (ENBiBa). All patients included were diagnosed with obesity and hypertension and were divided into two groups based on presence of type 2 diabetes and DKD (n = 6), while nondiabetic patients with no kidney disease were included as controls (n = 8).

Also, RNA sequencing was performed on snap-frozen kidney cortex samples from a model of advanced DKD facilitated by adeno-associated virus (AAV)-mediated renin overexpression in uninephrectomized (UNx) *db/db* mice and healthy non-diabetic *db/m* controls.

**Results:** A total of 105 differentially expressed genes (DEGs) were identified in human DKD FFPE kidney samples, when compared to the human controls. Of these DEGs, a significant overlap of 32 genes were regulated in both human DKD and *db/db* UNx-ReninAAV mice, including upregulation of genes associated with extracellular matrix remodelling (*COL1A1*, *COL1A2*, *MMP14*, *VCAM1*). The tubular specific marker *UMOD* was downregulated in both human DKD patients and in *db/db* UNx-ReninAAV mice, indicating tubular injury, while solute carrier family genes (*SLC5A3*, *SLC12A1*) were only downregulated in human DKD patients.

**Conclusions:** Identification of regulated genes associated with DKD in this cohort of patients with obesity, diabetes and chronic kidney disease confirms the applicability of RNA sequencing of FFPE samples for analysing global gene expression changes and investigating molecular mechanisms involved in the progression of DKD. Transcriptome signatures in the *db/db* UNx-ReninAAV mouse indicates good clinical translatability, highlighting the use of this model in preclinical DKD research.

## TH-PO224

### Allogeneic Neo-Islet (NI) Therapy of Spontaneously Type 1 Diabetic Dogs Durably Reduces Insulin Need and Hyperglycemia and Protects Renal Function: 3 Year Follow-Up From the INAD Study

Anna Gooch,<sup>1</sup> Sabiha Sultana Chowdhury,<sup>1</sup> Christof Westenfelder.<sup>1</sup> SymbioCellTech, Salt Lake City, UT.

**Background:** We published that treatment with allogeneic NIs, organoids of Mesenchymal Stromal Cells and culture expanded islet cells functionally cured the diabetic state in NOD mice without requiring antirejection drugs or encapsulation. Dog and human NIs produced euglycemia in streptozotocin-diabetic NOD/SCID mice. We tested NI therapy under an FDA guided pilot study (INAD 012-776) in spontaneously diabetic, insulin dependent pet dogs. 6 dogs have been treated and followed for 3 years. We report here the progress of those 6.

**Methods:** Insulin dependent, diabetic pet dogs were studied: 10 enrolled; 8 treated; 6 followed ≥3 yrs. Pre- and post-treatment sera were tested for islet autoantibodies. Comorbidities and BG were treated. Allogeneic NIs were given once i.p. (2.5x10<sup>6</sup>/kg bw) without encapsulation or antirejection agents. Vital signs, BG, insulin need, antibody responses, SCr, BUN, urine protein, lipid profiles, adverse events (AEs) were monitored multiple times for 3 years post-therapy.

**Results:** 3 dogs had pre-treatment islet autoantibodies indicating autoimmunity. 50% of NI treated dogs showed a significant and durable reduction in BG, Fructosamine and HbA1C (12 to 6.8) levels, and 75% showed a significant, durable reduction in daily Insulin requirements (up to 50%). Body weights remained stable; blood pressures were normal. There was no deterioration in renal function, as assessed by SCr and BUN, and no microalbuminuria or proteinuria developed. Hb levels remained normal. Other preexisting comorbidities did not progress.

**Conclusions:** NIs engraft in the omentum, re-differentiate and physiologically produce and deliver insulin and other islet hormones, and are neither rejected by auto- or allo-immune attacks, as evidenced by (i) absent IgG responses to the administered NIs, and (ii) durably (≥ 3 yrs) improved BG and lowered insulin need. While no dog has achieved insulin independence, preclinical results with human NIs indicate that redosing could accomplish this. NI therapy is feasible, durably effective, and safe as no AEs or SAEs related to therapy have been observed to date. This therapy has significant translational relevance for both dog and human T1DM. A successful Pre-IND meeting has been held, and a human clinical trial is under preparation.

**Funding:** Commercial Support - SymbioCellTech

## TH-PO225

### NCOA1 Modulates Glomerulosclerosis in Diabetic Kidney Disease Through Regulating ITGA5

Lili Gai,<sup>1</sup> Chun Zhang.<sup>1</sup> Huazhong University of Science and Technology, Wuhan, China.

**Background:** Nuclear receptor coactivator 1 (NCOA1) is a member of NCOA family, which coactivate and potentiate the expression of target genes, regulating various biological events such as cell proliferation and fibrosis. Recent findings revealed a potential role of NCOA1 in metabolic related diseases and tissue fibrosis. However, its role in glomerulosclerosis of diabetic kidney disease (DKD) remains unclear. Previous data reported NCOA1 could directly enhance integrin alpha 5 (ITGA5) expression and thus promoting ITGA5-mediated biological events. ITGA5 is a cell adhesion protein, which also plays an indispensable role in various tissue fibrosis. Therefore, our study aims to explore whether NCOA1 can be involved in glomerulosclerosis in diabetic kidney disease by regulating ITGA5.

**Methods:** 1. The model of DKD was established by intraperitoneally injection of 150mg/kg streptozotocin in 8-week-old mice. 2. The expression of NCOA1 in renal cortex of DKD mice and glomerular mesangial cells (GMCs) treated by high glucose (HG) were detected by quantitative real-time polymerase chain reaction (qRT-PCR), western blot (WB) and immunofluorescence. The expression of Fibronectin and Collagen IV was detected by WB after HG treated GMCs were transfected with NCOA1 overexpression plasmid. 3. The expression of ITGA5 in vivo and vitro was detected by qRT-PCR, WB

and immunofluorescence in DKD, and the expression of Fibronectin and Collagen IV was detected by WB after HG treated GMCs were transfected with ITGA5 siRNA. 4. The expression of ITGA5 was detected by WB after HG treated GMCs were transfected with NCOA1 overexpression plasmid.

**Results:** 1. The expression of NCOA1 was significantly downregulated in DKD mice and HG-treated GMCs, while overexpression of NCOA1 by plasmid could attenuate HG-induced extracellular matrix (ECM) accumulation in GMCs. 2. The expression of ITGA5 was significantly upregulated in vivo and in vitro of DKD, while knocking down ITGA5 by siRNA could attenuate HG-induced ECM accumulation in GMCs. 3. The activation of ITGA5 induced by HG was obviously attenuated by NCOA1 overexpression in GMCs.

**Conclusions:** NCOA1 might be involved in glomerulosclerosis of DKD by regulating the expression of ITGA5.

### Therapeutic Modulation by Combined SGLT2 and ACE Inhibition of Glomerular Filtration in Streptozotocin (STZ)-Diabetic Mice In Vivo

Hannah Kroeger, Friederike Kessel, Jan Sradnick, Vladimir T. Todorov, Florian Gembardt, Christian Hugo. AG Hugo *Universitätsklinikum Carl Gustav Carus, Dresden, Germany.*

**Background:** Diabetic kidney disease is the leading cause of end-stage renal disease in the Western world. SGLT2 inhibitors, besides ACE inhibitors show renoprotective effects in chronic kidney disease. The underlying renoprotective mechanism of combined SGLT2 inhibition and ACE inhibition therapy is not completely understood. Therefore, we aimed to investigate directly via intravital microscopy the hemodynamic changes in single glomeruli of diabetic mice treated with ACE and/or SGLT2 inhibitors.

**Methods:** Male C57BL/6 mice were injected with streptozotocin to induce type 1 diabetes. After five weeks of diabetes, mice were treated with enalapril, empagliflozin, or enalapril/empagliflozin for three days. We used longitudinal in vivo imaging to evaluate single nephron GFR (snGFR) and afferent as well as efferent arteriole diameter width during ACE and/or SGLT2 inhibition.

**Results:** The STZ-diabetic mice showed significant hyperfiltration (control 1003.0 ± 190.5 µl/min/100g b.w vs. diabetic 1329.4 ± 309.6 µl/min/100g b.w., p<0.05). Enalapril treatment led to a reduction of snGFR and significant efferent arteriole dilation (12.55 ± 1.46 µm vs. control 11.92 ± 1.04 µm, p<0.05) but did not affect afferent arteriole width. Reduced snGFR in diabetic mice as induced by empagliflozin was accompanied by afferent arteriole vasoconstriction (11.19 ± 2.55 µm vs. control 12.35 ± 1.32 µm, p<0.05) but no changes of the efferent arteriole width. Unexpectedly, combined treatment with enalapril/empagliflozin reduced snGFR without any significant alteration in afferent or efferent arteriole diameter width.

**Conclusions:** SGLT2 and ACE inhibitors appear as beneficial hemodynamic regulators of glomerular filtration during early stages of diabetes mellitus by regulating respectively the afferent and the efferent arteriole contractility. The underlying beneficial mechanisms of the combination therapy need further investigation.

## TH-PO227

### Role of Cellular Senescence and Epigenetic Drift in Interstitial Fibrosis of Diabetic Kidney Disease

Ayano Tsukagoshi, Yoshiro Maezawa, Hiyori Kaneko, Shintaro Ide, Masaya Koshizaka, Koutaro Yokote. *Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan.*

**Background:** In recent years, the number of elderly patients with diabetes has been increasing. In diabetic kidney disease, accumulation of senescent cells and senescence-related epigenome changes may contribute to renal fibrosis.

**Methods:** We investigated senescence markers, histone and its methylation in human renal fibroblasts (HKF) after replicative senescence. In addition, we created elderly diabetes model using streptozotocin injection to 108-week-old mice, and evaluated the phenotypes.

**Results:** HKF was mitotically arrested at passage 18 (p18). P18 HKF showed characteristics of cellular senescence including positive staining for senescence-associated βGal (SAβ-Gal), elevated expressions of *CDKN2A*, *CDKN1A* and *IL6*, one of the senescence-associated secretory phenotype (SASP). RNA-seq and pathway analysis revealed that senescent HKFs were associated with "SASP-related pathway" and "epigenetic gene regulation". Interestingly, gene expression of histone methyltransferases such as *EHMT2*, *EZH2*, *PRMT1* and *SUV39H2* were decreased by 41%, 43%, 29% and 59%, respectively in p18 HKF compared to p12. In addition, by western blot, senescent HKFs showed a marked decrease of HistoneH3 and a concomitant loss of H3K9me3 and H3K27me3, suggesting the HKFs are undergoing the epigenetic drift. The kidneys of aged mice showed enlarged Masson's Trichrome-positive area (18.6% at 18 weeks vs. 34.3% at 120 weeks of age), irregular vascular structure, and increased number of PDGFRβ-positive cells, indicating fibrosis. These findings were worsened in aged mice with STZ diabetes. Tubules, podocytes and some interstitial cells in aged mice were positive for SAβ-Gal and P16 staining. When examined by Nephroseq database, *EHMT2* expression was significantly decreased in the tubule-interstitial region of human diabetic kidney disease. In addition, Camptothecin-induced senescence in HKF resulted in decreased extracellular matrix expressions such as *Acta2*, *Col1a1* and *FN1* after Tgβ stimulation, suggesting that senescent kidney fibroblasts are responsible for inflammation, but they do not contribute to matrix production.

**Conclusions:** Senescent fibroblast with decreased histone methylation may provide increased SASP production, promote chronic inflammation and renal fibrosis.

## TH-PO228

### Multiparametric Magnetic Resonance Imaging Allows the Prediction of Diabetic Kidney Disease Progression

Kianoush Makvandi,<sup>1</sup> Paul Hockings,<sup>2,3</sup> Gert Jensen,<sup>1</sup> Johannes Hulthe,<sup>2</sup> Henrik Haraldsson,<sup>2</sup> Seema Baid-Agrawal,<sup>1,1</sup> *Sahlgrenska universitetssjukhuset, Göteborg, Sweden;* <sup>2</sup>*Antaros Medical, Gotenburg, Sweden;* <sup>3</sup>*Medtech West, Chalmers University of Technology, Gothenburg, Sweden.*

**Background:** We recently showed that a comprehensive non-contrast multiparametric Magnetic Resonance Imaging (mpMRI) allowed functional and structural assessment of diabetic kidney disease (DKD). We further investigated whether the MRI biomarkers could predict disease progression.

**Methods:** In this prospective study, 38 DKD subjects aged 18–79 years and 20 age- and gender-matched healthy volunteers (HV) were included at baseline. 31 DKD subjects (2 stage 2, 13 stage 3, 14 stage 4, and 2 stage 5) and 17 HV were reexamined at 2 years ± 6 months. Clinical examination, iothelox clearance for measured glomerular filtration rate (mGFR), urine albumin:creatinine ratio and mpMRI were done at both visits. A wide range of MRI biomarkers associated with kidney hemodynamics, oxygenation and macro/microstructure were evaluated. Disease progression was defined by at least one of the following at 2 years: a) decrease in mGFR slope of >5 mL/year/1.73m<sup>2</sup>, b) worsening UACR category or c) any major adverse kidney event defined as sustained decrease in eGFR of >40%/doubling of serum creatinine from baseline, development of kidney failure with mGFR <15 mL/min/1.73m<sup>2</sup> or death from renal cause. Univariable logistic regression analyses were performed to discriminate between progressors and non-progressors using each imaging endpoint as a predictor variable.

**Results:** Mean 2-year mGFR decline (mL/min/1.73m<sup>2</sup>) in DKD patients was -2.7 ± 5.37 and in HV -1.9 ± 10.71. R1 cortex (measure of longitudinal nuclear MR relaxation rate for molecular environment) showed an area under ROC curve of 0.88 (p=0.0074) in DKD subjects (Figure 1) and 0.69 (p=0.032) in the whole population.

**Conclusions:** The imaging biomarker R1 cortex, which reflects molecular environment- viscosity, fibrosis and inflammation (interstitial oedema, cellular swelling) showed significant predictive property for progression of DKD. A confirmatory study with R1 cortex as a pre-specified endpoint is required to confirm these results.

**Funding:** Commercial Support - Antaros Medical AB, AstraZeneca

Figure 1. ROC-curve of R1 cortex for predicting progression in DKD patients who have progressed according to at least one of criteria defined in a, b or c

## TH-PO229

### Kidney Fat by Magnetic Resonance Spectroscopy in Type 2 Diabetes and Diabetic Kidney Disease

Niels S. Heinrich,<sup>1</sup> Rune P. Pedersen,<sup>2</sup> Ulrich Lindberg,<sup>2</sup> Ulrik B. Andersen,<sup>2</sup> Bryan Haddock,<sup>2</sup> Tine Hansen,<sup>1</sup> Alessia Fornoni,<sup>3</sup> Peter Rossing,<sup>1</sup> *Steno Diabetes Center Copenhagen, Herlev, Denmark;* <sup>2</sup>*Rigshospitalet, København, Denmark;* <sup>3</sup>*University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.*

**Background:** Ectopic fat is a major pathogenic factor in type 2 diabetes (T2D). The kidneys may be susceptible to ectopic fat and its lipotoxic effects, disposing them toward chronic kidney disease (CKD). In few smaller studies, using discrepant magnetic resonance methods, intra-kidney fat content appeared to be slightly higher in people with T2D and perhaps even higher with concomitant CKD. We investigated the reproducibility of these findings.

**Methods:** Cross-sectional study including 50 adults with T2D and CKD, 27 with T2D and no CKD and 29 without T2D or CKD; CKD defined as urine albumin creatinine ratio ≥ 30mg/g. Fat content in the kidney parenchyma was assessed by magnetic resonance spectroscopy (MRS) in a 3 Tesla MRI scanner with a single voxel point resolved spectroscopy sequence; echo time 40 ms repetition time 3000 ms.

**Results:** See descriptive statistics in Table. In preliminary MRS data, median [IQR] intra-kidney triglyceride content was 1.1 [0.2-2.0]%, 1.0 [0.5-1.7]% and 1.7 [0.6-3.4]% (p = 0.08; Kruskal-Wallis test), respectively, in the T2D and CKD, T2D but no CKD and non-T2D groups. In linear regression adjusting for age and sex, there were likewise no associations between groups and triglyceride content.

**Conclusions:** In T2D with or without CKD we found no trend toward higher intra-kidney fat when evaluated by MRS, despite higher body mass index. Intra-kidney fat content was generally minuscule, making differences difficult to detect. The use of sodium-glucose cotransporter-2 inhibitors and glucagon-like peptide-1 receptor agonists, mostly among T2D participants with CKD, may have affected the results as these agents may reduce ectopic fat. It is also possible that lipid species other than triglyceride differ across the three groups.

**Funding:** Private Foundation Support

TH-PO230

**Trajectory of Kidney Function Correlates With Renal Blood Flow Evaluated by Magnetic Resonance Imaging in Diabetic Kidney Disease**  
Paul Hockings,<sup>1,2</sup> Kianoush Makvandi,<sup>3</sup> Gert Jensen,<sup>3</sup> Tim Unnerstall,<sup>3</sup> Henrik Leonhardt,<sup>3</sup> Henrik Haraldsson,<sup>1</sup> Johannes Hulthe,<sup>1</sup> Seema Baid-Agrawal,<sup>3</sup> <sup>1</sup>*Antaros Medical, Molndal, Sweden;* <sup>2</sup>*MedTech West, Chalmers University of Technology, Gothenburg, Sweden;* <sup>3</sup>*Sahlgrenska universitetssjukhuset, Goteborg, Sweden.*

**Background:** New non-invasive markers are needed to increase understanding of the pathogenesis of diabetic kidney disease (DKD). We recently showed that mean arterial flow (MAF) in renal arteries determined by magnetic resonance imaging (MRI) is tightly correlated with mGFR. Here we determine whether MAF tracks mGFR over two years in individual subjects.

**Methods:** In this prospective study, 38 subjects with DKD and 20 age- and gender-matched healthy volunteers (HV) were included at baseline (Visit 1). 31 DKD and 17 HV subjects were re-examined at 2 years (Visit 3) and included in the study. Measured glomerular filtration rate (mGFR) using iohexol clearance, urine albumin:creatinine ratio (UACR) and a variety of MRI techniques, including phase contrast MRI for MAF, were assessed at both visits.

**Results:** Mean and standard deviations (SD) for MAF, mGFR, and UACR for DKD and HV at both visits are shown in Table 1. Spearman rank correlation for mGFR vs MAF was 0.90 at Visit 1 and 0.89 at Visit 3. Figure 1 shows the trajectories of individual subjects over the 2-year period.

**Conclusions:** HV and DKD subjects showed similar mean changes in mGFR and MAF over 2 years, but much greater individual variability in HVs as shown by the increased SD of the delta values. In general, DKD subjects (mGFR <60 at baseline) follow the trend line with reduced MAF and mGFR at Visit 3. Changes in mGFR and MAF of HV may potentially be affected by hyperfiltration in some individuals whereas others may already have utilized their renal reserve. Changes may also be due to changes in medications.

	DKD Subjects			HV Subjects		
	MAF (ml/min)	mGFR (ml/min/1.73m <sup>2</sup> )	UACR (mg/g)	MAF (ml/min)	mGFR (ml/min/1.73m <sup>2</sup> )	UACR (mg/g)

TH-PO231

**Youth-Onset Type 2 Diabetes Associated With Higher Risk of Kidney Failure**  
Helen C. Looker,<sup>1</sup> Pierre Jean Saulnier,<sup>2</sup> Tim Vigers,<sup>3</sup> Laura Pyle,<sup>3</sup> Petter Bjornstad,<sup>3</sup> Robert G. Nelson.<sup>1</sup> <sup>1</sup>*National Institute of Diabetes and Digestive and Kidney Diseases; CKDS, Phoenix, AZ;* <sup>2</sup>*Universite de Poitiers, Poitiers, France;* <sup>3</sup>*University of Colorado Health, Aurora, CO.*

**Background:** The prevalence of youth-onset type 2 diabetes (T2D) is increasing and may have a more severe phenotype than adult-onset T2D. Youth-onset T2D in American Indians is associated with more severe structural lesions than adult-onset T2D of similar duration. We examine risk of kidney failure in youth-onset (<25 years) and adult-onset ( $\geq$ 25 years) T2D in the same population.

**Methods:** American Indians with T2D and repeated measures of GFR were followed from first GFR measurement in the study after the age of 25 years for onset of kidney failure. Risk of kidney failure was examined by Cox proportional-hazards in participants with youth-onset T2D compared to adult-onset T2D.

**Results:** 85 participants had youth-onset T2D and 239 had adult-onset T2D. Youth-onset participants were younger, more often female, and had longer diabetes duration, poorer glycemic control, and higher GFR at baseline than adult-onset participants (Table). Over a median follow-up of 19.9 (IQR 9.3-28.3) years there were 95 cases of kidney failure (34 in youth-onset, 61 in adult-onset). The Hazard Rate Ratio (HRR) for incident kidney failure in youth-onset T2D was 2.08 (95% CI 1.23-3.53) times as high as in adult-onset T2D after adjustment for sex and baseline age. The association was attenuated by inclusion of HbA1c in the model (HRR 1.43, 95% CI 0.80-2.56). When younger age at onset was considered as a continuous variable, the HRR for kidney failure per year was 1.07 (95% CI 1.04-1.09) after adjustment for sex, baseline GFR, blood pressure, and HbA1c, reflecting a 7% higher risk of kidney failure for each earlier year of age at diabetes diagnosis.

**Conclusions:** Youth-onset T2D is associated with more severe structural lesions and a greater risk of kidney failure despite higher GFR at baseline. Poorer glycemic control in the youth-onset group may contribute to their more rapid progression of kidney disease.

**Funding:** NIDDK Support

**Application of the Joslin Kidney Panel Using a Proximity Extension Assay: From Prognostics to Precision Medicine**  
Zaipun I Md Dom,<sup>1,2</sup> Narges M. Rashidi,<sup>3</sup> Helen C. Looker,<sup>4</sup> Mario Luca Morieri,<sup>1,2</sup> Eiichiro Satake,<sup>1,2</sup> Bozena Krolewski,<sup>1,2</sup> Joseph Ricca,<sup>1</sup> Jonathan M. Wilson,<sup>5</sup> Robert G. Nelson,<sup>4</sup> Kevin L. Duffin,<sup>5</sup> Alessandro Doria,<sup>1,2</sup> Andrzej S. Krolewski,<sup>1,2</sup> <sup>1</sup>*Joslin Diabetes Center, Boston, MA;* <sup>2</sup>*Harvard Medical School, Boston, MA;* <sup>3</sup>*Olink Proteomics, Watertown, MA;* <sup>4</sup>*National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ;* <sup>5</sup>*Eli Lilly and Company, Indianapolis, IN.*

**Background:** The Joslin Kidney Panel (JKP) of 21 circulating proteins is associated with increased risk of ESKD in patients with diabetes (Kobayashi *et al.* KI 2022). We evaluated the JKP as a tool for assessing prognosis in 4 diverse clinical settings.

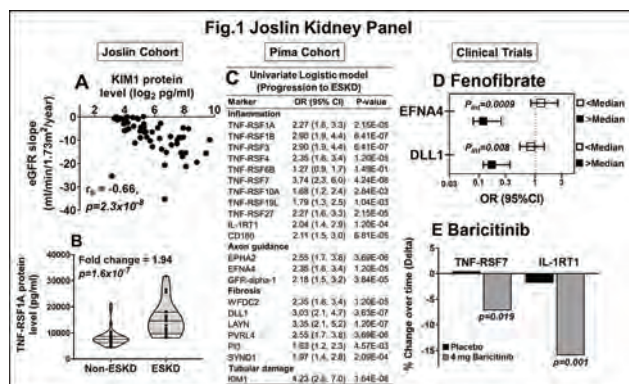

**Methods:** Concentrations of the JKP proteins were measured in 4 cohorts on a custom-made OLINK platform using a proximity extension assay. Prognostic value of the JKP proteins for eGFR slope and ESKD during 7-15 years of follow-up was examined in 60 Joslin Kidney Study patients with T1D; for 10-year risk of ESKD in a cohort of 162 Pima Indians with T2D; and for predicting the beneficial effect of fenofibrate in 450 ACCORD trial participants. In addition, the effect of the JAK1/2 inhibitor, Baricitinib, on the 1-year changes of the JKP proteins was examined in 42 Baricitinib trial participants (25 placebo/17 Baricitinib).

**Results:** In the Joslin cohort, baseline levels of all proteins correlated strongly with eGFR slope ( $r = -0.4$  to  $-0.7$ ;  $p < 10^{-7}$ ) (Fig. 1A for KIM1) and all were significantly higher in patients who developed ESKD than in those who did not ( $FC = 1.3$ - $5.4$ ;  $p < 10^{-8}$ ) (Fig. 1B for TNF-RSF1A). In the Pima cohort, baseline levels of 20 proteins were associated with ESKD risk in univariable logistic model (ORs =  $1.7$ - $4.2$ ;  $p < 10^{-7}$ ) (Fig. 1C) and the ORs remained significant for 19 proteins (excluding WFDC2 and PI3) after adjustment for key confounders. Fenofibrate treatment reduced loss of kidney function in ACCORD patients who had levels of two proteins above the median (Fig. 1D). Baricitinib significantly decreased levels of 5 proteins relative to placebo (Fig. 1E for TNF-RSF7 and IL-1RT1).

**Conclusions:** The JKP successfully identified patients at risk of progressive kidney disease and those with beneficial responses to specific reno-protective therapies.

### Correlation Between Albuminuria and Echocardiographic (Echo) Abnormalities in Individuals With Type 2 Diabetes (T2D): Insights From the Take Care of Me (TCoM) Program

Hardik Vasanwala,<sup>1</sup> Susana Goncalves,<sup>2</sup> Kamlesh Khunti,<sup>3</sup> Peter Fenici,<sup>4,5</sup> Hiddo J. L. Heerspink,<sup>6</sup> Shashank R. Joshi,<sup>7</sup> Mikhail Kosiborod,<sup>8</sup> Carolyn Lam,<sup>9,10</sup> Antonio Nicolucci,<sup>11</sup> Larisa Ramirez,<sup>12</sup> Alejandra Silva,<sup>12</sup> Filip Surmont,<sup>13</sup> Estefania Vazquez Mendez,<sup>14</sup> <sup>1</sup>AstraZeneca, India, Bangalore, India; <sup>2</sup>AstraZeneca, Argentina, Buenos Aires, Argentina; <sup>3</sup>University of Leicester, Leicester, United Kingdom; <sup>4</sup>AstraZeneca, S.p.A, Milan, Italy; <sup>5</sup>School of Medicine and Surgery, Catholic University of Sacred Heart, Rome, Italy; <sup>6</sup>Department of Clinical Pharmacology of the University Medical Center Groningen, Groningen, Netherlands; <sup>7</sup>Lilavati Hospital and Research Centre, Mumbai, India; <sup>8</sup>Saint Luke's MidAmerica Heart Institute, University of Missouri-Kansas City, Kansas city, MO; <sup>9</sup>National Heart Center, Singapore, Singapore; <sup>10</sup>Duke-National University of Singapore Medical School, Singapore, Singapore; <sup>11</sup>Center for Outcomes Research and Clinical Epidemiology, Pescara, Italy; <sup>12</sup>AstraZeneca, Latam, San Jose, Costa Rica; <sup>13</sup>AstraZeneca, China, Shanghai, China; <sup>14</sup>AstraZeneca, Mexico, Guadalajara, Mexico.

**Background:** Cardiovascular (CV) and renal diseases are the most common and morbid complications of T2D. The TCoM program, a subset of the iCaReMe global, cloud-based registry (NCT03549754), assessed the correlation between albuminuria and echo abnormalities in individuals with T2D.

**Methods:** Cross-sectional data of adults (>18 years) with T2D and no known cardiovascular complications (CRCs) at index visit, enrolled from routine clinical practice from Mexico, Argentina, Egypt, India, Malaysia, and the Philippines, were collected between December 2020 and December 2021. Correlation was assessed using Cramer's V-value and Fisher's exact/chi-square test.

**Results:** Of 12320 enrolled individuals (mean±SD age, 54.6±11.3 yrs; 59.3% women), 4853 had high/very high CV risk. Of these, 1506 (31%) had echo data; 450 (29.9%) of them had abnormal echo: 17.3% left ventricular hypertrophy, 16.8% left atrial enlargement, 4.3% diastolic dysfunction, 4.1% pulmonary hypertension, and 3.8% valvular disease. Echo abnormalities were significantly higher in individuals with albuminuria A2/A3 than those with A1 (33.5% vs 24.7%,  $p<0.05$ ,  $v=0.094$ ; Table). Significant correlation ( $p<0.05$ ) was found between albuminuria and T2D duration ( $v=0.117$ ), HbA1c ( $v=0.168$ ), and CV risk ( $v=0.857$ ).

**Conclusions:** Among individuals with T2D and high/very high CV risk from low-middle income countries, there is a significant correlation between albuminuria (stages A2/A3) and abnormal echo. Early detection of albuminuria through screening may be the key to effective management of CRCs in these individuals.

### Endotrophin as a Marker of Complications in a Type 2 Diabetes Cohort

Ninna H. Tougaard,<sup>1</sup> Alexandra L. Møller,<sup>3,2</sup> Pernille F. Rønn,<sup>1</sup> Tine Hansen,<sup>1</sup> Federica Genovese,<sup>3</sup> Morten A. Karsdal,<sup>3</sup> Daniel Guldager Kring Rasmussen,<sup>3</sup> Peter Rossing,<sup>1,2</sup> <sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, København, Denmark; <sup>3</sup>Nordic Bioscience, Herlev, Denmark.

**Background:** Hyperglycemia-mediated tissue injury eventually leads to fibrosis affecting various organ systems. We investigated whether endotrophin, a profibrotic signaling molecule, reflecting collagen VI formation, in serum and urine was associated with risk of developing complications in an unselected population with type 2 diabetes.

**Methods:** Endotrophin was measured by the PRO-C6 ELISA in serum and urine from 774 persons with type 2 diabetes recruited between 2012 and 2016. Urinary values were normalized to urine creatinine levels. Outcomes were identified through national registers and medical records and included a composite kidney endpoint ( $\geq 40\%$  decline in kidney function or kidney failure), first major adverse cardiovascular event (MACE), all-cause mortality, progression of albuminuria, incident heart failure and sight-threatening eye disease. Cox proportional hazards models adjusted for conventional risk factors were applied.

**Results:** The cohort included 254 (33%) females, mean ±SD age was 65 ±12 years, diabetes duration 17 ±8.8 years, eGFR 76 ±24 ml/min/1.73m<sup>2</sup> and median [Q1:Q3] urinary albumin excretion was 12.5 [5.5:73.5] mg/g or g/24h. Depending on outcome, median follow-up ranged from 3.0 to 6.0 years. A doubling of serum endotrophin was independently associated with the composite kidney endpoint, first MACE, all-cause mortality and incident heart failure, but not with progression of albuminuria or incident sight-threatening eye disease (Table). A doubling of urine endotrophin was independently associated with progression of albuminuria and incident heart failure, but not with the other outcomes (Table).

**Conclusions:** Serum endotrophin was a risk marker for mortality, kidney and cardiovascular complications in type 2 diabetes. Urine endotrophin was a risk marker for progression of albuminuria and incident heart failure.

	Hazard ratio by doubling of endotrophin (95% CI)			
	Serum (crude)	Serum (adjusted)	Urine (crude)	Urine (adjusted)

Associations between endotrophin and complications incidence estimated by Cox proportional-hazards model

TH-PO235

**Longitudinal Changes (Deltas) of Circulating Proteins During Fast Progression to ESKD in Diabetes: Results of a Global Proteomics Study**  
Hiroki Kobayashi,<sup>1,3</sup> Helen C. Looker,<sup>2</sup> Eiichiro Satake,<sup>1</sup> Robert G. Nelson,<sup>2</sup> Andrzej S. Krolewski,<sup>1</sup> <sup>1</sup>Research Division, Joslin Diabetes Center, Boston, MA; <sup>2</sup>Chronic Kidney Disease Section, National Institute of Diabetes and Digestive and Kidney Diseases, Phenix, AZ; <sup>3</sup>Division of Nephrology, Hypertension, and Endocrinology, Nihon University School of Medicine, Tokyo, Japan.

**Background:** We recently showed that approximately 6-10% of patients with diabetes have fast progressive kidney function decline (FPKD) that leads to ESKD from normal kidney function within 2-15 years. However, the disease processes underlying FPKD is not well understood. Similarly, the way to identify patients at risk of FPKD is unknown. This study aims to answer this question by examining longitudinal changes (referred to as DELTAs) in concentration of circulating proteins associated with FPKD.

**Methods:** Using the OLINK proteomics platform, we measured concentration of 452 proteins at baseline and at follow-up (median interval 3-4 years apart) in two cohorts of patients with diabetes and normal kidney function at baseline. These participants were followed for 7 to 15 years. The Joslin Cohort had 106 T1D patients; 47 developed ESKD. The Pima Indians Cohort had 77 patients with T2D; 37 developed ESKD. We evaluated the association of DELTAs (expressed as % change from baseline value/year) with progression to ESKD using logistic regression model.

**Results:** In both cohorts, DELTAs for the same 74 circulating proteins were robustly associated with fast progression to ESKD. The set of 74 proteins was significantly enriched for tumor necrosis factor (TNF) receptors (p<0.001) and immunoregulatory receptors (p<0.001) and was depleted of proteins classified as enzymes (p<0.001). DELTAs for four of these proteins CD27 (TNF-R7), TNF-R2, SIRPB1 and LAYN predicted ESKD with power similar to DELTAs for eGFR and UACR. The C-statistics for the clinical model was 0.879 and increased to 0.921 - 0.924 when combined with these proteins.

**Conclusions:** In conclusion, the disease process underlying fast progression to ESKD in diabetes manifests as increased circulation of multiple TNF and other receptors but no other proteins. Measuring DELTAs of the four proteins can be used to monitor fast progression to ESKD in addition to current clinical markers, such as eGFR.

TH-PO236

**Novel Urinary Metabolite Biomarkers in Diagnosis of Diabetic Kidney Disease**  
Caifeng Shi, Aiqin He, Xiaomei Wu, Junwei Yang, Yang Zhou. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Background:** To exploration and application of novel urinary metabolite biomarkers in diagnosis of diabetic kidney disease (DKD).

**Methods:** Healthy individuals and type 2 diabetes (T2DM) patients admitted to the Second Affiliated Hospital of Nanjing Medical University from January to December 2020 were enrolled. Two separated cohorts-discovery cohort (n = 116) and validation cohort (n = 119) were included, which were divided into three groups: healthy control group, simple T2DM group, and T2DM + DKD group. Demographic and laboratory data were collected, and the urinary metabolites were detected by ultraperformance liquid chromatography coupled to tandem mass spectrometry. Partial least squares discriminant analysis and orthogonal partial least squares discriminant analysis were used for multi-dimensional modeling. Machine learning based on Boruta algorithm was used to screen potential markers. Wilcox test was used for comparison of metabolite data between two groups, and Kruskal-Wallis test was used for comparison between multiple groups. Binary logistic regression analysis was used for statistical modeling, and receiver operating characteristic (ROC) curve was used to evaluate diagnostic efficacy.

**Results:** A total of 160 metabolites were detected in morning urine samples by targeted quantitative metabolomics. Sixty-two differential metabolites were screened out from the discovery cohort, mainly enriched in amino acid metabolic pathway, and 17 of them were candidate markers for diagnosis of DKD. Fifteen differential metabolites and seven candidate markers (isovaleric acid; isobutyric acid; leucine; s-adenosylhomocysteine; propionic acid; oxoadipic acid; propionylcarnitine) were verified in the validation cohort. The diagnostic model of the combined marker was constructed by integrating the 7-candidate urinary metabolic markers. The diagnostic efficacy of the combined marker in both the discovery cohort and the validation cohort (the area under ROC curve of the discovery cohort was 0.888, 95%CI 0.814—0.963; the area under ROC curve of the validation cohort was 0.811, 95%CI 0.734—0.887) were significantly higher than that of a single metabolic marker.

**Conclusions:** There were significant differences in urine metabolites between simple T2DM patients and T2DM with DKD patients. The combination of various urine metabolic markers may be a novel strategy to diagnose DKD.

**Funding:** Government Support - Non-U.S.

TH-PO237

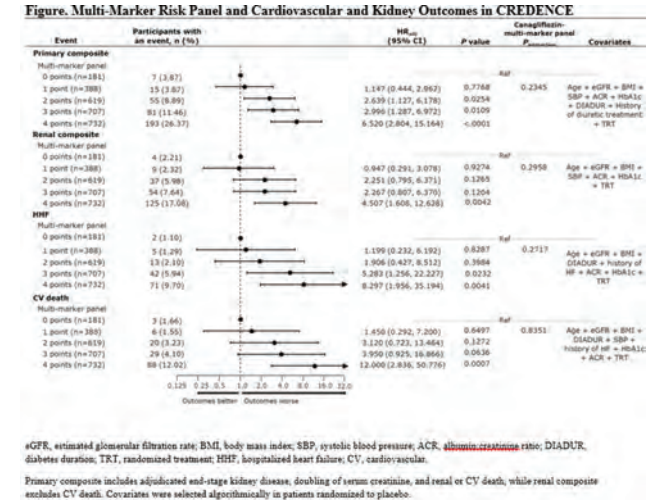

**Multi-Marker Biomarker Panel Predicts Adverse Cardiovascular and Kidney Outcomes in People With Diabetes and Albuminuric CKD in the CREDENCE Trial**  
Michael K. Hansen,<sup>1</sup> Muthiah Vaduganathan,<sup>2</sup> Eshetu Tefera,<sup>1</sup> Yshai Yavin,<sup>1</sup> Naveed Sattar,<sup>3</sup> Hiddo J. L. Heerspink,<sup>4</sup> James Januzzi,<sup>5</sup> <sup>1</sup>Janssen Research & Development, LLC, Spring House, PA; <sup>2</sup>Division of Cardiovascular Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; <sup>3</sup>University of Glasgow BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom; <sup>4</sup>Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; <sup>5</sup>Massachusetts General Hospital, Harvard Medical School, Boston, MA.

**Background:** Circulating biomarkers reflecting different mechanistic pathways may identify patients at greatest clinical risk and who may be most likely to benefit from sodium glucose co-transporter-2 inhibitors. We evaluated the prognostic value of 4 biomarkers (N-terminal pro-B-type natriuretic peptide [NT-proBNP], high sensitivity cardiac troponin T [hs-cTnT], insulin-like growth factor binding protein 7 [IGFBP7], and growth differentiation factor 15 [GDF15]) either alone or in combination in people with T2D and CKD.

**Methods:** Among 2,627 participants in the CREDENCE trial with available biomarker data, we created a multi-marker panel assigning 1 point for each elevated concentration of NT-proBNP, hs-cTnT, IGFBP7, and GDF15. Multivariable Cox regression analysis was used to examine the association with risk of cardiac and kidney outcomes using each biomarker alone or as a multi-marker panel compared to a base clinical model alone for each outcome.

**Results:** Among all participants at baseline, 61% had elevated levels of NT-proBNP >125 pg/mL, 69% had hs-cTnT ≥14 ng/L, 50% had IGFBP7 >122 ng/mL, and 77% had GDF15 >1800 pg/mL. Overall, 7%, 15%, 23%, 27%, and 28% had 0, 1, 2, 3, and 4 elevated biomarkers. Increasing numbers of elevated biomarkers independently predicted each outcome in a graded fashion (Figure). Canagliflozin consistently reduced outcomes across multi-marker scores (P<sup>interaction</sup> >0.20 for all).

**Conclusions:** Biomarkers of myocardial injury and remodeling are frequently abnormal in T2D and CKD and, when combined, may identify patients at the greatest risk of progressing to cardiovascular and kidney outcomes.

## TH-PO238

**Higher Plasma ADMA Levels and Lower ADMA and SDMA Fractional Excretion Were Associated With Risk of Atherosclerotic Cardiovascular Disease in Diabetic Kidney Disease**

Sarah J. Schrauben,<sup>1</sup> Amanda H. Anderson,<sup>2</sup> Chi-yuan Hsu,<sup>4</sup> Joachim H. Ix,<sup>6</sup> Tariq Shafi,<sup>8</sup> Michael Shlipak,<sup>9</sup> Jing Chen,<sup>3</sup> Thomas H. Hostetter,<sup>7</sup> Julia Brown,<sup>5</sup> Rupal Mehta,<sup>10</sup> Raymond R. Townsend,<sup>1</sup> Jesse C. Seegmiller,<sup>11</sup> Paul L. Kimmel,<sup>12</sup> Vasan S. Ramachandran,<sup>13</sup> Harold I. Feldman,<sup>1</sup> Jeffrey R. Schelling.<sup>14</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>Tulane University, New Orleans, LA; <sup>3</sup>Tulane University School of Medicine, New Orleans, LA; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>University of Illinois Chicago, Chicago, IL; <sup>6</sup>University of California San Diego, La Jolla, CA; <sup>7</sup>University of North Carolina System, Chapel Hill, NC; <sup>8</sup>University of Mississippi, University Park, MS; <sup>9</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>10</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>11</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>12</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>13</sup>Boston University School of Medicine, Boston, MA; <sup>14</sup>Case Western Reserve University, Cleveland, OH.

**Background:** CKD is associated with cardiovascular disease (CVD), especially among those with diabetes, but it is difficult to prospectively identify those who will experience such events. The uremic solutes asymmetric dimethyl arginine (ADMA), symmetric dimethyl arginine (SDMA), and trimethyl methylamine-N-oxide (TMAO), may help identify these high-risk individuals.

**Methods:** We performed a case-cohort study among 766 Chronic Renal Insufficiency Cohort Study participants with diabetes, eGFR <60 ml/min/1.73m<sup>2</sup> and no atherosclerotic CVD (ASCVD) or heart failure at baseline. Cases were those who developed the primary outcome: incident ASCVD events (myocardial infarction, stroke, peripheral artery disease). Participants were randomly selected for the subcohort. Secondary outcomes were incident heart failure, and CKD progression (end-stage kidney disease or 40% eGFR decline). Uremic solute concentrations of TMAO, ADMA, SDMA in plasma and urine were determined with liquid chromatography-tandem mass spectrometry. Weighted Cox regression models related uremic solute concentrations in the plasma (modelled per SD) and urine (modeled as fractional excretion) with primary and secondary outcomes and were adjusted for: age, sex, race, education, blood pressure, cholesterol, hemoglobin A1c, smoking, BMI, hsCRP, serum creatinine, cystatin C, and proteinuria.

**Results:** Higher ADMA plasma concentrations were associated with risk of ASCVD (HR 1.52, 95% CI: 1.16-1.96) but not with heart failure. Plasma TMAO and SDMA concentrations were not associated with ASCVD, heart failure, or CKD progression. Lower ADMA and SDMA fractional excretion were associated with risk of ASCVD (HR 3.13, 95% CI: 1.41-6.67 and HR 2.33, 95% CI 1.11-4.76, respectively).

**Conclusions:** In persons with CKD and diabetes, higher plasma ADMA concentrations were associated with increased risk of ASCVD events. The data suggest new mechanistic insights whereby altered renal handling of ADMA and its enantiomer, SDMA, may lead to increased plasma concentrations and CVD risk. If confirmed, strategies to enhance renal ADMA and SDMA excretion could have potential therapeutic value.

**Funding:** NIDDK Support

## TH-PO239

**The Pro-Fibrotic Molecule Endotrophin as a Risk Marker of Complications in a Type 1 Diabetes Cohort**

Alexandra L. Møller,<sup>1,2</sup> Ninna H. Tougaard,<sup>3</sup> Pernille F. Rønn,<sup>3</sup> Tine Hansen,<sup>3</sup> Federica Genovese,<sup>1</sup> Morten A. Karsdal,<sup>1</sup> Daniel Guldager Kring Rasmussen,<sup>1</sup> Peter Rossing,<sup>3,4</sup> <sup>1</sup>Nordic Bioscience A/S, Herlev, Denmark; <sup>2</sup>University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark; <sup>3</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>4</sup>University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark.

**Background:** Hyperglycemia can trigger pathological pathways leading to fibrosis where extracellular matrix (ECM) components are accumulated. We investigated the potential of endotrophin (ETP), a molecule generated during collagen type VI (COL6) formation, as a risk marker for complications in an unselected population with type 1 diabetes.

**Methods:** We measured ETP by the PRO-C6 ELISA in serum and urine from 1468 persons with type 1 diabetes recruited between 2012-2016. Urinary values were normalized to urine creatinine levels. Participants were followed for a median of up to 6.4 years. Outcomes were identified through national registers and included a composite renal endpoint (≥40% decline in kidney function or kidney failure), first MACE, all-cause mortality, progression of albuminuria, incident heart failure (HF), incident cardiovascular disease (CVD), and incident sight-threatening eye disease. Cox proportional hazards models adjusted for conventional risk factors were applied. For each outcome, we excluded participants previously diagnosed with the outcome.

**Results:** The cohort included 712 (49%) females, mean±SD age was 51±16 years, eGFR 94±23 ml/min/1.73m<sup>2</sup>, and median (IQR) urinary albumin excretion was 5.5 (3.5-11.5) mg/g or g/24h. A doubling of serum ETP was independently associated with the composite renal endpoint, all-cause mortality, and progression of albuminuria, but not with first MACE, incident HF, CVD, or sight-threatening eye disease after adjustment (Table). Urine ETP was not associated with outcomes after adjustment.

**Conclusions:** Serum ETP was a risk marker for mortality and kidney complications in type 1 diabetes. Biomarkers of ECM remodeling, such as serum ETP, may identify persons with active pro-fibrotic processes at risk for complications related to diabetes.

HR by doubling of serum ETP (95% CI)

	Unadjusted	P value	Adjusted	P value
Renal endpoint (n=36/1462)	4.83 (3.46-6.75)	<0.001	3.39 (1.98-5.82)	<0.001

## TH-PO240

**Interaction of Glycation and Carbamylation in Diabetic CKD: Insights From the CRIC Study**

Mengyao Tang,<sup>1</sup> James P. Lash,<sup>2</sup> Sahir Kalim.<sup>1,3</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>University of Illinois Chicago UI Health, Chicago, IL; <sup>3</sup>Harvard Medical School, Boston, MA.

**Background:** Glycated hemoglobin (A1c) is used to predict glycation burden and clinical outcomes in diabetic patients. However, the reliability of A1c in CKD has been questioned, with concerns including the competition between the two post-translational protein modifications, glycation and carbamylation, on the same protein amino groups. Whether carbamylation modifies the impact of A1c on outcomes in patients with diabetic CKD is unclear.

**Methods:** In 1,427 participants from the Chronic Renal Insufficiency Cohort (CRIC) study with co-existing CKD and diabetes, multivariable Cox regression models were applied to evaluate the association between A1c and CKD progression (ESRD or 50% eGFR decline) or first cardiovascular disease (CVD) event (congestive heart failure, myocardial infarction, or stroke), stratified by quartiles of carbamylated albumin (C-Alb) levels.

**Results:** The mean age of participants was 60 years, mean eGFR was 38.1 mL/min/1.73 m<sup>2</sup>, mean A1c was 7.5%, and median C-Alb was 8.4 mmol/mol. During an average of 7.9 years of follow up, every 1% increase in A1c was associated with higher risks of CKD progression (HR 1.07, 95% CI 1.02, 1.12), and CVD (HR 1.09; 95% CI 1.04, 1.15) in adjusted models. However, in the highest C-Alb quartile, A1c was no longer associated with CKD progression or CVD; while in the lowest C-Alb quartile, A1c remained an independent risk factor for the adverse outcomes (Figure 1). Interaction testing between A1c and C-Alb was significant for CKD progression.

**Conclusions:** In patients with co-existing CKD and diabetes, the association between A1c and adverse clinical outcomes is modified by high carbamylation levels. This finding may explain why A1c is not as reliable in patients with CKD compared to the general diabetic population.

**Funding:** NIDDK Support

**Figure 1.** Association of hemoglobin A1c with outcomes in CRIC participants with CKD and diabetes, stratified by quartiles of C-Alb levels. Note hemoglobin A1c's diminished HRs at higher C-Alb quartiles. The models are adjusted for age, sex, race/ethnicity, BMI, smoking status, CVD, HTN, ACEI/ARB, and LDL.

## TH-PO241

**Nesfatin-1 and Tubulointerstitial Damage in Diabetic Kidney Disease: A Possible Biomarker for the Histological Severity**

Sayoko Miyake,<sup>1,2</sup> Yoshihisa Nakatani,<sup>1</sup> Yukihito Nakano,<sup>1</sup> Shuji Arima,<sup>1</sup> <sup>1</sup>Kinki Daigaku Byoin, Osakasayama, Japan; <sup>2</sup>Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan.

**Background:** Although adipokines are known to contribute to the pathogenesis of diabetic kidney disease (DKD), pathological significance of nesfatin-1, an adipokine in DKD remains unclear. We studied the possible associations between serum nesfatin-1 concentrations and histological renal damages in 56 persons with biopsy-proved DKD.

**Methods:** The relation between serum nesfatin-1 concentrations, clinical parameters and renal histological damage were cross-sectionally investigated. The relation between serum nesfatin-1 concentrations and renal outcomes were also examined longitudinally.

**Results:** Serum nesfatin-1 concentrations showed a significant negative correlation with age, total cholesterol, and high-density lipoprotein cholesterol, but not with other clinical parameters. Persons were divided into the following three groups based on serum nesfatin-1 concentrations (pg/mL): low- (log average: 1.99), normal- (log average: 3.05), and high-group (log average: 3.60). Histological analysis of tubulointerstitial lesions showed higher interstitial fibrosis and tubular atrophy scores and more severe interstitial infiltration in the group with low serum nesfatin-1 concentrations than in

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

the other groups. However, there was no significant relation between serum nesfatin-1 concentrations and the severity of glomerular lesions nor renal outcomes.

**Conclusions:** Serum nesfatin-1 concentrations showed a strong correlation with diabetic tubulointerstitial damage level, suggesting its clinical utility as a biomarker for histological injury in DKD.

## TH-PO242

**Assessing the Inflammatory Landscape of Human Diabetic Kidney Disease (DKD) Through NanoString Digital Spatial Profiling Technology**  
Khaled Mosaad Elhusseiny,<sup>1</sup> Lynn D. Cornell,<sup>2</sup> Xiaohui Bian,<sup>1</sup> Yaohua Ma,<sup>1</sup> LaTonya J. Hickson,<sup>1</sup> Mayo Translational and Regenerative Nephrology Research Laboratory <sup>1</sup>Mayo Clinic in Florida, Jacksonville, FL; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

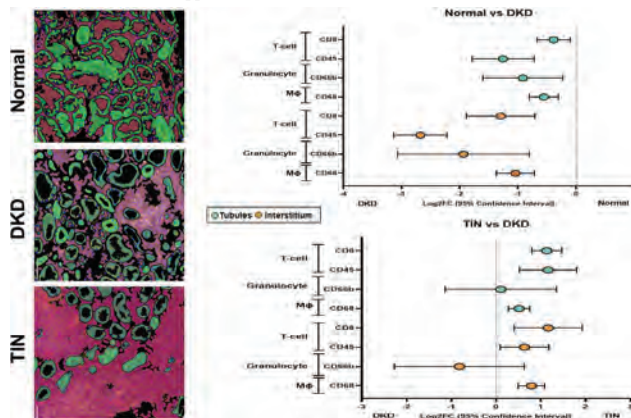

**Background:** Inflammation contributes to DKD pathogenesis and progression. We examined the inflammatory signature of kidney biopsy tissue from subjects with DKD compared to those with normal histology and tubulointerstitial nephritis (TIN)

**Methods:** Core needle biopsy samples were stained with a fluor-labeled antibodies against pan-cytokeratin (epithelium), CD45 (T-cell), and CD68 (macrophage) plus the nuclear dye (STYO13). It also contained 77 target antibodies, each labeled with a unique oligonucleotide barcode. Regions of interest (ROI) were selected based on kidney compartments, and two segments were collected from each ROI: cytokeratin-positive = tubule, cytokeratin-negative/STYO13-positive = interstitium. Antibody-bound oligonucleotides were liberated by UV laser irradiation of computer-defined masks to collect oligonucleotides and then quantified using nCounter technology. Data were normalized to the geometric mean of three housekeeping proteins (GAPDH, histone H3, S6). Differential expression was assessed using the linear mixed model

**Results:** Surface protein expression of inflammatory cells (**Figure:** red, yellow) were increased in the tubules and interstitium of DKD (n=5) and TIN kidney (n=4) compared to normal (n=2) patients. Infiltration of interstitial CD68+ macrophages were higher in DKD vs. normal, yet lower vs. TIN (P < 0.05). Similarly, CD45+ and CD8+ T-cells were significantly increased in DKD vs. normal tubulointerstitium but decreased vs. TIN. While, CD66b+ granulocytes were higher in DKD tubulointerstitium (vs. normal), it did not show significant difference between DKD and TIN

**Conclusions:** The inflammatory landscape of DKD is characterized by tubulointerstitial infiltration of macrophages, T-cells and granulocytes which is not as robust as TIN but significantly higher than normal healthy kidney tissue. Hence, targeting pro-inflammatory pathway in DKD may represent an important therapeutic targeting for DKD

**Funding:** NIDDK Support

## TH-PO243

**Association of Urine Biomarkers of Tubule Health With Mortality in Patients With Diabetes and CKD**

George Vasquez-Rios,<sup>1</sup> Ronit Katz,<sup>3</sup> Mary Cushman,<sup>4</sup> Chirag R. Parikh,<sup>5</sup> Paul L. Kimmel,<sup>6</sup> Sushrut S. Waikar,<sup>7</sup> Sarah J. Schrauben,<sup>8</sup> Jason H. Greenberg,<sup>9</sup> Mark J. Sarnak,<sup>10</sup> Michael Shlipak,<sup>11</sup> Joachim H. Ix,<sup>12</sup> Orlando M. Gutierrez.<sup>2</sup> CKD Biomarkers Consortium <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL; <sup>3</sup>University of Washington School of Medicine, Seattle, WA; <sup>4</sup>University of Vermont College of Medicine, Burlington, VT; <sup>5</sup>Johns Hopkins University, Baltimore, MD; <sup>6</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>7</sup>Boston Medical Center, Boston, MA; <sup>8</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>9</sup>Yale School of Medicine, New Haven, CT; <sup>10</sup>Tufts Medical Center, Boston, MA; <sup>11</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>12</sup>University of California San Diego, La Jolla, CA.

**Background:** Biomarkers of kidney tubular health are associated with the risk of kidney failure in individuals with chronic kidney disease (CKD) and diabetes, independently of other factors. Whether these biomarkers are also associated with mortality remains unclear.

**Methods:** Among 560 individuals with diabetes and an estimated glomerular filtration rate (eGFR)  $\leq 60$  ml/min/1.73m<sup>2</sup> randomly sampled from the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study (47% male, 53% Black), we measured urine biomarkers in stored baseline visit samples: monocyte chemoattractant protein-1 [MCP-1], alpha-1-microglobulin [a1m], kidney injury molecule-1 [KIM-1], epidermal growth factor [EGF], chitinase-3-like protein 1 [YKL-40], and uromodulin [UMOD]. Associations of biomarkers with all-cause and cause-specific mortality were examined in Cox regression models, adjusted for age, sex, race, education, and urine creatinine to account for differences in tonicity, blood pressure, body mass index, smoking, coronary heart disease, stroke, eGFR, and urine albumin.

**Results:** The baseline mean (SD) age was 70 (9) years, mean (SD) eGFR was 40 (3) ml/min/1.73m<sup>2</sup>, and median [IQR] albumin-to-creatinine ratio was 33 [10,213] mg/g. Over a mean (SD) of 6 (3) years of follow-up, 310 participants died from causes adjudicated as cardiovascular (n=121), cancer (n=30), or other (n=159). In fully adjusted models, each 2-fold higher concentration of KIM-1 and YKL-40 was associated with a higher risk of all-cause mortality: hazard ratio (HR) 1.15, 95%CI 1.01,1.31 and 1.13, 95%CI 1.07,1.20, respectively. Higher UMOD was associated with a lower risk of cardiovascular death (HR 0.87, 95%CI 0.77,0.99), and higher MCP-1 was associated with a higher risk of cancer-related death (HR 1.52, 95%CI 1.05,2.18) in fully adjusted models. Finally, biomarkers associated with other causes of death in fully adjusted models included: KIM-1 (1.25, 95%CI 1.04,1.50), EGF (1.38, 95%CI 1.05,1.82), and YKL-40 (1.18, 95%CI 1.08,1.29).

**Conclusions:** Higher urine concentrations of KIM-1 and YKL-40 are associated with an increased risk of all-cause mortality over 6 years in individuals with diabetes and CKD independently of established risk factors, eGFR, and urine albumin.

**Gene Polymorphism in Organic Anion Transporters Determine the Long-Term Efficacy and Safety of Atrasentan in Patients With Type 2 Diabetes and CKD**

Johannes D. Smeijer,<sup>1</sup> Jeroen Koomen,<sup>1</sup> Donald E. Kohan,<sup>2</sup> John McMurray,<sup>3</sup> George L. Bakris,<sup>4</sup> Ricardo Correa-Rotter,<sup>5</sup> Fan Fan Hou,<sup>6</sup> Dalane Kitzman,<sup>7</sup> Hirofumi Makino,<sup>11</sup> Vlado Perkovic,<sup>8,9</sup> Peter Rossing,<sup>10</sup> Dick de Zeeuw,<sup>1</sup> Hiddo J. L. Heerspink.<sup>1,8</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>University of Utah Health, Salt Lake City, UT; <sup>3</sup>University of Glasgow, Glasgow, United Kingdom; <sup>4</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>5</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; <sup>6</sup>Southern Medical University Nanfang Hospital, Guangzhou, China; <sup>7</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>8</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>9</sup>University of New South Wales, Sydney, NSW, Australia; <sup>10</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>11</sup>Okayama Daigaku, Okayama, Japan.

**Background:** The plasma exposure of the endothelin receptor antagonist atrasentan varies between individuals and is associated with nephroprotective effects and the risk of heart failure. We examined the influence of genetic polymorphisms on atrasentan plasma exposure and pharmacodynamic effects.

**Methods:** We performed a genetic sub-study of the SONAR trial in adults with type 2 diabetes, and estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73 m<sup>2</sup>, and urine albumin-to-creatinine ratio (UACR) of 300–5000 mg/g. Single nucleotide polymorphisms (SNPs) were determined in pre-specified membrane transporters, metabolizing enzymes and the endothelin-1 peptide, based on expected relevance for atrasentan PK/PD. The associations between genotype, atrasentan plasma exposure and the effect of atrasentan on the pre-specified kidney and heart failure hospitalization (HHF) outcomes was assessed with Cox proportional hazards regression models.

**Results:** Of 3668 randomized patients, 2329 (63.5%) consented to genotype analysis. Two SNPs in the SLCO1B1 gene (rs4149056 and rs2306283), encoding the hepatic organic anion transporter 1B1 (OATP1B1), showed the strongest association with atrasentan plasma exposure. Based on their SLCO1B1 genotype, patients were classified into normal- or slow OATP1B1 transporter phenotypes. The slow OATP1B1 transporter phenotype group (15.9% of total cohort) had a 20.3% higher atrasentan AUC<sub>0-inf</sub> compared to the normal phenotype (geometric mean AUC 49.7 versus 41.3 ng.h/mL; p<0.001). Among patients with a normal OATP1B1 transporter phenotype, the hazard ratio with atrasentan for the primary kidney and HHF outcomes were 0.61 (95%CI 0.45-0.81) and 1.35 (95%CI 0.84-2.13), respectively. In contrast, in the slow transporter phenotype HRs for kidney and HHF outcomes were 1.95 (95%CI 0.95-4.03, p-interaction normal phenotype=0.004), and 4.18 (95%CI 1.37-12.7, p-interaction normal phenotype=0.060) respectively.

**Conclusions:** Genetic polymorphisms in OATP transporters are associated with significant between-patient variability in atrasentan plasma exposure and long-term efficacy and safety.

TH-PO245

**Family-Based Whole-Genome Sequencing Identifies FRAS1 as a Novel Gene for Rapid Renal Decline in Diabetes**  
Matthew B. Neeley,<sup>1</sup> Barry Moore,<sup>2</sup> Shuwei Li,<sup>3</sup> Dermot F. Reilly,<sup>3</sup> Jose M. Lazaro guevara,<sup>2</sup> Melissa H. Pezzolesi,<sup>1</sup> Edgar J. Hernandez,<sup>2</sup> Mary Helen Black,<sup>3</sup> Mark Yandell,<sup>2</sup> Antonio R. Parrado,<sup>3</sup> Marcus G. Pezzolesi.<sup>1,2</sup>  
<sup>1</sup>University of Utah, Division of Nephrology and Hypertension, Department of Internal Medicine, Salt Lake City, UT; <sup>2</sup>University of Utah, Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT; <sup>3</sup>Janssen Research and Development LLC, Spring House, PA.

**Background:** Progressive renal decline is the central manifestation of diabetic nephropathy (DN) and ultimately leads to end-stage renal disease. To accelerate discovery of novel genes that contribute to rapid renal decline and DN, we developed an innovative family-based approach that integrates electronic medical record data, a unique population-based genealogy resource, and next-generation sequencing.

**Methods:** Kindred-specific risk of rapid renal decline was used to quantify the familial standardized incidence ratio and identify pedigrees with excess clustering of rapid renal decline. Whole genome sequencing (WGS) was performed in 60 individuals from 6 pedigrees ascertained for the Utah Diabetes Study, followed by unified linkage analysis and rare variant association testing. To replicate findings, we performed variant-/gene-level association tests using whole exome sequencing (WES, n=450K), WGS (n=150K), renal function biomarkers, and kidney disease endpoints available in the UK Biobank.

**Results:** Among these pedigrees, we identified a rare pathogenic variant in *FRAS1* shared by 5 affected members of one family. Sanger sequencing confirmed the carrier status of these affected family members and identified 2 additional carriers (including 1 with impaired renal function) and 4 non-carriers of the *FRAS1* variant in this family. In the UK Biobank, a population-based cohort of primarily healthy individuals at the time of baseline blood draw, we observed nominal variant association with increased risk of CKD, nephrotic syndrome, and glomerulonephritis (all p<5x10<sup>-3</sup>). *FRAS1* putative loss-of-function and deleterious singletons in aggregation were nominally associated with reduced eGFR (p<5x10<sup>-3</sup>).

**Conclusions:** These data suggest that rare pathogenic variants in *FRAS1* contribute to increased risk of DN and, importantly, progression of rapid renal decline. *FRAS1* encodes an extracellular matrix protein that mediates integrity of glomeruli and is downregulated in glomeruli of mice with DN; further supporting *FRAS1*'s potential role in kidney disease in individuals with diabetes. These findings highlight the power of family-based genetics in well-phenotyped cohorts and its ability to discover novel genes that contribute to rapid renal decline and DN.

**Phenome-Wide Association Study of Common Genetic Variants in the DPP4 Gene and GLP1R Gene and Kidney Outcomes of European Ancestry Individuals in the Million Veteran Program (MVP)**  
Jefferson L. Triozzi,<sup>1</sup> Hua-Chang Chen,<sup>1,2</sup> Ran Tao,<sup>1,2</sup> Otis D. Wilson,<sup>1,2</sup> Guanchao Wang,<sup>1,2</sup> Talat Alp Ikizler,<sup>1,2</sup> Alexander Bick,<sup>1</sup> Edward D. Siew,<sup>1,2</sup> Cassianne Robinson-Cohen,<sup>1</sup> Adriana Hung,<sup>1,2</sup> Million Veteran Program  
<sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>VA Tennessee Valley Healthcare System, Nashville, TN.

**Background:** Incretin mimetics, including dipeptidyl-peptidase 4 inhibitors and glucagon-like peptide 1 receptor agonists, are antihyperglycemic agents that activate neurohormonal pathways to suppress appetite and increase glucagon secretion. Although incretin mimetics are associated with glucose control and improved cardiovascular outcomes, their effect on kidney outcomes is not clearly demonstrated.

**Methods:** We tested the association of one single nucleotide polymorphism (SNP) in the *DPP4* gene encoding dipeptidyl peptidase 4 (rs11695223 [intronic]) and two SNPs in the *GLP1R* gene encoding glucagon-like peptide 1 hormone receptor (rs1030505420 [missense], rs2268647 [intronic]) in a phenome-wide association study (PheWAS) using electronic health record data from European ancestry individuals in the MVP. The *GLP1R* variants are considered drug proxies for agonism. We mapped 1311 clinical diagnoses based on ICD-codes using PheWAS methodology in up to 458,165 individuals of European ancestry. PheWAS was performed by fitting logistic regression models adjusting for age, sex, and ten principal components of ancestry, regressed against the SNPs of interest. Level of significance was set using Bonferroni at 0.05/1311 or p=3.81E-05.

**Results:** The *DPP4* variant was associated with multiple ICD-codes for kidney disease with PheWAS significance. The *GLP1R* variants did not reach PheWAS significance (Table 1).

**Conclusions:** Our study shows that the *DPP4* SNP is associated with kidney outcomes, including ESRD, CKD, urinary calculus, and microscopic hematuria. The *GLP1R* SNPs were associated with T2DM with renal manifestations and CKD, but these did not reach PheWAS significance. Further study is needed to elucidate mechanisms by which incretin pathways affect kidney outcomes.

**Proteomic Analyses Identify Novel Predictors of Diabetic Kidney Disease in Youth-Onset Type 2 Diabetes**  
Laura Pyle,<sup>1</sup> Tim Vigers,<sup>1</sup> Laure K. El ghormli,<sup>2</sup> Ian H. de Boer,<sup>3</sup> Robert G. Nelson,<sup>4</sup> Anita T. Layton,<sup>8</sup> Kumar Sharma,<sup>5</sup> Sushrut S. Waikar,<sup>6</sup> Hiddo J. L. Heerspink,<sup>9</sup> Neil H. White,<sup>10</sup> Kalie L. Tommerdahl,<sup>1</sup> Amy S. Shah,<sup>7</sup> Rose Gubitosi-Klug,<sup>11</sup> Petter Bjornstad.<sup>1</sup>  
<sup>1</sup>University of Colorado Anschutz Medical Campus, Aurora, CO; <sup>2</sup>The George Washington University Milken Institute of Public Health, Washington, DC; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>National Institutes of Health, Bethesda, MD; <sup>5</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>6</sup>Boston University, Boston, MA; <sup>7</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>8</sup>University of Waterloo, Waterloo, ON, Canada; <sup>9</sup>University Medical Center Gronigen, Gronigen, Netherlands; <sup>10</sup>Washington University in St Louis, St Louis, MO; <sup>11</sup>Case Western Reserve University, Cleveland, OH.

**Background:** Diabetic kidney disease (DKD) develops by young adulthood in up to 50% of people with youth-onset type 2 diabetes (Y-T2D), increasing risk of dialysis and premature death. Understanding mechanisms responsible for early DKD is key to management and prevention; accordingly, we sought to identify multiprotein signatures of DKD in Y-T2D.

**Methods:** We measured 7604 Aptamers in 374 baseline plasma samples from the Treatment Options for type 2 Diabetes in Adolescents and Youth (TODAY) study, using the SomaScan 7K Proteomic (SomaLogic) platform. Urine albumin-to-creatinine ratio (UACR) was assessed annually for up to 15 years. Incident micro- and macroalbuminuria were defined as UACR ≥30 and ≥300 mg/g on ≥2 of 3 measures. We evaluated prediction of micro- and macroalbuminuria in separate Cox regression models adjusted for HbA1c, triglycerides, blood pressure, and estimated insulin sensitivity. Gene set enrichment analysis (GSEA) identified pathways of interest. The false discovery rate was controlled at 5% and we report q-values.

**Results:** Participants were 14±2 years of age, 37% male; 43% developed either micro- or macroalbuminuria. Seven proteins predicted time to microalbuminuria, while 8 proteins predicted time to macroalbuminuria, with 2 proteins in common: nerve epidermal growth factor-like 1 (NELL1) (micro: HR 1.56 per 1 SD [95% CI 1.33, 1.83], q=0.0003; macro: 1.95 [1.44-2.63], q=0.017) and FAMI89A2 (micro: 1.58 [1.33, 1.87], q=0.0008; macro: 1.79 [1.36, 2.35], q=0.038). GSEA identified gene sets, including one related to semaphorin interactions, associated with microalbuminuria and macroalbuminuria (Figure).

**Conclusions:** Novel proteins, including those interacting with semaphorins, which play an important role in inflammation and cellular repair, predict incident albuminuria in Y-T2D.

**Funding:** NIDDK Support

## TH-PO248

**Transcriptome Analysis of Human Kidney Tissues to Explore Prognostic Factors in Diabetic Kidney Disease With Nodular Lesion**

Toshiyuki Imasawa,<sup>1</sup> Hiroyuki Unoki-Kubota,<sup>3</sup> Daishi Hirano,<sup>2</sup> Yasushi Kaburagi,<sup>3</sup> <sup>1</sup>National Hospital Organization Chiba-Higashi National Hospital, Chiba, Japan; <sup>2</sup>Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; <sup>3</sup>Diabetes Research Center, Research Institute, National Center for Global Health and Medicine, Tokyo, Japan.

**Background:** The prognosis of diabetic kidney disease (DKD) with nodular lesion (NL) is poor. However, there are cases in which the prognosis is not poor even in the presence of NL. The mechanism of why these patients do not have a poor prognosis remains unclear.

**Methods:** Twelve patients with a histological diagnosis of DKD with NL and no other renal comorbidities who had undergone kidney biopsy within the past 10 years and had been followed up for at least 3 years at a single institution with a uniform treatment strategy were included. Total RNA was extracted from renal biopsy tissues in formalin-fixed paraffin-embedded blocks and gene expression profile of the kidney was analyzed using microarray. The good prognosis (GP) group was defined as patients with an annual eGFR decline rate of <5 ml/min/1.73 m<sup>2</sup>.

**Results:** The eGFR, urinary protein, and rate of sclerotic glomeruli at the time of renal biopsy in the poor prognosis (PP; n=6) and GP groups (n=6) were 47±18 and 45±15 ml/min/1.73 m<sup>2</sup>, 7.5±4.2 and 4.0±2.7 g/gCre, and 19±13% and 26±14%, respectively, none of which differed between the two groups. In the microarray analysis, genes with little or no expression (raw signals <50 and [processed signals] <0.3) were excluded and then 14227 genes were used for the analyses. A total of 1496 differentially expressed genes (DEGs) were selected by the criteria of P-values < 0.05 and |fold change| ≥ 2. Using the Ingenuity Pathway Analysis system, 15 canonical pathways and 9 diseases or functions annotations were found to be enriched. In addition, 73 upstream regulators were enriched, including CCN5 which was predicted to be significantly activated in the GP group. Moreover, one regulatory effect and 25 networks were revealed to be associated with the DEGs. The associated regulatory effect was 'viral infection' in which CCN5 is predicted to regulate the expression of CDH1, CD24, and ESR1 genes. The top five networks with a score of > 30 contained ESR1, extracellular signal-regulated kinase, and AKT which were predicted to be activated in the GP group.

**Conclusions:** Some factors identified in the present study have been reported to be as renoprotective factors in the past, which imply that they function to prevent the progression of DKD with NL.

**Funding:** Government Support - Non-U.S.

## TH-PO249

**ND-13, a DJ-1 Derived Peptide, as a Novel Pharmacological Approach to Activated Nrf2 in the Prevention of Inflammasome Activation in Diabetic Nephropathy**

Santiago Cuevas,<sup>1,2</sup> Virginia C. Sanchez,<sup>1</sup> Adrián Luna García,<sup>1</sup> Maksym Kupchyk,<sup>1</sup> Leonor Andugar-Rocamora,<sup>2</sup> Cristina M. López,<sup>1</sup> Inmaculada Ros Madrid,<sup>2</sup> Laura H. Navarro,<sup>1</sup> Florentina Rosique,<sup>2</sup> <sup>1</sup>BioMedical Research Institute of Murcia (IMIB-Arrixaca), Murcia, Spain; <sup>2</sup>Clinical University Hospital Virgen de la Arrixaca, Murcia, Spain.

**Background:** The inflammasome is a crucial regulator of renal inflammation and a key factor in the pathogenesis of renal diseases. DJ-1 is a renal protein with antioxidant and anti-inflammatory properties with the capacity to prevent Nuclear factor erythroid 2-related factor 2 (Nrf2) degradation. Nrf2 is a transcription factor that activates the expression of numerous proteins with antioxidant properties. ND-13 is a peptide consisting of 13 highly conserved aas from the DJ-1 sequence. In this study, we determined the capacity of ND-13/Nrf2 pathway to attenuate inflammasome activation in renal diseases.

**Methods:** Mouse bone marrow macrophages (BMM) were treated with Bardoxolone, an Nrf2 inducer, and ND-13. Diabetes was induced in C57Bl/6 mice via injection of STZ and treated with ND-13. Peripheral blood mononuclear cells (PBMCs) were isolated from the blood of patients with diabetic nephropathy and controls and were plate and stimulated with LPS/ATP and treated with ND-13 and MCC950, an inflammasome inhibitor.

**Results:** The IL-1β concentration in the medium of BMM increased by NLRP3 inflammasome stimulation by LPS/ATP, and decreased in macrophages pre-treated with Bardoxolone (65.07±26%, n=4, P<0.05) but not pre-treated with ND-13, however, in presence of H<sub>2</sub>O<sub>2</sub> (100nM), ND-13 significantly decreased IL-1β release after NLRP3 activation (88.6±1.2%, n=4, P<0.05). These data were confirmed by Bardoxolone and ND-13 concentration-response curve. Peritoneal macrophages from diabetic mice were obtained and plated. STZ treatment increased the IL-1β production compared with the control, suggesting that inflammasome may be activated in diabetes and ND-13 treatment normalized its activity. PBMCs isolated from the blood of patients were plate and stimulated with LPS/ATP, and patients with diabetic nephropathy presented a trend to increase IL-1β release compared to controls and diabetic individuals and ND-13 could have a role in the prevention of inflammasome activation.

**Conclusions:** All these data point out that DJ-1/Nrf2 pathway stimulation is a promising approach to decreasing immune cells inflammasome activation, and ND-13 could be a new approach to attenuate inflammation in renal diseases.

## TH-PO250

**Glomerular Permeability Associates With Higher Risk of Kidney Failure and Death in Type 2 Diabetes**

Pierre Jean Saulnier,<sup>1,2</sup> Helen C. Looker,<sup>1</sup> Anita T. Layton,<sup>3</sup> Kevin V. Lemley,<sup>4</sup> Robert G. Nelson,<sup>1</sup> Petter Bjornstad,<sup>5</sup> <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Chronic Kidney Disease Section, Phoenix, AZ; <sup>2</sup>University of Poitiers, Poitiers, France; <sup>3</sup>University of Waterloo, Waterloo, ON, Canada; <sup>4</sup>University of Southern California, Los Angeles, CA; <sup>5</sup>University of Colorado, Aurora, CO.

**Background:** Hydrodynamic models of hindered solute transport are used to characterize the size selective properties of the glomerular barrier. One model assumes the glomerular capillary is perforated by restrictive cylindrical pores of identical pore radius and a parallel shunt pathway of nonrestrictive pores characterized by a parameter,  $\omega_0$ , that estimates the fraction of total filtrate passing through the shunt. We reported previously that type 2 diabetes (T2D) associated with an increase in  $\omega_0$ . Here we examine whether  $\omega_0$  associates with incident kidney failure or death in Pima Indians with T2D.

**Methods:** Iothalamate GFR and fractional clearance of dextrans of graded sizes were measured in 185 adults (74 men, 111 women) with T2D.  $\omega_0$  was computed from the dextran sieving data. Hazard ratios (HR) for kidney failure or death were expressed per 1 standard deviation (SD) increase of  $\omega_0$  by Cox regression after adjusting for age, sex, GFR, ACR, HbA1c and mean arterial blood pressure (MAP).

**Results:** At baseline, mean age (±SD) was 43±10 years, diabetes duration 8.8±8.7 years, HbA1c 8.9±2.4%, MAP 93±12 mm Hg, GFR 147±46 ml/min, and median (IQR) ACR was 41 (10-229) mg/g. During a median follow-up of 29 years, 70 participants developed kidney failure and 134 died, 60 after developing kidney failure. Baseline  $\omega_0$  was higher in participants who developed kidney failure (0.00262 ± 0.00095 vs 0.00204 ± 0.00077, P=0.0016) or died (0.00240 ± 0.00086 vs 0.00188 ± 0.00097, P=0.015). After adjustment, each 1 SD increase in baseline  $\omega_0$  associated with increased risk of kidney failure (HR: 1.60, 95% CI 1.20-2.14) and death (HR: 1.34, 95% CI 1.06-1.68) [Table].

**Conclusions:** Enhanced transglomerular passage of test macromolecules associated with kidney failure and death, independent of albuminuria and GFR, suggesting that mechanisms responsible for impaired glomerular barrier size selectivity are important determinants of adverse health outcomes in T2D.

**Funding:** NIDDK Support, Other NIH Support - N01-DK-6-2285 and N01-DK-7-2291

Hazard ratio for kidney failure and death according to baseline shunt coefficient ( $\omega_0$ )

		Kidney failure 70 events/185		Death 134 events/185

## TH-PO251

**Association of Triglycerides to High-Density Lipoprotein Cholesterol Ratio With Incident Cardiovascular Disease but Not ESKD Among Patients With Biopsy-Proven Diabetic Nephropathy**

Takayuki Uemura,<sup>1</sup> Masatoshi Nishimoto,<sup>1</sup> Masahiro Eriguchi,<sup>1</sup> Hiroyuki Tamaki,<sup>1</sup> Hikari Tasaki,<sup>1</sup> Riri Furuyama,<sup>1</sup> Fumihiro Fukata,<sup>1</sup> Takaaki Kosugi,<sup>1</sup> Katsuhiko Morimoto,<sup>2</sup> Masaru Matsui,<sup>3,1</sup> Ken-ichi Samejima,<sup>1</sup> Kazuhiko Tsuruya,<sup>1</sup> <sup>1</sup>Nara Medical University, Kashihara, Japan; <sup>2</sup>Nara Prefecture Seiwa Medical Center, Ikoma, Japan; <sup>3</sup>Nara Prefecture General Medical Center, Nara, Japan.

**Background:** Increased triglycerides (TG) and decreased high-density lipoprotein cholesterol (HDL-C) are dyslipidemias characteristic of diabetes. Here, we aimed to examine the associations of TG/HDL-C ratio with subsequent cardiovascular disease (CVD) and kidney outcomes among patients with diabetic nephropathy.

**Methods:** A retrospective observational study consists of patients with biopsy proven diabetic nephropathy between June 1981 and December 2014. Patients complicated with other kidney diseases were excluded. Exposure of interest was TG/HDL-C ratio measured at the time of kidney biopsy. The outcome variables were kidney histological findings, incident CVD and end-stage kidney disease (ESKD). The association between TG/HDL-C ratio and histological findings was examined using logistic regression models. The association of TG/HDL-C ratio with incident CVD and ESKD was examined using Cox proportional hazard models.

**Results:** A total of 353 subjects were divided into quartiles based on TG/HDL-C ratio: Quartile 1 (reference), <1.96; Quartile 2, 1.96–3.10; Quartile 3, 3.11–4.55; and Quartile 4, ≥4.56. TG/HDL-C ratio was not a predictor of any histological findings in the fully adjusted model. During median follow-up periods of 6.2 and 7.3 years, 152 and 90 subjects developed incident CVD and ESKD, respectively. Higher TG/HDL-C ratio was independently associated with a higher incidence of CVD even after adjustments for potential confounders (hazard ratio (HR) [95% confidence interval (CI)] for Quartile 3 vs. reference; 1.73 [1.08–2.79] and Quartile 4 vs. reference; 1.86 [1.10–3.17]). Although there was a weak association between TG/HDL-C ratio and incident ESKD in the univariable model, the association was not significant in the fully adjusted model.

**Conclusions:** Among patients with biopsy-proven diabetic nephropathy, higher TG/HDL-C ratio was independently associated with a higher incidence of CVD. The effect of TG/HDL-C ratio on kidney dysfunction would be inconclusive, and further studies are now warranted.

**An Interim Analysis of Clinical and Histopathological Results of the Transformative Research in Diabetic Nephropathy (TRIDENT) Study**

**Samer Mohandes**,<sup>1</sup> Amin Abedini,<sup>1</sup> Mustafa AL-Obaidi,<sup>1</sup> Kishor B. Devalaraja-Narashimha,<sup>2</sup> Lori Morton,<sup>2</sup> John T. Liles,<sup>3</sup> Erding Hu,<sup>4</sup> Lea Sarov-Blat,<sup>4</sup> Gurmanna Kalra,<sup>4</sup> Paolo Guarnieri,<sup>6</sup> Anil K. Karihaloo,<sup>5</sup> Matthew Palmer,<sup>1</sup> Katalin Susztak,<sup>1</sup> <sup>1</sup>University of Pennsylvania, Philadelphia, PA; <sup>2</sup>Regeneron Pharmaceuticals Inc, Tarrytown, NY; <sup>3</sup>Gilead Sciences Inc, Foster City, CA; <sup>4</sup>GlaxoSmithKline USA, Philadelphia, PA; <sup>5</sup>Novo Nordisk Inc, Plainsboro, NJ; <sup>6</sup>Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.

**Background:** The incidence of Diabetic Kidney Disease (DKD) continues to grow and remains a significant health burden. DKD presents with variable speed of decline in kidney function with little reliable indicators or understanding of underlying mechanisms. The TRIDENT study is a multicenter, prospective, observational study of patients with Diabetes mellitus undergoing a clinically indicated kidney biopsy with a goal to further understand the underlying mechanisms. Herein, we report an interim analysis of available results.

**Methods:** Subjects with DM undergoing clinically indicated kidney biopsy at 19 medical centers were eligible. Extra kidney biopsy core was obtained for the study. Histological lesions were scored by a single pathologist. Baseline characteristics were obtained at the time of enrollment. Follow up visits were scheduled every 6 months for 18 months and monitoring up to 4 years.

**Results:** We consented 412 subjects and obtained kidney tissue samples for 330 subjects. We did not encounter any major biopsy related adverse event. Using histological criteria 146 subjects had DKD. Baseline characteristics obtained include Age (mean 54 years), Gender (Male 55%), Race (White 52.3%, black 37.4%), DM type (90.6% type 2), BMI (mean 32.8 kg/m<sup>2</sup>), presence of hypertension (94.8% present), smoking (57%). The enrollment GFR ranged (4-123 ml/min/1.73 m<sup>2</sup>) baseline urine protein to creatinine ratio (UPCR) ranged (0-22 g/g). We observed that baseline GFR showed a significant but weak negative correlation with Interstitial fibrosis, intimal fibrosis and mesangial hyaline. Baseline UPCR correlated with insudative lesions, epithelial hyperplasia, interstitial fibrosis and foot process effacement. Patients with fast progression (average decrease of GFR >5 ml/min/1.73m<sup>2</sup>/year) had higher baseline HbA1c, baseline UPCR, arteriolar hyalinosis, foot process effacement, microvillous transformation and RPS class.

**Conclusions:** This interim analysis demonstrates the importance of histological analysis to determine kidney function decline in DKD.

**Role of Matrix Metalloproteinase-9 During Diabetic Ketoacidosis: Results From the Diabetic Kidney Alarm (DKA) Study**

**Isabella L. Melena**,<sup>1,2</sup> Federica Piani,<sup>1</sup> Kalie L. Tommerdahl,<sup>1</sup> Madison S. Baca,<sup>1</sup> Alexis Macdonald,<sup>1</sup> Laura Pyle,<sup>1</sup> Daniel H. van Raalte,<sup>3</sup> David Cherney,<sup>4</sup> Kelly R. Bergmann,<sup>5</sup> Robert G. Nelson,<sup>6</sup> Richard J. Johnson,<sup>1</sup> Gabriel M. Cara-Fuentes,<sup>1</sup> Petter Bjornstad,<sup>1</sup> <sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>3</sup>Amsterdam Universitair Medische Centra, Duiwendrecht, Netherlands; <sup>4</sup>University of Toronto School of Medicine, Toronto, ON, Canada; <sup>5</sup>Children's Minnesota, Minneapolis, MN; <sup>6</sup>National Institute of Diabetes and Digestive and Kidney Diseases Phoenix Epidemiology and Clinical Research Branch, Phoenix, AZ.

**Background:** Matrix metalloproteinases (MMPs) are involved in the pathophysiology of acute and chronic kidney disease. However, their role in acute kidney injury (AKI) and proximal tubular dysfunction, a common complication of diabetic ketoacidosis (DKA), is unknown. We examined changes in MMP-9 during and 3 months after episodes of DKA in youth with known or new onset type 1 diabetes (T1D).

**Methods:** Serum samples were collected from youth with DKA at 2 time points: 0-8 hours after starting an insulin infusion and 3 months after hospital discharge. Mixed-effects models evaluated the changes in serum MMP9 and associations with serum copeptin and uric acid and adjustments were made for estimated glomerular filtration rate (eGFR) calculated by serum creatinine and cystatin C. Data are reported as mean and standard deviation (SD) or standard error (SE), or  $\beta$ -estimates and SE for mixed-effects models.

**Results:** We enrolled 40 youth (52% boys, age [mean $\pm$ SD] 11 $\pm$ 4 years, venous pH 7.2 $\pm$ 0.1, blood glucose 451 $\pm$ 163 mg/dL). 17% of participants (n=7) met criteria for AKI. Concentrations of MMP-9 were significantly higher during episodes of DKA compared to 3 months follow-up (mean $\pm$ SE: 1504.6 $\pm$ 137 vs. 668.7 $\pm$ 159 ng/mL,  $p=0.0003$ ). At 0-8 hours, participants with AKI had significantly higher MMP-9 (2256.9 $\pm$ 310.1 vs. 1344.7 $\pm$ 143.5 ng/mL,  $p=0.01$ ). Higher serum MMP9 was associated with higher serum copeptin, a surrogate marker of vasopressin, ( $\beta$  $\pm$ SE: 12.4 $\pm$ 3.6 per 1 pmol/L increment in copeptin) and higher uric acid ( $\beta$  $\pm$ SE: 123.9 $\pm$ 42.2 per 1 mg/dL increment in uric acid).

**Conclusions:** In our study, DKA and accompanying AKI associated with elevated concentrations of serum MMP-9, a marker of oxidative stress and remodeling, potentially highlighting the underlying mechanisms of kidney injury during DKA.

## TH-PO254

**The Effect of Diabetes in Morbidly Obese Patients on Protein Profiles of Circulating Extracellular Vesicles Before and After Bariatric Surgery**

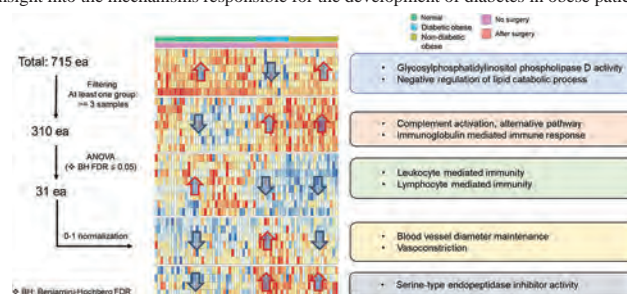

**Haekyung Lee**,<sup>1,2</sup> Junghyun Cho,<sup>1</sup> Eui Suk Chung,<sup>1</sup> Hyoungnae Kim,<sup>1,2</sup> Jin seok Jeon,<sup>1,2</sup> Soon hyo Kwon,<sup>1,2</sup> <sup>1</sup>Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; <sup>2</sup>Soonchunhyang University Hospital Kidney Center, Yongsan-gu, Seoul, Republic of Korea.

**Background:** Obesity and diabetes are often associated with cardiometabolic diseases, with substantial prognostic heterogeneity. We sought to identify proteomic signatures of circulating extracellular vesicles (EVs) of obesity with or without diabetes before and after bariatric surgery.

**Methods:** Circulating EV proteins were analyzed before and 6 months after bariatric surgery in 30 morbidly obese patients with (n = 12) or without (n = 18) diabetes and compared to those in 37 healthy volunteers.

**Results:** Bariatric surgery induced weight loss and improvements in fasting glucose, but urine albumin (p <0.01) decreased only in non-diabetic obese patients. A total of 26 and 271 EV proteins were significantly differentially expressed in diabetic obese patients compared to non-diabetic obese patients before and after bariatric surgery, respectively. Expression of proteins involved in the complement system and immunoglobulin-mediated immune response was upregulated in both non-diabetic and diabetic obese patients, whereas that of proteins involved in leukocyte- and lymphocyte-mediated immunity was downregulated in both groups after surgery (Figure 1). Expression of proteins involved in glycosylphosphatidylinositol phospholipase D activity and lipid catabolism was downregulated in diabetic obese patients, whereas that was upregulated in non-diabetic obese patients following surgery.

**Conclusions:** Diabetic obese patients have distinct EV protein signatures before and after bariatric surgery compared with non-diabetic obese patients. These obesity- and diabetes-specific EV protein expression profiles and their associated pathways may provide insight into the mechanisms responsible for the development of diabetes in obese patients.

**Figure 1.** Functional interpretation of significantly altered extracellular vesicle proteins after bariatric surgery

## TH-PO255

**Predictors of Persistent Medication Use in Diabetic Kidney Disease (DKD)**

**Susanne B. Nicholas**,<sup>1</sup> Kenn B. Daratha,<sup>2</sup> Radica Z. Alicic,<sup>2,3</sup> Cami R. Jones,<sup>2</sup> Lindsey M. Kornowski,<sup>2</sup> Samuel T. Fatoba,<sup>4</sup> Sheldon X. Kong,<sup>4</sup> Rakesh Singh,<sup>4</sup> Keith C. Norris,<sup>1</sup> Katherine R. Tuttle,<sup>2,3</sup> CURE-CKD <sup>1</sup>University of California Los Angeles, Los Angeles, CA; <sup>2</sup>Providence St Joseph Health, Spokane, WA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>Bayer AG, Leverkusen, Germany.

**Background:** Angiotensin-converting enzyme inhibitors (ACEi) or angiotensin II receptor blockers (ARB) have been the standard-of-care for DKD for >2 decades, yet few patients receive them. The aim of this study was to identify predictors of persistent use of medications used to treat DKD.

**Methods:** From the Providence and UCLA Health Center for Kidney Disease Research, Education, and Hope Registry (CURE-CKD) of electronic health records, we derived demographic, clinical, and prescription medication data for patients  $\geq$ 20 years old with DKD. ACEi/ARB, sodium-glucose cotransporter-2 inhibitor (SGLT2i), and glucagon-like peptide receptor agonist (GLP-1 RA) use was determined at baseline and over time during 2019-2020. A multiple logistic regression model was created for each medication class to predict persistent medication use ( $\geq$ 90 days).

**Results:** Patients with DKD (N=21,658) were 50% women, 70 $\pm$ 13 (mean $\pm$ SD) years of age and White (UCLA: 50%, Providence: 69%). Baseline measures were 2021 CKD-EPI eGFR of 58 $\pm$ 22 mL/min/1.73 m<sup>2</sup>, urine albumin-to-creatinine ratio of 66 (45-113; median, IQR) mg/g, and systolic blood pressure of 131 $\pm$ 16 mm Hg. Median follow-up time was 1 year during 2019-2020. Baseline versus persistent use of ACEi/ARBs were 66% versus 36%; SGLT2i, 5% versus 4%; and GLP-1 RA, 6% versus 5%, respectively. Longer follow-up time predicted higher, while lack of commercial insurance predicted lower, persistent use of each medication class. Positive predictors of persistent ACEi/ARB use were men, non-White race, hypertension, higher eGFR, other medication use, and longer follow-up time (Figure).

**Conclusions:** In typical patients with DKD treated in contemporary clinical practice, use of ACEi/ARB, SGLT2i, and GLP-1 RA is suboptimal and wanes over a short period of time with disparities in persistent use for those without commercial insurance. Inclusive strategies are needed to implement and maintain optimal DKD therapy for all groups of people.

**Funding:** Other NIH Support - NIMHD, Other U.S. Government Support, Commercial Support - Bayer

Predictors of persistent ACEi/ARB use in DKD, 2019-2020

## TH-PO256

## Network Collagen VIII Increases Fibrotic Remodeling and Risk of Arteriovenous Fistula Maturation Failure

Roberto I. Vazquez-Padron,<sup>1,2</sup> Miguel G. Rojas,<sup>1</sup> Marwan Tabbara,<sup>1</sup> Simone Pereira-Simon,<sup>1</sup> Nieves Santos,<sup>1</sup> Mohd Ahmar Rauf,<sup>1</sup> Akshara Sree Challa,<sup>1</sup> Juan C. Duque,<sup>1</sup> Laisel Martinez,<sup>1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>VA Miami Healthcare System, Miami, FL.

**Background:** Excessive postoperative fibrosis is associated with maturation failure of arteriovenous fistulas (AVF). Therefore, targeted therapies that modulate extracellular matrix (ECM) deposition may represent a plausible strategy to improve maturation outcomes.

**Methods:** Transcriptome-wide changes during the vein to AVF transformation were studied in 38 stage 5 chronic kidney disease patients undergoing surgeries for two-stage AVF creation (19 matured, 19 failed) using whole-genome RNA sequencing. Pairwise bioinformatic analyses followed by validation experiments were used to identify changes during postoperative ECM remodeling in association with maturation failure.

**Results:** A total of 3,637 transcripts were differentially expressed (DEG) between veins and AVFs independent of maturation outcome, with >87% upregulated after AVF creation. Over 250 core ECM and ECM-affiliated genes stood out in terms of expression levels and magnitude of fold change, including fibrillar collagens I and III, basement collagens IV and VIII, and multiplexin collagen XVIII. We identified 102 DEGs in association with AVF failure, only eight of which were upregulated in AVFs that failed and which included COL8A1. Upregulation of collagen VIII in AVFs that failed was validated by immunohistochemistry. In vitro experiments with primary smooth muscle cells (SMC) from basilic veins confirmed that the canonical TGFβ-Smad2/3 pathway was primarily responsible for COL8A1 expression. Importantly, inhibition of COL8A1 by siRNA modulated the SMC response to TGFβ signaling and decreased the expression of fibronectin and fibrillar COL1A1 in response to TGFβ stimulation.

**Conclusions:** This work supports an important role for collagen VIII in fibrotic remodeling and failure of newly created AVF.

**Funding:** NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

## TH-PO257

## Planning Vascular Access Creation: The Promising Role of the Kidney Failure Risk Equation

Bernardo Marques da Silva,<sup>1</sup> Onassis Silva,<sup>1</sup> Mariana Soares,<sup>2</sup> Cristina Outerelo,<sup>1</sup> Maria A. Fortes,<sup>1</sup> Jose A. Lopes,<sup>1</sup> Joana Gameiro,<sup>1</sup> <sup>1</sup>Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal; <sup>2</sup>Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal.

**Background:** Planning the vascular access (VA) is essential in pre-dialysis patients although optimal timing for VA referral and placement is still debatable. Current guidelines suggest referral for VA placement with an eGFR 15-20 mL/min/1.73m<sup>2</sup>. The kidney failure risk equation (KFRE) is an easily calculated equation to predict probability of KRT. The aim of this study was to validate KFRE in patients referred to VA assessment.

**Methods:** We conducted a retrospective analysis of all adult patients with CKD who were referred to the multidisciplinary VA consult, for the first VA placement, at C.H.U. Lisboa Norte between January 2018 and December 2019. The 4-variable KFRE was calculated. Requirement of KRT, mortality and vascular access placement were assessed in a 2-year follow-up. We used the Cox logistic regression to predict KRT requirement and calculated the ROC curve.

**Results:** 256 patients were included and 64.5% were male. At the time of VA consult, mean age was 70.4±12.9 years, eGFR was 16.09±10.43 mL/min/1.73m<sup>2</sup>, albuminuria was 1339.4±208.1 mg/24h and the mean calculated risk score was 30.44±24.80%. 159 patients required KRT (62.1%) and 72 (28.3%) died in the 2-year follow-up. VA was created in 214 (83.6%) patients, though only 50.9% patients had a functional VA for hemodialysis. The KFRE accurately predicted KRT requirement within 2-years [38.3±23.8 vs 17.6±20.9%, p<0.001; HR 1.05 95% CI (1.06-1.12), p<0.001], with an auROC of 0.788, [p<0.001, 95% CI (0.733-0.837)]. The optimal KFRE cut-off was >20%, with a HR of 9.2 [95% CI (5.06-16.60), p<0.001]. 135 (52.7%) patients had KFRE≥20% at the time for VA referral and mean time from VA consult to KRT initiation was significantly lower in these patients (10.98±9.64 vs 16.50±11.14 months, p=0.002). On a sub-analysis of patients with an eGFR<20 mL/min/1.73m<sup>2</sup>, a KFRE≥20% was also a significant predictor of 2-year requirement of KRT, with an HR of 6.61 [CI 95% (3.49-12.52), p<0.001].

**Conclusions:** KFRE accurately predicted 2-year KRT requirement in this cohort of patients. We have successfully demonstrated that a KFRE ≥20% can be used in addition to eGFR when referring patients for VA planning and help to establish higher priority patients for VA placement. The authors suggest referral for VA creation when eGFR<20 mL/min/1.73m<sup>2</sup> and KFRE≥20%.

## TH-PO258

## Successful Arteriovenous Fistula Creation Slows Rate of eGFR Decline

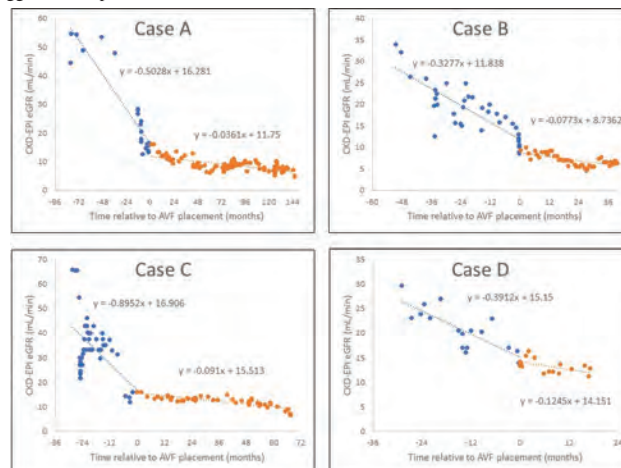

John Mowrey, Andrew I. Chin, Suresh Appasamy. University of California Davis, Sacramento, CA.

**Background:** In patients with advanced CKD, a slower rate of eGFR decline after arteriovenous fistula (AVF) placement has been observed. The mechanism(s) for these findings remain unclear. We retrospectively examined the rates of eGFR decline, before and after successful AVF creation in preparation for HD, in patients who had advanced CKD.

**Methods:** CKD-Epi equation without race correction was used to estimate GFR. Using linear regression of eGFR, before and after AVF placement, rate of eGFR decline in mL/min/month was found in a population of 4 patients with advanced CKD. Successful AVF maturation was defined as either successful use in patients who started HD or clearance for use by surgery in patients not yet on HD. The slope of eGFR decline before and after AVF creation was compared retrospectively.

**Results:** Mean eGFR of our population was 13.5 ± 2.69 mL/min at time of creation of AVF, with an average age of 69. We observed an average rate of eGFR decline of 0.52 ± 0.22 mL/min/month prior to AVF creation, the average rate of decline after successful AVF placement was 0.08 ± 0.03 mL/min/month. Average pre AVF placement observation time was 4.75 ± 2.05 years, and average pre-dialysis time observed after AVF creation was 5.75 ± 3.9 years.

**Conclusions:** In advanced CKD patients who have HD AVFs that successfully mature, eGFR rate of decline appeared to dramatically slow after AVF creation. We additionally analyzed blood pressure and medications in these fairly extensive observation periods before and after AVF placement, and believe AVF placement to have an independent benefit. Proposed mechanisms include alterations in vascular physiology, changes in hemodynamics, improved patient adherence and closer medical monitoring that often follows AVF placement. We believe this case series adds to the growing body of data that suggests an impact on eGFR after a successful AVF creation.

## TH-PO259

## Patient Perspectives on Arteriovenous Fistula Use: Implications for Racial Disparities

Dipal Patel,<sup>1</sup> Timmy C. Lee,<sup>2</sup> Yi Zhang,<sup>2</sup> Mae Thamer,<sup>3</sup> Michael Allon,<sup>2</sup> Deidra C. Crews,<sup>1</sup> <sup>1</sup>Johns Hopkins University, Baltimore, MD; <sup>2</sup>The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; <sup>3</sup>Medical Technology and Practice Patterns Institute, Bethesda, MD.

**Background:** Placement and maintenance of arteriovenous fistulas (AVFs) are a key quality metric in the care of patients on hemodialysis (HD). Compared to White patients, Black patients are less likely to undergo AVF placement, experience successful AVF use, and maintain AVF patency. We examined factors influencing AVF use in a group of predominantly Black patients receiving HD.

**Methods:** Semi-structured individual interviews were conducted via telephone or teleconference with 59 patients receiving HD at one of eleven facilities affiliated with an academic nephrology practice in the Southern U.S. Interviews were audiorecorded and transcripts were coded for thematic analysis.

**Results:** Transcripts from 53 Black and 6 White patients were used for analysis [Table 1]. Common themes influencing patient perspectives on AVF use centered around the circumstances of dialysis initiation, pre-dialysis and ongoing patient education, and comparisons of different access types including their impact on patients' lives [Figure 1].

The following experiences were highlighted: 1) the vast majority of patients experienced “crash” dialysis starts through a CVC, even when receiving pre-dialysis care, 2) patients who voiced trust of their medical care teams reported a higher level of comfort with AVF placement, 3) pre-AVF patients had a poor understanding of the steps of a fistula procedure and post-surgical care, and 4) when comparing access types, patients most commonly reported CVCs to be troublesome due to showering restrictions and infection concerns, whereas fistulas carried higher risks of pain, bleeding, and altering patient appearance.

**Conclusions:** Patient perspectives on AVF placement, use, and maintenance may inform our understanding of racial disparities in the AVF care continuum.

**Funding:** Other NIH Support - NIH R01MD013818

Circumstances of dialysis initiation	"I know that I couldn't get a fistula in the beginning, because they had to emergency dialysis on me."	"I kept swelling up and then they ended up taking me to the hospital. At the time, it wasn't going nowhere... during the next doctor's appointment, though, I went to the hospital."	"They told me I had a bad kidney. And after that, they were teaching me. I went to classes, looked at films, and they had a thing that showed how it could be done."
Patient education on continuum of fistula care	"I'm not sure about how it goes, where I do think it would be kind of easier."	"I have little weights that I try to use... my fistula was created by interventional radiology, and then it required three other procedures to try to get it to work... I don't think I've been told -- I've asked what I can do... But I haven't been told that I can do anything different than what I've been doing."	"Like certain people stick me or whatever, and then they bleed when I get home, overnight while I sleep. And then I have to get it checked out to make sure everything okay. That surprised me a lot. It scared me too."
Patient views of dialysis access options	"They've told me that it's easier, that they can deal with it better than the port-a-catheter, because as far as the port-a-cath is, you know it's hard."	"I don't know yet, because I'm still scared to get stuck myself, so I don't know what it's like to live. I don't want to get stuck. I've seen their needles. They huge."	"... With my fistula, it's inside my body so the chances there are less of getting infected than that catheter, because that catheter... I had to make sure I cleaned that area around there really, really good. It was a bunch of maintenance on that catheter... With the fistula, they put it in. It healed. We use it. Bingo."

## TH-PO260

### Isometric Exercise and Arteriovenous Fistula for Haemodialysis: The Impact on Maturation Process

Iratí Tapia, Diana Oleas. *Consorti Sanitari de Terrassa, Terrassa, Spain.*

**Background:** Arteriovenous fistula (AVF) is the gold standard vascular access (VA) for end-stage chronic kidney disease patients. Postoperative exercises may help to improve maturation. Nevertheless, scarce scientific evidence has been reported about their utility until date. **Objectives:** To assess the effect of a postoperative isometric exercises program on native VA maturation in our patients with stages 5-5D chronic kidney disease.

**Methods:** A 24 months prospective single-center study. After surgery, all patients were randomized to an isometric exercise group (EG) or a control group (CG). An agreed with Rehabilitation, isometric exercises protocolled program, was performed in EG. CG received usual care. Demographical data, muscle strength using handgrip (HG) dynamometer, main Doppler ultrasound (DUS) measurements (outflow vein (OV) diameter and humeral artery blood flow rate (BFR), clinical and DUS maturation as well as medical (hematoma, stenosis, thrombosis, pseudoaneurysm, aneurysm) or surgical VA complications were assessed at 4 and 8 weeks postoperatively.

**Results:** 67 patients; 7 drop out. 30 EG, 30 CG, 71.7 % men. Mean age 68.6±13.0 years. 60% Radiocephalic AVF. Demographic data, HG and DUS measurement at baseline were similar. A significant increase in HG was observed only in EG at the end of study (20.7±8.1 vs 25.1±10.3Kg, p=0.001). DUS measurements statistically increased for both groups (OV diameter: EG 3.2±0.8 vs. 6.2±1.5 mm; CG 2.9±0.7 vs. 5.6±6.2 mm; humeral artery BFR: EG 142.7±35.2 vs. 1536.2±679.2 ml/min; CG 134.6±36.6 vs. 1170.4±537.1ml/min) at the end of study. EG group obtained highest clinical maturation at 4 (CG 33.3% vs EG 70%; p=0.009) and 8 weeks (CG 33% vs EG 76.7%;p=0.002). Similarly, DUS maturation was better in EG at 4 (CG 40% vs EG 80%; p=0.003) and 8 weeks respectively (CG 43.3%vs EG 83.3%;p=0.003). These results were also observed in EG both distal and proximal territories for all these periods. There were not differences in medical or surgical VA complications during the study.

**Conclusions:** The isometric exercises protocolled program improve clinical and DUS maturation in our patients. This effectiveness was observed in both distal and proximal territories. Further studies are required to support the benefits of postoperative isometric exercises in the vascular access maturation process.

## TH-PO261

### Novel Method to Monitor Arteriovenous Fistula Maturation: Impact on Catheter Residence Time

Laura Rosales, Xiaoling Ye, Hanjie Zhang, Brenda K. Chan, Marilou Mateo, Seth Johnson, Peter Kotanko. *Renal Research Institute, New York, NY.*

**Background:** Timely assessment of arterio-venous fistula (AVF) maturation is essential to reduce the residence time of central venous catheters (CVC). We used central-venous oxygen saturation (ScvO<sub>2</sub>) and estimated upper-body blood flow (eUBBF) to monitor AVF maturation. We now report CVC residence time in patients with and without ScvO<sub>2</sub>-based AVF maturation monitoring.

**Methods:** Newly created AVF were monitored employing ScvO<sub>2</sub>-based AVF maturation during a clinical quality improvement project (QIP) conducted in two Renal Research Institute (RRI) clinics (QIP clinics). ScvO<sub>2</sub> was measured by Crit-Line (Fresenius Medical Care, Waltham, MA); eUBBF was computed as reported [Rosales (2019), doi: 10.1159/000494742]. Time-to-event analysis compared CVC residence time post-AVF creation between QIP and three non-QIP control groups (CG). CG 1: concurrent controls from 2 non-QIP RRI clinics (N=134 patients); CG 2: concurrent controls from the 2 QIP RRI clinics (N=48); CG 3: historic (2014-6) pre-QIP controls from the 2 QIP RRI clinics (N=57). Censoring events were death, dialytic modality change, transplantation, lost to follow up, and end of observation period (Nov. 2021).

**Results:** The QIP group comprised 44 patients (age 59 ±17 years; 27 males). The 4 groups did not differ regarding age, race, and sex. Six months after AVF creation, the fraction of patients with CVC still in place was 21% in the QIP group; CG 1 58%; CG 2 67%; CG 3 68%. The Kaplan-Maier curve differed significantly between groups (P<0.0001, log rank test. **Fig 1**).

**Conclusions:** Compared to three control groups, CVC residence time was shorter in patients with ScvO<sub>2</sub>-based assessment of AVF maturation. Tracking of ScvO<sub>2</sub> and eUBBF is a non-invasive means to follow AVF maturation, trigger timely interventions, and shorten CVC residence time.

## TH-PO263

## Long-Term Hemodialysis Access Survival of Arteriovenous Fistulas

Tiago L. Cerqueira,<sup>1,2</sup> Isabela L. Pimenta,<sup>1</sup> Roberto L. Oliveira,<sup>1</sup> Mayra M. Palotti,<sup>1</sup> Tamires O. Barros.<sup>1</sup> <sup>1</sup>Hospital Evangelico, Belo Horizonte, Brazil; <sup>2</sup>Dresden International University GmbH, Dresden, Germany.

**Background:** Vascular access is crucial for patients with End Stage Kidney Disease (ESKD) who choose hemodialysis (HD). Arteriovenous fistula (AVF) is the preferred type for its lowest risk of complications and mortality. Thus, it is important to consider AVF longevity when planning for a vascular access. We aim to compare three AVFs – radiocephalic (RC), brachiocephalic (BC) and brachio basilic (BB) – regarding their access survival to guide shared-decision making of the most appropriate vascular access for our patients.

**Methods:** This is a 4 dialysis centers' retrospective cohort of patients on HD who had their AVF created between April 2014 and September 2018 in Minas Gerais, Brazil. Follow-up was until March 2021. We conducted a survival analysis comparing RC, BC and BB AVFs by Kaplan-Meier curve and Cox-regression, controlling for age, gender, cause of ESKD, previous catheter on the AVF side and previously failed AVF history. When proportional hazards were not met, Cox-Regression with time-dependent covariate was done. Censoring: loss to follow-up, leaving HD modality or death. Software used: IBM® SPSS Statistics 23.

**Results:** 789 AVFs were included in the study: 28% (220) RC, 38% BC (304) and 34% (265) BB. 56% were male with 58±13.5 years of age. Common causes of ESKD were diabetic (40%), hypertensive (22%) and glomerular (8%) nephropathies. 63% had a previous catheter on the AVF side, while 49% had a previously failed AVF. 220 (28%) had early AVF failure after surgery. Median time to successful maturation was 10 weeks for RC and BC and 9 weeks for BB. Median follow-up time was 108 weeks. In the uncontrolled analysis, we found no differences in access survival between RC and BC AVFs ( $p = 0.3$ ). RC had better survival after 30 weeks than BB ( $p = 0.02$ , HR = 1.2, 95% CI 1.02-1.48) and BC was also better than BB after 7 weeks ( $p = 0.00$ , HR = 1.5, 95% CI 1.13-1.97). After controlling for confounders, we found that RC became worse than BB ( $p = 0.00$ , HR = 0.8, 95% CI 0.68-0.93) before 30 weeks, but had similar survival after that period. BC remained better than BB ( $p = 0.03$ , HR = 1.35, 95% CI 1.02-1.77) after 7 weeks. Surprisingly, RC became worse than BC ( $p = 0.46$ , HR = 0.78, 95% CI 0.61-0.99).

**Conclusions:** Patient characteristics influence AVF survival in several ways. BC AVFs appear to have the longest access survival after cofounder control.

**Funding:** Private Foundation Support

## TH-PO264

## Retrospective Analysis Comparing Atrioventricular Fistula Successful Use Rates for Hemodialysis (FUSH) at 6 Months to Prediction by Lok Failure-to-Mature Tool

Rashed Alfarra, Iskra Myers, Joseph C. Parker. East Carolina University, Greenville, NC.

**Background:** Atrioventricular fistula (AVF) is the preferred vascular access for dialysis patients. AVFs have high non-maturation rate. Lok et al, developed a clinical prediction tool to identify AVFs at risk for Failure To Mature (FTM). The equation includes patient's age, race, presence of peripheral vascular disease (PVD), coronary artery disease (CAD), and has achieved good prediction accuracy with 69% failure rate in the highest risk category. We aimed to validate the Lok's FTM equation in our patients at East Carolina dialysis unit.

**Methods:** Retrospective chart review identified 43 patients who received AVF from 12/01/2009 to 12/01/2020 at ECU dialysis unit. Demographic and clinical data was obtained from electronic medical records. The primary outcome was AV FUSH at 6 months. The FTM equation risk score was retrospectively applied to our patient cohort and compared with the observed clinical outcomes using Receiver Operating Characteristic in SPSS v28.

**Results:** In total 43 AVFs were created during the study period. Mean age was 55 +/- 20 years, 89% were African American, 30% of the patients had CAD, 14% had PVD. FUSH at 6 months was 53.5%. We examined the external validity of Lok's model by applying it to our population. 22% of patients with lowest risk score had non maturation at 6 months. 14% of the patients with highest risk scores all lost access within one year of AVF creation despite having FUSH at 6 months.

**Conclusions:** Despite increased number of AVF creations since Fistula First Initiative, outcomes on maturation rates are suboptimal. Reasonable FUSH rates at 6 months can be achieved. FTM equation was not validated in our cohort. Possible reason is our population cohort (mostly African American) vs Lok's FTM cohort (mostly Caucasian population).

Figure 1: Percentage of Fistulas Used Successfully for Hemodialysis (FUSH) based on AVF location.

Figure 2: ROC curve of the FTM predictor score in the ECU dialysis cohort.

## The Association Among Carotid Intima-Media Thickness, Pulse Wave Velocity, and Vascular Access Failure in Hemodialysis Patients

Jong-woo Yoon, Hyunsuk Kim, Jineop Kim, Seok-hyung Kim, Gwangho Choi. Hallym University Medical Center, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.

**Background:** Patients with chronic kidney disease (CKD) or end stage renal disease (ESRD) have an increased risk of cardiovascular mortality and morbidity. We aimed to compare the value of IMT with tests such as coronary CT and Pulse wave velocity(PWV) as predictors of cardiovascular risk in ESRD patients undergoing maintenance dialysis and examine their association with cardiovascular disease.

**Methods:** We reviewed the participants' medical records, including height, body weight, smoking status, alcohol intake, medication history, etiology of ESRD, HD vintage, and blood pressure which were measured during hemodialysis. Carotid doppler was performed by an skilled sonographer who are unaware of the aims of the study and blinded to the laboratory findings. For PWV measurement, Patients lie down, rest for at least 5 minutes, and prohibit smoking and coffee for 3 hours before the measurement. BaPWV is measured by recording pulse waves of both arm and both ankles from the pressure signal obtained by measuring 4-extremity blood pressure.

**Results:** One hundred patients were included, of whom 51 (50.5%) were men. The median age was 66years (interquartile range 58-76 years). The median vintage of hemodialysis was 47.5 months (range 31.3-89.1 months). There were no significant differences between high IMT group and low IMT group in sex, hemodialysis vintage, end-stage renal disease etiology, and type of vascular access. However, age was significantly older in the high IMT group. IMT was significantly associated with PWV (hazard ratio [HR] 2.109; 95% CI 1.037-4.291,  $P = 0.039$ ). After adjusting for age, sex and presence of diabetes, IMT was independently associated with PWV (HR 2.110, 95% CI 1.036-4.298,  $P = 0.040$ ). The risk of recurrent vascular access failure was higher in the high IMT group (HR 1.615, 95% CI 1.460-5.669,  $P = 0.034$ ).

**Conclusions:** IMT was associated with PWV and recurrent access failure. Thus IMT may be suggested as a potential predictor of vascular access failure.

## TH-PO266

## Long Term Outcomes of Stenting in Treating Thigh Arteriovenous Grafts

Ammar Almeahmi,<sup>1</sup> Masa Abaza,<sup>2</sup> Sloan Almeahmi,<sup>1</sup> Vinay Narasimha Krishna,<sup>1</sup> Alian Albalas.<sup>1</sup> <sup>1</sup>The University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>University of Alaska Anchorage, Anchorage, AK.

**Background:** Stents are used to manage the outflow stenotic lesions that complicate upper extremity arteriovenous grafts (AVGs) to improve the survival. In this study, we sought to investigate the effect of stents on the overall survival of "thigh" AVGs.

**Methods:** This was a retrospective review of patients who received dialysis via thigh AVGs. Data on demographics, comorbidities, AVG intervention history was collected. Both primary and secondary AVG survival rates were calculated using Kaplan-Meier analysis. Multivariate analysis was performed to determine the predictors of the graft survival.

**Results:** This study included 407 thigh AVGs; 53.2% females; 92.4% African Americans; and 92% hypertensive. Graft thrombosis (67.1%) and elastic recurrent stenotic lesions (32.9%) were the main indications for stent deployment. During follow up, the median secondary graft survival in the stent versus no-stent groups was 86.1 ( $\pm 15.5$ ) vs 34.1 ( $\pm 5.3$ ) months ( $p=0.001$ ), respectively. Multi-variables Cox-regression analysis revealed that AVG thrombosis, stenting and hypertension were the main predictors of the AVG survival (Table 1 and Figure 1).

**Conclusions:** The use of stents to manage the outflow lesions appears to improve the overall thigh AVG survival specially in thrombosed grafts.

**Figure 1: Thigh AVG cumulative secondary patency showing the different groups**

**Table 1: Significant predictors of thigh AVG secondary patency**

Variable	Hazard Ratio	95.0% CI		p
Hypertension	2.1	Lower 1.2	Upper 3.5	0.015
No-Stent and No thrombosis	1*			
No-Stent with thrombosis	1.0	0.7	1.3	0.821
Stent without thrombosis	0.5	0.2	1.2	0.128
Stent with thrombosis	0.6	0.4	0.9	0.008

\*No stent/no thrombosis is the reference category;  $p < 0.05$  is considered significant

## TH-PO267

### Arteriovenous-Oscillometry to Assess Fistula Function

Veit Busch,<sup>1,2</sup> Joachim Streis,<sup>1</sup> Niklas Mueller,<sup>4,5</sup> Sandra Müller,<sup>5</sup> Felix S. Seibert,<sup>6,7</sup> Thomas Felderhoff,<sup>1</sup> Timm H. Westhoff,<sup>6,7</sup> <sup>1</sup>Fachhochschule Dortmund, Dortmund, Germany; <sup>2</sup>Nephrothol, Kamen, Germany; <sup>3</sup>Universitätsklinikum Munster Medizinische Klinik D, Munster, Germany; <sup>4</sup>Klinikum der Universität München Medizinische Klinik und Poliklinik III, München, Germany; <sup>5</sup>Technische Universität Wien Institut für Diskrete Mathematik und Geometrie, Wien, Austria; <sup>6</sup>Marienhospital Herne Medizinische Klinik I Innere Medizin, Herne, Germany; <sup>7</sup>Ruhr-Universität Bochum Medizinische Fakultät, Bochum, Germany.

**Background:** We recently demonstrated that pulse wave analysis may be useful in functional fistula monitoring using tonometric measurement. We now aimed to evaluate if convenient oscillometry devices are applicable to detect flow below 500 ml/min.

**Methods:** We recorded pulse waves ambilaterally with the vicorder® device at the brachial artery in 53 patients with native fistula and analyzed them with the use of a specifically developed matlab® application. The key parameters consisted of normalized variables assessed by the mean slope in the time sections between the footpoint, the systolic maximum ( $T_1$ ), the diastolic notch, the first diastolic inflection point and the end of diastole. Specifically in the second section ( $slope_2$ ) and the sum of all four sections ( $slope_{\Sigma}$ ). We furthermore assessed the amplitude of uncalibrated relative volumetric change in the measuring cuffs of the vicorder® device during cardiac cycle ( $AMP$ ). Flow was measured with the use of duplex sonography.

**Results:** There were marked differences in the wave contours of the fistula and non-fistula side (Figure 1). Medians (fistula/non-fistula) of  $slope_2$ ,  $slope_{\Sigma}$  and  $AMP$  were  $-0.00150/-0.00322$  [relative amplitude/ms,  $p < 0.001$ ],  $0.01094/0.01187$  [relative amplitude/ms,  $p=0.006$ ] and  $1850/725$  [relative volumetric change,  $p < 0.001$ ] (Wilcoxon test of related samples).  $T_1$  was delayed at the fistula arm ( $204 \pm 3.4$  ms versus  $162 \pm 5.3$  ms at the non-fistula arm,  $p < 0.001$ ). ROC-analyses of parameter values measured at the fistula arm to detect low flow fistula demonstrated AUCs (with CI) of  $0.652$  ( $0.437-0.866$ ,  $p=0.167$ ) for  $slope_2$ ,  $0.732$  ( $0.566-0.899$ ,  $p=0.006$ ) for  $slope_{\Sigma}$  and  $0.775$  ( $0.56-0.991$ ,  $p=0.012$ ) for  $AMP$  (Figure 2).

**Conclusions:** Fistula functional monitoring with oscillometry is feasible and is a promising clinical application to detect a low flow fistula.

#### Clinical characteristics

### The Initial Experience of Endovascular Arteriovenous Fistula Creation in a Multi-Ethnic Population From Singapore

Ru Yu Tan, Hsien Ts'ung Tay, Kun D. Zhuang, Suh Chien Pang, Tng R. Alvin, Chee Wooi Tan, Chye Chung Gan, Chee Chin Phang, Kiang Hiong Tay, Tze tec Chong, Chieh-suai Tan. *Singapore General Hospital, Singapore, Singapore.*

**Background:** The technique of endovascular arteriovenous fistula (EndoAVF) creation was made available in Singapore end of 2021. This study reports the initial experience of EndoAVF creation in a tertiary center in Singapore.

**Methods:** The patients referred for creation of new AVF was offered EndoAVF. Enrolled patient had vein mapping performed according to protocol and underwent EndoAVF creation if suitable. Data was collected prospectively for patients who underwent EndoAVF creation.

**Results:** A total of 15 patients were enrolled and underwent vein mapping. Of which, 11 patients were deemed suitable for EndoAVF creation and underwent the procedure under regional anesthesia. The patients have a mean age of  $60 \pm 10$  years and were predominantly male (64%) and of Chinese (91%) ethnicity. The etiology of end-stage renal disease was diabetes mellitus (55%) followed by chronic glomerulonephritis (36.4%) and others (9%). Seven patients (64.6%) were already on hemodialysis via tunneled dialysis catheter while the remaining 4 patients were pre-emptive creation. EndoAVFs were successfully created in 10 (91%) patients. The anastomoses were radial-radial (50%) and ulnar-ulnar (50%). The brachial artery blood flow immediately, at 1- and 2-month post-creation was  $544 \pm 191$ ,  $612 \pm 217$ , and  $830 \pm 401$  mls/min, respectively. At 3-month, post-creation, 9 EndoAVF was assessed to be matured on clinical examination with a median maturation time of 70 (45, 95) days. Eight patients had successful 2-needle cannulation at a median time of 75 (52,128) days. Two patients required endovascular intervention to assist in maturation.

**Conclusions:** EndoAVF creation seemed feasible in the Asian population and may represent an attractive alternative to open surgery. Long-term data regarding its patency and cost-effectiveness needs to be evaluated in future studies

**Funding:** Private Foundation Support

## TH-PO269

### A Comparison Between the Efficacy and Safety of Endovascular Arteriovenous Fistula Creation and Surgically Created Fistulas: A Systematic Review and Meta-Analysis

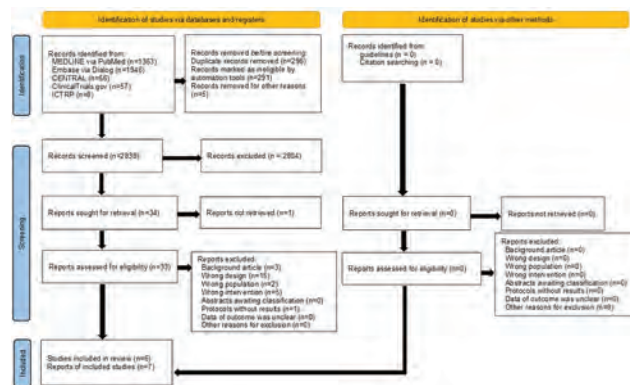

Yoshinosuke Shimamura,<sup>1,2</sup> Scientific Review WorkshopS Peer Support Group (SRWS-PSG) <sup>1</sup>Teine Keijinkai Byoin, Sapporo, Japan; <sup>2</sup>Scientific Review WorkshopS Peer Support Group, Osaka, Japan.

**Background:** Endovascular arteriovenous fistula (eAVF) is a novel strategy for hemodialysis vascular access. We aimed to determine whether eAVF had better clinical efficacy and safety than surgical AVF (sAVF) in patients with chronic kidney disease (CKD).

**Methods:** In May 2021, we searched Cochrane CENTRAL, MEDLINE, EMBASE, Clinical Trials.gov, and the WHO International Clinical Trials Registry Platform for systematic reviews and meta-analyses of randomized controlled trials and observational studies that had assessed the efficacy and safety outcomes of eAVF compared with sAVF in patients with CKD requiring AVF creation. Pairs of two authors independently and in duplicate extracted data, assessed the risk of bias, and rated certainty of evidence. Using random-effects models, pooled odds ratios (ORs) with 95% confidence intervals (CIs) were calculated for binary outcomes, and median differences (MDs) with 95% CIs were calculated for continuous outcomes. Heterogeneity and certainty of evidence were assessed using the Grading of Recommendation, Assessment, Development, and Evaluation approach.

**Results:** In seven studies (860 patients), ORs (95% CIs) for fistula maturation, procedural technical success, and all adverse events were 0.58 (0.05–6.91), 0.69 (0.04–11.98), and 6.31 (0.64–62.22), respectively. eAVF incurred less medical expenditure than sAVF (MD, USD \$12,760; 95% CI -197,100 to -58,200). No studies reported patient satisfaction. The certainty of evidence was very low in most outcomes.

**Conclusions:** eAVF use in routine clinical practice for patients with CKD is limited. Multicenter randomized controlled trials are needed to confirm the efficacy and safety of eAVFs in selected populations.

## A Novel Electronic Surveillance Program to Track Bloodstream Infections in Haemodialysis Patients (SPoT-BSI)

Ben Lazarus,<sup>1,2</sup> Kevan Polkinghorne,<sup>1,2</sup> Alex Duong,<sup>2</sup> Mechelle K. Seneviratne,<sup>2</sup> Benjamin A. Rogers,<sup>1,2</sup> <sup>1</sup>Monash University, Clayton, VIC, Australia; <sup>2</sup>Monash Health, Clayton, VIC, Australia.

**Background:** Accurate surveillance of ARBSI among haemodialysis patients is important for delivering high quality healthcare. Existing surveillance systems require substantial manual data collection, which may be prone to error and resource intensive. A system that uses automated analysis of routinely collected data may be more accurate and less burdensome. We aimed to measure the incidence of haemodialysis access-related bloodstream infection (ARBSI) using routinely collected electronic health data.

**Methods:** We linked routinely collected data from the electronic medical record (EMR) between 1<sup>st</sup> January 2021 and 31<sup>st</sup> December 2021 to laboratory blood culture data identifying haemodialysis (HD) treatments, access modality, and positive blood cultures among adult HD patients. We calculated exposure time by access type. For patients with a positive blood culture within 30 days of HD treatment the source of infection was assessed by manual review of the EMR. Definitions for HD catheter-related BSI (HDCRBSI) and arteriovenous ARBSI (AV-ARBSI) followed those used by the Center for Disease Control National Healthcare Surveillance Network.

**Results:** In total we identified 648 patients who received haemodialysis, 21,189 catheter days and 127,873 arteriovenous access days of exposure, and 51 cases of positive blood cultures, of which 10 were HDCRBSI, 4 were AV-ARBSI, 11 were contaminants, and 26 were from alternative sources. The incidence rate of HDCRBSI (0.47 events per 1000 catheter days, 95% CI, 0.18-0.76) was 15.1 times higher (95% CI 4.35 – 65.90) than for AV access-related BSI (0.03 events per 1000 access days, 95% CI, 0.0006-0.06)

**Conclusions:** Routinely collected electronic health data can be used to enhance the surveillance of access related bloodstream infections, although clinical assessment of positive cultures is still required.

**Funding:** Government Support - Non-U.S.

## TH-PO271

## Multifaceted Interventions to Prevent Haemodialysis Catheter-Related Bloodstream Infections Outside the Intensive Care Unit: A Systematic Review and Meta-Analysis

Ben Lazarus,<sup>1,2</sup> Elisa K. Bongetti,<sup>1,3</sup> Jonathan E. Ling,<sup>3,1</sup> Martin P. Gallagher,<sup>2,4</sup> Sradha S. Kotwal,<sup>2,5</sup> Kevan Polkinghorne,<sup>1,3</sup> <sup>1</sup>Monash University, Clayton, VIC, Australia; <sup>2</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>3</sup>Monash Health, Clayton, VIC, Australia; <sup>4</sup>University of New South Wales, Sydney, NSW, Australia; <sup>5</sup>Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia.

**Background:** Central venous catheters (CVCs) are widely used for haemodialysis access, but frequently lead to burdensome and costly bloodstream infections. It is unclear whether haemodialysis catheter-related bloodstream infections (HDCRBSI) or access-related bloodstream infections (ARBSI) can be prevented through multifaceted interventions. We sought to determine whether the implementation of a multifaceted intervention in ambulatory haemodialysis services can prevent HDCRBSI or ARBSI compared to usual care.

**Methods:** We searched PubMed, EMBASE, and the Cochrane Central Register of Controlled Trials from inception to 23<sup>rd</sup> April 2022 using a sensitive keyword search strategy (PROSPERO CRD42021252290). All randomized trials, interrupted time series (ITS), and before-after studies that examined the effect of multifaceted interventions on incidence of HDCRBSI or ARBSI were included. Two authors independently extracted data and assessed risk of bias and quality of evidence using validated tools. Random effects meta-analysis of the intervention effect was planned for HDCRBSI and ARBSI outcomes.

**Results:** We evaluated 8824 non-duplicate citations, 117 full texts and included 20 unique studies, of which 15 assessed HDCRBSI and 5 assessed ARBSI only. Among the eight HDCRBSI studies eligible for meta-analysis, two cluster randomized trials had conflicting results, two ITS studies reported an effective intervention but with conflicting patterns of effect, and all four before-after studies reported a favourable effect with serious risk of bias. None of the ARBSI studies were eligible for meta-analysis. The overall GRADE of evidence for an intervention effect on HDCRBSI and ARBSI was very low.

**Conclusions:** Most studies report a favourable effect of multifaceted interventions on HDCRBSI, but the quality of evidence is very low and studies with lower risk of bias showed less or no effect. Further high-quality studies are warranted.

**Funding:** Government Support - Non-U.S.

## TH-PO272

## Tunnelled Central Venous Haemodialysis Catheter Tip Design and Risk of Catheter Dysfunction

Ben Lazarus,<sup>1,2</sup> Kevan Polkinghorne,<sup>1,3</sup> Sarah E. Coggan,<sup>2</sup> Nicholas A. Gray,<sup>5,6</sup> Girish S. Talaulikar,<sup>7,8</sup> Martin P. Gallagher,<sup>2,9</sup> Sradha S. Kotwal,<sup>2,4</sup> on behalf of the REDUCCTON investigators <sup>1</sup>Monash University, Clayton, VIC, Australia; <sup>2</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>3</sup>Monash Health, Clayton, VIC, Australia; <sup>4</sup>Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; <sup>5</sup>Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; <sup>6</sup>University of the Sunshine Coast, Maroochydore DC, QLD, Australia; <sup>7</sup>Canberra Hospital, Canberra, ACT, Australia; <sup>8</sup>Australian National University, Canberra, ACT, Australia; <sup>9</sup>University of New South Wales Faculty of Medicine, Sydney, NSW, Australia.

**Background:** It is unknown whether the design of the tunnelled haemodialysis catheter (TCVC) tip influences the risk of catheter dysfunction. In small, randomized controlled trials symmetrical tip catheters have favourable rheology compared to step-tip catheters. We aimed to determine whether TCVC tip design influences the risk of catheter dysfunction requiring removal.

**Methods:** We conducted a post-hoc analysis using data from the REDUCing the burden of dialysis Catheter Complications study (2016-2020). TCVC were classified into three distinct designs: symmetrical, step or split tips. Non-tunnelled catheters were excluded as were TCVC with missing tip design (n=945), and those with missing reason for removal (n=267) leaving 6209 TCVC in 4652 participants. The primary outcome was time to catheter removal due to poor flow as assessed by the treating clinician. Death and other reasons for catheter removal were considered competing events. We compared the risk of catheter dysfunction across different catheter tip designs using raw proportions and a multivariable Fine and Gray model with robust cluster variance estimators for clustering by service.

**Results:** Overall, 354 of 3881 (9.1%), 258 of 1873 (13.8%), and 39 of 455 (8.6%) TCVC with symmetrical, step and split tip designs respectively, were removed for catheter dysfunction. Relative to catheters with a symmetrical tip, catheters with step tip had a 53% higher risk of catheter dysfunction, which persisted after multivariable adjustment (subdistribution hazard ratio = 1.53, 95% CI: 1.24 – 1.89). No difference was observed for split tip catheters (SHR = 0.66, 95% CI: 0.31 – 1.38).

**Conclusions:** Tunnelled HD CVCs with a step tip have a higher risk of dysfunction than those with a symmetrical tip. Prospective, large randomized controlled trials are warranted to confirm this observation.

## TH-PO273

## Reducing Staphylococcus epidermidis Catheter-Related Bloodstream Infections in Dialyzed Patients: Experience From the Hemodialysis Centre in Prince Mansour Military Hospital, Kingdom of Saudi Arabia

Najlaa AIMalki, Hichem Abidi. Al Hada Military Hospital, Taif, Saudi Arabia.

**Background:** Catheter-related bloodstream infections (CRBSIs) are a major cause of morbidity and mortality in hemodialysis. Although Methicillin-resistant Staphylococcus epidermidis (MRSE) is a leading causative agent, little literature deals with the mitigation of related CRBSIs, particularly in hemodialysis settings. A flare of MRSE CRBSIs occurred in PMMH HD center starting from August 2019, unveiled when instituting dialysis events surveillance (in March 2020) and studying historical data. A specific improvement project was designed to tackle this flare.

**Methods:** Fifteen percent of the patients had MRSE colonized catheters and were thought to represent a reservoir for the spread of the microorganism in the center. In the absence of specific international guidelines and the paucity of specific literature, mitigation actions were built on general infection control principles and analogy with Staphylococcus aureus, in consultation between nephrologists, infection control physician, infectious disease specialist, and nurses. An aggressive strategy of “seek and eliminate” against MRSE was adopted.

**Results:** Results were exceptional. MRSE CRBSI rates were significantly lowered towards the pre-flare period rates during the intervention period (April 2020 to August 2020), and post-intervention rates were maintained even lower to date (April 2022).

**Conclusions:** Assignment of a dedicated infection control professional to the hemodialysis center and implementation of the dialysis events surveillance with study of historical CRBSI data, allowed for the detection of the reported flare. Despite the lack of specific guidelines and literature, mitigation actions decided collectively allowed for a prompt and sustained control of MRSE CRBSIs.

#### Main interventions

<ul style="list-style-type: none"> <li>Targeted Active surveillance cultures:               <ul style="list-style-type: none"> <li>Newly accepted patients</li> <li>Patients resuming dialysis in the centre after hospitalization or dialysis in other centres (for three sessions or more)</li> </ul> </li> <li>Removal/exchange of CVC:               <ul style="list-style-type: none"> <li>Surveillance: Patients found to have paired central and peripheral positive blood cultures will have their CVC removed/exchanged and treated as per clinical CRBSI guidelines.</li> <li>CVC lumen colonization: Patients with isolated positive central line cultures (clinical or surveillance BC) will be treated by antibiotic lock. If colonization is still present after lock therapy, CVC will be removed/exchanged.</li> <li>Clinical CRBSIs:                   <ul style="list-style-type: none"> <li>Immediate removal for:                       <ul style="list-style-type: none"> <li>Clinically and hemodynamically unstable patient.</li> <li>Persistent fever 48 to 72 after initiation of systemic antibiotics.</li> <li>Metastatic complications, including suppurative thrombophlebitis, endocarditis.</li> </ul> </li> <li>Presence of a tunnel-site infection.</li> <li>Infections due to <i>S. aureus</i>, <i>Pseudomonas aeruginosa</i>, fungi, or mycobacteria. #### TH-PO274

### Catheter-Related Bloodstream Infections in Dialyzed Patients: Improvement Project in Hemodialysis Centre in Prince Mansour Military Hospital, Taif Region, Kingdom of Saudi Arabia

Najlaa AlMalki, Hichem Abidi. Al Hada Armed Forces Hospital Nephrology Department Al Hada Military Hospital, Taif, Saudi Arabia.

**Background:** Prevention of catheter-related bloodstream infections (CRBSIs) - a leading cause of morbidity and mortality in hemodialysis - is a multifaceted approach, mainly based on well-designed and implemented infection control and water quality programs. An extensive outbreak (attack rate of 35%) of CRBSIs with *Xanthomonas* occurred in PMMH HD Centre in 2019. A regional multidisciplinary team was invested with the mission of building on the investigation findings throughout the outbreak period, to set strategies to avoid similar situations in the future. We report the results of the improvement project that was built on the root cause analysis of this *Xanthomonas* outbreak.

**Methods:** The multidisciplinary team proceeded with an in-depth investigation including literature, system change, Reverse Osmosis/ raw water systems, and infection control practices reviews; incorporating findings and actions taken by the local team. A root cause analysis was conducted based on collected data. Recommendations from the committee were formulated as an improvement project.

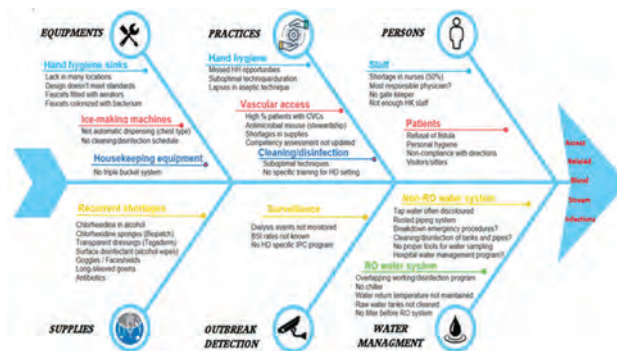

**Results:** The outbreak was officially declared over by the end of the intervention period (March 2020). During the post-intervention period (April 2020 to April 2022), a single case of *Xanthomonas* CRBSI occurred. An estimated overall 85% of the project recommendations were implemented.

**Conclusions:** Outbreaks of healthcare-associated infections are extremely stressful and challenging. Yet, lessons learned when investigating and mitigating such events could set sound foundations for quality improvement initiatives. The goals of the presented project were achieved successfully, mainly by instituting a new leadership system for the

hemodialysis center- with a physically present most responsible nephrologist, and a full-time infection control professional- which set the stage for further quality improvement initiatives.

#### Improvement project main interventions

<ul style="list-style-type: none"> <li>Point prevalence study for all patients with catheters.</li> <li>Draw Central and peripheral blood cultures from all patients with CVCs.</li> <li>Emphasize department's program of 'fistula first' for patients likely to be dialysed in a foreseeable future.</li> <li>Adopt % of patients first dialysed through fistula as a quality indicator.</li> <li>Adopt the % of patients with exclusive CVC &gt; 90 days as a quality indicator.</li> <li>Infection control job-specific training and monitoring of practices for HD staff.</li> <li>Assign a full-time infection control professional to oversee IPC related activities.</li> <li>Update competency checklists for nurses and remain. Assess competency regularly.</li> <li>Daily observations of procedures and practices.</li> <li>Housekeeping staff training and monitoring.</li> <li>Assign specific HK staff for HD units to be trained about the specificities of HD setting.</li> <li>Regular monitoring of HK practices with feedback.</li> <li>Use triple-bucket system to avoid contamination.</li> <li>Ensure permanent senior medical supervision of activities.</li> <li>Appoint a consultant nephrologist to be responsible (and physically present) for HD centre activities.</li> <li>Main raw (non-RO) water treatment and distribution systems.</li> <li>Empty all tanks urgently, clean and disinfect internal surfaces before refilling with water.</li> <li>Cleaning and then disinfection of the whole piping system either by superheating, hyper-chlorination or both is urgently needed. Contracting with a specialized company is warranted.</li> <li>Draw a new pipeline from the water treatment plant to directly feed the HD building (both RO and non-RO systems).</li> <li>Provide tools for water sampling and necessary containers and chemicals (e.g. sodium thiosulfate).</li> <li>Hand hygiene fountains and sinks need to be changed as design is not conform to standards. Add HH sinks missing in several areas of the HD units.</li> <li>Set a water management program for the facility supervised by a water management committee.</li> </ul>	<ul style="list-style-type: none"> <li>Implement surveillance of all positive blood cultures from haemodialysis patients.</li> <li>Calculate rates of CRBSIs and follow trends over time.</li> <li>Antimicrobial stewardship activities.</li> <li>Review appropriateness of empirical antibiotics according to local microbiology.</li> <li>Update policy for clinical management of CRBSIs according to latest international guidelines.</li> <li>Consult with ID specialist.</li> <li>Ensure Infection control/vascular access care supplies availability.</li> <li>Secure continuously a minimum stock of supplies for at least 3 months (PPE, Skin disinfectant, surface disinfectant, Biopatch, transparent dressing,...).</li> <li>Staffing level (nurse to patient ratio).</li> <li>Nurses are working at approximately 60% of the recommended nurse to patient ratio. Urgent recruiting of new staff is needed.</li> <li>Change ice-making machines.</li> <li>Install new machines with automatic dispensing (no direct contact with ice for dispensing).</li> <li>A schedule for cleaning and disinfection according to manufacturer's instructions should be implemented.</li> <li>Microbiological quality of water to be checked regularly.</li> <li>RO water system.</li> <li>Change the two raw water tanks in the RO room to be conforming with recommended design and easy to clean.</li> <li>Urgently follow up with the RO Company to fix the problem of low return water temperature. Closely monitor thereafter to make sure the problem is solved.</li> <li>A written policy for water sampling techniques from RO system should be in place.</li> <li>Install a water chiller after the raw water tanks in the RO room.</li> <li>Change the malfunctioning pumps to avoid critical situation of loss of pressure.</li> <li>Recruit or train a water technician for PMMH.</li> </ul>

#### TH-PO275

### Concordance Between Site Reporting and Clinical Adjudication of Catheter-Related Infectious Events in Australian and New Zealand Kidney Services

Jayson Catiwa,<sup>1</sup> Sarah E. Coggan,<sup>1</sup> Alan Cass,<sup>5</sup> Nicholas A. Gray,<sup>3</sup> Stephen Jan,<sup>1</sup> Stephen P. McDonald,<sup>6</sup> Kevan Polkinghorne,<sup>2</sup> Girish S. Talaulikar,<sup>4</sup> Martin P. Gallagher,<sup>1</sup> Sradha S. Kotwal,<sup>1</sup> REDUCTION Trial Investigators <sup>1</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>2</sup>Monash University, Clayton, VIC, Australia; <sup>3</sup>Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; <sup>4</sup>ACT Health, Canberra City, ACT, Australia; <sup>5</sup>Charles Darwin University, Casuarina, NT, Australia; <sup>6</sup>Royal Adelaide Hospital, Adelaide, SA, Australia.

**Background:** Hemodialysis catheter-related bloodstream infection (HD CRBSI) are a significant source of morbidity and mortality among dialysis patients. Varying definitions and interpretations of HD CRBSI have made meaningful comparisons difficult. Attempts at systematically improving infection rates require a consistent approach in measuring HD CRBSI and understanding the feasibility and accuracy of this reporting is crucial.

**Methods:** We conducted an analysis of HD CRBSI events reported prospectively by all participating Australian and New Zealand (ANZ) kidney services between December 2016 to March 2020 within the REDUCTION trial. Adult patients in a participating site who had a HD catheter inserted at any time after commencement of the trial or in whom the kidney service assumed the care of such catheter were included in the data collection. HD CRBSI events were assessed against the central adjudicators' outcomes using the REDUCTION trial's endpoint definition and adjudication process. We estimated the concordance between site-reported HD CRBSI and the corresponding adjudication outcomes using Cohen's kappa statistic ( $\kappa$ ) according to site clustering and implementation tranches in Australian sites as the New Zealand sites only participated in the observational phase.

**Results:** The REDUCTION trial has collected data on 7,258 patients and 12,630 catheters, representing 1.3 million catheter days across ANZ kidney services. A total of 779 HD catheter-related infectious events were reported by 42 ANZ sites within the 40-month trial period. The concordance from baseline to the last tranche of intervention

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

implementation range from moderate to almost perfect. The overall concordance for HD CRBSI between sites and central adjudicators was  $\kappa=0.71$  (95%CI 0.66-0.76).

**Conclusions:** Our study revealed a substantial level of concordance in HD CRBSI reporting between the participating kidney services and the *REDUCTION* trial adjudicators, demonstrating reliability in Australian and New Zealand site-based reporting of HD CRBSI rates. While ascertaining HD CRBSI using a standardized definition allowed for comparable adjudication of outcomes with reliable benchmarking among ANZ kidney services, this remains unknown elsewhere in the world.

### Rapid Incidence and Emergence of Catheter-Related Bloodstream Infections (CRBSIs) Among CVC-Dependent Hemodialysis Patients

Kenneth Massey,<sup>1</sup> Krithika Rajagopalan,<sup>2</sup> Roxanna Seyedin.<sup>2</sup> <sup>1</sup>CorMedix Inc, Berkeley Heights, NJ; <sup>2</sup>Anlitiks Inc., Dover, MA.

**Background:** Kidney failure patients receiving hemodialysis (HD) via a central venous catheter (CVC) are at high risk of developing catheter-related bloodstream infections (CRBSIs), resulting in increased mortality, hospitalizations, and long-term complications (LTCs). A claims-based algorithm was developed to assess real-world outpatient/inpatient (OP/IP) CRBSIs among CVC-dependent HD (CVC-HD) patients.

**Methods:** A retrospective analysis of merged data from United States Renal Data System (USRDS), CROWNWeb (dialysis orgs.), and Medicare claims (2013-2018) was conducted. Among incident CVC-HD (2014-2017) patients with 1 year pre- and  $\geq$  1-year post-index data (n=51,783), CRBSI incidence was the first date of OP/IP CRBSI occurrence. OP CRBSI was the first oral/intravenous antibiotic prescription within  $\pm$  1 day of the first OP emergency/urgent care visit post-CVC insertion. IP CRBSI was the first occurrence of either sepsis/bacteremia and ICD-9/10 CMs 999.32, T80211x; 999.31, T80219x, T80218x claims or sepsis/bacteremia diagnosis without occurrence for pneumonia, gangrene, or urinary tract infections. CRBSI incidence proportion and rates, median days to CRBSI, proportion of CRBSIs at days 30 and 90, and 1-year post-CRBSI LTC rates were assessed.

**Results:** The CVC-HD cohort's mean age was 63 (SD:15.3); 47% (n=7,822) were female and 29% (n=4,898) were African American. CRBSI incidence proportion and rates were approximately 33% (n=16,813) and 4.5 per 1000-catheter days, respectively. In total 81% (n=13,559) of CRBSIs were diagnosed IP and 19% (n=3,254) were diagnosed in OP settings. Overall, 33% and 47% developed CRBSIs within 30- and 90-days post-CVC insertion, respectively. Median days to CRBSI were 107 days (interquartile range: 294 days). Frequently reported LTCs were HF (58%), dysrhythmia (54%), PVD (41%), stroke (17%), and MI (13%).

**Conclusions:** Of the 1/3<sup>rd</sup> of CVC-HD patients with CRBSIs, 33% and 47% developed CRBSI within 30- and 90-days post-CVC insertion, respectively. High rates of HF, PVD, stroke, and MI were reported 1-year post-CRBSI. Assessment of the incremental burden of clinical complications and costs associated with CRBSIs is warranted and underway. Early and high incident CRBSI rates underscore the importance of interventions that can prevent CRBSIs among CVC-HD patients.

## TH-PO277

### Central Venous Catheters in Hemodialysis: A Reasonable Alternative?

Anna Buckenmayer, Bianca Möller, Claudia Ostermaier, Joachim Hoyer, Christian S. Haas. *Philipps-Universität Marburg, Marburg, Germany.*

**Background:** Arteriovenous fistulas are the gold standard for access in dialysis patients; central venous catheters (CVC) provide a potential alternative, especially in multimorbid and elderly patients. CVCs are considered to be of elevated risk for complications; however, it remains unclear, if they have relevant impact on clinical outcome. The objective of this study was to provide a quantitative and qualitative analysis of CVC associated complications in hemodialysis patients. Additionally, estimated and actual mortality should be evaluated.

**Methods:** In a retrospective study at the University Hospital Marburg, Germany, patients receiving hemodialysis via CVC between January 2015 and June 2021 were included. Data on duration of CVC use was collected, as well as reasons for catheter implantation and explantation, CVC related complications and comorbidities (diabetes, hypertension, heart failure, peripheral vascular disease, dementia). Additionally, estimated 6-month mortality at time of dialysis start was calculated by Cohen Modell and compared to actual death rate.

**Results:** 478 CVCs were analyzed in 351 patients. Mean patient age was 66.5 $\pm$ , comparable with the average age of dialysis patients in Germany. Initiation of dialysis was the main reason for CVC implantation and catheters were used 309 days on average. Death was the most common reason for termination of CVC use (31.1%), followed by a change of mode in renal replacement therapy (hemodialysis via fistula, begin of peritoneal dialysis, kidney transplantation) or termination of dialysis (29.6%). No correlation was noted between age, type and frequency of complications (dysfunction, thrombi, infection, death). Overall, CVC infections were rare (0.6 per 1.000 catheter days). Complications were significantly associated with arterial occlusive disease, heart failure and dementia (p<0.05). Of note, actual 6-month mortality was lower than the predicted risk to die within half a year (14.3% vs. 19.6%, p<0.05).

**Conclusions:** This study shows that (1) CVCs are predominantly implanted for initiation of hemodialysis; (2) serious complications are rare; (3) occurrence of complications is independent of age but associated with certain comorbidities; and (4) CVC patients survive longer than predicted. This data suggests that an individual approach for vascular access in hemodialysis patients is needed.

## TH-PO278

### Early Transition From Non-Tunneled to Tunneled Hemodialysis Vascular Access for Vessel Preservation in Critically Ill Patients With AKI

Mohammad A. Sohail, Tarik Hanane, James E. Lane, Tushar J. Vachharajani. *Cleveland Clinic, Cleveland, OH.*

**Background:** Strategies for vessel preservation currently remain focused on patients with advanced CKD to ensure future viable arteriovenous access. Given that AKI requiring kidney replacement therapy (KRT), or AKI-D, occurs in approximately 6-7% of critically ill patients, and that 10-30% of AKI-D survivors remain KRT dependent at hospital discharge, vessel preservation should be considered early in these patients as well. We report our experience of early conversion of non-tunneled dialysis catheters (NTDC) to tunneled dialysis catheters (TDC) in patients in whom KRT was anticipated beyond 7 days, as a potential strategy for vessel preservation in AKI-D patients in the medical intensive care unit (MICU).

**Methods:** We reviewed MICU patients with AKI-D from 5/2020-4/2021 who had their NTDCs converted early to TDCs within 10 days, based on our collaborative care model involving interventional nephrology and MICU teams. Data on the number of NTDCs placed prior to TDC insertion and time to conversion from NTDC to TDC was collected. The control group included patients who received TDCs between 5/2019-4/2020 prior to the implementation of our care model. Characteristics/outcomes of the two groups were compared using t-tests/chi-square tests and two-tailed P-values <0.05 were considered significant.

**Results:** 380 and 102 critically ill AKI-D patients underwent transition from NTDCs to TDCs prior to and after implementation of our care model respectively. The number of NTDCs placed prior to transition to TDCs was significantly higher (mean $\pm$ SD [range]: 1.51 $\pm$ 0.71 [1-6] vs. 0.95 $\pm$ 0.73 [0-3]; p<0.001), and the time to conversion from NTDCs to TDCs was significantly longer (mean  $\pm$  SD [range]: 11.17 $\pm$ 5.32 [2-27] vs. 4.82 $\pm$ 3.26 [0-10] days; p<0.001) in patients before vs. after the advent of our care model.

**Conclusions:** Critically ill patients with AKI-D often remain KRT-dependent past hospital discharge and may eventually progress to ESKD, which merits earlier enactment of vessel preservation strategies. Our collaborative care model was one such initiative which resulted in less frequent central venous trauma with fewer NTDC insertions as well as shorter time to conversion to TDCs. This may not only promote vessel preservation, but also streamline transitions of care and reduce the incidence of CLABSI and catheter dysfunction.

## TH-PO279

### Cytokines Associated With Changes in Echocardiographic Parameters After Arteriovenous Fistula Creation in Hemodialysis Patients

Juan C. Duque, Karen Manzur-Pineda, Laisel Martinez, Christopher Montoya, Adriana Dejan, Marwan Tabbara, Roberto I. Vazquez-Padron. *University of Miami School of Medicine, Miami, FL.*

**Background:** Pulmonary hypertension (PH) is common in patients with end-stage kidney disease (ESKD) and is associated with increased all-cause and cardiovascular mortality. It is widely believed that arteriovenous fistula (AVF) creation and long-term hemodialysis contribute to the pathogenesis and/or exacerbate PH. Systemic cytokines are elevated in CKD and ESKD patients compared with the general population. However, whether cytokine levels interfere with vascular and cardiac remodeling after AVF creation remains unknown. There is scarce data on the long-term effect of AVF creation and cytokine expression on PH and echocardiographic changes.

**Methods:** A retrospective study of 38 patients who underwent AVF creation between 2019 and 2020. Cytokine levels, including chemokines, interferons, interleukins, and growth factors, were measured in preoperative plasma samples using multiplex and echocardiographic evaluations before and after surgery. A stepwise linear regression analysis was performed looking for the correlation between right ventricular systolic pressure (RVSP) change pre- and post-AVF and demographic traits, comorbidities, cytokines, and other echocardiographic parameters such as right atrial pressure (RAP) during systole, left ventricular mass (LVM), tricuspid regurgitation (TR), mitral E/E' ratio, and ejection fraction (EF).

**Results:** The median time for the preoperative echocardiogram was 0.3 years (interquartile range [IQR] 0.2-0.7 years) before AVF creation, while the follow-up echo was done 1.3 (0.6-2.1) years after surgery. Thirty-seven percent of the patients had RVSP>37 mmHg at baseline. The RVSP after AVF creation decreased in 29% of the patients, and 24% remained stable. There was a significant decrease in LVM (224 [171-285] vs. 194 [147-236], P=0.045) after surgery. Smoking (p=0.047), along with high levels of GRO (p=0.001) and TGF $\beta$ -1 (p=0.012), are associated with worsening of RVSP post-AVF creation, while high levels of IL-4 (p=0.002) are associated with an improvement in RVSP post-AVF creation.

**Conclusions:** Our results suggest that elevated systemic cytokines pre and post AVF creation are associated with a significant elevation of RVSP in the ESKD population.

TH-PO280

Arteriovenous Shunts and Right Heart Function

Richard E. Wing, Nikhila S. Rao, Nilesh S. Rao, Peihsuan R. Tsai, Thu H. Le.  
*University of Rochester Medical Center, Rochester, NY.*

**Background:** Emerging evidence suggests that right ventricular dysfunction (RVD) is a major determinant of adverse health outcomes. Data regarding the effect of AV shunt placement on right heart function (RHF) is sparse.

**Methods:** We conducted a cross-sectional study on patients who received maintenance hemodialysis (HD) who were followed by URM nephrology faculty. We identified subjects who underwent ambulatory echocardiograms (echos) within two years of each other. Original echocardiographic images were re-analyzed to assess RHF. Subjects who underwent construction of an AV shunt between echocardiograms (Group 1) were compared to subjects who did not undergo AV shunt construction between echos (Group 2).

**Results:** We identified 558 subjects with echos completed within two years of each other. Screening 300 of these subjects identified 54 who had two ambulatory echos within 2 years. Thus far, pairs of ambulatory echos have been analyzed for 10 subjects. RVD is defined as abnormality in any of the following: Myocardial Systolic Excursion Velocity (S') < 9.5 cm/sec, Tricuspid Annular Plane Systolic Excursion (TAPSE) < 17 mm, Right Ventricular Free Wall Strain (RVFWS) > -20%, or Right Ventricular Fractional Area Change (RVFAC) < 35%. Details are summarized in Table 1. Findings are reported as counts for discrete parameters or means for continuous parameters (standard deviation). All 20 echos had measurable TAPSE and RVFAC. In Group 1, S' could not be determined in the 1st echo for one subject and the 2nd echo in another subject. In Group 2, RVFWS could not be determined in the 2nd echo in one subject. All unmeasurable parameters were assumed to be normal.

**Conclusions:** RVD is remarkably common in patients with ESRD receiving hemodialysis. Larger studies with longitudinal data are needed to assess the impact of AVF on RVD in patients receiving maintenance hemodialysis.

Parameter	AVF created between echos		AVF not created between echos

Saving Vascular Access and Reducing Risks of Complications in Catheter Related Thrombosis: Our Experience With the FlowTriever® Device  
Gabino M. Maza Rodas, Ali I. Gardezi. *University of Wisconsin-Madison, Madison, WI.*

**Introduction:** Among patients undergoing hemodialysis, around 18% of prevalent HD patients with ESRD use central venous catheter as vascular access. Catheter related thrombosis is a relatively common complication in patients with long term central venous catheter resulting in catheter malfunction, loss of vascular access and risk of venous thromboembolism.

**Case Description:** 71 years old female with a past medical history of heparin induced thrombocytopenia, diabetes type 2, hypertension, end stage renal disease on intermittent hemodialysis who presented with shortness of breath. On exam, patient was hypertensive and hypoxic on room air. She had a right femoral vein tunneled hemodialysis catheter. Patient had magnetic resonance angiogram (MRA), which was negative for pulmonary embolism but showed a thrombus within the inferior vena cava associated with the tip of the dialysis catheter. MRA of abdomen, pelvis and right lower extremity to evaluate extent of thrombosis. Thrombus was nonocclusive and extended from the level of the renal veins to the liver. Anticoagulation with Apixaban was started. Interventional cardiology performed aspiration thrombectomy of the right atrium, inferior vena cava and catheter related thrombi using FlowTriever® system, and which enabled us to preserve access and minimize risks of thromboembolism.

**Discussion:** Anticoagulation is the mainstay of treatment for catheter related thrombosis, provided there are no contraindications. For catheter-tip atrial thrombus, the catheter should remain in place to reduce the risk of embolization until the thrombus has resolved. If symptomatic thrombus is present, catheter should be removed. However, if vascular access is limited, it is possible to preserve the catheter. Other therapies include catheter directed therapy with local administration of a thrombolytic agent or physical aspiration of the thrombus, or both. In some instances, with thrombus extension > 6 cm, systemic thrombolysis may be considered as a second-line therapy. At our institution,

we have available the FlowTriever® system, in which a large bore sheath is introduced for placement of suction catheter, which is connected to a retraction aspirator, providing vacuum for clot aspiration. The advantage is that it can remove large volumes of thrombus rapidly.

TH-PO282

A Cross-Sectional Epidemiological Study on the Status of Vascular Access in Hemodialysis Patients in Southwest China  
Wei Zhou,<sup>1</sup> Santao Ou,<sup>10</sup> Xisheng Xie,<sup>2</sup> Rong Gong,<sup>3</sup> Jian Xiao,<sup>3</sup> Guang Zeng,<sup>4</sup> Youwen Xiao,<sup>5</sup> Song Wang,<sup>6</sup> Yu Wen,<sup>7</sup> Heping Zhang,<sup>8</sup> Qiang He,<sup>1</sup> Guisen Li,<sup>1</sup> Fei Deng,<sup>1</sup> *<sup>1</sup>Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China; <sup>2</sup>Department of Nephrology, Nanchong Central Hospital, Nan chong, China; <sup>3</sup>Department of Nephrology, Guangyuan Central Hospital, Guang yuan, China; <sup>4</sup>Department of Nephrology, No. 2 People's Hospital of Neijiang, Nei jiang, China; <sup>5</sup>Department of Nephrology, Leshan People's Hospital, Le shan, China; <sup>6</sup>Department of Nephrology, Mianyang Central Hospital, Mian yang, China; <sup>7</sup>Department of Nephrology, Ziyang People's Hospital, Ziyang, China; <sup>8</sup>Department of Nephrology, Affiliated Hospital of Chuanbei Medical College, Chuan bei, China; <sup>9</sup>Department of Nephrology, Chengdu Third People's Hospital, Cheng du, China; <sup>10</sup>The Affiliated Hospital of Southwest Medical University, Luzhou, China.*

**Background:** Hemodialysis is an important method to maintain the life of patients with end-stage renal disease. The number of hemodialysis patients in southwest China is increasing year by year, but there are few studies on the current situation of vascular access for hemodialysis patients in this region.

**Methods:** A cross-sectional survey study was conducted using a questionnaire. Statistical analysis was performed to determine the influence of the first choice of dialysis access modality, level of open surgery and interventional surgery in the hospital.

**Results:** A total of 228 hospitals in southwest China with 30,068 hemodialysis patients were included in this study. The number of patients with long-term hemodialysis access as autogenous arteriovenous fistula (AVF) was the highest, accounting for 81.35%. The number of patients whose first hemodialysis access was AVF was lower (32.29%) and the number of patients whose first hemodialysis access was temporary catheter was the highest (57.42%). 61.40% of physicians preferred femoral vein placement for initial hemodialysis patients. Grade A tertiary hospital (the highest level of hospital in China) had a significant effect (95% CI 0.021-0.744) on physicians' choice of whether to place a central venous temporary catheter or a long-term catheter for the first time. Local economic situation (estimated by house price per square meter) was an independent influence on the ability of hospitals to perform open procedures for hemodialysis access (95% CI 1.407-44.657, 95% CI 2.791-77.801).

**Conclusions:** Currently, more than half of hemodialysis patients in southwest China still have their first hemodialysis access as femoral vein placement, but 81.35% of patients end up with AVF as long-term hemodialysis access. Hospital grade had a significant impact on the physician's choice of the type of central venous catheter to be placed for the first time. The economic level of the city where the hospital was located also had a significant effect on the level of hospital prescribing and interventional procedures.

TH-PO283

Analysis of Use and Outcomes of Peripherally Inserted Central Venous Catheters in Advanced CKD and ESKD  
Richard Barrios, Marie A. Sosa, Efen Chavez. *University of Miami Health System, Miami, FL.*

**Background:** Peripherally inserted central venous catheter (PICC) placement is an independent risk factor for AVF failure suspected due to venous injury resulting from thrombosis, intimal hyperplasia, and stenosis. The overall probability of achieving any permanent vascular access is lower for patients exposed to PICCs.

**Methods:** This is a cross-sectional, retrospective study aimed to investigate incidence of PICC placement in adult patients with advanced CKD (defined as eGFR <30 ml/min/1.73m<sup>2</sup>) and ESKD based on ICD-10 diagnoses admitted to UHealth Tower (UHT) from 10/2020 to 2/2022. Hospice patients were excluded.

**Results:** From a total of 1,074 patients with advanced CKD/ESKD admitted to UHT over 15 months 87 out of 1,074 patients (8.1%) had a PICC placed. Of these 87 patients, 49%, 6.0%, and 45% carried a diagnosis of CKD-4, CKD-5, and ESKD, respectively. Most of the patients who experienced PICC placement were men (n=48) with a median age of 69 years, white (n=51) and Hispanic/Latino (n=50). A total of 9 out of 87 (9.1%) of PICCs placed within this population were complicated by DVT formation. The veins cannulated during PICC insertion were predominantly basilic vein (73.5%) and brachial vein (20.6%). The majority of the PICCs placed were dual lumen catheters (n=62). Indications for PICC placement were the following: ICU care (59.75%), prolonged antibiotic therapy (23%), chemotherapy (10.3%), TPN (4.6%) and other IV medications or frequent blood draws (3.45%).

**Conclusions:** There is a high prevalence of PICC insertion in advanced CKD/ESKD patients at UHT. We observed an incidence of PICC-related DVTs of 9.1% in our analysis, which is higher compared to a 2.4% PICC-related DVT incidence described in the literature. Nearly 60% of PICCs were placed in the ICU. 81% of PICCs were ≥2 lumens with a diameter ≥5 Fr. Catheters with a larger diameter and higher number of lumens are associated with a higher thrombotic risk. Nevertheless, in patients with CKD stage 3B or greater, PICC placement is generally contraindicated, and recommendations should be individualized considering the likelihood of requiring KRT, urgency of the situation, and

availability of resources. In advanced CKD/ESKD patients who have an absolute need for prolonged central venous access the implementation of alternative interventions should be encouraged.

## TH-PO284

### Arteriovenous Fistula (AVF) Placement Unmasking Chronic Aortic Dissection

Sagar Patel, Gautam B. Bhav. *Vanderbilt University Medical Center, Nashville, TN.*

**Introduction:** Swelling in the arm of an AVF can be a symptom of a stenotic or occlusive vascular process. It is often seen with a deep vein thrombosis (DVT) or central stenosis related to prior central lines or pacemakers. Here, we describe a rare presentation of a chronic aortic dissection being discovered as a result of AVF placement and subsequent swelling from mass effect of aorta.

**Case Description:** A 68 year old male with history of coronary artery disease, pacemaker placed 10 years ago, hypertension, and stage 5 chronic kidney disease with a left upper extremity brachio-basilic AVF placed 3 weeks prior presented with 2 weeks of worsening swelling in his left arm. He had some numbness and tingling in his arm but denied any pain. He was afebrile with BP 132/80 and HR 62. Exam showed significant swelling throughout his left arm even above the fistula and into the shoulder. Fistula had weak thrill and bruit. Collateral veins were noted in left chest/neck area that patient reported had been present for a few years. Duplex ultrasound showed DVT in the paired brachial veins. However, the degree and location of swelling was not consistent with the location of DVT. It was suspected that he had central stenosis related to his pacemaker. The initial plan was to perform a fistulogram to diagnose and treat such a stenosis. However, decision was made to pursue CT scan with contrast for further evaluation with understanding of risks of worsening kidney function. CT scan showed aneurysmal ascending aorta of 5.5cm and aortic dissection involving ascending thoracic aorta and aortic arch with mass effect on left brachiocephalic vein. Patient was transferred to ICU for esmolol drip. CT surgery reported there was no need for surgical intervention as the dissection appeared chronic in nature. Patient's kidney function worsened after contrast and a right IJ tunneled dialysis catheter was placed, and he was initiated on hemodialysis which was tolerated well without hemodynamic instability.

**Discussion:** Swelling associated with an AVF is often presumed to be from an intravascular process such as a thrombus or central stenosis which can be diagnosed and treated by fistulogram. However, external compression by mass effect should also be taken into consideration. Cases such as ours as well as other reported cases of tumors causing similar presentation highlight the importance of CT imaging in the evaluation of AVF related swelling.

## TH-PO285

### Arteriovenous Fistula Recirculation Results in Persistent Hypoglycemia in an ESRD Patient Through an Insulin-Independent Mechanism

Jun Li, Jyotsana Thakkar. *Montefiore Medical Center, Bronx, NY.*

**Introduction:** End-Stage Renal Disease (ESRD) patients who are on hemodialysis (HD) are vulnerable to low blood glucose levels due to reduced insulin clearance, changes of glucose metabolism and hemodialysis *per se*. It has been reported that up to 3.6% of ESRD admission presents with hypoglycemia. These patients have a poor prognosis, with a mortality up to 30%. We present a unique case in which persistent hypoglycemia was caused by arteriovenous fistula (AVF) recirculation.

**Case Description:** A 45-year-old African American male with medical history of ESRD on HD, pulmonary hypertension, presented with left upper extremity AVF malfunction and persistent hypoglycemia. Patient had no history of diabetes and was not on any glucose-lowering medications. The blood glucose level was 44-62 mg/dl which was refractory to 50% dextrose treatment. Laboratory tests including serum Insulin (2.2 µU/ml), C-peptide (4.03), Proinsulin and cortisol level were acceptable. Thyroid function tests and liver function tests were within normal range. AVF duplex showed a radial artery to cephalic vein fistula with average volume flow of 163.23 ml/min. The outflow cephalic vein with >50% stenosis seen at distal forearm and occluded in the upper arm. Angiogram demonstrated a stenosis in the fistula outflow just distal to the elbow. AVF recirculation study was performed during HD session. Peripheral BUN (blood urea nitrogen- mg/dl): 80, Arterial BUN: 32, Venous BUN: < 3. Percent recirculation =  $\frac{([P - A] \div [P - V]) \times 100}{([80 - 32] \div [80 - 3]) \times 100} = 62\%$ . This further confirms the AVF recirculation in addition to the AVF duplex study. Patient also exhibited persistent hyperkalemia due to the low clearance of malfunctioned AVF. Patient then underwent HD through a new HD catheter placed via the right internal jugular vein, after which patient's blood glucose level improved rapidly to 83-115 mg/dl without extra dextrose administration.

**Discussion:** Hypoglycemia in ESRD patients has been attributed to deficiency of precursors of gluconeogenesis, impaired glycogenolysis, diminished renal gluconeogenesis and reduced renal insulin clearance. In the present case, persistent hypoglycemia in the setting of normal insulin level, rapidly corrected by effective HD, indicates that an unknown dialyzable molecule suppressing glycogenolysis or gluconeogenesis might be involved in this process.

## TH-PO286

### A Dialysis Dilemma in Achondroplasia

Mahendra L. Agraharkar,<sup>1,2</sup> Neelam Jaju.<sup>3</sup> Space City Associates of Nephrology <sup>1</sup>The University of Texas Medical Branch at Galveston, Galveston, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>Bhaskar Medical College and Bhaskar General Hospital, Yenkapally, India.

**Introduction:** Achondroplasia is not an uncommon skeletal dysplasia caused by a variant Fibroblast Growth Factor Receptor 3 (FGFR3) gene leading to deformed limbs, spine and skull with an incidence of ~1:25,000 live births. Renal failure is not a feature but comorbidities may render them dialysis dependent. Unlike the general population, they encounter many problems such as erroneous GFR estimation due to poor musculature, limitations in modality selection and dialysis access placement, transportation, BP monitoring due to hypoplastic limbs, positioning in a recliner and selecting a dialysis unit that satisfies the above requirements.

**Case Description:** A 3' tall 51-yr-old achondroplastic female weighing 90 lbs presented with shortness of breath. She had multiple abdominal and lung surgeries causing ventral hernia and a tracheostomy. She was hypoxic, acidemic, hyperkalemic, and volume expanded with a creatinine of 2.99 mg/dl. Ventral hernia precluded peritoneal dialysis. We dialyzed her by placing a tunneled catheter.

**Discussion:** Achondroplastics needing dialysis can encounter a multitude of problems. Low muscle mass hinders GFR estimation. Respiratory compromise and abdominal surgeries prohibit peritoneal dialysis. Hypoplastic limbs prevent AV shunts and right sized central venous catheters for such patients are unavailable. In the US, there are no pediatric freestanding dialysis units and the adult dialysis centers are not equipped for such patients. Patients with tracheostomy are dialyzed in an isolation unit by a nurse certified in tracheostomy care. There are no applicable formulae for GFR estimation nor for measuring adequacy in such patients. Dialysis in this population has not been described. We describe the problems we faced and potential solutions that can be offered. Awareness of this condition is essential in this potentially growing population.

Note: BP cuff wraps entire limb.

## TH-PO287

### Case of Elevated Dialysis Access Venous Pressures From Cephalic Arch Pseudo-Stenosis

Abdul Hannan A. Rasheed,<sup>1,2</sup> Sylvester Barnes.<sup>1,2</sup> <sup>1</sup>Edward Hines Junior VA Hospital, Hines, IL; <sup>2</sup>Loyola University Health System, Maywood, IL.

**Introduction:** The patient is a 75-year-old male with ESRD getting hemodialysis via left brachiocephalic AVF created in March 2017. In May 2021, he was found to have elevated venous pressures (VP) of up to 260mmHg during dialysis causing frequent alarms.

**Case Description:** Duplex US of the access showed a patent brachiocephalic AVF with evidence of a significant stenosis at the cephalic / subclavian vein junction with a velocity ratio of 7.8 (659cm/s ÷ 83.8cm/s)(Fig 1). Based on the elevated VP and significant V2/V1 > 3.5 fistulogram was indicated. A fistulogram was performed which showed no significant stenosis within the fistula, as well as no significant stenosis in the central circulation. However, it showed significant angular entry of the cephalic vein at the subclavian junction (Fig 2)

**Discussion:** This case representing pseudo-stenosis, shows the difference of findings detected by the two modalities most commonly used for assessment of dialysis access. The duplex findings can be explained by the both the sharp angle of entry of the cephalic vein to the subclavian vein, along with the significant diameter difference. Since flow must remain constant then velocity has to increase accounting for the smaller diameter and increased vessel tortuosity. If the result was still in question, IVUS could be deployed to document the luminal diameter. The decision was made to follow the patient clinically and if the patient developed problems with prolonged bleeding or excessively high VPs then the patient would have a covered stent placed in the cephalic arch to straighten out the venous tortuosity. So far to date the patient has not had any increase in VPs from the current state nor any episodes of prolonged bleeding.

Figure 1: Duplex US

Figure 2: Fistulogram of AVF

## TH-PO288

### Morphometric Characterization of Arteriovenous Fistula (AVF) Explants Reveals Collagen and Versican as Dominant Components of Mature AVF Wall

Saran Lotfollahzadeh,<sup>1,2</sup> Nagla El zinad,<sup>4</sup> Yichi Zhang,<sup>5</sup> Murad Elsadawi,<sup>4</sup> Merche Balcells,<sup>6</sup> Vijaya B. Kolachalama,<sup>5</sup> Vipul C. Chitalia.<sup>1,3</sup> <sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>Renal Section, Department of Medicine, Boston University School of Medicine, Boston, MA; <sup>3</sup>Veterans Affairs Boston Healthcare System, Boston, MA; <sup>4</sup>Boston University Medical Campus, Boston, MA; <sup>5</sup>Computation Biology, Boston University School of Medicine, Boston, MA; <sup>6</sup>Institute of Medical Engineering and Sciences, Massachusetts Institute of Technology, Cambridge, MA.

**Background:** Arteriovenous Fistula (AVF) is the lifeline of patients with End-Stage Kidney Disease (ESKD) on hemodialysis. AVF undergoes profound remodeling to accommodate arterial pressure and flow, a process called arterIALIZATION of the vein. Despite the central importance of this process in functional AVF, there is a dearth of studies on humans characterizing the components of walls of the mature AVFs.

**Methods:** The morphology of AVF explants was probed with Masson Trichrome, Sirius Red, and Versican. This was followed by a color-based segmentation pipeline with a machine learning approach to quantify the components of AVF explants. Vascular smooth muscle cells were characterized using functional markers.

**Results:** Twenty-one patients had AVFs explanted for aneurysm (71.42%), pseudoaneurysm, stenosis, or aesthetic reasons (each in 9.52%). Neointimal hyperplasia characterized by intimal thickening was present in all AVFs. Other features included calcification, inflammatory infiltrate, needle track injury, and thrombus. Quantitative histological analysis of Masson Trichrome and Sirius red stains showed that in the AVF wall, collagen, vSMCs, and proteoglycan constituted 27.78%, 19.80%, and 31.45% of the

wall, respectively. Compared to vSMC, the collagen and Versican were in the ECM by 1.40 fold and 2.76 fold, respectively. ( $p < 0.001$ ) Collagen was deposited in a concentric manner in the explanted AVFs with aneurysms and in an eccentric manner in the AVFs with pseudoaneurysms. vSMCs showed minimal staining of Ki67 and prominent staining of MYH11,  $\alpha$ -smooth muscle actin, and Calponin, all markers of differentiated VSMCs with secretory phenotype.

**Conclusions:** This study confirms collagen and versican as prominent components of AVF walls and vSMCs with secretory features in the wall of AVF. This study now seeds future investigation to examine the regulation of the components of ECM in the arterIALIZATION of the vein.

## TH-PO289

### Impact of Dialysate Flow Rates on Dialysis Adequacy: A Systematic Review and Meta-Analysis

Yasmin A. Iman,<sup>1</sup> Paul Komenda,<sup>1,2</sup> Karen Hovhannisyan,<sup>2</sup> Ruth Ewhrudjakpor,<sup>1</sup> Kelley L. Gorbe,<sup>2</sup> Ryan J. Bamforth,<sup>1</sup> Reid Whitlock,<sup>1</sup> David T. Collister.<sup>3</sup> <sup>1</sup>Seven Oaks General Hospital, Winnipeg, MB, Canada; <sup>2</sup>Quanta Dialysis Technologies Ltd, Alcester, United Kingdom; <sup>3</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.

**Background:** Patients with kidney failure on hemodialysis (HD) require adequate removal of uremic solutes and fluid. Historically, dialysis adequacy is measured by multiplying dialyzer clearance of urea (K) by duration of dialysis session (t) adjusted for patient volume of distribution (V). There are many ways of improving dialysis adequacy, including, increasing dialysis time and frequency, maximizing blood flow rates, and using higher surface area dialyzers. However, the relative impact of dialysate flow rates on dialysis adequacy is poorly described. This systematic review and meta-analysis examines the impact of dialysate flow rates on dialysis adequacy.

**Methods:** We searched EMBASE, MEDLINE, and the Cochrane Library from inception until April 2022 for randomized controlled trials of any design and observational studies comparing higher dialysate flow rates (>500mL/min) and lower dialysate flow rates (<500mL/min) vs. a standard dialysate flow rate (500 mL/min) in adults (age ≥18 years) treated with chronic HD (>90 consecutive days) for the outcome of dialysis adequacy, measured by Kt/V. We used random effects meta-analysis to estimate pooled mean difference in Kt/V at fixed dialysis durations, blood flows and dialyzers.

**Results:** A total of 3118 studies were identified in the literature search. Of those, 11 met eligibility criteria and were included for analysis. In the 10 comparisons (n = 732) of a higher dialysate flow rate (560-800 mL/min) vs. a dialysate flow rate of 500 mL/min, a higher dialysate flow rate was associated with an increase in single pooled Kt/V (spKt/V) of 0.12 (95% CI: 0.06-0.18). In the 2 comparisons (n = 24) of a dialysate flow rate of 500 mL/min vs. a lower dialysate flow rate of 300 mL/min, a dialysate flow rate of 500 mL/min showed an increase in spKt/V (mean difference = 0.16) but limited data precluded a meta-analysis.

**Conclusions:** In our systematic review and meta-analysis, we found a higher dialysate flow rate is associated with an improvement in dialysis adequacy compared with a standard dialysate flow rate. More studies are needed to compare a dialysate flow rate of 500 mL/min vs. a dialysate flow rate of 300 mL/min as some self-care HD systems are unable to attain dialysate flow rates >500 mL/min due to the use of batch-based dialysate or limitations of water systems.

**Funding:** Commercial Support - Quanta Dialysis Technologies

## TH-PO290

### Effect of Dialysate Flow Rate (DFR) Reduction on Adequacy in a Chronic Hemodialysis Unit

Sam Beavin, Sadiq Ahmed. University of Kentucky, Lexington, KY.

**Background:** The Covid-19 pandemic has introduced a number of challenges in managing populations with both acute kidney failure and those dependent on chronic dialysis. Due to a shortage of outpatient dialysis supplies, on February 14, 2022, the Dpt. of Veteran's Affairs issued a memorandum to dialysis units requiring a contingency standard of care. This required a universal reduction of dialysate flow rate to 500 cc/min. Prior to this change, the standard prescription at the Lexington, KY VA unit was 750 cc/min. We evaluated the effect of this change on the adequacy of our dialysis population.

**Methods:** Data was collected for sp Kt/V urea and urea reduction ratio for 17 chronic hemodialysis patients for the two months prior and three months following the reduction of dialysate flow rate to 500 cc/min from the previous standard of 750 cc/min. There was no change of blood flow rate or dialysis time during this 5 month period for all the patients included.

**Results:** A trend towards lower clearance values as measured by single-pool Kt/V and urea reduction ratio was noted between January and April of 2022. Table 1 shows the average spKt/V and URR for each month. The majority of patients maintained adequate spKt/V of >1.2 and urea reduction ratio of >65%. However, 4 patients (23.5% of the population) failed to reach Kt/V and URR goal in April 2022.

**Conclusions:** Though this represents only 17 patients from one dialysis unit, the data suggests a significant decline in adequacy due to this reduction in dialysis flow rate to 500 cc/min. Until the current dialysis supply shortage has been addressed, adaptive measures such as utilizing higher efficiency dialyzers or increasing blood flow rates may be necessary.

Table 1

	Mean URR	Mean Kt/V
December	0.75	1.61
January	0.74	1.58
February	0.72	1.50
March	0.72	1.51
April	0.70	1.42

Average Kt/V trend

## TH-PO291

### Using the Seraph® 100 Microbind Affinity Blood Filter Under Slow Flow Conditions Through a Non-Dialysis Catheter

Malin-Theres Seffer,<sup>1</sup> Julius Schmidt,<sup>2</sup> Jan T. Kielstein.<sup>1</sup> <sup>1</sup>Academic Teaching Hospital Braunschweig, Braunschweig, Germany; <sup>2</sup>Medizinische Hochschule Hannover, Hannover, Germany.

**Background:** The Seraph® 100 is a single use biomimetic device aimed to remove pathogens from the bloodstream, usually operated under blood flow rates of 100 – 350 mL/min, requiring a large bore central line / dialysis catheter. Aim of our study was to evaluate the pressure / blood flow curve in vitro using saline as well as human plasma and to evaluate the usability of the Seraph® 100 in the clinical practice.

**Methods:** Patients and study protocol Blood plasma was obtained from five voluntary donors during regular therapeutic plasma exchange. Sham hemofiltration with the Seraph® 100 For all experiments primed a standard hemoperfusion blood tubing system as well as the Seraph® 100 (Exthera Medical, CA, USA) with a total filling volume of about 2200 mL with normal saline (n=5) or with human plasma and connected the hemoperfusion circuit with a 20 cm tri lumen central venous line (2 x 18 G and 1 x 16 G, Certifix® safety trio s720, B.Braun REF: 4167408S-07; Lot: 19D30A8551) that was inserted into a reservoir. The Multifiltrate (Fresenius Medical Care GmbH, Germany) was used to pump the saline through the adsorber. Blood flow was raised in steps of 10 ml beginning at 20 ml up to 100 ml. Arterial and venous pressure was recorded at the different blood pump speeds. In two patients the Seraph® 100 in the hemoperfusion circuit of a Multifiltrate (Fresenius Medical Care GmbH, Bad Homburg, Germany), was connected to a five lumen 20 cm catheter (Certifix Safety Quinto S1220, B. Braun, Melsungen, Germany) 1 x 12 G, 1 x 16 G, 3 x 18 G) that was inserted into the right internal jugular vein. Blood flow as well as arterial and venous pressure and TMP were recorded through the 24 h treatment.

**Results:** All five in vitro runs using either saline and human plasma could be performed without any technical difficulties.

**Conclusions:** A blood flow rate of 50 mL/min can be achieved with a 16 G and 18 G vascular access of central lines. Even long treatment hours (up to 25 hours) under low flow conditions to optimize exposure of patient's blood to the Seraph 100 adsorption media can be achieved.

Relationship between blood pump speed and the arterial as well as venous pressure using saline / plasma.

## TH-PO292

### Point-of-Care Ultrasound for Assessing Arteriovenous Fistula Maturity in Outpatient Hemodialysis

Jessie C. Fuller,<sup>1,2</sup> Steven Weiss,<sup>2</sup> George N. Coritsidis.<sup>1</sup> <sup>1</sup>Westchester Medical Center Health Network, Valhalla, NY; <sup>2</sup>Atlantic Dialysis Management Services, Queens, NY.

**Background:** Point-of-care ultrasound (POCUS) in end-stage renal disease (ESRD) is on the rise. Presently the decision to cannulate an arteriovenous fistula (AVF) is based on its duration since surgery, surgeon clearance, and physical exam. This study examines the effects of POCUS on decreasing the time to AVF cannulation and reducing time spent with a central venous catheter (CVC).

**Methods:** Patients were prospectively recruited between January 2021 and May 2022 after new AVF placement in patients at 5 separate dialysis units, while in patients at 5 other units patients had POCUS within 3 weeks of AVF creation and were followed for a minimum of 3 months following fistula creation. Recommendation for cannulation was made once the following parameters were met: diameter > 6 mm (with no depreciable narrowing of more than 20% throughout), depth < 6 mm from skin surface, and length > 6 cm. Demographic data, as well as time to cannulation and CVC removal, number of infections, complications, and interventions were compared between POCUS and non-POCUS cohorts. A Kruskal-Wallis test was conducted to compare the effect of the POCUS use on the number of successful cannulation in weeks 1 through 6.

**Results:** The POCUS cohort had significantly less cannulating complications than seen in the control group p<0.02. There were no blood stream infections seen in the POCUS group, and one in the control. The average time to decannulation from AVF placement was 103 days in the POCUS group vs 145 days in the control.

**Conclusions:** Point-of-care ultrasound facilitates early and safe arteriovenous fistula cannulation leading to a reduction in central venous catheter time and risk of cannulation injury. These findings on a larger scale should result in decreased infections seen when using POCUS.

## TH-PO293

### Application of Percutaneous Transluminal Angioplasty in the Replacement of Tunnel-Cuffed Catheter in Maintenance Hemodialysis Patients

Hao Ding, Hong Ye, Xueqin Bian, Yuan Luo. The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

**Background:** One of the emerging complications of tunnel-cuffed catheter (TCC) is the stuck catheter which is the condition that a catheter is not removable from a central vein using standard techniques. This article focuses on outcome and security of percutaneous transluminal angioplasty (PTA) in replacement of TCC in maintenance hemodialysis (MHD) patients.

**Methods:** The clinical data of 62 MHD patients with dysfunctional catheter from January 2015 to January 2021 admitted to the Second Affiliated Hospital of Nanjing Medical University were retrospectively analyzed. All patients underwent digital subtraction angiography (DSA) to identify superior vena cava stenosis and were treated with suitable balloon under the guidance of DSA. The technique of PTA was used to replace the stuck catheters and was also used to disrupt the fibrin sheaths or to dilate the occlusive vein. The pathological manifestations of the fibrin sheath around the catheter were then determined, and the complications during the operation and the function of the catheter were observed and follow up for 6 months.

**Results:** TCC was successfully replacement in 62 patients with treatment of superior vena cava stenosis by PTA under the guidance of DSA and no serious complications such as balloon rupture, severe bleeding, pulmonary embolism and malignant arrhythmia occurred during and after surgery. The dialysis blood flow of after surgery is about 220- 280ml/min and the primary catheter site patency rate was 85% at 3 months and 70% at 6 months. The stuck catheter in the superior vena cave were found in six cases which were successfully removed with the technique of PTA. Among them, 3 cases showed severe calcified fibrin sheath, and another 3 cases showed severe superior vena cava stenosis. The pathological showed the inner layer of fibrin sheath is composed of lymphocytes, plasma cells, neutrophils, macrophages and other inflammatory cells. The outer layer of fibrin sheath is composed of collagen and fibroblasts.

**Conclusions:** Endothelial injury, activation of inflammatory pathways and fibrin sheath formation caused by inflammatory cell aggregation during catheter placement are important pathophysiological mechanisms of catheter dysfunction. Embedded catheters can be successfully managed by PTA which shows advantages of minimal complications, lesser trauma and better tolerance.

**Funding:** Government Support - Non-U.S.

## TH-PO294

**FDA Reported Complications Associated With endoAVF Fistula Devices**  
 Rahul R. Abraham, Erin L. Mayeux, Oluwadamilola Adisa, Atlee Baker, Braeden Mccutchan, David Okuampa, Haley E. Gould, Marjorie Blochousse, Bharat Sachdeva. *LSU Health Shreveport, Shreveport, LA.*

**Background:** Medical device reports (MDRs) are submitted to U.S. Food and Drug Administration (FDA) for all suspected device-associated injuries and deaths. The Manufacturer and User Facility Device Experience (MAUDE) database compiles all MDRs to monitor device outcomes. We review all reported MDRs for WavelinQ® (Bard Peripherals) and the Ellipsys® (Medtronic) used for percutaneous creation of dialysis AVF.

**Methods:** All reported incidents of all endoAVF devices to the FDA database from August 2018-March 2022 were imported to excel, and descriptive statistical analysis was carried out.

**Results:** Events were divided into device-related when the incident involved mechanical device malfunction and patient-related if the subject experienced a complication during endoAVF creation. There were 200 events reported for WavelinQ® over 3.12 years, with a rate of 65 events/year. 81% of total events were device-related issues, with the most common reports of failure to cut (41%), material deformations (28%), and failure of magnets to align (23%) during the AVF creation. 19% were patient-related, including, vessel stenosis (35%), vessel spasm (14%), Ischemic neuropathy (11%), and death (8%). Ten events (5%) were reported with the 6F system, and all others were related to the 4F system. Eleven events were reported for Ellipsys® over a period of 2.03 years, with a rate of 5.41 events reported per year (3.44 device-related and 1.97 patient-related); 36% of total events were device-related issues, with the most common problems being failure to advance (50%), inability to activate the device (25%) and material deformation (25%). Nearly two-thirds (64%) of events were patient-related complications, including thrombosis (57%), hematoma (29%), and stenosis of the vessel (14%).

**Conclusions:** WavelinQ® system had predominant device-related issues, while two-thirds of the Ellipsys® related events were patient-related. MAUDE database cannot calculate the actual incidence rate of events or make comparisons, as physicians voluntarily report the complications, and the prevalence of the use of these devices is unknown. There is limited information available regarding post-market real-life experience on these two devices. Providers need to be aware of the commonly reported device and patient-related complications associated with endoAVF devices.

## TH-PO295

**Permcath Survival: A 3-Year Retrospective Study in a Tertiary Hospital**  
 Raymond S. Piggott, Lynn Redahan, Yvonne M. O'Meara, Denise M. Sadlier. *Mater Misericordiae University Hospital, Dublin, Ireland.*

**Background:** Arterio-venous fistula (AVF) are the preferred access for patient's requiring chronic intermittent haemodialysis. However, permanent dialysis catheters (*permcaths*) are frequently used as an alternative access. In this retrospective study the indications, complications and outcomes of permcath insertion were studied in a single tertiary centre.

**Methods:** Using the electronic medical record and interventional radiology database, all patients who underwent a permcath placement were examined from 1<sup>st</sup> January 2020 to 31<sup>st</sup> March 2022. In addition to demographic information, data with regard to subsequent permcath removal, exchange and outcome was obtained. Any patient undergoing permcath placement for any other purpose other than intermittent haemodialysis were excluded from the study. Data with regard to whether the patient had been referred and/or undergone AVF fistula or other vascular access formation was also reviewed. Permcath removal was defined as no further need of permcath while permcath exchange was defined as temporary removal and/or direct exchange due to malfunction and/or sepsis. All data recorded was done so in compliance with data protection legislation.

**Results:** 118 patients underwent permcath placement placed during this time, age range 18–90 years (median age = 63 years), male: female 58%:42%, average Kt/V >1.78/week and average blood flow 300 ml/min. The average life span of a removed permcath was 197 days (range = 7–819 days). 37 permcaths were removed: 45% (n = 17) due to renal recovery, 30% (n = 11) due to successful AVF placement, 2% (n = 1) transitioned to peritoneal dialysis and 18% (n = 3) underwent successful renal transplantation. 32 permcaths were exchanged: 19% (n = 6) were due to sepsis, 6 patients required more than one permcath exchange (range 2–5 exchanges) due to blocked permcath, permcath dislodgement, exposed cuff and inadequate flows. In all of these patients there was no alternative access.

**Conclusions:** Permcaths are a reliable method of vascular access but their utility is often impeded by complications and a relatively short lifespan. They should not replace AVFs as the preferred haemodialysis access

## TH-PO296

**Global Dialysis Vascular Access Care: A Multi-Specialty Interest**  
 Mohamed Hassanein,<sup>1</sup> Nora H. Hernandez Garcilazo,<sup>2</sup> Si Yuan Khor,<sup>2</sup> Hassan Elmaleh,<sup>3</sup> Khaled M. Moustafa,<sup>4</sup> Tushar J. Vachharajani,<sup>5</sup> <sup>1</sup>University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>Michigan State University, East Lansing, MI; <sup>3</sup>Ministry of Health In Egypt, Cairo, Egypt; <sup>4</sup>Medical Research Institute, Alexandria, Egypt; <sup>5</sup>Cleveland Clinic, Cleveland, OH.

**Background:** The history of dialysis vascular access dates back to 1924 in Germany when Dr. George Haas connected an artery and vein using a glass cannula. Since then, dialysis vascular access care has evolved robustly through scientific contributions from

researchers worldwide. We sought to identify the global distribution and contribution of medical specialties to the medical literature on dialysis vascular access care over the past 3 decades.

**Methods:** We performed a thorough literature search of articles related to dialysis vascular access published in the English medical literature from 1991 to 2021. We identified and analyzed 2,768 articles from 74 countries worldwide and stratified them by article type and medical specialty.

**Results:** Out of 2,768 articles, 41.5% (1148) originated from the United States, followed by China (5.1%), United Kingdom (4.6%), Germany (3.6%), India (3.4%), Japan (3.1%) and Canada (2.9%). Forty-three percent of search results (1205) were observational studies, followed by 27% (761) case reports/series, 16.5% (458) review articles, 12% (335) clinical trials and 0.3% (9) meta-analyses. The majority of articles (49%) were published in nephrology journals, followed by 14%, 10%, 8%, and 4% of articles published in general medicine, surgery, vascular medicine, and interventional radiology journals, respectively.

**Conclusions:** Dialysis vascular access care is provided by specialists with multiple backgrounds across the globe. Thirty-nine percent of the evidence is published from developing countries. Retrospective observational studies along with case reports/series provide 88% of the current evidence for clinical practice. Barely 12% of the published literature is from prospective clinical trials. Even though providers with multiple training backgrounds are involved with dialysis vascular access care, almost 49% of the scientific evidence is published in journals catering to the nephrologists. The literature trend highlights the need for better collaboration across all specialties to effectively improve patient care.

## TH-PO297

**Aging and Arteriovenous Fistula Remodeling in a Mouse Model**  
 Brayden Fairbourn,<sup>1</sup> Amani Oumar,<sup>1</sup> Marina Knysheva,<sup>2</sup> Yuxia He,<sup>1,3</sup> Lisa Lesniewski,<sup>1,3</sup> Tony J. Donato,<sup>1,3</sup> Alfred K. Cheung,<sup>1,3</sup> Yan-Ting E. Shiu.<sup>1,3</sup> <sup>1</sup>The University of Utah, Salt Lake City, UT; <sup>2</sup>The University of Utah School of Medicine, Salt Lake City, UT; <sup>3</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** Arteriovenous fistulas (AVFs) are the preferred type of hemodialysis vascular access, but up to 60% fail to mature, i.e., have sufficiently large vein lumen area and blood flow. This failure rate is higher in old than young patients, and yet the biology of AVF remodeling has not been studied in the context of aging. To investigate the effects of aging on AVF development, we focused on the mammalian target of rapamycin (mTOR) and sirtuin-1 (SIRT1), two primary regulators of aging and arterial functions. We hypothesized that aging-related increased mTOR and decreased SIRT1 in the veins impair AVF development in old mice.

**Methods:** The protein levels of mTOR and SIRT1 in native external jugular veins (EJVs) of young (3 months) and old (18 months) C57BL/6 mice were determined by immunohistochemistry. Carotid-external jugular AVFs were created in young and old mice with or without treatment of either the mTOR inhibitor rapamycin (8 mg/kg) or the SIRT1 activator SRT1720 (100 mg/kg) by intraperitoneal injections (IPs). IPs began on the day of AVF creation and were repeated daily for rapamycin and twice a week for SRT1720 for 1 week until the mice were euthanized. Histological morphometry was used to quantify AVF % open lumen area and neointimal lesion area, and the transcriptomes were quantified by RNA sequencing.

**Results:** The protein level of mTOR increased approx. 2.4 fold and SIRT1 decreased approx. 3.4 fold from young to old EJVs. Without treatments, the % open lumen area in old (20±4%, n=3) was smaller than in young (48±3%, n=2) AVFs. The RNAseq data showed that collagen degradation and extracellular matrix organization were downregulated while fibrosis and inflammation were upregulated in old vs. young AVFs (n=3 each). In young AVFs, rapamycin increased the % open lumen areas to 74±13% (n=3), but SRT1720 made no change (45±9%, n=4). In old AVFs, both treatments decreased neointimal lesion area approx. 1.9 fold and increased the % open lumen areas (rapamycin: 34±12%, n=3; SRT1720: 64±35%, n=3).

**Conclusions:** Our results suggest the potential of mTOR inhibition and SIRT1 activation to improve AVF maturation rates in patients of older age. With the population of older patients with end-stage kidney disease climbing quickly, it is imperative to develop methods to improve AVF maturation in older patients.

## TH-PO298

**Vascular Access Management Story in Outsourcing Hemodialysis Program in Saudi Arabia**

Dujanah H. Mousa, Elhussein K. Ibrahim, Abdulaziz O. Alqadhi, Ibrahim A. Assiri, Ahmed I. Abouras, Badawi A. Altaher, Mohammed H. Ismail, Hassan A. Musa, Ali Alharbi. *Diaverum AB, Riyadh, Saudi Arabia.*

**Background:** VA is the backbone of successful Hemodialysis. AVF is longer in survival and less in complications than an AVG or CVC. Outsourcing Program in Saudia has looked after more than 5K pats since 2014 and Provides VA management as part of the bundle service. Aim: To show our experience in managing VA challenges.

**Methods:** We retrospectively analyzed a VA project between 2014 to 2021.

**Results:** In 2014, we had an AVF of 60% and a high rate of CVC of almost 33%. Over time, more clinics are established and ramping up pats with a challenge to achieve the CVC contractual target of 15% or less. During the first 2 years, limited resources in three main cities serving all patients. Providing the services at local hospitals is on the contract's terms, and patients were resistant to travel for vascular procedures. Targets could not deliver, and the cost was high. We analyzed patient factors such as dialysis

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

vintage, resistance to change, and education. We headhunted for the right VA surgeon who is committed and willing to travel between different cities. Also looked for accredited theater facilities in different cities where our clinics are allocated and rented to deliver the VA procedures. A structured VA Management team was created with dedicated and knowledgeable staff to lead the roadmap to success. Our surgeons in one geographical region were inspired to start a new business model, and they were sub-contracted per capita to deliver our targets, which proved to be successful and valuable. Digitization to support and coordinate between clinics, surgeons, and regional vascular supervisors, keeping finance in the loop to eliminate discrepancies and secure budget efficiency. Therefore, a strategy was implemented, supervised, re-evaluated, and improved over time. Patient care is delivered as near home as possible, and patient satisfaction is ensured. Medical targets achieved and cost observed. Patients grew to 4300 in 2021; we achieved AVF/G 83.8% and CVC 16.1%, with a cost reduction of 25%

**Conclusions:** Organized and keen VA team with custom Designed System for Tracking and close supervision of different clinic's VA status and procedures will improve VA services, deliver targets and reduce costs in any hemodialysis setup.

## TH-PO299

### Predicting Hemodialysis Arteriovenous (AV) Access Stenosis Using Artificial Intelligence

Omar S. Elbitta,<sup>1</sup> Michael E. Brier,<sup>1,2</sup> Adam E. Gaweda,<sup>1</sup> Zygimantas C. Alsaukas,<sup>1</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>VA Robley Rex Medical Center, Louisville, KY.

**Background:** AV access flow dysfunction due to underlying stenosis or thrombosis is associated with significant morbidity and cost to the healthcare system. In this proof of concept study we have used artificial intelligence (AI) to reliably predict the occurrence of AV access stenosis using intradialytic data routinely collected and stored in the electronic medical record (EMR).

**Methods:** Data were obtained from the dialysis and interventional nephrology electronic medical record for the years 2018 to 2020. Routinely collected information were obtained and segmented by patient and treatment day into one-month sequences. A Recurrent Neural Network was trained to predict one week ahead of time for the following stenosis events: central venous, arterial anastomosis, venous anastomosis, or thrombosis, as obtained from interventional procedure records. The model was trained in Matlab/Simulink (MathWorks, Natick, MA) using 80% of the data for training and 20% for validation.

**Results:** Twenty-seven patients were included in the analysis with a total of 177 events. Two models were developed, a reduced model (Model 1) using mean systolic and diastolic blood pressure and mean venous and arterial pressure recorded during dialysis as predictors. Model 2 contained the variables in Model 1 plus the gradients of those parameters during dialysis. The ROC for the predictions are shown in Figure 1 (ROC=0.859). 75% of the events were identified one week in advance with a false positive rate of about 5%.

**Conclusions:** An AI-based approach using data from the EMR successfully predicted AV access stenosis. The strength of the approach is that predictions were trained using data from patients that had an event leading to discontinuation of dialysis and referral to interventional nephrology unlike procedures developed for access surveillance. This could be used as a supplementary tool to routine AV access monitoring.

### Kidney Failure Risk Equation for Vascular Access Planning: A Nationwide Observational Cohort Study From Sweden

Ulrika Hahn Lundström,<sup>1</sup> Chava L. Ramspek,<sup>2</sup> Friedo W. Dekker,<sup>2</sup> Juan J. Carrero,<sup>1</sup> Ulf Hedin,<sup>1</sup> Marie Evans,<sup>1</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands.

**Background:** The optimal timing of arteriovenous (AV) access creation remains a challenge. Our aim was to study if a Kidney Failure Risk Equation (KFRE) threshold would improve AV access planning.

**Methods:** From 28,798 patients included in the Swedish Renal Registry-chronic kidney disease 2008-2020 we generated two cohorts; first visit when KFRE was >40% (KFRE40), and first visit when estimated glomerular filtration rate (eGFR) <15 ml/min/1.73m<sup>2</sup> (eGFR15). The cohorts were followed until start of kidney replacement therapy (KRT) and death, the proportion of patients starting hemodialysis with a working access and test diagnostics for the two methods were described.

**Results:** The eGFR decline was faster in KFRE40 compared to the eGFR15 (-2.0 vs -0.95 ml/min/1.73m<sup>2</sup> per year). KFRE40 had superior positive predictive value for KRT initiation at 2 years (56% versus 43% for eGFR15). KFRE40 had higher specificity (90% versus 79% for eGFR15), while eGFR15 had higher sensitivity (88% versus 75% for KFRE40). If all patients potentially had undergone successful AV access surgery at KFRE40, 75% of patients would ever start dialysis with an AV access; in two years 13% would die and 31% be alive with an unused access. For AV access surgery at eGFR15, 88% would ever initiate KRT with an AV access; in two years 17% would die, and 40% live with an AV access never used.

**Conclusions:** Using KFRE >40% as decision threshold would increase the proportion of patients starting with a working AV access at the cost of more patients experiencing unnecessary surgery. The KFRE threshold >40% could complement decision making for vascular access creation.

Development of KFRE in nephrology-referred patients, in the year before Hemodialysis initiation

## TH-PO301

### Cardiac Tissue Chip Model of Arteriovenous Fistula-Associated Hemodynamics Recapitulates Changes Seen in Mouse AVF Model

Timmy C. Lee,<sup>1,2</sup> Tatyana Isayeva Waldrop,<sup>1</sup> Caleb Graham,<sup>1</sup> William A. Gard,<sup>1</sup> Kevin A. Ingle,<sup>1</sup> Palaniappan Sethu,<sup>1</sup> <sup>1</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL; <sup>2</sup>Birmingham Veterans Affairs Medical Center, Birmingham, AL.

**Background:** Cardiovascular events are the primary cause of death among dialysis patients. While arteriovenous fistulas (AVFs) are the access of choice for hemodialysis patients, AVF creation leads to a volume overload (VO) state. We developed a three-dimensional (3D) cardiac tissue chip (CTC) with tunable pressure and stretch to model the acute hemodynamic changes associated with AVF creation to complement our murine AVF model of VO. In this study, we aimed to replicate the hemodynamics of murine AVF models in vitro and hypothesized that if 3D cardiac constructs were subjected to "volume overload" conditions, they would display fibrosis and key gene expression changes seen in AVF mice.

**Methods:** Mice underwent either AVF or sham procedure and sacrificed at 28 days. Cardiac tissue constructs (Fig 1) composed of h9c2 rat cardiac myoblasts and normal adult human dermal fibroblasts in hydrogel were seeded into devices and exposed to 100 mg/10 mmHg pressure (0.4 s/0.6 s) at 1 Hz for 96 hours. Controls were exposed to "normal" stretch and experimental group exposed to "volume overload". RT-PCR and histology were performed on the CTC and mice left ventricles (LVs), and transcriptomics of mice LVs were performed.

**Results:** Our CTC constructs and mice LV both demonstrated cardiac fibrosis as compared to control fibers and sham-operated mice, respectively. Our gene expression studies in our CTC constructs and mice LV demonstrated increased expression of genes associated with extracellular matrix production, oxidative stress, inflammation,

and fibrosis in the VO conditions vs control conditions. Our transcriptomics studies demonstrated activated upstream regulators related to fibrosis, inflammation, and oxidative stress such as collagen type 1 complex, TGF $\beta$ 1, CCR2, and VEGFA and inactivated regulators related to mitochondrial biogenesis in LV from mice AVF.

**Conclusions:** Our CTC model yields similar fibrosis-related histology and gene expression profiles as our murine AVF model. The CTC can play a critical role in understanding cardiac pathobiology of VO states similar to what is present after AVF creation and used in evaluating therapies.

**Funding:** Other NIH Support - National Institutes of Heart, Lung, and Blood Institutes, Veterans Affairs Support

## TH-PO302

### Influence of Hemodynamic Changes on Venous Endothelial Cell Adaptation After Arteriovenous Fistula Creation

Taylor G. Lewis,<sup>1</sup> Tatyana Isayeva Waldrop,<sup>2</sup> Maheshika S. Somarathna,<sup>2</sup> Kevin A. Ingle,<sup>2</sup> Timmy C. Lee.<sup>2</sup> <sup>1</sup>Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL; <sup>2</sup>The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.

**Background:** The arteriovenous fistula (AVF) is considered the lifeline for ESRD patients, but AVF non-maturation is currently a great problem facing vascular access. Maturation is influenced by both hemodynamic changes and the uremic syndrome. Impaired vessel dilatation is the major characteristic of endothelial dysfunction, predominately explained by a decrease in bioavailable nitric oxide (NO) produced by eNOS. In response to oscillatory shear stress, immediate activation of the MCP1 gene results in monocyte adhesion to inflamed endothelium. The goal of this study is to evaluate the influence of hemodynamics on endothelial function using both in vivo and in vitro systems.

**Methods:** For the in vivo system, femoral end-to-side AVFs were created in rats. 7 days after creation, the AVFs and contralateral control veins were harvested, sectioned, and stained for eNOS expression. Samples were harvested for western blot analysis of MCP1 and eNOS protein expression. For the in vitro system, human umbilical venous endothelial cells (HUVECs) were cultured in silicone vessel-like structures set to mimic either laminar (LSS) or oscillatory (OSS) shear stress. HUVECs were isolated and stained for eNOS and MCP1 expression. Additionally, samples were isolated for western blot analysis of MCP1 and eNOS protein expression.

**Results:** In vivo AVF samples displayed less eNOS staining compared to contralateral vein samples. Western blot shows significantly greater eNOS expression in control veins (control=0.347, AVF=0.286,  $p=0.043$ ) and significantly greater MCP1 expression in AVF veins (control=0.181, AVF=0.599,  $p=0.0002$ ). In HUVECs, eNOS expression was significantly greater in LSS (eNOS=77.85, MCP1=22.49  $\mu^2$ /nuclei,  $p=0.0061$ ) and MCP1 expression was significantly greater in OSS (eNOS=54.83, MCP1=449.5  $\mu^2$ /nuclei,  $p=0.0049$ ). Western blot shows significantly greater eNOS expression under LSS (LSS=0.345, OSS=0.263,  $p=0.023$ ) and significantly greater MCP1 expression under OSS (LSS=0.369, OSS=0.689,  $p=0.033$ ).

**Conclusions:** In in vitro and in vivo studies, disturbed flow reduces eNOS production and increases inflammation as evidenced by increased levels of MCP-1 in the venous endothelium. Therapies that enhance endothelial function and reduce inflammation in the setting of disturbed flow may reduce AVF maturation failure.

**Funding:** NIDDK Support, Other NIH Support - National Heart, Lung, and Blood Institute, Veterans Affairs Support

## TH-PO303

### A 3D-Printed Ultrasound Probe Holder to Facilitate Ease of Ultrasound-Guided Arteriovenous Fistula (AVF) Cannulation

Hannah M. O'Keefe,<sup>1</sup> Noor Adeebah Mohamed Razif,<sup>2</sup> Ella B. Donders,<sup>2</sup> Daniel Byrne,<sup>2</sup> Basem Fouda,<sup>2</sup> Fiona Leigh,<sup>1</sup> Julio L. Chevarria.<sup>1</sup> <sup>1</sup>Tallaght University Hospital, Dublin, Ireland; <sup>2</sup>The University of Dublin Trinity College, Dublin, Ireland.

**Background:** Ultrasound guidance has the potential to reduce complications due to mis-cannulation such as haematomas and infiltration. Ultrasound-guided needle insertion requires confidence and practice, and particularly for early users can be cumbersome and even require an additional person to hold the probe. The creation of a probe holder was felt to have the potential to facilitate a single person to perform real time ultrasound-guided needling, rather than using ultrasound initially and marking the AVF, or requiring an additional person to assist.

**Methods:** Using an iterative prototyping approach, a 3D-printed probe holder was created which allows horizontal and vertical adjustment of the probe position, 360 degrees range of motion for the probe and the ability to hold the probe in a stationary position. The authors consist of Biomedical Engineering Masters students, Nephrologists and a Vascular Access Nurse Specialist from two Irish institutions who collaborated to create this 3D printed prototype. A computer-aided design (CAD) model was created using

SolidWorks (Dassault Systemes, USA). The model was designed in parts and printed with the Original Prusa i3 MK3S+ using polylactic acid thermoplastic as the material.

**Results:** The final design consists of a flat base which can be placed on a bed or table, with two semi-circular structures to keep the arm stable and reduce mobility, and a boss-head mechanism to be able to adjust the horizontal and vertical position of the probe holder. There is a proximal hinge and a ball and socket joint, which provide additional range of motion in all directions. The probe holder itself is ridged to facilitate different orientations of the probe. The probe is secured to the ridged probe holder by an elastic band. The model was tested using a Mindray TE7 linear probe.

**Conclusions:** The authors present a functional device which can potentially facilitate the use of real time ultrasound-guided cannulation. This solution is cost effective, estimated at \$20.01 including materials, print time and energy consumption. The instructions are freely available online at <https://www.med3dp.com/nice-us-probe-holder>. Further testing of use in the clinical setting is required to assess issues with utilisation and whether the potential benefits are realised.

## TH-PO304

### Sodium Zirconium Cyclosilicate (SZC) Binds Ammonium (NH<sub>4</sub><sup>+</sup>) in the GI Tract

Fernando A. Marmol Mosquera,<sup>1</sup> Mohammed Q. Badaruddin,<sup>1</sup> Athar Baig,<sup>1</sup> Minghao Ye,<sup>1</sup> Jan Wysocki,<sup>1</sup> Krister Bamberg,<sup>2</sup> Daniel Battle.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Translational Science and Experimental Medicine, Early Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.

**Background:** Sodium zirconium cyclosilicate (SZC) is a non-absorbed, non-polymeric inorganic cation exchanger that selectively captures Potassium (K<sup>+</sup>) in the exchange for hydrogen (H<sup>+</sup>) and Sodium (Na<sup>+</sup>) in the gastrointestinal tract. The ionic diameter of NH<sub>4</sub><sup>+</sup> and K<sup>+</sup> in aqueous solution are similar in size and both are bound by SZC in vitro, suggesting that SZC binds not only K<sup>+</sup> but also NH<sub>4</sub><sup>+</sup> in the gastrointestinal tract. This hypothesis was studied in mice placed in metabolic cages to collect feces and urine for comparison of ammonium excretion concurrently on a regular diet followed a diet with added SZC.

**Methods:** Mice (CD-1 background) on a regular diet for 2 days were switched to a diet containing SZC (6g/Kg BW) for the following 3 days and placed in metabolic cages designed to collect urine and feces separately but simultaneously over a period of 6 hours to be able to assess fecal and urine NH<sub>4</sub><sup>+</sup> excretion. Feces NH<sub>4</sub><sup>+</sup> was measured using a non-enzymatic assay, where ammonia forms indophenol, a highly colored product easily quantifiable by colorimetry. In all fecal samples NH<sub>4</sub><sup>+</sup> was concurrently measured with and without 50 mEq KCl solution to release NH<sub>4</sub><sup>+</sup> from SZC present in the feces.

**Results:** When SZC was added to the diet the fecal NH<sub>4</sub><sup>+</sup> excretion measured after release of NH<sub>4</sub><sup>+</sup> with KCl was significantly higher than in absence of KCl (2.2  $\pm$  0.2 and 1.6  $\pm$  0.2  $\mu$ mol/6hrs), respectively  $p=0.0005$  (fig, right panel). In the regular diet, used as a negative control, addition of KCl to the samples had no significant effect on measured fecal NH<sub>4</sub><sup>+</sup> (1.9  $\pm$  0.3 vs 1.8  $\pm$  0.3  $\mu$ mol/6hrs,  $p=0.55$ ) (fig, left panel).

**Conclusions:** In feces from normal mice on a diet with added SZC there is a substantial amount of NH<sub>4</sub><sup>+</sup> sequestered in the K<sup>+</sup> binder. This is consistent with the hypothesis that SZC binds NH<sub>4</sub><sup>+</sup> in the GI tract and hence may offer therapeutic opportunities on top of its known K<sup>+</sup> binding action used to treat hyperkalemia.

**Funding:** Commercial Support - AstraZeneca

## TH-PO305

### Renal Adaptation to Increased Fecal Potassium Excretion by Sodium Zirconium Cyclosilicate

Fernando A. Marmol Mosquera,<sup>1</sup> Mohammed Q. Badaruddin,<sup>1</sup> Athar Baig,<sup>1</sup> Minghao Ye,<sup>1</sup> Seyedmohammadebrahim Tahaei,<sup>2</sup> Jan Wysocki,<sup>1</sup> Paul A. Welling,<sup>2</sup> Krister Bamberg,<sup>3</sup> Daniel Battle.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>3</sup>Translational Science and Experimental Medicine, Early Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.

**Background:** Potassium (K<sup>+</sup>) binders, like sodium zirconium cyclosilicate (SZC) which is very selective for K<sup>+</sup>, are increasingly used for treatment of hyperkalemia. While the efficacy of SZC is clinically proven regardless of underlying condition associated with hyperkalemia, the renal response has not been well studied. We hypothesized that any enhancement on fecal K<sup>+</sup> excretion should elicit a renal response characterized by a switch from the normal secretory mode to a reabsorptive mode as a mechanism to conserve K<sup>+</sup> and prevent total K<sup>+</sup> depletion. This hypothesis was studied in normal mice and in mice with CKD caused by 5/6 nephrectomy to mimic the clinical setting where K<sup>+</sup> binders are typically used.

**Methods:** Mice (CD-1 background) on a regular diet for 2 days were switched to a diet containing SZC for the following 3 days and placed in metabolic cages designed to collect urine and feces separately but simultaneously over a period of 6 hours to be able to assess fecal and urine K<sup>+</sup> excretion.

**Results:** The SZC diet resulted in an increase in fecal potassium (K<sup>+</sup>) excretion in normal mice (from 15 ± 3 to 68 ± 9 umol/6hrs p<0.0003) and a similar increase in mice with CKD (from 25 ± 2.6 to 87 ± 7.1 umol/6hrs p=0.003). Urine potassium K<sup>+</sup> excretion, in normal mice decreased markedly (from 89 ± 6.9 to 52 ± 3.7 umol/6hrs p<0.0003), whereas in CKD mice urine K<sup>+</sup> excretion also decreased but to a lesser extent (from 81 ± 5.2 to 60 ± 5.1 umol/6hrs p<0.0086). As a result, the increase of total potassium excretion (Fecal + Urine) during the SZC containing diet was statistically significant in CKD (from 106 ± 8.5 to 147 ± 13 umol/6hrs p=0.012) but not in normal mice (from 104 ± 7.1 to 120 ± 10.9 umol/6hrs p=0.1428) (fig.1)

**Conclusions:** In a mouse model of CKD caused by kidney ablation there is a compensatory decrease in renal K<sup>+</sup> excretion during fecal K<sup>+</sup> loss caused by SZC which is less pronounced than in normal mice owing to less effective K<sup>+</sup> renal reabsorption.

**Funding:** Commercial Support - AstraZeneca

## TH-PO306

### A Novel Mouse Model of Renal Tubular Protein-Induced Nephropathy Mimics Sjögren Syndrome With Kidney Injury

Tiantian Ma, Xiaoxiao Shi, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

**Background:** By immunization with allogeneic renal tubular homogenate, we tried to establish an experimental mouse model of primary Sjögren's syndrome (SS) with renal injuries which was not available now.

**Methods:** Proteins extracted from the salivary glands (SG) of normal mice were emulsified in an equal volume of Freund's complete adjuvant at a concentration of 2 mg/mL (the SG group), while renal tubular proteins at a concentration of 1 mg/mL or 3 mg/mL (the RT group). For disease induction, each 8-week-old female C57BL/6 mouse received subcutaneous multi-injections on the back with 0.1 mL of the above emulsion on days 0 and 7, respectively. On day 14, a booster injection was carried out with a half dose of the proteins emulsified in Freund's incomplete adjuvant. Mice injected with phosphate buffered saline (PBS) served as the control group. At 5 weeks postimmunisation, serum creatinine, 24-hour water intake, urine volume and urine electrolyte excretion were determined. Serum levels of anti-SSA and anti-SSB autoantibodies were determined by ELISA. The pathology of SG tissues and the proximal tubular injury was evaluated by light microscopy and electron microscope.

**Results:** Both the SG group and the RT group developed a typical disease profile of SS, including increased water intake, reduced saliva secretion, positive serum anti-SSA and anti-SSB autoantibodies and pathologically lymphocytic infiltrations in SG. For kidney, despite similar serum creatinine and urea nitrogen levels, both the SG group and the RT group presented with renal tubular dysfunctions including decreased urine osmolality, increased urine output, proteinuria, decreased serum potassium levels, and increased urinary potassium and phosphorus excretion compared to the control group. Kidney pathology showed swollen and exfoliated tubular epithelial cells, brush border cilia lodging and dissolving with focal lymphocytic infiltrations in both the two groups. By electron microscope, we observed the disorderly dissolution of brush border cilia, smaller, ruptured mitochondria and increased mitochondrial membrane density were observed in the 1 mg/mL RT group, but not in the 3 mg/mL RT group.

**Conclusions:** This study first established a mouse model of SS with kidney injuries which was induced by immunizing mice with renal tubular protein and adjuvant.

## TH-PO307

### Cadmium Attenuates Tonicity Responsive Gene Expression in Kidney Cells via RNA Polymerase II Pausing

Amy Y. Zhao, Princes Kamuche, Don Delker, Jason A. Watts. National Institute of Environmental Health Sciences, Research Triangle Park, NC.

**Background:** The kidney is a target organ for many environmental exposures, such as the heavy metal cadmium. Cadmium is taken up by renal epithelial cells, where it accumulates, leading to acute and chronic renal injury. While cadmium is a known nephrotoxin, the transcriptional regulatory mechanisms preceding cadmium-induced renal injury remain largely unexplored. Previously, we identified RNA polymerase II (RNA Pol II) pausing as a mediator of the osmotic stress response. Here, we investigate the transcriptional response to environmental stress and identify cadmium as a modifier of RNA Pol II pausing regulation.

**Methods:** Cultured renal proximal tubule cells (RPTEC/TERT1) and inner medullary collecting duct cells (IMCD) were exposed to hypertonic salt and cadmium chloride. Changes in transcription were monitored by measuring RNA Pol II gene occupancy, and gene expression was measured by qPCR and RNA-seq.

**Results:** We began by characterizing the expression of *PAX2* and *PAX8*. These transcription factors are induced in response to hypertonic stress and acute kidney injury, and they are regulated by RNA Pol II pausing. In collecting duct and proximal tubule cells, hypertonic stress led to dose-dependent induction of *PAX2/8*, whereas cadmium treatment resulted in dose-dependent *PAX2/8* repression in both cell types. When combined with hypertonic stress, cadmium treatment abrogated the induction of *PAX2/8*. We extended these results by RNA-seq and identified over 600 genes where cadmium exposure resulted in attenuated gene activation following hypertonic stress. To determine how cadmium mediates this effect, we performed chromatin immunoprecipitation and found that RNA Pol II is recruited to gene promoters following hypertonic stress, but its release into productive elongation is impaired in the presence of cadmium.

**Conclusions:** Cadmium exposure attenuates tonicity responsive gene expression through stabilization of paused RNA Pol II. This effect on transcription regulation represents a new aspect of cadmium nephrotoxicity, where blocking induction of genes that allow adaptation to hypertonic stress leads to greater cellular injury. These results have implications for renal conditions associated with environmental exposures, such as chronic kidney disease of unknown etiology.

### Guanine Quadruplex-Mediated Pausing of Mitochondrial RNA Polymerase Regulates ATP Generation in Renal Proximal Tubule Cells

Jason A. Watts, Don Delker, Ryan J. Snyder. National Institute of Environmental Health Sciences, Research Triangle Park, NC.

**Background:** This project identifies the role of mitochondrial RNA polymerase (mtRNAP) pausing in the regulation of ATP production and transporter function in renal proximal tubule cells (RPTECs). In the nucleus, RNA polymerase II transcribes with punctuated pauses that are coupled to regulation of gene expression; however, RNA polymerase pausing has not been studied in the regulation of mitochondrial gene expression. Here, we sought to characterize the role of nucleic acid sequence and secondary structure in the regulation of mtRNAP pausing. Guanine quadruplexes (G4) are secondary structures formed by non-canonical base-pairing between guanine residues. We found that stabilization of G4 in RPTECs results in increased mtRNAP pausing and mitochondrial dysfunction.

**Methods:** We utilized the precision nuclear run-on assay (PRO-seq) to characterize the location of mtRNAP in cultured human fibroblasts and RPTECs. We assessed ATP production using the extracellular flux assay and quantified transporter function in RPTECs by measuring transport of a glucose analog (2-NBDG).

**Results:** Using fibroblasts from different individuals, we identified over 400 locations where mtRNAP pauses at precise locations on mtDNA. These brief stops occur most often after mtRNAP has transcribed through guanine-rich regions predicted to form G4 structures. We experimentally validated G4 formation at sites where mtRNAP pauses and show that G4-stabilization with a small-molecule (RHPS4) results in more mtRNAP pausing, impaired transcription, and decreased ATP production. As RPTECs are dependent on ATP from oxidative phosphorylation to drive solute reabsorption, we asked if impaired mitochondrial transcription affects transporter function. Using differentiated RPTECs grown on transwells, we show treatment with RHPS4 results in significantly decreased glucose transport.

**Conclusions:** Mitochondria dysfunction is implicated in acute and chronic kidney disease. The results presented here demonstrate that G4 regulate pausing of mtRNAP and that stabilization of G4s impedes mitochondrial transcription, compromises oxidative phosphorylation, and impairs proximal tubule function. In kidney disease, the role of G4-mediated mitochondria dysfunction warrants further study.

## TH-PO309

### The AE4 (Slc4a9) Transporter Is Essential for Renal Acid-Base Sensing

Helga Vitzthum,<sup>1</sup> Mirjam Koch,<sup>1</sup> Leya Eckermann,<sup>1</sup> Samuel L. Svendsen,<sup>2</sup> Peder Berg,<sup>2</sup> Kimberley Dreger,<sup>1</sup> Christian A. Hübner,<sup>4</sup> Carsten A. Wagner,<sup>3</sup> Jens G. Leipziger,<sup>2</sup> Catherine Meyer-Schwesinger,<sup>1</sup> Heimo Ehmke.<sup>1</sup>  
<sup>1</sup>Universitätsklinikum Hamburg-Eppendorf Zentrum für Experimentelle Medizin, Hamburg, Germany; <sup>2</sup>Aarhus University, Department of Biomedicine, Aarhus, Denmark; <sup>3</sup>University of Zurich and National Center of Competence in Research NCCR Kidney, Zurich, Switzerland; <sup>4</sup>University Hospital Jena Institute of Human Genetics, Jena, Germany.

**Background:** Renal acid (H<sup>+</sup>) and base (HCO<sub>3</sub><sup>-</sup>) secretion into the urine rapidly change upon systemic acid-base imbalances. Central for this task are specialized cells in the distal nephron, the  $\alpha$ - and  $\beta$ -intercalated cells (ICs). How these cells sense acid-base disturbances is a long-standing question. Interestingly, the base secreting  $\beta$ -ICs almost exclusively express the Na<sup>+</sup>-dependent Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger AE4 (Slc4a9). AE4 is considered to play an important role in the maintenance of salt-water balance. This proposed function could not be confirmed in our analyses of AE4 knockout mice. Here we analyzed whether the AE4 is involved in the regulation of pendrin-dependent HCO<sub>3</sub><sup>-</sup> secretion in  $\beta$ -ICs upon base or acid loading.

**Methods:** Ae4 knockout mice (Slc4a9<sup>-/-</sup>) and wild-type littermates (Slc4a9<sup>+/+</sup>) received a normal or salt deficient diet for up to 7 days combined with an oral alkali or acid loading. The acid-base status, renal abundance and subcellular distribution of pendrin and Ae4, and activity of pendrin were analyzed.

**Results:** Wild-type mice elicited a proper response to alkali loading, characterized by an increase of pendrin mRNA and protein abundance, a shift of pendrin to the apical membrane, an enhanced pendrin activity in  $\beta$ -ICs, and an elevated urinary  $\text{HCO}_3^-$  excretion. Upon acid loading both, Ae4 and pendrin abundance were reduced in wild-type mice. In contrast, AE4 knockout mice failed to initiate any change of pendrin abundance or subcellular distribution upon base or acid loading. The failure to adapt pendrin activity and urinary  $\text{HCO}_3^-$  secretion upon base loading culminated in severe metabolic alkalosis under salt restricted conditions.

**Conclusions:** The basolateral transporter AE4 is an essential part of the renal sensing mechanism for changes in acid-base status, and an insufficient function of AE4 precludes the proper reaction of  $\beta$ -ICs to alkalosis or acidosis.

## TH-PO310

### The Proximal Tubule Regulates Collecting Duct Phenotypic and Remodeling Responses to Acidosis

Hyun-Wook Lee,<sup>1</sup> Jill W. Verlander,<sup>1</sup> Susan M. Wall,<sup>2</sup> Autumn N. Harris,<sup>3</sup> I. D. Weiner.<sup>1,4</sup> <sup>1</sup>University of Florida College of Medicine, Gainesville, FL; <sup>2</sup>Emory University, Atlanta, GA; <sup>3</sup>University of Florida College of Veterinary Medicine, Gainesville, FL; <sup>4</sup>North Florida/South Georgia Veterans Health System, Gainesville, FL.

**Background:** The collecting duct responds to acidosis with several phenotypic and remodeling responses that increase net acid excretion. The current studies examine whether the proximal tubule (PT) regulates these collecting duct responses.

**Methods:** We examined mice with deletion of proteins present only in the PT, either the A variant or both A and B variants of the electrogenic Na-bicarbonate cotransporter, isoform 1 (NBCe1). These deletions disrupt PT bicarbonate, ammonia, and citrate responses to acidosis. We then quantified the collecting duct phenotypic responses to the spontaneous metabolic acidosis that was spontaneously present and the remodeling responses to exogenous acid loading. 2-oxoglutarate was measured using H-NMR.

**Results:** Both NBCe1-A KO and combined renal NBCe1-A/B KO caused severe metabolic acidosis. In NBCe1-A KO mice, despite this acidosis, Type-A intercalated cells in the inner stripe of the outer medulla (ISOM) exhibited decreased height and reduced H-ATPase, anion exchanger 1, Rhesus B glycoprotein, and Rhesus C glycoprotein expression. Similar findings were present in mice with combined kidney-specific NBCe1-A/B deletion. Pendrin expression in non-A, non-B intercalated cells and in Type B intercalated cells was not altered by NBCe1-A KO despite the associated acidosis. Ultrastructural analysis showed decreased apical plasma membrane and increased vesicular H-ATPase in the ISOM Type-A intercalated cell in NBCe1-A KO mice. The collecting duct remodeling response to acidosis was also disrupted by PT NBCe1 deletion. In WT mice, acid-loading increased the proportion of Type-A intercalated cells in the connecting tubule and the ISOM, and it decreased the proportion of non-A, non-B intercalated cells and Type-B intercalated cells in the CNT and cortical collecting duct, respectively. These changes were absent in NBCe1-A KO mice. Urinary 2-oxoglutarate, which can alter intercalated cell function, did not differ significantly between WT and KO mice, either under basal conditions or after acid-loading.

**Conclusions:** Collecting duct phenotypic characteristics and remodeling responses to acidosis depend on intact proximal tubule acid-base responsiveness in two different genetic models. We conclude that proximal tubule-dependent signaling mechanisms are a major determinant of the collecting duct responses to metabolic acidosis.

**Funding:** NIDDK Support

## TH-PO311

### Glycosuria in Tubule-Specific mTORC2 Knockout Mice Resolves on a High Potassium Diet

John E. Demko, Bidisha Saha, Enzo Takagi, Anna D. Manis, David Pearce. University of California San Francisco, San Francisco, CA.

**Background:** Insulin signaling promotes proximal tubule glucose transport and suppresses gluconeogenesis (GNG). An important feature of proximal tubule GNG is dual regulation by insulin and pH. The kinase mTORC2 is known to be regulated by insulin signaling in multiple cell types, but its mechanistic role in proximal tubule glucose homeostasis is unknown.

**Methods:** Rictor is a critical component of the mTORC2 complex. Tubule-specific Rictor KO mice (TRKO) were generated using doxycycline inducible Pax8-Cre Rictor<sup>fl</sup>/fl. Mice were adapted to 1% K<sup>+</sup> diet and then switched to either a 0.5% K<sup>+</sup> or 3% K<sup>+</sup> diet for 2 days. An additional cohort of mice were maintained on a 0.5% K<sup>+</sup> diet for 2 weeks for glucose (1g/kg), insulin (0.75U/kg), and pyruvate (2g/kg) tolerance testing after overnight fasts. Renal function, serum glucose, and urine glucose were measured in metabolic cages during the last 24 hours of all experiments. Proteins were measured via Western blot from whole kidneys.

**Results:** TRKO mice on a 0.5% K<sup>+</sup> diet had urinary glucose of 470±96.7mg/dL (n=5) and control mice had 30.0±7.98mg/dL (n=7; p<0.001). After 12 hours (n=3 per group) and 2 days (n=6 per group) on a 3% K<sup>+</sup> diet, there was no significant difference in urinary glucose between TRKO and control mice. TRKO mice on a 3% K<sup>+</sup> diet also developed hyperkalemia and elevated BUN after 2 days. There were no differences in serum glucose during glucose and insulin tolerance tests between groups at any timepoint. Serum glucose during pyruvate tolerance test was higher in TRKO mice compared to controls (n=6 per group) at 90 (194 vs 149mg/dL; p<0.01) and 120 minutes (182 vs 150mg/dL; p<0.05). There was no difference in PEPCCK, plasma membrane SGLT2 or GLUT2 abundance between TRKO and control mice after 2 days on either 0.5% or 3% K<sup>+</sup> diets.

**Conclusions:** This study demonstrates the importance of mTORC2 in glucose handling and metabolism by the renal tubules. Increased serum glucose during pyruvate tolerance testing in TRKO mice suggests increased GNG, likely because mTORC2 KO impairs insulin signaling and fails to suppress renal GNG. The resolution of glycosuria in TRKO mice on a 3% K<sup>+</sup> diet may be due to mTORC2-independent suppression of GNG by K<sup>+</sup> and merits further investigation. Future studies will focus on identifying the molecular defect causing increased GNG in TRKO mice, and the basis for glycosuria suppression by K<sup>+</sup>.

## TH-PO312

### NBCe1-B/C Knockout Mice Exhibit an Impaired Respiratory Response to Metabolic Acidosis Resulting in Increased Ammonia Excretion

Clayton Brady, Mark Parker. University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY.

**Background:** Sodium-bicarbonate cotransporter variants NBCe1-B and NBCe1-C (NBCe1-B/C) are expressed in the brainstem while variants NBCe1-A and NBCe1-B are expressed in the proximal tubule. NBCe1-A is the primary renal variant and is important to the kidney response to metabolic acidosis (MAc). Less understood is the role of NBCe1-B/C, but they are thought to play a role in both the respiratory and renal responses to MAc. We tested this hypothesis in NBCe1-B/C knockout (KO<sub>NBC</sub>) mice.

**Methods:** We validated an NBCe1-B/C specific antibody and used it to confirm the presence/absence of NBCe1-B in the kidney and NBCe1-B/C in the brainstem of WT and KO<sub>NBC</sub> mice. MAc was induced by adding 0.5% sucrose + 0.28M NH<sub>4</sub>Cl to drinking water. The abundance response of kidney NBCe1-B to MAc was quantified in WT mice by western blot. To assess the effect of MAc on acid-base status, WT and KO<sub>NBC</sub> mice were subjected to control (0.5% sucrose in drinking water) or MAc conditions for 1-3 days followed by cardiac puncture and blood-gas/electrolyte analysis. 24-hour urine collections were assessed for ammonia excretion, titratable acid (TA) excretion, and pH. The respiratory response was assessed using whole-body plethysmography, with WT and KO<sub>NBC</sub> mice assessed each day of a 3-day MAc-challenge.

**Results:** After 3-days of MAc, NBCe1-B kidney abundance was 3.6x that of controls in WT mice, supporting evidence of a role for NBCe1-B in the kidney during MAc. Surprisingly, however, KO<sub>NBC</sub> mice had a greater recovery in plasma [HCO<sub>3</sub><sup>-</sup>] and higher pCO<sub>2</sub> levels, but a similar recovery in plasma pH to WT mice. This was associated with a greater increase in ammonia excretion in KO<sub>NBC</sub> males but not females, whereas there were no differences in changes in TA excretion or urine pH between WT and KO<sub>NBC</sub> mice. In regards to the respiratory response, over the 3-day MAc challenge WT mice exhibited a maximum increase in minute volume of 10% whereas in KO<sub>NBC</sub> mice minute volume did not significantly change.

**Conclusions:** The impaired respiratory response to MAc in KO<sub>NBC</sub> mice leads to elevated ammonia excretion and a greater recovery in plasma [HCO<sub>3</sub><sup>-</sup>]. We suggest this is because, although normally the respiratory response to MAc lowers pCO<sub>2</sub> in order to help maintain plasma pH, this decrease in pCO<sub>2</sub> also has an inhibitory effect on renal ammoniagenesis.

### Generation of a ATP6V1G3-Cre Mice With High Kidney Intercalated Cell Specificity

Vijay Saxena, Samuel Arregui, David S. Hains, Andrew L. Schwaderer. Indiana University School of Medicine, Indianapolis, IN.

**Background:** The kidney collecting duct is composed of principal cells (PCs) and intercalated cells (ICs). Principal cells maintain sodium and water balance while intercalated cells maintain acid-base homeostasis. Recent studies have shown that ICs are the critical cells to defend against uropathogen invasion. For focused studies of IC cells, a novel *Atp6v1b1*-Cre (B1-Cre) mice (generated by Dr. Raoul Nelson group) were crossed with *Tdtomato-flox* mice to enrich ICs from kidney. B1-Cre mice strain is very useful for enriching ICs from kidney, we noticed that they also labeled kidney resident CD45<sup>+</sup> immune cells hence limiting their use for enrichment and gene expression studies. Additionally, *Atp6v1b1* is expressed in a range of tissues including the lung, brain, pancreas, skin and gastrointestinal tract. Here we report the generation of *Atp6v1g3*-Cre mice using CRISPR/CAS technology which labels kidney ICs without any expression on kidney resident immune cells and minimal extra kidney expression.

**Methods:** To generate the mouse, a CRISPR targeting site, *Atp6v1g3* gRNA 76/59 in intron 1 nearby the 3' end of exon 1 with acceptable predicted efficiency and specificity was designed. A T2A-cre-PolyA cassette was inserted into exon1 by CRISPR/Homology directed repair (HDR) strategy. The resulting transcript under the control of endogenous *Atp6v1g3* promoter express a short peptide (27aa of *Atp6v1g3* N terminal and 17aa of T2A) and the Cre recombinase. CRISPR/cas9 gRNA was injected to the zygotes of pronuclei of fertilized eggs and F0 progeny was generated. F0 progeny mice were genotyped by Real-Time PCR (RT-PCR) for G3-Cre expression and bred to wild type C57BL/6 mice to maintain colony of mice.

**Results:** *Atp6v1g3-Cre* were crossed with *Tdmtomato<sup>flac/lox</sup>* mice to generate *Atp6v1g3-Cre<sup>+</sup>/Tdmtomato<sup>flac/lox</sup>* mice. ICs were flowsorted and their relative enrichment was confirmed by RT-PCR. *Tdmtomato* expression was analyzed on Flowcytometer and immunofluorescence which revealed expression on ICs but not on CD45<sup>+</sup> immune cells along with minimal extra kidney expression in various tissues as examined by immunofluorescence and RT-PCR.

**Conclusions:** The *Atp6v1g3-Cre* mouse will be a useful tool for kidney IC specific studies.

## TH-PO315

### Stable Transduction of Recombinant NHERF1 Protein in Opossum Kidney Cells

**Kenneth B. Gagnon,<sup>1</sup>** Madhavi J. Rane,<sup>2</sup> Eleanor D. Lederer.<sup>1,3</sup> <sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>University of Louisville School of Medicine, Louisville, KY; <sup>3</sup>VA North Texas Health Care System, Dallas, TX.

**Background:** NHERF1 (Na<sup>+</sup>-hydrogen exchanger regulatory factor isoform 1) is a cytoplasmic scaffolding protein containing two internal postsynaptic density 95/disc large/zona occludens binding domains and a carboxy-terminal ezrin-binding domain. NHERF1 anchors the Na<sup>+</sup>-dependent phosphate cotransporter type IIa (Npt2a) in the brush border membrane of proximal tubules through its cross-linking of Npt2a with the actin-filament binding protein, Ezrin. The opossum kidney (OK) cell line, originally derived from a female Virginia Opossum (*Virginia delphi*), has been extensively used as a model of proximal tubular epithelia. A sub-clone of the OK cell line (OK-H) expresses low levels of endogenous NHERF1 and lacks PTH-mediated inhibition of sodium-dependent phosphate uptake.

**Methods:** We PCR cloned full-length mouse NHERF1 into a bacterial expression vector and transformed BL21 *E. coli* to over-express the HIS-tagged recombinant NHERF1 (rmNHERF1) protein. We purified rmNHERF1 utilizing the upstream poly-histidine tag and immobilized metal affinity chromatography. We added purified rmNHERF1 to OK-H cells at different concentrations and time points to assess the *in vitro* stability of the recombinant protein by SDS-PAGE and immunoblotting. We also transduced OK-H cells with rmNHERF1 for 4 and 24 h and measured radiolabeled phosphate uptake compared to non-transduced OK-H cells.

**Results:** Immunoblotting whole cell lysates transduced with rmNHERF1 for 4 h with both an anti-HIS and an anti-NHERF1 antibody demonstrate a significant dose-dependent increase in rmNHERF1 expression in OK-H cells. Similarly, OK-H cells transduced with rmNHERF1 for 4, 8, 24, and 48 h demonstrates stable temporal expression of the recombinant protein with minimal lysosomal degradation. We also detected Npt2a expression in transduced OK-H cells compared to non-transduced controls. Radiolabeled phosphate uptake of OK-H cells transduced with rmNHERF1 for 4 h and 24 h did not produce a significant increase in phosphate uptake.

**Conclusions:** We have demonstrated the stable introduction of recombinant mouse NHERF1 protein in NHERF1-deficient opossum kidney cells with a resulting increase in Npt2a expression but not concurrent increase in phosphate uptake activity suggesting that the recombinant fusion protein may be inert or trapped within an intracellular vesicle following endocytic transduction.

## TH-PO316

### Kidney Function Differs Between 4.5-Month Virgin and 12-Month Breeder Female Sprague Dawley Rats

**Timothy M. Reilly,<sup>1</sup>** Donna Ralph,<sup>1</sup> Brandon E. McFarlin,<sup>1</sup> Aurelie Edwards,<sup>2</sup> Alicia A. McDonough.<sup>1</sup> <sup>1</sup>University of Southern California Keck School of Medicine, Los Angeles, CA; <sup>2</sup>Boston University, Boston, MA.

**Background:** Most studies of experimental hypertension and kidney disease are conducted in young virgin rodents, whereas human diseases are often associated with mid-life, suggesting that studies in older animals may offer translational advantages.

**Methods:** To assess age-based differences, we compared kidney function in virgin female (F) rats at 4.5 mo (240 gm), equivalent to 18-20 yr old humans, to 12 mo female breeders (320 gm), equivalent to 40 yr humans (n=6/group).

**Results:** Body, kidney and heart weights, as well as GFR (FITC sinistrin) were increased 30% between 4.5 and 12 mo. During 3 hr after a saline volume challenge, 4.5 mo F excreted twice the %Na and volume injected as 12 mo F. Responses to a 2% K meal were equivalent in 4.5 and 12 mo F. Baseline lithium clearance fell ~25% (P=0.05) between 4.5 and 12 mo. Abundance of transporters, channels, and claudins varied along the nephron (Fig 1, \*P<0.05). SGLT1 (not SGLT2) and AQP2 phosphorylation increased 50% between 4.5 and 12 mo. Sodium pump (NKA) subunits were lower by ~50% in 12 mo vs 4.5 mo, paralleled by ~25% lower K-ATPase activity in both cortex and medulla at 12 mo indicating changes in kidney energetics with age. NKCC2 and NCC phosphorylation decreased between 4.5 and 12 mo, however, diuretic tests with thiazides and furosemide were not depressed in parallel, perhaps reflecting impact of tubular flow and/or renal energetics.

**Conclusions:** Kidney function is significantly different in adult (12 mo) vs young (4.5 mo) F rats suggesting that middle aged rats may be more appropriate for (patho) physiology studies.

## TH-PO317

### FOXI1 Promotes Expression of V-ATPase and Gpr116 in M1 Cells

**Mackenzie Kui,** Jennifer L. Pluznick, Nathan Zaidman. *Johns Hopkins Medicine, Baltimore, MD.*

**Background:** G protein-coupled receptors (GPCRs) are a diverse family of integral membrane proteins. We previously reported that GPR116 (ADGRF5), an adhesion-class GPCR, is a critical regulator of vacuolar-type H<sup>+</sup>-ATPase (V-ATPase) surface expression in A-type intercalated cells (AICs) in mouse kidney cortical collecting ducts. The V-ATPase is a multi-subunit proton pump that localizes to the plasma membrane in specialized acid-secreting epithelial cells. FOXI1 is a transcription factor that regulates V-ATPase expression in ICs and other mitochondria-rich cells. Recently, FOXI1 was identified as a key regulator of CFTR-rich pulmonary ionocytes which express both V-ATPase and GPR116. We hypothesized that GPR116 is transcriptionally regulated by FOXI1 in ICs.

**Methods:** We cloned FOXI1 from whole mouse kidney into an expression vector (pFOXI1), transfected it into the immortalized M1 mouse collecting duct cell line, and assessed changes. We localized FOXI1 by RNAscope *in situ* hybridization.

**Results:** Transfection with pFOXI1 increased expression (qRT-PCR) of GPR116 in M1 cells (N=3, CT±SD: pFOXI1=33.1±1.3, mock=38.4±1.4), but not HEK293 cells. GPR116 transcripts co-localize in pFOXI1 transfected M1 cells, as well as mouse collecting ducts, as determined by RNAscope. Furthermore, pFOXI1 upregulates transcripts of several V-ATPase subunits in M1 cells, including ATP6V1B1 (N=3, CT±SD: pFOXI1=32.9±1.5, mock=undetected), ATP6V1G3 (pFOXI1=30.2±0.6, mock=undetected), and ATP6V0D2 (pFOXI1=31.6±0.3, mock=37.7±2.0). Surprisingly, ATP6V0A4 was not sensitive to transfection with pFOXI1 (pFOXI1=34.3±0.7, mock=34.7±1.1). Immunofluorescence microscopy revealed cytoplasmic localization of V-ATPase (β1/2 antibody) in FOXI1-expressing M1 cells. No V-ATPase protein is detected by microscopy in mock transfected M1 cells. Additionally, transfection with pFOXI1 caused an increase in SLC4A9 (pFOXI1=33.5±1.1, mock=undetected), SLC26A4 (pFOXI1=33.2±1.0, mock=36.0±0.6) and GPR110 (pFOXI1=36.9±2.7, mock=undetected). AQP6, CAR2, and CLCN5 transcripts are not sensitive to pFOXI1 in M1 cells, and SLC4A1 is not detected.

**Conclusions:** FOXI1 upregulates GPR116 and V-ATPase in M1 cells, generating IC-like cells *in vitro*. FOXI1 is also a transcriptional regulator of GPR110 (ADGRF1), an adhesion GPCR similar to GPR116. Finally, GPR116 may be a universal and genetically coded regulator of V-ATPase surface expression in FOXI1-positive cells.

## TH-PO318

### PKA Regulates the WNK-SPAK-NCC/NKCC2 Signaling Pathway Through Phosphorylation of WNK4 and I-1

**Hector Carbajal-Contreras,<sup>1,2</sup>** Adrian R. Murillo-de-Ozores,<sup>1,2</sup> German R. Magaña,<sup>1,2</sup> Laurent Bourqui,<sup>3</sup> Norma H. Vázquez,<sup>1,2</sup> Johannes Löffing,<sup>3</sup> Gerardo Gamba,<sup>1,2</sup> Maria Castañeda-Bueno.<sup>1,2</sup> <sup>1</sup>Unidad de Fisiología Molecular <sup>1</sup>Universidad Nacional Autónoma de México, Ciudad de México, México; <sup>2</sup>Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Ciudad de México, México; <sup>3</sup>Universität Zurich, Zurich, Switzerland.

**Background:** We have previously shown that vasopressin signaling in the kidney increases the phosphorylation of the Na<sup>+</sup>-Cl<sup>-</sup> cotransporter (NCC) and the Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransporter 2 (NKCC2) through an increase in the phosphorylation of WNK4's RRX motifs. Previous work has also highlighted the importance of Inhibitor-1 (I-1) and protein phosphatase 1 (PP1) in the regulation of these transporters' phosphorylation in response to cAMP. Since WNK4, SPAK and NCC/NKCC2 have all been linked to PP1-mediated dephosphorylation, we sought to dissect the individual importance of each component in this proposed pathway.

**Methods:** We transfected HEK293 cells with NKCC2, NCC, PP1, I-1, SPAK, WT WNK4 or a WNK4 mutant which lacks a *bona fide* PP1-binding site (WNK4 PP1b) in distinct combinations. Cells were stimulated with 30 nM forskolin for 30 minutes. Protein extracts were subjected to immunoblot to assess the abundance of these proteins and their phosphorylated forms. Immunoprecipitation was carried out in order to assess pNCC and pNKCC2.

**Results:** We found an increase in pSPAK with forskolin exclusively in the presence of WNK4. While the presence of I-1 by itself is not sufficient to upregulate pSPAK in cells lacking WNK4, it increases the dynamic range of SPAK phosphorylation in the presence of WT WNK4. WNK4 PP1b is highly active at baseline and can be further phosphorylated and activated with forskolin, but is not phosphorylated to a greater degree in the presence of I-1. NKCC2's phosphorylation is decreased with the cotransfection of PP1 and can be regulated by forskolin in the presence of I-1, independently of WNK-SPAK upregulation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

The addition of WNK4 and I-1 to NKCC2-expressing cells further increased the dynamic range of pNKCC2 regulation by forskolin. pNCC was not increased by forskolin with I-1 alone, but was upregulated in the presence of WNK4.

**Conclusions:** WNK4 is a node in cAMP signaling where kinase and phosphatase signaling converge in the modulation of its phosphorylation-dephosphorylation balance. NKCC2 and NCC show distinct regulatory patterns by PP1, which hints towards specific regulatory mechanisms for each transporter. These findings add to the understanding of the transduction of cAMP signaling in the kidney in response to hormones such as ADH, PTH and epinephrine.

## TH-PO319

### Burmese Cat Mutation, the C-Terminus-Truncated WNK4, Diminishes NCC Activation by Potassium Depletion

Xiao-Tong Su,<sup>1</sup> Hector Carbajal-Contreras,<sup>2</sup> Maria Castañeda-Bueno,<sup>2</sup> Avika Sharma,<sup>1</sup> Gerardo Gamba,<sup>2</sup> Eric J. Delpire,<sup>3</sup> Chao-Ling Yang,<sup>1</sup> David H. Ellison.<sup>1</sup> <sup>1</sup>*Oregon Health & Science University, Portland, OR;* <sup>2</sup>*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico;* <sup>3</sup>*Vanderbilt University, Nashville, TN.*

**Background:** The Na-Cl cotransporter (NCC) in the distal convoluted tubule (DCT) plays an important role in regulating renal potassium (K) excretion by controlling sodium delivery to the distal nephron. NCC is inhibited when K intake is high and activated when K intake is low to modulate K excretion. WNKs (with-no-lysine kinases, mainly WNK1 and WNK4 in DCT) phosphorylate and activate SPAK (SPS1-related proline/alanine-rich kinase), which stimulates NCC phosphorylation and activation. An autosomal recessive mutation in Burmese cats, a popular pet breed, leads to hypokalemia. This mutation is responsible for a premature WNK4 protein truncation lacking the C-terminus, which contains a WNK/WNK interaction domain, SPAK binding motif and several phosphorylation sites. Here, we tested whether this mutation inhibits NCC activity by abrogating WNK activity *in vivo* and *in vitro*.

**Methods:** The Burmese cat mutation was introduced to create Burmese cat mouse line using CRISPR. Control and Burmese cat mice were treated with either control (NK) or low K (LK) diet for 7 days and blood and kidney were harvested.

**Results:** Burmese cat mice do not have any phenotype in blood chemistry at baseline. Yet, when challenged with LK diet for 7 days, they showed obvious hypokalemia (2.8 mM). Total and phospho-NCC were reduced in Burmese cat mice at baseline, and LK induced an increase in pNCC. Yet, the expression level was still lower than that in the control mice. WNK4 can be observed within WNK bodies in control mice on LK diet; whereas it is present within WNK bodies in Burmese cat mice on both NK and LK diets. Immunofluorescence showed less apical pS383- and pT243-SPAK, but more pS383-SPAK within WNK bodies in Burmese cat mice. WNK1/KS-WNK1 is not visible in control mice on both diets but is more evident within WNK bodies in Burmese cat mice. When the truncated WNK4 was transfected into HEK293 cells, direct WNK4-SPAK interaction was abolished. Thus, preserved WNK-WNK interaction may be responsible for the recruitment and phosphorylation of SPAK in WNK bodies.

**Conclusions:** Hypokalemia in Burmese cats results from defective NCC function, as the WNK4 C-terminus is crucial for SPAK-mediated effects. Loss of function in WNK4 leads to a compensatory increase in WNK1/KS-WNK1 WNK body formation.

## TH-PO320

### Dietary Potassium Restriction Activates a Proliferative Cell Population to Remodel the Distal Convoluted Tubule

Xiao-Tong Su, Ryan J. Cornelius, James A. McCormick, Chao-Ling Yang, David H. Ellison, Jonathan W. Nelson. *Oregon Health & Science University, Portland, OR.*

**Background:** Low dietary K intake has adverse health effects. Dietary K restriction rapidly activates a *potassium switch* in the distal nephron to maintain homeostasis by reducing K excretion at the expense of sodium retention. When prolonged, dietary K stress leads to profound remodeling of distal convoluted tubule (DCT), making chronic adaptation largely structural. Knepper and colleagues recently described a unique cell population in the DCT that expresses proliferative markers. Here, we tested whether dietary K restriction activates this population rapidly, and plays a central role in chronic K balance.

**Methods:** Female NCC (Na-Cl cotransporter)-Cre-INTACT (Isolation of Nuclei Tagged in specific Cell Types, which fluorescently labels nuclei) mice were provided either control (NK) or K deficient (KD) diet for 4 days and kidneys were harvested for targeted single-nucleus RNA-seq (NovaSeq) (3 mice per diet).

**Results:** Unbiased clustering and UMAP visualization revealed 12 clusters, with most cells from the DCT (78%) indicating the success of the enrichment process. Among those, 70% were from DCT1 and 30% from DCT2. There was a small population (<1%) enriched in proliferation-related genes, such as *Top2a*, *Cenpp*, and *Mki67*. KD resulted in a 6-fold increase in the number of proliferating cells. To determine the origin of this population, we performed trajectory analysis, which allows us to order each cell according to its progress along a learned trajectory, expressed as Pseudotime, to indicate the distance between a cell and trajectory start. This analysis indicated that the proliferating population arises from DCT1 cells. Four-day KD treatment also decreased the *EnaC* (*Scnn1g*) and *kallikrein* (*Klk1*) expression in DCT2, indicating that some DCT2 cells may reprogram to retain potassium in response to the short-term KD. We have shown previously that KD increases calciuresis; here, KD also decreased expression of calcium-handling genes, such as *Slc8a1*, *Calb* and *Vdr*.

**Conclusions:** Our results suggest that a unique population of cells originating from DCT1 has the potential to proliferate during KD leading to remodeling. DCT cells also reprogram transcriptionally to maintain electrolyte balance, likely contributing to the adverse effects of low potassium intake.

## TH-PO321

### Maintaining Potassium Balance on the High-Potassium Alkaline Diet via Proximal Tubule RAS-Stimulated Sodium Delivery

Bangchen Wang,<sup>1</sup> Jun Wang-France,<sup>2</sup> Steven C. Sansom.<sup>2</sup> <sup>1</sup>*Duke University Health System, Durham, NC;* <sup>2</sup>*University of Nebraska Medical Center, Omaha, NE.*

**Background:** The angiotensin II (ANGII) activated WNK4-SPAK pathway regulates the Na, Cl cotransporter (NCC) in the distal convoluted tubule (DCT) to control the Na delivered to the connecting tubule (CNT) and cortical collecting duct (CCD), where it stimulates K secretion as a mechanism to maintain K balance (3.6 mM < P[K] < 5.5 mM). We previously found that K balance was maintained in mice given a 5% K diet that was accompanied by alkaline loading anions (HK) but not by acid-loading anions (HK-Cl). We designed these experiments to determine whether HK enhances Na delivery as a mechanism to stimulate K secretion and whether ROMK and ANGII were involved in this process.

**Methods:** Wild type (WT), ROMK knockout (ROMK-KO), liver angiotensinogen II knockout (LKO), and liver plus proximal tubule angiotensinogen double knockout mice (DKO) were given either a high K diet with alkaline loading anions (HK; 5% K-citrate/carbonate/Cl) or a high K diet with acid loading anions (HK-Cl; 5% KCl) and placed in metabolic cages for 6 days. Glomerular filtration rate (GFR) was determined by FITC-inulin. Urine and plasma [Na] and [K] were determined by flame photometry. Urine pH was determined by a Mettler Toledo pH meter. The AT2 agonist, compound 21 (C21) was given to a group of DKO mice at 5 mg/Kg/min for 6 days.

**Results:** When WT were given HK (n=13) and HK-Cl (n=15), the respective means  $\pm$ SEM of urine pH were 8.40  $\pm$ 0.52 and 5.68  $\pm$ 0.49, P[K] were 4.62 mM  $\pm$ 0.16 and 5.72  $\pm$ 0.30 mM, and rates of Na excretion (UNaV; mmole/day) were 428.8  $\pm$ 29.6 and 289.3  $\pm$ 22.7. GFR was not significantly different between HK (370.8  $\pm$ 20.2 ml/day; n=6) and HK-Cl (419.9  $\pm$ 19.7 ml/day; n=5). When ROMK-KO was given HK (n=9) and HK-Cl (n=7), the P[K] was 5.15  $\pm$ 0.17 mM and 6.37  $\pm$ 0.35 mM, respectively and the UNaV was 308.2  $\pm$ 20.2 and 194.2  $\pm$ 12.0, respectively. When given HK, LKO (P[K] = 4.52  $\pm$ 0.11 mM, n=4), but not DKO (P[K] = 7.0  $\pm$ 1.0 mM, n=4), maintained K balance. C21 restored K balance in DKO on HK (P[K] = 4.28  $\pm$ 0.25 mM, n=3) and increased UNaV from 177.8  $\pm$ 25.3 to 326.9  $\pm$ 58.6 (n=3).

**Conclusions:** These results show that: 1. The thick ascending limb and ROMK were not involved in the ability of HK mice to enhance Na delivery and maintain K balance. 2. For HK mice, PT-generated ANGII, via AT2 receptors, enhances Na delivery to the CNT and CCD to stimulate K secretion and maintain K balance.

## TH-PO322

### GDF15 Is Necessary for the Physiological Adaptation to Hypokalemia

Samia Lasaad,<sup>1,2</sup> Christine Walter Lamouroux,<sup>1,2</sup> Chloe Rafael,<sup>1,2</sup> Luciana Morla,<sup>1,2</sup> Alain Doucet,<sup>1,2</sup> Nicolas Picard,<sup>4</sup> Anne Blanchard,<sup>1,3</sup> Gilles Crambert,<sup>1,2</sup> Lydie Cheval.<sup>1,2</sup> <sup>1</sup>*Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université Paris Cité, Laboratoire de Physiologie Rénale et Tubulopathies, Paris, France;* <sup>2</sup>*CNRS EMR 8228 – Unité Métabolisme et Physiologie Rénale, Paris, France;* <sup>3</sup>*Assistance Publique Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Centre d'Investigation Clinique, Paris, France;* <sup>4</sup>*Laboratory of Tissue Biology and Therapeutic Engineering, UMR 5305 CNRS, University Lyon 1, Lyon, France.*

**Background:** Population in industrialized countries consume less potassium (K<sup>+</sup>) than recommended and this may, in the long term, contribute to the development of cardiovascular pathologies. To face a K<sup>+</sup> restriction, and avoid hypokalemia two synergistic mechanisms are induced by our organism. The external regulation adapting the renal and fecal excretion of K<sup>+</sup> to the intake and the internal regulation controlling the storage or release of K<sup>+</sup> from cellular compartment (muscle). The kidney adapts its function to retain K<sup>+</sup> by increasing the number of type-A intercalated cells (ICA). A transcriptomic analysis, we published a few years ago, revealed that the TGFβ-related growth factor GDF15 was upregulated in renal collecting ducts of K<sup>+</sup> depleted animals. We hypothesize that GDF15 may have an impact on both the external and internal balance of K<sup>+</sup> homeostasis and is therefore necessary to the physiological adaptation to hypokalemia.

**Methods:** We used C57BL/6J mice wild type or knockout for the *Gdf15* gene, put on a control or low-K<sup>+</sup> diet. Metabolism cages were used for metabolic analysis. Number of ICA was determined by immunofluorescence on microdissected tubules. Muscle mass was assessed by TD-NMR. Urine samples of healthy human volunteers (HHV), K<sup>+</sup> depleted or not for a week, were collected from a previous study and GDF15 expression was analyzed by ELISA.

**Results:** Under a K<sup>+</sup> depletion we showed: 1/ an increase of *Gdf15* expression along the nephron, mostly in the collecting duct, and in the intestine, plasma and urine of mice, 2/ a relationship between GDF15 levels and K<sup>+</sup> restriction in HHV, 3/ a delayed renal adaptation in GDF15-KO mice, leading to hypokalemia. The adaptation issue is partly explained by the absence of proliferation of ICA. The renal effect of GDF15 depends on the ErbB2 receptor. Finally, we demonstrated that GDF15 also regulates the internal balance by inducing a loss of muscle, releasing K<sup>+</sup> in the plasma.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Altogether, these results demonstrate that GDF15 is a key factor that orchestrates synergetically both the regulation of the internal and external potassium balance.

## TH-PO323

### Utilizing Chemogenetic Tools to Study Sodium-Chloride Cotransporter Regulation

Tanner Bradford, Kevin J. Martz, David H. Ellison, Jonathan W. Nelson. Oregon Health & Science University, Portland, OR.

**Background:** In the Distal Convoluted Tubule (DCT), sodium balance is primarily determined by the sodium-chloride cotransporter (NCC). When phosphorylated, NCC reabsorbs sodium away from the lumen of the nephron. Dephosphorylation of NCC inactivates the transporter, resulting in increased sodium excretion. A similar effect is leveraged by a class of anti-hypertensive medications called thiazides, which block NCC activity. To determine whether GPCRs play a role in NCC regulation, we implemented a cell-specific chemogenetic approach with Designer Receptors Exclusively Activated by Designer Drugs (DREADDs). DREADDs stimulate GPCR (G-protein-coupled receptor) signaling within a targeted cell and have been previously used to activate neurons through calcium release. We hypothesize that DREADD activation within the DCT will change NCC activity.

**Methods:** We bred DCT-specific inducible Cre Recombinase mice (NCC-creERT2) to conditional Gq-GPCR coupled mice (Gq-DREADD) to create DCT-DREADD mice. First, we performed metabolic cage experiments examining thiazide responses within these animals. Next, we activated Gq-GPCR signaling in DCT cells by intraperitoneal injection of the DREADD-specific agonist deschloroclozapine (DCZ). To confirm that DCZ-induced DREADD activation alters electrolyte handling along the nephron we measured sodium excretion (UNaV) following DCZ administration. To investigate kinetics, we performed a timecourse experiment measuring pNCC from 15 minutes to 24 hours after DREADD activation using western blots.

**Results:** DREADD expression confirmed along the DCT in transgenic mice. DCT-DREADD mice maintain an intact thiazide response before DREADD activation, indicating DREADD expression does not alter DCT function at baseline. Intraperitoneal injection of the DREADD-specific agonist deschloroclozapine (DCZ) reduced NCC phosphorylation by more than 80% within 1 hour, with recovery of pNCC between 4-6 hours in both males and females. Concomitant with the effects on NCC, DCT-DREADD activation increased UNaV by 215% compared to controls.

**Conclusions:** We posit that the chemogenetic activation of DCT leads to a release of intracellular calcium and rapid activation of the phosphatase required for the dephosphorylation of NCC. We are currently using HEK293 cells co-transfected with DREADD and NCC to test various phosphatase inhibitors, to determine the identity of the DREADD-induced phosphatase.

### Single Tubule RNAseq From Gitelman Syndrome Mice Revealing Magnesium and Calcium Handling in Distal Renal Tubules

Chih-Chien Sung, Yu-Juei Hsu, Chien-Ming Lin, Shih-Hua P. Lin. Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.

**Background:** Gitelman syndrome (GS) is characterized by salt-losing hypotension, hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalciuria caused by a specific mutation in the thiazide-sensitive sodium chloride co-transporter (NCC) gene *Slc12a3*. However, magnesium ( $Mg^{2+}$ ) and calcium ( $Ca^{2+}$ ) regulation associated gene in the distal renal tubules remains unclear.

**Methods:** We performed small samples RNA-seq from manual microdissection of distal convoluted tubules (DCTs) in nonsense *Ncc* Ser707X (S707X) homozygous knockout mice (*Ncc*S707X/S707X mice) (n=4) and wild type (WT, n=4). Cortical thick ascending limbs of Henle (cTALs), connecting tubule (CNT), cortical collecting duct (CCD) were also microdissected.

**Results:** Among DCT makers, *Slc12a3* (NCC) and *Pvalb* (Parabumin) were significantly downregulated ( $\log_2$ TPM<sub>S707X/WT</sub>: -4.45, P=0.0003; -6.888258295, P=0.0003, respectively).  $Mg^{2+}$  transporters of *Trpm6*, and *Trpm7* gene expression were both significantly downregulated. *Egf* and *Cnnm2* have been reported to increase TRPM6 trafficking or activity, were also decreased in DCT segment. Among  $Ca^{2+}$  transporter related genes, *Trpv5* was only slightly increased, but other *Atp2b4*, *Calb1* and *Pvalb* decreased in DCT. Claudins including *Cldn10*, *Cldn16*, and *Cldn19*, involving paracellularly reabsorption of  $Ca^{2+}$  and  $Mg^{2+}$ , were not changed in cTALs.

**Conclusions:** Our small samples RNA-Seq from dissected DCT highlight the possible molecular pathway of hypomagnesemia and hypocalciuria in GS. Inactivation of *Slc12a3* gene may affect the DCT development causing loss of  $Mg^{2+}$  associated transporters. The pathogenesis of hypocalciuria is still complex and needs further experiments to explore.

### Discovery and Characterization of VU0493206, the First Small-Molecule Activator of Kir4.1/Kir5.1 Channels

Samantha J. Mcclenahan,<sup>1</sup> Elena Isaeva,<sup>2</sup> Christine A. Klemens,<sup>3</sup> Alexander Staruschenko,<sup>3</sup> Jerod S. Denton.<sup>1</sup> <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>3</sup>University of South Florida, Tampa, FL.

**Background:** Heteromeric  $K_{ir}4.1/K_{ir}5.1$  potassium channels play key roles in regulating distal tubule potassium sensing and sodium chloride transport. Mutations in *KCNJ10* and *KCNJ16*, encoding  $K_{ir}4.1$  and  $K_{ir}5.1$ , respectively, lead to several renal tubulopathies. Given the importance of  $K_{ir}4.1/K_{ir}5.1$  in maintenance of renal salt and water homeostasis, we sought to develop pharmacological tools for exploring its physiology, druggability, and therapeutic potential.

**Methods:** Fluorescence-based thallium flux assays were used for high-throughput screening (HTS) of small-molecule libraries for novel  $K_{ir}4.1/K_{ir}5.1$  activators. Whole-cell and cell-attached patch clamp techniques were used to characterize effects of VU0493206 on  $K_{ir}4.1/K_{ir}5.1$  channel activity. A voltage-sensitive dye was used to characterize effects of VU0493206 on mCCD<sub>cl</sub> cell membrane potential.

**Results:** We performed a HTS of 87,475 compounds for novel channel modulators, leading to the discovery of 427 inhibitors and 107 activators of heteromeric  $K_{ir}4.1/K_{ir}5.1$  channels. Here, we report the discovery and characterization of VU0493206, the first small-molecule activator of  $K_{ir}4.1/K_{ir}5.1$  channels. In whole-cell patch clamp experiments, VU0493206 activates  $K_{ir}4.1/K_{ir}5.1$ -mediated currents by approximately 600% at -120 mV with an  $EC_{50}$  of 11  $\mu$ M. Cell-attached patch clamp recordings indicates activation is mediated by an increase in single channel current amplitude and number of open channels. VU0493206 hyperpolarizes the membrane potential of mCCD<sub>cl</sub> renal epithelial cells, consistent with activation of endogenously expressed  $K_{ir}4.1/K_{ir}5.1$  channels. At doses up to 30  $\mu$ M, VU0493206 is selective for  $K_{ir}4.1/K_{ir}5.1$  over 11 other members of the  $K_{ir}$  channel family. Depletion of plasmalemmal PIP<sub>2</sub> and mutation of PIP<sub>2</sub>-binding sites on the channel prevents  $K_{ir}4.1/K_{ir}5.1$  activation by VU0493206. Heteromeric channels carrying a novel loss-of-function mutation in  $K_{ir}5.1$  (T64I) are activated by VU0493206, suggesting that some disease-causing mutations in  $K_{ir}4.1/K_{ir}5.1$  may be rescued with activators.

**Conclusions:** We anticipate that VU0493206 and other small-molecule modulators will be useful for exploring the integrative physiology and therapeutic potential of  $K_{ir}4.1/K_{ir}5.1$  heteromeric channels.

## TH-PO326

### A Role for the Adrenal Clock in Renin-Angiotensin-Aldosterone System Regulation

Annalisse R. Mckee, Hannah M. Costello, G. R. Crislip, Kityan Cheng, Alexandria Juffre, Victor M. Mendez, Lauren G. Douma, Michelle L. Gumz. University of Florida, Gainesville, FL.

**Background:** Circadian rhythms are regulated by the circadian clock and critical for most physiological functions, with disruption of these rhythms linked to adverse renal outcomes. Our lab has a particular interest in the clock protein BMAL1 as global BMAL1 knockout (KO) mice have impairment of diurnal rhythm of renal sodium (Na) handling. Although, rhythm of renal Na handling in kidney-specific BMAL1 KO mice remained intact. The adrenal hormone, aldosterone, which is stimulated by the renin-angiotensin system (RAS), has an influence on renal electrolyte handling. With limited known on the role of the adrenal clock on RAS, aldosterone, and renal excretory function, our goal was to test the hypothesis that adrenal BMAL1 is required for normal circadian rhythms of RAS and renal Na excretion.

**Methods:** AS-BMAL1 male mice and littermate controls (n=5-6) were placed in metabolic cages to assess urinary 12-hour aldosterone excretion by ELISA and renal Na rhythm by flame photometry during normal Na diet and 7 days Na depletion. Kidneys were collected from a separate cohort of mice (n=7-8 per genotype) at 6AM and 6PM on normal salt diet for isolation of RNA and then qPCR to analyze gene expression for *Renin*.

**Results:** Here, we show urinary aldosterone levels were increased with blunted night/day difference in AS-BMAL1 KO male mice under normal salt and low salt conditions compared with controls (ANOVA interaction p=0.0407). Na balance was calculated, showing a trend for a significant interaction between genotype and time (p=0.05), appearing more positive during their inactive period. Finally, there was a significant interaction between time and genotype in *Renin* gene expression (ANOVA interaction p=0.0126).

**Conclusions:** In conclusion, loss of BMAL1 in the adrenal gland resulted in altered rhythm of both *Renin* gene expression and aldosterone levels, with a trend for significant disturbance in renal Na handling. Future studies aim to look at sex differences in the RAS system in AS-BMAL1 KO mice, as only males were investigated here.

**Funding:** Private Foundation Support

## TH-PO327

**Adrenal-Specific Knockout of the Circadian Clock Protein BMAL1 Alters Kidney Clock Gene Expression**

Hannah M. Costello, Annalisse R. McKee, G. R. Crislip, Kityan Cheng, Alexandria Juffre, Lauren G. Douma, Michelle L. Gumz. *University of Florida, Gainesville, FL.*

**Background:** Circadian rhythms are internal variations in physiological function coordinated by the molecular clock, comprised of 4 core clock proteins – BMAL1, CLOCK, CRY, and PER. Our lab has an interest in how peripheral circadian clocks, including the kidney and adrenal clocks, contribute to renal function. Many renal processes exhibit a circadian rhythm, such as urine flow rate. It is known that kidney clocks contribute to its regulation, but the kidney clocks are disrupted in many animal models of kidney disease. However, little is known about how the kidney clocks tick. Previous data from the lab has shown that kidney-specific knockout (KO) of PER1 altered adrenal clock gene expression. This led to our hypothesis of adrenal-kidney clock cross talk and a role for the adrenal clock in the regulation of kidney clock expression.

**Methods:** To test this, we utilized the adrenal-specific aldosterone synthase Cre positive (AS)-BMAL1 KO mouse model. Kidneys from AS-BMAL1 KO male mice and littermate Cre negative, floxed control (CNTL) male mice ( $n=7-8/\text{genotype}$ ) were collected at 6AM and 6PM. Kidneys were separated into cortex and medulla before RNA was isolated for clock gene expression analysis using qPCR.

**Results:** Here, we show significant differences in clock gene expression in the kidney cortex but no changes in the kidney medulla of AS-BMAL1 KO compared with CNTL. There was a significant interaction between time and genotype in *Bmal1*, *Clock* and *Cry1* (ANOVA interaction  $p=0.010$ ,  $p=0.043$ , and  $p=0.024$ , respectively) in the kidney cortex. Sidak multiple comparisons showed increases in *Bmal1* ( $p=0.0070$ ) and *Cry1* ( $p=0.024$ ) at 6AM in KO animals vs. CNTL, whereas *Clock* was reduced at 6PM ( $p=0.011$ ). No genotype effects were detected in *Cry2* and *Per1* expression. There were no significant differences in clock gene expression in the kidney medulla between genotypes. All clock genes in both cortex and medulla demonstrated a significant time of day effect ( $p<0.01$ ).

**Conclusions:** BMAL1 KO in the adrenal gland has differential effects on kidney clock gene expression in a region-specific manner, with changes only in the cortex. Future work will utilize tissue-specific clock KO models to focus on whether peripheral clock cross talk contributes to regulation of renal function and how they work together in a cell-specific manner.

## TH-PO328

**Assessment of Sodium Excretion in Kidney-Specific BMAL1 Knockout Mice in Response to an Acute Salt Load**

G. R. Crislip, Hannah M. Costello, Kityan Cheng, Charles B. Drucker, I. Jeanette Lynch, Lauren G. Douma, Charles S. Wingo, Michelle L. Gumz. *University of Florida, Gainesville, FL.*

**Background:** BMAL1 is a core clock transcription factor responsible for the tissue-specific regulation of thousands of genes. Male kidney-specific BMAL1 knockout (KS-BMAL1 KO) mice exhibit lower blood pressure compared to control mice (CNTL). The goal of this study was to determine the natriuretic response to an acute salt load in the presence and absence of the sodium-potassium-chloride-cotransporter 2 (NKCC2) by inhibition with furosemide in KS-BMAL1 KO and control mice (CNTL).

**Methods:** We generated the KS-BMAL1 KO using floxed exon 8 BMAL1 mice crossed with kidney-specific cadherin Cre+ mice. These mice exhibit decreased BMAL1 expression in the thick ascending limb, distal convoluted tubule, and collecting duct cells. Floxed Cre- littermates were used as control mice (CNTL). Mice were placed in metabolic cages and fasted during their inactive period ( $N=6$ ). At the start of their active period, mice were injected with a saline bolus (1.5 mL)  $\pm$  furosemide (30 mg/kg). Urine was collected for each hour for 7 hours. Three- and two-way ANOVA were used for statistical analysis.

**Results:** There was no genotype difference in cumulative sodium excretion. Mice injected with furosemide excreted more sodium compared to saline alone (final volume in saline alone vs. furosemide; CNTL:  $0.14\pm0.01$  vs.  $0.22\pm0.02$ ; KS-BMAL1 KO:  $0.14\pm0.02$  vs.  $0.25\pm0.01$  mEq;  $P<0.0001$ ). Cumulative urinary volume exhibited the same trends. Likewise, cumulative sodium excretion rates were similar between genotypes and furosemide caused faster excretion over the course of collections.

**Conclusions:** BMAL1 does not appear to control NKCC2 activity under the conditions tested. As expected, furosemide leads to greater and quicker diuresis and natriuresis. We have shown that blood pressures difference between CNTL and KS-BMAL1 KO is amplified following potassium depletion with high salt diet. Assessing natriuresis in response to an acute salt load in mice fed a potassium depleted, high salt diet may provide additional insight.

## TH-PO329

**Claudin-10b Role in the Basolateral Infoldings of the Thick Ascending Limb**

Catarina Quintanova,<sup>1</sup> Nina Himmerkus,<sup>1</sup> Kerim Mutig,<sup>2</sup> Dominik Müller,<sup>2</sup> Tilman Breiderhoff,<sup>2</sup> Dorothee Günzel,<sup>2</sup> Markus Bleich.<sup>1,2</sup> *Christian-Albrechts-Universität zu Kiel, Kiel, Germany; <sup>2</sup>Charite Universitätsmedizin Berlin, Berlin, Germany.*

**Background:** The thick ascending limb (TAL) of the loop of Henle is responsible for salt reabsorption and thus for urine concentration. The paracellular pathway is determined by the combination of claudin expression in the tight junctions (TJ). In the TAL there is a mosaic expression of either claudin-10b or claudin-3/claudin-16/claudin-19 in a complex. Claudin-10b TJ confer a sodium ( $\text{Na}^+$ ) permeability. Remarkably, claudin-10b is also expressed extra-junctional in the infoldings of the basolateral membrane.

**Methods:** Freshly isolated single murine TAL segments of C57Bl6 and kidney specific (Ksp-Cre) Claudin-10 knockout (cKO) mice were investigated by immunofluorescence (IF) or western blot (WB). Dissected TAL were transferred into bath solution (37 °C) and microperfused under constant pressure and measured under different basolateral solutions to assess infolding accessibility by the  $\text{Na}^+/\text{K}^+$ -ATPase (NKA) inhibitor ouabain or by fluorescein. To loosen the intermembrane protein contacts, we removed calcium ( $\text{Ca}^{2+}$ ) from the basolateral bath solution.

**Results:** In single TAL segments, we performed triple staining with claudin-10, NKA and the chloride channel subunit Barttin. The localization of all proteins co-localized in the infoldings and NKA and Barttin expression were not changed in IF or WB by cKO. The relative speed of ouabain inhibition was higher in the cKO and in  $\text{Ca}^{2+}$ -free conditions. Further, we tested the diffusion of fluorescein into the infoldings. In the WT, upon re-addition of  $\text{Ca}^{2+}$  we were able to trap more fluorescein when compared to the cKO.

**Conclusions:** Claudin-10b KO has no direct influence on the expression and localization of other important basolateral transport proteins. However, the increased speed of ouabain inhibition and the decrease of fluorescein trapping in the absence of Claudin-10b and  $\text{Ca}^{2+}$ -free situations suggests a role of claudin-10b in the stabilization of the infoldings by forming a complex between neighboring invaginated membranes.

## TH-PO330

**CRISPR/Cas9-Mediated Suppression of the Focal Segmental Glomerulosclerosis Protein Actinin-4 (ACTN4) in Thick Ascending Limbs (TALs) Increases Sodium Chloride Reabsorption by Regulating NKCC2 Trafficking**

Dipak Maskey,<sup>1,2</sup> Pablo A. Ortiz,<sup>1,2</sup> <sup>1</sup>Department of Physiology, Wayne State University, Detroit, MI; <sup>2</sup>Hypertension and Vascular Research Division, Internal Medicine, Henry Ford Hospital, Detroit, MI.

**Background:** Mutations in ACTN4 are known to cause focal segmental glomerulosclerosis. However, the role of ACTN4 in nephron ion transport has not been studied. We used a proteomics screen to find interacting proteins for the  $\text{Na}/\text{K}/2\text{Cl}$  cotransporter NKCC2 in the Thick Ascending Limb (TAL) and identified ACTN4. We showed that NKCC2 levels at the apical surface are controlled by endocytosis. ACTN4 has been involved in endocytosis in other cells. Therefore, we hypothesized that ACTN4 is a part of protein complex that binds apical NKCC2 and promotes its endocytosis.

**Methods:** Adeno-associated virus (AAV)-mediated CRISPR/Cas9, Western blot, metabolic cages, Uni-nephrectomy, and Immunoprecipitation

**Results:** To study the role of ACTN4 in NKCC2 endocytosis, we developed an adeno-associated virus (AAV)-mediated CRISPR/Cas9 approach to decrease ACTN4 expression in TALs. We tested 4 gRNAs targeting ACTN4 in neuroblastoma Neuro 2a/HF-Cas9-ROSA26 cells and selected the most effective guide, which decreased ACTN4 protein expression by 70-80% ( $n=3$ ) and we packed this gRNA into AAV (AVV-U6-gRNA-ACTN4). To study the role of ACTN4 in TAL  $\text{NaCl}$  reabsorption, we uni-nephrectomized rats (right kidney removal), and a week later transduced the left kidneys with AV-pNKCC2Cas9 plus AAV-gRNA-ACTN4 or AV-pNKCC2-Cas9 alone (control). After 3 weeks, rats were placed in metabolic cages to measure bumetanide-induced natriuresis (4h) as an index of NKCC2-mediated  $\text{NaCl}$  absorption. We found that bumetanide induced  $\text{UNa}$  excretion was higher in rats transduced with Cas9-ACTN4, compared to rats transduced with Cas9 alone (Cas9 Control:  $2880\pm381$  vs Cas9-ACTN4:  $4181\pm190$   $\mu\text{mol Na}/4\text{h}$ ,  $n=5$ ,  $p<0.05$ ). Surface to total NKCC2 ratio was increased by  $30\pm5\%$  in TALs from rats transduced with Cas9-ACTN4 ( $p<0.05$ ,  $n=3$ ) whereas ACTN4 expression was  $40\pm4\%$  lower than control Cas9 rats ( $n=3$ ,  $p<0.05$ ). Recombinant ACTN4 (GST-ACTN4) or immunoprecipitation of ACTN4, pulled down NKCC2 from TAL lysates ( $n=4$ ), suggesting that ACTN4 regulates surface NKCC2 involves protein-protein interactions.

**Conclusions:** We conclude that ACTN4 binds NKCC2 to regulate its surface expression. Selective depletion of ACTN4 in TALs using CRISPR/Cas9 enhances surface NKCC2 and TAL  $\text{NaCl}$  reabsorption, indicating that regulation of the ACTN4-NKCC2 interaction is important for renal  $\text{NaCl}$  reabsorption.

## TH-PO331

**Differentiated Tubuloids to Model Human Distal Nephron (Patho) Physiology**

Carla Pou Casellas,<sup>1,2</sup> Fjodor Yousef Yengej,<sup>1,2</sup> Carola Ammerlaan,<sup>1,2</sup> Charlotte Olde Hanhof,<sup>3</sup> Emre Dilmen,<sup>3</sup> Joost Hoenderop,<sup>3</sup> Maarten B Rookmaaker,<sup>1</sup> Hans Clevers,<sup>2,1</sup> Marianne C. Verhaar.<sup>1</sup> <sup>1</sup>Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; <sup>2</sup>Hubrecht Institute, Utrecht, Netherlands; <sup>3</sup>Radboudumc, Nijmegen, Netherlands.

**Background:** The distal nephron segments are essential for electrolyte, acid-base and volume homeostasis. Tubuloid culture allows ample expansion (exp) of primary human renal epithelium from urine or tissue. Here we differentiate tubuloids into thick ascending limb of Henle (TAL) and principal cells (PC), characterize these at mRNA, protein and functional levels, and establish an *in vitro* human lithium (Li<sup>+</sup>) tubulopathy model.

**Methods:** Tubuloids were grown from kidney tissue of 4 donors in exp medium. After differentiation (diff) for 7 days, tubuloids were studied by qPCR, single cell RNA sequencing (scSeq) and immunofluorescence (IF)/-histochemistry (IHC). ScSeq data was compared with human kidney tissue. Electrolyte transport was tested using the FluxOR™ II assay. Diff tubuloids were exposed to 10 mM Li<sup>+</sup> or Na<sup>+</sup> (control) and analyzed by the same techniques.

**Results:** Diff increased transcription of NKCC2 in the TAL (1269-fold, P<0.05), NCC (39-fold, P<0.05) in the distal convoluted tubule (DCT), and ENaCa (8-fold, P<0.05) and AQP2 (569-fold, P=0.06) in PC (n=4). Tubuloids in exp consisted of proliferative progenitors, whereas diff produced TAL and PC, with some DCT cells (n>3.000 cells/sample). Diff reduced progenitor markers and upregulated clinically relevant genes (e.g. NKCC2, ROMK, ENaC, AQP2, Na/K-ATPase, HNF1β, CAII) to levels reflecting tissue counterparts. IF/IHC confirmed polarized NKCC2, AQP2 and AQP3 protein expression. Luminal NKCC2 demonstrated furosemide-inhibitable Tl<sup>+</sup> (replacing K<sup>+</sup>) uptake (n=3). Apical Li<sup>+</sup> treatment suppressed AQP2 and upregulated the intercalated cell marker Pendrin, in contrast to Na<sup>+</sup> or basolateral Li<sup>+</sup>. Li<sup>+</sup> also upregulated proliferation, pro-inflammatory and tumor-associated genes. In addition, Li<sup>+</sup> effects observed only in animal studies were seen, including downregulation of NKCC2, which was confirmed by IF and functional assays.

**Conclusions:** Tubuloid diff produces TAL and PC that resemble *in vivo* counterparts. TAL cells demonstrated electrolyte reabsorption, their main function. Treatment with Li<sup>+</sup> caused changes in line with diabetes insipidus, tubulointerstitial nephritis and tumors seen *in vivo*. Taken together, differentiated tubuloids enable modeling of the human distal nephron in health and disease.

**Funding:** Government Support - Non-U.S.

## TH-PO332

**Proteomic Characterization and Plasticity of Human Collecting Duct Principal and Intercalated-Like Cells Derived From Pluripotent Stem Cell-Derived Ureteric Bud Organoids**

Mohammad Zarei,<sup>1,4</sup> Kyle McCracken,<sup>2,4</sup> Ankit B. Patel,<sup>1,4</sup> Dennis Brown,<sup>3,4</sup> Amity F. Eaton,<sup>3,4</sup> Robyn J. Eisert,<sup>4</sup> Marian Kalocsay,<sup>4</sup> Joseph V. Bonventre.<sup>1,4</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Boston Children's Hospital, Boston, MA; <sup>3</sup>Massachusetts General Hospital, Boston, MA; <sup>4</sup>Harvard Medical School, Boston, MA.

**Background:** Using a new protocol to create human ureteric bud organoids we have developed a human collecting duct (hCD) principal cell (hPC) line from ureteric bud organoids differentiated from human pluripotent stem cells. hPC cells form a mitochondria-rich cuboidal epithelium that generates a high transepithelial resistance and ENaC-dependent transepithelial potential (TEP) when grown on transwell filters.

**Methods:** The hCD cells, including a cell line with stably integrated lentivirus to permit doxycycline-inducible FoxI1 expression were grown under standard conditions and on transwell filters. Tandem-Mass Tag (TMT) Mass Spectroscopy was performed on cells treated with various hormones +/- antagonists for 24 h and compared with untreated controls.

**Results:** EM revealed a mitochondrial-rich cuboidal hPC epithelium with small apical microvilli. Amiloride-sensitive TEP was responsive to aldosterone, dexamethasone, hydrocortisone, and vasopressin, and these hormones induced partially overlapping but distinct changes in the proteome. The mineralocorticoid antagonists finerenone and spironolactone both decreased the aldosterone-stimulated TEP but showed some differential effects on the proteome. Finerenone and spironolactone decreased the aldosterone-activated amiloride-sensitive TEP. Sixteen different conditions were evaluated, and principal component analysis revealed very good reproducibility of duplicates and good separation of conditions. Conversion of hPCs to intercalated-like cells (hICs) with FoxI1 was associated with the induction of certain carbonic anhydrase isoforms and multiple V-type H<sup>+</sup>-ATPase subunits (ATP6 [V1] A, B1, D, E1, F, G1, H) and [V0] A4, D2)). Expression of ATP6V1B1 and ATP6V0A4 confirmed by immunofluorescence.

**Conclusions:** hCD cells exhibit functional and proteomic responsiveness to both glucocorticoid and mineralocorticoid hormone signaling, which induce distinct and overlapping changes in protein expression. The transcription factor FoxI1 is sufficient to induce expression of V-type H<sup>+</sup>-ATPase subunits to drive the acid secretory phenotype.

## TH-PO333

**Claudin-19 Expression in the Thick Ascending Limb Is Required for Tight Junctional Localization of Claudin-16**

Caroline Prot-Bertoye,<sup>1,2</sup> Camille Griveau,<sup>1</sup> Wung-Man Evelyn Ling,<sup>1</sup> Gaëlle Brideau,<sup>1</sup> Lydie Cheval,<sup>1</sup> Henrik Dimke,<sup>3,4</sup> Pascal Houillier.<sup>1,2</sup> <sup>1</sup>Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université Paris Cité, CNRS ERL 8228 - Laboratoire de Physiologie Rénale et Tubulopathies, Paris, France; <sup>2</sup>APHP, Hôpital Européen Georges Pompidou, Service de Physiologie, Paris, France; <sup>3</sup>Department of Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark; <sup>4</sup>Department of Nephrology, Odense University Hospital, Odense, Denmark.

**Background:** The kidney plays a key role in mineral homeostasis. Paracellular calcium and magnesium reabsorption in the renal thick ascending limb (TAL) involves claudin (CLDN) 16 and CLDN19: accordingly, pathogenic variants in both gene cause Familial Hypomagnesemia with Hypercalciuria and Nephrocalcinosis (FHHNC) with severe renal calcium and magnesium wasting. In the TAL, the expression pattern of claudins at the tight junction is mosaic: tight junctions express either CLDN16/CLDN19 or CLDN10b. CLDN16 deficiency decreases paracellular permeability to calcium and magnesium and CLDN10 deficiency decreases paracellular sodium to chloride permeability ratio. However, the function of CLDN19 *in vivo* remains uncertain; whether CLDN19 alters CLDN16 or CLDN10 localization *in vivo* is unknown.

**Methods:** We determined the localization of CLDN19 in sections of frozen and paraffin embedded kidney from wild-type and *Cldn19* deficient mice using antibodies directed against the protein and examined the role of *Cldn19* deletion on CLDN16 and CLDN10 localization.

**Results:** CLDN19 localizes to the TAL, where it is expressed in basolateral membrane domains in the outer medulla and the cortex; its expression at the tight junction of TALs is restricted to the outer stripe of outer medulla and cortex, where it colocalizes with CLDN16. In TALs from *Cldn19* deficient mice, CLDN16 is expressed in basolateral membrane domains but not at the tight junction. In contrast, *Cldn19* deletion does not alter CLDN10 localization.

**Conclusions:** *In vivo*, the CLDN19 protein is required for the proper CLDN16 expression at the tight junction. This finding gives a molecular explanation to the shared renal phenotypic characteristics of FHHNC caused by either CLDN16 or CLDN19 variants.

## TH-PO334

**Sodium Magnetic Resonance Imaging Shows Impairment of the Counter-Current Multiplication System in the Diabetic Model Mice Kidney**

Yusuke Nakagawa,<sup>1</sup> Ryohei Kaseda,<sup>1</sup> Yuya Suzuki,<sup>1</sup> Yasuhiko Terada,<sup>2</sup> Tomoyuki Haishi,<sup>3,4</sup> Susumu Sasaki,<sup>1</sup> Ichiei Narita.<sup>1</sup> <sup>1</sup>Niigata University, Niigata, Japan; <sup>2</sup>Tsukuba University, Tsukuba, Japan; <sup>3</sup>International University of Health and Welfare, Narita, Japan; <sup>4</sup>MRTechnology Inc., Tsukuba, Japan.

**Background:** Sodium Magnetic Resonance Imaging (<sup>23</sup>Na-MRI) is a technique for imaging <sup>23</sup>Na. It is possible to non-invasively assess sodium distributions, especially sodium concentration in the counter-current multiplication system in the kidney, which forms a sodium concentration gradient from the cortex to the medulla, enabling efficient water reabsorption. Although knowledge regarding the mechanisms of sodium reabsorption through channels or transporters has been accumulated, the distribution of the sodium concentration in the entire kidney has not been delineated in kidney diseases. Applying <sup>23</sup>Na-MRI to disease model mice may expand the scope of prior studies and elucidate the pathogenesis of sodium gradient impairments. We investigated whether <sup>23</sup>Na-MRI can detect changes in sodium concentrations under normal conditions in mice and in disease models such as a mouse model with diabetes mellitus.

**Methods:** <sup>23</sup>Na-MRI was performed with a 9.4T vertical standard-bore superconducting magnet using C57BL/6Jcl administered of furosemide (10 mg/kg BW), BKS.Cg-Lepr<sup>db</sup>/+ Lepr<sup>db</sup>/Jcl (db/db) mice and its corresponding control BKS.Cg-m/+m/Jcl (m+/m+) mice. The sodium gradient of the kidney between the cortex and medulla was compared.

**Results:** The corticomedullary sodium gradient of the kidney significantly decreased 20 min after administration of furosemide, an NKCC2 inhibitor involved in the formation of the counter-current multiplication system (pre-1.53±0.16, post-2.19±0.3, P<0.05, N=7). The signal intensity of the medullary region in the kidney was lower in db/db mice (db/db 209.6±42.4 mmol/L, m+/m+ 333.5±54.4 mmol/L, P<0.01, N=7 each) and the corticomedullary sodium gradient of db/db mice was significantly decreased compared to m+/m+ mice (db/db 1.64±0.36, m+/m+ 2.28±0.21, P<0.01).

**Conclusions:** <sup>23</sup>Na-MRI revealed reductions in the corticomedullary sodium gradients and impairment in the counter-current multiplication system in db/db mice at very early stages of diabetes mellitus. <sup>23</sup>Na-MRI may be useful for diagnosing diabetic kidney disease and elucidating the pathogenesis of sodium gradient impairments.

## TH-PO335

**Activation of PDK1/RSK Results in Aquaporin-2 S256 Phosphorylation and Membrane Accumulation After Downregulation of EGFR Signaling**

Richard S. Babicz, Pui Susan W. Cheung, Richard Bouley, Noah Baylor, Dennis Brown. Program in Membrane Biology *Massachusetts General Hospital, Boston, MA.*

**Background:** Vasopressin (VP) activates PKA, resulting in phosphorylation and membrane accumulation of AQP2. Epidermal growth factor receptor (EGFR) inhibition with erlotinib also induces AQP2 membrane trafficking with a phosphorylation pattern similar to VP, but without increasing PKA activity. Here, we identified the novel kinase pathway(s) that are activated when EGFR signaling is inhibited.

**Methods:** We used several inhibitors that block EGFR signaling to identify which pathway inhibited erlotinib-induced AQP2 membrane accumulation in LLC-PK1 cells, and rat kidney slices. We incubated purified GST-AQP2 c-terminus with recombinant kinase and 10uCi (Y32P) ATP using PKA as a positive control and our purified kinase target (RSK). Inhibitors of PKA and RSK and purified GST-AQP2 S256A c-terminus were negative controls. RSK phosphorylated AQP2 at S256, and we asked if the intermediate kinase PDK-1 stimulated RSK activity and AQP2 phosphorylation by western blotting, and membrane accumulation by immunocytochemistry.

**Results:** Inhibiting 90 kDa ribosomal S6 kinase (RSK) significantly reduced erlotinib-induced S256 phosphorylation. Upon blocking or knocking down RSK, erlotinib no longer induced AQP2 membrane accumulation. In rat kidneys, RSK was expressed in medullary principal cells. Erlotinib did not induce AQP2 membrane accumulation when cells/tissues were pre-treated with the RSK inhibitor, BI-D1870. Using purified proteins, RSK directly phosphorylated WT- but not S256A-AQP2, similar to PKA. We conclude that RSK phosphorylates AQP2 at S256 upon EGFR inhibition by erlotinib. RSK is activated by phosphorylation of a critical S221 residue by the intermediate kinase PDK-1. Incubation of cells/tissues with PS210, a direct activator of PDK-1, caused a significant increase in both RSK S221 and AQP2 S256 phosphorylation, and plasma membrane accumulation of AQP2.

**Conclusions:** Activation of PDK1/RSK upon erlotinib exposure is a key step in stimulating AQP2 membrane accumulation via direct RSK-mediated phosphorylation of the critical S256 C-terminal residue. This represents a novel, VP-independent pathway by which collecting duct water permeability could be modulated.

**Funding:** NIDDK Support

## TH-PO336

**Using CRISPR-Cas9/Phosphoproteomics to Identify Kinase Substrates: Calcium/Calmodulin-Dependent Protein Kinase 2δ**

Euijung Park, Chin-Rang Yang, Lihe Chen, Viswanathan Raghuram, M. A. Knepper. *National Heart Lung and Blood Institute, Bethesda, MD.*

**Background:** Arginine vasopressin (AVP) plays a critical role in the regulation of water permeability in renal collecting duct (CD) cells via the V2 vasopressin receptor, which triggers a rise of intracellular cAMP and Ca<sup>2+</sup>. Ca<sup>2+</sup> stimulates a wide range of cellular processes including actin cytoskeleton rearrangement, in part through Ca<sup>2+</sup>/CaM-dependent signaling. One potential target, strongly expressed in CD cells, is Ca<sup>2+</sup>/CaM-dependent protein kinase 2δ (Camk2δ). Here, we deleted Camk2δ in mpkCCD cells and carried out phosphoproteomics to identify Camk2δ target proteins.

**Methods:** Using two different gRNAs which target the Camk2δ kinase domain, CRISPR/Cas9-mediated Camk2δ knock-out cell lines were created. We carried out large-scale proteomic and phosphoproteomic analysis in the presence of dDAVP, (V2 selective AVP analog, 0.1 nM, 30 min) using TMT quantification versus wild-type cells to identify direct targets of Camk2δ.

**Results:** The quantitative phosphoproteomics revealed that, of the 11570 phosphopeptides quantified, 78 were significantly increased and 60 were decreased. Of the 60 downregulated sites, *Tpd52* were previously identified as Camk2δ targets in existing literature, but 59 of the identified sites are novel. Motif analysis of the decreased phosphorylation sites revealed a novel target preference of -(R/K)-X-X-p(S/T)-X-D- where R,K,S,T and D are standard single letter amino acid codes, X means "any amino acid" and p indicates the phosphorylated amino acid. *Gene Ontology (GO)* analysis identified that Camk2δ-mediated protein phosphorylation is likely to be involved in regulation of actin polymerization as well as chromatin organization. In standard proteomics (n=5198), 23 proteins significantly increased and 24 were decreased. *GO* term analysis mapped the regulated proteins to chromatin organization and histone modification, consistent with the phosphoproteomic data.

**Conclusions:** We identified multiple novel Camk2δ phosphorylation targets that have potential roles in vasopressin's action to regulate water transport in the renal collecting duct, especially with regard to Ca<sup>2+</sup>/CaM-dependent regulation of the actin cytoskeleton and chromatin organization. The large increase in the number of recognized phosphorylation targets allowed identification of a new target sequence preference motif for Camk2δ.

## TH-PO337

**The Long-Term Effect of Vasopressin on Transcriptome and DNA Accessibility in Cortical Collecting Duct**

Hiroaki Kikuchi,<sup>1</sup> Lihe Chen,<sup>1</sup> Hyun Jun Jung,<sup>2</sup> Euijung Park,<sup>1</sup> Mark A. Knepper.<sup>1</sup> Epithelial Systems Biology Laboratory, Systems Biology Center <sup>1</sup>National Institutes of Health, Bethesda, MD; <sup>2</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Vasopressin binds to V2 receptors in collecting duct principal cells triggering protein kinase A (PKA) –dependent signaling and increased expression of the *Aqp2* gene. Vasopressin signaling is important not only for *Aqp2* transcription, but also for cyst genesis in autosomal dominant polycystic kidney disease (ADPKD), which is one of the world's most common inherited life-threatening conditions. However, signaling pathways responsible for long-term vasopressin action in native renal collecting duct cells are incompletely understood.

**Methods:** Experiments were done in mice undergoing administration of vehicle (Veh) or vasopressin analog, desmopressin (dDAVP) by osmotic minipumps (2 ng/hour, 5days) without water restriction (n=4 mice for each group). Spot urine samples were collected on each day until day 5 and the urine osmolality was monitored. RNA-seq transcriptomics and ATAC-seq- based DNA accessibility assessment were carried out in microdissected cortical collecting ducts (CDs).

**Results:** Spot urine osmolality was significantly increased by 5 day dDAVP treatment compared to Veh treatment (3063 ± 323, 2243 ± 354 mosm/kg, respectively). Single tubule RNA-seq of CCDs showed that there were 485 genes that were increased (Padj less than 0.05 and log2 dDAVP/Veh greater than 0.50) and 2317 transcripts that were decreased (Padj less than 0.05 and log2 dDAVP/Veh less than -0.50) out of a total of 12,653 transcripts with TPM values greater than 1. *Aqp2* mRNA abundance was increased by 140% in the cortical CD by dDAVP. *Aqp3* was also significantly increased by 90 %. In contrast to dDAVP effects in cultured mpkCCD cells, cell cycle-related transcript such as *Cdk1*, *E2f1* and *Mki67* were highly upregulated by dDAVP (dDAVP:Veh ratio=10.30, 5.76 and 5.03). Motif analysis (HOMER) of sequences corresponding to ATAC-seq peaks significantly upregulated by dDAVP, revealed binding site motifs corresponding to Ets-Family, Klf-Family and E2f-family transcription factors.

**Conclusions:** Long-term infusion of dDAVP is associated with gene expression changes consistent with cellular proliferative effects in native mouse CDs, which could be due to either a direct or an indirect action of dDAVP. Future studies will examine the molecular mechanisms involved and a possible connection to the role of V2 receptors in the development and/or progression of ADPKD.

## TH-PO338

**The Role of Poly (ADP-Ribose) Polymerase 1 in Vasopressin-Mediated AQP2 Expression**

Hyo-Ju Jang,<sup>1</sup> Euijung Park,<sup>2</sup> Hyun Jun Jung,<sup>3</sup> Tae-Hwan Kwon.<sup>1</sup> <sup>1</sup>Kyungpook National University School of Medicine, Daegu, Republic of Korea; <sup>2</sup>National Institutes of Health, Bethesda, MD; <sup>3</sup>Johns Hopkins University School of Medicine, Baltimore, MD.

**Background:** Poly(ADP-ribose)ylation (PARylation) mediated by poly(ADP-ribose) polymerases (PARPs), catalyzes the transfer of ADP-ribose from NAD<sup>+</sup> molecules to acceptor proteins. We previously demonstrated that tankyrase, one of PARPs family, regulates AQP2 expression via β-catenin-mediated transcription. We aimed to examine the role of PARP1, the most abundant protein in the PARPs family, in the AQP2 regulation.

**Methods:** 1) immunoblotting for PARP1 in mpkCCDc14 cells; 2) pull-down assay of biotin-conjugated NAD<sup>+</sup> and immunoprecipitation (IP) assay using poly(ADP-ribose) (PAR) antibody; 3) qRT-PCR and immunoblotting for AQP2; and 4) bioinformatics for elucidating PARP1 substrates and interacting proteins in kidney collecting duct (CD) cells.

**Results:** Immunoblots showed that PARP1 cleavage (both 89 kDa and 25 kDa) was induced by dDAVP (10<sup>-9</sup> M) treatment in whole cell lysate, nuclear, and cytoplasm extracts of mpkCCDc14 cells, respectively. dDAVP (10<sup>-9</sup> M, 24 h) increased the abundance of total PARylated proteins in biotin-NAD<sup>+</sup> pull-down and IP assays of PAR in mpkCCDc14 cells. dDAVP-induced AQP2 mRNA and protein expression was significantly attenuated in mpkCCDc14 cells with siRNA-mediated PARP1 knockdown. Since PARP1 cleavage induced by dDAVP was not affected despite PARP1 knockdown, PARP1 cleavage is unlikely to be involved in AQP2 regulation. In contrast to PARP1 knockdown, inhibition of PARP1 activity by PARP inhibitor (PJ34) did not affect dDAVP-induced AQP2 mRNA and protein upregulation, suggesting that PARylation mediated by PARP1 was not involved in AQP2 regulation. Bioinformatics study revealed 408 proteins interacting with PARP1 and 763 substrates proteins of PARP1 in the kidney CD cells. Among them, 604 proteins were mapped on the vasopressin V2 receptor (V2R) signaling pathway. β-catenin, which is phosphorylated (S552) by dDAVP, was identified as the PARP1 interacting protein mapped on the V2R signaling. Immunoblotting demonstrated that dDAVP-induced pS552-β-catenin expression in the whole cell lysate as well as nucleus in mpkCCDc14 cells was significantly attenuated in the presence of PARP1 knockdown.

**Conclusions:** PARP1 plays a role in vasopressin-mediated AQP2 regulation via β-catenin, as the vasopressin-responsive interacting protein of PARP1, but unlikely through the PARylation of proteins and/or PARP1 cleavage in the kidney CD cells.

**Funding:** Government Support - Non-U.S.

## TH-PO339

**LRBA Is Essential for Urinary Concentration and Body Water Homeostasis**  
 Yu Hara,<sup>1</sup> Fumiaki Ando,<sup>1</sup> Daisuke Oikawa,<sup>3</sup> Koichiro Ichimura,<sup>2</sup> Tamami Fujiki,<sup>1</sup> Shintaro Mandai,<sup>1</sup> Takayasu Mori,<sup>1</sup> Koichiro Susa,<sup>1</sup> Eisei Sohara,<sup>1</sup> Tatemitsu Rai,<sup>1</sup> Fuminori Tokunaga,<sup>3</sup> Shinichi Uchida,<sup>1</sup> <sup>1</sup>*Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan;* <sup>2</sup>*Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan;* <sup>3</sup>*Osaka Koritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osaka, Japan.*

**Background:** Protein kinase A (PKA) directly phosphorylates aquaporin-2 (AQP2) water channels in renal collecting ducts to reabsorb water from urine for the maintenance of systemic water homeostasis. Over 50 functionally distinct PKA-anchoring proteins (AKAPs) respectively create compartmentalized PKA signaling to determine the substrate specificity of PKA. Identification of an AKAP responsible for AQP2 phosphorylation is an essential step toward elucidating the molecular mechanisms of urinary concentration.

**Methods:** PKA activation by several compounds is a novel screening strategy to uncover PKA substrates whose phosphorylation levels were well correlated with that of AQP2. The leading candidate in this assay proved to be an AKAP termed lipopolysaccharide-responsive and beige-like anchor protein (LRBA). We generated *Lrba* knockout mice to examine pathophysiological roles of LRBA.

**Results:** LRBA colocalized with AQP2 at the same intracellular vesicles in the subapical region of renal collecting ducts. AQP2 phosphorylation at S256 and S269 via vasopressin / cAMP / PKA signaling was severely impaired in *Lrba* knockout mice, leading to the defective AQP2 trafficking to the apical plasma membrane. *Lrba* knockout mice showed water diuresis and subsequent compensatory increase in serum vasopressin levels. Urine osmolality did not elevate even by the administration of exogenous vasopressin. Most of the PKA substrates other than AQP2 were adequately phosphorylated by PKA in the absence of LRBA, demonstrating that LRBA-anchored PKA preferentially phosphorylated AQP2 in renal collecting ducts.

**Conclusions:** LRBA is the first PKA-anchoring protein discovered to be crucial for PKA-induced AQP2 phosphorylation and urinary concentration.

**Funding:** Government Support - Non-U.S.

## TH-PO340

**Insulin-Regulated Aminoamidase Is Required for Appropriate Dilution of Urine After Acute Hypotonic Stress**

Yvonne Zuchowski, Andrew S. Terker, Raymond C. Harris, Juan Pablo Arroyo Ornelas. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Vasopressin is a peptide hormone that regulates water balance and acts on the type 2 vasopressin receptor (V2R) to stimulate water reabsorption in the kidney via the water channel aquaporin-2 (AQP2). The insulin-regulated aminoamidase (IRAP) is a zinc-dependent aminoamidase that degrades vasopressin. However, the impact of IRAP KO on water balance is unknown.

**Methods:** Adult (8-12 week) IRAP wildtype (WT) and KO male mice were used for experimentation (4-6/group). Immunofluorescence and immunoblotting were performed on kidneys at baseline to localize IRAP and assess AQP2 protein amount. Urine and plasma electrolytes were measured before and after water load (1ml sterile water/IP) or 24hr water restriction. Urine osmolality was measured in IRAP KO before and after administration of the V2R antagonist, OPC 31260 (10mg/kg/IP).

**Results:** IRAP was expressed in the glomerulus, the loop of Henle, and the collecting tubules. At baseline, IRAP KO mice had increased urine osmolality (1995 vs 781 p<0.01 mOsm/L) and elevated copeptin (110 vs 53 p<0.05 pg/ml), but total AQP2 protein expression (1.10 vs. 1.00 p=NS) was not different between WT and KO mice. After 24hr water restriction, urine osmolality increased in both WT (781 to 3626 mOsm/L p<0.0001) and KO mice (1995 to 4200 mOsm/L p<0.001), but there were no differences between groups. However, after acute water load, urine osmolality in WT mice decreased (987 vs 380 mOsm/L p<0.05) but not in IRAP KO mice (3280 vs 2801 mOsm/L p=NS). Treatment with OPC31260 decreased urine osmolality in IRAP KO mice (221 vs 1067 p<0.05). Additionally, serum sodium levels after water load were lower in IRAP KO compared to WT (127 vs 133 mEq/L p<0.05).

**Conclusions:** At baseline, IRAP KO mice have higher urine tonicity and higher copeptin than WT mice. Urine osmolality is similar between groups after 24hr water restriction suggesting normal concentrating ability. However, IRAP KO mice are unable to dilute their urine in response to an acute water load. Treatment with a V2R antagonist decreased urine osmolality in IRAP KO, suggesting that persistent V2R activation contributes to the baseline elevated urine osmolality in IRAP KO mice.

**Funding:** NIDDK Support, Private Foundation Support

## TH-PO341

**Tight Junction Component-Encoding Gene Regulation in Renal Collecting Duct Principal Cells**

Shuang Cao,<sup>1,2</sup> Janna Leiz,<sup>1</sup> Christian Hinze,<sup>1,2</sup> Kai M. Schmidt-Ott,<sup>1,2</sup> <sup>1</sup>*Charité Universitätsmedizin Berlin, Berlin, Germany;* <sup>2</sup>*Max Delbrück Center, Berlin, Germany.*

**Background:** Tight junctions mediate epithelial barrier characteristics and paracellular transport. In renal collecting ducts, the molecular composition of tight junctions is important for the renal regulation of osmolality and electrolyte balance. It is incompletely understood how gene regulatory networks in collecting duct principal cells control tight junction component-encoding gene expression.

**Methods:** We conducted bioinformatic predictions based on mouse and human single-nuclei sequencing data sets and performed in situ hybridization on mouse kidney sections and CRISPRi-based knockdown experiments in inner medullary collecting duct (IMCD3) cells.

**Results:** Renal single-cell regulatory network prediction based on coregulation and motif enrichment identified a series of candidate collecting duct principal cell transcription factors predicted to be important for tight junction-encoding gene regulation, which included the transcription factor Ets homologous factor (Ehf). In situ hybridization validated co-expression of Ehf and its predicted target claudin 7 (Cldn7) in mouse collecting ducts *in vivo*. *In vitro* CRISPRi-mediated knockdown of Ehf in IMCD3 cells was successfully achieved and its effects on tight junction component-encoding gene expression are currently being evaluated.

**Conclusions:** Preliminary data suggest that the transcription factor Ehf regulates tight junction component-encoding genes in collecting duct principal cells.

**Funding:** Government Support - Non-U.S.

In situ hybridization validate co-expression of Ehf and Cldn7

Ehf knockdown show the mRNA level change of TJs

## TH-PO342

**Regulation of Glomerulotubular Balance IV: Implication of Aquaporin 1 in Flow-Dependent Proximal Tubule Transport and Cell Volume**

Zhaopeng Du,<sup>1</sup> Qingshang Yan,<sup>1</sup> Alan M. Weinstein,<sup>2</sup> Tong Wang,<sup>1</sup> <sup>1</sup>*Yale School of Medicine, New Haven, CT;* <sup>2</sup>*Weill Medical College of Cornell University, New York, NY.*

**Background:** In proximal tubule (PT), glomerulotubular balance (GTB) derives from the impact of axial flow to regulate Na<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> transport by modulating luminal membrane NHE3 and H-ATPase activity with little change of cell volume. The water channel, aquaporin-1 (AQP-1) is the principal water pathway for isotonic water absorption in the kidney proximal tubule.

**Methods:** We investigated flow-mediated fluid (J<sub>v</sub>) and HCO<sub>3</sub><sup>-</sup> (J<sub>HCO3</sub>) absorption in proximal tubules (S<sub>1</sub>) of mouse kidney by microperfusion *in vitro* in wild-type (WT) and AQP-1 KO mice. The PTs (S<sub>2</sub>) were isolated and perfused *in vitro* under low (5nl/min) and high (20nl/min) perfusion rates and the J<sub>v</sub> and J<sub>HCO3</sub> were measured. The experiments were simulated in an adaptation of a mathematical model of rat PT.

**Results:** An increase in perfusion rate from 5 to 20 nl/min increased  $J_v$  by 73% and  $J_{HCO_3^-}$  by 106% in proximal tubules of WT mice. AQP-1 knockout significantly decreased  $J_v$  by 28% and 72% at low and high flow rates respectively compared with WT control. In contrast, the  $J_{HCO_3^-}$  was not reduced at either low or high flow rates. The fractional increase in  $J_v$  by flow was completely abolished, but fractional increase in  $J_{HCO_3^-}$  was not reduced by AQP-1 KO. The cell volume showed no significant difference at either low or high flow rates or between WT and AQP-1 KO mice. In addition, renal clearance experiments showed significantly higher urine flow in KO mouse but there was no significant difference in either  $Na^+$  and  $K^+$  excretion or  $HCO_3^-$  excretion. The acid-base parameters of blood pH,  $PCO_2$ ,  $HCO_3^-$  and urine pH were the same in both WT and KO mouse. In model calculations, tubules whose tight junction (TJ) Pf was that assigned to rat TJ, showed no difference in  $J_v$  between WT and KO; whereas TJ Pf set to 25% of rat, predicted  $J_v$  concordant with our observations from AQP1 KO.

**Conclusions:** These results affirm the dominance of AQP-1 in mediating isotonic water absorption by mouse PT and demonstrate that flow-stimulated  $HCO_3^-$  reabsorption is intact and independent of AQP-1. With reference to the model, the findings also suggest that tight junctional water flux in proximal tubule is less prominent in mouse than in rat kidney.

## TH-PO343

### TAZ Regulates the Vasopressin-Induced AQP2 Trafficking and Protein Expression in Kidney Collecting Duct Cells

Hong Seok Choi, Hyo-Ju Jang, Tae-Hwan Kwon. *Kyungpook National University School of Medicine, Daegu, Republic of Korea.*

**Background:** Aquaporin-2 (AQP2) is the vasopressin-regulated water channel protein in the kidney collecting duct (CD) cells. Transcriptional coactivator with PDZ-binding motif (TAZ) is a downstream effector of the hippo signaling pathway. TAZ regulates the expression of target genes by acting as a transcription cofactor and acts as a mechanotransducer that detects various cell responses. Since TAZ is known to regulate the activity of Tonically-Responsive Enhancer Binding Protein (TonEBP), a transcription factor of AQP2, and to affect the arrangement of the cytoskeleton, we aimed to study the role of TAZ in the vasopressin-induced AQP2 trafficking and protein abundance.

**Methods:** 1) siRNA-mediated knockdown of TAZ in mpkCCDc14 cells; 2) immunocytochemistry of AQP2; 3) qRT-PCR and semiquantitative immunoblotting of AQP2.

**Results:** To induce AQP2 expression in mpkCCDc14 cells, cells were pretreated with dDAVP ( $10^{-9}$ M) for 48 h, and dDAVP stimulation was withdrawn for the next 6 h for the experiments. When the cells were treated again with dDAVP ( $10^{-9}$ M) for 15 and 30 min, AQP2 was translocated to the cell membrane. In contrast, the AQP2 trafficking was markedly attenuated, and it was mainly observed in the cytoplasm in the cells with siRNA-mediated TAZ knockdown (TAZ-KD). Phalloidin staining demonstrated that stress fiber formation was markedly enhanced in the TAZ-KD, suggesting that excessive stress fiber formation is likely to inhibit AQP2 trafficking. To study the changes of AQP2 mRNA and protein abundance, cells were treated with dDAVP ( $10^{-9}$  M) for 12 h. In the control mpkCCDc14 cells, dDAVP induced AQP2 mRNA ( $3,575 \pm 477\%$  of the control) and AQP protein ( $270 \pm 18\%$ ). In contrast, the dDAVP-induced increase of AQP2 mRNA ( $50 \pm 5\%$  of the control) and protein abundance ( $99 \pm 17\%$ ) was not observed in TAZ-KD. In addition, to avoid the effects of dDAVP pretreatment, cells were stimulated with dDAVP ( $10^{-9}$ M, 24 h) without the periods of pretreatment and withdrawal. Semiquantitative immunoblotting revealed that dDAVP increased AQP2 protein abundance in the control, whereas it was not observed in TAZ-KD. TonEBP was significantly decreased ( $52 \pm 4\%$ ) in TAZ KD.

**Conclusions:** TAZ knockdown is associated with an inhibition in AQP2 trafficking, at least partly, due to an excessive stress fiber formation, and downregulation of AQP2, possibly via decreased TonEBP expression.

## TH-PO344

### Tamoxifen Affects Regulation and Localization of AQP3 and AQP4 in Response to Lithium-Induced Nephrogenic Diabetes Insipidus and Unilateral Ureteral Obstruction in Rats

Stine Julie Tingskov,<sup>1</sup> Mariagrazia D'Agostino,<sup>2</sup> Frédéric H. Login,<sup>1</sup> Lene N. Nejsum,<sup>1</sup> Rikke Norregaard.<sup>1</sup> The Nørregaard Lab <sup>1</sup>Aarhus Universitet, Aarhus, Denmark; <sup>2</sup>Universita degli Studi di Bari Aldo Moro, Bari, Italy.

**Background:** Estrogen is known to play a role in the regulation of water homeostasis, and it has been shown that estrogen affects AQP2 expression. Previously, we have demonstrated that the selective estrogen receptor modulator, tamoxifen (TAM) regulates AQP2 in different animal models, namely the lithium-induced nephrogenic diabetes insipidus (NDI) model and the unilateral ureteral obstruction (UUO) CKD model. AQP3 and AQP4 are also affected in response to NDI and UUO. However, it is not known whether TAM influences AQP3 and AQP4 levels and cellular localization.

**Methods:** In the first model rats were treated for 14 days with lithium to induce NDI and TAM treatment (25 and 50 mg/kg by oral gavage) was initiated one week after onset of lithium administration. For the second model rats were subjected to 7 days of UUO. Tamoxifen (50 mg/kg) was given 5 days before the operation and was continued for 7 days after UUO. Levels and cellular localization of AQP3 and AQP4 were evaluated by immunohistochemistry and western blot analysis. To study the intracellular localization and trafficking of AQP3, Madin-Darby Canine Kidney (MDCK) cells stably expressing AQP3 (AQP3-EGFP) were treated with either LiCl or TGF- $\beta$  alone or combined to TAM.

**Results:** Western blot analysis showed that lithium treatment decreased AQP3 total protein levels, which was not significantly affected by TAM. However, TAM affects AQP3 localization to be more lateral in lithium-treated rats. After UUO, AQP3 and AQP4 protein levels were reduced, which was attenuated by TAM. Immunohistochemistry analysis confirmed these results. In AQP3-MDCK cells, AQP3 localized mainly within the cytoplasm after LiCl and TGF- $\beta$  treatment. In the presence of TAM, AQP3 seems to relocalize into the plasma membrane.

**Conclusions:** These findings indicate that TAM affects the localization of AQP3 in Li-exposed rats and MDCK cells. TAM also prevents downregulation of inner medullary AQP3 and AQP4 in UUO rats. Therefore, TAM might have a therapeutic potential in obstruction-associated dysregulation of fluid metabolisms.

## TH-PO345

### Nephrogenic Diabetes Insipidus a Rare Complication of Renal Tubular Acidosis

Alexandra Rosario Aulet,<sup>1,2</sup> Adrián A. Miró C6,<sup>2</sup> Jose Torres Cintron.<sup>1</sup> <sup>1</sup>Sistema de Salud Episcopal San Lucas, Ponce, Puerto Rico; <sup>2</sup>Hospital San Cristobal, Ponce, Puerto Rico.

**Introduction:** Hypokalemia is a common electrolyte disturbance, seen in hospitalized patient caused by either gastrointestinal or urinary losses. Although uncommon, the latter can occur due to renal tubular acidosis type 1 (RTA type 1), a disorder characterized by impaired distal tubular acidification leading to hypokalemia, nephrocalcinosis and recurrent renal stones. Severe hypokalemia, in turn, can lead to cardiac arrhythmias, weakness, paralysis, rhabdomyolysis, respiratory failure, and nephrogenic diabetes insipidus (DI).

**Case Description:** This is the case of a 50-year-old Hispanic female patient with a past medical history of systemic lupus erythematosus, lupus nephritis by kidney biopsy (type V membranous), chronic kidney disease stage G1/A3, nephrolithiasis, hypertension, and diabetes mellitus type 2 who presented to the emergency department due to a progressive flaccid paralysis ultimately requiring intubation for airway protection. Her laboratory work up was remarkable for severe hypokalemia (1.5mmol/L), hyperchloremia (128.70mmol/L), metabolic acidosis (pH:7.2), urinary alkalosis (pH of 7.0) and a positive urinary anion gap (37mmol/L), all compatible with the diagnosis of RTA type 1. Despite efforts to improve hypokalemia, patient's potassium levels remained critically low and she developed polyuria (5.5 L/day) which in turn resulted in severe hypernatremia. The diagnosis of nephrogenic DI was made, and the patient was treated with amiloride, aggressive intravenous fluid and electrolyte replacements. Eventually, with complete resolution of symptoms and plans of discharge.

**Discussion:** Nephrogenic DI is an uncommon complication of RTA type 1, triggered by severe electrolyte disturbances, in this case severe hypokalemia. Treatment of choice for Nephrogenic DI would be hydrochlorothiazide, but taking into account patients prevalent severe hypokalemia amiloride was prescribed. We want to bring into light the importance of diagnosing and treating of severe electrolyte disturbances to avoid severe complications as seen in nephrogenic DI, as seen in this patient.

## TH-PO346

### Hyponatremia Secondary to SIADH in a Patient With a Meningioma

Sarah Monaghan, Samantha Peterson, Chetachi E. Odelugo, Bradley S. Coolidge, Tauseef A. Sarguroh. *Franciscan Health Inc, Mishawaka, IN.*

**Introduction:** Severe hyponatremia, defined by a serum sodium less than 120 meq/L, is a serious and life-threatening electrolyte imbalance that may result in severe neurologic complications if not carefully managed. A common etiology is syndrome of inappropriate antidiuretic hormone secretion (SIADH) characterized by euvoletic hyponatremia in the setting of hypotonic serum and hyperosmolar urine. This is caused by increased antidiuretic hormone (ADH) from either the pituitary or ectopic source in the absence of stimuli, and results in impaired water excretion due to the inability to suppress ADH. While tumors are often associated with SIADH, a rare association is with a meningioma, as presented in this case.

**Case Description:** An 81 year old female with Hypertension not on a thiazide diuretic presented with weakness and fatigue. She was found to have severe symptomatic hyponatremia. Her initial serum sodium was 114 meq/L, serum osmolality was 257 mosm/kg, urine sodium was 49 mmol/L and urine osmolality was 433 mosm/kg. Further work up showed cortisol of 20.3 ug/dL and TSH of 1.57. Patient was euvoletic on physical exam and was given 100 mL bolus of 3% saline on presentation. Over the course of her admission, serum sodium improved with fluid restriction alone. A CT brain showed a 1.9 cm extra-axial calcified mass along the left frontal dura consistent with a meningioma. Patient's sodium gradually improved without complications and she was discharged.

**Discussion:** This case highlights a rare presentation of severe hyponatremia from SIADH due to a meningioma. SIADH maybe from a medication, central nervous system disturbances, or malignancies/tumors. In addition to treating hyponatremia, it is important for physicians to consider further workup of underlying malignancy or tumors in the absence of common causes of SIADH.

## TH-PO347

**WNK1 Is a Chloride-Sensing Scaffold That Potently Regulates mTORC2 Activity and ENaC**

Bidisha Saha,<sup>1</sup> Deise C. Leite-Dellova,<sup>1,2</sup> Enzo Takagi,<sup>1</sup> John E. Demko,<sup>1</sup> Waheed Shabbir,<sup>1</sup> David Pearce.<sup>1</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>Universidade de Sao Paulo Faculdade de Medicina Veterinaria e Zootecnia, Sao Paulo, Brazil.

**Background:** mTORC2 is a multiprotein signaling complex that regulates a variety of cellular processes induced by hormones and growth factors. Recent evidence suggests that mTORC2 is also involved in cell autonomous action, as it responds to local extracellular K<sup>+</sup> concentration to rapidly stimulate SGK1 phosphorylation and downstream target, ENaC, an epithelial sodium channel, in renal epithelial cells. Here we show that WNK1 has a pivotal role in mediating cell autonomous responses to local K<sup>+</sup> concentration that activates mTORC2.

**Methods:** We generated WNK1 knockout mpkCCD cells and WNK1 and SIN1 (a component of mTORC2 complex) double knockout HEK293 cells using CRISPR/Cas9 system. mpkCCD cells were grown on Transwell filters and incubated in media containing different [K<sup>+</sup>], with or without WNK kinase inhibitor. Amiloride-sensitive current was measured before the cells were processed for immunoblot analysis. For intracellular Cl<sup>-</sup> measurement, HEK293 cells were transfected with mCl-YFP plasmid and fluorescence signals were measured and analyzed. For modulation of intracellular [Cl<sup>-</sup>], cells were incubated in media containing different [Cl<sup>-</sup>] and ionophores. Cells were then processed for immunoblot and Co-IP analysis.

**Results:** Our results showed that the effect of extracellular K<sup>+</sup> on SGK1 phosphorylation and ENaC activity is dependent on elevated intracellular [Cl<sup>-</sup>] and on presence of chloride-binding protein kinase WNK1, but not on its kinase activity. Intracellular Cl<sup>-</sup> stimulates the scaffolding activity of WNK1, which physically interacts with both SGK1 and mTORC2 and enhances SGK1 recruitment to mTORC2. This results in a selective increase in SGK1 phosphorylation, and activation of ENaC which drives K<sup>+</sup> secretion.

**Conclusions:** These findings establish a novel mode of chloride-regulated WNK1 action that regulates mTORC2 activity selectively towards SGK1 phosphorylation and ENaC activation, independently of its kinase activity and reveals a dual role of WNK1's Cl<sup>-</sup>-sensing property on epithelial ion transport regulation: one, low [Cl<sup>-</sup>]-dependent activation of NCC through catalytic mechanism and the second, high [Cl<sup>-</sup>]-dependent activation of ENaC through non-catalytic scaffolding mechanism; the coupling of both pathways is significantly implicated in DCT2, controlling K<sup>+</sup> secretion.

## TH-PO348

**WNK1 Is a Central Osmolality Sensor for Arginine Vasopressin (AVP) Release**

Xin Jin, Jian Xie, Chou-Long Huang. *Department of Medicine, Division of Nephrology, University of Iowa Carver College of Medicine, Iowa City, IA.*

**Background:** Terrestrial animals are subject to constant stress of water deprivation. Maintaining internal osmolality constancy is essential for life. The circumventricular organs (CVO's) of brain including the organum vasculosum of the lamina terminalis (OVLT) and subfornical organ (SFO) lack a blood-brain barrier. Neurons in OVLT and SFO detect increases in serum osmolality (tonicity) that stimulates the production of AVP in paraventricular nuclei (PVN) to be released in the posterior pituitary. Current hypothesis for osmolality sensors focuses on mechanosensitive membrane proteins. The role of intracellular molecules is unknown.

**Methods:** Metabolic cage studies were performed in mice with neuronal-specific conditional knockout (cKO) of Wnk1, mice in which WNK1 in OVLT is deleted by stereotaxic injection of Cre-recombinase carrying retrograde AAV virus injected into PVN, and mice in which Kv3.1 channel on OVLT is knock down by injection of shRNA. Urine output, water intake, serum, urine osmolality, serum AVP and copeptin levels were measured. Action potential in OVLT neurons is recorded in isolated brain slice recording

**Results:** WNK1 kinase in OVLT is activated by water restriction evident by increased serine-382 phospho-WNK1. Neuronal-specific cKO of *Wnk1* causes polyuria with decreased urine osmolality that persists in water restriction. Circulating levels of AVP and copeptin are lower in water-restricted cKO mice versus controls. Neuronal tracing using retrograde virus reveals that WNK1 localized in PVN-projecting OVLT neurons is responsible. Hyperosmolality-induced increases in action potential firing in OVLT neurons is blunted by *Wnk1* deletion or pharmacological WNK inhibitors. Knockdown of Kv3.1b channel in OVLT by shRNA reproduces the phenotypes.

**Conclusions:** WNK1 in OVLT detects extracellular hypertonicity leading to AVP release by activating Kv3.1 and increasing action potential firing through OVLT→PVN neuronal network. Our results provide novel insights that an intracellular protein kinase WNK1 functions as an osmosensor for extracellular tonicity. They support the biophysical studies that extraction of water from the catalytic core of WNK kinase domain activates kinase activity.

**Funding:** NIDDK Support

## TH-PO349

**Dietary Magnesium Ion (Mg<sup>2+</sup>) Restriction Reduces Epithelial Sodium Channel (ENaC) Activity**

Yujiro Maeoka, Avika Sharma, Luan T. Nguyen, James A. McCormick. *Oregon Health & Science University, Portland, OR.*

**Background:** Hypokalemia occurs in 40 to 60% of patients with hypomagnesemia, and can result in cardiac arrhythmia and sudden death. Along the distal nephron, a decrease in intracellular Mg<sup>2+</sup> releases the Mg<sup>2+</sup>-mediated inhibition of renal outer medullary K<sup>+</sup> (ROMK) channels and increases K<sup>+</sup> secretion. However, several animal studies have shown that hypomagnesemia alone cannot cause hypokalemia. Epithelial sodium channel (ENaC)-mediated sodium entry provides the driving force for K<sup>+</sup> secretion via ROMK, but how hypomagnesemia affects ENaC activity remains unknown. We tested the hypotheses that (i) dietary Mg<sup>2+</sup> restriction lowers ENaC activity, maintaining K<sup>+</sup> homeostasis, and (ii) combined Mg<sup>2+</sup>/Na<sup>+</sup> restriction activates ENaC, causing hypokalemia.

**Methods:** To assess ENaC activity during Mg<sup>2+</sup> restriction, we performed Western blot for ENaC and an amiloride response test using C57/BL6 mice fed normal (NL) [Mg<sup>2+</sup> 0.15% (wt/wt); NaCl ~0.49%] or low Mg<sup>2+</sup> (LM) [Mg<sup>2+</sup> 0.0015–0.003% (wt/wt); NaCl ~0.49%] diets for 3 days. To evaluate the interaction with low Na<sup>+</sup> intake, which stimulates aldosterone secretion, we analyzed plasma [K<sup>+</sup>] and ENaC activity using mice fed NL or combined low sodium and low Mg<sup>2+</sup> (LS/LM) [Mg<sup>2+</sup> 0.0015–0.003% (wt/wt), Na<sup>+</sup> ~0.000007%] diets for 7 days. K<sup>+</sup> content was the same in each diet [K<sup>+</sup> ~0.8% (wt/wt)].

**Results:** The abundances of cleaved α- and γ-ENaC, which correlate with ENaC activity, were lower on a LM diet compared with NL diet. Amiloride response test showed a milder natriuretic effect on a LM diet, suggesting lower ENaC activity. In addition, plasma [Mg<sup>2+</sup>] correlated with cleaved α-ENaC abundance, but not plasma [K<sup>+</sup>] levels. In contrast, mice fed a LS/LM diet exhibited lower plasma [K<sup>+</sup>] levels compared with mice fed NL or LS diets. Cleaved α- and γ-ENaC abundances on LS/LM diet were similar to NL diet.

**Conclusions:** Together, these suggest that ENaC activity is lower following dietary Mg<sup>2+</sup> restriction but higher with combined Mg<sup>2+</sup>/Na<sup>+</sup> restriction, suggesting higher plasma aldosterone is required to stimulate K<sup>+</sup> secretion. This likely explains why Mg<sup>2+</sup> restriction alone cannot cause hypokalemia *in vivo*, and provides new insights into the mechanisms of hypomagnesemia-induced hypokalemia.

## TH-PO350

**Regulation of SGK1 Phosphorylation and Activity by mTORC2**

Enzo Takagi, Junliang Chen, Feng Wang, Bidisha Saha, David Pearce. *University of California San Francisco, San Francisco, CA.*

**Background:** mTORC2 is a multi-subunit kinase complex comprising core components mTOR kinase, Rictor, mSin1 and mLST8, which has received increasing attention during recent years. The principal direct targets of mTORC2 phosphorylation include Akt (known for glucose regulation) and SGK1 (known for regulation of renal

tubule ion transporters, particularly ENaC). However, structural information regarding mTORC2 has been limited, particularly in the context of SGK1 regulation. To gain greater structural insight into mTORC2 in the context of phosphorylating SGK1 we used cryo-EM complemented by mTORC2 kinase assays.

**Methods:** Core mTORC2 subunits were expressed in Expi293F cells and purified and cryo-EM grids prepared. Cryo-EM was performed using Krios at SLAC for high energy electrons for density maps of human mTORC2. Structures were solved for apo-complex at overall 3.23 Å resolution, and for co-complex with SGK1 at 3.38. Structural data predicted functional importance of mSin1-Arg-83, which was investigated through kinase assays in mSin1-deficient HEK293T cells transfected with WT and Arg-83-Ala mutant mSin1.

**Results:** The overall shape of mTORC2 in the SGK1 co-complex was similar to the apo-complex. Interestingly, the conformation of the mSin1 N-terminal domain was markedly altered in the SGK1 co-complex compared with the apo. First, an extended domain of mSin1 upstream of Arg-83 became unobservable, likely due to increased flexibility. Second, the Arg-83 side chain showed a large rotation toward a negatively charged patch within Rictor, appears to form a salt bridge with Rictor Asp-1679. Kinase assays performed using mTORC2 expressed in mSin1-deficient HEK-293T cells further supported the importance of mSin1 Arg-83: an Ala mutant of that residue selectively disrupted SGK1 phosphorylation, but not that of Akt.

**Conclusions:** These findings provide new structural and functional insights into mTORC2 substrate-specific activities and suggest new testable predictions, particularly with respect to mTORC2 regulation of SGK1 and ENaC. Further, these findings provide a potential avenue toward highly selective mTOR modulators with potential clinical utility.

## TH-PO351

### Genetic and Physiological Effects of Insulin-Like Growth Factor-1 (IGF-1) on Human Urate Homeostasis

David B. Mount,<sup>1,2</sup> Megan P. Leask,<sup>3</sup> Tony Merriman,<sup>3</sup> Asim Mandal.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Veterans Affairs Boston Healthcare System, Boston, MA; <sup>3</sup>Division of Rheumatology and Clinical Immunology, University of Alabama, Birmingham, AL.

**Background:** Metabolic syndrome and hyperinsulinemia are associated with hyperuricemia. Insulin infusion in healthy volunteers elevates serum urate (SU) by activating net urate reabsorption in the renal proximal tubule, whereas IGF-1 infusion reduces SU by mechanisms unknown. Variation within the *IGF1R* gene also impacts on SU levels.

**Methods:** Co-localization analyses of SU GWAS signal at *IGF1R* and eQTL signals in *cis* using COLOC2; RT-PCR, Western blotting, and urate transport assays in a proximal tubule cell line, transfected HEK 293T cells, and *Xenopus laevis* oocytes.

**Results:** Genetic association at *IGF1R* with SU is stronger in women and is mediated by control of *IGF1R* expression. Epistatic interaction between *IGF1R* and each of *SLC2A9* and *ABCG2* was found to affect SU differentially between men and women. IGF-1, via IGF-1R, stimulated urate uptake in human renal proximal tubule epithelial cells (PTC-05) and transfected HEK 293T cells, through activation of IRS1, PI3K/Akt, MEK/ERK and p38 MAPK; urate uptake was inhibited in the presence of uricosuric drugs, specific inhibitors of protein tyrosine kinase (PTK), PI3 kinase (PI3K), ERK and p38 MAPK. In *Xenopus laevis* oocytes expressing individual urate transporters, IGF-1 via endogenous IGF-1R stimulated urate transport mediated by GLUT9, OAT1, OAT3, ABCG2 and ABCC4 and inhibited insulin's stimulatory action on GLUT9a and OAT3. IGF-1 significantly activated Akt and ERK and IGF-1-stimulation of urate transport was significantly affected by specific inhibitors of PI3K, ERK and PKC in oocytes.

**Conclusions:** The combined results of infusion, genetics, and transport experiments suggest that IGF-1 reduces SU by activating urate secretory transporters and inhibiting insulin's action. IGF-1 antagonizes the effects of insulin on urate transporters, indicating complex interactions in hyperuricemia associated with metabolic syndrome and hyperinsulinemia.

## TH-PO352

### Caffeine Inhibits Basal and Insulin-Activated Urate Transport

David B. Mount,<sup>1,2</sup> Asim Mandal.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Veterans Affairs Boston Healthcare System, Boston, MA.

**Background:** Caffeine inhibits insulin signaling and has beneficial effects in metabolic syndrome/hyperinsulinemia. Coffee drinking also has beneficial effects in gout, via mechanisms unknown. We hypothesized that caffeine would specifically block insulin-activated urate transport, which in turn mediates the association between hyperinsulinemia and hyperuricemia.

**Methods:** We examined the effect of caffeine and adenosine on <sup>14</sup>C-urate transport in absence and presence of insulin, on activation of insulin signaling pathways in human renal epithelial cell line (PTC-05), and on individual urate transporters expressed in *Xenopus laevis* oocytes.

**Results:** We found that both caffeine and adenosine inhibited both basal and insulin-stimulation of net <sup>14</sup>C-urate uptake in PTC-05 proximal tubular cells. In *Xenopus laevis* oocytes expressing individual urate transporters, caffeine efficiently inhibited the basal urate transport activity of GLUT9 isoforms, OAT4, OAT1, OAT3, NPT1, ABCG2 and ABCC4 at >0.2 mM; adenosine had weaker effects on basal urate transport. The IC-50 of caffeine for basal urate transport was 613 μM for GLUT9a, 1080 μM for GLUT9b, 145 μM for OAT1, 8 μM for murine OAT3, 582 μM for OAT10, and 4860 μM for URAT1. Caffeine at lower concentrations (<0.2 mM) very effectively inhibited insulin-activation

of urate transport activity of GLUT9, OAT10, OAT1, OAT3, NPT1, ABCG2 and ABCC4, with concomitant inhibition of insulin-activated Akt and ERK phosphorylation. For example, the IC-50 of caffeine for insulin-activated GLUT9a urate transport was 205 μM. In contrast, adenosine had no effect on insulin-activated AKT and ERK phosphorylation.

**Conclusions:** Caffeine and adenosine inhibit basal urate transport mediated by multiple urate transporters. Caffeine also potentially inhibits insulin-activated urate transport, with a significantly lower IC-50 for GLUT9a insulin-activated transport versus basal transport. To the extent that GLUT9a is postulated to be the major insulin-activated reabsorptive pathway for urate in the proximal tubule (Front Physiol. 2021 Aug 2;12:713710), caffeine potentially provides a unique *in vivo* probe for insulin-activated renal urate reabsorption. Additionally, these results provide an explanation for the beneficial effects of caffeine in gout, worthy of further exploration.

## TH-PO353

### Molecular Simulation of the R154H Variation in Calcium Channel TRPV5 Associated With Kidney Stone Disease

Lingyun Wang, Ji-Bin Peng. Division of Nephrology, Department of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL.

**Background:** TRPV5 is a calcium channel that is essential for active calcium reabsorption in the kidney. Recent studies reveal that a single nucleotide polymorphism (rs4236480) in the TRPV5 gene is associated with the calcium stone multiplicity in patients from Taiwan and calcium stone risk in patients from India. The rs4236480 variation results in an arginine to histidine change in amino-acid position 154 (R154H) at the ankyrin repeat domain of TRPV5. Our previous study shows that the R154H variation slightly reduces the calcium transport activity of TRPV5, although the reduction did not reach statistical significance. A potentially small functional difference caused by the R154H variation may be challenging to detect using biochemical and physiological approaches. Thus, the molecular simulation approach was employed to assess the structural impact of this variation on the TRPV5 channel.

**Methods:** The model of human TRPV5 in complex with phosphatidylinositol 4,5-bisphosphate (PIP<sub>2</sub>) was set up based on the Cryo-EM structure of rabbit TRPV5 with diocanoyl PIP<sub>2</sub>. To mimic the membrane environment, the modeled TRPV5 was embedded in a lipid bilayer composed of 307 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine lipids using CHARMM-GUI web server, and then water molecules and counterions were added on both sides of the bilayer. The R154H variation was then introduced into the model. Three 100-ns independent molecular dynamics simulations were performed for the TRPV5 model with and without the variation using AMBER18.

**Results:** Structural analysis reveals that R154 in two of the four subunits forms a hydrogen bond with E250, which also forms a hydrogen bond with K301. This hydrogen bond network not only stabilizes the dynamics of K301 but also those of the adjacent residues R302 and R305. However, when the R154H variation is introduced into the TRPV5 model, the hydrogen bond network is disrupted and the dynamical flexibility of R302 and R305 is increased. Since R302 and R305 are involved in the binding of PIP<sub>2</sub>, the binding between PIP<sub>2</sub> and the channel was assessed by the binding free energy. Our results indicate that the R154H variation results in a modest yet significant reduction in binding free energy between the TRPV5 channel and PIP<sub>2</sub>.

**Conclusions:** The R154H variation alters the function of TRPV5 at least in part by weakening the binding of PIP<sub>2</sub> to the channel.

## TH-PO354

### Experimental CKD Increases Per-Nephron Sodium Reabsorption and Impairs Acute Kaliuresis

Kuangyu Wei,<sup>1</sup> Martin Gritter,<sup>1</sup> Hester van Willigenburg,<sup>1</sup> Joris I. Rotmans,<sup>2</sup> Ewout J. Hoorn.<sup>1</sup> <sup>1</sup>Erasmus MC, Rotterdam, Netherlands; <sup>2</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands.

**Background:** Chronic kidney disease (CKD) predisposes to salt-sensitive hypertension and hyperkalemia. This suggests alterations in tubular sodium (Na<sup>+</sup>) and potassium (K<sup>+</sup>) handling, but how CKD changes this is unclear.

**Methods:** CKD was induced by 5/6<sup>th</sup> nephrectomy (5/6<sup>th</sup> Nx) in rats. The estimated glomerular filtration rate (eGFR) was measured by a validated plasma creatinine- and urea-based equation. We compared Na<sup>+</sup> and K<sup>+</sup> transporter activity in CKD and sham-operated rats by assessing the response to furosemide, hydrochlorothiazide (HCTZ), or amiloride. Furthermore, the responses in plasma K<sup>+</sup> and urine K<sup>+</sup> excretion were studied after 16h fasting followed by 3h 0% K<sup>+</sup>, 2.5% potassium chloride (KCl), or 2.5% potassium citrate (KCi) diet.

**Results:** A trend towards a greater natriuretic response in 5/6<sup>th</sup> Nx than sham rats was observed after furosemide, while no differences were observed with HCTZ or amiloride (Table). After correction for eGFR, this corresponded to a 4.3, 2.7, and 4.2-fold increase in per-nephron Na<sup>+</sup> reabsorption in the thick ascending limb, distal convoluted tubule, and collecting duct, respectively in 5/6<sup>th</sup> Nx compared to sham rats. In 5/6<sup>th</sup> Nx rats, the kaliuretic response to furosemide and HCTZ was lower than in sham rats, although this only reached significance for the latter. Amiloride produced a similar K<sup>+</sup>-sparing effect in 5/6<sup>th</sup> Nx and in sham rats. This corresponded to an unchanged per-nephron kaliuresis in 5/6<sup>th</sup> Nx despite greater distal Na<sup>+</sup> delivery compared to sham rats. Both the 2.5% KCl and 2.5% KCi diet caused significantly less kaliuresis and higher plasma K<sup>+</sup> in 5/6<sup>th</sup> Nx compared to sham rats. After correction for eGFR, 5/6<sup>th</sup> Nx increased the kaliuretic response to the 2.5% KCl and 2.5% KCi diets compared to sham rats (2.9 and 2.6-fold, respectively).

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** Experimental CKD increases per-nephron Na<sup>+</sup> reabsorption in the thick ascending limb, distal convoluted tubule and collecting duct. The impaired thiazide-induced kaliuretic response points towards an impaired kaliuretic response to an increased distal Na<sup>+</sup> delivery in CKD. These alterations in Na<sup>+</sup> and K<sup>+</sup> handling may explain the tendency towards salt-sensitive hypertension and hyperkalemia in CKD.

TH-PO355

**A Case of Nephrotic Syndrome in an Individual With Severe Autosomal Dominant Polycystic Kidney Disease**  
Juan D. Salcedo Betancourt, Shani Shastri, Anil K. Pillai, Ronak Lakhia. *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Introduction:** Individuals with ADPKD often have sub-nephrotic range proteinuria. However, nephrotic range proteinuria with symptoms of nephrotic syndrome is rarely reported and presents a diagnostic challenge.

**Case Description:** A 36-year-old Indian woman with ADPKD diagnosed by imaging and genetic testing 12 years prior to evaluation presented with new-onset edema of hands, legs, and face and worsening hypertension. 24-hour urine collection revealed proteinuria of 6.7g. Serum creatinine remained at baseline. Comprehensive serological workup was negative. Additional history revealed that she was taking Ayurvedic supplements for several months prior to the onset of symptoms. Review of CT scan with interventional radiology identified one small area of preserved renal parenchyma as a potential biopsy target. US-guided kidney biopsy identified membranous nephropathy (MN). Serum and tissue anti-phospholipase A2 receptor antibodies were negative. Age-appropriate malignancy screening was negative. Treatment with Angiotensin II receptor blocker (ARB) and discontinuation of herbal supplements resulted in partial remission (UP/Cr 1.4 g/day) after 2 months, improved blood pressure and resolution of edema.

**Discussion:** Only a handful of ADPKD cases with biopsy-proven MN have been reported. Use of mercury-containing ayurvedic supplements has been implicated with MN. Renal biopsy is needed for ADPKD patients with nephrotic-range proteinuria to exclude coexisting glomerular disease. Though kidney biopsy confers a significantly greater risk of complications compared to a non-cystic kidney, it can often be safely performed by an interventional radiologist well versed with ADPKD. Referral to tertiary care centers with multidisciplinary teams for ADPKD should be considered. This case underlines the importance of renal biopsy in patients with ADPKD with nephrotic-range proteinuria, for accurate diagnosis and appropriate treatment.

**Figure 1.** A.Non-contrast CT sagittal section displays bilateral enlarged cystic kidneys. B. Renal ultrasound was used to perform kidney biopsy. The left kidney had a small region of non-cystic parenchyma that was biopsied (red arrows).

TH-PO356

**Confirmatory Genetic Testing Uncovers the Unexpected: A Rare Dual PKD1/PRKCSH Diagnosis in Familial Autosomal Dominant Polycystic Kidney Disease**  
Tarek Darwish,<sup>1</sup> Katya Brossart,<sup>2</sup> Kathryn M. Curry,<sup>2</sup> Sumit Punj.<sup>2</sup> <sup>1</sup>Kansas City Kidney Specialists, Overland Park, KS; <sup>2</sup>Natera, Inc., Austin, TX.

**Introduction:** Autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (ADPLD) have considerable genetic and phenotypic overlap and are characterized by hepatic and renal cysts. ADPKD and ADPLD show independent inheritance, and risk of progressive disease in either organ varies greatly by genotype. Molecular diagnosis can inform prognosis and clinical management. We report a rare dual diagnosis of ADPKD and ADPLD in the context of multigenerational ADPKD, and, to our knowledge, the first finding of dual PKD1/PRKCSH pathogenic variants.

**Case Description:** A 50-year-old woman with ADPKD and preserved renal function presented with significant abdominal distension consistent with hepatomegaly. Imaging revealed multiple renal and hepatic cysts. Family history was notable for ADPKD in the patient's mother, maternal grandmother, and the grandmother's siblings. The patient's 20-year-old daughter has renal cysts but normal kidney function. Genetic testing with a 385-gene NGS panel covering multiple genes associated with cystic diseases (the Renasight™ Test) was used to determine genetic etiology. Heterozygous pathogenic variants were identified in PKD1 (c.3957\_3994dup (p.Asp1332Glyfs\*27)), and PRKCSH (c.374\_375del (p.Glu125Valfs\*21)) which are associated with ADPKD and ADPLD respectively. Both variants are predicted to be truncating. Typically, truncating PKD1 variants cause severe PKD and mild-to-severe PLD. PRKCSH-associated pathogenic variants cause mild-to-severe PLD, with absent-to-mild PKD3. Family history suggests maternal inheritance of the PKD1 variant. Absence of severe hepatic features in prior generations suggests a de novo PRKCSH variant. A family history of ADPLD cannot be confirmed due to the variable expressivity and reduced penetrance of ADPLD, and limited ADPKD-ADPLD-related phenotypic data. Cascade testing is recommended.

**Discussion:** Single-gene confirmatory genetic testing for suspected ADPKD or ADPLD can be too narrow to capture an unexpected genetic etiology. This case highlights the value of unbiased genetic testing to confirm clinically diagnosed ADPKD. The presence of PRKCSH-related PLD in a patient with known ADPKD confers greater risk of hepatic disease progression, with implications for clinical management. This result enables familial testing for ADPKD and ADPLD risk in relatives.

TH-PO357

**Elucidating the Genetic Architecture of Cystic Kidney Disease**  
Omid Sadeghi-Alavijeh, Melanie M. Chan, Daniel P. Gale. *University College London Department of Renal Medicine, London, United Kingdom.*

**Background:** Up to 15% of polycystic kidney disease (PKD) cases are unsolved, leading to an unmet clinical need. Using whole genome sequencing data provided by the 100,000 Genomes Project (100KGP), we sought to systematically characterise the genetic architecture of PKD.

**Methods:** We performed a sequencing-based genome-wide association study in 1,102 unrelated PKD patients and 20,088 ancestry-matched unaffected controls. The analysis was inclusive of individuals with diverse genetic ancestry. Enrichment of common, low-frequency (minor allele frequency [MAF] > 0.1%) and rare (MAF < 0.1%) single-nucleotide variant (SNV), indel and rare structural variant (SV) alleles on a genome-wide and per-gene basis was sought using a generalised linear mixed model approach to account for population structure.

**Results:** Gene-based analysis of rare SNVs/indels predicted to be damaging revealed PKD1 (P=1.13x10<sup>-309</sup>), PKD2 (P=1.96x10<sup>-150</sup>), DNAJB11 (P=3.52x10<sup>-7</sup>) and COL4A3 (P=1.26x10<sup>-6</sup>) as significantly associated with the cystic phenotype. Depleting for “solved” cases led to the discovery of a significant association at IFT140 (P=3.46x10<sup>-17</sup>) and strengthening of the COL4A3 (P=9.27x10<sup>-7</sup>) association (Figure1), driven exclusively by heterozygous variants in both genes. After depleting for IFT140 and COL4A3 causative variants, no other genes were identified. Genome-wide analysis of over 18 million common and low-frequency variants did not reveal any statistically significant associations with disease.

**Conclusions:** These findings represent a thorough examination of the genetic architecture of a national PKD cohort using well-controlled statistical methodology. Causative monoallelic mutations in IFT140 have recently also been reported in other cohorts associated with a milder phenotype than PKD1/2-associated disease. The association with COL4A3 suggests that in some circumstances cystic kidney disease may be the presenting feature of type IV collagenopathy and further work is needed to understand the biological mechanism underlying this observation.

## TH-PO358

## Inherited Cystic Kidney Diseases Database for Individualized Genetic Analysis: Baseline Characteristics

Jeongmin Cho,<sup>1</sup> Yong Chul Kim,<sup>1</sup> Kook-Hwan Oh,<sup>1</sup> Curie Ahn,<sup>1</sup> Kyu-Beck Lee,<sup>3</sup> Yaerim Kim,<sup>4</sup> Eun Hui Bae,<sup>5</sup> Hee Gyung Kang,<sup>6</sup> Yo Han Ahn,<sup>6</sup> Yun Kyu Oh.<sup>2</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>3</sup>Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea; <sup>4</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>5</sup>Chonnam National University Hospital, Gwangju, Republic of Korea; <sup>6</sup>Seoul National University Children's Hospital, Seoul, Republic of Korea.

**Background:** Inherited cystic kidney disease (iCKD) is a genetic disorder caused by mutation of genes related to function of cilium resulting in renal and extrarenal cysts. Identification of iCKD genes in each case is necessary for precise treatment. However, pipeline for individualized genetic analysis has not been established yet.

**Methods:** This is a 3-year prospective, multicenter cohort study at 11 hospitals from May 2019 to December 2021. Patients with over 3 renal cysts in both kidneys were enrolled. Baseline demographics, co-morbidities, kidney complications, volume of kidney and liver, and genetic profiles are investigated.

**Results:** A total of 805 patients were enrolled. Clinically typical polycystic kidney disease (PKD) were 71.1% (577) whereas 21.1% (170) were atypical with absence of a family history or atypical findings in CT. Pediatric patients were 7.2% (58) (Figure 1). Median age of individuals was 45 years and 49.6% were male. Average eGFR was  $75.3 \pm 33.4$  mL/min/1.73m<sup>2</sup>. Median (25-75<sup>th</sup> percentile) total kidney volume (TKV) and total liver volume (TLV) were 1085.0 (595.0-1784) mL and 1557.0 (1277.0-2163.0) mL. Distribution by Mayo classification was as follows: 1A 108 (14.9%), 1B 198 (27.4%), 1C 234 (32.3%), 1D 111 (15.3%), and 1E 73 (10.1%). A total of 23 genes including PKD1, NV, PKD2, DM, COL4A5 were identified in 545 patients using targeted gene panel of 89 genes related to cilopathy (Figure 2). PKD1 mutation increased from 15.3% of Mayo 1A to 70.0% of 1E. PKD1 mutation was correlated with cyst infection, kidney pain, and cyst hemorrhage.

**Conclusions:** This is the first nationwide cohort for Korean iCKD. We report the baseline characteristics and genetic findings prior to detailed molecular analysis.

**Funding:** Government Support - Non-U.S.

Figure 2. Gene distribution by targeted gene panel of 89 cystogenesis-related genes (n=545)

## TH-PO359

## A Cohort of Patients With Autosomal Dominant Polycystic Kidney (ADPKD) With the Same Germline Mutation: The Contribution of Other Genetic Variants Can Determine the Extreme Phenotypic Variability

Carlotta Caprara,<sup>1</sup> Valentina Corradi,<sup>1</sup> Matteo Rigato,<sup>1</sup> Barbara Mancini,<sup>1</sup> Marta Proglia,<sup>1</sup> Fiorella Gastaldon,<sup>1</sup> Claudio Ronco,<sup>1</sup> Monica Zanella.<sup>1</sup> *Ospedale San Bortolo di Vicenza, Vicenza, Italy.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a major genetic disorder affecting up to 12.5 million individuals worldwide and it is the fourth most common global cause for renal replacement therapy. ADPKD is a chronic, progressive condition characterized by the development and growth of cysts in the kidneys and other organs and by additional systemic manifestations. Two principle causative genes have been identified: PKD1 and PKD2. ADPKD phenotype is highly variable intra and inter-family. The aim of the study was to describe a cohort of ADPKD patients with the same PKD2 genetic mutation and try to find a genetic contribution to the extreme phenotypic variability of the subjects.

**Methods:** We performed linkage analysis to define disease haplotype. We performed NGS with Sophia Genetic "Nephropathies Solution" Panel. This panel analyzed 44 genes (target region 105.8kb) involved in different types of nephropathies. We considered variants with autosomal dominant transmission, that are categorized as VUS or likely pathogenic (Class 3 and 4 of ACMG).

**Results:** We enrolled 29 patients (17 M, 12F) from 12 different families (same geographical area) characterized by the same PKD2 (NM\_000297.4) disease haplotype and the same germinal mutation c.2533C>T (p.Arg845Ter). 4 patients out of 29 (13.8%) reported a variant in collagen's genes: 2 patients share COL4A3 NM\_000091.5:c.4421T>C (p.Leu1474Pro) variant and 2 patients share COL4A4 NM\_000092.5:c.2996G>A (p.Gly999Glu) variant. These variants are associated to Thin Basement Membrane Nephropathy (TBMN) and patients with these variants express worst renal clinical phenotype (2pt microhematuria and proteinuria; 1 pt early ESRD).

**Conclusions:** The analysis did not find out a single "extra" variant that was common among patients with the same clinical course, but highlight variants that may be associated with some phenotypic manifestations not only associated with ADPKD. Study different variants in genes other than "classic" PKD1 and PKD2 can help to better interpret the phenotypic difference, especially in patients that share causative mutation where we expect a "similar genetic impact".

## TH-PO360

## PKD1 and PKD2 Copy Number Variations (CNVs) in Extended Toronto Genetic Epidemiologic Study of Polycystic Kidney Disease (eTGESP)

Amirreza Haghighi,<sup>2,1</sup> Ning He,<sup>1</sup> Saima Khawaja,<sup>1</sup> Matthew B. Lanktree,<sup>4</sup> Andrew Paterson,<sup>3</sup> York P. Pei.<sup>1</sup> <sup>1</sup>University Health Network, Toronto, ON, Canada; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>SickKids Research Institute, Toronto, ON, Canada; <sup>4</sup>St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is genetically heterogeneous and primarily due to mutations in *PKD1* or *PKD2*. Although CNVs including genomic deletion/duplication in *PKD1* and *PKD2* are uncommon, they explain a subset of cases with no mutations detected by NGS studies. Here, we report our results of a CNV screen in a cohort of 1,811 patients from 1,271 different families from eTGESP.

**Methods:** We screened all study patients for *PKD1* and *PKD2* mutations by targeted NGS and multiplex ligation-dependent probe amplification (MLPA) in NGS mutation-negative cases. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF  $\leq 1\%$ ) deleterious variants of high and moderate impact as predicted by multiple predictive algorithms. MLPA was performed using two kits (Probemix P351-D1 and P352-E1) from MRC Holland; all detected CNVs were validated by Sanger sequencing and droplet digital PCR (ddPCR) whenever possible.

**Results:** NGS-based screen failed to detect any definitive *PKD1* or *PKD2* mutations in 253/1,271 (20%) of families. Follow-up testing with MLPA identified CNVs in 29 of 253 (11.5%) NGS screen-negative families, including 15 with heterozygous *PKD1* deletions, 12 with heterozygous *PKD2* deletions, and 2 with heterozygous *PKD1* duplications; one *PKD1* CNV mosaic was also identified.

**Conclusions:** In this large cohort study from a single geographical region, we found *PKD1* and *PKD2* CNVs are rare causes of ADPKD, but account for 2.3% (29/1,271) of the entire study cohort and ~10% of our NGS screen-negative families. MLPA provides an important follow-up test for NGS-based *PKD1* and *PKD2* screen.

## TH-PO361

## Mutation Spectrum of the Extended Toronto Genetic Epidemiologic Study of Polycystic Kidney Disease (eTGESP)

Amirreza Haghighi,<sup>2,1</sup> Ighli di Bari,<sup>1</sup> Saima Khawaja,<sup>1</sup> Ning He,<sup>1</sup> Ioan Andrei Iliuta,<sup>1</sup> Xuewen Song,<sup>1</sup> Matthew B. Lanktree,<sup>4</sup> Andrew Paterson,<sup>3</sup> Jordan Lerner-Ellis,<sup>5</sup> York P. Pei.<sup>1</sup> <sup>1</sup>University Health Network, Toronto, ON, Canada; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>SickKids Research Institute, Toronto, ON, Canada; <sup>4</sup>St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; <sup>5</sup>Mount Sinai Hospital: Sinai Health, Toronto, ON, Canada.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease worldwide. Mutations in *PKD1* and *PKD2*, respectively, account for 85% and 15% of the genetically resolved cases in clinical series enriched with high-risk patients. Here, we report the ADPKD mutation spectrum of a large cohort of relatively unselected patients from a single geographical region.

**Methods:** We performed mutation screening in 2,171 patients from 1,606 different families from the Greater Toronto Area (population 6.8 million) using NGS targeted sequencing and multiplex ligation-dependent probe amplification of *PKD1* and *PKD2*, as well as NGS of a panel of 50 cystic disease genes. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF  $\leq 1\%$ ) deleterious variants as predicted by multiple algorithms.

**Results:** We detected *PKD1* and *PKD2* mutations in 1205 (75%) families, non-*PKD1* and *PKD2* (i.e. *ALG8*, *ALG9*, *PKHD1*, *GANAB*, *PRKCSH*, *SEC31B*, *LRP5*, *WFS1*, *TSC1-2*, *COL4A1*, and *COL4A3-5*) rare putative pathogenic variants in 120 (10%) families, with no mutations detected in 281 (15%) families. Among the *PKD1* and *PKD2* genetically resolved families, 916 (76%) and 289 (24%) were due to mutations in *PKD1* and *PKD2*, respectively. Adjusted for exon size across all 46 exons in *PKD1*, we found an enrichment of truncating mutations in exon 44. We also found over 100 recurrent mutations in  $\geq 2$  different families (haplotype analysis is in progress).

**Conclusions:** We found extensive genic and allelic heterogeneity in ADPKD with a higher prevalence of *PKD2* mutations than reported in the clinical series. We also found non-*PKD1* and non-*PKD2* cystic disease mutations in 10% of families, while 15% of the families remained genetically unresolved.

#### Recurrent PKD1 and PKD2 Mutations

Gene Name	Number of different pathogenic mutations	Number of pathogenic mutations in $\geq 2$ different families	Number of pathogenic mutations in $\geq 3$ different families
PKD1	840	72	28
PKD2	203	38	25

#### PKD1 and PKD2 mutation classes in genetically resolved cases

#### TH-PO362

##### Families With Complex Genetics in the Extended Toronto Genetic Epidemiologic Study of Polycystic Kidney Disease (eTGESP)

Amirreza Haghighi,<sup>1,2</sup> Ighli di Bari,<sup>2</sup> Saima Khowaja,<sup>2</sup> Ning He,<sup>2</sup> Ioan Andrei Iliuta,<sup>2</sup> Xuewen Song,<sup>2</sup> Matthew B. Lanktree,<sup>4</sup> Andrew Paterson,<sup>3</sup> York P. Pei,<sup>2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>University Health Network, Toronto, ON, Canada; <sup>3</sup>SickKids Research Institute, Toronto, ON, Canada; <sup>4</sup>St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is genetically heterogeneous and primarily due to mutations in *PKD1* or *PKD2*. Complex inheritance with bilineal disease arising from two independently segregating *PKD1*, or *PKD1* and *PKD2* mutations have been reported in a small number of families. Here, we define the prevalence and clinical features of ADPKD families with complex genetics in 1,811 patients from 1,271 different families from eTGESP.

**Methods:** All study patients underwent *PKD1* and *PKD2* mutation screening by targeted Next-Generation sequencing and multiplex ligation-dependent probe amplification in mutation-negative cases, as well as targeted NGS with a cystic disease panel of 50 genes. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF  $\leq 1\%$ ) deleterious variants of high and moderate impact as predicted by multiple predictive algorithms. Families with complex genetics were defined as those with two putative pathogenic mutations in *PKD1*, in *PKD1* and *PKD2*, or in *PKD1* or *PKD2* with another non-*PKD1* and non-*PKD2* cystic disease mutation.

**Results:** We found complex genetics in 71/993 (7.2%) of genetically resolved families. Among the families with complex genetics, 48 (68%) carried two *PKD1* mutations, 5 (7%) carried both a *PKD1* and *PKD2* mutation, and 18 (25%) carried either a *PKD1* or *PKD2* mutation with a second mutation in other cystic disease genes (i.e. *ALG8*, *ALG9*, *PKHD1*, *PRKCSH*, *SEC63*, *WFS1*, and *COL4A5*). Analyses of phenotype-genotype correlations in these families are currently in progress.

**Conclusions:** Gene locus and allelic heterogeneity have been shown to account for a significant proportion of disease variability in ADPKD. Here, we found complex genetics in 7% of a large cohort of families harboring two cystic disease mutations; the presence of a second mutation may potentially act as a modifier of the main effect mutation and contributes to the within-family disease variability.

#### TH-PO363

##### Patients With Autosomal Dominant Polycystic Kidney Disease (ADPKD) Without a Clear Family History Have Rapid Progression and Poor Prognosis

Vasiliki Gkika, Michaela Louka, Eirini Tigka, Angelos Drakopoulos, Myrto Kostopoulou, George I. Tsiropoulos. Department of Nephrology, General Hospital of Athens "G. Gennimatas", Athens, Greece.

**Background:** A small percentage of patients with ADPKD have no clear family history. The clinical course and prognosis of the disease in this subgroup of patients may be different. The present study investigates the progression and prognostication of End Stage Renal Disease (ESRD) in a large cohort of patients with and without a family history of ADPKD.

**Methods:** This study enrolled 291 patients who were being followed in a specialized outpatient ADPKD clinic. Patients having a total of more than 10 kidney cysts in a recent Magnetic Resonance Imaging (MRI) scan were included in the study even if they had no clear family history or confirmatory genetic test. At enrollment, Total Kidney Volume (TKV) was calculated by MRI and the Mayo Clinic Imaging Category (MCIC) was

determined. The prediction of ESRD based on the Mayo Clinic formula (which takes into consideration age, TKV, e-GFR, gender, race, and MCIC) was also calculated. Demographics, medical, and laboratory data were recorded using a standardized form. T-test,  $\chi^2$  and Mann-Whitney test were used for statistical analysis.

**Results:** Of the 291 patients included in the study, 34 (12%) had no clear family history of ADPKD and 257 (88%) had a clear family history. Age, gender, presence or not, and age at diagnosis of hypertension as well as BMI were similar in the two groups. The age at diagnosis of ADPKD was similar between patients with and without a clear family history as well as, the e-GFR, the stage of Chronic Kidney Disease and albuminuria. The TKV tended to be higher in patients without a clear family history than in those with a family history of ADPKD (2210 ml vs. 1650 ml,  $p=0.09$ ) and the same was valid for the height-adjusted TKV ( $p=0.08$ ). In MCIC 1C, 1D, and 1E, more patients without a known family history of ADPKD were classified than patients with a family history of ADPKD (89% vs 70%), and vice versa in MCIC 1A and 1B (11% vs 30%) ( $p=0.04$ ). Finally, the ESRD prediction was 16 years for the patients without a clear family history and 34 years for those with a clear family history of ADPKD ( $p=0.025$ ).

**Conclusions:** Patients with ADPKD without a clear family history tend to have a more rapid progression and a worse renal prognosis than those with a clear family history of ADPKD.

#### TH-PO364

##### Effects of Kinship on Disease Progression and Variability in Families With Autosomal Dominant Polycystic Kidney Disease

Elhussein A. Elhassan,<sup>1,2</sup> Kane E. Collins,<sup>2</sup> Edmund H. Gilbert,<sup>2</sup> Gianpiero Cavalleri,<sup>2</sup> Katherine A. Benson,<sup>2</sup> Peter J. Conlon,<sup>1,2</sup> <sup>1</sup>Beaumont Hospital, Dublin, Ireland; <sup>2</sup>Royal College of Surgeons in Ireland, Dublin, Ireland.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic nephropathy in humans that recognised with striking variability in kidney disease severity among affected relatives and families. Here, we evaluate variation in phenotype between families of adult Irish patients affected by ADPKD and the impact of kinship on disease progression.

**Methods:** Phenotypic details (age, sex, kinship with index patient, age at initial presentation, hypertension and urological events, and PROPK score) and renal survival (time to end-stage kidney disease (ESKD) and eGFR decline) were collected. A combination of molecular methods, including targeted NGS, were used for diagnosis of ADPKD, patients with disease-causing *PKD1* and *PKD2* variants were included for analysis. We assessed variability between families based on the age of onset of ESKD. To account for the impact of kinship on disease progression, we used a frailty model using detailed phenotypic features of patients with available genetic diagnosis.

**Results:** In total, we studied 103 unrelated families (369 patients), a majority (65/103; 63.1%) of whom had a diagnostic variant at *PKD1* gene, with average age of 55.2 $\pm$ 14.5 years; 55.3% females. Mean age at initial presentation was 30.2 $\pm$ 13.8 years. At last follow up, 262 (71%) patients developed ESKD at 49.3 $\pm$ 11 years. The remaining individuals had CKD with average creatinine and eGFR 133.2 $\pm$ 114.7 and 51.2 $\pm$ 25, respectively, and median annual eGFR decline 3.1 (IQR 1.3 – 5.25) ml/yr. Median variance in age at ESKD between families was 7 years, and among families with at least two ESKD patients, 34 (33%) families had wide delta difference in age of ESKD (i.e. >10 years difference). In the univariate frailty model, kinship has significantly associated with time to renal failure ( $P < 0.001$ ) taking into account each phenotypic and genetic factors of interest which are associated with disease severity. However, using a multivariate frailty model, we observed no statistical impact of kinship in age at ESKD among ADPKD families, except those with earlier initial presentation (HR: 0.96; 95% CI 0.94 – 0.98;  $P = < 0.001$ ).

**Conclusions:** Wide variability in age of ESKD among families with ADPKD is present in at least 33% of families and the impact of family effects was evident on factors related with disease progression.

#### TH-PO365

##### Genetic Identification of Inherited Cystic Kidney Diseases Using Next Generation Sequencing: Results From a 3-Year Korean Prospective Genetic Cohort

Hayne C. Park,<sup>1</sup> Jinwoo Lee,<sup>3</sup> Yong Chul Kim,<sup>3</sup> Curie Ahn,<sup>2</sup> Yaerim Kim,<sup>6</sup> Hee Gyung Kang,<sup>5</sup> Jungmin Choi,<sup>7</sup> Kook-Hwan Oh,<sup>3</sup> Yun Kyu Oh.<sup>3,4</sup> <sup>1</sup>Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; <sup>2</sup>National Medical Center, Seoul, Republic of Korea; <sup>3</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>4</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Seoul, Republic of Korea; <sup>5</sup>Seoul National University Children's Hospital, Seoul, Republic of Korea; <sup>6</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>7</sup>Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea.

**Background:** Inherited cystic kidney disease is a spectrum of disorders in which clusters of renal cysts develop as the result of genetic mutations. We performed a 3-year, prospective, multicenter cohort study to demonstrate genetic profiles in the Korean patients with inherited cystic kidney disease using next generation sequencing.

**Methods:** From May 2020 to May 2022, a total of 824 patients (751 adults, 73 children) with more than 3 renal cysts in both kidneys were enrolled from 11 centers. Demographic, laboratory, and imaging data as well as family pedigree were collected at baseline. Renal function was evaluated annually thereafter. The patients were clinically

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

divided into typical polycystic kidney disease (PKD), atypical PKD, and pediatric cases. We have introduced a gene panel with 89 ciliopathy-related genes as a screening method. We additionally performed *PKD1* targeted exome sequencing with long-range polymerase chain reaction (PCR) and/or multiplex ligation-dependent probe amplification (MLPA) for clinically typical PKD cases. We performed whole exome sequencing to reveal pathogenic variants in atypical PKD and pediatric cases as well as undiagnosed cases.

**Results:** The mutation detection rate of the gene panel was 57.5%. Long-range PCR & *PKD1* targeted exome sequencing were performed on 174 patients, which additionally documents pathogenic variants in 26 cases. Whole exome sequencing was performed in a total of 126 cases, and additional causative gene mutations were found in a total of 18 cases. Therefore, the final mutation detection rate through primary and secondary genetic analysis was 63%. In addition to the well-known *PKD1* and *PKD2* genes, *GANAB*, *HNF1B*, *COL4A1*, *COL4A3*, *COL4A5*, *PAX2*, *UMOD*, and *IFT140* were discovered as cystogenesis-related genes. As for prognosis-related genes, *PKD1* genotype was closely related to the poor prognosis of kidney disease, while *PKD2*, *GANAB*, and *HNF1B* were genotypes showing good prognosis. On the other hand, genotypes did not predict the severity of polycystic liver and cerebral aneurysms.

**Conclusions:** We found that the cyst formation-related gene panel was useful as a screening test and that genetic diagnosis can be useful for screening high-risk groups when the clinical prognosis is ambiguous.

TH-PO366

Factors Associated With Severity of Polycystic Liver in Patients With Autosomal Dominant Polycystic Kidney Disease: Results From an Inherited Cystic Kidney Disease Genetic Cohort Study

Hayne C. Park,<sup>1</sup> Jinwoo Lee,<sup>3</sup> Yong Chul Kim,<sup>3</sup> Curie Ahn,<sup>2</sup> Yaerim Kim,<sup>5</sup> Hee Gyung Kang,<sup>6</sup> Jungmin Choi,<sup>7</sup> Kook-Hwan Oh,<sup>3</sup> Yun Kyu Oh.<sup>3,4</sup> <sup>1</sup>Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; <sup>2</sup>National Medical Center, Seoul, Republic of Korea; <sup>3</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>4</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Seoul, Republic of Korea; <sup>5</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>6</sup>Seoul National University Children's Hospital, Seoul, Republic of Korea; <sup>7</sup>Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea.

**Background:** Polycystic liver (PLD) is the most common extrarenal manifestation of autosomal dominant polycystic kidney disease (ADPKD). We have analyzed genetic and clinical factors related to the severity of PLD among the patients with Korean ADPKD.

**Methods:** A total of 480 adult patients with ADPKD were enrolled from May 2019 to April 2022. Demographic, clinical, and laboratory data were collected at the initial study visit. Liver volumes were measured using Image J by one professional radiologist and adjusted for height (HtLV) before analysis. The severity of PLD was defined by previous study: no cyst (Gr0), HtLV<1000mL/m (Gr 1), HtLV 1000-1800mL/m (Gr 2), HtLV>1800mL/m (Gr 3). Targeted exome sequencing was done by gene panel including 89 ciliopathy-related genes. Genetic and clinical factors were compared between PLD groups.

**Results:** The mean age was 44 years old and female comprised of 54%. The patients with liver cysts (n=298 in Gr 1, n=120 in Gr 2, n=62 in Gr 3) showed higher frequency of ADPKD-related complication such as hypertension (87.4% vs. 71.5%, p<0.001), proteinuria (27.9% vs. 14.9%, p=0.001), and cerebral aneurysm (10.0% vs. 1.7%) compared to those without liver cysts (n=229 in Gr 0). The patients in Gr 2 and 3 showed older age (53.3±8.1 and 45.0±12.9 vs. 41.9±13.4, p<0.001), higher number of childbirth (1.78±0.82 and 1.64±1.05 vs. 1.27±1.07, p=0.004), and higher prevalence of hypertension (93.5% and 84.2% vs. 65.8%, p<0.001). The patients with severe PLD (Gr 3) demonstrated higher serum level of alkaline phosphatase compared to Gr1 and Gr 2 (95.9±75.4 vs. 56.6±30.1 and 66.1±35.3 IU/L, p<0.001). Interestingly, Gr 3 PLD group showed higher proportion of double variants (25.4 vs. 13.5% and 16.2%) compared to Gr1 and Gr2 groups. The combination of PKD1 and collagen type IV variants were highly prevalent in severe PLD groups.

**Conclusions:** The PLD severity was associated with female gender, higher number of childbirth, and frequent PKD-related complications. Double variants, especially the combination of PKD1 and collagen type IV variants, were associated with severe PLD.

**Funding:** Government Support - Non-U.S.

TH-PO367

Genetic Variants and Phenotypic Heterogeneity in Autosomal Dominant Polycystic Kidney Disease

Marta Vespa, Maria Teresa Sciarra Alibrandi, Giancarlo Joli, Romina Bucci, Martina Catania, Liliana Italia De Rosa, Lorena Citterio, Maria Vittoria Vergani, Michele Paolisi, Pierpaolo Bianco, Giuseppe Vezzoli, Paolo Manunta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

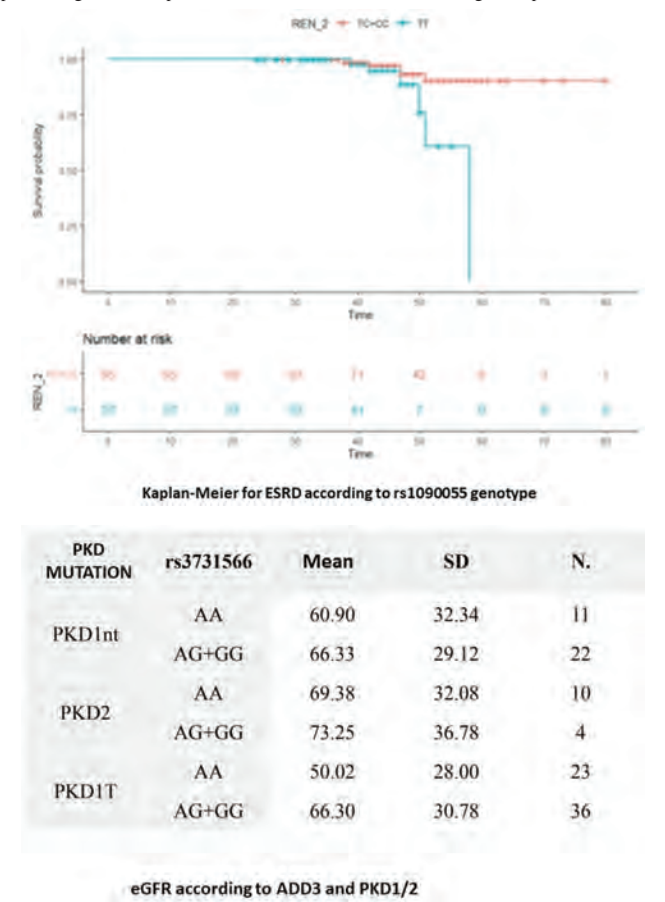

**Background:** Adpkd is the most common genetic renal disease usually caused by the mutation of the genes PKD1-PKD2. The main feature is bilateral renal enlargement with progressive loss of kidney function. One of the most typical aspect of this disease is the intra-interfamiliar phenotypical variability.

**Methods:** We led an observational retrospective cross sectional study on 191 PKD pts to evaluate the phenotypical variability based on causal genes and modifier genes, that can influence clinical features: hypertension, sodium sensitivity etc.

**Results:** Among the polymorphisms, rs4961, rs3731566, rs4293393, rs10900555 seem to have influence on renal phenotype. We observed different disease trend outcomes

between wild type patients and those with the rs4961 (ADD1) and rs4293393 (UMOD) variants. In our cohort rs3731566 (ADD3) significantly correlates with a worse kidney function and an early ESRD. On the other hand, rs10900555 (REN) correlates with ESRD before age 60. By analyzing the interactions between the potential modifier genes and the causal genes, we found that the most severe mutation, the PKD1 truncating one, seems to delete the effects of ADD1 and UMOD, something that did not happen with ADD3, which AA genotypic presence correlates with a worse outcome, despite the kind of PKD1 mutation. Our hypothesis is that, despite the phenotypic effect of PKD1T, we were still able to find modifier genes capable to generate a significant change in phenotype.

**Conclusions:** Our results lead the way to further analysis, specifically regarding the pharmacogenomics aspect and the functional interactions among these proteins

TH-PO368

Characterization of Genetically Defined ARPKD-PKHD1 Patients Enriched for Childhood/Adult Onset

Christian Hanna,<sup>1</sup> Tabinda Jawaaid,<sup>1</sup> Sarah R. Senum,<sup>1</sup> Maroun Chedid,<sup>1</sup> Charles D. Madsen,<sup>1</sup> Fouad T. Chebib,<sup>2</sup> Vicente E. Torres,<sup>1</sup> Mounif El-Youssef,<sup>1</sup> Peter C. Harris.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Mayo Clinic in Florida, Jacksonville, FL.

**Background:** ARPKD is generally considered a pediatric disorder with prominent phenotype variability related to kidney and liver involvement ranging from fetal demise to surviving into adulthood. Studies have shown phenotypic overlap between ARPKD and other ciliopathies. We aimed to characterize the clinical course in genetically defined ARPKD-PKHD1 patients (pts).

**Methods:** Through research or clinical genetic testing, pts were identified with biallelic *PKHD1* variants. Identified families were characterized by segregation, imaging, and clinical phenotypes from chart review.

**Results:** Out of 47 pts with biallelic *PKHD1*, 37 (31 families) with complete clinical data were included (Table 1). Median age (Q1, Q3) at diagnosis and last follow-up were 1 (0, 20) and 30 yrs (20, 44), respectively, with a mean ± SD follow-up period of 19 ±12.5 yrs. Seventeen pts (46%) had in utero/infantile-onset (<1 yr), 10 (27%) with childhood-onset (1-17 yrs), and interestingly 10 (27%) with an adult-onset presentation with a median age of 42 (40, 44). At last follow up, kidney replacement therapy was present in 38%, portal hypertension in 65%, and liver transplant in 8%. Three pts (8%) died (1 neonate and 2 with adult-onset ARPKD). Kidney cysts, liver cysts, and nephrolithiasis (NL)/nephrocalcinosis (NC) were found in 89%, 24%, and 49%, respectively. Nephromegaly, hypertension, and kidney failure were more prevalent in utero/infantile-onset, and NL/NC in adult-onset (p≤0.05). A truncating (T) plus nontruncating (NT) variant were identified in 46% (17/37) and two NT variants in 54% (20/37); none had two T variants. No correlation was found between the genotypic group and diagnosis age (p=0.17).

**Conclusions:** In ARPKD-*PKHD1* patients we found high variability in kidney and/or liver phenotypes, including adult-onset ARPKD in the 5th decade and high prevalence of NL/NC. ARPKD should be considered a differential diagnosis in adults with fibrocystic hepatorenal disease with or without nephromegaly and NL/NC.

**Funding:** NIDDK Support

Table 1. Characteristics of 37 genetically defined ARPKD-PKHD1 patients					
	to uterus/intestine onset (n=12)	Childhood onset (n=10)	Adult onset (n=10)	Total (n=32)	p-value

TH-PO369

**Experience With Genetic Testing at a Large Polycystic Kidney Disease-Focused Program**  
Allen Chao, Ying Gao, Jordan Jiang, Diana Etwaru, Adesuwa N. Osunde, Laalasa Varanasi, Stephen L. Gluck, Gabriel Loeb, Meyeon Park. *University of California San Francisco, San Francisco, CA.*

**Background:** We are a center that provides specialized care for patients with autosomal dominant polycystic kidney disease (PKD). Genetic testing in PKD has historically been used in the context of diagnostic uncertainty, pre-transplant evaluation, and pre-implantation genetic testing for mutation for in vitro fertilization. Since development of the Renasight panel test (Natera) in April 2020, we have offered genetic testing more routinely due to greater accessibility and ease of testing. We sought to determine how many patients seen in our center underwent genetic testing, results of testing, and differences between individuals who desired testing and those who declined.

**Methods:** We searched our electronic medical record to determine how many patients with PKD were seen in clinic appointments since the Renasight test became available (May 1, 2020). We described the range of genetic test results in the PKD1 and PKD2 genes and compared characteristics of individuals with and without genetic testing using t-test and chi-square.

**Results:** 225 patients in total were identified. 79 patients had genetic testing. 76 underwent Renasight panel test; 3 already had genetic testing by other companies (GeneDx, Prevention Genetics, Athena Diagnostics). 39 (49.4%) were women. 48 (60.8%) were White, 7 (8.9%) were Black, 16 (20.3%) were Asian, 2 (2.5%) were Latinx, 6 (7.6%) were another race category. Age range was 22 to 84 years and median age (IQR) was 47 (36, 59). Out of the 76 Renasight tests, 47 (61.8%) were positive for mutations in PKD1 (39) or PKD2 (8). 14 (18%) were noted to have variants of uncertain significance in either of these genes. Of the known pathogenic mutations, 33 (44%) were truncating, 24 (32%) were nontruncating. The majority of mutations were nonsense (35%) and missense (30%). Individuals with genetic testing had a lower presence of family history of PKD than those without genetic testing (63% v 80%, p=0.01). There was no difference in age or gender between groups.

**Conclusions:** Genetic testing for PKD1 and PKD2 has become more accessible due to development of the Renasight panel test. Individuals with PKD with no family history especially seem motivated to undergo testing. Future work to understand motivators and barriers to genetic testing as well as understanding of costs to patients associated with testing should be pursued.

TH-PO370

**Tolvaptan Use at a Large PKD-Focused Program**  
Allen Chao, Ying Gao, Jordan Jiang, Adesuwa N. Osunde, Diana Etwaru, Laalasa Varanasi, Stephen L. Gluck, Meyeon Park. *University of California San Francisco, San Francisco, CA.*

**Background:** We are a center that provides multidisciplinary care for patients with autosomal dominant polycystic kidney disease (PKD). We sought to evaluate current tolvaptan use and reasons for tolvaptan discontinuation at our center.

**Methods:** We used the Jynarque Risk Evaluation Mitigation System database to determine tolvaptan prescriptions for patients registered through our clinic. We used our clinic database to derive clinical and demographic characteristics of these patients. We compared characteristics of individuals who were actively taking tolvaptan with those who were prescribed tolvaptan but were not taking it using t-test and chi-square.

**Results:** 67 patients prescribed tolvaptan were identified. 36 (57.3%) were women. 49 (73.1%) were White, 1 (1.5%) were Black, 9 (13.4%) were Asian, 5 (7.5%) were Latinx, 3 (4.5%) were Other race category. Age range was 22 to 72 years; median age (IQR) 45 (39, 53). 24 (58.5%) were on therapy for longer than 18 months. Among

active patients, 34 (83%) were on the 45/15mg dose; 4 (10%) on 60/30mg; 3 (7%) on 90/30mg. 26 (38.8%) were inactive. Reasons for inactivity included 4 who never started. Discontinuation occurred due to aquaretic symptoms (4); reached transplant (2); acute kidney injury (2); insurance (2); "got tired of it" (2); liver function test abnormalities (1); pregnancy (1); gastrointestinal symptoms (1); the remainder had no specific reason (7). There was no difference between eGFR at time of initiation between active and inactive groups (67 v. 58 ml/min/1.72m<sup>2</sup>); family history of PKD (88% versus 77%); or Mayo classification (Table). Those without Mayo classification had ultrasound lengths > 16.5 cm.

**Conclusions:** Reasons for tolvaptan discontinuation cannot be immediately identified based on clinical or demographic characteristics. Physicians should work with patients who would benefit from tolvaptan to overcome potential barriers to continued use of this medication.

Mayo Class by Active (left column) versus Inactive (right column) status (Number of patients (%))

1A	1 (2.9%)	1 (5.6%)
1B	4 (11.8%)	1 (5.6%)
1C	11 (32.4%)	4 (22.2%)
1D	11 (32.4%)	4 (22.2%)
1E	6 (17.7%)	4 (22.2%)

TH-PO371

**PKD2 Founder Mutation Is the Most Common Mutation of Polycystic Kidney Disease in Taiwan**  
Daw-yang Hwang,<sup>1</sup> Chih-Chuan Yu,<sup>3</sup> An Fu Lee,<sup>1</sup> Ming-Yen Lin,<sup>3</sup> Siao Muk Cheng,<sup>1</sup> Yi-Wen Chiu,<sup>3</sup> Edgar A. Otto,<sup>4</sup> Friedhelm Hildebrandt.<sup>2</sup> Taiwan ADPKD Consortium <sup>1</sup>National Health Research Institutes, Zhunan, Taiwan; <sup>2</sup>Boston Children's Hospital, Boston, MA; <sup>3</sup>Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; <sup>4</sup>University of Michigan Michigan Medicine, Ann Arbor, MI.

**Background:** Autosomal Dominant polycystic kidney disease (ADPKD) is the most common inherited adult kidney disease. Although ADPKD is primarily caused by *PKD1* and *PKD2*, the identification of several novel causative genes in recent years has revealed more complex genetic heterogeneity than previously thought. To study the disease-causing mutations of ADPKD, a total of 920 families were collected and their diagnoses were established via clinical and image studies by Taiwan PKD Consortium investigators.

**Methods:** Amplicon-based library preparation with next generation sequencing, variant calling, and bioinformatic analysis was used to identify disease-causing mutations in the cohort. Microsatellite analysis along with genotyping and haplotype analysis was performed in the *PKD2* p.Arg803\* family members. The age of mutation was calculated to estimate the time at which the mutation occurred or the founder arrived in Taiwan.

**Results:** Disease-causing mutations were identified in 634 families (68.9%) by detection of 364 *PKD1*, 239 *PKD2*, 18 *PKHD1*, 7 *GANAB*, and 6 *ALG8* pathogenic variants. 162 families (17.6%) had likely causative but non-diagnostic variants of unknown significance (VUS). A single *PKD2* p.Arg803\* mutation was found in 17.8% (164/920) of the cohort in Taiwan. Microsatellite and array analysis showed that 80% of the *PKD2* p.Arg803\* families shared the same haplotype in a 250kb region, indicating those families may originate from a common ancestor 300 years ago.

**Conclusions:** Our findings provide a mutation landscape as well as evidence that a founder effect exists and has contributed to a major percentage of the ADPKD population in Taiwan.

**Funding:** Government Support - Non-U.S.

TH-PO372

**Reduced Penetrance of ALG9-Associated Cystic Kidney Disease in a Real-World Cohort**  
Lauren Beretich,<sup>1</sup> Umayma Abdullatif,<sup>2</sup> Kenan M. Alrejjal,<sup>2,4</sup> Emily Hendricks,<sup>1</sup> Darbey Raible,<sup>1</sup> Dinah Clark,<sup>1</sup> Sumit Punj,<sup>1</sup> Abdul A. Abdellatif.<sup>3,2</sup> <sup>1</sup>Natera, Inc., Austin, TX; <sup>2</sup>CLS Health, Webster, TX; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>MedStar Washington Hospital Center, Washington, DC.

**Background:** Recently, heterozygous loss-of-function variants in *ALG9* have been associated with autosomal dominant polycystic kidney and liver disease. Variable expressivity and reduced penetrance were reported in the limited cohorts studied with these conditions. The goal of this study was to assess the frequency of polycystic kidney and/or liver disease in individuals with heterozygous loss-of-function variants in *ALG9* from a real-world cohort of patients referred for clinical genetic testing.

**Methods:** A retrospective review of laboratory data and clinical information from test requisition forms was conducted. Participants with a clinically ordered genetic panel for kidney disease (the Renasight™ test) between May 2020 and April 2022 and a heterozygous pathogenic (P) or likely pathogenic (LP) variant in *ALG9* were included in this study.

**Results:** Among the 15 patients that met inclusion criteria, patients were predominantly female (10/15) and Caucasian (6/15). The median age at the time of genetic testing was 51 years (range 23-62 years). Patients were most often referred for genetic testing due to chronic kidney disease (8/15) and/or cystic kidney disease (7/15). All of the reported *ALG9* variants were classified as LP and were predominantly nonsense variants (8/15). In this cohort, 47% (7/15) patients were reported to have cystic or polycystic kidneys and one patient (1/7) was reported to have liver cysts. Only one patient (1/15) was reported to have a relevant family history.

**Conclusions:** In this real-world cohort, reduced penetrance was observed in *ALG9* heterozygotes, consistent with previous literature. These results may underrepresent the prevalence of autosomal dominant polycystic kidney and liver disease in *ALG9* heterozygotes as complete clinical information is not always provided on the test order form. In addition, 43% (3/7) of patients with a cystic phenotype and an *ALG9* variant also had a variant of uncertain significance (VUS) in separate genes related to cystic disease, for which additional data are needed to understand the impact on their phenotype. Future research can help further our understanding of the association between *ALG9* variants and cystic phenotypes.

### TH-PO373

#### Phenotypic Expression Among *HNF1B* Pathogenic Variant Carriers

Brian Fang,<sup>1</sup> Alex R. Chang,<sup>2</sup> Uyenlinh L. Mirshahi,<sup>4</sup> Kashyap A. Patel,<sup>3</sup> Michael Weedon,<sup>3</sup> <sup>1</sup>Geisinger Commonwealth School of Medicine, Scranton, PA; <sup>2</sup>Geisinger Medical Center, Danville, PA; <sup>3</sup>University of Exeter, Exeter, United Kingdom; <sup>4</sup>Geisinger Health, Danville, PA.

**Background:** Patients with *HNF1B* variants have shown variable phenotypic expression even between individuals with the same mutation between and within families. As most studies focus on patients with disease-specific cohorts, the phenotypic spectrum of *HNF1B* in the general population remains unclear.

**Methods:** We used data from 172,589 participants in the Geisinger MyCode/DiscoverEHR study, an unselected health system-based cohort with exome sequencing and EHR data. Variants were classified according to ACMG-AMP guidelines. Participants with pathogenic/likely pathogenic (PLP) variants in *HNF1B* and 17q12 microdeletion were identified and were matched 1:1 by age decile, sex, and genetic ancestry with individuals without *HNF1B* pathogenic variants or 17q12 deletion (non-carriers). Patient medical records were examined to ascertain phenotypic features related to *HNF1B* clinical spectrum. Comparisons between individuals with and without *HNF1B* were made using Fisher exact test and t-tests.

**Results:** There were a total of 25 participants with 17q12 microdeletion and 11 heterozygotes for PLP single nucleotide variants (6 individuals with 5 protein truncating variants, 5 individuals with 4 missense variants). All 36 participants with *HNF1B* PLP variants were matched 1:1 to 36 non-carriers. *HNF1B* pathogenic variants were associated with higher risk of diabetes (25% vs. 2.8%;  $p=0.01$ , any kidney/liver cyst ICD code 13.9% vs. 0%;  $p=0.05$ ), hypomagnesemia  $<1.75$  mg/dL (33% vs. 0%;  $p<0.001$ ), and lower mean eGFR (67.4 vs. 88.2 mL/min/1.73m<sup>2</sup>;  $p=0.01$ ). In focused chart review of the 36 carriers, 2 (5.6%) had end-stage kidney disease, and 22 (61.1%) had renal imaging, including 18 with computed tomography or magnetic resonance imaging of the abdomen. Of those with available imaging, 9/22 (40.9%) had bilateral renal cysts, 1/17 (6%) had liver cysts, 6/17 (35.3%) had atrophic or hypoplastic pancreas. Individuals with 17q12 microdeletion were more likely to have diabetes (40% vs. 9%;  $p=0.1$ ) and bilateral renal cysts (among 22 with imaging: 8/12 [66.7%] vs. 1/10 [10%];  $p=0.01$ ) compared to those heterozygous for PLP single nucleotide variants.

**Conclusions:** In an unselected health system-based cohort, we demonstrated variable penetrance and the wide spectrum of disease manifestations ranging from diabetes, renal cysts, and pancreatic abnormalities in patients with *HNF1B* pathogenic variants.

### TH-PO374

#### Six Novel *PDK1* Mutations Identified From Six Chinese Families With Autosomal Dominant Polycystic Kidney Disease

Jing Zhuang, Ailima Aierken, Dilina Yalikun, Jun Zhang, Xiaoqin Wang, Hong Jiang. People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China.

**Introduction:** ADPKD is the monogenic kidney cystic disease, mainly resulting from mutations in either polycystic kidney disease 1 (*PKD1*) or *PKD2* genes. Our study aimed to characterize variants in Chinese patients by identifying pathogenic genes related to ADPKD to further unravel its pathogenesis.

**Case Description:** Clinical data and genetic information of six Chinese ADPKD adult patients were analyzed using the next-generation sequencing technique. Their family members were analyzed for the specific variant using Sanger sequencing. In pedigree A, the male proband with chronic kidney disease (CKD) stage 2, hypertension (HT) and polycystic liver disease (PL) showed missense mutation (c.8447T>C and c.4247T>G) in *PKD1*. In pedigree B, the female proband with CKD stage 2, HT, PL and intracranial arachnoid cyst showed a nonsense mutation (c.3298\_3301delGAGT) in *PKD1*. In pedigree C, the female proband with CKD stage 5, HT and PL showed missense mutation (c.4798A>G and c.6406C>T) in *PKD1*. In pedigree D, the female proband with CKD stage 3 and ovarian cyst (OC) showed a missense mutation (c.7567G>A) in *PKD1*. In pedigree E, the male proband with CKD stage 5, HT, PL and Epididymal cyst (EC) showed a nonsense mutation (c.11215C>T) and a missense mutation (c.11717G>C) in *PKD1*. In pedigree F, the male proband with CKD stage 5 and HT showed a nonsense mutation (c.7703+5G>C) in *PKD1*. Family members carried the same mutations as the probands respectively. Six novel mutation sites have been discovered in *PKD1*: c.4247T>G; c.3298\_3301delGAGT; c.4798A>G; c.7567G>A; c.11717G>C; c.7703+5G>C.

**Discussion:** The newly discovered *PKD1* mutation site enriches the ADPKD gene mutation spectrum in the domestic population, which contributes to the early diagnosis and prognosis prediction of ADPKD patients, and provides relevant genetic information for early clinical intervention.

### TH-PO375

#### Clinical Characterization of Monoallelic-*PKHD1* Subjects

Tabinda Jawaaid, Christian Hanna, Sarah R. Senum, Charles D. Madsen, Vicente E. Torres, Peter C. Harris. Mayo Clinic Minnesota, Rochester, MN.

**Background:** ARPKD results from biallelic pathogenic variants of *PKHD1*. There is also limited literature indicating that monoallelic *PKHD1* variants can develop kidney and/or liver cysts. We aimed to characterize patients with monoallelic-*PKHD1* identified from ARPKD families or from genetic screening of subjects with kidney and/or liver cysts.

**Methods:** Genetic testing was performed using a target next-generation sequencing panel consisting of known PKD and ciliopathy genes and segregation was performed by Sanger sequencing. Individuals with single defined pathogenic or likely pathogenic *PKHD1* variants were characterized by imaging and the clinical phenotype determined from chart review; ones with other significant genetic variants were excluded.

**Results:** A total of 28 monoallelic-*PKHD1* subjects with complete clinical and imaging details were identified; 6 from ARPKD families and 22 from genetic screening. Females accounted for 57.1% (16/28) with a median age at diagnosis of 48 years (range 1.2-74). Only kidney cysts were found in 32.1% (9/28), 7.1% (2/28) had only liver cysts, and 60.7% (17/28) had cysts in both organs, with the number of cysts ranging from 1 to >20. Ten subjects were initially diagnosed following imaging for related symptoms: flank pain (6/22), hematuria (3/22), or abnormal physical examination (1/22). However, the majority (18/28) were diagnosed incidentally, with imaging performed for donor evaluation or reasons unrelated to cystogenesis. Hypertension was found in 57.1% (16/28). Two subjects (5.7%) with other kidney comorbidities had a kidney transplant, and 17.8% (5/28) were kidney donors, although a few cysts were present. The median eGFR was 60 mL/min/1.73m<sup>2</sup> (range 5-126), and only one patient died, at the age of 71. Other phenotypes included nephrolithiasis (35.7%), pancreatic cysts (7.1%), renal mass resulting in nephrectomy (7.1%), intracranial aneurysm (3.5%), and medullary sponge kidney (3.5%). The type of pathogenic variant was truncating in 35.7% (10/28) and non-truncating in 64.2% (18/28).

**Conclusions:** Monoallelic pathogenic *PKHD1* variants have a variable clinical impact and are not usually associated with a decline in kidney function but may account for a significant group of individuals diagnosed with kidney and/or liver cysts. Limited evidence of multiple family members being affected suggests reduced expressivity of the phenotype.

### TH-PO376

#### Monoallelic *COL4A3/A4/A5* Pathogenic Variants Mimicking Autosomal Dominant Polycystic Kidney Disease

Tabinda Jawaaid,<sup>1</sup> Sarah R. Senum,<sup>1</sup> Charles D. Madsen,<sup>1</sup> Hamad Ali,<sup>2,3</sup> Vicente E. Torres,<sup>1</sup> Peter C. Harris.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Kuwait University, Dasman, Kuwait; <sup>3</sup>Dasman Diabetes Institute, Dasman, Kuwait.

**Background:** Alport syndrome is caused by biallelic pathogenic variants to *COL4A3* and *COL4A4* and hemizygous *COL4A5* variants, but the pathogenicity of heterozygous variants at these loci is now apparent. The basement membrane disease phenotype results in hematuria, proteinuria and kidney failure, and deafness. Kidney cysts have also been occasionally associated with this disorder and we aimed to determine if the etiology of some ADPKD diagnosed patients are *COL4A3/A4/A5* pathogenic variants.

**Methods:** ADPKD spectrum patients were genetically screened with a targeted next-generation sequencing panel including PKD, other kidney, and ciliopathy genes, and segregation performed by Sanger sequencing. Individuals with single pathogenic/likely pathogenic *COL4A3/A4/A5* variants were characterized by imaging and the clinical phenotype determined from chart review. Cases with variants in more than one gene were excluded.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** A total of 16 families with an ADPKD spectrum diagnosis (25 patients) had single *COL4A3/A4/A5* pathogenic variants (Table 1), including 3 *COL4A5* males. Kidney cyst numbers ranged from 1 to >18 with significant variation in cyst size; liver cysts were documented in three individuals. Phenotypes identified at the diagnosis included: hematuria (36%), proteinuria (14.2%), and abdominal pain (19%) and on detailed workup, gross hematuria (16%) microhematuria (56%), proteinuria (44%), and hypertension (48%) were characterized. Two patients had kidney transplants. The median age at diagnosis was 46.5 years (4 - 73) with a median eGFR of 61 mL/min/1.73m<sup>2</sup>; ranging from 11 to 120; 1 male *COL4A5* subject had an eGFR of 15. Glycine substitutions in the triple helix region of the protein accounted for 22 out of 25 patients.

**Conclusions:** Individuals with heterozygous pathogenic variants to *COL4A3/A4/A5* can present with multiple kidney cysts, resulting in an ADPKD spectrum diagnosis, although most patients have additional Alport related phenotypes. Genetic screening panels of PKD patients should include the *COL4A3/A4/A5* genes.

**Funding:** NIDDK Support

TH-PO377

Type IV Collagen Variants in Patients With Polycystic Kidneys

Matthew B. Lanktree,<sup>1</sup> Amirreza Haghighi,<sup>2</sup> Saima Khawaja,<sup>2</sup> Ioan-Andrei Iliuta,<sup>2</sup> Andrew Paterson,<sup>3</sup> York P. Pei.<sup>2</sup> <sup>1</sup>McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; <sup>2</sup>University Health Network, Toronto, ON, Canada; <sup>3</sup>The Hospital for Sick Children, Toronto, ON, Canada.

**Background:** Gene panel and whole exome sequencing of patients with cystic kidney disease have led to the discovery of unexpected phenotypic heterogeneity of genetic kidney diseases. Mutations in type IV collagen genes (*COL4A3/COL4A4/COL4A5*) have long been recognized as the cause of Alport syndrome and thin basement membrane disease. More recently, type IV collagen mutations have also been associated with focal segmental glomerulosclerosis. Among patients clinically selected and submitted for genetic assessment of polycystic kidneys, we sought to compare the prevalence of type IV collagen mutations between those with and without a pathogenic *PKD1* or *PKD2* variant.

**Methods:** 808 participants of the Ontario Polycystic Kidney Disease registry provided DNA samples for targeted gene panel sequencing. Sequencing results from *PKD1*, *PKD2*, *COL4A3*, *COL4A4*, and *COL4A5* were analyzed here. Participant charts were reviewed to analyze their cystic phenotype and obtain measurements of total kidney volume and kidney function.

**Results:** 34 participants had a suspected pathogenic rare variant in a type IV collagen gene with a median age of 49 (range 24 – 72). One male was hemizygous for a *COL4A5* variant (p.P1517T), while the remaining variants were carriers of a heterozygous variant. Type IV collagen variants were more prevalent in patients who did not also have a *PKD1* or *PKD2* rare variant compared to those with them (31 out of 315 patients compared to 3 out of 493;  $P < 1 \times 10^{-5}$ ). Of 31 type IV collagen variants without a *PKD1* or *PKD2* mutation 20 had atypical cystic distributions, 11 had a cystic appearance consistent with typical autosomal dominant polycystic kidney disease (ADPKD), and only 2 had a high-risk Mayo classification (class C or worse). 3 of 34 patients with a type IV collagen variant had reached an eGFR < 30 mL/min/1.73m<sup>2</sup>.

**Conclusions:** In patients with polycystic kidneys and gene panel sequencing results, type IV collagen mutations were more common in those without a *PKD1* or *PKD2* mutation compared to those with them, suggesting type IV collagen mutations may be associated with a cystic phenotype. Both typical and atypical cystic imaging patterns were observed but generally smaller age- and height-adjusted kidney volumes were observed.

TH-PO378

Monoallelic IFT140 Variants and Atypical Cystic Kidney Disease in the 100,000 Genomes Project

Eric G. Olinger,<sup>1</sup> Ruxandra Neatu,<sup>1</sup> Ian J. Wilson,<sup>1</sup> John A. Sayer.<sup>1,2</sup> <sup>1</sup>Newcastle University Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom; <sup>2</sup>Freeman Hospital, Newcastle upon Tyne, United Kingdom.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive kidney cysts and is an important cause for kidney failure. ADPKD is genetically heterogeneous and most commonly caused by mutations in *PKD1* and *PKD2*. However, ~5% of families remain without a molecular diagnosis. Monoallelic

variants in *IFT140* have been recently described in atypical ADPKD and large databases are instrumental for a better description of this new disease entity.

**Methods:** Whole genome sequencing (WGS) in the context of the Genomics England 100,000 Genomes Project (100kGP) was carried out in 64,185 subjects, including 1,291 probands with cystic kidneys. This research was made possible through access to the data and findings generated by the 100kGP ([www.genomicsengland.co.uk](http://www.genomicsengland.co.uk)).

**Results:** We report a 28-year-old man with *PKD1/2*-negative cystic kidneys and recruited into the 100kGP. A review of his imaging revealed an atypical pattern of kidney cysts (Figure) and he was noted to have preserved kidney function and normotension. Of his two children one had kidney cysts aged 8 years. WGS data revealed a heterozygous predicted loss of function (pLOF) variant in *IFT140* in the index patient and his affected child. Analysis of 100kGP data identified 26 pLOF variants in a total of 152 individuals from 111 different families. Among these 152 individuals, kidney cyst(s) were described in 38 individuals (25%), CKD in only 7 (5%) and kidney failure in 6 individuals (4%). Overall, 26 out of 1,291 (2%) probands with cystic kidney disease as their primary recruitment groups had *IFT140* pLOF variants. Mean age at diagnosis was 48.4±18.1 years. Only ICD term Q61 (cystic kidney disease) showed phenome-wide significant association with *IFT140* monoallelic pLOF variants ( $p=2.9 \times 10^{-9}$ , OR=5.6 (3.3-9.2)).

**Conclusions:** *IFT140* pLOF variants are an important cause of atypical ADPKD without apparent extrarenal manifestations and should be considered in *PKD1/2*-negative patients, especially those with mild clinical course and preserved kidney function.

Figure: Abdominal CT showing few large kidney cysts

Design of a Prospective Observational Study of Patients With Rare Kidney Diseases

Kendrah O. Kidd,<sup>1</sup> Abigail Taylor,<sup>1</sup> Victoria C. Robins,<sup>1</sup> Lauren Martin,<sup>1</sup> Adrienne H. Williams,<sup>1</sup> Anthony J. Bleyer.<sup>1,2</sup> <sup>1</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>2</sup>Univerzita Karlova, Praha, Czechia.

**Background:** Autosomal dominant tubulointerstitial kidney disease (ADTKD) is a rare disease, with less than 2,000 patients identified. Obtaining prospective data on rare diseases is difficult due to small numbers of patients, a wide geographic distribution, and limited funding. We describe the use of the REDCap data system to develop a biorepository, send automated emails, and establish longterm follow-up. Here we present results at one year.

**Methods:** At baseline, we collect serum/urine for biomarkers, serum creatinine, and initial survey, including BP, medications, diet history. Serum creatinine is measured at a commercial laboratory or by participant's physician. Quarterly visits are paired with a short survey. There is a nested cohort study of pregnancy or SGLT2 inhibitor use. A secure REDCap project was designed to capture data. After the initial visit, the REDCap program sends email reminders for quarterly laboratory visits and survey.

**Results:** Recruitment began in March 2021, with current enrollment 145 (Table). We have collected 478 serum creatinine measurements from 132 patients with paired survey data. We have 87 patients who have completed Visit 1 (4 months), 60 who have completed Visit 2 (8 months) and 24 who have completed Visit 3 (12 months). 15 patients missed one quarterly visit, 6 missed 2, and one missed 3. Phone call reminders have been needed for approximately 35 patients.

**Conclusions:** Automation of data collection decreases study team manpower and is highly effective. Longer term follow-up is required to see if attrition develops. We believe this system could be employed for other rare kidney diseases.

**Funding:** Private Foundation Support

## TH-PO380

**Increased Susceptibility and 9-Fold Increased Mortality From COVID-19 in Patients With ADTKD-MUC1**

Kendrah O. Kidd,<sup>1,2</sup> Petr Vyletal,<sup>2</sup> Alice Kim,<sup>1</sup> Abigail Taylor,<sup>1</sup> Martina Zivna,<sup>2</sup> Christoforos Stavrou,<sup>3</sup> Peter J. Conlon,<sup>4</sup> Richard E. Hogan,<sup>4</sup> Gregory Papagregoriou,<sup>5</sup> Stanislav Kmoch,<sup>2,1</sup> Anthony J. Bleyer,<sup>1,2</sup> <sup>1</sup>Wake Forest Baptist Medical Center, Winston-Salem, NC; <sup>2</sup>Univerzita Karlova, Praha, Czechia; <sup>3</sup>Evangelismos Private Hospital, Pafos, Cyprus; <sup>4</sup>Baumont Hospital, Dublin, Ireland; <sup>5</sup>Panepistemio Kyprou, Nicosia, Cyprus.

**Background:** Patients with autosomal dominant tubulointerstitial kidney disease due to *MUC1* mutations (ADTKD-*MUC1*) have a frameshift mutation on one allele of the *MUC1* genotype, resulting in production of an abnormal MUC1frameshift protein on one allele and normal MUC1 on the other allele. The C variant of the rs4072037 SNP increases production of MUC1 or MUC1fs if it is contained in the corresponding promoter. In addition to the kidneys, MUC1 is expressed in the nose and lungs. ADTKD-*UMOD* has a very similar clinical presentation, but *UMOD* is expressed only in the kidney.

**Methods:** We conducted a survey (after emergence of the delta variant) using the REDCAP database of 957 individuals in our ADTKD cohort to determine if COVID-19 infection was more severe in ADTKD-*MUC1* patients.

**Results:** There were 89 ADTKD-*MUC1* and 132 ADTKD-*UMOD* respondents, with similar age, body mass index, transplant rates, vaccination rates., 25/89(28%) ADTKD-*MUC1* individuals developed COVID-19 vs. 21/132(16%) ADTKD-*UMOD* individuals (odds ratio 2.35(1.6-3.1) (p=0.028). 10/41 (24%) ADTKD-*MUC1* individuals died of COVID-19 vs. 1/30 (3%) ADTKD-*UMOD* individuals (p=0.013), with an odds ratio of 9.4 (7.2-11.5). The mean plasma mucin1 level in 13 infected and 23 uninfected ADTKD-*MUC1* individuals was 6.40±3.4 vs.10.89±3.82 U/mL (p=0.0012). Of ADTKD-*MUC1* individuals who developed COVID-19, only 19% had the CC phenotype (associated with increased MUC1 production) vs. 51% of the ADTKD-*MUC1* individuals who did not develop COVID-19 (p=0.01). There was no difference in rs4073037 genotype frequencies in the ADTKD-*UMOD* group. Of the 10 ADTKD-*MUC1* patients who died, 8 were transplanted, with only 3 greater than 60 years of age. 50 percent had received 2 COVID-19 vaccines.

**Conclusions:** Patients with ADTKD-*MUC1* have a 2-fold increased odds of developing COVID-19 and a 9-fold increased mortality from COVID-19. Among ADTKD-MUC1 patients, those producing less MUC1 were more likely to develop COVID-19.

**Funding:** Private Foundation Support

## TH-PO381

**Good Nutritional Status Is Associated With Preserved Kidney Function in Ambulatory Patients With Autosomal Dominant Polycystic Kidney Disease**

Jinwoo Lee,<sup>1,2</sup> Yong Chul Kim,<sup>1,2</sup> Hayne C. Park,<sup>4,5</sup> Curie Ahn,<sup>6</sup> Kyu-Beck Lee,<sup>7,8</sup> Yeong Hoon Kim,<sup>9,10</sup> Yae-rim Kim,<sup>11,12</sup> Seungyeup Han,<sup>11,12</sup> Eun Hui Bae,<sup>13,14</sup> Kook-Hwan Oh,<sup>1,2</sup> Yun Kyu Oh.<sup>1,3</sup> <sup>1</sup>Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>3</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>4</sup>Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea; <sup>5</sup>Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; <sup>6</sup>National Medical Center, Seoul, Republic of Korea; <sup>7</sup>Sungkyunkwan University School of Medicine, Suwon, Republic of Korea; <sup>8</sup>Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea; <sup>9</sup>Inje University College of Medicine, Busan, Republic of Korea; <sup>10</sup>Inje University Busan Paik Hospital, Busan, Republic of Korea; <sup>11</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>12</sup>Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; <sup>13</sup>Chonnam National University Medical School, Gwangju, Republic of Korea; <sup>14</sup>Chonnam National University Hospital, Gwangju, Republic of Korea.

**Background:** Malnutrition is one of common complications in autosomal dominant polycystic kidney disease (ADPKD). We examined whether nutritional status is associated with preservation of kidney function using a cohort of ambulatory ADPKD patients after stratification by subjective global assessment (SGA) score and propensity scores-based matching.

**Methods:** A total of 805 patients were prospectively enrolled in 11 tertiary medical centers of Korea from May 2019 to December 2021. Among those of 805 patients, 721 patients were included for descriptive analysis and 273 patients with 1-year follow-up data on kidney function and urine proteinuria were finally analyzed to evaluate the effect of nutritional status on kidney function. Subjective global assessment (SGA) was used to assess the nutritional status of patients with ADPKD. The primary outcome was eGFR decline >3 after 1 year follow-up according to nutritional status assessed by SGA (SGA 7 vs. SGA 3-6). Logistic regression model were used to calculate odds ratio (OR) for the primary outcome. Because several baselines differed between two groups, we matched propensity scores with nearest neighbor method.

**Results:** The mean patient age was 46.3 ± 13.9 years, and 51.0% of the patients were female. The mean eGFR was about 75 ml/min/1.73m<sup>2</sup> and CKD stage 1 was the most common with about 42%. Among 273 patients with available 1-year follow-up data, 107 patients (39.2%) had a eGFR decline >3. The incidence of 1-year eGFR decline

>3 was 391.9 per 1,000 person-year. When multivariable logistic regression model was conducted, SGA 3-6 (malnourished status) was identified as significant factors related with 1-year eGFR decline >3 (adjusted OR = 1.18 [1.01–1.37]; *P* < 0.001). Despite matching propensity scores, the preserved kidney function rate in SGA 7 group (well-nourished status) were still higher than in SGA 3-6 group.

**Conclusions:** Good nutritional status is associated with preserved kidney function in ambulatory ADPKD patients. Future randomized clinical trials should determine the causality between them, and the present results will be a basis for these.

**Funding:** Government Support - Non-U.S.

## TH-PO382

**Kidney Phosphate Wasting Predicts Worse Outcomes in Patients With Polycystic Kidney Disease**

Laixi Xue,<sup>1</sup> Esther Meijer,<sup>2</sup> Martin H. De Borst,<sup>2</sup> Ron T. Gansevoort,<sup>2</sup> Robert Zietse,<sup>1</sup> Ewout J. Hoorn,<sup>1</sup> Mahdi Salih,<sup>1</sup> on behalf of the DIPAK Consortium <sup>1</sup>Erasmus MC, Rotterdam, Netherlands; <sup>2</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited chronic kidney disease (CKD) which often leads to kidney failure. Patients with ADPKD have disproportionately high levels of the phosphaturic hormone fibroblast growth factor 23 (FGF23) for their CKD-stage, but only a subgroup seems to develop kidney phosphate wasting. Because phosphate wasting is considered a marker for tubular dysfunction, we hypothesize it is associated with worse kidney outcomes in ADPKD patients.

**Methods:** We included 670 patients with ADPKD from the DIPAK observational cohort with serial measurements of kidney function (eGFR) and MRI-based total kidney volume (TKV). We measured baseline serum c-terminal FGF23 levels and calculated the ratio of tubular maximum reabsorption rate of phosphate to glomerular filtration rate (TmP/GFR) using the Bijvoet formula. We defined a TmP/GFR <0.8 mmol/L as kidney phosphate wasting. We used linear mixed models and Cox regression models to study the association of TmP/GFR ratios with eGFR decline over time and the hazard ratios for composite kidney outcome (≥ 40% estimated GFR decline, incident of kidney failure or kidney replacement therapy).

**Results:** Phosphate excretion was measured in 604 patients (age 48± 12 years, 39% male, eGFR 63±28 mL/min/1.73m<sup>2</sup>). Mean TmP/GFR was 0.76± 0.23 mmol/L and mean FGF23 was 121± 74 RU/mL. Kidney phosphate wasting was observed in 357 (59%) patients. Male gender, eGFR and FGF23 were independently associated with TmP/GFR (*P*<0.05 for all). During follow-up of 3 years, 145 kidney outcomes were observed. After adjusting for risk factors for kidney function decline (including gender, genotype and TKV), every 0.1 mmol/L decrease in TmP/GFR was associated with a steeper eGFR decline of 0.15 mL/min/1.73m<sup>2</sup>/year (*p*=0.01) and 1.17 times higher risk of the kidney outcome (95% CI 1.04 to 1.31, *p*=0.007). FGF23 or hypophosphatemia were not associated with the composite kidney outcome.

**Conclusions:** In patients with ADPKD, phosphate wasting is highly prevalent and is independently associated with an increased risk for disease progression. This effect was not mediated by FGF23 or serum phosphate levels. Our results suggest that TmP/GFR adds to the current prognostic models for ADPKD.

## TH-PO383

**Urinary Citrate Is Associated With Kidney Outcomes in Early Polycystic Kidney Disease**

Laixi Xue,<sup>1</sup> Daniel R. Rocha,<sup>2</sup> Hiago M. Sousa,<sup>2</sup> Ana Matos,<sup>2</sup> Ewout J. Hoorn,<sup>1</sup> Mahdi Salih,<sup>1</sup> Ita P. Heilberg.<sup>2</sup> <sup>1</sup>Erasmus MC, Rotterdam, Netherlands; <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Patients with autosomal dominant polycystic kidney disease (ADPKD) are prone to develop hypocitraturia at early stages of disease, predisposing them to calcium microcrystal formation. Recent animal studies demonstrated that microcrystal lodging in the tubules initiate cyst formation and growth. Therefore, we hypothesize that patients with ADPKD and lower urinary citrate levels are at increased risk of rapid disease progression.

**Methods:** We included patients with ADPKD in which urinary citrate levels were measured between 2002-2021 at our outpatient clinic at the Universidade Federal de São Paulo, Brazil. We collected baseline urine metabolic profiling, ultrasound-based total kidney volumes (TKV) and eGFR values at baseline and follow-up. We used linear mixed models to evaluate the association of urine citrate excretion with eGFR slope and Kaplan-Meier and Cox-regression models to assess the risk rate to a kidney outcome (eGFR decline >40%, kidney failure or kidney replacement therapy).

**Results:** From a total of 736 screened patients, 95 met our inclusion criteria. Patients were 33± 14 years, 66% were females, with a relatively preserved kidney function (eGFR of 91± 29 mL/min/1.73m<sup>2</sup>). Median follow-up was 11 years (IQR 5-15y). Lower citrate levels were associated with male sex, larger TKV and lower eGFR (*p*<0.05 for all). The urine citrate/creatinine ratio (uCit/Cr) correlated with eGFR and TKV (*R*<sup>2</sup>= 0.17 and 0.22, *P*< 0.001 for both). Patients with the lowest tertile of uCit/Cr (T1) had an eGFR decline of 3.7, compared to 3.3 (T2) and 2.3 mL/min/1.73m<sup>2</sup>/year (T3) (*p*=0.04 for T1 vs. T3). Median kidney survival time was lower in patients with lower levels of uCit/Cr (9 vs. 18 years for T1 vs. T3, *p*= 0.002). Adjusted for age, sex and baseline eGFR, each log unit decrease in uCit/Cr was associated with a 5-fold higher risk for a kidney outcome.

**Conclusions:** Low urinary citrate excretion is associated with a more rapid eGFR decline and worse kidney survival in patients with ADPKD, independent of other disease determinants. Our findings suggest urinary citrate may add to current prognostic markers of disease progression in ADPKD.

The Burden of Psychiatric Disorders in Polycystic Kidney Disease  
Uyi J. Imasuen, Brady M. Dangelser, Ali D. Jandal, Gauri Bhutani. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

**Background:** Epidemiology of psychiatric illness in Polycystic kidney disease (PKD) is not well known.

**Methods:** We performed a retrospective cohort study using EMR data at our institution to determine the frequency of select psychiatric disorders in patients with “PKD” and chronic kidney disease from other causes (“non-PKD/CKD”) seen at our Nephrology clinic between 1/1/2000 – 4/30/2020. Psychiatric disorders and the two cohorts were identified using ICD-9/10 codes. Patients with unclear diagnostic codes and diabetes were excluded. The date of the first visit to Nephrology clinic was regarded as “Index date”. The prevalence of psychiatric disorders at the index date as well as incidence of these disorders after the index date were compared between “PKD” and “non-PKD/CKD” cohorts.

**Results:** A total of 661 PKD patients and 5,204 non-PKD/CKD patients were seen at our center over the study duration. Patients in PKD cohort were younger at presentation (Index date; mean 53 years vs 61 years in non-PKD/CKD;  $p<0.01$ ) and more often male (57% [376] vs 52% [2636];  $p=0.03$ ). Majority of patients in both groups identified as white (90% [594] vs 87% [4392]). At the Index date, PKD patients were more often employed (37% [244] vs 28% [1380],  $p<0.01$ ), married (58% [378] vs 56% [2748],  $p=0.048$ ), had higher eGFR (median [IQR] 55 [31-84] vs 45 [29-61] mL/min/1.73m<sup>2</sup>,  $p<0.01$ ) and lower Charlson comorbidity index (2 [0-4] vs 4 [3-6],  $p<0.01$ ). Follow-up was shorter in the PKD cohort pre-index date (18 [0-82] vs 35 [0-99] months;  $p<0.01$ ) but longer post-index date (84 [45-132] vs 52 [20-97];  $p<0.01$ ). Apart from depression, both the prevalence and incidence of other psychiatric disorders (bipolar, anxiety, schizophrenia, ADHD) were similar between the two groups. The multivariable models adjust for age, sex, race, Charlson score and appropriate follow up time. [table]

**Conclusions:** Despite lower burden of comorbid illness and better socio-economic factors, the burden of psychiatric disorders in PKD patients is considerable and similar in frequency to non-PKD/CKD.

Prevalence and Incidence of Psychiatric Disorders

	Prevalence, % (N)		Adjusted Odds ratio (PKD vs CKD)		Incidence, rate per 1000 person years		Adjusted hazard ratio (PKD vs CKD)	
	PKD N=661	CKD N=5024	Ratio (95% CI)	P-value	PKD N=661	CKD N=5024	Ratio (95% CI)	P-value
Depression	15 (98)	22 (1104)	0.78 (0.6-0.98)	0.04	23.1	23.5	1.09 (0.89-1.34)	0.41

The MANGROVE Phase 2 Trial: Study Design and Baseline Characteristics of Patients With Autosomal Dominant Polycystic Kidney Disease  
Ron T. Gansevoort,<sup>1</sup> Antonio Pisani,<sup>2</sup> Miguel Hueso,<sup>3</sup> Dávinia Van den Bergh,<sup>4</sup> Willem Hettema,<sup>5</sup> Karine Muller,<sup>4</sup> Ann Fieeuw,<sup>4</sup> Wladyslaw Sulowicz.<sup>6</sup>  
<sup>1</sup>Department of Nephrology, University Medical Centre Groningen, University Hospital Groningen, Groningen, Netherlands; <sup>2</sup>Department of Nephrology, University of Naples Federico II, Naples, Italy; <sup>3</sup>Department of Nephrology, Bellvitge University Hospital, Barcelona, Spain; <sup>4</sup>Galapagos, NV, Mechelen, Belgium; <sup>5</sup>Galapagos, NV, Leiden, Belgium; <sup>6</sup>Department of Nephrology, Jagiellonian University, Kraków, Poland.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is characterized by renal cyst development, mainly driven by chloride secretion that is mediated by the cystic fibrosis transmembrane conductance regulator (CFTR) channel.<sup>1</sup> Although the underlying molecular mechanism is not fully known, CFTR inhibitors have been shown to reduce cyst growth *in vitro* and *in vivo*.<sup>1</sup> With only one approved treatment, there is an unmet need for novel ADPKD therapies. MANGROVE is an ongoing phase 2a, proof-of-concept trial, evaluating the efficacy and safety of the CFTR inhibitor GLPG2737 in patients with ADPKD.

**Methods:** MANGROVE (NCT04578548; 2019-003521-21) comprises a randomized, double-blind, placebo-controlled treatment period and an open-label extension (OLE) treatment period (each 52 weeks with 4 weeks follow up). Adults (18–50 years) with rapidly progressing ADPKD (total kidney volume [TKV] >750 mL, Mayo class 1C–1E) and age-dependent estimated glomerular filtration rate (eGFR) (18–40 years: 30–90 mL/min/1.73 m<sup>2</sup>; >40–50 years: 30–60 mL/min/1.73 m<sup>2</sup>) were randomized 2:1 to receive GLPG2737 or matching placebo once daily for 52 weeks at baseline. Patients who completed double-blind treatment could enter the OLE. MANGROVE assessed treatment differences between GLPG2737 and placebo. Primary outcomes included change in height-adjusted TKV and frequency and severity of adverse events. Secondary outcomes included change in eGFR and estimated exposure to GLPG2737.

**Results:** The study enrolled 66 patients with ADPKD with a mean±SD age of 40.3±6.3 years, most of whom (92.4%) had arterial hypertension. Key disease characteristics and concomitant medication are reported in the table.

**Conclusions:** Study inclusion criteria were designed to enrich for patients with a high chance of rapid disease progression and were successful in doing so, as shown by the baseline patient characteristics. 1. Jouret F, Devuyst O. *Cell Signal* 2020;73:109703.

**Funding:** Commercial Support - Galapagos NV and AbbVie Inc.

Characteristics of the US ESRD Population With Autosomal Dominant Polycystic Kidney Disease  
Mirjana Stevanovic,<sup>1</sup> Martha L. Graber.<sup>2</sup> <sup>1</sup>Dartmouth Guarini School of Advanced Studies, Hanover, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Background:** We present recent data concerning US individuals with autosomal dominant polycystic kidney disease (ADPKD) and ESRD

**Methods:** We used data from the US Renal Data System (USRDS) 2014 - 2018 to compare prevalent persons with ESRD and ADPKD to those without ADPKD

**Results:** Persons with ADPKD (N = 42714) comprised 3.1% of the US ESRD population. ADPKD accounted for 99.4 % of all adult cystic disease categories (data not shown). Persons with ADPKD were younger on entry to the ESRD program by 4.9 years, more likely to be female and White, to have had nephrology care, to have initiated with peritoneal dialysis or transplant, and to have received a living donor kidney. There was no difference in the risk of death.

**Conclusions:** The vast majority, 99.4%, of persons with adult cystic diseases on entry to the ESRD program have a diagnosis of ADPKD. Those with ADPKD comprised 3.1% of the total US ESRD population, a figure consistent with data from the USRDS 1998 annual report, Europe and Japan, but lower than has been commonly reported in the US. We estimate that 3 - 7% of all US persons with ADPKD are on dialysis or have a transplant at any one time. On entry to the ESRD program individuals with ADPKD were younger, more likely to be White and female, to have had prior nephrology care, to have initiated renal replacement therapy with peritoneal dialysis or transplant and to have received a living donor graft than those with ESRD without ADPKD. There was no significant difference in the risk of death during a five year period. These findings contribute to our understanding of the epidemiology, risks, and outcomes of ADPKD.

**Funding:** Other NIH Support - NIDDK/COBRE award number P30DK117468

† Linear regression coefficient for Age at first ESRD service and DM, and odds ratios (OR) from logistic regression for all other variables. For all ORs, non-ADPKD patients were used as the reference group.

TH-PO387

The Predicting Renal Outcomes in Polycystic Kidney Disease (PROPKD) Score for Estimating Risk of Rapid Progression and Treatment Benefit in Autosomal Dominant Polycystic Kidney Disease (ADPKD)  
Vitalay Fomin, Huan Jiang, Sharin Roth. *Otsuka Pharmaceutical Development & Commercialization Inc., Princeton, NJ.*

**Background:** The PROPKD scoring system for ADPKD demonstrated its utility for identifying patients at risk of rapid progression to loss of kidney function in a post hoc analysis of the TEMPO 3:4 trial (Corney-LeGall *Nephrol Dial Transplant* 2018). Given that TEMPO 3:4 enrolled a relatively young cohort (18–50 years) with early chronic kidney disease (>80% in stages G1–G2), we evaluated PROPKD for predicting disease

progression and tolvaptan benefit in a broader population that included subjects in the REPRISE trial (Torres *N Engl J Med* 2017), who were older (18–65 years) with more advanced disease (95% in stages G3–G4).

**Methods:** Per PROPKD scoring, subjects were assigned points for male sex (+1), hypertension (+2) or first urologic event before age 35 (+2), and mutation (*PKD2*: 0; non-truncating *PKD1*: +2; truncating *PKD1*: +4). For subjects <35 years without hypertension or urologic events, 0 was assigned to these variables and overall score calculated as the sum of the remaining factors. Total score ranged from 0–9, with 0–3 low risk (LR), 4–6 intermediate risk (IR), and 7–9 high risk (HR) for rapid progression. Annualized decline in estimated GFR (eGFR; mL/min/1.73 m<sup>2</sup>/yr) was calculated by regressing eGFR against time by subject from month 1 to month 12 in REPRISE, and from week 3 to month 36 in TEMPO 3:4, to exclude the early hemodynamic effect of tolvaptan.

**Results:** A population of 210 LR, 548 IR, and 430 HR was analyzed. Whereas there were no significant differences in annualized eGFR decline between risk groups among tolvaptan-treated subjects (LR -2.57, IR -2.69, HR -2.86), in untreated (placebo) subjects, decline was more rapid in higher risk groups (LR -2.82, IR -3.49, HR -4.04; *P*<0.01 for HR vs LR). Tolvaptan had a significant treatment effect vs placebo for IR and HR, but not LR (Table).

**Conclusions:** In a population with a broad spectrum of disease characteristics, the PROPKD scoring system predicted rapidity of eGFR decline in untreated ADPKD and supported the benefit of tolvaptan in patients at elevated risk of rapid progression.

**Funding:** Commercial Support - Otsuka Pharmaceutical Development & Commercialization Inc.

Table. Annualized eGFR decline by PROPKD risk group and treatment in TEMPO 3:4 and REPRISE

	Low Risk		Intermediate Risk		High Risk	
	Tolvaptan (n=126)	Placebo (n=64)	Tolvaptan (n=326)	Placebo (n=222)	Tolvaptan (n=244)	Placebo (n=186)
Change in eGFR (mL/min/1.73 m <sup>2</sup> )	-2.57	-2.82	-2.69	-3.49	-2.86	-4.04
P-value for difference between treatments	0.6184		0.0102		0.0033	
Relative treatment effect	8.7%		22.9%		29.2%	

TH-PO388

**Parameters Associated With Progression, Prognosis, and Tolvaptan Indication in Autosomal Dominant Polycystic Kidney Disease (ADPKD)**  
Vasiliki Gkika, Michaela Louka, Eirini Tigka, Angelos Drakopoulos, Myrto Kostopoulou, George I. Tsirpanlis. *Department of Nephrology, General Hospital of Athens “G. Gennimatas”, Athens, Greece.*

**Background:** The identification of possible risk factors for the progression of ADPKD is an emerging field, especially after the introduction of tolvaptan as the first disease-specific treatment. This study aims to explore the associations between epidemiological, clinical, and imaging data in a large cohort of ADPKD patients.

**Methods:** This study was from a single ADPKD outpatient clinic and were included patients with a recent Magnetic Resonance Imaging (MRI) for the measurement of Total Kidney Volume (TKV). For all patients, the Mayo Clinic Imaging Category (MCIC) and the prediction of End Stage Renal Disease (ESRD) based on the Mayo Clinic formula were calculated. Patients eligible for tolvaptan treatment (MCIC 1C, 1D, 1E, age<55 years old and e-GFR≥25 mL/min) were identified. We examined for possible associations using multinomial logistic regression and linear regression models.

**Results:** A total of 250 patients were included. Based on measurements of height-adjusted TKV (ht-TKV) and age, 8% of the patients were classified as 1A, 20% as 1B, 34% as 1C, 25% as 1D and 13% as 1E, MCIC. In multivariable analysis, patient's age, male sex, parent's age at ESRD (adjusted for patient age) and hypertension were associated with log (ht-TKV). Parent's age at ESRD differed significantly between the MCICs of the offspring. The younger the parent diagnosed with ESRD, the more likely the patient will be diagnosed in the 1E stage. Similarly, there were significant differences in the presence and age of hypertension onset. In 157 patients (74 females and 83 males) who were eligible for tolvaptan treatment, the age at ADPKD diagnosis, at hypertension onset, and the parent's age at ESRD were significantly lower when compared to non-eligible patients. Finally, factors associated with the prediction score of ESRD were hypertension, uric acid, and the age at ESRD of the affected parent.

**Conclusions:** As a heritability estimator, the age at ESRD of the affected parent was significantly associated with a worse phenotype, prognosis, and tolvaptan indication. Hypertension was associated with poor prognosis and an aggravated phenotype, whereas age at diagnosis of the disease and hypertension onset were associated with tolvaptan indication in ADPKD.

TH-PO389

**The PROPKD Score Is Associated With the Progression of Renal Involvement in Patients With Autosomal Dominant Polycystic Kidney Disease Treated With Tolvaptan**  
Tomofumi Moriyama, Kensei Taguchi, Yusuke Kaida, Yunosuke Yokota, Goh Kodama, Sakuya Ito, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan.*

**Background:** The PROPKD score has been proposed to evaluate the risk of the progression to end stage renal failure in patients with autosomal dominant polycystic kidney disease (ADPKD), based on gender (male: 1point), hypertension under 35 years old (2 points), urological event under 35 years old (2 points), and gene mutation (PKD1

truncating mutation: 4 points, PKD1 non-truncating mutation: 2 points, PKD2: 0 point). Although tolvaptan has benefits for renal involvement, whether PROPKD score could predict future renal involvement in patients with ADPKD treated with tolvaptan is unknown. Thus, we explored the effects of tolvaptan on the annual changes in total kidney volume (%TKV) and estimated glomerular filtration rate (%eGFR) according to the PROPKD score in these patients.

**Methods:** 32 ADPKD patients treated tolvaptan for at least a year were retrospectively analyzed (the mean observation period: 3.6 years). We examined the decline in renal function, %TKV by computed tomography, and gene mutation. The association between %eGFR and %TKV change before and after tolvaptan treatment, annual TKV change (%TKV) and PROPKD score was analyzed.

**Results:** We identified gene mutations in ADPKD patients: PKD1 truncating mutation (n=15), PKD1 non-truncating mutation (n=5), PKD2 mutation (n=6), and mutation not found (n=6). Mean %TKV and eGFR were 1843 ± 986 mL and 54.7 ± 21.0 mL/min/1.73 m<sup>2</sup>, respectively. The mean PROPKD score was 3.3±2.4 points and showed a significant negative correlation with %eGFR before and after tolvaptan treatment (*p*=0.044/0.016), and no significant correlation with %TKV before and after tolvaptan treatment.

**Conclusions:** The higher PROPKD score, the faster the decrease in %eGFR during tolvaptan therapy, suggesting that the PROPKD score may be useful as a predictor of the risk of progression to renal failure after tolvaptan introduction.

TH-PO390

**Visceral Adiposity Is Strongly Associated With Kidney Growth in Early-Stage Autosomal Dominant Polycystic Kidney Disease (ADPKD)**  
Kristen L. Nowak,<sup>1</sup> Cortney Steele,<sup>1</sup> Zhiying You,<sup>1</sup> Sumana Ramanathan,<sup>2</sup> Adriana Gregory,<sup>2</sup> Berenice Y. Gitomer,<sup>1</sup> Michel Chonchol,<sup>1</sup> Timothy L. Kline.<sup>2</sup> *HALT-PKD trial <sup>1</sup>University of Colorado - Anschutz Medical Campus, Aurora, CO; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.*

**Background:** We have previously described that overweight and obesity, measured by body-mass index (BMI), are associated with kidney disease progression in individuals with early stage ADPKD. Adipocytes do not simply act as a fat reservoir, but are active endocrine organs, and particularly in visceral adipose tissue, can promote release of pro-inflammatory cytokines and adipokines. Numerous signaling pathways promoted by adipocytes are also implicated in cystogenesis, potentially by promoting a pro-cystogenic milieu. We hypothesized that greater abdominal adiposity would be associated with more rapid kidney growth in early-stage ADPKD patients.

**Methods:** 60 non-diabetic participants with ADPKD and estimated glomerular filtration rate (eGFR) >60 mL/min/1.73m<sup>2</sup> who participated in HALT Study A and had magnetic resonance imaging (MRI) with full coverage of visceral adipose tissue were selected. Body composition parameters, including subcutaneous and visceral adipose tissue, were calculated. The L3-level was determined based on sagittal views and the center slice was selected at the L3-level axial slice. The tissue regions were segmented using ITK-Snap in the axial view and area was calculated by the product of the number of voxels and the in-plane image resolution. The longitudinal (5-yr) association of abdominal adiposity (interaction of visceral, subcutaneous, and total adiposity with time) with height-corrected total kidney volume (htTKV) by MRI was evaluated using linear mixed effects regression models.

**Results:** Mean±s.d. age was 39±7 years, eGFR was 89±16 mL/min/1.73m<sup>2</sup>, and median (IQR) htTKV was 605 (409, 935) mL/m. Greater abdominal subcutaneous (β-estimate 0.16 [95% CI 0.016, 0.30]; all values are presented as x10<sup>2</sup>; *p*=0.03), visceral (β-estimate 0.22 [95% CI 0.13, 0.31]; *p*<0.0001), and total abdominal adipose tissue (β-estimate 0.28 [95% CI 0.15, 0.41]; *p*<0.0001) were associated with a greater increase in htTKV after adjustment for demographics, study randomization, clinical characteristics including eGFR, baseline liver volume, and genotype.

**Conclusions:** Abdominal adiposity, and particularly visceral adiposity, are strongly and independently associated with longitudinal increase in htTKV in a small cohort of patients with early-stage ADPKD.

**Funding:** NIDDK Support, Private Foundation Support

**Cerebrovascular Function in Early-Stage Autosomal Dominant Polycystic Kidney Disease (ADPKD)**  
Cortney Steele, Ester Oh, Taylor Struempff, Heather Farmer-Bailey, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

**Background:** Cerebrovascular dysfunction, characterized by reduced cerebrovascular reactivity, cerebral hypoperfusion, and increased pulsatile flow within the brain precedes the onset of dementia and is linked to cognitive dysfunction. PKD has been described to increase risk of dementia as compared to propensity score matched controls, and intracranial aneurysms are also more prevalent in patients with ADPKD. However, cerebrovascular function has not been previously characterized in patients with ADPKD.

**Methods:** Using Transcranial Doppler, we compared middle cerebral artery (MCA) blood flow-velocity response to hypercapnia (normalized for blood pressure and end-tidal CO<sub>2</sub>; a measure of cerebrovascular reactivity) and MCA pulsatility index (PI; a measure of cerebrovascular stiffness) in patients with early-stage ADPKD vs. age-matched healthy controls. We also administered the NIH cognitive toolbox (cognitive function) and measured carotid-femoral pulse-wave velocity (CFPWV; aortic stiffness).

**Results:** Fifteen patients with ADPKD (9F, 27±4 yrs [mean±s.d.], estimated glomerular filtration rate [eGFR]: 106±22 mL/min/1.73m<sup>2</sup>) were compared to 15 healthy controls (8F, 29±4 yrs, eGFR: 107±11 mL/min/1.73m<sup>2</sup>). MCA PI was unexpectedly lower in ADPKD (0.71±0.07) vs. controls (0.82±0.02 A.U.; *p*<0.001); however, normalized

MCA blood flow-velocity response to hypercapnia did not differ between groups  $2.0 \pm 1.2$  vs.  $2.1 \pm 0.8$  % $\Delta$ /mmHg;  $p=0.85$ ). Lower PI was associated with a lower crystallized composite score, which persisted after adjustment for age, sex, eGFR, and education ( $\beta = 0.55$ ,  $p<0.01$ ); the crystallized composite score (adjusted for education) was lower in ADPKD ( $109.9 \pm 11.7$ ) vs. controls ( $118.0 \pm 8.7$ ;  $p<0.05$ ). There was no association of PI with CFPWV (which was greater in the ADPKD group), suggesting PI reflects vascular properties other than arterial stiffness in this population ( $r=0.01$ ,  $p=0.96$ ).

**Conclusions:** PI is lower in early-stage ADPKD, with preservation of cerebrovascular reactivity to hypercapnia. Low PI could be a risk factor for aneurysms in APKD, as low MCA PI and carotid PI are associated with the presence of aneurysms in a population of middle-aged/older healthy adults. Follow-up research on this observation is merited.

### Altitude, Resting Metabolic Rate, and Autosomal Dominant Polycystic Kidney Disease

Cortney Steele, Erin R. Coleman, Taylor Struempf, Diana George, Claire Winslow H. Winslow, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. *University of Colorado - Anschutz Medical Campus, Aurora, CO.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease and is known to alter metabolic pathways and influence mitochondrial energy production, which in turn could modulate resting metabolic rate (RMR). Acute altitude exposure may influence RMR in those with ADPKD, however, data are lacking.

**Methods:** ADPKD patients were enrolled in clinical trials at the University of Colorado Anschutz Medical Campus. RMR assessments were performed at baseline in Aurora, CO (elevation 5,403') via indirect calorimetry. Living elevation was determined by city and state of residence. Participants were stratified into those living at low altitudes ( $<4,000'$ ) and those living at high altitudes ( $\geq 4,000'$ ). RMR equations Harris-Benedict (H-B) and Mifflin-St Jeor (M) were calculated. In a subset of participants, height adjusted-total kidney volume (htTKV) was measured via magnetic resonance imaging (MRI) as an indicator of disease severity. Independent t-tests were used to determine differences between those living at low/high altitudes. Analysis of covariance and linear regression analyses were also performed.

**Results:** Baseline characteristics of 64 participants were included (42 females (F),  $46 \pm 10$  yrs of age (mean $\pm$ s.d.), body mass index (BMI)  $32.3 \pm 5$  kg/m $^2$ , and RMR  $1721 \pm 289$  kcal/day). Those living at  $<4,000'$  and  $\geq 4,000'$  elevation had similar baseline characteristics ( $p>0.05$ ). After adjusting for age, sex, and BMI, those living at low altitudes tended to have a higher RMR when measured at high altitude than those living at high altitudes ( $p=0.09$ ). Percent differences between indirect calorimetry and prediction equations (H-B and M) were greater in those living at low altitudes performing the RMR assessment at altitude ( $p<0.05$ ). Only a subset of participants had calculated htTKV values ( $n=22$ , 11 F,  $46 \pm 10$  yrs of age, BMI  $33.9 \pm 5$  kg/m $^2$ , and RMR  $1809 \pm 239$  kcal/day). Increasing RMR was associated with an increase in htTKV ( $r=0.50$ ,  $p=0.02$ ); the association remained after adjusting for BMI ( $r=0.46$ ,  $p=0.04$ ).

**Conclusions:** In ADPKD patients living at low altitudes, altitude exposure appeared to elevate RMR when compared to those living at high altitude. Higher RMR may be associated with greater disease severity. Further research is needed to confirm these preliminary data.

### Impact of Pregnancy on the Progression of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease

Jin hyuk Paek, Yaerim Kim, Woo Yeong Park, Seungyeup Han, Kyubok Jin. *Keimyung University School of Medicine, Daegu, Republic of Korea.*

**Background:** Previous studies reported that pregnant women with autosomal dominant polycystic kidney disease (ADPKD) had poor fetal outcomes and maternal complications. In ADPKD, total kidney volume is recognized as a prognostic biomarker for risk assessment. During pregnancy, the kidneys increase in size about 30%. However, there has been no study to evaluate the impact of pregnancy on the progression of total kidney volume and renal outcome among ADPKD patients.

**Methods:** This prospective multicenter cohort study enrolled 693 adult patients from October 2019 to June 2021 at 8 medical centers in Korea. Patients with more than 3 renal cysts in both kidneys were eligible to be recruited. The height-adjusted total kidney volume (htTKV) and Mayo Clinic imaging classification were measured by the ellipsoid equation. Three hundred thirty-seven male patients were excluded from the analysis.

**Results:** In total of 356 female patients, 280 patients (78.7%) had experienced pregnancy. The mean estimated glomerular filtration rate was  $77.5 \pm 31.8$  ml/min/1.73m $^2$  and the mean htTKV was  $1316.3 \pm 1013.0$  ml/m. Patients who experienced pregnancy showed significantly larger htTKV compared with those without pregnancy ( $1367.2 \pm 1057.6$  vs.  $1128.5 \pm 806.4$ , respectively,  $p = 0.035$ ). In patients who experienced pregnancy, age, body mass index, waist circumferences, and creatinine level was higher than patients without pregnancy. There was significant relation between pregnancy and large htTKV (OR = 1.978, 95% CI = 1.174–3.333,  $p = 0.010$ ). However, gravidity was not significantly associated with the Mayo imaging classification (OR = 0.692, 95% CI = 0.412–1.162,  $p = 0.164$ ).

**Conclusions:** This study indicated that pregnancy might influence on the progression of htTKV in ADPKD patients. However, it did not affect the prognosis of the kidney.

## TH-PO394

### Bilateral Renal Cysts and CKD in Association With Neurofibromatosis

Seif Bugazia, Lisa A. Schimmenti, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

**Introduction:** Neurofibromatosis with CKD has rarely been reported. Cases lack description of kidney phenotype. Renal gene panels do not evaluate the *NF2* gene.

**Case Description:** A 67yo male was referred with CKD & bilateral renal cysts, bilateral sensorineural hearing loss, tinnitus & balance difficulty. He used a hearing aid to his left & was deaf in his right ear. He had bilateral cataracts & cataract surgery, bilateral vestibular schwannomas & a dural-based meningioma treated with gamma knife and bevacizumab (d/c'd due to side effects). Lumbar, thoracic & cervical MRI imaging showed no schwannomas. MRI (fig.1) revealed bilateral kidney cysts (total kidney vol= 1257ml). Functional studies revealed a functioning right & non-functional left kidney. Whole exome renal panel (custom  $>150$  genes) to determine the cause of cystic renal disease was unrevealing. We next performed next generation sequencing using a schwannomatosis panel revealing *NF2*: c. 1396C>T, with a mosaic truncating pathogenic variant in *NF2*, encoding a premature stop codon, p.Arg466Ter, in Exon 13 (variant allele fraction 2%, 28 variant reads/ 1112 wild type reads, both strands of 4 amplicons, Q score:36) & confirmed by High Resolution Melting Curve Analysis.

**Discussion:** We describe bilateral cystic disease in a *NF2* patient with CKD. Individuals with mosaic pathogenic variants occurring in distal exons tend to have a 'milder' clinical course. The pathogenic variant detected in Exon 13 was found in 2% of blood cells. *NF2* comprehensive variant analysis (sequencing all exons & del/dup analysis) detects pathogenic variants in  $>90\%$  of non-founder *NF2* patients & in 65-70% of sporadic patients (lower detection due to mosaicism frequently present in founder cases). The proband & his at risk children received genetic counseling.

Mild bilateral cystic kidney disease in *NF2* mosaic case.

## TH-PO395

### Four Year Outcomes, Efficacy, and Safety of Foam Sclerotherapy for Cysts in ADPKD and Autosomal-Dominant Polycystic Liver Disease (ADPLD)

Seif Bugazia, Adriana Gregory, Vicente E. Torres, Laureano J. Rangel, Emily Bendel, Newton Neidert, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** In 2017 we migrated from alcohol to sotradecol foam sclerotherapy (SFS) in our practice, because of perceived improved efficacy. We studied changes in liver/kidney vols (TKV/TLV), renal fxn (ADPKD SFS cases) & QOL (LASA, PLD-Q).

**Methods:** Four-year data was analyzed from 1/1/2017-12/31/2021 in those who completed at least one SFS procedure. Segmentation was used to determine TKV/TLV before & after SFS (coronal MRI/axial CT) using artificial intelligence software. Impact on GFR decline, changes in TKV/TLV & adverse events (AEs) following SFS were assessed. Paired t-test was used for TKV/TLV (absolute & % annual change wrt baseline, IQR [Q1, Q3], changes in PLD-Q scores pre/post, multivariable logistic regression examined GFR trajectories pre/post SFS.

**Results:** We performed 160 SFS sessions ( $n=127$  pts; 79 kidney; 41 with paired data; 81 liver, 6 liver/ kidney combined procedures (35 with paired data) in ADPKD ( $n=86$ ), ADPLD ( $n=10$ ), Cysts NOS ( $n=19$ ) cases. For cases with multi-procedures with available paired data: kidney (2 SFS,  $n=10$ , 3 SFS  $n=2$ ); for liver, six had 2, one had 5 sessions. SFS was associated with a 26% [IQR -44, -6] reduction in TKV ( $p<0.0001$ ) with respect to baseline ( $n=41$ ; median, -191ml [IQR, -682, -83mL];  $P<0.0001$ ). SFS

was associated with a median difference of 277ml/yr TKV reduction (mean % +/- from baseline) in the treated kidneys (n = 41; [IQR, 77, - 683] mL) when compared with the contralateral untreated kidney for the same patient;  $P < 0.001$ ). SFS was associated with 8% [IQR -15, 1%] reduction of TLV ( $p=.0007$ ) wrt baseline (n = 35; median,-243ml [IQR, -573, 47];  $P < 0.03$ ). There was no change in GFR slope in the SFS treated cases; ( $p=0.87$ ; signed rank test). Most patients with flank/back/abdominal pain & distension had improvement in their symptoms; PLDQ (n=14) improved ( $p=.004$ ) as did LASA QOL scores ( $p=.002$  (n=22)). AEs: Five contrast leaks (retroperit/intracalyceal), 5 (4%) pain requiring 2 ER visits, 1 cholangitis; (hospitalized); 1 abortive SFS where the proceduralist unable to penetrate cyst.

**Conclusions:** SFS led to substantial changes in TKV and TLV and corresponding improvement in QOL related reductions in mass effects. There was no detectable benefit on eGFR decline in those who had SFS of kidney cysts in the ADPKD cases.

TH-PO396

Bone Mineral Density in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patients After Kidney Transplantation

Dalia Zubidat,<sup>1</sup> Christian Hanna,<sup>1</sup> Maroun Chedid,<sup>1</sup> Jad G. Sfeir,<sup>1</sup> Fouad T. Chebib,<sup>2</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Mayo Clinic in Florida, Jacksonville, FL.

**Background:** ADPKD is caused by pathogenic variants in *PKD1* or *PKD2*, encoding polycystin-1 and -2 proteins. Polycystins are expressed in animal models' osteoblasts and chondrocytes, and their loss-of-function is associated with low bone density (BMD) and volume. It is unclear whether these variants have an impact on bone strength in patients with ADPKD; thus, we examined bone phenotype in ADPKD after kidney transplantation to minimize the confounding effect of chronic kidney disease-related renal osteodystrophy.

**Methods:** This single-center retrospective observational study retrieved data from adult patients who received a kidney transplant between 01/2005 and 03/2020. Patients with available at and post-transplant dual-energy X-ray absorptiometry (DXA) of the hip and/or lumbar spine (LS) were included. ADPKD patients (n=373) were matched 1:1 by age ( $\pm 2$  years) at kidney transplantation and sex with non-ADPKD patients (n=373). (Figure.1).

**Results:** DXA was obtained at a mean of 6 years following transplant. As compared to non-ADPKD, patients with ADPKD had slightly higher BMD T-scores at left femoral neck (FN) (-1.3 vs. -1.6,  $p<0.01$ ), right FN (-1.3 vs. -1.4,  $p<0.01$ ), left total hip (TH) (-0.5 vs. -1.1,  $p<0.01$ ) and right TH (-0.7 vs -1.1,  $p<0.01$ ) but worse T-score at LS (-0.8 vs -0.4,  $p=0.01$ ). ADPKD patients continued to have higher BMD T-scores in FN and TH, after adjusting for receiving preemptive kidney transplants.

**Conclusions:** Our findings suggest that BMD by DXA is generally preserved in patients with ADPKD following kidney transplantation, despite slightly lower T-scores at the LS.

	ADPKD (n=373)	non-ADPKD (n=373)	p value
Male, n (%)	210 (56.3)	210 (56.3)	1.000
Caucasian, n (%)	335 (95.1)	315 (84.4)	<0.001

TH-PO397

Effect of Kidney Transplantation on Total Kidney Volume in Subjects With Autosomal Polycystic Kidney Disease

Juan Carlos Ramirez-Sandoval, Aaron H. Perez, Estefania R. Linares, Elisa N. Hernández, Jorge Gaytan Arocha, Ricardo Correa-Rotter. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Background:** There is limited evidence of the rate of cyst progression after kidney transplantation in patients with Autosomal Polycystic Kidney Disease (APKD).

**Methods:** Prospective cohort study. The primary objective was to compare the total kidney volume (TKV) before and after transplantation in kidney transplant recipients (KTR) with ADPKD. As a secondary objective, we compared the growth rate of KTR with a cohort of APKD patients who did not undergo transplantation. TKV was assessed with computed tomography/magnetic resonance images performed consecutively. TKV was assessed using ellipsoid equation. TKV growth were classified according to the Mayo Clinic Criteria.

**Results:** We included 30 patients with APKD who underwent kidney transplant (age  $49 \pm 10.1$  years, 11 [37%] females, dialysis vintage 3 [1-6] years, unilateral peritransplant nephrectomy in 4 [13%]). A rapid progression previous transplant (TKV increase  $>4.5\%$  per year, class 1D and 1E) was identified in 20 (66%) cases. Transplantation was associated with a significant decrease in KTV after transplantation in 27 (90%) KTR. Median TKV reduced from 2964 (IQR 1843-3878) mL to 943 (IQR 383-1598) mL after 6 years of follow-up ( $P<0.001$ ), with a mean rate of volume decrease of 39% and 63% after 2 and 6 years of transplant respectively (Figure). Compared to the cohort of non-transplanted APKD patients (n=92), the growth rate was similar in KTR ( $P=0.67$ ). Even in 3 (10%) KTR without regression, the annual growth was  $<1.5\%$  per year after transplant.

**Conclusions:** Kidney transplantation reduced rapidly polycystic kidneys volume in the first 2 years after transplantation, and this decline was continuous during the 6 years of follow-up. These data would reduce the need for prophylactic nephrectomy in asymptomatic APKD patients prior to kidney transplantation.

TH-PO398

A Novel CT Imaging-Radiomics Approach for Kidney Function Evaluation in Autosomal Dominant Polycystic Kidney Disease

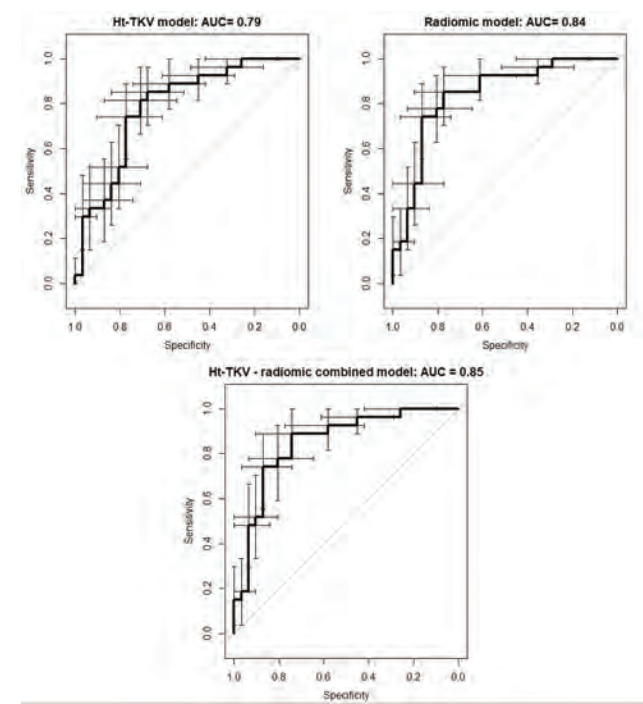

Luca Calvaruso,<sup>1,2</sup> Pietro Manuel Ferraro,<sup>1,2</sup> Pierluigi Fulignati,<sup>1,2</sup> Luigi Larosa,<sup>3</sup> Luca Boldrini,<sup>3</sup> Huang Elena Tran,<sup>3</sup> Claudio Votta,<sup>3</sup> Giuseppe Grandaliano.<sup>1,2</sup> <sup>1</sup>Dipartimento di Scienze Mediche e Chirurgiche, U.O.C. Nefrologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy, <sup>2</sup>Università Cattolica del Sacro Cuore, Largo Agostino Gemelli 8, 00168, Roma, Italy, <sup>3</sup>Department of Diagnostic Imaging, Oncological Radiotherapy, and Hematology – Fondazione Policlinico Universitario “A. Gemelli” IRCCS, Rome, Italy.

**Background:** The aim of this study is to develop and validate a model based on radiomics to predict kidney function among patients with autosomal dominant polycystic kidney disease (ADPKD) studied by CT for determination of total kidney volume (TKV).

**Methods:** We retrospectively selected a cohort of 58 patients with ADPKD who underwent CT scan in 2021, including 31 patients with  $eGFR \geq 60$  mL/min/1.73 m<sup>2</sup> (class 0) and 27 with  $eGFR < 60$  mL/min/1.73 m<sup>2</sup> (class 1). An expert radiologist generated a region of interest (ROI) segmentation for cystic kidney compounds, obtaining 58 ROIs from which we extracted 217 radiomic features using a dedicated software. We built three different logistic regression models: a height-adjusted TKV (Ht-TKV) model, a radiomic model based on the most statistically significant radiomic feature from univariate analysis ( $F_{cm.sum.var}$ ), and a model from the combination of the above. Area under the curve (AUC) of the receiver operating characteristic (ROC) and accuracy were employed to evaluate models performance in discriminating between the two eGFR classes. Internal 3-fold cross-validation (CV) was performed.

**Results:** The Ht-TKV, radiomic and combined models presented respectively an AUC (95% confidence interval) of 0.79 (0.67-0.91), 0.84 (0.73-0.94), 0.85 (0.75-0.95), confirmed by the CV. Mean (standard deviation) values of the accuracy over CV iterations were 0.67(0.09), 0.78(0.08), 0.79(0.08) for the three models.

**Conclusions:** The Ht-TKV-radiomic combined model based on CT images from polycystic kidneys resulted the most effective in the prediction of baseline kidney function in our cohort. Further studies should implement a model extension to predict kidney function slope in order to confirm the role of radiomics in ADPKD management.

TH-PO399

**Total Kidney Volume (TKV) Is Associated With Health-Related Quality of Life (HRQoL) Among Patients With Autosomal Dominant Polycystic Kidney Disease (ADPKD)**  
Istvan Mucsi, Muhammad T. Hassan, Seung Heyck Lee, Saima Khowaja, Ning He, David Hillier, Korosh Khalili, York Pei. *University Health Network, Toronto, ON, Canada.*

**Background:** ADPKD is the most common hereditary kidney disease and imposes significant physical and emotional burden on affected patients. The association of health-related quality-of-life (HRQoL) with disease severity markers (DSMs) including total kidney volume (TKV) has been assessed in a few previous studies, but results were inconclusive, in part due to small sample size. In this cross-sectional study we assessed the association between TKV and domains assessed by the short for (SF)-36 questionnaire in a large cohort of patients with ADPKD recruited in Toronto between January 2017 to December 2021.

**Methods:** Participants completed the study questionnaire that included questions about sociodemographic characteristics and the SF-36 questionnaire. Clinical data was abstracted from medical records. eGFR was estimated from serum creatinine using the CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) equation. All study patients had their TKV measured by MRI and completed a comprehensive *PKD1* and *PKD2* mutation screen. In addition to assess the association between HRQoL scores and TKV, both as continuous variables, we also generated binary HRQoL variable defining poor HRQoL as the lowest quartile; this quartile then was compared to the rest of the sample.

**Results:** Of the 306 participants (mean[SD] age 49[15] years) 45% were male. Mean (SD) eGFR was 79(27) ml/min/1.73m<sup>2</sup>, 12 (4%) of participants had eGFR <30, no patients were on dialysis. Median (interquartile range [IQR]) TKV was 567 (338-933) ml, 149 (49%) had TKV > 1000 ml. Of the SF-36 domains physical function (rho=-0.28, p<0.001) general health perception (rho=-0.19, p<0.001), bodily pain (rho=-0.13, p=0.02) and the physical component score (rho=-0.26, p<0.001) correlated with TKV. Mutation class was not associated with HRQoL domains. In multivariable regression models (adjusted for age, sex and eGFR) TKV was significantly associated with the general health perception domain.

**Conclusions:** In patients with ADPKD, TKV was significantly correlated with several HRQoL SF-36 domains. Some of these associations were confounded by age and eGFR, but poor general health perceptions remained independently associated with TKV.

**Funding:** Government Support - Non-U.S.

**TH-PO400**  
**Evaluation of Advanced MRI Cystic Biomarkers at Kidney Failure in Patients With Autosomal Dominant Polycystic Kidney Disease**  
Stijn Wigerinck,<sup>1,2</sup> Maroun Chedid,<sup>1</sup> Adriana Gregory,<sup>1</sup> Hasan-Daniel N. Kaidbay,<sup>1,3</sup> Christian Hanna,<sup>1</sup> Sarah R. Senum,<sup>1</sup> Peter C. Harris,<sup>1</sup> Timothy L. Kline,<sup>1</sup> Vicente E. Torres,<sup>1</sup> Fouad T. Chebib,<sup>1</sup> PKD Center Mayo Clinic Rochester <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Katholieke Universiteit Leuven, Leuven, Belgium; <sup>3</sup>Lebanese American University, Beirut, Lebanon.

**Background:** Height-adjusted total kidney volume, a surrogate of cystic expansion, is associated with decline in GFR. In a recent cohort of patients with ADPKD who reached end stage kidney failure (ESKD), HtTKV at ESKD was 12.3% smaller with each decade of age. This raised the question about the contribution of non-cystic volume to the worsening of kidney function in older patients. We aimed to assess various imaging biomarkers to understand the characteristics of the ADPKD kidneys at ESKD

**Methods:** This is a retrospective cross-sectional study of patients with ADPKD with ESKD evaluated at Mayo Clinic with available MRI imaging and genotype (N=50, 11 excluded due to incomplete MR coverage, 1 with NMD). Using an automated instance cyst segmentation algorithm, we obtained the following imaging parameters: HtTKV, Mayo Imaging Class (MIC), cyst number, total cystic volume (TCV), cyst index (TCV/TKV), cyst parenchyma surface area (CPSA), and total parenchymal volume (TPV).

**Results:** Thirty-nine patients were divided in 3 groups based on age at ESKD (<46, 46-56 and >56 yo) (Table). Baseline characteristics and ADPKD genotype are shown in table. Most patients in groups 1 and 2 were MIC1D-1E and most patients in group 3 were MIC1B-1C (P<0.01). Cyst index at ESKD was similar at all ages. Age correlated weakly (P<0.01) with HtTKV, cyst number, CSA, CPSA, and cyst index (R<sup>2</sup> 0.01, 0.01, 0.01, 0.02, and 0.03 respectively) and negatively with TPV (R<sup>2</sup> 0.1). HtTKV correlated (P<0.01) positively with cyst number, TCV, CPSA and TPV (R<sup>2</sup> 0.30, 0.95, 0.90 and 0.67, respectively).

**Conclusions:** The lower TPV in older patients and the negative correlation between age and TPV are consistent with the hypothesis that vascular changes and fibrosis are important determinants of GFR decline in older patients. HtTKV at ESKD correlated positively with cyst number, TCV, TPV CPSA. Cyst index at ESKD was similar at all ages.

TH-PO401

**The Effect of Trans-Arterial Embolization of Renal Artery for Autosomal Dominant Polycystic Kidney Disease on the Recurrence of Cyst Infection**  
Hiroki Mizuno. *Toranomon Byoin Bunin, Kawasaki, Japan.*

**Background:** Trans-arterial embolization of the renal artery (RTAE) is one of the procedures which reduces the mass effect of the enlarged polycystic kidney due to ADPKD after the initiation of renal replacement therapies (RRTs). In contrast, cyst infection is one of the life-threatening complications of ADPKD, however, the effect of RATE on recurrence of cyst infection has not been reported yet.

**Methods:** A retrospective analysis was conducted to assess the risk factors of recurrence of cyst infection. Cyst infection was defined as the in-hospital episode of fever, abdominal pain, and positive results of any cultures (blood, urine, or cyst fluid) after excluding the differential diagnosis of cyst infection. Patients not receiving RRTs were excluded because RTAE was a treatment for the patients under receiving RRTs. Recurrence was defined as the second episode of cyst infection within three years after the first episode of cyst infection. Predictors were collected from medical charts. Survival analyses were planned to determine the risk factors of recurrence.

**Results:** Among 883 episodes from 305 patients who were clinically suspected of renal cyst infection, 45 patients were eligible for the recurrence group and 58 patients were eligible for the no recurrence group. Compared with the no recurrence group, the recurrence group had a higher rate of the past history of recurrence and liver cyst infection. There was no difference in treatment status and conditions at discharge between groups. Kaplan-Meire curves showed that five factors, including (1) MRI detected cyst Infection, (2) age over 70 years old, (3) negative history of RTAE, (4) positive culture of extended-spectrum of beta-lactamase-producing Gram-negative rods or Enterococcus faecium (ESBL/faecium group), and (5) negative result of cyst culture, were significantly more likely to recurrence. After adjusting related variables, Cox hazard proportionally analysis revealed that previous history of RTAE (HR 0.49(0.26-0.94), p=0.03), ESBL/faecium group (1.96 (1.01-3.80)p=0.05), the negative result of drainage group (HR 2.27 (1.06-4.84)) were significantly associated with recurrence of cyst infection.

**Conclusions:** In this retrospective cohort study, we found the negative history of RTAE, ESBL/faecium group, and negative results of cyst culture could be the risk factors for recurrence of cyst infections.

### Antibiotic Use and Kidney Stone Disease in Patients With Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer,<sup>1</sup> Zhiying You,<sup>1</sup> Godela M. Brosnahan,<sup>1</sup> Wei Wang,<sup>1</sup> Katharina Hopp,<sup>1</sup> Kristen L. Nowak,<sup>1</sup> Arlene B. Chapman,<sup>2</sup> Ronald D. Perrone,<sup>3</sup> Vicente E. Torres,<sup>4</sup> Alan S. Yu,<sup>5</sup> Michel Chonchol.<sup>1</sup>  
<sup>1</sup>University of Colorado, Denver, CO; <sup>2</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>3</sup>Tufts Medical Center, Boston, MA; <sup>4</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>5</sup>The University of Kansas Medical Center, Kansas City, KS.

**Background:** Kidney stone disease (KSD) occurs in ~20% of patients with autosomal dominant polycystic kidney disease (ADPKD) and is associated with overall disease morbidity, including risk for faster kidney disease progression. Recent evidence suggests that changes in the normal gut microbiome linked with antibiotic use play a causal role in kidney stone disease in the non-ADPKD population. However, antibiotic exposure as a novel risk factor for kidney stone formation has not been explored in ADPKD patients, who are frequently treated with antibiotics for urinary tract and cyst infections.

**Methods:** We analyzed use of the following oral antibiotic classes: cephalosporin, fluoroquinolone, nitrofurantoin/methenamine, sulfa, and broad-spectrum penicillin in the HALT-PKD patient cohort. Antibiotic use preceding self-reported KSD (prior to the report of a kidney stone) was compared to those with no KSD (NKSD) by chi-square test.

**Results:** One hundred and forty three patients reported oral antibiotic exposure over the course of the HALT-PKD study. Antibiotic exposure was significantly higher in patients with subsequent KSD compared to those with no KSD (figure 1). Patients with KSD have a significantly faster rate of decline in eGFR compared to patients without a kidney stone, mean slope of annual decline in NKSD compared to KSD  $-3.64 \pm 4.1$  vs.  $-5.2 \pm 8.3$ .

**Conclusions:** Antibiotic exposure may represent a novel risk factor for kidney stone disease in patients with ADPKD or KSD may lead to antibiotic exposure in this population. Further studies are necessary to address these questions and to better understand the associated mechanisms.

**Funding:** NIDDK Support

## TH-PO403

### Systemic Inflammation and Kidney Stone Disease in Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer,<sup>1</sup> Zhiying You,<sup>1</sup> Godela M. Brosnahan,<sup>1</sup> Wei Wang,<sup>1</sup> Katharina Hopp,<sup>1</sup> Kristen L. Nowak,<sup>1</sup> Arlene B. Chapman,<sup>2</sup> Ronald D. Perrone,<sup>3</sup> Vicente E. Torres,<sup>4</sup> Alan S. Yu,<sup>5</sup> Michel Chonchol.<sup>1</sup>  
<sup>1</sup>University of Colorado, Denver, CO; <sup>2</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>3</sup>Tufts Medical Center, Boston, MA; <sup>4</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>5</sup>The University of Kansas Medical Center, Kansas City, KS.

**Background:** In preliminary studies, we have shown that autosomal dominant polycystic kidney disease (ADPKD) patients with kidney stone disease (KSD) experience faster decline in kidney function compared to those with no kidney stone disease (NKSD). Kidney stone disease affects ~20 to 30% of patients with ADPKD, a much higher prevalence compared to the general population. As KSD is associated with increased inflammation in non-ADPKD patients, we assessed whether KSD, also associates with increased inflammation in ADPKD patients with KSD.

**Methods:** Baseline serum levels of a panel of pro-inflammatory biomarkers (OLINK, Boston MA) were determined among participants in the HALT PKD clinical trials. Levels were compared between 40 ADPKD patients with self-reported KSD and 46 age, sex and estimated glomerular filtration rate (eGFR) matched NKSD ADPKD patients. Elevated IL-6 levels were confirmed by ELISA (Meso Scale Diagnostic Inc., Rockville, MD).

**Results:** Mean age and eGFR was  $40 \pm 11$  years and eGFR  $75 \pm 27$  ml/min/1.73m<sup>2</sup> in KSD patients and  $41 \pm 9$  years and eGFR  $80 \pm 26$  ml/min/1.73m<sup>2</sup> in NKSD. Six pro-inflammatory biomarkers in serum were significantly increased in ADPKD patients with KSD compared to ADPKD patients with no NKSD these included interleukin 6 (IL6), fibroblast growth factor 23 (FGF23), monocyte chemoattractant protein 3 (MCP3), chemokine C-C motif ligand 20 (CCL20), osteopontin (OPG) and interleukin 24 (IL24). Higher IL6 levels in KSD patients were confirmed by ELISA (KSD (N= 50)  $1.58 \pm 2.01$  vs NKSD (N = 75)  $0.97 \pm 1.07$  pg/ml; P = 0.03).

**Conclusions:** ADPKD patients with KSD have evidence of increased inflammation based on higher circulating levels of pro-inflammatory cytokines. Increased inflammation associated with KSD may represent a further injury to the cystic kidney. In the literature, it has been shown that further injury to the cystic kidney exacerbates disease progression. Thus, it is intriguing to speculate that KSD may be a risk factor for kidney disease progression in patients with ADPKD. Further studies will be required to determine the effects of inflammation on disease progression in ADPKD.

## TH-PO404

### Urinary Clusterin Associates With Height Corrected Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease

Berenice Y. Gitomer, Wei Wang, Jessica Ringling, Kristen L. Nowak, Anna Jovanovich, Zhiying You, Katharina Hopp, Michel Chonchol. *University of Colorado, Denver, CO.*

**Background:** Clusterin, also known as apolipoprotein J (ApoJ), is a secreted glycoprotein expressed in various tissues and body fluids. Kidney and urinary clusterin levels (uclusterin) are related to renal tubular injury and are induced in acute kidney injury, diabetic kidney diseases as well as animal and human cystic diseases including ADPKD. We have previously shown that urinary Kim-1 a kidney injury biomarker is associated with estimated glomerular filtration rate (eGFR) and height corrected total kidney volume (HtTKV) in different stages of ADPKD. Thus, we hypothesized that uclusterin may represent a similar biomarker of HtTKV or eGFR in ADPKD patients.

**Methods:** Baseline urinary clusterin/Cr levels were measured in ADPKD participants from our clinical trial examining the effect of pravastatin on ADPKD progression. Eighty patients with baseline estimated glomerular filtration rate (eGFR)  $\geq 45$  ml/min/1.73m<sup>2</sup> (CKD Epi equation) who completed the study were included in this cross-sectional study. Clusterin levels in a spot urine sample collected at baseline were measured by ELISA (R&D systems) and normalized by urine creatinine. The association of baseline urinary clusterin/Cr with Ln transformed height corrected total kidney volume (Ln-HtTKV) or eGFR were evaluated using correlation analysis and linear regression with covariate adjustment.

**Results:** Participants were  $42 \pm 11$  years old at the baseline. Forty-eight (60%) were female. Mean BMI was  $26.6 \pm 5.7$  kg/m<sup>2</sup> and systolic blood pressure (SBP) was  $123 \pm 11$  mmHg. Baseline eGFR was  $90 \pm 19$  ml/min/1.73 m<sup>2</sup> and HtTKV  $761 \pm 396$  ml/m. Baseline urinary clusterin/Cr was  $0.22 \pm 0.14 \times 10^{-3}$ . Urinary clusterin/Cr level correlated with baseline Ln-HtTKV  $0.31$  ( $\beta$  1.13, 95% CI 0.34, 1.92)  $p=0.006$ . The association remained significant even after adjustment for sex age, BMI and SBP. However, there was no association between uClusterin/Cr with eGFR.

**Conclusions:** Urinary Clusterin/Cr is associated with HtTKV in ADPKD. It might serve as an early biomarker in monitoring disease progression in ADPKD.

**Funding:** Other U.S. Government Support

## TH-PO405

### Microbiome-Related Changes In Autosomal Dominant Polycystic Kidney Disease

Jelena Klawitter, Peter H. Smith, Michel Chonchol, Berenice Y. Gitomer, Uwe Christians, Jost Klawitter. *University of Colorado Denver School of Medicine, Aurora, CO.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder characterized by uncontrolled growth of cysts in the kidney. Many studies have reported immune system activation and infiltration of immune cells in ADPKD. In recent years, more details have emerged about the symbiotic relationship between the immune system and the microbiome. Our previous metabolomics study showed that concentrations of several microbiota-originated metabolites were altered in children with ADPKD. Here, we aimed to identify these metabolites and their contribution to ADPKD severity and progression.

**Methods:** Indoles and short chain fatty acids (SCFAs) were quantified in 146 patient plasma samples collected at the baseline of HALT-A PKD trial as well as in 80 healthy subjects using liquid chromatography-mass spectrometry assays. Multiple stepwise linear regression was used to calculate the associations between the microbiota-derived metabolites and ADPKD severity and progression (as calculated by the height-corrected total kidney volume (HtTKV) and estimated glomerular filtration rate (eGFR)).

**Results:** Indole acetic acid (IAA) and 5-hydroxyindole acetic acid (5-HIAA) were not only higher in ADPKD patients as compared to healthy subjects but were also positively associated with HtTKV at baseline ( $\beta=0.201$ ,  $p=0.013$  and  $\beta=0.254$ ;  $p=0.002$ , respectively). SCFAs butyrate and hydroxybutyrate were lower in ADPKD patients versus healthy subjects and both negatively associated with HtTKV ( $\beta=-0.181$ ,  $p=0.004$  and  $\beta=-0.317$ ,  $p<0.001$ , respectively; all after adjustment for age, race, sex, body mass index, systolic blood pressure). Using the same model, 5-HIAA was shown to associate negatively and butyrate positively with kidney function/ eGFR. Furthermore,

baseline para-cresol was the only metabolite that significantly associated with yearly % change in HtTKV, whereas 5-HIAA and butyrate remained associated with yearly change in eGFR in patients with ADPKD.

**Conclusions:** Alteration in plasma levels of indole metabolites and SCFAs was observed between patients with ADPKD and healthy subjects. Several of these microbiota-derived metabolites associated with the disease severity (HtTKV and/or eGFR) and were predictive of disease progression. Follow-up studies using microbiome-targeted therapy to restore a healthy host-microbiota homeostasis could prove beneficial in patients with ADPKD.

## TH-PO406

### Matrix Metalloproteinase-7 in Urinary Extracellular Vesicles Predicts Disease Progression in Polycystic Kidney Disease

Martijn H. van Heugten,<sup>1</sup> Charles J. Blijdorp,<sup>1</sup> Esther Meijer,<sup>2</sup> Robert Zietse,<sup>1</sup> Mahdi Salih,<sup>1</sup> Ron T. Gansevoort,<sup>2</sup> Ewout J. Hoorn.<sup>1</sup> <sup>1</sup>Erasmus MC Afdeling Inwendige Geneeskunde, Rotterdam, Netherlands; <sup>2</sup>Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) has a highly variable rate of disease progression, and currently available biomarkers are unable to adequately identify high risk patients. Our aim was to identify a protein biomarker in urinary extracellular vesicles (uEVs) which can be non-invasively measured to differentiate rapid from slow disease progression.

**Methods:** Patients were selected from the clinical DIPAK trial. We created a discovery (n=10) and confirmation cohort (n=10) including patients with rapid and slow disease progression (eGFR decline  $\geq 4$  or  $< 2$  mL/min/1.73 m<sup>2</sup>/year). uEVs were isolated from 50 mL spot urines by a three-step differential ultracentrifuge protocol, and uEV-proteins were quantified by mass tag labeled and tandem mass spectrometry. A third validation cohort (n=24) was created to validate the mass spectrometry findings with immunoblotting. All patients were matched for established risk factors for disease progression, including age, sex, baseline eGFR, and genetic mutation, and had equal height adjusted total kidney volume.

**Results:** We identified 2,727 and 1,115 unique uEV-proteins with over 60% annotated for the extracellular exosome (Benjamini  $p < 0.01$ ). In the discovery and confirmation cohort, a significantly different uEV-protein abundance was found for 65 and 36 proteins, respectively. Matrix metalloproteinase 7 (MMP-7), a protein previously implicated in kidney disease progression in ADPKD, was consistently higher by 47% and 64% in patients with rapid disease progression in both cohorts ( $p < 0.05$ ). Pathway analysis showed enrichment of Wnt-signaling (q-value  $< 0.05$ ) of which MMP-7 is a downstream mediator. In the validation cohort, MMP-7 was also higher by 120% in uEVs of patients with rapid disease progression ( $p < 0.05$ ).

**Conclusions:** uEV-associated MMP-7 distinguishes patients with slow or rapid ADPKD progression independently of established disease progression markers. MMP-7 is a novel and biologically plausible urinary biomarker for ADPKD which we are currently validating in a larger cohort of patients using a high-throughput assay.

## TH-PO407

### Urinary Prostaglandin E2 Excretion Is Associated With Disease Progression in Polycystic Kidney Disease

Frank Geurts,<sup>1</sup> A. L. Messchendorp,<sup>2</sup> Ron T. Gansevoort,<sup>2</sup> Esther Meijer,<sup>2</sup> Robert Zietse,<sup>1</sup> Mahdi Salih,<sup>1</sup> Robert A. Fenton,<sup>3</sup> Ewout J. Hoorn.<sup>1</sup> <sup>1</sup>Erasmus MC, Rotterdam, Netherlands; <sup>2</sup>University Medical Center Groningen, Groningen, Netherlands; <sup>3</sup>Aarhus Universitet, Aarhus, Denmark.

**Background:** In cell and animal models of autosomal dominant polycystic kidney disease (ADPKD) cyst growth is enhanced by prostaglandin E2 (PGE2). Here, we hypothesize that higher urinary PGE2 excretion in patients with ADPKD is associated with faster disease progression.

**Methods:** We used samples from the DIPAK study, a prospective multi-center cohort of patients with ADPKD, and measured 24h urine PGE2 and its metabolites (PGEM). Linear mixed models were used to analyze the association of PGE excretion with disease progression assessed by eGFR slope. The relation between urinary PGE excretion and a composite outcome of 40% loss of eGFR or kidney failure was analyzed using Cox regression models. PGE excretions were log transformed prior to analysis.

**Results:** Urinary PGE2 and PGEM excretion was measured in 590 patients (48±12 years, eGFR 73±28 mL/min/1.73m<sup>2</sup>) and independently associated with height adjusted total kidney volume (htTKV,  $\beta$  0.10  $p=0.04$ ). A total of 504 patients were available for the eGFR slope and survival analysis (median of 4.2 eGFR measurements and 3.1 years of follow-up). The mean eGFR slope in the linear mixed model was -2.9 mL/min/1.73m<sup>2</sup>/year. A higher urinary excretion of PGE2 and PGEM were both significantly associated with faster eGFR decline. When correcting for htTKV, this effect persisted for PGEM (Table). Higher urinary PGE2 (HR 2.02  $p=0.02$ ) and PGEM (HR 3.65  $p=0.008$ ) excretion was associated with a higher incidence of kidney failure or 40% loss of eGFR after correcting for baseline characteristics, but this effect lost statistical significance after correction for htTKV (PGE2: HR 1.75  $p=0.12$ , PGEM: HR 2.51  $p=0.051$ ).

**Conclusions:** Higher urinary PGE2 and PGEM excretion is associated with faster eGFR decline in ADPKD. The relation of PGE2 with htTKV suggests cyst-related production. Our findings suggest that in patients with ADPKD, PGE2 and PGEM should be further investigated as markers of disease progression or even as potential therapeutic targets.

Table 1: Linear mixed model of urinary PGE and PGEM excretion with eGFR slope.

variables	Model 1		Model 2		Model 3	
	$\beta$	p-value	$\beta$	p-value	$\beta$	p-value
PGE2 ng/24h	-1.2	0.001	-1.2	0.002	-0.24	0.5
PGEM ng/24h	-1.9	<0.001	-1.5	0.004	-1.11	0.03

model1: unadjusted, model2: adjusted for age, sex BMI, albuminuria and PKD mutation, model3: model2+htTKV

## TH-PO408

### Discovery of Next-Generation Anti-miR-17 Oligonucleotide RGLS8429 for Treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Edmund Lee,<sup>1</sup> Tania M. Valencia,<sup>1</sup> Francesca Varrone,<sup>1</sup> Tate Owen,<sup>1</sup> Harini Ramalingam,<sup>2</sup> Ronak Lakhia,<sup>2</sup> Vishal Patel,<sup>2</sup> Cindy L. Berman,<sup>3</sup> Rekha Garg,<sup>4</sup> Denis Drygin.<sup>1</sup> <sup>1</sup>Regulus Therapeutics Inc, San Diego, CA; <sup>2</sup>The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; <sup>3</sup>Berman Consulting, Wayland, MA; <sup>4</sup>PharmaDRS Consulting, San Diego, CA.

**Background:** ADPKD is mostly caused by *PKD1* or *PKD2* mutations, which reduce levels of their encoded proteins polycystin-1 (PC1) or polycystin-2 (PC2). Levels of PC1 and PC2 in urinary exosomes are lower in ADPKD patients than healthy volunteers and correlate inversely with disease severity in ADPKD patients. The miR-17 family of miRNAs is upregulated in human and mouse forms of ADPKD. Genetic deletion or pharmacological inhibition of miR-17 increases PC1 and PC2 levels and attenuate cyst growth in preclinical ADPKD models. Likewise, re-expression of PC1 and PC2 rapidly reverses disease progression in ADPKD mice. Importantly, treatment with the first-generation anti-miR-17 oligonucleotide RGLS4326 (1mg/kg) resulted in a statistically significant increase in urinary exosome PC1 and PC2 levels in patients with ADPKD. Together, these results suggested targeting miR-17 is an attractive therapeutic approach for treating ADPKD.

**Methods:** During development of RGLS4326, dose-limiting CNS toxicity was observed in mice and monkeys receiving high doses of RGLS4326 in nonclinical toxicity studies. Further investigations revealed that CNS toxicity was caused by direct off-target inhibition of the neuroreceptor,  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPA-R), by RGLS4326. Here, we discuss the discovery and characterization of the next-generation anti-miR-17 oligonucleotide RGLS8429 which has a similar efficacy profile as RGLS4326 without the affinity for AMPA-R.

**Results:** Like RGLS4326, RGLS8429 was designed to distribute preferentially to the kidney and inhibit miR-17 function. RGLS8429 showed similar potency profiles in inhibiting miR-17 function compared to RGLS4326 in vitro. RGLS8429 also showed similar pharmacodynamic and pharmacokinetic profiles after a single subcutaneous dose, and similar efficacy profile in ADPKD mouse models after repeat dosing, compared to RGLS4326 in vivo. As RGLS8429 did not cause off-target binding and inhibition of the AMPA-R, no CNS-related toxicity was observed in single- or repeat-dose toxicity studies in mice and monkeys.

**Conclusions:** A Phase 1b clinical trial evaluating RGLS8429 in ADPKD patients is planned for the second-half of 2022.

**Funding:** Commercial Support - Regulus Therapeutics

## TH-PO409

### Altered Lipid Metabolism in Autosomal Dominant Polycystic Kidney Disease Patients Treated With Tolvaptan

Matteo Bargagli,<sup>1,2</sup> Manuel Anderegg,<sup>1</sup> Pietro Manuel Ferraro,<sup>3,2</sup> Daniel G. Fuster.<sup>1</sup> Daniel G. Fuster Research Team <sup>1</sup>Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; <sup>2</sup>Dipartimento Universitario di Medicina e Chirurgia Traslazionale, Università Cattolica del Sacro Cuore, Rome, Italy; <sup>3</sup>U.O.C. Nefrologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy.

**Background:** Dyslipidemia is a common finding in patients with autosomal-dominant polycystic kidney disease (ADPKD), and lower HDL is associated with faster disease progression. Vasopressin interacts with both glucose and lipid regulation pathways, hence Tolvaptan treatment might induce changes in lipid and glucose homeostasis in ADPKD patients.

**Methods:** We conducted an exploratory analysis in the Bern ADPKD registry, a prospective observational cohort study. Glucose and lipid metabolism parameters were measured at baseline and every 12 months thereafter. Patients taking Tolvaptan at baseline were excluded from the analysis. Multivariable mixed-effects regression models adjusted for age, sex, BMI, eGFR, TSH and medications use, including antidiabetic and lipid-lowering drugs, were used to assess changes in plasma glucose and lipid metabolism parameters associated with Tolvaptan treatment.

**Results:** A total of 189 participants (122 without and 67 with subsequent Tolvaptan treatment) were included in the analysis. At baseline, 58 (31%) patients had high total cholesterol, 26 (14%) low HDL, 61 (32%) high LDL and 41 (22%) high triglycerides. During follow-up, Tolvaptan treatment was associated with reduced HDL ( $\beta$  -0.186; 95% CI -0.260, -0.111;  $p < 0.001$ ), increased LDL ( $\beta$  0.216; 95% CI 0.001, 0.430;  $p = 0.048$ ) and triglycerides ( $\beta$  0.381; 95% CI 0.130, 0.633;  $p = 0.003$ ) levels. No significant changes were observed in total cholesterol, plasma glucose or hemoglobin A1c.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Chronic Tolvaptan treatment is associated with a significantly altered plasma lipid profile in ADPKD patients. Our data suggest that patients taking Tolvaptan should undergo regular lipid parameter testing.

## TH-PO410

### The Analysis of Long-Term Course of Tolvaptan Treatment and the Study Using Kidney and Liver Derived Cyclic AMP in Autosomal Dominant Polycystic Kidney Disease

Yoshihisa Nakatani, Yukihito Nakano, Shuji Arima. *Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan.*

**Background:** cAMP (Cyclic AMP) in the kidney and liver of ADPKD (Autosomal dominant polycystic kidney disease) persons cannot be measured directly. We will calculate the cAMP secreted from the kidney and liver and examine the increase of their volumes and renal prognosis.

**Methods:** Sixty ADPKD persons who have visited Kindai University hospital from January 2016 to January 2022. ADPKD was diagnosed, and twenty-five of them were introduced to TVP by hospitalization. After diagnosis, eGFR, plasma / urine cAMP and kidney volume were measured over time and examined. Renal and hepatic Plasma and urine cAMP was calculated.

**Results:** Renal cAMP was correlated with kidney volume at eGFR 30 or higher, but hepatic cAMP did not correlate with liver volume. However, abnormally high liver cAMP was observed in patients who had no longer infected with giant hepatic cyst, which was correlated with the size of the cyst. Renal cAMP was not significantly correlated with  $\Delta$ eGFR, but the higher the renal cAMP, the higher the rate of renal volume increase. Before and after oral administration of TVP, renal cAMP decreased significantly from  $18.0 \pm 8.0$  to  $10.4 \pm 3.4$ , but hepatic cAMP showed almost no change. TKV changed to the rate of +9.27% (before administration), -3.96% (1 year later), -0.80% (2 years later), and +4.24% (3 years later) by TVP administration. And the  $\Delta$ eGFR is -6.7 ml / min (before administration)  $\rightarrow$  1 year later -3.6 ml / min (1 year later), -3.0 ml / min (2 years later)  $\rightarrow$  -3.5 ml / min (3 years later). So, we could suppress enlargement on kidney volume and the decline in renal function. Although renal cAMP dramatically decreased in an abbreviated time in patients who began to take TVP, there were any cases in which renal cAMP increased again during treatment if the amount of TVP taken was not sufficient.

**Conclusions:** Renal cAMP can be a marker for the predict of ADPKD renal volume development and the increase of TVP dose. However, it was found that hepatic cAMP was not a marker for liver volume development and was not affected by TVP.

## TH-PO411

### Number Needed to Harm (NNH) Analysis of Tolvaptan in Patients With Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Sasikiran Nunna,<sup>1</sup> Keith A. Betts,<sup>2</sup> Retesh K. Kumar,<sup>3</sup> Xiaoyu Nie,<sup>2</sup> Ancilla Fernandes.<sup>1</sup> <sup>1</sup>Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; <sup>2</sup>Analysis Group Inc, Los Angeles, CA; <sup>3</sup>Otsuka Pharmaceutical Europe Ltd, Wexham, United Kingdom.

**Background:** ADPKD is the most prevalent monogenic kidney disease and can lead to progressive loss of kidney function and ultimately, kidney failure. Tolvaptan is the first approved treatment to slow kidney function decline in adults at risk of rapidly progressing ADPKD. The potential risk of liver injury associated with tolvaptan is closely monitored in the United States Food and Drug Administration Risk Evaluation and Mitigation Strategy (JYNARQUE REMS) program. The objective of this study is to assess the safety profile of tolvaptan related to liver function using the NNH approach.

**Methods:** Individual patient-level data from the TEMPO 3:4 trial (NCT00428948) was used to evaluate liver function abnormalities, serious alanine aminotransferase (ALT) or aspartate aminotransferase (AST) elevation adverse events (AEs) over 12 months and 24 months of treatment. Liver function abnormalities were defined as ALT > 3 times (3x) and > 5 times (5x) the upper limit of the normal range (ULN). NNH was calculated as the reciprocal of the difference in the proportion of patients experiencing a given outcome between tolvaptan and placebo.

**Results:** This study included 961 patients in the tolvaptan arm and 483 in the placebo arm. The NNHs for ALT > 3xULN were 56.19 (95% confidence interval [CI]: 33.60, 171.33) over 12 months and 39.81 (25.59, 89.57) over 24 months, which suggests that for every 100 patients treated with tolvaptan instead of placebo, only 1.78 and 2.51 additional patients would have ALT > 3xULN over 12 and 24 months, respectively. The proportions of patients with ALT > 5xULN and serious ALT or AST elevation were not statistically different between the two arms in either period, yielding NNH values above 135, which suggests that for every 100 patients treated with tolvaptan instead of placebo, fewer than one additional patient would experience ALT > 5xULN or serious ALT or AST elevation over 12 or 24 months.

**Conclusions:** The large NNH values help further characterize the safety profile of tolvaptan by demonstrating an acceptable benefit-risk profile.

**Funding:** Commercial Support - Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ, USA

## TH-PO412

### Multicenter Real-Life Experience With Tolvaptan Treatment in Patients With Autosomal Dominant Polycystic Kidney Disease

Parikshit Duriseti,<sup>1</sup> Stijn Wigerinck,<sup>1</sup> Maroun Chedid,<sup>1</sup> Yeshwanter Radhakrishnan,<sup>1</sup> Michael A. Mao,<sup>2</sup> Musab S. Hommos,<sup>3</sup> Arvind K. Garg,<sup>4</sup> Ziad Zoghby,<sup>1</sup> Mira T. Keddiss,<sup>3</sup> Christopher L. Trautman,<sup>2</sup> Erin Dahlen,<sup>1</sup> Melissa K. Gay,<sup>1</sup> Jennifer E. McFadden,<sup>3</sup> Samrat V. Bhat,<sup>4</sup> Peter C. Harris,<sup>1</sup> Stephen B. Erickson,<sup>1</sup> Marie C. Hogan,<sup>1</sup> Vicente E. Torres,<sup>1</sup> Fouad T. Chebib.<sup>2</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Mayo Clinic in Florida, Jacksonville, FL; <sup>3</sup>Mayo Clinic Scottsdale, Scottsdale, AZ; <sup>4</sup>Mayo Clinic Health System, La Crosse, WI.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic cause of ESKD. Tolvaptan was approved for the treatment of ADPKD patients who are at risk of rapid progression. The goal of our study is to examine the real-life experience of tolvaptan in ADPKD following its FDA approval.

**Methods:** We retrospectively identified 95 patients initiated on tolvaptan for management of ADPKD at Mayo Clinic across Minnesota, Florida, Arizona, and Wisconsin. Patients started on tolvaptan while enrolled in clinical trials were excluded. Baseline data including age, Mayo imaging classification (MIC), height-adjusted total kidney volume (htTKV) at tolvaptan initiation, and eGFR were documented. Monthly or quarterly laboratory monitoring including serum LFTs, sodium, creatinine, and urine osmolality were collected. Patient registry was created in electronic medical record and nursing surveillance program was utilized in monitoring labs and side effects on tolvaptan.

**Results:** Ninety-two patients started on tolvaptan between June 2018 and May 2022 were included in the study. Of whom, 58% were female, 91% were white with mean (SD) age at initiation of 40.7 (9.6) years. Mean (SD) htTKV at baseline was 1234.9 (909.9) mL/m. Based on Mayo imaging classification, 2% had MIC1B, 43% MIC1C, 28% MIC1D and 22% MIC1E. At last follow-up, 4% were on 30mg, 9% on 45mg, 57% on 60mg, 18% on 90 mg and 12% on 120mg. Tolvaptan was discontinued in 23 (25%) patients. Aquaresis-related side effect was the main reason for drop-out (10.8%). Other reasons included concern for hepatotoxicity (5.4%), non-compliance with lab monitoring (4.3%), nausea (1%), AKI (1%), and lack of coverage by insurance for prescription renewal (1%). Of 5 patients in whom tolvaptan was stopped with concern for hepatotoxicity, none (0%) reached Hy's Law for drug-induced liver injury.

**Conclusions:** In this multicenter real-life experience, tolvaptan was well tolerated in treating patients with ADPKD. The main reasons for discontinuation of therapy included aquaresis affecting quality of life and concern for hepatotoxicity. Our findings are concurrent with data from clinical trials for tolvaptan in ADPKD.

## TH-PO413

### Tolvaptan Modifies Patient Risk Class Distribution Over Time in Autosomal Dominant Polycystic Kidney Disease (ADPKD): An Analysis of Data From the TEMPO 3:4 Trial

Neera K. Dahl,<sup>1</sup> Fouad T. Chebib,<sup>2</sup> Frederic F. Rahbari-Oskoui,<sup>3</sup> Hina Japes,<sup>4</sup> Huan Jiang,<sup>4</sup> LaRee A. Tracy,<sup>4</sup> Linda McCormick,<sup>4</sup> Katherine Maringer,<sup>4</sup> Ronald D. Perrone,<sup>5</sup> Ali Nourbakhsh.<sup>4</sup> <sup>1</sup>Yale School of Medicine, New Haven, CT; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>3</sup>Emory University School of Medicine, Atlanta, GA; <sup>4</sup>Otsuka Pharmaceutical Development & Commercialization Inc., Princeton, NJ; <sup>5</sup>Tufts Medical Center, Boston, MA.

**Background:** The ADPKD risk classification system developed by Irazabal et al (*J Am Soc Nephrol* 2015;26:160) estimates the expected rate of eGFR decline based on patient height-adjusted total kidney volume (htTKV) and age. Patients with typical imaging findings on MRI (class 1) can be categorized for their anticipated slope of eGFR decline from slow progressors (subclass 1A) through rapid progressors (subclass 1E). Subclass assignment remains stable over time for most, but not all patients, dependent on htTKV growth. To evaluate effects of tolvaptan on ADPKD risk subclass over time, we analyzed data from the TEMPO 3:4 trial.

**Methods:** A post hoc analysis compared changes in risk subclass between subjects randomized to tolvaptan or placebo. Subjects in subclasses 1B-1E were identified from baseline MRI and age. The proportions of subjects (completers only) in each baseline subclass who shifted to a different subclass over 36 months were compared using a Cochran-Mantel-Haenszel mean score statistic for association between treatment groups.

**Results:** Consistent with earlier findings by Irazabal et al, most subjects in the TEMPO 3:4 placebo arm remained in their baseline subclass, with some progressing to a higher risk subclass and a smaller proportion dropping into a lower risk subclass (**Figure**). In the tolvaptan arm, by contrast, the proportion who progressed to a higher risk subclass was smaller than that who dropped into a lower risk subclass. Subjects receiving placebo were statistically more likely to progress to a higher risk subclass than those receiving tolvaptan in baseline subclasses 1C ( $P < 0.0001$ ) and 1D ( $P = 0.0087$ ).

**Conclusions:** Reduction of htTKV growth by tolvaptan in ADPKD improved the population risk profile during the 3-year period of treatment with tolvaptan or placebo.

**Funding:** Commercial Support - Otsuka Pharmaceutical Development & Commercialization Inc.

**Figure.** Shift in ADPKD risk subclass to month 36 by baseline subclass and treatment arm

TH-PO414

Treatment of Autosomal Recessive Polycystic Kidney Disease With CFTR Modulators

Liudmila Cebotaru, Murali K. Yanda. Johns Hopkins University, Baltimore, MD.

**Background:** ARPKD is associated with systemic and portal hypertension, fibrosis of the liver and kidney and enlarged kidneys, with fusiform dilation of the collecting ducts. Although it has been postulated that CFTR plays a role in fluid secretion in ADPKD, the opposite is true in ARPKD. For example, a double mutant of CFTR and polycystin/polyductin mice develop massively enlarged kidneys and die from renal failure at ~24 days after birth (Nakanishi et. al (2001). *J. Am. Soc. Nephrol.* **12**, 719-725). Thus, knocking down CFTR makes the disease worse.

**Methods:** We conducted experiments in *pkhd1<sup>pkhd1del3-4/del3-4</sup>* deletion model and cholangiocyte cultures from *pkhd1<sup>del4/del4</sup>* mice. We injected male and female mice with 30 mg/kg of VX-809 every other day for 30 days beginning at 5 days old and necropsied them at 35 days. Cultured cholangiocytes were treated with VX-809 (10  $\mu$ M).

**Results:** The *del3-4* mice develop biliary cysts by 35 days old. The biliary cysts were reduced by VX-809. To understand the factors responsible, we stained liver sections with Ki67 a marker of proliferation and CK19, a marker of cholangiocytes to evaluate proliferation. We detected a 50-fold higher % of cells staining positive for both Ki67 and CK 19, a substantial increase compared to WT, demonstrating that increased proliferation had occurred within the bile duct. The proliferation as indicated by a reduction in positive staining was significantly reduced by VX-809. Significantly, less CFTR protein was detected in the total cell lysate by western blot in the *del4* cholangiocytes compared to wt cells, showing that in the absence of functional FPC, the steady-state levels of CFTR fall. Next, we determined the location of CFTR in *del3-4* mouse cholangiocytes using confocal microscopy. CFTR co-localization with the apical membrane marker WGA in *del3-4* cholangiocytes was greater than in wt. Importantly, the co-localization was reduced in the presence of VX-809. VX-809 increased the co-localization of CFTR with the basolateral membrane marker Na<sup>+</sup>/K<sup>+</sup> ATPase in *del3-4* cholangiocytes.

**Conclusions:** These data indicate that VX-809 reduces proliferation and the presence of CFTR at the apical membrane while increasing CFTR at the basolateral membrane. These data suggest that in the absence of FPC, CFTR is degraded and mislocalized. Demonstration of liver cyst reduction increases the therapeutic potential of VX-809 as a treatment of ARPKD.

TH-PO415

Integrated Analysis of Human and Mouse Kidney Transcriptomic Profiling Unveils the Role of ELF3 in Kidney Fibrosis

Hailong Hu,<sup>1</sup> Xiangchen Gu,<sup>1</sup> Jeffrey H. Miner,<sup>2</sup> Katalin Susztak.<sup>1</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO.

**Background:** Progressive and irreversible glomerulosclerosis and tubulointerstitial fibrosis is associated with loss of kidney function in patients with chronic kidney disease (CKD). Mice could be an excellent model organism to model to study glomerulosclerosis and fibrosis, however, individual mouse models does not fully recapitulate the complexity of the human disease.

**Methods:** Here we performed phenotypic characterization (glomerulosclerosis, fibrosis and kidney function) and RNA sequencing of five mouse kidney disease models including unilateral ureteral obstruction (UO), folic acid nephropathy (FAN), tubule-specific overexpression of Notch1 and podocyte-specific expression of APOL1 risk variant, and the *Col4a3* knockout, Alport syndrome model. RNA sequencing was also conducted to quantify unbiased gene expression in 95 human kidney samples, including controls and diabetic kidney disease. We used ELF3 chromatin immunoprecipitation and sequencing (ChIP-seq) data. Finally, we generated mice with tubule-specific genetic deletion of *Elf3* and induced disease by folic acid injection.

**Results:** We identified 131 genes (including 6 transcription factors) that were commonly regulated in mouse kidney disease models and in CKD patients. Amongst the transcription factors, we identified ELF3 as a key transcriptional factor strongly associated with renal fibrosis in all mouse models and patient samples. ELF3 was mostly expressed in kidney tubular epithelial cells. Tubule-specific *Elf3* knockout mice (KspCre

*Elf3<sup>fl/fl</sup>*) were phenotypically normal at baseline. KspCre *Elf3<sup>fl/fl</sup>* mice showed less severe renal fibrosis compared with wild-type mice after folic acid injection. ChIP-seq data analysis indicated ELF3 binding to *Stat3* and *Twist1*; genes associated with epithelial-to-mesenchymal transition and disease development.

**Conclusions:** These results indicate the key role of tubule-specific *ELF3* in kidney fibrosis. Interfering *ELF3* expression may provide a new therapeutic target for CKD treatment.

TH-PO416

Single-Cell Transcriptomics Indicate That CD163+ Kidney Macrophages Are Pro-Inflammatory and May Orchestrate Further Immune Cell Recruitment to Kidney Lesions in ANCA-Associated Glomerulonephritis

Yosta Vegting,<sup>1,2</sup> Aldo Jongejan,<sup>3</sup> Ester B. Remmerswaal,<sup>1,2</sup> Perry Moerland,<sup>3</sup> Jesper Kers,<sup>4,5</sup> Liffert Vogt,<sup>1,6</sup> Frederike J. Benelman,<sup>1,2</sup> Marc Hilhorst.<sup>1,2</sup> <sup>1</sup>Amsterdam UMC location University of Amsterdam, Department of Internal Medicine, Section of Nephrology, Amsterdam, Netherlands; <sup>2</sup>Amsterdam Institute for Infection and Immunity, Amsterdam, Netherlands; <sup>3</sup>Amsterdam UMC location University of Amsterdam, Department of Epidemiology & Data Science (EDS), Bioinformatics Laboratory, Amsterdam, Netherlands; <sup>4</sup>Amsterdam UMC location University of Amsterdam, Department of Pathology, Amsterdam, Netherlands; <sup>5</sup>Leiden University Medical Center, department of Pathology, Leiden, Netherlands; <sup>6</sup>Amsterdam Cardiovascular Sciences, Microcirculation, Amsterdam, Netherlands.

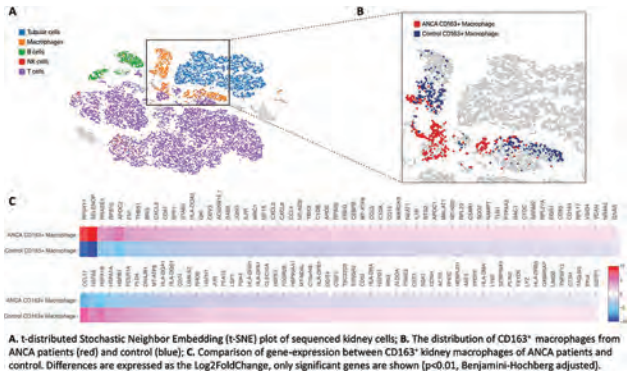

**Background:** Anti-Neutrophil Cytoplasmic Antibodies (ANCA)-associated glomerulonephritis (AGN) affects up to 90% of patients with ANCA-vasculitis and may result in end-stage kidney disease. In AGN kidney biopsies, CD163<sup>+</sup> macrophages are abundantly present and linked to disease activity. However, their exact role in the maintenance or resolution of local inflammation remains unclear.

**Methods:** CD163<sup>+</sup> kidney macrophages were studied using single-cell RNA sequencing of fresh kidney biopsies of 3 active ANCA patients and one patient receiving a nephrectomy for renal cell carcinoma. Cells were sorted for living (CD45<sup>+</sup>) immune cells by flowcytometry and whole transcriptome analysis was performed using 10X Genomics' technology. To aid in the multiomic characterization, 2 samples were incubated with an oligo-antibody cocktail and T and B Cell Receptor Repertoires were sequenced.

**Results:** Over 29,000 cells were sequenced; 2,300 (8%) were identified as CD68<sup>+</sup> macrophages. In patient and control samples, 498/19,689 (2.5%) and 320/9,605 (3.3%) cells expressed CD163, respectively. Comparison of gene-expression between CD163<sup>+</sup> macrophages of the two groups showed significant upregulation of pro-inflammatory cytokines and chemokines (Log2FoldChange ANCA vs control) (IL1B 1.62, CXCL2 2.25, CXCL3 3.26, CXCL8 2.19, CCL3 1.81, CCL4 2.04), and the complement system (C1Qa 1.79, C1Qb 1.94, C1Qc 1.37, C5aR1 1.43). Expression of CCL17 was downregulated (CCL17 -6.57).

**Conclusions:** CD163<sup>+</sup> kidney macrophages are pro-inflammatory and may orchestrate further immune cell recruitment to active kidney lesions in AGN.

## TH-PO417

**The Spatially Resolved Transcriptome Signatures of Glomeruli in CKD**

Laura Perin,<sup>1,2</sup> Hasmik Soloyan,<sup>1</sup> Jeremy Clair,<sup>6</sup> Paolo Cravedi,<sup>3</sup> Andrea Angeletti,<sup>4</sup> Laith Al-Rabadi,<sup>5</sup> Roger E. De Filippo,<sup>1</sup> Stefano Da Sacco,<sup>1</sup> Kevin V. Lemley,<sup>1</sup> Sargis Sedrakyan.<sup>1</sup> <sup>1</sup>Children's Hospital Los Angeles, Los Angeles, CA; <sup>2</sup>University of Southern California, Los Angeles, CA; <sup>3</sup>Mount Sinai Health System, New York, NY; <sup>4</sup>Istituto Giannina Gaslini, Genova, Italy; <sup>5</sup>University of Utah Health, Salt Lake City, UT; <sup>6</sup>Pacific Northwest National Laboratory, Richland, WA.

**Background:** Using Digital Spatial Profiling (DPS), we described for the first-time the human spatial glomerular transcriptomic map that may characterize the molecular mechanisms underlying progressive diseases in Alport syndrome (AS), focal segmental glomerulosclerosis (FSGS), and membranous nephropathy (MN).

**Methods:** Nanostring GeoMX DSP was performed in paraffin sections of AS, FSGS, and MN (normal biopsies from partial nephrectomy were used as control). Tabular and glomerular regions of interest (ROI, n=106) were manually selected and sequenced following Nanostring protocols. After QC analysis (dynamic range and gene expression above noise), and subsequent Q3 normalization, data processing was performed in R v4.0.2 using the package RomicsProcessor v1.0.0. Different analytical tools were used to determine similarities/differences between healthy and diseased glomeruli.

**Results:** By DPS, we revealed significant heterogeneity of transcriptional programs among glomeruli within the same disease as well as across different diseases. By regression analysis we showed that increasing pathology scores in AS, FSGS, and MN correlated with specific increasing or decreasing genes, mostly associated with cellular adhesion. By trajectory analysis we revealed that glomeruli (from all 3 diseases) having low pathology scores showed transcriptional signatures that were significantly different from non-diseased glomeruli, indicating that histological features may not always represent transcriptional changes. We identified a transcriptional signature comprised of genes (*ADAMTS13*, *HOXB8*, and *ZNF346*) and pathways for SRP-dependent co-translational protein targeting to membrane and selenocysteine synthesis that were modulated in all diseased glomeruli. By correlation analysis, we identified new glomerular cell-specific genes that highly correlated with known podocyte markers (WT1, NPHS1, NPHS2), glomerular endothelial cells (EHD3), and mesangial cells (PDGFR $\beta$ ).

**Conclusions:** Defining transcriptional programs at the single glomerulus level is a powerful way of gaining insight into the pathophysiology of kidney disease with the potential of clarifying biological processes key to understanding mechanisms of disease progression and allowing the discovery of potential new therapeutic targets for CKD patients.

## TH-PO418

**Biomarkers of the Aging Kidney: A Proteomic Analysis of Renal Microstructures at Different Cortical Depths**

Mariam P. Alexander, Akhilesh Pandey, Aidan F. Mullan, Nicholas B. Larson, Aleksandar Denic, Gunveen Sachdeva, Muhammad Sohail Asghar, Andrew D. Rule. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** While we have improved understanding of age-related microstructural changes of the glomeruli & tubulointerstitium, the molecular processes are unclear. We performed proteomic profiling of glomeruli & tubulointerstitium at different cortical depths in young & aged human kidneys to identify a signature of aging.

**Methods:** Laser capture microdissection of non-scarred glomeruli & tubulointerstitium from superficial & deep cortex from 16 young (mean age, 30y) & 16 old (mean age, 78y) radical nephrectomy wedge-sections with <10% fibrosis (non-tumor) followed by mass spectrometry-based proteomics.

**Results:** A total of 3228 & 3652 proteins were identified in the glomeruli & tubulointerstitium compartment, respectively. Protein signatures between old & young, differentially expressed at p<0.05 (ANOVA with a Holm-Bonferroni correction) with an absolute log2 fold change >1 were identified as potential markers for aging (Figure 1). More proteins were differentially expressed in the deep (19) vs superficial cortex (7). The glomeruli of older people, from the superficial cortex, showed decreased APOL1 & AHSF (Fetuin-A), [role in CKD], & PHGDH, [serine biosynthesis] & glomeruli of older people from deep cortex showed decreased complement factor D & GAS2 [regulator of apoptosis & senescence]. The glomeruli of older people from deep cortex, showed increased CSTA [anti-apoptotic role] & ApoD [an anti-stress protein induced by oxidative stress]. Superficial tubulointerstitium of older people showed increased HKDC1 [glucose homeostasis], &  $\alpha$ -crystallin B chain [p53-target gene for apoptosis]. The deep tubulointerstitium of older people, showed overexpression of proteins involved in mitochondrial function, as well as TIMP3 & elastin [increased in diabetic nephropathy].

**Conclusions:** Proteins, particularly of deep cortex, that regulate matrix remodeling, mitochondrial function, inflammation, & metabolic homeostasis may play a role in aging.

## TH-PO419

**Single Nuclei RNA-Seq Reveals Cell-Type Specific Responses to Disease and Enalapril in the gddY Mouse Model of IgA Nephropathy**

N. E. Olson,<sup>1</sup> Mark McConnell,<sup>1</sup> Phillip J. McCown,<sup>2</sup> Edgar A. Otto,<sup>2</sup> Viji Nair,<sup>2</sup> Marvin Gunawan,<sup>1</sup> Sean Eddy,<sup>2</sup> Jennifer H. Cox,<sup>1</sup> Matthias Kretzler,<sup>2</sup> Toshiki Kano,<sup>3</sup> Yusuke Suzuki,<sup>3</sup> Andrew J. King.<sup>1</sup> <sup>1</sup>Chinook Therapeutics Inc, Seattle, WA; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Juntendo University Faculty of Medicine, Tokyo, Japan.

**Background:** IgA nephropathy (IgAN) is defined by the deposition of IgA-containing immune complexes in the mesangium that induce kidney injury. To better understand the mechanisms of IgAN progression and cellular response to ACE inhibitor enalapril (ACEi) we performed snRNA-seq of kidney cortex from control mice, gddY mice, a spontaneous IgAN model and gddY mice treated with ACEi for 8 weeks.

**Methods:** Nuclei from naive (n=6), gddY (n=8), and ACEi-treated gddY mice (n=8) were isolated from kidney cortex and sequenced using the 10x Genomics Platform and analyzed using Seurat 4.0. QC filters were applied and nuclei were used to identify significant differentially expressed genes (DEGs) (log FC $\geq$ 0.25, p-adj $\leq$ 0.05). DEGs for each cell type were identified by comparing gddY vs. naive, or gddY vs. ACEi-treated gddY mice. Ligand/Receptor (L/R) analysis was performed using Connectome.

**Results:** After QC filters were applied, 152,059 nuclei remained, resulting in good representation across all major kidney cell types. We identified failed repair (FR) proximal tubule cells as the most expanded kidney cell type in gddY (5.6-fold) with the highest number of DEGs (779) compared to naive mice; the number of mesangial cells, fibroblasts, and endothelial cells also increased in gddY mice. FR cells showed a Tnf activation signature induction. L/R analysis shows FR cells are a source of Tnf stimulation for fibroblasts and Ccl2 stimulation of leukocytes. The response to ACEi, measured by gene expression changes, varied widely across kidney cell types. Ascending thin limb cells showed the smallest gene expression changes with 7 DEGs and VSMC/Pericytes showed the greatest gene expression changes with 377 DEGs. FR cells showed a modest response to ACEi, with 170 DEGs. When we compared gene expression changes after ACEi with those dysregulated in the gddY model, we found ACEi primarily induced *de novo* gene expression. For VSMC/P, 32 genes were reversed while 320 showed *de novo* expression with ACEi treatment compared to untreated gddY.

**Conclusions:** This study provides novel cell-type specific molecular insights into the pathogenesis of glomerulonephritis and subsequent tubular injury and identified cell-type specific differences in response to ACEi in an IgAN mouse model.

## TH-PO420

**Collapsing Phenotype Is a Consequence of HIV-Induced Profibrotic and Compromised Transition of Parietal Epithelial Cells in APOL1 Renal Risk Milieu**

Vinod Kumar,<sup>1,2</sup> Ashwani Malhotra,<sup>2</sup> Pravin C. Singhal.<sup>2</sup> <sup>1</sup>Post Graduate Institute of Medical Education and Research Department of Dermatology Venereology and Leprology, Chandigarh, India; <sup>2</sup>Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

**Background:** HIV-infected patients with African ancestry carrying APOL1 renal risk alleles (ARRAs G1 and G2) have a several-fold higher risk of developing HIVAN than patients having APOL1-G0. HIV induces APOL1 in parietal epithelial cells (PECs). Since the expression of APOL1 (wild-type, G0) in monocytes make them resistant to cellular injury and HIV replication, its potential in PECs in general and ARRAs, in particular, has not been investigated. We hypothesized that HIV-mediated PECs' proliferation and the transition are compromised in the ARRAs (G1/G2) milieu & result in their accumulation in Bowman's space, manifesting collapsing phenotype.

**Methods:** The cultured human parietal epithelial cells (hPECs) were transduced with vector, G0, G1 & G2 & analyzed for their proliferative, fibrotic, & podocyte (PD)-specific differentiation phenotype (transition markers) using western blotting (WB). For phenotype-specific proliferative, profibrotic, and transition markers under the HIV milieu, V/G0/G1/G2-PECs were transduced with HIV (NL4-3) for 48hr (n=4) & analyzed by WB. The expression of mTOR signaling and PECs' transition markers was measured

using Western blotting and miR193a expression by RT-PCR to evaluate the involved mechanisms. Renal tissues from control & Tg26 (a HIVAN model) mice were analyzed for miR193a & mTOR expression by FISH & IHC in PECs

**Results:** In vitro studies, G1/G2-PECs displayed an increased expression of profibrotic (CD44, PERK,  $\alpha$ -SMA, Fibronectin, Vimentin, MMP9, SNAIL) but an attenuated expression of transition markers in control and HIV milieu when compared to G0-PECs; in contrast, G0-PECs showed attenuated expression of profibrotic but an enhanced expression of transition markers in HIV milieu. These findings indicate that PEC to PD transition is compromised in G1/G2-PECs in the control and HIV milieu. G1/G2-PECs also displayed increased expression of p-mTOR, p-70S6K, p-4EBP, & p-eEF indicating the activation of mTOR signalling. Renal cortical sections of Tg26 mice showed an increased accumulation of PECs in their Bowman's space and increased miR193a & mTOR expression by PECs compared to control mice.

**Conclusions:** Accumulation of PECs in Bowman's space is a consequence of compromised transition in profibrotic PECs in APOL1 renal risk (G/G2) milieu in HIV-infected patients

**Funding:** NIDDK Support, Government Support - Non-U.S.

## TH-PO421

### Glomerular Annexin A3 and Cathepsin C Staining in COVID-19-Associated and HIV-Associated Nephropathy (HIVAN)-Associated Collapsing Glomerulopathy

Michelle T. Barati,<sup>1</sup> Jessica L. Hata,<sup>3</sup> Michael E. Brier,<sup>1,2</sup> Kenneth R. McLeish,<sup>1</sup> Jon B. Klein,<sup>1,2</sup> Michael Merchant.<sup>1</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>Robley Rex Va Medical Center, Louisville, KY; <sup>3</sup>Norton Healthcare, Louisville, KY.

**Background:** Prior studies demonstrated glomerular tuft staining for annexin A3 (Anxa3), a marker of parietal epithelial cells (PECs), and cathepsin C (Ctsc), a master regulatory protease, distinguishing primary collapsing glomerulopathy (CG) from other glomerular diseases. We hypothesized these staining patterns would differentiate COVID-19 associated CG (COVID-19+/CG+) from COVID-19(+) without CG (COVID-19+/CG-).

**Methods:** Biopsy sections used were from patients with COVID-19 infections and a pathologist-based tissue diagnoses including CG (COVID-19+/CG+; n=4) or lacking CG diagnosis (COVID-19+/CG-; n=6) were stained for Anxa3 and Ctsc using published protocols. HIVAN-associated CG (n=4) biopsies were used as a secondary CG control. Historical controls data for non-CG biopsies (PMID:32561683). Glomerular staining was tabulated as for PEC staining, phenotypic characteristics of normal and activated (enlarged nuclei, hypertrophic/enlarged cuboidal shape cells, vacuolization) PECs, and for glomerular tuft to Bowman's capsule adhesions or cellular PEC bridges. Globally scarred glomeruli were omitted from analysis. Serial section staining was used to demonstrate Anxa3 and Ctsc co-localization. Differences in the mean (i) number of glomeruli staining OR (ii) glomerular tuft area stained for Anxa3 and Ctsc per biopsy were compared by one-tailed t-test assuming an increase in staining in CG over non-glomerular disease. A p-value <0.05 was used for statistical significance.

**Results:** All COVID-19+/CG+ and HIVAN patients with CG demonstrated extensive Anxa3 and Ctsc glomerular tuft staining. The frequency of glomerular tuft Anxa3 and Ctsc staining and percent glomerular area was significantly (p<0.05) increased in biopsies with COVID-19+/CG+, compared to COVID-19+/CG- (log2FC 2.8-2.9). No statistical difference in frequency or area stained for Anxa3 and Ctsc was observed between COVID-19+/CG+ and HIVAN-associated CG.

**Conclusions:** Anxa3 and Ctsc glomerular tuft expression is increased significantly in COVID-19 and HIVAN patients with CG, mirroring our findings in primary CG. These data support the hypotheses that (a) migration of activated PECs into the glomerular tuft is a prevalent event in both primary CG and virus-associated secondary CG, and (b) glomerular Anxa3 or Ctsc may be therapeutic biomarkers of CG.

## TH-PO422

### Identification of Noninvasive Surrogates as Predictors of Response to FT011 in Kidney Disease

Sean Eddy,<sup>1</sup> Andrew Kompa,<sup>2</sup> John R. Hartman,<sup>1</sup> Felix H. Eichinger,<sup>1</sup> Brad A. Godfrey,<sup>1</sup> Wenjun Ju,<sup>1</sup> Amanda J. Edgley,<sup>2</sup> Robyn G. Langham,<sup>2,3</sup> Laura H. Mariani,<sup>1</sup> Darren J. Kelly,<sup>2,3</sup> Matthias Kretzler.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>University of Melbourne, Fitzroy, VIC, Australia; <sup>3</sup>Certa Therapeutics, Melbourne, VIC, Australia.

**Background:** Interstitial fibrosis is not only a common endpoint of injury in most kidney diseases, it is also a strong predictor of disease progression. With the development of a novel agent FT011, that has demonstrated anti-fibrotic efficacy in preclinical models, and an excellent safety profile in Phase I studies, a pharmacotranscriptomic analysis of the effects in rats was undertaken. Comparative analysis with human kidney RNAseq profiles was then performed to identify potential predictive clinical and biomarker profiles of patients from the NEPTUNE cohort most likely to respond to FT011 treatment.

**Methods:** RNAseq profiles were generated from kidneys harvested at 12 weeks in Sprague Dawley rats who had undergone Sham (n=9), subtotal nephrectomy (STNx, n=8), or STNx+FT011 treatment (n=8). Differentially expressed gene (DEG) profiles were generated, and enrichment analysis performed. Ortholog mapping was performed using Ensembl to map animal profiles onto human kidney RNAseq profiles from the NEPTUNE cohort (n=388). Urine biomarker profiles were generated NEPTUNE biobanked urine.

**Results:** At week 12 STNx+FT011 attenuated proteinuria and plasma creatinine compared to STNx (p<0.05). DEG profiles for STNx vs Sham (9373, q<0.01) and STNx+FT011 vs STNx (4996, q<0.1) comparisons were performed. 4546 DEGs were shared and direction of expression was reversed by FT011 in 99.9% of these genes. The top 500 DEGs were carried forward as an FT011 response signature. Top enriched pathways and upstream regulators of the signature were fibrosis pathways and TGF $\beta$ -1 (p<0.001). The signature was then mapped onto human expression profiles. The signature was elevated in kidney biopsy profiles of patients with FSGS and MN, was negatively correlated with eGFR (p<0.001), and positively correlated with UPCR (p<0.01). Non-invasive urine biomarkers also showed strong correlation with the signature (p<0.001).

**Conclusions:** FT011 treatment reduced a fibrosis-associated transcriptional profile in the STNx rat model. The signature was highly significant in human kidney disease profiles, associated with more advanced disease, and strongly correlated with non-invasive biomarkers, offering a promise of identifying patients with an intrarenal profile best responsive to FT011 in clinical trials.

## TH-PO423

### The Loss of Peroxidase Causes a Sex-Dependent Susceptibility to Vascular Mechanical Injury

Selene Colon, Gautam B. Bhawe. Division of Nephrology and Hypertension Vanderbilt University Medical Center, Nashville, TN.

**Background:** The normal inflammatory response consists of an immune system upregulation that protects by eliminating pathogens and promotes recovery through tissue repair. There is increasing evidence that inflamed tissues' remodeled extracellular matrix (ECM) directly affects the inflammatory response, leading to changes associated with diseases that affect various organ systems, including the vasculature and kidney. Peroxidase (Pxdn) is an extracellular matrix (ECM) associated heme peroxidase that catalyzes the formation of sulfilimine cross-links in collagen IV. Collagen IV is the prominent constituent of basement membranes (BM), a specialized sheet-like ECM that underlies cell layers in all tissues. The Pxdn knock-out (Pxdn<sup>-/-</sup>) mice generated in our lab exhibit reduced BM cross-links and strength. Using the unilateral nephrectomy with angiotensin II infusion (Unx + Ang II) model of kidney injury, we wanted to determine if the initiation and progression of glomerular injury depends significantly on GBM strength and resilience.

**Methods:** Utilizing 129S4/SvJaeJ wildtype and Pxdn<sup>-/-</sup> mice, we removed one kidney and simultaneously inserted an osmotic mini-pump for the constant subcutaneous dosing of angiotensin II, leading to hypertension-induced mechanical stress. We monitored blood pressure and body weight and collected blood and urine to measure kidney function every other week. We planned to sacrifice animals four weeks post-uninephrectomy, but Pxdn<sup>-/-</sup> female mice began to die around three weeks post-surgery. To account for this, we shortened the timeline to two weeks post-uninephrectomy.

**Results:** Injured female Pxdn<sup>-/-</sup> mice presented with a significant decrease in survival after 2-weeks and an increase in CD4<sup>+</sup> T-cells and F4/80<sup>+</sup> macrophages in the vasculature. They also had an increase in renal fibrosis and trended towards a decrease in renal function compared to all other mice. We also discovered that the exacerbated injury in female Pxdn<sup>-/-</sup> mice was reversed after ovariectomy.

**Conclusions:** In this work, we found that the loss of Pxdn disproportionately affects females more than males in the Unx + Ang II model of kidney injury. This dramatic vascular inflammatory phenotype is the first sex-specific phenotype attributed to Pxdn protein expression. It suggests that the loss of Pxdn and sex contribute to renal fibrosis and vascular inflammation in response to vascular mechanical injury.

## TH-PO424

### Pressure-Dependent Molecular Transport in Native and Enzymatically Crosslinked Glomerular Basement Membrane

Dan Wang, Nicholas J. Ferrell. The Ohio State University Wexner Medical Center, Columbus, OH.

**Background:** Glomerular basement membrane (GBM) is a thin layer of extracellular matrix (ECM) that supports podocytes and endothelial cells and regulates their behavior and function. The role of the GBM in determining the permeability of the glomerular filter in health and disease is not fully understood. The GBM has been proposed to act as a compressible membrane with increased selectivity under applied pressure. Multiple kidney diseases are characterized by increased enzymatic crosslinking of the ECM. We hypothesized that enzymatic crosslinking would increase GBM permeability under pressure by increasing GBM stiffness and reducing pressure dependent compression.

**Methods:** Glomeruli were isolated from porcine kidneys by sieving. Stiffness of native and microbial transglutaminase (mTG) crosslinked decellularized glomeruli were measured by a customized compression assay. GBM membranes were made by pressure compacting decellularized glomeruli on a supporting membrane in a stirred cell. FITC-Ficoll sieving coefficients were measured at high and low pressure on native and crosslinked GBM. Diffusional permeability was determined by measuring passive transport of Ficoll through the GBM in the absence of applied pressure.

**Results:** Stiffness of decellularized glomeruli was significantly increased (4.1-fold) after crosslinking with mTG (100  $\mu$ g/mL). mTG did not affect FITC-Ficoll diffusional permeability of GBM, suggesting minimal alteration of pore structure in the absence of applied pressure. The sieving coefficient curves of native GBM show a reduction in molecular cut-off with increasing pressure, indicative of membrane compression effects. Crosslinked membranes did not show significant compression effects on sieving coefficient.

**Conclusions:** We developed a GBM in vitro model to investigate the molecular transport. We use the native and crosslinked GBM as healthy and pathological conditions, respectively. mTG had minimal effect on molecular transport during diffusive transport. Native GBM behaved as a compressive filter, restricting large molecule transport at high pressure. This effect was mitigated in enzymatically crosslinked GBM due to the decreased degree of compressibility suggesting that disease mediated enzymatic crosslinking may contribute to glomerular filtration defects in chronic kidney disease.

### ZNF185 Prevents Stress Fiber Formation Through the Inhibition of RhoA in Endothelial Cells

Soichiro Suzuki, Fumiaki Ando, Yu Hara, Tamami Fujiki, Shintaro Mandai, Koichiro Suga, Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

**Background:** Cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA) signaling promotes endothelial barrier function to prevent plasma leakage induced by inflammatory mediators. Although PKA is a major effector of vascular permeability, the molecular mechanisms underlying PKA signaling pathway in endothelial cells remain to be determined. In this study, we used a cAMP inducer, forskolin, and a phospho-PKA substrate antibody to identify ZNF185 as a novel PKA substrate. ZNF185 has been described as a protein involved in the regulation of cell differentiation and proliferation of cancers. However, its physiological relevance in endothelial cells has not yet been established.

**Methods:** We investigated the function of ZNF185 in human umbilical endothelial cells (HUVECs).

**Results:** ZNF185 is an actin cytoskeleton-associated protein and colocalized with F-actin in endothelial cells. ZNF185 also interacted with PKA which autophosphorylated ZNF185 itself. Both phospho-ZNF185 and F-actin accumulated at plasma membrane region in response to forskolin to stabilize the cortical actin structure. By contrast, ZNF185 knockdown disrupted actin filaments and promoted stress fiber formation without inflammatory mediators. Constitutive activation of RhoA was induced by ZNF185 knockdown, which resulted in forskolin-resistant endothelial barrier dysfunction. ZNF185 was essential for cAMP/PKA/RhoA signaling for the suppression of endothelial hyperpermeability.

**Conclusions:** ZNF185 is necessary for the maintenance of cytoskeletal actin structures in endothelial cells.

## TH-PO426

### Adaptive Remodeling of Mesangial Matrix Proteoglycan Composition During IgA Nephropathy

Kerstin Ebefors, Alva Johansson, Roberto Boi, Jenny C. Nystrom. *Goteborgs universitet Sahlgrenska Akademin, Goteborg, Sweden.*

**Background:** IgA nephropathy (IgAN) is characterized by galactose deficient IgA (gd-IgA1) containing immune complexes in the mesangium, leading to activation of the cells, proliferation, matrix expansion and local inflammation. The exact composition of the mesangial matrix and its role in disease progression is not fully known. One important group of proteins in matrixes are proteoglycans (PGs). PGs are composed of a core protein to which glycosaminoglycan (GAG) side chains are attached. The most common GAGs are heparan sulfate (HS) and chondroitin sulfate (CS). Both the core protein and GAGs determine the properties of PGs and changes in PG composition could be of importance for disease progression. In this study, we aimed to elucidate the role of changes in the PG expression in IgAN.

**Methods:** Human MCs expression of PGs after stimulation with gd-IgA1 was investigated using a glycoproteomics which gives information about both the core protein identity and the the GAGs attached. Immunofluorescence was used for quantification of GAGs. ELISA was used to investigate specific PGs. In vivo and in vitro validation was done using a previously published transcriptomic data set of glomeruli from patients with IgAN in combination with a proteomic data set of HMCs treated with gd-IgA (Liu et al JASN 2017).

**Results:** Glycoproteomics identified 13 PGs in the medium and 5 in the cell lysate and their corresponding GAGs, of which the majority was CS PGs. More PGs were identified in the cells treated with control IgA (cIgA) or gd-IgA1 than the controls. Immunohistochemistry revealed that gd-IgA1 treatment of MCs does not lead to a total increase in GAGs, but rather to a switch from HS to CS GAGs. This was found to be true also in the already published proteomic data set on MCs treated with gd-IgA1. In vivo validation revealed that in IgAN there are more CS upregulated than HS in IgAN. Bikunin, the most upregulated CS PG, expression was validated using ELISA, and found to not be expressed by cells before stimulation with IgA, but then highly upregulated.

**Conclusions:** In conclusion, this study gives a comprehensive view of the PGs expressed by MCs and their alterations in response to gd-IgA1 as part of the expansion of the mesangium in IgAN. The switch of HS GAGs to CS GAGs could be involved in driving inflammation/proliferation but the role of this switch needs further investigation.

## TH-PO427

### Pathological Changes After Methylprednisolone (MP) Pulse Therapy in IgA Nephropathy

Byoung-Soo Cho. *Dr. Cho's Kidney Clinic, Seoul, Republic of Korea.*

**Background:** IgA nephropathy is one of the most common chronic glomerulonephritis and 30-45% fall into CKD over a period of 20-25 years. Lots of therapeutic regimens are tried such as ACEi, ARB, omega-3, corticosteroids, MP pulse therapy and recently many kinds of complement inhibitors, Nefecon, Atacicept, Atrasentan etc., however need a longterm follow up studies to confirm the efficacy. Up to now most centers regarded proteinuria as a most important prognostic marker in IgA nephropathy. In order to confirm the efficacy of proteinuria as a prognostic marker, we performed follow up renal biopsy who showed normalized proteinuria aDuring last 7 yearsour clinic performed 1,500 cases of renal biopsy after MP pulse therapy

**Methods:** During last 7 years our clinic performed 1,500 cases of renal biopsies at OPD level, of which 494 cases (32.9%) were IgA nephropathy patients. We performed follow up renal biopsy in 120 cases who showed normalized urinalysis findings Renal biopsy findings were divided into 3 groups, Group A: improved pathological findings. Group B : no significant pathologic changes. Group C: aggravated pathological findings such as increased glomerulosclerosis, tubulointerstitial changes, tubular atrophy etc. One cycle of MP pulse therapy consist of methylprednisolone (20-30mg/kg, max 1gm/day) IV for 3 consecutive days. Depends on pathologic findings we performed 3 to 15 cycles.

**Results:** Male to female ratio were 59:61, Mean age were 31.1 years old. Of the 120 follow up renal biopsies, 60 cases (50%) showed improved pathological findings (Group A) such as reduced or disappearance of electron dense deposits, restoration of foot processes, decreased mesangial proliferation, 50 cases (40%) showed no significant pathological changes compare to initial pathological findings (Group B), 10 cases (10%) showed aggravated pathological findings such as increased glomerulosclerosis, aggravated interstitial fibrosis and tubular atrophy even though clinically improved such as normalized urinalysis findings, stabilized BP and improvement of eGFR. (Group C)

**Conclusions:** Only 50% of the clinically improved IgA nephropathy patients showed improved pathological findings Decreased proteinuria could not be a prognostic marker of improvement of IgA nephropathy Follow up renal biopsy might be mandatory procedure even though clinically improved such as disappearance of proteinuria

## TH-PO428

### Interstitial LRP1 Expression Is Associated With Glomerular Disease

Marwin Groener,<sup>1,2</sup> Tilman Jobst-Schwan,<sup>3</sup> Mario Schiffer.<sup>3</sup> <sup>1</sup>*Yale School of Medicine, New Haven, CT;* <sup>2</sup>*Research Center on Rare Kidney Diseases (RECORD), Erlangen, Germany;* <sup>3</sup>*Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

**Background:** Low density lipoprotein receptor-related protein 1 (LRP1) is a large evolutionarily conserved endocytic transmembrane receptor that is ubiquitously expressed. However, little is known about its function in the kidney. The goal of this study was to investigate LRP1 expression in different nephron segments in healthy and diseased human renal tissue as well as the developing kidney.

**Methods:** Immunohistochemistry with two antibodies targeted towards the intracellular and extracellular domains of LRP1 were used to assess spatial distribution of LRP1 in healthy human renal tissue and in biopsies of minimal change disease, focal segmental glomerulosclerosis, and membranous nephropathy. Perinatal and adult mouse kidneys were assessed with immunohistochemistry for LRP1. Published kidney RNA and ATAC sequencing databases were used to evaluate LRP1 transcription levels in different renal cell types.

**Results:** In healthy human tissue, intracellular LRP1 signal was detected in distal tubules (DT), loop of Henle (LH), and collecting ducts (CD), whereas extracellular domain signal was found in proximal tubules (PT) and weaker in LH. No glomerular or interstitial signal was found with either antibody. Surprisingly, marked glomerular and interstitial LRP1 expression was seen in all glomerulopathies. Glomerular expression did not co-localize with nephrin and had a mesangial pattern. Interstitial LRP1 was pronounced in the peritubular space. In P0 mouse kidneys, LRP1 signal was primarily found in the interstitium and S-shaped body, whereas adult mouse tissue predominantly expressed LRP1 in the PT. RNA and ATAC sequencing database analysis indicated preferential transcription of LRP1 in mesangial cells and fibroblasts.

**Conclusions:** Interstitial LRP1 expression is markedly induced in human proteinuric glomerulopathies. Interestingly, the developing mouse kidney has similar interstitial LRP1 expression which is lost in mature renal tissue. Our findings demonstrate an association of interstitial LRP1 with glomerular disease and kidney development. Further research is needed to elucidate the role of LRP1 in renal disease and its potential as a drug target.

## TH-PO429

**A Novel Non-Invasive Biomarker Targeting LG3 From Perlecan Can Identify Lupus Nephritis (LN) Patients and Differentiate LN Subclasses**  
 Clara F. Laursen,<sup>1</sup> Alexandra L. Møller,<sup>1</sup> Nadja Sparding,<sup>1</sup> Federica Genovese,<sup>1</sup> Morten A. Karsdal,<sup>1</sup> Zdenka Hruskova,<sup>2</sup> Vladimir Tesar.<sup>2</sup> <sup>1</sup>*Nordic Bioscience, Herlev, Denmark;* <sup>2</sup>*Univerzita Karlova, Praha, Czechia.*

**Background:** Perlecan is an extracellular matrix (ECM) protein important for kidney development and function. Unbalanced turnover of ECM proteins is a hallmark of chronic and fibrotic diseases. Cleavage fragments of perlecan could thus provide important knowledge in kidney disease pathologies. LG3 is a fragment liberated from endorepellin, a signalling molecule from perlecan with antiangiogenic and autophagic properties where LG3 harbours most of the activity. LG3 has been demonstrated to be associated with e.g. end-stage renal disease (ESRD), chronic allograft nephropathy and lupus nephritis (LN). In LN, LG3 autoantibodies have been suggested to contribute to the characteristic microvascular damage occurring. Until now it has not been possible to distinguish LG3 from endorepellin or intact perlecan by ELISA.

**Methods:** We developed a technically robust and accurate competitive enzyme-linked immunosorbent assay biomarker, with a monoclonal antibody specifically targeting the N-terminal site of LG3 generated by BMP-1 cleavage. The LG3 assay was validated in healthy donor serum, plasma heparin, EDTA and urine samples. Moreover, the biological relevance of LG3 was evaluated in serum (n=48) and urine (n=52) from patients with LN, as well as serum (n=65) and urine (n=48) from age and gender-matched healthy controls for comparison. All urine values were corrected for urinary creatinine.

**Results:** Levels of LG3 were significantly elevated in patients with LN in both serum (P<0.0001) and urine (P=0.0008), compared to healthy controls. Moreover, urine LG3 levels were able to significantly distinguish patients diagnosed with class IV or class IV+V LN, with class IV being the most common subclass as well as having the worst prognosis, from the other subclasses (P=0.0023). Class IV LN can further be divided into diffuse segmental (S) or global (G) LN, with significantly increased levels of urine LG3 levels in class IV-G LN (P=0.0430), associated with a higher risk of ESRD compared to class IV-S.

**Conclusions:** These results suggest a possible association of LG3 with LN pathogenesis and demonstrates the diagnostic potential of the biomarker. To evaluate the prognostic, predictive and pharmacodynamic potential of the novel biomarker more studies need to be conducted.

## TH-PO430

### Study of Profile of Urinary TGF-β1 in Glomerular Diseases

Akshay R. Kulkarni, Atul Sajgure, Charan B. Bale, Pavan Wakhare, Nilesh Shinde, Abhijit S. Chavan, Tushar A. Dighe. *Dr. D.Y. Patil Medical College, Hospital & Research Centre, Pimpri, Pune, Dr. D. Y. Patil Vidyapeeth, Pune, India.*

**Background:** Transforming Growth Factor-β1 (TGF-β1) is associated with fibrosis in many organ systems including the kidney, where it can be induced by angiotensin, proteinuria and hypoxia. Numerous studies have identified TGF-β1 as being upregulated during the course of progressive renal injury. Similarly, inhibition of TGF-β1 has been shown to ameliorate renal injury. TGF-β1 is not only involved in extra cellular matrix accumulation, fibrosis and progressive renal impairment, but also plays a role in changes to the glomerular filtration barrier and induction of proteinuria. Direct inhibition of TGF-β1 in models of renal disease reduces proteinuria. Our study aimed to study the profile of urinary TGF-β1 in glomerular diseases.

**Methods:** It was a prospective, observational study, done at a tertiary care centre in western India, over a period of 1 year. 15 subjects with biopsy proven glomerular diseases and 5 healthy controls were enrolled in the study. These participants underwent all routine laboratory investigations and urinary TGF-β1 estimation on a 24 hour urine sample by Flowcytometry method. Cytometric array capture beads of 20 ul were mixed in 20 ul of urine in 1.5 ml tubes. After mixing, samples were incubated at room temperature for 2 hours. After incubation, 50 ul phosphate Buffered Saline was added and centrifuged at 5000 rpm for 5 mins. After centrifugation, 70 ul volume was removed. In the sample 20 ul Detection beads were added and samples were incubated for 2 hours. After incubation 160 ul buffer was added and samples were analyzed using multicolor flowcytometry. Every sample was processed thrice and average value (pg/ml) was considered for analysis of all the subjects.

**Results:** Of the 20 study participants, 11 were males and 9 were females. Average age in glomerular disease patients (group A) was 35.73± 14.25 years and that in control group (group B) was 30.2±5.02 years. Urinary TGF-β1 level in group A had mean value of 50.35 ±6.52 (pg/ml), while that in group B was 19.29 ±3.48 (pg/ml). The values for TGF-β1 in test samples (group A) were found significantly higher in comparison to control (group B). (p<0.0001). Mean value of UPCR was 5.50 ±5.11 in group A and 0.17±0.11 in group B.

**Conclusions:** Urinary TGF-β1 levels were significantly high in glomerular disease patients compared to healthy individuals.

## TH-PO431

**Piperazine Ferulate Protects Mice Against Unilateral Ureteral Obstruction-Induced Interstitial Renal Fibrosis Through TGF-β/Smad3 Signaling**  
 Jun H. Luo,<sup>1</sup> Yun Tang,<sup>1</sup> Bo Li,<sup>2</sup> Qiong Xiao,<sup>1</sup> Lu H. Ding,<sup>1</sup> Xiang Zhong,<sup>1</sup> Yi Li,<sup>1</sup> Guisen Li.<sup>1</sup> <sup>1</sup>*Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China;* <sup>2</sup>*Chengdu Hanpharm Limited Company, Cheng du, China.*

**Background:** Tubulointerstitial fibrosis is the ultimate pathological feature of CKD progression. Unfortunately, there is no clinical treatment with efficiency and no side effects. Piperazine ferulate (PF), a ferulic acid derivative, is commonly used as an adjunctive therapy for various types of glomerular diseases. However, the role of PF in tubulointerstitial fibrosis in CKD is still unclear. Current study aimed to elucidate the role and mechanism of PF in murine tubulointerstitial fibrosis with unilateral ureteral obstruction.

**Methods:** 36 male C57 mice aged from 6 to 8 weeks were randomly divided into six groups (n=6): sham-operated group, interstitial fibrosis group, PF low dose intervention for interstitial fibrosis group, PF medium dose intervention for interstitial fibrosis group, PF high dose intervention for interstitial fibrosis group, PF alone group. Mice with unilateral ureteral obstruction were operated to establish a mouse model of interstitial fibrosis. And the mice accepted PF once per day by gavage following surgery. The mechanism of action of ferulic acid piperazine on interstitial fibrosis in mice was investigated by immunohistochemistry and western blotting.

**Results:** The results showed that the degree of fibrosis in the interstitial fibrosis group was severe, compared to that of mice in the sham-operated group. However, the degree of fibrosis in PF intervention following unilateral ureteral obstruction group was moderate. There was a significant positive correlation between this reduction and the dose of PF. Immunohistochemistry and western blotting showed that the protein expression levels of FN, Col-1, α-SMA, TGF-β1 and p-smad3 were significantly increased in the kidney tissues of mice with interstitial fibrosis. However, the protein expression levels of FN, Col-1, α-SMA, TGF-β1 and p-smad3 were significantly decreased in the kidney tissues of mice with interstitial fibrosis compared with those with ferulic acid piperazine intervention. And the expression of these proteins was significantly and negatively correlated with the dose of ferulic acid piperazine.

**Conclusions:** It indicated the protective role of PF in mice against unilateral ureteral obstruction-induced interstitial renal fibrosis through TGF-β/Smad3 signaling.

## TH-PO432

### Ferroptosis Is Activated in TGF-β/Smad3 Dependent Renal Fibrosis

Kaixiang Liu, Yu Min, Yi Li, Guisen Li, Li Wang, Xiang Zhong. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

**Background:** Renal fibrosis is not only the main pathological feature of chronic kidney disease (CKD), but also a reliable prognostic index for disease progression. Ferroptosis is a new pattern of cell death, which is involved in many diseases. However, the role of ferroptosis in renal fibrosis is still unclear. The aim of the study was to explore the functional role and potential mechanism of ferroptosis in renal fibrosis of unilateral ureteral obstruction (UUO) mice.

**Methods:** Male C57 mice aged from 6 to 8 weeks were operated by UUO surgery to construct kidney fibrosis models. Erastin and Ferrostatin was separately intraperitoneally injected into UUO mice after ligating the ureter to increase or inhibit the expression of ferroptosis in the kidney. The expression of fibrosis markers (FN, Col-1, α-SMA), TGF-β/Smad3 signaling and ferroptosis indexes (GPX4 and SLC7A11) were determined by immunohistochemistry (IHC), western blotting and electron microscopy. The mechanism of ferroptosis in renal fibrosis was investigated in Smad3 KO mice, and full-length transcriptome was also applied in Sham and UUO group.

**Results:** The results showed that the fibrosis markers (FN, Col-1, α-SMA) and TGF-β, P-Smad3 were increased, and the expression of GPX4 and SLC7A11 were decreased in UUO group, further electron microscopy also revealed mitochondrial changes of ferroptosis. After treated with Erastin in UUO mice, the degree of renal fibrosis was significantly increased compared with UUO group. In contrast, Ferrostatin alleviated the expression of renal fibrosis by inhibiting ferroptosis. With knockdown of Smad3, ferroptosis were decreased while renal fibrosis was alleviated by IHC and western blotting. Full-length transcriptome showed the activation of TGF-β/smard3 pathway was related to the inhibition of GPX4 in renal fibrosis. Moreover, the result of Co-IP showed there is an interaction between GPX4 and P-Smad3.

**Conclusions:** This study found that ferroptosis played an important role in TGF-β/Smad3-dependent renal fibrosis and the inhibition of Smad3 could attenuated kidney fibrosis by inhibiting GPX4 mediated ferroptosis.

## TH-PO433

**REDX12271 Is a Novel, Selective DDR1 Inhibitor With the Potential to Treat Multiple Chronic Kidney Diseases**

Kay Eckersley, Inder Bhamra, James Ryan, Michal S. Andrae, Daniel J. Wilcock, Shân Preece, Peter R. Bunyard, Clifford D. Jones, Richard Armer. *Redx Pharma plc, Nether Alderley, United Kingdom.*

**Background:** Discoidin domain receptors (DDR1) are collagen-activated receptor tyrosine kinases which have been shown to be highly expressed in many fibrotic diseases. The protective role of REDX12271, a novel and selective orally bioavailable small molecule inhibitor of DDR1, was investigated in a mouse unilateral ureteral obstruction (UUO) model. REDX12271 exhibits nanomolar potency in cells and target engagement in the kidney as measured by suppression of phospho-DDR1. Efficacy was demonstrated via suppression of pro-fibrotic genes and through reduction of  $\alpha$ -SMA and collagen deposition.

**Methods:** For the prophylactic regime, mice were subjected to treatment with vehicle or REDX12271 via oral gavage at 15 mg/kg BID and 50 mg/kg BID for one day prior to surgery and for a further 7 days post UUO. Control animals were not subjected to UUO. At sacrifice, obstructed kidneys were collected and processed for kidney markers of inflammation and fibrosis. For therapeutic intervention, mice were subjected to UUO and subsequently from day 5 to treatment with vehicle or REDX12271 via oral gavage at 15 mg/kg BID and 50 mg/kg BID. Animals were sacrificed at day 10 and kidneys were collected and processed for histological analysis of collagen deposition and myofibroblast transformation in stained tissue sections.

**Results:** Animals treated with REDX12271 had a statistically significant reduction in histological markers of inflammation and fibrosis in the mouse UUO model. REDX12271 suppressed inflammation and fibrosis in the prophylactic model of UUO as measured by histological staining for F4/80 and  $\alpha$ -SMA respectively. In the therapeutic regime, animals treated with REDX12271 had a statistically significant reduction in fibrosis compared to vehicle as measured by histological staining for  $\alpha$ -SMA and Picrosirius Red.

**Conclusions:** These data show that REDX12271 reduces inflammation and fibrosis in UUO models. To our knowledge this is the first example of selective inhibition of DDR1 with a small molecule giving rise to efficacy in mouse UUO models. Selective inhibition of DDR1 represents an attractive approach for further investigation towards the development of new treatments for CKD.

**Funding:** Commercial Support - Redx Pharma PLC

## TH-PO434

**Importance of Monoclonal Gammopathy of Undetermined Significance (MGUS) Surveillance and Difficulty in Diagnosing Monoclonal Gammopathy of Renal Significance (MGRS) in Low-Grade Lymphomas**  
 Sidrah Abidi, Krishnakumar D. Hongalgi, Kelly H. Beers, Swati Mehta. *Albany Medical Center, Albany, NY.*

**Introduction:** Mantle cell lymphoma is considered a benign pathology rarely warranting treatment in an indolent phase. Immunoglobulin (Ig) deposition without clinically evident decline in kidney function is referred to as monoclonal gammopathy of unknown significance (MGUS). However, undetected kidney involvement could manifest as renal failure and multi-organ failure.

**Case Description:** A 49-year-old male with past medical history of untreated indolent mantle cell lymphoma was admitted to the hospital with hypoxic respiratory failure, pulmonary hemorrhage, purpuric lower extremity rash and acute kidney failure requiring hemodialysis. Patient's creatinine in 2018 was 1.24mg/dl corresponding to eGFR > 60ml/min/m<sup>2</sup>. Patient had a bone marrow biopsy in 2018 confirming mantle cell lymphoma but as per oncology it did not warrant treatment and his kidney function was not monitored. During the hospitalization, patient was non-oliguric. Creatinine was initially 1.98mg/dl then increased to a peak of 6.82mg/dL. Workup revealed non-nephrotic proteinuria, elevated rheumatoid factor, and low complement levels. Kidney biopsy showed membranoproliferative glomerulonephritis with IgM and C3 deposition on immunofluorescence and no evidence of vasculitis. Patient was diagnosed with cryoglobulinemia-associated glomerulonephritis. Our patient was treated with a combination of plasmapheresis, high dose glucocorticoids and IV immunoglobulins, but failed to improve. He was eventually started on chemotherapy including cyclophosphamide, rituximab, and vincristine. Patient was on kidney replacement therapy for several weeks then recovered renal function. He was in remission for several weeks but unfortunately expired after an episode of cardiac arrest secondary to severe anemia.

**Discussion:** Monoclonal gammopathy of renal significance (MGRS) in a smoldering or low-grade lymphoma needs close monitoring of renal function and clonal proliferation with close collaboration with oncology, nephrology and pathology. Our case demonstrates the importance of early detection and treatment.

## TH-PO435

**Unmasking a New Disease: Membranous Glomerulopathy With Masked IgG Kappa Deposits: A Case Report**

Sajeda Alleyne, Mohamed Anwar Abdus Samad. *WellSpan York Hospital Department of Internal Medicine, York, PA.*

**Introduction:** Membranous-like glomerulopathy with masked IgG kappa [IgG- $\kappa$ ] deposits (MG MID) is a novel glomerular disease first described in 2014. By light microscopy and electron microscopy, it is indistinguishable from membranous nephropathy. MG MID is characterized by weak to negative immunoglobulin staining on routine immunofluorescence (IF) but strong IgG- $\kappa$  restricted staining upon pronase

digestion of formalin-fixed paraffin-embedded tissue. Here, we describe a case of membranous-like glomerulopathy with masked IgG-kdeposits found in a pregnant woman with nephrotic range proteinuria.

**Case Description:** 34-year-old woman Gravida 2 Para 1 with history of hypertension was found to have 3+ proteinuria on routine prenatal work up at 11 weeks of gestation. Her urinalysis also showed microscopic hematuria and 24-hour urine proteinuria estimation revealed over 4 grams. She was also found to have mild hypoalbuminemia and hyperlipidemia. She did not have peripheral edema. She denied any history of kidney disease, preeclampsia or eclampsia with prior pregnancy or any miscarriages. Her CBC and kidney function were within normal limits. Subsequently serologic work up was sent which revealed weakly positive ANA ~1: 40 but negative anti double-stranded DNA, anti-PLA R2 antibody, ANCA, C3, C4, serum and urine protein electrophoresis, serum free light chain ratio. Relevant viral studies were negative. She then underwent a kidney biopsy which revealed MG MID. She deferred immunosuppressive therapy and chose to be managed conservatively with strict blood pressure and low salt diet.

**Discussion:** There have been 14 cases documented of patients with MG MID in the literature associated with female patients less than 40 years of age with some form of autoimmune disease or hemolytic anemia. To our knowledge, this will be the first reported case in a pregnant woman. The etiology of the phenomenon is unknown however given this new discovery, continued documentation of these case presentations can aid in furthering research to investigate pathogenesis and subsequently treatment.

## TH-PO436

**Smoldering Pauci-Immune Glomerulonephritis Associated With Recent Tofacitinib Induction in a Patient With Rheumatoid Arthritis**

Michael B. Neinast, Xueguang (Gary) Chen. *Southern Illinois University School of Medicine, Springfield, IL.*

**Introduction:** Pauci-immune glomerulonephritis is typically associated with rapidly progressive glomerulonephritis. Roughly 90% of cases involve circulating levels of ANCA antibodies associated with systemic vasculitis. We present a case of smoldering glomerulonephritis diagnosed after recent initiation of tofacitinib, a Janus kinase (JAK) inhibitor, for rheumatoid arthritis.

**Case Description:** 35-year-old female with seronegative rheumatoid arthritis (RA) was started on tofacitinib for increased flares associated with methotrexate discontinuation for pregnancy planning. Labs obtained prior to initiation included ANA, dsDNA antibodies, and anti-Smith antibodies, were negative. Her symptoms improved however kidney function began to decline. After eight months of treatment, her creatinine increased from 1.1 g/dL with eGFR 60 to 1.22 with eGFR of 50, prompting referral to nephrology. A broad workup was thus obtained. ANA and dsDNA were both positive at 1:320 in homogenous pattern and 50 IU (low positive), respectively. UA showed microscopic hematuria with 3-5 RBCs/hpf with dysmorphism. Anti-MPO was equivocal at 20 AU/mL. Anti-PR3 was negative at 3 AU/mL (normal <19; positive >26). Anti-GBM antibodies were negative. On follow up two weeks later, her creatinine had increased to 1.31 with eGFR 46. Renal biopsy was pursued to rule out lupus nephritis. Renal biopsy revealed sclerosing glomerulonephritis with 60% glomeruli affected, most consistent with pauci-immune type with accompanying mild interstitial fibrosis and tubular atrophy. The patient was started on high dose prednisone and weekly rituximab infusions for four weeks. Prednisone was tapered over three months until discontinued. Her renal function improved over the treatment course and stabilized at her pre-treatment level of creatinine 1.1 g/dL with eGFR 67. Rituximab infusions were continued every six months for maintenance suppression of vasculitis.

**Discussion:** This case raises the concern of a novel adverse event of tofacitinib given new auto-Abs and worsening renal function. There have not been any GN associations with this drug class in the literature though interestingly, tofacitinib has been trialed in treatment of giant cell arteritis with some success. More research is required for further clarification.

## TH-PO437

**AA Amyloidosis Presenting With Renal Amyloidoma**

Deepti Gunasekaran, Randy L. Luciano. *Yale University, New Haven, CT.*

**Introduction:** Amyloidoma is a localized tumor like deposit of amyloid protein. It has been described in a variety of tissues including skin, soft tissue, respiratory tract, and spleen; commonly in the absence of systemic disease. Very few cases of amyloidoma of the kidney are reported. Here, we describe a rare case of systemic amyloidosis with a renal mass showing biopsy proven AA amyloidosis.

**Case Description:** A 59-year-old male without comorbidities was admitted to the hospital following a motor vehicle collision with lower back pain. Physical exam was significant for 2+ pitting edema in bilateral lower extremities. Labs revealed a creatinine of 7.8 mg/dL from 1.0 mg/dL, four years ago. Urine albumin creatinine ratio was elevated at 4.1 g/g of creatinine. Further work up was significant for elevated CRP, positive Hepatitis C antibody and viral PCR. CT of the abdomen showed a 3.5 cm solid renal mass arising from the anterior aspect of the lower pole of the right kidney and L2-L3 osteomyelitis. Biopsy of the mass and renal parenchyma showed enlarged glomeruli with marked mesangial expansion by amorphous, pale eosinophilic and silver negative material. Similar deposits were also seen in the interstitium and in perivascular distribution. Congo red stain was positive for amyloid in glomerular (mesangial), perivascular and interstitial areas. Immunohistochemistry for Amyloid A was positive. He was started on maintenance hemodialysis and was discharged on long term intravenous antibiotics for osteomyelitis.

**Discussion:** The radiographic features of amyloidosis are typically non-specific. In early stages, kidneys may be enlarged but in 50% of cases, they are small with thinned cortex. Our case demonstrates a rare instance of renal amyloidoma formation by a focal,

tumor like infiltrative process as seen on CT abdomen. Radiographic findings may precede the clinical presentation and can expedite further work up and treatment. In the work up of solid renal mass, amyloidosis must be considered along with more common conditions such as renal cell carcinoma, multiple myeloma or lymphoma.

#### TH-PO438

##### Collagenofibrotic Glomerulopathy in a Patient With Waldenstrom Macroglobulinemia

Deepthi Gunasekaran, Anushree C. Shirali. *Yale University, New Haven, CT.*

**Introduction:** Collagenofibrotic glomerulopathy (CG) is a rare disease characterized by type III collagen deposition in the glomerular mesangial matrix and subendothelial space. It is unclear if this is a primary kidney disease or a systemic process. We report a unique case of CG in the setting of long-standing diabetes mellitus (DM) and malignancy.

**Case Description:** An 84-year-old female was referred to Nephrology for AKI. Her medical history was significant for CKD III, Waldenstrom macroglobulinemia (WM), lymphoplasmacytic lymphoma in remission after rituximab/bendamustine therapy, and DM with retinopathy, requiring insulin. She had no family history of kidney disease and an unremarkable physical exam. Labs were significant for creatinine of 1.9 mg/dl from a baseline of 1.3 mg/dl. UPCr was 0.33 mg/mg of creatinine and UACR was 95.3 mg/g of creatinine. Kappa-lambda light chain (LC) ratio was elevated at 4.98. Serum and urine immunofixation revealed IgM kappa monoclonal components. Kidney biopsy showed glomeruli with mesangial expansion and matrix deposition (weakly PAS positive, congo red negative) and diffuse tubular injury. Immunohistochemical stain for collagen type III showed 1+ mesangial staining. Electron microscopy showed mesangial deposits of collagen fibrils with periodicity. Her creatinine improved to baseline over the next 6 months without further therapy.

**Discussion:** Prior CG cases described patients ranging from 2-66 years, typically presenting with nephrotic proteinuria. While some cases have occurred de novo, others have shown association with lymphoma and DM. Our case is unique with advanced age and sub-nephrotic proteinuria. Although she had increasing kappa LCs and DM, there were no overt signs of WM, such as amyloid, or of DM on biopsy. This case raises the potential of CG as another manifestation of kidney involvement in WM.

#### TH-PO439

##### Granulomatosis With Polyangiitis (GPA) Presenting as a Renal Mass in a Young Man With a Solitary Kidney

Naief N. Abudaff, Sagar Patel, Agnes B. Fogo, Neil S. Sanghani. *Vanderbilt University Medical Center, Nashville, TN.*

**Introduction:** GPA is a rare autoimmune ANCA-associated vasculitis. GPA has varied extrarenal presentations including fevers, arthralgias, sinusitis, and respiratory failure from diffuse alveolar hemorrhage. In the kidney, it classically presents as RPGN with the quadrad of increased creatinine, microscopic hematuria, proteinuria and hypertension. Here, we describe a rare presentation of GPA with a renal mass.

**Case Description:** A 20M with a solitary left kidney presented due to persistent fevers and AKI. He had a one month history of fevers, arthralgias, nosebleeds, left flank pain, weight loss, and had been treated for presumed UTI. Vital signs were T 101.7F, HR 109 bpm, and BP 148/78mmHg. Urinalysis was positive for heme and albumin without any nitrites with 38 WBCs and 138 RBCs, urine protein/creatinine ratio was 1, creatinine 2.7 mg/dL (from 1.1 mg/dL), CRP 173 mg/L, ESR 140 mm/hr. Renal ultrasound showed a 16.5cm left kidney with a small amount of perinephric fluid and a complex fluid collection, 8.5x7.3x4.9cm, in the left upper pole, concerning for pyelonephritis and abscess. He was treated with IV antibiotics and percutaneous abscess drainage was planned. CT showed an atrophic right kidney with chronic UPJ obstruction and a left upper pole lesion that appeared more mass-like [A]. Biopsy of the mass was performed, revealing extensive necrosis, including vasculitis of arteries [B] and pauci-immune necrotizing crescentic glomerulonephritis [C]. Anti-PR3 was then detected. Urine, blood and tissue cultures returned negative. The patient was diagnosed with GPA and treated with rituximab and prednisone and defervesced. Six months later, creatinine was stable at 1.5 mg/dL from a peak of 3.8 mg/dL.

**Discussion:** Renal masses are a rare presentation of GPA. The diagnosis is often made incidentally after partial or radical nephrectomy. This case exemplifies the utility of percutaneous kidney biopsies as a nephron-sparing procedure, particularly useful in patients with reduced nephron mass, and the importance of histopathology in arriving at a diagnosis.

## TNF-Treated Kidney Organoids Recapitulate Poor Outcome Nephrotic Syndrome

Matthew Fischer,<sup>1</sup> Moritz Lassé,<sup>2</sup> Sean Eddy,<sup>1</sup> Jamal El Saghir,<sup>1</sup> V. Vega-Warner,<sup>1</sup> Matthias Kretzler,<sup>1</sup> Markus M. Rinschen,<sup>3,2</sup> Jennifer L. Harder.<sup>1</sup> <sup>1</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>2</sup>Universitätsklinikum Hamburg-Eppendorf Zentrum für Innere Medizin, Hamburg, Germany; <sup>3</sup>Aarhus Universitet, Aarhus, Denmark.

**Background:** Nephrotic syndrome (NS) includes heterogeneous rare diseases (i.e. FSGS and MCD) complicating therapeutic development and intervention; individuals with NS could benefit greatly from a precision medicine-based approach. Human pluripotent stem cell derived kidney organoids (hKOs) provide an opportunity to identify pathomechanisms and therapeutics pertinent to subgroups of NS patients. We recently identified 3 subgroups of proteinuric individuals in NEPTUNE (1 with poorer outcomes) based on kidney tissue transcription profiles. Differential gene expression and pathway analysis of the poor outcome subgroup revealed a 272-gene signature of TNF activation, a pattern also seen in TNF-treated hKOs. The aim of this study was to further evaluate alterations induced in TNF-treated hKOs to assess their ability to capture the TNF-associated disease state.

**Methods:** hKOs were treated with TNF up to 48h. hKO lysates and culture media were analyzed for changes in gene and protein expression by a combination of qRT-PCR, ELISA, IF, proteomics, bulk and single cell RNAseq. Genes reflecting the TNF-induced hKO response were then evaluated in the NEPTUNE cohort tissue based bulk and single nuclear RNAseq datasets.

**Results:** Proteomic analysis of hKOs identified 320 peptides differentially expressed by TNF treatment, an overlap of 1.7% with the 272-gene TNF signature. Interrogation of the NEPTUNE cohort subgroups revealed that summary expression of genes encoding this peptide set was significantly increased in the poor outcome subgroup. Further evaluation of proteins secreted in TNF-treated hKO cultures revealed increased C3 and VCAM, both in the original 272-gene TNF signature. Expression of C3 and VCAM1 was higher in kidney tubular cells in NEPTUNE individuals with high TNF activation scores.

**Conclusions:** We discovered a set of peptides from TNF-treated hKOs that captured disease relevant molecular events in poor outcome NS. Further, we found that genes encoding TNF-induced proteins secreted by hKOs were also expressed by tubular cells in individuals with poor outcome NS. Our findings demonstrate the ability of the TNF-treated kidney organoid model to identify pathomechanistic elements relevant to a subset of individuals with nephrotic syndrome and to aid in discovery of non-invasive biomarkers.

## APOL1 Inhibitors Reverse Established Proteinuria in an APOL1-Mediated Kidney Disease Mouse Model

Angelo Blasio, Kelly E. Sullivan, James J. Mann, Guanyu Wang, Shyamesh Kumar, Franklin Bright, Audrey Bouillez, Kevin Daniel, Suganthini Nanthakumar, Aldo A. Rosario, Monica A. Aragon Mejia, Thomas F. Heighton, Evanthea Nanou, Jennifer Proctor, Brinley Furey, Anne Fortier, Timothy J. Senter, Leslie Dakin, Brandon Zimmerman. *Vertex Pharmaceuticals Incorporated, Boston, MA.*

**Background:** APOL1-mediated kidney disease (AMKD) is a progressive, proteinuric nephropathy caused by gain-of-function variants (*G1* or *G2*) in *APOL1*. There are currently no treatments addressing the underlying cause of AMDK. Our previous data showed that novel small molecule APOL1 inhibitors prevent proteinuria prophylactically in a model of transient AMDK. In a Ph2a trial, the APOL1 small molecule inhibitor inaxaplin (IXP; VX-147) significantly reduced proteinuria in participants with 2 *APOL1* variants, proteinuria, and FSGS. Here we demonstrate that another small molecule APOL1 inhibitor with similar potency to IXP intervenes therapeutically in a novel mouse model of AMDK.

**Methods:** To develop a mouse model of AMDK, we utilized transgenic APOL1 mice homozygous for the *APOL1* *G2* mutation (*G2*<sub>Hom</sub>). Osmotic pumps were implanted into *G2*<sub>Hom</sub> and wild-type FVB (control) mice to deliver a continuous infusion of interferon  $\gamma$  (IFNg) or saline. *G2*<sub>Hom</sub> mice were treated with a small molecule APOL1 inhibitor or vehicle 5 days after IFNg or saline infusion was initiated. Proteinuria and body weight were assessed daily. Kidney sections were evaluated histologically and quantitative image analysis assessed APOL1 expression and nephrin levels in glomeruli.

**Results:** Administration of IFNg in *G2*<sub>Hom</sub> mice led to a dramatic increase in proteinuria within 5 days and significant loss in body weight. Proteinuria remained stable and elevated for 2 weeks. Treatment with APOL1 inhibitor significantly reduced proteinuria, returning it to baseline within a week, and restored body weight. Modest histological changes and nephrin loss in glomeruli were observed in the vehicle group and absent in the APOL1 inhibitor treatment group. Control mice injected with IFNg and *G2*<sub>Hom</sub> mice injected with saline did not develop proteinuria or have signs of kidney disease.

**Conclusions:** We demonstrated that APOL1 inhibitors reverse proteinuria after APOL1-mediated damage is initiated and protect against disease progression during constant inflammatory challenge. These data support the results of the Ph2a trial with IXP.

## TH-PO443

## Blocking CHOP-Dependent TXNIP Shuttling to Mitochondria Attenuates Albuminuria and Mitigates Kidney Injury in Nephrotic Syndrome

Sun-Ji Park,<sup>1</sup> Yeawon Kim,<sup>1</sup> Chuang Li,<sup>1</sup> Junwoo Suh,<sup>2</sup> Jothilingam Sivapackiam,<sup>1</sup> Tássia Mangetti Gonçalves,<sup>1</sup> George Jarad,<sup>1</sup> Guoyan Zhao,<sup>1</sup> Fumihiko Urano,<sup>1</sup> Vijay Sharma,<sup>1</sup> Ying M. Chen.<sup>1</sup> <sup>1</sup>Washington University in St Louis, St Louis, MO; <sup>2</sup>Case Western Reserve University, Cleveland, OH.

**Background:** Albuminuria, a defining feature of glomerular disease, also leads to glomerulosclerosis and interstitial fibrosis. The molecular mechanism underlying albuminuria-induced kidney injury remains poorly understood.

**Methods:** We utilized hereditary nephrotic syndrome (NS) (*Lamb2*<sup>-/-</sup> mice) and adriamycin-induced NS models, *Chop*<sup>-/-</sup> and *Txnip*<sup>-/-</sup> mice to investigate the regulation and function of TXNIP (thioredoxin-interacting protein). Glomeruli and tubule isolation, primary podocyte and tubular cell culturing, mitochondrial and nuclear fractionation, as well as confocal and electron microscopy were employed. Mitochondrial reactive oxygen species (ROS) levels were assessed by flow cytometry in cells and by <sup>68</sup>Ga-Galuninox PET/CT imaging in live animals for the first time.

**Results:** we have identified CHOP (C/EBP homologous protein)-TXNIP as critical molecular linkers between albuminuria-induced endoplasmic reticulum (ER) dysfunction and mitochondria dyshomeostasis. TXNIP is a ubiquitously expressed redox protein that binds to and inhibits antioxidant enzyme, cytosolic thioredoxin 1 (Trx1) and mitochondrial Trx2. However, little is known about the regulation and function of TXNIP in NS. *TXNIP* gene expression correlates with disease severity and decline of kidney function in human proteinuric kidney disease based on Nephroseq database. We demonstrate that CHOP upregulation induced by albuminuria drives TXNIP induction in both podocytes and tubules, as well as TXNIP shuttling from nucleus to mitochondria, where it is required for mitochondrial ROS production. The increased ROS accumulation in mitochondria oxidizes Trx2, thus liberating TXNIP to associate with mitochondrial NLRP3 to activate inflammasome, as well as releasing mitochondrial apoptosis signal-regulating kinase 1 (ASK1) to induce mitochondria-dependent apoptosis. Importantly, inhibition of TXNIP translocation and mitochondrial ROS overproduction by CHOP deletion suppresses NLRP3 inflammasome activation and p-ASK1-dependent mitochondria apoptosis, thereby improving kidney function in NS.

**Conclusions:** NS is a leading cause of chronic kidney disease affecting 500 million people worldwide. Targeting TXNIP represents a promising therapeutic strategy for the treatment of NS.

TH-PO444

**UPARANT Succinate and N19004 Preserve Podocyte Injury by Adriamycin and Focal Segmental Glomerulosclerosis Sera: Drug Screening by an In Vitro Model of Glomerular Filtration Barrier**  
Deborah Mattinzoli,<sup>1</sup> Silvia Armelloni,<sup>1</sup> Min Li,<sup>1</sup> Masami Ikehata,<sup>1</sup> Carlo Alfieri,<sup>1,2</sup> Giuseppe. Castellano.<sup>1,2</sup> <sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; <sup>2</sup>Università degli Studi di Milano, Milano, Italy.

**Background:** Idiopathic focal segmental glomerular sclerosis (FSGS) accounts for up to 25-40 % of nephrotic syndrome with a frequent post-transplant recurrence due to a circulating permeability factor causing glomerular filtration impairment. In FSGS, an elevated level of soluble urokinase-type plasminogen activator receptor (suPAR) is implicated in podocytes' (PODO) alteration. We investigated the potential role of uPAR receptor inhibitors UPARANT succinate (US) and N19004 in preserving PODO structure and function.

**Methods:** Both UPARANT inhibitors were tested on ADRIA and FSGS-PODO injury models investigating the actin dynamic by IF actin and cofilin (CFL1) quantification. PODO differentiation and adhesion capacity were assessed by Wilms tumor 1 transcription factor (WT1), Integrin (ITG3), Nephrin (NPHS1) mRNA and protein expression. The functional barrier filtration capacity was assessed by a three-dimensional PODO-endothelial cell co-culture system.

**Results:** US and N19004 significantly protected PODO cytoskeleton with a well-orderly actin-filament and a foot processes effacement recovery after ADRIA-induced damage (vs ADRIA p=0.007, p<0.0001). Moreover, US or N19004 inhibited the ADRIA-induced actin-binding CFL1 phosphorylation (vs ADRIA p<0.0001 for both) already at 10nM. The activation of WT1, transcription factors of major PODO functional molecules such as ITG3 and NPHS1, was assessed. In addition, we found a NPHS1 perinuclear and cell processes distribution restoration upon drug treatment. Finally, uPAR receptor inhibitors recovered the functional barrier filtration capacity by the PODO-ENDO co-culture system upon activation by 3 FSGS sera patients. In the ADRIA-model only for N19004 at 100nM the recovery appears (vs CTRL p=0.02), conversely in the FSGS-model both US (vs CTRL p<0.05) and N19004 (vs CTRL p<0.02) improved the filtration functionality.

**Conclusions:** In conclusion, both drugs initiate a regain of the PODO plasticity and functionality, strongly encouraging future in-depth studies.

TH-PO445

**SH3BP2-Mediated Immune Activation in Idiopathic Nephrotic Syndrome (NS)**

Tarak Srivastava,<sup>1,4</sup> Trupti Joshi,<sup>3</sup> Wei Hao,<sup>2</sup> Yujie Wang,<sup>2</sup> Debbie Gipson,<sup>2</sup> Laura H. Mariani,<sup>2</sup> Mukut Sharma.<sup>4</sup> <sup>1</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>University of Missouri, Columbia, MO; <sup>4</sup>Kansas City VA Medical Center, Kansas City, MO.

**Background:** Immunopathogenesis of NS in minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) remains largely unknown. SH3BP2, an adaptor protein, forms a signaling complex (signalosome) with Src, Syk, etc. to integrate immune signaling pathways involved in activation of T-, B-cells, MΦ, etc. Significance of the SH3BP2 signaling in NS-associated immune activation is not known.

**Methods:** RNA sequencing data from glomerular compartment of biopsy proven MCD or FSGS (NEPTUNE consortium) were analyzed to generate a Z-score for each gene for each patient. Individual gene Z-scores in the SH3BP2 signalosome were averaged to calculate the composite SH3BP2 Signalosome Score. IMPRes algorithm was used to visualize potential pathways for SH3BP2 gene. Clinical parameters from these subjects were used for statistical analysis to investigate outcome.

**Results:** Table shows significantly increased Z-score for the total SH3BP2 Signalosome Score in MCD (p=0.004) and in FSGS (p<0.001) compared to Control. SH3BP2 signalosome genes SH3BP2, VAV1, VAV2 and YWHAB were significantly increased in both MCD and FSGS. PLCG2 and YWHAG were also increased in FSGS. Downstream genes NFATc1 and MyD88 important in Sh3bp2-mediated signaling were also significantly upregulated in MCD and FSGS. IMPRes algorithm analysis suggests that SH3BP2 binds to PLCG2 and VAV2 for downstream signaling (Figure). SH3BP2 Signalosome Score was comparable between adults and children, and not associated with ESKD composite, ESKD and Remission.

**Conclusions:** SH3BP2 signaling complex is upregulated in biopsy from MCD and FSGS patients. SH3BP2-mediated immune activation needs comprehensive study using available mouse models with loss or gain of SH3BP2 function.

**Funding:** NIDDK Support, Private Foundation Support

**Table:** Table shows the Z-scores for the SH3BP2 Signalosome Score and individual genes in Control, minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS).

**Proteomic Identification of Urine Biomarkers of Pediatric Nephrotic Syndrome**

Timothy Cummins,<sup>1</sup> Michael Merchant,<sup>1</sup> Daniel W. Wilkey,<sup>1</sup> Saeed A. Jortani,<sup>1</sup> Madhavi J. Rane,<sup>1</sup> Laura H. Mariani,<sup>2</sup> Julie Dougherty,<sup>3</sup> Yu Kamigaki,<sup>3</sup> Wimal Pathmasiri,<sup>4</sup> Susan Mcritchie,<sup>4</sup> Susan J. Sumner,<sup>4</sup> William E. Smoyer,<sup>3</sup> Jon B. Klein.<sup>1,5</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Nationwide Children's Hospital, Columbus, OH; <sup>4</sup>University of North Carolina System, Chapel Hill, NC; <sup>5</sup>Robley Rex VA Medical Center, Louisville, KY.

**Background:** The molecular pathophysiology of nephrotic syndrome (NS) remains unclear for the majority of children. While most children with minimal change disease (MCD) have a good response to glucocorticoid (GC) therapy, those with focal segmental glomerulosclerosis (FSGS) often respond poorly, with either no remission or only partial remission of proteinuria. Development of glomerular disease biomarkers that reliably predict response to treatment and/or define molecular pathways regulating treatment responsiveness vs. resistance could greatly improve outcomes in pediatric NS. We hypothesized that comparison of urine proteomes in children with MCD vs. FSGS could identify urinary biomarkers able to distinguish disease activity and molecular pathways regulating these differences.

**Methods:** We performed quantitative proteomic analyses of sequential urine samples from children with biopsy-proven MCD and FSGS enrolled in the CureGN Consortium to identify and compare putative mechanistic differences between disease activity and remission in FSGS and MCD. We analyzed 216 patient urine specimens by 2D-LC-MS/MS and identified 1,100 unique proteins using MaxQuant and Scaffold-5 Q+, applying strict FDR (1%) with 2-peptide identification required. Proteomics data were analyzed using MetaboAnalyst 5.0 to conduct univariate and multivariate statistical analyses to identify candidate urine biomarkers of disease activity vs. remission in FSGS and MCD.

**Results:** Urine proteome profiles in children with partial remission (UPCR 0.3-1.5) in both FSGS and MCD were nearly indistinguishable from the active (UPCR 1.5-3.5) or nephrotic (UPCR >3.5) states. Notably, proteomic profiles in complete remission (UPCR<0.3) were clearly distinct from all other levels of disease activity for both FSGS and MCD. Additionally, urinary ORM1 and C3 levels were significantly elevated in the nephrotic state vs. complete remission, with proteomic findings confirmed on subsequent immunoassays.

**Conclusions:** These findings suggest urinary ORM1 and C3 are candidate biomarkers of disease activity in childhood nephrotic syndrome, which may also have mechanistic implications for disease progression or treatment resistance.

TH-PO447

Metabolomics Provides Insights Into Remission of Pediatric Nephrotic Syndrome During Treatment

Susan Mcritchie,<sup>1</sup> Wimal Pathmasiri,<sup>1</sup> Laura H. Mariani,<sup>2</sup> Timothy Cummins,<sup>3</sup> Michael Merchant,<sup>3</sup> Saeed A. Jortani,<sup>4</sup> Julie Dougherty,<sup>5</sup> Yu Kamigaki,<sup>5</sup> Jon B. Klein,<sup>3,6</sup> William E. Smoyer,<sup>5,7</sup> Susan J. Sumner.<sup>1</sup> <sup>1</sup>The University of North Carolina at Chapel Hill Nutrition Research Institute, Kannapolis, NC; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>University of Louisville School of Medicine, Louisville, KY; <sup>4</sup>University of Louisville, Louisville, KY; <sup>5</sup>Nationwide Children's Hospital, Columbus, OH; <sup>6</sup>VA Robley Rex Medical Center, Louisville, KY; <sup>7</sup>The Ohio State University, Columbus, OH.

**Background:** Children diagnosed with focal segmental glomerulosclerosis (FSGS) or minimal change disease (MCD) vary in response to therapy and risk of relapse. Those with persistent proteinuria and/or frequent relapses have the highest risk of disease progression, but little is known about the mechanism of kidney damage in these forms of nephrotic syndrome. Metabolomics studies the changes in downstream metabolites in biological pathways and enables capturing perturbations in metabolic pathways that can provide insights into mechanisms underlying disease pathophysiology and response to treatment. Developing non-invasive biomarkers to predict and/or define mechanisms of response to treatment is an urgent need for glomerular disease. Thus, we sought to identify perturbed biological pathways in pediatric patients with MCD or FSGS to understand the underlying mechanisms in nephrotic proteinuria (NP; UPCR>3.5) vs. complete remission (CR; UPCR<0.3).

**Methods:** Urine specimens obtained from pediatric patients enrolled in the prospective CureGN Study with biopsy-confirmed MCD or FSGS were analyzed with <sup>1</sup>H NMR metabolomics. 147 urine samples from those in CR or with NP were used as a discovery set. A second cohort of 112 similarly categorized samples acted as a replication set. Binned NMR data were analyzed using multivariate analyses, hypothesis testing, and logistic regression. NMR bins were library-matched to metabolites and those that were important to differentiating CR and NP in both data sets were used for pathway enrichment analyses.

**Results:** Metabolomics analysis could clearly differentiate CR from NP in patients with MCD or FSGS. Aminoacyl t-RNA biosynthesis, pathways related to immune responses, and amino acid metabolism were among the top enriched pathways in the remission state compared to those with NP.

**Conclusions:** Metabolomics can clearly differentiate pediatric patients with biopsy-confirmed MCD and/or FSGS with nephrotic proteinuria vs. complete remission. Metabolic perturbations in the identified pathways warrant further investigation using targeted metabolomics to develop non-invasive predictive biomarkers towards identifying potential novel therapeutic targets in patients with nephrotic syndrome.

**Funding:** NIDDK Support

TH-PO448

Patient-Specific Multi-Omic Analysis of Plasma Proteomics and Metabolomics of Steroid Resistance in Childhood Nephrotic Syndrome

Sagar Bhayana,<sup>1</sup> Yue Zhao,<sup>3</sup> Michael Merchant,<sup>4</sup> Timothy Cummins,<sup>4</sup> Julie Dougherty,<sup>2</sup> Yu Kamigaki,<sup>2</sup> Wimal Pathmasiri,<sup>5</sup> Susan Mcritchie,<sup>5</sup> Laura H. Mariani,<sup>6</sup> Susan J. Sumner,<sup>5</sup> Jon B. Klein,<sup>4</sup> William E. Smoyer.<sup>2</sup> <sup>1</sup>Novo Nordisk AS, Bagsvaerd, Denmark; <sup>2</sup>Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>The Ohio State University, Columbus, OH; <sup>4</sup>University of Louisville, Louisville, KY; <sup>5</sup>University of North Carolina System, Chapel Hill, NC; <sup>6</sup>University of Michigan, Ann Arbor, MI.

**Background:** Nephrotic syndrome (NS) is a clinical syndrome defined by massive proteinuria. Glucocorticoid (GC) therapy is the mainstay therapy for inducing remission, but 20-30% of children present with or develop GC resistance. Unfortunately, we lack both effective treatments for steroid resistant NS (SRNS) and clinically validated biomarkers to predict SRNS vs. steroid sensitive NS (SSNS) at presentation. To bridge this gap, we performed a patient-specific integrated analysis of published plasma proteomics and metabolomics data from children with SRNS and SSNS.

**Methods:** Proteomic LC-MS/MS and metabolomic NMR data from 15 paired (pre- and post-GC treated) NS plasma samples (n=7 SSNS; n=8 SRNS) underwent joint pathway analyses using MetaboAnalystR v3.0. The Log<sub>2</sub> fold change (LFC) was calculated as the ratio of post- to pre-GC-treatment. Proteins with LFC<-10 or >10 and metabolites with LFC<-1 or >1 were included. An enrichment index was calculated by: [(#SRNS w/ pathway activated/ Total #SRNS)-(#SSNS w/ pathway activated/ Total #SSNS)]x100%.

**Results:** Hypergeometric analyses identified 34 pathways (P<0.005) that were enriched in post- vs pre-GC-treated SRNS and/or SSNS patients. Using ±25% cut-off as an enrichment index, 12 of 34 pathways were enriched in SRNS and/or SSNS patients, narrowed to 5 pathways with enrichment in at least 3 patients within either group. Nicotinate/ Nicotinamide pathway & Butanoate metabolism were frequently enriched in SRNS patients, whereas Lysine metabolism, Mucin type O-glycan biosynthesis, & Glycolysis/ Gluconeogenesis were frequently enriched in SSNS patients. In-depth pathway network analyses performed in each patient indicated NAMPT, NMNAT1, NT5C2, SETMAR and 3-hydroxybutyrate as more frequently upregulated in SRNS patients, while ALDH1B1, ACAT1, AASS, ENPP1 and Pyruvate were more frequently upregulated in SSNS patients. Subsequent immunoblotting of the same plasma samples validated significant upregulations of NAMPT in SRNS and ALDH1B1/ACAT1 in SSNS.

**Conclusions:** These findings demonstrate the ability of patient-specific integration of omics data to distinguish pathway alterations in SRNS vs. SSNS, and highlight potentially distinct perturbations in energy metabolism between these groups.

TH-PO449

Immunological Profile in Nephrotic Patients With Minimal Change Nephrotic Syndrome Is Distinct From Focal Segmental Glomerulosclerosis

Chang-Yien Chan,<sup>1,2</sup> Liangjian Lu,<sup>2</sup> Sharon Teo,<sup>2</sup> Kong Peng Lam,<sup>3</sup> Kar Hui Ng,<sup>1,2</sup> Hui Kim Yap.<sup>1,2</sup> <sup>1</sup>Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; <sup>2</sup>Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; <sup>3</sup>Bioprocessing Technology Institute, Agency for Science, Technology and Research (A\*STAR), Singapore, Singapore.

**Background:** We have previously shown that immunological subtypes in patients with childhood-onset idiopathic nephrotic syndrome (INS) in relapse were different between focal segmental glomerulosclerosis (FSGS) and minimal change nephrotic syndrome (MCNS), where a subgroup of FSGS patients demonstrated T-cell downregulation of stimulated CD154 and IFN $\gamma$ . This study aimed to determine if the immunological profiles are indeed distinct in FSGS and MCNS by further characterizing the T-cell transcription regulator gene expression and phenotype.

**Methods:** A total of 38 patients with childhood-onset INS in relapse consisting of 21 MCNS (median age 14 years, range 2-35 years) and 17 FSGS (median age 13 years, range 4-25 years) and 8 healthy controls (median age 19 years, range 4-27 years) were recruited. Gene expression of T-cell transcription regulators were performed on purified stimulated CD4 T-cell using real-time PCR. Lymphocyte subset (T-cell exhaustion marker (PD1), T-cell subsets: memory (CD45RA, CCR7), naïve (CD45RO, CD62L), follicular helper (CXCR5, CD127), Treg (FoxP3, CTLA-4) and invariant NKT (TCR V $\alpha$ 24-J $\alpha$ 18) staining was performed by the lysed whole blood method. Statistical analysis was done using Mann-Whitney U tests.

**Results:** Gene expression of Th2 (*GATA3*) and Th17 (*RORGT* and *RORC*) transcription factors were significantly upregulated in relapse MCNS compared to relapse FSGS (Table 1). Moreover, gene expression of *NFATC2*, transcription factor regulating ROR $\gamma$ t transcription through RORC, was also significantly increased in relapse MCNS. Gene expression of *MAF* and *CMIP* (C-Maf-inducing protein) were significantly higher in relapse MCNS compared to healthy controls. Phenotype analysis showed that relapse FSGS had significant upregulation of Tfh cells (CXCR5) (18.0%±1.0%) compared to relapse MCNS (14.0%±1.1%) (*P*=0.005) and controls (11.5%±0.5%) (*P*<0.001).

**Conclusions:** We have demonstrated distinct T-cell profiles between relapse MCNS characterized by Th2 and Th17 phenotypes, and relapse FSGS characterized by Tfh phenotype.

**Funding:** Government Support - Non-U.S.

Differences in Peripheral Blood Cell DNA Methylation Between Nephrotic Syndrome Subgroups

Samantha J. Hayward,<sup>1,2</sup> Agnieszka Bierzynska,<sup>1</sup> Gavin I. Welsh,<sup>1</sup> Matthew Suderman,<sup>3</sup> Moin Saleem.<sup>1</sup> Bristol Renal <sup>1</sup>University of Bristol Translational Health Sciences, Bristol, United Kingdom; <sup>2</sup>Southmead Hospital, Bristol, United Kingdom; <sup>3</sup>MRC Integrative Epidemiology Unit, Bristol, United Kingdom.

**Background:** Genetic and observational research suggest that at least 4 mechanistically different subgroups of paediatric nephrotic syndrome (NS) exist: genetic steroid resistant NS (SRNS), non-genetic SRNS, steroid sensitive NS (SSNS) and circulating factor disease (CFD). We explored differences in DNA methylation (DNAm), an epigenetic mechanism, between the 4 different NS subgroups.

**Methods:** 322 patients were selected from the NephroS-NURTURE NS cohort. All patients were diagnosed with NS ≤30 years of age. Patients were split *a priori* into the 4 NS subgroups based upon their genetic and clinical data. Peripheral blood cell DNAm values were generated using the Illumina EPIC array (>850,000 CpG sites). Generalised linear models were used to assess differences in DNAm between the NS subgroups at each individual CpG site. Differentially methylated regions (DMRs) were assessed using the dmrff R package. All analyses were adjusted for cell type proportions, age and sex. Sex chromosomes were excluded from the analyses. A Bonferroni adjusted p value of 5.88x10<sup>-8</sup> was used as a significance threshold.

**Results:** Differing DNAm was identified at 7 individual CpG sites and 1 DMR (p values  $<5.88 \times 10^{-7}$ ) between the NS subgroups. Only 1 of these CpG sites reached our significance threshold (Figure 1,  $p=1.88 \times 10^{-8}$ ); differing DNAm at this site was detected between patients with non-genetic SRNS and genetic SRNS. This CpG is found in the transcriptional start site of a transcribed pseudogene, which has plausible biological links to kidney disease.

**Conclusions:** We have identified a shortlist of interesting sites of differing DNAm between the 4 NS subgroups. Further work, utilising machine learning approaches, to reveal DNAm-based signatures that discriminate between NS subgroups is underway.

**Figure 1. Differences in DNAm between the genetic SRNS and non-genetic SRNS groups**

#### TH-PO451

##### Childhood Membranous Nephropathy: A Histopathologic Analysis of 118 Cases

Tiffany Caza, Christopher P. Larsen. *Arkana Laboratories, Little Rock, AR.*

**Background:** Membranous nephropathy (MN) is a rare etiology of nephrotic syndrome in children, accounting for less than 5% of renal biopsies. Unlike MN in adults, where the majority of cases are positive for phospholipase A2 receptor (PLA2R), PLA2R positivity is less frequent and the antigen is unknown in a greater proportion of cases. We present the largest case series of pediatric MN to date with a total of 118 patients.

**Methods:** Cases of MN diagnosed in individuals  $\leq 18$  years of age were identified from a biopsy database. Light, immunofluorescence, and electron microscopy findings were reviewed. Antigenic subtyping was performed through immunostaining for phospholipase A2 receptor (PLA2R), thrombospondin type 1-domain containing 7A (THSD7A), exostosin 1/2 (EXT), neural epidermal growth factor-like 1 (NELL1), and semaphorin 3B (SEMA3B).

**Results:** A total of 118 cases of pediatric MN were identified over a 16-year period (2006-2022). The mean age of patients was  $14.7 \pm 2.6$  years and included 47 males and 71 females. The majority of cases did not show significant chronicity, with a mean global glomerulosclerosis of  $4.3 \pm 10.0\%$  and moderate or severe interstitial fibrosis in only 5.1%. Immunofluorescence studies showed 31.4% with IgA deposits, 100% IgG, 30.5% IgM, 78.8% C3, and 15.3% C1q. Mesangial deposits were seen in 62.7% and tubular basement membrane deposits in 9.3% of cases. Antigen types included 34.7% PLA2R, 0.8% THSD7A, 23.7% EXT1/2, 3.4% NELL1, 5.0% SEMA3B, and 32.2% of unknown antigen type.

**Conclusions:** Pediatric MN has a female predominance, often is without significant chronic injury, and has a high frequency of cases of unknown antigen type. There is a higher proportion of EXT1/2-positive cases than reported in adults.

##### Minor Antigens in Membranous Nephropathy Identified by Mass Spectrometry

Tiffany Caza,<sup>1</sup> Samar Hassen,<sup>1</sup> Christian Herzog,<sup>2</sup> Aaron J. Storey,<sup>2</sup> Ricky Edmondson,<sup>2</sup> John M. Arthur,<sup>2</sup> Daniel J. Kenan,<sup>1</sup> Christopher P. Larsen.<sup>1</sup>  
<sup>1</sup>Arkana Laboratories, Little Rock, AR; <sup>2</sup>University of Arkansas for Medical Sciences, Little Rock, AR.

**Background:** Multiple autoantigens have been identified in membranous nephropathy (MN) by tissue-based proteomics. However, the antigenic targets of disease are unknown for  $>10\%$  of MN and  $>50\%$  of cases of membranous lupus nephritis. We identified multiple new targets in PLA2R-/THSD7A-/EXT-/NELL1-quadruple negative MN biopsies through mass spectrometry (MS) of immune complexes recovered from biopsy tissue of patients with MN.

**Methods:** MN cases negative for PLA2R, THSD7A, EXT1/2, and NELL1 were identified from a biopsy database. Protein G immunoprecipitation was used to recover immune complexes from frozen kidney biopsy tissue, followed by interrogation by mass spectrometry (MS). Potential antigens were confirmed through paraffin immunofluorescence of protein targets, followed by co-localization of the candidate protein with IgG within immune deposits. A consecutive series of 81 PLA2R-negative MN biopsies was screened to determine the frequency for each of the protein targets in MN.

**Results:** Seven novel antigenic targets were identified within isolated immune complexes from MN biopsies by MS, including FCN3, CD206, EEA1, SEZ6L1, NPR3, MSP1, and VASN. Peptides from these proteins were not enriched in PLA2R (n=47), THSD7A (n=49), NELL1 (n=54), or EXT1/2 (n=51) control cases. Between 3-30 unique peptides were detected for each novel antigen. Separate from the index cases, a series of 81 PLA2R-negative MN cases were screened for each antigen by paraffin immunofluorescence. Frequencies were FCN3 (1/81), CD206 (1/81), EEA1 (5/81), SEZ6L1 (1/81), MSP1 (2/81), and VASN (7/81). No additional cases of NPR3 were identified in screening (likely  $<1\%$  of cases). All cases showed co-localization of IgG within glomerular immune deposits.

**Conclusions:** Seven novel protein targets were identified in MN, each having a low frequency of overall cases. Further work is required to examine for circulating antibodies and to determine whether unique histopathologic characteristics or disease associations exist.

**Funding:** NIDDK Support

#### TH-PO453

##### Neuron-Derived Neurotrophic Factor (NDNF) Is a Novel Protein Associated With Membranous Nephropathy (MN)

Sanjeev Sethi,<sup>1</sup> Benjamin J. Madden,<sup>1</sup> Fernando C. Fervenza,<sup>1</sup> Mark Haas.<sup>2</sup>  
<sup>1</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA.

**Background:** Primary MN is commonly associated with antibodies to target antigen PLA2R. The other target antigens in primary MN include THSD7A, NELL1, SEMA3B, HTRA1 and PCDH7. Taken together, these antigens account for approximately 80-90% of primary MN. The target antigen is unknown in the remaining 10-20% primary MN.

**Methods:** We performed laser microdissection of glomeruli followed by mass spectrometry (MS) in 250 cases of PLA2R-negative MN to identify novel antigenic targets in MN. This was followed by immunohistochemistry (IHC) to localize the target antigen along the glomerular basement membrane (GBM). Western blot analyses were performed to detect antibodies to novel antigen using serum/IgG eluate of frozen biopsy tissue.

**Results:** MS studies revealed high total spectral counts (average 29.6, range 19-36) of a novel protein Neuron-derived neurotrophic factor (NDNF) in 3 (1.6%) of the 250 cases (Fig 1). All cases were negative for known antigens including PLA2R, THSD7A, EXT1/EXT2, NELL1, SEMA3B, PCDH7, FAT1, CNTN1 and NCAM1. The median age was 53 years (range 30-73), serum creatinine 3.1 mg/dL (1.4-10), proteinuria 9.7 gms/day (3.1-11) at presentation. One patient had history of HIV and NSAID use, with the biopsy showing acute interstitial nephritis in addition to MN. All cases showed IgG (2-3+) and C3 (2-3+) along GBM, tubular atrophy and interstitial fibrosis was less than 20%, and EM showed stage I-II in all cases. IHC showed granular staining for NDNF along the GBM (Fig 2), control cases were negative. Western blot studies are ongoing.

**Conclusions:** NDNF is a likely novel antigenic target in primary MN.

MS studies show high total spectral counts of novel protein NDNF in 3 cases, IgG with higher counts of IgG1 and IgG3, and C3.

IHC shows granular staining for NDNF along the GBM in a case of NDNF-associated MN.

TH-PO454

NSAID-Associated Membranous Nephropathy (MN) Is Associated With PCSK6

Sanjeev Sethi, Marta I. Casal Moura, Benjamin J. Madden, Fernando C. Fervenza. Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** Drugs are an important secondary cause of MN. The most common drugs associated with MN are non-steroidal anti-inflammatory drugs (NSAIDs). The target antigen in NSAID-associated MN is not known.

**Methods:** We performed laser microdissection of glomeruli followed by mass spectrometry (MS) in 250 cases of PLA2R-negative MN to identify novel antigenic targets of MN. This was followed by immunohistochemistry to localize the target antigen along the glomerular basement membrane (GBM) and western blot analyses of serum/eluate of frozen biopsy tissue to detect binding of IgG to the novel antigenic target.

**Results:** MS studies revealed high total spectral counts (average 44.8) of a novel protein Proprotein Convertase Subtilisin/Kexin Type 6 (PCSK 6) in 4 (1.6%) of the 250 cases (Fig 1). The mean age was 55 (± 4.5) years, serum creatinine 0.88 (±0.2) mg/dL, proteinuria 8.0 (± 4.2) gms/day, and serum albumin 1.7 gms/dL (± 0.8) at presentation. No underlying disease association was found in all cases except for heavy NSAID use of >2 years in 3 of the 4 cases that included ibuprofen, naproxen, and meloxicam. In 1 patient, clinical charts were not available. All cases were negative for known antigens including PLA2R, THSD7A, EXT1/EXT2, NELL1, SEMA3B, PCDH7, FAT1, CNTN1 and NCAM1. All cases showed IgG (3+) and C3 (2+) along GBM, tubular atrophy and interstitial fibrosis was less than 10%, and EM showed stage I-II in all cases. Importantly, western blot analyses (Fig 2) using eluate from frozen tissue showed IgG binding to PCSK6 in the NSAID-associated MN (lane 2) but not in PLA2R-positive MN (lane 3).

**Conclusions:** PCSK6 is a likely novel antigenic target in NSAID-associated MN.

The Role of Complement in Primary Membranous Nephropathy

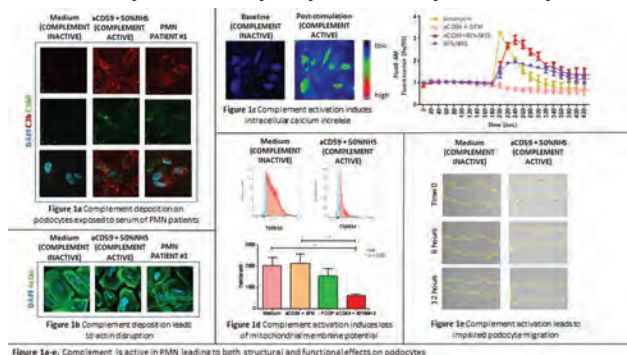

Valentina Bruno,<sup>1,2</sup> Carolina G. Ortiz-Sandoval,<sup>1</sup> Sarah M. Moran,<sup>5</sup> Emily E. Bowen,<sup>1,4</sup> Daniel C. Cattran,<sup>3</sup> Christoph Licht.<sup>1,2</sup> <sup>1</sup>The Hospital for Sick Children, Toronto, ON, Canada; <sup>2</sup>University of Toronto, Toronto, ON, Canada; <sup>3</sup>Toronto General Research Institute, Toronto, ON, Canada; <sup>4</sup>University of Bristol, Bristol, United Kingdom; <sup>5</sup>University College Cork, Cork, Ireland.

**Background:** Primary membranous nephropathy (PMN) is the leading cause of nephrotic syndrome in adults and a common cause of end-stage kidney disease (ESKD). The Heymann's nephritis rat model of PMN shows that proteinuria is complement-mediated. However, the pathogenetic role of complement in human PMN remains unclear. Our preliminary data showed complement deposition on podocytes exposed to serum of PMN patients (from the Toronto GN Registry), leading to disruption of actin cytoskeleton (Figure 1a-b). We aim to demonstrate that complement activation can have both structural and functional effects on podocytes.

**Methods:** An in-vitro model of immortalized human podocytes (from Moin Saleem, Bristol, UK) was used for all the experiments. Cells pre-sensitized with anti-CD59 were exposed to 50% normal human serum (NHS) to obtain complement deposition. Changes in intracellular calcium levels were monitored using a fluorescent dye (Fluo8-AM), acquiring images every 20 seconds (up to 10 minutes) by confocal microscopy. Calcium effects on mitochondrial membrane potential were measured by flow cytometry using tetramethylrhodamine, methyl ester (TMRM) dye. Intracellular adenosine triphosphate (ATP) changes were analyzed by bioluminescence. Wound healing assays were performed to study functional effects on cell migration.

**Results:** Complement activation led to a significant rise in the intracellular calcium levels. Loss of mitochondrial membrane potential was also observed, together with intracellular ATP decrease, disruption of the actin cytoskeleton and impaired cell migration (Figure 1c-e).

**Conclusions:** Complement is active in PMN, leading to both structural and functional effects on podocytes. Further studies are needed to better understand the consequences on the podocyte energy machinery and the possibility of its reversibility by using complement inhibitors. Our research of such alternate therapy could lead to improvement in outcome in PMN where, despite current therapies, up to one third of patients develops ESKD.

### TH-PO456

#### A Phase 1b/2a Single Arm Open-Label Study of VB119, an Anti-CD 19 Monoclonal Antibody (Mab), in Active Primary Membranous Nephropathy (PMN): An Interim Report

Frank B. Cortazar,<sup>1</sup> Jamie P. Dwyer,<sup>3</sup> Stephen B. Thomas,<sup>2</sup> Gregory F. Keenan,<sup>2</sup> New York Nephrology, Vasculitis and Glomerular Center, Albany, NY; <sup>2</sup>ValenzaBio, Inc, Bethesda, MD; <sup>3</sup>University of Utah Health, Salt Lake City, UT.

**Background:** PMN is a common cause of the nephrotic syndrome. Approximately 70% of cases of PMN are caused by autoantibodies directed against the phospholipase A2 receptor (PLA2R), with the remaining cases caused by autoantibodies against other target antigens, some of which are yet to be defined. Current immunosuppressive therapies fail to achieve complete remission in the majority of patients and treatment-related toxicity remains a concern. VB119 is a Mab which targets the CD19 epitope expressed on maturing B-cells- from pro-B-cell through short-lived plasma cells- but notably not on long-lived plasma cells. The broader spectrum of VB119 compared with anti-CD20 Mabs may translate into improved efficacy in the management of autoantibody-mediated diseases, including MN.

**Methods:** Enroll approximately 30 participants with biopsy-proven active PMN as evidenced by > 2 gm/gm UPCR proteinuria on first morning void. Eligible participants will receive VB119 at baseline and 14 days later. Participants with ≥ 25% improvement in proteinuria at 6 months are eligible to receive a subsequent cycle of VB119. Laboratory monitoring includes B-Cell counts, Anti-PLA2R, proteinuria and pharmacokinetic assessments of VB 119. Safety, tolerability and clinical status will be monitored over 18 months.

**Results:** As of May 2022, 3 participants have been enrolled and administered VB119. One participant has been followed for 18 weeks, he is a 59-yo with a hx of relapsing PLA2R-associated MN with a clinical relapse. He was treated with 100mg of VB119 at day 1 and an additional dose 14 days later. The infusions were well tolerated. The change in assessed laboratory values from baseline to week 18 are shown in the figure. There were no treatment related adverse events.

**Conclusions:** The initial participant treated with VB119 for PMN experienced a reduction in proteinuria and an immunological remission by 18 weeks. All participants receiving VB119 and having observations ≥6 weeks through September 15, 2022 will be reported.

#### Relevance of Anti-PLA2R Levels in Therapy Decision and Prediction of Therapy Outcome Using Cyclophosphamide and Steroid Treatment in Patients With Membranous Nephropathy

Ilana Heckler. EUROMMUN US Inc, Mountain Lakes, NJ.

**Background:** Detection of anti-phospholipase A2 receptor (PLA2R) antibodies in patients with primary membranous nephropathy (MN) supports diagnosis as well as disease monitoring. An individualised therapy approach was introduced for anti-PLA2R positive MN patients at the Radboud University Medical Center. Immunosuppressive treatment (cyclophosphamide combined with steroids) was stopped when anti-PLA2R results by indirect immunofluorescence testing (IIFT) became negative. Here, we evaluated the relevance of anti-PLA2R levels for therapeutic decisions and the outcome of MN, comparing qualitative and quantitative detection methods.

**Methods:** Stored serum samples were retrieved for beginning of treatment (baseline), decision point, and follow-up. Anti-PLA2R levels were determined qualitatively by IIFT as well as quantitatively by enzyme-linked immunosorbent assay (ELISA) and chemiluminescence immunoassay (ChLIA) at baseline as well as after treatment and correlated to immunological remission and persistence.

**Results:** Patients sampled at the beginning of the therapy were grouped according to tertiles of anti-PLA2R levels determined by ChLIA (n[lowest tertile] = 20, n[middle tertile] = 20, n[highest tertile] = 20). Lower anti-PLA2R levels were seen in patients with relapsing disease. Higher anti-PLA2R levels were associated with more severe proteinuria. Patients in the lowest tertile of anti-PLA2R were more likely to develop immunological remission after 8 weeks of therapy. At baseline, 50/50 (100%) tested positive in IIFT and ChLIA as well as 48/50 (94%) in ELISA. After 8 weeks on treatment, immunological remission based on IIFT was found in 37/51 (73%) patients. At this point, the overall agreement compared to IIFT was 92% for ChLIA and 82% for ELISA. With ChLIA, anti-PLA2R titers >5 RU/mL after 8 weeks of therapy were found in 4% of IIFT negative patients with persistent remission, vs 55% of IIFT negative patients with early relapse (p=0.006).

**Conclusions:** Individualised treatment of MN patients with cyclophosphamide and steroids has been recently introduced. In this respect, the quantitative determination of anti-PLA2R levels adds further value. Of the examined quantitative methods, ChLIA demonstrated the highest agreement with IIFT. Additional studies are needed to evaluate the impact on clinical decision making and outcome.

### TH-PO458

#### Urinary Single-Cell Sequence Analyzes the Urinary Macrophage in Different Outcomes of Membranous Nephropathy

Xi Liu, Chen Yu. Tongji University School of Medicine, Shanghai, China.

**Background:** Great progresses have been made in diagnosis and treatment of membranous nephropathy, but some patients still do not respond to the immunosuppressive treatment. We performed single-cell sequencing to analysis the urine cells of patients with and without complete remission of MN. Hope to provide some insights for understanding the different outcome of MN.

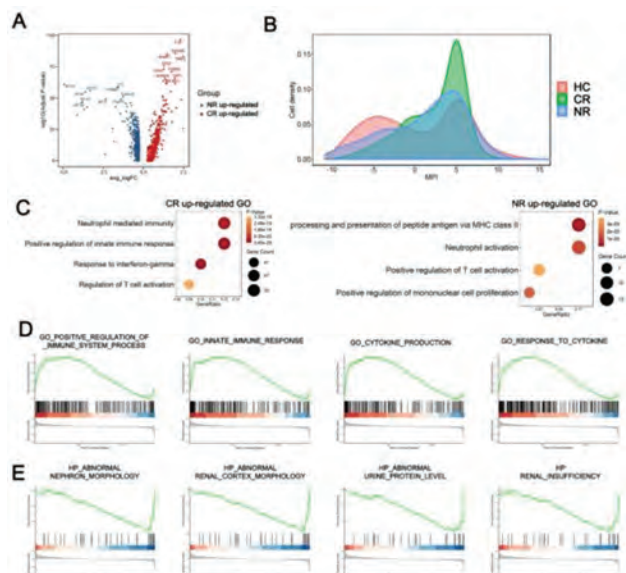

**Methods:** Urine single-cell RNA sequencing was performed on 12 healthy controls (HC) and 15 patients with MN. The patients were divided into complete remission group (CR, n=9) and no remission group (NR, n=6).

**Results:** 1) Macrophages were the largest group in urine cells, they were 48.02%, 68.96% and 20.95% in the HC, CR and NR group, respectively. 2) Urinary macrophages expressing FIColin-1 and S100 calcium binding protein A8 were mainly in HC group and CR group, indicating that they were derived from bone marrow and peripheral blood, while the urinary macrophages expressing the regulator of G-protein signaling 1 and HLA-DPA1, mainly in the NR group, were derived from renal resident macrophages. 3) In healthy adults, urine macrophages expressed the metallothionein family, indicating that they can regulate anti-inflammatory and proinflammatory functions bidirectionally. In the CR group, the urine macrophages showed strong proinflammatory properties. In the NR group, the urinary macrophages mainly associated with the level of proteinuria and the impaired renal function (Figure 1).

**Conclusions:** Our study confirmed the feasibility and effectiveness of urinary single-cell sequencing technology. We firstly delineated urinary cell maps of the MN patients. Not only in origin but also in function of urine macrophages were different in the NC, CR and NR group.

**Funding:** Government Support - Non-U.S.

Polarity analysis of urinary macrophages in the CR group and the NR group

### TH-PO459

#### Resolving Focal Segmental Glomerulosclerosis Recurrence in Human Allografts at Single Cell Resolution

Jennifer M. McDaniels,<sup>1</sup> Amol C. Shetty,<sup>1</sup> Thomas Rousselle,<sup>1</sup> Canan Kusu,<sup>3</sup> Cem Kusu,<sup>3</sup> Elissa Bardhi,<sup>1</sup> James D. Eason,<sup>3</sup> Daniel G. Maluf,<sup>1</sup> Lorenzo G. Gallon,<sup>2</sup> Valeria R. Mas.<sup>1</sup> <sup>1</sup>University of Maryland Baltimore, Baltimore, MD; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** FSGS, characterized by proteinuria and podocyte injury, is one of the leading causes of end stage renal disease. However, pathogenesis is poorly understood. This study identified cell-population changes, cell-cell interactions, and cell-type specific injury pathways contributing to FSGS recurrence in kidney allografts.

**Methods:** Single nuclei RNA-seq was performed on allograft biopsies showing normal histology (N=4) and FSGS-related glomerular damage (first (T1) N=3 and second recurrence (T2) N=2). Downstream analyses were done using UMAP, gene and pathway enrichment, and intra- and inter-cluster comparative transcriptomics.

**Results:** 40,078 single nuclei partitioned into 17 clusters (Fig.1A). Proximal tubular cluster 1 was most abundant in normal allografts (21.02%) and diminished in T1 (16.92%) and T2 (15.50%), likely due to apoptosis. Two distinct podocyte clusters (POD1-2) were identified (Fig.1A). Despite shared canonical cell markers (Fig.1B), 516 and 222 DEGs were identified in POD2 vs POD1 at T1 and T2, respectively, indicating phenotype heterogeneity. POD1 was enriched in Wnt signaling and actin filament pathways whereas POD2 was enriched in ECM accumulation, epithelial cell differentiation, and cell-cell adhesion pathways. We identified 8 immune clusters, of which T memory cells were increased in FSGS allografts (T1: 26.87%; T2: 35.74%) compared to normal (4.75%) (Fig.1C). Ligand-receptor analysis revealed proinflammatory signals transmitted between podocytes and immune cells.

**Conclusions:** FSGS is characterized by a complex cellular and transcriptomic landscape, leading to kidney injury. T1 and T2 interventions require a more targeted approach based on their unique cell-type specific molecular injury pathways.

**Funding:** NIDDK Support

### TH-PO460

#### Membranous Nephropathy Over the Counter? NELL Yes!

Umair Ali, Neriman Gokden, John M. Arthur, Manisha Singh. University of Arkansas for Medical Sciences, Little Rock, AR.

**Introduction:** Membranous nephropathy (MN) is a common cause of nephrotic syndrome. An autoimmune response to M-type phospholipase-A2-receptor (PLA2R) is usually associated with primary MN while antibodies like Neural-epidermal growth-factor-like-1 (NELL1) are related to secondary causes like malignancy or Lipoic acid (LA) ingestion. We present a case of MN with over-the-counter supplement use.

**Case Description:** A 65 year old man presented to hospital with lower limb swelling associated with a rash with history of diabetes, hypertension and benign prostatic hyperplasia. Examination showed bilateral pitting edema to lower limbs with a purpuric rash. Lab work showed HbA1c of 12.3%, serum albumin at 1.4 mg/dl, serum creatinine of 2.4 mg/dl. Urinalysis showed protein +3 and RBC +1 with 24-hour urine protein of 21 grams. Serological workup was negative for autoimmune conditions and infections. Renal biopsy showed MN. Immunotyping was negative for PLA2R and THSD7A but positive for NELL1 (figure shown). Age-appropriate malignancy screen was negative. Based on NELL-1 immunotyping, an extensive review of medications was done. He used NSAIDs intermittently and also over-the-counter multivitamins including lipoic acid 1800 mg. The over-the-counter medications were stopped. The patient was treated with IV methyl-prednisone 1 gm for three days, followed by tapering oral prednisone. However, due to severe exacerbation of hyperglycemia, we switched to a steroid-sparing regimen with rituximab and tacrolimus. His edema subsided at the one-month follow-up visit and proteinuria improved to 6 grams.

**Discussion:** Lipoic-acid supplements are considered antioxidants, insulin-mimetic, and are a frequently used over-the-counter medication. Studies show an association between NELL1 and LA ingestion, though the number of cases known is only a few. In our case, a search for supplement use was made after the biopsy results, especially the immunotyping, leading to a tailored treatment plan. Treatment options are limited. We used rituximab with tacrolimus for this patient with uncontrolled DM. Addressing the driver of the disease, optimizing patient-specific treatment, following proteinuria for assessing remission are the mainstays of treatment of secondary MN

Renal Biopsy with PAS, EM & Immunotyping (NELL1)

## TH-PO461

**NELL1 Renal Biopsy Antigen Staining of Membranous Nephropathy Preceded Clinical Lymphoma Recurrence**

Ayesha A. Khan, Sam Albadri, Nabeel Aslam, Michael A. Mao. *Mayo Clinic, Jacksonville, FL.*

**Introduction:** Membranous nephropathy (MN) is the most common cause of nondiabetic nephrotic syndrome (NS) in Caucasian adults. New MN associated antigens with clinicopathological relevance have been discovered. NELL1 antigen has a reported prevalence of 16% in PLA2R- or THSD7A-negative patients.

**Case Description:** A 70-year-old Caucasian male with history of primary GI follicular lymphoma diagnosed in 2015 and CLL presented for evaluation of nephrotic syndrome. Following Rituximab for one year, remission was declared with negative endoscopies with biopsies and inactive PET scan. Creatinine was 1.27 mg/dL, urine microscopy showed WBC 14/HPF and RBC 4/HPF, and a 24-hour urine revealed 12.9 g protein and measured CrCl 94.2 ml/min. Noninvasive work-up included negative hepatitis B, C, HIV, antiphospholipase A2 receptor, ANCA, ANA, and complement C3 and C4. Serum monoclonal protein study was positive, however serum free light chains and UPEP were normal. Renal biopsy was performed. Light microscopy showed immune complex membranous nephropathy with immunofluorescence showing 2-3+ granular capillary IgG and C3 staining with equal kappa/lambda staining. Immunohistochemistry was performed with PLA2R, THSD7A, and NELL1. NELL1 stained positive (Fig 1). After work-up for secondary etiologies, the patient was treated with Rituximab with ongoing improvement in proteinuria (24-hour urine protein 648 mg after one year).

**Discussion:** This case of NELL1-associated membranous nephropathy associated with lymphoma highlights the clinical utility of renal biopsy antigen staining for diagnosis and management. The onset of NS secondary to membranous nephropathy can occur at different stages in malignancies. It is possible that this NELL1-associated MN may precede clinically detectable underlying malignancy. Studies have proposed monitoring serologic NELL1 antibodies to aid management of progression, recurrence, or remission of the disease.

(b) IHC stain NELL-1

## TH-PO462

**A Rare Case of Membranous Nephropathy in a Patient With Immune-Mediated Necrotizing Myositis: Rituximab Escape**

Farah S. Abuazzam,<sup>1</sup> Sami M. Akram,<sup>1</sup> Amir Abdi Pour,<sup>1</sup> Roy O. Mathew,<sup>2</sup> Lakshmi Ganesan,<sup>1</sup> Sayna Norouzi.<sup>1</sup> <sup>1</sup>Loma Linda University, Loma Linda, CA; <sup>2</sup>VA Loma Linda Healthcare System, Loma Linda, CA.

**Introduction:** Rituximab (RTX) has been established as a treatment option for membranous nephropathy (MN). Here, we report a rare case of MN in a patient who was maintained on RTX for the treatment of immune-mediated necrotizing myositis (IMNM).

**Case Description:** A 42-year-old male with a history of IMNM, presented with bilateral lower limb edema. He reported frequent IMNM relapses followed by remission with RTX for 10 years as he failed the other immunosuppressive therapies due to serious adverse effects including leukopenia. On labs, the urine protein creatinine ratio was 7683 mg/g. Glomerular filtration rate by cystatin C was normal. Antinuclear antibodies (ANA) were positive. Complement levels were normal. Antibodies to double-stranded DNA (dsDNA) and phospholipase A2 receptors were negative. Renal biopsy showed diffuse subepithelial deposits and tubuloreticular inclusions on electron microscopy (EM) (Fig 1) and immunofluorescence staining for IgG and C3. Steroids and tacrolimus were added to RTX for the treatment of the new-onset MN and his condition remains stable.

**Discussion:** This is the first report of MN in the setting of RTX-treated IMNM. In our case, MN onset had occurred while the patient was on RTX for a long duration which suggests mechanisms other than B cell depletion may be at work. The presence of another autoimmune disease (IMNM) suggests immune-mediated MN unamenable to RTX. Another possible mechanism is the development of local or low level of antibody formation that would not be peripherally detected as positive dsDNA but may be enough to elicit a local response although the lack of hypocomplementemia, dsDNA, and the characteristic histopathological and clinical systemic lupus features makes lupus nephritis unlikely. This report demonstrates a need for further elucidation of the pathogenesis of secondary MN to improve patient care.

EM: subepithelial deposits in the glomerular basement membrane (arrows)

## TH-PO463

**Successful Remission of Exostosin-2 Positive Membranous Nephropathy Associated With Autoimmune Hepatitis With Azathioprine and Steroids**

Mohamed Hassanein, Maria Clarissa Tio, Bushra Syed. *University of Mississippi Medical Center, Jackson, MS.*

**Introduction:** Membranous Nephropathy (MN) is an autoimmune disease characterized by immune complex deposition in the glomerular basement membrane (GBM). Recently, Exostosin-1 and 2 (EXT1/EXT2) were reported as target antigens of the GBM especially in patients with autoimmune diseases, particularly lupus. We report a case of EXT2-positive MN associated with autoimmune hepatitis that was successfully treated with azathioprine (AZA) and steroids.

**Case Description:** A 46-year-old female with a history of hypertension, prediabetes, obesity, thrombotic thrombocytopenic purpura (treated with plasmapheresis, steroids and rituximab) and newly diagnosed biopsy-proven autoimmune hepatitis (on AZA) was referred to the nephrology clinic for hematuria and proteinuria. Labs showed intact kidney function with a creatinine 0.5 mg/dL, mild transaminitis and positive anti-nuclear antibodies (ANA). Urine studies showed 3-5 red blood cells per high power field and a urine protein: creatinine ratio of 1.2 g/g (normal <0.2 g/g). A complete serological workup including viral hepatitis, human immunodeficiency virus (HIV), anti-double stranded (DS) DNA antibodies, phospholipase A-2 Receptor (PLA2R) antibodies, and monoclonals were all unremarkable. Kidney biopsy showed EXT2-positive MN with background acute tubular injury and minimal interstitial fibrosis and tubular atrophy. She was started on losartan and prednisone taper with plan to transition from AZA to mycophenolate. Due to insurance related problems, she was unable to transition to mycophenolate. She was continued on AZA, losartan and steroids and went into complete remission 2 months later with a UPCR of 0.18 g/g.

**Discussion:** EXT-associated MN has been strongly linked to autoimmune diseases, particularly lupus. EXT positivity is thought to confer a better prognosis with lower progression to kidney failure compared to EXT-negative MN. Although our patient was positive for ANA and had no history or signs of lupus, patients with EXT-positive MN are thought to be more prone to develop lupus later in life. Treatment is controversial, including rituximab, cyclophosphamide, and steroids. To the best of our knowledge, this is the first case of EXT-positive MN associated with autoimmune hepatitis treated with AZA and steroids.

## TH-PO464

**A Case of Primary Membranous Nephropathy (MN) After Booster Injection of the BNT162b2 COVID-19 Vaccine (Pfizer-BioNTech)**

Cesar Zambrano, Andres J. Azuero, Hisham Bahmad, Ayman Layka. *Mount Sinai Medical Center, Miami Beach, FL.*

**Introduction:** All currently authorized COVID-19 vaccines have proven to be safe, effective and reduce risk of severe illness. Glomerular disease have been reported after administration of COVID-19 messenger RNA (mRNA) vaccines. We report on the development of nephrotic syndrome from Primary Membranous Nephropathy after third injection of the BNT162b2 COVID-19 vaccine.

**Case Description:** 34 years old female with no significant past medical history except migraine headaches, presented to the outpatient setting reporting intermittent and gradually progressing lower extremities edema for 3 months; accompany by abdominal and lower back swelling, facial edema and foamy urine. She received her 3<sup>rd</sup> dose of COVID-19 vaccine 1-2 weeks before symptoms appearance. On evaluation, she was normotensive, preserved kidney function (Creatinine 0.85 BUN 9 eGFR >60), hypoalbuminemia (Alb 1.1 g/dL), nephrotic-range proteinuria (Spot urine protein 869.9 mg/dL, Urine Creatinine 79.9 mg/dL, 24hr Urinary protein excretion estimation 11000 mg/g [11 g/day]), elevated cholesterol (572 mg/dL) and triglycerides (220 mg/dL). She has negative ANA, ANCA, DNA Ds Ab, Hepatitis profile, HIV. Her Anti-phospholipase A2 receptor (anti-PLA2R) antibody came back positive (247 relative units/ml [ $<14$ , negative;  $>20$ , positive]) She underwent kidney biopsy showing global 3+ Subendothelial electron dense deposits

(IgG, C3, Kappa, Lambda), 100 % foot process effacement, IF staining positive for PLA2R, consistent with Primary Membranous Nephropathy Stage II. She was started on High-dose steroids and later switched to Tacrolimus 2mg BID, and received Rituximab x 2 doses with major improvement in symptoms and proteinuria.

**Discussion:** MN is more common in male in their early 50s. The fact our patient doesn't fit this category, her temporal association with vaccination and the exclusion of other explanatory factors, supports a potential connection between COVID-19 vaccination and glomerular disease. To our knowledge, this is only the second case reporting association of COVID-19 mRNA vaccine and MN. Together with a report from Relapse MN after vaccination and one case of Minimal Change disease, we highlight the possible role of COVID vaccination causing immune glomerular dysregulation. Further studies are needed to elucidate the early postvaccination immune response mechanism.

#### TH-PO465

##### Relapsed Membranous Nephropathy After COVID-19 Vaccination

Roy Rajan,<sup>1,2</sup> Clay A. Block,<sup>1,2</sup> Thomas M. Kaneko,<sup>1,2</sup> Jason R. Pettus,<sup>1,2</sup> Elizabeth J. Brant,<sup>1,2</sup> <sup>1</sup>Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Introduction:** *De novo* and relapsed glomerulonephritis (GN), including membranous nephropathy (MN), have been reported after COVID-19 mRNA-vaccination. We report a case of MN that relapsed following COVID-19 vaccination after 26 years of remission.

**Case Description:** A 78-year-old man presented with nephrotic syndrome (UPC 8.0). His history was notable for primary MN diagnosed by kidney biopsy in 1994. He was treated with prednisone and ACE inhibitor with full resolution of proteinuria. He received COVID-19 vaccine (mRNA-1273, Moderna) March 3 and April 1, 2021. Between the two doses, he had onset of leg swelling. This was attributed to amlodipine, which was discontinued by his PCP. After the second dose of vaccine, edema progressed to anasarca. Urine protein was 5.73g/day. Two months later, the UPC was 8.0, serum creatinine 0.86 mg/dL, and serum albumin 2.7mg/dL. Anti-PLA2R was positive (24RU/mL, ref. >19RU/mL). Renal biopsy showed recurrent MN, EM stage 3-4, PLA2R1 positive. Due to regional surge of COVID-19 Omicron variant, immunosuppression was held to administer EvuShield for COVID-19 prophylaxis. Proteinuria improved initially without intervention (UPC 2.7) but increased again (UPC 4.7) a month later. Rituximab was initiated three months after biopsy resulting in undetectable anti-PLA2R 1 week after treatment, with reduction in UPC to 3.7 and improvement of anasarca 2 weeks after treatment.

**Discussion:** Onset or relapse of GN after vaccination historically has rarely been reported. There are numerous reports of *de novo* or relapsed GN after COVID-19 infection, and increasing reports of GN after COVID-19 vaccination with mRNA and traditional vaccine platforms. The pathogenesis of GN in this setting has not been established. Nonspecific immune activation and specific COVID-19-related immune reaction have been postulated. MN related to COVID-19 vaccination, although rarely reported, has been treated with standard immunosuppression with favorable results. Management of MN and other forms of GN will evolve with greater understanding of disease course in the setting of COVID-19 infection and vaccination. Patients with a history of GN, including MN, should be counseled about the possibility of relapse with COVID-19 infection or vaccination, even if their original disease was remote.

#### TH-PO466

##### Not All Light-Chain Restricted Pattern Is Light Chain Disease

Arvin Daneshmand,<sup>1,4</sup> Donghyang Kwon,<sup>2</sup> Steven A. Burka,<sup>2,3</sup> Negi Pourafshar,<sup>2</sup> <sup>1</sup>Georgetown University School of Medicine, Washington, DC; <sup>2</sup>MedStar Georgetown University Hospital, Washington, DC; <sup>3</sup>The George Washington University Hospital, Washington, DC; <sup>4</sup>University of Florida College of Medicine, Gainesville, FL.

**Introduction:** Light Chain Deposition Disease (LCDD) is a disease characterized by widespread tissue deposition of monoclonal Ig light chains (LC), often in association with immunoproliferative disorders.<sup>1</sup> The clinical course of LCDD most often involves the kidney, as this is the primary site of LC uptake and degradation, and results in renal insufficiency. Microscopy most often reveals nodular sclerosing glomerulopathy or tubular basement membrane thickening, particularly with κ-LCs.<sup>2</sup> Rarely, renal involvement may take the form of subepithelial deposits otherwise characteristic of membranous nephropathy (MN).<sup>3,4</sup> Here we highlight a case of kappa-predominant MN with no significant immunoglobulin deposition in a patient with monoclonal gammopathy.

**Case Description:** Our patient is a 66yo female who presented with severe lower extremity edema and hypertension (SBP 200's), found to have nephrotic syndrome with UPC 10.8, Cr 0.78. On further evaluation, labs revealed a small M spike of 0.12, gamma globulin 0.64, and alpha-2-globulin 1.26 on SPEP. Subsequent abdominal fat pad aspiration and colonoscopy with rectal biopsy were negative for amyloidosis. A bone marrow biopsy, FISH study, and flow cytometric analysis were all negative for hematologic malignancy. Left kidney biopsy in 05/2021 was notable for MN with granular kappa-predominant staining with no Ig deposition and mild chronic tubulointerstitial disease. Negative Congo Red stain excluded amyloidosis. She was determined to have monoclonal gammopathy of renal significance (MGRS) and was initiated on Velcade/dexamethasone. Initial serum Kappa free light chain level was 44.2, with subsequent improvement to 27.3 and reductions in proteinuria and edema.

**Discussion:** This patient found benefit to chemotherapy for MN secondary to MGRS. In summary, MGRS may cause nephrotic syndrome with only light chain subepithelial deposition in the absence of other tubular or glomerular toxicities.

Kappa Stain

#### TH-PO467

##### Two Case Reports of Cytomegalovirus Induced Collapsing Focal Segmental Glomerulosclerosis in Immunocompetent Hosts

Marco Ramos, Mohamed O. Omer, Ihab Jameel, Suhaib A. Andrabi. *Harlem Hospital Center, New York, NY.*

**Introduction:** Collapsing focal segmental glomerulosclerosis (cFSGS) refers to a distinct pattern of glomerulopathy characterized by a glomerular capillary collapse in a segmental global manner, podocyte proliferation, and tubulointerstitial injury. Viral infections like HIV, Parvovirus B19, and CMV seem to be prominent triggers for the development of a conventional histological pattern of FSGS. CMV-associated renal disease has been described only in transplant and immunocompromised patients.

**Case Description:** Case 1 18-year-old female with history of asthma and HbSS disease presented with fever, nausea, vomiting, and neck pain. Physical examination revealed a temperature of 102 F, icterus, negative meningeal signs, no rales, rhonchi or wheezing. Initial creatinine 0.2 mg/dL. COVID-19 PCR was negative but IgG antibodies positive. Patient developed non-oliguric AKI with fluid overload requiring hemodialysis. CMV IgM and CMV PCR were positive. She received antibiotic therapy and also ganciclovir. Biopsy revealed collapsing FSGS with acute tubular injury. A week after completion of ganciclovir therapy creatinine returned to baseline of 1.7 mg/dL. Case 2 40-year-old African American male with history of diabetes and asthma presented with fever, fatigue, epigastric pain and chest pain. Initial creatinine 1.2 mg/dL, hepatic function (AST 333 U/L, ALT 265 U/L, ALK 207 U/L), ferritin (13682 ng/ml), triglycerides (276 mg/dl) and proteinuria (urine protein/creatinine ratio: 2, urine albumin/creatinine: 1016 mg/gm). Patient developed anuric renal failure which required hemodialysis. Biopsy revealed collapsing FSGS with diffuse podocyte effacement, moderate tubular atrophy, and interstitial fibrosis. CMV DNA antibodies were positive. Methylprednisolone and valganciclovir were started with patient creatinine trending down to 3.7 mg/dL. Three weeks following discharge, creatinine levels were 1.5 mg/dL with decreased proteinuria.

**Discussion:** Collapsing FSGS in immunocompetent patients is uncommon. Reports mention benefits of ganciclovir and steroid therapy for CMV infection in immunocompromised patients. CMV infection should be considered in patients with systemic inflammatory disease and severe renal failure, as early treatment with steroids and antivirals helps preserve renal function.

#### TH-PO468

##### Biopsy Proven Minimal Change Disease in a Patient With Primary Biliary Cholangitis

Bahman J. Moghadam, William Wallace, Yan Zhong. *University of Southern California, Los Angeles, CA.*

**Introduction:** Primary biliary cholangitis (PBC) is an autoimmune liver disease characterized by circulating anti-mitochondrial antibodies (AMA). Though rare, PBC has been associated with varied renal disorders including glomerular diseases such as minimal change disease (MCD). This is a case of biopsy proven MCD in a patient with PBC treated with steroid and achieving complete recovery.

**Case Description:** A 70-year-old Hispanic lady with recent diagnosis of PBC presented with new onset dyspnea and anasarca. One month prior, she was evaluated for elevated alkaline phosphatase and abnormal liver function tests (LFTs) including AST/ALT and bilirubin. Workup showed antinuclear antibody titer of 1:1280 and AMA titer of 1:160 resulting in a clinical diagnosis of PBC without need for liver biopsy. On her current hospitalization, serum creatinine was at baseline 1.01 mg/dL, urine protein/creatinine ratio was 12.95 gm/day and serum albumin 1.7 g/dL. Nephrotic work up was unrevealing. Kidney biopsy showed extensive foot process effacement, consistent with MCD (Figure 1). Given worsening renal function and persistent anasarca, Prednisone 60mg with taper, diuretic and angiotensin-converting enzyme inhibitor were prescribed. At one month follow up she had resolution of nephrotic syndrome and normalization of LFTs.

**Discussion:** MCD is a clinical and pathological entity defined by proteinuria and hypoalbuminaemia without in the absence of glomerular infiltrates or immunoglobulin deposits. It is thought that MCD is caused by an aberrant immune response and as such, the coexistence of PBC and MCD has previously been postulated to be a result of induction of cell-mediated immunity. Perhaps the combined autoimmune nature of PBC and immune mediated pathology of MCD is what makes the clinical course responsive to steroids. Review of a larger case series could allow for more in-depth insights.

Extensive foot process effacement with minimal change nephropathy

#### TH-PO469

##### A Case of Minimal Change Disease Associated With Salmonella Infection, Treated Successfully With Antibiotics

Syed Hasni,<sup>1</sup> Jennine Michaud,<sup>2</sup> Michael Yudd.<sup>2</sup> Rutgers New Jersey Medical School <sup>1</sup>Rutgers New Jersey Medical School, Newark, NJ; <sup>2</sup>Veterans Health Administration Operations, East Orange, NJ.

**Introduction:** This case is the first to our knowledge of Salmonella bacteremia associated with Minimal Change Disease in adults. The patient's course lends further support to the hypothesis of a causal relationship between infections and MCD.

**Case Description:** 69-yom with pmh of HTN, treated HCV, who presented with a 3-week h/o diarrhea, abd. pain and LE edema. P/E showed ascites and LE edema. UA had >500 mg/dL protein, p/c ratio of 5, sediment with oval fat bodies and fatty casts, serum alb 2.2g/dL and cr of 1.1 mg/dL. Proteinuria workup negative for HIV, HBV, RPR, ANA, SPEP, UPEP, complements normal, HCV VL undetectable. Kidney biopsy showed MCD. Diarrhea resolved but proteinuria persisted, and patient was treated with oral prednisone 1mg/kg. 3 weeks later, patient developed UTI symptoms and received empiric ciprofloxacin. Urine culture grew Salmonella species group D. Blood cultures done following treatment were positive for Salmonella species group D. Clinical course complicated by relapsed Salmonella bacteremia, Salmonella vertebral osteomyelitis, ATN requiring temporary hemodialysis. With completion of steroid taper, prolonged IV antibiotic treatment and resolution of Salmonella infection, proteinuria resolved and never recurred.

**Discussion:** The infectious diseases leading to secondary MCD include Syphilis, Ehrlichiosis, Mycoplasma, HIV, TB, Echinococcus and Schistosomiasis. Our case demonstrates Salmonella can also cause a secondary MCD. In MCD, microbial products and/or interleukins bind to Toll-like receptors or IL receptors leading to CD80 expression, which in turn, may interfere with nephrin expression/phosphorylation. Angiopoietin-like-4 is thought to induce proteinuria by reducing anionic sites at the glomerular basement membrane level. Several candidate molecules have been considered as possible circulating factors. Often, with appropriate anti-microbial therapy of the underlying infectious disease, the MCD will abate.

Glomerular filtration barrier in healthy state (left) and in MCD (right)

#### TH-PO470

##### Syphilis and HIV Co-Infection: A Dual Attack on the Kidneys

Sylvester Dorobisz,<sup>1</sup> Ali Mehdi, George Thomas, Kristen Tomaszewski, Laura Ferreira Provenzano, Michael W. George. Cleveland Clinic, Cleveland, OH.

**Introduction:** HIV-associated nephropathy (HIVAN) remains an important cause of kidney failure in persons of African ancestry due to the association with APOL1. Syphilis infections are increasing in incidence and have notable kidney manifestations. Here we present a case of kidney failure in the setting of an HIV and syphilis co-infection.

**Case Description:** A 54-year-old black male presented to the emergency department with recurrent chest pain and malaise. His cardiac evaluation was unrevealing but he had lower extremity edema on examination. His creatinine on presentation was 1.5mg/dl (baseline: 1.1mg/dl) increasing to 5.83mg/dl during the hospitalization. A urinalysis had 3+ proteinuria and 3+ hematuria and urine protein creatinine ratio was 8.2 g/g. A kidney ultrasound revealed no hydronephrosis. His albumin was 1.8 g/dL and serologic work up revealed negative ANA, ANCA, M protein, PLA2R antibodies, hepatitis panel and normal complements. An HIV test was negative a week prior. His CBC was normal but he had a depleted haptoglobin and elevated LDH at 969 U/L. A kidney biopsy revealed focal segmental glomerulosclerosis with collapsing and membranous features along with acute tubular injury and mild interstitial fibrosis. Immunofluorescence was negative. An HIV RNA test came back positive at 1,980,000 copies/mL suggesting an acute retroviral illness. Syphilis screen also came back positive. It was thus thought that the HIV accounted for the collapsing features while the syphilitic infection led to the membranous component. Along with diuresis for volume overload, antiretroviral therapy and penicillin were started. His creatinine stabilized at 2 mg/dl at outpatient follow-up with improving proteinuria.

**Discussion:** Both syphilis and HIV can cause proteinuric kidney injury. HIVAN is well described with glomerular collapsing features on biopsy in the setting of uncontrolled HIV. This case illustrates that HIVAN can also occur in the setting of an acute HIV infection where the HIV screening test can be negative. HAART therapy remains the cornerstone of management with unfavorable prognosis. Membranous nephropathy is the most common pathologic finding of syphilitic nephropathy with excellent response to syphilis treatment. This case serves as a reminder to consider this entity in our differentials particularly with the resurgence of this infection.

#### TH-PO471

##### A Case of Anti-Brush Border Antibody Disease

Nicholas W. Salupo,<sup>1</sup> Laura Biederman,<sup>2</sup> Jennifer L. Jackson.<sup>1</sup> <sup>1</sup>Kettering Health, Dayton, OH; <sup>2</sup>The Ohio State University Wexner Medical Center, Columbus, OH.

**Introduction:** Anti-brush border antibody (ABBA) disease is a rare disorder characterized by tubulointerstitial damage due to antibodies against the renal proximal tubular brush border. IgG-containing deposits are found in the tubular basement membrane (TBM) and glomerular subepithelial space. Detection of anti-megalin (LRP2) antibodies is pathognomonic. There is not much evidence detailing this condition.

**Case Description:** A 65 year old male with hypertension, peripheral vascular disease, hepatitis C, and benign prostatic hypertrophy with worsening GFR after acute kidney injury. Serum creatinine was 1.8-2.0 mg/dL. There was no hematuria, proteinuria, or urinary eosinophilia. He had normal complements, antinuclear antibody was negative, no monoclonal proteins were seen on SPEP, urinary kappa lambda light chain ratio was 1.26, and unremarkable imaging. Kidney biopsy showed moderate chronic parenchymal changes with many TBM and Bowman's capsule electron dense deposits immunoreactive for polyclonal IgG and glomerular segmental, subepithelial electron dense deposits with membranous pattern immunodominant for polyclonal IgG. Anti-megalin staining was positive along tubular basement membranes.

**Discussion:** This case demonstrates a rare, but possibly increasing, disease process. The inciting cause remains unknown but the differential diagnosis includes systemic lupus erythematosus, Sjögren's syndrome, idiopathic hypocomplementemic tubulointerstitial nephritis, and IgG4-related disease. Biopsy findings of TBM deposits on the apical aspect of the TBM are most suspicious for anti-brush border antibody disease. Definitive diagnosis is made with the anti-megalin staining. Treatment, necessary if impaired renal function persists, consists of immunosuppression to stall further renal deterioration.

Tubular basement membrane deposits on the luminal aspect of TBM

#### TH-PO472

##### Incidence of Cardiovascular Events Among Glomerular Disease Participants in the Cure Glomerulonephropathy Network (CureGN)

Shikha Wadhvani,<sup>1</sup> Sarah Mansfield,<sup>2</sup> Abigail R. Smith,<sup>2</sup> Bruce M. Robinson,<sup>2</sup> Isa Ashoor,<sup>3</sup> Aftab S. Chishti,<sup>4</sup> Salim Hayek,<sup>6</sup> Michelle A. Hladunewich,<sup>13</sup> Siddharth S. Madapoosi,<sup>6</sup> Laura H. Mariani,<sup>5</sup> Amy K. Mottl,<sup>10</sup> Michelle M. O'Shaughnessy,<sup>8</sup> Afshin Parsa,<sup>9</sup> David T. Selewski,<sup>11</sup> Chia-Shi Wang,<sup>12</sup> Donald J. Weaver,<sup>7</sup> Myda Khalid.<sup>5</sup> CureGN ERO Writing Group <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>LCMC Health, New Orleans, LA; <sup>4</sup>Kentucky Children's Hospital, Lexington, KY; <sup>5</sup>Riley Hospital for Children at Indiana University Health, Indianapolis, IN; <sup>6</sup>University of Michigan, Ann Arbor, MI; <sup>7</sup>Levine Children's Hospital, Charlotte, NC; <sup>8</sup>University College Cork, Cork, Ireland; <sup>9</sup>National Institutes of Health, Bethesda, MD; <sup>10</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>11</sup>Medical University of South Carolina, Charleston, SC; <sup>12</sup>Emory University School of Medicine, Atlanta, GA; <sup>13</sup>Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

**Background:** Cardiovascular (CV) events are known extra-renal complications of glomerular disease that cause increased rates of hospitalization, morbidity, and mortality. This analysis describes CV outcomes in CureGN, a prospective cohort study of adults and children with biopsy-proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), or IgA nephropathy/vasculitis (IgA) from 65 US and 6 international sites.

**Methods:** Multivariable Cox regression was used to estimate associations with first post-enrollment CV event, among those without prior CV events.

**Results:** The cohort included 2423 participants (566 MCD, 615 FSGS, 546 MN, 696 IgA). At enrollment, median age was 31 yrs (IQR 14-51), with 35% children, 57% male, 13% Hispanic, and 16% Black. At enrollment, median eGFR was 83 mL/min/1.73m<sup>2</sup> (IQR 54-103) and median UPCR was 1.2 g/g (IQR 0.2-3.9). Median follow-up was 3.8 years (IQR 2.2-5.1). Overall, 96 participants (22 children, 74 adults) experienced at least one CV event post-enrollment, most commonly arrhythmia followed by heart failure. The cumulative incidence at 1-, 3-, and 5-years post-enrollment was 0.2%, 1.3%, and 1.9%, respectively, for children, and 1.4%, 4.4%, and 7.1%, respectively, for adults. Higher hazard of first CV event post-enrollment was associated with older age (HR=1.1 per 5 yrs), lower eGFR at enrollment (HR=0.88 per 10 mL/min/1.73 m<sup>2</sup>), and higher UPCR (HR=1.03 per g/g) [Figure]. Glomerular disease subtype was not associated with hazard of CV event (p=0.58).

**Conclusions:** CV events were associated with older age and kidney disease severity, but not glomerular disease subtype, in this cohort. Further study and longer follow-up will improve understanding of CV risk in patients with glomerular disease and inform practice guidelines.

##### Incidence of Thromboembolic Events Among Glomerular Disease Participants in the Cure Glomerulonephropathy Network (CureGN)

Myda Khalid,<sup>1</sup> Sarah Mansfield,<sup>3</sup> Abigail R. Smith,<sup>3</sup> Bruce M. Robinson,<sup>3</sup> Eman Abdelghani,<sup>4</sup> Amira Al-Uzri,<sup>5</sup> Sharon M. Bartosh,<sup>8</sup> Debbie Gipson,<sup>6</sup> Bryce A. Kerlin,<sup>4</sup> Michelle N. Rheault,<sup>9</sup> John Sperati,<sup>7</sup> Tarak Srivastava,<sup>11</sup> Craig S. Wong,<sup>10</sup> Shikha Wadhvani.<sup>2</sup> CureGN ERO Writing Group <sup>1</sup>Riley Hospital for Children at Indiana University Health, Indianapolis, IN; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>4</sup>Nationwide Children's Hospital, Columbus, OH; <sup>5</sup>Oregon Health & Science University, Portland, OR; <sup>6</sup>University of Michigan, Ann Arbor, MI; <sup>7</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>8</sup>University of Wisconsin-Madison, Madison, WI; <sup>9</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>10</sup>University of New Mexico School of Medicine, Albuquerque, NM; <sup>11</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO.

**Background:** Thromboembolic (TE) events are well-known complications of glomerular disease, but incidence rates and risk factors are not well-defined. This analysis describes TE outcomes in CureGN, a prospective cohort study of adults and children with biopsy-proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), or IgA nephropathy/vasculitis (IgA) from 65 US and 6 international sites.

**Methods:** Multivariable Cox regression was used to estimate associations with first post-enrollment TE event, among those without a prior event.

**Results:** Among 2423 participants (566 MCD, 615 FSGS, 546 MN, 696 IgA), enrollment characteristics were: median age 31 yr (IQR 14-51), 35% children, 57% male, 13% Hispanic, 16% Black, median eGFR 83 mL/min/1.73m<sup>2</sup> (IQR 54-103), median UPCR 1.2 g/g (IQR 0.2-3.9). Median follow-up was 3.8 years (IQR 2.2-5.1). Overall, 46 participants (12 children, 34 adults) experienced at least one TE event, most commonly deep vein thrombosis, followed by pulmonary embolism. The cumulative incidence at 1-, 3-, and 5-years post-enrollment was 0.6%, 1.5%, and 1.8%, respectively, for children, and 1.9%, 3.3%, and 4.4%, respectively, for adults. First TE events were associated with Black race (HR=2.3, 95% CI=1.2-4.5) and lower serum albumin ((HR=0.67 per g/dL, 95% CI=0.47-0.94), as well as with older age, tobacco use, higher body mass index, and lower eGFR [Figure]. Glomerular disease subtype was not associated with TE events (p=0.74).

**Conclusions:** TE events frequently complicate glomerular disease and in this cohort were associated with particular demographic and clinical characteristics. Additional data will extend understanding of thromboembolic risk in patients with glomerular disease and inform practice guidelines.

# COVID-19 Infection and Vaccination in Patients With Glomerular Disease: An Analysis of the Cure Glomerulonephropathy (CureGN) Study

Dorey A. Glenn,<sup>1</sup> Chia-Shi Wang,<sup>4,5</sup> Margaret Helmuth,<sup>3</sup> Gaia M. Coppock,<sup>10</sup> Myda Khalid,<sup>6</sup> Abigail R. Smith,<sup>3</sup> Katherine R. Tuttle,<sup>7,8</sup> Bruce M. Robinson,<sup>3</sup> Raed Bou Matar,<sup>9</sup> Debbie Gipson,<sup>2</sup> Andrew S. Bombard,<sup>11</sup> Laura H. Mariani,<sup>2</sup> on behalf of the CureGN consortium <sup>1</sup>University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>4</sup>Emory University, Atlanta, GA; <sup>5</sup>Children's Healthcare of Atlanta Inc, Atlanta, GA; <sup>6</sup>Riley Hospital for Children at Indiana University Health, Indianapolis, IN; <sup>7</sup>Providence Health and Services, Renton, WA; <sup>8</sup>University of Washington, Seattle, WA; <sup>9</sup>Cleveland Clinic Children's Hospital, Cleveland, OH; <sup>10</sup>University of Pennsylvania, Philadelphia, PA; <sup>11</sup>Columbia University, New York, NY.

**Background:** Persons with glomerular diseases (GD) are vulnerable to severe COVID19 infection, yet may be hesitant to receive vaccines. We sought to understand predictors for severe COVID19 infection in GD and the effectiveness and safety of COVID19 vaccines.

**Methods:** CureGN is a prospective observational study of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, or IgA Nephropathy. Beginning in July 2021, a questionnaire was administered at study visits to assess evidence of COVID19 infection, vaccination, and clinical features of COVID19-related hospitalizations. Severe infection was defined as COVID19-associated hospitalization or death. Predictors of severe infection were evaluated using multivariable logistic regression models, adjusting for age, vaccination status, and comorbidities (base model), then individually adjusting for immunosuppression, race, ethnicity, GD subtype, eGFR, and UPCR. eGFR slope pre- and post-infection or COVID19 vaccination were estimated using interrupted time series analyses.

**Results:** From July 2021 to March 2022, 1182 participants were surveyed with 177 (15%) reporting COVID19 infection. Of those, 39 (22%) developed severe illness, including 2 deaths. Over study follow-up, the proportion of vaccine-eligible participants who had received  $\geq 1$  COVID19 vaccine increased from 55% to 70%. Lower eGFR pre-infection was associated with a higher odds of severe infection (OR[95%CI]: 1.19 [1.04,1.37] per 10 unit decrease in eGFR (base model). COVID19 infection was associated with a 5.04 (SD 2.31) unit drop in eGFR at the time of infection. No change in eGFR was seen following vaccination (Figures 1a and b). Crude vaccine effectiveness was 80% for "any" and 86% for "severe" infection.

**Conclusions:** COVID19 infection resulted in high rates of hospitalization and acute decline in eGFR among GD patients. Vaccination was associated with lower rates of COVID19 infection and severe disease and did not affect kidney function in the short term.

**Funding:** NIDDK Support

Figure 1: eGFR slope pre- and post-COVID19 Infection (a) and vaccination (b).

## TH-PO475

# Challenges in Diagnosis and Management of Glomerular Disease in a Resource-Limited Setting

Raja Ramachandran,<sup>1</sup> Ifeoma I. Ulasi,<sup>3</sup> Ugochi C. Onu,<sup>3</sup> Vivekanand Jha,<sup>2</sup> <sup>1</sup>Postgraduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>George Institute for Global Health, UNSW, Delhi, India; <sup>3</sup>College of Medicine, University of Nigeria, Ituku-Ozalla, Nigeria.

**Background:** Glomerular diseases are the leading driver of non-diabetic chronic kidney disease (CKD) disability-adjusted life years in third world countries. Proper diagnosis and treatment rely on access to resources, including kidney biopsy, ancillary testing and access to evidence-based therapies.

**Methods:** After an initial pilot phase, we conducted a cross-sectional internet-based survey among nephrologists in countries of Asia, Africa and Eastern Europe, Asia, Africa and Eastern Europe. In the survey, we collected the baseline demographic data, the ability to perform and appropriately interpret a kidney biopsy, and access to complementary investigations and treatment practices.

**Results:** 298 kidney care specialists took part in the survey (64% from academic/university hospitals). Eighty-two percent performed kidney biopsy. About 61% of the respondents could not get a kidney biopsy in  $>50\%$  of patients with suspected glomerular disease. About 43% of the respondents from Africa had access only to light microscopy. Overall, the inability to undertake and fully evaluate a biopsy and perform ancillary investigations was more profound in Africa than in Asia. Sixty per cent of the participants reported  $>75\%$  of their patients meeting the cost of diagnosis and treatment by out-of-pocket expenses. Empirical use of immunosuppression was higher in Africa than in Asia. The main barriers to diagnosis and treatment included a delayed presentation, incomplete diagnostic work-up and high cost of treatment.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** There are major barriers to implementing a guideline-driven approach to the diagnosis and treatment of patients with glomerular disease in limited-resource countries.

## TH-PO476

# GSTM1 Deletion Associates With Progression of Glomerular CKD

Rebecca Levy,<sup>1</sup> Kimberly J. Reidy,<sup>2</sup> Rick Kaskel,<sup>2</sup> Thu H. Le,<sup>1</sup> Michal L. Melamed,<sup>2</sup> NEPTUNE Investigators <sup>1</sup>University of Rochester Medical Center, Rochester, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.

**Background:** Risk factors for progression in glomerular disease are not well-understood. A common deletion in *GSTM1* is associated with progression in a variety of CKD etiologies but has not been previously reported in glomerular disease.

**Methods:** We performed a secondary analysis of the prospective NEPTUNE cohort. The exposure is  $\geq 1$  copy of nonfunctional *GSTM1*. The primary outcome is 40% reduction in eGFR or ESKD. Secondary outcomes include proteinuria remission and relapse. Analysis was by multivariable logistic regression with adjustment for potential confounders.

**Results:** Baseline characteristics of the study cohort are shown in Table 1. Of the 513 subjects, 60% were male, 57% were White, and they had a mean age of 30.4. At baseline, subjects with *GSTM1* deletion were younger with worse kidney function; they were more likely to have FSGS and self-identify as Black. Participants were followed for a mean of  $2.4 \pm 1.6$  years; 118 participants developed the primary outcome, 88 (23%) in the *GSTM1* 1/1 group and 30 (32%) in the *GSTM1* deletion group. After adjustment for demographics and baseline severity, *GSTM1* deletion is associated with progression of CKD (OR 1.91, CI 1.12-3.27) but not with changes in proteinuria.

**Conclusions:** *GSTM1* deletion is associated with progression of CKD in glomerular disease but unlikely involves proteinuric pathways in this cohort.

	Total (n=513)	Reference (n=406)	Deletion (n=107)	p
Age	30.4±22.3	31.7±22.8	24.9±18.9	0.006

## TH-PO477

# Assessing the Form of Predictor-Outcome Association for Machine Learning Models of Patient-Reported Outcomes in Nephrotic Syndrome

Jeremy Rubin,<sup>1</sup> Laura H. Mariani,<sup>2</sup> Abigail R. Smith,<sup>3</sup> Jarcy Zee,<sup>1</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>3</sup>Arbor Research Collaborative for Health, Ann Arbor, MI.

**Background:** Penalized regression models can be used to identify and rank risk factors for poor quality of life, but they often assume covariates have linear associations with the outcome. There is no standard, automated method for determining the optimal functional forms (shapes of relationships) between predictors and the outcome in high-dimensional data settings.

**Methods:** We propose a novel algorithm, Ridge regression for functional form Identification of continuous Predictors (RIP), that models each continuous covariate with linear, quadratic, quartile, and cubic spline basis components in a ridge regression model to capture potential nonlinear relationships between continuous predictors and outcomes. We used a simulation study to test the performance of RIP compared to standard and spline ridge regression models. Then, we applied RIP to identify top predictors of baseline Patient-Reported Outcomes Measurement Information System (PROMIS) adult global mental and physical health scores using demographic and clinical characteristics among N=107 glomerular disease patients enrolled in the Nephrotic Syndrome Study Network (NEPTUNE).

**Results:** RIP resulted in better predictive accuracy in 56-80% of simulation repetitions under a variety of data characteristics. When applied to the PROMIS scores in NEPTUNE, RIP resulted in the lowest error for predicting physical scores, but the highest error for the mental scores. Further, RIP identified functional forms of top predictors of the physical scores that were missed by the other models [Figure 1].

**Conclusions:** The RIP algorithm can capture nonlinear functional forms of predictors that are missed by standard ridge regression models. The top predictors of PROMIS scores vary greatly across methods. RIP should be considered alongside other machine learning models in the prediction of patient-reported outcomes.

Figure 1. Top Predictors of Physical PROMIS Scores

Ranking	RIP	Regular Ridge Regression	Spline Ridge Regression
1	Annual household income	Annual household income	Annual household income
2	Hemoglobin (quartile)	Chloride	WBC
3	WBC (spline, quartile)	Alcohol use	Alcohol use
4	Alcohol use	Shortness of breath	Blood Urea Nitrogen
5	eGFR at baseline (quartile, spline)	Nausea and/or vomiting	Participant age
6	Blood Urea Nitrogen (spline, quad)	Number of times received ER care	Shortness of breath
7	Shortness of breath	Total number of days hospitalized	Age of biological father
8	Participant age (spline)	Any edema present	Chloride
9	Number of times seen provider for well/check visits (quartile, spline)	Hypertension at baseline	Nausea and/or vomiting
10	Age of biological father (spline)	eGFR at baseline	Number of times seen provider for well/check visits
11	Number of times seen by wellness provider for illness/injuries (quartile)	Blood Urea Nitrogen	Number of times received ER care
12		Race of father	

For the RIP algorithm, functional forms per predictor are given in parentheses by the predictor name. Num of times are past 6 mos.

TH-PO478

Evaluating the Predictors of Structural Features in Kidney Biopsies From Adults With Focal Segmental Glomerulosclerosis

Katherine R. Tuttle,<sup>1,2</sup> Clint Abner,<sup>3</sup> Patrick D. Walker,<sup>3</sup> Kaijun Wang,<sup>4</sup> Martin C. Bunke,<sup>4</sup> Ji Haeng Heo,<sup>5</sup> Andrew Rava.<sup>5</sup> <sup>1</sup>Providence Health, Spokane, WA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Arkana Laboratories, Little Rock, AR; <sup>4</sup>Travere Therapeutics Inc, San Diego, CA; <sup>5</sup>Genesis Research LLC, Hoboken, NJ.

**Background:** Focal segmental glomerulosclerosis [FSGS] is a lesion of glomerular injury in patients with nephrotic syndrome. The aim of this study was to assess clinical predictors of FSGS histological severity among adults undergoing kidney biopsy.

**Methods:** A real-world data study was performed using the Arkana Biopsy database (1Jan2016–31May2020). Inclusion criteria: ≥18 years, ≥1 FSGS positive biopsy, no prior kidney transplant. Associations between chronic kidney disease [CKD] stage (eGFR by 2021 CKD-EPI-creatinine equation) and nephrotic range proteinuria (<3.0 g/g or <3.5 g/day vs. ≥3.0 g/g or ≥3.5 g/day) at the time of biopsy and FSGS structural features (severe: interstitial fibrosis and tubular atrophy [IFTA] >25% and global glomerulosclerosis [GS] >50% vs. non-severe) were analyzed using multivariate logistic regression. Models were adjusted for age, sex, race, and hypertension status.

**Results:** In 2,011 patients with biopsy proven FSGS, CKD stage 3A (OR 4.5, p=0.002) and CKD stages 3B–5 (OR 12.2–22.1, p<0.001) predicted severe histological features, whereas nephrotic range proteinuria did not (Table 1). Younger age at biopsy, non-White racial identity, and hypertension also predicted severe histologic features (p<0.05).

**Conclusions:** Severe histologic features of FSGS are predicted by later CKD stage, but not nephrotic range proteinuria, at the time of kidney biopsy. Strategies for earlier diagnosis before onset of eGFR decline and severe structural injury, particularly in younger, non-White, and hypertensive patients, are needed to improve kidney disease outcomes in patients with FSGS.

**Funding:** Commercial Support - Travere Therapeutics, Inc

Longitudinal Proteinuria Trajectories and Their Association With Kidney Failure in Minimal Change Disease and Focal Segmental Glomerulosclerosis: A CureGN Study

Abigail R. Smith,<sup>1</sup> Margaret Helmuth,<sup>1</sup> Anand Achanti,<sup>1,3</sup> Salem Almaani,<sup>2</sup> Diego H. Aviles,<sup>3</sup> Isabelle Ayoub,<sup>2</sup> Pietro A. Canetta,<sup>4</sup> Daniel C. Cattran,<sup>5</sup> Dhruvi P. Chen,<sup>6</sup> Yelena Drexler,<sup>17</sup> Alessia Fornoni,<sup>7</sup> Debbie Gipson,<sup>15</sup> Rick Kaskel,<sup>8</sup> Jeffrey B. Kopp,<sup>9</sup> Louis-Philippe Laurin,<sup>14</sup> Dana Rizk,<sup>10</sup> Bruce M. Robinson,<sup>1</sup> William E. Smoyer,<sup>11</sup> Julia M. Steinke,<sup>16</sup> Brenda W. Gillespie.<sup>12</sup> <sup>1</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>2</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>3</sup>LSU Health New Orleans, New Orleans, LA; <sup>4</sup>Columbia University Irving Medical Center, New York, NY; <sup>5</sup>University of Toronto, Toronto, ON, Canada; <sup>6</sup>University of North Carolina System, Chapel Hill, NC; <sup>7</sup>University of Miami Health System, Miami, FL; <sup>8</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>9</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>10</sup>UAB Health System, Birmingham, AL; <sup>11</sup>Nationwide Children's Hospital, Columbus, OH; <sup>12</sup>University of Michigan, Ann Arbor, MI; <sup>13</sup>Medical University of South Carolina, Charleston, SC; <sup>14</sup>Universite de Montreal, Montreal, QC, Canada; <sup>15</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>16</sup>Spectrum Health Helen DeVos Children's Hospital, Grand Rapids, MI; <sup>17</sup>University of Miami School of Medicine, Miami, FL.

**Background:** Proteinuria often guides treatment decisions and measures response in glomerular disease. We characterized longitudinal proteinuria trajectories in patients with MCD and FSGS and assessed associations with kidney failure (KF).

**Methods:** Participants with MCD and FSGS enrolled in the Cure Glomerulonephropathy (CureGN) study with a first diagnostic kidney biopsy in the 5 years prior to enrollment and ≥2 years of follow-up were included. Participants were grouped based on proteinuria trajectory in the first 2 years post-enrollment using latent class trajectory analysis. Associations between group membership and incidence of KF beyond 2 years post enrollment were assessed using multivariable Cox regression.

**Results:** 887 participants (423 MCD, 464 FSGS) were included. Median age was 17 years (IQR 8–44); 53% were male; 22% were Black. Median follow-up time from enrollment was 4.5 years (IQR 3.4–5.7). Mean (SD) eGFR (ml/min/1.73m<sup>2</sup>) and UPCR (g/g) at enrollment were 89.3 (33.0) and 2.5 (3.2), respectively. Three groups were identified (Figure); Group 1 (78%) had consistently low UPCR (<1); Group 2 (12%) had high UPCR at enrollment that decreased by the start of year 2 to <2; Group 3 (10%) had consistently high UPCR (>6). Groups 1 and 2 were approximately evenly split between MCD and FSGS (48% and 52% for Group 1, 56% and 44% for Group 2), while Group 3 was predominantly FSGS (65%). Group 3 had higher hazard of progression to KF after 2 years post-enrollment compared to Group 1 (HR=3.4, 95% CI=1.6–7.3), after adjusting for diagnosis, age, eGFR at enrollment, and years from biopsy to enrollment. No interaction between diagnosis and proteinuria trajectory was detected (p=0.24).

**Conclusions:** Longitudinal proteinuria trajectories add additional information beyond diagnosis and baseline disease severity when characterizing risk of KF in patients with MCD and FSGS.

**Funding:** NIDDK Support

Mean UPCR trajectories with 95% confidence intervals.

TH-PO480

Design of a Phase 2/3 Adaptive Trial Evaluating Inaxaplin in APOL1-Mediated Kidney Disease

Ronald Falk,<sup>1</sup> Laura Barisoni,<sup>2</sup> David Friedman,<sup>3</sup> Debbie Gipson,<sup>4</sup> Michael Lipkowitz,<sup>5</sup> Akinlolu Ojo,<sup>6</sup> Martin Pollak,<sup>3</sup> Madalina Chiriac,<sup>7</sup> Mariana Faria-Urbina,<sup>7</sup> Yang Song,<sup>7</sup> George Manos,<sup>7</sup> Anna Ferreira,<sup>7</sup> Ogo I. Egbuna,<sup>7</sup> Glenn Chertow.<sup>8</sup> <sup>1</sup>UNC, Chapel Hill, NC; <sup>2</sup>Duke University, Durham, NC; <sup>3</sup>BIDMC, Harvard Medical School, Boston, MA; <sup>4</sup>University of Michigan, Ann Arbor, MI; <sup>5</sup>Georgetown University Hospital, Washington DC, DC; <sup>6</sup>University of Kansas School of Medicine, Kansas City, KS; <sup>7</sup>Vertex Pharmaceuticals Incorporated, Boston, MA; <sup>8</sup>Stanford University School of Medicine, Stanford, CA.

**Background:** There is a critical need for therapies targeting the underlying cause of APOL1-mediated kidney disease (AMKD), a proteinuric nephropathy caused by 2 APOL1 variants (G1 or G2) that affects about 100,000 people in US and Europe. Inaxaplin (IXP; VX-147) is a small molecule inhibitor of APOL1 pore function. In a Ph2a trial, IXP significantly reduced proteinuria by 47.6% in participants with 2 APOL1 variants, proteinuria, and focal segmental glomerulosclerosis (FSGS). We describe the design of a Ph2/3 trial evaluating IXP in adults with AMKD.

**Methods:** This randomized, double-blind, placebo-controlled, Ph2/3 adaptive trial in adults with AMKD will first evaluate different doses of IXP to select a dose for Ph3 and subsequently evaluate the efficacy and safety of the selected IXP dose in the Ph3 portion of the trial. Participants aged 18 to 60 years, with 2 *APOL1* variants, urine protein to creatinine ratio (UPCR) of  $\geq 0.7$ g/g to  $<10$ g/g, estimated glomerular filtration rate (eGFR) of  $\geq 25$  to  $<75$  mL/min/1.73m<sup>2</sup>, and on stable standard-of-care medications may be eligible to enroll. In Ph2, ~66 participants will be randomized to receive 1 of 2 daily doses of IXP or placebo for 12wks. Ph3 (~400 participants) will begin after Ph2 enrollment is complete.

**Results:** The primary endpoint for the final analysis is reduction in the rate of decline of kidney function as measured by eGFR slope in participants receiving IXP versus placebo at ~2 years. The secondary efficacy endpoint for the final analysis is time to composite clinical outcome, which is defined as a sustained decline of  $\geq 30\%$  from baseline in eGFR, the onset of end-stage kidney disease (i.e., maintenance dialysis for  $\geq 28$  days, kidney transplantation, or a sustained eGFR of  $<15$  mL/min/1.73m<sup>2</sup>), or death. The final trial analysis will occur when participants have  $\geq 2$  years of eGFR data and when ~187 composite clinical outcomes have occurred. The trial has a pre-planned interim analysis at Week 48 evaluating proteinuria, as measured by the percent change from baseline in UPCR, and eGFR slope.

**Conclusions:** This Ph2/3 adaptive trial will determine the efficacy and safety of IXP in preserving kidney function and reducing proteinuria in a broad population with AMKD.

**Funding:** Commercial Support - Vertex Pharmaceuticals

Egbuna,<sup>12</sup> Glenn Chertow.<sup>13</sup> <sup>1</sup>*King's College London, London, United Kingdom*; <sup>2</sup>*Nephrology and Renal Transplantation Department, Institut National de la Santé et de la Recherche Médicale (INSERM) U955, Henri Mondor Hospital, Assistance Publique des Hôpitaux de Paris (AP-HP), Paris Est Créteil University, Créteil, France*; <sup>3</sup>*Hôpital Tenon, Paris, France*; <sup>4</sup>*South Florida Nephrology Associates, Lauderdale Lakes, FL*; <sup>5</sup>*Necker Hospital, APHP, Université Paris Cité, Paris, France*; <sup>6</sup>*Bart's Health NHS Trust, London, United Kingdom*; <sup>7</sup>*Columbia Nephrology Associates, Columbia, SC*; <sup>8</sup>*St. Clair Nephrology, Detroit, MI*; <sup>9</sup>*Eastern Nephrology Associates, Greenville, NC*; <sup>10</sup>*Nephrology and Renal Transplantation Department, Bicêtre University Hospital, Assistance Publique des Hôpitaux de Paris (AP-HP), Paris Saclay University, Le Kremlin-Bicêtre, France*; <sup>11</sup>*Labcorp Drug Development, Morrisville, NC*; <sup>12</sup>*Vertex Pharmaceuticals Incorporated, Boston, MA*; <sup>13</sup>*Stanford University School of Medicine, Palo Alto, CA.*

**Background:** Two toxic gain-of-function variants (*G1* or *G2*) in *APOL1* are genetic factors driving a progressive, proteinuric nephropathy referred to as *APOL1*-mediated kidney disease (AMKD). *APOL1* variants are common in persons of recent African ancestry, but *APOL1* genotyping is not routine and therefore their prevalence is not well-known. We report interim data of a trial estimating the prevalence of *APOL1* genotypes in participants with chronic kidney disease (CKD).

**Methods:** Up to 2,500 participants of recent African ancestry or geographic origin with focal segmental glomerulosclerosis (FSGS) or other nondiabetic kidney disease (NDKD) and a urine protein to creatinine ratio of  $\geq 0.1$ g/g will be enrolled (Table). Blood samples are used to determine genotypes using a polymerase chain reaction (PCR) assay; Sanger sequencing is used to confirm accuracy of the PCR assay. We will assess the percent of participants with 2 *APOL1* variants.

**Results:** Interim analysis included 738 participants, 213 (28.9%) with FSGS and 525 (71.1%) with NDKD, of whom 110 (51.6%) and 124 (23.6%), respectively, have 2 *APOL1* variants (*G1* or *G2*). The table shows the distribution of participants with 2 *APOL1* variants by disease state and region.

**Conclusions:** Using a highly sensitive genotyping assay to generate one of the largest *APOL1* genotyping datasets, we show preliminary data on the noteworthy prevalence of 2 *APOL1* variants in participants with proteinuric CKD and recent African ancestry across geographies. These results underscore the importance of *APOL1* genotyping in routine care to identify AMKD, optimize patients' disease management, and enable referral for clinical trials of *APOL1* inhibitors.

**Funding:** Commercial Support - Vertex Pharmaceuticals

Table1. Baseline Demographics and <i>APOL1</i> Genotyping Results

*APOL1: Apolipoprotein L1; FSGS: focal segmental glomerulosclerosis; IA: interim analysis; NDKD: nondiabetic kidney disease*

Notes: Eligible participants are 12 to 60 years of age and of African ancestry or geographic origin (Black, Caribbean, African American, Sub-Saharan African, Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish culture/origin). For more information about the trial, please see <https://apol1program.com/>. This table includes participants in the Full IA Set with a genotyping result. Percentages were calculated based on the number of participants in the full IA set, unless otherwise specified.

<sup>a</sup> Percentages were calculated based on the total number of participants in each country per disease state.

**TH-PO482**

**A Steep Slope: *APOL1* High Risk Genotype and GFR Decline Among Black Patients With Membranous Nephropathy**

Dhruti P. Chen, Candace D. Henderson, Mary M. Collie, Yichun Hu, Susan L. Hogan, Ronald Falk. *University of North Carolina System, Chapel Hill, NC.*

**Background:** Genetic variants in the Apolipoprotein L1 (*APOL1*) gene contribute to kidney disease burden in black patients, but the influence in membranous nephropathy (MN) has not been studied.

**Methods:** Black MN patients enrolled in the Glomerular Disease Collaborative Network or Cure Glomerulonephropathy Network with DNA or *APOL1* genotyping and non-black MN patients were included. eGFR was calculated using the non-race-based CKD-Epi equation for adults  $>26$  years and Schwartz for  $<18$  years. For ages 18-26, equations were combined. eGFR slopes estimated using linear mixed effects models with random effect for each group, assuming an unstructured covariance and adjusting by group. Fisher's exact, Wilcoxon rank, and Kaplan-Meier curves with log rank tests were used for time to ESKD.

**Results:** Among 118 black MN patients, 16 (14%) had high risk *APOL1* risk alleles (2 *APOL1* alleles), and 102 (86%) had low risk alleles (0 or 1 alleles, n= 53 and n = 49, respectively). High risk *APOL1* patients were younger at disease onset compared to low risk *APOL1* and non-black patients (n=573). Despite similar GFR at diagnosis, GFR decline was worse in those with 2 *APOL1* risk alleles ( $-15.3$  mL/min/1.73m<sup>2</sup>/year) compared to black MN patients with 0 ( $-3.3$  mL/min/1.73m<sup>2</sup>/year) or 1 risk allele ( $-3.0$  mL/min/1.73m<sup>2</sup>/year) and non-black MN patients ( $-2.4$  mL/min/1.73m<sup>2</sup>/year). Time to ESKD was faster in the high risk *APOL1* group compared to low risk *APOL1* or non-black MN patients (logrank p<0.05).

**Conclusions:** The prevalence of high risk *APOL1* variant among black MN patients is comparable to the general black population. The high risk *APOL1* genotype conferred worse eGFR decline and faster time to ESKD in MN. Black patients with low risk *APOL1* alleles had a similar GFR decline to the non-black MN patients. *APOL1* is a valuable clinical prognostic marker in black patients with MN.

TH-PO483

Ofatumumab in Rituximab-Resistant and Rituximab-Intolerant Patients With Membranous Nephropathy

Manuel A. Podesta<sup>1,2</sup>, Valentina Portalupi,<sup>3</sup> Alessia Gennarini,<sup>3</sup> Alessandro Villa,<sup>2</sup> Nadia Rubis,<sup>2</sup> Giuseppe Remuzzi,<sup>2</sup> Piero L. Ruggerenti.<sup>3,2</sup>  
<sup>1</sup>Università degli Studi di Milano, Milano, Italy; <sup>2</sup>Istituto di Ricerche Farmacologiche Mario Negri Centro Aldo e Cele Dacco, Ranica, Italy; <sup>3</sup>Aziende Socio Sanitarie Territoriale Papa Giovanni XXIII, Bergamo, Italy.

**Background:** Rituximab (RTX) has become the mainstay therapy for patients with membranous nephropathy (MN) at high risk of progression to kidney failure. However, this treatment is effective only in ~65% of patients, and exposure to repeated RTX infusions may be complicated by hypersensitivity reactions, which contraindicate re-treatment. Ofatumumab, a human anti-CD20 antibody with higher cytotoxicity, could overcome these limitations.

**Methods:** In this retrospective cohort study, we enrolled adult patients with MN who either experienced hypersensitivity reactions (RTX-intolerant, n=5) or failed to achieve complete or partial remission after RTX administration (RTX-resistant, n=12), and were treated with ofatumumab as a rescue therapy (50-300 mg).

**Results:** After a median follow-up time of 1 year, 58.8% of patients achieved complete or partial remission of the nephrotic syndrome (41.7% in RTX-resistant and 100% in RTX-intolerant). In patients with positive anti-PLA<sub>2</sub>R at baseline (n=12), 58.3% achieved serological remission during the follow-up (50% in RTX-resistant and 100% in RTX-intolerant). Reduction in urinary protein excretion was closely mirrored by an increase in serum albumin levels (Figure 1). Measured GFR increased by a median of 13.4% at 24 months compared to baseline. There were 14 non-serious infusion-related adverse events in 9 patients, all of which completely resolved.

**Conclusions:** Ofatumumab may represent a viable option for the treatment of MN patients who are resistant or intolerant to RTX.

Baseline characteristics

	Overall (n = 17)	RTX-Resistant (n = 12)	RTX-Intolerant (n = 5)
Age (years)	51.0±13.6	53.3±14.5	45.6±10.3
mGFR (mL/min/1.73m <sup>2</sup> )	52.1 [38.6; 75.4]	41.9 [32.8; 72.8]	67.4 [55.8; 83.4]
Serum Albumin (g/dL)	2.5±0.5	2.5±0.5	2.6±0.6
Urinary Protein (g/24h)	9.0±4.3	10.3±4.3	6.2±2.8
Serum Anti-PLA <sub>2</sub> R (RU/mL)	66 [14; 117]	66 [11; 146]	53 [16; 89]
Ofatumumab Dose (mg)	300 [100; 300]	300 [63; 300]	300 [100; 300]
MN Onset (years)	9.9±5.1	8.5±5.3	13.2±2.4

(L) Cumulative incidence of CR/PR in RTX-intolerant and -resistant patients. (R) % change in proteinuria and serum albumin after Ofatumumab.

Analysis of Serum Belimumab Pharmacokinetics in Primary Membranous Nephropathy: Data From the REBOOT Study

Patrick H. Nachman<sup>1</sup>, Lia Weiner,<sup>2</sup> Sharon Chung,<sup>3</sup> Linna Ding,<sup>4</sup> William T. Barry.<sup>2</sup> ITN080AI REBOOT Study Investigators <sup>1</sup>University of Minnesota Health, Minneapolis, MN; <sup>2</sup>Rho, Inc., Durham, NC; <sup>3</sup>Immune Tolerance Network, San Francisco, CA; <sup>4</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD.

**Background:** Patients with primary membranous nephropathy (PMN) are known to lose immunoglobulin in the urine at rates affected by the severity of proteinuria. This loss could impact the dosing of monoclonal antibodies used for treatment. Belimumab (BEL), an IgG1 monoclonal antibody, has been detected in the urine of patients with PMN receiving this therapy. We conducted this study to examine the relationship between serum BEL exposure and baseline proteinuria to inform dosing in PMN.

**Methods:** REBOOT is a two-part clinical trial examining the efficacy of BEL and rituximab therapy in PMN (NCT03949855). Part A is an open-label study examining how baseline proteinuria affects BEL exposure. Participants received subcutaneous BEL at a dose of 200 mg weekly. Serum BEL trough levels were drawn after each of the first 4 doses. The relationship between BEL exposure and baseline proteinuria was assessed using longitudinal mixed models, which included the defined low (>4 ≤ 8 g/day) and high (≥ 8 g/day) proteinuria subgroups.

**Results:** The baseline proteinuria of the 12 evaluated participants ranged from 4.1-21.3 g/day, with 4 participants in the low and 8 participants in the high proteinuria groups. The ratio of the mean serum BEL trough levels at week 4 between the high and low proteinuria groups was 0.78 (95% CI 0.52-1.2). Regression models predicted that a 1 g/day increase in proteinuria results in a 1.9% decrease in trough levels (p=0.262). Figure 1 shows the serum trough levels after the fourth BEL dose by baseline proteinuria level, and the predicted BEL levels from regression modeling.

**Conclusions:** This data suggests that serum BEL exposure is not significantly associated with baseline proteinuria levels in PMN, and does not support increasing the dose of BEL in individuals with higher levels of proteinuria.

**Funding:** Other NIH Support - Division of Allergy, Immunology, and Transplantation, National Institute of Allergy and Infectious Diseases, Commercial Support - GlaxoSmithKline, plc

## TH-PO485

**A Large International Registry Study on Membranous Nephropathy Recurrence Post-Transplant**

Frank E. Hullekes,<sup>1,2</sup> Paolo Cravedi,<sup>3</sup> Leonardo V. Riella.<sup>1,2</sup> The Post-Transplant Glomerular Disease (TANGO) Consortium <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Membranous nephropathy (MN) is one of the major causes of nephrotic syndrome in adults worldwide and frequently recurs after transplant. Disease activity is driven by underlying autoimmune processes, leading to circulating autoantibodies directed against glomerular podocyte antigens. Multiple target proteins have been associated with MN in the past decade, including PLA2R and THSD7A. No clear clinical and immunological characteristics have been associated with recurrent MN, as most studies were single-centers and underpowered.

**Methods:** Through the Post-Transplant Glomerular Disease (TANGO) Consortium, we initiated a multi-center retrospective cohort study aiming to investigate MN recurrence after transplant. Adult patients with biopsy-proven MN, transplanted between 2005-2018 were identified to study the incidence of recurrent MN, any potential predictors, and treatment regimens. Serum samples were retrieved for a subset of patients to identify a potential role of podocyte autoantibodies in predicting and detecting recurrence.

**Results:** 22,921 patients were screened by 16 transplant centers across three continents. Among these, 188 kidney transplant patients with biopsy-proven MN were included for data analysis. The cumulative incidence for recurrence was 30% (95% CI: 16-42) at 10 years post-transplant. The median time to diagnose recurrence was 4.9 years [IQR: 2.2-7.6]. Graft survival rates were similar between patients with and without a recurrence. Age at diagnosis, race, time from diagnosis to end-stage kidney disease (ESKD), BMI, time on dialysis, HLA mismatch, living donor, and early steroid withdrawal were not associated with recurrence.

**Conclusions:** Through the TANGO-Consortium, we identified the largest cohort to date of MN transplant patients. MN recurred in 30% but did not impact graft survival. Ongoing analysis of pre- and post-transplant serum samples will assess the correlation between autoantibody titers and risk of recurrence.

Cumulative incidence of MN recurrence

## TH-PO486

**Voclosporin for Lupus Nephritis: Assessment of Long-Term Safety and Efficacy Including Renal Outcome Over 3 Years of Treatment in the Phase 3 AURORA 1 and AURORA 2 Studies**

Samir V. Parikh,<sup>1</sup> Cristina Arriens,<sup>3</sup> Lucy S. Hodge,<sup>2</sup> Christopher Mela,<sup>2</sup> Henry Leher.<sup>2</sup> <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>Aurinia Pharmaceuticals Inc, Victoria, BC, Canada; <sup>3</sup>Oklahoma Medical Research Foundation, Oklahoma City, OK.

**Background:** In AURORA 1, adding voclosporin to mycophenolate mofetil (MMF) and low-dose steroids led to significant reductions in proteinuria at 1 year in patients with lupus nephritis (LN). We report on the recently completed AURORA 2 study evaluating voclosporin compared to placebo in patients treated for an additional 2 years after AURORA 1.

**Methods:** Patients with LN completing AURORA 1 were eligible to continue on the same double-blinded treatment of voclosporin or placebo in AURORA 2; all patients received MMF and low-dose steroids. Outcomes assessed over the 3 year treatment period of both studies included adverse events (AEs), eGFR, urine protein-creatinine ratio (UPCR), good renal outcome and renal flare. Good renal outcome was defined based on achievement of an adequate response (i.e. sustained reduction in UPCR to  $\leq 0.7$  mg/mg) and without renal flare (i.e. an increase to UPCR  $> 1$  mg/mg from a post-response UPCR of  $< 0.2$  mg/mg or an increase to UPCR  $> 2$  mg/mg from a post-response UPCR of 0.2 to 1.0 mg/mg), as adjudicated by a blinded Clinical Endpoints Committee.

**Results:** Overall rates of serious AEs in the voclosporin (26.7% of 116 patients) and control arm (28.0% of 100 patients) were similar. There were no deaths in the voclosporin arm during AURORA 2; four deaths occurred in the control arm (pulmonary embolism, n=1; coronavirus infection, n=3). Mean corrected eGFR was within the normal range and stable over the study period. The reductions in UPCR achieved in AURORA 1 were

maintained in AURORA 2 and significantly more patients in the voclosporin arm achieved a good renal outcome (66.4% in voclosporin vs 54.0% in control; p-value=0.045). Renal flare occurred in 24 of 101 patients with adequate response in the voclosporin arm and 19 of 73 patients in the control arm (23.8% in voclosporin vs 26.0% in control; p-value=0.662); 69.8% of all patients with renal flares completed study treatment.

**Conclusions:** Voclosporin was well-tolerated over three years of treatment. The significant reductions in proteinuria initially achieved in AURORA 1 were maintained throughout AURORA 2 and more patients in the voclosporin arm achieved a good renal outcome. These data provide evidence of a long-term treatment benefit of voclosporin in patients with lupus nephritis.

**Funding:** Commercial Support - Aurinia Pharmaceuticals Inc.

## TH-PO487

**Zetomizomib (KZR-616), a First-in-Class Selective Immunoproteasome Inhibitor for the Treatment of Lupus Nephritis: Preliminary Results From the Phase 2 MISSION Study**

Samir V. Parikh,<sup>1</sup> Richard Furie,<sup>4</sup> Amit Saxena,<sup>2</sup> Richard Leff,<sup>3,5</sup> Steven Y. Hua,<sup>3</sup> Li Long,<sup>3</sup> Noreen R. Henig.<sup>3</sup> <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>NYU Langone Health, New York, NY; <sup>3</sup>Kezar Life Sciences Inc, South San Francisco, CA; <sup>4</sup>Northwell Health, New Hyde Park, NY; <sup>5</sup>Richard L Leff MD LLC, Chadds Ford, PA.

**Background:** The MISSION study (NCT03393013), a Phase 1b/2, open-label study is to evaluate safety, tolerability, and exploratory efficacy of zetomizomib in patients with systemic lupus erythematosus (SLE) +/- lupus nephritis (LN). In the completed Phase 1b portion, zetomizomib was safe and well-tolerated and resulted in improvement across disease activity measures as well as biomarkers. The Phase 2 fully enrolled in Nov 2021, and here we present preliminary results from this signal-seeking study.

**Methods:** MISSION Phase 2 evaluated zetomizomib at 60 mg subcutaneously (SC) once weekly (QW) for 24 weeks (1<sup>st</sup> dose: 30 mg) in patients with active LN (Class III or IV  $\pm$  Class V) with urine protein to creatinine ratios (UPCR)  $\geq 1$  despite background therapy. Safety, tolerability, UPCR, renal function, SLE disease activity, and biomarkers were measured. Interim analysis of laboratory data was performed.

**Results:** As of October 1, 2021, 5 patients reached end of treatment (Week [W] 25), and 10 patients reached W13; 80% female; mean age 39.4 years; median LN duration 7.6 years; mean UPCR 2.2 (assessed from 24-hour collections); mean eGFR 78.5 mL/min/1.73 m<sup>2</sup>; all patients were on prednisone, and 8 and 5 patients were on mycophenolate mofetil or mycophenolic acid and hydroxychloroquine, respectively. At end of treatment, 3 of 5 patients achieved a  $\geq 50\%$  reduction in UPCR; 4 of the 5 patients had renal responses (2 complete renal response and 2 partial renal response). Zetomizomib administration improved UPCR and key biomarkers (eg, anti-dsDNA) as early as W13, and was associated with a favorable safety/tolerability profile. The most common adverse event (AE) was injection site reaction. Most AEs were mild to moderate (Grade  $\leq 2$ ). Two Serious AEs were reported in 2 patients (1 related and 1 unrelated). There were no discontinuations due to drug-related AEs. No opportunistic infections were reported.

**Conclusions:** Zetomizomib 60 mg SC QW demonstrated a favorable safety and tolerability profile in patients with active LN who were on stable background therapy in MISSION Phase 2. Zetomizomib led to clinically meaningful reductions in proteinuria and improvement in key SLE biomarkers. An updated analysis of the completed Phase 2 MISSION study will be shared.

**Funding:** Commercial Support - Kezar Life Sciences, Inc

## TH-PO488

**Long-Term Safety and Efficacy of Voclosporin in Patients With Lupus Nephritis and Low eGFR**

Ramesh Saxena,<sup>1</sup> Christopher E. Collins,<sup>2</sup> Vanessa Birardi,<sup>2</sup> Anna Pavlova-Wolf.<sup>2</sup> <sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

**Background:** Voclosporin (VCS) is a novel calcineurin inhibitor approved for the treatment of adults with lupus nephritis. In the Phase 3 AURORA 1 study, addition of VCS to mycophenolate mofetil (MMF) and steroids increased rates of complete renal response at 1 year. Efficacy was maintained for an additional 2 years in the AURORA 2 continuation study. Here we report on a post-hoc analysis of the long-term safety and efficacy of VCS in patients with low estimated glomerular filtration rate (eGFR) at baseline using 3 years of pooled data from these studies.

**Methods:** Patients from AURORA 1 with a baseline eGFR  $> 45$  and  $< 60$  mL/min/1.73 m<sup>2</sup> who also participated in AURORA 2 were included in this analysis. Patients completing AURORA 1 were eligible to enter AURORA 2 on the same blinded therapy (VCS or placebo) in combination with MMF and steroids. Urine protein creatinine ratio (UPCR) and eGFR changes from baseline were measured.

**Results:** The analysis included 27 patients with low eGFR (13 in the VCS arm and 14 in the control arm) of whom 23 completed 3 years of treatment (12 and 11 patients, respectively). Mean corrected eGFR at baseline for the VCS and control arms was 52.6 and 50.9 mL/min/1.73 m<sup>2</sup>, respectively. At 6 months, mean eGFR was 62.0 and 63.4 mL/min/1.73 m<sup>2</sup> in each arm, respectively, and remained stable in both arms throughout the 3 years of treatment (Figure 1). Safety outcomes were comparable between arms and consistent with the overall study population. Mean UPCR at AURORA 1 baseline was 4.8 mg/mg in the VCS arm and 4.0 mg/mg for the control arm. At 3 months, mean UPCR decreased to 1.7 mg/mg and 2.5 mg/mg in each arm, respectively. Mean UPCR continued to improve throughout AURORA 1, and the reductions were maintained in AURORA 2 for both treatment arms.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** In this post-hoc analysis of patients with lupus nephritis and low eGFR at baseline, patients treated with VCS achieved rapid and sustained reductions in proteinuria with no decrease in mean eGFR or unexpected adverse events during 3 years of treatment.

**Funding:** Commercial Support - Aurinia Pharmaceuticals Inc.

TH-PO489

**Repeat Kidney Biopsy Findings of Lupus Nephritis Patients in Clinical Remission Treated With Mycophenolate Associated With Belimumab or Mycophenolate Plus Standard of Care Therapy**  
Ana Malvar,<sup>1,2</sup> Valeria G. Alberton,<sup>1</sup> Cecilia Recalde,<sup>1,2</sup> Pedro J. Davila Terreros,<sup>1</sup> Ricardo M. Heguilen.<sup>1</sup> <sup>1</sup>Hospital Fernandez, Buenos Aires, Argentina; <sup>2</sup>Organizacion Medica de Investigacion, Buenos Aires, Argentina.

**Background:** Early and intensive treatment of Lupus nephritis determines an accelerated decrease in inflammation and, subsequently, reduces the extent of tissue that progresses to scarring and future renal failure. Addition of Belimumab to standard of care treatment showed to increase the possibility of achieving a complete kidney response with less renal events during follow up. The aim of this study was to assess the “post hoc” analysis of the clinical and histological differences between patients enrolled in the BLISS LN trial (BLNT) in a single center

**Methods:** All the participants (20, one male) had an initial renal biopsy (Bx1), used at screening for the BLNT and fulfilled the trial satisfactorily. Once the BLNT and the Open Label Extension (OLE) were finished, they continued to receive mycophenolate (MMF) and concomitant medications. Mean follow up was 70,7 (± 8,2 months). All the patients were re-biopsied (Bx2) either if they presented a flare or after a minimum period of 36-month with at least 12 months of Complete Clinical Response (CCR) so as to assess inactivity. CCR was defined as proteinuria ≤ 500 mg/d and eGFR > 60 ml/min/m2 and eGFR > 60 ml/min/m2 with no decrease of > 20% from baseline (BLNT randomization). Complete Histological Remission (CHR) was defined as an activity index = 0 at Bx2. NIH activity (AI) and chronicity (CI) indices, CCR, CHR and the occurrence of flares in each arm were compared.

**Results:** Clinical and histological data are shown in the Table. AI and CI are presented as median (SD).

**Conclusions:** Though the small number of patients the arm treated with MMF plus belimumab seemed to achieve more frequently a complete histological and clinical response with lower CI in the Bx2 and fewer relapses during treatment and long follow up. (Statistical analysis was not done due to the small sample)

**Funding:** Private Foundation Support

Arm Treatment	CCR Bx2 (n)	CHR Bx2 (n)	AI Bx1	AI Bx2	CI Bx1	CI Bx2	Flares (n)
MMF + Placebo (n=10)	7	5	7,6 (4,1)	2,7 (3,8)	2,1 (1,9)	4,5 (2,4)	2
MMF + Belimumab (n=10)	10	9	5,8 (4,5)	0,4 (1,3)	1,6 (1,9)	3,5 (1,0)	0

TH-PO490

**Persistent Excretion of Serpin-A3 Indicates Lack of Response to Therapy in Class III and IV Lupus Nephritis**  
Miguel A. Martinez-Rojas,<sup>1,2</sup> Andrea Sanchez Navarro,<sup>2</sup> Juan M. Mejia-Vilet,<sup>2</sup> Rosalba Pérez-Villalva,<sup>1</sup> Norma Bobadilla.<sup>1,2</sup> <sup>1</sup>Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; <sup>2</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.

**Background:** We previously reported that urinary Serpin-A3 excretion (uSerpA3) is significantly elevated in patients with active lupus nephritis (LN). Here, we evaluated the course of uSerpA3 during the 1<sup>st</sup>-year of treatment and its association with response to therapy in patients with proliferative LN.

**Methods:** An observational longitudinal study including sixty Mexican adults with proliferative LN followed during the 1<sup>st</sup>-year after LN-flare. uSerpA3 was detected by Western blot at flare and after 3, 6, and 12-months. Response to therapy was determined 1-year after the LN-flare. We evaluated the correlation between uSerpA3 and histological parameters at LN-flare. The temporal association between uSerpA3 and response to therapy was analyzed with linear mixed models. uSerpA3 prognostic performance for response was evaluated with ROC curves.

**Results:** Among the 60 patients studied, 21 (35%) were class III and 39 (65%) class IV. The uSerpA3 was higher in class IV than in class III LN (6.98 vs. 2.89 DPI/mg-creatinine, p=0.01). Furthermore, uSerpA3 correlated with the histological activity index (r=0.29, p=0.02). There was a significant association between the temporal course of uSerpA3 and the response to therapy. Responders showed a significant drop in uSerpA3 at 6<sup>th</sup>-month compared to LN-flare (p<0.001), while non-responders persisted with elevated uSerpA3. Moreover, uSerpA3 was significantly lower at flare in responders compared to non-responders (2.69 vs. 6.98 DPI/mg-creatinine, p<0.05). Furthermore, uSerpA3 was able to identify non-responders since the 3<sup>rd</sup>-month after LN-flare, (AUC=0.77).

**Conclusions:** The uSerpA3 is an early indicator of kidney inflammation and predictor of clinical response to therapy in patients with proliferative LN.

TH-PO491

**Post Hoc Analysis of the DialCheck Tool to Predict Renal Failure in IgA Nephropathy (IgAN)**  
Francesco P. Schena,<sup>1,2</sup> Vito walter Anelli,<sup>3</sup> Giandomenico Cornacchia,<sup>3</sup> Daniela I. Abbrescia,<sup>4</sup> Tommaso Di noia.<sup>3</sup> <sup>1</sup>Universita degli Studi di Bari Aldo Moro, Bari, Italy; <sup>2</sup>Schena Foundation, Bari, Italy; <sup>3</sup>Politecnico di Bari, Bari, Italy; <sup>4</sup>Fondazione Schena, Bari, Italy.

**Background:** We have developed the DialCheck tool to predict renal failure (RF) in patients with IgAN (KI 2021). The tool is based on two different artificial neural networks. The first network predicts RF development while the second predicts the time frame to reach the outcome. The application of the tool in the clinical practice shows discordance between predicted and observed probabilities to develop KF in about 20% of IgAN patients. We have conducted a post-hoc analysis to evaluate the discordance between predicted and observed probabilities to reach KF.

**Methods:** Baseline demographic and laboratory data were analyzed using mean ± standard deviation (SD) or median and interquartile range (IQR) for continuous variables. The D’Agostino-Pearson normality test was applied to the data in order to assess their distribution. The categorical variables were expressed as absolute numbers or percent frequency. Dichotomous and polychotomous baseline characteristics were compared using the Chi-square test. Continuous baseline characteristics were compared using the Student’s t-test or the Mann-Whitney U test. All analyses were performed using GraphPad Prism Software version n.5 (GraphPad Software, San Diego, CA). The statistical significance value of p<0.05 was adopted.

**Results:** Tool performance was analyzed in the retrospective cohort of 1,116 European adult IgAN patients followed for a median time of 88 months (IQR 49 - 134). Discordance was observed in 216 (19.35%) IgAN patients. In the first set of patients with predicted no RF and reached outcome, subjects were older and hypertensives. They had high value of serum creatinine, reduced renal function and moderate or severe renal lesions. Many of those patients did not receive therapy or were non-responders to therapy. In the second set of patients the tool predicted RF but this outcome was not reached, the patients were responders to therapy. Thus, in the discordant group (prediction did not match the observed outcome) therapy was strongly associated with outcome (P<0.0001).

**Conclusions:** The DialCheck tool could help physicians to determine the prognosis of the disease as well as could help patients to plan for their future. The non-correct prediction of RF in a small number of cases may be due to no therapy or non-responders to therapy.

**Funding:** Government Support - Non-U.S.

TH-PO492

**The Significance of Crescents on the Clinical Features and Outcomes of Primary Immunoglobulin A Nephropathy**  
Yongjing Du,<sup>1,2</sup> Shasha Chen,<sup>1</sup> Wei Wang.<sup>1</sup> <sup>1</sup>Sichuan Academy of Medical Sciences and Sichuan People’s Hospital, Chengdu, China; <sup>2</sup>Chengdu Second People’s Hospital, Chengdu, China.

**Background:** It is still controversial whether the proportion of crescents below 50% can be an independent predictive risk factor for poor prognosis in IgAN patients.

**Methods:** We retrospectively analyzed biopsy-proven primary IgAN patients in Sichuan Provincial People’s Hospital from 2007 to 2019. The patients were divided into 5 groups based on crescent proportion as follows: 0 (n=647), <10% (n=221), 10% to 24% (n=272), 25% to 49% (n=80), and ≥50% (n=22). The primary endpoint was defined as ESKD, and the secondary endpoint was the combined renal endpoint (≥50% reduction in eGFR or ESKD).

**Results:** 1242 patients with biopsy-proven IgAN were recorded. 47.9% had different proportions of crescents. Compared with the non-crescent group, patients in the crescent group had lower levels of hemoglobin and albumin, higher levels of blood urea nitrogen, 24h urinary protein and hematuria, a higher proportion of mesangial hypercellularity, endocapillary hypercellularity, segmental glomerulosclerosis, and tubular atrophy/interstitial fibrosis (T1/T2) (p<0.05). During the median follow-up of 43 months (range 6-151), 63 individuals (7.0%) reached the primary outcome of ESKD and 99 patients (11.1%) reached the combined renal endpoint. 34 (7.5%), 21 (13.3%), 24 (12.2%), 14 (21.5%) and 6 (31.6%) patients reached the combined renal endpoint in the above five

groups in crescents 0, <10%, 10–24%, 25–49% and ≥50%, respectively. Multivariate Cox regression showed that crescents ≥50% was an independent risk factor for the progression of ESKD and crescents ≥25% was an independent risk factor for the combined renal endpoint. 274 (62.6%) cases in the crescent group and 254 (55.7%) cases in the non-crescent group received immunosuppressive therapy. The risk of combined renal endpoint increased with the increase proportions of crescents in IgAN patients without immunosuppressive therapy ( $p<0.05$ ). Crescents ≥25% was an independent risk factor for poor prognosis in IgAN patients receiving immunosuppressive therapy. The receiver operating characteristic curve showed that IgAN patients with crescents >43.7% had a higher risk of poor prognosis.

**Conclusions:** IgAN patients with crescents had more severe clinicopathological features and poorer prognosis. IgAN patients with crescents >43.7% had a higher risk of poor prognosis, even after receiving immunosuppressive therapy.

## TH-PO493

### External Validation of the International IGA Nephropathy Prediction Tool Among a Filipino Cohort of Patients

Princess Jasmine A. Mala. National Kidney and Transplant Institute, Quezon City, Philippines.

**Background:** IgA nephropathy is the most common glomerulonephritis in the world. The incidence rate of primary GN varies between 0.2/100,000/year and 2.5/100,000/year. It is the most common glomerulonephritis (34.4%) in the Philippines. Recently, a new International IgAN prediction tool was published and was validated in large multi-ethnic cohort, hence, this study aimed to validate this tool among Filipino cohort.

**Methods:** This was a retrospective, cohort study among Filipino IgA nephropathy patients determining their score utilizing the International IgAN prediction tool. This was conducted at National Kidney and Transplant Institute from January 2015- 2017. The list of all patients who fulfilled the inclusion criteria was retrieved.

**Results:** A total of 151 participants were included in the study, with a mean age of 33 years and predominantly females (61.59%). The mean creatinine was 1.5 mg/dL and an eGFR of 56 mL/min/1.73m<sup>2</sup>. Using the International IgAN prediction tool, the predicted eGFR decline was highest at 46% among the highest risk group. Model discrimination result showed C statistics = 0.66. Result using the International IgAN prediction tool overestimated the observed risk of primary outcome at 3 years post biopsy. Result showed both the observed and the predicted eGFR showed a higher decline among the highest IgAN risk group.

**Conclusions:** Utilizing the International IgAN prediction tool among Filipino cohort able to predict the decline in eGFR even as early as 36 months from the time of biopsy. This tool can be used among Filipinos in predicting decline in eGFR.

**Table 1. Clinical and demographic profile of patients at baseline (n=151)**

	Median (Range); Frequency (%)
Age, years	33 (18-71)
Sex	
Male	58 (38.41)
Female	93 (61.59)
Creatinine at biopsy, mg/dL	1.5 (0.5-9.9)
Estimated GFR at biopsy, mL/min/1.73m <sup>2</sup>	55 (7.37-147)
Blood pressure at biopsy, mmHg	
SBP	120 (100-150)
DBP	80 (60-90)
Proteinuria at biopsy, g/day	2.42 (0.11-7.60)
Use of ACE inhibitor or ARB at the time of biopsy	101 (66.89)
MEST histologic score	
M1	62 (41.06)
E1	33 (21.85)
S1	132 (87.42)
T1	66 (43.71)
T2	24 (15.89)
Crescents	0 (0)
Immunosuppression use at or prior to biopsy	17 (11.26)
IgAN predicted 3-year risk of 50% decline in eGFR or ESRD, %	13.88 (1.64-61.18)

MEST: M1, mesangial score >0.5; E1, presence of endothelial hypercellularity; S1, presence of segmental glomerular sclerosis or tuft adhesions; T0, T1, T2 if <25% 25–50%, >50% tubular atrophy or interstitial fibrosis.

## TH-PO494

### Proteinuria and Its Association With Disease Progression in IgA Nephropathy: Analysis of the UK National RaDaR IgA Nephropathy Cohort

David Pitcher,<sup>1</sup> Fiona E. Braddon,<sup>1</sup> Bruce M. Hendry,<sup>2</sup> Alex Mercer,<sup>3</sup> Kate Osmaston,<sup>1</sup> Moin Saleem,<sup>4,5</sup> Retha D. Steenkamp,<sup>1</sup> A. Neil Turner,<sup>6</sup> Kaijun Wang,<sup>2</sup> Jonathan Barratt,<sup>7,8</sup> Daniel P. Gale,<sup>9,10</sup> <sup>1</sup>UK Renal Registry, Bristol, United Kingdom; <sup>2</sup>Travere Therapeutics Inc, San Diego, CA; <sup>3</sup>JAMCO Pharma Consulting, Stockholm, Sweden; <sup>4</sup>University of Bristol, Bristol, United Kingdom; <sup>5</sup>Bristol Royal Hospital for Children, Bristol, United Kingdom; <sup>6</sup>University of Edinburgh, Edinburgh, United Kingdom; <sup>7</sup>University of Leicester, Leicester, United Kingdom; <sup>8</sup>Leicester General Hospital, Leicester, United Kingdom; <sup>9</sup>Royal Free Hospital, London, United Kingdom; <sup>10</sup>University College London, London, United Kingdom.

**Background:** Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis worldwide and a major cause of renal failure. Here we investigate the relationship between proteinuria (PU) measured over follow-up (FU) and rate of renal function loss and renal survival in patients from the UK National Registry of Rare Kidney Diseases (RaDaR) IgAN Cohort. Since 2013, patients with biopsy-proven IgAN and eGFR <60 mL/min/1.73m<sup>2</sup> or PU ≥0.5g/24h have been enrolled from 87 kidney units across the UK, with automated collection of retrospective and prospective laboratory data.

**Methods:** 923 patients met the eligibility criteria, including diagnosis date, PU measurements in FU (within 2yr from diagnosis and ≥2 values if FU >3yr), no ESKD (CKD stage 5 or renal replacement therapy) or death within 6mo from diagnosis or prior to first PU value. Longitudinal PU, assessed as time-average protein-to-creatinine ratio (TA-PCR), and eGFR slope were calculated over the full duration of FU or until ESKD or death. For survival analyses, ESKD/death was applied, with survival time calculated from diagnosis to last FU.

**Results:** Characteristics at diagnosis and clinical outcomes of the study population are summarized in Fig.1a. Increasing grades of TA-PCR were associated with more rapid decline in eGFR (ANOVA  $p<0.001$ , Fig.1c) and greater risk of ESKD/death (Log-rank  $p<0.001$ , Fig.1b; Cox regression  $p<0.001$ , Fig.1c).

**Conclusions:** Proteinuria exposure over time is significantly associated with disease progression and renal outcomes in IgAN. In particular, TA-PCR below 100 mg/mmol (~1g/24h) is very strongly associated with slower loss of renal function and lower risk of ESKD or death.

**Funding:** Commercial Support - Travere Therapeutics, Inc

Figure 1: Characteristics at diagnosis and clinical outcomes (a), Kaplan Meier survival curves (incl. 95% CI) (b) and outcomes (c) for patients categorized by TA-PCR.

## TH-PO495

## Gut Microbiota Profiles in IgA Nephropathy Patients and Their Household Members

Yaerim Kim,<sup>1</sup> Sehoon Park,<sup>2</sup> Jin hyuk Paek,<sup>1</sup> Woo Yeong Park,<sup>1</sup> Kyubok Jin,<sup>1</sup> Seungyeup Han,<sup>1</sup> Jung Pyo Lee,<sup>3</sup> Dong Ki Kim,<sup>2</sup> <sup>1</sup>*Keimyung University School of Medicine, Daegu, Republic of Korea;* <sup>2</sup>*Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea;* <sup>3</sup>*Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

**Background:** Although immunoglobulin A nephropathy (IgAN) is not a definite genetic disease, it has an autoimmune trait of complex architecture with a solid genetic predisposition. Herein, we aimed to evaluate the difference in microbiota profile among patients with IgAN, their household members and unrelated healthy controls.

**Methods:** We prospectively recruited subjects with IgAN and their household member and healthy control between July 2019 and August 2021. Gut microbiota was analyzed using the Illumina MiSeq system based on the 16S rRNA gene. We compared the abundance of the microbiome in each level of phylum, class, order, family, and genus between the groups using Mann-Whitney U test. Also, we tried to find a specific genus representing the disease severity based on the Oxford classification.

**Results:** A total of 73 subjects (IgAN 45, household member 14, healthy control 14) were finally included in the study. The mean age of each group was 38.2, 44.0, and 32.3 years old in IgAN, household members, and healthy controls, respectively. The mean eGFR was 97.6, 101.5, and 113.7 mL/min/1.73 m<sup>2</sup>, respectively. The primarily observed phylum was Actinobacteria, Firmicutes, and Bacteroidetes. Among Firmicutes phylum, *Blautia* and *Anaerobutyrium* were found to be significantly higher in subjects with IgAN (13.7% and 4.1%) than in household members (9.2% and 1.5%) and healthy controls (8.6% and 2.1%). The abundance of *Dorea* was higher in IgAN than a household member, but not than healthy control. On the contrary, *Prevotella* and *Ruminococcus* were higher in IgAN than healthy control, not a household member. *Bifidobacterium* was significantly lower in M1, but *Clostridium* was higher in M1. *Holdemanella* and *Coproccoccus* were significantly higher in E1. *Prevotella* and *Coproccoccus* were higher in S1, but *Streptococcus* was lower in S1. There was no identified genus to distinguish T and C scores.

**Conclusions:** The gut microbiota was well discriminated subjects with IgAN from household members and healthy controls. In addition, it was also differently observed according to the status of pathologic findings of IgAN. These results may provide a basis for further metagenomics analysis using a family cohort of IgAN.

## TH-PO496

## Health State Utility Values for Immunoglobulin A Nephropathy (IgAN)

Mo Zhou,<sup>1</sup> Mark E. Bensink,<sup>2</sup> Nisha C. Hazra,<sup>3</sup> Chunyi Xu,<sup>1</sup> Bruce M. Hendry,<sup>2</sup> Claire C. Sharpe,<sup>4</sup> Zheng-Yi Zhou,<sup>3</sup> <sup>1</sup>*Analysis Group Inc Boston, Boston, MA;* <sup>2</sup>*Traverse Therapeutics Inc, San Diego, CA;* <sup>3</sup>*Analysis Group Inc, London, United Kingdom;* <sup>4</sup>*Wilkins and Sharpe Ltd., London, United Kingdom.*

**Background:** IgAN has been shown to be associated with significant clinical burden to patients with progression to kidney failure resulting in reduced health-related quality of life (HRQL). Utility values are a preference-based measure quantifying the HRQL of a disease. To date, no studies have reported utility values specifically for IgAN. The objective of this study was to estimate utility values for the spectrum of health states related to IgAN from the societal perspective in the UK.

**Methods:** Utilities for IgAN were elicited from the UK general public via computer-assisted telephone interviews. Respondents were shown written vignettes describing several health states for IgAN with different chronic kidney disease (CKD) stages, proteinuria levels, and dialysis status, and for a health state with nephrotic syndrome. Vignettes were validated by five nephrologists experienced in treating IgAN in the UK. Time tradeoff (TTO) was used to estimate utilities. For each health state, the moderator assessed the number of years in an imperfect health state a respondent was willing to give up to live in full health. The utilities for the health states, ranging from -1 (worse than death) to +1 (perfect health), were calculated based on responses. TTO utilities were validated with Visual Analogue Scale (VAS) ratings.

**Results:** TTO-derived utilities (n=200) decreased as IgAN-associated CKD/proteinuria severity increased: mean (SD) CKD stage 1/2, 0.84 (0.17) and 0.71 (0.23); CKD stage 3, 0.68 (0.23) and 0.61 (0.25); CKD stage 4, 0.55 (0.26) and 0.49 (0.27) for proteinuria <1g/day and proteinuria ≥1g/day, respectively. Within a CKD stage, utilities associated with proteinuria ≥1g/day were 0.06-0.13 lower than those with proteinuria <1g/day (p<0.001), with mean decrement of 0.09. The mean (SD) utility for CKD stage 5 with and without dialysis was 0.38 (0.30) and 0.42 (0.28), respectively (p<0.001). The mean (SD) utility for nephrotic syndrome was 0.43 (0.33). VAS and TTO results were consistent.

**Conclusions:** Utilities decreased with IgAN CKD stage progression and increased proteinuria. Treatments that reduce proteinuria and slow the rate of decline in kidney function have the potential to improve the HRQL of patients with IgAN.

**Funding:** Commercial Support - Traverse Therapeutics, Inc., San Diego, CA

## TH-PO497

## Atrasentan for the Treatment of IgA Nephropathy: Interim Results From the AFFINITY Study

Anjay Rastogi,<sup>1</sup> Michelle N. Rheault,<sup>2</sup> Sung Gyun Kim,<sup>3</sup> Nam D. Vo,<sup>4</sup> Dwarakanathan Ranganathan,<sup>5</sup> Lesley A. Inker,<sup>6</sup> David K. Packham,<sup>7</sup> Mark Vishnepolsky,<sup>8</sup> Khushboo Sheth,<sup>9</sup> Todd DeVries,<sup>9</sup> Marianne Camargo,<sup>9</sup> Andrew J. King,<sup>9</sup> Charlotte Jones-Burton,<sup>9</sup> Muh Geot Wong,<sup>10</sup> <sup>1</sup>*University of California Los Angeles, Los Angeles, CA;* <sup>2</sup>*University of Minnesota Division of Pediatric Nephrology, Minneapolis, MN;* <sup>3</sup>*Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea;* <sup>4</sup>*Mountain Kidney and Hypertension Associates, Asheville, NC;* <sup>5</sup>*Royal Brisbane and Women's Hospital, Herston, QLD, Australia;* <sup>6</sup>*Tufts Medical Center, Boston, MA;* <sup>7</sup>*Melbourne Renal Research Group, Reservoir, VIC, Australia;* <sup>8</sup>*Kidney Specialists of Southern Nevada, Las Vegas, NV;* <sup>9</sup>*Chinook Therapeutics Inc, Seattle, WA;* <sup>10</sup>*Concord Repatriation General Hospital, Sydney, NSW, Australia.*

**Background:** Endothelin A (ET<sub>A</sub>) receptor activation drives proteinuria, inflammation, and fibrosis in patients with glomerular diseases. Atrasentan, a potent and selective ET<sub>A</sub> receptor antagonist, represents a potential therapy to reduce proteinuria and preserve kidney function in patients with IgA nephropathy (IgAN) and other glomerular diseases. AFFINITY is a global, phase 2, open-label basket study to evaluate the efficacy and safety of atrasentan in adult patients with IgAN, Alport syndrome, FSGS & DKD. Here we present interim results of the IgAN cohort through week 24 of treatment.

**Methods:** Eligibility criteria for the IgAN cohort include adults with biopsy-proven IgAN; eGFR ≥30 mL/min/1.73 m<sup>2</sup>, UPCR ≥0.5 g/g and <1.0 g/g (first morning void) and on max tolerated/stable RASi. Patients are treated orally with 0.75 mg atrasentan daily for 52 weeks. The primary endpoint is change in 24-hour UPCR from baseline to Week 12.

**Results:** Twenty patients have enrolled in the IgAN cohort. Median age was 45 years, with 50% women, 45% White and 45% Asian. Baseline 24-hour total urine protein was 1.1 g/day (geometric mean; GM), 70% of subjects having total urine protein of >1 g/day, and median eGFR is 46 mL/min/1.73m<sup>2</sup>. GM percent reduction from baseline in 24-hour UPCR was 49.9% at week 12 (95% CI 39.8, 58.3; n=18) and 58.6% at week 24 (95% CI 50.5, 65.5; n=13; Figure). There were no treatment-related severe adverse events (AEs). Treatment-emergent AEs observed in 16 patients were mild or moderate in severity, and most have resolved. One patient discontinued treatment due to a related AE of headache at week 13.

**Conclusions:** Treatment with atrasentan in addition to standard of care was generally well-tolerated and resulted in a clinically meaningful reduction in proteinuria at weeks 12 and 24, strongly supporting the therapeutic potential of ET<sub>A</sub> receptor blockade with atrasentan in patients with IgAN.

**Funding:** Commercial Support - Chinook Therapeutics, Inc

## TH-PO498

## A Phase 2a Study to Evaluate the Safety and Efficacy of Tegoprobart (AT-1501) in Patients With IgA Nephropathy (IgAN)

Jonathan Barratt,<sup>1</sup> Adrian Liew,<sup>9</sup> Dana Rizk,<sup>3</sup> Lisa Willcocks,<sup>10</sup> Richard A. Lafayette,<sup>4</sup> Muh Geot Wong,<sup>7</sup> Vladimir Tesar,<sup>6</sup> Jeffrey D. Bornstein,<sup>2</sup> Heather N. Reich,<sup>5</sup> Sydney C. Tang,<sup>8</sup> <sup>1</sup>*University of Leicester, Leicester, United Kingdom;* <sup>2</sup>*Eledon Pharmaceuticals, Irvine, CA;* <sup>3</sup>*University of Alabama at Birmingham, Birmingham, AL;* <sup>4</sup>*Stanford University School of Medicine, Stanford, CA;* <sup>5</sup>*University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada;* <sup>6</sup>*Univerzita Karlova, Praha, Czechia;* <sup>7</sup>*The University of Sydney, Sydney, NSW, Australia;* <sup>8</sup>*The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong;* <sup>9</sup>*Mount Elizabeth Medical Centre, Singapore, Singapore;* <sup>10</sup>*Addenbrooke's Hospital, Cambridge, United Kingdom.*

**Background:** IgAN is the most common autoimmune nephropathy, with a young age of onset and a slow progressive course. ~40% of affected patients progress to kidney failure within 20 years of diagnosis. Therapeutic options that delay progression are limited, and more options are needed. Tegoprobart is a next generation monoclonal antibody directed against CD40 ligand (CD40L; CD154), a target important in both cell and antibody mediated immunity. Inhibiting CD40L is expected to disrupt the

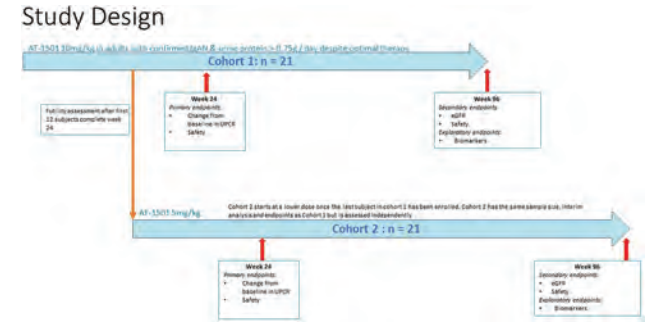

pathophysiology of IgAN both upstream, by blocking antibody and immune complex formation, and downstream, by interfering with the cell based inflammatory response in the glomeruli. A Phase 2a dose-finding, open-label study, AT-1501-N205, to evaluate the safety and efficacy of tegoprobart in patients with IgAN is underway.

**Methods:** 42 adults with biopsy proven IgAN and proteinuria  $\geq 0.75\text{g}/24\text{h}$  will be enrolled into 2 sequential open-label cohorts assessing the efficacy of 10mg/kg and 5mg/kg of tegoprobart administered IV every 3 weeks. The cohorts are staggered such that the 5mg/kg cohort will not proceed if futility is seen with the 10mg/kg cohort. The cohorts have the same inc/exc criteria, visit schedule and endpoints. The primary endpoint is change from baseline of urine protein to creatinine ratio after 24 weeks of therapy. The study will continue through Week 96 to assess change in eGFR.

**Results:** The study design includes interim analyses for futility after 12 subjects in each cohort complete 24 weeks. Futility in the 10mg/kg cohort would end the trial. Futility in the 5mg/kg cohort, would result in termination of that cohort only. Results will be presented for each cohort's interim analysis, when each cohort completes weeks 24 and 96.

**Conclusions:** Inhibition of CD40L has potential as a treatment for IgAN. This Phase 2 trial will assess 2 doses of tegoprobart in patients with IgAN, evaluating the drug's ability to reduce proteinuria and prevent decline in eGFR.

**Funding:** Commercial Support - Eledon Pharmaceuticals

TH-PO499

**Phase 1 Study in Healthy Adults of the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of ALPN-303, a Dual BAFF/APRIL Antagonist for the Treatment of Autoimmune Glomerulonephritides (GN)**

Stacey R. Dillon,<sup>1</sup> Pille Harrison,<sup>1</sup> Jason Lickliter,<sup>2</sup> Kristi L. Manjarrez,<sup>1</sup> Alina Smith,<sup>1</sup> Mary C. Lessig,<sup>1</sup> Russell J. Sanderson,<sup>1</sup> Allison G. Chnyk,<sup>1</sup> Katherine Lewis,<sup>1</sup> Hany Zayed,<sup>1</sup> Rupert H. Davies,<sup>1</sup> Stanford Peng.<sup>1</sup> <sup>1</sup>Alpine Immune Sciences Inc, Seattle, WA; <sup>2</sup>Nucleus Network Ltd, Melbourne, VIC, Australia.

**Background:** Therapeutic agents targeting the B-cell cytokines BAFF and/or APRIL have demonstrated promising clinical potential in antibody-related GN such as lupus nephritis (LN) and IgA nephropathy (IgAN), and other B-cell-related diseases such as systemic lupus erythematosus; however, there is still need for more safe and efficacious therapies. ALPN-303 is an Fc fusion protein of an engineered TACI variant TNFRSF domain (vTD) which mediates more potent inhibitory activity than WT TACI-Fc or BAFF- or APRIL-specific antibodies. In preclinical studies, ALPN-303 demonstrated enhanced PK and immunomodulatory properties vs. WT TACI-Fc, which may translate to lower and/or less frequent doses in humans. ALPN-303 also suppressed autoantibodies, renal IgG deposition, and nephritis in mouse models. ALPN-303 may therefore significantly improve clinical outcomes in GN and other B-cell-related diseases.

**Methods:** In this first-in-human study (NCT05034484), adult HVs are randomized into single ascending dose cohorts of intravenous (IV) or subcutaneous (SC) ALPN-303 or placebo. Subjects are followed to assess safety and PK, circulating immunoglobulins (Ig), and circulating leukocyte populations by flow cytometry.

**Results:** ALPN-303 has been well tolerated in all cohorts evaluated to date, and overall exhibits dose-related PK and expected PD effects, including dose-related reductions in serum Ig. To date there have been no treatment-related serious adverse events, no infusion-related or injection site reactions, and no adverse trends in safety laboratories. Dose escalation is expected to complete by the time of the meeting; the presentation will include all available safety, PK, and PD data.

**Conclusions:** ALPN-303 to date demonstrates acceptable safety and tolerability and exhibits PK and PD that appear to differentiate favorably vs WT TACI-Fc. These findings support future clinical development of ALPN-303 in multiple antibody-related GN, as well as other B-cell- and/or antibody-related diseases.

TH-PO500

**Characterization of Patients With Thrombotic Microangiopathy and Triggering/Associated Events: A Global aHUS Registry Analysis**

Andrew M. Siedlecki,<sup>1</sup> Imad Al-Dakkak,<sup>2</sup> Ekaterina Anokhina,<sup>3</sup> Nicole Isbel,<sup>3</sup> Veronique Fremaux-Bacchi,<sup>4</sup> Rodney D. Gilbert,<sup>5</sup> Larry A. Greenbaum,<sup>6</sup> Gema Ariceta,<sup>7</sup> Gianluigi Ardissino,<sup>8</sup> Franz S. Schaefer,<sup>9</sup> Eric Rondeau,<sup>10</sup> Christoph Licht.<sup>11</sup> <sup>1</sup>Department of Internal Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Alexion, AstraZeneca Rare Disease, Boston, MA; <sup>3</sup>Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; <sup>4</sup>Laboratoire d'Immunologie, Hôpital Européen Georges Pompidou, Paris, France; <sup>5</sup>Regional Paediatric Nephro-Urology Unit, Southampton Children's Hospital, Tremona Road, Southampton, United Kingdom; <sup>6</sup>Division of Pediatric Nephrology, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; <sup>7</sup>Department of Pediatric Nephrology, Vall d'Hebron Hospital, and the Autonomous University of Barcelona, Barcelona, Spain; <sup>8</sup>Centro per la Cura e lo Studio della Sindrome Emolitico-Uremica, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; <sup>9</sup>Division of Pediatric Nephrology, Heidelberg University Hospital, Heidelberg, Germany; <sup>10</sup>Urgences Néphrologiques et Transplantation Rénale, Hôpital Tenon, Paris, France; <sup>11</sup>Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.

**Background:** Atypical hemolytic uremic syndrome (aHUS), a rare disease of complement dysregulation, leads to thrombotic microangiopathy (TMA). In this study, we characterize patients (pts) with triggering/associated events occurring prior/up to aHUS onset from the Global aHUS Registry (NCT01522183).

**Methods:** All pts with triggering/associated events prior/up to aHUS onset and enrolled in the Registry from 2011 to July 2021 were included. Pts with an alternative clinical diagnosis after enrollment were excluded.

**Results:** In total, 349 pts with triggering/associated events were included, of which 75% were adults ( $\geq 18$  years) (n=229) and 25% (n=78) were pediatric pts ( $<18$  years). Most pts (n=307, 88%) had only one triggering/associated event, and in those, the most frequent triggering/associated events were malignancy in adults (n=51; 22%) and acute infection (n=28; 36%) in pediatric pts. The mean time from event to aHUS onset in these categories were 22 and 0.03 months, respectively. The least frequent were bone marrow transplant (1.7%) and C3 glomerulopathy (0.9%) in adults, and C3 glomerulopathy (0%), and drug-induced aHUS (0%) in pediatric pts. Autoimmune disorders (n=36) had the longest time from event to aHUS onset (41 months), while acute infection (n=53) and malignant hypertension (n=26) had the shortest (0.03 months). The most common triggering and associated events combinations were drug-induced aHUS and malignancy (n=7).

**Conclusions:** This study suggests that triggering events can be organized into clinically relevant categories. The frequency of triggering/associated events occurring prior/up to aHUS differ in pediatric and adult populations. The interval between triggering/associated events and the eventual diagnosis of aHUS differ by type of event.

**Funding:** Commercial Support - Alexion, AstraZeneca Rare Disease

Table: Patient characteristics per triggering/associated condition

Triggering/associated condition	Number of patients n (%)	Sex, F/M (%)	Number of patients <18 years n (%)	Age at aHUS onset, years median (Q1, Q3)	Time from triggering/associated condition to aHUS onset, month median (Q1, Q3)
Malignancy	56/507 (10.8)	28/58 (48.3)	7/65 (10.8)	52.13 (47.26, 59.25)	22.38 (7.65, 69.07)
Acute infection	53/507 (10.5)	25/53 (47.3)	28/53 (52.8)	15.68 (1.48, 38.16)	0.03 (0.03, 0.23)
Autoimmune Disease	36/507 (7.1)	25/35 (69.4)	4/30 (13.3)	29.43 (28.77, 59.06)	40.94 (3.65, 187.77)

**PLASMIC Score to Aid Diagnosis of Atypical Hemolytic Uremic Syndrome: A Post Hoc Analysis of Data From C5 Inhibitor Trials**

Miguel Uriol Rivera,<sup>1</sup> Ana I. Avila Bernabeu,<sup>2</sup> Robert Makar,<sup>3</sup> John Booth,<sup>4</sup> Frank R. Ernst,<sup>4</sup> Angels Comas,<sup>5</sup> Christoph Gasteyer,<sup>6</sup> Ching Lum,<sup>7</sup> Ioannis Tomazos,<sup>7</sup> Yan Wang,<sup>7</sup> Pavan K. Bendapudi.<sup>3,8</sup> <sup>1</sup>Glomerular Diseases Unit, Son Espases University Hospital, Palma de Mallorca, Spain; <sup>2</sup>Nephrology Department, Dr Peset University Hospital, Valencia, Spain; <sup>3</sup>Harvard Medical School, Boston, MA; <sup>4</sup>CTI Clinical Trial & Consulting Services, Covington, KY; <sup>5</sup>Alexion, AstraZeneca Rare Disease, Barcelona, Spain; <sup>6</sup>Alexion, AstraZeneca Rare Disease, Zurich, Switzerland; <sup>7</sup>Alexion, AstraZeneca Rare Disease, Boston, MA; <sup>8</sup>Division of Hematology and Blood Transfusion Service, Massachusetts General Hospital, Boston, MA.

**Background:** Thrombotic microangiopathies (TMAs) are rare disorders presenting as thrombocytopenia, microangiopathic hemolytic anemia and organ damage. Atypical hemolytic uremic syndrome (aHUS) is a complement-mediated TMA, with/without a trigger. aHUS is diagnosed by excluding thrombotic thrombocytopenic purpura (TTP) and other TMAs. PLASMIC scores (PSs) can facilitate earlier diagnosis of severe ADAMTS13 deficiency. In suspected TTP cases, a PS (min-max: 0-7, 7 components; see

Figure legend) is calculated. A score of  $\geq 6$  suggests a high probability of ADAMTS13 activity  $<10\%$  and TTP. This study aimed to understand PS distribution in aHUS patients and its importance in assisting earlier diagnosis and appropriate treatment.

**Methods:** PSs were calculated for patients with aHUS from the safety set of eculizumab (NCT01522170) and ravulizumab (NCT02949128) trials, using the first measure of PS components at screening. Relative and cumulative distributions of PS were calculated.

**Results:** PS distributions were similar in both trials, with all patients scoring between 3–7 and  $\sim 50\%$  scoring 4 (Figure). Scores 3–5, indicating probable aHUS rather than TTP, were observed in 86% of eculizumab patients and 88% of ravulizumab patients. Across PS components, platelet count and creatinine thresholds were met by the fewest patients ( $\leq 22.2\%$ ).

**Conclusions:** This analysis shows that PS  $< 6$  is observed in most patients with confirmed aHUS. However, a PS  $\geq 6$  does not completely exclude aHUS. Assessing ADAMTS-13 activity remains essential to accurately distinguish between TTP and aHUS.

**Funding:** Commercial Support - Alexion, AstraZeneca Rare Disease

Figure: Relative PLASMIC Score distributions in patients from eculizumab and ravulizumab trials

PLASMIC Score is comprised of 7 components: platelet count  $<30 \times 10^9/L$ , hemolysis (indirect bilirubin  $>2 \text{ mg/dL}$ , reticulocyte count  $>2.5\%$  or undetectable haptoglobin), no active cancer/cancer therapy within past year, no transplant history, MCV  $<9 \times 10^{14} L$ , INR  $<1.5$  and creatinine  $<2.0 \text{ mg/dL}$ . aHUS, atypical hemolytic uremic syndrome; INR, international normalized ratio; MCV, mean corpuscular volume

**Background:** The global atypical hemolytic uremic syndrome (aHUS) Registry (NCT01522183) is the largest repository of real-world data on patients with aHUS. We report long-term (LT) outcomes with eculizumab (ecu) treatment in two patient cohorts: those with LT follow-up (FU) without progression to end-stage kidney disease (ESKD) and those who developed ESKD during treatment. Our aim was to determine whether LT ecu preserves kidney function.

**Methods:** The analysis included registry patients enrolled between Apr 2012–Nov 2021 and treated with ecu for  $\geq 90$  days. Cohort A included patients with  $\geq 3$ -year FU, no ESKD, and two creatinine values; near treatment start and after  $\geq 3$ -year observation. Cohort B included patients who developed ESKD after treatment with no FU duration specified.

**Results:** Demographics and laboratory parameters (baseline [BL], last FU [LFU]) are shown in the Table. For Cohort A, 249 patients met inclusion criteria; at LFU, eGFR improved, 7% received acute dialysis (9% of adults, 6% of children) and two adults died. For Cohort B, 56 patients met inclusion criteria; at LFU, 48% received a kidney transplant (38% of adults, 68% of children), 89% received dialysis (95% of adults, 79% of children) and eight died (six adults, two children). BL eGFR was lower in patients who progressed to ESKD (Cohort B, N=56) than in patients who did not progress (Cohort A, N=249). Platelet and LDH levels improved in both cohorts at LFU.

**Conclusions:** In a real-world setting, eGFR was stable in most patients receiving ecu. Some patients demonstrated hematologic benefits but no renal response; they had lower BL eGFR and initiated treatment late.

## Clinical and Histologic Profile of C3 Glomerulopathy: A Retrospective Study

Soumita Bagchi,<sup>1</sup> Adarsh Barwad,<sup>2</sup> Geetika Singh,<sup>2</sup> Arunkumar Subbiah,<sup>1</sup> Dipankar M. Bhowmik,<sup>1</sup> Sanjay K. Agarwal.<sup>1</sup> <sup>1</sup>Nephrology Department, All India Institute of Medical Sciences, New Delhi, India; <sup>2</sup>Pathology Department, All India Institute of Medical Sciences, New Delhi, India.

**Background:** C3 glomerulopathy(C3G) is a type of glomerular disease characterized by the predominant deposition of complement component C3 in the glomeruli due to the abnormal activation of the alternate complement pathway. Our understanding of the disease is still evolving. We evaluated the clinical profile of patients with C3G in our renal biopsy cohort.

**Methods:** Patients with biopsy proven C3G diagnosed between 2015 to 2020 were included in this retrospective study. Demographic characteristics, laboratory investigations and treatment details were obtained from medical records. Biopsy records were reviewed for histologic features. Complete remission (CR) was defined as 24-hour urine protein of <500 mg/d with stable eGFR and partial remission (PR) was defined as atleast 50% reduction in proteinuria with stable eGFR with a decline of proteinuria to <3.5g/day. The study was approved by the institute ethics committee with a waiver of consent. Renal progression was defined as sustained >50% decline in eGFR or end stage renal failure.

**Results:** 33 patients were diagnosed with C3G during the study period. Median age at presentation was 23(IQR 18-30) years and 69.7% were males. 51.5% had hypertension. Median estimated glomerular filtration rate(eGFR) was 49(IQR 22.5-97.8) ml/min/1.73m<sup>2</sup>, median serum albumin was 2.7(IQR 2.3-3.5) g/dl and median proteinuria was 4.3(IQR 3.0-7.4) g/day at presentation. 51.5% patients had microscopic hematuria. 51.4% cases had low C3 levels. On histology 4 patients had dense deposit disease (DDD) while 29 were diagnosed with C3 glomerulonephritis (2 cases had crescents). 52.9% cases received renin angiotensin system (RAS) blockade therapy. 29 patients received initial immunosuppression with: steroids (8), mycophenolate mofetil+steroids (20) or cyclophosphamide+steroids (1). Only 9 patients achieved reduction in proteinuria with stable eGFR: 5 had partial remission and 4 had complete remission. Of the 20 patients who received MMF, only 7(35%) had remission. During a median follow up of 29 (IQR 6.7 to 44.1) months, 15(45.4%) patients had sustained >50% decline in eGFR or had progressed to end stage renal failure.

**Conclusions:** C3G presents at a young with significant proteinuria. Patients respond poorly to currently available immunosuppression with high risk of worsening kidney function.

## 12M Interim Analysis of an Open-Label, Non-Randomized Extension of a Phase 2 Study to Evaluate the Long-Term Efficacy, Safety, and Tolerability of Iptacopan in Subjects With C3G

Carla M. Nester,<sup>1</sup> Ute Eisenberger,<sup>2</sup> Alexandre Karras,<sup>3</sup> Liz Lightstone,<sup>4,5</sup> Manuel Praga,<sup>6</sup> Giuseppe Remuzzi,<sup>7</sup> Maria Jose Soler,<sup>8</sup> Junhao Liu,<sup>9</sup> Matthias Meier,<sup>10</sup> Ronda Tawfik,<sup>11</sup> Guido Junge,<sup>11</sup> Andrea Biondani,<sup>10</sup> Angelo J. Trapani,<sup>9</sup> Nicholas Webb,<sup>10</sup> Edwin K. Wong.<sup>12,13</sup> <sup>1</sup>University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; <sup>2</sup>Department of Nephrology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany; <sup>3</sup>Hopital European Georges Pompidou, Paris, France; <sup>4</sup>Centre for Inflammatory Disease, Department of Immunology and Inflammation, Imperial College London, London, United Kingdom; <sup>5</sup>Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, United Kingdom; <sup>6</sup>Department of Medicine, Complutense University. Hospital Universitario 12 de Octubre, Madrid, Spain; <sup>7</sup>Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; <sup>8</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>9</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ; <sup>10</sup>Novartis Pharma AG, Basel, Switzerland; <sup>11</sup>Novartis Institutes for BioMedical Research Basel Department of Translational Medicine, Basel, Switzerland; <sup>12</sup>Newcastle University, Newcastle upon Tyne, United Kingdom; <sup>13</sup>National Renal Complement Therapeutics Centre, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom.

**Background:** Iptacopan (LNP023) is an oral, first-in-class, selective inhibitor of factor B, a key component of the alternative complement pathway (AP). We have previously reported data from a Ph2 study in native and recurrent C3G (NCT03832114) showing that 12W iptacopan treatment results in a 45% reduction in proteinuria in native C3G. Here we present the effects of 12M iptacopan treatment.

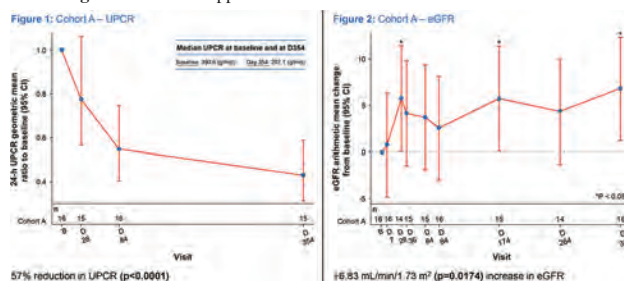

**Methods:** Adults with native (CoA) or recurrent C3G post kidney transplant (CoB) received iptacopan for at least 12W before entering this Ph2 extension trial (NCT03955445). The primary efficacy objective was to assess the effect of iptacopan on a composite endpoint of 1) stable/improved eGFR [ $\leq 10\%$  reduction from baseline], 2)  $\geq 50\%$  reduction from baseline in UPCr, and 3)  $\geq 50\%$  increase from baseline in serum C3 after 12M treatment.

**Results:** Of 27 patients completing the 12W Ph2 study, 26 (16CoA, 10CoB) entered the extension for treatment with iptacopan 200mg b.i.d. 53% of CoA patients met the composite renal endpoint criteria at 12M; proteinuria was reduced by 57% ( $p < 0.0001$ ; Fig1), eGFR increased by 6.83 mL/min/1.73 m<sup>2</sup> ( $p = 0.0174$ ; Fig2) and C3 increased by 253% ( $p < 0.0001$ ). eGFR was stable and C3 levels increased by 96% in CoB. Proteinuria

reduction was not assessed in CoB as median baseline proteinuria was normal (18.4g/mL). Iptacopan was generally well-tolerated and most AEs were of mild severity in both cohorts. Biomarkers demonstrated substantial AP inhibition.

**Conclusions:** Long-term treatment with iptacopan results in further proteinuria reduction and eGFR improvement beyond that previously reported following 12W treatment in native C3G. Stable eGFR was seen in recurrent C3G, with stable increases in serum C3 levels found in both cohorts. The ongoing Ph3 APPEAR-C3G (NCT04817618) study is evaluating the efficacy of iptacopan in native C3G patients.

## Impact of First-Line Use of Caplacizumab on Treatment Outcomes in Immune Thrombotic Thrombocytopenic Purpura: News From the REACT-2020 Cohort

Linus A. Volker,<sup>1,2</sup> Jessica K. Kaufeld,<sup>3</sup> Lucas Kuehne,<sup>1</sup> Thomas Osterholt,<sup>1</sup> Franziska Grundmann,<sup>1</sup> Martin Kann,<sup>1,2</sup> Paul T. Brinkkoetter.<sup>1,2</sup> <sup>1</sup>University Hospital of Cologne, Cologne, Germany; <sup>2</sup>Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany; <sup>3</sup>Medical School Hannover, Hannover, Germany.

**Background:** The von Willebrand factor-directed nanobody caplacizumab has greatly changed the treatment of immune thrombotic thrombocytopenic purpura (iTTP) in recent years. While data from randomized controlled trials established efficacy and safety, there has been a lack of information regarding patient selection, tailoring of therapy duration, effect on adjunct treatment, and outcomes in the real-world setting. Here, we report 113 iTTP episodes treated with standard of care including caplacizumab and 119 historical control episodes treated without caplacizumab.

**Methods:** Patients with an episode of iTTP defined by an ADAMTS13 activity below 10 percent or relapsing thrombotic microangiopathy in patients with an established diagnosis of iTTP and 18 years of age or older were eligible. REACT-2020, registered at clinicaltrials.gov as #NCT04985318, is an observational retrospective cohort study. From October 2018 until May 2021, data from patients in Germany and Austria with an acute episode of iTTP receiving caplacizumab were gathered retrospectively.

**Results:** Caplacizumab may lower iTTP-related mortality and refractoriness and decrease the number of daily plasma exchange and hospital stay. These benefits, however, vanish in patients not receiving caplacizumab first-line within 72 hours after diagnosis and until at least partial ADAMTS13 remission. In addition, we observed an increase in use of rituximab over time. Exacerbations were less frequent in caplacizumab-treated patients (14 % vs. 39 %). In an aggregated analysis of all available iTTP cohorts, caplacizumab resulted in significant absolute risk reduction of 2.87 % for iTTP-related mortality (number needed to treat 35) and a relative risk reduction of 59 %.

**Conclusions:** Caplacizumab may improve patient-centered outcomes if given in the first-line within 72 hours and until at least partial ADAMT13 remission.

## Practice Patterns of Induction Therapy in Severe ANCA-Associated Vasculitis: An International Physician Survey

Lillian Xu,<sup>1</sup> Faten F. Aqeel,<sup>1</sup> Ojaswi S. Tomar,<sup>2</sup> Tingting Li,<sup>2</sup> Duvuru Geetha.<sup>1</sup> <sup>1</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO.

**Background:** Therapies for ANCA-associated vasculitis (AAV) have evolved over the last 3 decades. In light of new data on plasma exchange (PLEX) and glucocorticoid (GC) use, as well as recent approval of avacopan (AVP), various medical societies have updated their AAV management guidelines. Here, we explored practice patterns of induction therapy in severe AAV and ascertained differences in management by physician specialty, practice setting, and volume of AAV patients.

**Methods:** A 65-item anonymous research survey addressing physician/practice characteristics, AAV induction therapy approaches, prophylactic measures, and laboratory monitoring was sent to physicians by e-mail and social media platforms after IRB approval. Practice patterns within the last 5 years were examined based on physician specialty, practice setting, and volume of AAV patients. Descriptive statistics, chi-square, t-test, and Fisher's exact were used as appropriate.

**Results:** There were 308 responses (52% nephrologists, 41% rheumatologists). Of all participants, 29% practiced in the United States, 20% in India, 9% in the United Kingdom, 6% in Canada, and the remainder in other countries. Pulse methylprednisolone (MeP) was used by 94%, reduced dose GC by 70%, PLEX by 38%, rituximab (RTX) by 92%, cyclophosphamide (CYC) by 89%, and AVP by 12%. There were significant differences

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in use of reduced dose GC, PLEX, and RTX brand by physician specialty and by AAV patient volume (Table). Significant differences were seen in regards to pulse MeP dose ( $p<0.001$ ), treatment of severe AAV presentations ( $p<0.001$ ), CYC route and duration ( $p=0.005$ ,  $p<0.001$ ), and PJP prophylaxis ( $p<0.005$ ) by physician specialty, RTX and AVP use by volume of AAV patients ( $p=0.003$ ,  $0.001$ ), and CYC use by practice setting ( $p<0.001$ ).

**Conclusions:** Our survey highlights significant differences in AAV induction therapy practices based on specialty, practice setting, and AAV patient volume. Additionally, one third of physicians continue to use standard GC.

### Kinetics of B Cell Repopulation After Rituximab in ANCA-Associated Vasculitis: Clinical Significance and Predictive Factors

Federica Mescia,<sup>1,2</sup> Chiara Salviani,<sup>1</sup> Stefania Affatato,<sup>1,2</sup> Mattia Tonoli,<sup>1,2</sup> Alice Guerini,<sup>1,2</sup> Martina Tedesco,<sup>1,2</sup> Daniele Moratto,<sup>3</sup> Gina A. Gregorini,<sup>3</sup> Marco Chiarini,<sup>1</sup> Francesco Scolari,<sup>1,2</sup> Federico Alberici,<sup>1,2</sup> <sup>1</sup>Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy; <sup>2</sup>Università degli Studi di Brescia, Brescia, Italy; <sup>3</sup>Independent researcher, Brescia, Italy.

**Background:** Despite the increasing use of Rituximab (RTX) in ANCA-Associated Vasculitis (AAV), it remains unclear what the optimal dosing is, especially for maintenance. A deeper understanding of post-RTX BC repopulation is needed to better tailor treatment.

**Methods:** This is a single center, 10-year retrospective study including newly diagnosed, ANCA-positive patients with GPA/MPA receiving RTX induction with no fixed-schedule maintenance. CD19+BC were monitored with flow cytometry. Data were censored after repeat RTX. Repopulation was defined as CD19+BC>10 cells/ $\mu$ l.

**Results:** The cohort included 71 AAV patients, with a majority of females (62%), MPA syndrome (75%) and MPO-ANCA positivity (75%). Most had renal involvement (79%), with median eGFR 23 ml/min/1.73m<sup>2</sup> (IQR 9-48). During median follow-up of 55 months, 44 patients (62%) repopulated BCs. Median time to repopulation was 39 months (range 7-102). Comparing patients with/without repopulation at 12/24/36/48 months, there was a trend for lower flare risk and higher infection risk with ongoing BC depletion, reaching statistical significance only at 48 months (log-rank test). In exploratory univariate Cox regression, risk of BC repopulation was positively associated with eGFR and female gender, with a trend for negative association with older age, MPA presentation (vs. GPA), and steroid pulses. Among these variables, only eGFR (HR 1.22 per 10 ml/min/1.73m<sup>2</sup>, 95%CI 1.04-1.43,  $p=0.016$ ) and gender (HR 2.73 for female, 95%CI 1.39-5.38,  $p=0.004$ ) were independent predictors of time to BC repopulation in the multivariate model (Figure 1).

**Conclusions:** A subset of AAV patients develop sustained post-RTX BC depletion, which associates with long-term reduced flare risk and increased infection risk. Renal impairment and male gender are key predictors of delayed BC repopulation. These observations further highlight the need for tailored immunosuppression.

Fig. 1: Expected time to BC repopulation curves across different eGFR groups and gender, according to multivariate Cox model

### Prognosis of Diffuse Crescentic Fibrillary Glomerulonephritis

Vincent Javaugue,<sup>1,2</sup> Samar M. Said,<sup>1</sup> Lihong Bu,<sup>1</sup> Frank Bridoux,<sup>2</sup> Fernando C. Fervenza,<sup>1</sup> Nelson Leung,<sup>1</sup> Samih H. Nasr.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Centre Hospitalier Universitaire de Poitiers, Poitiers, France.

**Background:** Diffuse crescentic involvement is very rare in fibrillary glomerulonephritis (FGN). Little is known about the prognosis and the therapeutic management of these patients.

**Methods:** We retrospectively reviewed the pathology archives at Mayo Clinic and University Hospital of Poitiers from 1997-2021 for FGN with crescents involving  $\geq 50\%$  of glomeruli.

**Results:** Twenty-two patients (50% female, 91% Caucasian, median age 59 years) were included (incidence of 2.7% in biopsies of FGN). All patients presented with rapidly progressive glomerulonephritis (RPGN) and 9 required dialysis at diagnosis.

Eight patients had CKD stage  $\geq 3$ . Associated conditions included autoimmune disease in 6, malignancy in 3 and hepatitis C in 2 cases. Four had positive ANCA and 1 had an anti-GBM antibody. By light microscopy, the median % of glomeruli with crescents was 64%. Glomeruli showed strong staining for DNAJB9 in 11 tested cases. By immunofluorescence, all cases showed glomerular positivity for IgG (polytypic in 19/22) with IgG4 restriction in most cases, and linear GBM staining mimicking anti-GBM nephritis in 6. Nineteen patients received immunosuppressive therapy (steroids alone,  $n=3$ ; or with cyclophosphamide,  $n=11$ ; rituximab,  $n=4$ ; rituximab + cyclophosphamide,  $n=1$ ) associated with plasmapheresis in 4 cases. Kaplan-Meier analysis showed poor renal outcome with a median renal survival of 3 weeks (Figure). Three patients received kidney transplantation without evidence of recurrence 18-, 48- and 56-months post transplantation, respectively.

**Conclusions:** Our study highlights a dismal kidney prognosis of crescentic FGN regardless of the type of therapy and suggests that kidney transplant is probably the best option for fit patients with RPGN secondary to diffuse crescentic FGN.

Kaplan-Meier renal survival analysis.

## TH-PO510

### Renal Tubulointerstitial Injury in Patients With Cryoglobulinemia

Chen Minting, Xiaoxiao Shi, Yubing Wen, Peng Xia, Xuemei Li, Limeng Chen. *Department of Nephrology, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China.*

**Background:** Kidney tubulointerstitial (TI) involvement in patients with cryoglobulinemia (CG-TI) was rare and their clinicopathological characteristics and renal prognosis remain unclear.

**Methods:** We recruited 199 inpatients with CG in our hospital. A total of nine cases of CG-TI were identified based on the tubular dysfunctions or TI injuries in kidney pathology. Their medical document, kidney pathology, treatment regimens, and follow-up data were reviewed and analyzed.

**Results:** The nine CG-TI patients had a median age at diagnosis of 49 (43-60) years with the male (44%). The primary causes of CG were primary Sjogren's syndrome (33.3%) and monoclonal gammopathy of renal significance (22.2%). Mixed (II + III) cryoglobulinemia accounted for the majority (88.9%). The anemia (66.7%), fever (55.6%), and cutaneous lesions (33.3%) were the most common extrarenal manifestations. The mean eGFR level was 40.04 ml/min/1.73m<sup>2</sup>. About 88.9% had proteinuria with a mean urine protein level of 1.01 g/d. Two patients had prominent proximal tubular injuries, presenting as Fanconi syndrome. Besides the cryoglobulinemic glomerulonephritis (GN) with a membranoproliferative GN, kidney pathology showed obvious tubulointerstitial injuries, with interstitial inflammatory infiltrates, tubular atrophy, and interstitial fibrosis. Intracapillary deposits were the short fibrillary substructure by electron microscopy. Seven patients received immunosuppressive treatment or chemotherapy. Followed the mean of 30 $\pm$ 4 months, their renal function recovered within a year and stabilized thereafter.

**Conclusions:** We reported the rare cases series of CG-TI, which responded well to immunosuppressive treatment or chemotherapy.

## TH-PO511

### Idiopathic Nodular Glomerulosclerosis Associated With APOL1 Mutation

Shahrazad Zonoozi, Divya Shankaranarayanan, Anam Tariq, Dominic S. Raj. *The George Washington University, Washington, DC.*

**Introduction:** Idiopathic nodular glomerulosclerosis (ING) is a pathologic diagnosis with features indistinguishable from diabetic nodular glomerulosclerosis in the absence of abnormal glucose metabolism. ING has been associated with hypertension (HTN), smoking and obesity. We present a case of ING in a non-smoker.

**Case Description:** A 58-year-old African American male non-smoker with HTN and obesity presented for evaluation of 5-6 months of leg edema and uncontrolled HTN. Evaluation revealed anemia, thrombocytopenia, creatinine (Cr) 2.7mg/dL, albumin 2.6g/dL and hemoglobin A1c 5.5%. Serologic work up was negative. Random urine protein/Cr ratio was 13.4g/g Cr and so patient underwent a kidney biopsy. Biopsy demonstrated 1/10 globally sclerotic glomeruli with nodular expansion and mild-moderate mesangial hypercellularity. Glomerular basement membrane was thickened. Interstitial fibrosis and tubular atrophy affected 60-70% of cortex with marked interstitial inflammatory infiltrate. Electron microscopy showed extensive podocyte foot process effacement. Immunofluorescence showed glomeruli with trace granular peripheral capillary wall staining with IgM, C1q and C3. Overall, findings suggestive of nodular glomerulosclerosis, chronic thrombotic microangiopathy (TMA), chronic active interstitial nephritis and moderate arteriosclerosis. Additionally, the patient underwent genetic evaluation, which revealed 2 risk alleles in the APOL1 gene (G1 and G2) as well as carrier status for SLC6A19 and a variant of unknown significance in NPHS1.

**Discussion:** Our patient presented with nephrotic syndrome and was found to have ING and TMA on biopsy. Although ING has been linked to HTN and smoking, our patient was a non-smoker, whose workup revealed risk alleles in the APOL1 gene. As far as we are aware this is the first report of an association between ING and the APOL1 gene.

Figure 1. Light microscopy showing nodular glomerulosclerosis

TH-PO512

**Hemophagocytic Lymphohistiocytosis (HLH) and Collapsing Focal Segmental Glomerulosclerosis (cFSGS) in an Immunocompetent Patient With Cytomegalovirus and Epstein-Barr Virus Viremia**  
Mingyue He, Edva Noel, Sheetal Koul, Avrum Gillespie, Serban Constantinescu, Iris J. Lee. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

**Introduction:** cFSGS is an aggressive variant of FSGS characterized by collapse and sclerosis of the glomerular tuft, nephrotic syndrome, and rapidly progressive renal failure often resistant to treatment. Patients of African ancestry are disproportionately affected. To our knowledge, this is the first reported case of cFSGS and HLH in an immunocompetent host with CMV and EBV viremia successfully treated with steroids and ganciclovir.

**Case Description:** A 56-year-old African American female was admitted with fever, dry cough, nausea/vomiting, and 30 lb weight loss over the past 6 months. Her persistent fevers led to an infectious workup and testing for HLH. Studies showed EBV viremia (9300 copies/ml), CMV viremia (15,567 IU/ml), hypertriglyceridemia, elevated soluble CD25, hyperferritinemia, and evidence of hemophagocytosis on bone marrow biopsy. 1 week later, she developed oliguric AKI with a peak creatinine of 8.3 mg/dl and 8.8 gm proteinuria. Serologies were all negative and complements were normal. A kidney biopsy showed cFSGS, acute tubulointerstitial nephritis. Immunofluorescence was negative. She was treated with dexamethasone for HLH and ganciclovir for CMV. 1.5 months later, her viremia resolved, abnormal markers improved, and her renal function normalized.

**Discussion:** The onset of HLH-related markers coinciding with CMV and EBV viremia suggests secondary HLH, likely triggered by viral infection. Rapid response to steroids and ganciclovir supports CMV infection as a driver of HLH and cFSGS development. HIV-associated cFSGS is well established, however, association with CMV and EBV are rare. Increased interferon production in response to viral infection may provide the “second hit” for podocyte damage in AA patients with high-risk APOL1 alleles. HLH-related inflammation and cytokine dysregulation with markedly elevated Interferon levels may also contribute to cFSGS. cFSGS is a rare complication of CMV, EBV infection and HLH. Testing for these is not routinely performed for immunocompetent patients, therefore these potential causes of cFSGS may be under-recognized. Cases of idiopathic cFSGS should be screened for viral infection and HLH, as anti-viral therapy combined with steroids may result in the resolution of renal disease.

TH-PO513

**Cerebral Venous Thrombosis in an Adult With Relapsing Minimal Change Disease: A Case Report and Literature Review**  
Matthias Bergmann,<sup>1,2</sup> Christine Segal,<sup>1</sup> Bertrand L. Jaber.<sup>1,2</sup> *<sup>1</sup>Saint Elizabeth's Medical Center, Brighton, MA; <sup>2</sup>Tufts University School of Medicine, Boston, MA.*

**Introduction:** Minimal change disease (MCD) is a well-known cause of fulminant nephrotic syndrome (NS) and associated with thrombotic events. Cerebral venous thrombosis (CVT) is a potentially fatal, albeit rare complication. We present a case of relapsing MCD complicated by CVT and intracranial hemorrhage (ICH), and provide a systematic review of cases with NS-associated CVT.

**Case Description:** A 51-year-old woman with biopsy-proven MCD in remission previously treated with glucocorticoids presented with headache, vomiting, and confusion after relapse of the NS. Proteinuria was 14.7 g/g creatinine and serum albumin was 2.5 g/dL. Brain MRI was consistent with CVT complicated by ICH. One month prior, she had been initiated on an oral combination contraceptive for menstrual cramps. She was treated with anticoagulation and glucocorticoids and died before being able to undergo catheter-based therapy.

**Discussion:** Our systematic review of 33 cases with NS-associated CVT is shown in Table 1. Average proteinuria was 9.32 g/day (0.05-24.30), and average serum albumin was 1.8 g/dL (0.7-3.6). 14 patients (70%) had MCD. Most reported symptoms were headache (83%), nausea/vomiting (47%), and altered mental status (30%). 5 patients (15%) developed ICH. 20 patients (91%) received anticoagulation and 5 patients (23%) underwent catheter-based therapies. 5 patients (19%) died from the sequelae of CVT, 3 of which (60%) had ICH. In conclusion, MCD might be related to a higher risk of CVT due to its fulminant manifestation of the NS. Additional prothrombotic triggers, such as oral contraceptives, should be avoided. Neurological symptoms are often non-specific and threshold for MRI should be low in patients with the NS.

Patient demographic characteristics	
Men (n = 28)	54%
Mean age (n = 28)	39 years old
Ethnicity (n = 6)	
White	50%
Black	17%
Asian	33%
Neurological clinical presentation (n = 30)	
Headache	83%
Nausea/vomiting	47%
Confusion/loss of consciousness	30%
Visual changes	23%
Seizure	10%
Diplopia	7%
Other focal neurological deficits	17%
Neurological imaging findings in addition to CVST (n = 33)	
Ischemic infarct	9%
Intracranial hemorrhage	15%
Nephrotic syndrome-related characteristics at time of neurological presentation	
Status of nephrotic syndrome (n = 25)	
Initial presentation	64%
Relapse	32%
In Remission	4%
Kidney biopsy findings (n = 20)	
Minimal change disease	70%
Lupus nephritis (membranous nephropathy and diffuse proliferative glomerulonephritis)	10%
IgM nephropathy	5%
Focal segmental glomerulosclerosis (FSGS)	5%
Amyloidosis	5%
Interstitial nephritis	5%
Mean urinary protein excretion (n = 21)	9.32 gm/gm or gm/day
Mean serum albumin (n = 25)	1.8 gm/dL
Current use of immunosuppressive therapies (n = 28)	
Glucocorticoids	21%
Azathioprine	14%
Rituximab	4%
Not reported	4%
Management of CVST (n = 22)	
Use of anticoagulation	91%
Parenteral anticoagulation	86%
Unfractionated heparin infusion	45%
Low-molecular-weight heparin	41%
Oral anticoagulation	77%
Use of antiplatelet agents	23%
Use of catheter-based thrombolytic therapy	23%
Chemical thrombolysis	14%
Mechanical thrombectomy	9%
Clinical outcomes	
Residual neurological deficits, excluding death (n = 21)	5%
Death (n = 26)	19%

The sample sizes provided in parentheses represent the number of evaluable cases for each variable of interest.

## TH-PO514

**Membranous Nephropathy in the Setting of Adult-Onset Still Disease: A Rare Association**Shruti Shettigar, Surafel K. Gebreselassie, Shane A. Bobart. *Cleveland Clinic Florida, Weston, FL.*

**Introduction:** Adult onset still's disease (AOSD), is a multi-system, autoimmune, inflammatory disorder. Typically, if a patient with AOSD presents with proteinuria, the initial concern is secondary renal amyloidosis given the severity and persistence of inflammation. We present a case of a patient with AOSD and proteinuria with biopsy proven membranous nephropathy (MN). The association of AOSD with MN is rare and to our knowledge, there is only one other published case of AOSD subsequently being diagnosed with MN.

**Case Description:** A 19 year old African American female presented to the Nephrology clinic for evaluation of non-nephrotic range proteinuria. Approximately 2 years prior at another institution, she presented with rash, arthralgia, and nightly fevers with severely elevated inflammatory markers and low positive ANA (1:80). She was diagnosed with Still's disease and treated initially with prednisone followed by canakinumab an IL-1 $\beta$  inhibitor for 1 year. Symptoms persisted with development of lymphadenopathy, hepatomegaly, ferritin as high as 15797 ng/ml and CRP 137 mg/dL. She was then treated with three other biologics including anakinra (IL-1R antagonist), tocilizumab (IL-6R antagonist) and then maintained on sarilumab (IL-6R antagonist). At Nephrology presentation, urinalysis showed no hematuria but 3+ proteinuria, confirmed to be 1.4 grams/24 hr. Serum albumin was 3.2 g/dL and serum creatinine 0.45 mg/dL. She was normotensive and had no edema on examination. Additional serological work up was unrevealing with negative dsDNA, normal C3 and C4, negative PLA2R, extractable nuclear antigens, ANCA, cryoglobulin, no infectious causes and HbA1c 5.8. Given persistent proteinuria, a kidney biopsy was done with unrevealing light microscopy, mild foot process effacement and subepithelial immune-complex type deposits on electron microscopy. On immunofluorescence, 3+ IgG, kappa and lambda within the distribution of subepithelial deposits confirmed the diagnosis of an early membranous nephropathy. PLA2R and Congo red stain were both negative. She was started on losartan with improvement in proteinuria to 0.6 grams.

**Discussion:** While secondary renal amyloidosis remains a clinical concern in AOSD presenting with proteinuria, clinicians should perform a kidney biopsy as other lesions such as membranous nephropathy may be rarely associated.

## TH-PO515

**Mercury Toxicity due to Skin Lightening Products as a Cause of Mercury-Associated Membranous Nephropathy (M-MN)**Karim El Hachem,<sup>1</sup> Joshua Trebach,<sup>2</sup> Rohan Bansal,<sup>2</sup> Stephen C. Ward,<sup>1</sup> Bob S. Hoffman,<sup>2</sup> Ira S. Meisels.<sup>1</sup> <sup>1</sup>*Icahn School of Medicine at Mount Sinai, New York, NY;* <sup>2</sup>*New York University, New York, NY.*

**Introduction:** Mercury-associated Nephrotic Syndrome (NS) presents as Minimal Change Disease or less commonly as Membranous Nephropathy. Skin lightening products (i.e., creams) are commonly used in certain areas of the world. Unfortunately, these products often contain inorganic mercury, which can be absorbed through the skin. Chronic mercury exposure leads to systemic toxicity with subsequent peripheral neuropathy, dermatitis, renal impairment and autoimmune phenomena. We report a case of M-MN.

**Case Description:** A 38-year-old woman recently immigrated from Senegal was referred for NS evaluation. Her exam was notable for a normal blood pressure, 1+ bipedal edema and eczematous lichenified lesions on her back, shoulders, hands and feet. Additional history taking elicited use of several skin lightening products for more than 10 years, which prompted testing for mercury levels. See Table1 for laboratory results, and Figure1 for biopsy findings. She received diuretics, ARB and high-intensity statin therapy and received no immunosuppression. In consultation with toxicology, she was treated with dimercaptosuccinic acid. After her first round of chelation, her proteinuria mildly improved, her serum mercury level decreased by half while her urine mercury levels appropriately rose. Additional chelation is planned.

**Discussion:** Although rare, M-MN can be encountered in the US despite the limited use of unregulated products containing mercury. We highlight the importance of careful history taking and suggest questioning patients about the use of such products as part of the initial work up and evaluation of NS.

	Initial Presentation	At completion of 1st round of DMSA
Creatinine, serum (0.57 - 1.00 mg/dL)	0.56	0.6
Albumin, blood (3.8 - 4.8 g/dL)	2.4	2.5
Total protein, serum (6.0 - 8.5 g/dL)	4.7	4.4
Hemoglobin (11.1 - 15.9 g/dL)	14.8	12.9
Platelet (150 - 450 x10E3/uL)	451	443
Total Cholesterol (100 - 199 mg/dL)	732	365
HDL Cholesterol (>39 mg/dL)	54	61
LDL Cholesterol, calculated (0 - 99 mg/dL)	630	268
Triglycerides (0 - 149 mg/dL)	163	191
Urine Protein/Cr ratio (mg/gm creatinine)	10,611	7,518
Urine Albumin/Cr ratio (mg/gm creatinine)	7,321	4,821
Phospholipase A2 Receptor Ab, IgG ; <14.0 - Negative; 14.0 - 12.8 - Borderline; >19.9 - Positive	<1.8	<1.8
WBC on UA	0	0
Mercury Blood (0.0 - 14.9 ug/L) [Environmental Exposure <15.0; Occupational Exposure BEI-Inorganic Mercury 15.0]	20.3	10.5
Mercury Urine, random (0 - 19 ug/L)	228	196
Urine Mercury/Cr ratio (0 - 5 ug/g creatinine) [Environmental Exposure: < 5; Occupational Exposure: BEI 35]	139	228

Table 1. Laboratory results of the patient on initial presentation and at completion of first round of therapy with Dimercaptosuccinic acid (DMSA) at 10 mg/kg, 3 times daily for 5 days followed by 10 mg/kg twice daily for 14 days. Total DMSA dose of 30.5 gm administered. Additional work up was negative including ANA, C3, C4, HSAIg, HCV Ab, HIV and RPR. Serum and Urine Immunofixation showed no monoclonal protein. Normal Kappa/Lambda ratio. Hemoglobin A1c 5.0%.

Figure 1. Kidney Biopsy findings- (A) and (B) - Light Microscopy showing thickened capillary loops on (A) PAS and (B) Jones Silver stain. (C), (D) and (E) - Immunofluorescence findings showing 1-2+ segmental staining for IgG, IgA and Kappa respectively. (F) - Immunohistochemical stain for Anti-Phospholipase A2 Receptor shows patchy and wispy staining - but without definitive granular diffuse or linear pattern such as that seen with primary PLA2R membranous nephropathy - interpreted as negative. (G) and (H) - Electron microscopy showing diffuse foot process effacement with several capillary loops containing small, patchy subepithelial deposits with associated subepithelial spikes (G) with no mesangial deposits (H) or endothelial tubuloreticular inclusions noted.

## TH-PO516

**Anti-PLA2R Membranous Nephropathy Associated With Multiple Sclerosis: First Case Report**Milena V. Cunha, Vinícius S. Silveira, Lucas A. Souza, Guilherme D. Silva, Leandro T. Lucato, Livia B. Cavalcante, Lectícia Jorge, Cristiane B. Dias, Irene L. Noronha, Luis Yu. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

**Introduction:** Membranous nephropathy (MN) is a common cause of adult nephrotic syndrome, 80% are considered primary, in which the main antigens are the M-type phospholipase A2 receptor (PLA2R), thrombospondin type 1 domain-containing 7A (THSD7A) and neuro epidermal like growth factor 1 (NELL-1). Recently, new antigens have been described, including contactin-1, a podocyte and neuronal adhesion molecule with similarities with PLA2R and THSD7A, responsible for a MN associated with chronic inflammatory demyelinating polyneuropathy (CIDP).

**Case Description:** 57 years old, white male, who complained of legs swelling, foamy urine and arterial hypertension in the last 4 months. He also complained of left acute painful vision loss 5 days ago. His laboratory exams demonstrated: Creatinine 1.4g/dL; Urine1 - protein 5g/L, Leukocytes0, Eritrocytes0; urine protein/creatinine ratio 8.8g/g; serum albumin 2.1g/dL; cholesterol 270mg/dL; Complement C3 and C4 normal. Serum anti-PLA2R 406UR/ml (Elisa). Screening for other autoimmune diseases, infections and cancer resulted negative. Kidney biopsy revealed stage 1/2 MN (Fig 1) and immunofluorescence showed diffuse granular subepithelial deposits of IgG and C3. Cranial NMR revealed periventricular white matter alterations suggestive of demyelinating CNS disease (Fig 2) and optic neuritis.

**Discussion:** This is the first report of an anti-PLA2R MN with concurrent MS. A common pathogenesis is suggested, similarly to MN associated to CIDP. We suggest that the immune response in the primary MN may have unmasked other podocyte antigens, such as contactin 1, causing simultaneously the neurological involvement. Further investigation is necessary for pathogenesis elucidation.

## TH-PO517

### Systemic AL Amyloidosis With an Undetectable Plasma Cell Dyscrasia: A Rare Entity

Jorge Gaytan Arocha, Juan Carlos Ramirez-Sandoval, Ricardo Correa-Rotter, Juan M. Mejia-Vilet. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Introduction:** AL Amyloidosis is characterized by a plasma cell dyscrasia that can be detected in 99% by monoclonal protein on abnormal serum free light chain (sFLC) concentrations or immunofixation electrophoresis (IFE).

**Case Description:** A 47-year-old man was admitted to the emergency department and afterward to the intensive care unit due to severe COVID-19-associated pneumonia. Initial laboratory studies showed: hemoglobin 12.1 g/dL, creatinine 2 mg/dL, albumin 1.69 g/dL, AST 20 U/L, ALT 19 U/L, urine analysis with no erythrocytes, urine protein/creatinine ratio 4.9 g/g, HbA1c 5.5%, C3 150 mg/dL, C4 35 mg/dL. Serological testing for hepatitis B, C, HIV, ANA, and anti-PLA<sub>2</sub>R were negative. After three months of hospitalization, the patient was discharged home and lost his outpatient follow-up. He returned five months later with a nephrotic syndrome. Laboratory studies showed: creatinine 1.47 mg/dL, urine proteins 5.7g/day, sFLC  $\lambda$  90.1 mg/L (8.3-27), sFLC  $\kappa$  43 mg/L (6.7-22.4), sFLC ratio 0.48 (0.31-1.56), urine and serum protein electrophoresis negative, urine and serum IFE negative. We performed a renal biopsy, consistent with amyloidosis with positivity for Congo red staining. Immunofluorescence reported light chain restriction +++ for  $\lambda$  (figure 1) and was negative for IgG, IgM, IgA, C1q, C3c,  $\kappa$ , and albumin. A bone biopsy reported no evidence of plasmatic cell neoplasia and was negative for Congo red staining. An echocardiogram showed no evidence of amyloid affection. Hematology stratified the patient as low risk, so they started protocol for autologous stem cell transplantation as definitive treatment but decided to consider CyBorD as induction therapy.

**Discussion:** This case illustrates a patient with systemic AL amyloidosis without evidence of plasma cell dyscrasia by conventional techniques. It could be explained because the hematologic disease is so subtle that it goes undetected. The parameter for response in his follow-up will be the improvement of proteinuria, as we cannot measure classic criteria of hematologic response.

Figure 1

## TH-PO518

### Abiotrophia defectiva-Induced Cryoglobulinemic Glomerulonephritis

Michael Turk, Patricia Khalil. *Allegheny Health Network, Pittsburgh, PA.*

**Introduction:** Infection-related glomerulonephritis (GN) has several unique presentations. Some microorganisms may not be detected on routine diagnostic testing. *Abiotrophia defectiva*, for instance, is a nutritionally deficient streptococcus that is slow growing on culture media. Here, we describe a case of *A. defectiva* associated GN and infective endocarditis (IE).

**Case Description:** A 65-year old female with past medical history of paroxysmal A-fib, mitral valve repair due to chordae tendinae rupture presented to her PCP office with myalgias in the setting of elevated inflammatory markers so was sent to Rheumatology for

further work up, which was significant for Creatinine (Cr) of 1.0, microscopic hematuria, positive c-ANCA, PR3 serologies and rheumatoid factor, but normal complement levels. She was negative for dsDNA and Hepatitis B & C. Her symptoms of worsened with fatigue and malaise so she was referred to the hospital for admission. At this point, her Cr had risen to 1.5. Urine microscopy showed dysmorphic RBCs. She underwent kidney biopsy which showed immune complex mediated focal segmental GN with crescent formation. Immunofluorescence showed granular, mesangial and capillary loop staining for IgM and C3. Electron microscopy showed subendothelial and mesangial immune deposits. CD68 staining was positive in macrophages, consistent with cryoglobulins. These results were consistent with cryoglobulinemic GN. In the meantime, she became more short of breath, and transthoracic echo was obtained which showed severe transvalvular mitral regurgitation along with a mobile echodensity arising from the mitral valve, new from echo 1 month prior. A transesophageal echo confirmed the presence of a vegetation, consistent with IE. Her blood cultures, drawn about 5 days prior, finally resulted as positive for pansusceptible *A. defectiva* in 1/4 bottles. She was treated with antibiotics and underwent surgical repair of her mitral valve.

**Discussion:** *A. defectiva* has been described in the literature as a rare cause of culture negative IE however there has only been one case of ANCA GN associated with this bacteria. This case highlights the importance of a thorough infectious workup that goes beyond blood cultures in patients with biopsy proven cryoglobulinemic GN, especially in hepatitis-negative patients. Should all patients with similar presentation undergo more advanced imaging such as TEE to evaluate indolent infections?

## TH-PO519

### When the Eyes Become the Window for the Kidneys: A Case of Rapidly Progressive C3 Glomerulonephritis

Andres J. Azuero,<sup>1</sup> Jillian Caldwell,<sup>2</sup> Adetokunbo A. Taiwo,<sup>2</sup> Alex A. Velaz,<sup>1</sup> Margaret K. Yu,<sup>2</sup> <sup>1</sup>Mount Sinai Medical Center, Miami Beach, FL; <sup>2</sup>Stanford University, Stanford, CA.

**Introduction:** C3 glomerulonephritis (C3GN) is a rare disease caused by dysregulation of the alternative complement pathway. We present a case of rapidly progressive C3GN with visual symptoms.

**Case Description:** A 21 year old woman presented to the Ophthalmology clinic for worsening blurry vision over 3 months. Blood pressure was 220/144 mmHg. Fundoscopic exam revealed bilateral central venous and arterial vascular occlusion, extensive cotton wool spots, few hemorrhages, and hypopigmented choroidal spots. Laboratory data was notable for hemoglobin 10.8 g/dL and serum creatinine of 3.49 mg/dL. Urinalysis had 3+ protein and 2+ blood. Urine protein/creatinine ratio was 5.3 g/g and 24 hour urine protein was 4.6 g. Serologic evaluation for glomerulonephritis was unremarkable. Kidney biopsy showed 75% global glomerulosclerosis, few fibrocellular crescents, 90% interstitial fibrosis and tubular atrophy. Immunofluorescence showed 3+ diffuse granular staining in the mesangium for C3, consistent with C3GN. Immunosuppression was not given due to the advanced fibrosis on her biopsy. The patient had rapid progression of disease and required initiation of hemodialysis 7 months after her diagnosis as a bridge to renal transplant. Genetic testing was inconclusive; several variants of uncertain significance were identified and thought to be benign. No gammopathy was identified.

**Discussion:** Most cases of C3GN manifest as nephritic or nephrotic syndrome and it is common for patients to have preserved kidney function at presentation. ESKD tends to develop over 10 years. It is unusual for C3GN to be a rapidly progressive disease, as observed in this case. In a series of 114 patients with C3GN, only 10% progressed to ESKD over a median of 22 months. This patient's eye exam was suggestive of hypertensive disease and Purtscher-like retinopathy, a rare angiopathy that may result from complement activation; its correlation with severity of renal disease remains uncertain. In addition to nonspecific therapy for proteinuria, MMF plus steroids or eculizumab alone may be considered based on the severity of proteinuria and degree of renal fibrosis. Additional studies are needed to establish if rapidly progressive cases are treatment responsive or have a higher recurrence risk after kidney transplantation.

## TH-PO520

### An Atypical Case of IgG4 Nephropathy

Andres J. Azuero, Cesar Zambrano, Alex A. Velaz, Jonathan Da Costa. *Mount Sinai Medical Center, Miami Beach, FL.*

**Introduction:** IgG4 disease is a rare fibroinflammatory condition that affects many organ systems. We present a case of isolated IgG4 Nephropathy in a patient with HIV.

**Case Description:** A 61 yr old male with history of controlled HIV on HAART presented to the Nephrology clinic for 1 year of progressively worsening bilateral lower extremity edema. He had no other associated urinary, respiratory, cardiovascular or rheumatologic symptoms. Laboratory data was remarkable for: UA with 4+ protein, 10 to 30 WBC, 10 RBC and hyaline casts. Creatinine was 1.45mg/dl, BUN 20mg/dl, Albumin 2.4g/dl and a 24 hr urine protein excretion of 9gr. Kidney biopsy showed chronic active tubulointerstitial nephritis with many IgG4 staining plasma cells and eosinophils. Glomerular capillary wall staining for IgG, C3, Kappa and lambda was present with negative PLA2R immunostaining. Findings suggested IgG4-KD with mixed phenotype of both TIN and MGN. IgG4 levels, serologies for post-infectious, autoimmune and hematologic diseases were normal and there were no imaging findings of retroperitoneal fibrosis, renal masses, hepatitis/pancreatitis or neoplastic disease. The patient was treated with an ARB, a diuretic and 1 mg/kg of prednisone. He has had a good response to treatment without signs of relapse.

**Discussion:** IgG4 disease with isolated renal involvement has been described in a minority of case report series. There is uncertainty of whether this is a distinctive phenotypic hallmark or a time sensitive matter. Most cases are characterized by TIN

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

and only about 7% present with MGN and nephrotic range proteinuria. Of those, half of the subjects had a mixed histology with both TIN and MGN as our patient did. TIN is presumed to be responsible for disease progression and fibrosis. Most cases have a favorable response to prednisone. Rituximab can be considered in case of severity or recurrence. Lack of robust data make it difficult to establish whether these histologic findings correlate with response to treatment and/or relapse. Our patient's case is extremely rare given the lack of systemic and serologic features of the disease on top of a complex renal histology. It is uncertain whether his history of HIV contributes to this atypical presentation as both conditions are T cell mediated. Lack of signs of HIV nephropathy on his biopsy make IgG4 the most likely etiology.

## TH-PO521

### Narsoplimab Treatment for Recurrent IgA Nephropathy Stabilized eGFR and Proteinuria

Joshua Storrar,<sup>1</sup> Francesco Rainone,<sup>1</sup> Rachel Middleton,<sup>1</sup> Jonathan Barratt,<sup>2</sup>  
<sup>1</sup>Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom;  
<sup>2</sup>Leicester General Hospital, Leicester, United Kingdom.

**Introduction:** IgA nephropathy (IgAN) recurrence is a risk post-transplantation, and treatment options are limited. The complement system plays an important role in the pathogenesis of IgAN. Narsoplimab is an investigational mAb that targets the effector enzyme of the lectin pathway of complement, MASP-2. We present the first report of a complement inhibitor being used for treatment of recurrent IgAN.

**Case Description:** A 53-year-old male with hypertension diagnosed with IgAN in 2010 underwent a live related kidney transplant in 2014. Transplant biopsy in 2019 due to rising proteinuria (peak urine protein:creatinine ratio [uPCR] 429 g/mol) revealed strong mesangial positivity for IgA with weaker C3 staining. EM supported diagnosis of recurrent IgAN. The patient was monitored for 17 months with repeat biopsy undertaken in Nov 2020 due to falling estimated glomerular filtration rate (eGFR, 30 ml/min/1.73m<sup>2</sup>), rising uPCR (818 g/mol), and symptomatic worsening oedema. The patient was treated with budesonide, along with compassionate use narsoplimab, which was started Feb 2021 for 18 weeks, and completed Jul 2021 (Fig). eGFR from start to end of treatment remained stable from 21 ml/min/1.73m<sup>2</sup> to 18 ml/min/1.73m<sup>2</sup>, whereas it dropped significantly in the 6 months prior from 36 ml/min/1.73m<sup>2</sup> to 21 ml/min/1.73m<sup>2</sup>. uPCR from start to end of treatment dropped significantly from 1,191 g/mol to 467 g/mol. A biopsy taken in Jul 2021 showed features of advanced recurrent IgAN. The patient received 5 more infusions of narsoplimab between Dec 2021 and Jan 2022, but subsequently progressed to end-stage kidney disease and began dialysis.

**Discussion:** This is the first time narsoplimab has been reported to stabilize eGFR and uPCR in a patient with recurrent IgAN. The lack of complement degradation products seen with IF on kidney biopsy post-treatment suggests that stabilization is due to complement inhibition. Further reports of narsoplimab use in progressive recurrent IgAN are eagerly awaited.

## TH-PO522

### A Case of Fibrillary Glomerulonephritis Presenting With Asthma Responsive to Corticosteroids

Bobak Sharifi,<sup>1</sup> Corey J. Cavanaugh,<sup>1</sup> Negini Pourafshar,<sup>2</sup> <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>Georgetown University, Washington, DC.

**Introduction:** Fibrillary glomerulonephritis (FGN) is a rare cause of rapidly progressive glomerulonephritis (RPGN). The typical FGN clinical presentation includes renal insufficiency, hematuria, proteinuria and nephrotic syndrome. Rarely extrarenal manifestations are seen. Herein we describe a case of FGN presenting with asthma.

**Case Description:** A 51-year-old female with a history of celiac disease, tobacco abuse, and Hashimoto's thyroiditis was admitted twice in a two-week period for refractory lower extremity edema, petechial rash, wheezing, and fevers. She was initially admitted to the medicine service for asthma exacerbation and bacterial pneumonia, which dramatically improved with antibiotics and corticosteroids. Unfortunately, she re-presented 2 weeks later, with recurrence of dyspnea and wheezing. Her creatinine rose to 2.5mg/dL, above a baseline of 0.8mg/dL over two weeks. Chest CT on admission showed ground glass opacities that resolved on repeat scan in three weeks. Her urinalysis was significant for large blood and protein to creatinine ratio of 5.8g/g. She had

hypoalbuminemia 2.2g/dL and edema. Serologic workup including SPEP, HIV, Hepatitis C, ANCA, and Anti-GBM were negative, only ANA was positive at 1:80. Kidney biopsy was performed, and electron microscopy revealed randomly arranged fibrils ranging from 15-23nm in diameter, immunofluorescence with linear deposition of IgG, C3, fibrin, kappa and lambda light chains. A single crescent was noted in one of seventeen glomeruli. Stains for DNAJB9 showed diffuse granular staining of both the mesangial and capillary loop basement membrane within the glomeruli. She was treated with prednisone (1mg/Kg) to target asthma and glomerular disease with a 3-month taper, losartan, and an SGLT2 inhibitor. Her proteinuria decreased from 5.8g/g to 1g/g at one year follow up for partial remission. She quit smoking completely and her pulmonary symptoms resolved. Creatinine fell to 1.8mg/dL and remained stable for 2 years.

**Discussion:** FGN has a poor prognosis and there are no randomized controlled trials to guide optimal therapy. Our case highlights the difficulty in recognition and management of patients with RPGN as multiple etiologies with unusual presentations can provide dilemmas in management. This atypical presentation of RPGN with asthma and improvement with steroids and smoking cessation is particularly unique.

## TH-PO523

### Membranoproliferative Glomerulonephritis (MPGN) in the Setting of Unicentric Castleman Disease

Ali W. Rizvi, Dale M. Kobrin, Naman Gupta, Michael Turk, Luba Muaddi, Swati Arora. Allegheny Health Network, Pittsburgh, PA.

**Introduction:** Castleman's disease (CD) is a rare lymphoproliferative disorder with histopathological abnormalities - divided primarily into unicentric and multicentric disease. Thought to be an inflammatory process, renal involvement has been described extensively in the setting of multicentric disease, especially associated with HHV-8. However, similar reports in unicentric disease are rather limited.

**Case Description:** A 33 year old female with asthma developed hematuria and proteinuria in the setting of chronic right flank pain and intermittent night sweats for about 2 years. With a stable creatinine (Cr) level of 0.7 mg/dL, blood work was negative for C3, C4, cryoglobulins, and hepatitis panels. UA showed no hematuria, but did reveal 0.6 - 1.0 g of proteinuria. Imaging revealed 2 mesenteric soft tissue nodules, largest measuring 2.4 cm. A renal biopsy was significant for immune complex MPGN with kappa and c3. PET-CT at 1 year revealed hypermetabolic mesenteric nodules suspicious for malignancy. Nodular biopsy showed atypical B-lymphoid infiltrate initially concerning for marginal cell lymphoma. Referral to Mayo Clinic was confirmatory for hyaline vascular unicentric Castleman's disease. HHV8, PCR for B-cell receptor gene rearrangement and FISH for t(11:18) were negative. Referral made to Rheumatology for MPGN and moderate concern for systemic lupus erythematosus (SLE) with ANA 1:160 and BC4d, however no systemic symptoms of SLE. Follow-up imaging showed a decrease in lymphadenopathy from 2.3 to 1.6 cm, with plan for conservative management. Patient's proteinuria persisted at 821.5 mg with plan for ACE inhibitor but avoided in the setting of the patient's third pregnancy.

**Discussion:** Renal involvement is typical in multicentric CD so, we present a unique case of unicentric CD associated with MPGN. Persistent proteinuria and MPGN with ANA 1:160 and BC4d placed lupus nephritis versus Castleman's induced nephropathy on the differential. However, lack of SLE symptoms, normal complement and double stranded DNA indicated a unique disease presentation of Castleman's with proteinuria.

## TH-PO524

### Membranoproliferative Glomerulonephritis Associated With Tuberculosis, "the Great Imitator": Case Report

Rodolfo A. Moreno,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>3,4</sup> Angel D. Natareno,<sup>1,2</sup> Werner De León,<sup>5</sup> Mario Sierra,<sup>1,2</sup> Jonathan Chavez.<sup>3,4</sup> <sup>1</sup>Centro Medico Militar, Guatemala, Guatemala; <sup>2</sup>Universidad Mariano Galvez de Guatemala Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala; <sup>3</sup>Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; <sup>4</sup>Universidad de Guadalajara, Guadalajara, Mexico; <sup>5</sup>SERPAT, Guatemala, Guatemala.

**Introduction:** Tuberculosis (TB) is a multisystemic disease of pulmonary predominance caused by Mycobacterium tuberculosis; the kidney can be affected in different ways but as Membranoproliferative glomerulonephritis (MPGN) its an unusual presentation.

**Case Description:** A 19-year-old Guatemalan male patient with a 3-day history of malaise and fever. No previous medical history. On evaluation at the ER presented with hypertension and AKI with progressive elevation of SCr (admission 2.54mg/dL, max 6.45mg/dL) associated with proteinuria and hematuria. Laboratories: hypoalbuminemia (2.5g/dL), proteinuria 12g/day, hypocomplementemia (C3 0.04, C4 normal) ANAs, ANCAs HIV, HBV, HCV, urine culture negative, Kinyoun stain in urine with BAAR (+). Renal biopsy was performed, that reported MPGN with 50% of globally sclerosed glomeruli, 3 cellular crescents, mesangial proliferation, endocapillary hypercellularity, basement membranes with formation of double contours and "wire loops". IF: IgM (+++), C4d (+++) with diffuse granular pattern in glomerular basement membranes and subendothelium, tubulointerstitium with lymphocytic infiltrates. The patient received methylprednisolone pulses for 3 doses, oral prednisone (1mg/kg/day) and tapered until suspended and 4-drug anti-TB regimen with improvement in SCr to 3.9mg/dL and normalization of complement C3 at 10 days.

**Discussion:** The pathogenesis of TB-associated MPGN is unknown. Histopathologically it can mimic different types of glomerulopathies (IgAN, collapsing, mesangiocapillary, membranous, crescentic GN, membranoproliferative and PIGN). Antibodies against M. tuberculosis activate the complement pathway generating the

formation of antigen-antibody complexes that generate MPGN. The specific treatment is not yet known due to the rarity of the presentation, but antifibrotics and steroids are suggested in case of crescents.

#### TH-PO525

##### **Methemoglobinemia With Dapsone Prophylaxis in a Patient With Minimal Change Disease**

Manuel J. Rovira-Gonzalez, Robert Pargament. *WellSpan York Hospital Department of Internal Medicine, York, PA.*

**Introduction:** Methemoglobinemia has been most commonly associated with medication and anesthetic use, dapsone and benzocaine being the most common agents. Methemoglobinemia leads to tissue hypoxia by creating ferric ( $\text{Fe}^{3+}$ ) hemes where oxygen is unable to bind, increasing the affinity of oxygen to hemoglobin, and therefore, reducing oxygen delivery to tissue. In the case of dapsone, it is the potent hydroxylated amine oxidant metabolites that causes dapsone's adverse effects including methemoglobinemia and hemolytic anemia. Clinical presentation of methemoglobinemia results in refractory hypoxemia, cyanosis, and dark-colored arterial blood.

**Case Description:** A case report about a 42-year-old male with minimal change disease required pneumocystis jiroveci pneumonia prophylaxis due to high dose steroids. Patient was started on dapsone due to side effects and availability from alternative medications. Patient was tested negative for glucose-6-phosphate dehydrogenase deficiency prior to starting dapsone. Since starting therapy, patient developed progressive dyspnea upon exertion for two weeks with intermittent hypoxia. He was also on therapeutic enoxaparin due to hypercoagulability state from nephrotic syndrome. Patient presented with hypoxia and dyspnea upon exertion, however, speaking in complete sentences and with no cyanosis or overt findings of hypervolemia. Patient remained hypoxemic despite supplemental oxygen. An arterial blood gas was performed and showed methemoglobin levels of 10.6 percent. Patient was treated with methylene blue with resolution of methemoglobinemia and hypoxemia after second dose. Trimethoprim-sulfamethoxazole was started for pneumocystis jiroveci pneumonia prophylaxis. He was safely discharged home.

**Discussion:** Patients can present with methemoglobinemia without classical symptoms; however, desaturations, a saturation gap, and shortness of breath are other signs and symptoms to be aware of in the absence of cyanosis. It is unclear if nephrotic syndrome increases risk of methemoglobinemia due to dapsone. We want to increase awareness of reported cases and further association is needed to understand the pathophysiology in dapsone-induced methemoglobinemia in patients with nephrotic syndrome.

#### TH-PO526

##### **Beguiling but Harmful: IgA Nephropathy Manifests**

Maria E. Rivera, Jesus D. Vega-Colon, Alexis Rivera Gonzalez, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

**Introduction:** IgA nephropathy (IgAN) is the most common pattern of primary glomerular disease worldwide and remains a leading cause of CKD. Given its prevalence, attention should be paid to risk factors of progression.

**Case Description:** A 22-year-old female with atopic dermatitis, complains of 6-month history of worsening bilateral leg edema associated with frothy dark urine. Denied recent skin, respiratory or gastrointestinal infections. No use of NSAID's or other nephrotoxins. No family history of renal disease. Toxic habits were remarkable for marijuana smoking. Examination revealed blood pressure 166/88 mmHg and pitting edema +2 up to shins. Laboratory results notable for anemia, BUN 25.7 mg/dL, creatinine 2.64 mg/dL, albumin 2.2 g/dL and bicarbonate 21.8 mmol/L and uric acid 5.9 mg/dL. Urinalysis with proteinuria, hematuria, granular casts and fat oval bodies. Urine protein-creatinine ratio of 8,300 mg/g, consistent with nephrotic range proteinuria. Testing for HIV, Hepatitis B and C, ANA, complements C3/C4, and serum free light chains were

normal. Renal biopsy showed mesangial proliferation with crescent formation by light microscopy with IgA staining in IF. EM showed mesangial and subendothelial deposits with foot processes effacement. There was moderate glomerulosclerosis and interstitial fibrosis. Treatment was started with prednisone 60 mg daily, furosemide, low sodium diet, losartan and atorvastatin. A month after diagnosis, patient presented with worsening renal function and edema. Despite medical treatment, patient continued to deteriorate requiring kidney replacement therapy. Unfortunately, patient did not recover and was discharged home dependent of hemodialysis.

**Discussion:** IgAN may present in a myriad of ways. From progressive CKD to nephritic syndrome, and all the spectrum in between. After diagnosis, one fourth of patients will progress to ESKD within 20-25 years of presentation. Our patient presented with nephrotic syndrome and rapidly progressive glomerulonephritis with multiple markers for poor prognosis like hypertension, proteinuria above 1 gm/day, and histologic predictors of disease progression such as chronic fibrotic disease, tubular atrophy and interstitial fibrosis on biopsy. Overall, the prognosis of IgAN may be difficult to predict but identifying these risk factors early may guide clinicians and patients.

#### TH-PO527

##### **A Case of Lupus Nephritis (LN) With Concomitant Renal Thrombotic Microangiopathy (TMA) Treated With Eculizumab as a Rescue Treatment**

Nehemias Guevara,<sup>1,2</sup> Mahmoud Ali,<sup>1,2</sup> Sae Morita,<sup>1,2</sup> Marjorie Mailing Flores Chang,<sup>1,2</sup> William M. Paredes,<sup>1,2</sup> Hamed Sarikhani,<sup>1,2</sup> Bessy Suyin Flores Chang,<sup>1,2</sup> <sup>1</sup>St Barnabas Hospital, Bronx, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.

**Introduction:** LN is a common and severe consequence of SLE, however, LN and TMA together are not common. When both are present the outcome is worse. To date, there are no clear guidelines for standard therapy, however, eculizumab has been used as rescue therapy with a favorable outcome

**Case Description:** 28 year old female with a PMH of SLE since 2013, LN class IV/V, recurrent serositis, sickle cell trait with chronic pain, schizophrania, and asthma consulted with encephalopathy and generalized pain. Vital signs: BP: 106/76, HR:100 beats/min, RR: 16 breaths/min, T: 97.5 F, SatO2: 100% on room air. The patient was found to be in acute respiratory failure due to fluid overload and was subsequently intubated. Physical examination: agitated, tachypneic, dry mucous membranes, lung crackles bilaterally in lower fields, S1 S2 present, bilateral lower pitting edema 2+ up to the thighs. Blood work was remarkable for normocytic anemia, hyperkalemia, acute renal failure superimposed to chronic renal failure, transaminitis, and elevated troponin levels. The patient was started on IV antibiotics and emergent hemodialysis. Pulse steroids with solumedrol were also initiated for a possible lupus flare. Immunological workup revealed low C3, C4 with positive anti-double-strand DNA antibodies. Patient underwent a kidney biopsy which revealed focal crescentic glomerulonephritis with membranous and sclerosing features consistent with lupus nephritis class IV (A/C) and V. As well revealed active chronic TMA, moderate tubular atrophy, and interstitial fibrosis. (Images 1,2 3) The patient did not improve with standard therapy (plasmapheresis, mycophenolate, steroids), prompting the use of eculizumab, after which the patient presented improvement (table 1), and dialysis was discontinued

**Discussion:** TMA associated LN represents a progressive and dismal outcome with variable responses to standard treatment. The mechanism of TMA in autoimmune diseases is associated with the alternative complement pathway where Eculizumab plays an important role and is currently being explored in the treatment for LN. Our patient presented with LN + TMA, failed standard treatment, and improved with Eculizumab. We hope in the near future Eculizumab will be the standard therapy for this type of association

#### TH-PO528

##### **Antinuclear Antibody Negative Lupus Presenting as Nephritis**

Ananthalexmi Vangapalli. *Albert Einstein Medical Center, Philadelphia, PA.*

**Introduction:** Lupus nephritis (LN) is a serious and common complication of systemic lupus erythematosus (SLE) that predisposes to significant morbidity and mortality. Studies show that prompt diagnosis and treatment improve patient survival.

**Case Description:** 24-year-old Asian-American female with no known past medical history presented to ED for 4 days of fatigue, shortness of breath, and rash. She reports symptoms were there for one year with arthralgias involving bilateral knees, hands and fingers and toes with morning stiffness without significant joint swelling. She noticed episodes of skin rash on extremities, worsened with scratching with an exaggerated pathergy. She has been taking Advil for joint pains. SH: She was born in America. She works as a designer for Pfizer. Labs showed creatinine 2.11 from normal baseline a year ago, with Urine protein to creatinine ratio of 2 grams. Hemoglobin 7 with normal MCV. Platelets, PT/INR, PTT, LDH, and haptoglobin are normal. D-dimer elevated to 2600. Her ANA was negative. CT abdomen pelvis showed hepatosplenomegaly and multiple enlarged lymph nodes. On exam vital signs are normal. Dry mucous membranes and diffuse popular rash in the lower extremities. She underwent a renal biopsy which revealed lupus-like glomerulonephritis, class v/class IV, mild acute tubular necrosis, moderate interstitial inflammation, and mild to moderate interstitial fibrosis. It was called lupus-like nephritis given immunofluorescence negative and multiple deposits on EM. Lymph node biopsy which showed reactive hyperplasia. She was started on Cellcept 1500 mg twice daily and prednisone 60mg daily.

**Discussion:** Literature review on antinuclear antibody (ANA)-negative and seronegative LN revealed the following patient presentations: (1) renal-limited or renal and extra-renal manifestations of SLE with negative serologies and (2) renal and extra-renal manifestations of SLE with negative serologies at presentation who develop positive

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

serologies later in follow-up. Both groups represent a unique and challenging cohort of patients who may require longer follow-up and further testing to rule out other glomerular diseases that may mimic LN on renal biopsy. The absence of SLE-related serologies should be weighed against a high pre-test probability of ANA-negative or seronegative LN. If highly suspected, the patient should be treated promptly with close monitoring.

## TH-PO529

### Identifying the Etiology of Thrombotic Microangiopathy (TMA) Diagnosed by Kidney Biopsy Using Machine Learning Tools (Unsupervised Clustering)

Simon Moubarak,<sup>1</sup> Mariam P. Alexander,<sup>2</sup> Jaleh Zand,<sup>1</sup> Mireille El Ters,<sup>1</sup> Ladan Zand.<sup>1</sup> <sup>1</sup>Mayo Clinic Department of Internal Medicine, Rochester, MN; <sup>2</sup>Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, MN.

**Background:** Thrombotic microangiopathy is a pathologic term that encompasses disorders with different etiologies. Identifying the cause of the TMA lesion remains a clinical challenge. Most TMA cases share similar morphologic findings on microscopy which poses a challenge to determine the cause based on biopsy alone.

**Methods:** We searched renal pathology database at Mayo Clinic between 2010-2020 and identified patients with lesion of TMA on native kidney biopsy as their primary diagnosis who had an established associated cause for TMA. We recorded features commonly associated with TMA lesion by reviewing the biopsy report. We used consensus clustering approach (an unsupervised machine learning technique) using only the kidney biopsy variables to cluster the patients. We then looked to see which etiology of TMA was most prevalent in each cluster and which biopsy features were most predictive of finding that specific etiology.

**Results:** There were 168 adult patients with average age of  $50.3 \pm 16.9$  with 52% male. The most common cause of TMA was malignant hypertension (mHTN) (n=81, 48.2%), drug-induced (n=36, 21.4%), lupus (9, 5.4%) and scleroderma (9, 5.4%). We identified 3 distinct clusters with cluster 1 (n=69), cluster 2 (n=47), cluster 3 (n=52). Cluster 1 was mainly composed of patients with mHTN followed by SRC. Presence of fibrin thrombi in the vessel in addition to presence of mucoid intimal edema and hyperplastic changes in the vessel ("onion skinning") with absence of arteriosclerosis and fibrin tactoids were predictive of such diagnosis. Cluster 2 was mainly composed of patients with pregnancy associated TMA, non-immune drug induced TMA (VEGF inhibitor most common 67%), post BMT and myeloproliferative disease. Presence of severe tubular injury and absence of mucoid intimal edema, fibrin thrombi and arteriosclerosis were predictive of this cluster. Cluster 3 was composed of patients with lupus associated TMA, immun-mediate drug-induced TMA (gemcitabine 60% of cases) followed by aHUS. Presence of mesangiolysis and absence of hyperplastic changes of the vessel were predictive of this cluster.

**Conclusions:** This is the first study to use unsupervised machine learning to help identify the etiology of TMA lesion that is seen on native kidney biopsies by identifying biopsy features that are predictive.

## TH-PO530

### Clinical and Molecular Correlates of Quantitative Foot Process Effacement Assessment in the NEPTUNE Cohort

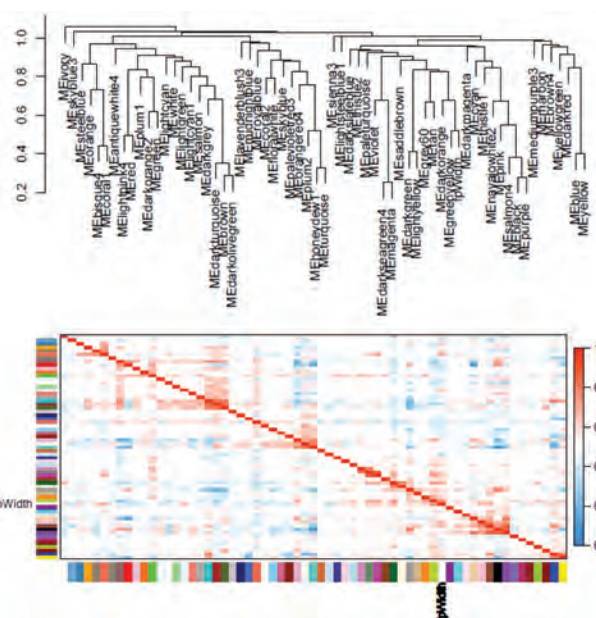

Marco Delsante,<sup>1</sup> Giovanni Maria Rossi,<sup>1</sup> Paride Fenaroli,<sup>1</sup> Giuseppe D. Benigno,<sup>1</sup> Francesco Peyronel,<sup>7</sup> Enrico Cocchi,<sup>2</sup> Jonathan P. Troost,<sup>3</sup> Sean Eddy,<sup>3</sup> Laura Barisoni,<sup>4</sup> Matthias Kretzler,<sup>3</sup> Jarcy Zee,<sup>5</sup> Umberto Maggiore,<sup>1</sup> Avi Z. Rosenberg.<sup>6</sup> <sup>1</sup>Università degli Studi di Parma, Parma, Italy; <sup>2</sup>Columbia University Irving Medical Center, New York, NY; <sup>3</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>4</sup>Duke Medicine, Durham, NC; <sup>5</sup>University of Pennsylvania, Philadelphia, PA; <sup>6</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>7</sup>Meyer Children's Hospital, Florence, Italy.

**Background:** Foot process effacement (FPE) is the ultrastructural hallmark of podocytopathies and is traditionally a visual estimate of percentage foot process loss (%FP). Foot process width (FP-W) could be a more accurate measure of FPE, but whether FP-W robustly correlates with clinical outcomes or gene expression is unknown

**Methods:** %FP was extracted from NEPTUNE study core data. FP-W was measured on micrographs >4000x in minimal change disease (MCD) or FSGS NEPTUNE participants. FPE relationship with laboratory markers of nephrotic syndrome (NS) and CKD was examined. We used weighted gene coexpression network analysis (WGCNA) of gene expression biopsy data to identify Gene Modules (GM) that correlated with FPE and tested a subset of single genes (Sub-GSE) known to be differentially expressed in podocytopathies

**Results:** 55 MCD and 36 FSGS patients had longitudinal follow-up, 42 had gene expression data. %FP were similar between the two groups, FP-W was slightly higher in FSGS versus MCD. %FP and FP-W were associated with longitudinal changes in clinical parameters of NS. Larger FPE extent on biopsy showed greater improvement of serum albumin, cholesterol, and UPCr during follow up ( $P < 0.05$ ); this correlation was attenuated when corrected for %FP. WGCNA (Fig. 1) and Sub-GSE showed that FPE is associated with increased expression of GM, including complement-related genes

**Conclusions:** FPE extent is associated with NS improvement, likely reflecting sensitivity to therapies. FP-W does not add prognostic information beyond %FP. FPE is associated with several genes expression (i.e., complement factors)

Eigengene network (Gene Modules and the FP-W)

## TH-PO531

### An In Situ Ascorbate Peroxidase Labeling in Secreted Exosomes Identifies Oxidative Stress-Induced Exosome Proteome Alteration in Renal Proximal Tubules

Sang-Ho Kwon,<sup>1</sup> Byung Rho Lee,<sup>1</sup> Sekyung Oh,<sup>2</sup> Chang Min Lee.<sup>1</sup> <sup>1</sup>Augusta University, Augusta, GA; <sup>2</sup>Catholic Kwandong University College of Medicine, Incheon, Republic of Korea.

**Background:** The extracellular vesicle exosome mediates intercellular communication by transporting macromolecules such as proteins and ribonucleic acids. Determining cargo contents with high accuracy will help decipher the biological processes that exosomes mediate in various contexts.

**Methods:** Here we report an *in situ* labeling approach for exosome cargo profiling, termed Exosome-Proximal APEX Labeling (EPAL), which bypasses the exosome isolation steps. In EPAL, proteins either in the exosome biogenesis vesicles in cells or in secreted exosomes in the conditioned medium can specifically be biotinylated by expressing a variant of the engineered ascorbic peroxidase APEX that is fused to an exosome cargo protein such as CD63.

**Results:** Mass spectrometry analysis of the proteins biotinylated in exosomes secreted by kidney proximal tubule-derived cells reveals that oxidative stress can induce an alteration in exosome protein contents, including accumulation of ribosomal proteins in exosomes.

**Conclusions:** In sum, our new method specifically labels exosome proteins with a genetic, chemical means *in situ* either in live cells or in secreted exosomes, thereby probing proteins packaged in exosomes and identifying where exosomes originate. This method might be useful to discover exosome-based biomarkers for kidney diseases.

**Funding:** NIDDK Support, Other NIH Support - NCI

## TH-PO532

### PPARα in Proximal Tubules Maintains Systemic Energy Homeostasis During Starvation

Daiki Aomura,<sup>1</sup> Takayuki Nimura,<sup>1</sup> Yosuke Yamada,<sup>1</sup> Makoto Harada,<sup>1</sup> Koji Hashimoto,<sup>1</sup> Motoko Yanagita,<sup>2</sup> Yuji Kamijo.<sup>1</sup> <sup>1</sup>Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan; <sup>2</sup>Kyoto Daigaku Igakubu Fuzoku Byoin, Kyoto, Japan.

**Background:** Peroxisome proliferator-activated receptor alpha (PPARα) is a nuclear transcription factor mainly expressed in the liver and renal proximal tubules (PTs). PPARα is especially activated under energy deficient conditions, such as starvation and severe organ injury, to maintain tissue energy homeostasis by accelerating fatty acid oxidation (FAO). Although earlier research has studied the importance of systemic PPARα in the homeostasis of renal energy metabolism, the role of renal PPARα remains unknown. The present study assessed this issue using PT-specific PPARα knock-out mice under fasting conditions.

**Methods:** *Ppara*<sup>flax/flax</sup> mice were bred with *Ndr1*-CreERT2 transgenic mice to generate *Ndr1*-CreERT2-*Ppara*<sup>flax/flax</sup> mice (PTs-PPARα-CKO). PT-specific defects in PPARα expression after 3 days of tamoxifen injection was then confirmed in the PTs-PPARα-CKO mice by quantitative PCR and immunohistochemical staining. To assess the role of PPARα in PTs, tamoxifen-treated 13-week-old *Ppara*<sup>flax/flax</sup> mice (controls) and PTs-PPARα-CKO mice were fasted for 0, 24, and 48 hours (n=5-7 in each group).

**Results:** Without fasting, the renal gene expressions related to FAO and ketogenesis were significantly lower in the PTs-PPAR $\alpha$ -CKO mice. Although observed phenotypes were similar between the groups, blood glucose level was slightly but significantly lower in the PTs-PPAR $\alpha$ -CKO animals. Under fasting conditions, the renal gene expressions concerning PPAR $\alpha$ , FAO, and ketogenesis were dramatically increased in controls, which was not seen in the knock-out mice. The decrease in blood glucose level with fasting was significantly more severe for PTs-PPAR $\alpha$ -CKO. Moreover, the hepatic gene expressions related to glycogenolysis, gluconeogenesis, PPAR $\alpha$ , FAO, and ketogenesis were all significantly more increased in PTs-PPAR $\alpha$ -CKO mice.

**Conclusions:** Our results demonstrated that PTs-PPAR $\alpha$ -CKO mice were prone to hypoglycemia upon starvation. PPAR $\alpha$  in PTs may play a role in the homeostasis of serum glucose level and systemic energy metabolism.

### Human Scattered Tubular Cells Represent a Heterogeneous Population of Glycolytic Dedifferentiated Proximal Tubule Cells

Martijn van den Broek,<sup>1,2</sup> Jennifer Eymael,<sup>1</sup> Laura Miesen,<sup>1</sup> Valerie J. Villacorta Monge,<sup>1</sup> Bartholomeus T. van den Berge,<sup>1,3</sup> Fieke Mooren,<sup>1</sup> Meyke Hermesen,<sup>1</sup> Péter Bándi,<sup>1</sup> Brigith Willemssen,<sup>1</sup> Sandrine Florquin,<sup>7,8</sup> Roy Wetzels,<sup>1</sup> Rafael Kramann,<sup>5,6</sup> Jack F. Wetzels,<sup>3,4</sup> Jitske Jansen,<sup>1,2</sup> Bart Smeets.<sup>1</sup> Smeetslab <sup>1</sup>Department of Pathology, Radboud Institute for Molecular Life Sciences, Radboud UMC, Nijmegen, Netherlands; <sup>2</sup>Department of Pediatric Nephrology, Radboud Institute for Molecular Life Sciences, Radboud UMC, Amalia Children's Hospital, Nijmegen, Netherlands; <sup>3</sup>Department of Nephrology, Radboud Institute for Molecular Life Sciences, Radboud UMC, Nijmegen, Netherlands; <sup>4</sup>Department of Nephrology, Radboud Institute for Health Sciences, Radboud UMC, Nijmegen, Netherlands; <sup>5</sup>Division of Nephrology and Clinical Immunology, RWTH Aachen University, Aachen, Germany; <sup>6</sup>Institute of Experimental Medicine and Systems Biology, RWTH Aachen University, Aachen, Germany; <sup>7</sup>Department of Pathology, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; <sup>8</sup>Amsterdam Institute for Infection and Immunology, Amsterdam, Netherlands.

**Background:** Scattered tubular cells (STCs) are a phenotypically distinct cell population in the proximal tubule that increase in number after acute kidney injury. Since much of our knowledge about STCs comes from animal experiments, we aimed to characterize the human STC population.

**Methods:** 3D tissue analysis was performed on consecutive immunostained kidney slides. The percentage of STCs was determined using immunofluorescent staining for aquaporin-1 to detect proximal tubule epithelial cells (PTECs) and phosphofructokinase-platelet (PFKP) to detect STCs. STC (CD13+CD24+CD133+) and PTEC (CD13+CD24-CD133-) cells were sorted (FACS) from 5 separate normal nephrectomy samples. Sorted cells were used as input for bulk RNA sequencing.

**Results:** 3D tissue analysis revealed that STCs prefer to locate in the sharp inner bends of the tubule in groups rather than as single cells. STCs are barely present in young kidney tissue (<2 years) and their number significantly increases with age. Also, we observed an increased number of STCs with increased acute tubular injury (KIM-1) as well as interstitial fibrosis (a-SMA). RNA bulk sequencing revealed an upregulation of NF $\kappa$ B, TNF $\alpha$  and other inflammatory pathways in STCs, whereas normal proximal tubular function, metabolism and especially the TCA cycle and oxidative phosphorylation were downregulated. Histologically, we confirmed a glycolytic isoform switch in STCs from pyruvate kinase-Liver (PKL) to PK-Muscle 2 (PKM2) and from PFKL to PFKF. The transcriptome of STCs did not show signs of cellular senescence, confirmed by immunostaining for p53, p16 and lamin B1. Immunostaining and a single-cell RNA sequencing database showed that STCs are in a transient state representing a heterogeneous population with different marker expression, ligand-receptor interactions and pathway activity.

**Conclusions:** Human STCs represent a heterogeneous population of dedifferentiated PTECs showing a metabolic shift towards glycolysis, which could facilitate cellular survival after kidney injury.

## TH-PO534

### The Location and Character of Focal Segmental Glomerulosclerosis Lesions: The Prevalence, Overlap, and Clinical Relevance

Takaya Ozeki,<sup>1</sup> Michifumi Yamashita,<sup>2</sup> Fadhl Alakwaa,<sup>1</sup> Viji Nair,<sup>1</sup> Jarcy Zee,<sup>3</sup> Jeffrey B. Hodgin,<sup>1</sup> Lihong Bu,<sup>4</sup> Avi Z. Rosenberg,<sup>5</sup> Cynthia C. Nast,<sup>2</sup> Matthias Kretzler,<sup>1</sup> Laura Barisoni,<sup>6</sup> Laura H. Mariani.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA; <sup>3</sup>University of Pennsylvania, and Children's Hospital of Philadelphia, Philadelphia, PA; <sup>4</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>5</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>6</sup>Duke University, Durham, NC.

**Background:** The glomerular lesions in focal segmental glomerulosclerosis (FSGS) are histologically heterogeneous for location (L) and characteristics (C). The aim of this study is to investigate the quantitative relationship and clinical relevance of L and C of FSGS lesions.

**Methods:** 134 FSGS participants from the Nephrotic Syndrome Study Network (NEPTUNE) with NEPTUNE digital pathology scoring system (NDPSS) glomerular descriptors, were included. 21 descriptors characterizing L and C of FSGS lesions were grouped into 4 L: Perihilar (PH), Tip (TIP), Mid-glomerular, and Undetermined (UN); and 7 C: Sclerosis (SCL), Hyalinosis (HYA), Cellular-lesion (CEL), Foam cells,

Collapsing-lesion (COL), Epithelial hypertrophy, and Epithelial hyperplasia (HYP). Prevalence and correlations of L and C were analyzed. Patients were grouped based on L or C using consensus clustering. Complete remission (CR) and composite renal outcome (eGFR 40% decline or ESKD) were compared among L-based and C-based clusters by Kaplan-Meier method. Subgroup analyses were performed in nephrotic (NS) (UPCR>3.5 with albumin<3.0 or diffuse foot process effacement, n=41) and non-NS group (n=93).

**Results:** 863/4614 (18.7%) glomeruli contained at least 1 of 21 descriptors.  $\geq$  2 L or C were observed in 48.3% and 91.0% of the biopsies, respectively. Correlations with Spearman's rho>0.5 were observed in TIP-CEL, UN-SCL and COL-HYP. TIP and CEL were more frequent in NS group, while PH, SCL and HYA were more frequent in non-NS group. There were no differences in the clinical outcomes among the L-based nor C-based clusters in overall cohort and non-NS group. In NS group, a difference in CR was observed between 2 C-based (but not L-based) clusters in NS group (p=0.048): A cluster with worse CR rate had higher frequency of all 7 C lesions than the better CR cluster.

**Conclusions:** The application of NDPSS allowed for the quantification of heterogeneity and overlap in location and morphologic characters of FSGS lesions within and across kidney biopsies, with different trends between NS and non-NS participants. In NS participants, high frequency and more variety of C were associated with lower CR rate; while neither L nor C showed impact on clinical outcomes in non-NS participants and NS + non-NS participants together.

## TH-PO535

### Visualizing and Quantifying Biological Age in the Kidney

Susan M. Sheehan, Seamus Mawe, Mandy Chen, Ron Korstanje, John M. Mahoney. The Jackson Laboratory, Bar Harbor, ME.

**Background:** The kidney is one of the organs with noticeable age-related changes in structure and function. However, we do not understand the mechanisms and timing involved in kidney aging. The Geropathology Research Network (GRN) published a grading scheme for aged mice in several tissues, including the kidney. Use of this grading scheme is labor intensive, requires expert knowledge to implement, and has large interscorer variability. Using image analysis and machine learning approaches, we developed a high-throughput classifier that can be used to improve the quantification and resolve the unknown mechanisms of aging.

**Methods:** Using the same slides as the GRN, which includes male mice from two strains (C57BL/6 and CB6F1) and combining them with additional C57BL/6J mice, we developed a training set that includes 12 mice at four ages (8, 13, 20 and 32 months). We adopted a light deep learning architecture (LinkNet) and trained the model on images from ImageNet to develop an ordinal classifier that provides us with pixel level information about aging. By looking at the predictions, we can ascertain how likely a tissue is young or old age at a given pixel. Additionally, we can generate an overall age score for each kidney.

**Results:** After we trained the classifier, we tested the classifier in an additional set of male and female C57BL/6J mice. We can distinguish between young and old tissue and see a strong correlation with the scores using the GRN grading. We wanted to determine whether kidneys age uniformly or if specific regions or structures age faster than others. We developed a method that allows us to 'paint' our aging scores onto kidneys and see that aging happens first in a thin band in the renal cortex, which aligns with the findings of pathologists.

**Conclusions:** Our tool can be used to measure biological age in the kidney and is critical in developing and evaluating interventions that affect kidney health span and overall lifespan. The tool, and tutorials about how to apply this to your own data set, are made publicly available at agingmice.org. We are now applying this tool to more diverse and larger datasets and refining our ability to quantify and localize kidney aging such that we can understand the mechanisms that change spatially and structurally with age.

## TH-PO536

### Modified Immune Cell (MIC) Therapy Disrupts Tertiary Lymphoid Structures in Murine Lupus Nephritis

Gerald Ponath,<sup>1</sup> Claudius Speer,<sup>2</sup> Iris I. Arnold,<sup>2</sup> Asa Hidmark,<sup>1</sup> Lei Wang,<sup>1</sup> Christian Kleist,<sup>3</sup> Anita Schmitt,<sup>4,1</sup> Volker Daniel,<sup>1,5</sup> Gerhard Opelz,<sup>1,5</sup> Peter Terness,<sup>1,5</sup> Michael Schmitt,<sup>4</sup> Martin G. Zeier,<sup>2</sup> Christian Morath,<sup>2,1</sup> Matthias Schaefer.<sup>2,1</sup> <sup>1</sup>TolerogenixX GmbH, Heidelberg, Germany; <sup>2</sup>University of Heidelberg, Department of Nephrology, Heidelberg, Germany; <sup>3</sup>University of Heidelberg, Department of Nuclear Medicine, Heidelberg, Germany; <sup>4</sup>University of Heidelberg, Department of Internal Medicine V, Heidelberg, Germany; <sup>5</sup>University of Heidelberg, Department of Immunology, Heidelberg, Germany.

**Background:** Induction of tolerance can be achieved with Modified Immune Cells (MIC) by infusion of mononuclear cells challenged with mitomycin C (MMC). Although MIC treatment has been successful in several animal models for autoimmunity and in clinical studies of solid organ transplantation, the mechanism of immunosuppression is not fully elucidated. In lupus nephritis, the glomerular deposition of immune complexes is associated with accumulating immune cells in the kidney. The infiltrating immune cells frequently establish tertiary lymphoid structures (TLS) supporting adaptive autoimmune responses toward locally displayed antigens. Since TLS display a high persistence to peripheral B cell depletion, the destruction of TLS presents an essential treatment goal in lupus nephritis. In this study, we used lupus nephritis prone NZB/W F1 mice to show the destruction of TLS in the kidney after MIC treatment.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Methods:** Splenocytes of syngeneic donor mice were incubated with MMC and injected into recipient's tail vein after matching for disease activity. Disease activity was monitored by body weight, protein excretion, serum creatinine and dsDNA. Kidney histopathology was performed by immunofluorescent microscopy. Densitometric measurement of regulatory markers in immune cell subsets were computationally quantified.

**Results:** Independent of treatment, >86% of animals displayed dense lymphocytic aggregates proximal to the pelvic wall of the medulla and the arcuate arteries within the cortex of kidneys. Cell type composition of TLS changed drastically after MIC treatment leading to diminished B-cells, a decreased B-cell/T-cell ratio, and a T cell dominated phenotype. Furthermore, a loss of organization of the TLS was observed after MIC treatment. The strict separation of B-cell and T-cell areas was abrogated, and germinal centers were disintegrated. However, regulatory T-cells remained unchanged indicative of a B-cell centric treatment mechanism.

**Conclusions:** Our data provides a putative *in vivo* mechanism how MIC treatment inhibits progression of active lupus nephritis by the destruction of tertiary lymphoid structures within the kidney.

### Expression of GLA, HNRNP2, and RPL36A Genes in Fabry Disease Male and Female Cell Lines

Md S. Islam, Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Texas Tech Health Science Center, Amarillo, TX.*

**Background:** Fabry disease (FD) is a rare genetic disorder caused by mutations in the  $\alpha$ -galactosidase A (GLA) gene resulting in  $\alpha$ -galactosidase A enzyme deficiency. Despite, enzyme replacement therapy, FD patients often remain symptomatic indicating that other mechanisms might be associated with this disease. Our previous in-vitro study showed that knockdown of the first locus (RPL36A) in the readthrough transcription RPL36A-HNRNP2 locus leads to decreased expression of GLA, RPL36A, and HNRNP2. We also observed GLA c.1033\_1034delTC deletion in male FD patients greatly reduces the expression levels of GLA, RPL36A, and HNRNP2, and at lower, but significant levels in females, as compared with healthy males and females. Based on this finding we have hypothesized that regulation of GLA genes by its adjacent loci RPL36A and HNRNP2 might play a significant role during the pathogenesis of FD. To analyze the expression status of GLA, RPL36A and HNRNP2 genes in different male and female FD patient-derived cell lines.

**Methods:** FD cell lines were purchased for three female and male patients along with one fibroblast-derived control cell line from Coriell Institute for Medical Research, and were grown as per supplier instructions. Then, harvested cell mRNA expression analysis by qRT-PCR was performed.

**Results:** qRT-PCR revealed that GLA mRNA expression was downregulated in both female and male FD cell lines except for Gm0881 (FD MALE with R220X). Unexpectedly, GLA had more reduction in expression in female than male cell lines. Although the Gm0881 cell line showed high GLA mRNA expression, it has no GLA enzymatic activity due to c.658C>T in exon 5, resulting in a stop codon [Arg220Ter (R220X)]. This suggested the key functional importance of this mutation in GLA activity vs. GLA expression. Downregulation of HNRNP2 expression was also observed in the FD cell lines irrespective of male and female source, except in the Gm02774 cell line. But, unlike GLA expression, HNRNP2 had a higher reduction in the male than the female cell lines. Similarly, RPL36A was downregulated in all FD cell lines irrespective of whether the cells were male or female-derived.

**Conclusions:** Dysregulation of expression of GLA and its two conjugative loci RPL36A and HNRNP2 demonstrate differences based on sex in cell lines derived from male and female FD patients.

## TH-PO538

### Osteopontin Is a Key Orchestrator of Plasminogen Activator Inhibitor-1 (PAI-1) Induced Tubular Pathologies

Cody C. Gifford,<sup>1,2</sup> Brian Meyerson,<sup>4</sup> Roel Goldschmeding,<sup>3</sup> Rohan Samarakoon,<sup>2</sup> Paul J. Higgins.<sup>2</sup> <sup>1</sup>*Brigham and Women's Hospital Department of Medicine, Boston, MA;* <sup>2</sup>*Albany Medical College Center for Cell Biology and Cancer Research, Albany, NY;* <sup>3</sup>*Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands;* <sup>4</sup>*Albany Medical Center, Albany, NY.*

**Background:** Sustained tubular PAI-1 expression, evident in various renal diseases, promotes epithelial dedifferentiation, G2/M arrest and a prominent fibrotic response. It is unclear whether PAI-1-induced tubular maladaptive repair is linked to induction/secretion of pro-inflammatory/fibrotic molecules.

**Methods:** Employing cytokine protein array analysis as an un-biased approach, we identified novel factors upregulated in human kidney epithelial cells (HK2) stably overexpressing PAI-1 (termed CMV-PAI-1) compared to vector controls (termed CMV-Con). We identified specific cytokines pertinent to PAI-1-driven tubular pathologies via gene silencing approaches. Human fibrotic kidneys and obstructed rat kidneys were used to investigate the in vivo correlation between PAI-1 and associated cytokines via immunohistochemistry.

**Results:** Stable tubular PAI-1 expression resulted in induction and secretion of several cytokines/growth factors, including robust upregulation (15-fold) of osteopontin (OPN). Upregulation as well as co-localization of OPN and PAI-1 in the tubules of

obstructed rat and human diabetic kidney sections (compared to respective control kidneys) suggested a potential relationship between PAI-1 and OPN during disease progression. shRNA-directed silencing of OPN in CMV-PAI-1 overexpressing HK2 renal tubular cells, indeed, attenuated PAI-1-mediated fibronectin, collagen-1 and p21 protein expression. Furthermore, OPN suppression in CMV-PAI-1 cells also reduced expression of the pro-fibrotic transcription factors, Twist, Snail1, p53 and phosphorylated-SMAD3. Twist gene depletion similarly ameliorated fibrotic maladaptive responses evident in CMV-PAI-1-transductants. Mechanistically, PAI-1-induced OPN upregulation requires downregulation of klotho and upregulation of TGF- $\beta$ 1-receptor signaling.

**Conclusions:** PAI-1 is a novel regulator of renal OPN induction observed during renal injuries. OPN is a key effector cytokine involved in PAI-1-induced tubular dysfunction and is an upstream control element of Twist and p53 transcription factors that drive fibrotic reprogramming. Targeting OPN induction in the kidney, therefore, is a new strategy to attenuate PAI-1-induced tubular dysfunction and CKD progression.

## TH-PO539

### Differential Alterations of Hippo Signaling Pathway in Kidney Cells After Unilateral Ureteral Obstruction

Yaochun Zhang,<sup>1,2</sup> Zhenhua Li,<sup>1,2</sup> Liangjian Lu,<sup>1,2</sup> Nurul Jannah Binti Ahmad,<sup>1,2</sup> Chang-Yien Chan,<sup>1,2</sup> Jun Li Ng,<sup>1,2</sup> Hui Kim Yap,<sup>1,2</sup> Kar Hui Ng.<sup>1,2</sup> <sup>1</sup>*National University of Singapore, Singapore, Singapore;* <sup>2</sup>*National University Health System, Singapore, Singapore.*

**Background:** The Hippo signaling pathway regulates physiological functions. Renal fibrosis enhances nuclear translocation of the Hippo signalling effectors YAP/TAZ. We previously analyzed single cell RNA sequencing (scRNA-Seq) databases and observed heterogeneity in Hippo signaling activation status in different kidney cells. Here, we aimed to study the differential alterations of Hippo signaling in kidney cell clusters after unilateral ureteral obstruction (UO), a process which causes fibrosis.

**Methods:** Ligation of left ureters was performed in rats. The kidneys were harvested after 7 days' obstruction (UUO7) and cell transcriptomics were profiled with RNA-Seq. Separately, publicly available single-cell transcriptomics of UUO2, UUO7 and wild-type mice (GEO: GSE140023) were re-analyzed with Seurat v4.0. Gene Set Enrichment Analysis (GSEA) was performed with evolutionary conserved YAP target genes to compare the Hippo pathway activation status in UUO and normal states. Cellular distributions of YAP were confirmed with immunohistochemistry.

**Results:** The UUO kidneys displayed extensive tubular dilation. Intense Yap nuclear localization was observed in all dilated tubules and some medullary interstitial cells. GSEA revealed upregulation of Yap target genes (NES = 1.50,  $P = 0.02$ ) in UUO rats. scRNA-Seq on the UUO2 mouse kidneys showed significant upregulation of Yap target genes in five kidney cell clusters, namely podocytes, cluster 5 (PT5) and cluster 9 (PT9) of proximal tubular cells (PT), principal cells of collecting duct and epithelial cells of inner medullary collecting duct. In contrast, only PT5 was upregulated in UUO7 kidneys. Additionally, two other cell clusters, PT1 and the distal convoluted tubular cells, showed significant upregulation of Yap target genes. Interestingly, while the evolutionary conserved gene set was upregulated in PT7, PT8, PT9, thick ascending limb and endothelial cells in UUO2, it was downregulated in UUO7, though these were not significant.

**Conclusions:** The Hippo signalling pathway was differentially altered in kidney cells after UUO. Different trends in some cell clusters between UUO2 and UUO7 mice may imply the Hippo signaling pathway exert different effects in the acute and chronic phases of ureteral obstruction.

**Funding:** Government Support - Non-U.S.

## TH-PO540

### Sodium Chloride Induces Human Tubular Epithelial Cell CCL26 Expression That Associates With Monocyte Accumulation in the Human Kidney

Jessica Schmitz,<sup>1</sup> Nicolas Brauns,<sup>1</sup> Anne M. Breloh,<sup>1</sup> Jan H. Braesen,<sup>1</sup> Hermann G. Haller,<sup>1</sup> Sibylle Von Vietinghoff.<sup>2,1</sup> <sup>1</sup>*Medizinische Hochschule Hannover, Hannover, Germany;* <sup>2</sup>*Universitätsklinikum Bonn, Bonn, Germany.*

**Background:** Renal immune cells serve as sentinels against ascending bacteria but also promote detrimental inflammation. The kidney medulla is characterized by extreme electrolyte concentrations. We here address how its main osmolytes, NaCl and urea, regulate tubular cell cytokine expression and monocyte chemotaxis.

**Methods:** Immunohistology was performed in human kidney sections, human monocyte function and tubular cell cytokine production was analyzed in cell culture.

**Results:** In the healthy human kidney, more monocytes were detected in medulla than cortex. The monocyte gradient was attenuated in patients with medullary NaCl depletion by loop diuretic therapy and in the nephrotic syndrome. Renal tubular epithelial cell gene expression responded similarly to NaCl and tonicity control mannitol, but not urea. NaCl significantly upregulated chemotactic cytokines, most markedly CCL26, CCL2 and CSF1. This induction was inhibited by ROS scavenger  $\alpha$ -acetylcysteine. In contrast urea, the main medullary osmolyte in catabolism, dampened tubular epithelial CCL26 and CSF1 expression. Renal medullary chemokine and monocyte marker expression decreased in catabolic mice. NaCl-, but not urea-stimulated tubular epithelium or CCL2 and CCL26 promoted human classical monocyte migration. CCL26 improved bactericidal function. In the human kidney medulla, monocyte densities correlated with tubular CCL26 protein abundance.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Medullary-range NaCl, but not urea, promotes tubular cytokine expression and monocyte recruitment. Our results delineate CCL26 expression in the kidney and determine its antibacterial function. This may contribute to the pyelonephritis vulnerability in catabolism but can possibly be harnessed against pathologic inflammation.

TH-PO541

**IgG Subclass Switch in Fibrillary Glomerulonephritis: Possible Natural History of the Disease**  
Laura Biederman, Dalia Y. Ibrahim, Anjali A. Satoskar, Tibor Nadasdy, Sergey V. Brodsky. *The Ohio State University, Columbus, OH.*

**Background:** Fibrillary glomerulonephritis (FGN) is an uncommon glomerular disease characterized by non-periodic fibrillar deposits of immunoglobulins usually positive for polyclonal IgG. Staining for IgG subclasses routinely performed and is usually dominant for IgG4. However, the natural history of this disease is not well documented.

**Methods:** Kidney biopsies with FGN were identified in a renal pathology database at Ohio State Wexner Medical Center from 12/1/2006 to 3/1/2022, when routine IgG subclass staining was performed. A total of 164 cases with IgG subclass data were reviewed, and seven patients with a diagnosis of FGN who had both an original diagnostic kidney biopsy and a follow up kidney biopsy were identified.

**Results:** A total of 164 cases of FGN were identified since 12/2006 with IgG subclass staining. Of those, 39 were dominant for IgG1, 67 were dominant for IgG4, and 58 had co-dominant staining for IgG1 and IgG4. Among these, a total of 7 patients had a repeat biopsy after their initial diagnosis. Of these 7, at initial biopsy, 71% of the patients with repeat biopsy showed dominant subclass staining for IgG4, with the remaining showing dominant staining for IgG1 alone or IgG1 and IgG2. Two patients showed IgG subclass switching, both from IgG4 dominance to IgG1, and both were biopsied at more than 4 years after the initial diagnosis. Of the 5 patients with repeat biopsies who did not show subclass switching, 2 had repeat biopsies at 1 year or less, 2 had repeat biopsies between 1 and 5 years after initial diagnosis, and 1 had a repeat biopsy at 9 years or more. The other patient biopsied at more than 9 years showed IgG1 dominance on both the initial and subsequent biopsies.

**Conclusions:** FGN is an uncommon disease with a poorly understood natural history. Changes in IgG subclass staining from IgG4 to IgG1 may be part or the natural history of the disease.

	Initial Biopsy Subclass	Subsequent Biopsy Subclass	Years after initial diagnosis
Patient 1	IgG4 and IgG1	IgG1	4
Patient 2	IgG4 and IgG1	IgG1	>10
Patient 3	IgG4 and IgG1	IgG4 and IgG1	3
Patient 4	IgG1	IgG1	9
Patient 5	IgG1 and IgG2	IgG1 and IgG2	3
Patient 6	IgG4 and IgG1	IgG4 and IgG1	<1
Patient 7	IgG4 and IgG1	IgG4 and IgG1	<1

**Utilization of 129S1/Sv Mice as a Model for Anticoagulant Related Nephropathy**  
Sergey V. Brodsky,<sup>1</sup> Ajay kumar Medipally,<sup>1</sup> Min Xiao,<sup>1</sup> Galina Mikhailina,<sup>2</sup> Anjali A. Satoskar,<sup>1</sup> Laura Biederman.<sup>1</sup> <sup>1</sup>*The Ohio State University, Columbus, OH;* <sup>2</sup>*Unity Hospital, Rochester, NY.*

**Background:** We previously demonstrated that excessive anticoagulation with warfarin or dabigatran may result in acute kidney injury in some patients with chronic kidney disease and named it anticoagulant related nephropathy (ARN). An animal model of 5/6 nephrectomy rats treated with warfarin or dabigatran reproduces the main pathologic features of ARN. We had reported that C57BL/6 mice only partially develop ARN showing increased serum creatinine and hematuria but no red blood cell (RBC) casts in the kidney. The aim of this study was to investigate whether ARN can develop in 129S1/SvImJ mice.

**Methods:** 5/6 nephrectomy was performed in 129S1/SvImJ mice. Three weeks after the surgery, mice were treated with warfarin (1.0 mg/kg/day and 1.5 mg/kg/day) for 7 days. Serum creatinine, hematuria, and prothrombin time (PT) were monitored daily. Renal morphology was evaluated at the end of the studies.

**Results:** Treatment with warfarin resulted in PT elevation 2-3 folds from baseline (1.0 mg/kg/day warfarin) and 4-5 folds from baseline (1.5 mg/kg/day warfarin) by day 7. Serum creatinine elevation by day 7 was dose-dependent. Similarly, hematuria was increased in a dose-dependent manner. Histologically, some animals had RBCs in the tubules with acute tubular epithelial cell injury.

**Conclusions:** Our findings suggest that 129S1/SvImJ mouse strain could be more suitable animal model to study ARN than C57BL/6 mouse strain.

**Funding:** NIDDK Support

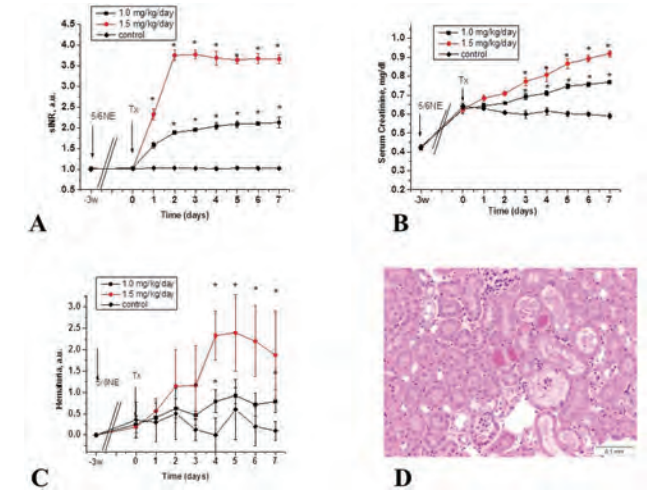

Figure 1. Effects of warfarin treatment on kidney function in 129S1/SvImJ mice.

A – Coagulation effects of warfarin treatment in 129S1/SvImJ mice. sINR was calculated as PT increase from control (as described in Methods).

B – Changes in serum creatinine in 129S1/SvImJ mice treated with warfarin.

C – Effects of warfarin treatment on hematuria in 129S1/SvImJ mice.

D – Representative image of red blood cell casts in the tubules in a 129S1/SvImJ mouse treated with 1.0 mg/kg/day warfarin for 7 days.

TH-PO543

**CD39 Expression Is Significantly Upregulated in Polarized Macrophage in ANCA Associated Vasculitis Patients**  
Benito Yard, Anna-Isabelle Kälsch. *Ruprecht Karls Universität Heidelberg, Mannheim, Germany.*

**Background:** Monocytes concurrently stimulated for 6 days with CSF1 and of IFN $\gamma$  followed by TLR4 activation, are poorly stimulating T-cell proliferation despite increased expression of co-stimulatory molecules. Substitution of IFN $\gamma$  for IL-4 increases the ability to stimulate T-cell proliferation. These concurrently stimulated (CS) macrophages are tentatively referred as CSM1 and CSM2 respectively. We assessed if CSM1 and CSM2 macrophages from active, therapy naïve, ANCA associated vasculitis (AAV) patients (MPA: n=4 GPA: n=7) differ in phenotype and function from healthy controls (HC, n=12).

**Methods:** Phenotype and function were assessed by FACS and allogeneic mixed leucocyte reaction (MLC) respectively.

**Results:** Our study reveals that: 1) AAV patients had significantly more monocytes in peripheral blood as compared to HC. 2) both CD39 and CD73 expression were significantly higher in CSM1 than in CSM2 Macrophages, both in AAV patients and HC. However, surface expression of CD39 on CSM1 macrophages in AAV patients was significantly higher than in HC. 3) IL-17 production in MLC was higher for CSM1 as compared to CSM2 macrophages and blunted by addition of adenosine deaminase. No differences between AAV patients and HC were found. 4) Addition of the pan adenosine receptor NECA to anti-CD3 stimulated T-cells increased IL-17 production and resulted in T-cells with a non-pathogenic Th17 phenotype that were able to suppress proliferation of mitogen activate T-cells.

**Conclusions:** In keeping that adenosine signalling plays important regulatory roles in immunity, the finding that CD39 on CSM1 macrophages is increased in AAV patient warrants further studies on the functionality of these cells.

TH-PO544

**Structures of Megalin/LRP2 at Extracellular and Endosomal pH**  
Andrew Beenken,<sup>1</sup> Jonathan M. Barasch,<sup>1</sup> Lawrence Shapiro.<sup>2</sup> <sup>1</sup>*Columbia University Irving Medical Center, New York, NY;* <sup>2</sup>*Columbia University, New York, NY.*

**Background:** The low-density lipoprotein receptor-related protein 2 (LRP2 or megalin) mediates endocytosis in species ranging from worms to humans and is implicated in diseases of the kidney and brain. The structural basis for its function remains one of the great unknowns of kidney biology. To understand the mechanisms of its ligand-binding and trafficking, we have solved structures of LRP2 at extracellular and endosomal pH.
