**Background:** Silicon nanopore membranes (SNM) are efficient blood-compatible membranes that enable novel approaches to renal replacement therapy (RRT). Previously, arteriovenous SNM hemodialyzers (SNMHD) were patent and effectively cleared solutes after retroperitoneal implant in healthy swine. Renal arterial embolization is a non-invasive approach to near-total nephrectomy that preserves retroperitoneal anatomy for subsequent device implants. An established embolization-to-implantation protocol is key to therapeutic investigation of implantable RRT devices.

**Methods:** A Yucatan minipig underwent staged bilateral renal artery embolization with PVA particles and microcoils to induce renal failure. The right renal artery was embolized until contrast stagnation on fluoroscopy. After a 2-week recovery, 50% of the left renal arterial system was embolized. The animal received intermittent hemodialysis (HD) with the Tablo HD System for 35 days and began daily aspirin (325 mg). A small-scale arteriovenous SNMHD prototype was then implanted in the right retroperitoneum. SNMHD dialysate catheters were tunneled externally for connection to a dialysate recirculation pump. The animal resumed HD in parallel to SNMHD testing for 7 days. SNMHD clearance was determined by intermittent sampling of the recirculating dialysate.

**Results:** Staged embolization successfully induced kidney failure. Embolization, subsequent HD sessions and retroperitoneal SNMHD implantation were well-tolerated. The animal developed anemia (nadir hematocrit 25%), which improved after darbepoetin injection. A chronic venous catheter inserted for HD access was replaced once for tip thrombosis prior to SNMHD implant. Creatinine and urea clearance through the SNMHD were 76-105 mL/min/m<sup>2</sup> and 140-165 mL/min/m<sup>2</sup>, respectively. No albumin was detected in the dialysate.

**Conclusions:** We successfully piloted an embolization-to-implantation protocol enabling the first implant of a SNMHD in a swine renal failure model. Normalized creatinine and urea clearance measured in the SNMHD may translate to a fully-implantable clinical-scale device. This pilot establishes a path toward therapeutic testing of the clinical-scale SNMHD and other implantable RRT devices.

### Human Mesenchymal Stromal Cells Cultured in a Hollow Fiber Bioreactor Produce Constant Levels of Exosomes in the Perfusion Medium: Relevance to the Simultaneous Production of Two Biotherapeutic Agents

Christof Westenfelder,<sup>1</sup> Mikhail Skliar,<sup>2</sup> Sabiha Sultana Chowdhury,<sup>1</sup> Anna Gooch.<sup>1</sup> <sup>1</sup>SymbioCellTech, LLC, Salt Lake City, UT; <sup>2</sup>University of Utah, Salt Lake City, UT.

**Background:** We have shown that the administration of allogeneic Mesenchymal Stromal Cells (MSCs) to patients at high risk for Acute Kidney Injury (AKI) following on-pump cardiac surgery prevents AKI and progression to Chronic Kidney Disease (CKD). Treatment of rats with severe, progressive IRI AKI with MSC-derived exosomes affords significant survival benefits and rescues their renal function. The current study examined the possibility to simultaneously collect MSC-derived exosomes while culturing human MSCs, both used for various therapies in renal and other diseases. This approach, if successful, would be cost saving, efficient and facilitate up-scaling of the production of both MSCs and their exosomes.

**Methods:** Human MSCs (20x10e6) were loaded into a hollow fiber Cell Expansion System (Quantum®, TERUMObct; pre-conditioned for cell adhesion with Fibronectin) and expanded using αMEM with 5% human Platelet Lysate (hPL). The number and size

of exosomes in aliquots of the perfusion medium were monitored (NanoSight instrument) throughout the course of cell expansion.

**Results:** MSCs reached ~ 90% confluence within 12 days, yielding 500x10e6 MSCs. The number of exosomes/nanoparticles derived from the 5% hPL per se was 4±1x10e11/mL. Post seeding of MSCs in the bioreactor, exosome numbers in the perfusate decreased and stabilized at 1-1.5x10e11/mL. The size of collected exosomes was between 60 and 100 nm.

**Conclusions:** The data from this pilot study demonstrate that hPL-derived exosomes or nanoparticles are taken up by the expanding MSCs, which lowers their total number in the perfusion medium. However, exosome numbers stabilized during the subsequent cell expansion, indicating that growing MSCs release high numbers of exosomes. This conclusion will be confirmed by speciating hPL- and MSC-derived exosomes, using specific markers for each type of nanoparticle. Together, these observations show promise for the efficient generation of MSCs and their exosomes to be used for various clinical applications.

### Mesenchymal Stromal Cells (MSCs) Exposed to Interferon Gamma (INFγ) Secrete Exosomes (Exos) With a More Potent Renoprotective Profile Than Unexposed Cells

Anna Gooch,<sup>1</sup> Mikhail Skliar,<sup>2</sup> Sabiha Sultana Chowdhury,<sup>1</sup> Christof Westenfelder.<sup>1</sup> <sup>1</sup>SymbioCellTech, Salt Lake City, UT; <sup>2</sup>University of Utah, Salt Lake City, UT.

**Background:** Preclinical and clinical studies have shown MSCs to be effective for prevention of AKI [NCT00733876]. Yet studies where MSCs are given 48 hrs. post-insult, a time at which most patients with severe AKI are diagnosed and when no rescue therapy is available, show them to be ineffective or even damaging due to compromised renal blood flow in capillary beds, where introduction of large cells has the potential to cause further deterioration of renal function [NCT01602328]. MSCs' renoprotection is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their Exos. The beneficial paracrine profile of MSCs can be enhanced through exposure to INFγ. Exos signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Others have shown that MSC-derived Exos can prevent AKI. We have found that their small size and ability to move through the compromised renal microvasculature allows them to provide effective rescue therapy for late-stage AKI. We hypothesized that priming of MSCs with INFγ would result in the release of Exos enriched in immune modulatory and other beneficial cargo compared to those not so primed, and thus provide a potentially more potent biotherapy for AKI.

**Methods:** 12 sets of human MSCs were cultured to 70% confluence. Serum was removed from the medium, and 6 were exposed overnight to 10ng/ml INFγ (*Expt*), and the other 6 to vehicle (*Control*). Exos were isolated from each of the 12 sets of medium. *Expt* and *Control* Exos were characterized and compared for size and number (Nanosite), mRNA (rtPCR) and miRNA (Rosalind) content.

**Results:** The number of Exos did not vary between *Expt* and *Control* groups. *Expt* Exos were slightly larger than *Controls* (163.2±4.1 vs 134.1±7.6 nm, respectively). *Expt* Exos' cargo showed significantly increased immune modulatory mRNA, specifically IDO-1, CCLE8, CXCL9, CXCL10 and PD-L1 vs *Control*. *Expt* Exos showed significant increases in 4 miRNAs associated with anti-inflammatory pathways.

**Conclusions:** Exposure of MSCs to INFγ results in release of Exos that carry significantly greater immune-modulatory and anti-inflammatory cargo, factors that are known to confer renoprotection. We predict such Exos to have enhanced renoprotective ability, which is currently being assessed.

## SA-PO021

### The CAM Model for Ex Vivo Modeling of Vascularized Kidney Tubuloid Epithelium

Murillo Dorileo Leite Bernardi, Maarten B. Rookmaaker, Marianne C. Verhaar. *Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

**Background:** Kidney tubuloids are 3D organoids composed of tubular epithelial cells. Tubuloids can be easily derived from tissue samples as well as urine and have an extensive proliferating capacity. After differentiation, tubuloid epithelium shows active and polarized transport *in vitro*. The next step toward clinical application is connecting epithelialized membranes to a vascular system. We here present a system for modeling the interaction between tubuloid epithelium and a circulating microvasculature, using the Chick Chorioallantoic Assay (CAM).

**Methods:** Fertilized Leghorn chicken eggs were cultured *ex ovo* for 10 days before cell culture inserts were implanted on the CAM. To assess and model the basolateral exposure of tubuloid epithelium in the insert to circulating compounds, the diffusion rate of endogenous urea, and and 70kD dextran-FITC (1mg/ml) from the CAM circulation over bare membranes was quantified with and without angiogenic factors (VEGF and Thrombin). Next, the viability of tubuloid epithelium cultured on the insert membranes on top of the CAM was evaluated. Finally, MRP2/4 dependent transport of CDFDA from the CAM circulation over the membrane as well as through the tubuloid epithelial cells was assessed.

**Results:** The vascularized bare membranes enabled diffusion from circulating compounds as was demonstrated by the time-dependent increase in the concentration of 10 and 70kD dextran-FITC in the insert after injection in the CAM circulation, with more than 10 fold higher diffusion of 10 than 70kD (2.94 ± 1.12, 0.17 ± 0.15 RFU respectively). We can also modulate the vascular permeability of the CAM with an angiogenic cocktail,

which increases the diffusion of 10kD dextran in 2.5 fold ( $4.02 \pm 0.37$  against  $1.65 \pm 0.96$  RFU in the control). Kidney tubuloids on inserts maintain their viability and monolayer integrity after the incubation in the embryo. Finally, we showed tubuloid function in the model by the selective secretion of CDFDA from the circulation to the apical compartment.

**Conclusions:** The CAM assay is a useful system to model crucial aspects of implantable membranes: epithelial integrity and maintenance, membrane vascularization, supply of circulating compounds over the membrane, and epithelial transport function. The presented CAM model enables rapid optimization of vascularized and epithelialized membranes for clinical application.

## SA-PO022

### Estimating Changes in Glomerular Filtration Rate During Dialysis With a Fluorescent Tracer

Christopher Pino,<sup>1,2</sup> Goldia Chan,<sup>3</sup> Kimberly Johnston,<sup>1,2</sup> H. David Humes,<sup>1,2</sup>

<sup>1</sup>Innovative BioTherapies, Ann Arbor, MI; <sup>2</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>3</sup>University of Michigan, Ann Arbor, MI.

**Background:** Fluorescein-isothiocyanate (FITC)-sinistrin can be used to measure glomerular filtration rate (GFR) as it's removed from the body exclusively by the kidneys and can be detected transdermally. Currently, there's a need to rapidly determine estimated GFR (eGFR) in acute kidney injury (AKI) patients during continuous renal replacement therapy (CRRT) to improve clinical decision-making. The viability of measuring changes in eGFR with FITC-sinistrin was tested in a swine model of progressive AKI during CRRT.

**Methods:** *In vitro* circuits (IVC) (n=2) were first trialed to mimic conditions that would be tested *in vivo*. A FITC-sinistrin solution was circulated through a hemofilter to mimic clearance from the kidneys and then through a dialyzer. Ultrafiltrate (UF) was removed from the hemofilter at three progressively decreasing rates to mimic loss of urine production. Dialysis was delivered at a constant rate. Transdermal devices were placed in the circuit to measure FITC-sinistrin. *In vivo* clearance of FITC-sinistrin was studied by placing anesthetized pigs on CRRT (n=3). Pigs underwent three phases progressing from normal to unilaterally nephrectomized and then bilaterally nephrectomized. FITC-sinistrin was administered prior to each phase and continuously measured transdermally. Dialysis was kept consistent throughout all three phases. Pre- and post-dialyzer blood samples were collected to calculate clearance from measured FITC-sinistrin concentrations in plasma.

**Results:** FITC-sinistrin clearance was reduced in all experiments, either *in vitro*, where UF was decreased or with successive nephrectomies *in vivo*. IVC studies showed agreement between transdermal device-estimated clearance and plasma-measured clearance ( $r^2=0.95$ ). *In vivo* experiments demonstrated no significant differences between transdermal device-estimated and plasma-measured methods of determining proportional changes in clearance from phase to phase. Clearance of FITC-sinistrin, urea, and creatinine by dialysis were demonstrated to be constant.

**Conclusions:** For a subject receiving a constant dialysis prescription, clearance of FITC-sinistrin is constant, allowing for changes in eGFR to be attributed to changes in kidney function. Therefore, measurement of FITC-sinistrin clearance is a viable method for estimating changes in GFR during dialysis.

## SA-PO023

### Intraoperative Urine Oxygen During Cardiac Surgery and 12-Month Kidney Injury

Samuel R. Parry,<sup>1</sup> Isaac E. Hall,<sup>2</sup> Natalie Silverton,<sup>3</sup> Gregory J. Stoddard,<sup>2</sup> Lars Lofgren,<sup>3</sup> Kai Kuck,<sup>3</sup> <sup>1</sup>Brigham Young University College of Physical and Mathematical Sciences, Provo, UT; <sup>2</sup>The University of Utah Department of Internal Medicine, Salt Lake City, UT; <sup>3</sup>The University of Utah Department of Anesthesiology, Salt Lake City, UT.

**Background:** Acute renal effects from changes in intraoperative urine oxygen during cardiac surgery are well documented; however, longer-term effects of these fluctuations are unknown. We created a non-invasive oximeter to continuously measure urine oxygen levels during cardiac surgery. We hypothesized that low intraoperative urine oxygen associates with poor 12-month kidney outcomes.

**Methods:** This is a secondary analysis of a prospective cohort of patients undergoing cardiac surgery. 63 patients with at least one serum creatinine measurement within the 12-month follow-up were eligible and included. We measured intraoperative urine oxygen during the post-cardiopulmonary bypass period to determine associations with 12-month kidney outcomes. The post-discharge primary outcome was patient death, chronic dialysis, or estimated glomerular filtration rate (eGFR) decline by more than 30% without recovery by 12 months post-surgery.

**Results:** A total of 9 (14%) patients developed the primary outcome (2 died, 1 started chronic dialysis, 6 had eGFR decline >30%). For every 5 minutes spent below urine oxygen tension cutoffs during the post-cardiopulmonary bypass period of <25, <20, <15, and <10 mmHg, risk for the primary outcome increased via an exposure-response relationship with hazard ratios (95% CI) of 1.15 (1.01-1.31), 1.37 (1.10-1.72), 1.93 (1.34-2.77) and 5.85 (1.42-24.1), respectively.

**Conclusions:** Lower intraoperative urine oxygen values were associated with worse 12-month kidney outcomes in this small cardiac surgery cohort. While these findings support our hypothesis, additional larger prospective studies are warranted for external validation. We believe additional studies are also needed to further explore the potential clinical importance of specific intraoperative urine oxygen tension cutoffs.

### Intracellular Complement Production and Activation in Lupus Nephritis Podocytes

Abhigyan Satyam,<sup>1,2</sup> Masataka Umeda,<sup>1,2</sup> Rhea Bhargava,<sup>1,2</sup> Maria Tsokos,<sup>1,2</sup> George C. Tsokos.<sup>1,2</sup> <sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that leads to systemic autoimmunity and damage of several tissues and organs. Inflammation of the kidney is one of the most severe exhibitions of SLE that leads to lupus nephritis (LN). Podocytes are critical for the maintenance of the glomerular filtration barrier and are injured in many kidney diseases including LN. Deposition of immune complexes and activation of the complement system are well-established processes involved in the pathogenesis of LN. It has been recognized that besides the well-established pathways of complement (C) activation, C3 can be activated within the cell cytoplasm prior to its secretion. Studies have shown cleavage of C3 and C5 by proteases of the cathepsin family, thus introducing a new pathway of complement activation. Here we explored the intracellular complement production and activation in LN podocytes.

**Methods:** Human immortalized podocytes were cultured on engineered cell-derived decellularized matrix (DCM) coated plates. Podocytes were then exposed to IgG from patients with LN or hypoxia. Podocytes from MRL<sup>lpr</sup> and MpJ control mice were also isolated and cultured on DCM coated plates. Cathepsins and complement molecules were inhibited using nanoparticle-based targeted delivery to impede the generation of intracellular complement split products.

**Results:** We found that MRL<sup>lpr</sup> podocytes and human podocytes exposed to LN IgG or hypoxia displayed changes in the actin cytoskeleton, and increased levels of C3, C4, C5, C5b9, and C3 activation products. Podocytes were also noted to produce cathepsins and inhibition of cathepsins suppressed the C3 activation.

**Conclusions:** Podocytes exposed to IgG from patients with LN or hypoxia produce complement components as do podocytes isolated from lupus-prone mice and this leads to cell injury. Reversal of podocyte injury with inhibitors of hypoxia or complement activation limits intracellular complement activation and may prevent kidney injury in patients with LN.

## SA-PO025

## Coaxial Printing of Convoluted Proximal Tubule for Kidney Disease Modeling

Rosalinde Masereeuw,<sup>1</sup> Anne Metje van Genderen,<sup>1,2</sup> Marta Garcia valverde,<sup>1</sup> Pamela E. Capendele,<sup>1,2</sup> Maj V. Kersten,<sup>1</sup> Elena Sendino Garv, Jitske Jansen,<sup>1</sup> Silvia M. Mihaila,<sup>1</sup> Tina Vermonden,<sup>1</sup> Y. Shrike S. Zhang.<sup>2</sup> <sup>1</sup>Universiteit Utrecht Utrecht Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Genetic defects in proximal tubule (PT) transporters can lead to metabolic complications and tubulopathies. To mechanistically study these pathologies, 3D (bio) printing offers new modeling alternatives to *in vivo* by incorporating cell-extracellular matrix (ECM) interactions. Here, we applied co-axial printing to create a convoluted channel within a gelatin-based microfiber to model the convoluted structure of the PT and address the ECM-cells interaction in a disease model. For this, we included a cystinosis-deficient (*CTNS*<sup>-/-</sup>) cell line to model cystinosis, a currently incurable kidney tubulopathy.

**Methods:** A 3D printing system consisting of syringe pumps, heaters, coaxial needles, and a silicon holder was designed. Fine-tuning of the gelatin/alginate-based ink composition, printing temperature and feeding rate allowed an optimal ink viscosity. CaCl<sub>2</sub> and microbial transglutaminase were used to stabilize the ink. Healthy conditionally immortalized PTECs (ciPTEC), and isogenic *CTNS*<sup>-/-</sup> cells were seeded to mimic two genotypes. Immunofluorescent stainings for cytoskeleton organization (F-actin), polarization markers (a-tubulin, Na<sup>+</sup>K<sup>+</sup>-ATPase), ECM-production (collagen IV), and barrier-formation (inulin-FITC leakage) were performed to evaluate the performance of the engineered PT.

**Results:** The printed microfibers (length:>50cm, OD:1.5mm, ID:150µm) exhibited prolonged structural stability (42 days) and cytocompatibility in culture. All cells showed homogenous cytoskeleton organization upon 14 days of culture in the microfibers, as indicated by F-actin directionality measurements, barrier-formation and polarization with the apical marker a-tubulin and the basolateral marker Na<sup>+</sup>K<sup>+</sup>-ATPase. Cell viability was slightly impaired (60%, *p*=0.028) in cystinotic cells upon prolonged culturing for 14 days. Finally, *CTNS*<sup>-/-</sup> cells showed reduced apical transport activity by two efflux pumps, *viz.* breast cancer resistance protein and multidrug resistance-associated protein 4 (*p*<0.0001).

**Conclusions:** Our novel printing device showed potential to mimic a 3D environment compatible with healthy PT and tubulopathy modeling. By further improving this setup, new insights in kidney disease development and progression can be gained. This eventually aids in new treatment options.

**Funding:** Private Foundation Support, Clinical Revenue Support, Government Support - Non-U.S.

## SA-PO026

## Targeting BH3 Domains in iPSC-Derived Tuberos Sclerosis Kidney Organoids for the Development of Novel Therapies for Renal Angiomyolipoma

Dario R. Lemos,<sup>1,2</sup> Marta Lpez-Marfil,<sup>1,2</sup> Ting-Chun Kuo,<sup>1,2</sup> Xichi Wang,<sup>1,2</sup> Lemos Lab HMS <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Kidney organoids can recapitulate genetic kidney diseases allowing the identification of novel druggable targets. Among those diseases, kidney tumors known as renal angiomyolipomas (AMLs) occur in a majority of patients with Tuberos Sclerosis (TS). Rapamycin analogs with cytostatic and pro-apoptotic activity, are the main therapy for AML. Rapalogs partially shrink AMLs by inhibiting mTORC1 activity, but tumor size stabilizes over time, making life-long treatment necessary. Tumor re-growth is often observed after treatment is interrupted due to adverse effects. A lack of appropriate experimental models, has precluded the development of more effective therapies.

**Methods:** We have developed a kidney organoid model that recapitulates kidney AML *in vitro* and *in vivo*, using patient-derived *TSC2*<sup>-/-</sup> iPSCs. Orthotopic transplantation of AML organoids allowed us to identify previously unknown molecular mechanisms and to test the effect of candidate compounds with prospective anti-tumor activity in immunodeficient rodents.

**Results:** Consistent with the genetic mechanisms observed in TS patients, kidney organoids generated from iPSCs carrying bi-allelic inactivating mutations in the *TSC2* gene (i.e. *TSC2*<sup>-/-</sup>) recapitulated key anatomical and molecular features of renal AML (Hernandez J. et al. Nat. Commun. 2021 Nov 11;12(1):6496). Transcriptional analysis of AML organoids against kidney AML transcriptomes further identified gene sets and major signaling mechanisms shared in common with kidney AML tumors. Among those mechanisms, we identified upregulation of anti-apoptotic members of the BCL-2 family of proteins as a putative mechanism of tumor resistance. Transplantation of *TSC2*<sup>-/-</sup> renal organoids into the kidneys of immunodeficient rats allowed us to investigate AML mechanisms *in vivo* for the first time. Using these novel tools, we have identified the BCL-2 inhibitor drug Venetoclax as a prospective novel therapy, inducing iPSC-derived AML cell death and AML organoid xenograft ablation *in vivo*.

**Conclusions:** Our *TSC2*<sup>-/-</sup> iPSC-derived AML organoid xenograft model allowed us to elucidate previously unknown tumor resistance mechanisms in TS-associated kidney AML, and to identify the BH3 mimetic molecule Venetoclax as an prospectively efficacious new therapy.

**Funding:** Private Foundation Support

## SA-PO027

## Hemodynamic Optimization of an Implantable Artificial Kidney Device Using Computational Analysis

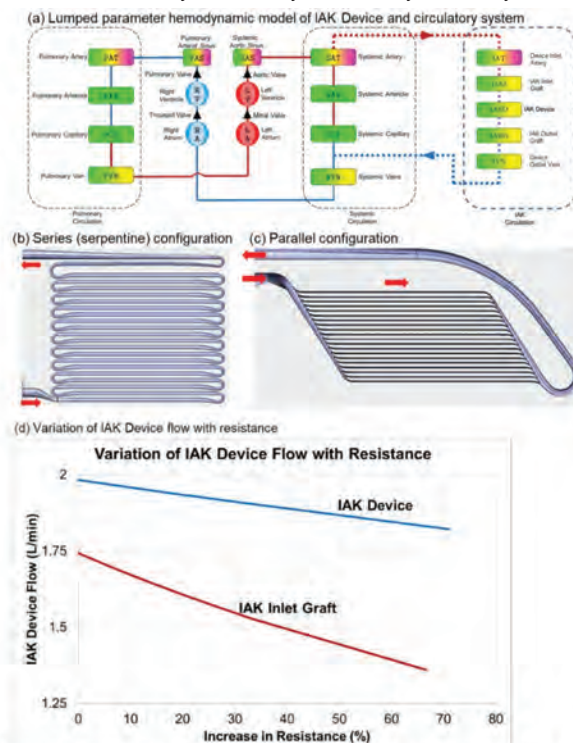

Andre Laffitte Farina,<sup>1</sup> William H. Fissell,<sup>2</sup> Shuvo Roy,<sup>3</sup> Venkat Keshav Chivukula,<sup>1</sup> <sup>1</sup>Florida Institute of Technology, Melbourne, FL; <sup>2</sup>Vanderbilt University, Nashville, TN; <sup>3</sup>University of California San Francisco, San Francisco, CA.

**Background:** Severe loss of kidney function is experienced by end-stage kidney disease patients. An exciting alternative treatment to hemodialysis would be an implantable artificial kidney device (IAKD) that filters blood using the natural pressure drop in the systemic circulation. This study aims to investigate the hemodynamic performance of potential IAKD designs using a computational hemodynamic model (HM).

**Methods:** A custom HM was developed to analyze the implantation of an IAKD (Fig 1a). The time-varying HM encompasses the complete circulation and the IAKD branch. Two IAKD designs were analyzed: serpentine and parallel configurations (Fig 1b and c). For each design, several scenarios for IAKD resistance, pressure drop across and flow through the IAKD and device inlet graft together with vital signs were varied to simulate patient-specific needs. Model optimization was performed by modifying several parameters.

**Results:** In both configurations, an increase in the internal device resistance twofold resulted in a reduction of flow by 25% through the IAKD. Strong interdependencies between the device resistance, the patient's MAP and flow through the IAKD were also observed. During model fine-tuning, the length and diameter of the inlet graft was the most influential parameter to modulate flow through the IAKD (up to 40% in the parallel configuration, see Fig 1d).

**Conclusions:** The HM can investigate clinically relevant scenarios to tailor an IAKD for renal failure patients. Our analysis suggests that there is a complex interplay between the patient's systemic circulation and the IAKD, necessitating detailed hemodynamic analysis. Depending on the patient's needs, it is possible to personalize an IAKD that can best serve to maintain hemodynamic stability and hemodialysis efficiency.

**Figure 1:** (a) Lumped parameter model, (b) and (c) – series and parallel device configurations, respectively, (d) variation of IAK device flow with resistance, indicating higher dependence on IAK inlet graft resistance compared to device resistance

## SA-PO028

## Perfusable Human Tubule Chip System to Model Polycystic Kidney Disease

Sophie Karp, Martin Pollak, Balaji karthick Subramanian. Pollak Lab Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** Ex-vivo systems modeling human kidney tubules may be used for high-throughput drug screening and mechanistic disease studies. Polycystic kidney disease (PKD) is an important tubular disease to model, as it is responsible for 2% of worldwide renal failure. Proximal and distal tubules are affected differently in PKD settings in terms of fluid-activated transport and inflammation, leading to GFR changes and ultimately

renal failure. It is thus important to establish a system in which segment-specific human-derived PKD tubules may be studied in physiologically relevant conditions, such as fluid flow.

**Methods:** Using photolithography, we created a microfluidic chip with a channel insert and ports for media delivery. We then derived kidney organoids from both normal and PKD patient-sourced induced pluripotent stem cells (iPSCs). We extracted proximal and distal tubule cells from these organoids, and delivered them to our chip system. Unidirectional fluid flow for various time frames was introduced through the system and changes in the tubule structure and function were examined. Tubule volume changes, marker protein expression and localization, and transport properties were assessed and compared between normal and PKD disease tubular chips.

**Results:** Kidney organoids formed tubular structures which mimicked human kidney structures and replicated PKD-like cyst formation. Kidney organoid-harvested cells exhibited nephron segment-specific marker protein localization and function, and formed tubular structures when introduced to the chip-system. Normal tubule chip systems exhibited human kidney-relevant structure and function, while PKD systems showed aberration in tubule volume. Diseased systems exhibited altered localization of marker proteins such as E-cadherin, as well as diminished transport capacity of solutes (e.g., 6-Carboxy fluorescein). More importantly, diseased tubules showed aberrations in structure and function in a segment-specific manner, mimicking *in vivo* disease pathology.

**Conclusions:** We have developed and validated a model system to study the effects of PKD *ex vivo*. Our platform will allow both mechanistic studies and drug testing in a nephron-segment specific way. Its conductivity to both distal and proximal human iPSC-derived tubules allows researchers to study disease in a personalized manner.

## SA-PO029

### High-Dimensional Imaging of Postnatal Glomerulogenesis in the PodocyteTRAP Model by Simplified Tissue-Clearing Approach

Mathieu Preußner,<sup>1,2</sup> Jonas Einloft,<sup>1</sup> Simon Bedenbender,<sup>1</sup> Andreas Hofmeister,<sup>1,3</sup> Ivica Grgic,<sup>1</sup> <sup>1</sup>Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany; <sup>2</sup>Goethe-Universität Frankfurt am Main, Frankfurt am Main, Germany; <sup>3</sup>BioNTech SE, Mainz, Germany.

**Background:** The development of glomeruli is complex. Its dynamics and spatio-temporal coordination during the formation of the glomerular architecture are still poorly understood. Classical histopathological methods and microscopy techniques yield a rather limited scope of visualization and reconstruction of evolving glomeruli that can only be fully comprehended in a 3-dimensional context.

**Methods:** To study the successive buildup and maturation of podocytes during glomerulogenesis, we used neonatal kidneys (P0-P7) from transgenic Podocyte<sup>TRAP</sup> mice in combination with an adjusted ethyl cinnamate (ECi)-based clearing approach for immunostaining and subsequent 2-photon and light-sheet microscopy. We used IMARIS for detailed morphometric analysis and 3D-reconstruction of podocytes and glomeruli during advanced stages of kidney development.

**Results:** Tissue clearing is a technique to render biological samples transparent, thereby allowing for high-dimensional 3D-imaging of structures deep within the tissue without the need for tissue-sectioning. We used this technique for 3D-visualization, reconstruction and analysis of different glomerular developmental stages (renal vesicles, S-phase, capillary loop, maturing glomerulus) in transparent kidneys of P0 to P7 and adult Podocyte<sup>TRAP</sup> mice. ECi-clearing followed by 2-photon and light-sheet microscopy allowed for 10-fold larger imaging depth compared to uncleared kidneys (~1500µm vs. ~150µm). EGFP-L10a<sup>+</sup> podocytes in ECi-treated Podocyte<sup>TRAP</sup> kidneys were easily identified by their robust epifluorescence, with eGFP-L10a intensifying as podocyte maturation progressed. We conducted detailed analyses which included comprehensive quantifications of glomerular volume changes during postnatal kidney development.

**Conclusions:** The combination of ECi-tissue clearing with 2-photon and light-sheet microscopy in the Podocyte<sup>TRAP</sup> model is well suited for high-dimensional imaging of renal tissue including detailed morphometry of maturing glomeruli in whole neonatal mouse kidneys. Moreover, this approach could also be useful for holistic histopathological analyses and assessments in various glomerular disease models including experimental GN and FSGS.

## SA-PO030

### Differentiation of Human Kidney Organoids Within a Microfluidic Chip Promotes Podocyte-Endothelial Cell Interaction

Sophie M. Blackburn, Giulia Spennati, Benjamin S. Freedman. University of Washington, Seattle, WA.

**Background:** Combining kidney organoids with microfluidic chips has promise as a powerful tool to improve organoid maturation, vascularization, and create a highly tunable environment for drug testing or disease modeling. Organoids can be transferred into microfluidic channels after differentiation, but this risks irreversibly damaging the newly formed structures or inducing their dedifferentiation upon attachment in the channel. Thus, we have developed a protocol to carry out kidney organoid differentiation entirely within a microfluidic device.

**Methods:** A positive-relief mold was generated using a stereolithography 3D printer to make a PDMS device with multiple channels separated by micro-pillars, which could accommodate a physiological flow rate. Then, we optimized our standard kidney organoid protocol for the microfluidic chip by altering the ECM surface coating, undifferentiated human pluripotent stem cell seeding density, and timing of media exchanges to support

the much smaller growth environment. Following these modifications, we identified several organoids in each device with brightfield microscopy by day 18 of differentiation and fixed them for immunostaining.

**Results:** The presence of kidney-specific cells and structures was confirmed by confocal microscopy after fixing and staining for podocyte, proximal tubule, and endothelial cells. The organization of these organoids was comparable to those made in 24-well plates indicating that we have successfully optimized our standard differentiation protocol for a microfluidic platform. Increased endothelial cells were observed in chip-differentiated organoids, compared to 24-well plates. The endothelial cells integrated into organoids in 3D, and demonstrated a tendency to interact with the basal membrane of podocytes which was not observed in 24-wells.

**Conclusions:** This protocol eliminates transfer steps during the differentiation process by creating a stable environment for organoid development within our microfluidic chips. In addition, the confined growth environment of the microfluidic chips or the intermittent shear stress from media changes may be inducing endothelial cell differentiation and podocyte-endothelial cell interactions. The endothelial interactions observed in organoids grown in these devices provides a strong foundation for future vascularization work.

## SA-PO031

### An Open Microfluidic Model to Investigate Podocyte-Parietal Epithelial Cell Cross-Talk In Vitro

Yuting Zeng,<sup>1</sup> Jeffrey W. Pippin,<sup>2</sup> Stuart J. Shankland,<sup>2</sup> Ashleigh B. Theberge.<sup>1,3</sup> <sup>1</sup>University of Washington Department of Chemistry, Seattle, WA; <sup>2</sup>University of Washington Division of Nephrology, Seattle, WA; <sup>3</sup>University of Washington Department of Urology, Seattle, WA.

**Background:** Although focal segmental glomerulosclerosis (FSGS) is initially caused by direct injury to podocytes, their neighboring parietal epithelial cells (PECs) also undergo secondary molecular changes that further damage the glomerulus. The crosstalk between injured podocytes and PECs is poorly understood, in part due to a lack of appropriate experimental models for study. The goal of this study is to establish an *in vitro* coculture model to determine what mediators derived from injured podocytes cause PECs damage.

**Methods:** We engineered a novel open microfluidic coculture device where two culture chambers are separated by a half wall that can be connected to study intercellular interactions. Diffusion calculations suggested that moderate sized (10 kDa) signaling molecules take ~ 2 d to reach the other chamber via diffusion. In mouse podocyte-PEC coculture studies, immortalized mouse podocytes were exposed to cytotoxic sheep anti-podocyte antibodies, puromycin, or Adriamycin, and cocultured with mouse PECs for up to 96 h. In human podocyte studies, primary human podocytes were also injured with anti-podocyte antibodies, puromycin, or Adriamycin. Podocyte responses were assessed by phase-contrast imaging, MTT assays, and immunostaining. Immunostaining also measured PEC activation and epithelial-mesenchymal transition (EMT).

**Results:** Immediately following podocyte injury, both mouse and human podocytes displayed foot process effacement and cell body shrinkage. In addition, cell viability was decreased of injured podocytes. The normal contiguous monolayer of mouse podocytes was disrupted, accompanied by a dose-dependent increase in the *de novo* expression of the injury marker desmin, and a decrease in the cytoskeletal marker F-actin along the cell borders. In podocyte-PEC coculture, PECs were activated (expressed CD44) accompanied by increased SM22, an EMT marker. A time course of bulk RNA seq results are pending.

**Conclusions:** This novel *in vitro* microfluidic model for coculturing injured podocytes and neighboring cells has the potential to study many pathways involved in podocyte-related intercellular crosstalk, glomerular disease mechanisms, and drug screening.

## SA-PO032

### Focal Fungal Granulomatous Interstitial Nephritis on a Background of Class II Lupus Glomerulonephritis

Pedro J. Martinez Pitre,<sup>1</sup> Ana I. Stark,<sup>1</sup> Tomas Fernandez-Correa,<sup>1</sup> Ramya Krishna Velagapudi,<sup>3</sup> Mark Lusco,<sup>3</sup> Juan Carlos Q. Velez,<sup>1,2</sup> Shirisha Bodana.<sup>1</sup> <sup>1</sup>Ochsner Nephrology <sup>1</sup>Ochsner Medical Center, New Orleans, LA; <sup>2</sup>The University of Queensland Ochsner Clinical School, Herston, QLD, Australia; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN.

**Introduction:** Fungal infections are an exceedingly rare form of granulomatous interstitial nephritis (GIN). Most cases of GIN are associated with sarcoidosis or drug exposure. The most common etiology of infectious GIN is mycobacteria. Herein, we report a case of fungal GIN diagnosed in a patient with systemic lupus erythematosus (SLE) receiving low-dose corticosteroids.

**Case Description:** A 54-year-old woman was hospitalized with acute respiratory failure, acute kidney injury (AKI), anemia and thrombocytopenia following 2 weeks of generalized weakness and altered mental status. The patient had a medical history of SLE and remote history of class III and V SLE glomerulonephritis (GN) for which she had received immunosuppression 27 years prior to presentation. Current medications included low-dose prednisone, hydroxychloroquine, nifedipine, furosemide and insulin glargine. Upon arrival, she was noted to be hypotensive and oliguric. Laboratory data showed a serum creatinine of 3.4 mg/dL (baseline 1.0 mg/dL). Urinalysis revealed hematuria, proteinuria and leukocyturia. Urine microscopy revealed budding yeast and

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

pseudohyphae. Urine culture was negative and blood culture was positive for *Proteus mirabilis*. CT of the abdomen revealed bilateral perinephric stranding consistent with pyelonephritis. She was started on broad spectrum antibiotics, pulse steroids for possible SLE flare, and dialysis for volume and metabolic derangements. Kidney biopsy was performed for suspected relapse of SLE-GN. Specimen revealed acute tubular necrosis, class II SLE-GN (activity index 0) and focal fungal granuloma with budding yeast and hyphae (by electron microscopy). Repeat cultures grew *Candida albicans* and *Candida glabrata* in blood and *Candida albicans* in the urine. The patient was started on liposomal amphotericin B and her kidney function recovered to a serum creatinine of 1.0 mg/dL.

**Discussion:** Candiduria is a common finding on routine evaluation of hospitalized patients with AKI and often represents colonization or a urinary tract infection. However, in the context of immunosuppression, those findings should raise suspicion for fungal GIN, as shown in this case, so that appropriate intervention can be promptly implemented.

## SA-PO033

### Creamy Clogged Dialysis Filter Indicating Something Serious: A Case of Propofol Infusion Syndrome With Hyperlipidemia in a Bariatric Surgery Patient

Ahmad S. Al-Alwan,<sup>1</sup> Harshil Fichadiya,<sup>1</sup> Nimit Dalal,<sup>2</sup> Muhammad Tayyeb,<sup>1</sup> Apurva Ketkar.<sup>1</sup> <sup>1</sup>Monmouth Medical Center, Long Branch, NJ; <sup>2</sup>Western Reserve Health Education, Warren, OH.

**Introduction:** Propofol is a short acting intravenous anesthetic and sedative agent. Propofol related infusion syndrome (PRIS) is rare but associated with very high mortality rate. Commonly seen in patients receiving dose >4 mg/kg/hr for prolonged period > 48 hours. The pathogenesis involves impaired beta oxidation of fatty acids, disruption in electron transport chain, blockage of beta adrenergic receptors and calcium channels on myocardial cell. Clinically presents as cardiac dysfunction (bradycardia, ventricular arrhythmia and asystole), high anion gap metabolic acidosis, rhabdomyolysis, hyperkalemia, hyperlipemia, AKI and hepatocellular injury.

**Case Description:** 69 year old male with ICU course complicated by sepsis from serratia bacteremia post gastric sleeve leak repair, ARDS, oliguric AKI, cardiac arrhythmia, hypotension had recurrent clogging of dialysis filter with a creamy greasy substance. The patient was being sedated with high dose of propofol >25mcg/kg/hr for 1 week. Elevated triglyceride level 799mg, worsening kidney function and acidemia, worsening hepatocellular transaminitis (ALT 283, AST 135) with mild elevation in CPK 293 was noted. Propofol infusion syndrome was suspected and the drug was held following which his transaminitis, acidosis, hyperlipidemia and rhabdomyolysis improved. His renal function continued to decline and required HD.

**Discussion:** A creamy clogged dialysis filter raised suspicion of hyperlipidemia and PRIS in our patient. Severe illness and use of exogenous catecholamines predisposed our patient to this condition. Bariatric surgery patients with possible carbohydrate depletion are at higher risk. Early identification and low threshold for suspicion of PRIS can help in reducing mortality from this condition.

## SA-PO034

### Falsely Low Serum Creatinine in an AKI Patient on Dopamine Drip

Tram Dao, Brian Y. Young. *University of California Davis Department of Internal Medicine, Sacramento, CA.*

**Introduction:** Two common methods to measure creatinine concentration in the blood are the Jaffe and enzymatic method. Enzymatic creatinine assays have been reported to be affected by the presence of catecholamines. Specifically, dopamine and dobutamine infusions are known to cause falsely decreased creatinine levels due to interference with the peroxidase reaction.

**Case Description:** We present a 68 year old male with a past medical history of CKD stage 3b (baseline creatinine 1.7 mg/dL), interstitial lung disease status-post double lung transplant, coronary artery disease, heart failure with mildly reduced ejection fraction, and restrictive pericarditis who was admitted for decompensated heart failure. The patient also had acute kidney injury (AKI), presumed from diuretic refractory cardiorenal syndrome, with consistently rising creatinine levels since hospital admission. On hospital day 16, the patient's creatinine decreased from 4.55 mg/dL to 1.28 mg/dL in 24 hours without any renal replacement therapy or medical changes other than dopamine infusion was started the day prior. Serum creatinine over the next few days sporadically fluctuated from 1.81 mg/dL to 5.28 mg/dL. After discussion with nursing staff, we confirmed that labs were drawn using the same intravenous line being used for dopamine infusion. When the nurse obtained labs via a peripheral venous puncture on hospital day 18, the creatinine level was 5.15 mg/dL, most consistent with the patient's AKI. The patient was started on dialysis soon after due to poor clearance and volume control.

**Discussion:** It is important for healthcare providers to be aware of the artifactual effects that dobutamine and dopamine infusions have on serum creatinine levels. A recent survey shows a lack of this awareness among healthcare providers. This issue can be avoided by educating nursing staff to avoid drawing creatinine levels using the same infusion lines for dopamine or dobutamine. It is also noted that the Jaffe method is unaffected by the presence of catecholamines, though the majority of labs now employ the enzymatic method. Consideration could also be made to use cystatin C if readily available.

## SA-PO035

### When Overdose With Doxylamine Leads to Severe Rhabdomyolysis and Renal Failure That Requires Hemodialysis: A Case Report and Literature Review

Salman Bhutta,<sup>1</sup> Samaan Mahmoudzadeh,<sup>2</sup> Bair Cadet.<sup>1</sup> <sup>1</sup>Nassau University Medical Center, East Meadow, NY; <sup>2</sup>UCI Health, Orange, CA.

**Introduction:** Antihistamines such as doxylamine, represent common components of over-the-counter sleep-inducing agents. The easy availability of these substances increases the potential for both intentional overdose by adults and inadvertent ingestion by children. Doxylamine overdose has increased in recent years due to its availability as an over-the-counter drug commonly used as a nighttime sleep aid. Clinical studies describe symptoms of severe doxylamine intoxication such as rhabdomyolysis, renal failure, impaired consciousness, seizures, and cardiopulmonary arrest

**Case Description:** A 52 year old male with a history of HTN and opioid dependence presented with acute onset right-sided weakness, numbness, right buttock pain, nausea, and vomiting. He reported taking 30 tablets of doxylamine the night prior to presentation due to difficulty sleeping. Upon admission, patient's labs showed elevated creatinine kinase >100,000, blood urea nitrogen/Creatinine 71/5.8, aspartate aminotransferase 2170, alanine aminotransferase 536, and phosphate 7.9. Patient was admitted to the medical intensive care unit (MICU) for severe rhabdomyolysis with acute renal failure, and acute liver failure secondary to doxylamine overdose. He received n-acetylcysteine for acute liver failure and was started on aggressive IV hydration. He remained oliguric and a hemodialysis catheter was placed on hospital day (HD) 1 for emergent dialysis. Throughout the hospital stay, patient received three cycles of dialysis. Urine output gradually improved and the patient was transferred to the medical floors on HD 5. He was subsequently discharged home on HD 13 with an outpatient nephrology appointment.

**Discussion:** Acute kidney injury from rhabdomyolysis due to doxylamine toxicity can result in poor prognosis, necessitating emergent dialysis and critical care management as seen in our patient. The accessibility of this drug alongside its potential for abuse warrants discussion among healthcare providers. Additionally, the adverse outcomes associated with doxylamine overdose demands that clinicians act immediately in treating patients with suspected intoxication. Rapid intervention may prevent progression of renal failure, ultimately reducing the risk of developing chronic kidney disease and requiring long-term dialysis.

## SA-PO036

### Vanishing Bactrim Stones: A Case for Urinary Alkalinization

Muhammad S. Khan,<sup>1,2</sup> David Geller.<sup>1,3</sup> <sup>1</sup>Yale University, New Haven, CT; <sup>2</sup>Yale New Haven Health System, New Haven, CT; <sup>3</sup>Veterans Health Administration, West Haven, CT.

**Introduction:** Trimethoprim/sulfamethoxazole (TMP-SMX) is a commonly used antibiotic in the clinical setting. It is also a rare cause of renal calculi, the management of which has not been well described. Here we present a case of AKI thought to be secondary to obstructive TMP-SMX stones with rapid resolution of AKI, obstruction and stones with urinary alkalinization.

**Case Description:** A 94 year old man with Waldenstrom's macroglobinemia, bladder areflexia managed with chronic Foley catheter use, and baseline normal renal function

(Cr 1.1 mg/dL, eGFR 62 ml/min) was treated for *E. coli* bacteremia with 2 double strength TMP-SMX tablets q12h for a total of 9 days. Imaging at the time showed no nephrolithiasis. He presented to the emergency department on the 9th day with decreased urine output, acute kidney injury (Cr 4.5 mg/dL), and hyperkalemia (K 6.8 meq/L). A repeat renal U/S showed the interval development of multiple bilateral renal calculi with moderate hydronephrosis. Urinalysis demonstrated birefringent crystals under polarized light, leading to a presumptive diagnosis of TMP-SMX nephrolithiasis. The patient was treated with IV and oral bicarbonate and discharged on oral bicarbonate for one month. Two weeks later, serum Cr had decreased to 1.3 mg/dL. A renal U/S done 6 weeks after alkalinization was initiated showed complete resolution of the hydronephrosis and renal calculi. Cr was 1.1 mg/dL.

**Discussion:** Nephrolithiasis caused by sulfamethoxazole crystals use is rare, and effective medical management strategies have not been well described. Urinary alkalinization is based on the premise of increased solubility of sulfonamides at an alkaline pH. We present a case in which rapid improvement in clinical trajectory occurred soon after urinary alkalinization. This report is unique in that we demonstrate both the growth and resolution of the stones in a rapid time frame. Further study will be required to determine if this regimen is an effective alternative to ureteral stenting or nephrostomy tubes.

## SA-PO037

### Enfortumab-Vedotin as a Cause of Severe Acute Interstitial Nephritis

Muhammad S. Khan,<sup>1,2</sup> David Geller,<sup>1,3</sup> <sup>1</sup>Yale University, New Haven, CT; <sup>2</sup>Yale New Haven Health System, New Haven, CT; <sup>3</sup>Veterans Health Administration, West Haven, CT.

**Introduction:** Enfortumab-vedotin is an antibody-drug molecule recently approved by the FDA for urothelial and other cancers. Data submitted to the FDA lists "increased creatinine in 20% of patients and ARF in a small minority of patients" as an adverse event noted in phase 3 clinical trials of this drug but little information is available beyond that. Here, we present a case of severe acute interstitial nephritis (AIN) thought to be secondary to enfortumab-vedotin use.

**Case Description:** An 86-year-old male with CAD s/p CABG, HTN, CKD3b (baseline Cr 2.1), chronic right hydronephrosis and recurrent transitional cell cancer of bladder s/p TURBT was initially treated with 5 cycles of pembrolizumab but was switched to enfortumab due to an ineffective response. Patient's last dose of pembrolizumab was administered 4 weeks prior to cycle 1 of enfortumab. He received a total of 4 monthly cycles (3 weekly doses each cycle) of enfortumab with CBC and BMP obtained with each infusion. During cycle 3 infusion 2, peripheral eosinophilia (15.8%) was noted, which worsened after the next infusion 8 days later to 23.2%. Eosinophilia normalized (2.7%) prior to initiation of cycle 4. A similar rise in eosinophilia to 9.1% was seen after cycle 4 infusion 1. Labs demonstrated AKI (Cr 6.2 mg/dl) prior to the 2nd infusion so further enfortumab infusions were held, but eosinophils rose to 27.1% and a renal biopsy was performed which showed extensive AIN on H&E staining. Patient was treated with steroids and enfortumab discontinuation with rapid recovery of renal function.

**Discussion:** To our knowledge, this is the first report of AIN caused by enfortumab-vedotin. While delayed AKI caused by AIN has been reported in the setting of pembrolizumab use, the rise and fall of eosinophilia seen during the 3rd and 4th infusion cycles argues strongly that this is the likely culprit, with pembrolizumab perhaps playing a role in immune system priming. Vedotin, a microtubule inhibitor, was first linked to brentuximab and used in hematologic malignancies, but it has been subsequently linked to a wide variety of other cancer targeting antibodies. There have been multiple reports of Karyomegalic interstitial nephritis (KIN) linked to brentuximab-vedotin. Our data coupled with these previous reports suggest that the eosinophil count should be monitored, and AIN should be considered in patients the steadily rising number of antibody drug complexes containing vedotin.

## SA-PO038

### Started With the Kidneys, Followed by the Lungs: A Rare Case of Sarcoidosis

Rui Song,<sup>1</sup> Laura Walters,<sup>1</sup> Rahat A. Memon,<sup>1</sup> Ali Arif,<sup>1</sup> Winston Shu,<sup>1,2</sup> <sup>1</sup>Abington Memorial Hospital, Abington, PA; <sup>2</sup>Hypertension Nephrology Associates, Willow Grove, PA.

**Introduction:** Sarcoidosis is a multisystem disorder. Only 8% of patients present with disease at extra-pulmonary sites without lung involvement. Granulomatous interstitial nephritis (GIN) is the classic kidney lesion found in sarcoidosis. However, clinically significant renal sarcoidosis is exceedingly rare. We present a case with acute renal failure (ARF) requiring temporary dialysis due to GIN without lung involvement on presentation.

**Case Description:** A 39-year-old female with a history of hypertension presented to the emergency room with nausea and vomiting. Labs showed a serum creatinine (Cr) 13.29 mg/dL (1.1mg/dL 3 months prior), blood urea nitrogen 106 mg/dL, bicarbonate 13 mg/dL. Arterial blood gas showed a pH of 7.23 with PaCO<sub>2</sub> of 33 mmHg. Urinalysis showed 1+ protein and 2 red blood cells. Dialysis was started for acidosis and uremia. Renal ultrasound showed no obstruction or chronic changes. IV methylprednisolone was started and she underwent kidney biopsy for ARF. Pathology showed GIN. The angiotensin-converting enzyme was 156 nmol/mL/min, and calcium was normal. CT scan of the chest showed no adenopathy or pulmonary disease. She was weaned off dialysis with adequate urine output and a Cr of 2mg/dL. She was discharged on 60 mg prednisone daily for 2 weeks followed by a 3-month taper. After stopping steroids, she developed nausea and vomiting again and presented to the ER with a Cr >10mg/dL. Repeat CT scan of the chest now showed bilateral hilar adenopathy. Bronchoscopy was performed

and lymph node biopsy showed non-caseating granulomas confirming sarcoidosis. She subsequently improved clinically with standard steroid treatment.

**Discussion:** The most common renal feature of sarcoidosis is nephrocalcinosis caused by dysregulated calcium homeostasis, followed by GIN. About 4-10% of renal sarcoidosis may progress to end-stage renal disease. Corticosteroids are the mainstay treatment. In this case, the patient was first found to have GIN with normocalcemia and was treated timely with steroids. Lung involvement was absent until steroids were tapered off 3 months later highlighting the importance of closely monitoring lung features if renal sarcoidosis is detected. Given the lack of treatment guidelines, a longer course of steroids for clinically significant renal sarcoidosis may be needed to prevent full-blown lung sarcoidosis.

## SA-PO039

### A Case of Eltrombopag-Associated Renal-Limited Thrombotic Microangiopathy

Nurit S. Katz, Catherine Gutierrez, Yihe Yang, Sujal I. Shah, Gearoid M. McMahon. *Brigham and Women's Hospital Department of Medicine, Boston, MA.*

**Introduction:** Medication-induced thrombotic microangiopathy (TMA) is a diagnostic challenge because specific testing is lacking. In addition, renal-limited TMA may lack classic hematological manifestations. We report a case of possible eltrombopag-associated TMA.

**Case Description:** A 46-year-old woman, with history of lupus and antiphospholipid syndrome (APLS) on anticoagulation, was admitted with acute kidney injury (AKI). She had recently been hospitalized with a subdural hematoma and thrombocytopenia that was attributed to immune thrombocytopenic purpura (ITP). This had been managed with cessation of anticoagulation, rituximab, IVIG and eltrombopag (a thrombopoietin receptor agonist). Her dose of eltrombopag had been increased just prior to discharge. Her labs were notable for: creatinine 2.91 mg/dl (baseline 0.6), thrombocytopenia, anemia. Markers of hemolysis including schistocytes were negative. A kidney biopsy revealed extensive microvascular thrombosis consistent with a TMA and widespread cortical necrosis. She was treated with corticosteroids and eculizumab and was initiated on hemodialysis.

**Discussion:** Eltrombopag has been associated with complications including venous thrombosis, stroke, and, rarely, TMA. The mechanism for this risk is unclear and appears to be independent of platelet levels in some cases. In this case, the patient had multiple risk factors for thrombosis including her underlying APLS and the cessation of anticoagulation. However, the AKI developed shortly after the dose of eltrombopag was increased suggesting a temporal relationship. Awareness to the possibility of eltrombopag-associated TMA is important for patient safety in patients with worsening kidney function, especially in the setting of recent dose adjustments. Patients with APLS and ITP may be at higher risk.

## SA-PO040

### Hiding in Plain Sight: Normotensive Scleroderma Renal Crisis

Eric J. Chacko, Anushree C. Shirali. *Yale School of Medicine, New Haven, CT.*

**Introduction:** Scleroderma renal crisis is a rare but recognized complication of systemic sclerosis most notably characterized by the presence of abrupt hypertension and progressive renal failure. Here we present a rare case of normotensive scleroderma renal crisis.

**Case Description:** A 51 year old female with history of systemic sclerosis, pulmonary hypertension, systemic lupus erythematosus presented with worsening lower extremity edema and shortness of breath. She was treated initially with diuretics and antibiotics for volume overload and pneumonia. 13 days later, respiratory status declined and patient became anuric with subsequent rapid creatinine rise from baseline of 1.5mg/dL to 4.98 mg/dL. Urinalysis was significant for 3+ protein and 3+ blood with urine protein-creatinine ratio of 3.2. Serologic workup was negative for the following: ANCA, MPO, PR3, dsDNA, SSA, SSB, C3, C4, and Anti GBM. There was noted positivity for Scl-70 antibody and ANA at 1:1280 in a homogenous pattern. Renal sonogram revealed normal kidney size, patent bilateral renal arteries, normal cortical thickness, and no hydronephrosis. Echocardiogram was obtained which revealed new reduction in ejection fraction to 30%. Blood pressure from admission and until this point remained within systolic range of 120-150mmHg. The patient was transferred to ICU and renal biopsy was obtained which revealed diffuse acute tubular injury and arteriolar vessels with onion skinning and severe luminal narrowing. She was initiated on continuous renal replacement therapy and captopril. Her course was complicated by worsening

respiratory failure and septic/cardiogenic shock requiring vasopressors and inotropes. She was unable to consistently tolerate captopril dosing due to subsequent hypotension and eventually passed.

**Discussion:** This case illustrates the diagnostic dilemma seen in patients with normotensive scleroderma renal crisis. Although only a small minority of patients with scleroderma renal crisis present without associated hypertension, these patients are at greater risk for delayed diagnosis and exposure to therapies that may worsen underlying disease process (i.e. steroids). Clinicians should retain high clinical suspicion for scleroderma renal crises with normotension and be aware of comorbidities that may be masking underlying hypertension. Furthermore, kidney biopsy should be considered in these patients for definitive diagnosis and management.

#### SA-PO041

#### AKI in Patients With Lymphoma Submitted to Autologous Hematopoietic Stem Cell Transplant: Incidence, Risk Factors, and Prognostic Impact, A Cohort Analysis

Carolina Branco, Natacha Rodrigues, Claudia Costa, Filipe Marques, Pedro D. Vasconcelos, Carlos M. Martins, Jose A. Lopes. *Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.*

**Background:** Studies on AKI in Hematopoietic Stem Cell Transplant (HSCT) consider heterogeneous definitions for AKI include a miscellaneous of hematologic diagnoses in their cohorts. We aimed to evaluate incidence, risk factors and prognostic impact on relapse and mortality of AKI occurring in the first 100 days post-HSCT in patients with lymphomas submitted to autologous HSCT considering KDIGO classification.

**Methods:** Single-center retrospective cohort study including patients with lymphomas admitted for autologous HSCT between 2005 and 2015. AKI classified by KDIGO classification with daily values of creatinine and 6-hour urinary output (UO) until hospital discharge, and weekly evaluations until 100 days post-HSCT. Survival analysis methods considering death as competing risk were used to evaluate AKI cumulative incidence, risk factors and impact on relapse. Cox regression was used for AKI impact on 3-year mortality.

**Results:** 115 patients were included, 51.3% male, 91.3% Caucasian, age 50.2 (33.9-59.5), BMI 25.3 (21.8-35.9), HCT-Cl <2 in 84.4% of patients and mean eGFR 107.5 ml/min (94.3-124.6). Hematologic diagnosis: 63.5% B-cell lymphomas, 32.2% Hodgkin lymphomas, 4.4% T-cell lymphomas. 19.3% submitted to radiotherapy in the past, number of chemotherapy cycles 9 (7-10). Conditioning regimen: 94.8% BEAM and 5.2% TEAM. Cumulative incidence of AKI: 62.8% 30 days post-HSCT and 63.7% 100 days post-HSCT. First diagnosis criteria: creatinine in 54.8%, UO in 41.1% and both in 4.1%. AKI highest stage: 1 in 57.5%, 2 in 17.8% and 3 in 24.7%. In multivariable model for AKI, variables independently associated with higher incidence were: nephrotoxic drugs (HR: 2.87, 95%CI: 1.07-7.65; p=0.035), mucositis (HR: 1.95, 95%CI: 1.16-3.29; p=0.012) and shock (HR: 2.63, 95%CI: 1.19-5.85; p=0.017). In survival analysis, moderate to severe AKI (stage ≥2) was independently associated with mortality (HR: 2.04, 95%CI: 1.06-3.94; p=0.033). No independent association was found between AKI and relapse.

**Conclusions:** AKI affects almost 2/3 of patients with lymphomas submitted to autologous HSCT. Nephrotoxic drugs, mucositis and shock are important independent AKI risk factors. More than 1/3 of AKI episodes are moderate to severe and these are associated to higher 3-year mortality.

#### SA-PO042

#### Multisystem Inflammatory Syndrome in Adults: A Consequence of COVID-19

Amara Sarwal, Ritika Ohri, Josephine Abraham, Monique E. Cho. *University of Utah Health, Salt Lake City, UT.*

**Introduction:** An association between COVID-19 and a novel pediatric inflammatory condition, coined as multisystem inflammatory syndrome (MIS), has recently prompted an international alert. While multi-organ involvement of COVID-19 is common in all ages, reports of MIS have predominantly involved children. Herein, we present a case of an adult who presented with MIS.

**Case Description:** A 38 year-old Caucasian male, who had contracted COVID-19 two months prior to presentation, was admitted with 1-week history of abdominal pain, frontal headache, fever of 104° F and dark urine. His exam was notable for erythematous, blanching macular rash on his trunk and arms. He quickly progressed to shock, requiring vasopressor and ventilator support. He developed acute kidney injury, with serum creatinine (SCr) increasing to 7.09 mg/dL from 1.9 mg/dL at presentation and required continuous renal replacement therapy (CRRT). Urinalysis revealed > 182 mostly non-dysmorphic RBCs and random urine protein-to-creatinine ratio of 1,273 mg/g. The previous urological evaluation was negative, prompting suspicion for IgA nephropathy. Serum IgG and IgE were elevated, with normal levels of IgA and IgM. Due to development of pulmonary infiltrate with hypoxia, there was concern for pulmonary-renal syndrome. The serologies were negative, including ANCA, anti-GBM, ANA, hepatitis B and C, HIV and complements. Blood cultures were also negative. Elevations were noted in interleukin (IL) 6 at 114.3 pg/mL, soluble IL-2 receptor at 42364.7 pg/mL, and IL-1β at 10.2 pg/mL. The patient had antibodies against COVID-19 IgG spike protein at 1.91 IV. Skin biopsy revealed vacuolar interface dermatitis with eosinophils, consistent with MIS in adults (MIS-A) in the setting of recent COVID infection. The decision was made to treat with solumedrol and IVIG. Within 2 days of IVIG therapy, his renal function improved significantly. CRRT was discontinued and he was transferred out of ICU. Three months following the hospitalization, his SCr improved to 0.9 mg/dL without hematuria.

**Discussion:** Acute renal injury is common in pediatric cases of MIS, with an excellent rate of renal recovery. The course and prognosis of renal injury in adults with MIS (MIS-A), however, have not been well described. Our case provides an important insight that even severe renal injury in MIS-A may carry a favorable prognosis with prompt immunomodulatory therapy.

#### SA-PO043

#### Diarrheal Dilemma: A Unique Cause of Atypical Hemolytic Uremic Syndrome

Arrsh Bajaj, Jin Huang, Hilmer O. Negrete. *Mercy Health St Elizabeth Youngstown Hospital, Youngstown, OH.*

**Introduction:** Thrombotic microangiopathies (TMA) comprise a variety of diseases ranging from ADAMTS13 deficiency, complement-mediated TMA, shiga-toxin mediated hemolytic uremic syndrome (STEC-HUS) and drug mediated TMA. Atypical HUS (aHUS) accounts for approximately 10% of HUS cases. Organisms implicated in aHUS include *Streptococcus pneumoniae*. Literature review demonstrates only ten adults with *C. difficile* associated aHUS (CD-aHUS). The case presented below would be the 11<sup>th</sup> known case.

**Case Description:** A 56-year-old female presented with abdominal pain, diarrhea and bright red blood per rectum. She recently had taken antibiotics for a dental procedure. Initial labs revealed a creatinine 0.9 mg/dL, WBC 30k, hemoglobin 15.9 g/dL, platelets 200k. Imaging showed proctocolitis. Further testing revealed negative stool cultures but positive EIA assay for CD. Her creatinine rapidly increased to 3.1. She also had new thrombocytopenia (18k), anemia (62g/dL) and urine sediment showed granular casts. Peripheral smear showed schistocytes. Lactate dehydrogenase (LDH) was 2131 U/L, haptoglobin was <10 mg/dL. Complement and ADAMTS13 levels were normal, anti-factor H antibodies were negative. Methylprednisolone 125mg daily for six days was started with daily PLEX (one volume exchange with fresh frozen plasma). Kidney biopsy showed diffuse global mesangiolysis, RBC fragmentation with scattered presence of luminal fibrin thrombi, all consistent with TMA and acute tubular injury. Her hospital course was complicated by right subcapsular kidney hematoma and COVID19 infection. She underwent eight PLEX sessions during her hospital stay. At the time of discharge, diarrhea had resolved, LDH and creatinine had reduced to 731 U/L and 1.7 mg/dL respectively. One month after discharge, the patient had completed 17 PLEX sessions and her serum creatinine had improved to 1.1 mg/dL. LDH was 297 U/L while haptoglobin continued to be <10 mg/dL, at that point was PLEX was discontinued.

**Discussion:** Atypical HUS is rare but has a high mortality rate, risk of progressing to end stage renal disease and relapse. About 40-60% of aHUS cases occur in individuals >18 years of age and has many triggers including CD. Literature review of CD-aHUS cases showed that out of ten patients, six underwent plasmapheresis with three patients using eculizumab. This case report highlights the efficacy of plasmapheresis as a treatment modality for CD-aHUS.

#### SA-PO044

#### Combined Bivalirudin and Citrate Anticoagulation for Recurrent Continuous Kidney Replacement Therapy Clotting in COVID-19-Associated AKI

Chaitanya A. Pal, Victoria Milano, Michelle Shieh, Preeyaporn Sarangarm, J. Pedro Teixeira. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

**Introduction:** Extracorporeal circuit (EC) thrombosis commonly complicates continuous kidney replacement therapy (CKRT), especially in prothrombotic COVID-19 patients in which refractory EC clotting is well described. We present a case of recurrent EC clotting in acute kidney injury (AKI) requiring CKRT in COVID-19 managed with regional citrate anticoagulation (RCA) and bivalirudin.

**Case Description:** A 70-year-old man presents with weakness and is diagnosed with COVID-19, pulmonary tuberculosis, left internal jugular (IJ) deep vein thrombosis treated with IV unfractionated heparin (UFH), and cerebellar stroke. He develops respiratory failure requiring mechanical ventilation, septic shock, rectal bleeding causing interruptions in anticoagulation (AC), oliguric AKI, and hyperkalemia for which CKRT is initiated with a PrismaMax device and a 15-cm-long 13-French Power-Trialysis catheter placed in the right IJ. Despite good access function and a mean filtration fraction of 15.3%, recurrent EC thrombosis develops, for which various AC strategies are trialed [Table]. Only the combination of systemic bivalirudin and RCA proves effective. However, he ultimately dies after the family opts to transition to comfort measures.

**Discussion:** The use of direct thrombin inhibitors (DTIs) as AC for CKRT had only been reported pre-pandemic in small studies or case series, with only one case report describing argatroban combined with RCA. Though RCA has repeatedly been shown in non-COVID-19 patients to be superior to UFH as AC for CKRT, both therapies in COVID-19 often fail to prevent EC thrombosis, leading many to try other strategies such as DTIs or RCA combined with UFH. In our patient, UFH with RCA allowed one EC to last >24h, but multiple subsequent ECs clotted in <12h. However, by combining bivalirudin and RCA we prevented premature thrombosis of the subsequent two ECs. This is the first report of using bivalirudin with RCA for CKRT AC and suggests the combination may be useful in COVID-19 patients with recurrent CKRT circuit clotting.

	Hemofilter	Mode	Anticoagulation	Circuit life (h)	Reason for Stopping
1	M-100	CVVHDF	None	4	Filter Clotting
2	M-100	CVVHDF	None	4	Filter Clotting

\*Systemic unfractionated heparin targeting anti-Xa level of 0.3-0.5 units/mL. <sup>†</sup>Regional citrate anticoagulation with Anticoagulant Citrate Dextrose Solution A targeting post-filter ionized calcium of 0.25-0.5 mmol/L. <sup>‡</sup>Targeting partial thromboplastin time of 45-75 seconds. <sup>§</sup>Includes two 1.5-hour periods in recirculation mode. CVVHDF, continuous venovenous hemodiafiltration.

## SA-PO045

### AKI Caused by Devastating Hemophagocytic Lymphohistiocytosis Triggered by Multiple Factors

Felipe Pascoal, Jose M. Vieira Jr., Lucia Andrade. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

**Introduction:** Hemophagocytic Lymphohistiocytosis (HLH) is an aggressive condition defined by cytokine storm and blood cell phagocytosis. Renal involvement is still poorly characterized, but includes hypoperfusion, tubular damage, nephrotic syndrome and thrombotic microangiopathy. We report a case in which a patient with HLH developed acute kidney injury requiring dialysis leading to death.

**Case Description:** A 63-year-old with stable HIV and Type 2 Diabetes was referred to the Emergency Department (ER) due to septic shock and an unsolved oral ulcer. For 3 months he had been seen at the Dermatology Clinic because of a slow-growing hard palate lesion, impairing food intake and leading to malnutrition and weight loss. After clinical stabilization at the ER, he was transferred to the ICU, developed significant pancytopenia (Hb 6.7 g/dL, 450 total leucocytes/ $\mu$ L, 41,000 platelets/ $\mu$ L), hyperferritinemia (41,377 mg/dL), hypertriglyceridemia (318 mg/dL) and was diagnosed with Hemophagocytic Lymphohistiocytosis according to HScore and bone marrow aspirate showing hemophagocytosis. Chest Computed Tomography revealed prominent mediastinal lymphadenomegaly, raising suspicion of lymphoma, and PCR for Epstein-Barr Virus was positive both on bone marrow (927,635 uL/mL) and blood (8,903 uL/mL) analyses. Days after guided antibiotic treatment for *Klebsiella pneumoniae* bloodstream infection, hemodynamic stability, absence of fever, nephrotoxic drug withdrawal and ongoing pancytopenia, serum creatinine levels rose from 1.74 mg/dL to 3.78 mg/dL, BUN levels rose from 67 mg/dL to 105 mg/dL and urinary output decreased from 800 mL/day to 200 mL/day. The patient was placed on Slow Low Efficiency Dialysis due to failure of conservative AKI management. Despite 15 days of treatment with Etoposide and Methylprednisolone, the patient developed painful abdominal distention and deceased from bowel perforation and fecal peritonitis secondary to angioinvasive aspergillosis and candidiasis.

**Discussion:** HIV patients are predisposed to HLH, which can be triggered by multiple factors, including infection (viral, bacterial and fungal) and malignancy, that likely occurred in this case. Although usually neglected in the pathophysiology of this syndrome, kidney involvement should be acknowledged, emphasized and tackled, as it worsens outcomes translating into high morbidity and mortality rates.

## SA-PO046

### Otological Manifestations in ANCA-Negative Pauci-Immune Vasculitis: A Compelling Clue When Serologies Are Negative

Megan L. Baker, Jeffrey M. Turner. *Yale School of Medicine, New Haven, CT.*

**Introduction:** Otological manifestations are often observed in ANCA-associated pauci-immune vasculitis (AAV), and include otalgia, hearing loss, vertigo, and tinnitus. The diagnosis of AAV in a patient presenting with otological manifestations can be challenging when otological symptoms are the predominant presenting feature or when ANCA testing results negative. A delayed diagnosis in these settings may result in more advanced hearing loss or recurrent AAV flares.

**Case Description:** A 66-year-old woman with CKDIIIa and hypertension presented with polyarthralgias, AKI, severe bilateral sensorineural hearing loss, vertigo, oral mucositis, scleritis, and hand joint pain with rash. Laboratory testing revealed leukocytosis, anemia, thrombocytopenia, negative anti-MPO and anti-PR3 titers, positive ANA(1:320), normal complement levels, and otherwise negative serologic workup. MRI brain showed left middle ear cavity scarring. She was given steroids for diagnosis of vestibular neuritis, labyrinthitis, and reactive arthritis with persistent hearing loss but recovery of AKI and other symptoms. Several months later she developed altered mental status, fevers, and AKI, and was found to have a UTI. After initial improvement with antibiotics, steroids, and IV fluids, she developed recurrent polyarthralgias and AKI. Kidney biopsy demonstrated pauci-immune necrotizing glomerulonephritis. Pulse dose steroids and rituximab for ANCA-negative pauci-immune glomerulonephritis resulted in improvement in Cr. With non-recovery of her hearing loss, she ultimately underwent cochlear implant surgery.

**Discussion:** Otological symptoms such as sensorineural hearing loss incurred in this case along with AKI should prompt an evaluation for AAV, as otitis media is a relatively common manifestation of disease. This case demonstrates the specific diagnostic challenge presented by an ANCA-negative pauci-immune vasculitis with otological involvement. In comparison to cases with positive ANCA serologies, cases of MPO- and PR3-negative pauci-immune vasculitis present a significant diagnostic challenge, being less common and less readily recognized. The co-occurrence of otological symptoms and AKI should prompt a higher clinical suspicion for AAV even in the absence of positive ANCA serologies, as these cases are estimated to represent a small fraction (~13%) of cases of otitis media associated with AAV.

## SA-PO047

### Native BK Polyomavirus Nephropathy in an Orthotopic Heart Transplant Recipient

Zachary M. Thompson,<sup>1</sup> George O. Ajene,<sup>1</sup> Mark Kandary,<sup>1</sup> Prathit A. Kulkarni,<sup>1,2</sup> Nidhi Aggarwal,<sup>1,2</sup> Savitri Fedson,<sup>1,2</sup> Maulin Shah.<sup>1,2</sup> *<sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Michael E DeBakey VA Medical Center, Houston, TX.*

**Introduction:** BK polyomavirus nephropathy (BKVN) is a common cause of kidney allograft dysfunction. It typically occurs within the first year post-transplantation. BKVN in native kidneys after extra-renal solid-organ transplantation (SOT) is unusual. Here, we report a case of native BKVN occurring 13 years after orthotopic heart transplant (OHT).

**Case Description:** A 75-year-old man with Grade 3b chronic kidney disease presented with acute kidney injury. He had undergone OHT 13 years prior with stable allograft function and no recent episodes of rejection. His immunosuppressive regimen consisted of tacrolimus, sirolimus, and mycophenolate mofetil (MMF). Three months prior to presentation, he had developed obstructive ureterolithiasis requiring ureteral stenting. Imaging at the time of his current presentation showed resolution of prior ureteral obstruction. Serum levels of immunosuppressive agents were within therapeutic range. The serum BK viral load was 362,000 copies/mL. Kidney biopsy revealed acute tubular injury with focal viral cytopathic changes and SV40 staining within tubular epithelium, consistent with BKVN. Immunosuppression was reduced by stopping sirolimus and exchanging MMF for leflunomide with subsequent improvement in kidney function.

**Discussion:** While BK virus seropositivity is common worldwide, BKVN is almost exclusively seen in kidney transplant patients. Native-kidney BKVN after extra-renal SOT is uncommon. Intensity of immunosuppression is a well-known risk factor for viral replication; ureteral stenting has also been associated with BKVN. However, since clinical manifestations of BKV infection often include genitourinary (GU) tract pathology, ureteral strictures may be either a symptom or risk factor of infection. Although rare, it is important for clinicians consider BKVN even in patients with non-renal SOT, especially in the clinical context of known GU disease. Treatment of native BKVN is based on experience from treatment of BKVN in kidney transplant patients. While there are no randomized controlled trials, the current mainstay of treatment is reduction of immunosuppression, backed by meta-analyses and observational studies. Additional possible therapies without strong evidence include intravenous immunoglobulin, leflunomide, cidofovir, brincidofovir, and fluoroquinolones.

## SA-PO048

### Utilizing Gadolinium 67 Scintigraphy to Diagnose Acute Interstitial Nephritis

Hiral Patel, Foram Bhagat, Siddhartha Kattamanchi. *Marshfield Clinic Health System, Marshfield, WI.*

**Introduction:** We aim to present a case of acute interstitial nephritis (AIN) secondary to nafcillin, which was diagnosed using gallium scintigraphy, and discuss its role in diagnosing AIN where a biopsy cannot be done.

**Case Description:** An 88-year patient presented to our clinic with altered mental status. The patient was found to have bacteremia with methicillin-susceptible *Staphylococcus aureus* and for which she was treated with nafcillin. After 20 days of nafcillin treatment, the patient's creatinine started to worsen and reached 2.5 mg/dL from a baseline of 0.9-1.0 mg/dL. Urine analysis showed pyuria, and interstitial nephritis from nafcillin was suspected. Nafcillin was stopped, and the patient was started on steroids. The patient was not a candidate for kidney biopsy due to multiple comorbidities and shock; hence we chose to do Gadolinium scintigraphy to diagnose AIN. Gadolinium 67-citrate intravenous 6.75-mCi scan showed diffuse activity in the kidneys bilaterally with at least grade 3 uptake, which was suggestive of AIN. After five days course of IV methylprednisone, creatinine improved to baseline.

**Discussion:** Kidney biopsy is the gold standard for diagnosing acute interstitial nephritis. But in cases where kidney biopsy is not possible, we don't have other alternate tests to confirm interstitial nephritis. Gallium 67 scintigraphy has been shown to be a very useful noninvasive tool to diagnose AIN; an uptake cutoff of 3 had a 75 % specificity, while an uptake cutoff of 1 had a 100% negative predictive value (1). Hence, in cases where kidney biopsy if not possible, gallium 67 scintigraphy can become a good noninvasive modality to diagnose AIN, as shown in our case.

## SA-PO049

### AKI After Taking the Extract of *Cudrania tricuspidata* in a Patient Taking Nonsteroidal Anti-Inflammatory Drugs

Sua Lee, Jaehyun Jun, Jeongwoo Kim. *Eulji University College of Medicine, Daejeon, Republic of Korea.*

**Introduction:** Acute tubulo-interstitial nephritis (ATIN) is an acute kidney disease characterized by infiltration of inflammatory cells localized in the renal tubules and interstitium. ATIN is well known to be developed by hypersensitivity reaction to drugs or infections. We reported an unusual case of ATIN after taking the extract of *Cudrania tricuspidata* (C. tricuspidata) with taking long-term nonsteroidal anti-inflammatory drugs (NSAIDs).

**Case Description:** A 69-year-old male patient visited the emergency room with complaints of general edema that occurred 2 weeks ago and oliguria that occurred 2 days ago. He was diagnosed hypertension 3 years ago. He had been taking Naproxen 500 mg intermittently for knee pain for 6 months and C. tricuspidata leaf tea every day for 3 months. Initial laboratory findings were as follows: blood urea nitrogen, 53 mg/dL; creatinine (Cr), 9.9 mg/dL; estimated glomerular filtration rate (eGFR), 5.3 ml/1.73m<sup>2</sup>/min; albumin, 3.3g/dL; total immunoglobulin E > 5000 IU/ml; urine protein-creatinine, 14.3 g/mg. He underwent emergent hemodialysis and kidney biopsy to evaluate the cause of acute kidney injury. Light microscopy revealed that numerous lymphoplasmacytic with some eosinophils were infiltrated in the tubulointerstitium, consistent with ATIN. Electron microscopy revealed diffused effacement of foot process and interstitial edema, consistent with minimal change disease (MCD). Steroids were administered intravenously for ATIN and MCD. He was discharged after 4 weeks with Cr 1.5 mg/dL and eGFR 47.1 ml/1.73m<sup>2</sup>/min.

**Discussion:** Each case of acute liver failure and acute generalized exanthematous pustulosis after taking the extract of C. tricuspidata was previously reported. Physicians should be concerned that C. tricuspidata can cause ATIN as a hypersensitivity reaction.

Numerous lymphoplasmacytic with some eosinophils were infiltrated in the tubulointerstitium, consistent with ATIN.

## SA-PO050

### A Rare Case of Light Chain Cast Nephropathy, Light Chain Proximal Tubulopathy, and Crystal-Storing Histiocytosis in a Patient With Multiple Myeloma

Albert Bui, Parikshit Duriseti, Mary E. Fidler, Sarwat Gilani, James R. Gregoire. *Mayo Clinic Minnesota, Rochester, MN.*

**Introduction:** We report a rare case of combined light chain (LC) cast nephropathy, LC proximal tubulopathy (LCPT) and crystal-storing histiocytosis (CSH) in a patient with multiple myeloma (MM).

**Case Description:** A 58-year-old female presented with several days of nausea, anorexia, weakness and on evaluation was found to have serum creatinine of 14.2 mg/dL, hemoglobin of 8.1 g/dL, and serum calcium of 13.2 mg/dL. She was diagnosed with MM/plasma cell leukemia in the context of IgA  $\lambda$ -monoclonal protein with circulating  $\lambda$ -restricted plasma cells, bone lytic lesions on skeletal survey, 80-90% marrow plasma cell infiltration, and  $\lambda$ -free light chain of 2850 mg/dL. A kidney biopsy revealed  $\lambda$ -LC cast nephropathy, crystalline LCPT and CSH. IF noted diffuse granular tubulointerstitial staining with  $\lambda$ -LC without distinct localization to the tubular or glomerular basement membranes. There was no accompanying staining with  $\kappa$ -LC. CD68 stain was positive in interstitial cells confirming large number of histiocytes/macrophages with crystals. EM confirmed numerous intratubular casts and intracytoplasmic needle-shaped and rhomboid crystals with similar crystals within interstitial histiocytes. For acute kidney injury, she required initiation of dialysis. She underwent plasmapheresis for 7 days for cast nephropathy and started chemotherapy with CyBorD. She remained dialysis-dependent at 3-month follow-up.

**Discussion:** Multiple myeloma (MM) is characterized by clonal plasma cell proliferation and is defined by 10% or more bone marrow plasma cells and one or more of myeloma-defining events (hypercalcemia, renal insufficiency, anemia, and bone lesions). About 15-20% of patients with newly diagnosed multiple myeloma present with severe renal insufficiency. The most common MM-related kidney disease is light chain cast nephropathy (LCCN) resulting from co-precipitation of immunoglobulin free light chains with Tamm-Horsfall glycoproteins. Rarely, paraproteins can crystallize within proximal tubular cells (crystalline LCPT) or interstitial histiocytes (CSH). LCCN, LCPT and CSH occurring together in MM as seen in our case is extremely rare. Other unique feature of our case was  $\lambda$ -restricted crystalline LCPT and CSH (majority of cases reported in the literature of crystalline LCPT and CSH are  $\kappa$ -restricted).

## SA-PO051

### Use of Medium Cut-Off Dialyzers in AKI Associated With Multiple Myeloma

Shahzad Zonoozi, Rasha Nakity, Ashte K. Collins, Renu Regunathan-Shenk, Janani Rangaswami. *The George Washington University Hospital, Washington, DC.*

**Introduction:** The pathogenesis of myeloma cast nephropathy (MCN) involves precipitation of serum free light chains (FLC) with uromodulin leading to acute kidney injury (AKI). The benefits of rapidly removing circulating FLC in MCN has not been established. Available literature suggests that along with chemotherapy, intensive hemodialysis using high and medium cut off (MCO) dialyzers is associated with a larger reduction in FLC and a higher rate of renal recovery compared to high flux dialyzers.

**Case Description:** We describe two patients with multiple myeloma (MM) and AKI requiring kidney replacement therapy (KRT) who along with chemotherapy were managed with MCO dialyzers (Theranova 400). Patient 1 is a 72 year old male with history of IgG lambda MM and CKD 4 with dialysis-dependent AKI and work up revealed elevated lambda FLC. Patient 2 is a 58 year old male with history of IgG kappa MM treated with stem cell transplantation and chemotherapy presenting for ongoing care for COVID-19 infection. Course was complicated by respiratory failure, infections and AKI. Rising kappa FLC led to patient receiving chemotherapy. Table 1 shows the trend of albumin, kappa and lambda FLC. MCO dialyzer was initiated on Day 0. After use of MCO dialyzer, Patient 1 had a reduction in lambda FLC of 377.5mg/L and albumin of 0.4g/dL while Patient 2 had an increase in kappa FLC of 3168mg/L and albumin of 0.8g/dL. During follow up neither patient had signs of recovery of kidney function.

**Discussion:** The utility of MCO dialyzers in the management of MCN remains unclear. In our patients, one had a reduction in FLC burden while the other had an increase. Further longitudinal research is required to elucidate the utility of MCO dialyzers in patients with MM.

Day	Albumin (g/dL)	$\beta$ 2M (mg/L)	FLC-k (mg/L)	FLC- $\lambda$ (mg/L)	Treatments	Albumin (g/dL)	FLC-k (mg/L)	FLC- $\lambda$ (mg/L)	Treatments

FLC-k = kappa free light chain; FLC- $\lambda$  = lambda free light chain;  $\beta$ 2M = beta 2 microglobulin, PLEX = plasmapheresis; D = daratumumab; VD = bortezomib (velcade) and dexamethasone; CyBorD = cyclophosphamide, bortezomib, dexamethasone; dexa = dexamethasone; MCO = medium cut off dialyzer

SA-PO052

Trabectedin-Associated AKI: A Case Report

Sarah Hryzak, Abdallah Sassine Geara. University of Pennsylvania, Philadelphia, PA.

**Introduction:** Trabectedin is an alkylating chemotherapeutic agent approved for the treatment of advanced soft tissue sarcoma and ovarian cancer. Pancytopenia is a commonly reported adverse event. Abnormal liver function tests, mainly transaminitis, is reported in more than half of the patients. Rhabdomyolysis is a rarely reported side effect. Most of these events are reversible and rarely require hospitalization as it is generally considered a well-tolerated treatment. Acute kidney injury (AKI) is a not a known side effect. We report a case of fatal trabectedin toxicity with AKI as the predominant feature.

**Case Description:** A 72-year-old woman with stage IA clear cell carcinoma and stage IB leiomyosarcoma status post hysterectomy with lung metastasis had received a single round of trabectedin 1.5 mg/m2 and was admitted the following day with acute liver injury (AST 1595 U/L, ALT 977 U/L) and AKI (baseline serum Creatinine (sCr): 0.9 mg/dL; admission sCr: 1.2 mg/dL). The urine sediment was bland; the creatinine kinase (CK) was not elevated. Since the FeNa was less than 1% the AKI was felt to be prerenal. With crystalloid hydration, the patient progressively became anasaric and the AKI continued to worsen making acute tubular injury the more likely diagnosis. Eventually, the sCr peaked at 5.39mg/dL and the patient had to be started on kidney replacement therapy (KRT) for progressive encephalopathy and worsening peripheral edema. She continued to decline clinically and became hypotensive requiring vasopressors and hypoxic requiring invasive ventilatory support. The patient eventually died three days after starting RRT. The patient developed rhabdomyolysis twelve days into her admission with the peak of CK of 14,000 and was not a felt to be a major contributor to the AKI that was well established by then.

**Discussion:** We present a case report of severe trabectedin-associated AKI ultimately resulting in patient death. A previous case report described treatment of trabectedin-induced rhabdomyolysis resulting in AKI that resolved with isotonic intravenous fluids. In this present case, the AKI had features compatible of prerenal etiology eventually leading to tubular injury with severe capillary leak physiology. Rhabdomyolysis was not a predominant feature. Although not known to have direct kidney toxicity, trabectedin treatment can lead to AKI through multiple mechanisms and should be further studied.

SA-PO053

Biopsy Proven Bilateral Pyelonephritis Caused AKI Requiring Hemodialysis: Case Report and Review

Najjar Yaseen, Laura Hernandez, Mauricio Monrroy. Albany Medical Center, Albany, NY.

**Introduction:** Severe acute kidney injury requiring dialysis caused by only acute pyelonephritis (APN) is rare. A study showed that APN caused AKI in 26.5% and kidney failure in 11.5%. Risk factors were chronic kidney disease, older age, bilateral renal involvement, and hemodynamic shock [1]. Here, we present a case of pyelonephritis leading to acute renal failure requiring hemodialysis with subsequent recovery of kidney function in a patient without prior kidney disease.

**Case Description:** 66-year-old woman presented with fever for 4 days and abdominal pain, no use of nephrotoxics. On exam, she was febrile (102.6F), tachycardic, normotensive, and fluid overload. Labs showed WBC 19.6x10<sup>3</sup>/uL, Na 126mEq/L, creatinine 3.69mg/L, (baseline 0.75 mg/l). CT showed normal kidneys. Blood and urine culture grew E. Coli. Dialysis was started for anuria and hypervolemia. To explain AKI, biopsy was done showing ATN and acute and chronic pyelonephritis with 80% parenchyma destruction with minimum scarring. Day 18, CT showed no renal abscess but new finding of multiple bilateral wedge-shaped hypodensities. Kidney function recovered completely. Dialysis was completely weaned off. Repeated CT showed resolution of kidney hypodense wedges. After 7 weeks of hospitalization, patient was discharge to physical rehabilitation with creatinine and urine output of 2.5mg/L and 1700ml/24hr.

**Discussion:** Only 16 cases were reported of biopsy proven renal failure secondary to APN with normal kidneys [2]. In absence of hemodynamic instability and nephrotoxicity, (APN) was sole cause for AKI-requiring dialysis. Rarity of pyelonephritis to cause AKI to this extent of severity along with complete recovery make this case novel to literature. 1. Jeon, D.H., et al., *Incidence, risk factors, and clinical outcomes of acute*

*kidney injury associated with acute pyelonephritis in patients attending a tertiary care referral center.* Ren Fail, 2019. 41(1): p. 204-210. 2. Jones, S.R., *Acute renal failure in adults with uncomplicated acute pyelonephritis: case reports and review.* Clin Infect Dis, 1992. 14(1): p. 243-6.

SA-PO054

Baclofen Poisoning in a Patient With AKI

Saad A. Alshihri, Angela H. Lam, Nicholas Husak, James B. Leonard, Joshua D. King. University of Maryland Medical Center, Baltimore, MD.

**Introduction:** A case of baclofen overdose is presented in a patient who was chronically taking the medication for muscle spasms and suffered acute kidney injury (AKI) while hospitalized, resulting in a prolonged and complicated hospital course. Restoration of the patient's baseline mental status was achieved with hemodialysis (HD). Baclofen is commonly used in patients with muscle spasms and caution should be applied when using the medication in patients with AKI given extensive kidney clearance.

**Case Description:** A 57-year-old female with a past medical history of tetraplegia, neurogenic bladder with a suprapubic catheter, diverting ileostomy presented to the hospital with fever, nausea, vomiting, and abdominal discomfort. She was found to have cholecystitis and underwent percutaneous cholecystostomy. Following the procedure, her kidney function declined with serum creatinine reaching 3.6 from a baseline of 1.16 mg/dL. On the fifth day of admission, the patient was found to be unresponsive and was transferred to the intensive care unit (ICU). On transfer to the ICU, the patient developed anuria, shock requiring vasopressors, and worsening mental status with subsequent intubation. Baclofen was discontinued on transfer to the ICU, and HD was performed on hospital day #7. Following a single session of HD, mental status notably improved allowing extubation. The patient continued to have a complicated hospital course involving reintubation for respiratory failure, emergent tracheostomy, prolonged mechanical ventilation, and percutaneous gastrostomy tube placement. An attempt was made to reinstitute baclofen, which resulted in lethargy and possible seizures, prompting discontinuation. Her mental status slowly improved and the patient was discharged after a 21-day stay.

**Discussion:** Baclofen is a GABA-B receptor agonist used primarily for spasticity. While it has a half-life of 2-6 hours in normal kidney function, baclofen is 70-85% eliminated unchanged in the urine and may accumulate in patients with reduced kidney function. Baclofen poisoning can result in severe neurotoxicity including confusion, somnolence, coma, seizures, and autonomic dysfunction. Prompt recognition of baclofen toxicity is essential in the management of baclofen overdose, HD may be necessary for patients with impaired kidney function as the estimated half-life in overdose can exceed 30 hours.

SA-PO055

Pancreatitis-Associated Atypical Hemolytic Uremic Syndrome

Avilasha Sinha, Jingyin Yan. Baylor College of Medicine Margaret M and Albert B Alkek Department of Medicine, Houston, TX.

**Introduction:** Atypical hemolytic uremic syndrome (aHUS) is a rare form of TMA that can present as AKI and can progress to ESRD and even be fatal making prompt diagnosis and treatment very important.

**Case Description:** A 41-year-old male with a history of recurrent, non-alcoholic pancreatitis presented with epigastric pain. His lipase level was elevated and CT showed acute pancreatitis. Exam was notable only for epigastric tenderness. Labs (Table 1) included an elevated creatinine (Cr) of 14.7 (baseline was 1.0) and were suggestive of hemolysis although ADAMTS13 activity level and platelet count were normal. As the cause of his AKI could not be elucidated and his Cr remained elevated, renal biopsy was performed and showed fibrin thrombi and fragmented red blood cells consistent with TMA. A genetic panel found several polymorphisms strongly associated with aHUS. He was started on eculizumab and is continuing treatment with hopes of renal recovery although he is currently dialysis-dependent.

**Discussion:** The differential for this patient's AKI included ATN, AIN, and IgG4-related membranous nephropathy. As there were many potential etiologies, biopsy was helpful to definitively determine the cause of his AKI especially because the lack of thrombocytopenia made TMA seem unlikely. The trigger for aHUS in this case was most likely pancreatitis as the inflammation activates complement which compounds the complement overactivation in patients genetically predisposed to produce factor H autoantibodies. Eculizumab, which prevents formation of the membrane attack complex, has shown great efficacy in aHUS and early initiation is associated with better outcomes underscoring the importance of early diagnosis. This case highlights the association of aHUS with pancreatitis and demonstrates how lack of thrombocytopenia does not rule out HUS.

	Measured Value	Normal Range
Lipase	304 U/L	8 – 78 U/L
Creatinine	14.7 mg/dL	0.57 – 1.25 mg/dL
Blood Urea Nitrogen	107 mg/dL	7 – 21 mg/dL
Hemoglobin	5.7 g/dL	13.7 – 17.5 g/dL
Haptoglobin	< 8 mg/dL	14 – 258 mg/dL
Lactate Dehydrogenase	1,008 U/L	125 – 220 U/L
IgG4	125.2 mg/dL	4 – 86 mg/dL
Reticulocyte Count	7.5%	0.5 – 1.8%
Total Bilirubin	0.6 mg/dL	0.2 – 1.2 mg/dL
Platelet Count	200,000/ $\mu$ L	150,000 – 400,000/ $\mu$ L

**A Unique Case of Acute Renal Failure With Plasmodium Falciparum Requiring Renal Replacement Therapy**

Aisha Batool<sup>1,4</sup>, Shahzad Chaudhry,<sup>2</sup> Khadija Batool,<sup>5</sup> Muhammad A. Omar,<sup>3</sup>  
<sup>1</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>2</sup>Aurora Health Care, Milwaukee, WI; <sup>3</sup>TidalHealth Nanticoke, Seaford, DE; <sup>4</sup>Ascension Columbia St Mary's Hospital Milwaukee, WI; <sup>5</sup>Services Institute of Medical Sciences, Lahore, Pakistan.

**Introduction:** Malaria is a serious and endemic parasitic disease in the developing world, causing high morbidity and mortality. Plasmodium falciparum is one of the five protozoa responsible for serious disease manifesting as endorgan damage particularly Acute Renal Failure.

**Case Description:** Our patient is a 54-year-old male of East African origin. Five days after his return from Uganda, he presented to the Emergency room with high grade fever, rigors, black urination and lethargy. In Emergency Room he was found to have Acute Renal Failure with BUN 106 mg/dl, Serum Creatine 5.62 mg/dl and Total Bilirubin 9.5 mg/dl. Rapid Malaria antigen was positive for Plasmodium Falciparum with peripheral blood Parasitemia level of 9.5%. He was admitted to the Intensive Care Unit and started on Intravenous artesunate 2.4 mg/kg. Given the severity of his electrolyte abnormalities and Acute Renal Failure, he was started on intermittent Hemodialysis. Patient was given a total of two sessions of Hemodialysis with enough renal recovery to come off Hemodialysis.

**Discussion:** Plasmodium Falciparum is being accounted for more than 90% of the world's malaria mortality and remains an important threat to public health on a global scale. It causes the most serious illness called Black Water Fever and Cerebral malaria. All suspected cases of malaria should be confirmed using parasite-based diagnostic testing to swiftly distinguish between malarial and non-malarial fevers. Acute Renal Failure complicates up to 40% of Plasmodium Falciparum malaria. Most cases of malaria in the U.S. are imported and could therefore be avoided with appropriate personal protective measures and compliance with prescribed chemoprophylaxis. Healthcare providers must be educated not only on the diagnosis and treatment of malaria but especially on the importance of prevention.

**Calciophylaxis Associated With AKI**

Patrick J. Jenkinson, Dihan Thilakararatne, Katherine W. Kwon, Wajdi Al-Shweiat.  
 Spectrum Health Lakeland, Saint Joseph, MI.

**Introduction:** Calciophylaxis, also known as calcific uremic arteriopathy, is a disease that carries high mortality and morbidity. It is predominantly found in patients with end-stage kidney disease and is associated with a myriad of risk factors, including hyperphosphatemia, calcitriol therapy, warfarin therapy, diabetes, and female gender. We report a case of biopsy-proven calciophylaxis that developed in a patient with acute kidney injury.

**Case Description:** A 79-year-old woman with a past medical history significant for atrial fibrillation on apixaban, chronic kidney disease stage four with a recent *Clostridium difficile* infection not fully resolved, presented with chest pain, fatigue, shortness of breath, and vomiting. The patient was found to have acute kidney injury, anion gap metabolic acidosis, and hyperkalemia. A urinary catheter was placed with minimal return of urine. A fluid challenge of 500 mL crystalloid did not lead to increased urine output. Computed Tomography of the abdomen and pelvis was unremarkable for obstruction or any structural renal abnormality. Urinalysis revealed bacteria, proteinuria, pyuria and hyaline casts. Hemodialysis was initiated, but had to be terminated due to hypotension and pain in the lower extremities. Subsequent dialysis sessions also had to be cut short due to continued pain exacerbated by dialysis. Patient's renal function did not improve, with persistent hyperkalemia and anuria. During the hospitalization, the patient developed painful purpuric lesions on the legs bilaterally which converted to confluent hemorrhagic

bullae. The lesions were biopsied and revealed calciophylaxis with acute inflammation. Due to the significant ongoing pain, and complicated medical comorbidities, the patient ultimately elected comfort measures.

**Discussion:** This case demonstrates a rare presentation of calciophylaxis from acute kidney injury. It is known that calciophylaxis carries a high mortality and morbidity. Pain control and discontinuing possible exacerbating medications is essential in initial management. Treatment consists of a multidisciplinary approach to treat pain, prevent infection and prevent progression with medical therapies such as sodium thiosulfate. Despite these therapies, the mortality from calciophylaxis remains high and diagnosis portends a grim prognosis.

## SA-PO058

**A Case of Tubulointerstitial Nephritis and Uveitis With Fanconi Features**

Andrew C. Liu, Haiyan Zhang, Rakesh Malhotra. University of California San Diego, La Jolla, CA.

**Introduction:** Tubulointerstitial nephritis with uveitis (TINU) syndrome is an uncommon auto-immune disease with ocular-renal manifestations. Here we report a rare case of a patient with TINU and Fanconi features.

**Case Description:** A 20-year-old Chinese male presented with nasal congestion, myalgia and arthralgia for several months. He also complained of bilateral painful red eyes and photophobia. He had no significant medical history and was not taking any prior medications. Patient was seen by ophthalmology and was found to have bilateral posterior uveitis with no granuloma. His physical exam was otherwise normal. He was started on prednisone eye drops. Laboratory results showed increased inflammatory markers (ESR 42mm and CRP 0.57 mg/dL), renal dysfunction (serum creatinine 1.92 mg/dL) and anemia (Hgb 11.0 mg/dL). The chest radiography was normal. Serologies for syphilis, toxoplasmosis, hepatitis B and C, HIV, and tuberculin skin test were negative. No auto-immune marker (HLA-B27, complement C3 and C4, anti-nuclear antibody, and anti-neutrophil cytoplasmic antibody) was positive. Serum potassium, bicarbonate and glucose levels were normal. Whereas urine test showed glucosuria, proteinuria (0.5 g/g) and elevated beta-2 microglobulin (20649 ug/L). Fractional excretions for uric acid and phosphorous were elevated to 16% and 24% respectively. Renal biopsy showed severe diffuse interstitial inflammatory infiltrate with predominantly lymphocytes mixed with other inflammatory cells (Figure 1). No granuloma was identified. Severe tubulitis was present and immunofluorescence staining was negative for immunoglobulin, thus establishing the diagnosis of TINU with Fanconi like features. He was started on oral systemic steroids with improvement in kidney function.

**Discussion:** TINU is an immune-mediated process that involves autoantigens targeting renal interstitium and ocular cells. In cases of more severe tubulitis Fanconi syndrome may present. Future studies should report long-term renal outcomes, duration of steroid therapy and recurrence rates in patients with TINU and Fanconi syndrome.

**Nephrotoxic STINGS: Envenomation Syndrome Caused by Bees**

Maria E. Rivera, Jesus D. Vega-Colon, Alexis Rivera Gonzalez, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera, Carlos G. Rivera-Bermudez.  
 Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.

**Introduction:** Hymenoptera stings may result in a wide range of presentations varying from localized pain to systemic reaction, organ dysfunction and multiple organ failure. Rhabdomyolysis and Acute Kidney Injury are rare manifestations of envenoming syndrome following bee stings.

**Case Description:** An 80-year-old male presented with facial and neck swelling after having been stung by more than 200 bees while working in his backyard during the morning. On scene, patient was treated with epinephrine for suspected anaphylactic reaction. Medical history remarkable for hypothyroidism, ischemic cerebrovascular accident, major depression, and anxiety. Home medications included levodopa, lorazepam and paroxetine. No previous history of renal disease. Vital signs with blood pressure 158/92 mmHg, heart rate 104 beats per minute, respiratory rate 20 breaths per minute, oxygen saturation 98% at room air, temperature 36.5°C and weight 58 kg. Physical exam was remarkable for a frail male with multiples stingers present on his face, scalp, bilateral upper and lower extremities, and chest. He had marked periorbital, lips and neck swelling without airway obstruction. Foley catheter with 100 mL of cola colored

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

urine. Laboratory results were significant for leukocytosis of 16.88 cells/ $\mu$ L, BUN 23.7 mg/dL, creatinine 1.31 mg/dL, bicarbonate 20.3 mmol/L, CPK 7,570 U/L, urinalysis with proteinuria of 500 mg/dL and blood 3+ but 0-3 RBC cells/hpf, bilirubin 4.12 mg/dL with elevated liver enzymes. Shortly after admission, despite medical management, renal parameters aggravated, concomitant with anuria, hyperkalemia and metabolic acidosis requiring kidney replacement therapy. After 3 weeks of intermittent hemodialysis, renal function recovered.

**Discussion:** Envenoming syndrome is a rare condition that carries significant morbidity and mortality when presents with multiple Hymenoptera stings. Due to small volume of distribution, elderly patients are at a major risk of severe complications as in our case that patient complicated with hepatic dysfunction, rhabdomyolysis, and acute kidney failure.

## SA-PO060

### A Rare Case of Severe Calciphylaxis in an Adolescent With AKI

Mingyue He, Sheetal Koul, Jean Lee, Suzanne Boyle. *Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

**Introduction:** Calciphylaxis is a rare, life-threatening condition characterized by vascular calcification and occlusion of microvessels in the subcutaneous adipose tissue and dermis, resulting in ischemia and painful skin necrosis, mainly diagnosed in end-stage kidney disease. We present a case of a woman without a history of reduced GFR who developed calciphylaxis in the setting of critical illness with acute kidney injury (AKI).

**Case Description:** An 18-year-old woman with morbid obesity (BMI 70) presented with acute hypoxic respiratory failure and shock. Her course was complicated by three weeks of dialysis-dependent AKI. On the first day of dialysis, multiple bullae and erosions overlying retiform violaceous patches were noticed on her bilateral thighs. These progressed to necrotic eschars in 2-3 weeks. Multiple skin biopsies had features of thrombotic vasculopathy without evidence of vasculitis or calciphylaxis. A bone marrow biopsy, viral and autoimmune serologies, hypercoagulability evaluation, and anti-phospholipid antibody syndrome panel were unrevealing. Although her AKI had clinically recovered, a kidney biopsy was performed to find a unifying diagnosis. It showed 10% interstitial fibrosis and tubular atrophy, IgA nephropathy (IgAN), and acute tubular injury without crescents or vasculitis. Her skin wounds continued to worsen despite debridement, empiric steroid therapy, and resolution of her AKI and critical illness. Another skin biopsy captured calcium deposition along deep vessels to finally make a diagnosis of calciphylaxis five months later.

**Discussion:** This case underscores the importance of a high index of suspicion for calciphylaxis with concerning skin findings even in the absence of classic risk factors. Also, a negative Van-Kossa stain for vascular calcium deposits is not necessary to make a diagnosis and initiate empiric treatment. Our patient's risk factors were gender, morbid obesity, transient AKI-related hyperphosphatemia and secondary hyperparathyroidism, ischemia from hypotension, and, potentially, an autoimmune disorder IgAN. However, many patients have these risk factors and never develop calciphylaxis. Therefore, more research is needed to elucidate the epidemiology and pathophysiology of this highly morbid condition.

## SA-PO061

### Study of Outcome of AKI in Scrub Typhus

Aswini P. Patnaik. *Kalinga Institute of Medical Sciences, Bhubaneswar, India.*

**Introduction:** Scrub typhus is one of the neglected tropical diseases in the world. Scrub typhus is a mite-borne infectious disease caused by the intracellular Gram-negative bacteria *Orientia tsutsugamushi*. The clinical prognosis of scrub typhus varies from mild-to-severe course. Renal involvement is not uncommon in scrub typhus<sup>1</sup>. Including acute renal failure, nephrotic syndrome and end-stage renal disease leading to long-term hemodialysis<sup>2</sup>. The risk factors and prognosis of AKI associated with scrub typhus have been poorly studied<sup>3</sup>.

**Case Description: Aim:** To study the incidence, outcome of AKI in scrub typhus. To study the requirement of renal replacement therapy. **Material and Methods:** The study was done in Kalinga Institute of Medical Sciences, Bhubaneswar over a period of 30 months (April 2019 to October 2021) after getting approval from the Institute's Research and Ethics committee. It is a Prospective Cohort Study, involving 210 scrub typhus RT PCR positive cases aged more than 18 years. 19 cases were excluded because of co infection with other tropical fevers. Cases with CKD, malignancy, tuberculosis and autoimmune diseases were excluded from our study.

**Discussion: Results:** 191 cases out of 210 cases of scrub typhus (PCR positive) were subjected for study after excluding the co infection. Out of which 95 (49.2%) cases were detected to have AKI. 61 (64.2%) patients were male and 34 (35.8%) were female. Mean duration of hospital stay was 13.6 days. 21 (22.1%) patients underwent hemodialysis. 16 (16.8%) patients had requirement of mechanical ventilation. Average number of sessions of hemodialysis done in patients without requirement of mechanical ventilation was 2.33 times compared to 4.1 times in those requiring mechanical ventilation. All the patients received doxycycline along with other supportive therapy. There was no mortality observed during the study period. 63 cases were followed up for a median of one year, out of which two (3.17%) patients have developed CKD. **Conclusion:** Incidence of AKI in scrub typhus is high and have good outcome if diagnosed and treated early.

## SA-PO062

### Granulomatous Tubulointerstitial Nephritis Preceding a Diagnosis of Polyarteritis Nodosa

Clarkson Crane, Bethany E. Karl. *University of California San Diego School of Medicine, La Jolla, CA.*

**Introduction:** The systemic vasculitides are classified based on the size of the vessels involved and ANCA vasculitis is the most common to involve the small vessels of the kidney. Granulomatous tubulointerstitial nephritis (TIN) without glomerular involvement has been described in ANCA vasculitis but is not commonly reported with medium vessel vasculitis. We present a case of necrotizing granulomatous TIN associated with systemic polyarteritis nodosa (PAN).

**Case Description:** A 71-year-old female was admitted with a two-day history of purpuric lower extremity rash, abdominal pain, and AKI (serum creatinine 1.8 mg/dL from baseline 0.6 mg/dL). There was initially concern for IgA vasculitis and prednisone was started. A skin biopsy revealed leukocytoclastic vasculitis but negative IF. A kidney biopsy was notable for necrotizing granulomatous TIN but otherwise unremarkable appearance of the glomeruli. As her AKI and overall clinical status worsened, she was started on HD. Due to worsening liver function, a liver biopsy was done showing neutrophilic inflammation but no granulomas. Rheumatologic workup notable only for ANA 1:360 (normal complements, negative ANCA, MPO, PR3, RF, cryoglobulins). Infectious workup (TB, fungal, and parasitic) was unremarkable. There was neither NSAID nor antibiotic exposure prior to the kidney biopsy. Only home medication was losartan. She received dose 2 of Moderna COVID-19 vaccination 4 weeks prior. Her kidney function improved and dialysis was stopped, however, she developed a new foot drop. A sural nerve biopsy showed necrotizing vasculitis of a medium sized vessel. The clinical picture was felt to be most consistent with PAN. Her steroid dose was increased and she started Cytoxan per CYCLOPS protocol with subsequent clinical improvement.

**Discussion:** There are few prior reports of isolated TIN associated with PAN and there are often confounding exposures that can potentially explain AIN. In the present case, the early histologic diagnosis of TIN in the absence of known exposures suggests the TIN is likely associated with, and potentially secondary to, the concurrent vasculitic process. Clinically, her presentation may represent a small and medium vessel vasculitis overlap syndrome as her pathology was not entirely consistent with an ANCA-negative pauci-immune vasculitis nor PAN. Alternatively, the TIN may simply be a response to the systemic inflammatory condition.

## SA-PO063

### Targeted Proteasomal Degradation of IRAK4 Ameliorates Kidney Fibrosis Caused by AKI

Dario R. Lemos,<sup>1,2</sup> Diana O. Lopez Cantu,<sup>1,2</sup> Miriam Segoviano.<sup>1,2</sup> Lemos Lab HMS <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Proteolysis targeting chimeras (PROTACs) are heterobifunctional molecules that can trigger the selective degradation of intracellular proteins through the ubiquitin-proteasome system (UPS). PROTACs are emerging as a promising therapeutic strategy for variety of diseases, including inflammatory disorders. Here we assessed the anti-fibrotic and anti-inflammatory efficacy of an IRAK4 degrader molecule in acute kidney injury.

**Methods:** We tested the IRAK4 degrader molecule KYM-001/IRW-1080 *in vitro*, on isolated kidney stroma PDGFR $\beta$ <sup>+</sup> pericyte/fibroblasts cells and on hPSC-derived kidney organoids incubated with interleukin 1 $\beta$ , (IL1 $\beta$ ) and *in vivo* in a mouse model of unilateral ischemia/reperfusion injury.

**Results:** Our data *in vitro* results indicate that KYM-001 effectively abrogates myddosome signaling in kidney stromal cells *in vitro*. The results also show inhibition of fibrogenic and pro-inflammatory gene expression. KYM-001 also effectively inhibited fibrosis in kidney organoids induced after incubation of the organoids with IL1 $\beta$  for 96h. In this system, KYM-001 significantly inhibited myofibroblast formation and fibrogenic gene expression, and expression of NF- $\kappa$ B target genes. *In vivo*, IRW-1080 delivered orally via gavage alone was well tolerated and did not cause animal death, nor did it affect normal behavior in healthy wild type C57BL/6 mice. After unilateral IRI, IRW-1080 delivered by gavage at a dose of 50mg/Kg, every 48h starting on the day of IRI surgery and over a period of 14 days, showed superior anti-inflammatory and anti-fibrotic activity compared to the IRAK4 kinase activity inhibitor small molecule CA-4948 delivered at a 75mg/Kg dose. In addition, animals that received IRW-1080 showed reduced levels of tubule injury and expression of the tubule injury marker KIM1.

**Conclusions:** Collectively, our findings validate the role myddosome signaling and particularly of IRAK4 in the process of kidney fibrosis, and indicated that targeted degradation of IRAK4 is an efficacious therapy for acute kidney injury.

**Funding:** NIDDK Support

## SA-PO064

**A Novel ATP Imaging System Using the Kidney Slice Culture Reveals ATP Dynamics in Whole Kidney Under Pathophysiological Conditions**  
 Shigenori Yamamoto,<sup>1,2</sup> Shinya Yamamoto,<sup>1</sup> Masahiro Takahashi,<sup>1</sup> Akihiro Okubo,<sup>1</sup> Masamichi Yamamoto,<sup>1,3</sup> Motoko Yanagita.<sup>1,2</sup> <sup>1</sup>Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; <sup>2</sup>Institute for the Advanced Study of Human Biology (WPI-ASHBi), Kyoto University, Kyoto, Japan; <sup>3</sup>Department of Research Promotion and Management, National Cerebral and Cardiovascular Center, Suita, Japan.

**Background:** Mitochondrial disorders and ATP depletion play the central role in the pathogenesis of renal diseases. Recently, we generated a mouse line (GO-ATeam2 mouse), which expresses FRET-based ATP biosensor systemically, and reported spatiotemporal ATP dynamics during ischemia-reperfusion (IR) using two-photon microscopy. However, observation from kidney surface did not allow visualization of deeper nephrons or accurate evaluation of ATP production pathways in each segment.

**Methods:** We established the novel *ex vivo* ATP imaging system using slice culture of GO-ATeam2 mouse kidney. We evaluated ATP production pathways in each segment by the administration of oligomycin as an oxidative phosphorylation (OXPHOS) inhibitor and phloretin as a glycolysis inhibitor. We also analyzed ATP dynamics during *ex vivo* IR and cisplatin nephropathy models.

**Results:** We, for the first time, succeeded in visualizing ATP dynamics in whole kidney. After oligomycin administration, ATP in proximal tubules (PTs) decreased most rapidly and severely, followed by the decrease in podocytes. On the other hand, after phloretin administration, ATP decreased in podocytes most severely, but less apparently in other segments, indicating PTs are strongly dependent on OXPHOS for ATP production and podocytes rely on both OXPHOS and glycolysis. We further confirmed that *ex vivo* IR model could recapitulate ATP dynamics in vivo: ATP recovery after reperfusion in PTs varied depending on the length of ischemia, whereas ATP in distal tubules (DTs) recovered well even after long ischemia. After cisplatin administration, ATP in PTs decreased first, followed by the decrease in DTs. The administration of higher concentration of cisplatin resulted in more rapid and severe ATP depletion. Cisplatin accumulation in kidney slices was confirmed using mass spectrometry, which was attenuated by the administration of cimetidine, an OCT2 inhibitor. Cimetidine administration led to ATP recovery in PTs, but not in DTs, suggesting DT injury is not OCT2-mediated. Finally, we confirmed MA-5, a mitochondria protection reagent, delayed cisplatin-induced ATP decrease.

**Conclusions:** This novel system could provide valuable information of energy dynamics and pathogenesis of renal diseases, and might be useful for drug screening.

## SA-PO065

**Tubular Cells Distant From the Site of Injury Enter the Cell Cycle and Undergo Polyplodization After AKI**

Elena Lazzeri,<sup>1</sup> Letizia De Chiara,<sup>1</sup> Paola Romagnani,<sup>1,2</sup> <sup>1</sup>Università degli Studi di Firenze, Firenze, Italy; <sup>2</sup>Meyer Children's University Hospital, Florence, Italy.

**Background:** Acute Kidney Injury (AKI) is defined as a sudden decrease in kidney function affecting specifically the S3 segment of the proximal tubule in the outer medulla, despite a widespread cell cycle marker positivity observed all over the cortex. Importantly, we described the occurrence of polyplodization in tubular cells (TC) in response to AKI instead of proliferation. However, the spatial distribution of tubular cells undergoing polyplodization has never been investigated. Recently, an elegant genetic system has been established to unequivocally identify and trace polyplod cells in vivo, using the multicolored reporter Confetti. In this study, we aimed to 1. characterize the temporal distribution and 2. quantify and localize polyplod TC to different tubular segments after AKI.

**Methods:** To analyze the temporal distribution of polyplod TC, we employed Pax8/FUCCI2aR mice to combine cell cycle phases analysis with the DNA content by flow cytometry. To detect the spatial distribution of polyplod TC in all the tubular segments, we employed heterozygous-Pax8/Confetti mice in which one of the two sets of chromosomes harbors a Confetti allele.

**Results:** Ischemic AKI induced a strong entry into the cell cycle in TC. We found that in the early phase of AKI most cycling TC undergo polyplodization, while the others die during the S or G2/M phase of the cell cycle. To quantify as well as to localize polyplod TC to different tubular segments, we induced AKI in heterozygous-Pax8/Confetti mice. Polyplod TC carrying two or more sets of chromosomes can activate two or more fluorochromes, resulting in multi-colored TC. Multi-colored polyplod TC localized mostly in the cortex and especially in S1 and S2 segments of the proximal tubule, stained positive for cell cycle markers, sparing the injured outer medulla. This study demonstrated that in the early phase of AKI most cycling TC undergo polyplodization and this process occurred mostly distant from the site of injury.

**Conclusions:** We have characterized the temporal and spatial distribution of polyplod TC after AKI. Specifically: 1. most cycling TC undergo polyplodization, while most of the others die; 2. TC polyplodization occurs mostly in the cortex, distant from the injury site, explaining why AKI involves widespread cell cycle marker positivity all over the cortex.

## SA-PO066

**CD8+CD103+ iTregs Attenuate Ischemia-Reperfusion AKI by Suppressing Pyroptosis**

Qiuju Chen, Zhenjian Xu, Xiao Zhang, Anping Xu. Sun Yat-Sen Memorial Hospital, Guangzhou, China.

**Background:** Acute kidney injury (AKI) is a disease related to high morbidity, mortality and healthcare costs. It has been reported that there is strong inflammation in AKI. However, specific or effective treatment for AKI hasn't been established at present. Previously, we have reported that CD8+CD103+ Treg induced *ex vivo* with TGF- $\beta$ 1 and IL-2 (CD8+CD103+ iTreg) inhibited response of immune cells to ameliorate excessive autoimmune inflammation. Here, we further explore whether CD8+CD103+ iTreg can ameliorate AKI and determine the potential molecular mechanism.

**Methods:** In vivo, we used mouse model of ischemia-reperfusion injury to investigate whether CD8+CD103+ iTreg can attenuate AKI by protecting tubular epithelial cells. In vitro, we co-cultured tubular cells with CD8+CD103+ iTreg to explore the mechanism of Treg for protecting against renal I/R injury.

**Results:** Adoptive transfer of CD8+CD103+ iTreg but not control cells to the mice of ischemia-reperfusion injury showed decreased levels of serum creatinine and blood urea nitrogen, reduced tissue injury, and lowered tubular apoptosis. Additionally, CD8+CD103+ iTreg treatment decreased infiltration of macrophages and T cells as well as renal levels of IL-6, IL-1 $\beta$ , TNF- $\alpha$ , and IFN- $\gamma$ , but it increased levels of IL-10, arginase-1. Moreover, administering CD8+CD103+ iTreg after ischemia-reperfusion injury limited the number of pyroptotic cells. In vitro, CD8+CD103+ iTreg reversed hypoxia/reoxygenation-induced cell injury partly by suppressing tubular cell pyroptosis via inhibiting the NLRP3/Caspase-1 axis.

**Conclusions:** CD8+CD103+ iTreg suppressed tubular epithelial cell pyroptosis to attenuate AKI after ischemia-reperfusion injury. Our data suggests therapeutic potential of CD8+CD103+ iTreg in renal ischemia-reperfusion injury.

**Funding:** Government Support - Non-U.S.

Fig 1. CD8+CD103+ iTregs protect against AKI in mice.

## SA-PO067

**KUS121, an ATP-Retaining VCP Modulator, Exerts Renoprotective Effects in Ischemia-Reperfusion Injury With Enhancing Endoplasmic Reticulum-Associated Degradation**

Ryosuke Date, Takashige Kuwabara, Yusuke Hata, Daisuke Fujimoto, Teruhiko Mizumoto, Yuichiro Izumi, Masashi Mukoyama. Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.

**Background:** Acute kidney injury (AKI) is a life-threatening condition and often progresses to chronic kidney disease or may develop other organ dysfunction even after recovery, but there has been no established treatment for AKI so far. Valosin-containing protein (VCP) is a major ATPase in the cells and is expressed ubiquitously in various organs including the kidney. VCP is also involved in many cellular functions including endoplasmic reticulum (ER)-associated degradation (ERAD). The aim of this study was to investigate the renoprotective effect of Kyoto University substance 121 (KUS121), a novel VCP modulator, on AKI.

**Methods:** In vitro experiments, we evaluated cell viability and ATP levels of cultured proximal tubular cells with or without KUS121 under ER stress conditions. In vivo experiments, the effects of KUS121 were examined in mice with AKI caused by

ischemia-reperfusion injury. ERAD-processing capacity was evaluated by quantification of the ERAD substrate CD3delta-YFP.

**Results:** KUS121 protected proximal tubular cells from cell death under ER stress. The apoptotic response was mitigated as indicated by the suppression of C/EBP homologous protein expression and caspase-3 cleavage, with maintained intracellular ATP levels by KUS121 administration. KUS121 treatment suppressed the elevation of serum creatinine and neutrophil gelatinase-associated lipocalin levels and attenuated renal tubular damage after ischemia-reperfusion. The expression of inflammatory cytokines in the kidney was also suppressed in the KUS121-treated group. VCP expression levels were not altered by KUS121 both *in vitro* and *in vivo*. KUS121 treatment restored ERAD-processing capacity associated with potentiation of its upstream pathway, phosphorylated inositol-requiring enzyme-1 $\alpha$ , and spliced X box-binding protein-1. Furthermore, KUS121 recovered from stagnation of CD3delta caused by Eeyarestatin I known as an ERAD inhibitor.

**Conclusions:** These findings indicate that KUS121 may contribute to protect renal tubular cells from ER stress-induced injury, suggesting that KUS121 could be a novel and promising therapeutic compound against ischemia-associated AKI.

## SA-PO068

### The Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor Enarodustat Protects the Kidney From Contrast-Induced Nephropathy Takashi Tani, Hitomi Tani, Akiko Mii. *Nihon Ika Daigaku, Bunkyo-ku, Japan.*

**Background:** Contrast-induced nephropathy (CIN) is an acute kidney injury (AKI) associated with the use of contrast medium. Vasoconstriction, oxidative stress, and hypoxic environment are considered the main causes of CIN. At under anaerobic conditions, hypoxia-inducible factors (HIFs) serve to restore tissue homeostasis by stimulating erythropoiesis, angiogenesis, and anaerobic glycolysis. HIF prolyl hydroxylase (HIF-PH) inhibitors stabilize HIFs, and then recent studies demonstrate that these drugs show protective effects on kidneys from renal ischemia/reperfusion injury, cisplatin-induced AKI, and diabetic kidney disease. In this study, we sought to show that the use of HIF-PH inhibitors plays a protective role in an animal model of CIN.

**Methods:** Sprague-Dawley rats were randomly allocated into sham-operated group (n=5), vehicle-treated CIN group (vehicle group; n=7), and drug-treated CIN group (enarodustat group; n=6). At 15-week-old, the right nephrectomy was performed. Enarodustat or vehicle was administered daily by oral gavage at a dose of 10 mg/kg from 3 days before the operation day to the induction of CIN. At 17-week-old, the rats were anesthetized and indomethacin (10 mg/kg) and L-NAME (10 mg/kg) were injected. After 30 min, rats were then injected intravenously with iopamidol (OYPALOMIN, 3.7 g iodine/kg). Rats were sacrificed 2 days after surgery.

**Results:** Hemoglobin and hematocrit levels were comparable in all groups. Significant elevation of blood urea nitrogen, serum creatinine, and decreases in 24hr creatinine clearance levels were observed in vehicle group, whereas those parameters were comparable in enarodustat group to sham-operated group. Kidney tissue mRNA expression of *Ngal*, *Kim-1*, and *TNF- $\alpha$*  were all markedly elevated in vehicle group, which were ameliorated by administration of enarodustat. Histopathological examination disclosed severe findings in the kidney of CIN rats, characterized by proteinaceous casts in tubuli, medullary congestion, and hemorrhage in the outer zone inner stripe of medulla, and tubular necrosis in the outer zone outer stripe of medulla. Administration of enarodustat attenuated these histopathological findings.

**Conclusions:** These results showed that HIF-PH inhibitor enarodustat protects the kidney from CIN in a rat model. HIF-PH inhibitors may be potential therapeutic agents for clinical CIN.

**Funding:** Government Support - Non-U.S.

## SA-PO069

### Urine-Derived Stem Cell Extracellular Vesicles Ameliorate Injury in a Human Kidney Organoid Model of Cisplatin-Induced Nephrotoxicity Julie Bejoy,<sup>1</sup> Richard C. Welch,<sup>1</sup> Lauren E. Woodard.<sup>1,2</sup> Woodard Lab <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>US Department of Veterans Affairs, Nashville, TN.

**Background:** Urine-derived stem cells (USCs) are adult stem cells that originate from the human kidney and can be expanded. Extracellular vesicles (EVs) are mainly comprised of exosomes secreted from the endosomal system and microvesicles formed by direct outward budding. All cells produce EVs which transfer cellular cargo to specific target cells. Stem cell-derived EVs have clinical applications in disease treatment and diagnostics. Therefore, we also investigated USC-secreted EVs (USC-EVs) as a potential therapy to treat nephrotoxic acute kidney injury (AKI).

**Methods:** We tested USCs and USC-EVs in a human kidney organoid model of nephrotoxic AKI. We cultured human kidney organoids from induced pluripotent stem cells. We created a nephrotoxic injury model by adding 5  $\mu$ m of the chemotherapeutic agent cisplatin to the kidney organoid culture for the first 24 h. For the next 48 h, we treated the injured organoids with either 5  $\times$  10<sup>4</sup> USCs or 5  $\mu$ g USC-EVs.

**Results:** First, we performed immunofluorescence for NEPHRIN, LTL, ECAD, and GATA3 to confirm differentiation of the organoids. In injured organoids treated with USCs, viability increased by MTT and LDH assay (p<0.001) and the expression of Kidney Injury Molecule-1 (KIM-1) appeared reduced by immunostaining. Treatment of injured organoids with USC-EVs also increased cell viability by MTT assay (p<0.0001) and decreased KIM1 release into the media by ELISA. USC-EVs lowered oxidative stress as we found increased superoxide dismutase (SOD) activity (p<0.05) and reduced Malondialdehyde (MDA) concentration (p<0.001). USC-EVs altered the levels of EGF (p<0.0001), IL-8 (p=0.0002), and IGF-15 (p<0.01).

**Conclusions:** USC and USC-EVs treatments increased viability of the cisplatin AKI organoids. USC-EVs reduced oxidative stress, KIM-1 and inflammatory cytokines. These results highlight the therapeutic effects of USC through release of USC-EVs in a human organoid model of nephrotoxic AKI, demonstrating the promise of future applications of USCs or USC-EVs for AKI treatment.

### Evaluation of BAM15 on Superoxide Generation in Sepsis AKI by In Vivo Imaging

Naoko Tsuji,<sup>1</sup> Takayuki Tsuji,<sup>1</sup> Yoshitaka Naito,<sup>1</sup> Naoki Hayase,<sup>1</sup> Carolyn C. Woodroffe,<sup>2</sup> Rolf E. Swenson,<sup>2</sup> Peter S. Yuen,<sup>1</sup> Robert A. Star.<sup>1</sup> Renal Diagnostics and Therapeutics Unit, Kidney Diseases Branch <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>2</sup>National Heart Lung and Blood Institute, Bethesda, MD.

**Background:** Non-invasive detection of kidney mitochondrial reactive oxygen species *in vivo* has been challenging. Recently, Huang et al (2019) developed a fluorescent superoxide molecular renal probe (MRP1) with high renal clearance and rapid detection. The probe enables real-time optical imaging of *in vivo* renal or *ex vivo* urinary superoxide by near-infrared fluorescence (NIRF). We previously showed that BAM15, a chemical mitochondrial uncoupler, decreased kidney superoxide generated by septic tubule cells exposed to serum of cecum ligation and puncture (CLP) mice *in vitro*, and improved survival and AKI in CLP mice (Tsuji et al., under review). Here, we tested if a MRP could detect sepsis induced superoxide generation in kidney or urine, and if BAM15 decreases it *in vivo*.

**Methods:** We synthesized a MRP that become fluorescent in the presence of superoxide (tested with KO<sub>2</sub> exposure *in vitro*), and then be rapidly cleared into urine. MRP was injected into mice at 1, 3, or 18 h after CLP or sham surgery, followed by NIRF *in vivo* imaging at several time points (0-120 min) after MRP probe injection. The fluorescent signal from urine collected 30 min after MRP injection was measured by NIRF imaging. BAM15 (5mg/kg) was administered immediately after CLP. GFR was measured by a transdermal fluorescent detector following IV injection of FITC-sinistrin.

**Results:** We detected a higher MRP signal *in vivo* kidney at 1, 3, and 18 h after CLP following MRP injection. MRP uptake was detected in tubular cells and glomeruli in kidney sections by confocal microscopy. MRP signal in urine of CLP treated with BAM15 was lower than that of CLP treated with vehicle at 1h after CLP, even though GFR had not changed at 2-3h after CLP. (Figure 1).

**Conclusions:** We detected increased kidney and urinary superoxide in a mouse model of sepsis AKI before GFR decreased. The superoxide was decreased in response to a drug (BAM15) that improves mouse and renal survival. BAM15 and MRP might be a drug-companion biomarker pair. More study is needed to determine if superoxide generation measured by MRP is a robust biomarker to ultimately develop it for clinical use.

### Leveraging Metabolomics to Detect Global Alterations in the Renal Cortices of Formoterol Treated Mice

Austin D. Thompson,<sup>1,2</sup> Rick G. Schnellmann.<sup>1,2</sup> <sup>1</sup>The University of Arizona, Tucson, AZ; <sup>2</sup>Veterans Health Administration, Tucson, AZ.

**Background:** Acute kidney injury (AKI) is defined as a sudden and rapid decline in renal function and is often accompanied by a persistent reduction in mitochondrial function and vascular/tubular injury/necrosis. AKI is a public health concern with no FDA-approved treatments. Stimulation of mitochondrial biogenesis (MB) via the  $\beta_2$ -adrenergic receptor agonist formoterol (FORM) has been demonstrated in murine studies to accelerate renal recovery, promote MB, and restore mitochondrial homeostasis post-AKI. Albeit, the renal metabolic alterations induced by FORM, remain unknown. Thus, we used global metabolomics to assess metabolic changes in the mouse renal cortex treated with FORM.

**Methods:** Male 8-week-old C57B/6J mice were administered 0.3mg/kg of FORM or normal saline every 24h over a 60h period (n=6/group). Kidneys were harvested and snap frozen in liquid nitrogen. Renal cortex samples were analyzed by Metabolon via multi-mass spectrometry analysis. After mass normalization, log-transformation, and imputation, Welch's two-sample t-test was used to identify metabolites that differed significantly between treatment groups. A p-value of p<0.05 and a false discovery rate of q<0.10 were used to identify global metabolite changes and correct for multiple comparisons.

**Results:** Total, 914 biochemicals (BC) were detected in the global metabolomic dataset. Of these BCs, we identified 165 BCs statistically different in FORM-treated mice compared to saline controls, 89 BCs increased, and 76 BCs decreased. FORM-treated

mice had elevated 3-hydroxybutyrate and reduced free fatty acids, endocannabinoid, and lysoplasmalogen, which is indicative of increased mitochondrial  $\beta$ -oxidation and reduced inflammation. A decrease in glycolysis was identified by reduced lactate and elevated dihydroxyacetone phosphate (DHAP). This was accompanied by elevated amino acid metabolism, in accord with Mechanistic Target of Rapamycin Kinase Complex 1 (MTORC1) activation by DHAP. Lastly, we observed an increase in antioxidant pathways via elevated gamma-glutamyl amino acids and nicotinate/nicotinamide.

**Conclusions:** These data reveal that global metabolomics can identify 165 metabolic alterations in the renal cortices of FORM-treated mice. This approach will allow us to identify and monitor metabolic changes during AKI and other kidney diseases, and the effects of drugs stimulating repair/recovery.

SA-PO072

Obesity Aggravates Ischemia-Reperfusion Injury (IRI)-Induced AKI in Mice

Igor O. Da Silva,<sup>1</sup> Nicole K. De Menezes,<sup>1</sup> Heloisa d. Jacobina,<sup>1</sup> Antonio C. Parra,<sup>1</sup> Felipe L. Souza,<sup>1</sup> Leticia U. De Castro,<sup>1</sup> Joris Roelofs,<sup>2</sup> Alessandra Tammara,<sup>2</sup> Talita R. Sanches,<sup>1</sup> Lucia Andrade.<sup>1</sup> <sup>1</sup>University of Sao Paulo School of Medicine, Sao Paulo, Brazil; <sup>2</sup>University of Amsterdam, Amsterdam, Netherlands.

**Background:** Obesity, which is becoming increasingly common worldwide, is known to be associated with cardiovascular disease and progression of chronic kidney disease, due to inappropriate activation of the renin-angiotensin system. Many angiotensin II effects are dependent on AT1 stimulation of reactive oxygen species (ROS). In COVID-19 patients, overweight and obesity are associated with acute respiratory distress syndrome and AKI. Although obesity increases oxidative stress, endothelial dysfunction and inflammation, its effect on IRI-induced AKI is unknown. We hypothesized that obesity would aggravate renal IRI in mice.

**Methods:** We fed mice a high-fat or standard diet (45 and 10 kcal% fat, respectively) for 8 weeks. Some then underwent bilateral 30-min clamping of the kidney hila and subsequent reperfusion (groups: obese, normal, obese+IRI and normal+IRI). All studies were performed 48 h after IRI. Data are mean $\pm$ SEM.

**Results:** Body weight (g) was 33 $\pm$ 1.7, 32 $\pm$ 0.7, 27 $\pm$ 1.4 and 26 $\pm$ 0.9 in the obese, obese+IRI, normal and normal+IRI groups, respectively (P<0.001). Mortality was 42% and 25% in the obese+IRI and normal+IRI groups, respectively (P<0.05); there were no deaths in the non-IRI groups. Serum glucose and cholesterol did not differ among the groups. Creatinine clearance (mL/min/100g BW) was 0.20 $\pm$ 0.05 and 0.20 $\pm$ 0.07 in the obese+IRI and normal+IRI groups, respectively, vs. 0.34 $\pm$ 0.06 and 0.40 $\pm$ 0.08 in the obese and normal groups, respectively. Renal p65 protein expression (%) was 127 $\pm$ 4.8 in the obese+IRI group, vs. 100 $\pm$ 4.1, 92.5 $\pm$ 4.8 and 107 $\pm$ 3.7, respectively, in the normal, obese and normal+IRI groups (P<0.05).

**Conclusions:** In obese individuals with AKI, ROS could be a therapeutic target (FAPESP, NWO).

**Funding:** Government Support - Non-U.S.

Calponin-2 Dictates Kidney Fate by Regulating Ketogenesis After AKI  
Yuan Gui, Dong Zhou. University of Connecticut School of Medicine, Farmington, CT.

**Background:** Energy generation is critical for tissue recovery from acute kidney injury (AKI). Amid the AKI repair process, the ketone body is a major energy source in the kidney. Our preliminary proteomic analysis indicates that the two topmost biological events after AKI are cell metabolism and actin filament binding. However, whether direct or indirect regulation exists between cell metabolism and mechanics after AKI remains unclear. To address this question, we systemically explored how Calponin 2 (CNN2), an actin filament-associated regulatory protein highlighted from our AKI proteome database, determines AKI prognosis by influencing energy consumption and generation.

**Methods:** AKI patients' kidney biopsy specimens were employed in this study. Two AKI animal models induced by ischemia-reperfusion injury (IRI) and cisplatin were constructed. Global-scale proteomics and *in vitro* / *in vivo* translational experiments were performed.

**Results:** CNN2 is induced in the diseased kidneys obtained from AKI patients and animals. It is predominantly localized in the kidney interstitial compartment. At 1 day after IRI or 3 days after cisplatin injection, knockdown of CNN2 preserved kidney functions, mitigated tubular cell death and inflammation, and promoted tubular cell proliferation. Global proteomic analysis identified that hydroxymethylglutaryl-CoA synthase 2 (HMGCS2), a key rate-limiting enzyme of endogenous ketogenesis that promotes cell self-renewal, was significantly increased in CNN2 knockdown mice kidneys compared with controls. Accordingly, knocking down CNN2 concentrated the levels of  $\beta$ -

hydroxybutyrate ( $\beta$ -OHB), the precursor of ketone bodies, and ATP production by which to release energy for AKI repair. To mimic *in vivo*, we silent CNN2 in cultured fibroblast and collected the conditioned medium. The conditioned medium increased the HMGCS2 level and reduced cell death in cultured tubular cells. However, these protective effects were largely abolished once knocking down HMGCS2 in tubular cells. Conversely, *in vitro*, exogenous CNN2 inhibited HMGCS2 expression and aggravated tubular cell death under hypoxia stress. In addition,  $\beta$ -OHB also exhibited a protective role in CNN2-induced tubular cell death.

**Conclusions:** Our results indicated that in addition to its capacity to regulate cell proliferation and motility, cell mechanics play a direct role in mediating cell metabolism to determine AKI prognosis.

SA-PO074

Lung-Kidney Injury Caused by Innate Derived Mediator suPAR  
Varsha Suresh Kumar, Mehmet M. Altintas, David C. Wei, Babak Mokhesli, Michael J. Liptay, Jochen Reiser. Division of Nephrology and Rush Lung Center, Rush University Medical Center Rush University Medical Center, Chicago, IL.

**Background:** Soluble urokinase plasminogen activator receptor suPAR is an innate-immune system derived circulating kidney disease risk factor that has its highest physiological expression at baseline in the upper airway. Critical illnesses with high mortality rates often exhibit both acute lung and kidney injury as complications. The objective of our study is to understand whether murine pulmonary airway injury can induce kidney injury, perhaps in a suPAR dependent manner. In the injured human lung, uPAR is documented in several pathological respiratory conditions including COPD, pneumonia and tuberculosis and recently also in COVID-19. Since suPAR levels increase prior to and during kidney injury, we aimed to explore a lung-kidney connection.

**Methods:** Injection of naphthalene, an aromatic hydrocarbon present in tobacco smoke constitutes a well-characterized model for acute airway injury in mice. SuPAR over-expressing mice (suPARTg) and UPAR knockout mice (UPARKO) were injected intraperitoneally with naphthalene. To begin to explore mechanisms of lung-kidney axis, lung lavage and serum inflammation was assessed by multi-plex ELISA and flow cytometry.

**Results:** SuPAR overexpression accelerated mortality in naphthalene injured mice by 40%. Furthermore, injecting an UPAR antibody in naphthalene injured suPARTg mice increased led to significant reduction in mortality. UPARKO mice exhibited a 100% survival rate post injury. Increased survival observed in UPARKO mice could be attributed to significantly increased IL6 levels in both lung lavage and serum, thereby altering the outcome of naphthalene mediated injury.

**Conclusions:** In conclusion, immune derived factors such as suPAR connect the lung with the kidney. Targeting suPAR may be beneficial in increasing survival in cases where mortality may be attributed to multi-organ failure induced by lung injury.

AKI due to Cocaine-Induced Thrombotic Microangiopathy  
Ingi A. Elsayed. UHNM, Stoke-on-Trent, United Kingdom.

**Introduction:** Thrombotic microangiopathy (TMA) is a rare potentially life-threatening condition caused by small-vessel platelet microthrombi. TMA Syndromes include thrombotic thrombocytopenia purpura (TTP), Shiga toxin mediated haemolytic uremic syndrome (STEC-HUS), drug induced TMA(DITMA) & complement mediated TMA. Clinical features include microangiopathic haemolytic anaemia & thrombocytopenia, & may have acute kidney injury, neurological abnormalities & cardiac ischemia. Drug induced TMA is either immune mediated or non-immune mediated. cocaine use is associated with non-immune DITMA.

**Case Description:** A case of 29-year-old male known HTN & T2DM, presented with abdominal pains, found to have microangiopathic haemolytic anaemia, thrombocytopenia & acute kidney injury (Table 1). Initially he denied the use of any recreational drugs. His presentation was suggestive of TTP; he was treated by plasma exchange & acute hemodialysis. Following day; he became comatose with a GCS of 7/15; He was transferred to ICU; where he was supported using, mechanical ventilation, inotropic support & he continued on plasma exchange. An emergency CT head showed multiple infarctions. National Complement Centre recommended starting IV Eculizumab; pending further results. Toxin mediated HUS (E.coli O157) was excluded. His ADAMTS13; was normal. Complement mediated TMA was investigated for (immunologic & genetic evaluation) & was also negative; by then he had received two doses of Eculizumab. The decision was to halt further Eculizumab & plasma exchange. Further corroboration from patient & his family; revealed he used cocaine recreationally prior to admission. Serum toxicology samples from admission, confirmed cocaine. We believe that this a case of non-immune DITMA. Performing a native renal biopsy, was deemed inappropriate due to high risk involved & minimal benefit. He remained dialysis-dependent throughout & was discharged after a period of neurorehabilitation, where he continues to dialyse three weekly.

**Discussion:** Cocaine use is associated with TMA although rarely reported & admitting physician need to be alert of this possibility.

**Renal Quinolate Accumulation May Reduce Cellular NAD+**  
Amanda J. Clark,<sup>1,2</sup> Marie Christelle Saade,<sup>1</sup> Brenda Mendoza Flores,<sup>1</sup> Samir M. Parikh.<sup>1</sup> <sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>Children's Health Children's Medical Center Dallas, Dallas, TX.

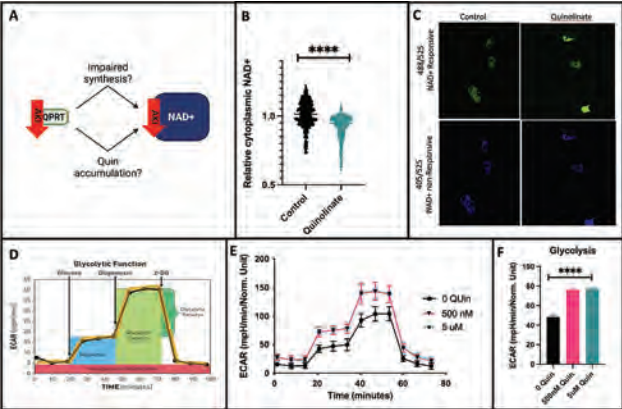

**Background:** Tubule energy metabolism is required for renal health, and its impairment is a feature of acute kidney injury (AKI). We previously reported that the biosynthesis of NAD<sup>+</sup>, an essential cofactor for oxidative energy metabolism, becomes suppressed during experimental and clinical AKI. A critical enzyme in this biosynthetic pathway is quinolate phosphoribosyltransferase (QPRT), whose suppression leads to an accumulation of quinolate (Quin) in kidneys during AKI along with a reduction in renal NAD<sup>+</sup> despite the existence of non-QPRT dependent pathways to generate NAD<sup>+</sup>. Therefore, we hypothesized that accumulation of quin may also contribute to NAD<sup>+</sup> reduction in AKI.

**Methods:** Intracellular NAD<sup>+</sup> was assessed using a recently developed NAD<sup>+</sup> biosensor. The effect of Quin on glycolytic flux was measured using a Seahorse XX96 flux analyzer. Intracellular lactate was measured using a commercial assay. Studies were conducted in HK2, human proximal tubule cells.

**Results:** Quin addition (1uM) for 12 hours reduced cytoplasmic NAD<sup>+</sup> (Fig1 B-C, p < 0.0001). Consistent with a reduced cellular NAD<sup>+</sup>, quin-exposed cells exhibited increased glycolysis (Fig1 E-F p < 0.0001) and increased intracellular lactate.

**Conclusions:** These data suggest that QPRT suppression during AKI may have distinct contributions to NAD<sup>+</sup> reduction, both via NAD<sup>+</sup> biosynthesis attenuation and through quin accumulation. Cellular NAD<sup>+</sup> reduction led to expected effects on fuel utilization with increased glycolytic acidification. There is no known mechanism where quin may exact these metabolic changes, though many studies have described quin as a non-inert metabolite capable of receptor activation and potential allosteric modulation of enzymes. Understanding NAD<sup>+</sup> homeostasis, its role in quin accumulation, and the activity of quin in the kidney may be critical to understanding AKI physiology, and developing novel therapies.

**Identifying the Cellular and Molecular Mechanisms That Contribute to Gadolinium-Based Contrast Agent-Induced Nephrotoxicity**  
Joshua Deaguero,<sup>1,2</sup> Karol Dokladny,<sup>1,2</sup> G. P. Escobar,<sup>1,2</sup> Brent Wagner.<sup>1,2</sup> Kidney Institute of New Mexico <sup>1</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>2</sup>New Mexico VA Health Care System, Albuquerque, NM.

**Background:** Gadolinium (Gd<sup>3+</sup>) chelates are a dynamic tool used for enhancing magnetic resonance imaging (MRI) examinations. Owing to the vital clinical diagnostic capabilities of Gd<sup>3+</sup>, hundreds of millions gadolinium-based contrast agent doses have been administered worldwide. Long-term tissue retention of gadolinium and nephrogenic systemic fibrosis are well correlated with exposures to these contrast agents. The kidney is the major organ of excretion for most gadolinium-based contrast agents. This study aimed at identifying cellular and molecular perturbations as a result of gadolinium chelate exposure in an *in vitro* model of mouse renal tubular epithelial cells.

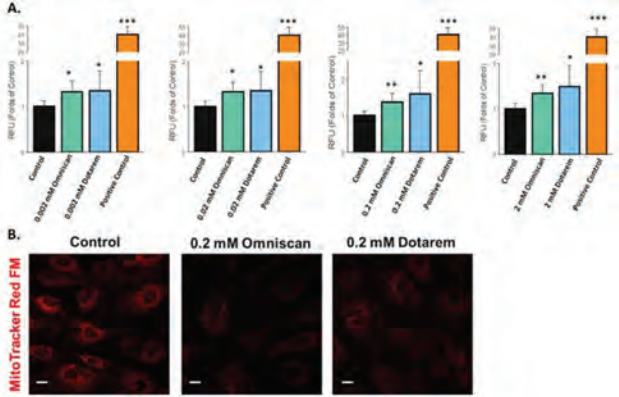

**Methods:** Mouse renal tubular epithelial cells (MRTEpiCs) were cultured at density of 25,000 cells/cm<sup>2</sup> and allowed to reach 70-80% confluence prior to exposure. For the

identification of perturbatory effects, cells were exposed to physiological concentrations (0.002 mM-2 mM) of Omniscan or Dotarem for 24h. Intracellular reactive oxygen species was measured using a fluorescent (DCFH-DA) assay. Mitochondrial and lysosomal activity was monitored using fluorescent probes and confocal microscopy.

**Results:** After 24h exposure both Omniscan and Dotarem induced a dose response effect on the increased generation of reactive oxygen species. Mitochondrial membrane potential decreased in response to agent exposure. Omniscan and Dotarem promoted the accumulation of lysosomes, as well as increased lysosomal-associated membrane protein 1 (LAMP1) protein expression.

**Conclusions:** In this study we identify potential cellular and molecular modulators involved in the observed nephrotoxicity of gadolinium-based contrast agents. We demonstrate that gadolinium chelates induces mitochondrial dysfunction and increased lysosomal activity indicating an impact on organelle dynamics. These data can be used to enhance preclinical safety studies by improving assay sensitivities.

**Funding:** NIDDK Support, Other NIH Support - UL1TR001449, Veterans Affairs Support, Other U.S. Government Support, Private Foundation Support

Cellular perturbations induced by GBCAs.

SA-PO078

**Efficacy of Mesenchymal Stromal Cells in Ameliorating Renal Ischemia/Reperfusion Injury In Vitro**  
João Faria,<sup>1</sup> Sandra Calcat-i-Cervera,<sup>2</sup> Renata Skovronova,<sup>3</sup> Benedetta Bussolati,<sup>3</sup> Timothy O'Brien,<sup>2</sup> Silvia M. Mihaila,<sup>1</sup> Rosalinde Masereeuw.<sup>1</sup> <sup>1</sup>Universiteit Utrecht, Utrecht, Netherlands; <sup>2</sup>National University of Ireland Galway, Galway, Ireland; <sup>3</sup>Universita degli Studi di Torino, Torino, Italy.

**Background:** Renal ischaemia/reperfusion injury (IRI) is the leading cause of acute kidney injury. The current standard of care focuses on treatments to support kidney function, reinforcing the need for more efficient therapies. Mesenchymal stromal cell (MSC) therapy has shown promising results in several preclinical studies. However, their full potential is still unknown.

**Methods:** To mimic ischemia, human conditionally immortalized proximal tubule epithelial cells (ciPTECs) were exposed for 24 hours to a combination of antimycin A (AA) and 2-deoxy glucose (2DG) under hypoxia and normoxia conditions. Furthermore, ischemic ciPTECs were treated for 24 hours with either conditioned medium (CM) or extracellular vesicles (microvesicles, MV or exosomes, EX) isolated from various sources of MSCs.

**Results:** When ciPTECs were exposed to ischemic injury (AA and 2DG), actin filaments were lost and nuclei fragmented. In ischemic cells, there was a decrease in metabolic activity (22% in normoxia, 42% in hypoxia; p<0.0001) and ATP production (6% in normoxia, 35% in hypoxia; p<0.001) compared to control cells. In normoxia, the increase in ROS production was more exponential than in hypoxia (p<0.01), and injured cells cultured in hypoxia showed a 75% decrease in mitochondrial mass compared to 20% in normoxia (p<0.0001). The metabolic activity of the injured cells after MSC treatment was similar to that of the injured cells treated with serum (reperfusion group). All cells treated with CM or EVs showed an increase in ATP production of 40-45% (p<0.001) in both normoxia and hypoxia. The Seahorse extracellular flux assay was performed to both injured cells and post-treatment, which revealed a 50% decrease in oxygen consumption rate compared to control cells, that was restored after treatment with either CM from adipose tissue or bone marrow-derived EVs. The extracellular acidification rate, an indicator of a metabolic switch to glycolysis, was reduced by 40% in injured cells and returned to baseline after MSC treatment.

**Conclusions:** Our findings showed that our *in vitro* model was capable of replicating *in vivo*-like morphological and molecular changes observed during IRI. Following MSC treatment, the changes observed in our ischemic cells were moderately reversed, demonstrating MSC's therapeutic potential.

**Funding:** Government Support - Non-U.S.

SA-PO079

**Kidney Prostaglandin Synthesis Alterations in a Case of NSAID-Induced AKI: A Clinical Pathologic Molecular Correlation**  
Steven Menez,<sup>1</sup> Richard A. Knight,<sup>3</sup> Avi Z. Rosenberg,<sup>1</sup> Chirag R. Parikh,<sup>1</sup> Brad H. Rovin,<sup>2</sup> Samir V. Parikh,<sup>2</sup> KPMP <sup>1</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>2</sup>*The Ohio State University Wexner Medical Center, Columbus, OH;* <sup>3</sup>*American Association of Kidney Patients, Tampa, FL.*

**Introduction:** The Kidney Precision Medicine Project (KPMP) seeks to establish a molecular atlas of the kidney in health and disease, to improve the understanding of molecular drivers of kidney disease. We describe the case of a woman who underwent a kidney biopsy in the setting of acute kidney injury (AKI) as part of the KPMP, with associated tissue proteomics.

**Case Description:** A 38-year-old woman with no significant medical history (baseline serum creatinine (sCr) 0.7-0.8 mg/dL), presented at 36 weeks gestation with premature rupture of membranes. She underwent successful cesarean section delivery. On post-operative day (POD) 0, she received 3 doses of the non-steroidal anti-inflammatory drug (NSAID) ketorolac (15 mg) intravenously, transitioned to oral ibuprofen 800 mg every 6 hours. She was discharged on POD 4, but presented to the emergency room the next day with new onset fatigue. Labs were notable for a sCr of 2.3 mg/dL, peaking at 3.7 on POD 7. Clinical adjudication determined the likely etiology of AKI to be associated with NSAID. She underwent percutaneous kidney biopsy on POD 11, with findings consistent with mild acute tubular injury and no significant interstitial fibrosis nor tubular atrophy. Tissue proteomic analysis demonstrated tissue inflammation and extracellular matrix changes in the glomeruli and tubule-interstitium (**Table 1**). These cellular changes were present without histologic correlates.

**Discussion:** As NSAIDs were considered to be the primary driver of the participant's AKI, at the molecular level we suspected that prostaglandin expression may have been altered. However, proteomic interrogation revealed a more dynamic molecular landscape, with changes noted in prostaglandin synthesis in response to NSAIDs as well as signs of intra-renal inflammation and fibrosis not evident by histopathology alone. These findings illustrate that routine histology techniques do not necessarily capture the full complexity of cellular injury.

**Methods:** Male C57 mice were intraperitoneally injected with cisplatin for 3 days. In vitro, NRK-52E cells were treated with cisplatin for 12h. Expressions of MCM4, NGAL, cleaved-caspase-3, Bax, p53, p21, 53BP1, USP28 and MAD2B were detected by Western blot and immunohistochemistry. MCM4, 53BP1 and USP28 knockdown were achieved by transfected with siRNA, respectively. Lentivirus transfection was utilized to knock down the expression of MAD2B. Flow cytometry was conducted for cell cycle. CCK-8 assay was conducted to evaluate the cell viability. TUNEL assay was used to detect the apoptotic cells and ROS detection kit was utilized for ROS detection.

**Results:** Here, we show that MCM4 is highly expressed in tubules while less in glomeruli, and the expression of MCM4 is upregulated in mice and NRK-52E cells under cisplatin treatment. Silencing of MCM4 inhibits cell proliferation and delays the entry of S phase, and then aggravates cell apoptosis in cisplatin-treated NRK-52E cells. Mechanistically, MCM4 deficiency results in augmented activity of the 53BP1/p53/p21 pathway, which is a key pathway for regulation of cell proliferation and apoptosis. Moreover, based on the previous studies of MAD2B in kidney diseases, we find that MAD2B deficiency inhibits the activity of CDK/Cyclin complex, the phosphorylation of Rb and the transcription level of E2F1, leading to the downregulation of MCM4.

**Conclusions:** Therefore, our data revealed the protective role of MCM4 in cisplatin-induced acute kidney injury. MCM4 was involved in cell proliferation and apoptosis by

53BP1/USP28/p53/p21 signaling pathway under the cisplatin stimulation. On the other hand, MAD2B could influence the the phosphorylation of Rb and the transcription level of E2F1, resulting in the changes in MCM4 proteins levels. In conclusion, MCM4 maybe a potential therapeutic target for the treatment of AKI.

**Gasdermin D Is Required for Control of Necroptotic Cell Death in AKI**  
Wulf Tonnus, Francesca Maremonti, Anne M. Brucker, Andreas Linkermann. *AG Linkermann Technische Universität Dresden, Dresden, Germany.*

**Background:** Within the last decade, it has been established that necrotic rather than apoptotic cell death critically mediates acute tubular necrosis in AKI. While the involvement of necroptosis and ferroptosis has been established, the role of pyroptosis, the third major form of necrosis, remains unclear in AKI. This form of regulated necrosis requires proteolytic activation of members of the gasdermin family and is considered highly immunogenic. Thus, we aimed to investigate the role of pyroptosis and its mechanism of action in AKI.

**Methods:** Immunohistochemistry (IHC) was utilized to detect gasdermin D (GSDMD) in kidney samples of mice after ischemia/reperfusion injury (IRI). Furthermore, gasdermin-deficient mice were investigated in IRI and cisplatin-induced AKI and cisplatin-induced AKI. Mechanistic approaches involved the isolation of renal tubules for studies on cell death propagation and standard biochemistry to detect protein expression kinetics. Finally, MLKL/GSDMD<sup>fl/fl</sup> mice were generated to investigate the interplay of these caspase-dependent forms of regulated necrosis in AKI.

**Results:** In GSDMD-IHC of kidney samples after IRI, we detected as specific signal surrounding necrotic tubules. No such signal was detectable within the tubular compartment at any time. Unexpectedly, GSDMD<sup>fl/fl</sup> mice exhibited higher levels of serum creatine and serum urea as well as more severe tubular damage compared to wild type controls. Unlike whole kidney lysates, freshly isolated renal tubules do not express the GSDMD protein. In isolated renal tubules, no changes in kinetics of cell death propagation were detectable upon genetic GSDMD deficiency. In addition, we generated combined necroptosis/pyroptosis-deficient MLKL/GSDMD<sup>fl/fl</sup> mice. Here, we demonstrate that co-deletion of MLKL rescued the sensitization of GSDMD<sup>fl/fl</sup> mice. Comparable effects were seen in cisplatin-induced AKI.

**Conclusions:** Our study reveals an unexpected protective role of GSDMD in AKI. Our mechanistic studies indicate the effect of GSDMD to function outside the tubular compartment, specifically surrounding areas of tubular necrosis. This infiltrate appears to limit tubular necroptosis in a non-cell autonomous manner. Alongside with these mechanistic insights, our data urge caution when inhibition of pyroptosis is therapeutically considered.

SA-PO082

**miR-486-5p Protects Against Ischemic AKI in Rat but Inhibits eNOS and Angiogenesis**  
Adrianna Douvris,<sup>1</sup> Jose L. Vinas,<sup>1,2</sup> Alex Gutsol,<sup>1</sup> Dylan Burger,<sup>1</sup> Kevin D. Burns.<sup>1,2</sup> <sup>1</sup>*University of Ottawa, Ottawa, ON, Canada;* <sup>2</sup>*Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

**Background:** Acute kidney injury (AKI) is a common complication of hospitalization for which no effective treatments exist. Patients with recovered AKI are at increased risk of progressive chronic kidney disease (CKD). In ischemia-reperfusion (IR) AKI, endothelial injury contributes to capillary rarefaction and development of tubulointerstitial fibrosis. We previously showed that microRNA (miR)-486-5p protects against IR AKI in mice associated with targeting of *phosphatase and tensin homolog (PTEN)*, activation of Akt, and downregulation of genes involved in apoptosis and tumor necrosis factor signaling in proximal tubular cells. However, the effects of miR-486-5p in rat IR AKI and on endothelial cell injury are unknown.

**Methods:** Kidney ischemic injury was induced in male rats by 45-min bilateral renal artery clamping followed by reperfusion, with outcomes after 24hr, 48hr, and 4 weeks. Lipid-encapsulated miR-486-5p (0.5mg/kg) was administered via tail vein injection at the start of reperfusion. Human umbilical vein endothelial cells (HUVECs) were transfected with miR-486-5p (1nM), and angiogenesis was evaluated with matrigel-based tube formation assay.

**Results:** Administration of miR-486-5p to rats with IR injury significantly protected against AKI with normalization of plasma Cr and BUN (p<0.05, n=3), and reduced KIM-1 levels (p<0.01, n=3) at 24 and 48hr. In rats with AKI, miR-486-5p did not affect plasma Cr after 4 weeks, compared to sham rats or rats with AKI alone. However, in rats with AKI, miR-486-5p protected against the development of interstitial fibrosis and tubular atrophy at 4 weeks. In HUVECs, miR-486-5p decreased the expression of *PTEN* (p<0.05, N=4), and endothelial nitric oxide synthase (eNOS) (p<0.001, N=4). Matrigel-based network formation assay showed that miR-486-5p reduced the angiogenic activity of normoxic HUVECs compared to untreated cells or cells treated with scramble miRNA (p<0.05, N=4).

**Conclusions:** These data suggest that miR-486-5p prevents ischemic AKI in rats, and protects against the development of CKD after AKI. However, miR-486-5p may affect endothelial function with reduced angiogenic activity, possibly related to decreased eNOS expression. Although miR-486-5p shows promise as a therapeutic tool in AKI, long-term effects on kidney microvascular structure and function *in vivo* require further study.

## SA-PO083

### The Role and Mechanism of Cyclophilin A in Cisplatin-Induced AKI

Li Tao. Huazhong University of Science and Technology *Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

**Background:** Nephrotoxicity is an important factor that limits the clinical use of cisplatin (CP), with approximately 20%-35% of patients suffering acute kidney injury (AKI) after treated with it. Cyclophilin A (CypA) is an intracellular receptor for the immunosuppressant cyclosporin A (CsA), and is reported to function in protein folding, signal transduction, inflammation, tumorigenesis and viral replication, while the specific role of CypA in CP-induced AKI still lacks in-depth research.

**Methods:** Here, we successfully established an AKI mice model via a single intraperitoneal injection of CP (25mg/kg), and a CsA derivative, NIM811, was used as an inhibitor of CypA to treat the CP mice. In addition, vitro experiment was performed using HK-2 cells.

**Results:** In CP-AKI mouse model, the expression level of iCypA and eCypA were increased; Serum eCypA content positively correlated with SCr. Both the expression level of iCypA and eCypA were increased in HK-2 cells stimulated by CP. SCr was decreased significantly in CP-AKI mice treated with NIM811 and the pathological lesion of renal tubules was reduced. At the same time, NGAL and Cleaved-Caspase3 protein levels were decreased significantly as well as the number of TUNEL positive apoptotic cells was decreased. After CypA knockdown by siRNA transfection, Cleaved PARP1 and CytC protein levels were decreased, the percentage of apoptotic cells was decreased, and cell viability was increased. In vitro, inhibition of CypA by NIM811 increased the cell viability, and decreased the levels of Cleaved PARP1 and CytC protein. Cleaved PARP1 and Cleaved-Caspase3 protein levels were increased after rCypA was administrated in HK-2 cells. In the CP-AKI mouse model, increased CD147 expression was detected by IHC and WB. In vitro of CP-induced HK-2 cell injury, increased CD147 expression was found by WB assay. Knockdown of CypA could down-regulate the expression of CD147 in CP-stimulated HK-2 cells. Using siCD147 in HK-2 cells could down-regulate the increased expression of Cleaved PARP1 and CytC protein levels as well as increase the cell viability. Knocking down CypA expression could alleviate the abnormalities of the AKT/AMPK/mTOR signaling pathway caused by CP stimulation.

**Conclusions:** CypA is increased and plays an injurious role in CP-induced AKI. And the underlying mechanism may attribute to promoting apoptosis by dysregulated CD147 and AKT/AMPK/mTOR signaling pathways.

## SA-PO084

### Identification of Enhancers and Their Impact on the Kidney Injury Regulator *Klotho*

Jakub Jankowski,<sup>1,2</sup> Hye kyung Lee,<sup>2</sup> Julia Wilflingseder,<sup>1</sup> Lothar Hennighausen.<sup>2</sup>  
<sup>1</sup>Veterinärmedizinische Universität Wien, Wien, Austria; <sup>2</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

**Background:** Enhancer activity provides new insights into the gene expression machinery and is emerging as a valuable target of research and therapy. Enhancer disruption is involved in development of human disease, but can also be used as a tool to investigate genes key for disease progression and recovery. There is a well-known connection between kidney function and *Klotho*. While decrease in *Klotho* is a known sign of kidney disease, deletion of the gene in mice results in severe phenotype and greatly shortened lifespan, making investigating *Klotho* knockouts challenging. Previously, we identified two putative enhancers of *Klotho*, which lost activity in a kidney injury setting. In this study, we used a novel way of gaining insight into the role of *Klotho*. We altered gene regulatory elements, rather than the gene itself, to investigate the impact of the two putative enhancers on *Klotho* expression, and physiological effects of their deletion.

**Methods:** We used Crispr/Cas9 to generate six viable mouse lines with deletions in the distal, proximal or both *Klotho* enhancers, including selective deletion of HNF1b transcription factor binding site. We used qPCR and RNA-seq to investigate gene expression in the kidney, and a blood biochemistry panel and ELISA to investigate phenotype. We also used Chip-seq to analyze changes in histone modifications with focus on the *Klotho* promoter and enhancer regions to assess their activity and verify deletions.

**Results:** Deletion of distal, but not proximal enhancer resulted in 50% lower *Klotho* expression, but only when HNF1b binding site was impacted. Inactivity of the proximal enhancer was confirmed by lack of further expression decrease in double knockout mice. Despite significant *Klotho* depletion, mice did not display *Klotho* knockout phenotype, as lifespan, weight, serum phosphate, calcium and FGF23 levels were not different compared to controls. RNA-seq analysis revealed altered expression of several genes associated with kidney disease.

**Conclusions:** Our study provides new insight into *Klotho* regulation. We identified a new regulatory element of the *Klotho* gene as well as the transcription factor responsible for its activity. Despite significantly lower *Klotho* expression levels, normal phenotype is preserved. Susceptibility of the mice to injury remains to be investigated and will further elucidate *Klotho*'s impact on renal health.

## SA-PO085

### Tnik, a Novel Pro-Repair Kinase That Promotes Renal Cell Differentiation After Injury

Shayna T. Bradford, Yuhei Kirita, Haojia Wu, Yoshiharu Muto, Benjamin D. Humphreys. Humphreys Lab *Washington University in St Louis School of Medicine, St Louis, MO.*

**Background:** Following acute kidney injury (AKI), epithelial cells lining proximal tubules of the nephron repopulate injured tubules to support repair. However, a portion of cells fail to undergo repair and are characterized by increased expression of proinflammatory/profibrotic molecules as well as decreased expression of markers of terminal differentiation. The molecular pathways driving the generation of failed-repair proximal tubule cells are undefined. However, we hypothesize that these cells cause local tissue inflammation and fibrosis, promoting the AKI to chronic kidney disease transition.

**Methods:** Using snRNA-seq, we identified a Traf2 and Nck Interacting Kinase, Tnik, to be exclusively expressed in failed-repair proximal tubule cells post AKI (2 and 6 weeks) in mice. Like failed-repair proximal tubule cells, primary human renal proximal tubule epithelial cells (hRPTECs) adopt an injury phenotype when cultured on plastic and can be used to model failed-repair proximal tubule cells. Therefore, we subjected primary-hRPTECs to 72 hours of Tnik silencing using pooled siRNA against human Tnik. We confirmed Tnik suppression by immunoblotting and proceeded with RNA-seq analysis to assess the transcriptome of Tnik depleted primary-hRPTECs (n = 6).

**Results:** 508 genes were upregulated, and 685 genes were downregulated in response to Tnik depletion (log<sub>2</sub> fold change > 1). Pathway analysis revealed upregulation of Type I Interferon signaling, while organic acid transport pathways were downregulated. By qPCR and immunoblotting, we validated increased levels of inflammatory and injury genes (CCL2, AXIN2), along with decreased levels of organic acid transport and differentiation genes (SLC3A1, HFN4a) found in our RNA-seq dataset.

**Conclusions:** Since Tnik depletion increases inflammatory signals and decreases renal cell differentiation markers, we conclude that Tnik is a novel proximal tubule pro-repair kinase that functions to reduce inflammation and shift cells toward differentiation and repair following injury. Data from these studies may serve as the basis for novel therapeutics that enhance proximal tubule Tnik activity, thereby improving AKI outcomes.

## SA-PO086

### Deletion of *Spns2* in Proximal Tubules Protects the Mouse Kidney During Ischemia-Reperfusion Injury

Sylvia Cechova, Junlan Yao, Nabin Poudel, Mark D. Okusa. Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine *University of Virginia, Charlottesville, VA.*

**Background:** *Spns2* (Spinster homolog 2) is a non-ATP dependent organic ion transporter of S1P (Sphingosine 1-phosphate) that transports S1P from the intracellular to the extracellular cell compartment. Since 2009, several studies demonstrated the important role of SPNS2 in lymphocyte trafficking, immune responses, vascular and embryonic development, many type of cancers, and human liver fibrosis. Previously we demonstrated that *Spns2* is expressed in proximal tubules and podocytes. In the present study, we investigated the effect of *Spns2* deletion in mice renal proximal tubules (PTs) after bilateral ischemia-reperfusion injury (bi-IRI).

**Methods:** Tamoxifen inducible proximal tubule tissue specific transgenic SLC34a1-GFP<sup>CreER</sup><sup>+/+</sup>/*Spns2*<sup>fl/fl</sup> mice (PT-KO mice) where injected with 1mg of tamoxifen for 5 days and rested for 2 weeks before they underwent bi-IRI (28 min). 24 hours later, we collected plasma and kidney tissues. The relative mRNA expression of *Spns2*, *Ngal*, *Kim1* and chemokines *Cxcl1* and *Cxcl10* in kidneys were estimated by qPCR. To detect protein level of *Spns2* we performed gel electrophoresis and Western blot analyses of kidney tissue lysates. To evaluate kidney injuries we measured plasma creatinine, BUN, and calculated ATN score of H&E stained kidney sections.

**Results:** After IRI, we observed significantly decreased mRNA expression of *Spns2*, *Ngal*, *Kim1*, and chemokines *Cxcl1* and *Cxcl10* in the kidney lysates of PT-KO mice compared to WT mice. In both genotypes after IRI, we also observed decreased protein level of *Spns2*. Results of plasma creatinine and BUN confirmed that deletion of *Spns2* from renal proximal tubules exert significant protection from IRI. Plasma creatinine: 1.13±0.19 mg/dl and 0.36±0.06 mg/dl, P<\*\*\*, and BUN: 112.8±10.10 mg/dl and 48.33±5.24 mg/dl, P<\*\*\*\* for WT and PT-KO mice, respectively (n=6). H&E staining and ATN scores (42.63±9.14 and 9.69±2.18 for WT and PT-KO mice, P<\*\*) provided additional evidence of severe damage to proximal tubules of WT mice compared to PT-KO mice after IRI.

**Conclusions:** Our results suggest that SPNS2 can serve as a potential target to prevent acute kidney injury. However, more studies are necessary to elucidate the SPNS2 signaling pathway.

## SA-PO087

**A Short Treatment With Resveratrol After Ischemia/Reperfusion Injury Prevents Maladaptive Repair and Long-Term CKD**

Miguel A. Martinez-Rojas,<sup>1,2</sup> Jesus M. Gonzalez Rivera,<sup>2</sup> Maria S. Ponce Nava,<sup>2</sup> Rosalba Pérez-Villalva,<sup>1</sup> Norma Bobadilla,<sup>1,2</sup> <sup>1</sup>*Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico;* <sup>2</sup>*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Background:** Acute Kidney Injury (AKI) leads to Chronic Kidney Disease (CKD) through maladaptive repair. The reversibility of this process after AKI has occurred remains unclear. Treatment with resveratrol (RSV) before AKI ameliorates renal dysfunction through multiple mechanisms. We aimed to evaluate if a transient administration of RSV after ischemia/reperfusion injury (IRI) is enough to prevent CKD.

**Methods:** Eighteen male Wistar rats weighting 300-350 g were randomized in three groups: Sham surgery, IRI for 30 min (IRI), and IRI + RSV. Daily treatment with RSV was initiated 24 h after IRI and maintained only 10 days. Rats were followed for 5 months. Proteinuria was determined monthly, while kidney function and fibrosis were evaluated at the 5<sup>th</sup> month. To study early reparative process, another 18 rats were included with the same design but euthanized at the 10<sup>th</sup> day. Histologic changes were evaluated with Sirius Red and PAS stains. Gene expression was evaluated with RT-qPCR and Western blot. Differences between groups were analyzed through ANOVA and post-hoc testing with a significance level of p<0.05.

**Results:** Treatment with RSV prevented late CKD as indicated by proteinuria, creatinine clearance and tubule-interstitial fibrosis. Despite having a severe initial AKI, rats receiving RSV for only 10 days after IRI improved drastically kidney histological changes and expression of *Il6*, *Tnfa*, *Ccl2*, *Il10*, *Tgfb1*, *Mrc1* compared to the IRI group, indicating accelerated immune cells clearance. This was accompanied by reduced levels of NfκB-p65. Also, RSV prevented the typical raise in tubular injury-related genes and recovered Sirt3, FoxO3, and catalase expression, leading to a lesser oxidative stress compared to IRI group.

**Conclusions:** A short treatment with RSV after IRI is enough to prevent maladaptive repair and CKD in rats. This renoprotective effect is mediated by a marked reduction in the inflammatory process, tubular injury, and oxidative stress. These findings highlight the relevance of the initial days of reperfusion, indicating that adaptive repair can be induced after severe AKI.

**Funding:** Government Support - Non-U.S.

## SA-PO088

**Contralateral Nephrectomy After AKI Leads to Functional Recovery by Stimulating Epithelial Progenitor Proliferation Whilst Inhibiting Endocycling-Related Hypertrophy**

Lies Moonen,<sup>1</sup> Elena Lazzeri,<sup>2</sup> Anna J. Peired,<sup>2</sup> Carolina Conte,<sup>2</sup> Letizia De Chiara,<sup>2</sup> Paola Romagnani,<sup>2</sup> Benjamin A. Vervaeke,<sup>1</sup> <sup>1</sup>*Universiteit Antwerpen, Antwerpen, Belgium;* <sup>2</sup>*Universita degli Studi di Firenze, Firenze, Italy.*

**Background:** Clinical studies of the last decade identified acute kidney injury (AKI) as an important risk factor for the development of chronic kidney disease (CKD). Hence, strategies to improve the reparative efficiency are of great therapeutic interest. We established a murine model in which the functional and histological recovery of a kidney is drastically enhanced by removal of the unharmed contralateral kidney, i.e. nephrectomy-induced recovery. It is unknown whether nephrectomy (Nx) achieves this by stimulating true epithelial regeneration and/or hypertrophy. Insight in the mechanisms underlying efficient nephrectomy-induced recovery may open new therapeutic strategies.

**Methods:** AKI was induced in 2 specific transgenic mouse lines by left unilateral ischemia/reperfusion (UIRI) for 21 min at 34°C, after which either right Nx or no Nx was performed 3 days later. Mice were euthanized 7 and 28 days after UIRI for functional and renal histopathological analyses. Pax2/Confetti mice were applied to track proliferation of individual genetically labeled tubular progenitor cells by histological clone size frequency analysis. Pax8/Fucci2aR mice were included to assess TEC hypertrophy (i.e. endocycling) by combining DNA content analysis via flow cytometry with expression analysis of genetic fluorescent cellular labels that reveal the cell cycle stage.

**Results:** Nx performed at day 3 after UIRI was confirmed to rescue function and histology. Clonal analysis in Pax2/Confetti mice revealed that Nx significantly stimulated individual progenitor cell proliferation as compared to no Nx and Nx recruited more progenitor cells to start proliferation as compared to no Nx. Analyses of Fucci mice revealed that Nx prevented accumulation of hypertrophic (endocycling) TECs (i.e. polyploid cells with ≥8C DNA content).

**Conclusions:** Nx-enhanced regeneration is driven by a stimulated clonal expansion of renal progenitor cells that significantly surpasses that of spontaneous repair after UIRI. Moreover, Nx attenuates the build-up of polyploid/hypertrophic epithelial cells. Hence, Nx stimulates recovery by promoting true epithelial regeneration, whilst suppressing endocycle-mediated hypertrophy.

## SA-PO089

**Effect of Ischemia-Reperfusion Injury on Nuclear Malondialdehyde Levels in Kidney Cortex and Medulla of Aged Rats**

Marianna J. Zmlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

**Background:** The present study was undertaken to determine the effect of ischemia-reperfusion injury (IRI) on nuclear malondialdehyde (MDA) levels in kidneys from aged rats. MDA is a product of lipid peroxidation of cell and organelle membranes by free

radicals and is used as an indicator of oxidative stress. Kidney dysfunction is associated with tissue damage caused by free radicals generated in IRI.

**Methods:** Anesthetized old female Lewis rats (22 months of age) were used in the study. The left and right renal pedicles were clamped for 60 min, followed by 60 min of reperfusion in the Experimental Group (n=6). The kidneys were then harvested, separated into cortex and medulla, and homogenized. Kidneys in the Control Group (n=6) were not subjected to IRI before being harvested. The nuclear fractions were isolated using differential centrifugation, and the MDA levels were measured using a spectrophotometric assay. The water contents of the cortex and medulla were determined to allow MDA to be expressed as nmol/g kidney dry wt. A Student's T Test was used to compare the data, and statistical significance was determined at p < 0.05. All data reported as X ± SEM.

**Results:** Nuclear MDA levels were significantly decreased in the kidney cortex of the Experimental Group when compared to the Control group. Nuclear MDA levels in kidney cortex decreased by 49 %, with Nuclear MDA being 36.5 ± 7.9 % nmol/g kidney dry wt in the Control Group and 18.0 ± 1.7 nmol/g kidney dry wt in the Experimental Group. Nuclear MDA levels in the kidney medulla were not different with IRI. Nuclear MDA levels were 45.0 ± 5.9 nmol/g kidney dry wt in the Control Group and 52.5 ± 2.6 nmol/g kidney dry wt in the Experimental Group.

**Conclusions:** The results suggest that in IRI, the nucleus in both the kidney cortex and medulla of aged rats may not be experiencing increased oxidative stress and damage, as indicated by a decrease or no change in MDA levels, respectively, after 60 min of reperfusion.

## SA-PO090

**Loss of Pax2 and Pax8 in Proximal Tubules Protects Against Failed Repair After Ischemic AKI**

Jeffrey A. Beamish,<sup>1,2</sup> Anas Alsuraimi,<sup>1</sup> Madison C. McElliott,<sup>1</sup> Abdul A. Soofi,<sup>1</sup> Greg R. Dressler,<sup>1</sup> <sup>1</sup>*University of Michigan, Ann Arbor, MI;* <sup>2</sup>*VA Ann Arbor Healthcare System, Ann Arbor, MI.*

**Background:** Pax2 and Pax8 are two highly homologous transcription factors with critical and overlapping functions in kidney development and physiology. Both proteins are also upregulated following acute kidney injury (AKI), but their function in injury and repair is unknown. Our aim was to determine if selective deletion of Pax2 and Pax8 in proximal tubules affects sensitivity to injury and recovery after AKI.

**Methods:** Pax double mutant mice were generated carrying conditional floxed Pax2 and Pax8 alleles, the proximal-tubule-selective phosphoenolpyruvate carboxykinase (PEPCK) Cre driver, and a Cre-activated green fluorescent protein (GFP) reporter. Control mice included PEPCK-Cre and GFP reporter with wild type Pax2 and Pax8. 12-week-old male mice were subjected to unilateral ischemia-reperfusion injury (uIRI). Animals were sacrificed at various times after uIRI. Kidney tissue was analyzed by immunofluorescence (IF). Areas of failed repair 14 d post uIRI were marked by Kim1 or Vcam1 expression. Stained sections were scanned then quantified using U-net image segmentation.

**Results:** At baseline, mutants showed no difference in histology or kidney function. Gene deletions in proximal tubules were confirmed by IF and PCR. Mutant animals showed significantly fewer Vcam1+ tubules (46.6±33.8 vs 94.1±38.4 per mm<sup>2</sup>, N=14-15, p=0.002) and Kim1+ tubules (31.0±28.0 vs 56.3±27.5 per mm<sup>2</sup>, N=14-15, p=0.017). In mutant animals, we found that areas of failed repair contained significantly fewer GFP+ mutant cells compared with control animals where GFP marks Cre activity without Pax2 and Pax8 deletion (35.9±5.0% vs 46.4±6.7% of Vcam1+ cells, N=14-15, p<0.0001).

**Conclusions:** Surprisingly, mice with proximal-tubule-selective loss of Pax2 and Pax8 were less sensitive to IRI, with fewer Vcam1+ cells indicative of failed repair. As Vcam1+ cells may represent a population of survivors that do not fully recover their proximal tubule phenotype after injury, the data suggest that Pax mutant cells may be less likely to survive the initial injury and are rapidly cleared such that fewer stressed or damaged cells remain. Alternatively, Pax mutant cells may be inherently more resistant to ischemic injury. Mechanisms and experiments that distinguish these possibilities will be discussed.

**Funding:** NIDDK Support

## SA-PO091

**PPARα in Proximal Tubules Attenuates Ischemic AKI**

Takayuki Nimura,<sup>1</sup> Daiki Aomura,<sup>1</sup> Yosuke Yamada,<sup>1</sup> Makoto Harada,<sup>1</sup> Koji Hashimoto,<sup>1</sup> Motoko Yanagita,<sup>2</sup> Yuji Kamijo,<sup>1</sup> <sup>1</sup>*Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan;* <sup>2</sup>*Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

**Background:** Peroxisome proliferator-activated receptor alpha (PPARα) is a nuclear receptor. The renal expression of PPARα is mainly localized in the proximal tubules (PTs). PPARα maintains tissue energy metabolism by regulating fatty acid oxidation (FAO), with several studies reporting a possible renoprotective effect of systemic PPARα against ischemic kidney injury. Since the contribution of renal PPARα to this function is unknown, we addressed the above notion using PT-specific PPARα knock-out mice.

**Methods:** Mice harboring *Ndrp1*-CreERT2 transgenes were crossed with *Ppara*<sup>flax/lox</sup> mice to generate *Ndrp1*-CreERT2-*Ppara*<sup>flax/lox</sup> (PTs-PPARα-CKO) mice, which were intraperitoneally injected with tamoxifen for 3 days to knock out PT PPARα. Then, bilateral 40-minute ischemia-reperfusion (I/R) was conducted on tamoxifen-treated 13-week-old *Ppara*<sup>flax/lox</sup> mice (controls) and PTs-PPARα-CKO mice to produce an ischemic acute kidney injury model (n=9 in both groups). A sham operation was also performed (n=3 in each group). All mice were sacrificed 24 hours after I/R or the sham operation.

**Results:** A deficiency in renal PPARα expression was confirmed in the PTs-PPARα-CKO mice for both I/R and sham procedures. PTs-PPARα-CKO animals subjected to

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

I/R showed significantly higher serum creatinine levels, with pathological findings of more severe renal tubular injury than in controls. Renal cytokine expressions were also significantly higher for PTs-PPAR $\alpha$ -CKO with I/R. Although the renal expressions of FAO-related genes were decreased by I/R in both mice groups, those depletions were significantly more severe in the PTs-PPAR $\alpha$ -CKO mice. The renal expressions of anti-oxidative stress enzymes were also significantly lower in the PTs-PPAR $\alpha$ -CKO mice with I/R versus controls.

**Conclusions:** PPAR $\alpha$  in PTs attenuates ischemic acute kidney injury, presumably through the maintenance of renal FAO and anti-oxidative enzyme expression.

## SA-PO092

### Succinylation of Park 7 Activates a Protective Metabolic Response to AKI

Katherine Pfister,<sup>1,2</sup> Anne C. Silva Barbosa,<sup>1,2</sup> Takuto Chiba,<sup>1,2</sup> Eric S. Goetzman,<sup>2</sup> Sunder Sims-Lucas.<sup>1,2</sup> <sup>1</sup>University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.

**Background:** Acute Kidney Injury (AKI) is extremely prevalent among hospitalizations and presents a significant risk for the development of chronic kidney disease and increased mortality. Ischemia caused by shock, trauma, and transplant are common causes of AKI. To attenuate AKI occurrence therapeutically we need a better understanding of the physiological and cellular mechanisms underlying damage. The most pronounced effect of AKI is on the Proximal Tubule Epithelial Cells (PTECs) which have the highest metabolic activity and are therefore most reliant on undisturbed blood flow and oxygen content.

**Methods:** We simulate AKI in vitro with hypoxia and glucose deprivation. Hypoxia signaling induces rapid posttranslational modifications (PTMs) on proteins. A growing list of PTMs have been identified and their effects described in AKI but among the understudied are succinylation and glycation.

**Results:** We have previously shown a protective effect on PTECs after depletion of the desuccinylase Sirtuin 5, however Sirtuin 5 is not a druggable target. Mass spectrometry analysis of Sirtuin 5 knockout PTECs revealed changes in mitochondrial and peroxisomal activity and we suggest that this activity is modulated in part by the protective effects of the deglycase Park7. Park7 expression is decreased after Ischemia-Reperfusion Injury but increased in Sirtuin 5 knockout cells.

**Conclusions:** These data in combination with published results of Park7's protective role in cardiovascular damage and chronic kidney disease lead us to hypothesize that Park7 may ameliorate oxidative damage resulting from AKI and prevent disease progression. We hope to harness this mechanism to develop novel therapies for AKI.

## SA-PO093

### Inhibition of KDM5 Attenuates Renal Fibrosis After Ischemic Kidney Injury

Wonji Jo, Junkyu Park, Eun Sil Koh, Sungjin Chung. The Catholic University of Korea, Seoul, Republic of Korea.

**Background:** The histone lysine demethylases 5 (KDM5) are members of the family of Jumonji C domain-containing histone demethylases and catalyze the removal of di- and tri-methyl moieties from the fourth lysine of histone 3 (H3K4me2/3). It has been reported that the KDM5 family mediates a range of physiological and pathological events including cell differentiation, motility, senescence and epithelial-mesenchymal transition (EMT) via activating or repressing transcription in demethylase-dependent or independent manners in both homeostasis and disease. This study investigated the potential role of KDM5 in the development and progression of renal fibrosis in acute kidney injury (AKI) or chronic kidney disease (CKD).

**Methods:** We evaluated therapeutic effects of KDM5 inhibition in AKI model of unilateral nephrectomy plus contralateral ischemia-reperfusion (IR) injury, AKI to CKD model of unilateral IR injury plus removal of contralateral uninjured kidney after 8 days of IR injury, and CKD model of unilateral ureteral obstruction (UUO) in mice.

**Results:** KDM5 C70 inhibitor prevented the increase of blood urea nitrogen and positive areas of trichrome, Sirius red, F4/80 and  $\alpha$ -smooth muscle actin in injured kidneys 7 days after IR injury. Significant reductions in renal mRNA levels of pro-inflammatory cytokine/chemokine, EMT and pro-fibrotic markers (IL-1 $\beta$ , IL-6, TNF- $\alpha$ , CCL2, CCL3, GM-CSF, MMP9, fibronectin, vimentin, TGF- $\beta$ 1, COL4A1) were also observed with attenuated mRNA levels of KDM5a-c. In addition, renal protein levels of antioxidants such as catalase, SOD1 and SOD2 were increased in injured kidneys of KDM5 inhibitor-treated mice. However, parameters of renal fibrosis and inflammation were similar between mice without and with KDM5 inhibitor in both AKI-CKD and CKD models.

**Conclusions:** These data demonstrate that inhibition of KDM5 could prevent renal inflammation and fibrosis after acute and severe IR injury. The activation of KDM5 might be an early step in the development of renal fibrosis after AKI insult.

### Microparticles Released From Renal Epithelial Cells Induce Endothelial Cell Activation

Begoña Campos, Robert C. Shondel, Samuel P. Bockhorst, Charuhas V. Thakar. College of Medicine, Division of Nephrology, Kidney C.A.R.E. Program. Kidney Injury Translational Laboratory. University of Cincinnati, Cincinnati, OH.

**Background:** Acute kidney injury (AKI) is associated with an interplay between endothelium and epithelium as a part of both injury and repair cycles. We have shown that microparticles (MP) derived from renal epithelial cells are released in the setting of AKI and can carry the biological activity that could induce inflammation.

**Methods:** In this study, we evaluated if the MP derived from renal proximal tubule epithelial cells (RPTEC) after exposure to inflammatory stress-induced human umbilical vein endothelial cells (HUVEC) by using the monocyte adhesion assay. HUVEC and THP1 monocytes were maintained under standard cell culture conditions and exposed to RPTEC derived MP, TNF $\alpha$ , or vehicle (control). For Adhesion of THP1 cells to treated HUVEC, THP1 cells were labeled with Calcein Red Orange at a final concentration of 10  $\mu$ mol/L. Total fluorescence intensity, automated THP1 cell counts, and fluorescence of blank media was measured with a Cytation 5 plate reader. Unbound THP1 cells were removed by washing, and the remaining fluorescence intensity and THP1 cell counts were measured again.

**Results:** Activation of endothelial cells is significantly greater in both RPTEC-derived MP activated (54.13 X 10<sup>3</sup>) and direct activation from TNF $\alpha$  (42.90 X10<sup>3</sup>) when compared with control (14.74X10<sup>3</sup>) (p= 0.0002 and p=0.0047, respectively, Fig 1). Endothelial cell activation between RPTEC-derived MP vs. direct activation from TNF $\alpha$  was similar (p=0.1135).

**Conclusions:** MP derived from renal epithelial cells can induce endothelial cells as demonstrated by their ability to cause monocyte adhesion. These results suggest that microparticles can mediate cellular cross-talk, and in turn can affect injury and repair cycles in AKI.

## SA-PO095

### Keap1 Inhibition Ameliorates Cisplatin-Induced Mitochondrial Injury and Oxidative Stress in Renal Proximal Tubule Epithelial Cells Through a Glutathione-Dependent Mechanism

Jose A. Chavez. Cardiovascular & Metabolism, Janssen Research & Development Janssen Global Services LLC, Spring House, PA.

**Background:** Mitochondrial impairment is strongly associated with renal function decline. The proximal tubule is typically the initial site of injury where mitochondrial dysfunction leads to disrupted tubular integrity and cellular energetics insufficient to perform critical energy-demanding processes essential for kidney function. Therefore, targets addressing mitochondrial dysfunction in kidney disease provide an opportunity to advance novel therapies. The Keap1-Nrf2-ARE pathway regulates the transcription of various genes that encode cytoprotective and detoxifying enzymes and has pivotal roles in the defense against cellular oxidative stress.

**Methods:** To examine the impact of Nrf2 activation on mitochondrial function in the setting of oxidative stress, we exposed human primary renal proximal tubule epithelial cells (RPTECs) to cisplatin and used an inhibitor that interrupt the Keap1-Nrf2 protein-protein interaction (PPI).

**Results:** Cisplatin treatment significantly elevated reactive oxygen species (ROS) production, increased casp3/7 activity, reduced mitochondrial membrane potential, impaired respiration, downregulated genes related to mitochondrial function and decreased nicotinamide adenine dinucleotide (NAD<sup>+</sup>) levels. These effects were notably

suppressed by co-treatment with the small-molecule Keap1–Nrf2 PPI inhibitor. To assess whether the mitochondrial protective effects of Keap1-inhibition in RPTECs are mediated by GSH, an important scavengers of ROS, we treated cells with L-buthionine-(S, R)-sulfoximine (BSO), an inhibitor of GSH synthesis. Notably, BSO treatment negated the protective effects of the Keap1–Nrf2 PPI inhibitor against cisplatin-induced mitochondrial depolarization and apoptosis, while not affecting its ability to induce the transcriptional activation of NRF2 target genes.

**Conclusions:** Together, our results show that inhibition of the Keap1–Nrf2 PPI activates the antioxidant machinery for ROS scavenging in RPTECs, and that increased levels of intracellular GSH plays an important protective role against cisplatin-induced mitochondrial dysfunction and cellular death.

## SA-PO096

### Notch Signaling Contributes to the Renoprotective Effects of the Cholinergic Anti-Inflammatory Pathway

Shuhei Kuwabara, Shuqiu Zheng, Junlan Yao, Mark D. Okusa. Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine *University of Virginia, Charlottesville, VA.*

**Background:** A novel strategy for the prevention and treatment of AKI is activating the cholinergic anti-inflammatory pathway (CAP), a neuroimmune circuit. The CAP is initiated by vagus nerve stimulation (VNS) and subsequent activation of splenic macrophages (MΦ) to suppress inflammation. Our previous findings suggest the possibility that Notch signaling pathway (Notch), contributes to the renoprotective effects of CAP. However, a direct relationship between the CAP and Notch has not been reported. In the current study, we focused on Notch in MΦ to unravel the molecular mechanism of CAP and to determine the utility of Notch in ameliorating AKI.

**Methods:** To test if VNS activates Notch in MΦ, we performed electrical VNS before ischemia-reperfusion injury (IRI). After IRI, the expression of cytokines and Notch2 receptor in MΦ were assessed by qPCR and flow cytometry. MΦ-specific *Notch2* knockout mice were also subjected to VNS to evaluate whether Notch2 mediates anti-inflammatory responses in MΦ. The vagus nerve is heterogeneous and composed of efferent and afferent fibers, and neural circuits related to each fiber bundle are independent though both efferent/afferent VNS attenuate AKI. Thus, to determine if specific neural circuits regulate Notch, we used optogenetics, a tool for controlling the functions of particular neurons by expressing light-responsive proteins such as channelrhodopsin 2 (ChR2).

**Results:** The mRNA and protein expression of Notch2 was upregulated in splenic MΦ of VNS-treated mice. This was accompanied by a decrease in *Tnf-α* and an increase in *Il-10*. In splenic MΦ of *Notch2* knockout mice subjected to VNS, *Tnf-α* was higher and *Il-10* was lower than VNS-treated littermates, indicating that anti-inflammatory effects of the CAP were attenuated by *Notch2* deficiency in MΦ. In addition, we performed optogenetic VNS by using transgenic mice expressing ChR2 on vagal efferent fibers. Flow cytometry analysis revealed that efferent VNS did not alter Notch2 protein levels in splenic MΦ.

**Conclusions:** Our findings suggested that: 1) Notch signaling in splenic MΦ contributes to renoprotection by the CAP, 2) optogenetic stimulation of the vagus nerve showed that efferent VNS does not mediate Notch2 upregulation, suggesting that afferent VNS may be responsible for initiating Notch signaling in splenic MΦ.

## SA-PO097

### Proximal Tubular FHL2 Protects Against Ischemia/Reperfusion-Induced AKI via HIF-1 and β-Catenin Signaling

Yan Wang, Weichun He. *2nd Affiliated hospital of NJMU, Nanjing, China.*

**Background:** Hypoxia inducible factor 1 (HIF-1) and β-catenin signaling pathways activated in proximal tubular epithelial cells (PTECs) play an important role in regulating cell proliferation and apoptosis during acute kidney injury (AKI). Four-and-a-half LIM domains protein 2 (FHL2), an adaptor protein, has been demonstrated involving in HIF-1 and β-catenin signaling, respectively. However, the potential effect of FHL2 on AKI remains to be elucidated.

**Methods:** The expression of FHL2 in PTECs was examined in AKI induced by bilateral ischemia reperfusion (I/R) in mice and in NRK-52E (rat PTECs) cultured in hypoxia/reoxygenation (H/R) conditions, respectively. Mice with PTECs-specific deletion of FHL2 (Tubule-FHL2<sup>-/-</sup>) were generated by mating FHL2-floxed mice with Ggt1-Cre transgenic mice. The function of FHL2 in PTECs during AKI was investigated in Tubule-FHL2<sup>-/-</sup> mice after I/R.

**Results:** The expression of FHL2 was upregulated in PTECs during AKI in vivo. Compared with control littermates, Tubule-FHL2<sup>-/-</sup> mice were phenotypically normal within 2 months after birth but developed more severe kidney dysfunction, tubular cell death, inflammatory cell infiltration and less tubular cell proliferation after I/R. The activation of both HIF-1 and β-catenin signaling pathways was attenuated in Tubule-FHL2<sup>-/-</sup> mice after I/R comparing with control littermates. In vitro, the induction of FHL2 was correlated with upregulation of HIF-1α. Two functional hypoxia responsive elements was identified in the promoter region of FHL2 gene, which interacted with HIF-1α under hypoxia conditions, suggesting that FHL2 is a novel direct target gene of HIF-1. Overexpression of FHL2 induced physical interactions between FHL2 and HIF-1α and between FHL2 and β-catenin, which promoted HIF-1α and β-catenin nuclear translocation, and enhanced the transcriptional activity of their downstream targets, respectively.

**Conclusions:** Our results suggest that FHL2, as a downstream target gene of HIF-1, plays a critical protective role in AKI through regulating the activities of HIF-1 and β-catenin signaling pathways simultaneously, and FHL2 could be a potential future therapeutic target for AKI.

### Lysozyme Induced Nephropathy: A Rare Mechanism of Renal Sarcoidosis

Sushmita Prabhu, Suryanarayanan Balakrishnan, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

**Introduction:** Classic mechanisms of renal injury in sarcoidosis include hypercalcemia with afferent vasoconstriction, nephrocalcinosis, and acute interstitial nephritis with or without granulomas. Lysozyme is a small cationic enzyme with bactericidal properties produced by monocytes and macrophages, which drive disease activity. Lysozyme is freely filtered by glomeruli and reabsorbed in proximal tubules (PTs), where it causes toxicity in excessive quantities, known as lysozyme-induced nephropathy.

**Case Description:** 75M presented with a creatinine of 5.87 mg/dL (eGFR 9cc/min) after not seeing a physician for years. He reported difficulty sweating and a 22lb weight loss over 18 months, but was otherwise asymptomatic. Blood pressure was 150/73 and exam was unremarkable. Urinalysis: specific gravity 1.020, pH 6, moderate blood, 100 protein, 100 glucose. Sediment: granular casts without RBCs or RBC casts. Urine albumin:Cr ratio (UACR) was 47 mg/g, urine protein:Cr ratio (UPCR) 1321 mg/g Cr, calcium 14 mg/dL, phosphate 6.3 mg/dL, PTH 1.57 pg/mL, PTHrP 30 pg/mL, and 1,25 OH2 vitamin D 138 pg/mL. Serum and urine immunofixation were negative. Renal biopsy showed moderately severe nephrocalcinosis, with a moderately severe chronic active interstitial nephritis without granulomas. Densely packed eosinophilic protein reabsorption granules were seen in PTs, which stained strongly for lysozyme. Advanced sclerosis was seen. He had high serum lysozyme (28mcg/mL) and ACE (84U/L) levels. Evaluation for Fanconi syndrome showed glycosuria and euglycemia, and a basic urine pH, but normal uric acid handling. He was treated with prednisone 1 mg/kg/day for 6 weeks followed by an 8-week taper, without improvement in GFR. BAL showed multinucleated giant cells, consistent with sarcoidosis.

**Discussion:** Rare case reports describe lysozyme-induced nephropathy in sarcoidosis. It is more commonly seen in chronic monocytic or myelomonocytic leukemia, as these clonal populations produce excessive lysozyme. Measurement of serum lysozyme levels could be considered in patients with sarcoidosis and a rising creatinine, or with UPCR and UACR discordance. This may guide future therapies directed at excessive macrophage activity, thereby improving renal function.

## SA-PO099

### Claudin-4, a Core Component of the Tight-Junctional Complex Along the Collecting System, Is Induced in Nephrotic Syndrome

Ali Sassi,<sup>1,2</sup> Valerie Olivier,<sup>1,2</sup> Gregoire Arnoux,<sup>1</sup> Isabelle Roth,<sup>1</sup> Alexandra Chassot,<sup>1</sup> Eric Feraille,<sup>1,2</sup> Suresh Ramakrishnan.<sup>1</sup> Department of Cell Physiology & Metabolism, Faculty of Medicine <sup>1</sup>Department of Cell Physiology & Metabolism, Faculty of Medicine, University of Geneva, Geneva, Switzerland; <sup>2</sup>National Centre of Competence in Research “Kidney.ch”, Geneva, Switzerland.

**Background:** Nephrotic syndrome (NS) is characterized by massive proteinuria, hypoalbuminemia and edema secondary to renal sodium chloride retention. Along the kidney tubule, sodium and chloride reabsorption are coupled *via* a combination of transcellular and paracellular transport pathways. The mechanism of sodium retention in NS has been extensively studied, but the associated chloride transport pathway has not been elucidated.

**Methods:** To investigate the pathway of chloride retention in NS, we assessed the expression levels of both paracellular and transcellular components of chloride transport in the CD of POD-ATTAC mice and PAN rats, two rodent models of NS. We also used cultured mouse cortical collecting duct cells to see how overexpression or silencing of claudin-4 affect paracellular permeability. Finally, human renal biopsies were used to confirm our *in vivo* results.

**Results:** In control animals, claudin-4 was expressed at low levels in collecting duct (CD). In POD-ATTAC mice and PAN rats, claudin-4 expression was strongly increased in CD beta-intercalated cells (B-IC) and to a lesser extent in CD principal cells and was also induced in connecting tubules. Similarly, we found that claudin-4 was expressed at low levels in normal human kidneys and was dramatically increased in CD cells of nephrotic human kidneys (focal and segmental glomerulosclerosis). In parallel, the expression of pendrin, which exchanges chloride for bicarbonates in B-IC, was decreased in nephrotic compared to control animals. However, the increase in claudin-4 expression observed in NS is likely independent of pendrin abundance. Increased claudin-4 abundance is coupled with increased ENaC-dependent sodium transport. Overexpression or silencing of claudin-4 in mCCD<sub>cl1</sub> cells confirmed the preferential permeability of claudin-4 to chloride over sodium.

**Conclusions:** These results suggest that during NS, transcellular Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> transport decreases while paracellular chloride transport *via* claudin-4 may increase along the collecting system. Paracellular chloride permeability may constitute a chloride shunt that favors Na<sup>+</sup> reabsorption and opposes K<sup>+</sup> secretion along the CD in NS.

## SA-PO100

**Renal Organic Anion and Cation Transporters Are Downregulated in Ischemia/Reperfusion and Cisplatin-Induced AKI Models, but Not in Cecal Slurry-Induced AKI**

Jenson Qi, Henriette Frikke-Schmidt, Kamal Albarazani, Nataliya Skrypnik, Li-Jun Ma, Katharine D'Aquino, Raul Camacho, Lili Guo, Janos Steffen, Tao Chen, Andrea R. Nawrocki, Seunghun P. Lee, Alessandro Pocai. Cardiovascular & Metabolic Research Janssen Research and Development LLC, Spring House, PA.

**Background:** Renal proximal tubules excrete metabolites through unidirectional solute transport systems facilitating active secretion of organic ions into urine. We explored 3 classes of transporters: (1) organic anion transporters (OAT), (2) organic cation transporters (OCT), and (3) aquaporins (AQP). We then investigated the effects of acute kidney injury (AKI) induced by ischemia/reperfusion (I/R), cisplatin, or cecal slurry (CS) on the expression of these transporters.

**Methods:** Male SD rats had bilateral renal ischemia or sham-surgery. Kidneys were harvested at 24h. Male C57BL/6N mice were IP dosed with a single injection of cisplatin. Kidneys were harvested at 96h. In the CS model, male C57BL/6N mice were IP dosed with vehicle or cecal slurry and sacrificed at 8 or 24h.

**Results:** SD rats express high levels of renal OAT1/3, OCT2, and AQP1 mRNAs. I/R rats with 33 min of bilateral renal ischemia showed significant decrease of renal OAT1, OAT3, OCT2, and AQP1 mRNAs (76%, 92%, 90%, and 61% reduction, respectively). 40 min I/R led to further decrease of these mRNAs. In C57BL/6N mice, OAT2/3, OCT1/2, and AQP1 are highly expressed in the kidney. We also observed significant decrease of these genes in kidney in I/R mice. In cisplatin-induced mouse nephrotoxic AKI, renal OAT2/3, OCT1/2, mRNAs were significantly reduced (>80%), while AQP1 mRNA was down by 65%. In contrast, no reduction of renal OAT2/3 and OCT1/2 mRNAs, nor any increase of kidney injury marker KIM1 were observed at 8 or 24 h in CS mouse AKI. Unlike I/R induced-tubular necrosis in the renal outer medulla, CS induced vacuolation and tubule dilation in the cortex. We detected low expression of OATs/OCTs in human renal primary proximal epithelial cells which renders it difficult to assess their regulation in vitro.

**Conclusions:** Our data show significant downregulation of renal OATs and OCTs in I/R and cisplatin-induced AKI. These reductions might lead to decreased transport activities in the proximal tubule and further deterioration of renal function after injury. The lack of downregulation of renal OATs and OCTs in the CS mouse AKI suggests that the injury of the renal tubule epithelial cells is less in this model.

**Funding:** Commercial Support - Janssen Research & Development of Johnson & Johnson

## SA-PO101

**Mechanism of Immunogenicity Change of Renal Tubular Epithelial Cells Induced by MDM2 Membrane Translocation in Ischemic AKI**

Jieyu Zeng, Hua Su, Chun Zhang, Huazhong University of Science and Technology, Wuhan, China.

**Background:** Increased immunogenicity of proximal tubular epithelium (PTE) contributes to donor acute kidney injury (AKI) associated TCMR. Formerly, we found MDM2, an E3 ubiquitin ligase, translocated from cytosol to basolateral membrane of tubules during AKI. To explore the underlying relationship between MDM2's translocation and tubular immunogenicity will provide reliable clues to alleviating the shortage of donor as well as preventing the loss of graft.

**Methods:** AKI was induced by ischemia/reperfusion treatment in 8-week C57BL/6 mice. After 45 minutes of bilateral renal pedicle clamping, they were divided into sham, 2 days and 4 days groups according to the time of reperfusion. The expression and distribution of MDM2 and PD-L1 were analyzed by immunostaining and Western blot. In vitro, NRK-52E cells were cultured in a hypoxic environment for different time points (1% O<sub>2</sub>) followed by reoxygenation, and mutated MDM2 plasmid were utilized to interfere the subcellular transportation of MDM2.

**Results:** The distribution of MDM2 gradually shifts to basolateral membrane after renal IRI. Moreover, in IRI groups the abundance of PD-L1, known as a T cell inhibitory co-stimulatory molecule, is weakened significantly. In vitro, by oxygen-glucose deprivation or genetic interfering techniques we demonstrated that MDM2's trafficking attributes to PD-L1 degradation during hypoxia.

**Conclusions:** During ischemic AKI or hypoxia, the translocation of tubular MDM2 leads to basolateral PD-L1 degradation which consequently results in the downregulated inhibitory co-stimulatory signaling with T cell activation.

**Funding:** Government Support - Non-U.S.

## SA-PO102

**Canagliflozin Improves Renal Oxidative Stress and Inflammation in Ischemia-Reperfusion Syndrome in Rats**

Maria de Fatima F. Vattimo,<sup>1,2</sup> Sara Ventura,<sup>1,2</sup> Eloiza O. Silva,<sup>1,2</sup> Victor Debbas,<sup>1,3</sup> Experimental Research Group on Acute Kidney Injury <sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>School of Nursing, Sao Paulo, Brazil; <sup>3</sup>Universidade de Sao Paulo Instituto do Coracao, Sao Paulo, Brazil.

**Background:** Recent studies have shown that sodium-glucose cotransporter 2 (SGLT-2) inhibitors alleviate acute kidney injury (AKI) in diabetic patients. Ischemia-reperfusion (I/R) syndrome is the most relevant cause of AKI. Several molecular

mechanisms, including oxidative stress as well as the inactivation of anti-inflammatory pathways such as Nrf2, contribute to the I/R syndrome. The aim of this study is to investigate the renoprotective effect of canagliflozin on I/R syndrome in non-diabetic rats.

**Methods:** Wistar rats were divided into: SHAM: surgery control; I/R: ischemic group (30 minute bilateral renal clamping); CANA: canagliflozin (30 mg/kg, once, daily, 5 days); CANA+I/R: as described. Renal hemodynamics such as renal blood flow (RBF) and renal vascular resistance (RVR); renal function (inulin clearance, plasma creatinine); oxidative metabolites (urinary peroxides, TBARS, urinary nitrate and thiols in renal tissue) and Nrf2 were analyzed.

**Results:** [Figure 1] [Figure 2]

**Conclusions:** Canagliflozin did not induce hypoglycemia and has significant potential as a therapeutic intervention to ameliorate renal injury after renal I/R and attenuate oxidative stress and inflammation.

**Funding:** Government Support - Non-U.S.

Figure 1. Hemodynamics, renal function and oxidative stress.

Values shown are mean±SE: a p<0,05 versus SHAM; b p<0,05 versus CANA; c p<0,05 versus I/R were significantly different as indicated; one way ANOVA followed by Tukey's pos test were performed.

Figure 2. Densitometry of Nrf2. I/R syndrome can inhibit the Nrf2 pathway.

## SA-PO103

**Deficiency of Long-Chain Acyl-CoA Dehydrogenase (LCAD) Protects Against AKI**

Takuto Chiba, Eric S. Goetzman, Sunder Sims-Lucas. University of Pittsburgh School of Medicine, Pittsburgh, PA.

**Background:** Acute kidney injury (AKI) is caused by distinct etiologies including renal ischemia/reperfusion injury (IRI) and nephrotoxins such as cisplatin. Proximal tubular epithelial cells (PTECs) are particularly vulnerable to such injuries, owing to high energy demands. While fatty acids are the preferred energy source for PTECs via fatty acid oxidation (FAO), FAO-mediated H<sub>2</sub>O<sub>2</sub> production in mitochondria has been shown to be a major source of oxidative stress in multiple diseases, including AKI. We have previously shown that mitochondrial flavoprotein long-chain acyl-CoA dehydrogenase

(LCAD), which catalyzes a key step in mitochondrial FAO, directly produces H<sub>2</sub>O<sub>2</sub> in vitro. However, the role of LCAD during AKI has yet to be determined.

**Methods:** LCAD deficient mice (-/-) and wild-type controls (+/+) were both derived from a common breeding pair of LCAD heterozygous deficient mice (+/-). Western blot analysis confirmed loss of LCAD expression in LCAD-/- kidneys. Male mice age 10-14 weeks were subjected to two distinct AKI models: 1. renal IRI (18 min ischemia) or 2. Single high dose cisplatin (24 mg/ kg bw. i.p.). The kidneys were monitored by histologic evaluation (H&E staining) and serum chemistry. Female mice age 10-14 weeks were also subjected to the high-dose cisplatin-AKI model (20 mg/ kg bw. i.p.).

**Results:** LCAD deficiency does not cause any overt change in renal histology or function in the absence of injury. However, following renal IRI or cisplatin treatment, age- and sex-matched LCAD-/- kidneys demonstrated protected kidney function (limited BUN/ creatinine increase) and less tissue injury when compared with controls. This was coupled with inhibited mitochondrial FAO. Additionally, LCAD-/- mice showed that mitigated reduction of serum albumin or bicarbonate following AKI.

**Conclusions:** LCAD deficiency confers protection against two distinct models of AKI in a sex independent manner. This suggests a therapeutically attractive mechanism whereby decreased mitochondrial FAO mediates protection against AKI.

**Funding:** NIDDK Support, Private Foundation Support

## SA-PO104

### The Fms-Like Tyrosine Kinase Receptor 3 Ligand/Dendritic Cell Axis Contributes to Kidney Recovery in AKI

Li Na,<sup>1</sup> Yao Guo,<sup>1</sup> Chuy Xie,<sup>1</sup> Meihua Lu,<sup>2</sup> Dengyang Zhang,<sup>1</sup> Yuming Zhao,<sup>1</sup> Jiasi Chen,<sup>1</sup> Zhuhua Zheng,<sup>1</sup> Yun Chen,<sup>1</sup> Zhizhuang J. Zhao,<sup>3</sup> <sup>1</sup>The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China; <sup>2</sup>Department of General Practice, BaNa Hospital of Chongqing Medical University, Chongqing, China; <sup>3</sup>Department of Pathology, University of Oklahoma Health Sciences Center, Lindsay, OK.

**Background:** Dendritic cells (DC) are involved in the recovery process of acute kidney injury disease (AKD). Lymphoid DC development is critically dependent on Fms-like tyrosine kinase receptor 3 ligand (Flt3L) in vivo. However, the role of Flt3L in the maintenance of kidney DC and the outcome of AKD are not defined. We hypothesized that Flt3L might improve the tubular recovery after AKD by fostering the accumulation of DC.

**Methods:** Blood were collected from patients of prerenal or renal AKD and healthy controls. Wild type mice and IRF8<sup>KO</sup> mice were treated with 15µg rFlt3L or 10mg/kg Flt3 inhibitor gilteritinib. They were subjected to ischemia-reperfusion (IR) to induce post-ischemic AKD or were injected with 15mg/kg cisplatin to induce nephrotoxic AKD. Serum and kidneys were collected. Kidney function, tubular injury, primary/proximal tubular cell numbers were quantified.

**Results:** Initially, we observed an increased level of serum Flt3L in patients with AKD. Further analysis revealed that this increase was specific for trauma- rather than heart failure- or sepsis-induced AKD. A similar increase in serum Flt3L was found in mice with IR-AKD but not cisplatin-induced AKD. This was accompanied by reduced blood DC but increased kidney DC in mice after IR-AKD. The numbers of type I conventional dendritic cell (cDC1) and CD64<sup>+</sup>DC in kidney were significantly decreased in gilteritinib-treated IR-AKD mice, which were associated with more severe tubular injury. With reduced kidney cDC1, IRF8<sup>KO</sup> mice also showed worsen kidney injury and aggravated functional failure upon IR-AKD. Therapeutic administration of rFlt3L significantly increased kidney cDC1 and CD64<sup>+</sup>DC upon IR-AKD in wild type but not IRF8<sup>KO</sup> mice. This was associated with reduced tubular injury, enhanced proliferation activity of tubular cells, and decreased expression of tubular injury markers (*Ngal*, *Timp-2*, *Igfbp-7* and *Hgf*) in kidney of wild type mice. In addition, pre-treatment of wild type mice with rFlt3L increased kidney cDC1 and protected the mice from severe IR-AKD.

**Conclusions:** Flt3L is upregulated in humans and mice during IR-AKD. It fosters the accumulation of kidney cDC1 and CD64<sup>+</sup>DC, thereby limiting the severity of kidney injury in mice. The current study implies the possibility of DC-based immunotherapy for treatment of AKD.

## SA-PO105

### Discovery of Osteopontin-Dependent and Independent Signaling Networks in AKI-Induced Remote Acute Lung Injury (AKI-ALI)

Yohei Komaru,<sup>1</sup> Liang Ning,<sup>1</sup> Eirini Kefalogianni,<sup>1</sup> Andreas Herrlich,<sup>1,2</sup> Division of Nephrology <sup>1</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>2</sup>St. Louis Veterans Administration Health Care System, St. Louis, MO.

**Background:** Using scRNAseq and ligand-receptor pairing analysis across organs, we identified circulating osteopontin (OPN) released from the AKI kidney and deposited into the lung as a causal agent of AKI-ALI [Khamissi et al. *Science Advances* 2022]. Direct ALI complicated by AKI is a frequent clinical problem with high mortality. How AKI modifies ALI outcomes and whether AKI-released OPN deposited into the lung acts as a negative modifier of direct ALI is unknown.

**Methods:** Single-cell RNA sequencing (scRNAseq) of lung or kidney after sham or AKI (ischemia reperfusion injury). Interorgan cell communications were identified using scRNAseq analysis with CellPhone DB or CellChat. Direct ALI was induced with intratracheally instilled lipopolysaccharide (LPS-ALI). In a two-hit model, renal IRI was added 24 hours after LPS-ALI.

**Results:** OPN injection is not sufficient to induce ALI in uninjured mice, thus additional AKI-released mediators are involved. We initially focused on OPN-dependent

kidney-lung networks, which were increased by 3-fold in AKI as compared to the sham. In AKI, the average interaction strength was increased by 90%. Baseline OPN signals towards lung immune cells mainly originated from the proximal and distal tubules. These OPN-dependent signals likely represent early AKI-ALI mediators that don't require transcriptional upregulation. Analysis of OPN-independent kidney to lung networks revealed that total kidney-lung connections were very similar in number and strength between sham and AKI. However, several signaling networks significantly differed in AKI vs sham, likely indicating novel relevant signals for AKI-ALI emanating from the kidney. We hypothesized further that AKI-released osteopontin could modify pre-existing ALI outcomes. We found that OPN protein expression in the directly LPS-injured lung was moderately elevated. However, addition of AKI after direct LPS-induced ALI further significantly increased OPN protein accumulation in the lung. This suggests a mechanistic connection between kidney-released and lung deposited OPN and the clinically observed worsening of direct ALI outcomes in the context of AKI.

**Conclusions:** Studies integrating single-cell transcriptomics and *in vivo* models enable elucidation of novel mechanism(s) of AKI-ALI in clinically relevant contexts at the cell-type and signal-pathway level.

**Funding:** NIDDK Support, Veterans Affairs Support

## SA-PO106

### Kidney HMGC2 Protects Against Ischemic Kidney Injury

Andrea H. Venable, Lauren Elizabeth Lee, Kyle C. Feola, Sarah C. Huen. *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Chronic kidney disease (CKD) is a growing global health problem. Evidence for abnormal renal fatty acid oxidation (FAO) in kidney disease suggests that dysregulated metabolism is a key component of kidney disease pathogenesis. Ketogenesis is a central metabolic pathway in which ketone bodies are produced from FAO. While the liver is the main ketogenic organ, the rate-limiting enzyme for ketogenesis, mitochondrial Hydroxymethylglutaryl-CoA synthase 2 (HMGCS2), is induced in the proximal tubule of the kidney during fasting. We previously demonstrated that HMGCS2 induced in the kidney does not contribute to the circulating pool of ketones during fasting and cannot compensate for hepatic ketogenic deficiency. We hypothesized that kidney HMGCS2 may be acting locally within the kidney to maintain normal function during metabolic stress or injury.

**Methods:** Using novel mouse models with proximal tubular hemagglutinin (HA)-tagged mitochondria with (*Ggt1-Cre;Hmgcs2<sup>fl/fl</sup>;MITO-Tag*, Ggt<sup>Hmgcs2KO-MT</sup>) or without (*Ggt1-Cre;MITO-Tag*, Ggt-MT) *Hmgcs2* deletion, proximal tubular-specific mitochondria were isolated using anti-HA magnetic beads and mitochondrial respiration was determined by Seahorse. *Six2-Cre;Hmgcs2<sup>fl/fl</sup>* (*Six2<sup>Hmgcs2KO</sup>*) mice with kidney-specific *Hmgcs2* deletion and *Hmgcs2<sup>fl/fl</sup>* littermate controls were subjected to ischemia/reperfusion injury (IRI). An acute kidney injury (AKI) model with right nephrectomy and left IRI and a chronic kidney disease (CKD) model with unilateral IRI were used. Plasma creatinine and/or kidney mRNA expression was assessed 24 hours (AKI) and 14 days (CKD) after IRI.

**Results:** Proximal tubular-specific mitochondria isolated from 24-hour fasted Ggt-MT and Ggt<sup>Hmgcs2KO-MT</sup> mice demonstrated that mitochondria lacking HMGCS2 had significantly lower basal and ADP-stimulated Complex I and II activity as measured by mitochondrial oxygen consumption rate. Compared to littermate controls, *Six2<sup>Hmgcs2KO</sup>* mice had significantly higher plasma creatinine levels and expression of the kidney injury marker *Kim1* after AKI. In the CKD model, inflammation (*Tnfα*) was significantly elevated and markers of fibrosis (*Colla1*, *Col4a1*, *Tgfb1*) trended higher in *Six2<sup>Hmgcs2KO</sup>* injured kidneys.

**Conclusions:** Our data provide evidence that proximal tubular HMGCS2 may play an important role in maintaining mitochondrial function and protecting against ischemic kidney injury.

### Hypoxia Induces Pro-Regenerative Activity of Renal Fibroblasts via Hif1α

Michael Zeisberg, Gunsmay Nyamsuren. *University of Goettingen Medical Center, Goettingen, Germany.*

**Background:** Fibroblasts are the prototypical cells of connective tissue. In the kidney they are known to be the main mediators of fibrosis. It is often overlooked that renal fibroblasts have important physiological functions, such as control of regeneration from acute damage and the synthesis of erythropoietin. Recent studies demonstrated that acute kidney injury is associated with transient accumulation of activated fibroblasts, which aid regeneration of the injured tubular epithelium. Increased expression of growth factors by activated fibroblasts such as VEGF and FGF4 suggests that fibroblasts aid repair of the injured tubular epithelium through paracrine mechanisms. This study aimed to gain additional insight into the contribution of FGF4 to kidney regeneration and the underlying mechanisms.

**Methods:** Ischemia-reperfusion injury was induced by clamping of the of the left kidney pedicle for 45 min. For reporter assays full length human FGF4 promoter DNA from -650 to +886 bp including three hypoxia response elements were cloned into pGL4.10 luciferase reporter plasmid and subjected to site-directed mutagenesis.

**Results:** We report that acute ischemic kidney injury in mice and in humans was associated with increased expression of FGF4 by interstitial cells and with increased expression of FGF-receptors by tubular epithelial cells. Conditional ablation of FGF4 or administration of FGF4-neutralizing antibodies blunted renal regeneration upon ischemia-reperfusion injury. Cultivation of normal human kidney fibroblasts under

hypoxic conditions induced FGF4 expression. Overexpression of a dominant-negative Hif1 $\alpha$ -mutant blunted FGF4 expression in response to hypoxia, whereas hypoxia-independent intracellular accumulation of Hif1 $\alpha$  under normoxic conditions through its superphysiologic transgenic overexpression induced FGF4 transcription. Use of an FGF4 reporter construct in which hypoxia response elements (HREs) had been mutated further confirmed that hypoxia induces FGF4 expression in renal fibroblasts in Hif1 $\alpha$ -dependent manner.

**Conclusions:** Our studies provide evidence that fibroblast aid in the repair of acute kidney injury through secretion of growth factors such as FGF4. Our studies further demonstrate that FGF4 expression is induced in response to hypoxia via Hif1 $\alpha$ , suggesting that modulation of Hif1 $\alpha$  responses may be an attractive therapeutic target to enhance renal regeneration.

### Tubular MPC1 Reduction Is a Protective Adaptive Response to Maintain Redox Balance in Rhabdomyolysis Induced AKI

Gabriela Vasquez Martinez,<sup>1</sup> Ji Young Kim,<sup>2</sup> Gabriel Mayoral Andrade,<sup>1</sup> Ashley R. Jackson,<sup>1,2</sup> Navjot Singh P. Pabla,<sup>2</sup> Diana Zepeda-Orozco,<sup>1,2</sup> <sup>1</sup>Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University, Columbus, OH.

**Background:** Pyruvate is the end product of both glucose and lactate metabolism, and it is a key tubular mitochondrial metabolic fuel with important antioxidant properties that is disrupted in AKI. Pyruvate requires mitochondrial pyruvate carrier (MPC) to enter mitochondria. MPC deletion causes redox alteration characterized by disruptions in glutathione metabolism. We hypothesize tubular MPC is disrupted in AKI and has important contribution to redox responses after AKI.

**Methods:** Glycerol-induced rhabdomyolysis (7.5 ml/kg 50% glycerol in the hind-leg muscles) was induced in male ROSA mT/MG/Gt1-Cre that express membrane-localized GFP in renal tubular epithelial cells, whereas all the other cell types express membrane-localized tdTomato. Kidneys were collected at 24 hours, followed by isolation of GFP positive (RTECs) and negative cells for immunoblot and gene expression analysis. Pax8<sup>Cre/+</sup>-Mpc1<sup>fl/fl</sup> (TMPC1-KO) mice and Pax8<sup>Cre/+</sup>-Mpc1<sup>fl/fl</sup> (TMPC1-WT) littermates underwent glycerol-induced rhabdomyolysis, blood and kidneys were collected at 30 hours after injury for kidney function, histology and redox response analysis.

**Results:** Rhabdomyolysis induced AKI result a reduction of MPC1 mRNA and protein expression only in tubular cells. TMPC1-KO mice who underwent rhabdomyolysis induced AKI had significant reduction on serum cystatin C, blood urea nitrogen (BUN), and tubular tunnel positive cells compared to WT. TMPC1-KO mice with rhabdomyolysis induced AKI had a significant increase in kidney glutathione and thioredoxin reductase activities, as well as glucose-6-phosphate dehydrogenase activity that was not significant in WT mice

**Conclusions:** Rhabdomyolysis induced AKI results on tubular MPC1 reduction. Tubular MPC1 deletion protects from rhabdomyolysis induced AKI and results on increased hydrogen peroxide antioxidant systems response capacity after injury, suggesting that MPC inhibition could be a novel therapeutic approach to manipulate redox response and protect from AKI

## SA-PO109

### Novel Exosome-Based Therapeutics Targeting NF- $\kappa$ B/p65 for AKI Chulhee Choi. ILIAS Biologics Inc., Daejeon, Republic of Korea.

**Background:** Either systemic or local inflammation-induced by infection or ischemic reperfusion is the key pathophysiological event driving sepsis associated (SA)- and cardiac surgery-associated (CSA)-AKI development. NF- $\kappa$ B signaling pathway plays a pivotal role in driving inflammation in both SA- and CSA-AKI. Effective/specific inhibition of NF- $\kappa$ B signaling pathway may ameliorate the course of SA- and CSA-AKI. Recent advancements in nano-technology made it feasible to specifically target NF- $\kappa$ B signaling. The intracellular delivery of protein API (NF- $\kappa$ B inhibitor) with exosome as DDS is an attractive approach for tackling NF- $\kappa$ B signaling in the target cells without off-target effect in both SA- and CSA-AKI.

**Results:** Utilizing ILIAS Bio's EXPLOR® (EXosome engineering for Protein Loading via Optically Reversible protein-protein interactions) technology, we have developed Exo-srI $\kappa$ B with srI $\kappa$ B as API which is a constitutively active form of I $\kappa$ B $\alpha$  with a prolonged half-life in the target cells. Exo-srI $\kappa$ B exhibits anti-inflammation function via specific inhibition of stimuli-induced NF- $\kappa$ B/p65 activation. In the septic mice, the treatment of Exo-srI $\kappa$ B inhibits systemic inflammation and improves survival with the amelioration of SA-AKI. In the renal ischemic-reperfusion mice, the treatment of Exo-srI $\kappa$ B alleviates IRI-AKI by down-regulating NF- $\kappa$ B signaling and ameliorating inflammation/apoptosis in the ischemic injured kidney.

**Conclusions:** The direct intracellular delivery of immunosuppressive protein (srI $\kappa$ B) into target cells using exosomes can be used as a promising therapeutic approach for both SA- and CSA-AKI. The therapeutic potential of Exo-srI $\kappa$ B in both SA- and CSA-AKI should be explored further by clinical trials. Via GLP-toxicology and safety pharmacology studies, it has been determined that Exo-srI $\kappa$ B has no toxicity with minimum 20 folds safety margin compared to the efficacy dose, and based on repeated dose study, both NOAEL and HED were determined, which grant Exo-srI $\kappa$ B first-in-human (FIH) study.

## SA-PO110

### Resident Macrophages Occupy Distinct Microenvironments in the Mouse and Human Kidney

Matthew D. Cheung, Elise Erman, Kyle H. Moore, Gelare Ghajar-Rahimi, Anupam Agarwal, James F. George. The University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** Kidney resident macrophages (KRM) are a unique, self-renewing F4/80<sup>hi</sup>CD11b<sup>int</sup> population important for renal homeostasis and the response to acute kidney injury (AKI). Since they are present throughout the kidney tissue, which contains many distinct microenvironments, we hypothesized that subpopulations of KRMs are functionally diverse and location-specific. Here, we combined single-cell and spatial transcriptomics to characterize mouse and human KRM subpopulations during homeostasis and injury.

**Methods:** KRMs were isolated from C57BL/6J mice without treatment and after 19 min bilateral ischemia- reperfusion injury (BIRI) as well as from human kidneys from 2 kidney donors with creatinines of 0.9 and 2.5 mg/dL. We combined single-cell RNA sequencing (scRNAseq), spatial transcriptomics, flow cytometry, and immunofluorescence imaging to localize, characterize, and validate KRM populations during quiescence and following kidney injury in both mice and humans. scRNAseq and spatial gene expression data were analyzed using the R package, Seurat 4.0.

**Results:** scRNAseq and spatial transcriptomics revealed seven distinct KRM subpopulations in untreated mice that each reside within distinct zones associated with specific nephron structures. Each subpopulation was identifiable by a unique transcriptomic signature suggesting distinct functions. Specific protein markers were identified for several clusters allowing analysis by flow cytometry or immunofluorescence imaging. After injury, the localization of the KRM subpopulations change indicating either movement or changes in functional phenotypes. The pre-injury KRM topology is not fully restored for at least 28 days post-injury. Several human KRM subpopulations appear analogous to those of the mouse and also localize to specific regions.

**Conclusions:** KRMs consist of subpopulations organized into zones associated with nephron structures. The organization of these zones appear to change after function of injury, likely reflecting a differential response to the various damaged kidney structures. Similar subpopulations of KRMs were identified in the human kidney. Therefore, further study of the temporal and spatial characteristics and signaling pathways of these subpopulations in the context of homeostasis and injury is warranted.

## SA-PO111

### Platelet-Instructed SPP1 Macrophages Drive Myofibroblast Activation in Fibrosis in a CXCL4-Dependent Manner

Konrad Hoefft,<sup>1,2</sup> Gideon Schaefer,<sup>1</sup> David Schumacher,<sup>1,3</sup> Hyojin Kim,<sup>1</sup> Barbara M. Klinkhammer,<sup>4</sup> Christoph Kuppe,<sup>1,2</sup> Peter Boor,<sup>4</sup> Sikander Hayat,<sup>1</sup> Rafael Kramann,<sup>1,2</sup> Kramann Laboratory for Translational Cardiovascular and Kidney Research <sup>1</sup>University Hospital Aachen Institute of Experimental Medicine and Systems Biology, Aachen, Germany; <sup>2</sup>Universitätsklinikum Aachen Klinik für Nieren- und Hochdruckkrankheiten rheumatologische und immunologische Erkrankungen, Aachen, Germany; <sup>3</sup>Universitätsklinikum Aachen Klinik für Anesthesiologie, Aachen, Germany; <sup>4</sup>Universitätsklinikum Aachen Institut für Pathologie, Aachen, Germany.

**Background:** Fibrosis represents the common end-stage of chronic organ injury independent of the initial insult, destroying tissue architecture and driving organ failure. Immune cells are key players in fibrosis, which regulate mesenchymal cell activation. However, the signals driving profibrotic immune cell differentiation and subsequent fibroblast crosstalk remain ill-defined.

**Methods:** We analyzed single cell RNA sequencing (scRNA-seq) data of mice after myocardial infarction (MI) to identify profibrotic immune cells. To validate CXCL4 as a mediator of fibrosis we investigated the effect of a CXCL4-KO in monocytes *in vitro*, as well as in mouse models of MI and kidney ischemia reperfusion injury (IRI). To elucidate profibrotic macrophage-fibroblast crosstalk we performed single nuclear RNA sequencing (snRNA-seq) of WT and *Cxcl4*<sup>-/-</sup> mice after IRI. The role of platelet-derived CXCL4 was assessed by co-culturing WT and CXCL4<sup>-/-</sup> platelets with PBMC. Lastly, we analyzed *SPP1* macrophages in open-source scRNA-seq data of human heart failure (HF) and chronic kidney disease (CKD) as well as via immunostaining/in situ-hybridisation in a cohort of 43 human kidneys.

**Results:** We discovered a profibrotic macrophage population marked by *Spp1* (*Spp1* Mac), which expands after MI. Trajectory inference analysis of *Spp1* Mac identified CXCL4 as one of the top upregulated genes during *Spp1* Mac differentiation. *In vitro* and *in vivo* studies demonstrated that loss of *Cxcl4* abrogates *Spp1* Mac differentiation and fibrosis after MI and IRI. SnRNA-seq of WT and *Cxcl4*<sup>-/-</sup> mice after IRI revealed that macrophages orchestrate fibroblast activation via *Spp1*, *Fnl1* and *Sema3* crosstalk. Importantly, we uncovered that platelets drive profibrotic *Spp1* Mac differentiation via CXCL4. Lastly, we show that *SPP1* Mac expand in human HF and CKD and that *SPP1*<sup>+</sup> Mac correlate closely with *COL1A1* expression in 43 human kidneys.

**Conclusions:** We identified a novel profibrotic macrophage population defined by *Spp1* expression and demonstrate that *Spp1* macrophage differentiation is driven by CXCL4. Strikingly, we uncovered an unexpected link between platelets, the main source of CXCL4, macrophages and fibrosis. Targeting platelet-macrophage interaction could serve as a springboard for novel strategies aimed at mitigating fibrosis.

## SA-PO112

## AKI Enhances Aortic Plaque Formation in a Mouse Model of Atherosclerosis in a CCR2-Dependent Manner

Anne M. Breloh,<sup>1</sup> Vera C. Wulfmeyer,<sup>1</sup> Svenja Gaedcke,<sup>1</sup> Susanne V. Fleig,<sup>1</sup> Song Rong,<sup>1</sup> David S. Deluca,<sup>1</sup> Hermann G. Haller,<sup>1</sup> Roland Schmitt,<sup>1</sup> Sibylle Von Vietinghoff,<sup>2</sup> <sup>1</sup>Medizinische Hochschule Hannover, Hannover, Germany; <sup>2</sup>Universitätsklinikum Bonn, Bonn, Germany.

**Background:** Acute kidney injury enhances the risk of subsequent cardiovascular events. To determine underlying mechanisms, we established a model of atherosclerosis after renal ischemia reperfusion (IR) injury. Leukocytes promote atherosclerotic plaque growth and instability. We here studied underlying recruitment mechanisms.

**Methods:** Atherosclerotic lesions and inflammation were investigated in native and bone marrow-transplanted LDL receptor deficient (*LDLr*<sup>-/-</sup>) mice after unilateral renal IR injury by histology, flow cytometry and gene expression analysis.

**Results:** Aortic root atherosclerotic lesion size was significantly larger after renal IR than in controls. A gene expression screen revealed enrichment of chemokines and their cognate receptors in aortas of IR mice in early atherosclerosis. In advanced disease, this was complemented by T cell-associated genes. Increased aortic macrophage proximity to T cells was observed by confocal microscopy. Differential aortic inflammatory gene regulation in IR mice largely paralleled the pattern in the injured kidney. Renal cell types that produced soluble mediators upregulated in the atherosclerotic aorta were identified by single cell analysis. It revealed a marked early increase in *Ccl2*, which was mainly expressed by CCR2<sup>+</sup> myeloid cells. CCR2 mediated myeloid cell homing to the post-ischemic kidney in a cell-individual manner. Reconstitution with *Ccr2*<sup>-/-</sup> bone marrow dampened renal post-ischemic inflammation, and abrogated excess aortic atherosclerotic plaque formation after renal IR. Ablation of CCR2 significantly altered the inflammatory gene expression profile in the atherosclerotic aortas after renal IR.

**Conclusions:** Our data introduce an experimental model of remote proatherogenic effects of renal IR and delineate myeloid CCR2 signaling as a mechanistic requirement. Further investigations will need to address regulation of aortic gene expression and monocytes as mobile mediators of vascular sequelae after kidney injury.

## SA-PO113

## A Pathological Immunological Approach in Evaluating Immune Checkpoint Inhibitor-Induced Nephritis

Ala Abudayyeh,<sup>1</sup> Liye Suo,<sup>2</sup> Omar Mamlouk,<sup>1</sup> Noha Abdel-Wahab,<sup>1</sup> Yan Heather Lin,<sup>1</sup> Valda D. Page,<sup>1</sup> Jamie S. Lin,<sup>1</sup> Amanda Tchakarov.<sup>2</sup> <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.

**Background:** Immune related adverse events (irAEs) are a management challenge with an associated increased morbidity and mortality. The most common renal toxicity is acute interstitial nephritis (AIN) which may be analogous to kidney transplant rejection. Using both clinical variables and tissue findings focusing on immune cells subtypes we evaluated a cohort of immune checkpoint inhibitor (ICI) cases to determine factors associated with renal response, progression free survival (PFS) and overall survival (OS).

**Methods:** We retrospectively reviewed all patients treated with ICI (2007 to 2020) at MD Anderson. A total of 35 patients with biopsy confirmed AIN were identified and immunofluorescence for CD4, CD8, CD20, and CD68 was performed on 25 cases. All slides were reviewed by two blinded board-certified renal pathologists and the severity of inflammation was graded using BANFF criteria. Patients were categorized as renal responders if creatinine improved or returned to baseline after treatment. Fisher's exact tests for categorical variables and Wilcoxon rank-sum or Kruskal-Wallis for continuous variables were used to compare patient's characteristics between groups. Log-rank test was performed to test the difference in survival between groups.

**Results:** Based on the pathological findings, patients with increased interstitial fibrosis were less likely to have renal response compared to patients with less fibrosis, ( $p = 0.027$ ). Interstitial inflammation, tubulitis, number of eosinophils and neutrophils had no impact on renal response. When evaluating immune subtypes there was no strong association with response ( $p > 0.061$ ). Patients with response within 3 months of AKI had a superior OS (OS rate: 77% vs 27%,  $p = 0.025$ ) compared to late responders. Notably, patients who received concurrent ICI and achieved renal response within 3 months had the best OS in comparison to patients who did not receive concurrent ICI nor achieved renal response (OS rate: 100% vs 27%,  $p = 0.041$ ). Similar trends were observed between response to AKI treatment and PFS.

**Conclusions:** This is the first analysis of ICI induced nephritis where a detailed pathological, immunological and clinical evaluation were performed to predict renal response. Our findings highlight the importance of early diagnosis and treatment of ICI-AIN while continuing concurrent ICI therapy.

## SA-PO114

## A Case of Focal Immune-Complex Membranoproliferative Glomerulonephritis (MPGN) in Low-Risk Chronic Lymphocytic Leukemia

Akira F. Tan, Shin Yeu Ong, Alwin Hwai Liang Loh, Jason Choo Chon Jun, Hui Zhuan Tan. Singapore General Hospital, Singapore, Singapore.

**Introduction:** A broad spectrum of kidney diseases is associated with chronic lymphocytic leukemia (CLL). Optimal treatment of low-risk CLL with renal involvement (CLL-R) is unknown.

**Case Description:** A 48 year-old Chinese man with low-risk CLL presented with new-onset microhematuria and subnephrotic range proteinuria (uPCR 1.88g/g) for evaluation. Peak serum creatinine (sCr) was 115µmol/L (baseline 81µmol/L). Investigations were notable for low C3 (0.88g/L), C4 (<0.06g/L) and IgG-λ monoclonal gammopathy (2g/L). Autoimmune markers, virologies, and serum cryoglobulins were negative. Kidney biopsy showed focal membranoproliferative (MPGN) pattern of injury. No TMA changes were seen. Immunofluorescence showed C3-dominant glomerular and mesangial staining (2+), and segmental IgM mesangial staining (1+). Segmental C4d staining was observed. No deposits were seen on electron microscopy (EM). Pronase digestion was not performed. Findings were most consistent with CLL-related immune-complex MPGN. Venetoclax and Obinutuzumab (Ven-Obi) was commenced. Thrombocytopenia developed 2 days after the first obinutuzumab infusion, leading to gross hematuria and acute kidney injury (AKI) (sCr 161µmol/L). Tumour lysis syndrome was excluded. AKI resolved with conservative management. Interestingly, normalization of complements and proteinuria reduction (uPCR 0.38g/g) were observed within 2 weeks of treatment. Treatment is ongoing but remain uncomplicated.

**Discussion:** We report a case of focal MPGN with C3 dominance in a patient with low-risk CLL. Lack of antigen retrieval techniques precluded the search for masked deposits. Positive C4d staining, together with low C3 and C4, suggested an immune-complex, instead of an alternative pathway mediated process. The absence of deposits on EM was likely due to early focal disease. Studies suggest that clone-directed therapies improve renal outcomes in dysproteinemic-related kidney disease, but the optimal regimen and timing of treatment in early/mild CLL-R is unknown. We demonstrated early renal response to Ven-Obi in our patient. No tumor lysis syndrome was observed during treatment, although thrombocytopenia, a rare adverse effect of Obinutuzumab, did occur together with AKI, the latter possibly due to tubular obstruction by red blood cells casts. Longer follow-up is needed to determine treatment efficacy of Ven-Obi in CLL-R.

## SA-PO115

## On-Treatment Cancer Safety Events With Daprodustat vs. Erythropoiesis-Stimulating Agents: Post Hoc Analyses of ASCEND-ND and ASCEND-D

Ajay K. Singh,<sup>1</sup> Finnian R. McCausland,<sup>1</sup> Brian Claggett,<sup>1</sup> Christoph Wanner,<sup>2</sup> Andrzej Wiecek,<sup>3</sup> Michael B. Atkins,<sup>8</sup> Kevin Carroll,<sup>10</sup> Vlado Perkovic,<sup>4</sup> John McMurray,<sup>3</sup> Janet Wittes,<sup>9</sup> Steven M. Snapinn,<sup>7</sup> Allison Blackorby,<sup>6</sup> Tara Barker,<sup>6</sup> Tara L. Dimino,<sup>6</sup> Stephen Mallett,<sup>6</sup> Amy M. Meadowcroft,<sup>6</sup> Alexander R. Cobitz,<sup>6</sup> Scott D. Solomon.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>University Hospital of Würzburg, Würzburg, Germany; <sup>3</sup>Slaski Uniwersytet Medyczny w Katowicach, Katowice, Poland; <sup>4</sup>The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; <sup>5</sup>University of Glasgow, Glasgow, United Kingdom; <sup>6</sup>GlaxoSmithKline plc, Collegeville, PA; <sup>7</sup>Seattle-Quilcene Biostatistics, Seattle, WA; <sup>8</sup>Georgetown-Lombardi Comprehensive Cancer Center, Washington DC, DC; <sup>9</sup>WCG Statistics Collaborative, Washington, DC; <sup>10</sup>KJC Statistics Limited, Cheshire, United Kingdom.

**Background:** Prespecified on-treatment analyses of ASCEND-ND (NCT02876835) raised concerns for a higher relative risk of cancer-related adverse events (AE) with daprodustat (dapro; a hypoxia inducible factor-prolyl hydroxylase inhibitor) vs darbepoetin (darbe) in patients with anemia of CKD. This was not observed in dialysis patients in ASCEND-D (NCT02879305). As there may be a long latency between onset and diagnosis of cancer AE, we performed post-hoc analyses to estimate risks over time.

**Methods:** ASCEND-ND randomized 3,872 patients to dapro or darbe. ASCEND-D randomized 2,964 patients to dapro or ESAs. Both were open-label; ESA comparators used different dosing intervals (3/week, 1/week, every 2 or every 4 weeks). Cancer-related AE were identified by predefined medical dictionary for regulatory activities terms. The pre-specified approach examined relative risks for cancer AE up to one day after the last dose date (LDD) of randomized therapy. The present analyses used Cox models, adjusted for baseline ESA use and region, to estimate dapro effects by various follow-up periods (censoring at LDD, LDD+dosing intervals, or end of study).

**Results:** In ASCEND-ND, the effect estimate of dapro vs darbe for cancer-related AE depended on the length of follow-up time after LDD (**Fig 1**): hazard ratios 1.04 (95%CI 0.77-1.40) at end of study; 1.12 (95%CI 0.81-1.56) for LDD+dosing interval; 1.50 (95%CI 1.04-2.15) for LDD+1 day. These variations were not seen in ASCEND-D, where shorter ESA dosing intervals were more comparable to dapro.

**Conclusions:** Prespecified on-treatment analyses for cancer-related AE appeared to result in biased estimates of risk in ASCEND-ND, as they preferentially excluded events from patients in the darbe arm. Analyses that account for longer darbe dosing intervals, plus analyses that extend duration of follow-up, may provide a more valid estimate of risk. These resulted in attenuation of effect estimates towards neutrality, similar to ASCEND-D.

**Funding:** Commercial Support - GSK

## SA-PO116

## Urinary Cell BKV-VP1 mRNA Levels in Early Symptomatic Hemorrhagic Cystitis and Kidney Injury in Hematopoietic Stem Cell Transplant Recipients

Victoria Gutgarts,<sup>1,2</sup> Catherine Snopkowski,<sup>2</sup> Yeon Joo Lee,<sup>1,2</sup> Ann A. Jakubowski,<sup>1</sup> Genovefa A. Papanicolaou,<sup>1</sup> Ilya Glezerman,<sup>1,2</sup> Manikkam Suthanthiran,<sup>2</sup> Darshana M. Dadhania,<sup>2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Background:** Asymptomatic BK virus (BKV) viremia is frequent (up to 60%) peri hematopoietic stem cell transplantation (HCT), however a minority develop BKV hemorrhagic cystitis (HC). We aimed to determine if BKV-VP1 mRNA levels, previously validated urinary biomarker of BKV nephropathy (Dadhania et al, Transplantation 2010) can predict HC and acute kidney injury (AKI) within 3 months of HCT.

**Methods:** Urine samples were collected prospectively from adults undergoing first allogeneic HCT at MSKCC. 4 samples (median) per patient were collected within 3 months of HCT. Urine cell pellets were prepared, total RNA isolated and reverse transcribed to cDNA. Real-time quantitative PCR was used to measure BKV-VP1 mRNA copy number/ug of total RNA. HC was defined as grades 1 to 4; microscopic to macroscopic hematuria with clots, respectively. AKI was defined as Cr  $\geq 1.5\times$  baseline at 3 months of HCT.

**Results:** 19 HCT recipients (median age 45, range 24-73, 53% acute leukemia) were profiled and 5 (26%) developed symptomatic HC (4 graded as 1, 1 graded as 3) within 3 months. Eight patients developed AKI at 3 months, majority grade 1. The Figure below shows the average number of BKV VP1 copies per patient. Although the median number of copies were not significantly different between those who developed symptomatic HC and not and those who developed AKI and not in the first three months of HCT, levels in 4 patients exceeded BKV nephropathy (BKV-N) diagnostic threshold ( $>6.5\times 10^8$  BKV VP1 mRNA/microgram RNA).

**Conclusions:** Our novel finding that the BKV VP1 mRNA level exceeded BKVN diagnostic threshold in 21% cases raise the hypothesis that BKVN may be an underappreciated entity in HCT recipients.

Figure: Levels of BKV VP1 in Urinary Cells of HCT Recipients

Patient	Average Urine BKV VP1 mRNA Copies/ug RNA	HC grade	Symptomatic HC Group (N=5) Median (copies/ug total RNA, [IQR])	Asymptomatic and no HC Group (N=14) Median (copies/ug total RNA, [IQR])	Baseline Cr at time of HCT (mg/dl)	Creatinine at 3 months (mg/dl)	AKI (N=8) Median (copies/ug total RNA, [IQR])	No AKI (N=9) Median (copies/ug total RNA, [IQR])

## SA-PO117

## Elevated Creatinine With Selpercatinib Therapy in RET-Dependent Malignancies

Victoria Gutgarts,<sup>1,2</sup> Monica F. Chen,<sup>1</sup> Lauren A. Kaplanis,<sup>1</sup> Guilherme Harada,<sup>1</sup> Alexander Drilon,<sup>1,2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Background:** Selpercatinib (LOXO-292) is a novel selective RET inhibitor for RET-dependent malignancies. The adverse effect profile estimates ~9% elevated creatinine (Cr) after therapy initiation (Drilon et al, NEJM, 2020). Creatinine however may not be the best estimator of kidney function given selpercatinib is a MATE-1 inhibitor that may potentially lower tubular secretion of Cr. To date, there is no literature that describes Cr in these patients or the role of cystatin C (which is not secreted like Cr), as an alternative estimator of kidney function.

**Methods:** We retrospectively reviewed 94 patients at MSKCC initiated on selpercatinib. Baseline Cr was defined as Cr level prior to start of therapy. Creatinine levels that met criteria for acute kidney injury (AKI) (KDIGO stage 1:  $\geq 1.5\times$  but  $<2\times$  baseline, stage 2:  $\geq 2\times$  but  $<3\times$  baseline, stage 3  $\geq 3\times$  baseline) at any point after start of therapy were recorded. Cystatin C data was recorded when available.

**Results:** 11% (10/94) met criteria for AKI after selpercatinib initiation. The Figure below shows five patients had stage 1 (50%), 3 patients stage 2 (30%), and 2 patients stage 3 (20%) AKI. At 12 months Cr remained  $\geq 0.5$  in 2 patients (20%). Only 50% of patients had cystatin C levels checked and the Figure below shows that in the majority of cases, cystatin C is lower than Cr when checked at the same encounter. Two patients had kidney biopsies. Kidney biopsy for patient 6 showed acute tubular injury in the setting of diarrhea. Patient 9 had a kidney biopsy at an outside hospital that showed interstitial nephritis but details not known since he was lost to follow up.

**Conclusions:** As the use of selpercatinib grows in patients with RET-fusion malignancies, it is essential to better characterize the significance of elevated Cr findings. At this point, it is unclear if this is true AKI or elevated serum Cr due to inhibition of tubular Cr secretion. Prospective studies that involve Cr and simultaneous cystatin C should be performed to better estimate true kidney function in patients on selpercatinib.

Figure: Creatinine levels for patients on Selpercatinib with AKI

	Baseline Cr (mg/dl)	Cr at time of AKI (mg/dl)	KDIGO Stage 1: yellow 2: green 3: orange	6-month Cr after AKI (mg/dl)	12-month Cr after AKI (mg/dl)	Change in Cr 12 months after AKI	Cr (grey) and Cystatin C (blue) level at same encounter

## GFR in the Era of Precision Medicine: The Relevance of a Measured GFR in the Onco-Nephrology Universe and Solitary Kidney

Francesco Trevisani,<sup>1</sup> Melania Franchini,<sup>2</sup> Giulia Quattrini,<sup>1</sup> Alessandra Cinque,<sup>3</sup> Arianna Bettiga,<sup>1</sup> Umberto Capitanio,<sup>1</sup> Andrea Salonia,<sup>1</sup> Massimo Locatelli,<sup>1</sup> Giorgio Pizzagalli,<sup>1</sup> Francesco Montorsi,<sup>1</sup> <sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Azienda Ospedaliera Universitaria Federico II, Napoli, Italy; <sup>3</sup>Biorec s.r.l., Milano, Italy.

**Background:** A reliable assessment of renal function in onconeurology (ON) is fundamental. The most used tool to measure GFR is the estimated GFR (eGFR) which harbors a significant error compared to gold standards (mGFR). Aim of this study was to determine the extent of the error of eGFR compared to mGFR in ON and solitary kidney (SK) patients (pts).

**Methods:** A consecutive cohort of 403 ON pts was collected to compare the most used eGFR formulas (MDRD, CKD-EPI SCr 2012, CKD-EPI 2021 SCr, CKD-EPI Cys 2012, CKD-EPI Cys 2021, CKD-EPI Cys/SCr, Cockcroft-Gault) with mGFR (Iohexol Plasma Clearance). Among them, 126 pts were SK for radical nephrectomy. We performed statistical analyses on the overall population and a sub-analysis in SK pts. True positives and False positives were classified in CKD stages. Comparisons between groups were performed using Wilcoxon ranks sum test for numerical variables and Pearson's Chi square test for categorical ones.

**Results:** Clinical data: overall median age was 67 years, median BMI 24.8, Male: 74.9%, F: 25.1%, Diabetes: 10.9%, Hypertension: 53.8%, CKD stage I: 3.7%, II: 25.5%, IIIA: 28%, IIIB: 27.5%, IV: 13.4%, V: 1.74%, mean Creatinine: 1.46 mg/dl, cystatin: 1.23. Both overall population (Figure 1) and SK cohort (Figure 2) harbored a non-negligible errors in each CKD class with a huge discrepancy between eGFR and mGFR, suggesting the great relevance of mGFR in the decision making algorithm.

**Conclusions:** The error in the classification of CKD stages using eGFR by formulas was too common, with a poor agreement with mGFR in all CKD classes. The use of mGFR should be mandatory to obtain a tailored management in ON, especially in SK.

reported for each pt. SCr and eGFR were measured at 24h, 48 h, 72 h and at dismissal in the acute setting for the AKI; at 12,24,36,48,60 months for the chronic setting for CKD. Comparisons between groups were performed using Kruskal-Wallis ranks sum and Pearson's Chi square test Anova was used to identify differences in the evolution of eGFR between groups.

**Results:** Clinical data are present in table. AKI and CKD onset are shown in the figure 1. The results of a four-way ANOVA for each AKI/CKD displayed that surgery is the variable that impacts more on AKI/CKD onset. Regarding the comorbidities, diabetes impact more in CKD stages onset in both the global and the pts population.

**Conclusions:** AKI and CKD are common both in D and in RN, with a similar eGFR decrease over time both in acute than in chronic. Surgery appears to be the predominant factor in the onset of AKI/CKD, while comorbidities, especially diabetes, may have a major impact on the long-term deterioration of kidney function.

Table 1. Clinical data	Measurement	Total	D	RN	PN	P value
Age	Median (IQR)	56 (48-64)	51 (44-58)	59 (51-66)	58 (50-65)	<0.0001

### Renal Safety of FLOT Regimen for Gastroesophageal Cancer: Time for Break Boundaries?

Francesco Trevisani,<sup>1</sup> Matteo Floris,<sup>2</sup> Alessandra Cinque,<sup>3</sup> Roberto Minnei,<sup>2</sup> Antonello Pani,<sup>2</sup> Andrea Angioi,<sup>2</sup> Mario Scartozzi,<sup>4</sup> Marco Puzzone,<sup>4</sup> Jaime Amodeo,<sup>4</sup> Nicole Liscia,<sup>1</sup> Elena A. Mazza,<sup>1</sup> Stefano Cascinu.<sup>1</sup> <sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Azienda Ospedaliera Brotzu, Cagliari, Italy; <sup>3</sup>BIOREK s.r.l., Milan, Italy; <sup>4</sup>Università degli Studi di Cagliari, Cagliari, Italy.

**Background:** Currently, peri-operative docetaxel, oxaliplatin, leucovorin, and 5-fluorouracil (FLOT) chemotherapy (CTx) is the gold standard treatment for pts with locally advanced gastric cancer (LAGC), who undergo peri-operative CTx and surgery. The nephrotoxicity of both docetaxel and oxaliplatin may limit the use in CKD pts. Since limited evidence is available, we explored FLOT effects on renal function in our LAGC population.

**Methods:** Retrospective data on patient with LAGC in 3 tertiary hospital between jan/2018 to jan/2022 have been analyzed. Pts have been treated with FLOT, administered every 2 weeks, 4 times before surgery. SCr, Hb, and CKD-EPI eGFR were detected before each cycle. AKI and CKD onset/prevalence were determined according to K-DIGO criteria.

**Results:** A consecutive cohort of 73 pts was enrolled. Baseline CKD was present in 16 pts (21.9%). Median eGFR was 106.2 ml/min. ANOVA showed no significant differences between cycles in eGFR decay and CKD onset; p=0.323 (Table 1 and Figure 1). AKI was very low (1 episode of stage2 (0,7%). New onset anemia was the only significant adverse event observed (p=0.003).

**Conclusions:** Surprisingly, the pre-operative FLOT regimen seems to have a negligible impact on renal function suggesting the possibility to extend its use even in patient with advanced CKD.

**Funding:** Private Foundation Support

## SA-PO119

### Surgery or Frailty: Who Is the Master in eGFR Decline After Renal Surgery in Living Donor and Renal Cancer Patients?

Francesco Trevisani,<sup>1</sup> Matteo Floris,<sup>2</sup> Lucrezia Furian,<sup>3</sup> Umberto Capitanio,<sup>1</sup> Francesco Trepiccione,<sup>4</sup> Alessandra Cinque,<sup>5</sup> Giuseppe Rosiello,<sup>1</sup> Melania Franchini,<sup>6</sup> Arianna Bettiga,<sup>1</sup> Giovambattista Capasso,<sup>4</sup> Paolo Rigotti,<sup>3</sup> Nicola Lepori.<sup>2</sup> <sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Azienda Ospedaliera Brotzu, Cagliari, Italy; <sup>3</sup>Università degli Studi di Padova, Padova, Italy; <sup>4</sup>Università degli Studi della Campania Luigi Vanvitelli Scuola di Medicina e Chirurgia, Napoli, Italy; <sup>5</sup>BIOREK s.r.l., Milano, Italy; <sup>6</sup>Azienda Ospedaliera Universitaria Federico II, Napoli, Italy.

**Background:** AKI and CKD are the 2 main complications after nephrectomy both on living donor(D) and on renal cancer pts(RC). It is still debatable if RN with a normal pre-operative renal function could have worse functional outcomes in term of eGFR decline in comparison to RN due to the comorbidities and frailty. Aim of this study was to evaluate in both D and RN the incidence of AKI andCKD, using a control cohort of oncological partial nephrectomy (PN) to evaluate the impact of surgery and comorbidities.

**Methods:** We collected a multicentric(4 different tertiary hospitals) consecutive cohort of 718 patients:256 D and 462 RC pts of which 236 PN and 226 RN. Inclusion criteria: baseline eGFR higher than 70 ml/min/1.73. Clinical and lab variables were

Age - years [Median/ Interquartile range]	65.7 (56.0 - 75.4)
Female sex - no. (%)	29 (39.7)
Diabetes - no. (%)	3 (3.9)

### GFR Estimation Using $\beta_2$ -Microglobulin and $\beta$ -Trace Protein in Adults With Solid Tumors: A Prospective Cross-Sectional Study

Veronica T. Costa e Silva,<sup>1</sup> Luiz A. Gil,<sup>2</sup> Lesley A. Inker,<sup>3</sup> Renato A. Caires,<sup>1</sup> Elerson Costalonga,<sup>1</sup> George B. Coura-Filho,<sup>1</sup> Gilberto Castro,<sup>1</sup> Andrew S. Levey,<sup>3</sup> Emmanuel A. Burdmann.<sup>2</sup> <sup>1</sup>Universidade de Sao Paulo Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>3</sup>Tufts Medical Center, Boston, MA.

**Background:** We previously showed that estimated glomerular filtration rate (eGFR) based on serum creatinine (Scr) and cystatin C (Scys)(eGFRcr-cys) is more accurate than equations based on Scr (eGFRcr) or Scys (eGFRcys) in solid tumor patients in Brazil (Onco-GFR Study).  $\beta_2$  microglobulin (B2M), and  $\beta$ -trace protein (BTP) are filtration markers (FM) that can further improve the accuracy of GFR estimation when used in multi-marker panels with Scr and Scys, but have not been assessed in patients with cancer. The aim of this study is to evaluate the performance of the CKD-EPI equations without race including B2M and/or BTP with creatinine in the Onco-GFR Study.

**Methods:** Measured GFR (mGFR) was determined using the plasma clearance of <sup>51</sup>Cr-EDTA. Assays for FM were performed at the University of Minnesota.

**Results:** A group of 1,200 patients with active cancer but mostly (85%) not yet treated were recruited between April 2015 and September 2017 and included for analysis. Patients were 58.8±13.2 years, 50.8% male. Mean (SD) mGFR was 78.5±21.7 ml/min/1.73 m<sup>2</sup>. Mean (SD) serum B2M and BTP were 2.32 (1.05) and 0.72 (0.35) mg/L, respectively. eGFRcr-B2M and eGFRcr-BTP had similar accuracy (similar 1-P<sub>30</sub>) compared to eGFRcr-cys, whereas the three-marker panels (eGFRcr-cys-B2M and eGFRcr-cys-BTP) and the four-marker panel (eGFRcr-cys-B2M-BTP) were more accurate (smaller 1-P<sub>30</sub>) than eGFRcr-cys (Table).

**Conclusions:** B2M and BTP can improve the accuracy of GFR estimation and may be useful as a confirmatory test in patients with solid tumors, either by inclusion in multi-marker panel with Scr and Scys, or by substituting for Scys in combination with Scr. This may be of particular importance for use of B2M, which may be more available than Scys in cancer centers. We suggest further evaluation of B2M and BTP in other cancer centers.

**Table 1. Performance of eGFR equations using B2M or BTP with creatinine compared to eGFRcr-cys**

Filtration marker (eGFR)	Equation and Year	Median bias (mGFR - eGFR) (ml/min/1.73 m <sup>2</sup> )	Precision (IQI) (ml/min/1.73 m <sup>2</sup> )	Accuracy (1-P <sub>30</sub> ) (%)	Accuracy (RMSE)
eGFRcr-cys	CKD-EPI 2021	-4.1 (-4.8 to -3.3)	15.7 (14.6 - 17.1)	9.8 (8.0 - 11.4)	0.171 (0.163 - 0.179)
eGFRcr-B2M	CKD-EPI 2020/2021	-3.5 (-4.4 to -2.9)	15.1 (14.1 - 16.5)	9.5 (7.8 - 11.1)*	0.168 (0.161 - 0.177)
eGFRcr-BTP	CKD-EPI 2020/2021	-2.2 (-3.3 to -1.2)	15.2 (14.2 - 16.3)	8.4 (6.9 - 10.0)**	0.163 (0.156 - 0.171)
eGFRcr-cys-B2M	CKD-EPI 2020	-1.5 (-2.3 to -0.8)	14.3 (13.3 - 15.2)	5.6 (4.3 - 6.8)***	0.155 (0.147 - 0.163)
eGFRcr-cys-BTP	CKD-EPI 2020	3.4 (2.7 to 4.1)	16.7 (15.3 - 17.9)	6.4 (4.9 - 7.8)***	0.181 (0.173 - 0.190)
eGFRcr-cys-B2M-BTP	CKD-EPI 2020	-1.8 (-2.6 to 1.1)	13.5 (12.7 - 14.6)	5.8 (4.5 - 7.1)***	0.152 (0.144 - 0.159)

\*p-value (MolSlope test) vs eGFRcr-cys = 0.8  
\*\*p-value (MolSlope test) vs eGFRcr-cys = 0.2  
\*\*\*p-value (MolSlope test) vs eGFRcr-cys < 0.001

### Outcomes of Kidney Transplantation in Patients With Myeloma and Amyloidosis

Jia Hwei Ng,<sup>1</sup> Naoka Murakami,<sup>2</sup> Amy Sharma,<sup>1</sup> Vinay Nair,<sup>1</sup> Kenar D. Jhaveri.<sup>1</sup> <sup>1</sup>Northwell Health, Great Neck, NY; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** Recent improvement in treatment and patient survival has opened the eligibility of kidney transplantation for patients with ESKD due to plasma cell dyscrasias (PCD), such as multiple myeloma, AL amyloidosis and MGRS.

**Methods:** We conducted a retrospective study of UNOS database (2006-2018) to compare patient and graft outcomes of kidney transplant recipients with ESKD due to PCD vs other causes. The primary outcome was patient survival time, defined as the time from transplantation to death. Secondary outcomes included death-censored graft survival time. First, we described the frequency of transplant in ESKD from various forms of PCD. Also, we determined the absolute and relative outcomes of kidney transplant recipients who had ESKD due to PCD vs other causes.

**Results:** Among 168,369 first kidney transplant adult recipients, 0.22-0.43% per year had PCD as the cause of ESKD. The PCD group had worse survival than the non-PCD group for both living and deceased donor types, (aHR: 2.24 [95% CI: 1.67, 2.99]) and (aHR: 1.40 [1.08, 1.83]), respectively. The PCD group had worse survival than the diabetes group, but only among living donor type (aHR: 1.87 [1.37, 2.53]) vs (aHR: 1.16, [0.89, 1.2]). Graft survival in patients with PCD were worse than non-PCD in both living and deceased donor type (aHR 1.72 [1.91, 2.56], aHR 1.30 [1.03, 1.66]). Patient and graft survival were worse in amyloidosis but not statistically different in multiple myeloma, compared to non-PCD group.

**Conclusions:** The study provides novel data on survival in patients with PCD who received kidney transplant. More study are needed to determine the specific group of patients with PCD who benefit from kidney transplant.

## A Living Donor Recipients

## B Deceased Donor Recipients

### Multicenter Study of Renal Outcomes in AL Amyloidosis Patients After Autologous Stem Cell Transplant

Umut Selamet,<sup>1</sup> Kole Joachim,<sup>1</sup> Yan Heather Lin,<sup>2</sup> Shveta S. Motwani,<sup>1</sup> Valda D. Page,<sup>2</sup> Naoka Murakami,<sup>1</sup> Ala Abudayyeh.<sup>2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** Renal impairment is a common complication with negative impact on survival in AL amyloidosis patients. Autologous stem cell transplant (ASCT) is standard of care for treatment of AL amyloidosis, but data on renal outcomes after ASCT are lacking. We aimed to analyze longitudinal trends in kidney function and its impact on progression-free (PFS) and overall survival (OS) post ASCT in AL amyloidosis patients.

**Methods:** We performed a retrospective review of 314 patients with AL amyloidosis who underwent ASCT at MD Anderson Cancer Center and Dana Farber Cancer Center from 2010 to 2020. We collected data on demographics, comorbidities, ISS stage, disease status at time of ASCT, eGFR (CKD EPI), and laboratory variables at day 0, day 100, 6-months, years 1, 2 and 3 post ASCT. We evaluated the change in eGFR over time using linear mixed effect models. The association between eGFR change and PFS and OS were evaluated using the Cox proportional hazards models.

**Results:** A higher ISS stage at diagnosis was significantly associated with a lower GFR ( $p = 0.0042$ ). Black and Hispanic races were associated with lower eGFR across all time points ( $p \leq .006$ ). Higher serum light chains were associated with lower eGFR across all time points (decrease by 0.059-fold per 1 fold increase,  $p < 0.0001$ ). There was no significant decline in eGFR over time. A higher eGFR at the time of ASCT ( $>$ median) was significantly associated with a longer PFS at baseline (HR (95% CI) = 1.610 (1.102, 2.354),  $p = 0.0139$ ) and at 2 years post ASCT (HR (95% CI) = 2.351 (1.041, 5.308),  $p = 0.0396$ ). A higher eGFR at baseline (HR (95% CI) = 1.676 (1.054, 2.663),  $p = 0.029$ ) and at 6 months post ASCT (HR (95% CI) = 3.218 (1.709, 6.057),  $p = 0.0003$ ) was associated with better OS. A good disease risk category, lack of kidney amyloid, lower light chains, lower ISS score, were all associated with a higher PFS and OS at different time points. Higher hemoglobin and albumin were also associated with longer PFS.

**Conclusions:** This study provides valuable data on renal outcomes in patients with AL amyloidosis who underwent ASCT. Disease related factors were the main predictors of eGFR, however no significant decline in eGFR observed in AL amyloidosis patients after ASCT. Higher eGFR was associated with better PFS and OS at baseline and at year 2 post ASCT.

## SA-PO124

### TRPC3, a Key Target in Cisplatin-Induced Renal Fibrosis

Hinda Najem, Joelle Hajal, Youakim Saliba, Nassim Fares. *Universite Saint-Joseph, Beirut, Lebanon.*

**Background:** Cisplatin (Cisp) is a chemotherapy drug that induces renal cellular lesions with excessive accumulation of extracellular matrix leading to renal fibrosis. Transient receptor potential canonical channels type 3 (TRPC3) are non-selective  $\text{Ca}^{2+}$  channels strongly implicated in cardio-renal diseases. We previously demonstrated the role of TRPC3 in renal fibrosis of obstructive origins. Herein, we evaluate TRPC3 implication in renal toxicity mediated by Cisplatin.

**Methods:** 34 adult male C57BL/6 mice were divided into four groups: WT Sham ( $n=8$ ), WT Cisp ( $n=8$ ), KO Sham ( $n=9$ ), and KO Cisp ( $n=9$ ). Cisp was administered by intraperitoneal injections ( $7\text{mg.kg}^{-1}$ , one injection per week) for four weeks. Kidney tissues, blood, and urine samples were harvested for histological and biochemical studies.

**Results:** KO Cisp mice showed a decrease in urinary albumin/creatinine ratio, associated with a reduction of fibrotic TGF- $\beta$ /SMADs and NFATc3 pathways compared to WT. Moreover, kidneys of KO Cisp mice showed a significant alleviation in apoptosis and oxidative DNA damage, as well as a reduction of Tcf21/PDGFR $\alpha$  activated fibroblasts.

**Conclusions:** TRPC3 channels seem to play a substantial role in cisplatin-induced renal fibrosis. TRPC3 might constitute a key therapeutic target for improving renal remodeling in cisplatin chemotherapy.

## SA-PO125

### Infliximab for Treatment of Immune Adverse Events

Vishnupriyadevi Parvathareddy,<sup>1</sup> Umut Selamet,<sup>2</sup> Aditi A. Sen,<sup>1</sup> Noha Abdel-Wahab,<sup>3</sup> Juhee Song,<sup>3</sup> Omar Mamlouk,<sup>3</sup> Valda D. Page,<sup>3</sup> Maen Abdelrahman,<sup>4</sup> Ala Abudayyeh.<sup>3</sup> <sup>1</sup>The University of Texas Health Science Center at Houston, Houston, TX; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>4</sup>Houston Methodist, Houston, TX.

**Background:** Immune related adverse events (irAEs) challenge the use of immune checkpoint inhibitors (ICIs). We performed a retrospective study to evaluate the use of infliximab for irAE management, and its role on irAE response, progression free survival (PFS) and overall survival (OS) with a focus on melanoma patients.

**Methods:** This study is a retrospective review of all cancer patients exposed to infliximab after ICI from 2004 to 2021 at MD Anderson. Overall survival was assessed using Kaplan-Meier method. Univariate and multivariate logistic regression models were used to evaluate the predictors of response to infliximab, OS and PFS at months 3, 6 and 12.

**Results:** We identified 185 cancer patients (93 melanoma). Median follow up was 36 months with a median time from ICI initiation to irAE of 2.4 months and from irAE to infliximab of 0.3 months. 71% of the patients responded to infliximab, 27% of the patients had no response and 1.62% had unknown response at 3 months. Among different types of irAEs, colitis was associated with response to infliximab. Patients who had acute kidney injury (AKI) within one month of infliximab were less likely to respond to infliximab at all time points. Subanalysis of melanoma patients showed similar results as the entire cohort. Regarding tumor response in relation to infliximab: 21 were in remission before infliximab 81% continued to be in remission after infliximab. In 135 patients which were not in remission 86% continued to be the same after infliximab. In both entire cohort and melanoma the percent of patients in remission after infliximab is higher than that of patients in remission before infliximab ( $p=0.002$ ). Median OS was 29.4 months in the entire cohort and 42.3 months in melanoma cohort. In melanoma cohort, AKI prior to infliximab initiation was associated with worse survival (HR 2.131,  $P=0.046$ ).

**Conclusions:** Our study is one of the largest retrospective analysis of infliximab use for irAE management. Patients with colitis were the best responders to infliximab. In addition, AKI within one month of infliximab was associated with worse response to infliximab. In melanoma cohort, AKI before initiation of infliximab was also associated with higher risk of death. Interestingly the percent of patients in remission after infliximab is higher than that of patients in remission before infliximab.

## SA-PO126

### A Case of Immune Checkpoint Inhibitor Related Osmotic Tubular Injury

Vishnupriyadevi Parvathareddy,<sup>1</sup> Biruh Workeneh.<sup>2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Checkpoint inhibitor therapy is associated with a variety of kidney complications, like acute interstitial nephritis with or without tubular necrosis, thrombotic microangiopathy and a variety of glomerulonephritis. Here, we describe a case with a rare pattern of injury, osmotic tubulopathy, after exposure to CPI, pembrolizumab.

**Case Description:** 48 y/o Caucasian female with triple negative breast cancer with liver metastasis received a regimen of carboplatin, paclitaxel and pembrolizumab over 16 weeks followed by lumpectomy and sentinel lymph node dissection. Subsequently, she presented with AKI. Her creatinine was 2.19 mg/dl on admission, worsening to 2.53 mg/dl and persisted despite stopping CPI treatment and starting empiric corticosteroids for suspected CPI toxicity, thus prompting kidney biopsy. Biopsy revealed marked vacuolization of proximal tubules, normal appearing glomeruli and no evidence of AIN.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

She did not receive medications usually implicated in toxic tubulopathy, nor was she exposed to any other nephrotoxins. Her kidney function started to improve reaching a nadir of 1.15 mg/dl 4 weeks after corticosteroids were initiated.

**Discussion:** This case highlights the possible association of vacuolar tubular injury pattern associated with CPI therapy. Pembrolizumab contains L histidine, polysorbate 80 and sucrose. Of these, sucrose may be a predisposing factor to toxic tubulopathy. This has been described once before in literature by Sekulic et al, where it was male with lung cancer receiving nivolumab which contains small amount of mannitol as an active ingredient which was postulated as being the culprit. **Learning points:** Toxic tubulopathy of proximal tubules is a possible side effect of CPI therapy. Exclude other possible etiologies that can contribute to osmotic tubulopathy e.g., mannitol, CNI toxicity, amphotericin B exposure etc. Treatment remains supportive, possibly steroids and discontinuation of the offending agent until recovery of kidney function.

#### SA-PO127

##### Hyperuricemia and Kidney Function in Patients Diagnosed With Multiple Myeloma

Tadej Petreski,<sup>1,2</sup> Nejc Pulko,<sup>3</sup> Katja Sapek,<sup>2</sup> Sanja Puljek,<sup>2</sup> Nejc Piko,<sup>4</sup> Sebastjan Bevc.<sup>1,2</sup> <sup>1</sup>Department of Nephrology, Clinic for Internal Medicine, University Medical Center Maribor, Maribor, Slovenia; <sup>2</sup>Faculty of Medicine, University of Maribor, Maribor, Slovenia; <sup>3</sup>Department of Hematology, Clinic for Internal Medicine, University Medical Center Maribor, Maribor, Slovenia; <sup>4</sup>Department of Dialysis, Clinic for Internal Medicine, University Medical Center Maribor, Maribor, Slovenia.

**Background:** Multiple myeloma (MM) is a common hematologic malignancy with a high incidence rate in the elderly. Its characteristics include hypercalcemia, anemia, renal impairment, and bone lesions. The presence of CKD makes the diagnosis more difficult, and treatment related morbidity and mortality may complicate management. However, less is known about the effect of serum uric acid in MM. The aim of our study was to assess the impact of hyperuricemia and CKD on survival of patients with MM.

**Methods:** We retrospectively included 42 Caucasian patients from the Hematology outpatient clinic (HOC) who were diagnosed with MM between 2015 and 2020. Average age was 69.5±11.5 years. We recorded past medical history, laboratory tests, and basic demographic data upon first visit to the HOC before treatment was initiated. CKD was defined as eGFR <45 ml/min/1.73m<sup>2</sup> and hyperuricemia as serum uric acid >420 mmol/L.

**Results:** Included patients (54.8% female), who were observed for a median of 760.0 (IQR 746) days, had diabetes mellitus (23.8%), arterial hypertension (64.3%), previous malignant disease (14.3%), dyslipidemia (28.6%), CKD (31.8%), and hyperuricemia (35.7%). Their ECOG performance status (PS) median was 2.0 (IQR 2.0). Most common subtypes of MM were IgG kappa (40.5%), IgG lambda (19.0%), and free light chain lambda (16.7%). Kaplan-Meier survival analysis showed no difference in mortality between the CKD and non-CKD group, however there was a difference between the hyperuricemic and normouricemic group (p=0.007, Log Rank 7.185). Furthermore, the uricemic groups differed in median beta-2-microglobulin, 8.1 (IQR 10.7) and 4.5 (IQR 3.8) mg/L (p=0.021), serum calcium, 2.45 (IQR 0.38) and 2.13 (IQR 0.15) mmol/L (p<0.001), and presence of CKD, 62.5% and 19.2% (p=0.004), respectively. In Cox regression models, hyperuricemia remained a significant marker (p=0.03, Exp(B) 4.4, 95% CI 1.2-16.9), even when adjusted for age, sex, PS, variables that proved different in univariate analysis, and LDH and albumin.

**Conclusions:** Elevated serum uric acid levels showed to be a possible additional prognostic marker for patients diagnosed with MM regardless of baseline kidney function.

#### SA-PO128

##### AKI Post CD19-CAR T-Cell Therapy Among Pediatric Patients at a Tertiary Hospital

Yonique P. Petgrave,<sup>1,2</sup> Subodh R. Selukar,<sup>2</sup> Noel Delos Santos,<sup>1,2</sup> John J. Bissler,<sup>1,2</sup> Aimee Talleur.<sup>2</sup> <sup>1</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>2</sup>St Jude Children's Research Hospital, Memphis, TN.

**Background:** Chimeric antigen receptor (CAR) T-cell therapy has shown promising responses in patients with relapsed/refractory B-cell acute lymphoblastic leukemia. In the pediatric population, the incidence of acute kidney injury (AKI) post treatment with CD19-CAR T-cell therapy remains unknown, unlike other well-established immune related complications such as cytokine release syndrome (CRS) and neurotoxicity (NTX).

**Methods:** The objective was to retrospectively identify the incidence of AKI in pediatric patients post treatment with lymphodepleting chemotherapy and CD19-CAR T-cell therapy, potential risk factors for AKI, and kidney function recovery. Serum creatinine values prior to CAR T-cell therapy through day 30 post therapy were used to assess AKI, defined by the Kidney Disease Improving Global Outcomes (KDIGO) criteria

**Results:** In the study period (11/2018 – 4/2021), 34 patients received a total of 35 CD19-CAR T-cell infusions for relapsed and/or refractory B-lineage malignancy. The median age was 9.7 yrs old (range 1.8 –23.6) at time of infusion, with most patients male (55.9%) or white (73.5%), and 28.6% previously treated with a hematopoietic cell transplant (HCT). Median baseline renal function using 24hr creatinine clearance (n=7) was 125 ml/min/1.73m<sup>2</sup> (range 60-207) and by Technetium99 scan (n=19) 155 ml/min/1.72m<sup>2</sup> (range 71-280). The incidence of immune related toxicities included: CRS, 60% (grade 3-4 CRS, 17%), NTX, 25.7%, and HLH-like toxicity, 11.4%. The cumulative incidence of any grade AKI by day 30 was 20% (95% CI 6.5%-33.5%) with severe AKI (Stage 2-3) developing in 5 patients (14.3%). One patient required dialysis. Patients who developed AKI did so within the first 14 days of CAR T, and 50% of patients had kidney function return to baseline within 30 days. There was no association with AKI and pre-treatment risk factors, including level of disease burden in the marrow or prior HCT. In patients experiencing immune mediated side effects, AKI developed after the onset of NTX and HLH in all patients, and all but one patient with CRS.

**Conclusions:** Although the incidence of AKI is low in our pediatric cohort, it developed rapidly after CD19-CAR T-cell therapy. Early recognition and management of CAR T-cell therapy related complications is beneficial, as we see half of patients recovering kidney function within 30 days

#### SA-PO129

##### AKI and CKD in Pediatric Cancer Survivors

Ahmed S. Zeid, Sara M. Delap, Randal S. Olshefski, Joseph Stanek, Lory Guthrie, Diana Zepeda-Orozco. Nationwide Children's Hospital, Columbus, OH.

**Background:** Pediatric cancer survivors are exposed to nephrotoxins and procedures during treatment that put them at risk of kidney disease. Here we evaluated factors associated with acute kidney injury (AKI) and chronic kidney disease (CKD) in a cohort of pediatric cancer survivors.

**Methods:** This was a retrospective chart review that included pediatric cancer survivors who received nephrotoxic chemotherapy, irradiation treatment, and/or had pelvic tumors and were under follow-up at Nationwide Children's Hospital between 01/01/2011 and 06/30/2021. Patients with pre-existing kidney disease were excluded. Variables included demographics, primary malignancy, nephrotoxin and radiotherapy exposures, nephrectomy, and last encounter's laboratory results. AKI was defined as stage 2 or 3 AKI by KDIGO creatinine-based guidelines during therapy. CKD was defined as eGFR < 90 ml/min/1.73 m<sup>2</sup> per Schwartz calculation at the date of last follow-up. Data were summarized and factors associated with AKI and CKD were analyzed with logistic regression models.

**Results:** A total of 128 patients met the inclusion criteria. The median age at cancer diagnosis was 5.4 years and the median duration of follow-up was 6 years. Twenty-six AKI episodes were identified in 25 patients (19.5%). The incidence was more in hematological malignancies (68%) and 41% occurred in the first month after cancer diagnosis. Patients with AKI were more likely to have impaired initial GFR (OR=0.96; p=0.0023). The leading etiology for AKI was dehydration (Table 1). A nephrologist was consulted in 39% of AKI episodes. Eighteen patients developed CKD during follow-up (14%); of whom 2 were followed by a nephrologist. Solid tumors survivors accounted for 83.3% of patients with CKD. Risk factors associated with CKD included nephrectomy (OR=10.5; p=0.005), carboplatin (OR=3.03; p=0.0364), Ifosfamide (OR=8.89; p=0.002), and vincristine (OR=6.7; p=0.0040). There was no significant association between AKI and CKD development in cancer survivors (OR=1.73; p=0.35).

**Conclusions:** Renal complications in pediatric cancer patients are common. In our cohort, renal service involvement in the management of patients with AKI and CKD was limited. Nevertheless, we believe it is crucial for proper diagnosis and management.

Table 1: Causes of AKI in our cohort

Possible etiology of AKI	Tumor lysis syndrome	Dehydration due to fluid losses or poor intake.	Drug related nephrotoxicity	Shock and hypotension	Malignant infiltration of the kidney	Urinary tract obstruction by tumor	Glomerulonephritis
Number of episodes	6	10	4	3	1	1	1

## SA-PO130

## Onconeurology, an Essential Subspecialty: Experience of a University Hospital Center

Sheila Bermejo,<sup>1</sup> Mónica Bolufer,<sup>1</sup> Davide Viggiano,<sup>2</sup> Ana Callejo,<sup>1</sup> Marina López-Martínez,<sup>1</sup> Ander Vergara,<sup>1</sup> Irene Agraz,<sup>1</sup> Oriol Bestard,<sup>1</sup> Maria Jose Soler.<sup>1</sup> <sup>1</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>2</sup>Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy.

**Background:** Kidney complications of cancer patients and cancer in renal patients have increased in recent years. This study evaluates the characteristics of the patients referred to the Onco-Nephrology Unit from January 2021 to December 2021, studying the cognitive and mood status of these patients.

**Methods:** This is a prospective observational study of the Onco-Nephrology consultation at our hospital during 2021. Clinical and analytical characteristics of the patients and clinical indication for referral were analyzed. In addition, sleep quality, mood and cognitive status were assessed using validated rating scales (Epsworth, Geriatric Depression Scale and Montreal).

**Results:** Seventy-four patients were evaluated, mean age was 69.6(±11) years, 41(55.4%) men, 47(63.5%) had hypertension, 18(24.3%) diabetics, and 11(14.9%) were affected by heart disease. In addition, creatinine 1.93(±1.1)mg/dl, eGFR 39.97(±20.3) mL/min, proteinuria 187[29-515.9]mg/g, and 4(5.4%) had microhematuria. The most frequent cancers were intestinal, gynecological and mammary with 12.16%(n=9) each. 58.3%(n=42) of patients had metastatic disease. 48.7%(n=36) received chemotherapy and 58.1%(n=43) targeted therapies. Platinum was the most frequently used chemotherapy and anti-VEGF in terms of targeted therapies. The most frequent clinical indication for referral was acute renal failure(n=36;48.7%). Rating scales were obtained in 51 patients: 49%(n=25) were snorers, followed by 17.6%(n=9) with insomnia and 11.8%(n=6) with OSAS. 27 patients(36.5%) had cognitive impairment. Mild depression was detected in 13 cases(25.5%) and moderate depression in 11.6%(n=6). 21 renal biopsies were performed, the most frequent diagnosis was acute interstitial nephritis(71.4%, n=15) followed by thrombotic microangiopathy(19% n=4). A total of 15 patients(20.3%) died during the year.

**Conclusions:** Most patients referred to Onco-Nephrology are affected by advanced oncological disease and consequently had a high mortality. The most frequent indication for referral was acute kidney injury(48.7%). Comprehensive patient care is important, given the prevalence of depressive syndrome. Onco-Nephrology is an example of a comprehensive and multidisciplinary approach to improve the survival and quality of life of patients with advanced cancer and renal disease.

## SA-PO131

## Differential Epidemiology of Prostate Cancer Specific Mortality for Black Men With ESKD

Sohilkumar Manvar,<sup>1</sup> Weichuan Dong,<sup>2</sup> Siran M. Koroukian,<sup>2</sup> Nagaraju Sarabu.<sup>1</sup> <sup>1</sup>University Hospitals, Cleveland, OH; <sup>2</sup>Case Western Reserve University, Cleveland, OH.

**Background:** Studies exploring racial disparity in mortality among ESKD patients with prostate cancer (PCa) are limited.

**Methods:** We used Surveillance, Epidemiology and End Results data linked to Medicare to identify men (age >40) diagnosed with PCa years 2004-2015. After excluding patients with missing data, we categorized participants into ESKD (dialysis + kidney transplant) and non-ESKD by using international classification of disease, 9th revision, clinical modification. We compared overall and PCa specific mortality among Blacks, Whites, Hispanics and others using Cox proportional hazards and Fine and Gray competing risk models respectively.

**Results:** We included 18282 Blacks, 107457 Whites, 2397 Hispanics, and 6785 others for analysis. Blacks were five times more likely to having ESKD, more likely to present with metastatic disease, younger, had similar Gleason Score, more likely to be single, and live in higher poverty areas than Whites (Figure 1). Compared to Whites, Blacks had similar all-cause mortality (Hazard Ratio (HR): 0.8, 0.9, 1.1) and PCa mortality (HR: 0.4, 0.6, 1.0) in ESKD group while they had higher all-cause (HR: 1.1, 1.2, 1.2) and PCa mortality (HR: 1.1, 1.2, 1.3) in non-ESKD group (Figure 2).

**Conclusions:** ESKD and prostate cancer are more common among Blacks than Whites. Despite presenting with higher metastatic disease, prostate cancer mortality for Blacks with ESKD is similar but higher for those without ESKD than Whites. Future research should focus on understanding these racial differences.

Baseline Characteristics

## SA-PO132

## Clinical Characteristics and Outcomes of Membranous Nephropathy Post Stem Cell Transplant

Nattawat Klomjit,<sup>1,2</sup> Ladan Zand,<sup>2</sup> Mariam P. Alexander,<sup>2</sup> Nelson Leung.<sup>2</sup>

<sup>1</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** Glomerulonephritis is rare but one of the important causes of kidney injury in patients with stem cell transplant (SCT). Membranous nephropathy (MN) is the most common etiology but data regarding clinical characteristics and outcomes of these patients are limited.

**Methods:** We included all patients who developed MN post SCT between 2000-2021 from the Mayo Clinic Health System and University of Minnesota. Baseline demographics and pertinent clinical outcomes are collected.

**Results:** Between 2000 to 2021, we identified 16 patients (13 from Mayo Clinic and 3 from University of Minnesota). The median age at the time of SCT and MN diagnosis was 57.1 (21.8-68.4) and 63 (25.7-70.2) years respectively. The most common hematological disease was acute leukemia (62.5%), lymphoma (12.5%), multiple myeloma (6.25%) and other. The median time from SCT to MN diagnosis was 2.6 (1.5-20.8) years. About two-third of patients were female and all were white. Patients typically presented with nephrotic syndrome (13/16, 81.3%). The median serum creatinine was 1.2 (ranged 0.5-4.0) mg/dL with median urine protein 6.6 (ranged 2.0-40.0) g/d. Nearly all patients developed graft-versus-host disease (GVHD) (15/16, 93.8%) with skin manifestation as the most common site (10/15, 66.7%). One patient had PLA2RAb. Of 16 patients, 10 (62.5%) received rituximab (RTX), 5 (31.3%) received other immunosuppression (mycophenolate mofetil, prednisone, cyclosporine and tacrolimus), and 1 (6.2%) did not receive therapy. The median follow-up time was 2.7 (0.2-20.9) years. Twelve patients (75%) achieved complete remission with a median time to remission of 8 (ranged 3-12) months. Eighty percent of RTX and 66.6% of non-RTX group achieved complete remission (p=0.7). Four patients initially did not respond to non-RTX regimen and subsequently RTX was added, resulting in CR in all cases. Three patients relapsed (1 RTX and 2 non-RTX).

**Conclusions:** MN post-SCT typically occur in patients with concomitant GVHD. Patients often respond to immunosuppression and achieve CR relatively quickly compared to MN in non-SCT patients. RTX therapy may portend better outcome compared to other immunosuppression. Future studies are needed to assess the efficacy of RTX.

## SA-PO133

### The Development of “Mayo MGRS” Score to Predict Likelihood of Monoclonal Gammopathy of Renal Significance in Patients With Monoclonal Gammopathy

Nattawat Klomjit,<sup>1,2</sup> Ladan Zand,<sup>2</sup> Fernando C. Fervenza,<sup>2</sup> Sanjeev Sethi,<sup>2</sup> Nelson Leung,<sup>2</sup> <sup>1</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** MGRS is found in only 3-4% of CKD with monoclonal gammopathy (MG). Therefore, there is a need for clinical tool to predict the likelihood of MGRS lesions in patients with MG.

**Methods:** The Mayo MGRS score was developed using all patients from 2013 to 2018 with biopsy proven MGRS and available MG and urine monoclonal protein. A multivariable logistic regression model between the predictors and MGRS status was fit. Using the odds ratios, score weights were derived for each variable and a MGRS risk score was computed for each patient. Internal validation of the risk score model was conducted by 10-fold cross-validation.

**Results:** Between 2013-2018, we included 130 patients in the cohort and 62 patients have MGRS. We found that urine protein (UP)  $\geq 1.5$  g/d (OR 4.01), hematuria (OR 4.88), affected/unaffected free light chain (FLC) ratio  $\geq 4$  (OR 10.87), and diabetes mellitus (DM) (OR 0.30) significantly predicted MGRS. Positive urine MG significantly predicted MGRS in univariate model but did not in multivariate model (OR 1.88). All significant parameters and positive urine MG were included in the scoring system due to clinical relevancy. We assigned the score to each parameter as follows: score 1 for UP  $\geq 1.5$  g/d, hematuria, positive urine MG; score 2 for affected/unaffected free light chain (FLC) ratio  $\geq 4$  (due to magnitude of the OR); score -1 for DM. Therefore, the score could range from -1 to 5. A univariate logistic regression model between the score and MGRS status showed a C-statistic of 0.831 (95% CI 0.758, 0.890) with predicted probability of MGRS increasing linearly from 0.026 (score -1) to 0.957 (score 5), **figure 1**. Ten-fold cross-validation has a median C-score of 0.73 (IQR 0.68, 0.75).

**Conclusions:** Mayo MGRS score is a useful tool to assist clinician in assessing the risk of having MGRS and decide who to biopsy. Future external validation study is needed.

Figure 1

## SA-PO134

### Renal Pathologies and Patient Outcomes Post Allogeneic Stem Cell Transplantation

Praveen Ratanasrimetha,<sup>1</sup> Omar Mamlouk,<sup>1</sup> Amanda Tchakarov,<sup>2</sup> Ala Abudayyeh,<sup>1</sup> <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>The University of Texas Health Science Center at Houston, Houston, TX.

**Background:** Renal complications associated with hematopoietic stem cell transplantation (HSCT) have been reported to be as high as 55% with acute kidney injury (AKI) and proteinuria being the most common presentations. With AKI impacting both renal and survival outcomes, a renal biopsy remains the gold standard to diagnose the etiology of AKI. Below we investigated the scope of renal pathologies in allogeneic SCT recipients and their renal outcomes.

**Methods:** A single center retrospective chart review of all patients who underwent a renal biopsy post allogeneic SCT from 2007-2022. We collected baseline characteristics, serum creatinine, proteinuria, treatment for the renal pathology, and the renal outcomes. Renal response was defined as any improvement in creatinine after treatment either complete return to baseline or partial response.

**Results:** We identified 60 cases with the three most common underlying cancers being leukemia, lymphoma and myeloma. Indications for kidney biopsy were mostly due to unexplained AKI (83.3%) and proteinuria/hematuria (17%). TMA was the most common pathology finding at 28.3%, followed by BK nephropathy (15%), FSGS and membranous nephropathy (14.9%), acute tubular injury (13%), acute interstitial nephritis (10%), amyloidosis (6.6%), MGUS (5%), diabetic nephropathy (3%), and IgA nephropathy and MPGN (3.2%). Acute and chronic TMA was the most common pathology. Two out of 5 treated with rituximab had partial response, 1 out of 3 treated with eculizumab had a partial response, all 3 patients switched from tacrolimus to rapamycin had a complete renal response, 3 patients had no treatment with one patient with improved renal function, one patient was treated with cellcept with partial response, and one patient was treated with naprosoliumab with no renal response. One third of the patients with renal TMA had died.

**Conclusions:** Based on a single center 15-year experience of kidney biopsies post allogeneic SCT it is evident that transplant related TMA remains the leading cause of SCT related AKI post allogeneic SCT. Renal TMA carries a poor overall prognosis and there is still no established guideline for its treatment in recipient of SCT. Based on our center experience, switching GVHD prophylaxis from tacrolimus to sirolimus might improve renal outcome. Renal response to anticomplement therapy and rituximab was variable.

## SA-PO135

### The Impact of a Low-Normal Protein High Calorie Diet in the Onco-Nephrological Scenario: Do the Opposites Attract?

Arianna Bettiga, Francesco Fiorio, Federico Di marco, Francesca Liguori, Riccardo Vago, Umberto Capitanio, Andrea Salonia, Francesco Montorsi, Francesco Trevisani. *IRCCS Ospedale San Raffaele, Milano, Italy.*

**Background:** Nutritional therapy (NT) based on controlled protein intake represents the cornerstone when managing chronic kidney disease (CKD), however the international guidelines do not clearly define an adequate protein intake for onco-nephrological patients. Aim of our study is to investigate the impact of a low-normal protein high calorie diet (LNPHCD) on the quality of life (QoL) and on the renal and nutritional status in a consecutive cohort of 85 nephrological pts affected or not by urological non-metastatic neoplasia treated with a nephrologist-nutritionist combined approach (NNCA).

**Methods:** Pts were enrolled in the Urological Department at San Raffaele hospital between 2018-2020, screened for absence of malnutrition and were administered a conventional CKD protein-controlled diet (0.7-1 g/Kg/die: calories: 30-35 kcal per kg body weight/die) for a period of 6 months. The diet was based on the CKD onco-nephrological clinical conditions and the pts' nutritional state. Anthropometrical outcomes, lab test exams (including Iohexol test for mGFR) and clinical variables were examined at baseline and after 6 months. To evaluate the impact of the combined approach on perceived QoL, multiple 8 scale assessments in a generic QoL-Short Form36 (SF36) questionnaire were administered to each patient.

**Results:** The NNCA was effective in improving mGFR ( $\Delta=+1.8$ ) and uremia ( $\Delta=-16$ ), outlining its effectiveness in managing nephrological complications in the entire population, regardless of the presence of neoplasia. BIA outcomes showed significant improvement, especially when the parameters were malnutrition-related (MR) ( $\Delta\text{PhA}=+0.1^\circ$ ;  $\Delta\text{BCMI}=+0.5$ ;  $\Delta\text{FFMI}=+0.5$ ). The SF36 questionnaire highlighted a good perceived QoL in subjects treated with the NNCA, even if social activities were negatively affected.

**Conclusions:** Our work demonstrated that LNPHCD, as part of a multidisciplinary approach, ameliorates not only the nephrological scenario in this asset of patients but above all the MR parameters, while maintaining a high QoL and a healthy nutritional status. Following NNCA treatment, perceived QoL has improved and does not appear to be influenced by physical health and emotional status. Despite this, we observed that social activities are greatly and negatively affected.

## SA-PO136

### Bortezomib Increases ER Stress in Myeloma-Associated Glomerulopathy

Dao-Fu Dai. *The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA.*

**Background:** Kidney involvement by multiple myeloma (MM) is associated with worse prognosis. The success of Bortezomib, a proteasome inhibitor has been a major breakthrough in the treatment of MM patients and it is believed to have a nephroprotective effect. Bortezomib induces ER stress to kill myeloma cells, but its role in myeloma-associated glomerulopathy is unclear.

**Methods:** Using MM mice carrying IL-6 Tg with concomitant Tg of i-Myc with deregulated expression of the Myc and enhancers in the IgH locus (designated IL6/Myc mice), we compared the glomerulopathy before and after treatment with 50 mg/kg single dose of Cyclophosphamide (C), Cyclophosphamide + Bortezomib at 1 mg/kg at Day 1 and 4 (BC), Cyclophosphamide + TUDCA molecular chaperone 3 doses/ week for 4 weeks (CT), or TUDCA (T) only.

**Results:** IL6/Myc mice developed MM at 3-6 months, characterized by significant paraproteinemia, splenomegaly and bone involvement. The presence of splenomegaly is well correlated with glomerulopathy, characterized by glomerular capillary IgM. Kappa monoclonal deposits and segmental membranoproliferative glomerulonephritis (MPGN) pattern of injury. High magnification EM showed that some of the deposits have repetitive structures, suggestive of cryoglobulinemic glomerulonephritis. Compared with pre-treatment biopsy, post-treatment kidney pathological examinations show substantial improvement in glomerulopathy in IL6/Myc mice treated with C or CT. In contrast, mice treated with BC or T show significant progression of glomerulopathy, assessed by endocapillary hypercellularity, the extent of deposits and intracapillary “hyaline / cryo-plugs”. The worsening of glomerulopathy in BC-treated kidneys is associated with increased markers of ER stress and Integrated Stress Response ATF4.

**Conclusions:** IL6/Myc multiple myeloma mice showed excellent chemotherapy response to Cyclophosphamide treatment. Surprisingly, the addition of Bortezomib to Cyclophosphamide significantly worsened myeloma-associated glomerulopathy, likely due to increased ER stress induced by Bortezomib. Reduction of ER stress by TUDCA by itself was not effective. However, reduction of ER stress by TUDCA in combination with Cyclophosphamide showed the best kidney protective effect. Our findings suggest that Bortezomib does not have a direct nephroprotective effect. An alternative nephroprotective strategy may need to be developed to ameliorate myeloma-associated kidney diseases.

## SA-PO137

## The Urine Protein-Albumin Gap as a Predictor of Multiple Myeloma

Gregory L. Hundemer,<sup>1</sup> Haris Insirovic,<sup>2</sup> Ayub Akbari,<sup>1</sup> Manish M. Sood,<sup>1</sup>  
<sup>1</sup>Ottawa Hospital, Ottawa, ON, Canada; <sup>2</sup>Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada.

**Background:** Multiple myeloma (MM) frequently presents as an unexplained decline in kidney function. Nephrologists often assess for discordance between the urine protein-creatinine ratio (UPCR) and urine albumin-creatinine ratio (UACR) as a proxy for free light chains in the urine consistent with cast nephropathy. However, thresholds for the urine protein-albumin gap (UPCR-UACR) and its association with MM are not well established.

**Methods:** We conducted a population-level, retrospective cohort study of adults in Ontario, Canada with same day measurements of UPCR/UACR and without a history of MM between 2009-2021 (N=28,231) using provincial health data. Individuals were categorized by quartile of urine protein-albumin gap and stratified by UPCR ( $\leq$  or  $>50$  mg/mmol). Multivariable Cox regression models estimated the association between the urine protein-albumin gap and MM.

**Results:** 116 individuals were diagnosed with MM (0.4%) at a median time of 31 days. In the overall cohort, MM diagnoses increased with each successive quartile of urine protein-albumin gap (Fig. A). However, compared to Quartile 1 ( $\leq 9.3$  mg/mmol), only Quartile 4 ( $>43.4$  mg/mmol) was associated with a significantly higher risk for MM (HR 4.49 [95%CI 2.47-8.15]). Among individuals with a UPCR  $\leq 50$  mg/mmol, no association was observed (Fig. B). In contrast, among individuals with a UPCR  $> 50$  mg/mmol, a higher urine protein-albumin gap was associated with a higher risk of MM (Q1  $\leq 34.2$  mg/mmol: ref, Q2 34.3-57.5 mg/mmol: HR 1.98 [95%CI 0.59-6.62], Q3 57.6-111.8 mg/mmol: HR 3.94 [95%CI 1.29-11.97], and Q4  $>111.8$  mg/mmol: HR 10.97 [95%CI 3.85-31.25]; Fig. C).

**Conclusions:** The urine protein-albumin gap is associated with MM, predominantly when the UPCR is  $>50$  mg/mmol and the urine protein-albumin gap exceeds  $\sim 50$  mg/mmol. These results establish clinically meaningful thresholds for clinicians to utilize when interpreting discordance between UPCR and UACR values as a predictor of MM in cases of unexplained kidney dysfunction.

## A. Overall Study Population (N = 28,231)

B. UPCR  $\leq 50$  mg/mmol (N = 20,632)C. UPCR  $> 50$  mg/mmol (N = 7,599)

## SA-PO138

## Crescents: An Eclipsed Presentation of Multiple Myeloma

Arsh Bajaj, Kathleen Castillo, Erdal Sarac, Hilmer O. Negrete. *Mercy Health St Elizabeth Youngstown Hospital, Youngstown, OH.*

**Introduction:** Kidney involvement is common in multiple myeloma (MM) and is associated with increased mortality. Light chain cast nephropathy, monoclonal immunoglobulin deposition disease and light chain amyloidosis are the most frequent presentations. Very few cases are reported of MM presenting as crescentic glomerulonephritis (CGN). Here, we present a case of a female with rapidly progressive loss of renal function and proteinuria who was found to have MM and CGN.

**Case Description:** A 45-year old woman with h/o hypertension, diabetes mellitus, GERD, iron deficiency anemia, nephrolithiasis and COVID infection six months presented with worsening renal function. Her baseline creatinine three months prior was 0.88 mg/dL eGFR  $>60$  and had recently increased to 2.81 mg/dL eGFR of 22. Laboratory investigations revealed a hemoglobin 8.3 g/dL, platelet count 404 x 10<sup>9</sup>/L. Serum calcium and uric acid levels were within normal limits. Urinalysis showed proteinuria without hematuria with a urine protein/creatinine ratio 1.9 g/g, urine albumin/creatinine ratio 506 mg/g and urine albumin/protein ratio of 0.27. Complement levels, ANCA, Anti-GBM, ANA, RF and hepatitis serology were all unrevealing. Serum Kappa and Lambda free light chains were elevated with ratio being of 0.09. Bone marrow was done which demonstrated approximately 10% lambda restricted plasma cell clones. In view of progressive renal dysfunction she was admitted with the suspicion of light chain nephropathy for consideration of plasma exchange therapy. Kidney biopsy was obtained which showed findings consistent with crescentic GN, with weak linear IgG staining along glomerular basement membranes without evidence of cast nephropathy, monoclonal immunoglobulin deposition or amyloidosis. The patient was started on Cyclophosphamide-Bortezomib-Dexamethasone regimen and since then her kidney function has remained stable.

**Discussion:** Rare kidney findings in patients with MM include membranoproliferative GN, cryoglobulinemia, immunotactoid and fibrillary glomerulopathy. MM associated Crescentic GN is extremely rare. Its etiology and pathophysiology is unclear but it seems that treatment of MM may temporarily halt its progression as in this case.

## SA-PO139

## Spontaneous Remission of Membranous Nephropathy in Hematopoietic Stem Cell Transplantation Patients

Claudia M. Brauer Ornelas,<sup>1</sup> Ilya Glezerman,<sup>1</sup> Surya V. Seshan,<sup>2</sup> Steven Salvatore.<sup>2</sup>  
<sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Introduction:** Secondary membranous nephropathy (MN) is a known complication of hematopoietic stem cell transplantation (HSCT) and is considered a form of the graft versus host disease (GVHD). It usually presents 2 months after discontinuation of GVHD immunosuppression prophylaxis. Patients with secondary MN are treated with immunosuppression. We present two cases of spontaneous remission of the MN in HSCT patients.

**Case Description:** Case 1. 54-year-old male with history of diffuse large B-Cell lymphoma and HSCT (day +1007) presented with edema. Patient had a history of skin GVHD. He completed the course of tacrolimus for GVHD prophylaxis. Patient developed lower extremity swelling over one month. The vital signs and exam were unremarkable except to lower extremity edema. Serum creatinine was 1.1 (0.6-1.3) mg/dL, urinary protein to creatinine ratio (UPCR) was 9.2. Phospholipase A2 receptor (PLA2R) antibody was negative. Patient was started on an ACE inhibitor and a diuretic and underwent a kidney biopsy. Biopsy revealed diffuse membranous nephropathy with negative PLA2R staining. Proteinuria gradually improved and UPCR was 0.1 approximately 33 months after the kidney biopsy. Case 2. 71-year-old male with history of Crohn's disease, myelodysplastic syndrome and HSCT (day+649) presents to renal clinic with edema. Patient was on tacrolimus taper with currently undetectable trough level for GVHD prophylaxis. The vital signs and physical exam were unremarkable except for lower extremity edema. Serum creatinine level was 1.0 mg/dL, UPC was 5.75. Anti PLA2R antibody was negative. Patient underwent a kidney biopsy which revealed diffuse membranous nephropathy with negative PLA2R staining. Patient was managed conservatively. Patient's proteinuria gradually improved and UPC was 0.8 approximately 21 months after the biopsy.

**Discussion:** In secondary MN associated with HSCT the treatment is geared to address presumed underlying GVHD. Our experience illustrates that conservative management may be an option in selective cases. It is also possible that our patients had PLA2R negative MN. This also highlights the need for wider access to other markers of MN to distinguish between PLA2R negative primary MN such as Thrombospondin type-1 domain-containing 7A and secondary forms of MN for example Protocadherin 7 recently linked to GVHD associated MN.

## SA-PO140

## Clinching the Diagnosis: A Case of Marginal Zone Lymphoma Diagnosed on Kidney Biopsy

Chelsea Gertze, Kavitha Vellanki, Maria M. Picken. *Loyola University Health System, Maywood, IL.*

**Introduction:** Marginal zone lymphomas are low-grade non-Hodgkin B-cell lymphomas that rarely has renal involvement. We describe a case of lymphomatous involvement of the kidneys.

**Case Description:** A 73-year-old female with h/o breast cancer, HTN, HLD, hypothyroidism, monoclonal gammopathy was transferred from an outside hospital for evaluation as extensive work up (as shown in table 1) for diffuse lymphadenopathy, hypercalcemia, acute kidney injury, was inconclusive despite high clinical suspicion for metastasis. Labs were significant for Cr 2.29 (baseline 1.3) calcium 11.3 and ionized calcium 1.8. In the setting of worsening renal function and no unifying diagnosis, the decision was made to pursue kidney biopsy. Biopsy results were consistent with low grade B-Cell Lymphoma with plasmacytic differentiation most consistent with marginal zone lymphoma (Figure 1). The patient underwent guideline directed therapy with normalization in her serum calcium and return of renal function near her baseline.

**Discussion:** This case illustrates the rarity of low grade b cell lymphoma involvement of the kidneys and the role of kidney biopsy in establishing a diagnosis despite multiple an exhaustive work up. At a time where there is a huge debate regarding the necessity of biopsy as a requirement for nephrology training graduation, our case emphasizes that kidney biopsy as diagnostic tool still reigns supreme.

## A Journey From Primary Membranous to Secondary Membranous Nephropathy

Rana Raheel H. Khan,<sup>1</sup> Shoaib B. Fareedy,<sup>1</sup> Amanda Tchakarov,<sup>1</sup> Ala Abudayyeh.<sup>2</sup>  
<sup>1</sup>The University of Texas Health Science Center at Houston, Houston, TX; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Membranous Nephropathy (MN) has been well recognized as a common cause of nephrotic syndrome as primary membranous (autoimmune induction) vs secondary membranous, with up to 20% related to cancers in older patients. We are presenting a case of recurrent proteinuria in a patient who had primary MN in remission that many years later develops secondary MN

**Case Description:** 68 years old male with a history of chronic kidney disease, primary MN, diagnosed in the 1970s and off immunosuppression since 2016. He has a history of prostate cancer, treated melanoma in situ, hypertension, diabetes, with no proteinuria and creatinine at baseline of 1.4mg/dl. On 2022 patient presented with 2.2gms of proteinuria with negative 2<sup>nd</sup> workup. He underwent a renal biopsy, showing MN, negative Phospholipase A2 receptors, 22% global sclerosis and 10% interstitial fibrosis. Imaging studies revealed a lung nodule with a biopsy confirming melanoma with adrenal and brain metastases. The patient was started Ipilimumab and nivolumab with significant tumor response but progression of proteinuria to over 15gms. He has also developed grade II colitis and was started on steroids and rituximab with improved proteinuria to 4g.

**Discussion:** It is well documented that, compared to the general population, patients with MN have a higher cancer incidence. This unique case demonstrates the evolution from primary MN to 2<sup>nd</sup> MN in the same patient which was an indicator of patients underlying malignancy. The patients advanced cancer necessitated emergent treatment in hopes of response of MN in setting of cancer response. Unfortunately, the overwhelming immune activation further impacted the MN and rituximab was successful to attain renal response and continue patient on Immunotherapy. This case demonstrates much more needed research in this field of autoimmune disease in a cancer patient and the use of ICI which is an unmet need.

## SA-PO142

## AKI due to Light Chain Cast Nephropathy in Non-IgM Lymphoplasmacytic Lymphoma

Natalie Rodziewicz,<sup>1</sup> Meghan Kapp,<sup>1</sup> Arash Rashidi.<sup>1</sup> *University Hospitals, Cleveland, OH.*

**Introduction:** Plasma cell dyscrasia most notably multiple myeloma known to cause cast nephropathy, we report a case of non- IgM lymphoplasmacytic lymphoma causing an acute kidney injury due to lambda light chain cast nephropathy.

**Case Description:** 74-year-old white male with history of chronic kidney disease stage III, heart failure with reduced ejection fraction of 35%, hypertension, diabetes type II, presented to hospital with chief complaint of 2 days of left lower quadrant abdominal pain. Non-contrast CT scan imaging reported acute diverticulitis, and patient was started on IV antibiotics with Zosyn. Symptoms promptly subsided the following day. Patient was noted to have acute kidney injury on presentation. Laboratory data showed initial serum creatinine (SCr) 2.03 mg/dL, blood urea nitrogen (BUN) 53 m/dL, by day three of hospitalization patient had developed anuria and SCr increase to 4.13 mg/dl and day nine SCr, further increase to 11 mg/dl. Serum protein electrophoreses and free light chains analysis revealed IgG Lambda M-protein 1.7g/dl, Kappa light chain 15.4 mg/dl, Lambda light chain 150.3 mg/dl, with a K/L ratio 0.1. Patient was advised to have bone marrow biopsy due to high concern for plasma cell dyscrasia, which revealed non- IgM lymphoplasmacytic lymphoma. PET scan revealed mild diffuse bone marrow uptake, with no avid lymph node or spleen uptake. Renal biopsy showed atypical granular casts that stain for only lambda, suggestive of early light chain cast nephropathy. Patient was started on hemodialysis due to concerns for uremic encephalopathy and volume overload, with no sign of renal recovery. The following week hematology team initiated patient on chemotherapy with bendamustine and rituximab.

**Discussion:** Lymphoplasmacytic lymphoma is very rare diagnosis that does not commonly produce monoclonal immunoglobulins. It is likely that this malignancy was underlying for some time due to indolent course of the lymphoma, and the acute kidney failure due to light chain cast nephropathy was precipitated by the acute diverticulitis, possible due to volume depletion and NSAID use.

## SA-PO143

## Treatment Patterns for Low-Risk Prostate Cancer in Dialysis, Kidney Transplant, and Non-Dialysis

Nagaraju Sarabu,<sup>1</sup> Weichuan Dong,<sup>2</sup> Siran M. Koroukian.<sup>2</sup> *<sup>1</sup>University Hospitals, Cleveland, OH; <sup>2</sup>Case Western Reserve University, Cleveland, OH.*

**Background:** Patients with end stage kidney disease being evaluated for transplant are screened for prostate cancer. When a cancer is found, it is often treated given concerns about transplant eligibility in the presence of a malignancy.

**Methods:** Retrospective population based observational cohort study, using Surveillance, Epidemiology, and End Results-Medicare data (Males > 40 years with localized prostate cancer (2010 – 2015). Compared low risk localized prostate cancer treatment patterns and mortality rates among dialysis, kidney transplant and non-dialysis patients using logistic regression and cox proportional hazards models.

**Results:** A total of 46 low risk prostate cancer dialysis patients and 20 kidney transplant patients were identified. We age-matched 42 dialysis patients to 210 non-dialysis patients (Table 1). Non-dialysis patients with low-risk prostate cancer were less likely, OR: <sub>0.08</sub><sup>0.27</sup> to get curative treatment, and high mortality, as compared to dialysis patients. None of the kidney transplant patients in low-risk group died of prostate cancer.

**Conclusions:** Dialysis patients, who are more likely to die of other causes, are paradoxically more likely to be treated for low-risk prostate cancer. Active surveillance should be performed in this population, and should not preclude transplant eligibility.

##### Capmatinib-Associated AKI: A Case Series

Leticia A. Sandoval, Yeshwanter Radhakrishnan, Ashley Potter, Aaron Mansfield, Sandra Herrmann. *Mayo Clinic Research Rochester, Rochester, MN.*

**Background:** Capmatinib is a MET inhibitor used in non-small cell lung cancers that harbor MET exon 14 skipping mutations. It can cause serum creatinine (SCr) elevation without evidence of a kidney injury (AKI), termed pseudo-AKI, and likely due to

inhibition of renal transporters multidrug and toxic extrusion protein 1 and 2-K (MATE1 and MATE2-K). We present 13 patients who developed AKI with capmatinib therapy.

**Methods:** We performed a retrospective multi-center observational study of all patients who received capmatinib at Mayo Clinic campus between 05/2020 and 10/2021. We analyzed demographics, comorbidities, laboratory values, and outcomes of those who developed AKI.

**Results:** Among 38 patients on capmatinib, 13 (34%) had an elevation of SCr and were diagnosed with AKI based on KDIGO criteria (table 1). Patients had a median age of 78 years  $\pm$  SD 10.28% were male, with a mean baseline SCr of 1.05  $\pm$  SD 0.42 mg/dL. Seven patients presented with dyspnea, fatigue, and lower extremity edema without acid-base or electrolyte disturbances. Patients who had available urinalysis had no active sediment. Cystatin C and Iothalamate Glomerular Filtration Rate (GFR) clearance during AKI did not show variation from baseline, although SCr was elevated, raising the possibility of pseudo-AKI (figure 1). All patients had SCr reduction within three months. None of these patients required kidney replacement therapy.

**Conclusions:** In our experience, one-third of patients at our institution had elevations in SCr while on capmatinib. Pseudo-AKI is possible, as two patients did not have variations in cystatin C or Iothalamate-based GFRs during AKI. Pseudo-AKI may result in inappropriate dose-adjustments. Estimating GFR with cystatin C and iothalamate should be considered in these patients instead of relying on SCr.

Table 1:

	Comorbidities	SCr (mg/dL)		Time to (Days)		Management
		Baseline	Peak	AKI	Mean	
1	n/a	0.88	1.40	114	95 $\pm$ 72	$\Delta$

#### SA-PO145

##### One Serum Creatinine, Several Dosings of Cytotoxic Drugs: Different Estimations of Filtration Rate Influence Conditioning Intensity (N=959)

Luca-Marie Heinze,<sup>1</sup> Nicole Brueder,<sup>1</sup> Steven Talbot,<sup>2</sup> Elke Dammann,<sup>1</sup> Sophia Koehler,<sup>3</sup> Arnold Ganser,<sup>1</sup> Matthias Eder,<sup>1</sup> Michael Heuser,<sup>1</sup> Jan T. Kielstein,<sup>4</sup> Gernot Beutel.<sup>1</sup> HON Circle of the iCHOP initiative (www.ichop.eu) <sup>1</sup>Hannover Medical School, Department of Hematology, Hemostaseology, Oncology and Stem Cell Transplantation, Hannover, Germany; <sup>2</sup>Hannover Medical School, Institute for Laboratory Animal Science and Central Animal Laboratory, Hannover, Germany; <sup>3</sup>Hannover Medical School, Enterprise Clinical Research Data Warehouse, Hannover, Germany; <sup>4</sup>Academic Teaching Hospital Brunswick, Clinic for Nephrology, Rheumatology and Blood Purification, Brunswick, Germany.

**Background:** Allogeneic stem cell transplantation (alloSCT) is a potentially curative therapy for high-risk patients with hematologic diseases. However, since conditioning is based on classical chemotherapy, dose reduction of cytostatic drugs is required in case of impaired renal function. Our study aimed to evaluate different methods for estimating renal function using creatinine clearance (CrCl) and estimated glomerular filtration rate (eGFR) and to compare the calculated dosage of drugs.

**Methods:** Between 2003 and 2020, 1394 alloSCT were performed at our center. In 959 patients, clinical data were linked to serum creatinine (N=92,229) exported from our data warehouse. CrCl/eGFR was calculated with Cockcroft-Gault, MDRD, and CKD-EPI, classified according to KDIGO criteria, and compared against each other based on the creatinine before the start of conditioning. Within the current recommendations, the required dose reduction for each cytostatic drug was calculated based on the aforementioned methods.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only  
Underline represents presenting author.

**Results:** CrCl/eGFR show different results depending on the method used. Before conditioning, the proportion of patients with a GFR <60 ml/min was 4.4% (Cockcroft-Gault), 7.1% (MDRD) and 5.0% (CKD-EPI). The need for dose reduction ranged from 0.1% (cyclophosphamide) to 5.8% (fludarabine). In the case of fludarabine, the SmPC recommendation is based on CrCl and requires dose reduction in 8.4% of cases. Using MDRD, reduction would be necessary in 14.2% of cases, 5.8% more than with the SmPC recommendation. Applied to all conditioning regimens, the use of Cockcroft-Gault causes the need for action in only a few cases, while MDRD displays a considerably higher rate of dose adjustments (Fig 1).

**Conclusions:** Dosing of cytotoxic drugs depends on renal function. Although Cockcroft-Gault is rarely used in the clinic nowadays, many dose adjustments still utilize this method. However, our data show that compared with MDRD or CKD-EPI, Cockcroft-Gault usually overestimates renal function. Since a rapid determination of renal function is currently unavailable, therapeutic success and toxicity predictions are hampered by the use of various methods.

SA-PO146

**A Risk Prediction Model for Contrast-Associated Acute Kidney Injury (CA-AKI)**  
Robert H. Seitter Pérez,<sup>1</sup> Yi Mu,<sup>4</sup> Bernard A. Rosner,<sup>4</sup> Donald F. Chute,<sup>2</sup> Shveta S. Motwani,<sup>3</sup> Gary C. Curhan,<sup>4</sup> Shruti Gupta.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Massachusetts General Hospital, Boston, MA; <sup>3</sup>Lahey Hospital and Medical Center, Burlington, MA; <sup>4</sup>Brigham and Women's Hospital Channing Division of Network Medicine, Boston, MA.

**Background:** Cancer patients undergo frequent CT scans with contrast and may be uniquely predisposed to CA-AKI due to decreased effective circulating volume or concomitant treatment with nephrotoxic chemotherapy. Nevertheless, large-scale data regarding specific risk factors for CA-AKI in this population are lacking.

**Methods:** We collected data on all CT scans with contrast obtained in adult cancer patients without ESKD from 2016 through 2020 at 2 large cancer centers. With each scan serving as an individual unit, we collected data on demographics, comorbidities, labs, and medications related to each scan. CA-AKI was defined either as a  $\geq 0.3$  mg/dl rise in serum creatinine (SCr) from baseline within 48 hours of the CT scan or a 1.5-fold rise in SCr to the peak measurement in the 14 days following the scan. Regression models accounting for correlated data were used to identify risk factors for CA-AKI.

**Results:** CA-AKI occurred in 2435 of 46,593 scans (5.2%). Non-white race, contrast volume, diabetes mellitus, congestive heart failure, hypoalbuminemia, thrombocytopenia, baseline proteinuria, lower baseline eGFR, and use of diuretics and ACEI/ARBs were each associated with a higher risk of CA-AKI (Table), and the risk of CA-AKI progressively increased with a higher risk score (Figure).

**Conclusions:** A clinically relevant scoring system is predictive of CA-AKI and can be used to help risk-stratify cancer patients undergoing CT scans with contrast.

**Funding:** Commercial Support - GE Healthcare

Table: Variable and Score Assigned for CA-AKI		
Variable	Odds Ratio	Points
Non-white race	1.28	2
Contrast volume 100 to 200 ml	1.13	1
Contrast volume >200 ml	1.86	6
Diabetes mellitus	1.28	2
Congestive heart failure	1.37	3
Serum albumin <3.0 g/dL	2.72	10
Serum albumin 3 to <3.5 g/dL	1.73	5
Platelets <150,000 per $\mu$ L	1.30	3
Baseline proteinuria on urinalysis	1.31	3
eGFR <30 ml/min/1.73 m <sup>2</sup>	3.82	13
eGFR 30 to <60 ml/min/1.73 m <sup>2</sup>	1.45	4
Diuretic use	1.59	5

**Association of Kidney Volume Measurement to 2021 CKD-EPI Estimating Equations Improves the Prediction of Measured Glomerular Filtration Rate in Cancer Patients**  
Fernando L. Strufaldi,<sup>1,2</sup> Regis F. Bezerra,<sup>2</sup> Veronica T. Costa e Silva.<sup>2</sup> <sup>1</sup>Universidade de São Paulo Hospital das Clínicas, São Paulo, Brazil; <sup>2</sup>Universidade de São Paulo Instituto do Cancer do Estado de São Paulo, São Paulo, Brazil.

**Background:** It has been demonstrated that adding total kidney volume (TKV) measurement to glomerular filtration rate (GFR) estimating equations in multivariate linear regression models can improve the prediction of measured GFR in cancer patients. However, the 2021 CKD-EPI equations, now recommended in the United States, have not been assessed in this context.

**Methods:** We enrolled 189 patients with solid tumors at an academic cancer Hospital in Brazil (Instituto do Câncer do Estado de São Paulo) who had undergone abdominal imaging and GFR measurement by plasma clearance <sup>51</sup>Cr-EDTA within 60 days. eGFR was determined based on the 2021 CKD-EPI equations using Scr (eGFR<sub>Scr</sub>) and Scr combined with Scys (eGFR<sub>Scr-cys</sub>). eGFR and mGFR were non-indexed for body surface area. TKV was measured using a semi-automatic segmentation program, excluding non-functional tissues. The correlations between mGFR and TKV, as well as, mGFR and eGFR, were calculated using the Pearson Correlation Coefficient (PCC). Linear regression models were built, having TKV and eGFR equations as predictors and mGFR as the outcome.

**Results:** Patients were 56.3(14.0) years old, 49.2% male. Most common cancer sites were breast (18.0%), colorectal (12.7%), and stomach (10.1%). 96% of patients were ECOG 0/1. Mean (SD) Body mass index was 27.18 (5.6). Mean (SD) mGFR, eGFR<sub>Scr</sub> and eGFR<sub>Scr-cys</sub> were 81.2(22.2), 91.5(20.9), and 87.6(23.2), ml/min, respectively. Mean(SD) TKV for both kidneys was 311.6 (76.2) cm<sup>3</sup>. PCC for mGFR-TKV, mGFR-eGFR<sub>Scr</sub> and mGFR-eGFR<sub>Scr-cys</sub> were 0.79, 0.81, and 0.87, respectively. TKV improved the coefficient of determination of the linear regression models when added to both eGFR<sub>Scr</sub> and eGFR<sub>Scr-cys</sub>, in overall and assessed subgroups (Table 1).

**Conclusions:** In conclusion, our results suggest that TKV measurement improves the prediction of mGFR in association with the 2021 CKD-EPI equations in cancer patients. Thus, TKV could potentially be incorporated to enhance GFR estimation in clinical practice.

## SA-PO148

## Impact of Renal Impairment Criteria on Survival of Patients With Newly Diagnosed Multiple Myeloma

Fernando L. Strufaldi,<sup>1,2</sup> Gabriela C. Segura,<sup>1,2</sup> Renato A. Caires,<sup>2</sup> Francisco Z. Mattedi,<sup>2</sup> Elerson Costalonga,<sup>2</sup> Gracia Martinez,<sup>2</sup> Veronica T. Costa e Silva.<sup>2</sup> <sup>1</sup>Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; <sup>2</sup>Universidade de Sao Paulo Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil.

**Background:** The International Myeloma Working Group(IMWG) defines renal impairment(RI) as serum creatinine (SCr)>2.0 mg/dL or estimated glomerular filtration rate(eGFR)<40 ml/min/1.73m<sup>2</sup> at the diagnosis of multiple myeloma(MM)(RI-IMWG). Our aim is to assess if different criteria used to evaluate RI have an impact on the overall survival(OS) in newly diagnosed MM patients(pts)

**Methods:** We screened all pts with newly diagnosed MM admitted for treatment at the Sao Paulo State Cancer Institute, between January 2009 and September 2018. Exclusion criteria were: age<18 y, maintenance dialysis, treatment ineligibility, and follow-up< 3 months. eGFR was determined by the 2009 CKD-EPI equation and expressed as ml/min/1.73m<sup>2</sup>. Chronic Kidney Disease(CKD) criteria was eGFR<60. Acute Kidney Injury(AKI) was classified according to the KDIGO criteria. Baseline SCr was defined as the lowest SCr within 3 months before admission or, if absent, as the lowest SCr during follow-up. Clinical stage was assessed by International Staging System(ISS)(based on serum albumin [Alb] and beta 2 microglobulin [B2M])

**Results:** We enrolled 557 pts. Median age(IQR) was 62.0(54.2-69.9)y, 56.5% were male. ISS stage III(ISS-III) was observed in 36.1%. Alb<3.5g/dL(Albu), B2M>3.5mg/L(B2Ma), and lactate dehydrogenase above normal limit(LDHa) were observed in 42.4,55.6, and 20.6%, respectively. eGFR at baseline and at diagnosis were 78.7(53.4-97.4), and 68.9(40.8-92.9), respectively. At diagnosis, CKD, RI-IMWG, AKI, and AKI-3 were observed in 28.6, 23.3, 25.5, and 10.6% of patients, respectively. OS was 3.0(1.0 – 4.25)y. In the univariate analysis(long-rank test), variables related to reduced OS(p<0.05) were: age, diabetes, LDHa, ISS-III, B2Ma, CKD, AKI-3, RI-IMWG, Albu and AKI-1 were not associated with reduced OS. Variables retained on Cox Regression Model(CRM) are described in table. RI-IMWG and CKD were not retained in additional CRM(data not shown)

**Conclusions:** Although highly accepted, RI-IMWG definition neither distinguishes CKD from AKI nor performs as well as AKI-3 as an independent predictor of mortality in newly diagnosed MM

Table 1. Cox Regression Model

Variables	p value	Hazard Ratio (95% Confidence interval)
Above limit LDH	0.034	1.37 (1.02-1.85)
ISS = 3	0.001	1.57 (1.20-2.05)
Age at diagnosis	<0.001	1.03 (1.02-1.04)
AKI KDIGO 3	0.059	1.43 (0.98 - 2.09)

## SA-PO149

## Cytokines and Immune Cell Profiling in AKI Associated With Immune Checkpoint Inhibitors

Naba Farooqui, Eram Ahsan, Lisa E. Vaughan, Timucin Taner, Nelson Leung, Mariam P. Alexander, Sandra Herrmann. Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** Immune checkpoint inhibitors(ICIs) can cause acute kidney injury(AKI-ICI), the most common histopathological finding being acute interstitial nephritis (AIN). Biomarkers can provide mechanistic insight into the pathophysiology of the AKI and may allow for early AKI-ICI detection which would help guide management. In this study, we investigated the associations between cytokines and immune cell profiling and AKI-ICI.

**Methods:** We prospectively included patients with AKI who were on ICI therapy and evaluated T-cell responses in peripheral mononuclear blood cells(PBMCs) and kidney tissue as well as urine and blood cytokines. Patient were adjudicated to either have a histological or clinical diagnosis of AIN [AKI-ICI(N=14)] or AKI due to other causes(e.g., acute tubular injury)[AKI-other (N=10)]. Kidney donors' samples were also used as healthy controls(N=12). Imaging mass cytometry was used for immune cells profiling, and kidney tissue from a subset of patients with archived biopsy samples were also evaluated. Luminex assay was used to obtain urine and blood cytokines.

**Results:** Urine TNF- $\alpha$  levels were higher in the AKI-ICI group compared to AKI-other and healthy controls(Fig 1A), and tissue TNF- $\alpha$  expression was also significantly increased in AKI-ICI patients compared to controls.(Fig 1B). However, systemic TNF- $\alpha$  levels were not found to be significantly different between groups.(Fig 1C). Results from logistic regression predicting AKI type(AKI-ICI vs AKI-other) from TNF- $\alpha$  yielded strong discriminatory ability(AUC=0.814, 95% CI: 0.623-1.00). We also observed more pronounced increases of specific immune cells including CD4 memory, T helper and dendritic cells in the kidney tissue of patients who developed AKI-ICI compared to healthy controls.(Figs 1D, 1E, 1F).

**Conclusions:** These results suggest that increases in TNF- $\alpha$  and specific T-cell responses may contribute to AKI-ICI injury and could potentially serve as targets for therapeutic intervention as well as potential biomarkers.

Figure 8. Urine TNF- $\alpha$  levels of patients with AKI-ICI compared with AKI-other and healthy controls (A). Kidney Tissue TNF- $\alpha$  expression (B). Plasma TNF- $\alpha$  level (C). Immunohistochemistry showing elevated CD4 memory, T helper and dendritic cells in AKI-ICI (D-F). \*P value Control vs AKI-ICI (p<0.05), \*\*P value AKI-ICI vs AKI-other (p<0.05).

## SA-PO150

## AKI After Bone Marrow Transplantation

Andreea Andronesi,<sup>1,2</sup> Bogdan Sorohan,<sup>1,2</sup> Andreea Burcea,<sup>2</sup> Cristina Stanescu,<sup>2</sup> Gabriela Lupusoru,<sup>1,2</sup> Danut Andronesi,<sup>2</sup> Mircea Lupusoru,<sup>1</sup> Gener Ismail.<sup>1,2</sup> <sup>1</sup>“Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania; <sup>2</sup>Fundeni Clinical Institute, Bucharest, Romania.

**Background:** Bone marrow transplantation (BMT) is the best therapeutic approach for an increasing number of blood disorders, as well as for some autoimmune diseases, offering the best disease-free survival in eligible patients. Acute kidney injury (AKI) is a serious complication, with significant impact upon outcomes, including progression to chronic kidney disease (CKD) and overall survival.

**Methods:** The aim was to evaluate the incidence, risk factors and severity of AKI during the first 100 days after BMT. We performed a prospective observational study. AKI definition and staging were done using KDIGO criteria. Renal recovery was defined as a reduction in serum creatinine within 0.3 mg/dl compared to baseline at 3 months after AKI. Cox regression analysis was used to identify independent risk factors for AKI.

**Results:** We included 405 consecutive patients- pts (203 F) with BMT- 240 auto-BMT and 165 allo-BMT. Pts with allo-BMT were significantly younger (mean age 57.8 years in auto-BMT, 39.3 years in allo-BMT, p=0.01). AKI incidence was 40.7%. The incidence (20.4% in auto-BMT, 70.3% in allo-BMT, p<0.001) and severity (in auto-BMT: AKI grade 1- 9.7%, grade 2- 0.5%, no grade 3 cases; in allo-BMT: grade 1- 36.7%, grade 2- 33.9%, grade 3- 47.2%, p=0.02) were significantly higher in allo-BMT. Emergency hemodialysis (HD) was initiated in 15 pts (3.7%), all with allo-BMT. Death was recorded exclusively in the allo-BMT. In allo-BMT, mortality during the first 100 days was 2.05 more frequent in the group of pts who developed AKI, but without statistical significance. The mortality in pts who required HD was very high- 85.5%. Renal recovery was recorded in 70.6% pts. In Cox regression analysis, allo-BMT (HR 9.01, CI 95% 3.1-34.3, p=0.001), preexisting CKD (HR 5.5, 95%CI: 2.4-19.2, p=0.002), and calcineurin inhibitors (CNI) overdosage (HR 2.3, CI 95% 1.1-3.2, p=0.003) were independent risk factors for AKI, while sepsis was the only independent risk factor for AKI stage 3 (HR= 5.1, CI 95% 1.9-17.5, p=0.003).

**Conclusions:** AKI occurs with reduced incidence and severity after auto-BMT and does not have impact upon survival. AKI after allo-BMT is much more severe and has a significant impact upon outcome. A better fluid management, avoidance of the nephrotoxins especially in preexisting CKD, and carefully monitoring of CNI may significant reduce this risk.

## SA-PO151

## AKI Treated With Kidney Replacement Therapy in Allogeneic Hematopoietic Stem Cell Transplantation (aHSCT) Patients Admitted to the Intensive Care Unit: Incidence, Risk Factors, and Outcomes

Helena Kim,<sup>1</sup> Rafia W. Ali,<sup>1</sup> Samuel Short,<sup>3,4</sup> Roman Shapiro,<sup>4</sup> Robert Soiffer,<sup>4</sup> Zachariah Defilipp,<sup>2</sup> Charlotte Thomas,<sup>1</sup> Isabel Park,<sup>1</sup> Shruti Gupta,<sup>1,4</sup> David E. Leaf.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Massachusetts General Hospital, Boston, MA; <sup>3</sup>University of Vermont College of Medicine, Burlington, VT; <sup>4</sup>Dana-Farber Cancer Institute, Boston, MA.

**Background:** Acute kidney injury (AKI) following allogeneic hematopoietic stem cell transplantation (aHSCT) is a common complication associated with substantial morbidity and mortality. Those who develop AKI treated with kidney replacement therapy (AKI-KRT) have even higher mortality. Few studies have investigated the incidence, risk factors, and outcomes associated with AKI-KRT in critically ill patients following aHSCT.

**Methods:** We performed a retrospective cohort study of 179 patients admitted to an ICU within 1 year following aHSCT (transplanted between 2013 and 2019) at two academic medical centers in Boston, MA. Data on demographics, comorbidities, lab values, medications, and clinical outcomes were obtained through both automated and manual review of medical records. We assessed independent risk factors for development of AKI-KRT using multivariable logistic regression. We assessed mortality during hospital admission and at 3- and 6-months after ICU admission according to maximum KDIGO AKI stage during ICU admission.

**Results:** A total of 42 of 179 patients (23.5%) developed AKI-KRT during ICU admission. Independent risk factors for AKI-KRT included veno-occlusive disease

(VOD) and thrombotic microangiopathy (TMA) prior to ICU admission, receipt of invasive mechanical ventilation on ICU admission, and admission to the ICU within 180 days following aHST (Figure 1A). Mortality increased with higher AKI stage, and was highest in those with AKI-KRT, reaching 78.6% during hospitalization and 88.1% at 6 months (Figure 1B).

**Conclusions:** Among aHST patients admitted to the ICU, independent risk factors for AKI-KRT included VOD, TMA, receipt of invasive mechanical ventilation, and admission to the ICU within 180 days following aHST. Nearly 90% of patients who developed AKI-KRT died with 6 months of ICU admission.

Figure A. Independent risk factors for AKI-KRT. \*Odds ratios are adjusted for each of the four variables shown above. B. Mortality at hospital discharge and 3- and 6-months following ICU admission, stratified by AKI stage.

## SA-PO152

### Characterization of Hemoglobin and Renal Function Trends After Reoperative Partial Nephrectomies in Patients With Recurrent Renal Cell Carcinoma (RCC)

Maria Antony, Nikhil Gopal, Zoe Blake, Sandeep Gurram, Mark Ball. Center for Cancer Research: Urologic Oncology Branch *National Cancer Institute, Bethesda, MD.*

**Background:** Patients with renal tumor syndromes may undergo multiple reoperative partial nephrectomies (RePN) conferring volume loss and functional sequelae. Though partial nephrectomy is oncologically safe and delays the need for renal replacement therapy compared to radical nephrectomy, few studies quantify outcomes in the reoperative setting. We studied a cohort of RePN to assess renal and hematologic outcomes following second, third-, and fourth-time partial nephrectomy of the same renal unit.

**Methods:** We performed a retrospective query of an institutional registry of nephrectomies for RCC in 2006 to 2021. Demographics, creatinine (SCr), and hemoglobin within one week prior to surgery were reviewed, as well as intraoperative blood loss. SCr was used to calculate eGFR using CKD-EPI 2021. Nephrectomy history was reconstructed based on documented surgical history between 1976 and 2021.

**Results:** Between 2006 and 2021, a total of 424 institutional nephrectomies (415 partial, 9 radical) conducted on 308 patients (60% male, 48 years old (IQR: 38-57)) were analyzed. Time between subsequent ipsilateral nephrectomy was 6.98 years (IQR: 4.4-10.5). We observed a stepwise decline in preoperative GFR with an average GFR decline of 6.3 with each RePN ( $p < 0.001$ ). Estimated blood loss ( $p = 0.002$ ) increased and hemoglobin decreased ( $p = 0.006$ ) with each RePN. On multivariate analysis, patients displayed odds of anemia with subsequent RePN at hemoglobin cut-off of 11 (OR: 1.88,  $p < 0.001$ ) and 12 (OR: 1.74,  $p < 0.001$ ) when controlling for gender, race, solitary kidney, and preoperative GFR.

**Conclusions:** RePN conveys renal functional decline, as well as increased intraoperative blood loss with each subsequent surgery. Our analysis suggests functional anemia is driven by partial nephrectomy frequency. Together, these impacts must be considered when counseling patients on available treatments to balance oncologic efficacy with prevention of chronic kidney disease and anemia.

**Funding:** Other NIH Support - Supported by the National Institutes of Health (NIH) IRP and the NIH MRSP, a public-private partnership supported jointly by the NIH and contributions to the Foundation for the NIH from the Doris Duke Charitable Foundation, The American Association for Dental Research, the Colgate-Palmolive Company, and other private donors.

### Association Between Monoclonal Gammopathy of Undetermined/Renal Significance (MGUS/MGRS) and ESKD and Mortality in Patients With CKD

Janina Paula T. Sy-Go, Simon Moubarak, Jason K. Viehman, Lisa E. Vaughan, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Little is known about the prognostic significance of MGUS/MGRS in patients with CKD. The objective of this study was to determine the association between MGUS/MGRS and ESKD and mortality in patients with CKD.

**Methods:** We identified 109,638 adult patients with CKD at Mayo Clinic from January 1, 2013 to December 31, 2018. We excluded those who did not have monoclonal (M) protein testing ( $n = 98,270$ ). Of 4558 patients, 3142 were diagnosed with MGUS based on positive M protein by either SPEP/UPEP confirmed by immunofixation or abnormal FLC ratio while 64 were considered to have an MGRS lesion based on biopsy.

**Results:** We identified a total of 1535 patients (828 with no MGUS, 648 with MGUS, and 59 with MGRS). Median age was 73.5 years (65.3, 80.2), and 57.9% were male. Median eGFR was 45 mL/min/1.73m<sup>2</sup>. Median follow-up was 4.86 years. Patients with MGRS were younger (68.5 years) and had lower eGFR (41 mL/min/1.73m<sup>2</sup>) and higher proteinuria. Patients with MGRS also had the highest mortality compared to those with MGUS and no MGUS with infection being the most common known cause of death (25%). MGRS was associated with an increased risk of ESKD in unadjusted model, but after adjustment for eGFR, it was no longer significant (Table 1). MGUS was also associated with an increased risk of ESKD compared to no MGUS in unadjusted model and after adjusting for age, sex, eGFR, and proteinuria, but after adjusting for comorbidities, it was no longer significant (Table 1).

**Conclusions:** MGUS and MGRS are not independently associated with a higher risk of ESKD in patients with CKD after adjusting for other clinical characteristics. Patients with MGRS had higher rates of death compared to the other groups.

Unadjusted and Adjusted Associations Between Non-MGUS/MGRS, MGUS, and MGRS Status and Risk of ESKD

Adjusting Variables	MGUS	MGRS
	HR (95% CI) P	HR (95% CI) P

## SA-PO154

### Urinary NGAL (uNGAL) as a Biomarker to Predict Late Nephrotoxicity in Pre-Clinical Models of Peptide-Based Radioligand Therapy (PRRT) for Cancer

Gabriela Vasquez Martinez,<sup>1</sup> Mengshi Li,<sup>5</sup> Prerna Rastogi,<sup>3</sup> Dijie Liu,<sup>5</sup> Sarah C. Linn,<sup>4,1</sup> Gabriel Mayoral Andrade,<sup>1</sup> Michael K. Schultz,<sup>5,6</sup> Diana Zepeda-Orozco,<sup>1,2</sup> <sup>1</sup>Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH; <sup>3</sup>The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; <sup>4</sup>The Ohio State University College of Veterinary Medicine, Columbus, OH; <sup>5</sup>Viewpoint Molecular Targeting, Inc., Coralville, IA; <sup>6</sup>The University of Iowa Hospitals and Clinics, Iowa City, IA.

**Background:** PRRT for cancer has gained traction in oncology due to favorable tumor-targeting performance. A dose limiting organ for most PRRTs is the kidney, and toxicity is thought to be caused by proximal-tubule reabsorption of radiolabeled peptide. The objective of this study was to evaluate the use of uNGAL to predict chronic renal damage after PRRT therapy in a murine pre-clinical model.

**Methods:** We conducted a PRRT dose escalation study to anticipated renal injury levels in CD-1 Elite mice (0.9, 3 and 6.7 MBq of a <sup>212</sup>Pb labeled peptide,  $n = 6$  per group). Urine was collected on days 1, 3, 53, and at 7 months. Serum was collected on weeks 1, 5,

8, and at 7 months. Mice were euthanized at 7 months for histology. NGAL was measured by ELISA. BUN and Creatinine were measured by blood chemistry panel. Histological tubular injury (TI), interstitial inflammation (IF), glomerulosclerosis (GS) and interstitial fibrosis (FIB) scores (0 to 5) were performed by pathologist in PAS and trichrome stained sections

**Results:** uNGAL concentration was higher with increasing dosages of the  $^{212}\text{Pb}$  labeled peptide 24 hours after therapy (Table 1). High PRRT dose of the  $^{212}\text{Pb}$  labeled peptide (6.7 MBq) resulted on late TI, IF, GS and FIB ( $2.6 \pm 1.34$ ,  $2.2 \pm 1.095$ ,  $1.4 \pm 1.14$ ,  $3.2 \pm 0.836$  respectively,  $p < 0.05$ ). uNGAL positively correlated with alpha dose ( $r = 0.89$ ,  $p < 0.0001$ ), TI ( $r = 0.71$ ,  $p = 0.0001$ ), IF ( $r = 0.65$ ,  $p = 0.0008$ ) and FIB ( $r = 0.75$ ,  $p < 0.0001$ ). BUN and creatinine were significantly increased at 7 months with high PRRT doses (Table 1) but not significantly different at 1, 5 or 8 weeks.

**Conclusions:** uNGAL could be a potential early biomarker to predict the progression of AKI to CKD after PRRTs. Comparisons to other radionuclides are needed to develop a more detailed understanding.

**Funding:** Other NIH Support - CA174521 P50, R01 CA243014, Commercial Support - Viewpoint

##### Short- and Long-Term Adverse Kidney Outcomes of CDK 4/6 Inhibitors for Breast Cancer

Paul Hanna,<sup>1</sup> Ian A. Strohbehn,<sup>1</sup> Qiyu Wang,<sup>1</sup> Tianqi Ouyang,<sup>1</sup> Shruti Gupta,<sup>2</sup> Seth Wander,<sup>1</sup> Meghan E. Sise,<sup>1</sup> <sup>1</sup>Massachusetts General Hospital Department of Medicine, Boston, MA; <sup>2</sup>Brigham and Women's Hospital Department of Medicine, Boston, MA.

**Background:** Cyclin-dependent kinase (CDK) 4/6 inhibitors have transformed the treatment landscape for patients with advanced or metastatic breast cancer. Small studies have suggested that CDK 4/6 inhibitors may interfere with creatinine secretion. Yet, there are also case reports of biopsy-proven acute tubular necrosis and acute interstitial nephritis in patients receiving CDK 4/6 inhibitors. We sought to study the short and long-term kidney outcomes in a large cohort of women treated with CDK 4/6 inhibitors.

**Methods:** Retrospective cohort study of women receiving abemaciclib or palbociclib at two cancer centers. We compared the risk of acute 20% estimated glomerular filtration rate (eGFR) decline within 30 days of treatment initiation and the 1-year risk of a composite adverse kidney outcome ( $>40\%$  eGFR decline sustained  $>90$  days,  $\text{eGFR} < 10 \text{ mL/min/1.73m}^2$ , or need for dialysis).

**Results:** 253 women received abemaciclib and 238 received palbociclib. Mean age was 61 years ( $\text{SD} = 13$ ), baseline eGFR was  $87 \text{ mL/min/1.73m}^2$  ( $\text{SD} = 21$ ); there were no significant differences between the two cohorts at baseline. The rate of acute 20% eGFR decline within 30 days was significantly higher in patients receiving abemaciclib vs. palbociclib (60% vs. 22%,  $p < 0.001$ ). After adjusting for age, race/ethnicity, baseline eGFR, comorbidities, and medication use, the adjusted odds ratio was 5.38, CI: 3.60 – 8.13,  $p < 0.001$ . Despite the initial decline in eGFR, kidney function was stable over the next 11 months for both abemaciclib and palbociclib-treated patients (Figure), and no patients experienced the composite adverse kidney outcome at 1 year.

**Conclusions:** CDK 4/6 inhibitors cause an acute decline in eGFR that is significantly more common in patients receiving abemaciclib than palbociclib. Our data suggest benign inhibition of creatinine secretion, as eGFR stabilized, and there was no progressive decline in kidney function or kidney failure events.

Figure 1. Mean eGFR over 12 months after starting CDK 4/6 inhibitors

#### SA-PO156

##### Impact of the 2021 CKD-EPI Equation on Anticancer Drug Eligibility and Dosing in Black and Non-Black Patients

Morgan A. Butrovich,<sup>1</sup> Jiyue Qin,<sup>3</sup> Xiaonan Xue,<sup>3</sup> S. P. Ivy,<sup>4</sup> Thomas D. Nolin,<sup>1,2</sup> Jan H. Beumer,<sup>1,2</sup> <sup>1</sup>University of Pittsburgh School of Pharmacy, Pittsburgh, PA; <sup>2</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA; <sup>3</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>4</sup>National Cancer Institute, Bethesda, MD.

**Background:** Cancer and kidney disease disproportionately impact Black patients, and kidney function is a key consideration in anticancer pharmacotherapy decision-making. In 2021, the new CKD-EPI equation that omits race was recommended to replace the 2009 CKD-EPI equation. The current study evaluated the impact of using the 2021 vs 2009 CKD-EPI equation to determine anticancer drug eligibility and dosing in Black and non-Black patients.

**Methods:** A retrospective analysis of patients enrolled in phase 1 CTEP-sponsored studies from 1995-2010 was performed. eGFR was calculated by the 2021 and 2009 CKD-EPI equations ( $\text{eGFR}_{2021}$  and  $\text{eGFR}_{2009}$ , respectively) and converted to absolute eGFR (i.e., mL/min) by multiplying by  $\text{BSA}/1.73 \text{ m}^2$ . Dosing simulations based on  $\text{eGFR}_{2021}$  and  $\text{eGFR}_{2009}$  were performed for ten anticancer drugs with renal eligibility or dosing cutoffs. Discordance in eligibility and dosing recommendations for  $\text{eGFR}_{2021}$  and  $\text{eGFR}_{2009}$  were compared between races by  $\chi^2$  test. Difference in drug eligibility based on eGFR equation was assessed by GEE logistic regression.

**Results:** 3931 patients were included, 8.6% of whom were Black. The mean change between  $\text{eGFR}_{2021}$  and  $\text{eGFR}_{2009}$  for Black ( $-10.5 \text{ mL/min}$ ) and non-Black ( $4.1 \text{ mL/min}$ ) patients was significantly different ( $p < 0.001$ ). The proportion of patients with discordant recommendations did not differ between Black and non-Black patients. However, Black patients were 48% (95% CI: 14%–94%) more likely to be ineligible for cisplatin using  $\text{eGFR}_{2021}$  vs  $\text{eGFR}_{2009}$ , controlling for sex, age, and BSA. Non-Black patients were 27% (95% CI: 18%–35%) less likely to be ineligible for cisplatin using  $\text{eGFR}_{2021}$  vs  $\text{eGFR}_{2009}$ .

**Conclusions:** Although discordance rates in eligibility and dosing were similar between Black and non-Black patients,  $\text{eGFR}_{2021}$  was lower than  $\text{eGFR}_{2009}$  for Black patients, translating to Black patients being more likely than non-Black patients to be deemed ineligible for drugs when using  $\text{eGFR}_{2021}$ .  $\text{eGFR}_{2021}$  is negatively biased for Black patients at lower eGFRs, where most drug eligibility and dosing cutoffs lie; this may lead to inappropriate exclusion of therapy for some Black patients. These findings highlight the importance of clinical judgement and use of confirmatory kidney function tests when prescribing anticancer agents, particularly in Black patients with low GFR.

#### SA-PO157

##### A Predictive Model for Kidney Failure After Nephrectomy for Localized Kidney Cancer: The Kidney Cancer Risk Equation

Oksana Harasemiw,<sup>1,2</sup> Jasmir G. Nayak,<sup>1</sup> Nicholas Grubic,<sup>3,4</sup> Thomas W. Ferguson,<sup>1,2</sup> Manish M. Sood,<sup>5,6</sup> Navdeep Tangri,<sup>1,2</sup> <sup>1</sup>University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; <sup>2</sup>Seven Oaks Chronic Disease Innovation Centre, Winnipeg, MB, Canada; <sup>3</sup>Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; <sup>4</sup>Ottawa Hospital Research Institute, Ottawa, ON, Canada; <sup>5</sup>University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; <sup>6</sup>Ottawa Hospital, Ottawa, ON, Canada.

**Background:** Nephrectomy is the mainstay treatment for individuals with localized kidney cancer. However, surgery can potentially result in functional kidney impairment leading to kidney failure requiring dialysis or transplantation. There are currently no clinical tools available for clinicians to pre-operatively identify which patients are at risk of kidney failure, and therefore, the aim of our study was to develop and validate a prediction equation for kidney failure after nephrectomy for kidney cancer.

**Methods:** A population-level cohort study was conducted with adults ( $\geq 18$  years old;  $n = 1,026$ ) from Manitoba, Canada who were diagnosed with non-metastatic kidney cancer between January 1, 2004 and December 31, 2016, were treated with either a partial or radical nephrectomy, and had at least 1 estimated glomerular filtration rate (eGFR) measurement available pre and post nephrectomy. Demographic, clinical, and laboratory data were used to develop the prediction models using Cox proportional hazards regression methods. We subsequently externally validated the models using data from 12,043 individuals from Ontario, Canada. The primary outcome was dialysis, transplantation, or an  $\text{eGFR} < 15 \text{ mL/min/1.73m}^2$  during the follow-up period.

**Results:** Among individuals in the development cohort (mean age  $61.2 \pm 11.7$ ; mean  $\text{eGFR} 79.5 \pm 22.8 \text{ mL/min/1.73m}^2$ ; 39.0% partial nephrectomy/61.2% radical), 10.4% reached kidney failure during the follow-up period. The final model included 6 variables: age, sex, baseline eGFR, urine albumin-to-creatinine ratio, nephrectomy type, diabetes mellitus. The 5-year C-statistic was 0.83 (74.8, 91.4) in the development cohort and 0.86 (0.84, 0.88) in the validation cohort.

**Conclusions:** We developed and externally validated a simple equation that incorporates easily accessible data and can accurately predict kidney failure in individuals undergoing nephrectomy for treatment of localized kidney cancer. This tool can help inform pre-operative discussion about kidney failure risk in patients facing surgical options for localized kidney cancer.

## SA-PO158

## A Humanized Mouse Model as a Preclinical Tool to Evaluate Nephrotoxicity due to Cancer Immunotherapies

Lauren E. Thompson,<sup>1</sup> Michael J. Goedken,<sup>2</sup> Kenneth R. Reuhl,<sup>2</sup> Adrian T. Dominguez,<sup>1</sup> Todd Pitts,<sup>1</sup> Katja Kiseljak-Vassiliades,<sup>1</sup> Lauren Aleksunes,<sup>2</sup> Julie Lang,<sup>1</sup> Melanie S. Joy,<sup>1</sup> <sup>1</sup>University of Colorado Health, Aurora, CO; <sup>2</sup>Rutgers The State University of New Jersey, New Brunswick, NJ.

**Background:** Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of cancer by targeting inhibitory receptors on tumor and T cells. However, post-marketing surveillance has demonstrated that these therapies cause immune-mediated adverse events including nephrotoxicity. We evaluated a mouse model with a humanized immune system as a preclinical and translational tool to identify kidney toxicities in response to cancer immunotherapies.

**Methods:** Three feasibility studies were conducted in newborn BALB/c-Rag2<sup>tm1.1</sup>/Il2r<sup>tm1.1</sup> (BRGS; nonhumanized) mice which were irradiated and injected with CD34+ hematopoietic cells isolated from human umbilical cord blood to generate mice with a humanized immune system (HIS-BRGS). After 2 weeks of tumor growth followed by 2-4 weeks of ICI treatment (Table 1), H&E-stained sections of kidneys from the mice were analyzed for histomorphological evidence of injury. Incidence and severity scores (range of 0 to 3) were recorded. Statistical analyses were conducted using rank order one-way ANOVAs with Tukey-Kramer post-hoc tests (R).

**Results:** Humanization of the immune system caused minimal glomerulonephritis (p<0.0001) in all HIS-BRGS mice compared to BRGS mice. Compared to vehicle-treated HIS-BRGS mice, treatment with nivo/ipi trended towards worsening glomerulonephritis (p=0.056). Nivo alone, as well as nivo/ipi, resulted in interstitial nephritis (nivo: p=0.016, ipi/nivo: p=0.004) and periarteritis (nivo: p=0.027, ipi/nivo: p=0.003) in HIS-BRGS mice compared to vehicle-treated HIS-BRGS mice. Pembro/mito- and pembro/cetux/CD-47 antagonist-treatment resulted in increased periarteritis compared to vehicle-treated and single agent-treated HIS-BRGS mice (pembro/mito: p=0.042, pembro/cetux/CD-47 antagonist: p=0.090).

**Conclusions:** Humanized HIS-BRGS mice represent a highly innovative and promising preclinical and translational model to evaluate immune-related kidney toxicities including glomerulonephritis, periarteritis, and interstitial nephritis from ICIs.

## Clinicopathologic and Molecular Characteristics of Light Chain Crystalline Podocytopathy

Samih H. Nasr,<sup>1</sup> Satoru Kudose,<sup>2</sup> Vincent Javague,<sup>3</sup> Samar M. Said,<sup>1</sup> Stéphanie Harel,<sup>6</sup> George A. Osuchukwu,<sup>4</sup> Arjun Das,<sup>5</sup> Elliot J. Suchin,<sup>7</sup> Nelson Leung,<sup>1</sup> Frank Bridoux,<sup>3</sup> Vivette D. D'Agati,<sup>2</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Columbia University, New York, NY; <sup>3</sup>Université de Poitiers, Poitiers, France; <sup>4</sup>Victoria Kidney and Dialysis Associates, Victoria, TX; <sup>5</sup>Nephrology Consultants of Northwest Ohio, Toledo, OH; <sup>6</sup>Saint-Louis Hospital, Paris, France; <sup>7</sup>Center for Kidney Care, Hainesport, NJ.

**Background:** Monoclonal immunoglobulin (Mlg) light chain (LC) crystalline inclusions within podocytes is a rare finding usually seen in association with LC proximal tubulopathy (LCPT).

**Methods:** We describe the first clinicopathologic and molecular series on LC crystalline podocytopathy (LCCP) defined by the presence of extensive podocyte LC crystals.

**Results:** This multicenter cohort included 24 patients (63% male, 75% Caucasian, median age 57 yrs). Presentations included proteinuria (median 3.4 g/day, 56% albuminuria), CKD (median creatinine 2.1 mg/dl), hypertension (54%), nephrotic syndrome (29%), Fanconi syndrome (14%) and visual impairment from crystalline keratopathy (17%). The underlying hematologic condition was MGRS in 81% and symptomatic MM in 19%. The serum Mlg was IgGκ in 86%, with urinary Mlg detected in 94%, and abnormal serum FLC in all 19 tested (median ratio 12.6). Podocyte crystals were visible by light microscopy in 71%, with FSGS in 63% (including collapsing in 9 cases, NOS in 5 and tip in 1). All 20 cases studied by electron microscopy (EM) exhibited extensive podocyte crystals and 45% had diffuse effacement. Crystals were also present in proximal tubular cells (75%, indicating concurrent LCPT), distal tubular cells (33%), interstitial histiocytes (33%; crystal storing histiocytosis), endothelial cells (17%), mesangial cells (17%) and plasma cells (4%). Concurrent mild LC cast nephropathy was present in 7 cases, AL amyloidosis in 1, and LCDD in 1. While frozen-immunofluorescence (IF) failed to reveal the LC composition of crystals in 22 (91%) cases, this was successfully identified using paraffin-IF (14/20) or immunoEM (3/3) and was κ LC in 87%. The pathogenic LC variable gene segment determined by laser

microdissection of glomeruli followed by mass spectrometry (n=3) or bone marrow plasma cell sequencing (n=2) was IGKV1-33 in 3 cases, IGKV1-39 in 1 and IGKV3-20 in 1. On follow up (median 30 months) in 23 patients, 19 received plasma-cell directed therapy. Outcomes were renal response in 40%, ESKD in 22% and death in 22%.

**Conclusions:** LCCP is a rare entity, mostly associated with IgGκ MGRS. Despite frequently concurrent LCPT and associations with IGKV1-33 & IGKV1-39, Fanconi syndrome is rare. Paraffin-IF and EM are needed to prevent misdiagnosis as FSGS.

## SA-PO160

## AKI and Chimeric Antigen Receptor T Cell Therapy in Hematologic Neoplasms

Juan C. León Román, Gloria Iacoboni, Sheila Bermejo, Cecilia Carpio, Mónica Bolufer, Oriol Bestard, Pere Barba, Maria Jose Soler. *Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

**Background:** CAR-T cell is a treatment for refractory hematologic malignancies (RHM). AKI occurs between 20-30% after infusion. The purpose of this study was to identify risk factors for AKI and long-term outcomes.

**Methods:** Medical records of 115 patients treated with CD19-targeted CAR-T cells for RHM at HUVH between July 2018 and May 2021 were reviewed. Clinical data was reviewed within 60 days after CAR-T cells therapy. We performed statistically analysis to identify risk factors for AKI and mortality.

**Results:** 24/115 patients presented AKI after therapy. AKI was diagnosed: day+1 in 3 patients, day+7 in 13 patients, day+14 in 1 patient, day+21 in 2 patients, day+28 in 2 patients, day+60 in 1 patient, and 2 patients in conditioning therapy. 19 patients recovered kidney function within the first month. The most frequent hematological neoplasm was diffuse large B-cell lymphoma (90.5%). Investigational product was infused in 27.8%, tisagenlecleucel in 49.6%, axicabtagene ciloleucel in 20%, and brexucabtagene autoleucel in 2.6%. The most frequent complications were CRS (72.2%), febrile neutropenia (67%) and neurotoxicity (16.5%). 3/36 patients died after CAR-T infusion. Male sex, type of CAR-T cell therapy, neurotoxicity, calcium levels at day+21 and +28, phosphorus levels at day+1 and +28, and albumin levels at day+7 and +21 were associated with AKI. Only male sex (p=0.03) and neurotoxicity (p=0.02) were identified as independent risk factors for AKI. Gender, neurotoxicity, and creatinine showed no significant differences for mortality after one-year follow-up.

**Conclusions:** AKI is frequent but mild disease with a fast recovery in patients treated with CAR-T.

Table 1. Demographic and Clinical Characteristics of the 115 patients

Variable	All	AKI patients (n=24)	Non-AKI patients (n=91)	p value
≥61 years old	61 [20-81]	16	46	0.16
Male	76	20	56	0.04
Hypertension	43	13	30	0.05
Type of CAR-T cell therapy	115	24	91	0.04
Neurotoxicity	19	8	11	0.01
Death by any cause	36	6	30	0.001

Table 2. Adjusted OR for AKI development

Variable	aOR	CI 95%	P value
Male	5.14	1.14-23.0	0.03
Neurotoxicity	9.27	1.31-65.7	0.02

Figure 1. Mortality risk factors for patients treated with CAR-T cell therapy

## SA-PO161

## Vascular Calcification Is Associated With Fetuin-A and Cortical Bone Porosity in Stone Formers

Fernanda G. Rodrigues,<sup>1,2</sup> Rodrigo A. Neves,<sup>3</sup> Milene S. Ormanji,<sup>1</sup> Priscila L. Esper,<sup>1</sup> Lucio R. Requião-moura,<sup>1,3</sup> Martin H. De Borst,<sup>2</sup> Ita P. Heilberg.<sup>1</sup>  
<sup>1</sup>Universidade Federal de São Paulo, São Paulo, Brazil; <sup>2</sup>Rijksuniversiteit Groningen, Groningen, Netherlands; <sup>3</sup>Universidade Federal de São Paulo Hospital do Rim e Hipertensão, São Paulo, Brazil.

**Background:** Nephrolithiasis has been associated with bone loss and cardiovascular disease as well as vascular calcification (VC), reflecting abnormal extraosseous calcium deposition. Fetuin-A (Fet-A) acts as a potent inhibitor of ectopic mineralization. The aim of the present study was to evaluate the prevalence of VC in stone formers (SF) compared to non-stone formers (NSF) and to investigate the relationship of Fet-A and bone microarchitecture with VC among SF.

**Methods:** Post-hoc analysis of a cross-sectional trial that evaluated bone microarchitecture parameters by high-resolution peripheral quantitative computed tomography (HR-pQCT) in young SF. Abdominal aortic calcification (AAC) was assessed as a marker of VC, using computed tomography in SF and in age-, sex- and BMI-matched NSF (potential living kidney donors). The association of AAC with serum Fet-A, measured in SF stored blood samples, and with HR-pQCT parameters and other factors was studied using multivariable logistic regression analysis.

**Results:** A total of 62 SF (age 38.0 [28.0-45.3] years) and 80 NSF (40.0 [37.0-45.8] years) were included. There was no statistically significant difference in AAC scores between SF (5.8 ± 0.8 %) and NSF (5.6 ± 0.7 %, p = 0.27). When dividing SF according to their mean value of AAC score, below <5.8% (n=33) or above ≥ 5.8% (n=29), SF with higher AAC had significantly higher BMI and tibial cortical porosity (Ct.Po) and significantly lower serum HDL, klotho, Fet-A and eGFR. Urinary calcium did not differ between groups but fractional excretion of phosphate was higher in SF with higher AAC. Upon multivariate regression analysis, BMI (β 0.31, p<0.01), serum Fet-A (β -0.29, p=0.02) and tibial Ct.Po (β 0.26, p=0.03) were independently associated with AAC (Table 1).

**Conclusions:** This study demonstrates associations of reduced circulating Fet-A levels and higher tibial porosity with AAC, supporting Fet-A as central mediator in the kidney-bone-vasculature axis.

## Breast Artery Calcification as a Surrogate Marker for Vascular Calcification in CKD

Pattarid Mueangpaisarn, Pamila Tasanavipap, Narongrit Siriwattanasit, Pitchamon Inkong, Narittaya Varothai, Paramat Thimachai, Amnart Chairprasert, Naowanit Nata, Theerasak Tangwonglert, Wisit Kaewput, Ouppatham Supasynhdh, Bancha Satirapoj. *Phramongkutklao College of Medicine, Bangkok, Thailand.*

**Background:** Arterial calcification is common in patients with chronic kidney disease and contributes to excess cardiovascular mortality. Breast artery calcification could be a potential marker of medial vascular calcification in CKD but is limited for screening vascular calcification in patients with CKD. The study aimed to determine the performance of BAC for detecting vascular calcification in CKD patients and investigate the relationship between BAC and associated factors in CKD patients.

**Methods:** A total of 103 women aged >40 years with estimated glomerular filtration rate (GFR) of less than 90 mL/min/1.73 m<sup>2</sup> with digital mammography, lateral lumbar spine radiographs, and non-contrast computed tomography was included. BAC score (0-12) was calculated by the number of calcified vessels, the longest length and the

density of calcification. Cardiovascular disease risk factors and laboratory profiles were assessed for each patient.

**Results:** BAC was identified 8 (39.1%) in CKD stage II, 26 (56.5%) in CKD stage III, and 26 (76.5%) in CKD stage IV-V (P<0.017). Patients with the presence BAC were significantly older, had lower GFR, higher hemoglobinA1C and increased AAC score than patients without calcification. In a multivariate model including the traditional cardiovascular risk factors, the presence of BAC was significantly associated with lower estimated GFR (adjusted HR=5.67, 95%CI 1.78-17.83) and older age (adjusted HR:1.009, 95%CI 1.02-1.17). BAC increased in sensitivity (85.7%) and accuracy (67.6%) in accordance with coronary artery calcification score (CAC) in patients with GFR less than 30 mL/min/1.73 m<sup>2</sup>. BAC and AAC scores showed significant implications of CAC score in which area under curve (AUC) were 0.67 (95%CI 0.57- 0.78) and 0.84 (95%CI 0.76-0.92), respectively. Remarkably, the combination of AAC and BAC scores showed better CAC score prediction (AUC 0.88, 95%CI 0.81-0.96).

**Conclusions:** The presence and severity of BAC is markedly increased in advanced CKD and it is significantly associated with older age and lower GFR. A combination of BAC and AAC performed good performance in predicting coronary calcification, especially in advanced CKD.

## SA-PO163

## Effect of Menaquinone-7 Supplementation on Arterial Stiffness in Chronic Hemodialysis Patients: A Multicenter Randomized Controlled Trial

Nuanjanthip Naiyaraksaeree,<sup>1</sup> Jeerath Phannajit,<sup>1</sup> Wichai Naiyaraksaeree,<sup>2</sup> Sookruetai Lekhyananda,<sup>3</sup> Yingyos Avihingsanon,<sup>1</sup> Kearkiat Praditpornsilpa,<sup>1</sup> Somchai Eiam-Ong,<sup>1</sup> Paweena Susantitaphong,<sup>1</sup> <sup>1</sup>Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; <sup>2</sup>The Bangkok Christian Hospital, Bangkok, Thailand; <sup>3</sup>Kidney Foundation of Thailand, Bangkok, Thailand.

**Background:** Vitamin K deficiency is one of the most important risk factors of vascular calcification and arterial stiffness in chronic kidney disease and dialysis patients. However, the benefit of vitamin K supplementation on structural and functional vascular health are still not established. This study was aimed to evaluate the efficacy of menaquinone-7 (MK-7) supplementation on arterial stiffness in chronic hemodialysis (HD) patients.

**Methods:** This open-label multicenter randomized clinical trial was conducted in 96 HD patients who had arterial stiffness, defined by high carotid femoral pulse wave velocity (cfPWV ≥ 10 m/s). The patients were randomly assigned to receive oral MK-7 (375 mcg once daily) for 24 weeks (n = 50) or standard care (control group; n = 46). The change of cfPWV was evaluated as primary outcome.

**Results:** The baseline parameters were comparable between two groups. At 12 weeks, patients who received MK-7 had a trend in decreasing in cfPWV compared with standard care (-13.0 ± 20.7% vs -6.8 ± 21.1%, p=0.18). This effect is more prominent in diabetes patients (-9.9±13.8% vs 1.9±17.2%, p = 0.065). In addition, the MK-7 group had lower rate of arterial stiffness progression compared with control group (21.4% vs 34.1%, p = 0.20), especially in diabetes patients (21.4% vs 58.3%, p = 0.054). There were no serious adverse events observed during 12 weeks.

**Conclusions:** Vitamin K supplementation provided a trend in decreasing arterial stiffness at short term follow up without serious adverse effects, especially patients with diabetes. However, the benefit on vascular health and cardiovascular outcomes are still needed.

**Funding:** Private Foundation Support

## SA-PO164

## Clinical Features and Outcomes of Calciphylaxis in Chinese Patients With CKD

Yongyi Jiao, Xiaoliang Zhang. *Zhong Da Hospital affiliated to Southeast University, Nanjing, China.*

**Background:** Calciphylaxis is a rare disease, predominantly in chronic kidney disease (CKD), characterized by high morbidity and mortality. Data from the Chinese population have been an invaluable resource for a better understanding of natural history, optimal treatments, and outcomes of calciphylaxis.

**Methods:** A retrospective study was conducted in 51 Chinese patients diagnosed with calciphylaxis at Zhong Da Hospital affiliated to Southeast University from December 2015 to September 2020. Descriptive statistical analysis was used in summarizing patients' characteristics, treatments and disease outcomes. Kaplan-Meier method was used to calculate survival. Univariate COX regression models were used to determine survival predictors of patients with calciphylaxis.

**Results:** Between 2015 and 2020, 51 cases of calciphylaxis were registered in The China Calciphylaxis Registry (<http://www.calciphylaxis.com.cn>), which were developed by Zhong Da Hospital. The mean age of the cohort was 52.02±14.09 years, and 37.3% of them were female. 43 patients (84.3%) were on hemodialysis, with a median dialysis vintage of 88 months. 18 patients (35.3%) had a resolution of calciphylaxis and 20 patients (39.2%) died. Patients in later stages had worse survival than those in earlier stages. Time of skin lesions and calciphylaxis-related infection were risk factors in both early mortality and overall mortality. Additionally, dialysis vintage and infections were significant risk factors in calciphylaxis-specific mortality. Among therapeutic strategies, only the use of STS ≥3 courses was significantly associated with decreased hazard of death.

**Conclusions:** For Chinese patients with calciphylaxis, time of skin lesions and infection secondary to wounds are risk factors for the prognosis of patients with

calciophylaxis. Additionally, patients in earlier stages have a better survival rate and early continuous use of STS is highly suggested.

Overall mortality survival for stratified into calciophylaxis patients in earlier and later stages

**Fracture, Vascular Calcification, and Bone Turnover: The Important Interrelationship in Disorder of Bone and Mineral Metabolism in CKD**  
Ana Paula Gueiros,<sup>1</sup> Luiz A. Coutinho,<sup>1</sup> Julia B. Vaz,<sup>2</sup> Eduarda C. Russo,<sup>1</sup> Vanda Jorgetti,<sup>2</sup> Jose E. Gueiros.<sup>1</sup> <sup>1</sup>Universidade Federal de Pernambuco, Recife, Brazil; <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Disorders in bone and mineral metabolism are ubiquitous in hemodialysis (HD) patients. The aim of this study was to assess factors associated with the occurrence of fracture in HD patients undergoing bone biopsy (BB).  
**Methods:** The medical records of 250 patients were reviewed. Clinical data: age, sex, time on HD and fracture. Laboratory: Calcium, phosphorus (P), intact parathyroid hormone (iPTH), total alkaline phosphatase. Vascular calcification (VC) was assessed by x-rays. A qualitative analysis of BB considered the diagnoses: osteitis fibrosa (OF), mixed disease (MD), adynamic bone disease (ABD), osteomalacia (OM) and osteoporosis (OP). A comparative analysis was performed between patients with and without fracture. Univariate and multivariate analyses verified the predictors of fracture and OP.  
**Results:** Median age of patients: 48 years; 57.6% were women and the median time on HD was 9 years. The prevalence of fracture, OP and VC were 8.3%, 43.6% and 45.5%, respectively. In relation to BB, 54.4% of patients presented OF, 30% MD, 12.4% ABD and 3.2% OM. Patients with and without fracture (F x NF) were distinguished by the presence of VC (75% x 41.9%; p=0.01), OP (68.4% x 40.9%; p=0.02), a diagnosis of ABD (31.5% x 10% ; p=0.01), bone turnover (High/Low) (63.1% x 87.6%/36.8% x 12.3%; p=0.01) and by P (mg/dL) (4.6 x 5.9; p=0.003); and a tendency towards iPTH (pg/mL) (415 x 1190; p=0.05). Univariate analysis for risk of fracture: VC (OR 4.15, 95% CI 1.39-15.3; p=0.01), OP (OR 3.12, CI 1.19-9.19; p=0.02), bone turnover (Low OR 4.13, CI 1.43-11.3; p=0.006) and P (OR 0.67, CI 0.49-0.89; p=0.007). In the multivariate model, VC (OR 3.73, CI 1.21-14; p=0.03) and P (OR 0.75, CI 0.53-1.02; p=0.007) remained. Univariate analysis for OP risk: age (OR 1.02, CI 1.00-1.04; p=0.02), fracture (OR 3.12, CI 1.19-9.19; p=0.02), P (OR 0.85, CI 0.73-0.97; p=0.02) and a diagnosis of OF (OR 0.54, CI 0.33-0.90; p=0.01). In the multivariate model, only fracture remained (OR 3.03, CI 1.06-10; p=0.04).  
**Conclusions:** 1. There was a high prevalence of OP and VC in HD patients. 2. We have confirmed the important interrelationship of bone metabolism with the vessel. 3. We have demonstrated the association of low bone turnover with fracture.

SA-PO166

**Association Between Probiotic Consumption and Kidney Stone**  
Api Chewcharat,<sup>1</sup> Sagar U. Nigwekar.<sup>2</sup> <sup>1</sup>Mount Auburn Hospital, Cambridge, MA; <sup>2</sup>Massachusetts General Hospital, Boston, MA.

**Background:** Gut microbiota plays a pivotal role in calcium oxalate kidney stone formation. Probiotic preparations, especially those with Lactobacillus and Bifidobacterium, may help degrade oxalate and reduce the risk of kidney stones. However, data is still controversial.  
**Methods:** We conducted a cross-sectional study among 6,354 US adults aged 20-80 years old in the National Health and Nutrition Examination Survey (NHANES) from cycles 2015-2016 and 2017-2018. Probiotic consumption was defined as self-reported yogurt consumption from 24-hour dietary recall or probiotic supplement based upon dietary supplement use 30-day questionnaire. Our outcomes were a history of kidney stones and symptomatic kidney stones in the past year. We examined the association between yogurt consumption and probiotic supplementation and history of kidney stones and symptomatic kidney stones in the past year using weighted multivariable logistic regression.  
**Results:** Of 6,354 US adults, 1,274 (20.1%) participants reported probiotic consumption. There were 710 (11.2%) participants who reported a history of kidney stones and 107 (1.7%) participants with symptomatic kidney stones in the past year. The prevalence of kidney stones was 10.2% among those who reported probiotic consumption

vs. 11.4% among those without probiotic consumption (p-value = 0.21). The prevalence of symptomatic kidney stones in the past year was 2.1% among those who reported probiotic consumption vs. 1.6% among those without probiotic consumption (p-value = 0.18). After adjusting for confounders, there were no associations between probiotic consumption and history of kidney stones (OR = 0.98, 95%CI [0.71, 1.34], p-value = 0.88) and symptomatic kidney stones in the past year (OR = 1.34, 95%CI [0.65, 2.78], p-value = 0.42) (Table 1).

**Conclusions:** Probiotic consumption is not associated with either history of kidney stones or a risk of symptomatic kidney stones in the past year.

Table 1. The association between probiotic consumption and the risk of kidney stones

	Odds ratio of history of kidney stones				Odds ratio of symptomatic kidney stones			
	Crude	p-value	Adjusted	p-value	Crude	p-value	Adjusted	p-value

**Association of Serum Klotho and Risks of Fractures and Osteoporosis in Patients With and Without CKD**  
Api Chewcharat,<sup>1</sup> Sagar U. Nigwekar.<sup>2</sup> <sup>1</sup>Mount Auburn Hospital, Cambridge, MA; <sup>2</sup>Massachusetts General Hospital, Boston, MA.

**Background:** Serum soluble Klotho (sKlotho) levels are associated with bone abnormalities in animal models. The extension of these findings to clinical bone outcomes in humans, however, remains controversial.  
**Methods:** We conducted a cross-sectional study among 8,660 US adults aged 40-79 years old in the National Health and Nutrition Examination Survey (NHANES) 2007-2010 and 2013-2014. Fractures were identified based on self-reported hip, wrist, or spine fractures diagnosed by doctors on standardized questionnaires. Osteoporosis was defined as T-score ≤ -2.5 at either femoral neck or lumbar spine. sKlotho was divided into 4 quartiles. We examined the association between sKlotho and risks of fractures and osteoporosis using weighted multivariable logistic regression among participants with and without chronic kidney disease (CKD)  
**Results:** Of 8,660 US adults aged 40-79 years old (847 participants with CKD and 7,813 participants without CKD), 1,042 participants reported history of fractures in either hip, wrist, or spine. Among those who reported a history of fractures, 113 participants were with CKD and 929 participants were without CKD. Median sKlotho among participants with a history of fractures was 788.9 pg/ml vs 804.9 pg/ml among those without a history of fractures. Among non-CKD participants, there was no association between the quartile of sKlotho and the risk of fractures (OR highest vs lowest quartile 0.95, 95%CI [0.75, 1.19], p = 0.64) after adjusting for confounders. Among participants with CKD, after adjusting for confounders, there was no association between the quartile of sKlotho and the risk of fractures (OR highest vs lowest quartile 0.65, 95%CI [0.35, 1.19], p = 0.15) (Table 1). There were no associations between sKlotho and risk of osteoporosis among either CKD or non-CKD (Table 2).  
**Conclusions:** sKlotho does not appear to be a predictor of fractures or osteoporosis in either CKD or non-CKD participants.

Table 1. The association between sKlotho and risk of fractures among CKD (n = 847) and non-CKD (n = 7,813)

**Lipid Profile Increased the Risk of Incident Kidney Stones in a Population-Based Cohort Study**  
Xiaohong Fan, Jie Ma, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

**Background:** The prevalence and incidence rate of kidney stones has increased in the past ten years in China. The kidney stone was associated with metabolic diseases such as hypertension, diabetes, and obesity and is also considered to be a higher risk factor for cardiovascular diseases. However, the association between lipid profile and kidney stones has not been thoroughly examined in the Chinese population.

**Methods:** We performed a retrospective cohort study in the Department of Health and Medicine in Peking Union Medical College Hospital from January 2014 to December 2021. Thirty-three thousand nine hundred ninety-nine subjects having repeat physical examinations with an interval of 5 years or more were enrolled. Renal ultrasonography was used to define the presence of kidney stones. Lipid profiles such as triglyceride (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL\_C), low-density lipoprotein cholesterol (LDL\_C), and TC/HDL ratio were categorized by lipid profiles quartiles.

**Results:** 26,594 subjects were included in the final analysis, and the mean age was  $40.9 \pm 12.5$  years; 50.4% were males. All subjects were followed for  $71.5 \pm 11.4$  months. The prevalence rate of renal ultrasound confirmed kidney stones at baseline was 1.33%, and the incident rate was 289.6 cases per 100,000 person-years. The incident rate increased with the higher quartiles of lipid profiles such as TC, TG, LDL\_C, and TC/HDL\_C ( $P$  for trend < 0.01) but decreased with higher quartiles of HDL\_C ( $P$  for trend < 0.001). After adjusting for age, gender, body mass index, estimated glomerular filtration rate, hypertension, and diabetes, the subjects with quartile 4 of TC/HDL\_C ( $> 4.26$ ) had a 1.415-fold higher risk of incident kidney stone formation compared to those with quartile 1; quartile 4 of HDL\_C ( $> 1.65$  mmol/L) was significantly associated with decreased risk of incident kidney stones (HR 0.563, 95%CI 0.407-0.778).

**Conclusions:** In the present cohort study, a higher level of TC/HDL\_C showed a significantly increased risk of incident kidney stones, and higher HDL\_C protected against developing kidney stones. The management of dyslipidemia maybe contributes to a lower risk of kidney formation.

## SA-PO169

### Contribution of Endogenous Oxalate Synthesis to Urinary Oxalate Excretion

**Sonia Fargue**, John Knight. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

**Background:** Urinary oxalate excretion is a known risk factor for calcium oxalate kidney stones and dietary oxalate absorption can contribute to 50% of urinary oxalate. In the absence of adequate dietary control, the rate of endogenous synthesis of oxalate is unknown. Using isotope tracer methodology, we determined the turnover rate of oxalate in healthy volunteers and compared it with urinary excretions on a controlled diet.

**Methods:** A primed, continuous infusion of  $^{13}\text{C}_2$ -oxalate was administered for 5 hrs in the fasted state to 16 healthy adults (7M/9F) between 24 and 56 years of age and BMI 23-44 kg/m<sup>2</sup> after 2 days of equilibration on a low oxalate, normal calcium fixed diet. Blood and urine were collected for analysis of oxalate by Ion Chromatography coupled with Mass Spectrometry and the rate of oxalate turnover rate calculated using urine  $^{13}\text{C}_2$ -oxalate mole percent enrichments at steady-state. Two 24-hr urines and 5 hourly urines in the fasted state were collected after dietary equilibration. Body composition was assessed by impedance.

**Results:** Mean 24-hr urinary oxalate excretion on the fixed diet was  $20 \pm 4$  mg oxalate/day (range 12-28 mg/day), or  $13 \pm 3$  mg oxalate/g creatinine. Projected 24-hr urinary oxalate was  $17 \pm 4$  mg/day using fasted hourly collections. Isotopic equilibration was achieved within 3 hrs for most subjects. Mean urine enrichment with  $^{13}\text{C}_2$ -oxalate at steady-state was  $19 \pm 5\%$ . Mean plasma enrichment at steady-state was  $19 \pm 1\%$  in a subset of subjects analyzed. Average recovery rate of  $^{13}\text{C}_2$ -oxalate infused was  $100 \pm 10\%$ . Oxalate turnover rate was  $107 \pm 26$  nmol/hr/kg and endogenous oxalate synthesis  $17 \pm 4$  mg/day (range 11-24 mg/day,  $19 \pm 4$  and  $16 \pm 4$  mg/day for males and females, respectively). There was a positive correlation between lean body mass and oxalate endogenous synthesis.

**Conclusions:** The range of oxalate synthesis rates spanned a two-fold interval even under fasting conditions and the use of fixed diet. The main factor associated with oxalate synthesis was lean body mass. There was good agreement with 24-hr and fasting hourly urinary oxalate excretions under these conditions. Future studies in oxalate kidney stone formers will address whether endogenous synthesis of oxalate is increased in this population and what factors underlie oxalate turnover.

### Variability in Uromodulin Production and Its Response to Water Loading in Healthy Subjects and Patients With Stone Disease

**Kaice A. LaFavers**,<sup>1</sup> Anna R. Gaddy,<sup>2</sup> Radmila Micanovic,<sup>1</sup> James C. Williams,<sup>1</sup> Fredric L. Coe,<sup>3</sup> Tarek M. El-Achkar,<sup>1</sup> Elaine M. Worcester.<sup>3</sup> <sup>1</sup>Indiana University Purdue University Indianapolis, Indianapolis, IN; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>3</sup>University of Chicago Pritzker School of Medicine, Chicago, IL.

**Background:** Uromodulin is a protein made only by the kidney and released in the urine and circulation. This protein has multiple functions and its high abundance in the urine inhibits stone formation. The physiological determinants of uromodulin production are incompletely understood.

**Methods:** We investigated the dynamic hourly changes in uromodulin levels and the key factors governing its production and release in urine and serum. We specifically tested the effect of water loading, a common intervention prescribed to prevent stone formation. During a two-day period, 17 stone patients and 14 healthy controls were subjected to water loading (day 1) and compared with normal fluid intake (day 2). Uromodulin levels along with other analytes and creatinine were measured by ELISA on timed hourly measurements in the urine and plasma during the period of the study.

**Results:** Compared to the rate of creatinine excretion, there was a significant variability in the rate of uromodulin secretion within subjects during the hours of the

study in both days. Water loading increased urinary uromodulin secretion (35 vs. 9 ug/min at baseline,  $p < 0.0001$ ) in stone formers and healthy controls. Despite high urine volumes, most patients maintained a relatively stable range of urinary uromodulin concentration. Native Western blots for polymerizing and non-polymerizing uromodulin forms suggest that polymerizing uromodulin was the form predominantly produced at higher urinary flow volumes. In addition to urine flow rates, urine sodium excretion and stone disease were significant determinants of increased urinary uromodulin production. Serum uromodulin levels were unaffected by water loading and were not associated with urinary uromodulin.

**Conclusions:** Increased water intake and high urine volumes enhance the secretion of urinary polymerizing uromodulin, which is likely to be beneficial in stone formers. Our study underscores the differential regulation of serum and urine uromodulin. We propose that in a physiological setting, kidney maintains a stable range of polymerizing urinary uromodulin concentration by increasing uromodulin production in the settings of high urine volumes.

## SA-PO171

### Lanthanum Dioxycarbonate Effectively Reduces Urinary Phosphate Excretion in Healthy Volunteers

**Pramod Gupta**, Atul Khare. *Unicyclic Therapeutics Inc., Los Altos, CA.*

**Background:** ~600K kidney failure patients in the US undergo dialysis. Over 43% of these patients have phosphate(P)  $> 5.5$  mg/dL, leading to an increased risk of death. Patients rely on dietary restriction and phosphate(P) binders to avoid hyperphosphatemia. However, current P binders often do not achieve normal P levels and have high pill burdens (many large pills per day). A treatment that reduces pill burden while maintaining efficacy would improve patient adherence, quality of life and may be more likely to achieve P goals. Currently available 3000 mg/day lanthanum carbonate effectively reduces urinary P excretion by 236-468 mg/day. Lanthanum dioxycarbonate, RENAZORB(LDC), is a novel nanotechnology product that combines lanthanum, which has the highest binding capacity vs. other P binders, with a potentially smaller pill size that is swallowed with water rather than chewed. We present results of a phase 1 study evaluating LDC's P binding capacity and tolerability.

**Methods:** A phase 1, double-blind, placebo-controlled study evaluated LDC's P binding capacity and tolerability in 4 cohorts of 8 healthy adults. 3 separate LDC doses of 500 mg tablets were administered after meals for 5 days: 1500, 3000, 4500, 6000 mg/day.

**Results:** All doses reduced the amount of P excreted in urine and increased the amount excreted in feces. Mean overall change in P excretion showed a statistically significant dose-response trend. LDC showed statistically significant mean reduction in urine P excretion with 3000 mg/day ( $p = 0.0004$ ), 4500 mg/day ( $p < 0.0001$ ), and 6000 mg/day ( $p = 0.0001$ ). All treatment-related adverse events (AEs) were mild. There were no severe/life-threatening AEs, serious AEs, deaths, or AEs leading to discontinuation.

**Conclusions:** LDC was effective in binding to dietary P and the efficacy was dose proportional. It was well tolerated. LDC may be a welcome choice for patients as it is effective and is a small swallowable pill.

## SA-PO172

**A Phase 2 Dose Ranging Study to Evaluate the Efficacy, Tolerability, and Safety of VS-505 in Hemodialysis Patients With Hyperphosphatemia**

**Background:** VS-505 is a novel non-absorbed phosphate binder with the component of iron and gum Arabic. This was a phase II, 6-week open-label, randomized, active controlled dose-ranging study in hemodialysis (HD) patients with hyperphosphatemia. The primary objective was to investigate the ability of different fixed dose of VS-505 to lower serum phosphorus in this population.

**Methods:** Adult HD patients with serum phosphorus level between 6 - 10 mg/dL were randomized to VS-505 at dosages of 1.50, 2.25, 4.50, 6.75 g/d or sevelamer 4.80 g/d divided into 3 times administered orally with meals for 6 weeks. No dose titration was allowed. Patients were withdrawn if their serum phosphorus > 8.5mg/dL or < 2.5mg/dL during the treatment.

**Results:** There were 133 patients randomized, 131 received the study drugs and 108 patients completed 6-week treatment. A statistically significant decrease in serum phosphorus level from baseline to end of treatment was observed in all VS-505 and sevelamer groups (Table 1). No significant changes of serum calcium, iPTH and iron parameters were observed during the treatment phase. In pooled VS-505 groups, 81.0% patients reported ≥ 1 TEAE; discolored feces (51.4%) and diarrhea (10.5%) were most common TEAEs. No SAE was related to VS-505 as assessed by the investigator. 4.8% of VS-505 and 3.8% of sevelamer treated patients discontinued treatment due to AEs.

**Conclusions:** The dose-dependent serum phosphorus lowering effect of VS-505 has been demonstrated. VS-505 4.50 g/d, 6.75g/d and sevelamer 4.80 g/d groups showed clinically significant serum phosphorus reduction. VS-505 was safe and well tolerated in HD patients with hyperphosphatemia. ClinicalTrials.gov Identifier: NCT04551300.

Study Drugs and Doses	n	Mean [SD] Serum Phosphorus (mg/dL) Full Analysis Set (ITT)		
		Baseline	Change from Baseline to End of Treatment	p-value
VS-505 1.50 g/d	27	7.58 [0.79]	-0.80 [1.29]	0.004
VS-505 2.25 g/d	26	7.44 [0.95]	-0.94 [1.42]	0.003
VS-505 4.50 g/d	26	7.48 [0.80]	-1.62 [1.38]	<0.001
VS-505 6.75 g/d	26	7.41 [1.10]	-1.78 [1.54]	<0.001
Sevelamer 4.80 g/d*	25	7.46 [1.19]	-1.38 [2.03]	0.002

## SA-PO173

**A Dose Escalation Study to Evaluate the Tolerability, Safety, and Efficacy of VS-505 in Hemodialysis Patients With Hyperphosphatemia**

Liangying Gan,<sup>1</sup> Bing Zhuang,<sup>2</sup> Junwei Yang,<sup>2</sup> Song Wang,<sup>3</sup> Yuan Luo,<sup>2</sup> Hong Ye,<sup>2</sup> Zhizheng Zhang,<sup>4</sup> Jiajun Hong,<sup>4</sup> Weifeng Zhang,<sup>4</sup> Xiaoling Li,<sup>4</sup> Jin Tian,<sup>4</sup> Li Zuo.<sup>1</sup> <sup>1</sup>Peking University People's Hospital, Beijing, China; <sup>2</sup>Nanjing Medical University, Nanjing, China; <sup>3</sup>Peking University Third Hospital, Beijing, China; <sup>4</sup>Alembund Biotech Inc., Shanghai, China.

**Background:** VS-505 is a novel non-absorbed phosphate binder with the component of iron and gum Arabic. This was a dose escalation study to evaluate the safety and efficacy of VS-505 in hemodialysis (HD) patients with hyperphosphatemia.

**Methods:** Adult HD patients with serum phosphorus (P) level between 6 - 10 mg/dL were enrolled. Treatment with VS-505 was 6 weeks with dose escalation every 2 weeks from 2.25 g/d, 4.5 g/d to 9.0 g/d, guided by serum P levels. The dose was divided into 3 times administered orally with meals. Primary efficacy endpoint was the change from

baseline to end of treatment in serum P. Secondary efficacy endpoints were time course of serum P, the change from baseline to end of treatment in serum calcium (Ca), Ca×P product and iPTH. Safety endpoints include adverse events, etc. Analyses were based on intent to treat set.

**Results:** 24 out of 25 patients completed 6-week treatment and 15 out of 25 patients received full dose escalation to 9.0 g/d. The average dose intensity was 4.34 g/d and the average exposure was 40.8 days. At the end of treatment, serum phosphorus level decreased by  $2.01 \pm 1.55$  mg/dL (95% CI -2.65 to -1.37) from baseline ( $7.73 \pm 1.12$  mg/dL), which was clinically and statistically significant. Serum P was back to baseline in 2 weeks after study drug discontinuation. The time course of serum P is showed in Figure 1. Serum Ca×P product decreased by  $18.07$  mg<sup>2</sup>/dL<sup>2</sup> (95% CI -23.89 to -12.25) from baseline ( $69.25 \pm 11.91$  mg<sup>2</sup>/dL<sup>2</sup>). No significant change of Ca and iPTH were observed during the treatment. The most frequently reported AEs were gastrointestinal reactions, mainly fecal discoloration (76%) and diarrhea (28%) in mild severity. No increase in the frequency of AEs was recorded with dose escalation. No SAE was related to VS-505 as assessed by the investigator.

**Conclusions:** VS-505, a novel non-absorbed phosphate binder, was safe and well tolerated and showed great effect on lowering serum phosphorus in HD patients with hyperphosphatemia.

## SA-PO174

**Sucroferic Oxyhydroxide Therapy Reduces Endogenous Calciprotein Particle Formation in Dialysis Patients and Attenuates Calcification and Inflammation in Vascular Cells In Vitro**

Ursula Thiem,<sup>1,2</sup> Timothy D. Hewitson,<sup>3,4</sup> Nigel D. Toussaint,<sup>3,4</sup> Stephen G. Holt,<sup>4</sup> Maria C. Haller,<sup>1,5</sup> Andreas Pasch,<sup>6,7</sup> Daniel Cejka,<sup>1</sup> Edward R. Smith.<sup>3,4</sup> <sup>1</sup>Ordensklinikum Linz GmbH Elisabethinen, Linz, Austria; <sup>2</sup>Johannes Kepler Universität Linz, Linz, Austria; <sup>3</sup>The Royal Melbourne Hospital, Parkville, VIC, Australia; <sup>4</sup>The University of Melbourne, Melbourne, VIC, Australia; <sup>5</sup>Medizinische Universität Wien, Wien, Austria; <sup>6</sup>Calciscan AG, Nidau, Switzerland; <sup>7</sup>Lindenhofspital, Bern, Switzerland.

**Background:** Calciprotein particles (CPP), colloidal mineral-protein nanoparticles, have emerged as potential mediators of phosphate toxicity in patients on dialysis, with putative links to vascular calcification, endothelial dysfunction, and inflammation. We hypothesized that treatment with the non-calcium-containing phosphate binder sucroferic oxyhydroxide (SO) would reduce endogenous CPP levels, also manifesting in attenuated pro-calcific and pro-inflammatory effects of patient serum towards human vascular cells *in vitro*.

**Methods:** Secondary analysis of a randomized, controlled cross-over study in 28 hemodialysis patients comparing the effect of two-week binder washout with high-dose (2000 mg/d) and low-dose (250 mg/d) SO therapy on serum CPP, inflammatory cytokine/chemokine arrays and *in vitro* bioassays using aortic smooth muscle cells (HASMC) and human coronary endothelial cells (HCAEC).

**Results:** In our cohort (75% male, 62±12 years) high-dose SO reduced primary (amorphous) and secondary (crystalline) CPP [-62 (-76 to -44)%, p<0.0001 and -38 (-62 to -14)%, p<0.001, respectively] compared to washout. Nine of 14 plasma cytokines/chemokines significantly decreased with high-dose SO, with consistent reductions in Interleukin-6 [IL-6, -31(-51 to -1)%, p<0.001] and Interleukin-8 [IL-8, -46 (-73 to -17)%, p<0.0001]. Compared to treatment with serum collected after washout, exposure of HASMC and HCAEC cultures to serum of SO-treated patients reduced calcification and markers of activation (IL-6, IL-8 and vascular cell adhesion protein 1), respectively. Serum-induced HASMC calcification and HCAEC activation was ameliorated by removal of CPPs from patient sera and enhanced by uremic conditioning of synthetic CPP.

**Conclusions:** High-dose SO reduces endogenous CPP formation in dialysis patients and yielded serum with attenuated pro-calcific and inflammatory effects *in vitro*.

## SA-PO175

**Impact of Targeting Bone Mineral Flow on Achievement of KDIGO Guidelines for CKD-MBD**

Eleanor D. Lederer,<sup>1,2</sup> Michael E. Brier,<sup>3,4</sup> Adam E. Gaweda,<sup>4</sup> <sup>1</sup>VA North Texas Health Care System, Dallas, TX; <sup>2</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>3</sup>VA Robley Rex Medical Center, Louisville, KY; <sup>4</sup>University of Louisville School of Medicine, Louisville, KY.

**Background:** KDIGO guidelines for CKD-MBD management in patients on dialysis focus on achieving calcium (Ca), phosphate (Pi), and parathyroid hormone (PTH) targets. We have developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD that estimates mineral flow out of bone and into soft tissue. We used an Artificial Intelligence method called Reinforcement Learning (RL) to discover treatment strategies directly aimed at minimization of Ca and Pi flow out of bone and into vascular smooth muscle. We hypothesized that direct optimization of Ca and Pi flux instead of biochemical proxies would result in improved bone mineral metabolism and reduction in soft tissue calcification.

**Methods:** We used a QSP model of CKD-MBD to simulate a virtual cohort of 80 ESRD subjects. The RL Agent representing the treatment strategy was implemented as a Deep Neural Network and trained for 10,000 episodes, each episode representing a 5 year treatment period. The RL Agent observed the Ca, Pi, PTH trajectories and adjusted the doses of Pi binder, Calcitriol, and a Calcimimetic on a monthly basis, to minimize the mineral flow out of bone and into soft tissue estimated by the model (Flux RL). All simulations were performed in Matlab / Simulink (Natick, MA). We compared the results to those achieved by a simulated physician (SP) and a RL Agent trained to achieve KDIGO guidelines for Ca, Pi, and PTH (KDIGO-RL).

**Results:** The Flux-RL Agent achieved 23.9% reduction in Ca flux into the soft tissue, compared to 15.1% (p=0.001) (SP) and 15.6% (p<0.001) (KDIGO-RL). Ca flux out of the bone was reduced by 42.6% (Flux-RL), compared to 28.9% (p<0.001) (SP) and 39.1% (p=0.322) (RL-KDIGO). Mean Pi level was 5.1 (Flux-RL) mg/dL, compared to 5.3 (p<0.001) (SP) and 5.2 (p=0.100) (RL-KDIGO). Mean Ca level was 9.2 mg/dL (Flux-RL), compared to 8.9 (p<0.001) (SP) and 9.0 (p=0.068) (RL-KDIGO). Mean PTH level was 226 pg/mL (Flux-RL), compared to 276 (p=0.012) (SP) and 238 (p=0.779) (RL-KDIGO). Flux-RL Agent utilized greater amounts of Calcitriol than SP or KDIGO-RL.

**Conclusions:** CKD-MBD treatment designed to optimize bone mineral flow significantly reduces the undesired Ca flow into soft tissue compared to targeting conventional biochemical parameters. These findings suggest that Pi control can be achieved even with higher vitamin D use and that the resultant higher Ca levels do not promote soft tissue calcification.

## SA-PO176

**Intact PTH Remains a Good Marker of Bone Turnover in Disorder of Bone and Mineral Metabolism in CKD**

Luiz A. Coutinho,<sup>1</sup> Jose E. Gueiros,<sup>1</sup> Julia B. Vaz,<sup>1</sup> Eduarda C. Russo,<sup>1</sup> Vanda Jorgetti,<sup>2</sup> Ana Paula Gueiros,<sup>1</sup> <sup>1</sup>Universidade Federal de Pernambuco, Recife, Brazil; <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Bone biopsy (BB) is the gold standard for diagnosing renal osteodystrophy (RO). Given its invasive nature and low availability in most centers, biomarkers are most commonly used to diagnose and guide the treatment of RO. Among these biomarkers, intact parathyroid hormone (iPTH) and alkaline phosphatase are widely used, but their predictive value is still questioned. There are few available data comparing BB and bone metabolism biomarkers. The aim of this study was to assess the ability of iPTH and total alkaline phosphatase (TAF) to predict bone turnover in hemodialysis (HD) patients.

**Methods:** This was a retrospective cross-sectional study in a single center. The medical records of 250 patients who underwent BB from April 2004 to September 2021 were reviewed. Clinical and laboratory data: age, sex, time on HD, iPTH and TAF (due to methodological differences, it was expressed in the number of times it was above the upper limit of normal; xTAF). According to bone turnover, patients were divided into two groups: High turnover, represented by patients with a histological diagnosis of osteitis fibrosa and mixed disease, and Low turnover, comprising those with adynamic bone disease and osteomalacia. To assess iPTH and TAF as predictors of bone turnover, univariate and multivariate analyzes were performed and an ROC curve was produced.

**Results:** The median age of patients was 48 years, 57.6% were females, and had been on HD for a median time of 9 years. Univariate analysis: iPTH (OR 1.01, 95% CI 1.00-1.01; p<0.001); xTAF (OR 2.83, 95% CI 1.78-5.18; p<0.001); Multivariate analysis: only iPTH was significant (OR 1.01, 95% CI 1.0-1.01; p<0.001). The produced ROC curve demonstrated an area under the curve of 0.9414 for iPTH, with 368 pg/mL as the best cut-off point to discriminate between high and low bone turnover (accuracy 87%, sensitivity 84%, specificity 100%). For xTAF, the area under the curve was 0.782, and the best discriminatory cut-off point for turnover was 1.16 TFA (accuracy 70%, sensitivity 69%, specificity 73%).

**Conclusions:** Our results have demonstrated that iPTH represents a good marker of bone turnover and may be used in clinical practice to discriminate between high and low turnover.

## SA-PO177

**Uremia and Parathyroid Tormone Have Distinct Effects on Protein and Gene Expression on Bone**

Carolina S. Martins,<sup>1</sup> Luciene dos Reis,<sup>1</sup> Marta Martinez-Calle,<sup>2</sup> Ivone B. Oliveira,<sup>1</sup> Ana C. Coelho,<sup>1</sup> Aline Martin,<sup>2</sup> Vanda Jorgetti,<sup>1</sup> Rosilene M. Elias,<sup>1</sup> Valentin David,<sup>2</sup> Rosa M. Moyses,<sup>1</sup> Laboratório de Investigação Médica 16, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo <sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Bone disease is a well-recognized complication of chronic kidney disease (CKD), characterized by reductions in bone quantity and quality. The uncoupling of bone formation and resorption can be found in high and low bone turnover conditions. Parathyroid hormone (PTH) is a main regulator of bone turnover and increased serum PTH levels is a classical alteration of mineral metabolism in CKD. However, the specific effect of PTH on the bone environment in CKD is still unclear.

**Methods:** To separate these effects, we analyzed bone samples from 76 patients on hemodialysis [grouped according to serum PTH levels: < 130 (n= 28), 130-600 (n= 20) and > 600 pg/ml (n=28)] and 19 healthy controls. Protein and gene expression were quantified through immunohistochemistry and RNA sequencing (RNAseq).

**Results:** Most PTH<130 patients (79%) had low, whereas 93% of those with PTH>600 had a high bone turnover. In comparison with healthy controls, PTH<130 group presented a lower osteocytic number, as well as a higher bone expression of DKK1. In patients with PTH>600, we observed a normal osteocytic number and DKK1 expression, but a decrease in bone sclerostin, phosphorylated beta catenin, and osteoprotegerin. Using RNAseq, we found a significant difference in the expression of almost 2,000 genes between CKD and healthy controls. CKD was associated with an increase in inflammatory signaling, cell death, and impairment of osteoblastic differentiation and bone quantity. In contrast, these changes were attenuated in patients with PTH>600, showing a significant increase in the expression of genes associated with fibrosis, matrix proteins and remodeling. In addition, the increase in PTH did not influence the genes related to bone quantity.

**Conclusions:** Using an unprecedented approach, we showed that CKD bone disease is characterized by an increased expression of markers related to suppression in bone formation. An increase in PTH favors bone resorption more significantly than bone formation further aggravating the formation/resorption uncoupling. These findings help us to better understand the complex physiopathology of renal osteodystrophy, creating a perspective of new therapeutic strategies for these patients.

## SA-PO178

**Osteosarcopenia Predicts Fractures and Mortality in Hemodialysis Patients**

Shun Yoshikoshi,<sup>1,2</sup> Shohei Yamamoto,<sup>3</sup> Yuta Suzuki,<sup>4</sup> Keigo Imamura,<sup>1</sup> Manae Harada,<sup>2</sup> Yuri Uchida,<sup>1</sup> Takuya Nakajima,<sup>1</sup> Narumi Fukuzaki,<sup>1</sup> Atsuhiko Matsunaga,<sup>1</sup> <sup>1</sup>Kitasato University Graduate School of Medical Sciences, Sagami-hara, Japan; <sup>2</sup>Sagami Circulatory Organ Clinic, Sagami-hara, Japan; <sup>3</sup>National Center for Global Health and Medicine, Shinjuku-ku, Japan; <sup>4</sup>National Institute of Public Health, Wako, Japan.

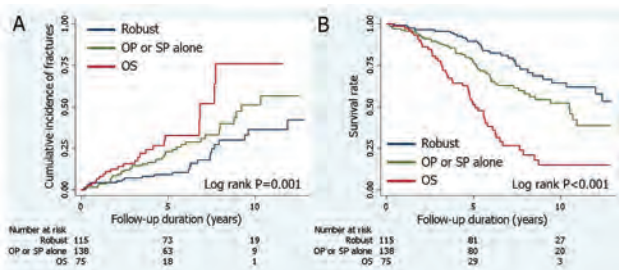

**Background:** With the aging of patients on hemodialysis (HD), the prevalence of osteoporosis (OP) and sarcopenia (SP) is increasing in the HD population. Osteosarcopenia (OS) is a unique syndrome that describes the co-existence of OP and SP. Since the causes of OP and SP share many common risk factors, OS may have a synergistic effect on the clinical outcomes. We investigated the associations of OS with mortality and fractures in HD patients.

**Methods:** This was a retrospective cohort study that targeted outpatients undergoing HD in Japan. OP was defined as T-score < -2.5 according to the WHO criteria. SP was defined according to the Asian Working Group for Sarcopenia criteria 2019. Patients were divided into 3 groups: robust ("non-OP and non-SP"), OP or SP alone ("OP and non-SP" or "non-OP and SP"), and OS ("OP and SP"). The outcomes were all-cause mortality and fractures. We used Cox proportional hazard and negative binomial regression models to estimate these associations.

**Results:** Data from 328 patients (mean age, 66 years; men, 59%) were analyzed. During the follow-up (median, 5 years), 113 fractures and 131 deaths occurred. OP, SP, and OS was identified in 54.6%, 33.5%, and 22.9%, respectively. Compared with the robust group, the incidence of fracture (**Figure A**) and mortality (**Figure B**) was significantly higher in those of OP or SP alone and OS, respectively (all P<0.01). Patients with OP or SP alone (incidence rate ratio [IRR], 1.80; 95% confidence intervals [CIs], 1.08-3.02) and those with OS (IRR: 2.90, 95% CIs: 1.45-5.81) had significantly higher risks for fractures than the robust group. Associations of OS with mortality were similar to those between OS and fractures.

**Conclusions:** The prevalence of OP, SP, and OS was high among patients on HD. Patients with OP or SP had a poor prognosis, and combining OP and SP further worsened their prognosis, suggesting the need for screening and developing the treatment strategy against both OP and SP.

**Funding:** Government Support - Non-U.S.

Kaplan-Meier analysis for the incidence of fractures (A) and mortality (B). OP; osteoporosis, OS; osteosarcopenia, SP; sarcopenia.

### Skeletal Responsiveness to Parathyroid Hormone in Hemodialysis Patients: International Variation and Association With Factors and Risk of Fractures in the DOPPS

Suguru Yamamoto,<sup>1</sup> Junhui Zhao,<sup>2</sup> Angelo Karaboyas,<sup>2</sup> Hirotaka Komaba,<sup>3</sup> Hanne S. Joergensen,<sup>7</sup> Marc G. Vervloet,<sup>6</sup> Sandro Mazzaferro,<sup>5</sup> Etienne Cavalier,<sup>8</sup> Brian Bieber,<sup>2</sup> Bruce M. Robinson,<sup>2</sup> Pieter Evenepoel,<sup>4</sup> Masafumi Fukagawa.<sup>3</sup> <sup>1</sup>Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>Tokai University School of Medicine, Isehara, Japan; <sup>4</sup>University Hospitals Leuven, Leuven, Belgium; <sup>5</sup>Sapienza University, Rome, Italy; <sup>6</sup>Amsterdam University Medical Center, Amsterdam, Netherlands; <sup>7</sup>Aarhus University Hospital, Aarhus, Netherlands; <sup>8</sup>Centre Hospitalier Universitaire de Liege, Liege, Belgium.

**Background:** Bone response to parathyroid hormone (PTH) is impaired in chronic kidney disease (CKD) owing to multiple factors including phosphate loading, calcitriol deficiency, and accumulation of uremic toxins. Other factors may also affect PTH responsiveness including regional and/or ethnic differences, and pharmacological treatment. Using alkaline phosphatase (ALP)/PTH ratio as a proxy for skeletal responsiveness to PTH, we investigated (1) the differences in ALP/PTH by international region and race, (2) patient factors associated with ALP/PTH, and (3) association between ALP/PTH and incidence of fracture in hemodialysis (HD) patients.

**Methods:** The analysis includes 31,701 HD patients with dialysis vintage >120 days in 9 countries in DOPPS phase 3-7 (2005-2021). The primary exposure variable was ALP/PTH. ALP and PTH levels were both divided by the facility upper normal limit to normalize the values. Cox models were used to estimate hazard ratios (HR) of fracture across levels of ALP/PTH and also for normalized ALP alone. Logistic regression was used to model associations between low ALP/PTH (<0.1) and clinical factors. All models were adjusted for potential confounders including country, case-mix, and laboratory values.

**Results:** Median ALP/PTH was 0.21, 0.33, 0.17, and 0.23 in Europe, Japan, US-Black, and US-Nonblack, respectively. ALP/PTH <0.1 was associated with male gender, Black race, higher body mass index, higher serum levels of albumin, phosphorus and calcium, and use of vitamin D analogues and cinacalcet. ALP/PTH was not associated with any fractures (p=0.81). In contrast, normalized ALP had a strong monotonic association with fracture rate; the HR (95% CI) compared to the reference group of 0.75-0.99 ranged from 0.77 (0.60,0.97) for ALP <0.50 to 1.35 (1.06,1.74) for ALP 1.50+.

**Conclusions:** In this large international cohort study, skeletal responsiveness to PTH in HD patients showed regional and ethnic differences and may be affected by pharmacological treatment and clinical factors. We did not observe a direct association between ALP/PTH and fracture, but higher ALP production reflecting bone responsiveness to PTH may increase fracture risk in HD patients.

## SA-PO180

### Seasonality in Hip Fracture Among Hemodialysis Patients and Kidney Transplant Recipients in South Korea

Young Woo Song, Jin Ah Park, Seok Joon Shin, Joo Eun Lee, Sang Hun Eum, Hye Eun Yoon, Yeonhee Lee. Catholic University of Korea Incheon Saint Mary's Hospital, Incheon, Incheon, Republic of Korea.

**Background:** The seasonality of hip fracture in hemodialysis (HD) patients and kidney transplant recipients (KTRs) have not been reported. We assessed seasonal variations in hip fractures among patients with end-stage kidney disease who undergo maintenance HD and KTRs.

**Methods:** Using the Korean National Health Insurance System database from January 2012 to December 2017, monthly counts of hip fracture were calculated among HD patients (n = 77,420) and KTRs (n = 8,921)(Fig 1.). The 6-year normalized monthly fraction and seasonal fractions of hip fractures were calculated. A cosinor analysis was performed to determine the seasonality of the monthly incidence of hip fractures.

**Results:** The 6-year average monthly fraction of hip fractures was lowest in June and highest in October in HD patients, and lowest in February and highest in November in KTRs. The 6-year average seasonal fraction among HD patients was lowest in summer and highest in winter, and lowest in summer and highest in autumn among KTRs, both

without statistical significance. The incidence ratio of hip fractures was lowest in June and highest in January in HD patients, and lowest in August and highest in November in KTRs. On cosinor analysis, HD patients showed significant seasonality in hip fracture incidence, with a trough in summer and a peak in winter (P = 0.002), whereas KTRs did not exhibit a significant trend (P = 0.293)(Fig 2.).

**Conclusions:** Hip fractures occurred more frequently in winter and less frequently in summer in patients undergoing HD, whereas KTRs did not show a seasonal trend.

## SA-PO181

### Association Between Cause of Kidney Failure and Fracture Incidence in a National US Dialysis Population Cohort Study

Susan Ziolkowski,<sup>1</sup> Sai Liu,<sup>1</sup> Maria E. Montez-Rath,<sup>1</sup> Michelle Denburg,<sup>2</sup> Wolfgang C. Winkelmayer,<sup>3</sup> Glenn Chertow,<sup>1</sup> Michelle M. O'Shaughnessy.<sup>4</sup> <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>3</sup>Baylor Scott & White Health, Dallas, TX; <sup>4</sup>Cork University Hospital, Cork, Ireland.

**Background:** Whether fracture rates, overall and by fracture site, vary by cause of kidney failure in patients receiving dialysis is unknown.

**Methods:** Using the US Renal Data System (USRDS), we compared fracture rates across seven causes of kidney failure in patients who started dialysis between 1997 and 2014. We computed unadjusted and multivariable adjusted proportional sub-distribution hazard models, with fracture events (overall, and by site) as the outcome and IgA nephropathy as the reference group. Kidney transplantation and death were competing events.

**Results:** Among 491,496 individuals, with a median follow-up of 2.0 (0.9-3.9) years, 62,954 (12.8%) experienced at least one fracture. Patients with diabetic nephropathy, vasculitis, or autosomal polycystic kidney disease (ADPKD) had the highest (50, 46, and 40 per 1000 person-years, respectively), and patient with lupus nephritis had the lowest (20 per 1000 person-years) fracture rates. After multivariable adjustment, diabetic nephropathy (HR 1.43, 95% CI 1.33-1.53), ADPKD (HR 1.37, 1.26-1.48), vasculitis (HR 1.22, 1.09-1.34), membranous nephropathy (HR 1.16, 1.02-1.30), or FSGS (HR 1.13, 1.02-1.24) were associated with a significantly higher, and lupus nephritis with a significantly lower (HR 0.85, 0.71-0.98) fracture hazard. The hazards for upper extremity and lower leg fractures were significantly higher in diabetic nephropathy, ADPKD, FSGS, and membranous nephropathy, while the hazard for vertebral fracture was significantly higher in vasculitis.

**Conclusions:** Fracture risk, overall and by fracture site, varies by cause of ESKD. Future work to determine underlying pathogenic mechanisms contributing to differential risks might inform more tailored treatment strategies.

**Funding:** NIDDK Support

## SA-PO182

### Therapy With Romosozumab Followed by 1 Year of Denosumab in Hemodialysis Patients With Osteoporosis: An Observational Study

Tomohiro Saito,<sup>1</sup> Masahide Mizobuchi,<sup>1</sup> Tadashi Kato,<sup>1</sup> Taihei Suzuki,<sup>1</sup> Yasuro Fujiwara,<sup>2</sup> Naoaki Kanamori,<sup>2</sup> Mikio Makuuchi,<sup>2</sup> Hirokazu Honda.<sup>1</sup> <sup>1</sup>Showa Daigaku, Shinagawa-ku, Japan; <sup>2</sup>sannoudai hospital, Ibaraki, Japan.

**Background:** Evidence of the treatment with romosozumab (ROMO) in hemodialysis (HD) patients is limited. Accordingly, here we report clinical characteristics of ROMO in these patients.

**Methods:** We conducted a 24-month prospective, observational, single-center cohort study that analyzed 17 HD patients with osteoporosis. These patients received ROMO (210mg) subcutaneously once monthly for 12 months and were then followed by denosumab (60mg) subcutaneously every six months for an additional 12 months. We examined the incidence of new fractures, safety, changes in bone mineral density (BMD), bone metabolism markers, and coronary artery calcification.

**Results:** There were no cases of new fractures in the study period. The annual percent changes from baseline in the lumbar spine (LS), total hip (TH), and femoral neck (FN) BMD were +9.3%, +3.2%, and +6.9%, respectively. These effects were maintained for 24 months. Relative changes from baseline to 24 months were +14.4%, +5.7%, and +5.6%, respectively. The percent change in TH ( $r = -0.80$ ;  $P < 0.001$ ) and FN ( $r = -0.84$ ;  $P < 0.001$ ) showed negative correlation with the BMD at baseline. Although coronary artery calcification scores slightly increased from 1094.2 at baseline to 1313.1 at 12 months ( $P = 0.013$ ), fatal events including CVD death and all causes of death were not observed during the ROMO treatment period. Asymptomatic hypocalcemia was observed from 1 to 2 months after the start of ROMO. However, no concomitant drug administration was required, and serum calcium levels returned to approximately baseline levels.

**Conclusions:** Our study suggests that ROMO followed by denosumab treatment is safe and has effectiveness in increasing LS, TH, and FN BMD. Studies with larger sample sizes are necessary to confirm the clinical utilities of ROMO in HD patients with osteoporosis.

## SA-PO183

### Ten Years' Experience Treating Osteoporosis in Hemodialysis Patients

Kentaro Sakai,<sup>1</sup> Kei Fukami,<sup>2</sup> <sup>1</sup>Our Lady of the Snow Social Medical Corporation St. Mary's Hospital, Kurume, Japan; <sup>2</sup>Kurume Daigaku, Kurume, Japan.

**Background:** The treatment of osteoporosis in hemodialysis (HD) patients has not been established, as there is insufficient evidence regarding the treatment of osteoporosis. We began treating osteoporosis in HD patients in 2011. Herein, we describe the effects of the treatment based on our 10-year experience.

**Methods:** This was a single-center prospective observational study of 141 HD patients (age 73.9±11.4 yrs; 77 females) treated for osteoporosis from 2011 to 2021. The average observational period was 4.8±2.9 years. We introduced osteoporosis treatment with alendronate in 2011, ibandronate in 2016, and denosumab in 2018. The patients' BMD values including the lumbar spine, femoral neck, and total hip were determined by dual-energy X-ray absorptiometry. We have administered alendronate or ibandronate to patients whose first T-score was ≤-2.5. Beginning in 2018, if a patient's T-score did not improve after the second year, we changed the medication to denosumab. The patients' yearly values of bone metabolism markers such as parathyroid hormone (PTH), bone alkaline phosphatase (BAP), and tartrate-resistant acid phosphatase 5b (TRACP-5b) were assessed.

**Results:** In the alendronate group (n=79), the lumbar spine BMD was significantly improved at 1 year (-3.2±1.0 vs -2.9±0.9,  $p < 0.05$ ), but this BMD did not improve after the second year. In the denosumab group (n=40), the femoral neck BMD has improved significantly since the second year (-2.9±0.8 vs. -2.5±0.6,  $p < 0.05$ ). Serum calcium decreased significantly only in the denosumab group after the start of treatment (8.5±0.6 vs. 7.8±0.9 mg/dL,  $p < 0.01$ ). The PTH level was unchanged during the study period in each group, but the BAP and TRACP-5b levels decreased significantly in the denosumab group ( $p < 0.01$ ). A multivariate analysis demonstrated that a low baseline BMD was significantly associated with BMD improvement in the alendronate group (OR 11.08, 95%CI: 2.67-41.00,  $p < 0.01$ ).

**Conclusions:** The results of this long-term study suggest that the treatment of osteoporosis with the above-mentioned drugs may be effective in patients undergoing HD. Alendronate may be effective the first year, but its effect may not continue after the second year. Although denosumab can decrease serum calcium, it may be more effective than alendronate and ibandronate (especially after the second year).

## SA-PO184

### Active Vitamin D Use and Fractures in Hemodialysis Patients: Results From the International DOPPS

Hirota Komaba,<sup>1</sup> Junhui Zhao,<sup>2</sup> Angelo Karaboyas,<sup>2</sup> Suguru Yamamoto,<sup>3</sup> Indranil Dasgupta,<sup>8</sup> Mohamed H. Hassan,<sup>4</sup> Li Zuo,<sup>5</sup> Anders Christensson,<sup>7</sup> Christian Combe,<sup>6</sup> Bruce M. Robinson,<sup>2</sup> Masafumi Fukagawa,<sup>1</sup> <sup>1</sup>Tokai University School of Medicine, Isehara, Japan; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; <sup>4</sup>Seha Kidney Care, Abu Dhabi, United Arab Emirates; <sup>5</sup>Peking University People's Hospital, Beijing, China; <sup>6</sup>Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; <sup>7</sup>Skåne University Hospital, Malmö, Sweden; <sup>8</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

**Background:** Active vitamin D is used commonly to control secondary hyperparathyroidism and associated high-turnover bone disease in dialysis patients. It is unknown whether active vitamin D improves bone strength and prevents fracture through direct action on bone metabolism, independent of its action to suppress parathyroid hormone (PTH).

**Methods:** We included 41,677 in-center hemodialysis patients from 21 countries in phases 3-6 (2005-2018) of the Dialysis Outcomes and Practice Patterns Study (DOPPS). We analyzed the association between prescription (yes/no) of active vitamin D at study enrollment and incidence of (1) any fracture and (2) hip fracture. We used Cox regression, adjusted for PTH and other potential confounders, and used a per-protocol approach to censor patients at treatment switch during follow-up. As a sensitivity analysis, we also performed a facility preference approach to reduce confounding by indication, assigning exposures at the facility-level based on the proportion of patients prescribed active vitamin D in the facility.

**Results:** The proportion of patients prescribed active vitamin D at study enrollment was 55% overall and ranged from 72% in Sweden to 25% in France. Event rates (per patient-year) were 0.024 for any fracture and 0.010 for hip fracture. The adjusted HR (95% CI) comparing patients prescribed vs. not prescribed active vitamin D was 1.01 (0.89, 1.16) for any fracture and 0.99 (0.80, 1.22) for hip fracture. In the facility preference approach, compared to the reference group of <40% of patients prescribed active vitamin D, the adjusted HR (95% CI) for fracture was 1.07 (0.88, 1.31) for 40-54%, 1.11 (0.90, 1.37) for 55-69%, and 1.21 (0.99, 1.49) for ≥70%. Results were similar when treating hip fracture as the outcome.

**Conclusions:** Active vitamin D use was not associated with the risk of any fracture or hip fracture in hemodialysis patients. Our results do not support the role of active vitamin D in fracture prevention beyond the suppression of PTH. Randomized clinical trials are needed to confirm these findings.

## SA-PO185

### The Vitamin D Metabolite Ratio and Coronary Artery Calcification in the Multi-Ethnic Study of Atherosclerosis

Charles Ginsberg,<sup>1</sup> Andrew N. Hoofnagle,<sup>2</sup> Ronit Katz,<sup>2</sup> Jonathan Cheng,<sup>1</sup> Simon Hsu,<sup>2</sup> Matthew J. Budoff,<sup>3</sup> Deborah M. Kado,<sup>4</sup> Bryan R. Kestenbaum,<sup>2</sup> Erin D. Michos,<sup>3</sup> David Siscovick,<sup>2</sup> Joachim H. Ix,<sup>1</sup> Ian H. de Boer,<sup>2</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Johns Hopkins University, Baltimore, MD; <sup>4</sup>Stanford Medicine, Stanford, CA; <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Background:** Studies examining the relationship between 25(OH)D deficiency and coronary artery calcification (CAC) are conflicted. The vitamin D metabolite ratio (VMR) (ratio of 24,25(OH)<sub>2</sub>D<sub>3</sub> to 25(OH)D<sub>3</sub>) is more strongly associated with fracture and mortality risk and may be a superior marker of vitamin D adequacy compared to 25(OH)D. The relationship of the VMR with CAC remains unknown.

**Methods:** We measured vitamin D metabolites using liquid chromatography mass-spectrometry in 5,945 participants from the Multi-Ethnic Study of Atherosclerosis (MESA). CAC was measured at baseline and then again annually through year 5. We assessed the relationship of the 25(OH)D and the VMR with CAC prevalence (Agatston scores of >0), severity, and incidence (Agatston scores of >0 in follow-up). We used logistic, linear and Poisson regression to evaluate these associations in models adjusting for demographics, season physical activity, BMI, smoking, diabetes, blood pressure, C-reactive protein, cholesterol levels, eGFR, urine albumin to creatinine ratio (ACR), serum calcium, phosphate, PTH and FGF-23.

**Results:** The mean age was 62 ± 10 years, 54% were women and the median (IQR) 25(OH)D<sub>3</sub> and VMR were 21(15, 30)ng/ml and 15.0(12.3, 18.1)(ng/ml / ng/ml), respectively. The mean eGFR was 79 ± 18 ml/min/1.73m<sup>2</sup> and 10% had an eGFR < 60 ml/min/1.73m<sup>2</sup>. 2,985 participants had prevalent CAC at baseline. In minimally and fully adjusted models, there was no statistical association of 25(OH)D<sub>3</sub> or the VMR with CAC prevalence or severity. Among 2,090 persons without CAC at baseline and follow-up CAC imaging, neither 25(OH)D<sub>3</sub> nor the VMR were associated or the development of incident CAC in follow-up (Table).

**Conclusions:** Among a large sample of community-living individuals without clinically apparent cardiovascular disease, 25(OH)D<sub>3</sub> and the VMR were not associated with prevalence, severity or incidence of CAC. While prior studies associate a low VMR with an increased mortality, it appears unlikely that this risk is mediated through development of CAC.

**Funding:** NIDDK Support

Table 1: Association of 25(OH)D<sub>3</sub> and the VMR with CAC Among MESA Participants

	Prevalence		Severity		Incidence	
	OR Per 100% Higher (95%CI)	P	% Higher CAC Per 100% Higher (95%CI)	P	IRR Per 100% Higher (95%CI)	P
25(OH)D <sub>3</sub>	0.97 (0.87, 1.09)	0.66	6 (-17, 6)	0.35	1.05 (0.93, 1.18)	0.43
VMR	0.94 (0.79, 1.13)	0.53	-4 (-23, 15)	0.66	1.01 (0.84, 1.21)	0.99

SA-PO186

Free 25(OH)D Concentrations and Clinical Outcomes in Elderly Community-Living Adults: The Health, Aging, and Body Composition Study

Jonathan Cheng,<sup>1,2</sup> Andrew N. Hoofnagle,<sup>3</sup> Ronit Katz,<sup>3</sup> Stephen B. Kritchevsky,<sup>6</sup> Michael Shlipak,<sup>4</sup> Mark J. Sarnak,<sup>5</sup> Joachim H. Ix,<sup>1,2</sup> Charles Ginsberg,<sup>1</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>Nephrology Section, Veterans Affairs San Diego Healthcare System, San Diego, CA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>Tufts University School of Medicine, Boston, MA; <sup>6</sup>Wake Forest University, Winston-Salem, NC.

**Background:** 25(OH)D deficiency is believed to contribute to mineral-bone and cardiovascular diseases. 25(OH)D exists as free (~1%) or bound (~99% to vitamin D binding protein) and studies have suggested that serum 25(OH)D may not accurately reflect active, free 25(OH)D concentrations. The associations between measured free 25(OH)D concentrations with clinical outcomes have not been well studied.

**Methods:** We used a case-cohort study design and compared the strength of associations between measured free 25(OH)D with either kidney function decline (≥30% decline in estimated glomerular filtration rate (eGFR) from baseline), fracture, incident cardiovascular disease (CVD), or incident heart failure (HF) in well-functioning community-living adults aged 70 to 79 years in the Health, Aging, and Body Composition Study. Baseline free 25(OH)D concentrations were measured in a random sub-cohort of 459 participants and in participants with kidney function decline (n=381), fractures (n=174), incident CVD (n=151), and incident HF (n=117) during a median 10 years of follow-up. Weighted Cox regression adjusting for age, sex, race, BMI, season of measurements, clinic site, eGFR, calcium, phosphorus, FGF-23, iPTH, and vitamin D supplementation status was used for statistical analysis.

**Results:** In fully adjusted models, a two-fold higher concentration of free 25(OH)D was associated with a 25% higher risk of kidney function decline (95% CI 1.03-1.52) and a 25% lower risk of incident HF (95% CI 0.58-0.96). Free 25(OH)D was not associated with incident CVD (HR=0.87; 95% CI 0.66-1.16) or fractures (HR=1.00; 95% CI 0.66-1.50).

**Conclusions:** Higher concentrations of free 25(OH)D are independently associated with increased risk of kidney function decline and decreased risk of incident HF in community-living older adults. Future studies are needed to determine if these relationships are causal.

**Funding:** NIDDK Support, Other NIH Support - NIH Loan Repayment Grant, National Institute of Health K23DK118197

Association between Measured Serum 25(OH)D Concentration and Clinical Outcomes

Effects of Vitamin D3 Supplementation on Cardiovascular and Cancer Outcomes by Estimated Glomerular Filtration Rate in the Vitamin D and Omega-3 Trial

Christine P. Limonte,<sup>1,2</sup> Leila R. Zelnick,<sup>1,2</sup> Andrew N. Hoofnagle,<sup>6,2</sup> Ravi I. Thadhani,<sup>8</sup> Michal L. Melamed,<sup>3</sup> Samia Mora,<sup>7,4</sup> Nancy R. Cook,<sup>4,5</sup> Heike Luttmann-Gibson,<sup>4,9</sup> Howard D. Sesso,<sup>4,5</sup> I-Min Lee,<sup>4,5</sup> Joann E. Manson,<sup>4,5</sup> Ian H. de Boer,<sup>1,2</sup> <sup>1</sup>University of Washington Division of Nephrology, Seattle, WA; <sup>2</sup>Kidney Research Institute, University of Washington, Seattle, WA; <sup>3</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>4</sup>Brigham and Women's Hospital Division of Preventive Medicine, Boston, MA; <sup>5</sup>Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA; <sup>6</sup>University of Washington Department of Laboratory Medicine & Pathology, Seattle, WA; <sup>7</sup>Brigham and Women's Hospital Division of Cardiovascular Medicine, Boston, MA; <sup>8</sup>Office of the Chief Academic Officer, Mass General Brigham, Boston, MA; <sup>9</sup>Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA.

**Background:** Metabolism of 25-hydroxyvitamin D (25[OH]D) is reduced and secondary hyperparathyroidism is common with lower eGFR. These abnormalities may contribute to cardiovascular disease and cancer risk, which may be mitigated via vitamin D supplementation.

**Methods:** We assessed for heterogeneity by baseline eGFR of the effects of vitamin D<sub>3</sub> on cardiovascular and cancer outcomes in the Vitamin D and Omega-3 Trial (VITAL). Participants were randomized to 2000IU vitamin D<sub>3</sub> and/or 1g omega-3 fatty acids daily using a placebo-controlled, two-by-two factorial design and followed a median 5 years. The primary study endpoints were incident major cardiovascular events and invasive cancer. Changes in serum 25(OH)D and parathyroid hormone (PTH) were examined as intermediate outcomes.

**Results:** Baseline eGFR was available for 15,917 participants. Vitamin D<sub>3</sub> resulted in higher serum 25(OH)D compared to placebo (difference in change throughout the trial 12.5 [95% CI 12.0, 13.0] ng/mL), without heterogeneity by eGFR. Difference in change in PTH between vitamin D<sub>3</sub> and placebo was larger with lower eGFR: -6.9 (95% CI -10.5,

-3.4), -5.8 (-8.3, -3.4), -4.0 (-5.9, -2.2), and -3.8 (-5.6, -2.0) pg/mL for eGFR <60, 60-74, 75-89, and ≥90 ml/min/1.73m<sup>2</sup>, respectively. The primary cardiovascular and cancer endpoints were observed among 508 (3%) and 1051 (7%) participants. Effects of vitamin D<sub>3</sub> supplementation on cardiovascular events (p-interaction, continuous eGFR=0.61) and cancer (p-interaction=0.89) did not differ by eGFR: HR (95% CI) 1.14 (0.73, 1.79), 1.06 (0.75, 1.50), 0.92 (0.67, 1.25), and 0.92 (0.66, 1.27), across increasing eGFR categories for cardiovascular events and 1.63 (1.03, 2.58), 0.85 (0.64, 1.11), 0.84 (0.68, 1.03), and 1.11 (0.92, 1.35) for cancer, respectively. There was no significant heterogeneity in adverse events (hypercalcemia, kidney stones).

**Conclusions:** We observed no significant heterogeneity by baseline eGFR on the effect of long-term supplementation with vitamin D<sub>3</sub> versus placebo on cardiovascular or cancer outcomes in VITAL. No benefits for these outcomes were observed within any eGFR subgroup despite substantial increases in circulating 25(OH)D and decreases in PTH concentrations.

SA-PO188

Plasma Activin A Rises Through CKD Stages but Is Unrelated to Vascular Calcification and Cardiovascular Events

Anders Nordholm,<sup>1,2</sup> Ida M. Sørensen,<sup>1</sup> Sasha S. Bjergfelt,<sup>1</sup> Andreas Fuchs,<sup>3</sup> Klaus F. Kofoed,<sup>3</sup> Nino E. Landler,<sup>4</sup> Tor E. Biering-Sørensen,<sup>4</sup> Bo Feldt-Rasmussen,<sup>1</sup> Christina Christoffersen,<sup>5</sup> Susanne Bro,<sup>1</sup> <sup>1</sup>Dept. of Nephrology, Rigshospitalet, Copenhagen, Denmark; <sup>2</sup>Dept. of Nephrology, Herlev & Gentofte Hospital, Copenhagen, Denmark; <sup>3</sup>Dept. of Cardiology, Rigshospitalet, Copenhagen, Denmark; <sup>4</sup>Dept. of Cardiology, Herlev & Gentofte Hospital, Copenhagen, Denmark; <sup>5</sup>Dept. of Clinical Biochemistry, Rigshospitalet, Copenhagen, Denmark.

**Background:** Activin A (ActA) is a hormone related to CKD and mineral and bone disorder (MBD). Animal studies show that ActA is elevated in CKD and that ActA signaling inhibition ameliorates renal fibrosis, vascular calcification (VC) and bone disease in CKD. We examined plasma ActA (p-ActA) levels in a large cohort of CKD and controls and determined if p-ActA was associated with radiographic measures of VC and bone mineral density (BMD) as well as cardiovascular events (MACE).

**Methods:** Prospective cohort study. Patients with CKD stages 1-5 not on dialysis (N=741) and age-/sex-matched healthy controls (ctl) (N=175). Baseline p-ActA was measured by ELISA (DAC00B, R&D). VC in coronary arteries (CA) and thoracic aorta (TA) was determined by non-contrast 320-multidetector CT scans, quantified by Agatston score. Thoracic BMD (Th7-9) in mg/cm<sup>2</sup> was assessed from the CT scans using a Phantom. Comparison between p-ActA and continuous variables were done by linear regression and Spearman's correlation. Comparing p-ActA to CKD stage, Agatston-, and BMD groups was done by ANOVA. MACE (median follow-up 4±1 yrs) was assessed and related to p-ActA quartiles using Kaplan-Meier and Cox regression.

**Results:** P-ActA is inversely correlated to eGFR (r=-0.53, p<0.001), and rises continuously from ctl and through CKD stages (ctl 136±71pg/mL, CKD1 148±90, CKD2 175±106, CKD3 239±120, CKD4 330±218, CKD5ND 397±202), significant from CKD3 to CKD5 (p<0.001). P-ActA was correlated with Agatston score in CA (r=0.23, p<0.01) but not in TA of CKD patients. P-ActA was significantly increased in the Agatston score >400 group from 219±166 to 285±144 (p<0.01) in CA, and from 206±135 to 280±146 (p<0.01) in TA. The associations lost significance when adjusted for either age or eGFR. Thoracic BMD was not correlated to p-ActA and there was no difference in p-ActA levels when stratified into BMD groups groups of very low (<80), low (80-120), and normal (>120) BMD. The HR of MACE in the highest quartile of p-ActA (>289pg/mL) was 3.98 [2.39-6.61], but 1.67 [0.97-2.88] when adjusting for eGFR.

**Conclusions:** Plasma activin A rises with declining kidney function but was not independently associated with radiographic parameters of BMD, VC or MACE.

SA-PO189

Bone Marrow Adiposity Is Associated With Aging and Markers of Bone Remodeling in Non-Dialysis CKD Patients

Joao Victor Salgado, Aluizio B. Carvalho, Maria Eugenia F. Canziani. Division of Nephrology, Federal University of São Paulo, São Paulo, Brazil.

**Background:** Patients with moderate to severe CKD are associated with greater bone marrow adiposity than those with normal renal function or mild CKD. However, little is known about the factors related to marrow fat accumulation, particularly in CKD patients. We evaluated the relationship between bone marrow adiposity and, clinical and laboratory parameters in CKD patients.

**Methods:** This was a post hoc analysis of 37 transiliac bone biopsy samples obtained from CKD stage 2-5ND patients (age 50±11 yrs., 68% male, 35% diabetes, GFR 34±17 ml/min/1.73m<sup>2</sup>). Serum concentrations of FGF21, sclerostin (Scl) and undercarboxylated osteocalcin (uOC) were measured by enzyme-linked immunosorbent assay. Quantitative histomorphometry of bone marrow adipocytes was performed including adipose area (Ad.Ar/Ma.Ar, %), adipocyte number (N.Ad/T.Ar, n°/mm<sup>2</sup>) and adipocyte width (Ad.Wi, µm).

**Results:** Ad.Ar/Ma.Ar was positively correlated with age (r=0.33, p=0.04), FGF21 (r=0.41, p=0.01) and osteoprotegerin (r=0.41, p=0.01). N.Ad/T.Ar was negatively correlated with TG/HDL-c ratio (r=-0.35, p=0.03) and Scl (r=-0.37, p=0.02). Ad.Wi showed a positive correlation with age (r=0.43, p<0.01), FGF21 (r=0.33, p=0.04), uOC

( $r=0.55, p<0.01$ ),  $\text{ScI}$  ( $r=0.57, p<0.01$ ), total cholesterol ( $r=0.34, p=0.04$ ), LDL-cholesterol ( $r=0.32, p=0.04$ ), triglycerides ( $r=0.50, p<0.01$ ), TG/HDL-c ratio ( $r=0.43, p<0.01$ ) and a negative correlation with estimated GFR ( $r=-0.34, p=0.04$ ). After adjustment for eGFR, the regression analyses showed that age, osteoprotegerin and sclerostin levels were independently associated with marrow adipocyte parameters.

**Conclusions:** Bone marrow adiposity was independently associated with aging and markers of bone remodeling in non-dialysis CKD patients.

**Funding:** Government Support - Non-U.S.

SA-PO190

**Relative Contributions of Excretion (EP) and Reabsorption (TRP) of Phosphate to Fractional Excretion of Phosphate (FEP) in CKD**  
Elvira O. Gosmanova,<sup>1,2</sup> Darren E. Gemoets,<sup>1</sup> Kenneth R. Phelps.<sup>1,2</sup> <sup>1</sup>*Albany Stratton VA Medical Center Albany, Albany, NY;* <sup>2</sup>*Albany Medical College, Albany, NY.*

**Background:** In a steady state, net flux of phosphate (P) into plasma determines  $E_p$ .  $F_{EP}$  is commonly used to depict the tubular reabsorption rate of P ( $TR_p$ ).  $E_p/C_{cr}$  and  $TR_p/C_{cr}$ , the amounts of P excreted and reabsorbed per volume of filtrate, determine both  $F_{EP}$  and the serum P concentration ( $P_s$ ) (Phelps, et al. Clin Nephrol 2015;83:167-76). However, the relative effects of  $E_p/C_{cr}$  and  $TR_p/C_{cr}$  on  $F_{EP}$  have not been studied. We analyzed relationships among  $F_{EP}$ ,  $E_p/C_{cr}$  and  $TR_p/C_{cr}$  in CKD stages G1-G5 (dialysis excluded).

**Methods:** This was a retrospective study of 387 veterans seen in the nephrology clinic of the Albany VAMC between 1/2020 and 9/2021. CKD stages were based on eGFR (2012 CKD-EPI). There were 687 concurrent determinations of serum and urine P and creatinine (cr), PTH, and eGFR.  $E_p/C_{cr}$  was calculated as  $P_{u,cr}/C_{cr}$ .  $TR_p/C_{cr}$  as  $P_s - E_p/C_{cr}$  and  $F_{EP}$  as  $P_{u,cr}/C_{cr} \times P_s$  or  $1/(1+(TR_p/C_{cr})/(E_p/C_{cr}))$  (both formulas yield the same values). Relationships among variables were examined with linear regression.

**Results:** Measured and calculated values are shown in Table 1.  $E_p/C_{cr}$  and  $F_{EP}$  increased from CKD G1 to G5 by 380% and 226% but  $TR_p/C_{cr}$  fell by only 15%.  $F_{EP}$  correlated with  $E_p/C_{cr}$  ( $R^2=0.66$ ) and less strongly with eGFR ( $R^2=0.44$ ), PTH ( $R^2=0.28$ ), and  $TR_p/C_{cr}$  ( $R^2=0.20$ ) (all  $p<0.001$ ).  $F_{EP}$  was robustly determined by  $(TR_p/C_{cr})/(E_p/C_{cr})$ .  $F_{EP}$  was  $>20\%$  when  $(TR_p/C_{cr})/(E_p/C_{cr})$  was  $<4$  regardless of individual  $TR_p/C_{cr}$  or  $E_p/C_{cr}$  values. In 27% of cases with  $F_{EP}>20\%$ ,  $TR_p/C_{cr}$  exceeded mean values seen in CKD G1-2, and high  $F_{EP}$  was due solely to increased  $E_p/C_{cr}$ .

**Conclusions:**  $F_{EP}$  is a function of both  $E_p/C_{cr}$  and  $TR_p/C_{cr}$ . At reduced GFR,  $E_p/C_{cr}$  has a stronger effect on  $F_{EP}$  than  $TR_p/C_{cr}$  and PTH (a regulator of P reabsorption) have.  $E_p/C_{cr}$  rises as GFR falls if influx of P does not fall proportionately. If  $E_p/C_{cr}$  is sufficiently increased,  $F_{EP}$  can be  $>20\%$  even when  $TR_p/C_{cr}$  is  $\geq$  normal.  $F_{EP}$  is an inaccurate and sometimes misleading marker of P reabsorption in CKD.

**Funding:** Veterans Affairs Support

**Phosphate Overload Index and Risk of Cardiovascular Disease and Death in CKD: The CRIC Study**  
Jing Chen,<sup>1</sup> Myles Wolf,<sup>2</sup> Tamara Isakova,<sup>3</sup> Siyi Geng,<sup>4</sup> Hua He,<sup>4</sup> Sylvia E. Rosas,<sup>8</sup> Claudia M. Lora,<sup>7</sup> Bernard G. Jaar,<sup>5</sup> L. Lee Hamm,<sup>1</sup> Alan S. Go,<sup>6</sup> Jiang He.<sup>4</sup> <sup>1</sup>*Tulane University School of Medicine, New Orleans, LA;* <sup>2</sup>*Duke University, Durham, NC;* <sup>3</sup>*Northwestern University, Evanston, IL;* <sup>4</sup>*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA;* <sup>5</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>6</sup>*Kaiser Permanente Division of Research, Oakland, CA;* <sup>7</sup>*University of Illinois Chicago, Chicago, IL;* <sup>8</sup>*Harvard University, Cambridge, MA.*

**Background:** Phosphate (Pi) overload may lead to adverse outcomes in CKD, but challenges persist in evaluating Pi overload because serum Pi levels remain in the normal range via tight regulation until later CKD stages, while FGF23 and PTH levels may be affected by factors including eGFR besides Pi. We developed a Pi overload index and studied its relationship with CVD and death in CKD.

**Methods:** The CRIC Study enrolled 3939 adults with CKD and without cirrhosis in the US. 3578 participants without missing data were included in this analysis. Atherosclerotic CVD (ASCVD) was defined as ischemic stroke, myocardial infarction, or peripheral artery disease. Incident ASCVD, heart failure (HF), and death events were adjudicated by the outcome assessment committee. Pi overload index was calculated as [serum Pi x (urinary Pi/Cr ratio) x alkaline phosphatase (ALP- a marker reflecting bone turnover)] to synergistically reflect the effect of high Pi intake on serum Pi, kidneys, and bones. Cox proportional hazards models were used to examine the multivariable association of baseline Pi overload index with the outcomes.

**Results:** During up to 13-year median follow-up, 769 ASCVD, 862 HF, and 1502 death events occurred. ALP was significantly correlated with serum Pi and PTH and

began trending up at CKD stage 2. Pi overload index was significantly and positively correlated with 24-hour urinary Pi, FGF23, PTH, and dietary Pi and also began trending up at CKD stage 2. Higher Pi overload index was associated with higher rates of CVD outcomes and death in multivariable models (Table).

**Conclusions:** Pi overload index was independently associated with CVD outcomes and death and began trending up at CKD stage 2. Its value in diagnosing Pi overload needs to be confirmed in future studies.

**Funding:** NIDDK Support, Other NIH Support - National Institute of General Medical Sciences (NIGMS)

Multivariable-Adjusted Hazard Ratios of Clinical Outcomes Associated with Phosphate Overload Index

Quantile	ASCVD HR (95% CI)	HF HR (95% CI)	Death HR (95% CI)
Phosphate Overload Index			
< 121	Reference	Reference	Reference

**Associations of Calciprotein Particle Maturation Time With Echocardiographic Measures in the CRIC Study**  
Ashwin Sunderraj,<sup>1</sup> Xuan Cai,<sup>1</sup> Andreas Pasch,<sup>2</sup> Matthew Feinstein,<sup>1</sup> Rupal Mehta,<sup>1</sup> Anand Srivastava,<sup>1</sup> Ana C. Ricardo,<sup>3</sup> Debbie L. Cohen,<sup>4</sup> Tamara Isakova.<sup>1</sup> <sup>1</sup>*Northwestern University Feinberg School of Medicine, Chicago, IL;* <sup>2</sup>*Caliscan AG, Biel, Switzerland;* <sup>3</sup>*University of Illinois Chicago UI Health, Chicago, IL;* <sup>4</sup>*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

**Background:** Low T50 may indicate a high propensity for calcification. Low T50 is associated with severe coronary artery calcification (CAC) and CAC progression in patients with CKD. Vascular calcification is associated with left ventricular (LV) hypertrophy and ventricular dysfunction, but data on association of T50 with adverse echocardiographic outcomes are sparse. We examined associations of T50 with LV mass, LV concentric remodeling, LV concentric hypertrophy, and LV eccentric hypertrophy in the Chronic Renal Insufficiency Cohort (CRIC) study.

**Methods:** Multivariable linear regression tested the cross-sectional association between year 1 T50 levels and LV mass. Multivariable logistic regression models tested the associations of T50 with concentric remodeling, concentric hypertrophy, and eccentric hypertrophy. Models were adjusted for age, sex, race, smoking status, BMI, systolic blood pressure, history of CVD, diabetes, eGFR and albuminuria.

**Results:** Among 2280 CRIC Study participants, at year 1, mean age was  $59 \pm 11$  years and mean eGFR was  $43.2 \pm 16.1$  ml/min/1.73m<sup>2</sup>. Mean LV mass was  $105.7 \pm 26.2$  g/m<sup>2</sup>, and LV concentric remodeling was present in 28.5%, LV concentric hypertrophy in 15.0%, LV eccentric hypertrophy in 36.3% of participants. One-SD lower T50 was associated with increased odds ratio (OR) of LV eccentric (OR = 1.37, 95% CI = [1.19 – 1.58]) and concentric (1.35 [1.20 – 1.52]) hypertrophy in unadjusted models; these associations were no longer statistically significant in fully adjusted models. In unadjusted models, one-SD lower T50 was associated with higher LV mass index ( $\beta = 3.04$ , 95% CI = [1.97 – 4.10]); this association was no longer statistically significant in fully-adjusted models. When we examined T50 in quartiles, the findings were similar.

**Conclusions:** Among the CRIC cohort, T50 was not associated with echocardiographic outcomes after multivariable adjustment.

**Funding:** Other NIH Support - R01DK110087

Table. Multi-variable adjusted<sup>1</sup> associations of T50 with LV concentric remodeling, eccentric hypertrophy, concentric hypertrophy, and with LV mass index

	Concentric Remodeling	Eccentric Hypertrophy	Concentric Hypertrophy	LV Mass Index
	Odds ratio (95% CI)	Odds ratio (95% CI)	Odds ratio (95% CI)	$\beta$ Coefficient (95% CI)
T50, expressed on continuous scale, per 1-SD (79 min) lower T50				
	0.98 (0.85 – 1.12)	1.11 (0.94 – 1.32)	1.07 (0.93 – 1.24)	0.46 (-0.51 – 1.44)
T50 Quartile				
Quartile 4	Reference	Reference	Reference	Reference
Quartile 3	1.03 (0.73 – 1.44)	1.01 (0.64 – 1.59)	1.14 (0.78 – 1.67)	0.22 (-2.38 – 2.82)
Quartile 2	1.10 (0.77 – 1.58)	1.63 (1.04 – 2.56)	1.38 (0.93 – 2.04)	1.66 (-0.97 – 4.29)
Quartile 1	0.95 (0.65 – 1.39)	1.22 (0.75 – 1.97)	1.16 (0.77 – 1.74)	1.15 (-1.59 – 3.89)

<sup>1</sup> Adjusted for age, sex, race, clinical site, systolic blood pressure, BMI, diabetes, smoking, LDL, history of CVD, eGFR, and albuminuria

## SA-PO193

**Changes in Bone Quality Over 2 Years in Patients With CKD Stages 2-4**  
 Amr E. Mohamed,<sup>1</sup> Florence Lima,<sup>1</sup> Kelly Meulendyke,<sup>1</sup> Mohamed M. Abdalbary,<sup>2</sup> Eman Nagy,<sup>2</sup> Habib Srour,<sup>1</sup> Marie-Claude M. Faugere,<sup>1</sup> Hartmut H. Malluche.<sup>1</sup> <sup>1</sup>University of Kentucky Medical Center, Lexington, KY; <sup>2</sup>Mansoura University, Mansoura, Egypt.

**Background:** Renal osteodystrophy develops early with loss of kidney function. It encompasses loss of bone quantity and reduced bone quality. This study used Fourier Transformed Infrared Spectroscopy (FTIR) to measure bone quality.

**Methods:** 20 patients (pts) with CKD II-IV underwent iliac crest bone biopsies for FTIR, bone histomorphometry, and dual-photon absorptiometry (DXA) for bone mineral density (BMD) of hip and spine. FTIR parameters included mineral:matrix ratio (M/M), carbonate:phosphate ratio (C/P), collagen crosslinks (Cx) and crystal size (CS). In addition, serum biochemical parameters were measured, including eGFR, Ca, P, iPTH, BSAP, Trap-5B, sclerostin, i and c-term FGF-23,  $\alpha$ -klotho, and Activin A. All tests were done at baseline and after 2-3 years of observation with continuation of the same clinical management following KDIGO guidelines.

**Results:** Age of pts was  $60 \pm 11$  y with 55% female, 65% White, 30% Black, 5% Asian, 55% DM2, 100% HTN, 10% CKD II, 70% CKD III, and 20% CKD IV. Mean eGFR did not significantly change but declined in 9 pts. At beginning of study bone turnover was low in 85% of pts versus 75% at the end; bone volume was low in 25% versus 47% at the end. Mineralization was normal throughout. There was a trend for M/M and CS to go down and histologically, bone turnover increased significantly with increase in the number of pts in the normal range. Change in (D) Cx correlated negatively with DP ( $p=0.026$ ). There was a negative correlation between DM/M and baseline iPTH ( $p=0.002$ ), and a positive correlation between DCS and DiPTH. DC/P correlated positively with  $\Delta\alpha$ -Klotho ( $p=0.002$ ), and negatively with baseline  $\alpha$ -klotho ( $p=0.011$ ). DCS correlated negatively with D trabecular separation ( $p=0.017$ ) and positively with D spine T score ( $p=0.050$ ).

**Conclusions:** The study confirms presence of abnormal bone quality in addition to loss of bone quantity in pts with CKD II-IV. Over 2 years of observation, there was a significant further loss of bone volume by DXA and an increase in turnover towards the normal range by histology. Bone quality parameters trended towards normal and were significantly correlated with changes in parameters indicative of improvement in bone turnover. These results call for management strategies addressing both bone quality and quantity in pts with CKD.

## SA-PO194

**Risk of Hypocalcemia With Denosumab Use in CKD Patients**

Sri Mahathi P. Kalipatnapu,<sup>1</sup> Juhi Bhargava,<sup>1</sup> Shirin Hasan,<sup>2</sup> Stuart M. Sprague.<sup>2,1</sup> <sup>1</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>2</sup>NorthShore University HealthSystem, Evanston, IL.

**Background:** Several case reports and retrospective studies have demonstrated that denosumab (DNB) can cause hypocalcemia in advanced CKD (4-5) and ESRD patients. However, these are predominantly anecdotal reports and the prevalence of hypocalcemia in patients with CKD 3-4 is unclear. We evaluated the change in serum calcium (Ca) in patients treated with DNB with CKD stage 3B and 4.

**Methods:** A retrospective study on 52 patients with CKD 3B-4 who were treated with DNB between 2017-2021 was performed. Mean ( $\pm$  SE) number of doses of DNB received was  $2.4 \pm 0.14$  with minimum of 1 and maximum of 4 doses. Mean pre and post Ca, PTH, vitamin D and phosphorus (Phos) were evaluated. The patients were stratified based on their eGFR into CKD 3B and CKD 4. The subgroup of patients with hypocalcemia (defined  $< 8.0$  mg/dL) and decrease in calcium greater than 1mg/dl from baseline were also identified.

**Results:** The 52 patients received 122 ( $2.4 \pm 0.14$ ) doses of DNB and had a mean eGFR of  $37 \pm 0.7$ . Mean serum Ca (mg/dL) was  $9.6 \pm 0.05$  and  $9.3 \pm 0.05$  before and after DNB, respectively. Mean change in serum Ca was  $0.29 \pm 0.06$ . There were 21 patients with CKD stage 4, mean eGFR  $24.2 \pm 7.7$ . Mean serum Ca with was  $9.5 \pm 0.16$  before DNB and  $9.2 \pm 0.13$  after DNB. Mean change in Ca was  $0.4 \pm 0.14$ . In the 99 patient events with eGFR between 30-45 ( $39.7 \pm 0.58$ ), the mean Ca was  $9.7 \pm 0.05$  before DNB  $9.4 \pm 0.06$  after DNB. Mean change in Ca was  $0.3 \pm 0.07$ . In 15 patients (18 patient events) there was a decrease in serum Ca  $> 1$  mg/dl. The mean eGFR was  $32.1 \pm 1.9$  with mean Ca of  $10.0 \pm 0.14$  and  $8.6 \pm 0.18$  pre and post DNB, respectively, and a mean change in Ca of  $1.36 \pm 0.09$ . Only one patient had overt hypocalcemia, with a post DNB Ca of 7.7 and an eGFR of 27. Vitamin D was available in 6 patients with mean vitamin D (ng/mL) of  $50.7 \pm 2.3$  and  $51.2 \pm 3.8$  before and after DNB, respectively. PTH was available in 5 patients with mean PTH (pg/mL)  $90.6 \pm 29.0$  and  $93.8 \pm 34.3$  before and after DNB, respectively. Phos was available in 11 patients and mean phos (mg/dL) was  $3.4 \pm 0.10$  and  $3.3 \pm 0.39$  before and after DNB, respectively.

**Conclusions:** DNB did not cause a significant drop in Ca in this random sample of CKD 3B-4 patients. Patients with CKD 4 should be monitored for hypocalcemia, further larger and prospective studies should be performed.

**Funding:** Clinical Revenue Support

## SA-PO195

**Mineral and Bone Disorder in Patients Living With the Human Immunodeficiency Virus on Hemodialysis: A Series of Cases**

Julia B. Vaz, Ana Paula Gueiros, Jose E. Gueiros. Hospital das Clinicas, Recife, Brazil.

**Background:** The survival rate of patients living with the human immunodeficiency virus (HIV) has increased after the intensification of antiretroviral therapy. Decreased bone mineral density and fractures are reported in this population. Chronic kidney disease (CKD) causes mineral and bone disorder (CKD-MBD), which also contributes to low bone mineral density, fractures, and vascular calcification. This study aimed to assess the osteometabolic profile and the occurrence of vascular calcification in HIV patients undergoing hemodialysis.

**Methods:** The clinical and demographic data of 21 patients were assessed. Laboratory parameters were measured: total calcium, phosphorus, albumin, intact parathyroid hormone (iPTH), total alkaline phosphatase, 25OH-vitamin D, CD4 count and HIV viral load. Bone mineral density was assessed by bone densitometry, and x-rays of the pelvis, hands and abdomen were also taken to determine vascular calcification scores.

**Results:** The median age of patients was 48 years; 81% were male and the median times of HIV infection and hemodialysis were 132 and 120 months, respectively. Patients presented with hypertension (95%), heart disease (67%) and a history of smoking (85%). Median serum calcium and phosphorus levels were normal and the median iPTH was 360 pg/mL. Osteopenia was diagnosed in 33% of patients and osteoporosis in 33%. Around 24% of patients had previously suffered fractures. The Kaupilla score was higher in patients with fractures ( $p=0.040$ ). Vascular calcification was identified in 12 (57%) patients. Inverse correlations were demonstrated between the Kaupilla score and the T-score of the femoral neck ( $p<0.001$ ) and the T-score of the lumbar spine ( $p<0.001$ ); and between the Adragão score and T-score of the femoral neck ( $p=0.001$ ) and the T-score of the lumbar spine ( $p=0.001$ ).

**Conclusions:** A high prevalence was observed of low bone mineral density, fractures and vascular calcification in HIV patients on hemodialysis. Our results corroborate the important relationship between bone metabolism and vessel. It is necessary to confirm these results with larger studies and preferably with a control group of non-HIV patients.

## SA-PO196

**Metastatic Calcinosis (MC) in Hemodialysis Patients: May Rheopheresis Play a Role?**

Giuseppe Gernone. ASL BA Nephrology and Dialysis Unit - S. Maria degli angeli and S. Giacomo Hospitals, Putignano- Monopoli, Italy.

**Introduction:** MC cutis primarily occurs in CKD because an underlying defect of Ca/P metabolism that precipitate calcium. Dystrophic Calcinosis, the most common Calcinosis Cutis, frequently in autoimmune connective disease, must be excluded. The management of MC in ESKD is challenging because is based mainly on risk factor control, sometimes with administration of sodium thiosulfate. As data are lack for standardized treatment other approaches are reasonable. LDL-apheresis and rheopheresis successfully treat calciphylaxis but there are no specific indications for MC by ASFA. Aim is to test Double Filtration PlasmaPheresis (DFPP), a rheopheresis technique, to improve the outcome of MC.

**Case Description:** 57-years-old man with Hypertension, Diabetes complicated by neuropathy, fingers amputation and plantar ulcers (left foot) by peripheral vasculopathy. Obese. ESKD in HD for over 6 years. Diagnosis of MC, involving face, trunk and limbs, was made. Despite autoimmunity was negative, AVK never used, intralesional corticosteroids were given, calcium-based phosphate binders and Vitamin D analogues were replaced by Sevelamer and calcimimetics, PTH and Ca/P were in the normal range, there was good dialysis adequacy and no increased plasma viscosity: no clinical improvement was attended. A program of 12 treatment (T) of DFPP was started: 3 times/week (T/W) for the first 2, 2 T/W in week 3 and 1 T/W for the following 4. DFPP was conducted by Rheofilter ER-4000. For the first 8 T a single plasma unit (PU) was treated according to the formula:  $(0.07 \times \text{weight}) \times (1 - \text{Hct}/100)$ ; instead 1.5 PU in the remaining 4 T. Complete blood count, albumin, C-Reactive Protein (CRP), LDL-Chol. and Fibrinogen was evaluated. After 8th T there is a remarkable clinical improvement in all body areas, but unexpectedly between the 9th and 10th T there is a flare-up. Protocol was extending up to 24 T: 2 T/W for further 5 weeks, therefore 1 T/W for the last 4 weeks. So after the 16th T there is a remission of skin manifestations. At T0-T12-T24 complete blood count is unchanged, whereas albumin, CRP and LDL-Chol. show significant reduction. Fibrinogen:  $p=ns$

**Discussion:** DFPP is a promising approach for MC as it leads to clinical remission because specifically improve blood rheology and tissue perfusion with a good safety profile. Larger studies could confirm it as a therapy in patients with MC, but in the meantime, it could help to build a new scientific evidence.

## SA-PO197

**Uremic Leontiasis Ossea Case**

Sara Fakhredine,<sup>1</sup> Jafar Alsaid,<sup>2</sup> Teerath Kumar,<sup>1</sup> Rayees Y. Sheikh.<sup>1</sup> <sup>1</sup>BSH, Manama, Bahrain; <sup>2</sup>Ochsner Medical Center, New Orleans, LA.

**Introduction:** Uremic leontiasis ossea (ULO) is a rare complication of untreated severe hyperparathyroidism in patients with ESRD. It is characterized by abnormal bone mineralization with severe and diffuse enlargement of the maxilla and mandible bones resulting in lion's face features. Given the widespread use of dialysis, calcimimetics, and phosphate binders, ULO is now rare.

**Case Description:** A 37-yr-old woman with ESRD secondary to FSGS. She had developed secondary hyperparathyroidism. She was poorly adherent to her dialysis sessions and prescribed medications. Her condition progressed to tertiary hyperparathyroidism over 10 years with a parathyroid hormone (PTH) level of 1,249 pg/mL and a serum calcium of 12.3 mg/dL. She had refused to undergo parathyroidectomy and was not compliant to her treatment despite multiple discussions. Her PTH increased to 5,814 pg/mL, serum calcium and serum phosphate were 8.8 and 3.9 mg/dl, respectively. Her complaints were headache, diplopia on lateral gaze, gum bleeding and nasal blockage. Over the course of 7 years, she sustained progressive facial changes with deformity of the maxillary and mandibular bones with widening of the interdental spaces (Image). Calciphylaxis, fractures of vertebra and right humerus ensued over the last two years. Maxillofacial computed tomography showed “pepper pot” appearance of skull. Parathyroid scan showed multiple nodules, the largest 3x3 cm. A DEXA scan revealed severe osteoporosis. The patient remains adamant not to have the surgery and the last PTH value of 3,476 pg/mL, serum calcium of 9.0 mg/dL and serum phosphate of 4.2 mg/dL.

**Discussion:** ULO is a rare and disabling complication of tertiary hyperparathyroidism in ESRD. Without treatment, irreversible bony deformities can occur. Adherence to treatment is critical to optimize its prognosis. The term was first used by by Kienböck in 1940. The treatment includes parathyroidectomy, percutaneous fine needle ethanol injection or Calcitriol in non-surgical candidates. Reconstructive surgery might be used to correct the bony deformities.

Figure1: Skin changes in the right leg before (a) and after (b) skin biopsy.

## SA-PO199

### Two Cases of Brown Tumors in ESRD Patients

Nihal Bashir. Seha Kidney Care-Tawam, Al Ain, United Arab Emirates.

**Introduction:** Two patients among our dialysis cohort were diagnosed with brown tumors, one young male had disfiguring maxillary growth.

**Case Description:** Case 1 A 40-year-old female, known case of lupus nephritis and end stage renal disease on haemodialysis, and history of parathyroidectomy due to tertiary hyperparathyroidism. MRI of the lumbar spine in 2017 showed a well-margined bone lesion involving the left iliac bone, measuring about 2 x 1.2 cm, second lesion is seen inferior to the former, measuring about 0.8 x 0.7 cm. Bone Scan showed delayed images show increased linear uptake in posterior left 12th rib and focal uptake at left eighth costochondral junction. There are foci of increased uptake in the cranium and mandible. DEXA scan showed T score of -3.1 and confirmed osteoporosis. Due to her Renal status - Bisphosphonate not suitable, other treatment options are Denosumab and Teriparatide but could not start neither of them as the patient had severe hypocalcaemia. Patient was started on teriparatide. Bone biopsy was negative for malignancy. Case 2 A 27 year old male, known to have renal transplant 2006 reinitiated on haemodialysis in 2009. He also suffered secondary hyperparathyroidism of renal origin with Brown tumour of the facial bone with gross distortion with previous debulking surgery, the patient is currently on etelcalcetide 7.5 mg intravenously on dialysis days. He had multiple disfiguring tumours as shown on images.

**Discussion:** Take home messages 1. Brown tumours are devastating and difficult to treat unless detected early in background of CKD-bone mineral disease. 2. Osteoporosis is difficult to diagnose and treat in ESRD patients.

Images of patient 1 showing PTH graph pre and post parathyroidectomy, pelvic x-ray showing red arrow pointing at bony lesion and skull x-ray red arrows showing 2 lesions.

## SA-PO198

### Calcific Uremic Arteriolopathy (CUA) Mimicking Infectious Cellulitis

Mina Awad,<sup>1</sup> Elvira O. Gosmanova.<sup>1,2</sup> <sup>1</sup>Albany Medical Center, Albany, NY; <sup>2</sup>Albany Stratton VA Medical Center Albany, Albany, NY.

**Introduction:** CUA is caused by dermis and subcutaneous fat small vessel calcifications leading to skin ischemia and necrosis. CUA is mainly observed in patients with ESKD. CUA usually presents with intensely painful skin nodules or lesions with characteristic purple net-like patterns in areas with high fat content. In this case, the initial presentation of CUA was a diffuse right lower extremity (RLE) erythema and severe pain that were misdiagnosed as infectious cellulitis.

**Case Description:** A 57-yo male with ESKD on HD developed progressively worsening RLE pain and redness. On exam, RLE was diffusely tender, swollen and erythematous but without skin breaks. There were no associated fever, leukocytosis or DVT. After 10 days of intravenous (IV) vancomycin for the diagnosis of infectious cellulitis, there was no improvement (Fig1a). X-ray of RLE (done to exclude fracture) showed prominent vascular calcifications. Therefore, diagnosis of CUA was suspected. After skin biopsy, empiric treatment with IV sodium thiosulfate 25grams after each HD was started with marked improvement in RLE pain within 1 week. A punch biopsy of RLE skin showed no signs of CUA; however, characteristic stellate lesion for CUA developed at the biopsy site (Fig1b). Patient's CUA risk factors included ESKD with high fluid gains, diabetes, uncontrolled hyperphosphatemia, treated with lanthanum (previously was on Ca acetate), secondary hyperparathyroidism (PTH>1000pg/ml) on etelcalcetide and paricalcitol.

**Discussion:** It is critical to know unusual presentations of CUA, such as CUA presenting with diffuse skin erythema resembling cellulitis rather than patchy retiform purpura with ulcerative lesions. Misdiagnosis may lead to inappropriate antibiotic use and a delay in CUA treatment. Constellation of severe pain and arterial calcifications in the affected area on x-ray were clues for the diagnosis of CUA. Skin biopsy may lead to skin ulceration and be unrevealing in 50% of cases. We advocate to avoid skin biopsy when clinical suspicion for CUA is high.

## SA-PO200

**The Masked Parathyroid Adenoma in CKD: Is It Overlooked?**

Mohammad Atari. *The University of Mississippi Medical Center, Jackson, MS.*

**Introduction:** Primary hyperparathyroidism (PHPT) is the leading cause of hypercalcemia in the outpatient setting, most commonly resulting from a solitary adenoma. PHPT is associated with hypercalciuria, kidney stones, chronic kidney disease (CKD), and/or nephrocalcinosis. On the other hand, CKD is associated with bone and mineral homeostasis abnormalities. PHPT can be masked or unmasked in certain conditions.

**Case Description:** Case 1: An 80-year-old female patient with multiple myeloma and CKD IV secondary to membranous nephropathy presented for follow-up. Calcitriol was resumed six months before this visit due to high parathyroid hormone (PTH) at 866 pg/mL and adjusted later due to a rise in serum calcium to 11.2-11.6 mg/dL. However, calcium continued to rise reaching 12.1 mg/dL and PTH increased to 1172 pg/mL. Phosphorus was normal. The findings prompted further evaluation; sestamibi scan revealed a large hyperfunctioning parathyroid adenoma in the mid-upper right lobe with concomitant mild hyperplasia on left. Case 2: A 60-year-old female patient with a history of nonischemic cardiomyopathy, atrial fibrillation, obstructive sleep apnea, and progressive CKD of unclear etiology presented for follow up. Labs showed worsening creatinine secondary to loop diuretic-induced hypovolemia with concomitant hypophosphatemia of 1.8 mg/dL, hypokalemia, and hypomagnesemia. Serum calcium was normal at 9.8 mg/dL. Furosemide was held and hydration was recommended, PTH was 360 pg/mL, and repeated labs showed calcium of 10.7 mg/dL and phosphorus of 4.3 mg/dL with improvement in serum creatinine. Sestamibi scan showed a hyperfunctioning adenoma in the inferior left lobe.

**Discussion:** Masked PHPT has been described in the setting of hypothyroidism and hypovitaminosis D secondary to malabsorption or malnutrition. Vitamin D replacement and thiazide therapy have been reported to unmask PHPT. Here we describe unmasking two cases of parathyroid adenoma-induced PHPT in CKD, one case was unmasked by starting calcitriol, and the other was unmasked by stopping furosemide. These cases emphasize the importance of carefully interpreting mineral metabolism parameters in CKD populations where PHPT can be subclinical, normocalcemic, and masked by vitamin D deficiency. Normocalcemic PHPT cannot be easily differentiated from secondary hyperparathyroidism in CKD patients, requiring high clinical suspicion and imaging studies to establish the diagnosis.

## SA-PO201

**When the Mouse Click Becomes a Mouse Bite**

Fatima Ayub,<sup>1</sup> Nithin Karakala,<sup>1</sup> Md R. Hasan.<sup>2</sup> <sup>1</sup>University of Arkansas System, Little Rock, AR; <sup>2</sup>Arkansas College of Osteopathic Medicine, Fort Smith, AR.

**Introduction:** Vitamin D supplements are readily available both over the counter as well as online. Intoxication from vitamin D supplements though rarely reported occurs more frequently, nowadays. We, hereby present a classic case of iatrogenic hypervitaminosis D with recurrent symptomatic hypercalcemia

**Case Description:** 66 years old female with past medical history of bipolar disorder was brought to the hospital for altered mentation. The patient was in her usual state of health until 2 days prior to presentation when she started having generalized weakness followed by confusion. Her only medications at home were over-the-counter vitamin supplements. Upon presentation, she was tachycardic, agitated and only oriented to self. Labs showed a serum calcium level of 17.5 mg/dL, ionized calcium of 2.28 mmol/L, 25-hydroxyvitamin D (25-OH vit D) of 310 ng/mL and a parathyroid hormone (PTH) level of 19.8 pg/mL. She also had acute kidney injury with a serum creatinine of 3.7 mg/dL. The patient was started on aggressive fluid resuscitation. Serum 1,25-dihydroxy vitamin D was reported more than 300 pg/mL. The serum calcium improved over the next 72 hrs with aggressive fluid resuscitation and loop diuretics, with improvement in mental status. Subsequent interview revealed that she was taking 10,000 units of vitamin D supplements for the last 5 years that she was purchasing from an online store as a treatment for her depression. She was recommended to stop taking vitamin D supplements and was subsequently discharged once her symptoms and hypercalcemia had resolved. However, she was readmitted for similar complaints and lab abnormalities within a week. She was again managed supportively with complete resolution of symptoms

**Discussion:** Vitamin D toxicity causing hypercalcemia, is extremely rare. The 25 OH vit D is converted to its active form, 1,25 OH vit D in the kidney, whose half-life is 4-6 hours. However, it is imperative to realize that the half-life of 25 OH vit D which primarily comes from diet is around 2-6 weeks. Hence, despite the normalization of serum calcium levels in a hypercalcemic patient there is usually a rebound increase in serum calcium due to the ongoing conversion of 25 OH vit D to 1,25 OH vit D for weeks. We, therefore, suggest that in patients presenting with concerning symptoms and hypercalcemia, particularly in the presence of normal parathyroid hormone level, a diagnosis of vitamin D toxicity should be suspected

## SA-PO202

**Hypercalcemia Secondary to Granulomatous Disease Caused by Cosmetic Injections**

Shilpi Shah, Jehan Z. Bahrainwala, Amanda K. Leonberg-Yoo. *University of Pennsylvania, Philadelphia, PA.*

**Introduction:** Polymethylmethacrylate (PMMA) is an injectable filler used cosmetically for the augmentation of body parts though only FDA approved for the face and hands. PMMA fillers can cause foreign body granulomas which can rarely

result in calcitriol mediated chronic hypercalcemia. We present a case of a patient with hypercalcemia, recurrent nephrolithiasis, and chronic kidney disease (CKD) due to PMMA injections received fifteen years prior.

**Case Description:** A 54-year-old man was admitted for serum calcium of 14.0 mg/dL (8.9-10.3 mg/dL) and ionized calcium level of 1.83 mmol/L (1.00-1.25 mmol/L). He reported ten years of hypercalcemia and recurrent nephrolithiasis of unknown etiology. He presented with acute kidney injury with a creatinine of 2.94 mg/dL (prior baseline 1.8 mg/dL), intact parathyroid hormone (iPTH) level 2.3 pmol/L (1.6-6.9 pmol/L), 25-OH vitamin D level 23 ng/mL (25-80 ng/mL), 1,25-OH vitamin D level 72 pg/mL (19.9-79.3 pg/mL), parathyroid related peptide <2 pmol/L (0-2.3 pmol/L). He had no paraproteinemia. He received PMMA fillers in his face, forearms, calves, and buttocks fifteen years ago and his exam showed raised nontender nodules in these areas. Skin biopsy of a lesion showed foreign body granulomas in the dermis. He was treated acutely with fluids and calcitonin with improvement in serum calcium and creatinine levels to 9.8 mg/dL and 2.13 mg/dL respectively. He was discharged on prednisone 20mg daily. He is off steroids and is now maintained on hydroxychloroquine (HCQ) 200mg twice daily, as reversal or dissolving of PMMA is not possible given the extent of his injections.

**Discussion:** PMMA filler induced hypercalcemia is rare, can be severe, and may present years after injections. Hypercalcemia is due to overactivity of extrarenal 1- $\alpha$ -hydroxylase activity in activated macrophages in granulomas resulting in pathological calcitriol production. Concomitant CKD may result in iPTH and calcitriol levels that are less suppressed and elevated than expected. Treatment options include steroids, bisphosphonates, or ketoconazole. Our patient is maintained on HCQ, which inhibits 1- $\alpha$ -hydroxylase activity and decreases calcitriol production. Early diagnosis of dermal filler-related disease is key to avoid complications such as CKD and recurrent nephrolithiasis as seen in our patient.

## SA-PO203

**Stone Formation in an Ileal Conduit due to a Refluxed Surgical Staple**

Justina Ray,<sup>1</sup> Latoya N. Gayle,<sup>2</sup> Aisha Shaikh.<sup>3,2</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY; <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY.

**Introduction:** Ileal conduits for urinary diversion are created following cystectomy. Patients with ileal conduits are at high risk for urinary tract calculi. Several factors predispose to stone formation following ileal conduit creation, including metabolic abnormalities, infections due to urea-splitting organisms, and the presence of foreign material in the ileal conduit. We describe a case of ileal conduit stone formation around a refluxed surgical staple.

**Case Description:** A 73-year-old female with a solitary left kidney and a history of bladder cancer underwent radical cystectomy and ileal conduit creation 10-years ago. She did not have a previous history of nephrolithiasis. She presented to the hospital after passing a stone in her urostomy bag. The stone was white in color, 2 cm in diameter, with a surgical staple encased within it (Image). The patient did not complain of abdominal or flank pain, and no hematuria or pyuria was present. CT Urogram showed no filling defect, foreign body, calculus, or dilatation of the renal calyces and pelvis. Metabolic acidosis, hypercalcemia, hyperuricemia, or hyperparathyroidism were not present. The stone was composed of 90% magnesium ammonium phosphate (struvite) and 10% calcium phosphate (apatite). No intervention was performed as no residual stones, or foreign bodies were present in the kidney or the ileal conduit.

**Discussion:** In ileal conduits, a loose surgical staple can serve as a nidus for stone formation. In most cases, the stone is passed spontaneously without any complications. However, in some cases, the loose surgical staple can reflux from the ileal conduit into the kidney leading to nephrolithiasis. Furthermore, the surgical staple can be completely embedded within the stone and not be visible to the naked eye. In such cases, radiographic imaging of the stone can reveal the encased staple. Nephrologists must be aware of this rare complication in patients with ileal conduits where a loose surgical staple can serve as a nidus for stone formation.

Image. A stone encasing a loose surgical staple.

**Frustratingly Frail: Following the Phosphorous**

Nolan M. Giehl,<sup>1,2</sup> Minhtri K. Nguyen.<sup>1</sup> <sup>1</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>2</sup>Kaiser Permanente Southern California, Woodland Hills, CA.

**Introduction:** Determining the etiology of persistent hypophosphatemia can be humbling and elusive. We present an extraordinary case of tumor-induced osteomalacia (TIO) after steadfast investigation.

**Case Description:** A 71-year-old man presented after 4 years of progressive muscle weakness, bony pain and debilitating osteoporosis with multiple pathologic fractures. He had no history of kidney disease, steroid use, growth deficiencies, hypogonadism, thyroid, or prostatic disease. Past bone marrow biopsy was normal. Initial laboratory data revealed severe hypophosphatemia (1.8 mg/dL), low vitamin-D-1,25 (10 pg/mL), but high-normal parathyroid hormone (57 pg/mL). Subsequent urine testing showed inappropriate phosphate wasting (740 mg/24hr) and high fractional excretion of phosphate (20.4%). Urinalysis was negative for glucosuria or proteinuria. Further serum testing for FGF23 was remarkably high (321 RU/mL). Follow up functional radiographic testing via <sup>68</sup>Ga-DOTATATE-based PET/CT showed a hyperdense lesion in C7-T1 concerning for mesenchymal tumor (Figure 1). This was confirmed on cervical spine MRI. Upon surgical consultation for tumor removal, he was deemed not a candidate based on tumor location. Started on anti-FGF23 therapy with IV burosumab monthly while awaiting reassessment for surgical candidacy, he has had normalization of serum phosphate and near resolution of musculoskeletal symptoms.

**Discussion:** TIO is a rare paraneoplastic syndrome of abnormal phosphorus metabolism caused by small mesenchymal tumors that secrete FGF23 leading to impaired bone metabolism and disability. Delayed diagnosis is common due to nonspecific symptoms, and years may elapse before patients receive a correct diagnosis and proper treatment. Increased awareness of the appropriate recognition and management of TIO is vital among providers who may encounter patients with suspected TIO to reduce morbidity. Furthermore, our case demonstrates that while curative surgical intervention is preferred, the newly FDA-approved anti-FGF23 therapy (burosumab) is an effective second line therapy at achieving phosphorus homeostasis and clinical improvement.

## SA-PO205

**Burosumab: An Option for Adults With Symptomatic X-Linked Hypophosphatemia**

Amer A. Belal, Rupam Ruchi. University of Florida College of Medicine, Gainesville, FL.

**Introduction:** X-linked hypophosphatemia (XLH) is a dominant disorder caused by an inactivating mutation in the PHEX gene. This increases fibroblast growth factor 23 (FGF23) that subsequently acts to inhibit phosphate reabsorption in the proximal renal tubules. While traditional treatment with phosphate replacement and calcitriol meets some goals, side effects such as nephrocalcinosis limit their use. Thus in 2018 the FDA approved Burosumab as a human anti-FGF23 monoclonal antibody for adults.

**Case Description:** We discuss the case of a 39-year-old woman with history of hypophosphatemic vitamin D resistant rickets diagnosed at 18 months. She has been followed by adult nephrology since age 19. At that time, she had lab work notable for 1, 25 Vitamin D level 61 pg/mL and PTH 134 pg/mL. Her urinary phosphate was inappropriately high at 0.6 g/24 hours despite hypophosphatemia of 1.8 mg/dL. As a child she was on phosphate supplementation but this was stopped due to nephrocalcinosis. She was maintained on dietary phosphate and calcitriol for the past twenty years with stable severe hypophosphatemia resulting in profound fatigue. Recently she completed genetic testing for PHEX gene mutation and FGF23[RR1]. Her FGF23 was normal at 140 RU/mL and her PHEX gene mutation was heterozygous positive for the pathogenic c.1715G>A (p.Gly572Asp) variant. She has a symptomatic son and a healthy daughter. Given her symptoms of fatigue and bone pain in setting of hypophosphatemia, she was started on Burosumab at 60 mg q4 weeks. Her phosphate improved to 3.2 mg/dL from 1.5 mg/dL with increase in total calcium to 10.3 mg/dL and ionized calcium 1.41 mmol/L. Her dose was decreased to 40 mg monthly with repeat labs showing normal calcium and phosphorous of 2.6 mg/dL with improved symptoms. On this dose her phosphate levels remained between 2.3-3.2 mg/dL and calcium levels 9.9-10.2 mg/dL until she was unfortunately lost to follow up resulting in need for cessation of Burosumab therapy with return of her symptoms of fatigue, bone/joint pain, and severe hypophosphatemia of 1.3 mg/dL. She has now been restarted on Burosumab therapy.

**Discussion:** This case is emblematic of the benefits of Burosumab therapy for adults with XLH. In keeping with clinical trials, treatment with Burosumab resulted in increased activity levels and overall quality of life along with improved phosphorus levels. Thus, we hold that it should be offered to symptomatic adults with XLH.

## SA-PO206

**Idiopathic Hypokalemia in a Patient With Autosomal Dominant Hypocalcemia (ADH) Type 2 With a GNA11 Point Mutation**

Rachael A. Silverberg, Maurice I. Khayat. Madigan Army Medical Center, Tacoma, WA.

**Introduction:** Calcium-sensing receptors (CaSR) expressed on parathyroid and renal tubule cells contribute to calcium homeostasis through negative-feedback. Activating mutations of the CaSR or downstream signaling components may result in Autosomal Dominant Hypocalcemia (ADH) Types 1 and 2. These rare disorders are characterized by hypocalcemia, hyperphosphatemia, and low PTH. While hypokalemia and metabolic alkalosis are reported among patients with ADH Type 1, this is not well established in ADH Type 2.

**Case Description:** A 22-year-old male presented with headaches, irritability, lethargy, perioral paresthesia, muscle and facial spasms progressive over several years with recurrent evaluations in the Emergency Department. Serial labs revealed hypocalcemia, hyperphosphatemia, and low iPTH as well as hypokalemia, hypomagnesemia, and metabolic alkalosis. Treatment comprised oral calcitriol and daily supplementation with calcium citrate, cholecalciferol, potassium chloride, and magnesium citrate. Genetic testing revealed a heterozygous likely pathogenic variant in the GNA11 gene (c.178C>T) associated with ADH Type 2. Testing for Gitelman Syndrome, ADH Type 1, and 22q11.2 deletion were negative. Despite daily supplementation and a high potassium diet, he reported continued symptomatic episodes of hypokalemia characterized by palpitations, headaches, nausea, and irritability. His aldosterone and plasma renin activity were within normal limits. A 24-hour urine study showed high renal excretion of potassium, calcium, and phosphorus.

**Discussion:** ADH type 2 results from a gain-of-function mutation in the GNA11 gene encoding a G-protein in the CaSR signaling pathway. Increased activation of this pathway reduces calcium reabsorption in the renal tubule and inhibits PTH synthesis and secretion. Hypokalemia from a Bartter's like syndrome has been reported in ADH Type 1 suspected from an inhibitory effect of the CaSR on the sodium-potassium-chloride (NKCC2) cotransporter. To our knowledge this is the first described case of hypokalemia in ADH type 2. While it may be due to similar downstream constitutive activation of the CaSR signaling pathway, his normal aldosterone and renin activity may suggest an alternative etiology. The views expressed above are those of the authors and do not reflect the official policy of the Army, Department of Defense, or US Government.

## SA-PO207

**Antibiotic Exposure and Kidney Stone Disease Across the Life Course**

Michelle Denburg,<sup>1,2</sup> Zeyu N. Li,<sup>2,1</sup> Jing Huang,<sup>2,1</sup> Lauren E. Parlett,<sup>3</sup> Kevin Haynes,<sup>4</sup> John R. Asplin,<sup>5</sup> Ingrid Y. Luna,<sup>1</sup> Charles Bailey,<sup>1,2</sup> Gregory E. Tasian.<sup>1,2</sup> <sup>1</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>2</sup>University of Pennsylvania, Philadelphia, PA; <sup>3</sup>HealthCore, Wilmington, DE; <sup>4</sup>Janssen Global Services LLC, Titusville, NJ; <sup>5</sup>LithoLink Corp, Chicago, IL.

**Background:** Kidney stone disease (KSD) is increasingly common and associated with considerable morbidity. Antibiotic (ABX) exposure may be a risk factor for KSD.

**Methods:** We examined the association between 12 classes of oral ABX and KSD in a case-control study nested in the HealthCore Integrated Research Database (HIRD) of longitudinally integrated medical and pharmacy claims from healthcare encounters of members with ≥6 months of continuous enrollment in commercial health plans across the United States from Jan 2006 to Jan 2020. Incidence density sampling was used to match cases 4-65 years of age at initial KSD diagnosis to up to 5 controls on year of birth, index date, pre-index enrollment time, sex, and geographic region. Exclusion criteria were inflammatory bowel disease, celiac disease, urinary obstruction, bariatric surgery, malignancy, cystic fibrosis, immobility, and neurogenic bladder. Conditional logistic regression models were stratified by age 18 and adjusted for other ABX use, healthcare utilization, comorbidities, UTI, thiazide and loop diuretics, H2 blockers, proton-pump inhibitors, statins, corticosteroids, and certain anti-epileptic agents.

**Results:** 69,793 children (11,622 cases/58,171 controls; 59.9% female) and 2,990,207 adults (498,393 cases/2,491,814 controls; 43.6% female) were included. Exposure to any of the 12 ABX classes in adults and 8 different ABX classes in children within 3-12 months prior to index was associated with KSD at the Bonferroni adjusted significance threshold (Table). The magnitude of association was greatest for fluoroquinolone, nitrofurantoin, and sulfa ABX with adjusted OR of 1.37-1.66 and similar effect estimates in sensitivity analyses excluding those with UTI during the exposure window and restricting to cases who had KSD surgery on or after index and their controls.

**Conclusions:** Leveraging a large claims database, we confirmed that exposure to oral ABX is associated with KSD diagnosis in children and adults.

Hypercalciuria and Risk for Hypercalcemia Among Veterans With Urinary Stone Disease

Calyani Ganesan,<sup>1</sup> I-Chun Thomas,<sup>2</sup> Carolyn D. Seib,<sup>1,2</sup> Simon Conti,<sup>1</sup> John Leppert,<sup>1,2</sup> Alan C. Pao,<sup>1,2</sup> <sup>1</sup>Stanford University School of Medicine, Stanford, CA; <sup>2</sup>VA Palo Alto Health Care System, Palo Alto, CA.

**Background:** Approximately 70-80% of patients with urinary stone disease form calcium-based stones. The most common abnormality detected in the urine of these patients is hypercalciuria. At the time of their stone diagnosis and urine calcium measurement, most patients have a normal serum calcium concentration. It remains unknown whether the level of urine calcium excretion associates with higher risk for developing hypercalcemia.

**Methods:** We used national Veterans Health Administration data to define patients with urinary stone disease as those with one or more inpatient or two or more outpatient encounters for urinary stone disease or one or more stone procedures between 2007 and 2019. We then selected patients who had a 24-hour urine measurement within 6 months of their stone diagnosis. We defined normocalcemia as a measured or albumin-corrected serum calcium measurement ≤ 10.2 mg/dL. We defined the primary outcome hypercalcemia as a measured or albumin-corrected serum calcium measurement > 10.2 mg/dL. We performed Cox proportional hazards regression to identify the risk of developing hypercalcemia by level of 24-hour urine calcium excretion.

**Results:** We identified 11,926 Veterans with urinary stone disease, normocalcemia, and a 24-hour urine calcium measurement. Within this cohort 23.8% (2841 individuals) had an elevated 24-hour urine calcium measurement ≥200mg/day and 4.6% (546 individuals) developed hypercalcemia. We found that level of 24-hour urine calcium excretion did not associate with risk of developing hypercalcemia.

**Conclusions:** Patients with urinary stone disease and normal serum calcium concentration are not at higher risk for developing hypercalcemia even if they have higher levels of 24-hour urine calcium excretion. Therefore, initial treatment should be aimed at correcting urinary risk factors. Further research is needed to clarify the utility of PTH measurement to guide further evaluation and surveillance in this population.

SA-PO209

Effects of Consistently Strict Phosphate Control on Vascular and Valvular Calcification in Incident Hemodialysis Patients

Mao Shimizu, Hideki Fujii, Keiji Kono, Kentaro Watanabe, Kazuo Sakamoto, Shunsuke Goto, Shinichi Nishi. *Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan.*

**Background:** Vascular calcification (VC) is a critical complication associated with cardiovascular disease in hemodialysis (HD) patients. The progression of VC is multifactorial, and serum phosphate control is particularly important. A recent randomized controlled trial (RCT) in maintenance HD patients showed that strict phosphate control slowed the progression of VC. Therefore, we investigated the effects of strict phosphate control on vascular and valvular calcification in incident HD patients.

**Methods:** This study was a post hoc analysis of our previous RCT regarding the effects of phosphate binders on VC in the incident hemodialysis (HD) patients. Computed tomography (CT) and ultrasoundcardiography (UCG) were performed at baseline and 18 months after initiation of HD, and we evaluated coronary artery calcium score (CACS) and cardiac valve calcification score (CVCS). Subsequently, the absolute changes in CACS (ΔCACS) and CVCS (ΔCVCS), and the percent change in CACS (%ΔCACS) and CVCS (%ΔCVCS) were calculated. Serum phosphate levels (serum P) were measured at 6, 12, and 18 months after initiation of HD, and phosphate control status was evaluated using the data as follows:(1) area under the curve (AUC) by multiplying the time spent with the extent to which serum P exceeded 4.5mg/dL, and (2) the number of times which serum P exceeded 4.5 mg/dL. The association of serum phosphate control with CACS and CVCS were investigated in this study.

**Results:** This study included 64 patients and they were divided into two groups depending on the median of AUC for serum P, both ΔCACS and %ΔCACS were significantly lower in the low AUC group (L-AUC) than in the high AUC group (H-AUC) (p <0.05). ΔCVCS and %ΔCVCS was also significantly lower in the L-AUC group than in the H-AUC group. Furthermore, ΔCACS and %ΔCACS were significantly lower, and ΔCVCS and %ΔCVCS tended to be lower in patients whose serum P were consistently below 4.5mg/dL than in those whose serum P were consistently over 4.5 mg/dl.

**Conclusions:** This study suggests that the consistently strict phosphate control could slow the progression of vascular and valvular calcification in incident HD patients.

Effects of Lanthanum Carbonate on Whole-Body Calcium Balance, Vascular Function, and Mineral Metabolites in Adults With CKD 3b-4 and Normophosphatemia

Anna Jovanovich,<sup>1</sup> Zhiying You,<sup>2</sup> Tyson J. Marden,<sup>2</sup> Moshe Levi,<sup>3,2</sup> Gregory G. Schwartz,<sup>1</sup> Michel Chonchol,<sup>2</sup> Kathleen M. Hill Gallant,<sup>4</sup> <sup>1</sup>VA Eastern Colorado Health Care System, Aurora, CO; <sup>2</sup>University of Colorado Health, Aurora, CO; <sup>3</sup>Georgetown University, Washington, DC; <sup>4</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** We previously showed long-term treatment with the phosphate binder lanthanum carbonate (LC) may reduce whole-body phosphorus (P) balance in adults with CKD 3b-4 and normophosphatemia (ASN <sup>21</sup> PO-0543). Long-term effects of LC on total body calcium (Ca) balance, vascular function, and mineral metabolites are unknown. We determined Ca balance in normophosphatemic adults with CKD 3b-4 after a 12w RCT of LC v. placebo, and relationships of Ca and P balance with vascular function and mineral metabolites.

**Methods:** A subset of 15 subjects with CKD 3b-4 were randomized to receive 12w of LC or placebo investigating effects of phosphate lowering on vascular function, assessed by brachial artery flow-mediated dilation (FMD), (NCT02209636) volunteered to participate in this ancillary aim. At the end of 12w, subjects consumed a control diet (1000 mg/d phosphorus and 800 mg/d calcium) for 9d and continued their randomized treatment (n=7 LC, n=8 placebo). Fasting AM blood samples and stool and urine were collected during a 48h inpatient balance study on day 8-9 of the controlled diet. Ca balance (mg/d) was determined by values averaged over the 48h period: dietary Ca intake – urine Ca – fecal Ca. We used T-tests to compare means, correlation coefficients to examine relationships between P and Ca balance with FMD, and fixed effects models to examine mineral metabolites change within groups.

**Results:** Subjects were 65±7y with eGFR 33±6 mL/min/1.73m<sup>2</sup>. We excluded 1 LC subject from balance results due to insufficient stool. 24h urine Ca was similar with LC and placebo (46±28 v. 40±32 mg, p=0.73). Fecal Ca was higher with LC compared with placebo (737±446 v. 317±138 mg, p=0.03), and whole-body Ca balance was lower with LC compared with placebo (-46±410 v. 410 ±131 mg, p=0.01). Neither P nor Ca balance correlated with FMD in either group (all p>0.05). FGF-23 decreased over the study with LC (p=0.03), but 25D, 1,25D, and PTH did not change.

**Conclusions:** Long-term treatment with LC may reduce whole-body Ca balance in adults with CKD 3b-4 and normophosphatemia, but neither P nor Ca balance correlated with FMD. FGF23 decreased with LC, which coincided with negative Ca balance and a trend towards negative P balance.

Etelcalcetide Improves Bone Turnover in Renal Osteodystrophy Possibly Through Regulation of Bone Immunity and Inflammation

Zheng Cai-Mei,<sup>1</sup> Kuo-Cheng Lu,<sup>2</sup> Yi-Chou Hou,<sup>2</sup> Chien-Lin Lu,<sup>2</sup> Hui-Wen Chiu,<sup>1</sup> <sup>1</sup>Taipei Medical University College of Medicine, Taipei, Taiwan; <sup>2</sup>Fu-Jen Catholic University, Taipei, Taiwan.

**Background:** Etelcalcetide, a new calcimimetic agent, allosterically binds the extracellular N terminal domain of calcium-sensing receptor (CaSR) and consequently decreases PTH secretion. As such, it is approved to use in chronic kidney disease-mineral and bone disorder (CKD-MBD) among dialysis patients. We hypothesized that the direct protective effects of etelcalcetide on bone exist in these patients and might be explained by direct anti-oxidant and/or anti-inflammatory effects on bone cells other than lowering PTH levels.

**Methods:** Osteoclasts (OC) and osteoblasts (OB) were differentiated by the mice macrophage cell line RAW264.7 and mouse muscle myoblast C2C12, respectively. OC differentiation was analyzed by tartrate resistant acid phosphatase (TRAP). OB proliferation was evaluated by ALP activity. Furthermore, RNA-Sequencing (RNA-seq) was determined by next-generation sequencing (NGS). Genes with a 1.5-Fold change threshold are uploaded to the Ingenuity Pathway Analysis (IPA) in RAW264.7 cells. In addition, PCR analysis on RAW264.7 cells confirm these IPA-based molecular mechanisms underlying etelcalcetide on osteoclast differentiation.

**Results:** Etelcalcetide dose-dependently inhibited OC differentiation as indicated by decreased TRAP levels. On the other hand, etelcalcetide dose-dependently increases OB proliferation as indicated by increased ALP activity. It also affects several pathways in RANKL-induced differentiation of macrophages to osteoclasts. Possible molecular mechanisms as expressed by IPA analysis include: etelcalcetide induced activation of interferon regulatory factor IRF-7/IFN-alpha/beta dependent inhibition of NF-kB related RANK-L induced osteoclastogenesis. On the other hand, it possibly inhibited

the TRIM24/IRF3-STAT signaling pathways to inhibit osteoclastogenesis. PCR analysis revealed an increase in IRF7 expression but had no significant effect on TRIM24.

**Conclusions:** We found the beneficial roles of etelcalcetide in improving bone anabolism by a dual mechanism on bone cells, inhibiting osteoclast differentiation and increasing osteoblast maturation and differentiation. The underlying novel pathways might be through regulation of the cellular energy metabolism, immunity and inflammatory pathways in CKD-MBD-related bone loss.

AKI Promotes Osteoid Formation Through Increased PTH Secretion in Rats

Yosuke Nakagawa, Hirotaka Komaba, Naoto Hamano, Kaichiro Sawada, Takehiko Wada, Michio Nakamura, Masafumi Fukagawa. *Tokai Daigaku Igakubu Jin Naibunpi Taisha Naika, Isehara, Japan.*

**Background:** Acute kidney injury (AKI) can induce alterations in mineral metabolism, but little is known about the longitudinal changes in bone morphology in the course of AKI and renal recovery. The purpose of this study was to determine the effect of AKI on mineral and bone metabolism and the underlying mechanism in a rat model of ischemia reperfusion injury (IRI).

**Methods:** Six-week-old male Sprague-Dawley rats were subjected to 35-min bilateral IRI or sham surgery. We evaluated the time course of changes in kidney function and mineral metabolism after surgery and assessed bone morphology at 3 days and 4 weeks by bone histomorphometry. We also repeated the experiment after performing parathyroidectomy followed by continuous infusion of 1-34PTH at a physiological dose.

**Results:** Rats with IRI exhibited acute hyperphosphatemia, decreased 1,25-dihydroxyvitamin D, and progressively increasing FGF23 and PTH levels, and demonstrated a striking increase in osteoid volume on day 3. During renal recovery, alterations in mineral metabolism and bone morphology normalized almost completely by week 4. To investigate the mechanism of the transient induction of osteoid formation after IRI, we performed qPCR of RNA isolated from femurs at 24 hours after surgery and found increased expression of *secretory leukocyte protease inhibitor (SLPI)*, a downstream mediator of PTH-induced bone formation, suggesting a causal role of PTH in the osteoid formation after IRI. Supporting this possibility, we confirmed that parathyroidectomy prevented the induction of osteoid formation at 3 days after IRI.

**Conclusions:** AKI induces a transient, but marked increase of osteoid formation in association with alterations in mineral metabolism and increased PTH. The induction of osteoid formation after AKI can be attributed to the anabolic effect of PTH on bone.

SA-PO213

Increased Expression of DKK-1 in an Adynamic Bone Disease Model: Role of Phosphate

Tânia P. Truyts, Juliana C. Ferreira, Katia R. Neves, Ivone B. Oliveira, Wagner Dominguez, Vanda Jorgetti, Rosa M. Moyses, Luciene dos Reis. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

**Background:** Adynamic Bone Disease (ABD) is a common complication of Chronic Kidney Disease (CKD). We have previously shown that the Wnt/ $\beta$ catenin signalling pathway is inhibited in the early stages of CKD, in association with an increased bone expression of sclerostin. DKK1 is also increased in CKD in a high-turnover animal model characterized by high phosphate (P) and PTH levels. Here we tested whether DKK1 expression is increased in an ABD model, trying to identify the isolated effects of P on this pathway.

**Methods:** Wistar rats were submitted to 5/6 nephrectomy (NX) and Parathyroidectomy (PTX). They were divided into 3 groups that underwent pair-feeding with different concentrations of P. Bone expression of sclerostin, Dkk1 and  $\beta$ Catenin was evaluated using mRNA levels and immunohistochemistry (IH), whereas FGF23 was evaluated by IH.

**Results:** NX animals presented higher levels of creatinine and P, but lower serum FGF23 (figure). Compared with SHAM, a high-P diet was associated with an increase in SOST and DKK1 mRNA levels, which was corrected by a decrease in P content in the diet. In IH, a high-P diet was associated with increased osteocytic expression of FGF23 and DKK1, but not sclerostin. A low-P diet increased active  $\beta$ catenin IH expression. A significant correlation between bone FGF23 and DKK1 expression ( $r=0.5628$ ;  $p=0.0028$ ) was observed.

**Conclusions:** ABD is associated with a high bone expression of DKK1 and FGF23, which was normalized by P diet restriction. Our results suggest that in a low PTH environment, decreasing P content in the diet can stimulate the Wnt/ $\beta$ catenin pathway. These findings have to be confirmed in a clinical scenario.

Severe Bone Loss Occurs in Slow but Not in Fast CKD Progression

Hao-Hsuan Tsai, Dominik Kentrup, Xueyan Wang, Bridget Hunt-Tobey, Jadeah J. Spindler, John C. Von Drasek, Valentin David, Aline Martin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Alterations in mineral metabolism contribute to bone fragility and increased mortality in chronic kidney disease (CKD). The pathogenic mechanisms of CKD-associated bone disease are unclear.

**Methods:** We studied the Col4a3 knockout model of progressive CKD on two genetic backgrounds: the fast progressing 129X1/SvJ (129Sv-CKD) mice (lifespan: 11 weeks) and the slow progressing C57BL6/J (B6-CKD) mice (lifespan: 23 weeks) and age-matched wild-type (WT) littermates. In all mice, we assessed markers of kidney function, mineral metabolism and 3D bone microarchitecture every 2 weeks in 129Sv mice, and every 4 weeks in B6 mice.

**Results:** 129Sv-CKD mice showed a rapid decline in kidney function from 6 to 10 weeks of age shown by a progressive increase in blood urea nitrogen (BUN) levels ( $p<0.05$  vs. WT at 8 and 10 weeks). At 6 weeks, 129Sv-CKD mice showed mild elevations of fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) levels that severely worsened as kidney function declined ( $p<0.05$  at 6, 8 and 10 weeks). Overt hyperphosphatemia developed only at 10 weeks ( $p<0.05$ ). Starting at 8 weeks, 129Sv-CKD mice showed mild bone loss (-3% in bone mineral density (BMD), +8% in cortical bone porosity (Ct.Po)) ( $p<0.05$ ). Compared to 129Sv-CKD mice, B6-CKD mice showed a delayed and slow decline in kidney function marked by rising BUN levels starting only at 12 weeks ( $p<0.05$  vs. WT at 16, 20 and 23 weeks). Of note, BUN levels were similar in 10 week-old 129Sv-CKD and 23 week-old B6-CKD mice. In B6-CKD mice, FGF23 and PTH levels started to increase also at 12 weeks ( $p<0.05$  vs. WT at 16, 20 and 23 weeks). Despite a severe increase in PTH levels, FGF23 increase was milder in B6-CKD than in 129Sv-CKD mice, resulting in more pronounced hyperphosphatemia ( $p<0.05$  vs. WT at 20 and 23 weeks). In contrast with 129Sv-CKD mice, B6-CKD mice showed severe bone loss from 12 weeks of age, and reaching dramatic reductions in trabecular bone volume (-40%) and BMD (-15%), cortical thickness (-26%) and BMD (-6%), and increased Ct.Po (+60%) at 23 weeks ( $p<0.05$  vs. WT from 12 to 23 weeks).

**Conclusions:** To conclude, sustained alterations in mineral metabolism and kidney function induce severe bone loss in CKD.

The Cross-Talk Between Bone and Iron Overload in Hemodialysis Patients

Hanna Karla A. Guapyassu Machado,<sup>1</sup> Luciene dos Reis,<sup>1</sup> Lucas A. Nunes,<sup>1,2</sup> Ivone B. Oliveira,<sup>1</sup> Cleonice Silva,<sup>1</sup> Wagner Dominguez,<sup>1</sup> Rosa M. Moyses,<sup>1</sup> Melani Custodio,<sup>1</sup> Vanda Jorgetti.<sup>1</sup> <sup>1</sup>Laboratorio de Fisiopatologia Renal, LIM16, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>Hospital Universitario Joao de Barros Barreto, Belem, Brazil.

**Background:** Chronic kidney disease (CKD) has several complications, including mineral and bone disorder (MBD) and anemia, whose correction can favor iron overload. Little is known about the effects of iron overload on bone, as well as of Deferoxamine (DFO) treatment.

**Methods:** We prospectively evaluated the effects of 12-month of DFO therapy on CKD-MBD markers and bone histomorphometry in 18 hemodialysis patients. Osteocytic proteins expression was quantified through immunohistochemistry (DMPI, MEPE,

Sclerostin, FGF23, OPG, RANKL, DKK1 and CD44), and bone marrow iron positive cells (CellsFe+) were counted. During follow-up, we maintained CKD-MBD therapy to keep serum PTH in the target range.

**Results:** DFO decreased markers of iron overload, as well as CellsFe+. Few changes in CKD-MBD markers were seen (Image). Bone histomorphometry showed an increase in trabecular separation and a decrease in the osteoblast surface. Mineralization defect was present in most patients (67%), which was not corrected with DFO (61%). We found a significant increase in DMP1 and a decrease in DKK1 expression after DFO. No significant changes were seen in the other proteins.

**Conclusions:** Although few histomorphometric changes were seen after DFO therapy, it seems that bone marrow iron overload is associated with a suppression in DMP1, a protein involved in bone mineralization. In addition, the reduction in CellsFe+ might be involved with the decreased DKK1 expression, suggesting that iron accumulation in bone marrow might affect the osteocytic expression of proteins that are involved and bone mineralization and formation. Therefore, iron supplementation must be done cautiously in CKD patients.

Comparison of Cat to Human Calcium Oxalate Monohydrate Kidney Stone Matrix Proteomes  
Jeffrey Wesson,<sup>1,2</sup> <sup>1</sup>Department of Veterans Affairs, Milwaukee, WI; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.

**Background:** Despite its critical nature, the role of matrix in calcium oxalate stone formation is poorly understood. The wide diversity of proteins comprising matrix has contributed to the ambiguity. Because cats share many clinical characteristics of their stone disease with humans, we have compared the protein distributions measured by mass spectrometry in human calcium oxalate stone matrix to that observed in cat stone matrix.

**Methods:** Raw data from previously published proteomic studies of human urine and calcium oxalate monohydrate stone matrix were acquired and re-analyzed with similarly acquired proteomic data for calcium oxalate monohydrate stones obtained from cats. All data were analyzed using in house developed algorithms at the Mayo Clinic Proteomic Facility using the human or cat protein databases as appropriate. The observed protein distributions were analyzed in the context of a recent model of stone formation based on the aggregation of strongly anionic and strongly cationic proteins which includes selective adsorption of other proteins based on total charge.

**Results:** Matrix protein distributions shared many common features between humans and cats, including enrichment of both strongly anionic and strongly cationic proteins, increased total charge in matrix proteins compared to urine proteins, and a high degree of similarity of prominent strongly anionic proteins in the matrix of both species. However, there was weaker overlap of the specific dominant proteins in other regions of the net charge distribution.

**Conclusions:** Collectively, these observations support the conceptual model where the strongly anionic proteins associate most strongly with the calcium oxalate crystal surfaces, while the other proteins associate with the strongly anionic proteins through nonspecific, charge interactions with each other to create stones. Also, cats appear to be the best animal model of human stone disease identified to date based on these similarities.

To Study the Association of Bone Mineral Density With Clinical Activity in Adult-Onset Nephrotic Syndrome  
Arun Prabhakar, Prabhjot K. Johal, Joyita Bharati, Vinod Kumar, Raja Ramachandran. Post Graduate Institute of Medical Education and Research, Chandigarh, India.

**Background:** Nephrotic syndrome and its treatment culminate in multifarious bone and mineral metabolism abnormalities. Dual Energy X-ray Absorptiometry (DEXA) scan predicts bone mineral density (BMD) alterations in children with Nephrotic syndrome. Bioavailable 25(OH)-vitamin D (free plus albumin-bound) is a better measurement of vitamin D status than total 25(OH)-Vitamin D. There is a paucity of clinical studies evaluating BMD and bioavailable 25(OH)-vitamin D and its association with clinical activity in patients with adult-onset nephrotic syndrome.

**Methods:** We partook in a prospective observational study in adult-onset nephrotic syndrome (podocytopathy or primary membranous nephropathy) followed-up for 1-year. Patients underwent bioavailable 25(OH)-Vitamin D levels and DEXA (Dual Energy X-ray Absorptiometry) scan before and after 1-year of immunosuppressive therapy. We determined the bioavailable 25 (OH)-Vitamin D using modified Vermeulen Equations. All patients received steroid-based therapy consistent with the current standard of care along with vitamin D and calcium supplementation. Remission was defined as per the latest KDIGO 2021 clinical practice guideline for the management of Glomerular disease.

**Results:** We enrolled a total of 30 patients in the study. The median proteinuria, serum albumin and creatinine at baseline were 7.1 gm/day (5.25, 15.5), 2.34 gm/dl (2, 2.26) and 0.945 mg/dl (0.70, 1.25), respectively. The median bio-available 25(OH)-Vitamin D significantly increased from 3.67 ng/mL (1.29, 6.44) to 16.86 ng/mL (8.24, 28.16) (p<0.001). But, the BMD of the lumbar spine and the hip did not change significantly from the baseline (0.91±0.12 g/cm2 and 0.94 ± 0.14 g/cm2 to 0.89± 0.12 g/cm2 and 0.91 ± 0.11 g/cm2 respectively). No significant change was observed in bio-available 25(OH)-Vitamin D and BMD (both hip and lumbar spine) between those who achieved remission and those who did not.

**Conclusions:** Treatment of nephrotic syndrome with immunosuppressive therapy is not associated with BMD decline. Reduction in proteinuria along with calcium and vitamin D supplementation probably mitigates the deleterious impact of steroids on BMD in patients with nephrotic syndrome.

SA-PO218

Low Bone Density as a Risk Factor for Depressive Symptoms in Elderly Patients With Non-Dialysis Dependent CKD  
Dong-Young Lee. Seoul Veterans Hospital, Gangdong-gu, Seoul, Republic of Korea.

**Background:** Chronic kidney disease (CKD) is a common disease especially among older people. Moreover, major depressive disorder is one of the most common comorbid conditions in persons with CKD. Both conditions can predispose morbidity and mortality. We aimed to evaluate the etiology of CKD and comorbid depression by investigating bone disorders that are observed in persons affected by both CKD and depression.

**Methods:** We conducted a cross-sectional study with a total of 646 patients with CKD. Depressive symptoms were defined as a score on the K-BDI II greater than 11. We compared the sociodemographic factors, kidney function, markers for CKD-Mineral and Bone Disorder and bone mineral density according to the depressive symptoms. We conducted a multivariate logistic regression analysis to calculate adjusted odd ratios and 95% confidence interval for depressive symptoms in patients with CKD.

**Results:** Individuals with CKD and depressive symptoms was associated with lower level of education attained, living alone, exercising less, low 24-hour urine phosphorus, and low bone density. Depressive symptoms were significantly associated with low bone density in lowest parts (1.55 [1.06-2.29]) and in total hip (1.72 [1.17-2.53]) even after adjusting for diabetes mellitus, hypertension, kidney function, proteinuria, age, sex, smoking, and body mass index.

**Conclusions:** Low bone density was identified as a risk factor for depressive symptoms in elderly patients with non-dialysis chronic kidney disease.

## Association of Vitamin D Levels and Bone Mineral Density in Elderly CKD Patients With Hip Fracture

Debajyoti M. Roy, Chee Yong Ng, Wenxiang Yeon, Sreekanth Koduri. *Changi General Hospital, Singapore, Singapore.*

**Background:** Vitamin D deficiency is common in chronic kidney disease (CKD) and is associated with lower bone mineral density (BMD), decreased muscle strength, and increased hip fracture risk. Guidelines have suggested optimal Vitamin D levels between 20-30ng/ml. However, Vitamin D metabolism is altered in CKD, and optimal levels are unknown.

**Methods:** We included 1097 patients with hip fractures. CKD was defined as estimated glomerular filtration rate <60ml/min/1.73m<sup>2</sup>, and low BMD defined as T score ≤-2.5 at femoral neck. We assessed the utility of using a 25-Vitamin D (25(OH)D) threshold of 30ng/dl, as well as a new threshold, to predict low BMD, in patients with, and without CKD.

**Results:** CKD was present in 479 (44%) patients. Using threshold of 25(OH)D <30ng/ml, there was no significant differences in patients with CKD and low BMD, compared to the other groups. We identified 27ng/ml as a better threshold with the Youden index. Using 25(OH)D <27ng/ml as a threshold, 360 of 482 patients (74.7%) with low Vitamin D had low BMD, compared to only 185/276 (67%) of patients with adequate Vitamin D, p=0.02, which was irrespective of presence or absence of CKD. Furthermore, patients with CKD and 25(OH)D <27ng/ml had a higher odds ratio of mortality upon follow-up, 1.61, 95% CI: 1.08 – 2.39, compared to those with CKD and 25(OH)D ≥ 27ng/ml.

**Conclusions:** Vitamin D <27ng/ml is associated with low BMD in patients with, and without, CKD. Further prospective studies targeting Vitamin D repletion to at least 27ng/ml, and outcome of hip fractures will be useful to validate these findings.

**Table: Demographic characteristics of patients based on CKD status**

Characteristics	CKD (n=479)	Non CKD (n=678)

## Bone Marrow-Derived C5aR Contributes to Kidney Inflammation and Tubulointerstitial Fibrosis in Streptozotocin (STZ)-Induced Diabetic Nephropathy

Jingyuan Ma, Wai Han Yiu, Sarah W.Y. Lok, Yixin Zou, Loretta Y.Y. Chan, Sydney C. Tang. *The University of Hong Kong, Hong Kong, Hong Kong.*

**Background:** Emerging evidence shows a pathogenic role of C5a in the progression of diabetic nephropathy (DN). However, the contribution of C5aR signaling from circulating leukocytes and resident kidney cells to the progression of DN has not yet been investigated.

**Methods:** Bone marrow chimeras were generated by transplanting GFP-expressing bone marrow cells from donor mice (GFP-C5aR<sup>+/+</sup> WT or GFP-C5aR<sup>-/-</sup> KO) into irradiated recipient mice (C5aR<sup>+/+</sup> WT or C5aR<sup>-/-</sup> KO) via intravenous injection. They were: 1) GFP-C5aR<sup>+/+</sup> to C5aR<sup>+/+</sup> (WT→WT), 2) GFP-C5aR<sup>+/+</sup> to C5aR<sup>-/-</sup> KO (WT→KO), 3) GFP-C5aR<sup>-/-</sup> to C5aR<sup>+/+</sup> (KO→WT) and 4) GFP-C5aR<sup>-/-</sup> to C5aR<sup>-/-</sup> KO (KO→KO). Peripheral blood and bone marrow samples from the chimeras were used for engraftment analysis by flow cytometry. Six weeks after transplantation, all chimeric mice were subjected to low-dose (50 mg/kg; 5 consecutive days) streptozotocin (STZ)-induced diabetes for 12 weeks. Blood samples and kidneys were harvested for determination of kidney function, inflammation and fibrosis.

**Results:** Chimerism was confirmed with more than 97% of bone marrow cells and 95% of circulating CD45<sup>+</sup> cells being GFP positive. At 12 weeks after STZ injection, blood glucose levels were significantly increased which were not different among all diabetic groups. Serum creatinine in diabetic WT→WT recipients was elevated while that from diabetic WT→KO, KO→WT and KO→KO recipients was lower. Kidney expression levels of MCP-1, TNF-α and fibronectin were also significantly increased in diabetic WT→WT recipients, but they were only suppressed in the diabetic KO→WT and KO→KO groups.

**Conclusions:** Diabetic chimeric mice reconstituted with C5aR<sup>-/-</sup> bone marrow cells were protected from kidney inflammation and fibrosis, suggesting that C5aR signaling in bone marrow-derived cells is a key driver in STZ-induced DN.

## Comparison of Renal and Metabolic Effects of Empagliflozin and Dapagliflozin on Type 2 Diabetes-Induced Rats

Nadir Emre Herdan, Meltem Gursu, Sahabettin Selek, Ganime Coban, Rumeysa Kazancioglu. *Bezmialem Vakif Universitesi Tıp Fakultesi, Istanbul, Turkey.*

**Background:** Diabetes mellitus is a disease that affects millions of people worldwide. Extensive clinical studies are ongoing on Empagliflozin and Dapagliflozin, in patients with heart failure and chronic renal failure. The aim of this study is to investigate the equivalence and superiority of different SGLT2 inhibitors by comparing the metabolic and renal effects.

**Methods:** 44 Sprague-Dawley rats were divided into four groups, which had unrestricted access to food and water (ad libitum). Following a three-week high-fat diet, streptozotocin was administered, and groups were randomly divided based on mean glucose levels. Treatment was applied for one month. Serum and urine samples were collected before and after 1 month of the treatment. Urine samples were analysed with NMR and confirmed with Mass Spectrometry. Kidneys were collected at the end of the experiment for histological analysis.

**Results:** The Empa-treated group had considerably decreased blood glucose levels as compared to the Dapa group (p<0.001). While treatment groups did not exhibit a meaningful increase in plasma insulin levels, the placebo group did (p=0.027). The placebo group had a significant increase in BUN levels (p=0.006), but the treatment groups did not exhibit this change. Both Empa and Dapa-treated groups ameliorated interstitial inflammation, mesangial expansion, and basal membrane thickening equally well.

**Conclusions:** In conclusion, different molecules from the SGLT2-inhibitors are not equally effective on various parameters. In terms of blood and urine parameters, Empagliflozin outperformed Dapagliflozin, while both medicines showed equal improvement in terms of kidney histology. Our research demonstrates that SGLT2 inhibitors' renoprotective effects extend beyond their glucose-lowering properties.

**Funding:** Commercial Support - The Scientific and Technological Research Council of Turkey (TUBITAK)

## Nephroprotective Effects of Semaglutide in a Mouse Model of Hypertension-Accelerated Diabetic Kidney Disease

Stine T. Bak,<sup>1</sup> Louise Dalbøge,<sup>1</sup> Michael Christensen,<sup>1</sup> Thomas Secher,<sup>1</sup> Nicole Endlich,<sup>2</sup> Vedran Drenic,<sup>2</sup> Martin R. Madsen,<sup>1</sup> Henrik H. Hansen,<sup>1</sup> Ida Rune,<sup>1</sup> Lisbeth N. Fink,<sup>1</sup> Mette V. Østergaard.<sup>1</sup> <sup>1</sup>Gubra, Hoersholm, Denmark; <sup>2</sup>NIPOKA GmbH, Greifswald, Germany.

**Background:** Obesity, hyperglycemia and hypertension are critical risk factors for development of diabetic kidney disease (DKD). Emerging evidence suggests that glucagon-like peptide-1 receptor (GLP-1R) agonists improve cardiovascular and renal outcomes in type 2 diabetes patients. Here, we characterized the effect of long-acting GLP-1R agonist semaglutide alone and in combination with an ACE inhibitor in a model of hypertension-accelerated, advanced DKD facilitated by adeno-associated virus-mediated renin overexpression (ReninAAV) in uninephrectomized (UNx) female *db/db* mice.

**Methods:** Seven weeks after ReninAAV administration and six weeks post-UNx, *db/db* UNx-ReninAAV mice were administered (q.d.) vehicle, semaglutide (30 nmol/kg, s.c.) or semaglutide (30 nmol/kg, s.c.) + lisinopril (30 mg/kg, p.o.) for 11 weeks. Endpoints included blood pressure, plasma/urine biochemistry, kidney histopathology and RNA sequencing.

**Results:** Semaglutide robustly reduced hyperglycemia, hypertension and albuminuria concurrent with notable improvements in glomerulosclerosis severity, podocyte filtration slit density, urine/renal kidney injury molecule-1 (KIM-1) levels and gene expression markers of inflammation and fibrogenesis. Co-administration of lisinopril further ameliorated hypertension and glomerulosclerosis.

**Conclusions:** Semaglutide improves disease hallmarks in the db/db UNX-ReninAAV mouse model of advanced DKD. Renal outcomes were further improved by combined antihypertensive standard-of-care.

## SA-PO223

### Declining GFR and Advanced Pathology in a Translational Mouse Model of Diabetic Kidney Disease

Arianne Van Koppen,<sup>1</sup> Andrea R. Nawrocki,<sup>2</sup> Tri Q. Nguyen,<sup>3</sup> Simon A. Hinke,<sup>2</sup> Reinout Stoop,<sup>1</sup> <sup>1</sup>TNO, Leiden, Netherlands; <sup>2</sup>Janssen Research and Development LLC, Raritan, NJ; <sup>3</sup>Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands.

**Background:** The incidence of diabetic kidney disease is increasing world wide. Development of novel therapeutics is hampered by the lack of animal models since most models only resemble the early phases of the disease. We developed a translational diet-induced mouse model. To evaluate which phases of diabetic nephropathy could be reached, we investigated decline of renal function over time and quantitatively measured histopathological damage.

**Methods:** Male KKAY mice underwent uninephrectomy (UNX). After a recovery mice were fed a high fat diet (45% LARD) and received 50 mg/L LNNA in the drinking water. Body weight, food and water intake were measured weekly. Retro orbital injection with FITC-inulin were used to measure GFR transdermal over time. UACR was also evaluated over time. Mice were terminated after 20 weeks and kidney damage was quantitatively scored by a team of renal pathologists.

**Results:** We previously showed that using a dietary intervention in combination with a vasoconstrictor in the drinking water, male KKAY develop hyperglycemia, hyperlipidemia and hypertension. Hyperfiltration was detected as early as 2 weeks after diet induction after which GFR continuously declined until termination (week 20). UACR was strongly increased and reached a plateau phase around week 12. Pathological evaluation revealed that only 18% of the glomeruli were healthy and scoring showed diffuse and nodular mesangial expansion and global glomerulosclerosis, interstitial fibrosis and tubular atrophy and tubulo-interstitial fibrosis.

**Conclusions:** Time course GFR measurements showed that in male KKAY mice on a HFD and LNNA (50 mg/L) the kidney goes through a period of hyperfiltration followed by continuous decline resulting in significant renal pathology. Together with a maximized UACR this indicated that the model reached the overt phase (4) of disease development and can be used to studied the more advanced stages of the disease as well as the early phases.

## SA-PO224

### Gender Affects Diabetes and Diabetic Nephropathy Development in KKAY Mice

Arianne Van Koppen,<sup>1</sup> Andrea R. Nawrocki,<sup>2</sup> Tri Q. Nguyen,<sup>3</sup> Simon A. Hinke,<sup>2</sup> Reinout Stoop,<sup>1</sup> <sup>1</sup>TNO, Leiden, Netherlands; <sup>2</sup>Janssen Global Services LLC, Titusville, NJ; <sup>3</sup>Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands.

**Background:** We are developing a translational mouse model of advanced diabetic nephropathy which resembles both pathophysiology and pathology of the human situation. Diabetes affects men and women differently but treatment guidelines remains equal. Understanding gender differences is key to develop personalized therapeutics. We aim to study how gender influences diabetes induction and development of diabetic nephropathy in mice.

**Methods:** Male and female KKAY mice of 8 weeks underwent a uninephrectomy. After recovery, all mice were fed a high fat diet (HFD). Females received 100 mg/L LNNA in drinking water. Males were split in two groups and received either 50 or 100mg/L LNNA in drinking water. Body weight, food and water and blood glucose were monitored regularly. GFR by FITC-inulin clearance was measured transdermal. Albuminuria, BUN and organ weights were measured terminally. Pathology was scored by renal pathologists. KK females were used as non-induced control mice.

**Results:** Despite equal starting weights, females ate less but gained more weight on HFD compared to males. Blood glucose did not increase in females compared to controls but increased in males (12 vs 20 mmol/L). Initial (2-kidney) GFR was 1.6x higher females compared to males (554±73 vs 371±64 µL/min) and 1.5x after UNX. GFR in the females dropped towards the males GFR 4 weeks after diet initiation. UACR increased from 600 µg/mg towards 41200 µg/mg in all groups. BUN was highest in males on 100 mg/L LNNA (40 mg/dL) followed by males on 50 mg/L LNNA (28 mg/dL) and females on 100 mg/L LNNA (23 mg/dL). Kidneys of males (50 mg/L LNNA) were significant heavier than females (100 mg/L LNNA). Pathology showed extensive glomerular and mild tubular damage with arteriolar hyalinosis in males (50 and 100 mg/L LNNA). Females showed moderate glomerular damage and very mild tubular damage with sporadic arteriolar hyalinosis.

**Conclusions:** Males and females respond different to a diabetes-inducing diet. Females has larger initial kidney function, comparable UACR, lower BUN and lower kidney weight and showed less renal damage compared to male mice. Despite the same dietary induction, females stayed metabolic healthy whereas males developed more pronounced diabetes and kidney damage. This is in accordance with clinical data and indicates the need for adjusted treatment guidelines for men and woman.

## SA-PO225

### Role of Ceruloplasmin in Diabetic Nephropathy

Sharma S. Prabhakar, Hemalata Deshmukh. Texas Tech University Health Sciences Center, Lubbock, TX.

**Background:** We have previously demonstrated that diabetic nephropathy (DN) is associated with oxidative stress and decreased renal nitric oxide (NO) levels (Prabhakar et al JASN 2007). While many factors such as hyperglycemia, reactive oxygen species and angiotensin may account for inhibition of NO in DN, the exact mechanism remains unclear. Ceruloplasmin (Cp) is a copper-transporting protein that was incriminated in many glomerular diseases including Lupus nephritis and Ig A nephropathy. Increased urinary excretion of Cp has been proposed as an early biomarker of DN but the precise role of Cp in DN has not been studied. We hypothesized that diabetic kidneys may overexpress Cp which might play a role in the pathogenesis of DN.

**Methods:** To test our hypothesis we used ZSF rats, an established rat model of nephropathy of diabetes. They were studied from 8<sup>th</sup> week until 40 weeks. Both male and female rats were used while CD rats were used as non-diabetic controls. ZSF rats were fed a high fat high calorie (Purina 5008) diet, to maintain hyperglycemia while CD rats were fed normal rat chow. At 40 weeks all rats were euthanized, kidneys harvested, and homogenates used to examine the expression of Cp by western blot technique. Blood and urine samples were collected at the start and end of the study to evaluate the kidney function.

**Results:** By 12 weeks of age ZSF rats developed obesity, diabetes, hypertriglyceridemia, hypertension and proteinuric renal failure while CD rats remained nondiabetic without hypertension, obesity or kidney involvement. Male ZSF rats were heavier than females (650 gm vs 510 gm) and more hyperglycemic (295 mg/dl vs.210 mg/dl) while proteinuria and azotemia were also more severe in male ZSF rats. Expression of Cp was increased in the kidneys of ZSF rats (male more than female) compared to CD rats.

**Conclusions:** We conclude that rat kidneys with experimental DN overexpress Cp. Since Cp is involved in metabolizing NO to nitrosothiols, Cp may contribute to oxidative/nitrosative stress and progression of DN. Additional studies are in progress to further explore the role of Cp in DN in our model. Cp could play a pathogenic role in and could also be a biomarker of DN.

# Sex Differences in Renal Physiological Parameters and Kidney Expression of NOX-4, TGF- $\beta$ , and Fibronectin in Mice With Streptozotocin (STZ)-Induced Diabetes Mellitus

Alexis A. Gonzalez, Geraldine M. Lazcano-Páez, Pilar Cárdenas, Felipe S. Casado-Barragán. Group of Renal Physiology and Biochemistry Pontificia Universidad Catolica de Valparaíso, Valparaíso, Chile.

**Background:** A hallmark of DM is the hyperglycemia but also hyperglycosuria, along with the presence of proteinuria and signs of renal damage that includes deposition of extracellular matrix, glomerular damage and tubulointerstitial fibrosis. All these aspects are usually observed during advanced stages of the disease. Among the markers observed in chronic DM in experimental animal models, the profibrotic factors transforming growth factor-beta 1 (TGF- $\beta$ 1), fibronectin and renal NADPH oxidase (NOX)-4 which contributes to increased reactive oxygen species (ROS) generation, are mostly responsible for the profibrotic phenotype in tubular cells enhancing the proliferation of fibroblasts and collagen deposition. Most of the diabetic animal models described in the literature analyzed the effects of chronic DM on renal physiology or kidney injury markers. Sex differences in glucose metabolism in animal models of DM have been described. Furthermore, it is known that women and men with DM have alterations in sex hormones. Our aim was to evaluate the physiological parameters and kidney expression of TGF- $\beta$ 1, fibronectin and NOX-4 in male and female mice with streptozotocin (STZ)-induced DM during 6 days.

**Methods:** CF-1 male or female mice were injected with or without STZ (150 mg/kg) in a single dose. Levels of fasting blood glucose (FBG), sodium excretion and urine protein/creatinine were measured at 0, 3 and 6 days. After 6 days of treatment the animals were euthanized and kidneys were removed to evaluate TGF- $\beta$ 1, fibronectin and NOX-4 expression by immunoblotting, qRT-PCR and immunofluorescence.

**Results:** Despite the augmentation in FBG in STZ male and female mice, males showed significantly higher levels than females at day 3. STZ males also showed higher urinary protein vs. creatinine levels than STZ females. Males showed a slight but significant sodium retention. STZ males showed higher expression of fibronectin as compared to control mice and also compared to females STZ. By contrast, STZ female mice showed higher expression of TGF- $\beta$  and NOX-4.

**Conclusions:** Our data suggest that there are sex differences on the induction of the expression of TGF- $\beta$ , fibronectin and NOX-4 in mice subjected to (STZ)-induced DM as early as 6 days.

## SA-PO228

# Placental Growth Factor Deficiency Aggravates Diabetic Nephropathy Through AMP-Activated Protein Kinase-Dependent Pathway

Yaeni Kim, Ji Hee Lim, Eun Nim Kim, Cheol Whee Park. The Catholic University of Korea, Seoul, Republic of Korea.

**Background:** Reduced angiogenesis is implicated in the progression of diabetic kidney disease (DKD). Placental growth factor (PIGF) is a member of the vascular endothelial growth factor (VEGF) family, that promotes angiogenesis through VEGF receptor (VEGF-R) and AMP-activated protein kinase (AMPK) in hypoxic tissues under pathologic condition. We aimed to investigate the role of PIGF in the development of DKD.

**Methods:** Diabetes was induced by a low-dose streptozotocin injection in 9-week-old male C57BL/6J PIGF-KO and wild-type mice and biochemical and morphological parameters were examined at 12 weeks later.

**Results:** Streptozotocin-induced PIGF-KO diabetic mice showed aggravation of albuminuria and pathogenic phenotypes of DKD due to decreases in the expression of VEGF-receptor2 (VEGF-R2) and CaMKK/phosphorylation of LKB1 and AMPK and their downstream signaling pathways including PI3K/phospho-Akt/FoxO3a/phospho-eNOS and PPAR $\alpha$ /PGC-1 $\alpha$ /ERR $\alpha$ /ChREBP/SREBP-1c, which caused endothelial dysfunction and lipotoxicity-induced renal inflammation (M1 polarization), oxidative stress, and apoptosis in the kidney. PIGF expression in glomerular endothelial cells (GECs) and PDGFR-B-positive-mesangial cells was significantly decreased in diabetic PIGF-KO compared to non-diabetic PIGF-KO mice in association with vascular rarefaction as demonstrated by reduced PECAM-1 expression. In cultured human GECs and mesangial cells in high-glucose condition, PIGF-deficiency induced by siPIGF decreased the expression of VEGF-R2 and AMPK-PI3K-Akt phosphorylation/eNOS and suppressed PGC-1 $\alpha$ /PPAR $\alpha$ , which ultimately led to increased level of oxidative stress and apoptosis.

**Conclusions:** This study provides a new insight into the role of PIGF in renal damage and that PIGF activation may be a promising therapeutic target for DKD.

## Expression of PIGF, PDGFR- $\beta$ and PECAM-1

## SA-PO229

# Diabetes-Induced Renal Inflammation Is Facilitated by Expression of the Stress Response Protein REDD1

Siddharth Sunilkumar, Esma I. Yerlikaya, Michael D. Dennis. Penn State College of Medicine, Hershey, PA.

**Background:** Diabetic nephropathy (DN) results in chronic loss of kidney function and is the leading cause of end-stage renal disease. Hyperglycemia is a key mediator of DN pathophysiology; promoting oxidative stress and inflammation associated injury. Presently, much remains unknown regarding the molecular events that contribute to chronic inflammation in the context of DN. Herein, we investigated the hypothesis that hyperglycemia-induced expression of the stress response protein REDD1 acts to exacerbate renal inflammation in response to the diabetes.

**Methods:** Wild-type (WT) and REDD1 knockout (KO) mice were administered streptozotocin to induce diabetes. Kidneys were isolated after 16 weeks of diabetes and analyzed for protein and RNA expression. Urinary albumin and creatinine levels were determined. Kidneys were fixed and renal sections were examined by immunofluorescence labeling. Similar analyses were performed on human podocyte cultures. GSK3 $\beta$  inhibition was carried out using VP3.15. Activation of the transcription factor nuclear factor kappa B (NF- $\kappa$ B) was assayed using a luciferase-based assay.

**Results:** REDD1 expression in the kidney of diabetic mice correlated with albuminuria and renal hypertrophy. Diabetes induction also increased NF- $\kappa$ B activation, pro-inflammatory gene transcript and IL-1 $\beta$  cytokine expression in the kidney of diabetic wild-type mice. In contrast, REDD1 KO mice failed to exhibit a diabetes-induced renal inflammatory response. Macrophage infiltration was observed in kidneys of diabetic WT mice but not in diabetic REDD1 KO mice. In cultured human podocytes, exposure to hyperglycemic conditions elevated REDD1 expression concomitant with increased inflammatory signaling. Pro-inflammatory gene transcript expression and IL1 $\beta$  release were not observed in podocyte cultures upon REDD1 deletion. Prior studies support that REDD1 acts via an Akt-GSK3 $\beta$  signaling axis. Indeed, inhibition of GSK3 $\beta$  prevented NF- $\kappa$ B mediated inflammation and reduced podocyte apoptosis associated renal injury in diabetic mice.

**Conclusions:** These findings provide new insights into how diabetes contributes to development of renal inflammation and support the possibility that therapeutics targeting REDD1 could be beneficial in the context of DN.

# Integrative Transcriptome Analysis Reveals TEK2 and PIAS2 Involvement in Diabetic Nephropathy

Yuanqing Li,<sup>1</sup> Hongchun Lin,<sup>1</sup> Shuangshuang Shu,<sup>1</sup> Yuxiang Sun,<sup>1</sup> Weiyan Lai,<sup>1</sup> Zhaoyong Hu,<sup>2</sup> Hui Peng.<sup>1</sup> <sup>1</sup>Nephrology Division, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; <sup>2</sup>Nephrology Division, Department of Medicine, Baylor College of Medicine, Houston, TX.

**Background:** Cell heterogeneity has impeded the accurate interpretation of the bulk transcriptome data from patients with diabetic nephropathy (DN). We performed an analysis by integrating bulk and single-cell transcriptome datasets to uncover novel mechanisms leading to DN, especially in the podocytes.

**Methods:** Microdissected glomeruli and tubules transcriptome datasets were selected from Gene Expression Omnibus (GEO). Then the consistency between datasets was evaluated. The analysis of bulk dataset and single-nucleus RNA dataset was integrated to reveal the cell type-specific responses to DN. The candidate genes were validated in kidney tissues from DN patients and diabetic mice.

**Results:** We compared 4 glomerular and 4 tubular datasets and found considerable discrepancies among datasets regarding the differentially expressed genes (DEGs), involved signaling pathways, and the hallmark enrichment profiles. Deconvolution of the bulk data revealed that the variations in cell-type proportion contributed greatly to this discrepancy. Integrative analysis uncovered that the dysregulation of spermatogenesis-related genes, including *TEK2* and *PIAS2* was involved in the development of DN. Importantly, the mRNA level of *TEK2* was negatively correlated with the mRNA levels of *NPHS1* ( $r = -0.66$ ,  $p < 0.0001$ ) and *NPHS2* ( $r = -0.85$ ,  $p < 0.0001$ ) in human diabetic glomeruli. Immunostaining confirmed that the expression of *TEK2* and *PIAS2* were up-

regulated in podocytes of DN patients and diabetic mice. Knocking down *TEKT2* resisted high glucose-induced cytoskeletal remodeling and down-regulation of NPHS1 in cultured podocyte.

**Conclusions:** The integrative strategy can help us to efficiently use the publicly available transcriptomics resources. Using this approach and combining with classical research methods, we identified *TEKT2* and *PIAS2*, two spermatogenesis-related genes involved in the pathogenesis of DN. Furthermore, *TEKT2* is involved in this pathogenesis by regulating the podocyte cytoskeleton.

### Long Non-Coding RNA DANCER Synergizes With IGF2BP2 to Attenuate Diabetic Kidney Disease Induced Glomerulosclerosis by Negatively Regulating the TGF- $\beta$ /Smad3 Pathway

Feng Liu, Chun Zhang. *Department of Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

**Background:** Diabetic kidney disease (DKD) is a major microvascular complication of diabetes mellitus and the leading cause of end-stage kidney disease. Despite transforming growth factor- $\beta$  (TGF- $\beta$ ) has been implicated as a major pathogenic factor in the development of glomerulosclerosis in DKD, clinical trials with monoclonal antibodies to TGF- $\beta$  have failed to demonstrate therapeutic benefit. Thus, developing alternative therapeutic strategies to effectively block the TGF- $\beta$ /Smad signaling could be of paramount importance for the treatment of DKD. To date, whether lncRNAs can regulate the TGF- $\beta$ /SMAD signaling in the development of DKD-associated glomerulosclerosis is still unknown.

**Methods:** Through integrating analysis of a public RNA sequencing dataset of 61 DKD glomerular cases, RNA fluorescence in situ hybridization, RNA pulldown assay, and mass spectrometry analysis, DANCER was identified and its interaction with insulin-like growth factor 2 mRNA-binding protein 2 (IGF2BP2) was confirmed. Biological implications of DANCER and IGF2BP2 in human renal mesangial cells (HRMCs) under high glucose (HG) or TGF- $\beta$  stimulus were explored by flow cytometry and western blot analysis. Weighted gene co-expression network analysis and real-time quantitative RT-PCR (qRT-PCR) verification were performed to identify candidate target genes for DANCER in DKD. RNA immunoprecipitation (RIP), dual-luciferase assay, qRT-PCR and western blot assays were used to investigate the molecular mechanisms underlying the functions of DANCER and IGF2BP2.

**Results:** DANCER was predominantly detected in the cytoplasm, and was downregulated in DKD glomerular tissues and HG stimulated HRMCs. Ectopic expression of DANCER abolished the synthesis of fibronectin, Col I, and  $\alpha$ -SMA induced by the HG or TGF- $\beta$ 1 stimulation and restored the expression of NLK. Mechanistically, DANCER functioned to stabilize nemo-like kinase (NLK) mRNA through interaction with IGF2BP2, resulting in enhanced phosphorylation on the linker region of activated Smad2/3 that blocked TGF- $\beta$ /Smad signaling.

**Conclusions:** This study identifies long non-coding RNA DANCER as a new TGF- $\beta$ /Smad signaling blocker that inhibits the development of glomerulosclerosis in DKD through interacting with IGF2BP2 to stabilize NLK mRNA, indicating a potential therapeutic target for treatment of glomerulosclerosis in DKD.

## SA-PO232

### Inhibition of Xanthine Oxidase Protects Diabetic Nephropathy Through Amelioration of Oxidative Stress via VEGF-NOX-FoxO3a Signaling Pathway

Yu Ah Hong,<sup>1,2</sup> Keum-Jin Yang,<sup>2</sup> Wonjung Choi,<sup>1,2</sup> Yoon-Kyung Chang,<sup>1,2</sup> Suk young Kim,<sup>1,2</sup> Cheol Whee Park.<sup>1</sup> *<sup>1</sup>Catholic University of Korea School of Medicine, Seoul, Republic of Korea; <sup>2</sup>Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

**Background:** Xanthine oxidase (XO) is one of major source of reactive oxygen species, and a XO inhibitor, febuxostat has been reported to the protection of kidney diseases. We investigated whether febuxostat exerts renoprotective effects against diabetic kidney disease (DKD).

**Methods:** Febuxostat (5 mg/kg) was administrated to 8-week Male C57BL/6 mice via intraperitoneal route for 8 weeks in streptozotocin (STZ)-treated diabetic mice. We also evaluated the antioxidant effects of febuxostat and its mechanism using high glucose (HG)-treated cultured human glomerular endothelial cells (HGECS).

**Results:** Serum cystatin C, albuminuria and mesangial matrix expansion were significantly decreased in febuxostat-treated diabetic mice. Febuxostat also reduced serum uric acid, kidney XO and xanthine dehydrogenase levels in diabetic mice. Febuxostat suppressed the expression of vascular endothelial growth factor (VEGF) mRNA, VEGF receptor (VEGFR)1 and 3, NADPH oxidase (NOX)1, 2, and 4, and the levels of their catalytic subunit mRNA in diabetic mice. Febuxostat was accompanied by the downregulation of Akt phosphorylation, followed by the suppression of transcription factor forkhead box O3a (FoxO3a) phosphorylation and the enhancement of endothelial nitric oxide synthase (eNOS). In addition, the blockade of VEGFR1 or VEGFR3 abolished the antioxidant effects of febuxostat via NOXs-FoxO3a-eNOS signaling in HG-treated cultured HGECS. Finally, febuxostat improved oxidative stress in both *in vivo* and *in vitro* models of DKD.

**Conclusions:** The inhibition of XO by febuxostat was associated with the inhibition of VEGF, which consequently ameliorated oxidative stress related to NOXs-FoxO3a-eNOS signaling in DKD.

**Funding:** Government Support - Non-U.S.

## SA-PO233

### The Insulin/Insulin-Like Growth Factor Axis Is Critically Important in the Podocyte and Controls Gene Transcription and Spliceosome Function

Jenny Hurcombe,<sup>1</sup> Lusyan Dayalan,<sup>1</sup> Fern Barrington,<sup>1</sup> Lan Ni,<sup>1</sup> Paul T. Brinkkoetter,<sup>2</sup> Martin Holzenberger,<sup>3</sup> Gavin I. Welsh,<sup>1</sup> Richard Coward.<sup>1</sup> *<sup>1</sup>University of Bristol, Bristol, United Kingdom; <sup>2</sup>University Hospital Cologne, Cologne, Germany; <sup>3</sup>Sorbonne University, INSERM, Paris, France.*

**Background:** Insulin signalling to the podocyte via the cognate insulin receptor (IR) is crucial for kidney function and insulin-like growth factor 1 (IGF1) signalling through the structurally related insulin-like growth factor 1 receptor (IGF1R) is also known to directly affect the podocyte. Since the IR and IGF1R may act redundantly in some contexts, this study sought to elucidate the role of the insulin/IGF1 axis in podocyte function using mouse and cell culture models deficient in both receptors.

**Methods:** To examine the effects of combined receptor loss *in vivo*, a transgenic mouse model with conditional inactivation of podocyte IR and IGF1R was generated. *In vitro*, conditionally immortalized genetic IR/IGF1R dual knockout podocytes were characterised using proteomic, transcriptomic and metabolomic analysis.

**Results:** Podocyte specific IR/IGF1R knockout mice developed significant albuminuria and a severe renal phenotype with global sclerosis, renal failure and death occurring between 4 and 24 weeks. >90% loss of the IR and IGF1R in cultured mouse podocytes was also detrimental resulting in >50% cell death 7 days after receptor gene excision. Enrichment analysis of total proteomic data revealed a striking downregulation of gene ontology terms associated with splicing and RNA processing activity in IR/IGF1R deficient cells. Genome-wide and targeted long-read RNA sequencing was performed to further explore the effect of dual receptor suppression on spliceosome function alongside metabolomic studies to elucidate key metabolic pathways regulated by these receptors.

**Conclusions:** This work underlines the critical importance of podocyte insulin/IGF signalling and reveals a novel role for this signalling axis in RNA processing by regulating spliceosome activity.

**Funding:** Government Support - Non-U.S.

## SA-PO234

### Decoy Receptor 2 Mediates the Apoptosis-Resistant Phenotype of Senescent Renal Tubular Cells and Accelerates Renal Fibrosis in Diabetic Nephropathy

Jia Chen. *Army Medical Center of PLA, Chongqing, China.*

**Background:** Apoptotic resistance leads to persistent accumulation of senescent cells and sustained expression of a senescence-associated secretory phenotype, playing an essential role in the progression of tissue fibrosis. However, whether senescent renal tubular epithelial cells (RTECs) exhibit an apoptosis-resistant phenotype and the mechanism remain unclear.

**Methods:** A total of 241 DN patients diagnosed by biopsy in our hospital from January 2012 to December 2019 were included. The STZ-induced DN mouse model was constructed. DcR2-siRNA and DcR2 overexpression plasmids were transfected into the kidney using ultrasonic microbubble technology. TECs senescence was constructed by high glucose treatment. The co-localization of DcR2 and apoptosis-related markers (FLIP, Bcl-2, caspase-3, caspase-8, TUNEL) and fibrotic markers ( $\alpha$ -SMA, collagen IV, fibronectin) were analyzed. DcR2 interacting proteins were screened and analyzed by co-immunoprecipitation combined with quantitative proteomics in renal tissue from DN patients and TECs.

**Results:** DcR2 was co-localized with fibrotic markers, and anti-apoptotic proteins FLIP and Bcl2 but rarely co-localized with caspase 3 or TUNEL. DcR2 overexpression promoted renal fibrosis in mice with STZ-induced DN, as evidenced by augmented Masson staining and upregulated expression of fibrotic markers. DcR2 overexpression also enhanced FLIP expression while reducing the expression of pro-apoptotic proteins, resulting in apoptotic resistance. In contrast, DcR2 knockdown produced the opposite effects *in vitro* and *in vivo*. Moreover, quantitative proteomics demonstrated that DcR2 interacted with GRP78, which has been shown to promote apoptotic resistance in cancer. GRP78 exhibited co-localization with senescent and anti-apoptotic markers but was rarely co-expressed with caspase 3 or TUNEL. Additionally, GRP78 knockdown decreased the apoptosis resistance of HG-induced senescent RTECs with upregulated cleaved caspase 3 and increased the percentage of apoptotic RTECs. Mechanistically, DcR2 mediated apoptotic resistance in senescent RTECs by enhancing GRP78-caspase 7 interactions and promoting Akt phosphorylation.

**Conclusions:** DcR2 mediated the apoptotic resistance of senescent RTECs and renal fibrosis by interacting with GRP78, indicating that targeting the DcR2-GRP78 axis represents a promising therapeutic strategy for DN.

## SA-PO235

### Tyro3 Agonist as a Novel Therapy for Glomerular Disease

Fang Zhong, Hong Cai, Kyung Lee, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Drugs directly targeting podocytes as a therapy for glomerular disease are still lacking. Our previous studies suggest that Tyro3 is a podocyte-specific TAM (Tyro3, Axl, Mertk) tyrosine kinase receptor. In human, glomerular Tyro3 expression negatively correlates with the progression of primary glomerular disease and diabetic kidney disease (DKD). Knockout of Tyro3 aggravates podocyte injury in Adriamycin-induced nephropathy (ARDN) and DKD mice while induction of Tyro3 expression in

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

podocytes ameliorates kidney injury in these two animal models,. These data suggest a protective role of Tyro3 against podocyte injury in glomerular disease. Here, we liked to further dissect the mechanisms of Tyro3 in podocytes and develop Tyro3 agonists as potential drugs to treat glomerular disease.

**Methods:** In vitro studies: culture of human podocytes with overexpression or knockdown of Tyro3, western blot, co-immunoprecipitation, and mass spectrometry. In vivo studies: OVE26 diabetic mice and ARDN treated with Tyro3 agonists or vehicle. Kidney histology, albuminuria, and renal function will be assessed in these mice.

**Results:** By immunoprecipitation combined with mass spectrometry analysis we identified TCTP and nicalin as the top Tyro3-interacted proteins. Nicalin is a member of the  $\gamma$ -secretase complex. TCTP is known to inhibit apoptosis through interaction with multiple partners such as p53 and Bax. We showed that Tyro3 interacted with TPTC to induce its phosphorylation and thereby inhibiting apoptosis of podocytes. Tyro3 also interacted with nicalin to induce the cleavage of Tyro3 into a soluble form. Overexpression of soluble Tyro3 inhibits its protective effects of Tyro3 in podocytes. Circulating Tyro3 increased in DKD patients. Therefore, our data suggest that increased soluble Tyro3 in DKD patients could suppress the protective effects of Tyro3 in podocytes, leading to more podocyte injury. In addition, we screened and identified a specific Tyro3 agonist (C10) which induced phosphorylation in Tyro3 but not in other TMA receptors. This Tyro3-specific agonist reduced apoptosis of human podocytes cultured in high glucose condition and ameliorated podocyte loss and glomerular injury in mice with ARDN and DKD.

**Conclusions:** In conclusion, we reveal a novel protective mechanism of Tyro3 in podocytes and develop a novel class of podocyte-specific drugs which could be potentially developed to treat glomerular disease.

### Alterations of the Kidney Inflammatory Landscape in Patients With Diabetic Nephropathy

Martina Chirra,<sup>1</sup> Ameet A. Chimote,<sup>1</sup> Arya Dahal,<sup>1</sup> Sonia Bhati,<sup>1,2</sup> Heather Duncan,<sup>1</sup> Kotagal S. Kant,<sup>1</sup> Laura Conforti,<sup>1</sup> <sup>1</sup>University of Cincinnati, Cincinnati, OH; <sup>2</sup>University of Kentucky College of Medicine, Lexington, KY.

**Background:** Diabetic nephropathy (DN) is the leading cause of chronic kidney disease in the USA. Inflammation has a crucial role in the pathogenesis of DN and a deeper knowledge of the inflammatory state of DN kidneys could provide rationales for new treatments. Our aim was to investigate the transcriptomic immune signature of kidney biopsies from patients with DN, in comparison with healthy kidney (NK) biopsies and kidney biopsies of patients affected by lupus nephritis (LN), a well-known example of immune-related kidney disease.

**Methods:** We performed a transcriptomic analysis of formalin-fixed paraffin-embedded kidney biopsies from NK (n=7), DN (n=7) and LN (n=4) using the NanoString nCounter MAX system and the nCounter Human Autoimmune Profiling Panel. Gene expression and pathway score data analyses were performed with the nSolver 4.0 Data Analysis Software, the Advanced Analysis 2.0 plug-in (NanoString Technologies) and the ROSALIND® platform. All the LN patients were receiving immunosuppressant drugs during the sample collection.

**Results:** 31% (239/750) of the genes defining autoimmune and autoinflammatory disorders were upregulated (fold increase  $\geq 1.5$ , adjusted P-value  $\leq 0.05$ ) in DN compared to NK. When comparing DN with LN, there were 159 differentially expressed genes (fold increase  $\geq 1.5$  or fold decrease  $\leq 1.5$ , adjusted P-value  $\leq 0.05$ ) and 140/159 were upregulated in DN compared to LN. Almost all the pathways (34/35) associated with autoimmune and chronic inflammatory disorders were significantly increased in DN (n=5) compared to NK (n=7). The majority of these pathways (19/35) were still increased in DN (n=2) compared to LN (n=4).

**Conclusions:** Transcriptomic profiling of DN kidney biopsies reveals an increase of the pathways associated with autoimmune and chronic inflammatory disorders, potentially identifying new therapeutic targets.

### The Molecular Effect of Empagliflozin (SGLT2i) on the Autophagy Pathway in Type 2 Diabetic Mice Model With Diabetic Nephropathy

Farid M. Nakhoul,<sup>1,3</sup> Offir Ertracht,<sup>5</sup> Nakhoul Nakhoul,<sup>2,3</sup> Hagar Tadmor,<sup>4</sup> <sup>1</sup>Cardiovascular research lab The Galilee Medical Center, Nahariya, Israel; <sup>2</sup>Ophthalmology Division, baruch Padeh Poriya medical Center, Lower galilee, Israel; <sup>3</sup>Faculty of Medicine Bar Ilan University, Tsfat, Israel; <sup>4</sup>Diabetes and Metabolism Lab, Baruch Padeh Poriya Medical Center, Tiberias, Israel; <sup>5</sup>Cardiovascular research institute The galilee medical Center, Nahariya, Israel.

**Background:** Diabetes mellitus (DM) type II (Hyperglycemia), is associated with increased glucose cell toxicity and inflammation leading to irreversible damage to the kidney cells. Autophagy plays a key role in the degradation of damaged intracellular proteins in order to maintain intracellular homeostasis and cell integrity. During DM, their is decreased in the autophagy with consequent development & progression of diabetic nephropathy (DN). Our aim is to investigate the molecular effect of SGLT2i (EMPA) on the expression of ATG5 and its downstream collaborator LC3-II in DM mice model

**Methods:** The 8 weeksold male type II DM mice were used: 20 C57BL/6J Wild Type (C57), 20 BTBR ob/ob vehicles (DM), 20 BTBR ob/ob that were treated with EMPA in drinking water Body weight, urinary & blood glucose were measured at basal & 1 and 2 months. Lysates from murine renal cortex were subjected to histological,

immunohistochemically, western blot analysis (WB) and fibrosis(Fibronectin). All mice were sacrificed 13 week after the beginning of the experiment.

**Results:** At two months, the DM and DM+EMPA mice groups gain weight considerably vs C57/BI (P>.0.01). Urine output increased as soon as 1 & 2 month of treatment (TX) in DM & DM+EMPA group VS control (P<0.001). Western blots (WB) significant reduction in ATG5 level in renal lysate of DM mice compared with C57/BI mice (P< 0.01). Quantification of the WB indicate significant reduction in ATG5 level in renal lysate of DM mice compared with C57/BI mice (P< 0.01), and moderate yet non-significant increased by the EMPA TX (P>0.05). ATG5 immunostaining was significantly decreased in DM mice compared with C57/BI (P<0.001), and significant increased in DM+EMPA mice compared with DM mice (P<0.001). Renal LC3-II protein level & immunostaining were significantly reduced in DM mice compared with C57/BI (P<0.001), and increased levels in DM+EMPA group VS untreated DM mice (P<0.001). Fibronectin level was reduced in DM mice compared to control and restored toward normal with EMPA TX.

**Conclusions:** Decrease in ATG5 & LC3-II proteins levels during chronic hyperglycemia (DM) contributes to deficiencies in the autophagy process, with development and progression of DN. EMPA TX significantly reduce the development & progression of DN in people with type II DM and should be recommended in early stages of the disease.

**Funding:** Government Support - Non-U.S.

## SA-PO238

### Endurance Exercise Training Prevented the Progression of Diabetic Kidney Disease With Muscle Weakness in Type 2 Diabetic Animal Models With Obesity, Hypertension, and Hyperlipidemia

Hitoshi Kotake, Takeshi Sugaya, Yugo Shibagaki, Atsuko Ikemori. *St. Marianna University School of Medicine, Kawasaki, Japan.*

**Background:** The aim of this present study was to evaluate protective effects of endurance exercise training against diabetic kidney disease (DKD) with muscle weakness by using male spontaneously diabetic Torii (SDT) fatty rats as type 2 diabetic animal models with obesity, hypertension, and hyperlipidemia.

**Methods:** Eight-week-old SDT fatty rats (n = 12) and Sprague-Dawley (SD) rats (n = 10) were randomly divided into exercise (Ex; SDT-Ex: n = 6, SD-Ex: n = 5) and sedentary groups (SDT-Cont: n = 6, SD-Cont: n = 5), respectively. Each group underwent regular treadmill exercise four times a week from ages 8 to 16 weeks. After finishing the exercise protocol, the kidneys were isolated and leg muscle tissue was removed. The extracted muscle specimens were categorized as slow (soleus) or fast (EDL) muscle.

**Results:** The exercise attenuated hypertension and hyperlipidemia and prevented increases in renal parameters levels without affecting of blood glucose levels. In the SDT fatty rats, it ameliorated renal morphological abnormalities in the interstitium of the surface and intermediate layers of the cortex. Downregulated expression of endothelial nitric oxide synthase in the glomerulus of the SDT fatty rats was significantly upregulated by the exercise. The exercise upregulated the renal expressions of both medium-chain acyl-CoA dehydrogenase and peroxisome proliferator-activated receptor  $\gamma$  coactivator-1 $\alpha$  related to fatty acid metabolism. In addition, the exercise training increased the muscle strength and cross-sectional area of the type IIb muscle fibers in the EDL muscle, but not soleus muscle. The exercise training upregulated the protein expression of CD31, insulin receptor substrate-2, and phosphorylated endothelial nitric oxide synthase in the EDL muscle, suggesting acceleration of angiogenesis.

**Conclusions:** Endurance exercise training exerts protective effects by preventing glomerular endothelial abnormality and enhancing renal fatty acid metabolism, and suppresses muscle weakness by acceleration of angiogenesis of EDL muscle, in type 2 diabetes with obesity, hypertension, and hyperlipidemia, independently of blood glucose.

## SA-PO239

### Deletion of iPLA2 $\gamma$ Protects Mice From Diabetic Nephropathy

Andrey V. Cybulsky,<sup>1</sup> Julie Guillemette,<sup>1</sup> Joan Papillon,<sup>1</sup> José R. Navarro-Betancourt,<sup>1</sup> Hanan Elimam,<sup>1,2</sup> Ivan G. Fantus.<sup>1</sup> <sup>1</sup>McGill University Health Centre, Montreal, QC, Canada; <sup>2</sup>University of Sadat City, Sadat City, Egypt.

**Background:** Calcium-independent phospholipase A2 $\gamma$  (iPLA2 $\gamma$ ) is localized in glomerular epithelial cells (GECs)/podocytes at the mitochondria and endoplasmic reticulum, and can mediate release of arachidonic acid and prostanoids. Global knockout (KO) of iPLA2 $\gamma$  in mice did not cause albuminuria, but resulted in mitochondrial structural abnormalities and enhanced autophagy in podocytes. In acute glomerulonephritis (GN; anti-glomerular basement membrane GN and adriamycin nephrosis), deletion of iPLA2 $\gamma$  exacerbated albuminuria and podocyte injury. This study addresses the role of iPLA2 $\gamma$  in diabetic nephropathy.

**Methods:** Hyperglycemia was induced in male mice (mean age 6.5 months) with streptozotocin (STZ). Cultured GECs were produced from control and iPLA2 $\gamma$  KO mice; the GECs express synaptopodin and nephrin.

**Results:** STZ induced progressive albuminuria in control (Ctrl) mice (~5 mg/mg creatinine at 21 weeks), while albuminuria did not increase in iPLA2 $\gamma$  KO mice (~0.5 mg/mg creatinine), remaining comparable to untreated groups (9-15 mice/group). Despite similar exposure to STZ, the STZ-KO mice developed a lower level of hyperglycemia compared to STZ-Ctrl. However, there was no significant correlation between the degree of hyperglycemia and albuminuria, and even KO mice with greatest hyperglycemia did not develop significant albuminuria. Mortality at 21 weeks was greatest in STZ-Ctrl mice (20%). Sclerotic glomeruli and enlarged glomerular capillary loops were increased significantly in Ctrl-STZ compared to KO-STZ mice. Glomerular LC3-II (a marker of autophagy) was increased in KO and KO-STZ mice compared to respective Ctrl groups.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

Glomerular matrix was expanded in both Ctrl-STZ and KO-STZ groups. STZ did not alter podocyte number, nor amounts of glomerular synaptopodin, nephrin, podocalyxin, F-actin, and macrophages. Treatment of cultured GECs with H<sub>2</sub>O<sub>2</sub> resulted in increased cell death in Ctrl GECs compared to iPLA<sub>2</sub> $\gamma$  KO, and the increase was slightly greater in medium with 18 mM glucose compared to 8 mM. H<sub>2</sub>O<sub>2</sub>-induced cell death was not affected by inhibition of prostanoid production with indomethacin.

**Conclusions:** In contrast to acute GN, mice with global deletion of iPLA<sub>2</sub> $\gamma$  are protected from developing chronic glomerular injury in diabetic nephropathy. This may be related at least in part to increased glomerular autophagy.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

### Human Translational Data and Preclinical Models Support LPAR1 Antagonist as a Candidate Treatment for Diabetic Kidney Disease

Monika Sharma, Swati Kaushik, David Lopez, Katie Kassa, Wesley Minto, Thomas E. Hudson, Shusil Pandit, Shawn S. Badal, John T. Liles, Anna Zagorska. *Gilead Sciences Inc, Foster City, CA.*

**Background:** LPA-LPAR1 signaling has been implicated in kidney fibrosis. LPAR1 activation promotes epithelial cell injury and myofibroblast proliferation. *Lpar1*<sup>-/-</sup> mice are protected from fibrosis in kidney injury models. Here we evaluate LPAR1 pathway in human DKD and effect of a small molecule antagonist of LPAR1 *in vitro* and in two distinct models of kidney injury.

**Methods:** European Renal cDNA Bank DKD datasets were used to evaluate *LPAR1* expression. Small molecule LPAR1 antagonist, GS-1148569, was evaluated *in vitro* in kidney fibroblasts, mesangial cells, tubular epithelial cells, and *in vivo* in a) rat adenine model of tubulointerstitial injury (8 weeks 0.25% adenine in diet, 6 week of treatment, PO, BID) and b) a mouse *db/db eNos*<sup>-/-</sup> mouse model of glomerulosclerosis (10 weeks of treatment starting from week 10, PO, BID).

**Results:** *LPAR1* mRNA expression is elevated in DKD kidney biopsies compared to healthy donors and negatively correlates with eGFR. In fibroblasts, mesangial cells and tubular epithelial cells, LPAR1 antagonist, GS-1148569 blocked LPA-induced Myocardin Related Transcription Factor A (MRTFA) nuclear translocation and profibrotic gene expression. In the rat adenine model, GS-1148569 significantly reduced plasma creatinine (1.0 ± 0.08 mg/dL vs 2.2 ± 0.22 mg/dL in vehicle), plasma BUN (37 ± 4.9 mg/dL vs 80 ± 6.8 mg/dL in vehicle), and plasma tubular injury markers, KIM1 (3.0 ± 1.3 ng/mL vs 9.6 ± 4.6 ng/mL vehicle) and NGAL (0.61 ± 0.43 µg/mL vs 1.1 ± 0.3 µg/mL in vehicle). GS-1148569 reduced tubulointerstitial fibrosis measured by Picrosirius Red (PSR) (12.5 ± 1.7 % area vs 21.7 ± 2.1% area in vehicle). In *db/db eNos*<sup>-/-</sup> mouse model, GS-1148569 reduced global glomerular sclerosis (6.5 ± 2.4 % glomeruli vs 26 ± 13.4 % glomeruli in vehicle) and increased GFR as assessed by FITC-sinistrin half-life change from week 10 to week 20 (-3.2 ± 3.3 min vs 2.2 ± 6.8 min in vehicle).

**Conclusions:** LPAR1 expression increases in DKD in correlation with disease severity. LPAR1 antagonism blocks profibrotic gene expression in fibroblasts and mesangial cells. LPAR1 antagonism preserves kidney function and halts fibrosis progression in adenine model and reduces global glomerular sclerosis in *db/db eNos*<sup>-/-</sup>. Altogether, LPAR1 is a promising therapeutic target for DKD.

## SA-PO241

### Nuclear Receptor Coactivator 3 Deficiency Damages Podocyte Injury Through Targeting Fyn/AMPK/mTOR Signaling Pathway

Xie Yaru. *Wuhan Union Hospital Department of Neurology, Wuhan, China.*

**Background:** Diabetic kidney disease (DKD) is one of the most common chronic complications of diabetes and has become the main cause of end-stage renal disease. Podocytes, the visceral epithelial cells of the renal capsule, adhere to the outer surface of the glomerular basement membrane (GBM), and form the glomerular filtration barrier with vascular endothelial cells and GBM. Podocytes are terminally differentiated cells that cannot efficiently proliferate and renew after damage. Therefore, once the podocytes are damaged to a certain extent, it will lead to damaged capillary loops and glomerulosclerosis. It is well known that high glucose is closely related to intercellular interactions and apoptosis of podocytes. However, the exact mechanism in high glucose-mediated podocyte injury has not been fully elucidated. Therefore, the study of podocyte injury and protection mechanisms is the key to the treatment of DKD.

**Methods:** C57 male mice were injected with STZ intraperitoneally to establish a diabetic nephropathy model, and the changes of NCOA3 and downstream indicators Fyn/AMPK/mTOR/autophagy were detected; at the same time, podocytes were stimulated with high glucose to verify the changes of the above indicators *in vitro*. The NCOA3 podocyte-specific knockout mice were constructed and STZ was injected. The blood and urine biochemical levels, renal pathological changes and the downstream indicators of Fyn/AMPK/mTOR/autophagy were detected. C57 male mice were injected with NCOA3 overexpressing virus via tail vein and intraperitoneally injected with STZ to establish a diabetic nephropathy model. Biochemical levels of blood and urine, renal pathological changes and downstream indicators of Fyn/AMPK/mTOR/autophagy were detected.

**Results:** This study found that NCOA3 expression was down-regulated in DKD. Knockout of NCOA3 in renal podocytes leads to renal pathological changes in mice, and upregulation of NCOA3 promotes the Fyn/AMPK/mTOR/autophagy pathway to inhibit the progression of diabetic nephropathy.

**Conclusions:** The current findings suggest that NCOA3 is a key molecule in the development of diabetic nephropathy. NCOA3 can activate autophagy, thereby inhibiting disease progression, providing new ideas and targets for the treatment of diabetic nephropathy.

## SA-PO242

### Effects of Non-Steroidal Mineralocorticoid Antagonist (Finerenone) in Western Diet-Induced Kidney Disease

Komuraiah Myakala, Patricia de Carvalho Ribeiro, Xiaoxin Wang, Kyle E. Korolowicz, Olga C. Rodriguez, Chris Albanese, Moshe Levi. *Georgetown University Medical Center, Washington, DC.*

**Background:** Mineralocorticoid receptor (MR) overactivation plays a crucial role in the pathogenesis of chronic kidney disease, several cardiovascular and arterial diseases. Clinical studies demonstrated the beneficial effects of steroidal MR antagonists (MRAs) spironolactone and eplerenone on kidney disease. However, long term usage of MRAs increases the risk of hyperkalemia with reduced kidney function. We aim to test the non-steroidal MR antagonist Finerenone as a novel treatment of kidney disease in a mouse model of diet induced obesity and insulin resistance.

**Methods:** 2-month old C57BL/6J mice fed on low fat (LF) or western diet (WD) were treated with vehicle or FINERENONE for 6-months until they were 8 months old. Food intake and body weight was measured for every week during the entire study period. At the end of the study, 24-hour urine collected and serum and tissues were harvested for further evaluation. Blood pressure also measured via tail cuff. To assess the kidney function, dynamic contrast-enhanced (DCE) magnetic resonance imaging (MRI) was performed using Gadoxetate disodium (Eovist).

**Results:** The body weight and kidney weight were increased significantly in mice fed WD compared to LF fed mice (N=12), which were significantly reduced with Finerenone administration although the blood glucose levels did not change between all the groups. The WD fed mice exhibited significantly increased albuminuria, which was decreased with Finerenone treatment. In kidney of mice fed WD, we detected increased expression levels of pro-inflammatory cytokines MCP1 and TNF $\alpha$ , innate immunity pathways TLR2, STING and STAT3, and senescence marker p21. Their expression was significantly decreased with Finerenone. The DCE-MRI indicated that mice fed WD showed a more rapid and sustained uptake of Eovist in the kidney compared to mice fed LF, suggestive of reduced clearance capacity. In contrast, finerenone treatment in WD fed mice exhibited Eovist uptake and clearance rates more similar to those seen in the LF diet control mice.

**Conclusions:** Our data shows that administration of Finerenone exhibits renal protective role and prevent the progression of kidney disease in a mouse model of diet induced obesity and insulin resistance.

**Funding:** Commercial Support - BAYER

## SA-PO243

### High Glucose Stimulates Basolateral Secretion of Semaphorin 3G by Proximal Tubule Cells: Role in Anti-Angiogenesis

Paulo S. Caceres.<sup>1,2</sup> <sup>1</sup>Henry Ford Health System, Detroit, MI; <sup>2</sup>Wayne State University School of Medicine, Detroit, MI.

**Background:** Hyperglycemia in the diabetic kidney causes tubular and microvascular abnormalities that eventually lead to kidney damage. Given the close association between the proximal tubule and peritubular capillaries, a thorough understanding of their interaction could help identify mechanisms of diabetic kidney disease. Microvascular abnormalities are known to occur in diabetic patients and animal models. Despite known growth factors produced by the proximal tubule that could potentially target neighboring endothelial cells, it is not well understood whether the proximal tubule regulates angiogenesis. Here we propose that proximal tubule secretes Semaphorin-3G (Sema3G), an anti-angiogenic protein. We hypothesize, that high glucose stimulates Sema3G secretion by proximal tubule cells and inhibits angiogenesis.

**Methods:** We utilized co-cultures of RPTEC proximal tubule and HUVEC endothelial cell lines. We analyzed angiogenesis *via* tubulogenesis assays in Matrigel and cell migration *via* wound-healing assays. We assessed kidney angiogenesis in primary cultures of mouse kidney endothelial cells and sprouting angiogenesis in cortex explants from diabetic Akita mice.

**Results:** We observed decreased sprouting angiogenesis (baseline and VEGF-stimulated) in kidney cortex explants of diabetic Akita mice vs. C57BL counterparts. To identify a potential proximal tubule anti-angiogenic factor, we measured release of Sema3G from polarized RPTEC cells. We found that RPTEC cells secreted Sema3G basolaterally and this was stimulated by high glucose (25 mM). Conversely, RPTEC cells pre-grown on high glucose lost their ability to stimulate angiogenesis in co-cultured HUVEC endothelial cells. When we administered recombinant Sema3G to endothelial cells in culture, we found that Sema3G had little effect in baseline angiogenesis, but it inhibited VEGF-stimulated angiogenesis in HUVEC and primary culture of kidney endothelial cells. Finally, when we silenced the semaphorin receptor Plexin-D1 *via* shRNAs in endothelial cells, we observed accelerated cell migration in the absence or presence of co-cultured RPTEC cells, confirming the inhibitory role of semaphorin signaling in endothelial cells.

**Conclusions:** We conclude that RPTEC proximal tubule cells secrete Sema3G, which is stimulated by high glucose, and this anti-angiogenic factor inhibits angiogenesis in HUVEC and mouse kidney endothelial cells.

## SA-PO244

## Developing a Small Molecule Therapeutic to Treat Diabetic Kidney Disease

Hassan Al-Ali,<sup>1</sup> Javier T. Varona Santos,<sup>1</sup> Haley M. Donow,<sup>2</sup> Marc Giulianotti,<sup>2</sup> Judith T. Molina David,<sup>1</sup> Alessia Fornoni,<sup>1</sup> Sandra M. Merscher,<sup>1</sup> Katz Center Drug Discovery <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Florida International University, Miami, FL.

**Background:** Injury and loss of podocytes underly the development and progression of DKD. We previously showed that accumulation of lipid droplets (LDs) in podocytes is associated with increased lipotoxicity and cell death, and that reducing LD accumulation in podocytes combats DKD. We hypothesize that a targeted small molecule that directly blocks LD accumulation in podocytes can halt or reverse the progression of DKD.

**Methods:** A robust phenotypic screening assay utilizing immortalized human podocytes was developed to identify compounds that reduce LD accumulation in these cells. A combinatorial chemical library from the Torrey Pines Institute for Molecular Studies (TPIMS) containing over 45 million molecules was screened in the assay. Hits were identified based on their ability to reduce LD accumulation and rescue podocytes from cell death. RNAseq libraries from podocytes treated with one of the identified hits in the presence of sera from subjects with or without DKD were generated and analyzed.

**Results:** The assay identified several hits from the FIU library. Preliminary structure activity relationship (SAR) studies showed strong feasibility for hit-to-lead optimization of one series. A representative compound reduced the expression of genes related to TNF-signaling, a pathway associated with LD accumulation and podocyte injury, and the expression of lysosome-associated membrane glycoprotein (LAMP), which correlates with improved autophagy/lipophagy. Follow up mechanistic studies confirmed that the compound induces autophagic flux in podocytes, including strong induction of lipophagy, providing a candidate mechanism by which the compound protects these cells from lipotoxic stress. Our initial medicinal chemistry efforts have generated lead-like analogs that are appropriate for *in vivo* testing.

**Conclusions:** Our screen identified a promising molecular series that strongly reverses features of podocyte toxicity and death in DKD. We have launched a medicinal chemistry campaign to extend the SAR studies and have generated optimized compounds for *in vivo* validation in a mouse model of DKD. The compounds are currently being tested in db/db mice. Our results will enable the identification of novel drug targets and initiate the development of a therapeutic candidate for DKD.

**Funding:** NIDDK Support

## SA-PO245

## L-Lysine Dietary Supplementation Attenuates Hyperglycemia in Type 2 Diabetic Nephropathy Rats

Olha Kravtsova,<sup>1</sup> Elena Isaeva,<sup>3</sup> Oleg Palygin,<sup>2</sup> Alexander Staruschenko,<sup>1,4</sup> <sup>1</sup>University of South Florida, Tampa, FL; <sup>2</sup>Medical University of South Carolina Department of Medicine, Charleston, SC; <sup>3</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>4</sup>VA James A Haley Hospital, Tampa, FL.

**Background:** Diabetic kidney disease (DKD) is one of the main complications of diabetes, leading to the progression of end-stage kidney failure. Recent studies provide evidence that dietary supplementation of the essential amino acid lysine significantly attenuates proximal tubule reabsorption and is critical for the regulation of kidney function. To explore the effect of lysine on hyperglycemia in the late stage of DKD progression, we used Type 2 Diabetic Nephropathy (T2DN) rats, a non-obese model of spontaneous development of diabetes, and similar renal injuries to clinical manifestation of DKD in humans.

**Methods:** Male T2DN rats (>48 weeks old) were kept on a Purina diet. L-lysine chloride or L-lysine acetate (91 mol/l) was supplied ad libitum in drinking water for 10 days. Fasting blood was collected from the tail vein, and glucose levels were determined with a glucometer. pH and electrolytes were measured with a blood gas analyzer. Plasma and kidney tissue were collected at the end of the experiment. RT-PCR and Western blotting were performed for mRNA and protein expression analysis.

**Results:** We found that L-lysine administration (chloride or acetate) attenuates hyperglycemia ( $197 \pm 53$  to  $119 \pm 10$  after L-lysine chloride &  $121 \pm 6$  to  $73 \pm 15$  after L-lysine acetate, mg/dL glucose,  $p < 0.01$ ) in T2DN rats. mRNA expression of *Slc5a2*, the gene that encodes SGLT2, did not differ in both groups compared to untreated controls. Interestingly, chloride salt of lysine leads to acidosis compared to acetate ( $7.25 \pm 0.02$  vs.  $7.46 \pm 0.02$  blood pH, respectively), probably due to increased Cl<sup>-</sup> supplementation. In comparison with untreated diabetic rats, lysine supplement leads to a lower abundance of transporters responsible for pH homeostasis. In particular, the expression of NHE3, and NBCe1 (only chloride group), mostly abandoned in proximal tubule cells, were decreased. Similarly, cortical collecting duct expression of V-ATPase B1/2 was reduced.

**Conclusions:** Our data suggest that essential dietary lysine supplementation results in a marked reduction of blood glucose in T2DN rats. That indicates that simple amino acid administration could be used for the treatment of hyperglycemia and type 2 diabetes complications.

**Funding:** Other NIH Support - R35 HL135749, Veterans Affairs Support

## Reno-Protective Effect of Liraglutide in Type 1 Diabetes Mellitus (T1DM): Shifting Macrophage Polarization Towards the M2 Anti-Inflammatory Phenotype Through NADPH/TRP Dual Inhibition

Natalie Youssef, Mohamad Nourledein, Fuad N. Ziyadeh, Assaad Antoine Eid. American University of Beirut, Beirut, Lebanon.

**Background:** Diabetic kidney disease (DKD) is a major complication of diabetes. It is speculated that macrophages may be involved in the initiation as well as the progression of the immune response in DKD. After infiltrating the glomeruli, macrophages can polarize into an M1 pro-inflammatory phenotype or an M2 anti-inflammatory one. In addition to inflammation, extensive data from the literature highlight the deleterious effects of reactive oxygen species (ROS) over-production as well as dysregulation of calcium signaling on progression of DKD. Several hypoglycemic agents such as liraglutide, a GLP-1RA, have been investigated for their reno-protective effects. However, their exact mechanism of action still needs to be elucidated. Herein, we aim to investigate the reno-protective effect of liraglutide in type 1 diabetes mellitus (T1DM) by regulating macrophage polarization through the NADPH/TRP signaling pathway.

**Methods:** Functional, histopathological, biochemical and molecular parameters were assessed in control, T1DM, and T1DM C57/BL6J mice treated with liraglutide (0.3 mg/kg body weight) for 13 weeks.

**Results:** Liraglutide treatment improves kidney injury as assessed by improved BUN, urinary albumin to creatinine ratio (ACR), and proteinuria. This reno-protective effect of liraglutide was further confirmed using histopathology analysis exhibited by reduced glomerular hypertrophy, decreased glomerulosclerotic index and collagen deposition. Of interest, these results were associated with decreased mRNA expression of inflammatory cytokines, as well as the M1 phenotype specific markers STAT1, CCL5, CXCL9, and CXCL10. This was paralleled by an increase in the mRNA expression of anti-inflammatory cytokines, as well as the M2 phenotype specific markers ARG-1, CD206, Retnla, CCL17 and CCL22. In addition, liraglutide treatment attenuated ROS overproduction by reducing NADPH oxidase activity by decreasing DUOX-1 and DUOX-2 levels. These observations were paralleled by a decrease in diabetes-induced TRPC6 and TRPM2 protein expression and mRNA levels.

**Conclusions:** To our knowledge, this is the first study to show an anti-inflammatory reno-protective effect of liraglutide in T1DM manifested by a shift in macrophage polarization towards the M2 phenotype possibly through NADPH/TRP dual inhibition.

## Runciciguat, a Novel Soluble Guanylate Cyclase (sGC) Activator, Shows Kidney Protection in Models of CKD

Jan R. Kraehling,<sup>1</sup> Tibor Schomber,<sup>1,3</sup> Agnes M. Benardeau,<sup>1,2</sup> Antje Kahnert,<sup>1</sup> Laura Popp,<sup>1</sup> Julia Vienenkoetter,<sup>1</sup> Heidrun C. Ellinger-Ziegelbauer,<sup>1</sup> Mira Pavkovic,<sup>1</sup> Axel Kretschmer,<sup>1</sup> Bettina Lawrenz,<sup>1</sup> Elke Hartmann,<sup>1</sup> Krystyna Siudak,<sup>1</sup> Alexius Freyberger,<sup>1</sup> Ina Hagelschuer,<sup>1</sup> Ilka Mathar,<sup>1</sup> Jörg Hüser,<sup>1</sup> Michael G. Hahn,<sup>1</sup> Johannes-Peter Stasch,<sup>1</sup> Volker Geiss,<sup>1</sup> Frank Eitner,<sup>1</sup> Peter Sandner.<sup>1</sup> <sup>1</sup>Bayer AG, Leverkusen, Germany; <sup>2</sup>Novo Nordisk AS Global Research, Malov, Denmark; <sup>3</sup>Vincex Pharma, Leverkusen, Germany.

**Background:** The novel sGC activator runciciguat is currently being studied in a Phase II trial in proteinuric CKD patients (NCT04507061) and targets the oxidized and heme-free form of sGC, restoring cGMP production under oxidative stress.

**Methods:** Runciciguat was tested in hypertensive rats, the renin transgenic (RenTG) rat, and angiotensin-supplemented (ANG-SD) rat as well as in rats with diabetic and metabolic CKD, Zucker diabetic fatty (ZDF), and ZSF-1 rats. The model specific treatment duration ranged up to 42 wks Runciciguat was applied orally in doses of 1, 3, and 10 mg/kg/bid.

**Results:** In all four rat CKD models, runciciguat significantly and dose-dependently reduced proteinuria by 40% to 55% (Table 1, Figure 1). Long-term, 42 wks treatment of ZDF rats demonstrated additional improvements in GFR decline as well as improvements in tubular degeneration, glomerulopathy, protein casts, and fibrosis.

**Conclusions:** Runciciguat exhibits kidney protection in a broad range of CKD models with hypertensive as well as diabetic and metabolic etiologies that justifies its further exploration in proteinuric CKD patients.

## uPCR reduction

	RenTG	ANG-SD	ZDF	ZSF-1
uPCR	39.4%	56.6%*	49.8%*	53.7%*

\*, statistical significant difference at 3 mg/kg bid compared to placebo

#### Proteinuria (uPCR) in ZSF1 obese rats

black, placebo; red, 1 mg/kg/bid; blue, 3 mg/kg/bid; green, 10 mg/kg/bid

At weeks 4 and at 12 of treatment, all three doses lower proteinuria significantly. At week 8, 3 mg/kg/bid and 10 mg/kg/bid lower proteinuria significantly.

Data are mean  $\pm$  SEM. Statistics determined by one-way ANOVA followed by Tukey's multiple comparison test.

#### SA-PO248

**The Novel, Clinical Stage Soluble Guanylate Cyclase Activator BI 685509 Slows the Progression of Diabetic Nephropathy in db/db Mice**  
Nisha Sharma,<sup>1</sup> Wenjin Liu,<sup>1</sup> Anna Tang,<sup>1</sup> Michael P. Pieper,<sup>2</sup> Glenn A. Reinhart,<sup>2</sup> Yufeng Huang.<sup>1</sup> <sup>1</sup>University of Utah Health, Salt Lake City, UT; <sup>2</sup>Boehringer Ingelheim International GmbH, Ingelheim, Germany.

**Background:** Activation of soluble guanylate cyclase (sGC) to restore cyclic guanosine monophosphate (cGMP) and improve functionality of nitric oxide (NO) pathways impaired by oxidative stress is a potential treatment for chronic and diabetic kidney disease (CKD and DKD). Administration of BI-685509, a novel, orally active small molecule sGC activator has been shown to reduce tubulointerstitial fibrosis in the rat UUO model. This study sought to determine whether administration of BI-685509 could slow the progression of glomerulosclerosis in db/db mouse, a model of type 2 diabetes often characterized by relative NO deficiency.

**Methods:** Five groups of 10 mice including normal control, diabetic db/db mice without treatment but being terminated at 14 weeks and 20 weeks respectively, diabetic db/db mice treated with one of two doses of BI-685509 (30 and 100 mpk/day mixed in mouse diet) from weeks 14 to 20. All mice received uninephrectomy at 8 weeks of age to accelerate the development of kidney disease.

**Results:** Untreated db/db mice that had obesity, hyperglycemia, and hypertriglyceridemia (TG), developed progressive albuminuria and glomerular mesangial matrix expansion between weeks 14 and 20, linked with increased renal production of fibronectin (FN) and type IV collagen (Col-IV); renal oxidative stress was evident by increased Nox4 expression and urinary malondialdehyde (MDA) secretion. Although body weight was comparable in diabetic groups, BI-685509 at the two doses reduced both blood HbA1c (10.4 $\pm$ 1.4%, 9.7 $\pm$ 1.9% respectively, vs. 11.8 $\pm$ 1.6% of untreated db/db at 20 weeks, P<0.05) and TG levels (41.2 $\pm$ 14.9, 22.7 $\pm$ 12.6 mg/dL respectively, vs. 64.1 $\pm$ 21.6 mg/dL of untreated db/db at weeks, P<0.05). Importantly, high dose of BI-685509 slowed the progression of albuminuria. BI-685509 at both doses markedly retarded the increases in glomerular matrix accumulation similarly (by 33%, P<0.05) seen in db/db mice. However, high dose of BI-685509 markedly reduced the renal FN and Col-IV production and renal oxidative stress markers.

**Conclusions:** These results suggest that treatment with BI-685509 for 6 weeks slow the progression of diabetic nephropathy in db/db mice via multiple actions and underscores its therapeutic potential in CKD and DKD. Currently, BI-685509 is in Phase II clinical trial to be tested for CKD and DKD.

#### SA-PO249

#### High Glucose Induces Podocyte Dedifferentiation and Morphological Modification in Kidney Organoids

Giulia Spennati,<sup>1</sup> Heather H. Ward,<sup>2</sup> Anil K. Karihaloo,<sup>2</sup> Benjamin S. Freedman.<sup>1</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>Novo Nordisk Inc Seattle, Seattle, WA.

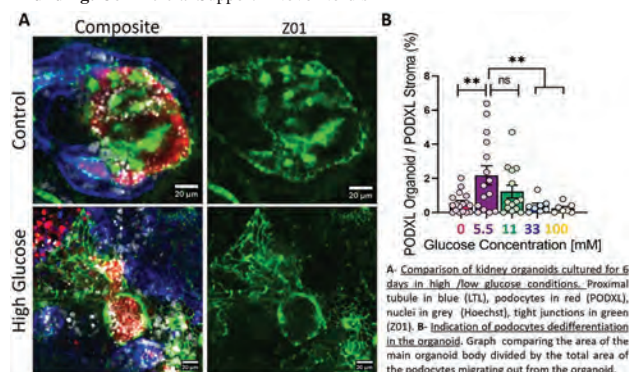

**Background:** Human kidney organoids are self-assembled 3-dimensional structures containing nephron components. Healthy organoids exhibit distal and proximal tubules interconnected with podocytes organized in a sphere. Kidney organoids represent a valid platform to study disease mechanisms due to the ability to replicate pathway aberration and altered cell-cell interaction to mimic human disease. Nevertheless, the impact of high glucose in these cultures is not yet known. We compared the effects of high and low glucose on kidney organoids with the aim of building a model for diabetic nephropathy.

**Methods:** Organoids were differentiated under standard glucose until maturation, then cultured 6 days under glucose ranging from 0 to 100 mM. Equivalent mannose concentrations evaluated the osmotic effect. At days 0, 3, and 6 each whole well was imaged and organoids scored, along with morphologic and metabolic analysis (LDH, lactate). Immunofluorescent analysis and live and dead assay were performed on day 6.

**Results:** Data showed reduction of organoid number and increased metabolism under high glucose. Surprisingly, the effect of high glucose did not correlate with cell death but organoids appeared to be changing in structure and marker expression. Mannose culture indicated a non-osmotic cause of injury. Under high glucose, we observed increased numbers of podocytes that appeared to be dedifferentiating and undergoing epithelial to mesenchymal transition. This observation was supported by Zo1 staining indicating an interconnection of podocytes migrating out from the main glomerular area.

**Conclusions:** We have induced a diabetic-like phenotype in kidney organoids under high glucose conditions, indicating that this platform may represent a valid model to study diabetic nephropathy. The dedifferentiation of podocytes is of particular interest, given that glomerular function is often compromised in patients. Future work will be directed to further develop this model with the aim of screening novel therapeutics.

#### SA-PO250

#### Histone Deacetylase Inhibitors Enhance the Urinary Tract's Immune Response in Diabetic Mice

Aaron A. Simoni,<sup>1</sup> Laura Schwartz,<sup>1</sup> M. Skye N. Bochter,<sup>1</sup> Kristin Bender,<sup>1</sup> John D. Spencer.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** People with diabetes mellitus (DM) have an increased risk for developing urinary tract infection (UTI). With UTI, people with DM are more likely to experience acute kidney injury and develop chronic kidney disease. Epigenetic mechanisms such as histone and protein acetylation have emerged as factors contributing to DM and may impact UTI risk. Recently, a class of drugs called histone deacetylase inhibitors (HDACi) have been shown to improve glucose sensitivity as well as decrease infection risk. To investigate the role of HDACi on UTI antibacterial defenses, we treated diabetic mice with MS-275, a class I HDACi.

**Methods:** Type 2 DM db/db mice, which have increased UTI susceptibility, were treated with 10mg/kg intraperitoneal (i.p.) MS-275 every 48 hours for a total of 8 doses. Weight, blood glucose, urine glucose, and serum insulin concentrations were measured after MS-275 or vehicle treatment. We also assessed insulin sensitivity by performing a glucose tolerance test in which mice were fasted for 6 hours and given i.p. glucose (1g/kg) prior to obtaining serial blood glucose measurements. Quantitative real-time PCR (qRT-PCR) was used to quantify innate immune genes that prevent UTI, including urothelial barrier genes that prevent bacterial invasion and antimicrobial peptides (AMP) which kill invading pathogens.

**Results:** After 4 doses of MS-275, serum glucose and insulin concentrations in diabetic mice normalized and decreased 7-fold. MS-275 treated mice also had significantly lower glucosuria, showing an 8-fold reduction compared to vehicle treated mice. MS-275 treatment improved glucose tolerance while vehicle treated mice showed minimal glucose clearance. qRT-PCR showed suppressed bladder HDAC expression with MS-275 treatment. Importantly, we observed an induction of bladder urothelial barrier genes (*Tjp1*, *Cldn2*, *Cldn4*, *Upk1a*, and *Upk2*) and AMPs (*Camp*, *Defb1*, *Lcn2*, *Rnase4*, *Spli*) in MS-275 treated mice compared to vehicle.

**Conclusions:** These results suggest that histone acetylation status may play a role in DM-mediated UTI defense. By increasing bladder barrier strength and AMP production using MS-275, the kidneys may be shielded from the deleterious effects of DM and UTI. Further studies are needed to assess the effectiveness of using MS-275 in individuals with DM to reduce UTI susceptibility and protect the kidneys.

## SA-PO251

**FRMD3/Protein 4.1O Splice Variants Regulate Hippo Signaling and Cell Migration**

Eva Koenigshausen,<sup>1</sup> Timo Reisewitz,<sup>1</sup> Larissa Matten,<sup>1</sup> Theresia Vienken,<sup>1</sup> Thorsten Wiech,<sup>2</sup> Lars C. Rump,<sup>1</sup> Lorenz Sellin.<sup>1</sup> <sup>1</sup>Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany; <sup>2</sup>University Hospital Hamburg-Eppendorf Department of Pathology, Hamburg, Germany.

**Background:** FRMD3 has been identified as a candidate gene for diabetic nephropathy and encodes for protein 4.1O. Different protein 4.1O splice variants have been identified. In diabetic kidney disease Hippo signaling (key effectors Yes-associated kinase (YAP) and its paralogue TAZ) is increased. Unphosphorylated YAP/TAZ activates target genes via different transcription factors (e. g. c-myc). Phosphorylated YAP/TAZ remains within the cytoplasm and is degraded. Activation of YAP/TAZ is increased by Myosin light chain kinase (MLCK). C-myc, YAP/TAZ and growth factors, e. g. EGF, have been shown to promote cell migration.

**Methods:** Human kidney biopsy samples from healthy and diabetic patients were stained for protein 4.1O. HEK293T cells were stimulated with low (5 mM), high (25 mM) glucose concentrations or an osmotic control (5mM glucose + 19.5 mM mannitol). RNA was isolated and PCR performed. A c-myc reporter assay was analyzed. HEK293T cells expressed protein 4.1O splice variants or the control and were stimulated with low, high glucose or mannitol. After cell lysis, western blot was performed for phospho-YAP, myosin light chain (MLC), phospho-MLC and actin. Human podocytes were stably transduced with 4.1O splice variants. For migration assays, human podocytes were stimulated with FCS or EGF.

**Results:** Protein 4.1O expression is detected in healthy human glomeruli. In diabetic patients with CKD stage 3b to 5 and gross proteinuria protein 4.1O expression seems to be increased in podocytes. High glucose leads to enhanced transcription of FRMD3. Under high glucose condition protein 4.1O significantly increases YAP phosphorylation. This effect is abrogated if a splice variant lacking a c-terminal domain is expressed. In line with this finding, protein 4.1O decreases c-myc transactivation. MLC phosphorylation is not altered by 4.1O splice variants in high, low glucose or mannitol. Protein 4.1O (lacking the FERM domain and a c-terminal domain) reduces podocyte migration.

**Conclusions:** Expression of protein 4.1O is increased in human diabetic kidney disease and under high glucose conditions. Protein 4.1O splice variants have differential effects on c-myc transactivation, YAP/TAZ activation and migration. This improved understanding of protein 4.1O splice variant function helps to better understand its role in diabetic nephropathy.

## SA-PO252

**Gene-Based Burden Analysis of De Novo Sphingolipid Pathway Genes Identifies CERS3 as a Potential Risk Gene in Advanced Diabetic Kidney Disease**

Christopher A. Simeone,<sup>1,2</sup> Joseph L. Wilkerson,<sup>3</sup> Scott Summers,<sup>3</sup> Marcus G. Pezzolesi.<sup>1,2</sup> <sup>1</sup>University of Utah, Department of Human Genetics, Salt Lake City, UT; <sup>2</sup>University of Utah, Nephrology & Hypertension, Salt Lake City, UT; <sup>3</sup>University of Utah, Department of Nutrition and Integrative Physiology, Salt Lake City, UT.

**Background:** Identifying the genetic factors influencing diabetic kidney disease (DKD) susceptibility remains challenging. Recent studies have demonstrated that ceramides, a class of sphingolipids, are antagonists for insulin signaling and drivers of DKD progression. Sphingolipid profiles have been explored in DKD, although little is known about the genetic architecture underlying aberrant sphingolipid levels in DKD. Here, we investigated the burden of rare, pathogenic variants in genes within the *de novo* sphingolipid pathway in patients with advanced DKD.

**Methods:** We examined 33 genes in two cohorts with advanced DKD (eGFR < 30): The Chronic Renal Insufficiency Cohort (CRIC, n=656) and the Utah Kidney Study (UKS, n=185). Genotype data from CRIC was imputed ( $R^2 \geq 0.4$ ) using the Michigan Imputation Server and variants localized to genes of interest were selected, while targeted sequencing of these same genes was performed for participants of the UKS. Using summary data from gnomAD (71,702 control genomes), we performed a two-stage, gene-based burden analysis of rare variants (gnomAD global AF filter < 0.01) using the TRAPD software package to identify reproducible candidate genes across cohorts. We performed immunofluorescence in kidneys and functional analyses of the top candidate gene identified in these analyses.

**Results:** Gene-based burden analyses identified *CERS3* as a significant, reproducible candidate gene in both the CRIC and UKS cohorts. Nominal significance was observed in two *ORMDL* genes after filtering variants for CADD score  $\geq 20$ . Immunofluorescence demonstrated the presence of *CERS3* in the tubules of mouse and human kidney tissues. Additionally, metabolic flux assays suggest that genetic variation in *CERS3* reduces Cer d18:1/26:0 produced in HEK293T cells.

**Conclusions:** *CERS3* is a ceramide synthase that produces longer acyl chain ceramides ( $\geq C26$ ). Interestingly, common variants in a similar family member, *CERS2*, have also been associated with renal phenotypes in patients with diabetes, suggesting that this family of enzymes may play a role in DKD susceptibility. Further examination is necessary to fully characterize the influence of *CERS3* on DKD progression.

**Funding:** NIDDK Support

## SA-PO253

**Exosomal or Non-Exosomal Profiles: Origin of Circulating miRNAs Associated With ESKD in Diabetes**

Eiichiro Satake,<sup>1,2</sup> Natalia Z. Nowak,<sup>1,3</sup> Zaipul I Md Dom,<sup>1,2</sup> Hiroki Kobayashi,<sup>1,4</sup> Joseph Ricca,<sup>1</sup> Bozena Krolewski,<sup>1,2</sup> Marcus G. Pezzolesi,<sup>5</sup> Ronald Kahn,<sup>1,2</sup> Andrzej S. Krolewski.<sup>1,2</sup> <sup>1</sup>Joslin Diabetes Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Trinity College Dublin School of Medicine, Dublin, Ireland; <sup>4</sup>Nihon Daigaku Igakubu Daigakuin Igaku Kenkyuka, Itabashi-ku, Japan; <sup>5</sup>University of Utah, Salt Lake City, UT.

**Background:** microRNAs (miRNAs) are 22 nt non-coding RNA molecules that can regulate gene and protein expression both in the cells that produce them and, potentially, in distant cells acting via secretion into the circulation. Previously, we identified 17 miRNAs in plasma that were either positively (risk) or negatively (protection) associated with progression to ESKD (*JASN* 2021). To elucidate possible mechanisms of transport of these miRNAs in the circulation, we compared levels of these miRNAs in plasma with their levels in exosomes.

**Methods:** Plasma from 55 T1D patients was divided into 11 pools (5 patients per pool), and exosomes isolated using size exclusion chromatography. miRNA levels in the 11 plasma and exosome pools were then assessed using the HTG EdgeSeq platform. The data were quantile normalized and analyzed using the R packages edgeR and limma.

**Results:** Out of 2083 miRNAs on the HTG platform, 463 (22%) were detected only in plasma, 72 (3%) were only in exosome, while 1358 were detected in both specimens. Of these, 437 (21%) had significantly higher (fold-change  $>2$  and  $p < 3.7 \times 10^{-5}$ ) concentrations in exosomes than in plasma, 402 miRNAs (19%) were higher in plasma than in exosomes, and 519 (25%) were similar in both specimens. All of the 17 ESKD-associated miRNAs were detected in both specimens, however, the relationship between concentration in exosomes and plasma were different between protective and risk miRNAs. Among the 9 protective miRNAs, 4 had similar concentration in plasma and exosomes, and 5 were significantly higher in plasma than in exosomes. Among the 8 risk miRNAs, all had low concentrations in exosomes and dramatically higher (5–400 fold) in plasma.

**Conclusions:** This study shows that the majority of the ESKD-associated miRNAs have low concentrations in exosomes but very high in plasma, indicating that the ESKD-associated miRNAs are present mainly in non-exosomal plasma fraction. Mechanisms of their release into circulation and uptake by target tissue(s) are unknown but differ from those for the miRNAs transported mainly in exosomes. Understanding how these non-exosomal miRNAs are secreted and act on the kidney should provide new insights into the mechanism of the progression of diabetic kidney disease to ESKD and its possible treatment.

**Funding:** NIDDK Support, Private Foundation Support

## SA-PO254

**Characterising the Pro-Oxidant Enzyme NOX5 as a Potential Therapeutic Target for Diabetic Kidney Disease**

Jay C. Jha,<sup>1</sup> Aozhi Dai,<sup>1</sup> Vincent Jaquet,<sup>2</sup> Mark E. Cooper,<sup>1</sup> Karin Jandeleit-Dahm.<sup>1</sup> Diabetic Kidney Disease Lab. <sup>1</sup>Monash University Department of Diabetes, Melbourne, VIC, Australia; <sup>2</sup>Universite de Geneve, Geneva, Switzerland.

**Background:** Diabetic kidney disease (DKD) is the leading cause of end stage renal failure. Enhanced level of renal reactive oxygen species (ROS) produced by the pro-oxidant enzyme NADPH oxidase- NOX5 is considered a major contributor in aggravating renal injury in DKD. We aim to characterise the pathogenic role of NOX5 and associated ROS-sensitive pathways in DKD using various experimental models including human diabetic kidney biopsies, human diabetic renal organoids and cells as well as humanised NOX5 transgenic diabetic mice models.

**Methods:** We examined the expression of NOX5 in association with ROS-sensitive factors including a transcription factor, EGR1 (early growth response 1), a protein kinase, PKC- $\alpha$  and a key metabolic gene involved in redox balance, TXNIP (thioredoxin-interacting protein), as well as ROS production in human kidney biopsies as well as in human renal organoids and cells. We assessed the effect of NOX5 inhibition using genetic manipulation and pharmacological inhibition approaches in human renal cells and organoids exposed to diabetic milieu environment. In vivo, we also assessed the effect of Nox5 overexpression independent of NOX4 in humanised Nox5 transgenic mice in the presence or absence of diabetes.

**Results:** We identified increased expression of renal NOX5 in diabetic patients in association with upregulation of EGR-1, PKC- $\alpha$  and TXNIP. Silencing of Nox5 attenuated high glucose induced gene expression of markers of fibrosis and inflammation as well as downregulation of EGR-1, PKC- $\alpha$  and TXNIP. Our data also suggest that Nox5 appears to be upstream of Nox4 and that Nox5 inhibition also downregulates Nox4, but not vice versa. In vivo, overexpression of Nox5 independent of NOX4 pathways demonstrated an increase in albuminuria, renal fibrosis and inflammation in association with upregulation of EGR-1, ERK1/2, PKC- $\alpha$ , PKC- $\epsilon$  and TXNIP via enhanced ROS production in comparison to diabetic mice not expressing Nox5.

**Conclusions:** These findings suggest that NOX5 plays a key pathogenic dominant role in human DKD, thereby providing the fast track validation of NOX5 specific inhibitors to combat DKD in humans.

## SA-PO255

**Mechanistic Role of Renal Tubular Mitochondrial AKT1 in Metabolic Syndrome-Induced Renal Injuries**

Hugo Y. Lin,<sup>1,2</sup> Chia-Hung Yen,<sup>5</sup> Yi-Siao Chen,<sup>5</sup> I-Ya Chen,<sup>3</sup> Jee-Fu Huang,<sup>5,2</sup> Tzongshi Lu,<sup>4</sup> *'kaohsiung municipal Ta-Tung Hospital, Kaohsiung, Taiwan;* <sup>2</sup>*Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan;* <sup>3</sup>*Chang Gung University, Taoyuan, Taiwan;* <sup>4</sup>*Brigham and Women's Hospital Department of Medicine, Boston, MA;* <sup>5</sup>*Kaohsiung Medical University, Kaohsiung, Taiwan.*

**Background:** Metabolic syndrome (MetS) is associated with kidney diseases, but the etiology is inconclusive. Recent evidence suggests that mitochondrial dysfunction, which can be modulated by AKT1, may play a critical role in kidney injury. We hypothesized that renal tubular mitochondrial AKT1 signaling plays a mechanistic role in the pathogenesis of kidney injuries in MetS.

**Methods:** We executed the study with 8-week C57BL/6 male mice fed with high fat diet (21.1% fat, 41% sucrose, and 1.25% cholesterol by weight) and a high sugar solution (23.1g/L d-fructose, and 18.9g/L d-glucose) for six months, compared with mice fed with normal chow diet and normal tap water.

**Results:** In our murine MetS model, the body weight was raised ( $p < 0.001$ ). The kidney size as a percentage of body weight was similar ( $p = 0.765$ ). For the glucose tolerance test, the fasting glucose level was significantly higher in MetS mice as compared to normal diet mice ( $p = 0.003$ ). From 15 to 120 minutes, the glucose levels were significantly elevated ( $p = 0.022$ ). The shape of the intraperitoneal glucose tolerance test curve at three months was dissimilar to that at six months, and the AUC value at six months was higher ( $p = 0.013$ ). The fasting hyperinsulinemia ( $p = 0.017$ ) and insulin resistance measured by Homeostatic Model Assessment for Insulin Resistance was elevated ( $p = 0.003$ ). For renal function, although serum BUN ( $p = 0.785$ ) and creatinine ( $p = 0.654$ ) in MetS mice were not changed, the proteinuria ( $p = 0.023$ ), and the urine KIM-1 ( $p = 0.014$ ) were raised. There were prominent glomerulosclerosis index ( $p = 0.032$ ), tubulointerstitial fibrosis score ( $p = 0.015$ ), tubular dilatation score ( $p = 0.038$ ), tubular vacuolation score ( $p = 0.028$ ), and tubular casts ( $p = 0.031$ ) of renal histology. To further dissect the role of mitochondrial AKT1 signaling during MetS in the renal tubules, we have examined the mitochondrial AKT1 protein. There was increasing accumulation of phosphorylated AKT1 ( $p = 0.030$ ) in the mitochondria at proximal tubule after MetS. AKT1 translocation was confirmed with immunohistochemistry stain and western blots of mitochondria proteins.

**Conclusions:** These findings shed new light on the mechanistic role of renal tubular mitochondrial AKT1 in MetS-induced kidney injuries and may be used to develop new strategies for the prevention and treatment of kidney diseases.

**Funding:** Government Support - Non-U.S.

## SA-PO256

**Store-Operated Ca<sup>2+</sup> Entry Inhibition Ameliorated High Glucose- and Ang2-Induced Podocyte Apoptosis and Mitochondria Damage**

Yu Tao,<sup>1</sup> Parisa Yazdizadeh Shotorbani,<sup>1</sup> Zhenglan Chen,<sup>1</sup> Denise M. Inman,<sup>2</sup> Rong Ma,<sup>1</sup> <sup>1</sup>*University of North Texas Health Science Center, Department of Physiology and Anatomy, Fort Worth, TX;* <sup>2</sup>*University of North Texas Health Science Center, North Texas Eye Research Institute, Pharmaceutical Science, Fort Worth, TX.*

**Background:** Diabetic Nephropathy (DN) is the most common cause of end stage renal disease. Podocyte apoptosis is one of early features of the disease and mitochondria impairment is a contributor to podocyte injury in diabetic kidney. Hyperglycemia and increased renal angiotensin II (ANG II) are two pathogenic stimuli for onset and progression of podocyte pathology in DN. However, the mechanism of the podocyte injury induced by the diabetes-related stress is not fully understood. Store-operated Ca<sup>2+</sup> entry (SOCE) has multiple functions in both excitable and non-excitable cells. It is known that ANG II activates SOCE by releasing endoplasmic reticulum Ca<sup>2+</sup>. Our previous study demonstrated that high glucose (HG) treatment enhanced SOCE by increasing Orai1 protein abundance in podocyte. However, the role of SOCE in podocyte apoptosis and mitochondria dysfunction in the setting of diabetes remains unclear. The present study was carried out to test the hypothesis that enhanced SOCE mediated HG- and ANG II-induced podocyte apoptosis and mitochondria damage.

**Methods:** All experiments were performed using cultured human podocytes. BTP2 (4  $\mu$ M) was used as the SOCE inhibitor. Podocyte apoptosis was determined by flow cytometry using Annexin V/Propidium iodide (PI) staining. Mitochondria function was evaluated by measuring: 1) the mitochondria membrane potential (MMP) using TMRE fluorescence, 2) generation of mitochondria reactive oxygen species (ROS) using MitoSox Red Mitochondrial Superoxide Indicator, 3) ATP production using ATP assay kit, and 4) mitochondria respiratory function [oxygen consumption rate (OCR)] and mitochondria ATP production by seahorse analysis.

**Results:** Both HG (25 mM) and ANG II (1  $\mu$ M) treatments for 24 hours significantly increased podocyte apoptosis. All responses were significantly blunted by BTP2 (4  $\mu$ M). HG (25 mM) treatment significantly decreased podocyte MMP, ATP production and increased mitochondrial ROS generation, all of which were significantly inhibited by BTP2 treatment. Furthermore, HG (25 mM) and ANG II (1  $\mu$ M) treatment for 24 hours significantly reduced podocyte OCR and mitochondria ATP production, which were significantly blunted by BTP2.

**Conclusions:** SOCE contributed to HG- and ANG II-induced podocyte apoptosis and mitochondria damage.

**Funding:** NIDDK Support

**SGLT2 Inhibitors Attenuate Hypoxia and HIF1A Expression in Young Persons With Type 2 Diabetes**

Jennifer A. Schaub,<sup>1</sup> Viji Nair,<sup>1</sup> Fadhl Alakwaa,<sup>1</sup> Phillip J. McCown,<sup>1</sup> Abhijit S. Naik,<sup>1</sup> Patricia E. Ladd,<sup>2</sup> Roger K. Harned,<sup>2</sup> Helen C. Looker,<sup>4</sup> Pottumarthi V. Prasad,<sup>3</sup> Luping Li,<sup>3</sup> Laura Pyle,<sup>2</sup> Frank C. Brosius,<sup>5</sup> Robert G. Nelson,<sup>4</sup> Matthias Kretzler,<sup>1</sup> Petter Bjornstad,<sup>2</sup> <sup>1</sup>*University of Michigan, Ann Arbor, MI;* <sup>2</sup>*Children's Hospital Colorado, Aurora, CO;* <sup>3</sup>*NorthShore University HealthSystem, Evanston, IL;* <sup>4</sup>*National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD;* <sup>5</sup>*The University of Arizona College of Medicine Tucson, Tucson, AZ.*

**Background:** SGLT2 inhibitors (SGLT2i) are protective in diabetic kidney disease. Their potential impact on kidney oxygenation and transcriptional responses to hypoxia were assessed.

**Methods:** Blood oxygen level dependent-MRI data were available in young persons with type 2 diabetes (T2D, n=22, 13 on SGLT2i). Single-cell RNA sequencing data were generated from research kidney biopsies in a subset of T2D (n=16, 10 on SGLT2i) and healthy controls (HC, n=6) and compared to tubulointerstitial microarray data from kidney biopsies of American Indians with T2D (n=47). The transcriptional profile of Hypoxia Response Genes (HRG), comprising 172 target genes of Hypoxia Inducible Factor-1A (HIF1A), were examined in HC and T2D, with and without SGLT2i.

**Results:** The average (SD) age of participants with T2D was 16 $\pm$ 2 years and median (IQR) measured GFR was 185 (160-242) ml/min. Higher cortical and medullary oxygen availability was associated with SGLT2i treatment (Fig.1). Increased HIF1A expression in T2D (without SGLT2i) compared to HC in proximal tubules (PT) was suppressed with SGLT2i. Correspondingly, 27% of HRG was suppressed with SGLT2i in PT, with glycolytic enzymes including phosphoglycerate kinase (PGK1) and phosphofructokinase (PFKL) as major contributors. PGK1 ( $r = 0.53$ ,  $p < 0.05$ ) and PFKL ( $r = 0.58$ ,  $p < 0.05$ ) expression, rather than HIF1A, in PT cells correlated with increased cortical hypoxia (higher R2\*). In American Indians with T2D, increased HIF1A expression was associated with increased interstitial fibrosis ( $r = 0.47$ ,  $p < 0.05$ ) and future loss of kidney function ( $r = -0.44$ ,  $p < 0.05$ ).

**Conclusions:** SGLT2i associate with improved kidney oxygenation, which may mitigate the deleterious morphometric and clinical outcomes associated with high kidney HIF1A expression and contribute to the beneficial kidney effects of SGLT2i.

## SA-PO258

**Nephron Segment Specific Response to SGLT2 Inhibitors in Young Persons With Type 2 Diabetes**

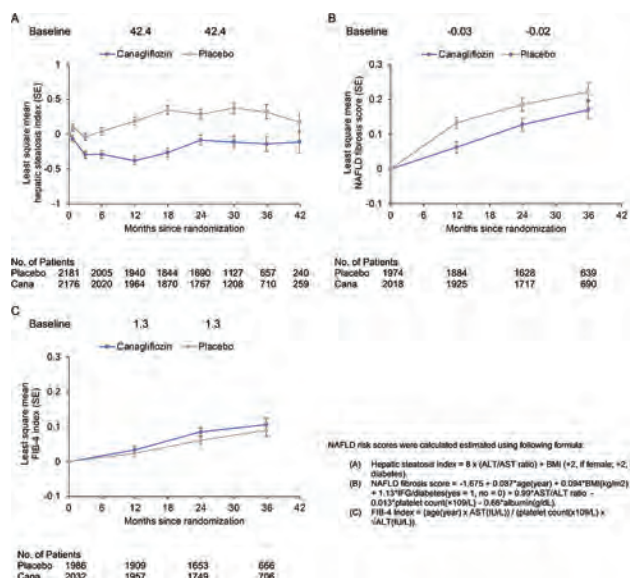

Petter Bjornstad,<sup>1</sup> Fadhl Alakwaa,<sup>2</sup> Phillip J. McCown,<sup>2</sup> Jennifer A. Schaub,<sup>2</sup> Abhijit S. Naik,<sup>2</sup> Sean Eddy,<sup>2</sup> Viji Nair,<sup>2</sup> Roger K. Harned,<sup>1</sup> Patricia E. Ladd,<sup>1</sup> Laura Pyle,<sup>1</sup> Jeffrey B. Hodgin,<sup>2</sup> Frank C. Brosius,<sup>2</sup> Robert G. Nelson,<sup>3</sup> Matthias Kretzler,<sup>2</sup> <sup>1</sup>*University of Colorado Denver School of Medicine, Aurora, CO;* <sup>2</sup>*University of Michigan, Ann Arbor, MI;* <sup>3</sup>*National Institute of Diabetes and Digestive and Kidney Diseases Division of Intramural Research, Phoenix, AZ.*

**Background:** Youth-onset type 2 diabetes (T2D) carries a higher risk of diabetic kidney disease (DKD) than type 1 and adult-onset type 2 diabetes of similar duration, with few treatment options. SGLT2 inhibitors (SGLT2i) are protective against DKD, but the mechanisms of nephroprotection are incompletely understood.

**Methods:** Single-cell RNA sequencing (scRNAseq) data and morphometrics were obtained from protocol kidney biopsies in healthy controls (HC, n=6) and participants ranging from 12-21 years with T2D (n=16), either treated with SGLT2i (T2Di+, n=6) or not (T2Di-, n=10). Transcripts elevated in T2D vs. HC but reduced in T2Di+ vs. T2Di- were considered "suppressed", similarly transcripts depressed in T2Di- but elevated in T2Di+ were termed "enhanced". mTOR activity scores were calculated based on expression of 39 reactome pathway genes.

Effects of canagliflozin on (A) hepatic steatosis index, (B) NAFLD fibrosis score, and (C) FIB-4 index

## SA-PO262

### Effects of Canagliflozin (CANA) on Cardiovascular (CV), Kidney, and Albuminuria Outcomes by Diabetes Duration: Pooled Analysis From the CANVAS Program and CREDENCE

Sheldon W. Tobe,<sup>1</sup> Harpreet S. Bajaj,<sup>2</sup> Adeera Levin,<sup>3</sup> Thomas Mavrakanas,<sup>4</sup> Navdeep Tangri,<sup>5</sup> April E. Slee,<sup>6</sup> Wally Raptanoti,<sup>7</sup> Fernando G. Ang.<sup>7</sup>  
<sup>1</sup>Sunnybrook Research Institute, Toronto, ON, Canada; <sup>2</sup>LMC Healthcare, Toronto, ON, Canada; <sup>3</sup>Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; <sup>4</sup>Division of Nephrology, Department of Medicine, McGill University Health Centre, Montreal, QC, Canada; <sup>5</sup>Max Rady College of Medicine, University of Manitoba, Winnipeg, MB, Canada; <sup>6</sup>New Arch Consulting, Seattle, WA; <sup>7</sup>Janssen, Inc, Toronto, ON, Canada.

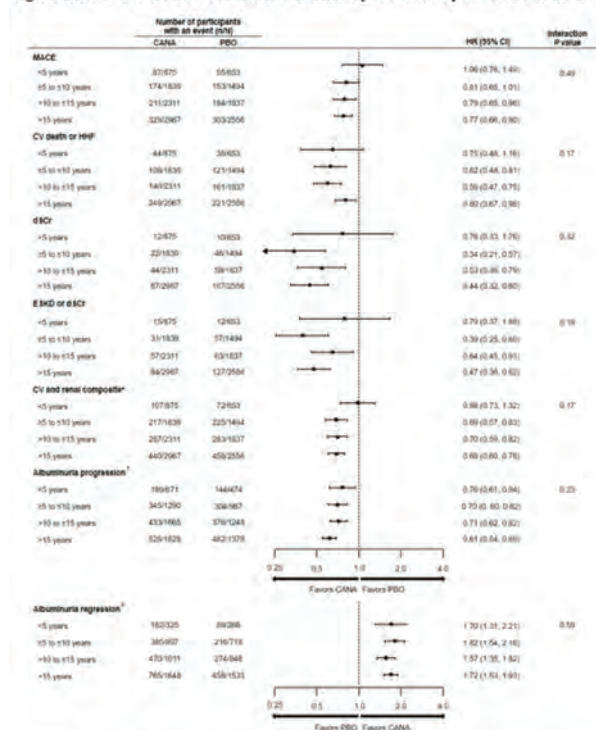

**Background:** Type 2 diabetes (T2DM) is a progressive disease and increasing duration is associated with heightened risk of morbidity and mortality. CANA reduced CV and kidney events in patients (pts) with T2DM and CV risk or nephropathy. We assessed the effects of CANA on CV and kidney outcomes and albuminuria progression by disease duration.

**Methods:** This post hoc analysis pooled patient-level data from the CANVAS Program (N=10,142) and the CREDENCE trial (N=4401) to examine the effect of CANA vs placebo on CV events (major adverse cardiovascular events [MACE] and CV death or hospitalization for heart failure), kidney events (doubling of serum creatinine [dScr] and end-stage kidney disease or dESK), a composite of CV and kidney events, and albuminuria progression and regression (change in albuminuria class [normo-, micro-, macro-] plus  $\geq 30\%$  urinary albumin to creatinine ratio change) in pts with diabetes duration of  $<5$ ,  $\geq 5$  to  $\leq 10$ ,  $>10$  to  $\leq 15$ , and  $>15$  y. HRs and 95% CIs were estimated using a Cox proportional hazards model, stratified by duration of diabetes.

**Results:** Overall, there were 1528, 3333, 4148, and 5523 pts with diabetes duration of  $<5$ ,  $\geq 5$  to  $\leq 10$ ,  $>10$  to  $\leq 15$ , and  $>15$  y. CANA reduced the risk of CV, kidney, composite cardiorenal outcomes, with no statistical heterogeneity amongst subgroups by diabetes duration. Similarly, CANA reduced the rate of albuminuria progression and increased rate of albuminuria regression across diabetes duration subgroups (Figure).

**Conclusions:** CANA reduced the risk of CV, kidney, and composite cardiorenal events consistently, regardless of diabetes duration. Results show within 5 years of developing T2DM, CANA positively impacts on albuminuria, an important consideration in primary care setting.

Figure. Effects of CANA vs PBO on CV and kidney outcomes by diabetes duration.

PBO, placebo; HHF, hospitalization for heart failure; ESKD, end-stage kidney disease; UACR, urinary albumin to creatinine ratio.

\*Composite that includes MACE, HHF, dScr, or ESKD.

<sup>†</sup> $\geq 1$  step increase in UACR category along with an increase in ACR  $\geq 30\%$  from baseline.

<sup>‡</sup> $\geq 1$  step decrease in UACR category along with a decrease in ACR  $\geq 30\%$  from baseline.

## SA-PO263

### Sotagliflozin, a Dual SGLT1 and SGLT2 Inhibitor, Reduces the Risk of Cardiovascular and Renal Disease as Assessed by Steno Risk Engines in Adults With Type 1 Diabetes

Elisabeth B. Stougaard,<sup>1</sup> Peter Rossing,<sup>1,2</sup> Dorte Vistisen,<sup>1,3</sup> Phillip Banks,<sup>4</sup> Manon Girard,<sup>4</sup> Michael J. Davies,<sup>4</sup> Frederik Persson.<sup>1</sup> <sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; <sup>3</sup>Department of public health, University of Copenhagen, Copenhagen, Denmark; <sup>4</sup>Lexicon Pharmaceuticals, Inc., The Woodlands, TX.

**Background:** Sotagliflozin (SOTA) demonstrated cardiovascular and renal benefits in high-risk adults with type 2 diabetes. No studies have shown whether this can be demonstrated in type 1 diabetes (T1D). Treatment with SOTA is associated with increased risk of diabetic ketoacidosis (DKA). The potential cardiorenal benefits may outweigh the risk of DKA when evaluating SOTA for T1D. This analysis estimated the risk of cardiovascular disease (CVD) and end-stage kidney disease (ESKD) in adults with T1D treated with SOTA.

**Methods:** Participant-level data were used from the inTandem trials evaluating 2977 adults with T1D randomized to once-daily placebo, SOTA 200 mg or SOTA 400 mg for 24 weeks. For each participant, the cumulative risks of developing CVD and ESKD were estimated using the Steno T1 Risk Engines, which are prediction models for the 5- and 10-year risk of CVD and 5-year risk of ESKD. The estimated risk was calculated at baseline and week 24. The difference in least-square mean percent change in estimated risk from baseline (95% CI and p-value) was compared between groups using a mixed model with percent change from baseline as dependent and including the treatment group as fixed effect, and the baseline value as covariate.

**Results:** SOTA significantly reduced 5- and 10-year CVD risk scores by approximately 4 to 7% compared to placebo (Table). ESKD risk score was numerically reduced with SOTA 200 mg and significantly reduced with SOTA 400 mg relative to placebo. Similar results were observed with SOTA pooled.

**Conclusions:** Using the Steno T1 Risk Engines, the estimated risk of CVD and ESKD was significantly reduced with SOTA compared to placebo. This provides additional results that may positively enhance the benefit/risk assessment of SOTA use in T1D.

**Funding:** Commercial Support - Lexicon Pharmaceuticals, Inc. funded the inTandem studies

Table. Effect of sotagliflozin on CVD and ESKD Risk Score using Steno T1 Risk Engines

	Sotagliflozin 200 mg N = 524		Placebo N = 526		Difference in LSM % change (95% CI)
	BL mean (SD)	Mean % change from baseline (SD)	BL mean (SD)	Mean % change from baseline (SD)	
5-yr CVD risk	7.5% (6.6)	-3.5 (18.5)	6.8% (6.4)	1.5 (17.3)	-4.5 (-6.8, -2.5)*
10-yr CVD risk	14.0% (11.4)	-3.4 (17.7)	12.7% (11.0)	1.4 (16.6)	-4.8 (-6.5, -2.4)*

## Effect of Sotagliflozin (SOTA) on Albuminuria in Patients With Type 2 Diabetes (T2D) and CKD

David Cherney,<sup>1</sup> Deepak L. Bhatt,<sup>2</sup> Michael Szarek,<sup>3</sup> Franklin W. Sun,<sup>4</sup> Michael J. Davies,<sup>4</sup> Bertram Pitt,<sup>5</sup> Philippe Gabriel Steg,<sup>6</sup> The SCORED Investigators <sup>1</sup>Toronto General Hospital, Toronto, ON, Canada; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>University of Colorado Anschutz, Aurora, CO; <sup>4</sup>Lexicon Pharmaceuticals Inc, The Woodlands, TX; <sup>5</sup>University of Michigan, Ann Arbor, MI; <sup>6</sup>Hôpital Bichat, Assistance Publique - Hôpitaux de Paris, Paris, France.

**Background:** Albuminuria in patients with/without diabetes presents a higher risk for adverse renal and cardiovascular (CV) outcomes. SGLT inhibitors demonstrate improved albuminuria. The study observed the impact of the SGLT1/SGLT2 inhibitor SOTA on urine albumin-to-creatinine ratio (UACR).

**Methods:** SCORED—a Phase 3, multicenter, double-blind, placebo-controlled, parallel-group study—randomized 10,584 patients with T2D, CKD, and other CV risk factors to SOTA or placebo. Kidney inclusion criteria were eGFR 25–60 mL/min/1.73 m<sup>2</sup> and any UACR. Percentage treatment difference was estimated by geometric mean ratio for the overall cohort and by eGFR and UACR subgroups. Progression/regression of UACR were assessed. Hazard ratios, 95% confidence intervals (CI), and p-values were estimated by Cox proportional hazards model.

**Results:** Median baseline eGFR was 44.5 mL/min/1.73 m<sup>2</sup>, with 8% at <30 mL/min/1.73 m<sup>2</sup>. At baseline, median UACR was 82 mg/g, and 1/3 of patients had normoalbuminuria, 1/3 had micro, and 1/3 had macro. Median follow up was 16 months. The UACR difference for SOTA vs placebo was -21.3% (95% CI -23.4, -19.1; p<0.0001). Reductions were similar across eGFRs. In UACR 30–299 mg/g and ≥300 mg/g, reductions were significant in SOTA (p<0.0001; Fig 1). Progression risk was lower and regression risk higher in SOTA vs placebo (p<0.0001; Fig 2).

**Conclusions:** SOTA significantly reduced UACR and had favorable effects on UACR progression and regression.

**Funding:** Commercial Support - Sanofi and Lexicon Pharmaceuticals

## SA-PO265

Semaglutide Improves eGFR Slope vs. Placebo Regardless of Baseline HbA<sub>1c</sub> and Blood Pressure in People With Type 2 Diabetes: A Post Hoc Analysis of SUSTAIN 6 and PIONEER 6

David Cherney,<sup>1</sup> Heidrun Bosch-Traberg,<sup>2</sup> Samy Hadjadj,<sup>3</sup> Anja B. Kuhlman,<sup>2</sup> Soren Rasmussen,<sup>2</sup> Katherine R. Tuttle,<sup>5,6</sup> Hiddo J. L. Heerspink,<sup>4</sup> <sup>1</sup>University Health Network, Toronto, ON, Canada; <sup>2</sup>Novo Nordisk AS, Søborg, Denmark; <sup>3</sup>L'institut du thorax, Nantes, France; <sup>4</sup>University Medical Center Groningen, Groningen, Netherlands; <sup>5</sup>University of Washington, Spokane, WA; <sup>6</sup>Providence Washington, Spokane, WA.

**Background:** Previous analyses of SUSTAIN 6 and PIONEER 6 cardiovascular (CV) outcome trials indicate that semaglutide (respectively, subcutaneous and oral) reduces the decline rate (slope) of estimated glomerular filtration rate (eGFR) vs placebo in people with type 2 diabetes on standard of care antidiabetes medication at high CV risk. The effect was more pronounced in those with a comparatively lower eGFR (<60 mL/min/1.73 m<sup>2</sup>). This *post hoc* analysis evaluated whether the effect of semaglutide vs placebo on eGFR slope was consistent across different levels of glycemic control (HbA<sub>1c</sub>) or blood pressure (BP) at baseline.

**Methods:** Pooled SUSTAIN 6 and PIONEER 6 data were analyzed for change in eGFR slope from baseline in HbA<sub>1c</sub> (<8 and ≥8%) and BP (<140/90 and ≥140/90 mmHg) subgroups. A sensitivity analysis was performed adjusting for age, sex, diabetes duration, antidiabetes medication, smoking status, prior CV events, geographic region, and eGFR at baseline. Groups were also analyzed by baseline eGFR (<60 and ≥60 mL/min/1.73 m<sup>2</sup>).

**Results:** Baseline characteristics were similar across HbA<sub>1c</sub> and BP subgroups. The mean urine albumin:creatinine ratio, measured in SUSTAIN 6 only, was higher in HbA<sub>1c</sub> ≥8% and BP ≥140/90 mmHg subgroups (29.6 and 39.1 mg/g, respectively) than the HbA<sub>1c</sub> <8% and BP <140/90 mmHg subgroups (17.2 and 17.0 mg/g, respectively). Semaglutide consistently reduced eGFR slope decline vs placebo in all subgroups (Figure), as supported by the sensitivity and eGFR subgroup analyses.

**Conclusions:** Semaglutide reduces eGFR slope decline vs placebo regardless of glycemic control or BP level, suggesting a consistent effect of semaglutide on eGFR preservation.

**Funding:** Commercial Support - Novo Nordisk A/S

Data shown are at 1 year (all data points across visits from SUSTAIN 6 and PIONEER 6 are used in the analyses), for the full analysis set in subjects with baseline and at least one post-baseline measurement. Random slope model of repeated eGFR measures analyzed with eGFR values as dependent variable adjusted by baseline value, and time interacting with treatment and subgroup. Intercept and slopes of effect of time are assumed to vary randomly amongst subjects based on a two-dimensional normal distribution. All subjects in the SUSTAIN 6 trial had a HbA<sub>1c</sub> ≥7.0 at screening to be randomly enrolled. No HbA<sub>1c</sub> requirements were defined for subject inclusion in the PIONEER 6 trial. BP, blood pressure; CI, confidence interval; eGFR, estimated glomerular filtration rate; ETD, estimated treatment difference.

Estimated annual eGFR slopes according to treatment, and HbA<sub>1c</sub> and BP subgroups at baseline

## Long-Term Use of Empagliflozin vs. DPP4 Inhibitors Mitigates eGFR Slopes in Patients With Type 2 Diabetes: Real-World Evidence

Ofri Mosenzon,<sup>1,2</sup> Cheli Melzer Cohen,<sup>3</sup> Ilan Yanuv,<sup>1,2</sup> Aliza Rozenberg,<sup>1,2</sup> Gabriel Chodick,<sup>3,5</sup> Meir Schechter,<sup>1,2</sup> Avraham Karasik,<sup>3,4</sup> <sup>1</sup>*Diabetes Unit, Department of Endocrinology and Metabolism, Hadassah Medical Center, Jerusalem, Israel;* <sup>2</sup>*Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel;* <sup>3</sup>*Maccabi Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv, Israel;* <sup>4</sup>*Tel Aviv University, Tel Aviv, Israel;* <sup>5</sup>*School of Public Health Sackler, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

**Background:** Randomized controlled studies showed that sodium-glucose cotransporter 2 inhibitors (SGLT2i) mitigate kidney function loss in patients with type 2 diabetes (T2D) at high cardiovascular (CV) and kidney risk. However, long-term efficacy studies in general population with T2D are lacking.

**Methods:** In Maccabi Healthcare Services, a large Israeli database (2015-2021), we compared the change in eGFR in patients with T2D who initiated empagliflozin (EMPA) or any SGLT2i, vs dipeptidyl peptidase-4 inhibitor (DPP4i). Treatment arms were propensity score-matched by 96 baseline characteristics. Subjects were followed until death, end of data availability, exposure discontinuation, initiation of the comparator drug, after 5 years, or October 2021. In a previous analysis we showed that compared to DPP4i, EMPA and any SGLT2i reduce the risk of the primary kidney outcome ( $\geq 40\%$  eGFR declined or end-stage kidney disease). In this secondary analysis, we compared the change in eGFR overtime between arms.

**Results:** The matched population included overall 15992 initiators of EMPA or DPP4i (1:1 ratio), of them 12781 (79.9%) had eGFR measurement at follow-up. Median [IQR] follow-up was 17.9 [9.5-33.5] months, and 4924 (38.5%) were followed for  $\geq 2$  years. Mean eGFR slope were less steep with EMPA compared to DPP4i (-1.33 vs -2.26 mL/min/1.73m<sup>2</sup>/year) with mean absolute between-arms difference in favor of EMPA of 0.93 mL/min/1.73m<sup>2</sup>/year (95%CI 0.67-1.18; both  $p < 0.001$ ). Mitigation of eGFR slope with EMPA continued to increase with longer treatment (figure). Similar significant effects were obtained when comparing initiators of any SGLT2i to DPP4i.

**Conclusions:** Compared with DPP4i, long-term use of EMPA or any SGLT2i is associated with mitigation of kidney function loss in a general population with T2D.

**Funding:** Commercial Support - Boehringer Ingelheim

## SA-PO267

## Perceived Barriers to SGLT2i Prescription in Primary Care vs. Nephrology Providers: Findings From the Michigan Kidney Improvement Collaborative

Michael Heung, Rajiv Saran, Julie A. Wright Nunes, Jacob E. Reiss, Katherine L. Khosrovaneh, Jacqueline Rau. Michigan Kidney Improvement Collaborative University of Michigan, Ann Arbor, MI.

**Background:** Newer medications such as SGLT2i's and GLP1a's reduce cardiovascular, renal, and metabolic complications in patients with type 2 diabetes, yet studies suggest slow uptake in prescribing among eligible populations. Here we report initial findings from the Michigan Kidney Improvement Collaborative (MKIC), a statewide nephrology initiative launched in 2021 to improve care of diabetic kidney disease. MKIC is embedded within the Michigan Collaborative for Type 2 Diabetes (MCT2D) which focuses on primary care physicians (PCPs).

**Methods:** 11 nephrology practices (37% of all Michigan nephrologists) and 238 PCP practices were recruited. An initial joint MKIC/MCT2D goal is to increase use of SGLT2i's and GLP-1a's. To assist in these efforts, a baseline practice readiness assessment survey was completed to identify barriers to SGLT2i and GLP1a prescribing.

**Results:** Nephrology practices had more experience prescribing SGLT2i's than GLP1a's (73% vs 27%). Despite this, 73% of nephrology practices responded that they were "Very" or "Mostly" confident about implementing measures to improve prescribing of these medications, similar to the response from PCPs (68%,  $p=0.70$ ). More PCP than nephrology practices worked with an affiliated pharmacist (33% vs 18%,  $p=0.355$ ). Differences in perceived barriers to prescribing are shown in the Table. Both nephrology and PCP practices had high level of concerns related to cost and insurance coverage. However, PCP practices identified greater educational needs and higher concern about patient acceptance of injections.

**Conclusions:** PCPs and nephrologists perceive different barriers to increasing usage of newer diabetes medications and may have differential access to resources. Population health-based strategies to promote uptake of these medications need to be tailored to the specific audience. Initial such efforts by MKIC/MCT2D have been well-received, and subsequent analyses will assess impact on medication prescription rates.

Perceived Barrier	Nephrology Practice (n=11)	Primary Care Practice (n=196)	p-value
Cost of medication	7 (64%)	174 (89%)	0.63
Insurance coverage challenges	11 (100%)	163 (83%)	0.83
Patient injectable hesitancy	1 (9%)	83 (42%)	0.19
Insufficient provider knowledge regarding medications	0	117 (60%)	<0.001

## SA-PO268

## Consistent Kidney Benefits With Semaglutide vs. Placebo Regardless of Baseline Urine Albumin Creatinine Ratio in Subjects With Type 2 Diabetes at High Cardiovascular Risk: A Post Hoc Analysis of SUSTAIN 6

Hiddo J. L. Heerspink,<sup>1</sup> Anja B. Kuhlman,<sup>2</sup> Johannes F. Mann,<sup>3</sup> Soren Rasmussen,<sup>2</sup> Peter Rossing,<sup>4,5</sup> Blaz Vrhnjak,<sup>2</sup> David Cherney,<sup>6</sup> <sup>1</sup>*University Medical Center Groningen, Groningen, Netherlands;* <sup>2</sup>*Novo Nordisk A/S, Søborg, Denmark;* <sup>3</sup>*KfH Kidney Center, München, Germany;* <sup>4</sup>*Steno Diabetes Center Copenhagen, Herlev, Denmark;* <sup>5</sup>*University of Copenhagen, Copenhagen, Denmark;* <sup>6</sup>*University Health Network, Toronto, ON, Canada.*

**Background:** In a previous analysis of SUSTAIN 6 and PIONEER 6 (cardiovascular [CV] outcomes trials in subjects with type 2 diabetes [T2D] at high CV risk), semaglutide reduced estimated glomerular filtration rate (eGFR) slope vs placebo, both in addition to standard of care antidiabetes medication. This was most pronounced in those with eGFR  $< 60$  mL/min/1.73 m<sup>2</sup>; it is of clinical interest to understand if this benefit is consistent across urine albumin:creatinine ratio (UACR) groups. The aim of this *post hoc* analysis was to investigate the effects of semaglutide on eGFR slopes in subjects with different albuminuria levels at baseline in SUSTAIN 6 (PIONEER 6 was excluded as UACR was not collected in this trial).

**Methods:** eGFR slope estimated by a random effect model was compared in subjects by baseline UACR:  $< 30/\geq 30$  or  $< 300/\geq 300$  mg/g. To account for potential differences in baseline characteristics, a sensitivity analysis was performed. These subgroups were also compared in those with baseline eGFR  $\geq 30$  or  $\geq 60$  mL/min/1.73 m<sup>2</sup>.

**Results:** Across the three subgroups (N=3,232), baseline characteristics were similar, except for higher blood pressure and lower eGFR in subjects with UACR  $> 300$  mg/g vs other subgroups. Overall, subjects receiving semaglutide had a slower decline in eGFR at 2 years vs placebo, an effect that was consistent across the three subgroups (p-value for interaction: 0.99; Figure). Results were consistent in the sensitivity analysis and those with eGFR  $\geq 30$  or  $\geq 60$  mL/min/1.73 m<sup>2</sup>.

**Conclusions:** Semaglutide appears to slow eGFR decline vs placebo in subjects with T2D at high CV risk regardless of baseline albuminuria status.

**Funding:** Commercial Support - Novo Nordisk A/S

ETDs are shown as values at 2 years from the full analysis set. Random slope model of repeated eGFR measures analyzed with eGFR value as dependent variable adjusted by baseline value, and time interacting with treatment and subgroup. Intercept and slopes of effect of time are assumed to vary randomly among subjects based on a 2-dimensional normal distribution. CI, confidence interval; eGFR, estimated glomerular filtration rate; ETD, estimated treatment difference; geom., geometric; UACR, urine albumin:creatinine ratio.

Estimated annual eGFR slopes according to treatment and UACR groups at baseline

Effects of Tirzepatide vs. Insulin Glargine on Kidney Function Evaluated by Cystatin C-Based eGFR: A Post Hoc Analysis From the SURPASS-4 Trial

Hiddo J. L. Heerspink,<sup>1</sup> Naveed Sattar,<sup>2</sup> Imre Pavo,<sup>3</sup> Axel Haupt,<sup>3</sup> Kevin L. Duffin,<sup>3</sup> Zhengyu Yang,<sup>3</sup> Russell J. Wiese,<sup>3</sup> Jonathan M. Wilson,<sup>3</sup> Andrea Hemmingway,<sup>3</sup> David Cherney,<sup>4</sup> Katherine R. Tuttle.<sup>5</sup> <sup>1</sup>*Rijksuniversiteit Groningen, Groningen, Netherlands*; <sup>2</sup>*University of Glasgow, Glasgow, United Kingdom*; <sup>3</sup>*Eli Lilly and Company, Indianapolis, IN*; <sup>4</sup>*Toronto General Hospital, Toronto, ON, Canada*; <sup>5</sup>*Providence Washington, Seattle, WA*.

**Background:** In patients with type 2 diabetes and increased cardiovascular risk (SURPASS-4 trial, N=1995; mean age 64 years, HbA1c 8.5%, BMI 33 kg/m<sup>2</sup>, eGFR [CKD-EPI-creatinine] 81.3 ± 21 mL/min/1.73m<sup>2</sup>), including 707 (35%) with UACR>30 mg/g and 342 (17%) with eGFR<60 mL/min/1.73m<sup>2</sup>, tirzepatide (TZP) treatment markedly reduced weight and slowed creatinine-based eGFR (eGFR<sub>creatinine</sub>) decline vs. insulin glargine (iGLAR). As weight reduction affects muscle mass, eGFR<sub>creatinine</sub> may change independently of kidney function, while cystatin C-based eGFR (eGFR<sub>cystatin C</sub>) is not similarly affected. The aim of this analysis was to determine whether the effect of TZP on kidney function was confirmed by eGFR<sub>cystatin C</sub>.

**Methods:** Mixed model for repeated measurements over time was used to analyze on-treatment eGFR data.

**Results:** After 1-year in the overall study population, the decline from baseline in eGFR<sub>cystatin C</sub> was significantly less with TZP vs. iGLAR (Table). No statistically significant interaction was observed in subgroup analyses by baseline UACR, eGFR<sub>creatinine</sub>, BMI, smoking status, or SGLT2i treatment (Table). Baseline (r=0.765, p<0.0001), 1-year (r=0.771, p<0.0001), and 1-year change from baseline (r=0.326, p<0.0001) values correlated between cystatin- and creatinine-based eGFR. eGFR<sub>cystatin C</sub> reductions at 1 year were dose dependent (between group difference vs. iGLAR 1.2 [-0.2, 2.7], 2.1 [0.7, 3.6] and 2.0 [0.6, 3.5] mL/min/1.73m<sup>2</sup> with 5, 10, and 15 mg, respectively). 1-year changes in body weight did not correlate with changes in eGFR<sub>cystatin C</sub> (r=0.054, p=0.125) or eGFR<sub>creatinine</sub> (r=0.012, p=0.728).

**Conclusions:** The effect of TZP on the slowing of eGFR decline is confirmed by cystatin C-based measurements, supporting the concept of a kidney-protective effect.

**Funding:** Commercial Support - Eli Lilly and Company

Improvement of Albuminuria by the Endothelin Receptor Antagonist Atrasentan Correlates to PCSK9 Reduction in Type 2 Diabetic Nephropathy Patients

Pragvi Shrestha, Tanja R. Zijp, Michelle Pena, Robin P. Dullaart, Hiddo J. L. Heerspink, Jacob van den Born. *Universitair Medisch Centrum Groningen, Groningen, Netherlands*.

**Background:** The endothelin receptor antagonist atrasentan reduces albuminuria. This effect coincides with striking reductions in LDLc and triglycerides. Albuminuria has been shown to increase proprotein convertase subtilisin kexin type 9 (PCSK9), syndecan-1 shedding, and/or PCSK9-syndecan-1 interaction, leading to impaired hepatic lipoprotein clearance. Here, we investigated whether reduction of albuminuria and lipids with atrasentan, reduces PCSK9 and/or syndecan-1 shedding.

**Methods:** Patients with type 2 diabetes and chronic kidney disease (CKD) participating in a phase II clinical trial (RADAR; NCT01356849) were randomized to placebo (N=26) or atrasentan (0.75mg/d or 1.25mg/d) (N=94) treatment for 12 weeks. Patients were stabilized to a maximum labeled dose of RAAS inhibitor. Urine albumin creatinine ratio (UACR), serum lipids, PCSK9 and syndecan-1 were measured at baseline and week 12.

**Results:** Atrasentan treatment reduced UACR by 37.1% (95% CI 30.1, 43.4; p<0.01), LDLc by 17.12 mg/dL (95%CI 8.8, 25.4; p<0.01), triglycerides by 47.4 mg/dL (95% CI 40.4, 90.5; p<0.01) and PCSK9 by -25.9 ng/mL (95% CI -52.7, 1.0; p=0.061) compared to placebo. No effects were observed on HDLc and syndecan-1. Multivariate analysis, adjusted for baseline demographics, lipid and kidney function parameters revealed that achieved albuminuria levels during atrasentan treatment correlated with achieved PCSK9 levels (β 0.00227 per unit increment in PCSK9; P=0.0094).

**Conclusions:** In patients with type 2 diabetes and CKD, atrasentan reduces albuminuria, LDLc and triglycerides. At 12 weeks of atrasentan treatment, achieved albuminuria correlated with achieved PCSK9. Our study might suggest a mechanism by which atrasentan provides cardio-protection in high-risk patients with type 2 diabetes and CKD.

SA-PO271

Safety and Efficacy of Maximally Tolerated RAS Therapy Alone or in Combination With Spironolactone in Diabetic Kidney Disease: Effect on Proteinuria and eGFR in the MRA-ACE Trial

James A. Tumlin,<sup>1,2</sup> Nelson P. Kopyt,<sup>1</sup> Daniel J. Wilson.<sup>1</sup> *NephroNet Clinical Trials Consortium* <sup>1</sup>*NephroNet Clinical Trials Consortium, Atlanta, GA*; <sup>2</sup>*Emory University School of Medicine, Atlanta, GA*.

**Background:** DKD is generally characterized by proteinuria and progressive of CKD. Although RAS inhibitors reduce proteinuria and slow the progression there is a high residual risk for ESRD at 8-10 years. Despite these benefits, few studies have examined the combination of mineralocorticoid receptor antagonists (MRA) with maximally tolerated RAS therapy (maxRAS). Herein we present the results of the MRA-ACE trial; a prospective, randomized, open labeled study investigating the safety/efficacy of spironolactone in combination with (maxRAS) therapy on proteinuria, delta eGFR and hyperkalemia (HK).

**Methods:** Thirty-two pts with T2D and DKD were randomized to (maxRAS) alone or in combination with spironolactone 25 mg/day (Spiro). Pts developing HK (K<sup>+</sup> > 5.5 mmol/L) during therapy received patiomer 8.4 gm Q MWF and titrated as needed. Twenty-seven (85%) of the 32 pts had biopsies confirming DKD. At entry all patients were 1) receiving insulin or oral agents, 2) BP <140/90 mm/Hg on max tolerated ACE or ARB, 3) two consecutive, pre-study UP/Cr >500 mg/gm, 4) CKD-Epi eGFR >20 mL/min/1.73M<sup>2</sup>. The primary endpoint was reduction in proteinuria at 24 months. A complete response was as defined UP/Cr <500 mg/gm, while a partial response was >50% reduction from baseline. Mean follow-up was 29 months.

**Results:** Results appear in Table-1. Addition of Spiro to RAS reduced UP/Cr at 24 months (p<0.028). The rate of complete/partial response was significantly higher with Spiro (76.6%) vs. maxRAS (38.8%) (P<0.025). HK occurred in 22.2% maxRAS and 57.1% Spiro pts (p<0.027). There were no withdrawals due to HK. ESRD developed in 8 pts; maxRAS-(6) and Spiro-(2). There was 3 deaths; 2-controls and 1-Spiro group; none due to HK. All HK patients were successfully controlled with Patiomer.

**Conclusions:** Combination therapy with Spironolactone and max-RAS was more effective than max RAS alone in reducing nephrotic range proteinuria and slowing eGFR decline DKD, with a trend to fewer cases of ESRD. Patiomer was effective in management of HK in both groups, and enabled continuous therapy.

Effect of Spironolactone Wash-Out on Albuminuria After Long-Term Treatment: The AFTER-PRIORITY Study

Victor Wasehuus,<sup>1</sup> Viktor Rotbain Curovic,<sup>1</sup> Nete Tofte,<sup>1</sup> Morten Lindhardt,<sup>1,2</sup> Christian Delles,<sup>3</sup> Marie Frimodt-Moller,<sup>1</sup> Harald Mischak,<sup>4</sup> Frederik Persson,<sup>1</sup> Heiko von der Leyen,<sup>5</sup> Tine Hansen,<sup>1</sup> Peter Rossing.<sup>1</sup> *PRIORITY Study Group* <sup>1</sup>*Steno Diabetes Center Copenhagen, Herlev, Denmark*; <sup>2</sup>*Department of Medicine, Holbæk Hospital, Holbæk, Denmark*; <sup>3</sup>*University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom*; <sup>4</sup>*Mosaïques Diagnostics, Hannover, Germany*; <sup>5</sup>*Hannover Clinical Trial Center Hannover Medical School, Hannover, Germany*.

**Background:** The PRIORITY study showed that treatment with spironolactone did not prevent progression to microalbuminuria in high kidney risk individuals as classified by the urinary proteomic risk classifier – CKD273. As spironolactone has previously shown to significantly lower albuminuria levels in chronic kidney disease, we have investigated the difference in albuminuria and kidney risk markers 6 weeks after spironolactone discontinuation.

**Methods:** Observational study following the nested randomized clinical trial in the PRIORITY study. A total of 115 individuals with type 2 diabetes and normoalbuminuria but high-risk for progression based on urinary proteomics, previously randomized to daily

spironolactone or placebo were seen 6±2 weeks after the final visit in PRIORITY. The primary endpoint was change in urinary albumin-creatinine ratio (UACR) between the final visit in PRIORITY (baseline) and follow-up. Secondary endpoints were change in estimated glomerular filtration rate (eGFR), systolic and diastolic blood pressure (BP), and serum potassium. Statistical analysis was done using paired t-test to assess the change between baseline and follow-up and unpaired t-test for between-group analysis of end-to-end results.

**Results:** The mean age of the study subjects was 66±6 years and 90 (78.3%) were male. Baseline HbA1c was 56±17 mmol/mol, and eGFR was 78±19 ml/min/1.73m<sup>2</sup>. No change in UACR was observed in neither the spironolactone group (Median change: 33%, IQR -37;104, p=0.28) nor the placebo group (9%, -27;81, p=0.63) at follow-up. No difference between the groups was observed at end of study (Log difference: 0.05 mg/g, -0.22;0.13, p=0.60). Assessing the secondary endpoints, eGFR and systolic BP are seen increasing after discontinuation of spironolactone, and for systolic BP after placebo discontinuation as well. Potassium levels were lower after discontinuation of spironolactone, but higher after placebo discontinuation (all p<0.05).

**Conclusions:** This study supports the findings of the PRIORITY trial, that spironolactone exerted no effect on UACR in a high-risk kidney population, as classified by CKD273 score. Our findings do not support the use of spironolactone for preventing progression to microalbuminuria in high kidney risk individuals.

**Effect of Finerenone on CKD Outcomes in Type 2 Diabetes: A Chinese Subgroup Analysis of the FIDELIO-DKD Study**  
Haitao Zhang,<sup>1</sup> Jingyuan Xie,<sup>2</sup> Chuanming Hao,<sup>3</sup> Xuemei Li,<sup>4</sup> Dalong Zhu,<sup>5</sup> Hongguang Zheng,<sup>6</sup> Xudong Xu,<sup>13</sup> Zhaohui Mo,<sup>7</sup> Weiping Lu,<sup>8</sup> Yibing Lu,<sup>9</sup> Chaoqing Wu,<sup>10</sup> Nanwei Tong,<sup>11</sup> Li Wang,<sup>12</sup> Zhihong Liu.<sup>1</sup> <sup>1</sup>National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; <sup>2</sup>Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; <sup>3</sup>Huashan Hospital Fudan University, Shanghai, China; <sup>4</sup>Peking Union Medical College Hospital, Dongcheng-qu, China; <sup>5</sup>Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China; <sup>6</sup>General Hospital of Northern Theater Command, Shenyang, China; <sup>7</sup>The Third Xiangya Hospital of Central South University, Changsha, China; <sup>8</sup>The Affiliated Huaian No.1 People's Hospital of Nanjing Medical University, Huaian, China; <sup>9</sup>The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; <sup>10</sup>The People's Hospital of Guangxi Zhuang Autonomous Regio, Guangxi, China; <sup>11</sup>Sichuan University West China Hospital, Chengdu, China; <sup>12</sup>Bayer Healthcare Company, Beijing, China; <sup>13</sup>Fudan University Minhang Hospital, Shanghai, China.

**Background:** This subgroup analysis of FIDELIO-DKD trial aimed to evaluate the efficacy and safety of finerenone in chronic kidney disease (CKD) patients with type 2 diabetes mellitus (T2DM) in China.

**Methods:** Three hundred and seventy-two participants who were recruited from 67 centers in China were randomized 1:1 to oral finerenone or placebo with standard therapy for diabetes. The primary outcome was a composite of kidney failure, sustained decrease of estimated glomerular filtration rate (eGFR) ≥40% from baseline over at least 4 weeks, or renal death. The key secondary composite outcome was a composite of death from cardiovascular causes, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure.

**Results:** After a median follow-up of 30 months, the finerenone group showed a relative risk reduction (RRR) of 41% (hazard ratio [HR]=0.59, 95% confidence interval [CI], 0.39 to 0.88; p=0.009) for the primary composite outcome compared to the placebo group, and was consistent across its components with treatment benefit in finerenone group. For the key secondary composite outcome, the finerenone group showed a RRR of 25% (HR=0.75, 95% CI, 0.38 to 1.48; p=0.408), while the global results showed significant differences in favor of finerenone with a RRR of 14% (HR=0.86, 95% CI, 0.75 to 0.99; p=0.03). Adverse events were similar between the two groups. Hyperkalemia leading to discontinuation occurred in 8 (4.3%) and 2 (1.1%) participants in the finerenone and control groups, respectively.

**Conclusions:** Finerenone resulted in lower risks of CKD progression than placebo and a balanced safety profile in Chinese CKD patients with T2DM.

**Cardiorenal Outcomes With Finerenone in Asian Patients With CKD and Type 2 Diabetes: Post Hoc Analysis From FIDELIO-DKD**  
Daisuke Koya,<sup>1,2</sup> Stefan D. Anker,<sup>3</sup> Luis M. Ruilope,<sup>4,5</sup> Peter Rossing,<sup>6,7</sup> Byung-Wan Lee,<sup>8</sup> Chien-Te Lee,<sup>9</sup> Zhi Hong Liu,<sup>10</sup> Charlie Scott,<sup>11</sup> Peter Kolkhof,<sup>12</sup> Robert Lawatschek,<sup>13</sup> Lili Wang,<sup>14</sup> Amer Joseph,<sup>15</sup> Bertram Pitt.<sup>16</sup> On behalf of the FIDELIO-DKD Investigators <sup>1</sup>Department of Diabetology and Endocrinology, and the Division of Anticipatory Molecular Food Science, Kanazawa Medical University, Kanazawa, Japan; <sup>2</sup>Department of General Internal Medicine, Omi Medical Center, Kanazawa, Japan; <sup>3</sup>Department of Cardiology (CVK) and Berlin Institute of Health Center for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; <sup>4</sup>Cardiorenal translational Laboratory and Hypertension Unit, Institute of Research inas12, Madrid, Spain; <sup>5</sup>CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain; <sup>6</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>7</sup>Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; <sup>8</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; <sup>9</sup>Division of Nephrology, Department of Internal Medicine, Kaohsiung Chang-Gung Memorial Hospital, College of Medicine, Chang-Gung University, Nanjing, Taiwan; <sup>10</sup>National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; <sup>11</sup>Data Science and Analytics, Bayer PLC, Reading, United Kingdom; <sup>12</sup>Research and Development, Cardiovascular Precision Medicines, Bayer AG, Wuppertal, Germany; <sup>13</sup>Clinical Research, Bayer AG, Berlin, Germany; <sup>14</sup>Bayer Pte Ltd, Singapore, Singapore; <sup>15</sup>Research and Development, Cardiology and Nephrology Clinical Development, Bayer AG, Berlin, Germany; <sup>16</sup>Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI.

**Background:** In FIDELIO-DKD, finerenone significantly improved cardiorenal outcomes in patients with chronic kidney disease (CKD) and type 2 diabetes (T2D). A post hoc analysis of FIDELIO-DKD data was conducted to explore the cardiorenal effects of finerenone in patients from the Asian region.

**Methods:** In FIDELIO-DKD (NCT02540993), 5674 patients were randomized to receive finerenone or placebo, of whom 1327 were from 10 Asian countries and territories. Eligible patients had T2D, and either urine albumin-to-creatinine ratio (UACR) ≥30 to <300 mg/g and estimated glomerular filtration rate (eGFR) ≥25 to <60 mL/min/1.73 m<sup>2</sup>, or UACR ≥300 to ≤5000 mg/g and eGFR ≥25 to <75 mL/min/1.73 m<sup>2</sup>, and were treated with optimized renin-angiotensin system blockade. The primary efficacy outcome was a kidney composite outcome (time to kidney failure, death from renal causes, and sustained decrease of ≥40% in eGFR from baseline). Secondary efficacy outcomes included both kidney (time to kidney failure, death from renal causes, and sustained decrease of ≥57% in eGFR from baseline) and cardiovascular (CV; time to CV death, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure) composite outcomes.

**Results:** In the Asian subgroup, 665/1327 (50%) patients received finerenone. The finerenone cohort of the Asian subgroup showed reduced ≥40% and ≥57% eGFR kidney composite outcomes and CV composite outcome vs the placebo group (hazard ratio [HR] 0.70, 95% confidence interval [CI] 0.56–0.87; HR=0.73, 95% CI 0.55–0.97; and HR=0.85, 95% CI 0.59–1.21, respectively). No apparent differences were observed between the Asian subgroup and patients from the rest of the world for these outcomes (HR=0.88, 95% CI 0.77–1.02 [*P*<sub>interaction</sub>=0.09]; HR=0.78; 95% CI 0.64–0.95 [*P*<sub>interaction</sub>=0.71]; and HR=0.86, 95% CI 0.74–1.00 [*P*<sub>interaction</sub>=0.95], respectively). Finerenone demonstrated similar safety across subgroups.

**Conclusions:** The beneficial effect of finerenone on cardiorenal outcomes in the Asian population are comparable to the overall results observed in FIDELIO-DKD.

**Funding:** Commercial Support - Bayer AG

## Abstract Withdrawn

## SA-PO276

**The Effect of Magnesium Supplementation on Albuminuria in Patient With Type 2 Diabetic Mellitus in Phramongkutklao Hospital: A Randomized Double-Blinded Controlled Trial**

Sriladda Santhitsate, Narittaya Varothai. *Phramongkutklao Hospital, Bangkok, Thailand.*

**Background:** Hypomagnesemia is associated with the development of microvascular complications including albuminuria in type 2 diabetes mellitus patients. It can also worsen glycemic control by promoting insulin resistance. Although there are several studies showed benefits of magnesium in patients with type 2 diabetes mellitus, there is no recommendation in recent guidelines that dietary mineral supplementation can improve outcomes in patients who do not have underlying deficiencies. This study was aimed to compare the effect of magnesium supplementation on albuminuria in type 2 diabetes mellitus patients.

**Methods:** This randomized double-blinded controlled trial included 26 patients who have moderately or severely increased albuminuria and normomagnesemia. Subjects were randomly divided in two groups to receive either 200 mg magnesium oxide or placebo daily for 6 months. Urine albumin-to-creatinine ratio, fasting plasma glucose, HbA1C, lipid profiles, kidney function were recorded at baseline and after the intervention. Magnesium intake was also assessed by 3-day food record.

**Results:** Every patients in this study had inadequate magnesium intake (lower than 30% of recommended daily allowance). Mean urine albumin-to-creatinine ratio were 143.61 +/- 115.87 mg/g in magnesium group and 466.36 +/- 989.28 mg/g in placebo group (p-value 0.247). Mean serum magnesium were 1.88 +/- 0.16 mg/dL in magnesium group and 1.77 +/- 0.10 mg/dL in placebo group (p-value 0.052). After 6-month treatment, there was no significant difference in degree of albuminuria between two groups (-47.48 +/- 89.05 vs 127.05 +/- 859.45, p-value 0.511). Fasting plasma glucose, HbA1C, lipid profiles and kidney function were also no significant differences except serum cholesterol level. Serum cholesterol were increased in both groups but significantly higher in placebo group (5.07 +/- 26.43 vs 24.25 +/- 18.68, p-value 0.049).

**Conclusions:** Magnesium supplementation showed no significant effect in albuminuria among patients with type 2 diabetes mellitus.

## SA-PO277

**Vacuolar Tubular Necrosis Caused by Hyperglycemia in a Diabetic Patient**

Sua Lee, Jaehyun Jun, Jeongwoo Kim. *Eulji University College of Medicine, Daejeon, Republic of Korea.*

**Introduction:** Acute tubular necrosis (ATN) is a disease in which the epithelial cells of the renal tubules are necrotic, accounting for about 45 % of acute renal injury, and the main causes are nephrotoxic drugs and lowering of blood pressure. Vacuolar ATN is a rare form of ATN known to be caused by hyperosmolar substances such as contrast agents, immunoglobulins, and mannitol. We reported a rare case of vacuolar ATN caused by temporary hyperglycemia in a diabetic patient.

**Case Description:** A 45-year-old man had symptoms of abdominal pain and vomiting for 5 days and a decrease renal function at a primary medical institution. He diagnosed hypertension and type 2 diabetes 5 years ago and was taking medications. He had a feeling of lethargy, general edema and abruptly decreased urine volume 3 weeks ago. On physical examination, blood pressure was 138/80 mmHg, and pretibial pitting edema was observed. In blood chemistry, serum urea/creatinine (Cr) was 78/19.52 mg/dL, and estimated glomerular filtration rate (eGFR) was 2.62 ml/1.73m<sup>2</sup>/min. serum albumin and spot urine protein-creatinine ratio were 4.5 g/dL and 4.628 g/mg. Glycated hemoglobin A1c and blood glucose level were 8.3 % and 133 mg/dL. Emergent hemodialysis was performed and kidney biopsy was done to identify the cause of acute kidney injury. The vacuolar degeneration and necrosis of renal tubular epithelial cells were observed on light microscopy, and thickening of the glomerular basement membrane was observed on electron microscopy. At 3 months after treatment, renal function was maintained with serum Cr 1.13 mg/dL and eGFR as 70.18 ml/1.73m<sup>2</sup>/min.

**Discussion:** Vacuolar ATN may be the cause of acute renal injury in diabetic patient, so it is necessary to differentiate the cause through renal biopsy when there is abrupt renal function decline in diabetic patients.

## SA-PO278

**Improving Daily Physical Activity in Patients Undergoing Hemodialysis Using Plantar Electrical Nerve Stimulation: A Randomized Double-Blinded Controlled Trial**

Myeounggon Lee,<sup>1</sup> Abdullah I. Hamad,<sup>2</sup> Rania A. Ibrahim,<sup>2</sup> Heba M. Ateya,<sup>2</sup> Mincy Mathew,<sup>2</sup> Anmol S. Momin,<sup>1</sup> Bijan Najafi,<sup>1</sup> Fadwa S. Al-Ali.<sup>2</sup> *<sup>1</sup>Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, TX; <sup>2</sup>Hamad Medical Corporation, Doha, Qatar.*

**Background:** Physical inactivity among patients undergoing hemodialysis (HD) is a persistent clinical problem. Intradialytic electrical stimulation (E-stim) can be a practical solution as it can be used by patients during lying down or sitting, and does not require any effort in the patients. Especially, E-stim to the plantar region of the feet can have the benefit of activating lower limb muscles and enhance the sensitivity for the somatosensory signal from the foot, which may improve the stability and increase the physical activities in HD patients.

**Methods:** Participants were randomized into either an intervention group (IG: n=24, age=55.8 ± 13.4 years, BMI = 30.2 ± 5.9 kg/m<sup>2</sup>, female = 28.0%) receiving PENS or a control group (CG: n=25, age = 57.28 ± 12.2 years, BMI = 30.8 ± 5.9 kg/m<sup>2</sup>, female = 40.0%). The IG received 1-hour PENS during the routine HD (3 sessions/week) for 12 weeks. The CG received an identical but non-functional device for the same period.

**Results:** All participants in the IG tolerated the PENS and completed all therapy sessions, indicating the feasibility of incorporating PENS during clinic visit. As an IG, there was a significant increase in standing duration between baseline and 12-weeks ( $d = 0.91$ ,  $p = 0.036$ ); and there were also increase trends, but not significant, in walking duration ( $d = 0.79$ ,  $p = 0.071$ ) and daily step count ( $d = 0.82$ ,  $p = 0.063$ ) in those periods (Figure 1). As a CG, there was no significance in those periods.

**Conclusions:** Findings suggest PENS during the routine HD process may improve mobility in daily life of HD patients. We recommend this practical therapy as an alternative way for the patients who can not do regular exercise if the results will be held with a larger sample.

**Funding:** Government Support - Non-U.S.

### Fasting Blood Glucose and the Risk of Cause-Specific Death in Hemodialysis Patients With Diabetes

Soo-Young Yoon,<sup>1</sup> Sojin Lim,<sup>1</sup> Geon Woo Kim,<sup>1</sup> Jongho Kim,<sup>1</sup> Gang Jee Ko,<sup>2</sup> Jin sug Kim,<sup>1</sup> Ju young Moon,<sup>1</sup> Kyung hwan Jeong,<sup>1</sup> Hyeon Seok Hwang,<sup>1</sup>

<sup>1</sup>Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; <sup>2</sup>Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea.

**Background:** Glycemic control is fundamental to optimize the care of hemodialysis patients (HD) with diabetes. Most relevant studies focused on hemoglobin A1c values as an representative marker in general population. Therefore, current guidelines could not suggest any clear target of fasting blood glucose (FBG). The aim of the study is to examine the association between FBG and the risk of mortality and to sort out the HD patients who may benefit from strict FBG control.

**Methods:** Through reviewing the National Health Insurance Database of Korea, a total of 6,605 patients starting HD treatment with diabetes were included between 2002 and 2018. The participants were grouped into six following FBG categories: (1) <80 mg/dL, (2) 80-100 mg/dL, (3) 100-125 mg/dL, (4) 125-150 mg/dL, (5) 150-180 mg/dL, and (6) ≥180 mg/dL. Conventional and time-varying Cox regression models evaluated the association between FBG and all-cause mortality. We conducted baseline covariate-adjusted subsequent subgroup analyses.

**Results:** In a conventional Cox model compared to patients with FBG 80-100 mg/dL, adjusted hazard ratios (aHR) for all-cause mortality were significantly higher in patients with FBG 100-125 (aHR, 1.21 [95% confidence interval (CI), 1.07-1.36]), 125-150 (aHR, 1.20 [95% CI, 1.05-1.38]), 150-180 (aHR, 1.38 [95% CI, 1.19-1.61]), and ≥180 mg/dL (aHR, 1.46 [95% CI, 1.27-1.68]) except for patients with FBG <80 mg/dL. According to a time-varying Cox regression analysis, the mortality risks increased in participants with FBG <80 (aHR, 1.17 [95% CI, 1.08-1.27]), 100-125 (aHR, 1.08 [95% CI, 1.02-1.15]), 125-150 (aHR, 1.18 [95% CI, 1.10-1.28]), 150-180 (aHR, 1.31 [95% CI, 1.20-1.43]), and ≥180 mg/dL (aHR, 1.30 [95% CI, 1.21-1.39]). Compared with participants grouped into FBG 80-100 mg/dL, patients who were younger than 65, female, belonged to both normal and over body mass index, and low Charlson comorbidity index score were at a relatively higher mortality risk in case of FBG ≥100 mg/dL.

**Conclusions:** Targeting FBG from 80 to 100 mg/dL significantly alleviated the risk of all-cause mortality in diabetic HD patients when compared to those with FBG <80 mg/dL or ≥100 mg/dL. Further research needs to be done to elucidate the target level of FBG to minimize the mortality risk in subgroup of HD patients with diabetes.

## SA-PO280

### Cost-Effectiveness Analysis of a Prognostic Risk Assessment Test for Diabetic Kidney Disease G1-G3b in the United States

Jacie T. Cooper,<sup>1</sup> Karen Beltran,<sup>1</sup> Steven G. Coca,<sup>2</sup> John E. Schneider.<sup>1</sup>

<sup>1</sup>Avalon Health Economics LLC, Morristown, NJ; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** KidneyIntelX™ was developed and validated to predict rapid progressive decline in kidney function in patients with early-stage diabetic kidney disease (DKD). KidneyIntelX can assist primary care providers to guide resource utilization and prescription of new therapeutic agents, and improve efficiency of care among physicians. We sought to develop a model that estimates the incremental cost-effectiveness of KidneyIntelX compared to risk stratification using eGFR and UACR (GAC).

**Methods:** We modeled a hypothetical cohort of 100,000 patients with DKD in stages G1/G2 with A2/A3, or G3a/G3b with A1-A3 that received a prognostic test (GAC vs. KidneyIntelX) one time at the start of the model and cardiorenal agents for treatment. We employed a 10-state Markov state transition structure, made up of the following states: Stages G1 through G5, dialysis, kidney transplant, cardiovascular death, and non-cardiovascular death. The model projects outcomes, including cardiovascular events, over a lifetime time horizon with a maximum patient age of 100 years old and presents results for both Medicare and Commercial payer perspectives.

**Results:** Our results showed that the average Medicare patient population would experience fewer dialysis starts and kidney transplants, increased life span, and increased quality adjusted life-span by using KidneyIntelX compared to GAC. Medicare patients would incur incremental costs of approximately -\$428 per patient and incremental QALYs of 0.09. In the commercial scenario analyses, cost savings were about \$14,116 per patient and QALY gains of 0.15, indicating that KidneyIntelX is a dominant strategy in comparison to GAC (Figure).

**Conclusions:** This analysis demonstrated that population-based KidneyIntelX testing for the prognosis of progression in a DKD G1-G3b population is a dominant strategy for both Medicare and commercial populations in comparison to prognosis relying on eGFR and UACR alone.

**Funding:** Commercial Support - Renalyticx

Figure. Incremental benefit vs. incremental costs in Base Case/Medicare Scenario (Panel A) and Commercial Scenario (Panel B)

## SA-PO281

### Percutaneous Renal Biopsy Is Associated With Higher Bleeding Risks in Diabetics: A National Population Based Study

Vijaya Chelikani,<sup>1</sup> Nischit Baral, Arvind R. Kunadi. McLaren Flint Hospital, Flint, MI.

**Background:** Percutaneous renal biopsy (PRB) is required in the diagnosis of glomerular, vascular and tubulointerstitial diseases of the kidney, providing essential information regarding prognosis and management, especially in diabetic nephropathy with atypical features. However, there are complications that develop after a renal biopsy, most commonly in the form of bleeding. The association between diabetes and major bleeding post PRB is not well studied.

**Methods:** This is a retrospective cohort study from PRB hospitalizations between January 1, 2016, and December 31, 2019, using the National Inpatient Sample (NIS). Our study sample included any hospitalizations with PRB procedure with valid information on DM, age 18 years or older, using the ICD 10 procedural and diagnostic codes validated in previous studies. Our outcome of interest is major bleeding requiring transfusion post procedure.

**Results:** From 2016 to 2019, a total of 40,177 (weighted N=190,720) hospitalizations with principal or secondary PRB procedure were identified. Among them, 44% (n=17670) were females and 33% (n=13,318) were diabetics. Mean age was 56.81 ± 15.9 years. Moreover, 57.7% of total PRB were performed in Whites, 20.5% in Blacks, 14.2% in Hispanics, and 3.7% in Asians. Compared to non-DM, those who had DM, were older in age (mean age: 59.6 vs. 54.3;  $p < 0.001$ ), had higher post procedural major bleeding (15% vs 11%,  $p < 0.001$ ) and had similar in-hospital mortality (1% vs 1%,  $p = 0.469$ ). Multivariate regression analysis showed that, compared with non-DM, DM had a significantly increased odds of post procedural major bleeding (aOR: 1.26; 95% CI: 1.18, 1.34;  $p < 0.001$ ) after controlling for age, race, regional location of the hospital, income, and insurance provider. The annual number of PRB procedures done per 100,000 hospitalizations has been increasing at 135.6 in 2016, 138.6 in 2017, 143.9 in 2018 and 146.2 in 2019 ( $p$ -trend<0.001).

**Conclusions:** The number of PRB procedures performed has been increasing over recent years. DM is associated with high bleeding risk after the procedure.

## SA-PO282

## Development in eGFR Trajectories in People With Diabetic Nephropathy

Christina G. Poulsen,<sup>1</sup> Kristin Jesse,<sup>1</sup> Bendix Carstensen,<sup>1</sup> Marie Frimodt-Møller,<sup>1</sup> Tine Hansen,<sup>1</sup> Frederik Persson,<sup>1</sup> Dorte Vistisen,<sup>1,2</sup> Peter Rossing.<sup>1,2</sup>  
<sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Kobenhavns Universitet, København, Denmark.

**Background:** Diabetic nephropathy (DN) is a frequent and serious complication to type 1 diabetes (T1D) and type 2 diabetes (T2D). The effect of advancing diabetes care over the past decades on progression in DN requires update. We analyzed the development over calendar time in eGFR trajectories from time of DN diagnosis.

**Methods:** Retrospective cohort study, with data collected from electronic health records from persons attending the outpatient clinic at Steno Diabetes Center Copenhagen, Denmark between 2001-2020. Inclusion criteria were: T1D/T2D and DN, defined as urine albumin to creatinine ratio > 300 mg/g or urine albumin excretion rate > 300 mg/24h in two occasions > 60 days apart. Individual eGFR trajectories were calculated separately for T1D and T2D, using mixed-effects models with fixed effects of age and interactions of splines of DN duration and date of diagnosis.

**Results:** The T1D cohort included 888 persons, 59.7% male and median (IQR) age at DN diagnosis was 50 (38-62) years. Figure 1A shows estimated trajectories for eGFR for a person with T1D diagnosed with DN at age 50 in 2000, 2005, 2010 or 2015. eGFR at time of DN diagnosis increased with 1.8 ml/min/1.73m<sup>2</sup>/year. Improvement in eGFR trajectories with calendar time was not evident, but with a tendency toward attenuating decline after 2010. The T2D cohort included 1480 persons, 71.9% male and median (IQR) age at DN diagnosis was 65 (58-72) years. Figure 1B shows estimated trajectories for eGFR for a person with T2D diagnosed with DN at age 65 in 2000, 2005, 2010 or 2015. eGFR at time of DN diagnosis increased with 0.7 ml/min/1.73m<sup>2</sup>/year. Most pronounced increase was between 2000 and 2005. The eGFR trajectories for T2D were similar across calendar time.

**Conclusions:** Kidney function at time of DN diagnoses has increased over the past 20 years, most pronounced in T1D, where eGFR decline appears attenuating in most recent years. This may be explained by improved awareness and treatment.

**Funding:** Private Foundation Support

Figure 1. Average trajectories for eGFR for persons diagnosed with DN in 2000, 2005, 2010, or 2015.

A. T1D, diagnosed with DN at age 50.

B. T2D, diagnosed with DN at age 65.

## SA-PO283

## A Global Validation of a Minimal-Resource Pre-Screening Model for Reduced Kidney Function in Patients With Type 2 Diabetes

Rose Sisk,<sup>1</sup> Camilla Sammut-Powell,<sup>1</sup> Jayne Budd,<sup>1</sup> Rory S. Cameron,<sup>1</sup> Mark P. Edge,<sup>1</sup> Estefania Vazquez Mendez,<sup>2</sup> Aleksandr Bedenkov,<sup>3</sup> Hardik Vasawala,<sup>5</sup> Susana Goncalves.<sup>4</sup> <sup>1</sup>Gendius Ltd, Macclesfield, United Kingdom; <sup>2</sup>AstraZeneca, Mexico City, Mexico; <sup>3</sup>AstraZeneca, Cambridge, United Kingdom; <sup>4</sup>AstraZeneca, Buenos Aires, Argentina; <sup>5</sup>AstraZeneca, Bangalore, India.

**Background:** A minimal-resource (MR) pre-screening model has been developed in UK data for people with type 2 diabetes (T2DM) with no previous diagnosis of chronic kidney disease (CKD). It identifies those at higher risk of having reduced kidney function (eGFR < 60ml/min/1.73m<sup>2</sup>) using readily available non-clinical inputs. The model was developed to support prioritization of CKD screening resource, particularly where resources are limited. The model has previously been validated in global study data and whilst strong performance was observed, the data were limited in volume and collected prior to 2018. The goal of this study is to test the performance of the model in up-to-date data, reflective of the application setting.

**Methods:** The model was applied to the observational iCaReMe registry data covering 21 countries in 7 regions globally from 2018. We evaluated the global and regional positive predictive values (PPV) at thresholds that ensured a sensitivity of at least 80%. We compared the PPV of the MR model against current practice (i.e. "screen all", testing the entire T2DM population).

**Results:** 5618 patients with a valid eGFR measurement were included. The MR model resulted in a PPV of 28.0% [95% CI: 26.5% - 29.6%] with a sensitivity of 82.4% [95% CI: 80.2% - 84.7%] - a relative improvement of 44.8% compared with the screen all approach (PPV 19.3% [95% CI: 18.3% - 20.4%]). Regional variation in performance was observed (Figure 1, PPV range of 23.8% - 34.9%), but the improvement remained significant in regions with sufficient sample size.

**Conclusions:** The MR model can be used globally to identify people with T2DM that are likely to have kidney function impairment, but should be adapted to regional populations. The model can be used to conduct targeted screening where resources are limited. Prioritized screening of high-risk individuals could help to address the backlog in routine care provision due to the COVID-19 pandemic.

A forest plot of the performance of the MR model. Positive predictive value of the model is compared against the "screen all" approach, overall and by region.

## SA-PO284

## Transition Probabilities of Diabetic Kidney Disease (DKD) and Death in a Multi-Ethnic Asian Population

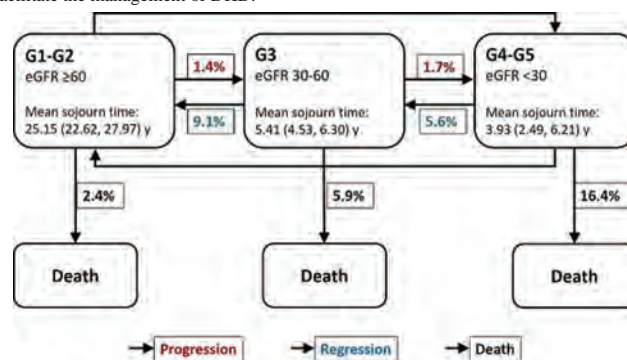

Charumathi Sabanayagam,<sup>1,2</sup> Feng He,<sup>1</sup> Kavita Venkataraman,<sup>3</sup> Cynthia C. Lim,<sup>4</sup> Gavin Tan.<sup>1,2</sup> <sup>1</sup>Singapore Eye Research Institute, Singapore, Singapore; <sup>2</sup>Duke-NUS Medical School, Singapore, Singapore; <sup>3</sup>National University of Singapore, Singapore, Singapore; <sup>4</sup>Singapore General Hospital, Singapore, Singapore.

**Background:** The severity and rate of progression/regression of diabetic kidney disease (DKD) are important for making clinical decisions. We examined the transitions in DKD severity stages over time in an Asian population.

**Methods:** We analysed 17,081 clinic visits by 6,453 Chinese, Malay and Indian adults with type 2 diabetes who attended the annual DKD screening visits in primary care clinics from 2010-2015 with death data until 2020. CKD stage transition was defined as change in estimated glomerular filtration rate (eGFR) categories: ≥60, 30-60 and <30 mL/min/1.73 m<sup>2</sup> (corresponding to G1-G2, G3, G4-5)+ eGFR decline ≥25% from the previous visit. A multistate Markov model was used to estimate the annual transition probabilities between 4 consecutive stages (G1-G2, G3, G4-5 and death) and the expected waiting (sojourn) time in each state adjusted for risk factors including age, gender, ethnicity, duration of diabetes, HbA1c %, systolic blood pressure (SBP), LDL-cholesterol, and diabetic retinopathy (DR) status.

**Results:** The median (interquartile range) follow-up duration was 2.68 (1.08-4.29) years, and most patients had at least 3 assessments. The annual transition probability from G1-2 to G3, G3 to G4-5 in the adjusted model were 1.4%, and 1.7%, and of death from each state were 2.4%, 5.9%, and 16.4%; mean sojourn time in each state were 25.15, 5.41, and 3.93 years. Probability of regression from G3 to G1-2, and G4-5 to G3 were 9.1%, and 5.6%; DKD progression was significantly associated with older age, Malay ethnicity, DR, higher levels of HbA1c and SBP, and lower LDL-cholesterol, while regression with younger age, female gender, and lower HbA1c; Death was significantly associated with older age, male gender, longer duration of diabetes, DR, and higher levels of HbA1c and LDL-cholesterol.

**Conclusions:** Progression of DKD in people with diabetes is a gradual but steady process. Surveillance and control of blood pressure, glucose, cholesterol and DR may facilitate the management of DKD.

## SA-PO285

## CKD-Associated Pruritus (CKD-aP) in Hemodialysis (HD) Patients: Comparison of Instruments Used to Measure Self-Reported Itch Severity

Angelo Karaboyas,<sup>1</sup> Charlotte Tu,<sup>1</sup> Nidhi Sukul,<sup>2,3</sup> Elham Asgari,<sup>6</sup> Fitsum Guebre Egziabher,<sup>5</sup> Sebastian Walpen,<sup>4</sup> Thilo Schaufner,<sup>4</sup> Bruce M. Robinson,<sup>1,2</sup> Ronald L. Pisoni.<sup>1</sup> <sup>1</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>2</sup>University of Michigan Department of Internal Medicine, Ann Arbor, MI; <sup>3</sup>VA Ann Arbor Healthcare System, Ann Arbor, MI; <sup>4</sup>Vifor Pharma Ltd, Glattbrugg, Switzerland; <sup>5</sup>Hospices Civils de Lyon, Lyon, France; <sup>6</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

**Background:** The associations between self-reported CKD-aP and patient reported outcomes (PROs) have been well reported, but have generally been limited to a single baseline CKD-aP assessment. Collection of multiple CKD-aP instruments allows for

evaluation of different domains and approaches to measure CKD-aP burden, and may further help tailor data capture for future research or clinical care.

**Methods:** An electronic PRO (ePRO) survey was distributed to HD patients enrolled in the Dialysis Outcomes and Practice Patterns Study (DOPPS) in 2021-2022, and included 4 CKD-aP instruments: (1) a single question from the KDQOL-36 about the extent patients were bothered by itchy skin; (2) the 5-D itch, which assesses five dimensions of itch; and questions about the (3) worst itch [WI-NRS] and (4) average itch [AI-NRS] experienced. We calculated the Spearman correlation between each instrument, and stratified mean 5-D itch and NRS scores by response to the single KDQOL-36 question.

**Results:** Data collection is ongoing; 250 patients from 24 HD facilities in 4 countries (France, Germany, Spain, UK) have thus far completed the baseline survey. Patients 'not at all' bothered by itchy skin (N=104; 41%) were not asked to complete other CKD-aP instruments. Among the remaining 146 patients, the KDQOL-36 response was correlated with the WI-NRS (0.49), AI-NRS (0.52), and 5-D itch (0.56) – more so with the degree (0.67) and duration (0.55) domains than the distribution (0.42), disability (0.32), and direction (0.21) domains. Across response levels (somewhat, moderately, very much, extremely) of the KDQOL-36 question, the respective mean scores of other CKD-aP instruments were 10.0, 11.7, 14.7, 20.8 for 5-D itch; 2.7, 3.7, 5.6, 8.3 for AI-NRS; and 3.0, 4.1, 6.1, 8.4 for WI-NRS.

**Conclusions:** Correlation between CKD-aP instruments was relatively high; differences can be partially attributed to the recall period for the KDQOL-36 (4 weeks) vs. the 5-D itch (2 weeks) and NRS (24 hours). Understanding the relationships between CKD-aP instruments will help us interpret and link findings across observational and randomized studies that use different approaches to measure CKD-aP.

## SA-PO286

### Improvement of Itch With Difelikefalin in CKD Patients on Dialysis by Baseline Itch Severity

Daniel E. Weiner,<sup>1</sup> Marc G. Vervloet,<sup>2</sup> Frederique Menzaghi,<sup>3</sup> Warren Wen,<sup>3</sup> Sebastian Walpen,<sup>4</sup> Thilo Schaulfer,<sup>4</sup> Isabelle Morin,<sup>4</sup> Michael J. Germain.<sup>5</sup>  
<sup>1</sup>Tufts Medical Center, Boston, MA; <sup>2</sup>Amsterdam University Medical Center, Amsterdam, Netherlands; <sup>3</sup>Cara Therapeutics Inc, Stamford, CT; <sup>4</sup>Vifor Pharma Ltd, Glatbrugg, Switzerland; <sup>5</sup>Baystate Medical Center, Springfield, MA.

**Background:** Difelikefalin (DFK) is a peripherally restricted  $\kappa$ -opioid receptor agonist that reduces itch severity in patients with chronic kidney disease-associated pruritus (CKD-aP) undergoing hemodialysis (HD). The purpose of this analysis was to determine if baseline severity of itch impacts the efficacy of DFK.

**Methods:** This was a secondary analysis of a multicenter, open-label study (3105) of intravenous DFK treatment (0.5  $\mu$ g/kg, 3x per week) in patients on HD with moderate-to-severe CKD-aP (worst itch numerical rating scale [WI-NRS]  $\geq 5$ ). Participants were categorized based on itch severity at baseline as assessed by WI-NRS scores as either moderate (WI-NRS <7) or severe (WI-NRS  $\geq 7$ ). Patients were treated for 12 weeks and mean change in WI-NRS from baseline to the end of week 12 was determined.

**Results:** Among 222 participants, 70 patients had moderate pruritus (mean  $\pm$  standard deviation WI-NRS: 6.0  $\pm$ 0.5) and 152 patients had severe pruritus (8.3  $\pm$ 0.9) at baseline. Patients with moderate and severe itch at baseline reported on average mild pruritus (WI-NRS <4) at Week 12 (2.9  $\pm$ 2.2 and 3.1  $\pm$ 2.3) following an improvement of -3.0  $\pm$ 2.0 and -5.2  $\pm$ 2.4 points, respectively, with similar relative improvements in the means from baseline of 51.7% and 62.7%, respectively (Figure).

**Conclusions:** Following 12 weeks' treatment with DFK, itch was on average reduced to mild intensity in patients with both moderate and severe disease at baseline. Together, these data suggest that DFK effectively reduces itch severity in patients with CKD-aP on HD, irrespective of baseline itch severity.

**Funding:** Commercial Support - Vifor Pharma

Figure: Reduction in itch by baseline itch severity following 12 weeks' treatment with difelikefalin

\*WI-NRS score of 5 to <7.

WI-NRS, worst itch numerical rating scale; SD, standard deviation.

## SA-PO287

### Pruritus in Patients With ESKD on Hemodialysis: Initial Results From a Prospective Patient Survey Study

Jeffrey Thompson,<sup>1</sup> Jennifer A. Kammerer,<sup>2</sup> Juliana H. Oliveira,<sup>2</sup> Lauren L. Ashka,<sup>1</sup> Kirsten L. Johansen,<sup>3</sup> Gil Yosipovitch.<sup>4</sup> <sup>1</sup>Cerner Enviva, North Kansas City, MO; <sup>2</sup>Vifor Pharma Ltd., Redwood City, CA; <sup>3</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>4</sup>University of Miami School of Medicine, Miami, FL.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is common in patients on hemodialysis (HD). Real-world assessment of the patient's perspective of pruritus is needed. A US-based patient survey assessed treatment, and the humanistic and economic burden of CKD-aP.

**Methods:** Eligible participants were  $\geq 18$  years old with healthcare provider (HCP) diagnosed ESKD on 3 times/week HD. They self-reported itch assessed on a modified 28-day recall period using the worst itch numerical rating scale (WI-NRS; 0=no itch to 10=worst itch), from which they were stratified into mild (1–3), moderate (4–6), and severe (7–10) cohorts. Sleep quality was assessed on a 0–10 scale (10=itch completely interfered with sleep in the past 24 hours).

**Results:** Of 299 completed surveys (2/3 planned population) from December 2021 to May 2022: 50, 126, and 123 were stratified into mild, moderate, and severe itch cohorts, respectively. Overall participants were 53% female, 53% white/non-Hispanic, 43% on Medicare plans, and 70% on in-center HD. Proportions of patients who had discussed chronic itch with an HCP, were diagnosed with CKD-aP, received HCP-recommended treatment, or were currently taking itch treatment increased with itch severity (Figure). Greater itch severity was associated with high/extremely high self-reported itch burden (mild=4.0%, moderate=26.2%, severe=39.8%), and sleep disruption (mild=2.3, moderate=4.6, and severe=6.4). Topical treatment was ubiquitous in all cohorts (100%) while systemic treatment was limited even in moderate to severe itch cohorts (24–40%).

**Conclusions:** More severe itch scores were associated with a greater likelihood of patient-HCP engagement about itch and related treatment, and poorer sleep quality. A gap in addressing itch is suggested by a lower rate of HCP-recommended treatment (57%) or HCP-diagnosed CKD-aP (56%) vs patients reporting itch to HCPs (69%), and limited use of systemic treatment in moderate to severe itch cohorts.

**Funding:** Commercial Support - Vifor Pharma

## SA-PO288

### Impact of Difelikefalin on 5D-Itch Domains in Patients With CKD-Associated Pruritus

Anjay Rastogi,<sup>1</sup> Joel M. Topf,<sup>2</sup> Thilo Schaulfer,<sup>3</sup> Isabelle Morin,<sup>3</sup> Frederique Menzaghi,<sup>4</sup> Warren Wen,<sup>4</sup> Kieran McCafferty,<sup>5</sup> David Geffen School of Medicine, Los Angeles, CA; <sup>2</sup>Oakland University, William Beaumont School of Medicine, Rochester, MI; <sup>3</sup>Vifor Pharma Ltd, Glatbrugg, Switzerland; <sup>4</sup>Cara Therapeutics Inc, Stamford, CT; <sup>5</sup>Barts Health NHS Trust, London, United Kingdom.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is common in hemodialysis (HD) patients, impacting quality of life (QoL). In the Phase 3 KALM studies, difelikefalin (DFK), a selective kappa opioid receptor agonist approved in the United States and Europe for the treatment of moderate-severe pruritus in adults undergoing HD, improved itch intensity and QoL. The impact of DFK treatment on the subdomains of the 5D-itch scale (a multidimensional questionnaire validated in patients with chronic pruritus) were explored.

**Methods:** In this pooled KALM-1 and KALM-2 analysis (n=712), HD patients with moderate-severe CKD-aP were randomized 1:1 to receive intravenous DFK 0.5  $\mu$ g/kg or placebo (PBO) 3 times/week (Wk) for 12 Wks (double-blind [DB], PBO-controlled phase), followed by an up to 52-Wk open-label extension ([OLE] all patients receiving DFK). The change from DB baseline (BL) in 5D-itch scale domains was assessed including duration, degree, direction, and body distribution of itch and disability (sleep and daily activities) with a 2-Wk recall period.

**Results:** In the DB phase, patients on DFK reported greater improvements than PBO in all domains. Throughout the OLE, patients reported ongoing improvements: Duration of itch (~6 h/day at OLE Wk 52 vs ~12–18 h/day at BL); Degree ("mild-moderate" vs "moderate-severe" at BL); Direction ("a little/much better" vs

“unchanged” at BL); Disability, (“rarely” affected daily activities [including sleep] vs “frequently/occasionally” affected at BL); and Distribution (3–5 body parts affected vs 6–10 at BL).

**Conclusions:** In the 12-wk DB period patient-reported improvements in 5D-itch scale domains were greater with DFK than PBO. In the OLE, with all patients receiving DFK up to 52 wks, further improvements were observed across all domains.

**Funding:** Commercial Support - Vifor Pharma

**Figure:** Impact of DFK treatment on the subdomains of the 5D-itch scale: duration, degree, direction, disability, and distribution

Patients in the placebo/difelikefalin arm were on placebo for a 12-week DB period, then switched to difelikefalin for the OLE. Patients in the difelikefalin/difelikefalin arm received difelikefalin for both the DB period and OLE. For the distribution domain, the number of affected body parts is tallied (potential sum 0–16) and the sum is sorted into five scoring bins: sum of 0–2 = score of 1, sum of 3–5 = score of 2, sum of 6–10 = score of 3, sum of 11–15 = score of 4, and sum of 14–16 = score of 5. For the disability domain, daily activities include sleep, leisure social, housework/errands, and work/school. DB=double-blind; DFK= difelikefalin; OLE = open-label extension; PBO= placebo; SE = standard error; Wk = week.

## SA-PO289

### Insights Into Current Practices and Unmet Needs Relating to CKD-Associated Pruritus: Results From a Canadian Nephrologist Survey

Daniel Schwartz,<sup>1</sup> Gerald Miciak,<sup>2</sup> Arthur Magnaye.<sup>2</sup> <sup>1</sup>The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; <sup>2</sup>Otsuka Canada Pharmaceutical Inc., Saint-Laurent, QC, Canada.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is a common condition in patients with CKD undergoing hemodialysis (HD). In this real-world study, Canadian nephrologists were surveyed to gain insight into current practices and unmet needs related to the treatment of CKD-aP.

**Methods:** Quantitative data regarding the perception of current treatment practices for CKD-aP were collected in November and December 2021 by a 20-minute survey completed by 62 nephrologists across Canada. Respondents' level of agreement was assessed using a 7-point scale.

**Results:** In current practice, the mean perceived prevalence of CKD-aP in HD patients was 30.5%. Of these, 33.6% and 18.3%, respectively, experience moderate or severe CKD-aP. CKD-aP was most frequently identified (75.8% of cases) through patients complaining of itch to the multidisciplinary health care team. In clinical practice 63% of respondents currently do not use formal scales to diagnose and assess CKD-aP. Treatments used for severe and moderate CKD-aP are shown in the table. Nephrologists used topical moisturizers / emollients (85%), oral antihistamines (14%), and gabapentinoids (2%) as first-line treatments. Nephrologists reported 42% of patients with severe CKD-aP and 41% with moderate CKD-aP do not respond to treatment. Most nephrologists (94%) agreed there is a need for new treatments specifically designed to address CKD-aP, 68% agreed they do not expect to resolve a patient's CKD-aP with currently available treatments, 89% agreed CKD-aP is challenging to treat, and 69% agreed there is a need for guidelines for the treatment of CKD-aP.

**Conclusions:** This real-world Canadian study of nephrologists showed that CKD-aP is challenging to treat and many patients do not respond to currently-available treatments. There is an urgent unmet need for new, more effective treatments and for guidelines to aid nephrologists in selecting therapy for their patients with CKD-aP.

### Quantifying Physical Activity Behavior Among Adults Undergoing Hemodialysis Using a Gait Assistive Device: A Prospective Observational Study

Ram kinker Mishra,<sup>1</sup> Fadwa S. Al-Ali,<sup>2</sup> Myeounggon Lee,<sup>1</sup> Rania A. Ibrahim,<sup>2</sup> Mincy Mathew,<sup>2</sup> Heba M. Ateya,<sup>2</sup> Bijan Najafi,<sup>1</sup> Abdullah I. Hamad.<sup>2</sup> <sup>1</sup>Interdisciplinary Consortium on Advanced Motion Performance (iCAMP), Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, TX; <sup>2</sup>Hamad Medical Corporation, Doha, Qatar.

**Background:** People undergoing Hemodialysis (HD) have a higher burden of frailty and physical inactivity. This study aimed to quantify physical activity, strength, depression, and fall risk in people undergoing HD using gait assistive devices (GADs).

**Methods:** Participants undergoing routine HD were grouped based on the use of any GADs. Physical activity was measured over two consecutive days using a validated pendant sensor. Grip strength, concerns for falling and depression were assessed on FES-I and Center for Epidemiological Studies-Depression Scales.

**Results:** 136 participants were grouped into those prescribed GADs (n = 39, age = 55.7 ± 1.3 years, female = 40.6%) and no NGAD (n = 97, age = 68.6 ± 1.4 years, female = 61.5%). The proportion with cognitive impairment (40% vs. 23%), depression (51% vs. 16%), and concern of falling (84% vs. 38%) were greater in the GAD vs. NGAD group. Furthermore, number of postural transitions was negatively correlated with FES-I (ρ = -0.33, p < 0.01) and CES-D (ρ = -0.22, p = 0.025) scores.

**Conclusions:** People undergoing routine HD and using GADs showed high fear of falling, depression, and cognitive decline. Furthermore, reduced postural transition was associated with heightened fear of falling and depression level.

**Funding:** Government Support - Non-U.S.

**Table 1.** Demographic, clinical, patient reported outcomes of the subject using and not using GAD. Continuous parameters are reported as mean ± standard error and categorical outcomes are reported as Number of subjects with the condition/Total subject (percentage).

## SA-PO291

**Cognitive and Physical Functioning in Relation to Survival in Patients on Chronic Hemodialysis**

Robert Ekart,<sup>1,2</sup> Sebastjan Bevc,<sup>1,2</sup> Nejc Piko,<sup>1</sup> Tadej Petreski,<sup>1,2</sup> Luka Varda,<sup>1</sup> Radovan Hojs,<sup>1,2</sup> <sup>1</sup>Univerzitetni Klinični Center Maribor, Maribor, Slovenia; <sup>2</sup>Univerza v Mariboru, Maribor, Slovenia.

**Background:** Little is known about the relationship between cognitive and physical function and survival of patients on chronic hemodialysis (HD). The Mini-Mental State Examination (MMSE) is an instrument that can help quickly diagnose whether a person has mild cognitive impairment by answering questions in several cognitive domains. The Barthel Index (BI) is an ordinal scale that measures performance in activities of daily living (ADL). The aim of the present study was to determine whether the MMSE and the BI score are predictors of mortality in patients on chronic HD.

**Methods:** Eighty-eight patients (mean age: 63.7±13.1 years, 61.4% male) on chronic HD (dialysis vintage 62±64 months) were studied cross-sectionally and longitudinally. Their cognitive function was assessed with the MMSE and physical function with the BI questionnaire at baseline. The MMSE and BI were performed during a midweek HD session, avoiding the beginning and end of each treatment. A MMSE score ≤23 was considered to indicate cognitive impairment, and a BI score ≤15 was considered to indicate physical impairment. Demographic, clinical, and laboratory parameters were recorded for each patient.

**Results:** The mean (SD) MMSE score was 24.7±4.5, and the mean BI score was 19.2±2.5. Patients with a MMSE score ≤23 had a higher dialysis vintage (82.6 vs. 52.4 months; p=0.039), patients with a BI score ≤15 had lower serum albumin (39 vs. 35 g/L; p=0.031). After a mean follow-up of 1334±640 days (range: 21-2149 days), 47 (53.4%) patients died and 3 were transplanted. None of the patients were lost or transferred to another department. The deceased patients were statistically significantly older (p<0.001), had lower serum albumin (p=0.025) and lower BI score (p=0.036). Kaplan-Meier analysis showed that survival was significantly lower in patients with a BI score ≤15 (log rank  $\chi^2$ :13.15; p<0.001). We found no difference in survival with a MMSE score regardless of the MMSE score. According to the adjusted Cox regression analysis, mortality was associated with higher age (HR 1.06, 95% CI: 1.03-1.09, p<0.001) and inversely associated with BI score (HR 0.86, 95% CI 0.78-0.94, p=0.001).

**Conclusions:** The BI score is associated with an increased risk of death in HD patients and it should be routinely assessed to predict survival of HD patients.

## SA-PO292

**Physical Activity and Sleep Levels in Hemodialysis Patients as Quantified by a Wearable Device**

Maggie Han,<sup>1</sup> Ohnmar Thwin,<sup>1</sup> Xia Tao,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Amrith U. Patel,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Hemodialysis (HD) patients have a high prevalence of sedentary lifestyle and poor sleep. Decreased physical activity level (PAL) and sleep are associated with negative outcomes. Wearable activity trackers (WAT) allow the remote monitoring of PAL and sleep parameters. We aimed to objectively quantify PAL and sleep using a WAT in HD patients.

**Methods:** HD patients from 4 New York City clinics were enrolled starting June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use the Fitbit Charge 2. The 1<sup>st</sup> month of the study was the baseline period. PAL was measured by steps/day (s/d). Sleep duration was measured by total time asleep; sleep efficiency was calculated as (total time asleep)/(total time in bed). PAL were categorized based on average number of s/d: sedentary: < 5K s/d; fairly active: 5-10k s/d; active: 10-15k s/d; very active: > 15k s/d. Sleep duration of ≥ 7 hrs were categorized as having good sleep.

**Results:** We enrolled 119 patients (age 54±12 years; 59% Black; 37% lived alone; 54% had an education level of college and above). 1,561 and 1,066 patient days PAL and sleep data, respectively, from the baseline period were included in the analysis. Results of the PAL and sleep data are shown in Fig. 1. On average, patients walked 6,120 s/d, slept 292 minutes/day, and had a sleep efficiency of 93%.

**Conclusions:** Most patients walked less than the daily recommended 10k s/d and slept less than 7 hrs. However, they had high sleep efficiency indicating that though they have shortened sleep durations, their time in bed is mostly spent asleep. Barriers to PAL and good sleep should be explored to improve these factors which attribute greatly to a patient's quality of life and health outcomes.

**Funding:** Commercial Support - Renal Research Institute

**Short Physical Performance Battery, Mortality, and Hospitalization in Patients on Hemodialysis**

Juri Uchida,<sup>1</sup> Yuta Suzuki,<sup>2</sup> Keigo Imamura,<sup>1,4</sup> Shun Yoshikoshi,<sup>1,3</sup> Takuya Nakajima,<sup>1</sup> Narumi Fukuzaki,<sup>1</sup> Manae Harada,<sup>3</sup> Atsuhiko Matsunaga.<sup>1</sup> <sup>1</sup>Kitasato University Graduate School of Medical Sciences, Sagamiara, Japan; <sup>2</sup>National Institute of Public Health, Saitama, Japan; <sup>3</sup>Sagami Circulatory Organ Clinic, Sagamiara, Japan; <sup>4</sup>Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

**Background:** Patients on hemodialysis (HD) are more frail compared with the general old population. Frailty increases vulnerability to stressors; however, appropriate intervention can restore the robust state. Hence, regularly evaluating the physical functions of patients on HD to detect frailty at an early stage is critical. Short Physical Performance Battery (SPPB) is a widely known practical tool for assessing physical functions in patients on HD. However, there is limited clear clinical data examining the association between SPPB and long-term health outcomes in patients on HD. This study examined the association between SPPB and adverse health outcomes in patients on HD.

**Methods:** A retrospective cohort study involving 326 outpatients (mean age: 68 years; 62% men) who received maintenance HD was conducted. They were categorized into two groups: low SPPB (≤ 9) or high SPPB (> 9). We examined the association of SPPB score with all-cause death, all-cause hospitalization, and cardiovascular hospitalization using the Cox proportional hazards model. In addition, we calculated the population attributable fraction (PAF) to estimate the attributable fraction of low SPPB to health outcomes.

**Results:** Patients in the low SPPB group demonstrated a higher risk of all-cause death (hazard ratio (HR): 3.19; 95% confidence interval (CI), 1.89–5.38), all-cause hospitalization (HR: 2.01; 95% CI, 1.44–2.82), and cardiovascular hospitalizations (HR: 2.20; 95% CI, 1.45–3.35). PAF suggested that 42.1% of all-cause deaths, 19.8% of all-cause hospitalizations, and 28.5% of cardiovascular hospitalizations were attributable to low SPPB.

**Conclusions:** Low SPPB was associated with a higher risk for all-cause death, all-cause hospitalization, and cardiovascular hospitalization in patients on HD. SPPB is useful for assessing physical frailty and prognostic management. Treatments to prevent low SPPB may be an effective disease management strategy to control the high mortality and admission rates in patients on HD.

## SA-PO295

## Understanding the Personal Experiences of Patients on Hemodialysis

Wen Qing Wendy Ye,<sup>1</sup> Jinbaek Kim,<sup>1</sup> Azim S. Gangji,<sup>1,2</sup> *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; <sup>2</sup>St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

**Background:** Patients with end stage kidney disease on hemodialysis (HD) have complex medical, social, and emotional needs. The symptom burden of patients on HD is well documented; however, literature has not fully described the holistic patient experience, such as the social and emotional impact of HD. The objective of this study is to capture the lived experiences of patients on HD, including effects on their emotional health, relationships, and quality of life.

**Methods:** This is a qualitative study. Patients on chronic HD in Hamilton, Ontario were invited to participate. Semi-structured interviews were conducted to understand the effect of HD on their emotional and mental health, and quality of life. Interviews were transcribed and coded to identify emerging themes. A framework of the impact of HD was developed using constructivist grounded theory.

**Results:** 16 interviews were completed as of January 2022. Three themes were identified: 1) expectations of HD, 2) personal and professional impacts, and 3) changes in personal identity (Figure 1). Participants felt their experiences on HD were different from their expectations based on counselling provided by healthcare staff. This included positive and negative experiences. Participants experienced loss of employment opportunities, intimate relationships, and hobbies since starting HD. Some participants noted the emergence of a new identity anchored to HD due to the significant role it played in their lives.

**Conclusions:** Initiating HD leads to unanticipated losses for patients both personally and professionally. This requires them to undergo a number of complex changes to accommodate HD in their lives. The impact of these changes are far reaching, resulting in patients taking new identities as they cope with their chronic health concerns. Overall, this data provides new insight on the patient experience, and can be used to engage in meaningful conversations about initiation of HD.

Figure 1: Professional and personal impact of hemodialysis on identity formation.

## SA-PO296

## Starting Hemodialysis: A Qualitative Study of Patients' Experiences and Perspectives

Kshama R. Mehta,<sup>1</sup> Kerstin Leuther,<sup>1</sup> Alexandra L. Fegler,<sup>1</sup> Brigitte Schiller,<sup>1,3</sup> Paul N. Bennett,<sup>1,2</sup> Wael F. Hussein,<sup>1,3</sup> *Satellite Health Care <sup>1</sup>Satellite Healthcare, San Jose, CA; <sup>2</sup>University of South Australia, Adelaide, SA, Australia; <sup>3</sup>Stanford University School of Medicine, Stanford, CA.*

**Background:** People commencing dialysis experience anxiety, depression and hospitalizations. Limited qualitative data is available to describe the experience and perspectives of people starting dialysis.

**Methods:** Adult English speaking patients within 90 days of starting in-center hemodialysis (HD) at centers of a nonprofit dialysis provider in Northern California were invited to join the study using a convenience based sampling method until theme saturation was reached. Audio-recorded, individual, semi-structured interviews conducted by trained qualitative researchers were de-identified and transcribed verbatim before being inductively coded into Level 1 codes, Level 2 categories, and Level 3 themes.

**Results:** Three overarching themes emerged from twenty participants (55% male, 45% Caucasian, mean age 63, 66% with some college education, median HD vintage of 2 months). Theme 1, *Being overwhelmed when starting dialysis*, realizes the emotional unpreparedness of patients starting dialysis, dialysis side effects, the all-encompassing lifestyle changes and how trust and confidence in the dialysis center staff decreases anxiety to enable a positive dialysis start experience. Theme 2, *Making sense of it all (for better or for worse)*, covers how impressions of the dialysis environment (waiting and treatment areas) and building a community with other patients/staff contributes to a positive start. Theme 3, *Moving forward*, describes how the right education at the right time supports optimal informed decision-making and positions patients for success by increasing hope for a longer and better life.

**Conclusions:** Understanding the life-changing experience that patients encounter when starting dialysis can benefit hemodialysis clinicians in individualizing patient care to help patients adjust and develop long-term coping strategies. Improved patient experience is realized by : improving the center's physical environment, developing peer support programs, providing lifestyle support, implementing more person-centered care models, offering learning style-tailored education, providing care focused on individual patient goals, and enabling shared decision-making.

**Funding:** Commercial Support - Satellite Dialysis

## SA-PO297

## The Safety of Driving Among Patients With ESRD on Hemodialysis: How to Stop Burying Our Head in the Sand and Start Saving Patients

Abdulkareem Alsawaida,<sup>1</sup> Ghada Ankawi,<sup>2</sup> Anas A. Alsawaida,<sup>1</sup> Ali E. Shehadah,<sup>1</sup> Mohammed T. Alzahrani,<sup>1</sup> *King Saud University, Riyadh, Saudi Arabia; <sup>2</sup>King Abdulaziz University, Jeddah, Saudi Arabia.*

**Background:** Human error is the main cause of car accidents and whether specific cognitive impairments related to dialysis session and/or comorbid medical conditions increase the risk of car accidents is still unclear. Our objective is to explore patient's perceptions and experiences in driving to the dialysis unit.

**Methods:** A cross sectional questionnaire survey done in two university hospitals in Saudi Arabia. All adults' patients on in center hemodialysis more than 3 months were included in the study.

**Results:** Data were collected from 88 adults (39.7% women) enrolled in the Study. Among participants 46.6% were diabetic, 73.9% with hypertension and 25.0% with coronary artery disease. Forty eight patients stopped driving after starting dialysis. The most frequent cause for stop driving were fatigability, blurred vision and dizziness. Thirteen patients noted significant impact of dialysis session on their capacity to drive post treatment. Twenty participants continued to drive with 4 patients (25%) sustained a road traffic accidents since starting dialysis.

**Conclusions:** Most of dialysis patients felt continuing driving after starting dialysis was unsafe and stopped driving. Those continue to drive were likely they could not afford public transportation or do not want to burden their family. However, driving is not without its dangers. Those continued to drive are at higher risk of road traffic accidents. Creating a safe transportation program is critical for patients on in-center hemodialysis as part of comprehensive care to patients with end stage renal disease. Otherwise, bigger studies are needed to develop screening programs for patients on dialysis to periodically assess suitability to drive.

**Funding:** Government Support - Non-U.S.

## SA-PO298

## Prevalence of Depression in an Urban, Predominantly Black ESKD Population During the COVID-19 Pandemic

Chijioke K. Ofoche,<sup>1</sup> Matthew A. Brown,<sup>1</sup> Terry Klemensen,<sup>1</sup> Clifford Collins,<sup>2</sup> Winnfred L. Timmons,<sup>3</sup> Janice P. Lea,<sup>1</sup> Laura Plantinga,<sup>1</sup> Jason Cobb,<sup>1</sup> *Emory University School of Medicine, Atlanta, GA; <sup>2</sup>American University of the Caribbean School of Medicine BV, Cupecoy, Sint Maarten (Dutch part); <sup>3</sup>Emory Healthcare, Atlanta, GA.*

**Background:** The COVID-19 pandemic has had far-reaching implications in terms of physical and mental health ramifications, and minority communities have been disproportionately impacted; particularly, prevalence of depression increased. Throughout the pandemic, ESKD patients have continued thrice-weekly in-center hemodialysis sessions or home therapies. We explored whether there was an increase in depression prevalence after the start of the pandemic in our urban predominantly Black ESKD population.

**Methods:** We used data from social worker-administered PHQ-2 questionnaire depression screenings (required by Centers for Medicare & Medicaid Services) in eligible patients treated at four Emory University affiliated in-center dialysis units and three home dialysis units from 2018-2019 (pre-pandemic) to 2020-2021 (pandemic). Excluded from this study were patients with no assessments or incomplete assessments. Data were analyzed using chi-square tests comparing the prevalence of depression in pre-pandemic versus pandemic period.

**Results:** In 2021, 91.5% of our patients were Black. There were 2433 in-center patient depression scores and 586 home dialysis patient depression scores. Excluded from the study were 1045 patients in the in-center and 214 patients in the home population. Of the 2433 patient scores analyzed in the in-center group, 1289 were pre-pandemic and 1144 were in the pandemic period. 155 (12%) in-center patient scores in the pre-pandemic period were classified as depressed while 128 (11.2%) in-center patient scores during the pandemic were classified as depressed (two-sided p-value 0.5272). Of the 586 home dialysis patient scores, 325 were pre-pandemic and 261 in the pandemic period. 71 (21.8%) patient scores in the pre-pandemic period had a positive depression screening while 29 (11.1%) patient scores during the pandemic period had depression (two-sided p-value 0.0006).

**Conclusions:** We did not observe an increase in depression prevalence during the COVID-19 pandemic in in-center dialysis patients, and surprisingly observed a statistically significant decrease in depression among our home dialysis patients. The decrease in depression in our home dialysis patients during the pandemic may reflect being at home is a protective mechanism, and this observation should be further investigated.

## SA-PO299

**Regional Differences in Quality of Life in a Large Multinational Population of Chronic Hemodialysis Patients**

Carla Alexandra R. Santos Araujo,<sup>1,2</sup> Eliana M. Silva,<sup>1</sup> Mathias Haarhaus,<sup>1</sup> Israel P. Silva,<sup>1</sup> Suzanne H. Pearce,<sup>1</sup> Carlos Lucas,<sup>1</sup> Fernando Macario.<sup>1</sup>  
<sup>1</sup>*Diaverum Renal Services Group, Lund, Sweden;* <sup>2</sup>*UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine of the University of Porto, Porto, Portugal.*

**Background:** Health-related quality of life (QoL) is increasingly recognized as an important patient-centered outcome in hemodialysis (HD). Relevant differences between countries may exist, despite high standardization in HD care. We aimed to evaluate the effect of regional location in QoL in a large, multinational population of HD patients.

**Methods:** This was a multicenter prospective observational study using a quality database from a large HD organization. All adult patients that voluntarily responded to KDQOL-36 were included. Six months after the survey, demographic (age, gender and country) and clinical data (diabetes, comorbidity index, type of vascular access, death) were collected. Patients were allocated to different regions, according to the country of origin: Western and East Europe, Euroasia, Latin America and Iberia. Various domains of KDQOL-36 (2 generic and 3 kidney specific) were analyzed and related to the different covariates using multiple linear regression (results presented as hazard ratios and 95% confidence intervals).

**Results:** 30 614 HD patients with valid responses to KDQOL-36 were included. The majority reported poor QoL: this was particularly evident for Burden of kidney disease (46.57±26.68) and Mental (MCS) (45.29±10.31) and Physical Composite Scales (PCS) (37.80±9.40). In multivariate analysis, female gender and comorbidity index were independently associated with a poorer QoL in all domains. Older age was an independent predictor of lower PCS, but of a higher MCS, whereas time on HD was positively correlated with both MCS (1.36 [0.90–1.82],  $p<0.01$ ) and PCS (0.73 [0.34–1.12],  $p<0.01$ ). Six-month mortality was independently associated with worst scores in all levels of QoL. Western Europe patients presented significantly worst scores, particularly in MCS (–3.37 [–3.81]–(–2.92)],  $p<0.01$ ) and general scales, when compared to kidney specific domains.

**Conclusions:** In our population, we have documented a lower QoL in Western Europe patients, more evident in general and social than in kidney specific domains. These results may reflect the high level of standardization of HD care worldwide and prompt the adoption of region specific QoL strategies, oriented to the particular necessities of HD patients in certain locations of the globe.

## SA-PO300

**Quality of Life and Outcome in Patients on Hemodialysis: The Role of Dialysis Shift**

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

**Background:** Patients with end-stage renal disease (ESRD) undergo hemodialysis (HD) during the morning, afternoon or at night, with time of treatment generally based on space availability or patient preference. This report examines the extent to which hemodialysis treatment time of day was associated with morbidity and quality of life.

**Methods:** Dialysis start time defined dialysis shift: morning beginning between shift 1 (7am and 11am) (n = 38); shift 2 (12pm and 4pm) (n = 38); shift 3 (5pm and 9pm) (n = 43) and shift 4 (10pm and 2am) (n = 56). Outcome measures included quality of life parameters, morbidities, dialysis care or hospitalization.

**Results:** Out of 300 patients dialyzed at the Dialysis Facility, 175 (116 males and 59 females) met the inclusion criteria (adult patients aged between 18 and 90 years, on maintenance hemodialysis for more than 3 months and with no psychiatric or severe disabling diseases) were studied. Of these patients, shift 4 patients had a significant higher mean age compared to other shifts ( $p=0.001$ ) and significant higher number of widows (8.6%,  $P=0.007$ ). Most of the patients in all shifts were high school educated but with significant trend to loss of their jobs due to employer attitude in shift 4 (28.6% compared to 13.2%, 10.5% and 9.3% in shifts 1–3,  $p=0.001$ ). The patients in all four groups are comparable in terms of transportation methods, travel abroad, number of missed sessions weekly, nursing vascular access care, hemodialysis session related complications, exercise performance. Shift 4 was associated with more flexible social life,  $p=0.020$ ). Shifts 1 and 2 have high admission rates to the hospital (31.1% and 26.3%, respectively) compared to (9.3% and 7.2%, in shift 3 and 4,  $p=0.004$ ) with no significant difference in the causes of admission being the infections and cardiovascular morbidities are commonest causes. Physician care was significantly missed in shift 4 (28.6%) compared to other shifts ( $p=0.0001$ ). Shift 4 patients' spouses are more affected by losing their jobs (18%) compared to other groups ( $p=0.017$ ).

**Conclusions:** The time of the hemodialysis schedule could affect the social life, social relationships, and income of the patients by losing their jobs. The physician care was not adequate in the evening shifts. Our results of the study provide evidence for medical professionals to prioritize healthcare and effective treatment plans

## SA-PO301

**Psychometric Properties of the Kidney Disease Quality of Life Short Form 36 (KDQOL-36) Scale for the Evaluation of Quality of Life in Colombian Chronic Dialysis Patients**

Martha C. Valderrama Rios,<sup>1</sup> Ricardo Sanchez,<sup>1</sup> Mauricio Sanabria.<sup>2</sup>  
<sup>1</sup>*Universidad Nacional de Colombia, Bogota, Colombia;* <sup>2</sup>*Baxter Renal Care Services, Deerfield, IL.*

**Background:** Quality of life is one of the most important health outcomes during kidney failure treatment. The quality of the results obtained through PROMs depends on the psychometric properties with which the instrument quantifies the construct of interest in each population. **Objective** To establish the psychometric properties of the KDQOL-36 instrument in Colombian dialysis patients.

**Methods:** Scale validation study carried out in adult hemodialysis or peritoneal dialysis patients treated at Baxter Renal Care Services (BRCS) network, in Bogotá, Colombia to whom the KDQOL-36 instrument was applied. The clinimetric properties assessed were content validity, internal consistency, reliability analysis through test-retest method, applying the instrument in a second moment, 8–10 days after, criterion validity through concurrent validity, with the application of the Kidney Disease Questionnaire (KDQ) at the same time; and the sensitivity to change, applying the instrument in a second moment, after an event that could generate a change in the construct.

**Results:** A sample of 506 patients were included (table 1). Regarding content validity, the exploratory factor analysis confirmed an adequate adjustment of the model (figure 1). Item 28 did not obtain an adequate factorial load in any of the three domains. For internal consistency the McDonald's  $\alpha$ , GLB and Cronbach's alpha coefficients showed values  $\geq 0.89$ . Adequate test-retest reliability was confirmed with a Lin's correlation-concordance coefficients  $\geq 0.77$  and Bland and Altman plots evidencing a high level of concordance (figure 2). Spearman correlation values significantly different from zero ( $> 0.50$ ) were found between KDQOL-36 scale and the KDQ instrument domains. And adequate sensitivity to change was confirmed with a  $p$  value for Friedman test equal to 0.0000.

**Conclusions:** The validation of the KDQOL-36 instrument for the evaluation of quality of life in Colombian population showed it has an adequate reliability, validity, and sensitivity to change.

## SA-PO302

**Effects of the Long Interdialytic Period on Physical Performance in Patients on Hemodialysis**

Elliott Arroyo,<sup>1</sup> Andrew R. Coggan,<sup>2</sup> Sharon L. Karp,<sup>1</sup> Sharon M. Moe,<sup>1</sup> Kenneth Lim.<sup>1</sup> *<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN;* *<sup>2</sup>Indiana University Purdue University Indianapolis, Indianapolis, IN.*

**Background:** Reduced physical function in patients on hemodialysis (HD) is strongly associated with increased risk of falls, fractures, disability, morbidity, and mortality. The long (3-day) interdialytic period is linked to fluid overload, metabolic acidosis, electrolyte imbalances, and cardiac and skeletal muscle failure—physiologic alterations that can impair physical function. Despite this, the effects of interdialytic periods on metrics of physical performance are largely unknown. Herein, we sought to determine whether physical performance is impaired following the long interdialytic period.

**Methods:** We analyzed data from the ongoing, “Effects of long interdialytic intervals on Cardiovascular Functional Capacity (ECON)” study, a randomized crossover trial of patients on conventional HD. Comprehensive assessment of mobility and performance capacity were performed on three study visits: post-HD (baseline; BL), and at the end of the 2-day and 3-day interdialytic intervals. Fluid status was assessed via bioelectrical impedance spectroscopy.

**Results:** A total of 17 patients (n=12 men, age=52±11 years, dialysis vintage=76±68 months) were included in this analysis. Body weight (BL=79.8±20.2 kg; 2-day=81.1±20.6 kg; 3-day=82.1±21.0 kg;  $p<0.001$ ), total body fluid (TBF;  $p<0.001$ ), extracellular fluid (ECF;  $p<0.001$ ), and fluid overload ( $p<0.001$ ) were significantly higher at 3-day intervals compared to both 2-day and BL. Both usual gait speed (BL=1.1±0.2 m/s; 2-day=1.0±0.1 m/s; 3-day=0.9±0.2 m/s;  $p=0.02$ ) and fast gait speed (BL=1.5±0.4 m/s; 2-day=1.4±0.3 m/s; 3-day=1.3±0.3 m/s;  $p=0.033$ ) were significantly slower in 3-day compared to BL, while no significant differences were observed between 2-day and BL. Usual gait speed was significantly correlated with TBF% ( $r=0.39$ ,  $p=0.005$ ) and ECF% ( $r=-0.42$ ,  $p=0.002$ ). Fast gait speed was significantly correlated with TBF% ( $r=0.52$ ,  $p<0.001$ ), ECF% ( $r=-0.49$ ,  $p<0.001$ ) as well as body weight ( $r=-0.39$ ,  $p=0.004$ ).

**Conclusions:** Our preliminary findings indicate that the 3-day interdialytic interval is associated with impaired physical performance. We postulate that excess volume accumulation during the 3-day interdialytic period may be a major contributor to impaired physical function.

## SA-PO303

# Tailoring a Pain Coping Skills Training Intervention for Patients Receiving Maintenance Hemodialysis for Kidney Failure With Chronic Pain

Daniel Cukor,<sup>1</sup> Carrie E. Brintz,<sup>2</sup> Alicia Heapy,<sup>9</sup> Francis J. Keefe,<sup>3</sup> Jennifer L. Steel,<sup>4</sup> Manisha Jhamb,<sup>4</sup> Martin Cheate,<sup>8</sup> Daniel W. Mcneil,<sup>5</sup> Amanda J. Shallick,<sup>6</sup> Paul L. Kimmel,<sup>7</sup> Laura M. Dember.<sup>8</sup> HOPE Consortium <sup>1</sup>Rogoin Institute, New York, NY; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Duke University School of Medicine, Durham, NC; <sup>4</sup>University of Pittsburgh, Pittsburgh, PA; <sup>5</sup>West Virginia University, Morgantown, WV; <sup>6</sup>New York University, New York, NY; <sup>7</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>8</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>9</sup>VA Connecticut Healthcare System - West Haven Campus, West Haven, CT.

**Background:** Patients with kidney failure undergoing maintenance hemodialysis (HD) have a substantial burden of pain symptoms that are consistently identified as underdiagnosed and undertreated. Pain Coping Skills Training (PCST) is a first-line behavioral treatment for pain, but there are unique challenges in applying these skills to patients treated with in-center HD. We describe PCST adaptations that address these challenges as part of an ongoing multi-center clinical trial (HOPE study) designed to evaluate the effectiveness of telehealth PCST compared to usual care for reducing pain interference among patients treated with HD.

**Methods:** Prior to initiating the trial, a team of psychologists specializing in psychosocial treatments for kidney disease or chronic pain adapted the intervention protocol from standard PCST with input from patient representatives. PCST adaptations were based on unique considerations for HD patients (e.g., treatment demands, unique pain complaints, psychiatric comorbidity, and diverse socioeconomic and health literacy levels). PCST was adapted for remote delivery with flexible options so patients could complete sessions using video or audio, with their own or a provided device, and at dialysis or another location. Content adaptations included pain coping skills applied to disease/treatment-related pain, addressing pain-related depression, sleep difficulty and anxiety, and incorporating motivational interviewing to facilitate desired opioid reduction or other individual value-based goals. Patient-facing materials used patient-centered language with input from patient representatives. Participants were recruited from dialysis facilities across the United States and those randomized to PCST received 12 weekly, 45-minute sessions via telemedicine.

**Results:** Among the 139 participants who had, as of May 18, 2022, reached Week 12 of PCST study participation a total of over 1330 PCST sessions have been completed, and the mean number of sessions conducted was 11 with 93.5% (n=130) completing the minimum target of ≥8 sessions.

**Conclusions:** The high level of engagement to date supports the acceptability of a tailored, scalable nonpharmacologic treatment for reducing pain burden in patients on HD.

## SA-PO304

# Medication Utilization Among US Veterans With Advanced CKD Receiving Conservative Management vs. Dialysis

Yoko Narasaki,<sup>1</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Susan T. Crowley,<sup>2</sup> Csaba P. Kovacs,<sup>3</sup> Dana B. Mukamel,<sup>1</sup> Amy S. You,<sup>1</sup> Ji Hoon Yoon,<sup>1</sup> Danh V. Nguyen,<sup>1</sup> Connie Rhee.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

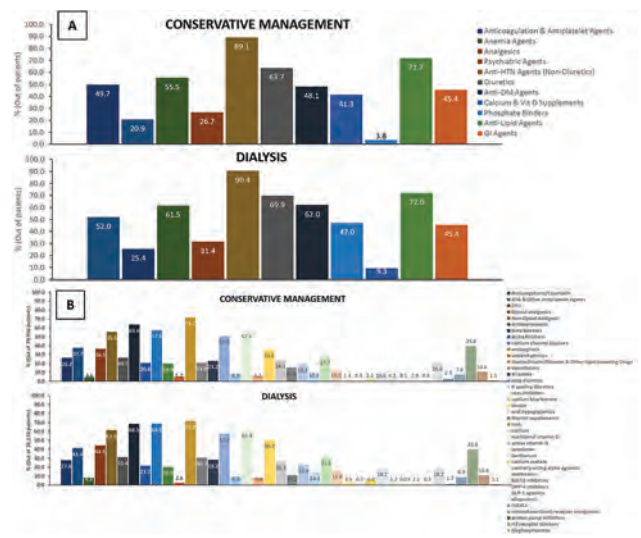

**Background:** Within the Veterans Health Administration, the largest integrated healthcare system in the US, 1.1 million Veterans (16%) have CKD among whom ~10% annually progress to ESKD requiring dialysis or transplant. While dialysis has been the prevailing paradigm in this population, there has been growing interest in non-dialytic conservative management (CM) as an alternative patient-centered treatment strategy for advanced CKD. We sought to examine medication utilization patterns among Veterans with advanced CKD treated with CM vs. dialysis.

**Methods:** In a national cohort of US Veterans, we examined patients with advanced CKD (≥2 eGFRs <25ml/min/1.73m<sup>2</sup> separated by ≥90 days) from 10/2010-9/2019. Using linked USRDS and Medicare (CMS) data, we compared medication utilization within 1-year prior to the index eGFR (1<sup>st</sup> eGFR <25ml/min/1.73m<sup>2</sup>) among patients categorized according to 1) receipt of CM, defined as those who did not receive dialysis within 2-years of the index eGFR, vs. 2) receipt of dialysis within 2-years of the index eGFR.

**Results:** Among 106,089 advanced CKD patients who met eligibility criteria, 25% (N=26,113) and 75% (N=79,956) were treated with dialysis vs. CM, respectively. Compared to the CM group, the dialysis group had higher utilization of anticoagulation/antiplatelet, anemia, analgesic, psychiatric, diuretic, anti-diabetes, and calcium/vitamin D agents (Fig); however, there was a similar prevalence of anti-HTN, phosphate binder, and GI medications.

**Conclusions:** Among US Veterans with advanced CKD, there tended to be higher utilization of most medication classes in the dialysis group as compared with CM patients. Further studies are needed to define the optimal pharmacotherapeutic management strategies among advanced CKD patients treated with CM vs. dialysis.

## SA-PO305

# A “Best Fit” Framework Synthesis to Guide Adherence Interventions for Patients on Hemodialysis

Kathryn Taylor,<sup>1</sup> Ebele M. Umeukeje,<sup>2</sup> Sydney Santos,<sup>3</sup> Katherine C. McNabb,<sup>1</sup> Deidra C. Crews,<sup>4</sup> Melissa D. Hladek.<sup>1</sup> <sup>1</sup>Johns Hopkins University School of Nursing, Baltimore, MD; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Johns Hopkins University, Baltimore, MD; <sup>4</sup>Johns Hopkins Medicine, Baltimore, MD.

**Background:** Patients with end-stage kidney disease (ESKD) treated with hemodialysis in the U.S. have higher rates of nonadherence compared to patients in other countries. Published adherence interventions demonstrate limited efficacy. Qualitative research that explores patient perspectives about adherence may point to gaps in existing interventions. The aim of this review was to synthesize qualitative data about adherence to hemodialysis treatment, medications, or fluid and dietary restrictions to inform development of patient-centered adherence interventions.

**Methods:** We conducted a “best fit” framework synthesis of qualitative studies on adherence to hemodialysis treatment, medications, and fluid and dietary restrictions. We searched PubMed, CINAHL, PsychInfo, Embase, and Web of Science for relevant literature. We analyzed qualitative data via thematic analysis, initially identifying codes from the World Health Organization’s adherence framework.

**Results:** We screened 1775 articles and extracted qualitative data from 12. The data revealed 20 factors unique to hemodialysis treatment across the World Health Organization’s five dimensions of adherence. Two themes emerged from the data: (1) adherence in the context of patients’ whole lives and (2) dialysis treatment as a double-edged sword. Patients described a profound grieving process over loss of their “old self”. They navigated complex challenges as they balanced ESKD treatment, life tasks, and social roles.

**Conclusions:** One-size-fits-all approaches to improving adherence among patients on hemodialysis are inadequate. Adherence may improve when care incorporates patient context and provides ongoing support to patients and families as they navigate the logistical, physical, and psychological hardships of living with dialysis.

### Effect of Hemodialysis on Lamina Cribrosa of Optic Nerve Head Measured by Swept-Source Optical Coherence Tomography

Won June Lee. Hanyang University, Seongdong-gu, Seoul, Republic of Korea.

**Background:** The eyes and kidneys have numerous common structural, developmental, and physiologic pathways, suggesting that eye and kidney disease may be interlinked. Hemodynamic changes due to hemodialysis (HD) may affect the blood flow to the eyes, which may influence many structures of the eye. In this study, we investigated the effect of HD on lamina cribrosa (LC) of optic nerve head (ONH) by swept-source optical coherence (SS-OCT) and other ophthalmologic parameters in patients with end-stage kidney disease (ESKD).

**Methods:** A prospective observational study was performed on 28 patients who underwent HD for ESKD. Detailed ophthalmologic examinations and SS-OCT were performed immediately before and after HD. The ONH parameters including the LC position, were measured using built-in software. Changes in ONH parameters before and after HD were statistically analyzed.

**Results:** The mean anterior LC depth (LCD) significantly decreased from  $441.6 \pm 139.8 \mu\text{m}$  before HD to  $413.5 \pm 141.7 \mu\text{m}$  after HD ( $P=0.001$ ). Mean neural canal diameter and mean papillary vertical height did not show significant change after HD ( $P=0.841$ ,  $P=0.574$ , respectively). Significant correlation was found between changes in LCD and changes in mean ocular perfusion pressure ( $\rho=0.397$ ,  $P=0.036$ ).

**Conclusions:** We observed significant decrease in anterior LCD after HD. Our study suggest that HD can give influence on the ONH, especially in LC.

## SA-PO307

### Treatment Response and Dosing of Patiromer in Veterans With Dialysis-Dependent ESKD and Hyperkalemia

Csaba P. Kovacs,<sup>1</sup> Navdeep Tangri,<sup>2</sup> Derek Pinnell,<sup>3</sup> Steven D. Woods,<sup>4</sup> Sylvie Boutin,<sup>5</sup> Brian C. Sauer.<sup>5</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>University of Manitoba, Winnipeg, MB, Canada; <sup>3</sup>Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT; <sup>4</sup>Vifor Pharma Inc., Redwood City, CA; <sup>5</sup>Otsuka Canada Pharmaceutical Inc, Saint Laurent, QC, Canada.

**Background:** Hyperkalemia (HK) is a common, potentially life-threatening metabolic disorder that presents a challenge for clinicians caring for dialysis patients with end-stage kidney disease (ESKD). Patiromer is a non-absorbed, sodium-free potassium ( $\text{K}^+$ )-binding polymer approved for HK treatment. This historical cohort study aimed to describe patiromer utilization and associated serum  $\text{K}^+$  ( $\text{sK}^+$ ) changes in veterans with ESKD and HK on dialysis.

**Methods:** Patiromer utilization and  $\text{sK}^+$  changes were evaluated using the National VA Corporate Data Warehouse between 1/1/16 and 2/28/21. Inclusion criteria were adults aged  $\geq 18$  years old, receiving patiromer, with at least 2 ICD codes for ESKD, on dialysis, and a  $\text{sK}^+ \geq 5.1 \text{ mEq/L}$  recorded within 91 days of the index date (date of first patiromer dispensing).  $\text{sK}^+$  was assessed at baseline (BL) and 1-, 3-, and 6-months follow-up (FU) from index date.  $\text{sK}^+$  change from BL to each FU timepoint was assessed by paired t-test.

**Results:** 1,267 patiromer users were identified with ESKD based on ICD code during the BL period; 458 meet the inclusion criteria and had a  $\text{sK}^+$  available for evaluation during the 3 months pre-index. BL characteristics included mean age 66 years old, 97% male,

45% African American, and mean  $\text{sK}^+ 5.91 \text{ mEq/L}$ . Comorbidities of interest included 72% diabetes, 50% heart failure, and 45% coronary artery disease. Dosing of patiromer was daily in 87% of cases with an average daily dose of 8.4 g. A dose increase was observed in 11% ( $n=52$ ) and dose decrease in 5% ( $n=24$ ) during the FU period. Following patiromer initiation, significant reductions ( $P<0.01$ ) in mean  $\text{sK}^+$  concentrations from BL were observed within 1 month ( $-1.02 \text{ mEq/L}$ ;  $n=307$ ), 3 months ( $-1.04 \text{ mEq/L}$ ;  $n=351$ ), and 6 months ( $-1.05 \text{ mEq/L}$ ;  $n=351$ ; **Figure**).

**Conclusions:** Among US veterans with ESKD and HK on dialysis, patiromer use was associated with clinically relevant reductions in  $\text{sK}^+$  concentrations at all study timepoints.

**Funding:** Commercial Support - Otsuka Pharmaceuticals Canada

## SA-PO308

### Research Participation Rates by Hemodialysis Shift and Schedule

Vladimir Rigodon,<sup>1</sup> Yue Jiao,<sup>2</sup> John W. Larkin,<sup>2</sup> Len A. Usvyat,<sup>2</sup> Michael S. Anger,<sup>1</sup> Franklin W. Maddux,<sup>3</sup> Russell Smith.<sup>4</sup> <sup>1</sup>Fresenius Medical Care North America, Waltham, MA; <sup>2</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>3</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>4</sup>Frenova Renal Research, Waltham, MA.

**Background:** Trial conduct is fundamental to the development of better therapeutics/devices that maintain health and treat the ailments of mankind. In kidney failure, most patients are treated by in-center hemodialysis (HD) for 240 minutes thrice weekly, which offers ample opportunities to invite patients to participate in trials. HD occurs in shifts through the day that are typically performed on Monday, Wednesday, Friday (MWF) or Tuesday, Thursday, Saturday (TTS) schedules. Many clinics are involved in trials, however, there have been questions on the equivalence of offerings and participation rates by HD shifts and schedules. To start to understand this, we assessed trial participation rates by HD shift and weekday at a clinic network.

**Methods:** We used data from all adults at HD clinics that participated in industry-sponsored trials and enrolled  $\geq 1$  participant during Oct 2018-2021. We computed the proportion of research participants (i.e. enrolled in  $\geq 1$  trial) to non-research patients per HD shift and per weekday.

**Results:** Among 218 HD clinics, 2.0% of patients (1,274/63,014) were enrolled into  $\geq 1$  trial during the 3 years. The greatest % of patients enrolled were treated in the 1<sup>st</sup> shift on a MWF schedule and participation rates decreased with each later shift (**Figure 1**). Consistent signals were seen in shifts 1-5 for patients treated on a TTS schedule, however, the highest % of patients were enrolled in the 6<sup>th</sup> shift (nocturnal HD).

**Conclusions:** Findings identified disparities in research enrollment by HD shift and schedule, with the most trial participants receiving HD in the 1<sup>st</sup> shift of the morning on an MWF schedule. These findings are likely showing research staff resourcing patterns and representative of when the largest subset of patients is treated. Nonetheless, it suggests there may be less opportunities afforded to patients in certain shifts and schedules. Given patient characteristics (e.g. age, comorbidities) are often distinct between shifts these observations will be important to be considered.

## SA-PO309

## Does Sodium Magnetic Resonance Imaging Help for Initiation of Incremental Dialysis?

Sandrine Lemoine,<sup>1,2</sup> Alireza Akbari,<sup>2</sup> Jarrin D. Penny,<sup>2</sup> Christopher W. McIntyre.<sup>2</sup>  
<sup>1</sup>Université de Lyon, Lyon, France; <sup>2</sup>Lawson Health Research Institute, London, ON, Canada.

**Background:** Incremental HD (twice a week) can be proposed to some patients who had a significant residual renal function (RRF) when hemodialysis (HD) is initiated. However renal urea clearance is a very limited tool to assess the totality of crucial functions of the kidney, such as ability of the kidney to control salt and water excretion. We hypothesized that corticomedullary gradient (CMG) measurement with <sup>23</sup>NaMRI could provide a new tool to select HD patients potentially suitable for incremental dialysis.

**Methods:** We conducted a prospective observational study to better characterize CMG in HD patient with <sup>23</sup>NaMRI. We performed CMG measurement with <sup>23</sup>NaMRI in fasting patients. All MR experiments were carried out on a GE MR750 3T (GE Healthcare, WI). A custom-built two-loop (18cm in diameter) butterfly radiofrequency surface coil tuned for <sup>23</sup>Na frequency (33.786 MHz) was used to acquire renal <sup>23</sup>Na images. We compared CMG in healthy controls (n=15) and HD patients (n=10) with or without conventionally assessed RRF.

**Results:** For healthy controls, median (IQR) age was 50 (32-60), years old, 46% men, eGFR 103 (84-108) mL/min/1.73m<sup>2</sup>, urinary osmolality (osmU) 786 (587-938) osm/L. For HD patients, median(IQR) age was 50 (32-60) years old, 40 % men, urinary osmolality (osmU) 313 (193-317) osm/L, 40% with residual renal function (RRF). Corticomedullary gradient for controls (1.53 (1.47-1.61)), was significantly different to HD 1.32 (1.24-1.36) (p=0.001). There was a significant correlation between osmolality and CMG (r=0.92, p<0.001). We were able to see a difference in salt repartition between HD patient with RRF and control. Anuric HD patients had lost medullary sodium entirely. Figure 1 shows difference in corticomedullary pictures (A) control; (B) HD patients with RRF; (C) HD patients with no RRF

**Conclusions:** We showed that it is possible to assess corticomedullary gradient in HD patients. Additional study is justified to explore the ability to the <sup>23</sup>NaMRI to discriminate patients who might benefit best from an incremental dialysis approach.

## SA-PO310

## Establishing a Standardized Central Venous Catheter Rate

Thomas P. Deluca,<sup>1</sup> Caitlin Monaghan,<sup>1</sup> Kathleen Belmonte,<sup>1</sup> John W. Larkin,<sup>1</sup> Len A. Usvyat,<sup>1</sup> Jeffrey L. Hymes,<sup>1</sup> Franklin W. Maddux.<sup>2</sup> <sup>1</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>2</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany.

**Background:** High central venous catheter (CVC) rates negatively affect dialysis patients around the world, with ailments such as CR-BSIs and thrombosis (Sohail, EKIR 2021). The process for getting a patient ready for AV access can be complex, thus catheter rates at clinics may be higher than expected. This model will be used as a tool to identify clinics that are performing worse than expected with CVC rates and aid to improve them.

**Methods:** The analysis was conducted on a sample of 143,411 active hemodialysis dialysis patients as of March 1<sup>st</sup>, 2022, with end stage kidney disease. Patients must have had a CVC for greater than 90 days to be included in the study. A stepwise logistic regression model was trained on the data, with outcome as CVC or not. The model used BMI, age, location (Rural or Urban), sex, vintage, comorbidities, and nursing home residence.

**Results:** Using a nationwide catheter prevalence threshold of 19% for classifying predictions as having a CVC or not, the model performance on a test dataset showed balanced accuracy=61% and area under the curve=0.68. Predicted probabilities for clinics of size greater than 25 patients, had similar predictions to the actual rates (Figure 1). The top 3 most important predictors are vintage, age, and BMI.

**Conclusions:** The standardized CVC rate model gives clinics a tool to identify patients that look like they may be a good candidate for AV access but currently have a CVC. This tool will allow direct intervention into the practices of clinics to reduce their catheter rates. The model is in early development and a pilot will be initiated to continue validation of the model.

**Funding:** Commercial Support - Fresenius Medical Care

**Figure 1:** Prediction of clinic's catheter rates on the x axis vs their true catheter rates on the y axis. The oval highlights the clinics that are targeted for intervention.

## Hyperkalemia Disease Burden and Dialysis Patterns in Chinese Hemodialysis Patients: An Interim Analysis of the Precede-K Study

Zhaohui Ni,<sup>1</sup> Haijiao Jin,<sup>1</sup> Renhua Lu,<sup>1</sup> Lihong Zhang,<sup>2</sup> Li Yao,<sup>3</sup> Guojian Shao,<sup>4</sup> Li Zuo,<sup>5</sup> Shuguang Qin,<sup>6</sup> Xinzhou Zhang,<sup>7</sup> Qinghong Zhang,<sup>8</sup> Weimin Yu,<sup>9</sup> Qun Luo,<sup>10</sup> Yuqing Ren,<sup>11</sup> Hui Peng,<sup>12</sup> Jie Xiao,<sup>13</sup> Qiongqiong Yang,<sup>14</sup> Qinkai Chen,<sup>15</sup> Yifan Shi.<sup>16</sup> PRECEDE-K study team <sup>1</sup>Department of Nephrology, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; <sup>2</sup>Department of Nephrology, The First Hospital of Hebei Medical University, Shijiazhuang, China; <sup>3</sup>Department of Nephrology, The first hospital of China Medical University, Shenyang, China; <sup>4</sup>Department of Nephrology, Wenzhou Central Hospital, Wenzhou, China; <sup>5</sup>Department of Nephrology, Peking University People's Hospital, Beijing, China; <sup>6</sup>Department of Nephrology, Guangzhou First People's Hospital, Guangzhou, China; <sup>7</sup>Department of Nephrology, Shenzhen People's Hospital, Shenzhen, China; <sup>8</sup>Department of Nephrology, Taihe Hospital, Shiyan, China; <sup>9</sup>Department of Nephrology, Shanxi Bethune Hospital, Taiyuan, China; <sup>10</sup>Department of Nephrology, Hua Mei Hospital, University of Chinese Academy of Sciences, Ningbo, China; <sup>11</sup>Department of Nephrology, Yangquan Coal Industry (Group) General Hospital, Yangquan, China; <sup>12</sup>Department of Nephrology, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; <sup>13</sup>Department of Nephrology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; <sup>14</sup>Department of Nephrology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China; <sup>15</sup>Department of Nephrology, First Affiliated Hospital of Nanchang University, Nanchang, China; <sup>16</sup>Medical Affairs, AstraZeneca Investment China Co, Shanghai, China.

**Background:** Hyperkalemia (HK); common in hemodialysis (HD) patients, is a life-threatening electrolyte imbalance disorder. Studies have shown that long-term control of serum potassium (sK<sup>+</sup>) in HD patients cannot be achieved. However, data on the disease burden and dialysis pattern of HK in Chinese patients on HD is scarce.

**Methods:** In this prospective, multicenter, observational cohort study (NCT04799067), dialysis prescription, sK<sup>+</sup> and other biochemistry measurements data of HD patients was collected. Data was collected on occurrence of HK, sK<sup>+</sup> fluctuation, and dialysis patterns to analyze the disease burden of HK and dialysis patterns in Chinese HD population.

**Results:** In total, 600 patients (67.2% male, 54 years mean age) were enrolled, and 60% of HD patients had heavy disease burden and medical history of HK (sK<sup>+</sup>>5.0 mmol/L) in last 6 months. At baseline visit, the prevalence of HK was 40%, proportions of sK<sup>+</sup>>5.5 mmol/L, >6.0 mmol/L and >6.5 mmol/L [17%, 6%, and 3%, respectively]. Dialysis potassium concentration mostly used was 2.0mmol/L (97.7%). Mean HD duration was 4 hours with thrice a week dialysis frequency in 86% of patients. The dialysis adequacy was standard, with average urea reduction ratio of 68% and Kt/V of 1.45. The sK<sup>+</sup> fluctuation between pre- and post-dialysis was 1.4 mmol/L, with fluctuation proportions of [0 - < 1], [1 - < 2], [2 - < 3], [≥3] were 24%, 62%, 13% and 1%, respectively. Potassium gradient between serum and dialysate was 2.8 mmol/L, with gradient proportion of [1 - < 2], [2 - < 3], [3 - < 4], [≥4] were 14%, 45%, 36% and 5%, respectively.

**Conclusions:** Prevalence of HK in Chinese HD patients was high. Rebound of sK<sup>+</sup> during the inter-dialytic period cannot be controlled under standard dialysis mode. The previous research confirmed that the potassium fluctuation > 1 mmol/l and the potassium gradient ≥ 3 mmol/L is associated with the acute clinical events. Hence, effective potassium-lowering treatments on non-dialysis days to control potassium level and fluctuation requires exploration and further validation.

Disease burden of HK

## SA-PO312

### A Comparison of Mortality Between Unplanned and Planned Hemodialysis Initiation in Incident ESKD Patients: A Long-Term Observational Study

Keisuke Okamoto, Masahiro Eriguchi, Ken-ichi Samejima, Kazuhiko Tsuruya, Nara Kenritsu Ika Daigaku, Kashiwara, Japan.

**Background:** Planned hemodialysis (HD) initiation with a matured vascular access is recommended in terms of patients' survival compared to unplanned HD initiation with a temporary vascular catheter in several guidelines across the world. This is based on several short-term observational studies, whereas long-term outcomes have been rarely evaluated.

**Methods:** We consecutively assessed newly declared ESKD patients who started HD between 1/1/2007 and 12/31/2014 at Nara Medical University Hospital. We excluded patients who had dialysis-dependent acute kidney injury (AKI) leading to ESKD, recovered from AKI, underwent continuous kidney replacement therapy as the only dialysis modality, or had HD for extra-renal indication. We stratified patients into 2 groups (unplanned vs planned HD initiation) and compared survival using the Kaplan-Meier method with or without a propensity score matching. The primary outcome was all-cause mortality during the observational period until 12/31/2020.

**Results:** Of the 460 newly declared ESKD patients who were assessed for eligibility, 345 patients (172 unplanned and 173 planned HD initiation) were included in this study. The median follow-up duration of the entire cohort was 4.59 years (range, 1.45-7.84 years). Figure 1 showed Kaplan-Meier survival curves which presented no statistically significant difference in crude survival between unplanned and planned HD initiation (Figure 1A, Log-rank  $P = 0.235$ ), however, revealed a statistically significant difference in survival in the propensity score-matched cohort (Figure 1B, Log-rank  $P = 0.046$ ). The hazard ratio for mortality in the unplanned HD initiation group was 1.515 [95% confidence interval 1.005-2.282] in the propensity score-matched cohort.

**Conclusions:** In this cohort of newly declared ESKD patients who started HD, those who were in the planned HD initiation group had better long-term survival in the propensity score-matched cohort. This finding supports the usefulness of creating permanent vascular access before starting HD for not only short-term but also long-term survival.

## SA-PO313

### How Does the United States Compare With Europe in ESRD?

Ivan Cancarevic,<sup>1,2</sup> Mahmoud Nassar,<sup>1,2</sup> Ismail Omran,<sup>1,2</sup> Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>New York City Health and Hospitals Corporation, New York, NY.

**Background:** End-stage renal disease (ESRD) requiring renal replacement therapy (RRT) due to renal disease or secondary to another disorder, predisposes to numerous complications. In the United States (US), ESRD patients are on Medicare. Europe has public systems. We aimed to find out if either does better at managing ESRD.

**Methods:** Data for 2015 and 2019 was extracted from the United States Renal Data System (USRDS) and the European Renal Association (ERA) registry. We analyzed ESRD incidence, management and survival.

**Results:** ESRD incidence in the US rose from 402 to 412, while in Europe from 119 to 132. In Europe, 26-27% of patients are over 75, while in the US >40%. Diabetes was the most common cause in both populations. 75 in a million Americans got transplants, while 35 Europeans did (from 3 in the East to 73 in Spain). The 5-year survival on dialysis was higher in Europe (47% vs 42%). Among 40-50 years olds, Europeans lived 2 years longer on dialysis. Survival after transplant was 24-30 years in the US, 22-27 in Europe.

**Conclusions:** Older Americans are more likely to be started on dialysis. Survival differences may be explained by better management and adherence among Europeans on dialysis, while the inclusion of developing countries affects survival post-transplant. Analysis of prescribing patterns would be helpful.

## SA-PO314

## Survival After Transplant Allograft Failure (TAF) and Return to Dialysis in Latin America

Adrian M. Guinsburg, Maria Ines Diaz Bessone, Juan Carlos Berbessi, Benjamin E. Hippen. *Fresenius Medical Care Global Medical Office, Waltham, MA.*

**Background:** Dialysis initiation with a permanent access and in-target clinical parameters for patients (pts) returning to dialysis after TAF are less frequently achieved than in incident dialysis population, even though transplanted pts usually enjoy specialist care. We aimed to compare rates of hospitalization (hosp) and survival between pts incident to dialysis after TAF or native kidney failure (NKF) in Fresenius Medical Care clinics in Latin America

**Methods:** We selected all incident dialysis pts between Jan 2017 and Dec 2021. Pts were classified as TAF or NKF according to ESRD cause reported. Baseline parameters were collected within first 30 days after dialysis initiation and Hosp were observed during 6 months. Pts were tracked until death, lost-to-follow-up, or end of study. Three models were fitted: Model 1 (KM): univariate, Model 2 (Cox): case-mix adjusted (age, gender, diabetes) and Model 3 (Cox): fully adjusted (model 2 + vascular access + baseline labs)

**Results:** 34,630 incident pts to dialysis were selected: 630 (1.8%) TAF and 34,000 (98.2%) NKF. Hosp (6 months) showed no significant difference in model 1. However, TAF showed Hosp HR 1.35,  $p < 0.005$  and HR 1.45,  $p < 0.005$  in model 2 and 3 respectively. Mortality risk was lower for TAF in model 1 (fig 1A, left), invert to TAF HR 1.23,  $p < 0.03$  in model 2, and no difference was found in model 3 (fig 1B, right)

**Conclusions:** In the first 6 months after dialysis initiation, risk of hosp for pts with ESRD after TAF was not significantly different from ESRD after NKF in univariate analysis, but after full multivariate adjustment, HR for hosp for TAF increased to 1.45. TAF pts showed higher survival in univariate analysis, with no significant mortality differences after full multivariate adjustment. Observed survival differences may be ameliorated by attention to CVC prevalence, Ca, P, Hb, and albumin for pts with ESRD after TAF

Fig1A: Mortality risk for patients with ESRD after TAF and NKF, univariate analysis. Fig2A: Hazard ratio for death in patients with ESRD after TAF, full multivariate adjustment

## SA-PO315

## Clinical Conditions After Transplant Allograft Failure (TAF) and Return to Dialysis in Latin America: Can We Do Better?

Adrian M. Guinsburg, Maria Ines Diaz Bessone, Juan Carlos Berbessi, Benjamin E. Hippen. *Fresenius Medical Care Global Medical Office, Waltham, MA.*

**Background:** Dialysis (dial) initiation with permanent access and in-target clinical parameters for patients (pts) returning to dial after TAF are less frequently achieved than in incident dial population, even though transplanted pts usually enjoy specialist care. We aimed to compare baseline characteristics between TAF and native kidney failure pts (NKF) incident to dial in Fresenius Medical Care Latin America clinics

**Methods:** We selected all incident pts between Jan 2017 and Dec 2021. Pts were classified as TAF or NKF according to ESRD cause reported. Baseline parameters were collected within 30 days of dial initiation. Values expressed as mean $\pm$ SD. Means compared using Student t-test for normal or Mann-Whitney for non-normal distributed variables

**Results:** We selected 56,247 new pts from which 34,630 were incident to dial: NKF 34,000 (98.2%), TAF 630 (1.8%). TAF were younger (46.2 $\pm$ 16 vs 59.2 $\pm$ 16 yrs;  $p < 0.0001$ ), had lower diabetes prevalence (10.3% vs 36.8%;  $p < 0.0001$ ), were more likely to start PD and had lower CVC prevalence. TAF had higher creatinine (Cr) (7.1 $\pm$ 3.0 vs 6.7 $\pm$ 3.1 mg/dl;  $p < 0.02$ ) at start, lower hb (8.9 $\pm$ 1.9 vs 9.4 $\pm$ 1.8 g/dl), higher ferritin (787 $\pm$ 603 vs 461 $\pm$ 466 ng/ml;  $p < 0.0001$ ), TSAT (26.9 $\pm$ 15.6 vs. 24 $\pm$ 12.9%), CRP (22.2 $\pm$ 22.7 vs 18.8 $\pm$ 22.2 mg/l;  $p < 0.01$ ) and iPTH (533 $\pm$ 552 vs 306 $\pm$ 337 pg/ml), and were less likely to use ESA or iron therapy. AVF/AVG prevalence was higher in TAF but 30.7% started dial with a CVC (Table 1)

**Conclusions:** In our cohort, pts with TAF were younger and had lower prevalence of diabetes. At initiation, Cr was higher and Hb was lower in TAF group, indicative of delay in dial initiation and suboptimal pre-ESRD anemia management. Despite lower observed CVC prevalence in TAF, nearly one-third of pts with TAF started dial with a CVC

## Patient Survival Analysis on Hemodialysis: A Mexican Cohort

Edgar Solis, Sergio Hernández-Estrada, Víctor M. Hernandez Mora, Juan C. Rodriguez, Juan M. Ardavin Ituarte. *Medica Santa Carmen, San Miguel de Allende, Mexico.*

**Background:** 5-year cumulative survival on HD patients is variable: 41% USRDS, 45% ERA-EDTA, 65% ANZDATA. Survival of patients on HD modality in Mexico is scarce: median survival 700 d.

**Methods:** We did a retrospective cohort analysis from Nov 2015-Nov 2021 on HD pts from a network of 6 facilities across Mexico. Death was registered as the interest event, time to event was expressed in days and used to estimate survival. Clinical and laboratory data were considered in a comparative analysis between groups and as explanatory variables. Survival analysis with K-M method and Cox hazards were used.

**Results:** Total 1165 pts included, 246 (21%) died, 919 (79%) censored. 401 (44%) were lost (facility or modality change or KTR) and 518 (56%) continue alive. 5 year cumulative survival was 73%, median survival 3463 d. Multivariate analysis showed significantly increased risk of death for KtV <1.2 (HR 1.73, IC1.16-2.58), Na <135 (1.63, 1.09-2.43), Creat <10 (1.83, 1.14-2.94), Non-tunneled VA (3.32, (1.85-5.96) and age (1.02, 1.01-1.03).

**Conclusions:** We report higher survival rates compared with other series, which might be partly explained by selection and survival biases; also a high proportion of patients lost to follow up. National kidney disease register is needed.

**Funding:** Private Foundation Support

### Ornithine Transcarbamylase Deficiency in the Time of Pregnancy: The Role of Hemodialysis in Promoting Protein Nutrition

Michelle Tran, Anubhav Kumar. *UVA Health, Charlottesville, VA.*

**Introduction:** Ornithine transcarbamylase deficiency (OTC-d) is a rare X-linked urea cycle disorder leading to hyperammonemia. It is exacerbated by periods of catabolic stress, including pregnancy, with treatments including protein restriction. We describe a case of a patient with OTC-d who developed hyperammonemia in her third trimester of pregnancy, complicated by protein malnutrition, for which dialysis was initiated to improve nutritional status.

**Case Description:** A 30-year-old female with OTC-d diagnosed at 27 weeks gestation presented with acute encephalopathy and ammonia level of 205 umol/L. Mentation and ammonia levels initially improved with sodium phenylacetate-sodium benzoate, arginine supplementation, and nutritional protein restriction until stable for discharge. She re-presented five days later with serum ammonia of 338 umol/L, nausea, vomiting, and worsening encephalopathy requiring intubation. While mental status improved with the therapies above, her ammonia level remained persistently elevated above the goal of <75 umol/L despite holding feeds, suggestive of protein malnutrition and muscle catabolism. Nephrology was consulted. Intermittent hemodialysis at typical flow rates was initiated for ten sessions, eight sequential, allowing the patient's dietary protein intake to be liberalized as ammonia levels and symptoms improved. No ultrafiltration was prescribed. She underwent planned Caesarian section complicated by emergency hysterectomy about one month after her final hemodialysis session. She did not require dialysis post-operatively. During her hospitalization, a multidisciplinary team consisting of Nephrology, Medical Genetics, Nutrition, High Risk Obstetrics, and Critical Care were involved in her management.

**Discussion:** Patients with OTC-d must be maintained in delicate metabolic homeostasis. We describe the complex management of a patient with OTC-d in the inherently catabolic state of late pregnancy. In this patient refractory to initial drug therapy and demonstrating muscle catabolism, hemodialysis improved her ammonia levels thus allowing for improved protein intake. This case further highlighted the degree of multidisciplinary collaboration required to achieve therapeutic goals when caring for these medically complex patients.

## SA-PO318

### The Prevalence of Thrombocytopenia in Chronic Hemodialysis Patients Using Low-Molecular-Weight Heparin (Enoxaparin Sodium) vs. Standard Unfractionated Heparin for Hemodialysis Anticoagulation

James A. Sobremisana, Rafael Montepio. *Armed Forces of the Philippines Medical Center, Diliman, Quezon City, Philippines.*

**Background:** Anticoagulation is essential for the prevention of blood clots in the extracorporeal circuit during hemodialysis. For decades, unfractionated heparin has been used for this purpose, however there were noted several disadvantages, hence the search for other anticoagulants with better effects have been studied. One of the effects of anticoagulation during hemodialysis is thrombocytopenia. This study aims to determine the prevalence of thrombocytopenia in chronic kidney disease patients on hemodialysis using unfractionated heparin and using low molecular weight heparin.

**Methods:** This study used a cross-sectional study design of hemodialysis patients comparing the prevalence of thrombocytopenia from the Enoxaparin arm with the unfractionated Heparin arm of the study. Low molecular weight heparin was given at 0.2cc as bolus 30 minutes to 1 hour prior to hemodialysis. Unfractionated heparin was administered at 50 IU/kg bolus then at 1000 IU per hour. Thrombocytopenia was defined as decrease of 50% from baseline platelet count prior to usage or <150 x 10<sup>9</sup>/L.

**Results:** The total number of patients recruited that was currently on hemodialysis were 161 patients. A total of 127 patients were included in the study due to exclusion criteria. The Heparin arm (n1=119 patients), and Enoxaparin arm (n2= 42 patients) were included and compared. Overall mean age of the included patients is 48.2 ± 15.2 years. Majority were males and the most common reason for dialysis was Chronic Glomerulonephritis. The age, marital status, cause and reason for HD were homogenous. Among the 127 patients, 22 patients had thrombocytopenia, 16 patients (17.2 %; 95% CI: 10.6 to 25.8) were under the heparin group, while 6 patients (17.6 %; 95% CI: 7.7 to 32.8) were under the enoxaparin group.

**Conclusions:** It is observed in this study that there is a high prevalence of thrombocytopenia in these study population (17.2-17.6%), compared to the known incidence of hemodialysis-related thrombocytopenia (0.2-12%). Although data is not sufficient to conclude that thrombocytopenia among these patients can be solely attributed to heparin use. Thrombocytopenia occurrence in patients who use unfractionated heparin and low-molecular weight heparin was not statistically significant between the two groups.

## SA-PO319

**Hemodialysis-Associated Increase in Plasma Glial Fibrillary Acidic Protein, an Acute Brain Injury Biomarker**

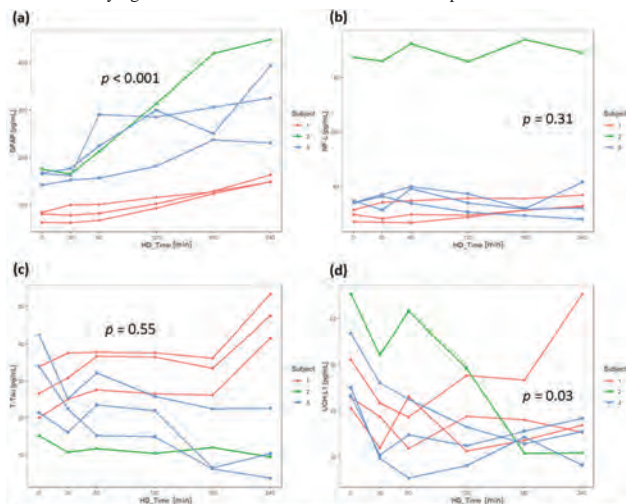

Lin-Chun Wang,<sup>1</sup> Ohnmar Thwin,<sup>1</sup> Amrish U. Patel,<sup>1</sup> Hanjie Zhang,<sup>1</sup> Ludovic Debure,<sup>2</sup> Xin Wang,<sup>1</sup> Nadja Grobe,<sup>1</sup> Xia Tao,<sup>1</sup> Stephan Thijssen,<sup>1</sup> Thomas Wisniewski,<sup>2</sup> Peter Kotanko.<sup>1,3</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>NYU Langone Health, New York, NY; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Structural and functional brain pathologies (e.g., cerebral hypoperfusion, silent cerebral infarcts, leukoariosis, osmotic stress, edema) are common in hemodialysis (HD) patients, but their etiologies are poorly understood. The acute effect of HD on blood biomarkers of brain injury has not yet been studied. We measured biomarkers for astroglial injury (GFAP, glial fibrillary acidic protein), axonal injury (NF-L, neurofilament-light), post-injury neurodegeneration (T-Tau, total Tau protein), and neuronal cell body injury (UCH-L1, ubiquitin C-terminal hydrolase-L1).

**Methods:** Three chronic HD patients (age 36±9 years; dialysis vintage 7±4 years) were enrolled in this one-week pilot study and dialyzed for 4 hours each on Monday, Wednesday, and Friday. Plasma samples were collected 6 times throughout each HD session. One study subject did not proceed after Monday HD and was withdrawn. A total of seven HD treatments were completed. GFAP, NF-L, T-Tau, and UCH-L1 were quantified by Neuro 4-Plex SIMOA assays (Quanterix, MA, USA). For biomarkers larger than 50kDa (GFAP, NF-L, and T-Tau), levels were corrected for hemoconcentration using total plasma protein levels.

**Results:** GFAP increased 2.1-fold by the end of HD (Fig 1a,  $p < 0.001$ ). NF-L (Fig 1b) and T-Tau (Fig 1c) results showed no conclusive change throughout HD. UCH-L1 decreased 0.8-fold by the end of HD (Fig 1d,  $p = 0.03$ ).

**Conclusions:** We report, for the first time, an increase of GFAP, a biomarker that is associated with astroglial injury, during routine HD. The results of our pilot study provide motivation to further explore the dynamics of brain injury biomarkers in HD patients to elucidate underlying mechanisms and aid research into neuro-protective interventions.

**Figure 1.** Intradialytic plasma levels of brain injury biomarkers from three study subjects (seven hemodialysis treatments in total): (a) GFAP, glial fibrillary acidic protein; (b) NF-L, neurofilament-light; (c) T-Tau, total Tau protein; and (d) UCH-L1, ubiquitin C-terminal hydrolase-L1. Data were corrected by total protein levels for biomarkers larger than 50kDa (GFAP, NF-L, and T-Tau) to account for hemoconcentration. Analysis was done by linear mixed-effects model, considering random effects over time throughout the hemodialysis treatments.

## SA-PO320

**Temporal Relationship Between Prior Estimated Glomerular Filtration Rate Testing and Dialysis Initiation in a Real-World Population of Incident Dialysis Patients**

Steph Karpinski, Adam G. Walker, Carey Colson, Scott Sibbel, Francesca Tentori, Steven M. Brunelli. *Davita Clinical Research, Minneapolis, MN.*

**Background:** Properly preparing for dialysis initiation can lead to better short and long-term outcomes for new dialysis patients. These preparation activities usually require ≥6 months lead time and knowledge of the severity of a patient's kidney disease. We sought to describe the patterns of dialysis starts with respect to timing and severity of prior estimated glomerular filtration rate (eGFR) testing.

**Methods:** For this analysis, we used the Optum® de-identified Integrated Dataset that links administrative claims and clinical data from providers across the continuum of care. We examined 5,900 adults who initiated dialysis across multiple outpatient provider networks between 2012 and 2019. Patients without continual insurance coverage for at least 61 days prior to dialysis start were excluded. All eGFR test results were obtained in outpatient settings prior to the start of dialysis.

**Results:** External data results show that 34.8% of patients who start dialysis did not have an ambulatory eGFR measured 6 months or more prior to initiation of dialysis. This includes 23.9% of subjects with no documented eGFR before starting outpatient dialysis

and an additional 10.9% with less than 6 months between 1<sup>st</sup> eGFR and dialysis start. Only 55.9% of patients have had a documented eGFR less than 60 mL/min/1.73m<sup>2</sup>, 6 months or more prior to arrival at a dialysis clinic.

**Conclusions:** Increased surveillance of eGFR prior to dialysis start will lead to better outcomes for patients.

## SA-PO321

**The Mechanisms That Shape the Care Trajectory Leading to an Emergency Dialysis Start: Crossing Patients', General Practitioners', and Nephrologists' Perspectives**

Maxime Raffray,<sup>1</sup> Sahar Bayat,<sup>1</sup> Cecile M. Vigneau.<sup>2</sup> <sup>1</sup>Univ Rennes, EHESP, CNRS, Inserm, Arènes - UMR 6051, RSMS (Recherche sur les Services et Management en Santé) - U 1309, Rennes, France; <sup>2</sup>Univ Rennes, CHU Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR\_S 1085, Rennes, France.

**Background:** Emergency dialysis start (EDS) is an important issue to understand and tackle in CKD care. Late referral, absent previous nephrology care and higher comorbidity scores have been associated with EDS. However, how those quantitative risk factors happen and contribute to EDS remains unexplored. We conducted a qualitative study in France to identify and describe the mechanisms that shape the trajectories that lead to EDS, using patients, GPs and nephrologists perspectives.

**Methods:** Three groups of participants were recruited in Brittany, north-west France: Patients who started dialysis in emergency between 2017 and 2019, GPs and nephrologists. Maximum variation sampling approach was used based on patients' socio-economic profiles and GPs' and nephrologists' years and settings of practice. Semi-structured interviews were conducted between 2017 and 2020. A crossed thematic analysis between the 3 groups of transcripts was performed, informing how EDS trajectories come to be.

**Results:** Twenty patients, 12 GPs and 18 nephrologists were interviewed. Five main themes were identified: 1) Learning about dialysis, 2) Dialysis and nephrology care representations: a) an unacceptable biographical disruption, b) a dreadful invasive machinery, c) a straw that breaks the camel's back, 3) The gap between the "illness" perceived and the "disease" treated, 4) Slipping through the primary care prevention net, 5) the unavoidable unpredictability of CKD course.

**Conclusions:** This study shows how quantitative risk factors of EDS such as low or absent previous nephrology care are, in part, the results of an interplay between patients' constructed representations of dialysis, relation with the medical sphere and CKD physiopathology. The results suggests a need for evaluation of kidney replacement therapy education programs and reinforcement of psychological care. Finally, results also support ambitious mass prevention campaign focused on kidney health to counter the persistent negative representation of dialysis and seal off prevention cracks younger patients slip through.

**Rethinking Potentially Preventable Emergency Department Use Among People Receiving Dialysis: A Population-Based Study**

Meghan J. Elliott,<sup>1</sup> Jennifer M. MacRae,<sup>1</sup> Eddy Lang,<sup>1</sup> Andrew Mcrae,<sup>1</sup> Maoliosa Donald,<sup>1</sup> Brenda Hemmelgarn,<sup>2</sup> Paul E. Ronksley.<sup>1</sup> <sup>1</sup>University of Calgary, Calgary, AB, Canada; <sup>2</sup>University of Alberta, Edmonton, AB, Canada.

**Background:** People with kidney failure receiving maintenance dialysis visit the emergency department (ED) 3 times per year on average, which is 3- to 8-fold higher than the general population. Little is known about the clinical and socio-demographic factors that contribute to potentially preventable ED use.

**Methods:** In this retrospective cohort study, we used administrative data to identify adults receiving maintenance dialysis for >3 months between April 1, 2010 and March 31, 2019 in Alberta, Canada. We captured clinical characteristics and rates of ED use and followed patients until death or end of study (March 31, 2019). We determined age- and sex-adjusted rates of all-cause and potentially preventable ED use (defined by kidney disease-specific ambulatory care sensitive conditions: hyperkalemia, heart failure, volume overload, and malignant hypertension). We examined the association between clinical and socio-demographic factors and rates of potentially preventable ED encounters using multivariable negative binomial regression models.

**Results:** Our cohort included 4,402 people with kidney failure (2,781 hemodialysis; 1,621 peritoneal dialysis) followed for a mean of 2.8 years. 3,440 patients had 29,927 all-cause ED encounters (adjusted rate 3,065/1,000 person years). Of these, 654 patients had 1,153 potentially preventable ED encounters (adjusted rate 107/1,000 person years). Potentially preventable ED encounters were more likely in those who were socioeconomically disadvantaged, had higher comorbidity burden, and had longer dialysis vintage. Multivariable regression identified that preventable ED use was significantly higher for younger adults (age <45 years; IRR: 1.37 [95% CI 1.08-1.75]) and those with chronic pain (IRR: 1.33 [95% CI 1.06-1.66]), greatest material deprivation (IRR: 1.39 [95% CI 1.02-1.90]), and a history of hyperkalemia (IRR: 1.34 [95% CI 1.11-1.63]).

**Conclusions:** We identified that potentially preventable ED use among people receiving dialysis is related to both socio-demographic and clinical factors. Our findings underscore the need to implement and test strategies that address social determinants of health to avert potentially preventable ED use in this population.

SA-PO323

**Primary Causes of ESRD in the US Cystic Fibrosis Population**  
Mirjana Stevanovic,<sup>1</sup> Martha L. Graber.<sup>2</sup> <sup>1</sup>Dartmouth Guarini School of Graduate and Advanced Studies, Hanover, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Background:** We have previously shown that individuals with with cystic fibrosis (CF) have a greater than ten fold risk of end stage renal disease (ESRD) relative to the general population. Persons with CF have higher rates of AKI and CKD, higher rates of lung and other organ transplantation, and an approximately 40% risk of developing diabetes. However, the roles of diabetes and other possible etiological risk factors for ESRD in CF are not defined

**Methods:** We analyzed data from the US Renal Data System (USRDS) 2014-2018 inclusive

**Results:** Non-type I diabetes was the leading cause of ESRD in the age-adjusted CF population, but was significantly less frequent compared to the general ESRD population. There was no difference in the age-adjusted frequency of type I diabetes as a cause of ESRD. The second and third most frequent causes of ESRD in CF were complications of lung transplant, and nephropathy due to drugs and other agents respectively. Hypertension was significantly less frequent in the CF population. There was no difference in the rates of glomerulonephritis and cystic diseases.

**Conclusions:** Individuals with CF have a greater than ten-fold risk of developing ESRD compared to the general US population. Non-type I diabetes mellitus is the leading casue of ESRD in CF, however diabetes is approximately 50% less frequent an etiology than in the general ESRD population. Complications of lung transplantation and medication toxicities are additional important etiologies in CF, rarely identified in the non-CF population. Glomerulonephritis was no more common as an etiology amongst CF individuals than those without CF, and hypertension was significantly less frequently identified as the casue of ESRD. Our future studies aim to identify more specificity within these categories and to evaluate the impact of CFTR activating agents. Demographic characteristics of CF persons with ESRD are described in a separate abstract submission to this meeting

**Funding:** NIDDK Support

Table 1. Primary Causes of End Stage Renal Disease in the US Cystic Fibrosis Population

Primary-disease causing ESRD	CF (N=379)	Non-CF (N=953,824)	Univariable		Age-adjusted	
			OR <sup>1</sup>	95% CI	OR <sup>2</sup>	p-value

**Calcimimetics Adherence and Preference in the Management of Uremic Secondary Hyperparathyroidism (SHPT) in Europe**

Chidozie U. Nduka,<sup>1</sup> Karly S. Louie,<sup>1</sup> Jo Taylor,<sup>2</sup> Matt Hall,<sup>3</sup> Filippo Aucella,<sup>4</sup> Pablo A. Urena Torres,<sup>5,6</sup> Laura Labriola,<sup>7</sup> Pieter Evenepoel,<sup>8</sup> Junjie Ma,<sup>12</sup> Najma Saleem,<sup>12</sup> Ronald L. Pisoni,<sup>9</sup> Bruno L. Fouqueray,<sup>10</sup> Robert Horne.<sup>11</sup> <sup>1</sup>Amgen, Uxbridge, United Kingdom; <sup>2</sup>Dorset County Hospital NHS Foundation Trust, Dorchester, United Kingdom; <sup>3</sup>Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; <sup>4</sup>Fondazione IRCCS “Casa Sollievo della Sofferenza”, San Giovanni Rotondo, Italy; <sup>5</sup>AURA Paris-Nord, Saint-Ouen, France; <sup>6</sup>Necker Hospital, University of Paris Descartes, Paris, France; <sup>7</sup>Department of Nephrology, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium; <sup>8</sup>Department of Immunology and Microbiology, Division of Nephrology, University Hospitals Leuven, Leuven, Belgium; <sup>9</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>10</sup>Amgen GmbH, Rotkreuz, Switzerland; <sup>11</sup>University College London School of Pharmacy, London, United Kingdom; <sup>12</sup>Amgen, Thousand Oaks, CA.

**Background:** Oral cinacalcet (CIN) and intravenous etelcalcetide (ETEL) are approved for treating hemodialysis (HD) patients with SHPT. Data on patient-reported outcomes and calcimimetic preference from nephrologists/nurses’ perspectives are provided in this cross-sectional study.

**Methods:** Patient questionnaires assessed CIN adherence (Medication Adherence Report Scale [MARS]), calcimimetic perceptions [Beliefs about Medicines Questionnaire (BMQ) and Treatment Intrusiveness Scale (TIS)] and gastrointestinal (GI) symptom experience in the month before enrolment. Nephrologists/nurse questionnaires assessed calcimimetic preference (CIN vs ETEL) based on effectiveness, side effects, patient burden and quality of life (QoL).

**Results:** 414 patients (204 CIN & 210 ETEL) responded to the surveys. Patient characteristics were similar between CIN vs ETEL: mean age 65 vs 64yrs; men 57% vs 61%; mean no. of medications 9 vs 8. CIN adherence was high (mean MARS 4.8), and 78% of patients reported using all CIN prescribed in the month before enrolment. There were no significant differences in perceptions of Calcimimetic Necessity (mean BMQ-Necessity CIN vs ETEL = 3.5±0.7 vs 3.6±0.5, p=0.49), Calcimimetic Concerns (mean BMQ-Concerns CIN vs ETEL = 2.3±0.6 vs 2.3±0.9, p=0.17), or treatment intrusiveness (mean TIS CIN vs ETEL= 1.6±0.7 vs 1.8±0.9). ETEL and CIN patients attributed GI symptoms to calcimimetic use at similar rates: nausea (ETEL 23%; CIN 21%); vomiting (ETEL 26%; CIN 24%) and Diarrhea (ETEL 21%; CIN 21%). Nephrologists (n=111) and nurses (n=113) preferred ETEL for patient adherence (Nephrologist 89%; Nurses 78%); reducing patient burden (Nephrologist 87%; Nurses 86%); minimizing side effects (Nephrologist 78%; Nurses 66%); improving QoL (Nephrologist 72%; Nurses 75%); and effectiveness (Nephrologist 60%; Nurses 74%).

**Conclusions:** Nephrologists/nurses preferred ETEL for encouraging patient adherence, reducing patient burden, minimizing side effects, improving QoL, and effectiveness. High levels of patient engagement were observed for ETEL and CIN.

**Funding:** Commercial Support - Amgen

SA-PO326

**Market Competition and Anemia Management in the United States Following Dialysis Payment Reform**

Anshul Bhatnagar, Wolfgang C. Winkelmayer, Kevin F. Erickson. Baylor College of Medicine, Houston, TX.

**Background:** Hemodialysis markets are highly concentrated. It is unknown whether market competition influences how dialysis providers respond to reimbursement reforms. We examined whether changes in anemia management following the 2011 expansion of Medicare’s Prospective Payment System (PPS) for end-stage kidney disease varied with market competition.

**Methods:** From the US dialysis registry, we identified patients undergoing in-center hemodialysis in 2009 and 2012, representing periods before and after reimbursement reform. We used a difference-in-differences (DID) study design to estimate the independent associations among market competition and changes in erythropoiesis stimulating agents (ESAs) and intravenous iron dosage, the probability of having a hemoglobin <9 g/dl, and hospitalizations. We also examined serum ferritin concentrations, an indicator of the body’s iron stores, in 2012 to understand patient management practices. Market competition was represented as a dichotomous variable, with less competitive areas defined as with those with ≤2 competing dialysis providers.

SA-PO324

**Characteristics of US Individuals With Cystic Fibrosis and ESRD**  
Mirjana Stevanovic,<sup>1</sup> Martha L. Graber.<sup>2</sup> <sup>1</sup>Dartmouth Guarini School of Graduate and Advanced Studies, Hanover, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Background:** Persons with cystic Fibrosis (CF) have increased rates of diabetes, lung transplantation, acute kidney injury (AKI), and chronic kidney disease (CKD). Data are lacking concerning the prevalence and outcomes of end stage renal disease (ESRD) in this population

**Methods:** We analyzed data from the US Renal Data System (USRDS) for the years 2014-2018 inclusive

**Results:** Baesd on population prevalence individuals with CF have a 10-20 fold rate of ESRD compared with the general population (USRDS 2016 data). Prevalent individuals with CF and ESRD were significantly younger (41.8 vs 59.5 years), had lower BMI, were more likely to be White and female, to initiate renal replacement therapy with peritoneal dialysis or transplantation, and to receive a living donor kidney. There was no significantly increased risk of death in a five year period.

**Conclusions:** The characterisites of US individuals with CF and ESRD have not been previously described. Relative to the general US population persons with CF have a markedly increased (10-20-fold) risk of developing ESRD. We describe the demographic characteristics of these individuals, who are younger, more likely to be White and female and more likely to start renal replacement therapy with peritoneal dialysis or transplantation and to receive a living donor kidney than those without CF. These findings have important implications for awareness, management, and prevention of AKI and CKD in this vulnerable population. Details of etiologies of ESRD in CF are submitted in a separate abstract.

**Funding:** NIDDK Support

**Results:** Among 326,150 patients identified, 39% received dialysis in less competitive areas. Compared to areas with more competition, patients in less competitive areas had slightly more pronounced declines in ESA dose (60% versus 57%) following reimbursement reform (DID estimate: -3%; 95% Confidence Interval (CI) -5% to -1%) and less pronounced declines in intravenous iron dose (-14% versus -19%; DID estimate: 5%; 95% CI 1% to 9%). The estimated likelihoods of hemoglobin <9 g/dl, mortality, and hospitalization did not vary with market competition. Serum ferritin concentrations in 2012 were 4% (95% CI 3% to 6%) higher in less competitive areas.

**Conclusions:** Following expansion of the ESRD PPS, ESA use declined by slightly more and intravenous iron use declined by less in less competitive markets. These changes reflected a shift in anemia management towards more intensive use of intravenous iron relative to ESA and higher serum ferritin concentrations in areas with less market competition. While this suggests greater changes in cost management occurred in less competitive markets, there were no associated adverse effects on observed health outcomes.

**Funding:** NIDDK Support

## SA-PO327

### Patient Views Regarding Cannabis Use in CKD and Kidney Failure: A Survey Study

David T. Collister,<sup>1</sup> Reid Whitlock,<sup>2</sup> Karthik K. Tennankore,<sup>3</sup> Navdeep Tangri,<sup>2</sup> Remi Goupil,<sup>4</sup> Annie-Claire Nadeau-Fredette,<sup>4</sup> Sara N. Davison,<sup>1</sup> Ron Wald,<sup>5</sup> Michael Walsh.<sup>6</sup> <sup>1</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>2</sup>University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; <sup>3</sup>Dalhousie University Faculty of Medicine, Halifax, NS, Canada; <sup>4</sup>Universite de Montreal, Montreal, QC, Canada; <sup>5</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>6</sup>McMaster University, Hamilton, ON, Canada.

**Background:** Cannabis is frequently used recreationally and medicinally including for symptom management in patients with kidney disease.

**Methods:** We elicited the views of Canadian adults with kidney disease regarding their cannabis use. Participants were asked whether they would try cannabis for anxiety, depression, restless legs, itchiness, fatigue, chronic pain, decreased appetite, nausea/vomiting, sleep, cramps and other symptoms. The degree to which respondents considered cannabis for each symptom was assessed with a modified Likert scale ranging from 1-5 (anchored at 1 "definitely would not" and 5 being "definitely would"). Multilevel multivariable linear regression was used to identify respondent characteristics associated with considering cannabis for symptom control.

**Results:** Of 320 respondents, 290 (90.6%) were from in-person recruitment (27.3% response rate) and 30 (9.4%) responses were from online recruitment. 160/320 respondents (50.2%) had previously used cannabis including smoking (140, 87.5%), oils (69, 43.1%) and edibles (92, 57.5%). The most common reasons for previous cannabis use were recreation (84/160, 52.5%), pain alleviation (63/160, 39.4%) and sleep enhancement (56/160, 35.0%). Only 33.8% of previous cannabis users thought their physicians were aware of their cannabis use. >50% of respondents probably would or definitely would try cannabis for symptom control for all 10 symptoms. Characteristics independently associated with interest in trying cannabis for symptom control included symptom type (pain, sleep, restless legs), online respondent (B 0.7, 95% CI 0.1-1.4) and previous cannabis use (B 1.2, 95% CI 0.9, 1.5).

**Conclusions:** Many patients with kidney disease use cannabis and there is interest in trying cannabis for symptom control.

## SA-PO328

### Coordination of Pharmaceutical Care in Dialysis Patients Is Associated With Lower Hospital Admission Rates

Hao Han,<sup>1</sup> David Hart,<sup>2</sup> Sheetal Chaudhuri,<sup>1</sup> Terrell W. Fox,<sup>2</sup> Len A. Usvyat.<sup>1</sup> <sup>1</sup>Fresenius Medical Care North America, Waltham, MA; <sup>2</sup>FreseniusRx, Franklin, TN.

**Background:** It is estimated in the literature that >50% of ESRD patients do not take their phosphate binders as prescribed. The renal pharmacy FreseniusRx provides coordinated mineral and bone disorder (MBD) medication delivery and adherence support for enrolled patients. We investigated whether coordinated MBD pharmaceutical care is associated with improvements in hospital admission in dialysis patients.

**Methods:** We included all hemodialysis patients who received ≥2 BMM shipments from FreseniusRx pharmacy in Q1 and Q2 2018 and did not have any shipments from FreseniusRx in 2 years prior to 1/1/2018. We identified control patients not enrolled in the pharmacy by nearest neighbor 1:1 matching on the logit of the propensity score for demographics, comorbidities, state, insurance type, as well as, baseline lab values, vintage, treatment rates and hospitalization rates in baseline period, and hospital admission rate in 1 year prior to enrollment. We compared hospital admission rates in 6 and 12 months after the end of Q2 2018. Then the same analysis was repeated for Q1-Q2 2019.

**Results:** For the Q1-Q2 2018 analysis, we analyzed data on 16898 patients (8449 in Rx and 8449 matched patients not in Rx). Rx patients had lower hospital admission rates per patient year (non-Rx vs Rx at 6 and 12 months: 1.63 vs 1.53, 1.68 vs 1.63). For the Q1-Q2 2019 analysis, we analyzed data on 12184 patients (6092 in Rx and 6092 matched patients not in Rx). Rx patients had lower hospital admission rates per patient year (non-Rx vs Rx at 6 and 12 months: 1.64 vs 1.55, 1.59 vs 1.46).

**Conclusions:** Coordinated pharmaceutical care is associated with lower hospital admission in the hemodialysis patient population. Further analyses are needed to understand the outstanding characteristics of the pharmaceutical patient population and what elements of this coordinated care are associated with improvements.

**Funding:** Commercial Support - Fresenius Medical Care North America

## SA-PO329

### RNA Interference (RNAi) Treatment in Patients With Primary Hyperoxaluria Type 1 on Dialysis: How to Prove Treatment Success?

Cristina Martin Higuera,<sup>1</sup> Armando Torres,<sup>2</sup> Constantinos J. Stefanidis,<sup>4</sup> Bodo B. Beck,<sup>3</sup> Bernd Hoppe.<sup>1</sup> <sup>1</sup>German Hyperoxaluria Center, Bonn, Germany; <sup>2</sup>Universidad de La Laguna Facultad de Humanidades, La Laguna, Spain; <sup>3</sup>Uniklinik Köln, Köln, Germany; <sup>4</sup>Mitera Children's Hospital, Athens, Greece.

**Background:** Primary hyperoxaluria type 1 is a rare genetic disease of glyoxalate metabolism, leading to massively elevated oxalate production in the liver. Concomitant hyperoxaluria induces recurrent kidney stones, or progressive nephrocalcinosis and eventually (early) end stage kidney failure. Two RNA interference medication selectively block endogenous oxalate production. Oxlumo (Alnylam Pharmaceuticals, USA), is authorized for treatment. It blocks glycolate oxidase, reducing oxalate, but increasing glycolate production. Nedosiran (Dicerna/NovoNordisk, Denmark, compassionate use) blocks liver specific LDHA, the final step of oxalate production.

**Methods:** We treated seven patients (age 9-54 years, 4 female) for up to 20 months, with 5 receiving Oxlumo and 2 (the child and a 40-year-old woman) receiving Nedosiran. Dosages provided were according to companies' recommendations. All but one patient received vitamin B6 (VB6), hemodialysis (HD) regimens were constant. Plasma oxalate (Pox) and glycolate (PGlyc) were measured by ion-chromatography/mass spectrometry at baseline and before every dosage. Speckle echocardiography and bone MRI (3Tesla, left knee) were done at baseline and repeated every 6-8 months.

**Results:** Pox and PGlyc showed different follow ups: in 2 Oxlumo/VB6 and one Nedosiran/VB6 treated patients Pox was stable, or declined, meanwhile PGlyc increased only in one Oxlumo/VB6 patient (360 µmol/l before 6<sup>th</sup> dose, normal < 10.3). They only showed, if any, minor systemic oxalate deposits. In all other patients, Pox first decreased, but later fluctuated at high levels (70-130 µmol/l, normal < 7.4). PGlyc increased significantly in all but one Oxlumo, and intermittently in the Nedosiran patient. Lactic acidosis was diagnosed before the 6<sup>th</sup> Oxlumo dose in the patient without VB6 (PGlyc 1.04 mmol/l). PGlyc further increased to 4.14 mmol/l after the 7<sup>th</sup> dose. Speckle Echo and bone MRI ameliorated in all, but more rapidly under Nedosiran treatment.

**Conclusions:** Pox and PGlyc values should be repeatedly controlled in PH 1 HD patients on RNAi treatment. Lactic acidosis can appear in Oxlumo-treated patients with PGlyc values comparable to ethylene glycol intoxication. Pox values remaining elevated do not preclude, that treatment is failing. Imaging procedures then give better evidence of treatment success.

**Funding:** Commercial Support - Dicerna Pharmaceuticals provided compassionate use medication

## SA-PO330

### Different Modes of Action of Two Hypoxia-Inducible Factor Prolyl Hydroxylase (HIF-PH) Inhibitors, Roxadustat (Rox) and Daprodustat (Dap), in the Treatment of Anemia in Hemodialysis (HD) Patients

Satoshi Funakoshi,<sup>1</sup> Mineaki Kitamura,<sup>1</sup> Kosei Yamaguchi,<sup>1</sup> Tomoya Nishino.<sup>2</sup> <sup>1</sup>Nagasaki Kidney Center, Nagasaki, Japan; <sup>2</sup>Nagasaki Daigaku Igakubu Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan.

**Background:** Several types of HIF-PH inhibitors are now available for the treatment of anemia in HD patients, but there are no reports comparing each drug so far. In this study the effects of two HIF-PH inhibitors with separate launch dates in Japan, Rox and Dap, on anemia were compared in HD patients at a single institution.

**Methods:** To determine hematopoietic effect and iron metabolism of Rox and Dap, this study involved 64 HD patients who were initially treated with epoetin alfa (EPO), and then switched to Rox on January of 2020. Then, 61 patients were also converted from EPO to daprodustat (Dap) on September of 2020. We measured erythrocyte and iron-related factors at every two weeks after the treatment switch.

**Results:** As shown in Figure, in the Rox group treated three times a week at a dose of 100 mg, Hb levels significantly increased early after administration, whereas Dap group treated daily dose of 6 mg, no such early and rapid increase of Hb levels was observed. Total iron binding capacity (TIBC) values were significantly increased in both drugs, and transferrin saturation (TSAT) levels significantly increased in Rox but not Dap.

**Conclusions:** These results suggest that Rox may promote faster hematopoiesis by improving iron metabolism earlier than Dap after administration.

**Funding:** Private Foundation Support

## Changes in hemoglobin level and iron-related factors over time

## SA-PO331

**Risk Factors of Acute Dialysis Initiation in CKD Patients Followed in Multidisciplinary Low Clearance Clinics: A Retrospective Cohort Study**  
Tarek A. Ghonimi,<sup>1</sup> Abdullah I. Hamad,<sup>1</sup> Mohamed T. Abdellatif,<sup>2</sup> <sup>1</sup>Hamad Medical Corporation, Doha, Qatar; <sup>2</sup>Misr University for Science and Technology College of Medicine, 6th of October City, Egypt.

**Background:** A significant proportion of advanced CKD patients followed in multidisciplinary clinics (MDCs) clinics still initiate dialysis in an unplanned fashion rather than electively started. The aim of the present study is to identify risk factors that could help predicts the need for unplanned dialysis initiation among patients with advanced CKD.

**Methods:** We performed a retrospective study involving advanced CKD patients followed in MDCs for the last 2 years. Patients were classified as having an acute unplanned dialysis start or electively started dialysis.

**Results:** 378 patients are included in the study. 100 patient started acute dialysis while 75 patients started dialysis electively. CHF, CAD were significantly more in patients with acute start ( $p = 0.05$  and  $p = 0.000$  respectively). Patients with acute start had less educations, less numbers of clinic visits and less seen in vascular clinic ( $p = 0.000$ ,  $p = 0.000$  and  $p = 0.002$  respectively). Patients with acute dialysis start had significant hospital stay and significant high icu admission ( $=0.003$  and  $P = 0.00$ ). In regression analysis, absence of diabetes and CHF significantly reduce the odds for acute dialysis start (OR 0.452, 95% CI 0.212–0.965,  $P = 0.04$ ), (OR 0.120, 95% CI 0.037–0.388,  $p = 0.000$  respectively). Also, Patient not seen in vascular clinic have significant risk factor for acute dialysis start (OR 24.675, 95% CI 6.856–88.811,  $p = 0.000$ )

**Conclusions:** Acute dialysis initiation is common among advanced CKD patients, even if they are followed in a multidisciplinary chronic kidney disease clinic. Timely education, follow up and access creation for patients at risk may lower hospital admission, hospital stay, ICU admission, decrease cost and morbidity in those type of patients.

Characteristic	Acute dialysis No 100 (%)	elective dialysis No 75 (%)	p

### Machine Learning Approach for Hemodialysis Prescription: Model Development and Validation Study

Xueqin Bian, Yang Zhou, Hong Ye, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Background:** The prediction model of hemodialysis prescription is established based on machine learning to achieve precise hemodialysis treatment.

**Methods:** We obtained 108,638 hemodialysis sessions in 965 independent maintenance hemodialysis (MHD) patients in our hospital from October 1, 2020 to June 31, 2021 using random sampling. The sessions were randomly divided into training (70%), calibration (10%), and testing (20%) sets. Apply XGBoost to analyze and extract effective feature data. XGBoost, Random Forest Regression, K-Nearest Neighbor, Support Vector

Regression and Linear Regression were used to develop the prescription model and model fusion. Training and update the model using reinforcement learning. The area under the receiver operating characteristic curves, the area under the precision-recall curves, F1 scores and MSE obtained to assess model stability and accuracy.

**Results:** There were 108,638 dialysis records in 965 patients, of whom 62.2 were male, the average age was 59.3 ± 13.2 years, the median dialysis age was 102.3 months, BMI was 23.8 ± 3.9, and the primary disease was diabetic nephropathy (38.6%). There are 13 labels in the hemodialysis prescription, of which 6 labels are continuous variables and the regression model is used, and 7 labels are discontinuous variables. The average accuracy is greater than 0.88, and the mean square error is less than 0.067. The average compliance rate of dialysis prescriptions was 86%.

**Conclusions:** The artificial intelligence dialysis prescription established based on machine learning has better stability and accuracy.

**Funding:** Government Support - Non-U.S.

## SA-PO333

### Obesity in Patients on Haemodialysis: Looking Beyond BMI

Sarah Cooney,<sup>1,2</sup> Peter J. Conlon,<sup>1</sup> Carel W. le Roux.<sup>2</sup> <sup>1</sup>Beaumont Hospital, Dublin, Ireland; <sup>2</sup>University College Dublin, Dublin, Ireland.

**Background:** Obesity has important implications for patients on dialysis for a number of reasons- from making them more complex to treat, to affecting the likelihood of transplantation. The WHO has changed the clinical definition of obesity from BMI >30kg/m<sup>2</sup> to “abnormal or excessive fat that presents a risk to health”. While BMI, similar to eGFR, is useful as a screening tool, it does not always reflect health status in individuals and thus neither BMI nor eGFR are diagnostic tools. In clinical practice the King’s Obesity Staging Criteria can be used to diagnose obesity by identifying complications of obesity to determine whether a patient would benefit from obesity treatment. Using the new WHO definition, patients who were previously classed as overweight (BMI >25kg/m<sup>2</sup>) who have a complication related to excess adipose tissue can be classed as having obesity and as such may benefit from obesity treatment. Equally some patients with a BMI >30kg/m<sup>2</sup> may not have clinically definable obesity.

**Methods:** This was a retrospective, cross-sectional audit of the prevalence of obesity in patients on haemodialysis in Beaumont Hospital, Dublin. Weight and height were extracted from the renal electronic database, which was used as a screening tool to determine patients with a BMI >25kg/m<sup>2</sup>. The King’s Obesity Staging criteria was then used to define if they had any complications of obesity.

**Results:** BMI was used as a screening tool on the current patients on haemodialysis (n=196). This identified 34.1% of patients as having obesity by the older definition of BMI >30kg/m<sup>2</sup>. In our series 62.5% of patients over BMI 25kg/m<sup>2</sup> had a non-kidney disease related obesity complication and therefore using the new WHO definition 49.4% of the total patients on dialysis have obesity. Mean BMI was 28.4kg/m<sup>2</sup>. The most common complication was type two diabetes (n=58).

**Conclusions:** The disease of obesity affects 49.4% of patients on dialysis in Beaumont hospital. Evidence is now required to show whether treating obesity in this population will result in substantial health gain.

### BMI and obesity

## SA-PO334

### Impedance-Derived Phase Angle Is Associated With Muscle Strength and Physical Performance in Maintenance Hemodialysis Patients

Xin Li, Chen Yu. *Department of Nephrology, Tongji Hospital, School of Medicine, Tongji University, Shanghai, China.*

**Background:** Phase angle (PhA) derived by bioelectrical impedance analysis (BIA) is an index of cellular health and cell membrane integrity. In maintenance hemodialysis (MHD) patients, PhA has been proposed as a predictor for protein-energy wasting (PEW). Declining in physical function is common in MHD patients, due to a variety of factors such as PEW and sarcopenia. It remains unclear if PhA is a valid marker to detect muscle function in MHD patients. The aim of this study was to identify the association between PhA and muscle function (muscle strength and physical performance) in MHD patients.

**Methods:** This was a multi-center, cross-sectional study included 864 (61% males; mean age 61.5 ± 12.6 years) MHD patients from seven dialysis centers in Shanghai of China from 2020 to 2021. Muscle strength was measured by handgrip strength (HGS), and physical performance was measured via Short Physical Performance Battery (SPPB).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

4-meter gait speed and Timed Up and Go Test (TUGT). Nutritional status was assessed by Malnutrition inflammation score (MIS). Body composition, including PhA at 50kHz, was measured by BIA. Linear regression models were performed to determine the associations between PhA and muscle function.

**Results:** PhA (4.6±0.9) was negatively associated with age, MIS, extracellular water/total body water, visceral fat area and TUGT, and positively associated with hemoglobin, serum albumin, body mass index (BMI), skeletal muscle mass index, SPPB, 4-meter gait speed and HGS. PhA values of five body segments- right arm, left arm, trunk, right leg and left leg – also correlated well with muscle strength and physical performance. In the linear regression model further adjustments for age, gender, spKt/v, dialysis vintage, Charlson comorbidity index, MIS and BMI, PhA was positively correlated with SPPB ( $\beta=0.37$ , p-value <0.001), gait speed ( $\beta=0.32$ , p-value <0.001), HGS ( $\beta=0.32$ , p-value <0.001), and negatively associated with TUGT ( $\beta=-0.24$ , p-value <0.001).

**Conclusions:** Higher PhA was independently associated with better muscle strength and physical performance in MHD patients. Our study suggest that PhA can be used as a good marker to determine muscle function.

## SA-PO335

### Early Body Weight Change During Continuous Renal Replacement Therapy and Subsequent Mortality in Critically Ill Patients

Sung Bin Yoon, Seongwon Han, Sungmi Kim, Minsuk Seo, Hye Ryoung Jang, Jung eun Lee, Woosong Huh, Yoon-Goo Kim, Junseok Jeon. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

**Background:** Fluid overload in critically ill patients is associated with adverse outcome. It has been reported that negative fluid balance during continuous renal replacement therapy (CRRT) was associated with better mortality. However, measured fluid balance often does not match body weight change. We evaluated the association between early weight change during CRRT and patient outcome.

**Methods:** This retrospective study included 1694 adult patients undergoing CRRT for 3 or more days from 2009 to 2017. The day of CRRT initiation was expressed as D0. Because weight change in D0 can be significantly influenced by initial resuscitation rather than fluid control by CRRT, we divided patients according to weight change from D0 to D1: group 1 (<-1 kg, 407 patients), group 2 (-1 to 0 kg, 409 patients), group 3 (0 to 1 kg, 398 patients) and group 4 (>1 kg, 480 patients). Early weight change (kg) during CRRT was defined as D3 weight – D1 weight. Primary outcome was 90-days mortality.

**Results:** Overall, weight increased during the first day of CRRT and decreased thereafter, and weight gain from D0 to D3 was associated with higher mortality. Early weight change during CRRT was positively associated with higher mortality in group 4 (OR 1.14, 95% CI 1.03-1.25,  $P < 0.01$ ), but not in group 1, 2 and 3. In subgroup analyses of group 4, early weight change during CRRT was positively associated with higher mortality in the surgical and cardiac ICU (OR 1.25, 95% CI 1.09-1.44,  $P = 0.001$  and OR 1.20, 95% CI 1.00-1.36,  $P = 0.007$ , respectively), but not in the medical ICU.

**Conclusions:** Early weight reduction during CRRT, especially in patients who gain weight > 1 kg on first day of CRRT, may be beneficial. However, medical ICU patients may require more careful decisions for fluid balance management.

**Funding:** Government Support - Non-U.S.

## SA-PO336

### Lab Abnormalities Can Be Seen as Early as 3 Months Prior to Hospitalization and Mortality Among Malaysian Dialysis Patients

Yusuke Ozawa,<sup>1,3</sup> Tze L. Ting,<sup>1</sup> Pao Kuen Koh,<sup>1</sup> Rosnawati Yahya,<sup>4</sup> Li Ping Tan.<sup>1,2</sup> *<sup>1</sup>Davita Malaysia, Kuala Lumpur, Malaysia; <sup>2</sup>Ramsay Sime Darby Health Care, Selangor, Malaysia; <sup>3</sup>Mitsui Bussan Kaisha, Chiyoda-ku, Japan; <sup>4</sup>General Hospital Kuala Lumpur, Kuala Lumpur, Malaysia.*

**Background:** Data on associations between lab parameters with death and hospitalization among dialysis patients in Malaysia are limited. This study attempted to identify the blood test items with the highest impact on hospitalization and death.

**Methods:** We hypothesized that blood test monitoring parameters would affect the risk of being hospitalized and / or dying due to cardio/cerebrovascular events, fluid overload and infections. Patient data was extracted from 40 Davita dialysis clinics across Malaysia from January to December 2021. Variables of interest were Hemoglobin, Phosphate, Albumin, Calcium, Potassium, and Sodium. Data was analysed using 1. Sample Variance test, 2. Sample T-Test, and 3. One way Anova analysis. Regression analysis was done in order to devise a model that would predict mortality.

**Results:** A total of 774 patients were identified with data available for analysis, 515 patients were not hospitalized. 259 patients were hospitalized with 341 hospitalization events. Of the 259 hospitalized patients, 131 patients died within three months of admission giving a yearly mortality rate of 16.9%. Significant differences in mean values were observed in hospitalized patients and death as early as 3 months predating their hospitalization. These were seen in hemoglobin, albumin, calcium, potassium values. A model incorporating hemoglobin, albumin and calcium values was formulated that was able to predict the risk of mortality in 3 months.

**Conclusions:** Lab abnormalities were prevalent as early as 3 months prior to hospitalization events and were associated with hospitalization and death. Variables that were significantly different were hemoglobin, albumin, calcium and potassium. Sodium values were significantly different only when death was analyzed as the outcome. A model that incorporated hemoglobin, albumin and calcium was able to predict the risk of death.

**Funding:** Commercial Support - Davita Malaysia

Differences between hospitalized and non-hospitalized patients and Death

Category	HB(P-value)	Phos(P-value)	Alb(P-value)	Ca(P-value)	K(P-value)	Na(P-value)
Non-hospitalized patients	10.85	1.8232	30.195	2.244	5.25	136.2
Hospitalized patients	9.87(0.00)	1.781(0.25)	39.371(0.00)	2.1716(0.00)	5.01(0.01)	136.3(0.67)
Death	9.283(0.00)	1.7383(0.08)	36.8(0.00)	2.090(0.00)	4.78(0.00)	135.6(0.06)

## Regression Equation

$$\text{Mortality Risk} = -3.836 + 1.4063 \text{ Alb} + 1.3692 \text{ HB} + 1.927 \text{ Ca}$$

## SA-PO337

### Comparative Effect of Pre-Dialysis Nephrologic Care on Long-Term Mortality and Hospitalization After Dialysis Initiation

Mathias Haarhaus,<sup>1,2</sup> Lavinia O. Bratescu,<sup>3</sup> Nicolae Pana,<sup>3,4</sup> Emanuela M. Gemene,<sup>3</sup> Olivera Stojceva,<sup>5</sup> Eliana M. Silva,<sup>1</sup> Carla Alexandra R. Santos Araujo,<sup>1,6</sup> Fernando Macario.<sup>1</sup> *<sup>1</sup>Diaverum, Malmö, Sweden; <sup>2</sup>Karolinska Institutet Institutionen för klinisk vetenskap intervention och teknik, Huddinge, Sweden; <sup>3</sup>Diaverum Romania, Bucharest, Romania; <sup>4</sup>Universitatea de Medicina si Farmacie Carol Davila, Bucuresti, Romania; <sup>5</sup>Diaverum North Macedonia, Skopje, Macedonia (the former Yugoslav Republic of); <sup>6</sup>Faculty of Medicine, Cardiovascular Research and Development Unit, Porto, Portugal.*

**Background:** A structured pre-dialysis nephrologic care model may impact on patient outcome after dialysis initiation. We aimed to determine the effect of a structured nephrologic care program on mortality and hospitalizations during the first 5 years after dialysis initiation.

**Methods:** Between January 2015 and July 2018, 349 patients with end-stage renal disease who started dialysis in 9 Romanian dialysis clinics were included. In a retrospective analysis, patients followed by a nephrologist prior to dialysis initiation (N=124) were compared to patients followed in primary care (N=225). The observational period ended December 2020 or at death or loss to follow-up. anonymized clinical and laboratory data were retrieved from the dialysis provider's quality database. Patients followed for at least 1 month after dialysis initiation were included in the data analyses. Missing data were imputed using multiple imputations.

**Results:** Patients were followed for a median (25-75%) of 42 (26-50) months. Baseline age was 64 (54-70) years, there were 42.2% females and 34.9% diabetics with no significant differences between groups. At dialysis start, patients followed by a nephrologist had higher hemoglobin (9.9 (9.1-10.6) g/dL vs. 8.4 (7.8-9.4)g/L,  $p < 0.001$ ) and higher albumin (3.5 (3.2-4.1) g/dL,  $p < 0.001$ ) than patients followed in primary care, whereas Charlson Comorbidity Index was comparable between groups (6 (4-7) vs. 6 (4-7),  $p=0.9$ ). Logistic regression analysis, correcting for age, gender, hemoglobin, albumin, mean arterial pressure (MAP), and Charlson Comorbidity Score, demonstrated a lower risk for an annual hospitalization rate >1 for patients followed by a nephrologist (Exp(B) 0.30 (confidence interval 0.13-0.67),  $p=0.005$ ). A Cox regression model, correcting for the same covariables, revealed a lower mortality risk in patients followed by a nephrologist (Exp(B) 0.45 (CI 0.27-0.74),  $p=0.002$ ).

**Conclusions:** Our structured pre-dialysis care model was associated with improve survival and lower hospitalization rate during a median follow-up period of more than 3 years after dialysis initiation, compared to patients followed in primary care. These results may impact on the design of pre-dialysis care models for patients with advanced CKD. Note: This presentation will include updated results.

## SA-PO338

### Improvement of Calcinosis Cutis With Sodium Thiosulfate Infusion in a Peritoneal Dialysis Patient

Panupong Hansrivijit,<sup>1,2</sup> Viswanathan S. Iyer.<sup>2</sup> *<sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>UPMC Pinnacle Harrisburg, Harrisburg, PA.*

**Introduction:** Calcinosis cutis, defined by calcifications of the skin, and soft tissue is a rare disease. One subtype, calciphylaxis, defined as calcified blood vessels, can be mostly seen in hemodialysis patients. However, subcutaneous calcification form is extremely rare especially in peritoneal dialysis (PD) and the treatment is unknown.

**Case Description:** A 49-year-old Caucasian female with end-stage kidney disease from membranous nephropathy on PD for 3 years was evaluated in clinic for chronic bilateral leg pain. Her past medical history included essential hypertension, and history of right chronic deep vein thrombosis in 2009 with resolution of thrombosis from a repeated venous Doppler ultrasound 2 years prior to current presentation. Physical examination is remarkable for lumpy nodular swelling in circumferential pattern with local tenderness in both legs, right more than left. Serum creatinine 6.3 mg/dL, blood urea nitrogen 52 mg/dL, calcium 9.3 mg/dL, phosphorus 5.5 mg/dL, CaP product 51.2 mg<sup>2</sup>/dL<sup>2</sup>, parathyroid hormone 772 pg/mL. Radiographic imaging of both legs shown in Figure 1A. A diagnosis of calcinosis cutis was made. She was started on sodium thiosulphate infusion 12.5 g three times weekly for 5 months then 25 g weekly as well as cinacalcet and sevelamer. Eight months after treatment, patient reported significant improvement in pain and radiological findings (Figure 1B). Patient tolerated treatment well.

**Discussion:** This case provided some key learning points. First, calcinosis cutis without calciphylaxis in this patient is unusual especially with PD and normal CaP product. Second, sodium thiosulfate might be helpful in treatment of extra-vascular

calcification. However, the efficacy, dosage and duration of treatment require further investigation.

Figure 1. A) extensive bilateral subcutaneous lower leg calcifications from mid tibia to ankle, with absence of vascular calcifications; B) near resolution of calcifications on the left side, and improved calcification density on the right side.

### SA-PO339

#### Managing Sickle Cell Patients on Renal Replacement: The Struggle Is Real

Sri Vibhavari Guntupalli, Jonathan Keyes, Pooja D. Amarapurkar. *Emory University School of Medicine, Atlanta, GA.*

**Background:** Hemodialysis (HD) and peritoneal dialysis (PD) have been successfully performed in patients with sickle cell disease (SCD) and trait (SCT). However, mortality in this group remains high. Kidney transplantation is a preferred modality of renal replacement therapy (RRT) but poses great challenges. The data on longitudinal outcomes in this group various immensely. We describe our experience with sickle cell patients on various RRT.

**Methods:** This is a retrospective analysis of data from 2004-2021, across 4 dialysis units. 29 (3.99%) out of 726 patients with sickle cell were identified. Age, gender, race, genotype, type of RRT, RRT vintage, blood pressures, transplant referral, graft function duration, hemoglobin (Hb) and Kt/v were evaluated. Patients were grouped into SCD and SCT for comparison. Statistical analysis was performed.

**Results:** All 29 patients were African American with at least 3 years of pre-dialysis nephrology care. 27.5% (8) were on PD and 72.4% (21) were on HD. 51.7% (15) patients had SCD and 48.2% (14) had SC trait. Among the SCD patient, 60% (9) started dialysis between 20-40 years of age and 40% (6) between 45-70 years of age. The patients who started dialysis at a later age had a higher Hb. 85.7% (13) SCT patients started dialysis between 45-70 years of age. 66.7% (10) patients with SCD and 28.5% (4 patients) of SCT expired and only 50% (7) of all patients survived greater than 5 years after initiation of dialysis. The average intradialytic blood pressure in patients who survived < 5 years was lower when compared to those who survived > 5 years. There was no difference in Kt/V in SCD and SCT patients who survived < or > 5 years. Of the 8 PD patients 50% (4) from each group (SCD and SCT) expired in < 5 years. 20.6% (6) of all patients received transplant. 83.3% (5) of which failed at 10-year mark with 60% (3) from BK virus and 40% (2) from rejection.

**Conclusions:** The mortality in patient with SCD and SCT on RRT is extremely high. Intradialytic hypotension is a significant co-morbidity. Graft survival is also limited. A multi-disciplinary approach in required to care for these complex patients to improve outcomes. We aim to collaborate with other centres to improve access to care and data reporting in this population.

### SA-PO340

#### End-of-Life Care Planning Among Dialysis Patients: A Mixed-Methods Study

Ania Filus, Katie T. Harmeyer, Steven M. Brunelli, Francesca Tentori. *Davita Clinical Research, Minneapolis, MN.*

**Background:** Despite high mortality rate for older adults with end-stage kidney disease, little is known about the end-of-life (EoL) care needs and preferences among patients on chronic dialysis. In an effort to better understand patient comprehension of the EoL planning process and their preferences, we elicited insight from a cohort of dialysis patients using a mixed methods approach.

**Methods:** In step one we conducted semi-structured qualitative interviews with in-center dialysis patients in January-February 2021. The results from the qualitative part informed design of the online follow-up survey (step two). The online survey data was collected from in-center and home dialysis patients from August-September 2021.

**Results:** In step one a total of 14 patients were interviewed. The average time on dialysis was 4.7 years. Results showed that patients had low understanding of EoL care terminology such as advance directive, health-care proxy, or hospice. Most patients reported that EoL conversations with their family members focused predominantly on practical issues related to dying (i.e., assets, burial) rather than EoL care (Figure 1). Common barriers to EoL care planning were: fear of death and belief that the best timing for EoL care planning are final months of one's life. In step two, online survey data was collected from 796 patients. In the survey, a majority of patients reported that preparing

and planning for their death was important to them. And 74% of patients reported that they gave some or a great deal of thought to their wishes about EoL care. Additionally, 64% of patients had discussed preferences with a family member, but only 22% discussed these with their doctor, social worker or nurse. Only 28% reported having completed a legal document that states their EoL preferences.

**Conclusions:** Dialysis patients have little awareness and understanding of steps involved in EoL care planning, and typically do not engage in EoL care conversations with their health care team. This study emphasizes the need for better patient education regarding the necessity of legal formalization of EoL preferences.

### SA-PO341

#### Differences in Demographic and Clinical Outcomes Between Modalities for Patients 60 Days Post-Transitional Care Unit Initiation

Derek M. Blankenship, Michael A. Kraus, Dinesh K. Chatoth, Rachel A. Lasky, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care, Global Medical Office, Waltham, MA.*

**Background:** Transitional Care Units (TCUs) are designed to enhance patient support at time of dialysis initiation and provide comprehensive education on renal replacement therapies. Much remains to be learned about TCUs and their performance. As an initial step, the purpose of this study is to describe and compare the demographics and clinical characteristics by patients' modality at 60 days post TCU enrollment.

**Methods:** This retrospective study identified Fresenius Kidney Care (FKC) patients new to dialysis and starting in-center hemodialysis (ICHD) within a TCU between Oct. 1<sup>st</sup>, 2019 and Sept. 30<sup>th</sup>, 2020. Patients less than 18 years of age and with Acute Kidney Injury preceding End Stage Kidney Disease were excluded. Demographic and clinical outcomes were measured 60 days post TCU enrollment. Tests for differences among modalities were conducted using Kruskal-Wallis and Chi-Square tests.

**Results:** 725 patients who initiated treatment at one of 57 TCUs were studied. After 60 days, 9.5%, 10.5%, 70.1%, and 9.9% were on peritoneal dialysis (PD), home hemodialysis (HHD), ICHD, or remained within a TCU, respectively. Gender, race, US region, educational status, albumin, BMI, and vascular access type were statistically significant between modalities (p<0.10). Of note, ICHD and PD had a higher proportion of female patients than HHD and those remaining in a TCU (42 vs 29%). Similarly, ICHD and PD had a higher patient proportion who live in the south (22 vs 8%). ICHD had a lower proportion with college or higher education (36 vs 49-52%) and higher proportion of blacks (45 vs 26-41%). Lastly, HHD had a higher mean BMI than other modalities (33 vs 27-29). Age, ethnicity, primary cause of ESRD, and history of diabetes, heart failure, and coronary heart disease were not statistically significant.

**Conclusions:** This preliminary study identified several demographic and clinical differences between modalities and could be used for TCU enhancements. Selection bias for patients referred to a TCU is likely. In the future, TCUs should be available for all patients and long-term follow-up of clinical outcomes should be assessed.

**Funding:** Commercial Support - Fresenius Medical Care

### SA-PO342

#### Diagnosis of Obstructive Sleep Apnea (OSA) Using NightOne (Nite1) and Crit-Line (CLD) Devices During In-Center Hemodialysis

Hassaan Iftikhar, Katherine P. Newberry, Frank J. O'Brien, Daniel W. Coyne. *Washington University in St Louis, St Louis, MO.*

**Background:** OSA is highly prevalent and underdiagnosed in in-center hemodialysis patients (ICHD). Diagnosis of OSA by simultaneous utilization of CLD monitor and portable sleep apnea testing devices has not been well studied. The CLD detects changes in relative blood volume and continuous arterial O2 saturation (SaO2) data during ICHD. We conducted a study to compare SaO2 changes on CLD to a validated OSA monitor, Alice NightOne (Nite1).

**Methods:** This single center study performed a protocolized, nurse-supervised sleep study using simultaneous Nite1 and CLD at a single ICHD in 6 patients with known OSA, 8 high and 10 low-suspicion OSA patients based on screening survey. Data from Nite1 was used to diagnose OSA based on a respiratory event index of  $\geq 5$ /hr, and compared to the SaO2 oscillation pattern on CLD (figure 1).

**Results:** 21 patients had valid results from both devices during their in-center sleep/dialysis. Mean duration of dialysis was  $3.5 \pm 0.5$  hours. Graphs representing various degrees of suspected OSA on CLD are in figure 1. Using Nite1 as the standard, all 6 known OSA patients had a positive ICHD sleep study, and the CLD SaO2 curves supported OSA. Among those with high suspicion for OSA, 4 of 6 had OSA, and CLD

curve was discordant in 2 of the 6 (1 false positive, 1 false negative). In the low suspicion group, 6 of 9 had OSA and only those 6 had Crit-line curves supporting OSA.

**Conclusions:** The recordings on Crit-Line can provide presumptive evidence of OSA, but validated device confirmation is needed. A protocolized sleep study during ICHD using NiteOne can diagnose OSA.

SA-PO343

**A Retrospective Analysis of All-Cause Hospitalization and 30-Day Readmission in Clinics Participating in ESRD Seamless Care Organizations**  
Benjamin E. Hippen, Rachel A. Lasky, Linda Ficociello, Len A. Usvyat, Terry L. Ketchersid. *Fresenius Medical Care, Waltham, MA.*

**Background:** In 2015, the Center for Medicare and Medicaid Innovation (CMMI) implemented a pilot program known as ESRD Seamless Care Organizations (ESCOs) to reduce costs and maintain/improve care. This retrospective data analysis aims to evaluate hospitalizations in ESCO-eligible patients who received dialysis at ESCO vs non-ESCO clinics.

**Methods:** Adult, Fresenius Kidney Care (FKC) hemodialysis pts who met ESCO eligibility criteria between 10/2015-3/2017 were included. ESCO pts received dialysis at 1 of 6 FKC ESCO markets. The Non-ESCO pts were dialyzed at nearby FKC facilities that were propensity score matched on the following: number of ESCO eligible pts, mean dialysis vintage, mean pt age, %pts with diabetes, %pts with dual-eligibility, median income by zip code, and geographical proximity. Pts were further stratified by central venous catheter (CVC) use. Hospitalizations were identified using electronic medical records. Crude and adjusted Poisson regression models and chi-square testing were used.

**Results:** 13,994 pts (7,398 ESCO and 6,596 non-ESCO) were included. Pts attending ESCO clinics had 0.97 times the rate of hospitalization when compared to non-ESCO clinics (p=0.013). In the multivariate model, ESCO clinic pts had 0.95 times the rate of hospitalization when compared to pts attending non-ESCO clinics (p=0.001). The difference between groups was narrowed when controlling for CVC; thus we stratified by CVC use (table). ESCO CVC pts had 0.90 the rate of hospitalization (p=0.0004) compared to non-ESCO CVC pts. There was no significant difference in the non-CVC subgroup. 30-day readmission rate did not differ between groups (p=0.59).

**Conclusions:** ESCO-eligible pts that received hemodialysis in FKC ESCO clinics experienced a lower rate of all-cause hospitalizations when compared to pts in non-ESCO clinics, a benefit primarily associated with pts that dialyzed using a CVC.

**Funding:** Commercial Support - Fresenius Medical Care

SA-PO344

**Association Between Intradialytic Central Venous Oxygen Saturation and Relative Blood Volume in Chronic Hemodialysis Patients**  
Hanjie Zhang,<sup>1</sup> Priscila Preciado,<sup>4</sup> Laura Rosales,<sup>1</sup> Jeroen Kooman,<sup>3</sup> Frank van der Sande,<sup>3</sup> Peter Kotanko.<sup>1,2</sup> *<sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Maastricht University Medical Center, Maastricht, Netherlands; <sup>4</sup>Traverse Therapeutics Inc, San Diego, CA.*

**Background:** Central venous oxygen saturation (ScvO<sub>2</sub>) is correlated with upper body blood flow and usually declines during hemodialysis (HD). While relative blood volume (RBV) monitoring is widely used to guide ultrafiltration, little is known about the relationship between intradialytic changes of ScvO<sub>2</sub> and RBV.

**Methods:** We conducted a retrospective study in maintenance HD patients with central venous catheter as vascular access. Crit-Line (Fresenius Medical Care, Waltham, MA) was used to measure intradialytic ScvO<sub>2</sub> and hematocrit (hct). RBV was calculated from hct changes. We applied linear mixed effects models to assess the association between intradialytic changes of ScvO<sub>2</sub> and RBV at the end of dialysis.

**Results:** We studied 5,231 dialysis sessions in 216 patients (age 62.2±15.7 years; 47% males, UFR 7.1±2.7 mL/kg/h). We observed a significant, direct relationship between intradialytic changes of ScvO<sub>2</sub> and RBV with slope of 0.8 (Fig. 1). Results were materially identical in sessions with an UFR >13 or ≤13 mL/kg/h, respectively.

**Conclusions:** Our study shows that ScvO<sub>2</sub> declines in parallel with RBV in most patients. We posit that this relationship is driven by a decrease in cardiac preload due to intradialytic blood volume decline. The decrease in cardiac preload would then result in a lower cardiac output, hemodynamic stress, and decreased tissue perfusion. Further studies should evaluate the instantaneous, contemporaneous changes of ScvO<sub>2</sub> and RBV during HD.

**Funding:** Commercial Support - Renal Research Institute

**Figure 1.** Relationship between ScvO<sub>2</sub> and RBV changes. Light lines represent individual patients. Green lines indicate a positive (N=187) and red ones (N=29) indicate a negative relationship. The heavy, purple line shows the population-level fixed-effect slope estimated from the linear mixed model.

SA-PO345

**Extracellular Volume Overload Is Associated With Increased Endothelin-1 in Hypertensive Hemodialysis Patients**  
Peter N. Van Buren,<sup>1,2</sup> Bethany A. Roehm,<sup>1</sup> Kamalanathan K. Sambandam.<sup>1</sup> *<sup>1</sup>The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; <sup>2</sup>Dallas Veterans Affairs Medical Center, Dallas, TX.*

**Background:** Extracellular volume (ECV) overload contributes to hypertension in hemodialysis (HD) patients and is associated with increased mortality. The potent vasoconstrictor endothelin-1 (ET-1) is associated with both high HD-unit blood pressure (BP) as well as morbidity and mortality. It is unclear if ECV and ET-1 are related. We sought to determine if ECV predicted ET-1 levels in hypertensive HD patients.

**Methods:** In a cohort of hypertensive HD patients, we obtained measurements of pre-HD plasma ET-1 and ECV using whole-body multifrequency bioimpedance spectroscopy. We determined the Pearson correlation coefficient between ET-1 and ratio of ECV to body weight (ECV/Wt). We then used linear regression analysis with ET-1 as the outcome and ECV/Wt as the predictor variable to determine the independent association between these variables in univariate models as well as models controlling for demographics, interdialytic weight gain, pre-HD systolic BP, and diabetes.

**Results:** There were 64 participants with a mean age of 48.9 (12) years including 38 men, 56 that were Black or Hispanic, and 37 with diabetes. All had hypertension with mean pre-HD systolic BP 157 (20) mmHg. The mean pre-HD ECV/Wt and ET-1 were 0.26 (0.05) L/kg and 2.38 (1.5) pg/mL, and there was significant correlation between these variables (r=0.3, p=.03). In a model controlling for demographics, there was a significant association between ECV/Wt and ET-1 (β=0.15, p=.002; both variables underwent reciprocal transformation). This significant association was unchanged when controlling for BP, weight gain, and diabetes.

**Conclusions:** Higher pre-HD ECV/Wt is independently associated with higher ET-1 levels in hypertensive HD patients. This association requires further investigation to establish a potentially novel mechanism related to volume induced hypertension as well as well as therapeutic strategies to consider for patients with hypertension and refractory volume overload.

**Funding:** NIDDK Support, Veterans Affairs Support

There is a significant correlation between pre-HD ECV/Wt and ET-1 ( $r=0.3$ ,  $p=.03$ )

## SA-PO346

### Bio-Impedance-Guided Target Weight Correction Improves Fluid Overload in Hemodialysis Patients: A Feasibility Study

Branko Braam, Anna de Ruiter, Judy A. Ukrainetz. *University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

**Background:** Fluid overload in hemodialysis (HD) patients is highly prevalent and is associated with adverse cardiovascular outcomes. The hypothesis of this study was to implement a target weight correction protocol overseen by nursing staff in a hemodialysis unit to reduce fluid overload. This was successfully tested in a feasibility study. Arterial stiffness was measured in response to the intervention.

**Methods:** Of the 16 patients included in the study, 10 were subjected to the intervention (in center 1) and 6 served as time controls (in center 2). Time-average fluid overload (TAFO = pre-dialysis fluid overload – ½ of the one-week averaged interdialytic weight gain) was used as fluid overload parameter. Fluid status was assessed at baseline and then monthly for 2 months before the start of mid-week dialysis run using multi-frequency bioimpedance (Body Composition Monitor, BCM, Fresenius Medical Care) and arterial stiffness using (Arteriograph24™, Budapest, Hungary). In the intervention group, target weight was adjusted every two weeks based on the BCM measurements. No adjustment of target weight was performed in the control group and the treatment team was blinded from the results.

**Results:** At baseline, groups were comparable. After two months, TAFO had significantly decreased in the intervention group by 40% from  $2.8 \pm 1.2$  to  $1.6 \pm 1.2$  L ( $P < 0.012$ ), no change was seen in the control group ( $2.9 \pm 1.4$  to  $2.5 \pm 2.0$  L, NS). With that, traditional pre-dialysis fluid overload decreased from  $3.8 \pm 1.2$  to  $2.7 \pm 1.2$  L ( $P < 0.009$ ) in the intervention group and no change was observed in the control group ( $3.6 \pm 1.3$  to  $3.6 \pm 2.2$  L, NS). Blood pressure after two months did not significantly differ in both groups ( $P > 0.05$ ). Arterial stiffness (PWV and AIX) remained unchanged in both groups.

**Conclusions:** This feasibility study clearly demonstrates that fluid management using a target weight correction protocol based on TAFO assessed by BCM measurements can improve fluid status in HD patients. It did not coincide in this short study with changes in arterial stiffness.

## SA-PO347

### Use of Bioimpedance Techniques in Patients With CKD: A Meta-Analysis

Laura Horowitz, Oliver A. Karadjian, Thomas Mavranakas, Catherine L. Weber. *McGill University, Montreal, QC, Canada.*

**Background:** Bioimpedance technologies are increasingly used to determine extracellular volume status in patients with chronic kidney disease (CKD). We aimed to determine if this technology improves clinical outcomes as compared to usual care.

**Methods:** We performed a systematic review and meta-analysis of trials comparing fluid management guided by Body-Composition Monitoring or Bioimpedance analysis to standard care in patients with CKD, including patients on dialysis. Our primary outcome was all-cause mortality. Secondary outcomes included blood pressure (BP) control, all-cause hospitalization, major adverse cardiovascular events (MACE), change in left ventricular mass index (LVMI), and residual renal function. The relative risk (RR) or Hedges' g standardized mean difference (SMD) were estimated using a random-effects model.

**Results:** Our search identified 819 citations of which 12 randomized-controlled trials (RCTs) and one observational study were included (2670 patients with 1046 on peritoneal dialysis). No studies of non-dialysis dependent CKD patients met inclusion criteria. Mean age was 56 years and mean follow up was one year. There was no difference in all-cause mortality between the bioimpedance and the standard of care arms (RR 0.72, 95% confidence interval [CI] 0.47-1.11). Better diastolic BP control was observed in the bioimpedance arm of RCTs (SMD -0.18, 95% CI -0.34 to -0.02). No difference was observed between the two arms for MACE (RR 0.73, 95% CI 0.49-1.10) or LVMI (SMD -0.17, 95% CI -0.39 to 0.05). All-cause hospitalizations were not significantly different between the two groups (RR 1.08, 95% CI 0.92-1.26). Residual renal function could not be assessed.

**Conclusions:** Amongst patients on dialysis, bioimpedance-guided volume management showed improved diastolic BP control but no significant difference in all-cause mortality, MACE, and LVMI. Moreover, our study identified a knowledge gap in the use of this technology in non-dialysis dependent CKD patients and the possible effect it may have on clinical outcomes in this population.

## SA-PO348

### Impact of Phase Angle and Sarcopenia Estimated by Bioimpedance Analysis on Clinical Prognosis in Patients Undergoing Hemodialysis: A Retrospective Study

Tae won Lee,<sup>1</sup> Eunjin Bae,<sup>1</sup> Dong Jun Park.<sup>1,2</sup> *<sup>1</sup>Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea; <sup>2</sup>Gyeongsang National University, Jinju, Gyeongsangnam-do, Republic of Korea.*

**Background:** Bioimpedance analysis (BIA) has been widely used in the evaluation of body composition in patients undergoing maintenance hemodialysis (MHD). We conducted this study to evaluate impact of PA and sarcopenia measured by BIA on clinical prognosis in these patients.

**Methods:** This longitudinal retrospective study enrolled patients who underwent hemodialysis between January 2016 and March 2019. The patients were stratified into higher ( $> 4^\circ$ ) and lower ( $\leq 4.0^\circ$ ) PA groups. Sarcopenia was defined when the appendicular skeletal muscle mass (ASM) was  $< 20$  kg in men and  $< 15$  kg in women.

**Results:** Of the 191 patients, 63.4% were men. The mean age was  $64.2 \pm 12.4$  years. The lower PA group was older, had a higher proportion of women, a lower BMI, lower albumin, cholesterol, uric acid, and phosphorus levels, and a higher incidence of history of coronary artery disease (CAD) than the higher PA group. Linear regression analysis revealed that PA was significantly associated with BMI ( $B=0.18$ ,  $p=0.005$ ), serum albumin ( $B=-0.23$ ,  $p=0.001$ ), and creatinine levels ( $B=0.32$ ,  $p<0.001$ ). During a median follow-up of 16.7 months, 14.1% ( $n=27$ ) of patients experienced MACE and 11.0% ( $n=21$ ) died. Kaplan-Meier survival analysis showed that the higher PA group had significantly better survival, regardless of sarcopenia. Multivariate Cox analyses revealed that lower PA (0.51 [0.31-0.85],  $p=0.010$ ), higher IDWG (1.06 [1.01-1.12],  $p=0.028$ ) and C-reactive protein level (1.01 [1.01-1.02],  $p<0.001$ ), and a history of CAD (3.02 [1.04-8.77],  $p=0.042$ ) were significantly related to all-cause mortality after adjusting for other covariates.

**Conclusions:** PA measured by BIA was an independent factor in the prediction of mortality in MHD patients, regardless of sarcopenia. Intervention studies are needed to confirm if the improvement in PA is associated with better clinical outcome.

## SA-PO349

### Non-Invasive Hemodynamic Monitoring in Hemodialysis Using Electrical Impedance Tomography

Tongin Oh,<sup>1</sup> Jinwon Mok,<sup>1</sup> Ju young Moon,<sup>2</sup> Yang gyun Kim,<sup>2</sup> Sangho Lee,<sup>2</sup> Su Woong Jung.<sup>2</sup> *<sup>1</sup>Kyung Hee University, Seoul, Republic of Korea; <sup>2</sup>Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

**Background:** Intradialytic hypotension (IDH) is the most common complication in 20-30% of patients during hemodialysis (HD). Although blood pressure is monitored intermittently, it is insufficient to detect an IDH in real-time due to the rapidly changing hemodynamic status. Electrical impedance tomography (EIT) obtained from the thorax could simultaneously measure air-volume and blood-volume changes. We monitored the hemodynamic parameters from high-speed EIT images during HD.

**Methods:** In this clinical trial (IRB No.: KHNMC2020-08-006), 75 measurements were performed on 19 patients who had IDH in the past 3 months. An E-pad including 16 electrodes was attached to the surface of the thorax. Impedance images were acquired at 100 frames/s using a high-speed EIT system (AirTom-R, BiLab, Korea). Additionally, blood pressure was periodically obtained every 15 minutes using the NIBP unit in a hemodialysis machine. Extracted cardiac volume signal (CVS) from EIT images was used to calculate hemodynamic parameters like stroke volume (SV) and so on. Additionally, we obtained the thoracic fluid content (TFC) from the electrical admittivity changes at the end-expiration points. The equivalence of processed hemodynamic variables before and after the IDH occurrence or interventions was examined using the paired t-test.

**Results:** When various hemodynamic parameters were observed from 10 minutes before the onset of IDH to IDH time, we found that the SV significantly decreased by about 40-50%. As analyzing the type of clinical interventions during HD, SV was about 20-30% increase after 150 seconds of reducing the ultrafiltration rate (UF-) and about 50-60% increase after 180 seconds of injection of normal saline (S+) in Figure 1(a) and (b).

**Conclusions:** In this paper, real-time EIT images were non-invasively collected from patients during HD, and they could monitor hemodynamic changes caused by IDH and

clinical interventions. In the future study, we will apply this hemodynamic information to predict IDH, which allows personalized treatment based on real-time monitoring of hemodynamic indicators.

**Funding:** Government Support - Non-U.S.

Figure 1. Relative percentile changes of TFC, SV, HR, and CO when applying (a) UF and (b) S+.

## SA-PO350

### The Application of a Wearable Diffuse Reflectance Spectroscopy Monitor in the Assessment of Volume in Haemodialysis Patients

Vicki K. Sandys,<sup>1</sup> Lavleen Bhat,<sup>1</sup> Anna Ninan,<sup>1</sup> Colin Edwards,<sup>1</sup> Donal J. Sexton,<sup>2</sup> Conall M. O'Seaghda.<sup>1</sup> Haemodialysis Outcomes & Patient Empowerment group <sup>1</sup>Royal College of Surgeons in Ireland, Dublin, Ireland; <sup>2</sup>The University of Dublin Trinity College, Dublin, Ireland.

**Background:** The 2019 Kidney Health Initiative identified a need for solutions addressing fluid management in-between dialysis sessions. We aimed to assess the validity and reproducibility of a wearable hydration monitor in maintenance dialysis patients.

**Methods:** Prospective, single-arm observational study on 20 haemodialysis patients between January-June 2021 in a single haemodialysis centre. Participants wore a prototype wearable infrared spectroscopy device on their forearm during dialysis and nocturnally, termed the Sixty device. Bioimpedance measurements were performed 4 times using the body composition monitor (BCM) over 3 weeks. Sixty outputs a scale concordant with hydration level whereby 1 is euvoolemia. Values in kg are calculated from this scale. Sixty measurements were compared with the BCM overhydration (OH) index pre and post dialysis and with standard haemodialysis parameters.

**Results:** 12 out of 20 patients had usable data. 55% female, 80% white. Mean age was  $52 \pm 12.4$  years. The overall accuracy for predicting pre-dialysis categories of fluid status using Sixty was 0.56 [ $\kappa = 0.01$ ; 95% CI -0.39 – 0.42]. The accuracy for the prediction of post-dialysis categories of volume status was low [accuracy= 0.33,  $\kappa = 0.07$ ; 95% CI= -0.14 to 0.27]. Agreement using Bland-Altman plots is shown in Figure 1. Sixty outputs at the start and end of dialysis were weakly correlated with pre and post dialysis weights ( $r = 0.27$  and  $r = 0.27$ , respectively), as well as weight loss during dialysis ( $r = 0.31$ ), but not ultrafiltration volume ( $r = 0.12$ ). There was no difference between the change in Sixty readings during an overnight session, and the change in Sixty readings during a dialysis session [mean difference 0.09kg,  $t(39) = 0.38$ ,  $p = 0.71$ ].

**Conclusions:** A prototype wearable infrared spectroscopy device was unable to accurately assess changes in fluid status during or between dialysis sessions. In the future, hardware development and advances in photonics may enable the tracking of interdialytic fluid status.

**Funding:** Commercial Support - Enterprise Ireland Disruptive Technologies Innovation Fund grant DTIF 2019\_86

### Proof-of-Concept Model for the Prediction of Dry Weight in Hemodialysis Patients

Vicki K. Sandys,<sup>1</sup> Lavleen Bhat,<sup>1</sup> Donal J. Sexton,<sup>2</sup> Conall M. O'Seaghda.<sup>1</sup> Haemodialysis Outcomes & Patient Empowerment group <sup>1</sup>Royal College of Surgeons in Ireland, Dublin, Ireland; <sup>2</sup>The University of Dublin Trinity College, Dublin, Ireland.

**Background:** An automated, accurate and periodic assessment of dry weight using hemodialysis data would be a clinically useful, low cost, and rapidly scalable method of assessing fluid status.

**Methods:** A post-hoc analysis of a 3 week observational study in 20 patients (HOPE-02, ClinicalTrials.gov: NCT04623281). 143 features were created using clinical and calculated parameters over 1 or 2 weeks prior to the targeted session including variability

measures, differences, confidence intervals and interdialytic calculations. Averaged data was combined with single-session data. Dry weight was defined as the mean of BCM normohydration weights. Data was split 70:30 into training and testing sets. The algorithm was trained to predict overhydration (OH) index pre and post-dialysis as determined by the Fresenius Body Composition Monitor (BCM). Dry weight was derived by subtracting OH status from pre or post-dialysis weight. Model performance was evaluated using adjusted  $R^2$ . The error metrics used were mean absolute error (MAE) and root mean squared error (RMSE). Accuracy was calculated using categories of fluid status defined as overhydration  $> 1.1$  L, normohydration  $1.1 - 1.1$  L and underhydration  $< 1.1$  L.

**Results:** 20 subjects involving 44 haemodialysis sessions were used. A linear regression (LR) model combining single-session data with moving averages of data from the preceding 1 or 2 weeks was created. The final model had 9 features (Figure 1). The LR model predicting post-dialysis OH status outperformed a pre-dialysis OH model. Adjusted  $R^2$  for the model was 0.719. Training RMSE for post-dialysis OH= 1.12 kg, testing RMSE= 1.21 kg. The training RMSE for dry weight= 1.21 kg, the testing RMSE= 1.13 kg. The model had a classification accuracy of 81.8%.

**Conclusions:** This model represents an initial step in the creation of an automated assessment of dry weight. Work has begun on external validation and further development of this algorithm in a large dialysis dataset. A final model could potentially be embedded in a clinical decision support system for dry weight management.

**Funding:** Commercial Support - Enterprise Ireland Disruptive Technologies Innovation Fund grant DTIF 2019\_86

## SA-PO352

### When Is It Most Appropriate to Estimate Pulmonary Congestion Using Lung Ultrasound in Hemodialysis Patients?

Saleh Kaysi, Frederic Collart, Bakhtar Pacha, Joelle L. Nortier. *UVC Brugmann, Brussels, Belgium.*

**Background:** Lung ultrasound (LUS) helps detecting pulmonary congestion (PC) among hemodialysis (HD) patients, even when it is clinically asymptomatic. However, the best moment to measure PC in order to obtain the most useful and significant value is not clear. We conducted a longitudinal study comparing PC measured by LUS before and after the 1<sup>st</sup> and the 2<sup>nd</sup> HD session of the week.

**Methods:** Eighteen adult patients on maintenance HD for at least 6 months in our high care unit were included in this observational prospective study. Those diagnosed with interstitial lung disease or recent pneumonia, with previous lung surgery, and those with active cancer were excluded. B-lines scores were obtained by the same investigator using the 8-sites method by LUS, performed in near supine position before and after the regularly scheduled 1<sup>st</sup> and 2<sup>nd</sup> HD sessions of the week. The cut-off for B-lines scores was fixed to 0.54 line per zone. Total body volume using Bio-electrical Impedance Analysis (BIA) was measured before both HD sessions in each patient.

**Results:** Mean ultrafiltration (UF) volumes were not statistically different between both HD sessions ( $2,044 \pm 927$  vs  $1,820 \pm 865$  mL). Mean B-lines scores pre-HD N°1 ( $16 \pm 5.53$ ) were quite similar to those post-HD N°1 ( $15.3 \pm 6.63$ ) but were statistically different before and after HD session N°2 ( $16.2 \pm 5.26$  vs  $13.6 \pm 5.83$ ,  $P=0.03$ ). Mean B-lines scores measured before both HD sessions were unrelated to the inter-dialytic interval (72h vs 48h) but were strongly correlated together ( $R^2 = 0.688$ ,  $P < 0.0001$ ). A significant correlation was found between B-lines scores and BIA only before HD session N°2 ( $R^2 = 0.372$ ,  $P = 0.007$ ).

**Conclusions:** Our data suggest that PC, even if it decreased after HD session where UF was applied, remains quite frequent. The liquid shift from extra- to intra-vascular compartments performed at mid-week is probably more effective in reducing alveolar water to the point that might be detected as a significant lower level by LUS. Due to a shorter inter-dialysis interval, a reduced level of uremic toxins on mid-week HD session could also impact the pulmonary endothelium and capillary permeability. Consequently, we think that PC is most well correlated with dry weight when measured after the 2<sup>nd</sup> HD session of the week.

SA-PO353

Estimated Dry Weight: The Elusive Target

Juliet Gatiba, Momen Alsayed. *Hennepin Healthcare, Minneapolis, MN.*

**Introduction:** Volume assessment and management in end stage kidney disease (ESKD) has been shown to have a significant effect on intradialytic morbidity and long-term cardiovascular complication. In this report, we hope to elucidate the effects of volume management on cardiac function in dialysis patients and the importance of non-invasive imaging in volume assessment.

**Case Description:** A 40-year-old female with a history of ESKD on dialysis and heart failure with reduced ejection fraction of 45-50%, as well as other comorbidity was admitted for optimization of volume status prior to arteriovenous graft placement. She had been consistently above her estimated dry weight (EDW) of 52 kg and had failed outpatient volume optimization. On admission, she weighed 56 kg. She underwent hemodialysis on hospital days 1 and 2, with a total of 8 kg of ultrafiltration. Her weight decreased to 51.4kg. After achieving her EDW, a dobutamine stress echocardiogram done on day 3, showed severe biventricular systolic dysfunction with an ejection fraction of 27%. Cardiology evaluated the patient and recommended continued volume optimization followed by coronary angiography to evaluate for underlying coronary artery disease. She had 3 additional days of ultrafiltration of 10kg. Her weight decreased to 46.5kg. A repeat transthoracic echocardiogram on day 5, showed significant improvement in cardiac function as shown in Table 1. Coronary angiogram was deferred, and an arteriovenous graft was placed.

**Discussion:** This case reinforces the importance of assessing volume status in patients with ESKD on dialysis with underlying heart failure with reduced ejection fraction. It specifically points out the importance of using non-invasive imaging like transthoracic echocardiograms rather than solely depending on clinical picture and EDW for volume assessment. It also highlights how volume management can mitigate an elemental constituent of mortality in renal patients, cardiac function, and recovering ejection fraction with ultrafiltration.

Table 1

	Dobutamine Echo (Hospital day 3)	TTE (Hospital Day 5)
Left ventricular EF	27%	50%
Right ventricular EF	Severely decreased	Normal
Estimated RA pressure	17mmHg	13mmHg
Tricuspid valve insufficiency	2+ to 4+	1+

**Is Interdialytic Weight Gain Really All Fluid? A Longitudinal Study on Short Term Variability of Bioimpedance-Derived Normohydration Weight in Hemodialysis Patients**

Maximilian Waller,<sup>1,2</sup> Simon Krenn,<sup>3</sup> Sebastian Mussnig,<sup>2</sup> Manfred Hecking,<sup>2</sup> HD Research & Co. <sup>1</sup>Klinik Favoriten, Wien, Austria; <sup>2</sup>Medizinische Universität Wien, Wien, Austria; <sup>3</sup>Austrian Institute of Technology GmbH, Wien, Austria.

**Background:** Hemodialysis (HD) aims at reaching normohydration. The patient's weight measured predialysis and the desired target weight postdialysis usually determine the ultrafiltration volume, following the assumption that weight gain from the previous HD session (IDWG) consists of excess fluid.

**Methods:** Longitudinal bioimpedance spectroscopy (BIS) measurements with the Body Composition Monitor (BCM, Fresenius Medical Care Germany, v3.2) were obtained predialysis in 14 consecutive HD-sessions from 25 patients treated at the Chronic Hemodialysis Unit of Vienna General Hospital between October and December 2021. Short term variability of BIS derived parameters of fluid status was analyzed in an explorative fashion.

**Results:** The normohydration weight was 78.4±13.9 kg on average ± standard deviation (SD) and varied longitudinally for each patient, with the intra-patient SD ranging from 0.36 to 2.24kg (average: 0.8 kg). When the predialysis weight increased from one HD session to the next, the normohydration weight increased also, indicating that the patient had not only gained fluid (Figure 1).

**Conclusions:** Under the assumption that the BCM yields adequate results, and even if the target weight was set to perfect normohydration with 0L fluid overload remaining postdialysis, any weight gain above the previous predialysis weight will likely not consist of fluid alone. These results suggest that the target weight should not be fixed.

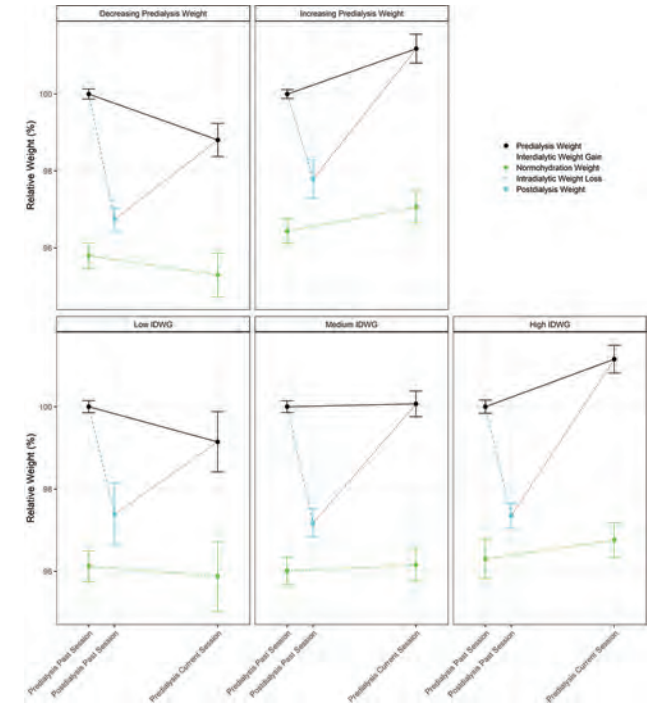

Figure 1

SA-PO355

Percent of Patients That Exceed Candidate Ultrafiltration Rate (UFR) Warning Levels Based on 3 Different Scaling Approaches (Unscaled UFR, UFR per kg, or UFR per kg^0.4)

Ariella E. Mermelstein,<sup>1</sup> John T. Daugirdas,<sup>2</sup> Jochen G. Raimann,<sup>1</sup> Yuedong Wang,<sup>3</sup> Peter Kotanko.<sup>1</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>University of Illinois Chicago College of Medicine, Chicago, IL; <sup>3</sup>University of California Santa Barbara, Santa Barbara, CA.

**Background:** Exceeding a UFR warning level of 13 ml/h per kg is associated with higher mortality hazard ratios (MHR) in large patients (*KI Reports*, 2022) while exceeding UFR warning levels not scaled to body size is less affected by body weight. UFRs associated with an MHR of 1.0 (average risk) can be estimated as 105 x kg^0.40 ml/hr. Thus, a new candidate UFR warning level might be set 33% (140/105) higher: 140 x kg^0.40 (ml/hr).

**Methods:** This retrospective cohort study was performed on 2542 incident U.S. hemodialysis (HD) patients. We examined the prevalence (12-mo average) of exceeded UFR warning levels: 800 ml/h, 10 ml/h per kg, or 140 x kg^0.40. Each warning level was associated with an MHR of 1.2 for an 80 kg patient.

**Results:** The estimated MHRs when exceeding each warning level are shown in the Table. The percent patients exceeding each warning level by weight decile is shown in the figure. Most patients exceeding the UFR/kg warning were smaller, while patients exceeding 800 ml/h were larger. A UFR warning based on 40 x kg^0.4 ml/hr was exceeded in about 15% of patients across a broad spectrum of body weight.

**Conclusions:** The percentage of patients exceeding unscaled UFR or UFR/kg warning levels is highly dependent on body weight. Warnings scaled by UFR/kg^0.4 may be more practical to implement, as they are exceeded by similar percentages of patients of different sizes; however, MHRs associated with exceeding UFR/kg^0.4 scaled warning levels still vary somewhat with body weight.

Weight (kg)	4-h max. weight removal (kg)			Mortality Hazard Ratio (MHR)		
	800 ml/h	140 x kg <sup>0.4</sup>	10 ml/h per kg	800 ml/h	140 x kg <sup>0.4</sup>	10 ml/h per kg
60	3.2	2.9	2.8	1.16	1.12	1.06
80	3.2	3.2	3.2	1.20	1.23	1.20
100	3.2	3.5	4.0	1.20	1.30	1.45
120	3.2	3.6	4.8	1.16	1.45	1.90

## SA-PO356

### Awareness, Understanding, and Self-Reported Adherence to Fluid and Salt Restriction Amongst a Maintenance Haemodialysis Population: A Survey Study

Yimeng Zhang, Mohammed A. Hameed, Khai Ping Ng, *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

**Background:** Fluid overload is a common complication amongst haemodialysis (HD) population and a major risk factor for cardiovascular and all-cause mortality. The majority of maintenance HD population are oligo-anuric, thus patients' consistent adherence to salt and fluid restrictions are critical. However, low or non-adherence is not uncommon. This study aimed to (1) examine awareness of salt restriction (SR) and fluid restriction (FR); (2) evaluate self-reported adherence to SR/FR and (3) their effect on clinical recorded interdialytic weight gain (IDWG) in HD population.

**Methods:** It was a survey study of maintenance HD patients in two HD centres in Birmingham, UK, conducted in October 2021. The self-administered survey consists of 21 questions, focusing on participants' awareness and adherence to SR/FR. Retrospective patient data were obtained from an electronic patient database (PROTON) on demographics, dialysis vintage and clinical recorded IDWG (mean of most recent six dialysis sessions). The data is analysed using SPSS version 27 and Microsoft Excel.

**Results:** In total, 81 patients completed the questionnaires. The median age was 65 (SD=14) years, 33 (41%) were females, mean dialysis vintage of 4 (SD=4) years and mean IDWG of 1.8 (SD=0.9) kg. Majority (70%) recalled being informed about FR but less so about SR (59%). Dialysis nurse was reported to be their key source of advice (57%), followed by dialysis doctor (43%), and renal dietician (27%). One in 5 did not recall advice on either restriction. Although the majority reported adherence to SR/FR as 'very often' (82%) or 'always' (67%), most have limited understanding on reasons of restriction with 21% not knowing the rationale. There was no significant difference in IDWG between participants who were aware of fluid restriction compared to those who were not (1.9kg vs 1.7kg,  $p=0.31$ ). There was also no significant correlation between self-reported fluid intake, compliance to restriction IDWG and their clinical recorded IDWG.

**Conclusions:** A significant proportion of HD patients reported to have limited awareness and understanding of SR/FR despite dedicated renal dietitian input in each HD centres. Dialysis nurses played a key role in educating HD patients. Self-reported awareness or adherence to SR/FR did not appear to be correlated with clinical IDWG in this HD cohort.

## SA-PO357

### Does Dialysis Drive Patients to Drink?

Anamika Adwaney, *Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background:** Greater fluid intake clearly leads to greater fluid removal. But reverse causality is also possible: greater fluid removal could lead to increased thirst, causing greater fluid intake. This study uses a within-patient analysis, to examine the relationship between ultrafiltration during dialysis sessions, and weight gained during the subsequent inter-dialytic interval.

**Methods:** In a urban dialysis centre, a random sample of patients was selected and stratified by unit, gender and access type. Patients were eligible if they had been receiving thrice-weekly dialysis for >1yr, and were clinically stable during this period, with no hospitalisations >14days. Data were analysed within patients, as well as between patient averages. Correlations were sought between variables within patients: the number of patients with a significant within-patient linear association ( $p<0.05$ ) is reported, as well as the significance of this number, as an observation from a binomial distribution with  $N=100, p=0.05$ .

**Results:** From 100 patients, median(IQR) age 67(53-75) years, observed over a year, complete records were available for 15263 (98%) dialysis sessions with the subsequent inter-dialytic interval. Mean( $\pm$ within-patient sd) pre-dialysis weight was 2.71( $\pm$ 1.15)% above target weight. Larger ultrafiltration volume was associated with greater subsequent inter-dialytic weight gain in 87/100 patients ( $p<0.001$ ), and 15% of the within-patient variation in inter-dialytic weight gain was explained by variation in ultrafiltration volume at the previous dialysis session. Lower post-dialysis weight (relative to target weight) was also associated with greater subsequent inter-dialytic weight gain in 77/100 patients ( $p<0.001$ ). In addition, the rate of weight gain was dependent on the duration of the inter-dialytic interval, being 1.21( $\pm$ 0.53)%/day during 2-day gaps, and 1.11( $\pm$ 0.38)%/day during 3-day gaps ( $p<0.001$ ), suggesting a non-linear pattern of fluid intake, greatest immediately after dialysis and diminishing over the course of the inter-dialytic interval.

**Conclusions:** Fluid intake in haemodialysis patients is determined by the ultrafiltration volume and end-weight of the most recent dialysis session, and diminishes during the inter-dialytic interval. Greater fluid intake is therefore a consequence, as well as a cause, of larger ultrafiltration volumes. This bidirectional relationship suggests the need to re-examine protocols for fluid removal in haemodialysis patients.

## SA-PO358

### Dialysate Sodium and the Risk of Intradialytic Hypertension: A Post Hoc Analysis of a Randomized Controlled Trial

Daniel S. Del Castillo Rix,<sup>1,2</sup> Despina Georgiadis,<sup>1,2</sup> Anika T. Singh,<sup>1,2</sup> Finnian R. McCausland,<sup>1,2</sup> *Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.*

**Background:** Higher dialysate sodium (DNa) concentrations are sometimes utilized to manage intradialytic hypotension. However, higher DNa has also been associated with thirst, inter-dialytic weight gain, and higher blood pressure (BP). Few studies have evaluated the risk of intra-dialytic hypertension (IDHyper) with higher DNa, especially among hospitalized hemodialysis (HD) patients.

**Methods:** We performed a post-hoc analysis of a double-blinded single center, randomized controlled trial (NCT02145260) in hospitalized patients on maintenance hemodialysis (N=139) that randomized patients to higher (142 mmol/L) vs. lower (138 mmol/L) DNa for up to six sessions. BP was measured pre-HD, every 15 minutes intra-HD, and post-HD. Mixed effects Poisson regression models were fit to assess the effect of higher vs. lower DNa on the rate of IDHyper, defined as any increase in systolic BP (SBP) from pre-HD to post-HD. Additional models were considered that adjusted for imbalances in baseline characteristics (SBP, sex, heart failure and pre-HD weight).

**Results:** 139 patients (305 study visits) were included in the present analyses. A total of 125 (41%) sessions were complicated by IDHyper. Using an intention-to-treat approach, there was no significant difference in rates of IDH for higher vs. lower DNa arms (IRR 1.17; 95% confidence interval (CI) 0.82,1.66). Effect estimates were accentuated in the adjusted models but did not reach statistical significance (IRR 1.60; 95% CI 0.95,2.70). A sensitivity analysis, where IDHyper was defined as SBP increase  $\geq 10$  mmHg from pre- to post-HD had similar patterns of association in the intent-to-treat (IRR 1.16; 95% CI 0.71,1.92) and adjusted analyses (1.50; 95% CI 0.74,3.04).

**Conclusions:** In this post-hoc analysis of a DNa trial in hospitalized HD patients, we found no significant difference in rates of IDHyper for higher vs. lower DNa. As effect estimates were accentuated in fully adjusted analyses, larger studies are needed to investigate the possible association of higher DNa with IDHyper in this population.

## SA-PO359

### The Unresolved Quest: The Higher the Dialysate Sodium, the Better?

Julie Pinter,<sup>1,2</sup> Hemodialysis registry working group from European Clinical Database 5 *Universitätsklinikum Würzburg, Würzburg, Germany; <sup>2</sup>University of Oxford, Oxford, United Kingdom.*

**Background:** Half of all people receiving maintenance dialysis die within 5-years of treatment. Mortality is largely driven by cardiovascular disease. A key contributor to cardiovascular disease in dialysis recipients is persistent fluid and sodium overload. During dialysis, sodium removal occurs largely via convective (ultrafiltration, weight loss) but also through diffusive losses (dialysate-plasma sodium gradient), the latter being largely dependent on the difference between serum and dialysate sodium concentration. Whether a higher or lower dialysate sodium influences survival is unknown, recognizing that other factors (i.e.; volume status, hemodynamic conditions) may influence the outcome.

**Methods:** We conducted an observational time-to-event analysis in a large international database of incident hemodialysis patients to assess the relation between dialysate sodium and all-cause mortality. We utilized the European Clinical Database 5 from Fresenius Medical Care, which is a real-time electronic health record repository for hemodialysis patient care management. From 72,163 incident hemodialysis patients in 25 countries dialysate sodium measurements were retrieved over a period of ten years. The cox regression model for time to death assessed dialysate sodium concentrations and serum sodium concentrations ( $< 137$  mmol/L, 137-139.9 mmol/L,  $\geq 140$  mmol/L). Age, sex, ethnicity, body mass index, comorbid conditions, laboratory values, treatment variables and mediators were adjusted for before the final model accounted for fluid overload, ultrafiltration, antihypertensive medication, diuretics and overweight.

**Results:** A dialysate sodium concentration of  $> 140$  mmol/L (21,705 observations) was consistently associated with lower all-cause mortality risk (adjusted HR 0.58 (0.46-0.73),  $<0.001$ ), as compared to 137-139.9 mmol/L (adjusted HR 0.74 (0.61-0.90), 0.003; 49,470 observations). We observed a lower mortality risk in iso-, and hyponatremic patients dialyzed against higher dialysate sodium prescriptions ( $> 140$  mmol/L).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Higher dialysate sodium concentrations are independently associated with better survival. This observational finding clearly delineates the need for high quality randomized evidence. The Randomised Evaluation of Dialysate Sodium on Vascular Events Study is currently underway to evaluate the practice of default dialysate sodium concentrations to guide policy development and improve hemodialysis outcomes.

### Muscle Sodium (Na<sup>+</sup>) Reduction by 2-Month Low-Na<sup>+</sup> Diet in Hemodialysis (HD) Patients

Hsin-Yu Fang, Kwan-Jin Jung, Shu H. Kwan, Ashley Morgan, Bailey J. Damore, Kenneth R. Wilund. *University of Illinois System, Urbana, IL.*

**Background:** Skeletal muscle is a tissue Na<sup>+</sup> reservoir. Higher muscle Na<sup>+</sup> concentration ([Na<sup>+</sup>]) is associated with pathological conditions in HD patients. This study aimed to test if 2 months of low-Na<sup>+</sup> intervention reduces muscle [Na<sup>+</sup>] in HD patients.

**Methods:** Eight HD patients (75% male; 61±11 yr) received commercial low-Na<sup>+</sup> meals and dietary counseling for 2 months. Meal provision frequencies for month 1 and 2 were 2 and 1 meal/day, respectively. Pre- and post-meal muscle [Na<sup>+</sup>] were assessed by <sup>23</sup>Na-MRI on non-HD days in 6 muscles: tibialis anterior (TA), extensor digitorum longus (EDL), peronei (PER), soleus (SOL), and lateral (LG) and medial (MG) gastrocnemius. Total <sup>23</sup>Na-MRI signals were split into intracellular (IC) and extracellular (EC)-weighted signals by biexponential fitting for further analysis. Changes in variables were tested by paired t-test or nonparametric equivalents.

**Results:** Muscle [Na<sup>+</sup>] was reduced in LG (P=.008) and MG (P=.02) but unchanged (P>.05) in other muscles from pre- to post-intervention (Fig. 1). IC-weighted <sup>23</sup>Na-MRI signal was reduced after intervention in 50% of muscles, while EC-weighted signal remained stable in all muscles tested (P-values shown in Fig. 2).

**Conclusions:** We found that the [Na<sup>+</sup>] in some muscles were decreased after the 2-month low-Na<sup>+</sup> diet, which may reflect more of the change in IC-weighted <sup>23</sup>Na signal. More studies are needed to confirm this and to determine its clinical implication.

**Funding:** Private Foundation Support

### Measured Serum Osmolality, Patient Symptoms, and Blood Pressure During Hemodialysis

Timothy E. Yen,<sup>1,2</sup> Despina Georgiadis,<sup>1</sup> Daniel S. Del Castillo Rix,<sup>1</sup> Finnian R. McCausland,<sup>1,2</sup> *Brigham and Women's Hospital, Boston, MA;*  
<sup>2</sup>*Harvard Medical School, Boston, MA.*

**Background:** End stage kidney disease (ESKD) is accompanied by accumulation of uremic solutes in the blood. Many of these are rapidly cleared during hemodialysis (HD), leading some to postulate that rapid decline in serum osmolality may be associated with development of adverse symptoms and intra-dialytic hypotension (IDH).

**Methods:** We performed a prospective cohort study of 50 hospitalized adult patients with ESKD receiving thrice-weekly HD. Measured Osmolality (mOsm) and intradialytic symptoms (ascertained by SMARRT-HD questionnaire) were measured at three time points during a single inpatient HD session (pre-HD, 60 minutes, and post-HD). Blood pressure was measured every 15 minutes during HD. Spearman correlations were used to compare the pre-HD mOsm with patient reported outcome symptom scores; logistic regression was used to assess the association of mOsm with IDH (any decline in SBP <90 mmHg).

**Results:** Mean age was 65±15 years; 42% were female. The calculated Osm was an average of 1 unit higher than the mOsm, but varied widely (median difference 1 [-1, 4] milliOsm/kg). Mean mOsm decreased from 292±9mOsm/kg pre-HD, to 286±6 at 60 mins, 284±5 post-HD. The mean total symptom score was 14.8±3 pre-HD, 14.5±2.8 at 60mins, 15.1±3.4 post-HD. Correlations between pre-HD mOsm and symptom scores are shown in Table 1. IDH occurred in 9 of 50 (18%) sessions; each 5 unit increase in mOsm was associated with 43% higher risk of IDH (OR 1.43; 95%CI 0.95 to 2.14). Similar estimates were noted upon adjustment for age, sex, and pre-HD SBP (OR 1.44; 95%CI 0.90 to 2.32).

**Conclusions:** This prospective cohort study in hospitalized HD patients found substantial variability between measured and calculated Osm. Minimal correlation between mOsm and symptoms were noted, but may have been limited by minimal symptom scores overall. Signals for association of higher pre-HD mOsm with higher risk of IDH require investigation in larger studies.

**Funding:** NIDDK Support, Commercial Support - Advanced Instruments

### Telehealth-Assisted Home Blood Pressure (BP) Monitoring for In-Center Hemodialysis Patients

Yoshitsugu Oji, Yunxi Zhang, Saurabh Chandra, Maria Clarissa Tio, Catherine C. Wells, Neville R. Dossabhoy, Tariq Shafi. *The University of Mississippi Medical Center, Jackson, MS.*

**Background:** Home BP monitoring is essential to guide BP management for in-center hemodialysis (HD) patients but is exceedingly difficult to obtain in clinical practice. We designed a pragmatic feasibility study of a telehealth-assisted protocolized home BP monitoring program (TH-BP) at an academic dialysis clinic.

**Methods:** From 02/03/22 to 05/13/22, we referred 37 in-center HD patients to the TH-BP, of which 25 started monitoring. All patients were provided a BP monitor with an appropriately sized cuff and a connected iPad. We averaged pre-HD sitting systolic BP (preSBP) over 30 days before and after TH-BP initiation and compared them with home SBP from the TH-BP.

**Results:** Patients had a mean age of 50 years and had been on dialysis for 6.5 years; 52% were females. The median (IQR) number of antihypertensives was 2 (1, 3). During a median follow-up of 63 days, the mean±SD frequencies of TH-BP measurements (per day) were 1.1±0.4 and 1.4±0.9 on HD days and non-HD days, respectively. After TH-BP initiation, the 30-day preSBP was 146±15 mmHg (p=NS vs. the pre-TH-BP period; **Table**). Home SBP was significantly lower than preSBP by 12±18 mmHg (p=0.005; **Figure**). Similar results were observed with diastolic BP (**Table**). Baseline patient characteristics did not predict patient willingness to participate in the TH-BP or the differences between preSBP and home SBP.

**Conclusions:** This is the first report to demonstrate successful pragmatic implementation of home BP monitoring for in-center HD patients in a routine clinical setting. Our findings of lower home SBPs suggest that BP management based on dialysis BPs alone may overeat.

**Funding:** Other U.S. Government Support

Comparison of 30-day pre- and post-TH-BP pre-HD BP and home BP

	Systolic BP			Diastolic BP		
	Pre-HD	Home	P-value	Pre-HD	Home	P-value
Before TH-BP	149±18	—	—	95±15	—	—
After TH-BP	146±15	134±26	<0.005	92±14	80±15	<0.001

Values are expressed as mean±SD, mmHg.  
P-values were calculated using the paired sample t-test.

**The Clinical Outcomes of Blood Pressure in Maintenance Hemodialysis Patients: A Single Center Study**  
Yuan Luo, Bing Zhuang, Guiling Wei, Hong Ye, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Background:** The prevalence of hypertension among patients on dialysis and the degree to which it is controlled is difficult to ascertain, and the relationship between blood pressure (BP) and clinical outcomes among hemodialysis patients is complex and incompletely understood. This study sought to assess the relationship between interdialytic blood pressure and clinical outcomes.

**Methods:** We enrolled 456 maintenance hemodialysis patients from January to May 2022 in our center, measured interdialytic office blood pressure and volume load, and the demographic characteristics, duration of dialysis, laboratory tests, as well as the cardiac function were collected and analyzed.

**Results:** A total of 456 patients were included in the investigation with the mean age of 58.3±12.1 years old and 58.5% were male. The most common cause of dialysis was diabetic nephropathy (32.3%) and the second was hypertensive nephropathy (21.8%). Only 30.1% of the population blood pressure was controlled, under 140/90mmHg and over 100/60mmHg. 29.4% of the patients BP was more than 140/90mmHg. 59.2% of the study population used 1-2 antihypertensive drugs, and the most commonly used antihypertensive drugs were calcium antagonists. We observed the relationship between blood pressure and duration of dialysis and found a positive correlation with blood pressure with dialysis age (P<0.0001). There is also a positive correlation between LV wall thickness and systolic blood pressure, with thicker LV walls in patients with high systolic blood pressure. We measured the blood pressure of the patients before and after the six-minute walk test. We found that after the exercise, most of the patients had an increase in blood pressure, but 33.8% of the patients had a decrease in blood pressure. 59.8% of patients with a decrease in blood pressure used calcium antagonists (P<0.0001).

**Conclusions:** Although most hypertensive patients were on antihypertensive drugs, the proportion of patients with interdialytic blood pressure under 140/90mmHg is low. Hypertension is also associated with cardiac remodeling, with thicker left ventricular wall in patients with higher blood pressure.

**Funding:** Government Support - Non-U.S.

SA-PO364

**Associations of Iron Sucrose and Intradialytic Blood Pressure**  
Anika T. Singh,<sup>1,2</sup> Timothy E. Yen,<sup>1,2</sup> Suraj Sarvode Mothi,<sup>3</sup> Sushrut S. Waikar,<sup>4,5</sup> Finnian R. McCausland,<sup>1,2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>St Jude Children's Research Hospital, Memphis, TN; <sup>4</sup>Boston Medical Center, Boston, MA; <sup>5</sup>Boston University School of Medicine, Boston, MA.

**Background:** Intradialytic hypotension (IDH) and intra-HD hypertension (IDHyper) are associated with higher morbidity and mortality in hemodialysis (HD). Many factors can contribute to intra-HD blood pressure (BP) changes, such as drugs with vasoactive properties that could destabilize already tenuous BP. Intravenous iron sucrose (IS) is commonly administered to correct iron deficiency, however, associations with altered hemodynamics are not consistent.

**Methods:** Using the DaVita Biorepository (n=950), unadjusted and adjusted Poisson and linear repeated measures models were fit to assess the association of IS administration

with IDH, IDHyper, and systolic BP (SBP) parameters. Model 1 was adjusted for age, sex, race, access, pre-HD SBP, Model 2; same as model 1, plus ultrafiltration (UF) rate, diabetes, heart failure, ischemic heart disease, peripheral vascular disease, lung disease, and erythropoietin (ESA) dose. Exploratory models were additionally adjusted for hemoglobin and endothelin-1 concentrations.

**Results:** Mean age was 56 ±20 years, 43% were females, and 38% were Black. Mean pre-HD SBP was 152 ±26 mmHg. Patients who received IS were younger, diabetic, had higher UF rate, and higher frequency of ESA use than those who did not. In fully adjusted models, the risk of IDH was 4% lower (incidence rate ratio [IRR] 0.96; 95%CI 0.93 to 0.99) in HD sessions where IS was administered. There was no association of IS with the risk of IDHyper (IRR 1.02; 95%CI 1.00 to 1.04). Further, in adjusted models, IS was associated with a 1.2 (95%CI 1.0 to 1.5) mmHg higher pre-HD systolic BP, 0.6 (95%CI 0.4 to 0.8) mmHg higher nadir SBP, and 0.7 (95%CI 0.5 to 1.0) mmHg higher post-HD SBP.

**Conclusions:** We observed an independent association of intravenous IS administration with a lower risk of IDH and higher intra-HD SBP parameters. Future studies to better understand the mechanisms underlying this pattern are warranted.

Association of iron sucrose administration with intradialytic hypotension and hypertension

	IRR Ratio (95% CI) for Iron Sucrose administration versus not				
	Unadjusted	Model 1	Model 2	Model 2 +Hb	Model 2 +Hb, +ET-1
IDH	0.93 (0.90 to 0.96)	0.94 (0.91 to 0.98)	0.96 (0.93 to 0.99)	0.96 (0.93 to 0.99)	0.95 (0.92 to 0.99)
IDHyper	1.00 (0.98 to 1.03)	1.04 (1.02 to 1.06)	1.02 (1.00 to 1.04)	1.02 (1.00 to 1.04)	1.02 (1.00 to 1.04)

**Development of a Deep Learning Model for Predicting Intradialytic Hypotension Using Multicenter Clinical Data Warehouse**  
Hanbi Lee,<sup>1</sup> Sungjin Chung,<sup>2</sup> Chul Woo Yang,<sup>1</sup> Eun Sil Koh,<sup>2</sup> Byung ha Chung,<sup>1</sup> <sup>1</sup>Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; <sup>2</sup>Catholic University of Korea Yeouido Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea.

**Background:** Intradialytic hypotension (IDH) is a serious complication of hemodialysis, and is associated with subsequent vascular access thrombosis, inadequate dialysis dose, cardiovascular morbidity, and mortality. Since the mechanism of IDH is multifactorial, its prediction is a clinical challenge. This study aims to develop a deep learning model to predict the occurrence of IDH using data from multicenter clinical data warehouse.

**Methods:** Data from 2,008 patients who underwent a total of 928,070 hemodialysis sessions at seven university hospitals in South Korea between Mar 2009 and Dec 2019 was used in this study. IDH was defined according to the following criteria: (i) nadir systolic blood pressure (SBP)<100mmHg when the initial SBP≥160mmHg, (ii) nadir SBP<90mmHg when the initial 90≤SBP<160mmHg, or (iii) ≥20mmHg intradialytic SBP fall when initial SBP<90mmHg. Patients were randomly divided into training, validation and test sets. The importance of features in the occurrence of IDH was calculated from logistic regression, random forest, and XGBoost models. A deep 1-dimensional convolutional neural network model was constructed to predict IDH and the prediction performance was compared with other machine learning models.

**Results:** The machine learning classifiers demonstrated that the important common features associated with IDH were the occurrence of IDH and the mean SBP of last hemodialysis session. The deep convolutional neural network model with medical records of the last session predicted IDH with recall of 51.2%, F1 score of 44.6%, and negative predictive value of 97.2%, underperforming than other machine learning classifiers. However, combining the medical records of last 3 sessions boosted the prediction performance by recall to 60.6% and F1 score to 58.3% with negative predictive value of 97.2%, outperforming all other classifiers.

**Conclusions:** The past hemodialysis information enables stronger classification performances on predicting IDH occurrences. Our deep learning model would be a reliable screening tool of IDH and allow clinicians to adjust hemodialysis settings before hemodialysis treatment to prevent IDH.

**Combined Impact of Mean and Variability of Non-HDL-Cholesterol on Cardiovascular Risk in Patients Undergoing Hemodialysis**  
Hanbi Lee, Chul Woo Yang, Byung ha Chung. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

**Background:** Non-HDL-cholesterol (non-HDL-C) is considered as a predictor of cardiovascular risk and outcomes in general population. However, dialysis patients show inconsistent association between serum cholesterol and mortality due to the presence of protein energy wasting and inflammation. Recently, a high visit-to-visit variability in cholesterol suggested to lead to the fluctuations in the composition of atherosclerotic plaques and link to cardiovascular events. This study is aimed to stratify cardiovascular risk with the mean and variability of non-HDL-C in patients undergoing hemodialysis.

**Methods:** A total of 457 hemodialysis patients who had no history of myocardial infarction (MI) or stroke and who underwent ≥5 lipid profile at the seven university hospitals in South Korea between Mar 2009 and Dec 2019 were included. Sex-specific quartiles of non-HDL-C mean were used. Visit-to-visit non-HDL-C variability was

calculated using the coefficient of variation, variability independent of the mean and average real variability. The low mean and high variability groups were defined as the lowest and highest quartiles of non-HDL-C mean and variability, respectively. The endpoints of the study were newly diagnosed MI, stroke, or all-cause death.

**Results:** The incidence of MI was significantly higher in the low mean/high variability group than in other 3 groups. In addition, multivariable cox regression analysis demonstrated that age (hazard ratio (HR) 1.053, 95% confidence interval (CI) 1.024-1.082) and low mean/high variability group were independent risk factor for MI (HR 3.311, 95% CI 1.380-7.944). When the subjects were divided into quartile groups, neither mean nor variability of non-HDL-C was associated with MI, stroke, and all-cause mortality.

**Conclusions:** Our results suggested that the combination of low mean and high variability of non-HDL-C is associated with an increased risk of MI in hemodialysis patients, while the mean and variability *per se* could not stratify cardiovascular risk.

SA-PO367

**Deep Learning Model for Predicting Intradialytic Hypotension Without Privacy Infringement: A Retrospective Two-Center Study**  
Hyung Woo Kim,<sup>1</sup> Seok-Jae Heo,<sup>2</sup> Minseok Kim,<sup>2</sup> Jakyung Lee,<sup>2</sup> Keun Hyung Park,<sup>1</sup> Gongmyung Lee,<sup>1</sup> Song in Baeg,<sup>3</sup> Young Eun Kwon,<sup>3</sup> Hye Min Choi,<sup>3</sup> Dong-jin Oh,<sup>3</sup> Chung-Mo Nam,<sup>2,4</sup> Beom Seok Kim.<sup>1</sup> <sup>1</sup>*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea;* <sup>2</sup>*Department of Biostatistics and Computing, Yonsei University Graduate School, Seoul, Republic of Korea;* <sup>3</sup>*Department of Internal Medicine, Hanyang University College of Medicine, Myongji Hospital, Goyang, Republic of Korea;* <sup>4</sup>*Division of Biostatistics, Department of Biomedical Systems Informatics, Yonsei University College of Medicine, Seoul, Republic of Korea.*

**Background:** Previously developed Intradialytic hypotension (IDH) prediction models utilize clinical variables with potential privacy protection issues. We developed an IDH prediction model using minimal variables, without the risk of privacy infringement.  
**Methods:** Unidentifiable data from 63,640 hemodialysis sessions (26,746 of 79 patients for internal validation, 36,894 of 255 patients for external validation) from two Korean hospital hemodialysis databases were finally analyzed, using three IDH definitions: (1) systolic blood pressure (SBP) nadir <90 mmHg (Nadir90); (2) SBP decrease ≥20 mmHg from baseline (Fall20); and (3) SBP decrease ≥20 mmHg and/or mean arterial pressure decrease ≥10 mmHg (Fall20/MAP10). To predict the IDH event after 10 minutes, segments for the previous 40 minutes from 10 minutes before each time points at which blood pressure was created. Areas under receiver operating characteristic (AUROCs) and precision-recall curves were used to compare machine learning and deep learning models by logistic regression, XGBoost, and convolutional neural networks.

**Results:** Among 344,714 segments, 9,154 (2.7%), 134,988 (39.2%), and 149,674 (43.4%) IDH events occurred according to three different IDH definitions (Nadir90, Fall20, and Fall20/MAP10, respectively). Compared with models including logistic regression, random forest, and XGBoost, the deep learning model achieved the best performance in predicting IDH (AUROCs: Nadir90, 0.905; Fall20, 0.864; Fall20/MAP10, 0.863) only using measurements from hemodialysis machine during dialysis session.

**Conclusions:** The deep learning model performed well only using monitoring measurement of hemodialysis machine in predicting IDH without any personal information that could risk privacy infringement.

SA-PO368

**Rescue Therapy for an Old Challenging Problem: Droxidopa in the Management of Intradialytic Hypotension**  
Lakshna Sankar, Kartik Kalra. *Geisinger Health, Danville, PA.*

**Introduction:** Intradialytic hypotension (IDH) is a common complication affecting 20-30% of hemodialysis (HD) sessions resulting in adverse outcomes. Here we describe the effect of droxidopa in our patient with resistant IDH.

**Case Description:** 72-year-old year old woman with past medical history of end stage kidney disease on HD since 2003, previous failed 2 kidney transplants, failed peritoneal dialysis, aortic and mitral valve replacement, atrial fibrillation on chronic anticoagulation. Her HD sessions were complicated by episodes of symptomatic hypotension for the last 1 - 2 years. Systolic blood pressure (SBP) ranging in between 60 - 70 mm Hg pre-dialysis. As a result, her HD sessions were cut short, and she was often symptomatic with altered mental status requiring multiple hospitalizations. Her symptoms during inter dialytic period were fatigue and exhaustion despite pharmacological measures such as midodrine 15 mg TID and fludrocortisone 0.2 mg on HD. To counter this, her intradialytic temperature was adjusted (cool dialysate), ultrafiltration (UF) goal was limited (different UF profiles were attempted), counseling on interdialytic weight gain and dietary sodium intake, blood flow and dialysate flow were reduced, dry weight was continuously reassessed, time on HD was increased. Despite above measures, she developed symptoms of volume overload as her HD sessions were continuously interrupted by IDH requiring multiple fluid boluses. Her cardiology and neurology evaluation were unremarkable. No evidence of adrenal insufficiency noted. Eventually she was prescribed droxidopa 100 mg TID and gradually escalated to 300 mg TID. Patient overall felt better (SBP improved to 110-120s mm Hg) and is currently tolerating UF removal without further interruptions in HD sessions and no further hospitalizations in the last 6 months.

**Discussion:** Management strategies for treatment and prevention of IDH is challenging. Droxidopa, a synthetic amino acid analogue metabolized to norepinephrine by dopa-decarboxylase increases blood pressure through peripheral arterial and venous

vasoconstriction. It is currently approved for neurogenic orthostatic hypotension. We propose that Droxidopa can be considered for off label use for symptomatic IDH after work up for other etiologies of hypotension is ruled out, potentially as a rescue therapy failing other pharmacological and conservative measures.

SA-PO369

**Higher NT-ProBNP Levels and the Risk of Intradialytic Hypotension at Hemodialysis Initiation**  
Katherine Curtis,<sup>1,2</sup> Sushrut S. Waikar,<sup>3</sup> Finnian R. McCausland.<sup>1,2</sup> *Mc Causland Lab* <sup>1</sup>*Brigham and Women's Hospital, Boston, MA;* <sup>2</sup>*Harvard Medical School, Boston, MA;* <sup>3</sup>*Boston University School of Medicine, Boston, MA.*

**Background:** Elevated N-terminal pro B-type natriuretic peptide (NT-proBNP) accompanies cardiac dysfunction and hypervolemia and is a potent predictor of adverse outcomes in patients initiating hemodialysis (HD). These patients often experience intradialytic hypotension (IDH), which may partially reflect cardiac dysfunction, but the association of NT-proBNP with IDH is not clear.

**Methods:** We performed a post-hoc analysis of a double-blind, placebo-controlled, randomized trial that tested mannitol vs. placebo in 52 patients initiating HD (NCT01520207). Pre-HD NT-proBNP was measured in samples obtained prior to the 1<sup>st</sup> and 3<sup>rd</sup> sessions (n=87). Mixed-effects models (adjusting for randomized treatment, sex, Black race, age, diabetes, heart failure (HF), catheter use, pre-HD systolic blood pressure (SBP), pre-HD weight, ultrafiltration (UF) volume, sodium, bicarbonate, serum urea nitrogen, phosphate, albumin, and hemoglobin) were fit to examine the association of NT-proBNP with intradialytic SBP decline (pre-HD minus nadir SBP). Additionally, mixed-effects Poisson regressions were fit to determine the association with IDH (≥20 mmHg decline in SBP from pre-HD SBP).

**Results:** Mean age of patients was 55±16 years and 32% had baseline HF. The median pre-HD NT-proBNP across all sessions was 5498 [2011, 14790] pg/mL. A total of 26 sessions were complicated by IDH. In adjusted models, each unit higher log-NT-proBNP was associated with 5.8mmHg less decline in intra-dialytic SBP (95%CI -9.2 to -2.5, P=0.001). Higher pre-HD NT-proBNP was associated with a 54% lower risk of IDH per log unit NT-proBNP (IRR 0.46, 95%CI 0.23-0.92, P=0.03). There was no evidence for effect modification by randomized treatment (P-interaction=0.68).

**Conclusions:** In patients initiating HD, higher pre-HD NT-proBNP is associated with less decline in intradialytic SBP and lower risk of developing IDH. Future studies should investigate if higher pre-HD NT-proBNP levels can help identify hypervolemic patients who might tolerate more aggressive UF.

**Funding:** NIDDK Support

Baseline SBP characteristics according to tertiles of NT-proBNP

Characteristic	NT-proBNP tertiles (pg/mL)			P-trend
	Tertile 1 N = 16	Tertile 2 N = 12	Tertile 3 N = 15	
Pre-HD SBP	141 ± 20 138 [126, 158]	148 ± 24 142 [129, 160]	151 ± 30 153 [124, 178]	0.25 0.23
Minimum SBP	119 ± 21 120 [110, 126]	134 ± 15 136 [124, 141]	139 ± 30 137 [116, 168]	0.02 0.03
Post-HD SBP	143 ± 18 147 [133, 156]	148 ± 18 146 [140, 159]	161 ± 29 164 [144, 182]	0.03 0.06
SBP drop	23 ± 22 19 [11, 23]	14 ± 17 8 [2, 27]	13 ± 14 11 [7, 13]	0.12 0.06

**Associations of Body Compositions, Intradialytic Hypotension, and Mortality in Hemodialysis Patients**  
Sonoo Mizuiri,<sup>1</sup> Yoshiko Nishizawa,<sup>1</sup> Toshiki Doi,<sup>1,5</sup> Kazuomi Yamashita,<sup>1</sup> Kenichiro Shigemoto,<sup>1</sup> Koji Usui,<sup>2</sup> Takayuki Naito,<sup>3</sup> Michiko Arita,<sup>4</sup> Takao Masaki.<sup>3</sup> <sup>1</sup>*Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan;* <sup>2</sup>*Ichiyokai Ichiyokai Clinic, Hiroshima, Japan;* <sup>3</sup>*Ichiyokai Yokogawa Clinic, Hiroshima, Japan;* <sup>4</sup>*Ichiyokai East Clinic, Hiroshima, Japan;* <sup>5</sup>*Hiroshima Daigaku Byoin, Hiroshima, Japan.*

**Background:** Intradialytic hypotension (IDH) is a serious complication of hemodialysis. We studied the relationship among body composition, intradialytic hypotension, and mortality in dialysis patients.

**Methods:** Subjects were maintenance hemodialysis (HD) patients. The study timeline included the baseline (day 1), exposure assessment period (days 1–22), and outcome assessment period (day 23–3 years). IDH was defined as a nadir systolic blood pressure (SBP) <90 mmHg for at least two of ten HD sessions during the exposure assessment period. Clinical data at baseline and post-dialysis body composition parameters using bioimpedance spectroscopy in days 1–22 were assessed. Patients were divided into IDH and non-IDH groups. Kaplan–Meier curves and Cox proportional hazard models were used to assess patient survival.

**Results:** Overall (n=306), age, dialysis duration, and diabetes (DM) prevalence were 65±12 years, 108±100 months, and 42%, respectively. The IDH group (n=30) showed significantly (P <0.05) lower serum albumin and intracellular water (ICW) (14.7±3.6 vs. 16.2±3.7 L) levels and lower lean tissue index (LTI) (11.7±2.7 vs. 12.3±2.6 kg/m<sup>2</sup>,

$P=0.06$ ) but higher extracellular/intracellular (E/I) water ( $0.96\pm 0.17$  vs.  $0.92\pm 0.13$ ,  $P=0.16$ ) compared with those in the non-IDH group ( $n=276$ ). Fifty all-cause deaths and 11 cardiovascular (CV) deaths occurred over 3 years. ICW (odds ratio [OR] 0.78), LTI (OR 0.79), and E/I (OR 27.52) were significant predictors for IDH, independent of age, pre-dialysis SBP, and ultrafiltration volume ( $P<0.05$ ). Patients were also grouped based on the mortality cut-off values for ICW, LTI and E/I. Patients with ICW  $\geq 13.6$  L, LTI  $\geq 15.5$  kg/m<sup>2</sup>, and E/I  $<0.90$  showed significantly higher 3-year Kaplan–Meier survival curves than those in the other groups ( $P<0.05$ ). Cox models (adjusted for DM and dialysis duration) showed that ICW, LTI, E/I, and IDH were significant predictors for all-cause mortality ( $P<0.01$ ). After adjusting for DM, dialysis duration, age, sex, CV diseases, serum albumin, C-reactive protein, phosphate, and magnesium levels, only IDH was a significant predictor for 3-year all-cause and CV mortality ( $P<0.05$ ).

**Conclusions:** Associations between IDH, body composition, and mortality were confirmed, and an optimal body composition to prevent IDH needs to be determined.

**Funding:** Private Foundation Support

## SA-PO371

### Impact of Intradialytic Hypotension Following Transition From Continuous Renal Replacement Therapy to Intermittent Hemodialysis on Mortality

Seong Geun Kim, Donghwan Yun, Jinwoo Lee, Yong Chul Kim, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Seung Seok Han. Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Transition of dialysis modalities from continuous renal replacement therapy (CRRT) to intermittent hemodialysis (iHD) is frequently conducted during a recovery phase of critically ill patients with acute kidney injury. Herein, we addressed the occurrence of intradialytic hypotension (IDH) after transition, and its association with the risk of mortality.

**Methods:** A total of 541 patients with acute kidney injury who attempted transition from CRRT to iHD were retrospectively collected from 2010 to 2020 at Seoul National University Hospital, Korea. IDH was defined as a discontinuation of dialysis because of hemodynamic instability plus when nadir systolic blood pressure was less than 90 mmHg or a decrease in systolic blood pressure  $\geq 20$  mmHg occurred during the 1<sup>st</sup> session of iHD. Odds ratios (ORs) of outcomes, such as in-hospital mortality and weaning from RRT, were measured using logistic regression model after adjusting multiple variables.

**Results:** IDH occurred in 197 (36%) patients, and their mortality rate (44%) was higher than 19% in those without IDH (OR, 2.64 [1.70–4.08]). The iHD sessions with IDH delayed a successful weaning from RRT with a OR of 0.62 [0.43–0.90] compared with those without IDH. Factors, such as low blood pressure, high pulse rate, low urine output, use of mechanical ventilator and vasopressors, and hypoalbuminemia, were associated with the IDH risk.

**Conclusions:** The IDH occurrence following transition from CRRT to iHD is associated with high mortality and delayed weaning from RRT.

## SA-PO372

### Proteomic Biomarker to Predict Intradialytic Hypotension During Hemodialysis

Hyung Eun Son,<sup>1</sup> Seokwoo Park,<sup>2</sup> Ho Jun Chin.<sup>2</sup> <sup>1</sup>Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; <sup>2</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

**Background:** Predicting intradialytic hypotension would be beneficial for the survival of patients on HD. Yet, previous studies on proteomic approach to novel biomarkers are rare.

**Methods:** 150 patients undergoing maintenance hemodialysis were enrolled. Proteomic analysis was done using liquid chromatography-tandem mass spectrometry in serum samples. We also attained clinical information, laboratory tests, and body composition by bioimpedance analysis. The main outcome was IDH over 3 months following the enrollment. IDH was defined as more than 2 episodes of hypotension requiring intervention. Patients were divided into two groups according to the development of IDH. After data processing, differentially expressed protein (DEP)s according to

the development of IDH were obtained. Feature selection was done by least absolute shrinkage and selection operator (LASSO) analysis.

**Results:** Among 150 patients, 35 patients developed IDH. Comparing to those without IDH, they were older, obese, diabetic, and had low skeletal muscle mass per body weight. Among 18 DEPs according to the development of IDH ( $p<0.05$ ), ITIH4 was remained as a DEP cut by FDR  $< 5\%$ . Comparing with DEPs by 2 quantiles of skeletal muscle mass per weight, 8 DEPs were overlapped: C4BPA, VWF, VTN, IGFBP2, PROS1, LGALS3BP, CHI3L1, and DAG1. In feature selection, 9 proteins including ITIH1, C4BPA, ATRN, ITIH4, VWF, VTN, CP, FCN3, IGFBP2 as gene names, were important as much as clinical factors. In additional analysis, no DEPs were selected except skeletal muscle mass per weight.

**Conclusions:** In this study, we suggested biomarkers that showed feature importance as much as well-known clinical variables influencing intradialytic hypotension. Measurement of novel serum biomarkers would be useful to predict intradialytic hypotension.

Diagrams of DEPs indicating overlapping proteins among DEPs to IDH (List 1) or skeletal muscle mass by body weight (List 2), analyzed by student's t test

### Intradialytic Exercise on Cardiac Response to Hemodialysis

Lisa Hur,<sup>1</sup> Jarrin D. Penny,<sup>2</sup> Justin R. Dorie,<sup>2</sup> Christopher W. McIntyre.<sup>2</sup> <sup>1</sup>Western University, London, ON, Canada; <sup>2</sup>London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada.

**Background:** Hemodialysis (HD) is associated with high rates of cardiovascular mortality due to recurrent cardiac ischemia-reperfusion injury during each HD session. Intradialytic exercise (IDE) can improve intradialytic hemodynamic tolerability, although its mechanisms remain elusive. The objective of the present study was to use intradialytic CT perfusion imaging and echocardiography to evaluate cardiac injury during HD with and without exercise.

**Methods:** 10 participants underwent two intradialytic imaging sessions: (1) the control visit (no IDE) and (2) the IDE visit, cycling on a stationary ergometer during the first 30 mins of HD treatment. In both visits, dynamic contrast-enhanced CT scans (Revolution CT, GE) were conducted at baseline, peak HD stress, and 30 mins post HD. Following each dynamic CT scan, apical 4-chamber and 2-chamber views of the heart were acquired with 2D echocardiography (Vivid Q, GE). The dynamic CT images were analyzed using the Johnson-Wilson-Lee tracer kinetic model to quantify global myocardial perfusion (MP) of the left ventricle. Using echocardiography, systolic function was evaluated by measuring segmental longitudinal strain (LS) using commercially available software (EchoPAC, GE). Myocardial segments demonstrating  $>20\%$  reduction in LS compared to baseline were defined as regional wall motion abnormalities (RWMA).

**Results:** During the control visit, MP significantly dropped from baseline to peak HD stress ( $1.0 \pm 0.4$  to  $0.8 \pm 0.2$  ml/min/g,  $p=0.02$ , Fig 1A), followed by partial recovery post HD ( $0.9 \pm 0.2$  ml/min/g,  $p=0.5$ , Fig 1A). Similar results were found during the exercise visit (baseline:  $0.9 \pm 0.3$  ml/min/g, peak HD:  $0.7 \pm 0.1$  ml/min/g, post HD:  $0.8 \pm 0.2$  ml/min/g,  $p=0.05$ , Fig 1B). MP of control and exercise visits were not significantly different. The number of myocardial segments experiencing RWMA at peak stress were comparable between the two visits (5 segments, Fig 2). However, fewer RWMA post HD were observed with intradialytic exercise compared to no exercise ( $p=0.2$ ).

**Conclusions:** Preliminary results indicate that MP response to HD remain unaffected by the IDE. A decrease in the number of RWMA post-HD with exercise suggests potential exercise-associated cardiac resilience to HD-induced cardiac injury.

## SA-PO374

## The Effect of Coronary Artery Status on Myocardial Perfusion Response to Hemodialysis

Lisa Hur,<sup>1</sup> Ali Islam,<sup>3</sup> Jarrin D. Penny,<sup>2</sup> Justin R. Dorie,<sup>2</sup> Christopher W. McIntyre.<sup>2</sup> <sup>1</sup>Western University, London, ON, Canada; <sup>2</sup>London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada; <sup>3</sup>Saint Joseph's Health Care London, London, ON, Canada.

**Background:** Hemodialysis (HD) is associated with repetitive ischemia-reperfusion cardiac injury occurring during each treatment that accumulates with subsequent treatments. Conventional cardiovascular therapies effective in patients with atherosclerotic disease or myocardial infarction have been largely ineffective in treating HD-induced injuries. The objective of the present study was to use coronary CT angiography (CCTA) and intradialytic CT perfusion imaging to noninvasively evaluate the myocardial perfusion response during HD in patients with and without significant coronary artery stenosis.

**Methods:** CCTA images were acquired prior to HD (baseline) on ten patients and assessed by an experienced radiologist for clinically significant stenoses. In addition, dynamic contrast-enhanced CT scans (Revolution CT, GE) were conducted at baseline, peak HD stress, and 30 mins post HD. The dynamic CT images were analyzed using the Johnson-Wilson-Lee tracer kinetic model to quantify global myocardial perfusion (MP) of the left ventricle.

**Results:** Three patients were identified with clinically significant stenoses. In all patients, MP decreased from baseline to peak HD. However, MP response to HD was not significantly different between patients with clinically significant stenoses and those with no stenosis (Fig 1).

**Conclusions:** Preliminary results indicate that the coronary artery status does not affect the myocardial perfusion response to HD. This suggests that the decrease in MP during HD is caused by the treatment itself, rather than by coronary artery stenosis.

Fig 1. Mean global MP at baseline, peak HD stress, and 30 mins post HD in patients with no stenosis and with significant stenosis. Error bars represent standard error of the mean. Significance of \*\* and \* in no stenosis group denote  $p < 0.01$  and  $p < 0.05$ , respectively.

## SA-PO375

## Residual Kidney Function and Sudden Cardiac Death Among Incident Hemodialysis Patients

Masaki Okazaki,<sup>1,2</sup> Yoshitsugu Obi,<sup>3</sup> Tariq Shafi,<sup>3</sup> Connie Rhee,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Nagoya University Graduate School of Medicine, Nagoya, Japan; <sup>3</sup>The University of Mississippi Medical Center, Jackson, MS.

**Background:** The survival benefit of residual kidney function (RKF) in hemodialysis patients is likely tied to advantages in fluid and electrolyte management. However, data have been lacking on the relationship between the RKF and sudden cardiac death (SCD). We therefore conducted a nationally representative cohort study to examine the association of RKF with SCD in patients initiating thrice-weekly in-center hemodialysis.

**Methods:** We analyzed a longitudinal data from a retrospective cohort study examining incident dialysis patients at a facility operated by a large dialysis organization in the U.S. from 2007 to 2011. The predictor was RKF measured by renal urea clearance ( $CL_{urea}$ ) at baseline and 6 months after initiating hemodialysis. Multivariable cause-specific proportional hazards models were fitted for primary analysis, and restricted cubic splines were fitted for secondary analysis for change in RKF to estimate SCD mortality.

**Results:** Baseline cohort of 39,749 patients were categorized into five groups according to baseline renal  $CL_{urea}$  ( $<1.5$ ,  $1.5$  to  $<3.0$ ,  $3.0$  to  $<4.5$ ,  $4.5$  to  $<6.0$ , and  $\geq 6.0$  mL/min/1.73 m<sup>2</sup>). The mean age was 61.6 years, and the median baseline renal  $CL_{urea}$  was 3.1 mL/min/1.73 m<sup>2</sup>. Among a total of 7,737 all-cause deaths, 1,909 SCDs (24.7%) with the incidence rate of 34.0 per 1,000 person-years were observed. Compared with patients who had baseline renal  $CL_{urea}$  of  $>6.0$ , those of  $<1.5$  was associated with higher risk of SCD: case-mix adjusted hazard ratio was 1.47 (95% CI, 1.27–1.73). Of 12,169 patients with available data on change in renal  $CL_{urea}$ , a decline in renal  $CL_{urea}$  during the first 6 months of hemodialysis also showed a gradient association with increased SCD mortality.

**Conclusions:** Lower RKF and loss of RKF were associated with higher SCD mortality in patients starting thrice-weekly in-center hemodialysis.

## Sudden Cardiac Death

## SA-PO376

## Dietary Protein Intake and Coronary Artery Calcification Changes Over Time in a Prospective Hemodialysis Cohort

Masaki Okazaki,<sup>1,2</sup> Yoko Narasaki,<sup>1</sup> Connie Rhee,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Nagoya University Graduate School of Medicine, Nagoya, Japan.

**Background:** Hemodialysis (HD) patients are recommended a targeted protein intake of 1.0–1.2 g/kg/day. Increasing dietary protein intake while maintaining total daily food intake can be compensated by increasing the ratio of total protein per energy, and a higher ratio may be sought to achieve by increasing animal protein content. This study aimed to examine the relationship between dietary protein intake as a percentage to daily energy intake and their association with coronary artery calcification (CAC) and its changes over time in HD patients.

**Methods:** In a secondary analysis of 93 participants from the Anti-Inflammatory and Anti-Oxidative Nutrition in Hypoalbuminemic Dialysis Patients (AIONID) trial, we examined the association of total dietary protein to energy percentage assessed by 3-day food records with log-transformed annualized change in Agatston CAC score. Linear regression model was used for the comparison of tertile groups, and restricted cubic splines were fitted for continuous model.

**Results:** Analytic cohort of 70 patients with 2-point CAC measurements were categorized into tertiles according to the percentage of total protein to energy intake. Mean±SD age was 59.1±12.8 years. There were statistically significant trends toward higher plant protein proportion across lower total protein to energy proportion. Compared to the reference of the lowest tertile protein ratio group, middle tertile protein group exhibited a positive slope of  $\ln[\text{CAC score}+1]$  ( $\beta=0.93$ , 95% CI: 0.18 to 1.56,  $p=0.007$ ). In continuous spline models, we observed reverse U-shaped association of protein to energy proportion with CAC progression.

**Conclusions:** Compared to the group with the lowest tertile of dietary protein to energy intake ratio, the middle tertile group was associated with a higher risk of CAC progression. Our findings may indicate that the modulating dietary protein intake by increasing quantity without modulating quality including proportion of animal vs plant protein may not achieve the goal of preventing vascular calcification.

SA-PO377

Predictors of Accelerated Residual Kidney Function Loss on Incremental Hemodialysis

Joana Medeiros, Bárbara Ribeiro, Renata Carvalho, José M. Bastos, Rui M. Costa, Antonio Ramalheiro. *Hospital de Braga, Braga, Portugal.*

**Background:** Preservation of residual kidney function (RKF) has been the driving impetus for incremental hemodialysis (IHD). Factors such primary renal disease, comorbidities and haemodialysis prescription may predispose to an earlier loss of residual renal function.

**Methods:** Retrospective analysis of 37 patients who begun twice-weekly IHD from March 2017 to May 2022 at Braga’s Hospital Dialysis Unit (Portugal). RKF was assessed monthly by residual renal urea clearance and normo-hydrated weight (NHW) was evaluated quarterly by bioelectrical impedance analysis. Inclusion criteria to IHD were: urea clearance  $\geq 3\text{mL/min/1.73m}^2$ , absence of advanced heart/liver failure and absence of active cancer. Transition on low-flux to high-flux dialysis/haemodiafiltration occurred according to the RKF loss and a maximum ultrafiltration rate of 10mL/kg/hour was determined. An accelerated RKF loss was defined as a loss of at least 25% in the first 3 months.

**Results:** The mean age was 58 $\pm$ 13years, 54.1% were male, and 97% were Caucasian. Diabetic nephropathy (32.4%) was the most common cause of ESRD and arteriovenous fistula was the primary vascular access (54.1%). The Charlson comorbidity index was 4.7 $\pm$ 2.2 with 89.2% of patients having hypertension and 40.5% diabetes. Baseline measured glomerular filtration rate (GFR) was 7.5 $\pm$ 2.3mL/min/1.72m<sup>2</sup> and 93.3% had a urinary output greater than 1000mL/day. During the first trimester, accelerated RKF loss occurred in 30% of patients, mainly those with older age, diabetes, Charlson comorbidity index higher than 6 and lower GFR at the baseline. Association with first month intradialytic symptomatic hypovolemia events and dry weigh exceeding NHW (>1kg) was also found. In multivariate analysis, only baseline GFR <7mL/min/1.73m<sup>2</sup> was a predictor of accelerated decline in RKF (OR 25.4, CI 95% 1.2-530). Loss of RKF at 3 months was significantly associated with lower IHD survival during the first year (28% vs 69%, log Rank test p=0.04).

**Conclusions:** Factors such as age, comorbidities, first month intradialytic complications and unadjusted dry weigh prescription may influence the rate of RKF loss. Moreover, lower baseline GFR was an independent predictor of accelerated decline in RKF. Late referral to IHD or accelerated loss RKF trend that begun in pre dialysis stages may explain these findings.

SA-PO378

A Retrospective Analysis of Fluid and Infection-Related Hospitalizations in Clinics Participating in ESRD Seamless Care Organizations

Rachel A. Lasky, Linda Ficociello, Len A. Usvyat, Terry L. Ketchersid, Benjamin E. Hippen. *Fresenius Medical Care, Waltham, MA.*

**Background:** In a pilot program aimed at controlling costs and improving care for patients (pts) with end-stage renal disease (ESRD), the Center for Medicare and Medicaid Innovation (CMMI) created ESRD Seamless Care Organizations (ESCOs) in 2015. We conducted a retrospective data analysis to evaluate potentially preventable hospitalizations, namely fluid-related and infection-related, in ESCO-eligible pts who received dialysis at ESCO vs non-ESCO clinics.

**Methods:** Adult, Fresenius Kidney Care (FKC) hemodialysis pts who met ESCO eligibility criteria between 10/2015-3/2017 were included. ESCO pts received dialysis at 1 of 6 FKC ESCO markets, while non-ESCO pts were dialyzed at nearby FKC facilities propensity score matched on: # ESCO eligible pts, mean dialysis vintage, mean pt age, %pts with diabetes, %pts with dual-eligibility, median income by zip code, and geographical proximity. Fluid and infection-related hospitalizations were identified using ICD codes from electronic medical records. Crude and adjusted Poisson regression models were used to compare the risk of fluid- and infection-related hospitalizations between ESCO and non-ESCO groups, overall and stratified by the presence of catheters (CVC).

**Results:** 13,994 pts (7,398 ESCO and 6,596 non-ESCO) were included. Compared to pts attending non-ESCO clinics, pts attending ESCO clinics had 0.88 (p=0.0001) and 0.85 (p < 0.0001) times the rate of infection-related and fluid-related hospitalizations, respectively (table). With multivariate adjustment, only fluid-related hospitalizations remained statistically significant (RR:0.84, p=0.0002). The stratified analysis demonstrates that the pts with most reduced risk of infection and fluid-related hospitalizations are the pts being dialyzed with CVC (table).

**Conclusions:** Pts that received hemodialysis in FKC ESCO clinics experienced a lower rate of fluid-related hospitalizations when compared to pts in non-ESCO clinics, a benefit primarily realized by patients dialyzing with a CVC.

**Funding:** Commercial Support - Fresenius Medical Care

Circulating Follistatin-Like Protein-1 Levels Predicts the Risk of Cardiovascular Events and Death in Hemodialysis Patients

Dae Kyu Kim,<sup>1</sup> Seok hui Kang,<sup>2</sup> Jin sug Kim,<sup>3</sup> Yang gyun Kim,<sup>1</sup> Yu ho Lee,<sup>4</sup> Dong-Young Lee,<sup>5</sup> Ju young Moon,<sup>1</sup> Sangho Lee,<sup>1</sup> Kyung hwan Jeong,<sup>3</sup> Hyeon Seok Hwang,<sup>3</sup> <sup>1</sup>*Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea;* <sup>2</sup>*Yeungnam University Medical Center, Daegu, Republic of Korea;* <sup>3</sup>*Kyung Hee University Medical Center, Seoul, Republic of Korea;* <sup>4</sup>*CHA Bundang Medical Center, Seongnam, Republic of Korea;* <sup>5</sup>*Korea Veterans Health Service, Wonju, Republic of Korea.*

**Background:** Follistatin-like protein-1 (FSTL-1) is cardiokine which are involved in the induction of angiogenesis, stimulation of cardiomyocyte proliferation and improvement of endothelial function. However, the clinical significance of circulating FSTL-1 levels remains unclear in hemodialysis patients.

**Methods:** A total 376 HD patients from the K-cohort were prospectively enrolled from June 2016 to March 2020. Plasma FSTL-1 level, plasma concentration of biomarkers and echocardiographic findings at baseline were examined. The primary endpoint was defined as a composite of CV events and death.

**Results:** Plasma FSTL-1 level had positive correlation with circulating cardiac remodeling (matrix metalloproteinase-2) and inflammatory markers (TNF- $\alpha$ , MCP-1). In multivariate linear regression analysis, FSTL-1 level was negatively associated with left ventricular ejection fraction ( $\beta$  = -0.36;  $P$  = 0.011). The cumulative event rate of the composite of CV event and death was significantly greater in FSTL-1 tertile 3 ( $P$  = 0.037). FSTL-1 tertile 3 was also associated with an increased cumulative event rate of CV events ( $P$  = 0.048). In Cox regression analysis, FSTL-1 tertile 3 was associated with a 1.80-fold risk for the composite of CV events and death (95% confidence interval [CI], 1.06–3.08), and a 2.29-fold risk for CV events (95% CI, 1.15–4.54) after adjustment for multiple variables.

**Conclusions:** Plasma level of FSTL-1 levels were independently associated with left ventricular systolic dysfunction and higher circulating FSTL-1 levels independently predicted the composite of CV events in HD patients.

Evaluation of Myocardial Ischemia in Maintenance Hemodialysis Patients

Bing Zhuang, Yuan Luo, Guiling Wei, Hong Ye, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Background:** Myocardial ischemia is a common and complex phenomenon in maintenance hemodialysis patients; however, their clinical manifestations are very insidious. The main purpose of this study was to analysis and evaluate myocardial ischemia in in our dialysis center, explore the influencing factors and propose effective intervention measures.

**Methods:** This study is a prospective study. From January 2022 to April 2022, 306 patients on maintenance hemodialysis were enrolled the research in our center. The patients completed cardiovascular assessment, including: data collection of hemodialysis, six-minute walk test(6-MWT), electrocardiogram before and after 6-MWT, and body composition analysis and noninvasive hemodynamic assessment. One third patients received coronary computed tomography angiography(CTA) and fraction flow reservation(CT-FFR).

**Results:** Among the 306 hemodialysis patients, 44% had abnormal electrocardiogram, manifested as abnormal ST segment, abnormal T wave, abnormal Q wave and arrhythmia. 8.8% of the patients had obvious myocardial ischemia after 6-minute walk test. 59% of patients had more severe coronary artery disease with coronary artery disease-reporting and data system (CAD-RADS) score of 3 and 4. Only 13% of the patients had chest pain symptoms, and 88.4% of the patients denied the history of coronary heart disease. Coronary stenosis was mainly in the right coronary artery and left anterior descending artery. Severe stenosis was mainly positively correlated with age (R=0.19, P=0.00), calcium score (R=0.27, p<0.00), and six-minute walking distance (R=0.13, P=0.00) was negatively correlated. FFR showed that the fraction of coronary flow reserve in the left anterior descending artery decreased the most, which was mainly related to left ventricular septal hypertrophy (r=0.10, P=0.01), systolic blood pressure (r=0.15, P=0.00), cards score (r=0.31, P<0.00) and calcification score (r=0.34, P<0.00).

**Conclusions:** The incidence of myocardial ischemia patients in our dialysis center is common and insidious, however, the incidence of coronary stenosis is high. The stenosis

was mainly in the right coronary artery and the left anterior descending artery, and the decrease of the coronary flow reserve was mainly in the left anterior descending artery. Both coronary stenosis and decreased fractional flow reserve were associated with higher coronary calcium scores.

### SA-PO381

#### Impact of the Platelet Distribution Width on Mortality and Cardiovascular Events in ESKD Patients

Young Woo Song, Seok Joon Shin, Sang Hun Eum, Joo Eun Lee, Jin Ah Park, Hye Eun Yoon, Yeonhee Lee. *Catholic University of Korea Incheon Saint Mary's Hospital, Incheon, Incheon, Republic of Korea.*

**Background:** Platelet distribution width (PDW) was known to a risk factor and an indicator of a variety of diseases. We evaluated impact of PDW on the all-cause mortality and cardiovascular (CV) event in end-stage kidney disease (ESKD) patients who started dialysis.

**Methods:** The medical records of 386 ESKD patients who started maintenance dialysis between January 2006 and July 2017 were reviewed. Patients were divided into three groups; low, median and high groups based on the tertile PDW value. The primary outcome was a comparison of all-cause mortality and CV events among the PDW tertile groups. The secondary outcome is the possibility of PDW as an independent risk factor for all-cause mortality and CV event.

**Results:** Overall death event was 83 cases; 17 in the low PDW group, 13 in the median PDW group, and 53 in the high PDW group. CV event was 110 cases; 20 in the low PDW group, 34 in the median PDW group, and 56 in the high PDW group. The all-cause mortality was significantly higher in the high PDW group compared to the low PDW group (40.2% vs. 14.5%,  $P = 0.012$ ). The CV event rate was also higher in the high PDW group compared to the low PDW group (42.4% vs. 17.1%,  $P = 0.027$ ). In multivariate Cox regression analysis, high PDW was an independent predictor for all cause death before adjustment (HR 1.138, 95% CI, 1.062-1.220;  $P = 0.000$ ), and even after adjustment for age, smoking, diabetes, body mass index, C-reactive protein, and previous CV disease (HR 1.120, 95% CI, 1.035-1.213;  $P = 0.005$ ).

**Conclusions:** PDW value at the time of initiating dialysis in the ESKD patients may be a simple and useful method for predicting all-cause mortality and CV event.

### SA-PO382

#### Monocyte-to-High-Density Lipoprotein (HDL) Ratio, an Independent Risk Factor of Survival in Hemodialysis Patients: Results From the International MONDO Consortium

Xiaoling Ye,<sup>1</sup> Rupert B. Bright,<sup>2</sup> Kevin Woollard,<sup>2</sup> Charles D. Pusey,<sup>2</sup> Peter Kotanko,<sup>1</sup> Neill D. Duncan.<sup>2</sup> The MONDO Initiative <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Imperial College Renal and Transplant Centre, London, United Kingdom.

**Background:** Previous studies had demonstrated that elevated monocyte count to high-density lipoprotein cholesterol ratio (MHR), a novel marker of inflammation, was associated with higher mortality in patients with CKD, on peritoneal dialysis, and deceased donor kidney transplant recipients. However, the association between MHR and mortality in patients undergoing hemodialysis (HD) has received little attention. We aimed to study the relationship between MHR and mortality in a diverse HD population.

**Methods:** Four cohorts were identified: 1) acute phase: first 90 days on HD as the baseline period with the subsequent 9 months as the follow-up, 2) early-stable phase: 91 days to the end of 1st year as the baseline followed with 1 year's follow-up, 3) mid-stable phase: 2nd year as the baseline and the following 1 year as the follow-up, and 4) late-stable phase: 3rd year as the baseline followed by a 7-year follow-up. All-cause & CVD mortalities were recorded during the 4 phases. Kaplan-Meier curves were constructed to explore the association between MHR quartiles and mortalities.

**Results:** 21,059 patients were included in the acute phase cohort, 19,776 in the early-stable phase cohort, 16,680 patients in the mid-stable cohort, and 13,893 patients in the late-stable phase cohort. Notably, patients in the higher baseline MHR quartile had higher levels of NLR, MLR, CRP, platelets, and ferritin and lower albumin and phosphate in all phases. All-cause (Fig. 1) and CVD mortalities were higher in patients in higher MLR quartiles in all cohorts.

**Conclusions:** A higher MHR was an independent risk factor for all-cause and CV mortality in this large and ethnically diverse HD population. MHR may be a reliable biomarker due to the connection between HDL and monocytes. This work corroborates previous findings in more restricted cohorts and warrants further mechanistic investigation.

### SA-PO383

#### Leptin-to-Adiponectin Ratio and Survival in a Prospective Hemodialysis Cohort

Thuy-Anh Bui, Amy S. You, Yoko Narasaki, Ji Hoon Yoon, Yalitzi Guerrero, Sara S. Kalantar, Ria Arora, Tracy Nakata, Danh V. Nguyen, Kamyar Kalantar-Zadeh, Connie Rhee. *University of California Irvine, Irvine, CA.*

**Background:** Leptin and adiponectin are two major adipocytokines believed to play key roles in the regulation of CV and metabolic status. While animal studies show leptin and adiponectin have inverse effects on the CV system (leptin promotes atherosclerosis, while adiponectin reduces vascular injury), it is suggested that the leptin-to-adiponectin (L/A) ratio may be an important predictor of CV disease and death. Despite their exceedingly high CV risk, no studies have examined the association between the L/A ratio and mortality in HD patients.

**Methods:** In a multicenter prospective cohort of 448 HD patients from the NIH "Malnutrition, Diet, and Racial Disparities in Kidney Disease" Study who underwent protocolized serum leptin/adiponectin measures, we examined the association of L/A ratio (categorized as tertiles) with all-cause mortality in unadjusted, case-mix, and case-mix+laboratory (adjusted for serum albumin, creatinine, nPCR, and IL-6) Cox models. We additionally examined clinical characteristics associated with high leptin and adiponectin levels (defined as the highest tertile) using logistic regression.

**Results:** We observed that increasingly higher L/A ratio tertiles were associated with incrementally lower death risk across all Cox models (ref: lowest tertile): HR (95%CI) 0.37 (0.18, 0.76) and 0.18 (0.07, 0.46), respectively for the middle and highest tertiles, respectively, in case-mix+laboratory models (Fig). In case-mix+laboratory logistic regression models, female sex, diabetes, AV access use, and lower serum albumin were associated with higher leptin, whereas female sex, Black race, and longer vintage were associated with higher adiponectin.

**Conclusions:** In a multicenter prospective cohort of HD patients, higher L/A ratios were associated with lower mortality. Further studies are needed to determine mechanistic pathways underlying the relationship between adipocytokines, CV health, and survival in HD.

**Funding:** NIDDK Support

## SA-PO384

**Serum GDF-15/Albumin Ratio Is a Survival Marker of CKD Patients Initiating Maintenance Hemodialysis**

Youngrok Ham, Eu Jin Lee, Soo hyun Han, Kang Wook Lee, Kiryang Na, Dae Eun Choi. *Chungnam National University Hospital, Daejeon, Republic of Korea.*

**Background:** It is valuable to identify risk factors related to mortality in chronic kidney disease (CKD) patients starting renal replacement therapy. Recently, several studies proposed that growth-differentiation factor-15 (GDF-15) is a possible biomarker for the prognosis of patients on maintenance hemodialysis. Here, we investigated the predictive value of serum GDF-15/Albumin ratio on two-year mortality in ESRD patients initiating maintenance hemodialysis.

**Methods:** The study was a single center, retrospective study on CKD patients starting maintenance hemodialysis with a follow-up of two years. We reviewed the medical records of the patients who were diagnosed with CKD, naive to renal replacement therapy and prescribed to start maintenance hemodialysis from May 2014 to August 2019. 159 patients were eligible for analysis. The biospecimens and data used for further analysis on GDF-15 were provided by the Biobank of Chungnam National University Hospital, a member of the Korea Biobank Network.

**Results:** The patients were stratified into quartiles according to the quartiles of serum GDF-15/Albumin ratio. Among the 159 patients, the mean age was  $61.78 \pm 12.52$  years and median survival was  $20.03 \pm 7.73$  months. The highest GDF-15/Albumin quartile was significantly more associated with the increased risk of all-cause mortality than other quartiles (unadjusted hazard ratio (HR): 8.468, 95% CI 2.981–24.054,  $p < 0.001$ ). Older age and a higher overhydration state were associated with GDF-15/Albumin ratio. The ROC analysis confirmed that the ability of the GDF-15/Albumin ratio to predict mortality was superior to GDF-15 or albumin alone.

**Conclusions:** the GDF-15/Albumin ratio measured at the initial maintenance hemodialysis is an independent prognostic marker of two-year mortality in CKD patients.

**Funding:** Government Support - Non-U.S.

**Comparison of Performance of an Artificial Intelligence Risk Prediction Model and Surprise Question: A Prospective Study**

Huan-Sheng Chen,<sup>1</sup> Chen-Chou Lei,<sup>2</sup> Ming-Hsien Chou,<sup>3</sup> Chu-Cheng Lin,<sup>4</sup> Hsueh-Wen Lu,<sup>5</sup> Wen-Chieh Wu,<sup>6</sup> Tsai-Ying Lin,<sup>7</sup> Tsuan-Shih Yu,<sup>8</sup> Hung-Hsiang Liou,<sup>9</sup> Chen-Ting Cheng,<sup>10</sup> Lim Paik Seong,<sup>11</sup> Hanjie Zhang,<sup>12</sup> Weihao Tan,<sup>13</sup> Kakiu Ho,<sup>13</sup> Margaret Li,<sup>13</sup> Carmen So.<sup>13</sup> <sup>1</sup>An Hsin Qing Shui Clinic, Taichung, Taiwan; <sup>2</sup>An Hsin Nan Zi Clinic, Kaohsiung, Taiwan; <sup>3</sup>He Tai Clinic, Taipei, Taiwan; <sup>4</sup>Ho Hospital, Changhua, Taiwan; <sup>5</sup>An Hsin Da Se Clinic, Taoyuan, Taiwan; <sup>6</sup>Shin Loong Clinic, New Taipei, Taiwan; <sup>7</sup>An Hui Clinic, Taoyuan, Taiwan; <sup>8</sup>He Yang Clinic, Taoyuan, Taiwan; <sup>9</sup>Hsing-Jen Hospital, New Taipei, Taiwan; <sup>10</sup>Saint Paul's Hospital, Taoyuan, Taiwan; <sup>11</sup>Tungs' Taichung Metro Harbor Hospital, Taichung, Taiwan; <sup>12</sup>Renal Research Institute, New York, NY; <sup>13</sup>Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong.

**Background:** Hemodialysis (HD) patients encounter a significantly high risk of morbidity and mortality. The surprise question (SQ) ("Would you be surprised if this patient were still alive in 6 or 12 months?") is used as a mortality prognostication tool in HD patients. We aimed to apply a risk prediction model (RPM) and compare its performance with SQ on 6- and 12-month mortality prediction for HD patients in Taiwan.

**Methods:** We conducted a 1-year prospective observational study in 422 chronic HD patients from 8 dialysis clinics. Demographic, clinical, laboratory and dialysis treatment indicators (158 features) were used to model 6- and 12-month mortality probability using logistic regression. All patients were assessed by SQ upon enrolment and, subsequently, by RPM every month. The performance of RPM against SQ was evaluated independently using area under the receiver operating characteristics curve (AUC). We compared sensitivities and specificities of RPM and SQ.

**Results:** A total of 207 high-risk patients were identified. During the 12-month follow-up, 47 patients died. For 6-months mortality prediction, AUC for SQ and RPM were 0.56 (95%CI 0.48, 0.63) and 0.70 (95%CI 0.62, 0.79), respectively ( $p=0.006$ ). For 12-month mortality prediction, AUC for SQ and RPM were 0.56 (95%CI 0.51, 0.62) and 0.73 (95%CI 0.68, 0.78) respectively ( $p<0.0001$ ). Sensitivities of the 6- and 12-month RPM were 0.88 (95%CI 0.73, 1) and 0.89 (95%CI 0.81, 0.98), respectively. The sensitivities of the 6- and 12-month SQ were 0.12 (95%CI 0, 0.27) and 0.17 (95%CI 0.063, 0.28), respectively. The specificities of 6- and 12-month RPM were 0.53 (95%CI 0.48, 0.57) and 0.56 (95%CI 0.51, 0.61), respectively. The 6- and 12-month SQ specificities were 0.99 (95%CI 0.98, 1) and 0.95 (95%CI 0.93, 0.97), respectively.

**Conclusions:** RPM is a more reliable predictor of mortality in HD patients compared to SQ. Sensitivity of SQ was rather low in this HD patient population.

**Funding:** Commercial Support - Fresenius Medical Care Asia Pacific Ltd.

## SA-PO387

**Predictors of Urgent Dialysis and Hospitalization Following Ambulance Transport to the Emergency Department**

Aran Thanamayooran,<sup>1</sup> Megi Nallbani,<sup>1</sup> Amanda J. Vinson,<sup>1,2</sup> David Clark,<sup>1,2</sup> Patrick T. Fok,<sup>1,2</sup> Judah Goldstein,<sup>1</sup> Keigan More,<sup>1,2</sup> Janel M. Swain,<sup>1</sup> Hana Wiemer,<sup>1,2</sup> Karthik K. Tennankore,<sup>1,2</sup> <sup>1</sup>Nova Scotia Health Authority, Halifax, NS, Canada; <sup>2</sup>Dalhousie University, Halifax, NS, Canada.

**Background:** Dialysis patients may require timely, monitored dialysis (urgent dialysis) or hospitalization after ambulance transport to the emergency department (ambulance-ED). We developed and internally validated risk prediction models for urgent dialysis and hospitalization for ambulance-ED in a cohort of chronic dialysis patients.

**Methods:** We included all ambulance-ED transports for hemodialysis patients affiliated with a large regional program from 2014-2018. "Urgent dialysis" was defined as dialysis within 24 hours of ED arrival in a monitored setting or with the first ED patient blood potassium level  $>6.5$  mmol/L. Predictors included categorized vital signs prior to ambulance transport (taken by paramedics) and time from last dialysis. Logistic regression models were used to predict urgent dialysis and hospitalization and internally validated using bootstrapping. Model discrimination was evaluated using the C-statistic and calibration using the Hosmer-Lemeshow test.

**Results:** A total of 271 dialysis patients experienced 878 ambulance-ED transports. 63 transports (7.2%) required urgent dialysis and 299 (34.0%) resulted in hospitalization. Hypoxemia (odds ratio; OR: 4.04, 95% CI: 1.75-9.33) and a time from last dialysis of 24-48 hours (OR: 3.43, 95% CI: 1.05-11.9) and  $>48$  hours (OR: 9.22, 95% CI: 3.37-25.23) were associated with urgent dialysis. A risk prediction model for urgent dialysis had good discrimination (C-statistic: 0.83) and calibration (Hosmer-Lemeshow: 0.89). The prediction model for hospitalization had no individually significant predictors of hospitalization and moderate discrimination (C-statistic: 0.67) but good calibration (Hosmer-Lemeshow: 0.74).

**Conclusions:** This study highlights the possibility of predicting certain short-term outcomes in dialysis patients using information available to paramedics during ambulance-ED transport.

## SA-PO388

**Risk Factors of Unplanned Intensive Care Unit Admission Among Hospitalized Patients With Maintenance Hemodialysis**

Nozomi Kadota, Takuya Fujimaru, Kotaro Shimoyama, Kasumi Konishi, Yugo Ito, Fumika Taki, Masahiko Nagahama, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

**Background:** In general, 6.4% of hospitalized patients were admitted to intensive care unit (ICU) due to deterioration of the clinical condition, and about 40% of these patients die. For all patients, the risk factors of deterioration of the clinical condition were male, older age, complication of diabetes or chronic heart failure, and abnormal vital signs on hospitalization. However, although hemodialysis (HD) patients have higher in-hospital mortality rate than general population, the factors that predict the deterioration of the clinical condition of these patients are not understood.

**Methods:** We conducted a retrospective study in a single hospital (520 beds, including 25 intensive care beds) in Tokyo, Japan. We investigated the adult patients with maintenance HD who admitted to general ward during January 2003 to November 2022. The patients who discharged within 7 days were excluded. The primary outcome is unplanned ICU admission between 72 hours and 30 days after hospitalization. The secondary outcomes are an unplanned ICU admission or death in the same duration. We used cox proportional regression model for statistical analysis adjusted for age, sex, comorbid conditions, positive blood culture and serum albumin value on hospitalization.

**Results:** Of the 492 eligible patients, 318 (64%) were male, mean age was 73 years old, mean length of hospital stay was 36.7 days, and 44 (8.9%) patients were admitted to ICU due to deterioration of the clinical condition. Multivariate analysis with Cox proportional regression model showed that patients with cardiovascular disease on hospitalization were significantly admitted to ICU (HR 2.99 (95%CI, 1.54-5.81)

P=0.0012). Additionally, ICU admission or in-hospital death was associated with low serum albumin on hospitalization (HR 0.45 (95% CI, 0.31-0.67) P<0.001).

**Conclusions:** For maintenance HD patients, complication of cardiovascular disease could be the risk factor of deterioration of the clinical condition during hospitalization.

Patient Characteristics on hospitalization (n=492)	n (%) or mean ± SD	Primary Outcome		Secondary Outcome	
		Hazard Ratio (95%CI)	p-value	Hazard Ratio (95%CI)	p-value
Male	318 (65)	0.9623 (0.497 - 1.863)	0.6104	0.7990 (0.5017 - 1.2726)	0.3448

The Prognostic Value of Objective Nutritional Scores in Patients Undergoing Maintenance Hemodialysis

Qian Wang, Zengchun Ye, Hui Peng. The Third Affiliated Hospital of Sun Yat-Sen University Lingnan Hospital, Guangzhou, China.

**Background:** Malnutrition is one of the common complications in patients undergoing maintenance hemodialysis (MHD), which affects their life quality and expectancy. But there is lack of simple and effective nutritional screening tools for MHD patients.

**Methods:** A retrospective cohort of 831 patients on MHD were enrolled from three hospitals. We applied three objective nutritional scores including prognostic nutritional index (PNI), controlling nutritional states scores (CONUT), geriatric nutritional risk index (GNRI) to longitudinally assess the nutritional status of MHD patients and its relationship with prognosis, and to compare the predictive value of the three scores by using the concordance index (C-index), the integrated discrimination improvement (IDI), and net reclassification improvement (NRI) ; to explore the relationship of changes in nutritional status of MHD patients with their prognosis. The primary and secondary endpoint events were all-cause and cardiovascular mortality, respectively.

**Results:** During a median follow-up period of 31.13 months, 195 patients (23.5%) died, and 116 (14%) of them died from cardiovascular events. There was no significant difference in the risk of all-cause and cardiovascular mortality between the normal nutrition and malnutrition groups before hemodialysis in our cohort. The risk of all-cause mortality or cardiovascular mortality was greater in the malnutrition group at 6th, 12th and 18th months of dialysis. None of the PNI, GNRI, and CONUT score during pre-hemodialysis status was independent factor for both all-cause mortality and cardiovascular mortality of the cohort. The mortality predictability of the GNRI was similar to the PNI, and both GNRI and PNI score are better than the CONUT score. Patients with decreased PNI or GNRI scores had a significantly increased risk of all-cause and cardiovascular mortality compared with patients with higher PNI or GNRI scores. Meanwhile, patients with increased CONUT scores had a greater risk of all-cause mortality.

**Conclusions:** Each of the three nutritional screening tools was significantly associated with an increased risk for all-cause and cardiovascular mortality at 6th, 12th, and 18th month of hemodialysis. The predictive value of both GNRI and PNI score are better than the CONUT score

SA-PO390

Prediction of Gastrointestinal Bleeding Hospitalization in Hemodialysis

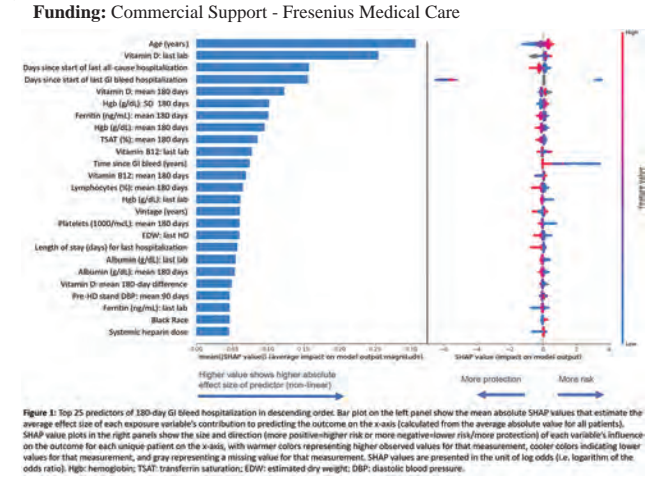

Suman K. Lama,<sup>1</sup> John W. Larkin,<sup>1</sup> Sheetal Chaudhuri,<sup>1</sup> Joanna Willets,<sup>1</sup> Anke Winter,<sup>2</sup> Yue Jiao,<sup>1</sup> Manuela Stauss-Grabo,<sup>2</sup> Len A. Usvyat,<sup>1</sup> Jeffrey L. Hymes,<sup>1</sup> Franklin W. Maddux,<sup>4</sup> Peter Stenvinkel,<sup>5</sup> Jürgen Floege,<sup>3</sup> on behalf of the INSPIRE Core Group <sup>1</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>2</sup>Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; <sup>3</sup>University Hospital Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany; <sup>4</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>5</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** INItiativeS on advancing Patients’ outcomes IN REnal disease (INSPIRE) is a collaboration set forth to conduct investigations fundamental to advancing nephrology. Early detection of gastrointestinal (GI) bleeding events was chosen as a priority and the group built a machine learning model to identify a hemodialysis (HD) patient’s 180-day GI bleed hospitalization risk.

**Methods:** Data from adult HD patients in the United States (Jan 2016-Dec 2020) were randomly split for training (50%), validation (30%), and testing (20%). Model (XGBoost) was built with >400 exposures, and refined to top 50 exposures, for classification of 180-day GI bleed hospitalization risk. Unseen testing data determined model performance and effect sizes.

**Results:** Among 27,796 HD patients in the test data, 322 had a GI bleed hospitalization. Model showed an area under the curve=0.70, sensitivity=56.2%, specificity=70.7%, and accuracy=70.6%. Exposures with largest effect size per Shapley values were older age (68±13 years GI bleed event vs 63±14 years no event), higher serum 25 hydroxyvitamin D level (25OH Vit D) (33.4±17.0 ng/mL GI bleed event vs 30.5±16.1 ng/mL no event), shorter days since all-cause hospitalization (203±246 days GI bleed event vs 253±269 days no event). Other important exposures included days since GI bleed hospitalization, hemoglobin and iron, time since known GI bleed, and heparin dose (**Figure 1**).

**Conclusions:** Model appears to be suitable for early detection of HD patients at risk of a GI bleed requiring hospitalization within 180 days. Prospective testing is needed with hopes of timely actions to avoid events. The association between higher 25OH Vit D and GI bleeding was unexpected and needs to be explored further in HD patients. Similar signals have been seen in warfarin users without kidney disease at 25OH Vit D levels >30 ng/mL (Keskin U, 2019).

SA-PO391

Thromboinflammatory Biomarkers and Their Relationship With Circulating Glycosaminoglycans in ESRD Patients

Vinod K. Bansal, Madeline T. Allen, Fakiha Siddiqui, Debra Hoppensteadt, Emily G. Krupa, Bulent Kantarcioglu, Jawed Fareed, Loyola University Health System, Maywood, IL.

**Background:** End stage renal disease (ESRD) is a complex progressive medical condition that affects multiple organ systems. Given the high risk of morbidity and mortality of ESRD as well as its rising incidence, it is critical to understand the relevance of thromboinflammatory biomarkers in disease development and progression of kidney dysfunction. The purpose of this study is to profile the levels of thromboinflammatory biomarkers in ESRD patients including D-Dimer, C-reactive protein (CRP), von Willebrand factor (vWF), plasminogen activator inhibitor 1 (PAI-1), and thrombin activatable fibrinolysis inhibitor (TAFI). In addition, the levels of anti-PF4 IgG and endogenous circulating glycosaminoglycans (GAGs) were measured.

**Methods:** Citrated plasma samples were collected from seventy-three ESRD patients. Control plasma samples (NHP) from healthy, non-smoking adults aged 19 to 53 were obtained commercially. Validated ELISA methods have been used to profile each of the biomarkers. The levels of endogenous GAGs were determined (Redprobes UG, Germany). To compare the levels of thromboinflammatory biomarkers, anti-PF4 IgG, and endogenous GAGs in different groups, appropriate statistical methods included Mann-Whitney U, t-tests, Kruskal-Wallis ANOVA and experiment correlation analysis methods were performed.

**Results:** All of the biomarkers and GAGs were significantly elevated in the ESRD patients, with the exception of TAFI (p < 0.05). The ESRD patients exhibited varying levels of increase in the D-Dimer, CRP, vWF, PAI-1, anti-PF4 IgG, and GAG levels (p < 0.05). D-Dimer showed the most pronounced increase (1075%) followed by PAI-1 (361.31%), anti-PF4 IgG (209.78%), CRP (101.77%) and endogenous GAGs (17.29%). The correlation analysis revealed varying degrees of association among these biomarker levels, in particular the endogenous GAGs and PAI-1.

**Conclusions:** These results suggest that thromboinflammatory biomarkers offer the potential utility of identifying inflammation in end-stage renal disease. Marked increase in thromboinflammatory mediators due to endothelial damage may result in the upregulation of glycosaminoglycans and may contribute to platelet activation and vascular dysregulation.

## Nephrologist Ownership of Dialysis Facilities and Dialysis Outcomes

Eugene Lin,<sup>1</sup> Genevieve Kanter,<sup>2</sup> Matthew S. McCoy,<sup>2</sup> Khristina I. Lung,<sup>4</sup> Derick Rapista,<sup>3</sup> Jeffrey S. Berns.<sup>2</sup> <sup>1</sup>University of Southern California Keck School of Medicine, Los Angeles, CA; <sup>2</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>3</sup>Duke University School of Medicine, Durham, NC; <sup>4</sup>University of Southern California, Los Angeles, CA.

**Background:** Nephrologist ownership of dialysis facilities presents a financial conflict of interest because owners can change dialysis prescriptions to increase profitability. Alternatively, facility owners could be more motivated to provide patient-centered care. In this study, we investigated the association between the ownership of dialysis facilities and dialysis outcomes.

**Methods:** Through a Freedom of Information Act request, we obtained a list of freestanding dialysis facilities' owners in 2018 from the Centers for Medicare and Medicaid Services (CMS), which we linked to a 100% sample of adults with fee-for-service Medicare receiving dialysis for end-stage kidney disease from January 2017 to November 2017 at freestanding facilities. In a multivariable analysis at the patient-month level, we studied the association between outcomes and facility ownership. We conducted a difference-in-differences analysis to mitigate selection bias. For each outcome, we compared patients managed by nephrologist owners at their own facilities versus at other facilities. To eliminate systematic differences between facilities owned by nephrologists and owned by non-nephrologists, we conducted the same comparison for patients managed by nephrologist non-owners. The difference between these comparisons (difference-in-differences) is the change in outcome associated with nephrologist ownership. We adjusted for patient, facility, and geographic confounders.

**Results:** Nephrologist ownership was associated with a 2.6 percentage point increase (95% CI: 1.4%, 3.8%,  $p=0.0005$ ) of home dialysis use over a baseline rate of 9.7% (a 27% relative increase). We observed no statistically significant differences in other outcomes, including mortality, transplantation or waitlisting, hospitalizations or 30-day readmissions, missed dialysis treatments, receipt of an erythropoietin-stimulating agent, blood transfusions, use of a fistula or a catheter, or dialysis adequacy ( $p > 0.05$  for all other outcomes).

**Conclusions:** Nephrologist ownership was associated with a large increase in home dialysis use. We did not observe adverse events associated with a profit motive. However, because it was difficult to obtain ownership data, our analysis was limited to a cross-sectional analysis of nephrologist owners. CMS should make nephrologist ownership of dialysis facilities more transparent.

## SA-PO393

## Risk of Death in Hospital-Based vs. Free-Standing Dialysis Facilities in the United States

Lucy Zhang,<sup>1</sup> Sandra Amaral,<sup>2</sup> Charles E. McCulloch,<sup>1</sup> Barbara A. Grimes,<sup>1</sup> Elaine Ku.<sup>1</sup> <sup>1</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>2</sup>The Children's Hospital of Philadelphia, Philadelphia, PA.

**Background:** Prior studies have shown that dialysis facility type is associated with differential patient outcomes, including access to transplantation and mortality risk. It is unclear whether there are any differences in survival in patients receiving care at dialysis facilities that are affiliated with a hospital versus free-standing, and whether such mortality risk varies by race/ethnicity.

**Methods:** We included adults  $>18$  years who started dialysis between 2014-2018 who were registered in the USRDS and examined the association between dialysis facility affiliation (hospital-based versus free-standing) and risk of death using Cox models and adjusting for age, race, sex, region, cause of kidney disease, dialysis facility network, insurance, county size, co-morbidities, distance to dialysis facility, year of dialysis initiation, and dialysis modality. We then tested for interaction between facility type and race/ethnicity and performed subgroup analysis due to the presence of an interaction ( $p<0.05$ ).

**Results:** We included a total of 283,957 patients with a mean age of 55 years. Approximately 59% were men and 30% were Black patients (Table 1). Patients receiving dialysis from hospital-affiliated dialysis facilities had a 12.1% higher risk of death than those receiving dialysis at free-standing facilities (95% CI 7-17%). We detected an interaction between type of dialysis facility and race/ethnicity ( $p<0.05$ ). Black patients showed a higher differential between hospital and free-standing than other races (Table 2).

**Conclusions:** Hospital-affiliation (vs. free-standing status) was associated with higher risk of death in dialysis facilities, but findings varied by race. This finding may be due to different patient mix, with hospital-affiliated facilities treating sicker patients. Further studies are needed to further explore drivers of these findings.

**Funding:** NIDDK Support

**Table 1:** Baseline Characteristics at dialysis initiation by type of dialysis facility

Variable*	Free-Standing	Hospital-Based
Total patients (N)	269,890	14,067
Age	55 ± 11.2	55.1 ± 11.6
Sex (% male)	158372 (58.7%)	8935 (63.5%)
Modality (% hemodialysis)	242317 (89.8%)	12489 (88.8%)
Race		
Black	81995 (30.4%)	4195 (29.8%)
Hispanic	47155 (17.5%)	2331 (16.6%)
White	123,771 (45.9%)	6391 (45.4%)
Other race	16969 (6.3%)	1150 (8.2%)

\*All characteristics are statistically significantly different comparing patients treated at hospital-affiliated versus free-standing facilities.

**Table 2:** Risk of death by type of dialysis facility and race/ethnicity.

Hospital-based versus free-standing dialysis facility	Adjusted Hazard Ratio (95% CI)
Black	1.23 (1.13-1.34)
Hispanic	1.01 (0.88-1.16)
White	1.09 (1.03-1.16)
Other	1.19 (1.01-1.42)

## SA-PO394

## Parameters Influencing Survival After Hemodialysis Withdrawal: An Experience From a Single Center

Kosei Yamaguchi,<sup>1,2</sup> Mineaki Kitamura,<sup>1,2</sup> Satoshi Funakoshi,<sup>1</sup> Tomoya Nishino.<sup>2</sup> <sup>1</sup>Nagasaki Renal Center, Nagasaki, Japan; <sup>2</sup>Nagasaki University School of Medicine, Nagasaki, Japan.

**Background:** Withdrawal from maintenance hemodialysis is unavoidable in some patients who have a poor general condition; however, their survival rate varies. The factors associated with survival prognosis in the terminal phase of patients undergoing hemodialysis remain unclear.

**Methods:** This study included patients who died after withdrawal from hemodialysis between 2011 and 2021 at Nagasaki Renal Center. Patient background data were collected, and the associations between the patients' clinical features and survival duration were analyzed.

**Results:** The withdrawal group included 174 patients (79.8±10.8 years old; 50.6% men; median dialysis vintage, 3.6 years). The most common (95%) reason for withdrawal was that hemodialysis was more harmful than beneficial because of the patient's poor general condition. The median time from withdrawal to death was 4 days (interquartile range: 3-10 days). Multivariable Cox proportional regression analysis showed that oral nutrition (hazard ratio (HR), 1.98; 95% confidence interval (CI), 1.12-3.50;  $P=0.03$ ), hypoxemia (HR, 2.32; 95% CI, 1.55-3.47;  $P<0.01$ ), ventilator use (HR, 0.26; 95% CI, 0.11-0.58;  $P<0.01$ ), and pleural effusion (HR, 1.54; CI, 1.01-2.37;  $P=0.04$ ) were associated with increased survival. In contrast, antibiotics and vasopressor administration were not associated with survival.

**Conclusions:** We clarified the parameters affecting the survival of patients who withdrew from hemodialysis. Physicians may use our results to establish more accurate predictions, which in turn will help patients and their families emotionally accept and implement the desired care plan.

## SA-PO395

## A Predictive Model of the Time to ESKD Using Machine Learning

Jun Okita,<sup>1</sup> Takeshi Nakata,<sup>1</sup> Emiko Noguchi,<sup>1</sup> Nobuchika Koumatsu,<sup>1</sup> Ayako Tasaki,<sup>1</sup> Hiroki Uchida,<sup>1</sup> Akiko Kudo,<sup>1</sup> Akihiro Fukuda,<sup>1</sup> Tsuyoshi Shimomura,<sup>2</sup> Masato Tanigawa,<sup>3</sup> Hirotaka Shibata.<sup>1</sup> <sup>1</sup>Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan; <sup>2</sup>Hospital informatics center, Oita Medical University Hospital, Yuhu, Japan; <sup>3</sup>Department of Biophysics, Faculty of Medicine, Oita University, Yuhu, Japan.

**Background:** Predicting the risk of end-stage kidney disease (ESKD) and the time to renal replacement therapy (RRT) is useful not only for healthcare providers to treat CKD and prepare for renal replacement therapy (RRT) but also for patients to plan their life. Many studies have assessed the risk for ESKD using machine learning, but none have focused on the time to RRT. In this study, we investigated how to predict the time to RRT using machine learning.

**Methods:** This study was a retrospective cohort study. Patients who started RRT between April 2016 and March 2021 at Oita University Hospital were enrolled. A total of 13,323 data groups were extracted from the electronic medical records, including 34 laboratory data items (e.g., BUN and creatinine [Cr]) and 8 patient background items (e.g., age and gender) from the start of follow-up to the start of RRT. Items with missing values of more than 30% were excluded. The residual 9,838 data groups without missing values were trained by the machine; 80% of the data were randomly divided for training and 20% for testing, and supervised learning was performed with multiple algorithms

(mainly nonlinear regression models, such as Random Forest and gradient-boosted decision trees) to create predictive models and evaluate the accuracy of the test data.

**Results:** In all, 147 patients (99 males) were enrolled with a mean age of 60.8 years. The most common ESRD etiology was diabetic nephropathy (44%). The mean Cr was  $7.6 \pm 2.0$  mg/dL, and the estimated glomerular filtration rate (eGFR) was  $6.1 \pm 1.7$  mL/min/1.73 m<sup>2</sup> at induction. The optimal algorithm was the Random Forest regression, which created a predictive model that used six identical time variables (age, gender, height, weight, Cr, and eGFR). The model was highly accurate with a coefficient of determination ( $R^2$ ) of 0.96 and a mean absolute error of 159 days. The values predicted from the test data strongly correlated with the true values.

**Conclusions:** We predicted the time to start RRT with high accuracy using machine learning. Predicting the time to start RRT is useful for CKD treatment, and we plan to improve the accuracy of the model and consider its application to actual clinical practice in the future.

## SA-PO396

### Novel Risk Score to Predict 3-Year Mortality in Patients on Hemodialysis

Aiko Okubo,<sup>1</sup> Toshiki Doi,<sup>1,2</sup> Kenichi Morii,<sup>1,2</sup> Yoshiko Nishizawa,<sup>1</sup> Kazuomi Yamashita,<sup>1</sup> Kenichiro Shigemoto,<sup>1</sup> Sonoo Mizuiri,<sup>1</sup> Takao Masaki,<sup>2</sup> <sup>1</sup>Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; <sup>2</sup>Hiroshima Daigaku Byoin, Hiroshima, Japan.

**Background:** The risk of death in patients on hemodialysis (HD) is high. Therefore, identifying patients at a high risk of death at the induction of HD is essential in clinical practice. However, few reports have examined the models predicting all-cause mortality in patients on HD using clinical factors, including electrocardiographic findings. This study aimed to investigate the clinical factors that have the most effect on the mid-term prognosis in patients on HD and to evaluate a novel risk model using these risk factors for predicting all-cause death.

**Methods:** We analyzed 385 patients with initiated HD at our four facilities from November 2008 to February 2019. We investigated demographics, medical history, laboratory data, and electrocardiographic findings at the initiation of HD therapy. We used the logistic regression model to predict 3-year all-cause mortality and evaluated it by cross-validation.

**Results:** During the 3-year follow-up, 86 (24.2%) patients died. Age ( $P<0.01$ ), prior stroke ( $P<0.01$ ), and the corrected QT interval ( $P=0.03$ ) were identified as independent predictors of all-cause death by a multivariate logistic regression analysis. The predictive model was constructed using all these parameters with good discrimination of all-cause death (area under the curve: 0.80, with 80.1% sensitivity and 76.7% specificity). The area under the curve based on the 10-fold cross-validation was 0.82, with 78.2% sensitivity and 70.9% specificity, which suggested a good model. Patients above the cut-off value of the risk model were more likely to have a significantly higher risk of all-cause death than those below the cut-off value (hazard ratio: 9.13, 95% confidence interval: 5.16–16.16,  $P<0.001$ ).

**Conclusions:** This novel risk model composed of age, prior stroke, and the corrected QT interval can stratify high-risk patients and be useful in predicting 3-year all-cause death in patients on HD. Our new risk score is easily measured at the bedside and provides good prediction of the mortality risk of patients on HD.

## SA-PO397

### Prediction of Death in Dialysis Patients Using Artificial Intelligence

Sungmin Kim, Jung Nam An, Dong Hee Lee, Jwa-kyung Kim, Sung Gyun Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

**Background:** It is very important to predict the death and to detect and manage risk factors in dialysis patients. In this study, we aimed to build a prognostic prediction model that can predict the death of dialysis patients through a deep learning technique using dialysis-related clinical variables and vital signs during dialysis that change in real time in addition to traditional risk factors.

**Methods:** Data of patients who underwent maintenance dialysis at Hallym University Sacred Heart Hospital from January 2015 to December 2019 were extracted from electronic medical record. Changes in vital signs (before dialysis, during dialysis, immediately after dialysis), dry weight, weight gain between dialysis, ultrafiltration amount, blood test results, and in-hospital deaths were investigated. Out-of-hospital deaths were investigated using data from the National Statistical Office. Using refined data, a recurrent neural network-based long short-term memory deep learning model that can predict death from vital signs was trained.

**Results:** Of a total of 1,772 patients, 322 died in-hospital and 337 died out-of-hospital. Among these, patients with vital signs measured during dialysis within 72 hours were included. When learning with 4-fold cross validation for the prediction of death within 72 hours from each vital sign measurement time during dialysis (including both out-of-hospital and in-hospital death), the performance was AUROC  $0.9591 \pm 0.0115$  and AUPRC  $0.2408 \pm 0.0290$ . Afterwards, the test set was composed of only 16 patients who died out of hospital within 100 hours from the time of the last vital sign measurement. As a result of checking the predictive performance, it was AUROC 0.8714 and AUPRC 0.1440.

**Conclusions:** In this study, a death prediction model using a deep learning technique that maximizes the correlation between data was constructed using vital signs and test results during dialysis, which are regularly measured in hemodialysis patients. A prospective study will be needed.

## SA-PO398

### eGFR Trajectory Pre-Dialysis Initiation Predicts 90-Day Hospitalization and Mortality Risk

Michael A. Kraus,<sup>1</sup> Yuedong Wang,<sup>2</sup> Catherine Y. Wang,<sup>4</sup> Carly Hahn Contino,<sup>1</sup> Len A. Usvyat,<sup>1</sup> Peter Kotanko,<sup>3,5</sup> Robert J. Kossmann,<sup>1</sup> Harvey W. Kaufman,<sup>6</sup> <sup>1</sup>Fresenius Medical Care North America, Waltham, MA; <sup>2</sup>University of California System, Oakland, CA; <sup>3</sup>Renal Research Institute, New York, NY; <sup>4</sup>Carnegie Mellon University, Pittsburgh, PA; <sup>5</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>6</sup>Quest Diagnostics Inc, Secaucus, NJ.

**Background:** Previous VA study<sup>1</sup> showed 1-year hospitalization and mortality in ESRD patients was linked to eGFR rate decline in 2 yrs pre-dialysis. This study evaluated males and females and applied the CKD-EPI 2021 eGFR equation to define clusters that estimate risk of hospitalization and death within 90 days after dialysis initiation.

**Methods:** Patients initiated on dialysis at Fresenius Medical Care with matched Quest Diagnostics clinical testing, 1/1/2015 - 9/30/2020 were included and deidentified. Inclusion criteria: a) 2 yrs of lab data; b)  $\geq 10$  serum creatinine (Scr) measurements; c)  $\geq 1$  Scr within 45 days; d)  $\geq 2$  Scr distributed over 2 quarters. Exclusion criteria were sudden eGFR increase  $> 20$  mL/min/1.73 m<sup>2</sup>, or mean eGFR  $> 30$  mL/min/1.73 m<sup>2</sup> within 45 days of dialysis. The revised CKD-EPI 2021 eGFR calculation was applied. A cubic spline was fitted to eGFRs from each patient followed by functional data clustering methods to learn patterns of eGFR trajectories. Both K-mean and functional principal component analysis were used. One-way ANOVA and  $\chi^2$  tests were used to compare the trajectory groups for continuous and categorical variables.

**Results:** 2341 patients: 42% female, mean age  $64.9 \pm 12.3$  years, 62.7% White, non-Hispanic, 15.7% Black non-Hispanic, 15.0% Hispanic. Patients grouped into 4 clusters of eGFR progression velocity: 1076 stable low cluster (slc); 920 slow decay cluster (sdc); 285 fast decay cluster(fdc), and 60 in the very fast decay cluster (vfdc). Comparing clinical laboratory test measures, faster decay groups tended to have lower levels of 25-Vit D, iPTH, and albumin; higher uACR, and slightly higher hgb A1C. Vfdc had higher WBC. 90-day mortality rates: 0.034 (slc), 0.043 (sdc), 0.084 (fdc), and 0.117 (vfdc). 90-day hospitalization rates: 0.219 (slc), 0.252 (sdc), 0.295 (fdc), and 0.500 (vfdc). Mortality HR compared to the slc was 2.98 fdc and 4.53 vfdc. Hospitalization odds ratio compared to slc 1.57 fdc and 3.84 vfdc. Cluster category was significantly associated with hospitalization and mortality, even after adjusting for demographic variables.

**Conclusions:** fdc and vfdc were associated with higher risk of hospitalization and mortality within 90-days after dialysis initiation. 1. O'Hare AM, et al. Am J Kidney Dis 2012 April; 59(4): 513-522

## SA-PO399

### Glycated Albumin to Glycated Hemoglobin Ratio and Mortality in Diabetic Patients on Dialysis

Junichi Hoshino,<sup>1,2</sup> Masanori Abe,<sup>3,2</sup> Takayuki Hamano,<sup>4,2</sup> Takeshi Hasegawa,<sup>5,2</sup> Atsushi Wada,<sup>6,2</sup> Shigeru Nakai,<sup>7,2</sup> Norio Hanafusa,<sup>1,2</sup> Ikuto Masakane,<sup>8,2</sup> Kosaku Nitta.<sup>1,2</sup> <sup>1</sup>Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; <sup>2</sup>The Japanese Society for Dialysis Therapy, Tokyo, Japan; <sup>3</sup>Nihon Daigaku Igakubu Daigakuin Igaku Kenkyuka, Iwabashi-ku, Japan; <sup>4</sup>Nagoya Shiritsu Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagoya, Japan; <sup>5</sup>Showa Daigaku, Shinagawa-ku, Japan; <sup>6</sup>Kitasaito Byoin, Asahikawa, Japan; <sup>7</sup>Fujita Ika Daigaku, Toyoake, Japan; <sup>8</sup>Yabuki Hospital, Yamagata, Japan.

**Background:** Hemoglobin A1c (A1c) and glycated albumin (GA) are two blood glycosylated proteins commonly used to monitor glycemic control in dialysis patients with diabetes. However, little is known about the association between the GA/A1c ratio and mortality in these populations. Here, we examine these associations using a nationwide cohort.

**Methods:** We enrolled 28,994 dialysis patients with diabetes who met our inclusion criteria (female, 32.9%; mean age,  $67.4 \pm 11.6$  years; mean dialysis duration,  $6.3 \pm 5.8$  years). After dividing the patients into groups based on GA/A1c quantiles and adjusting for 18 potential confounders, adjusted hazard ratios and 95% confidence limits were calculated for 3-year mortality and cause-specific mortalities. Additionally, propensity score matching analyses were used to compare mortalities between the low and high GA/A1c groups.

**Results:** After adjusting for possible confounders, significantly worse mortality was found in patients with GA/A1c ratios of 3.6–4.0 (HR 1.21 (1.10–1.34)) or higher (HR 1.43 (1.30–1.58)) than in those with GA/A1c ratios of 3.0–3.3. The risks of infectious and cardiovascular death were higher in these patients regardless of their nutritional status. In the propensity score matching analyses, significantly worse mortality was consistently found in those with a higher ratio ( $\geq 3.3$ ) (HR 1.23 (1.14–1.33)) than in those with a lower ratio.

**Conclusions:** The GA/A1c ratio was significantly associated with 3-year mortality, especially infectious and cardiovascular mortality, in dialysis patients with diabetes. It is a promising new clinical indicator of survival in these patients, independent of their current glycemic control and nutritional markers.

## SA-PO400

### Tenapanor Plus Phosphate Binder Reduces Interdialytic Weight Gain (IDWG) in Patients With CKD on Hemodialysis (HD): Post Hoc Analysis of the AMPLIFY Study

Steven Fishbane,<sup>1</sup> Stephen Z. Fadem,<sup>2</sup> Yang Yang,<sup>3</sup> Susan A. Edelstein,<sup>3</sup> David M. Spiegel,<sup>3</sup> <sup>1</sup>Zucker School of Medicine, Great Neck, NY; <sup>2</sup>Kidney Associates, PLLC/Baylor College of Medicine, Houston, TX; <sup>3</sup>Ardelyx, Inc., Waltham, MA.

**Background:** Excessive IDWG in patients with CKD on HD is associated with poor outcomes. Tenapanor, a novel investigational phosphate absorption inhibitor (PAI), inhibits intestinal NHE3 and increases stool Na and water content. To assess whether tenapanor might decrease IDWG and allow patients to achieve target dry weight, we performed post hoc analysis of pre-HD weights from the phase 3 AMPLIFY study (NCT03824587). We hypothesized that, compared to phosphate binder treatment alone, CKD patients treated with tenapanor and phosphate binder would have decreased IDWG and more easily approach target dry weight as reflected by a pre-HD weight decrease.

**Methods:** In AMPLIFY, patients with CKD on dialysis with high serum phosphorus (despite phosphate binder treatment) were randomized to add tenapanor 30 mg bid or placebo to their treatment regimen for 4 weeks. Pre-HD weights were recorded at baseline and week 4 after a short interdialytic interval. We evaluated the impact of tenapanor on pre-HD weight over the 4-week study.

**Results:** At week 4, mean pre-HD weight decreased with tenapanor and increased with placebo (Table), and weight percent change differed significantly between tenapanor and placebo groups (LS mean difference: -0.81%,  $P=0.0284$ ; Table). At week 4, pre-HD weight decreased by a greater percentage in the tenapanor vs placebo groups (Table), and pre-HD weights decreased in a greater number of patients from the tenapanor group and increased in a greater number from the placebo group (Figure).

**Conclusions:** These results suggest that tenapanor may reduce IDWG. The potential to control serum phosphorus while helping patients achieve target weight may be beneficial for patients on HD.

**Funding:** Commercial Support - Ardelyx, Inc.

Treatment group	Baseline mean (SD) pre-HD weight, kg	Week 4 mean (SD) pre-HD weight, kg	LS mean (SE) pre-HD weight percent change, %	LS mean difference (SE) in percent change, ANCOVA P value*	Patients with any decrease in pre-HD weight at week 4, n (%)	Odds ratio, CMH test P value**
Tenapanor + phosphate binder (n=103)	96.2 (23.0)	95.8 (23.0)	-0.24 (0.27)		58 (56.3)

### Correlation of Serum Phosphate With Pruritus Severity and Response to Difelikefalin

Geoffrey A. Block,<sup>1</sup> Pieter Evenepoel,<sup>2</sup> Steven Fishbane,<sup>3</sup> Jeffrey J. Budden,<sup>4</sup> Isabelle Morin,<sup>4</sup> Frederique Menzaghi,<sup>5</sup> Warren Wen,<sup>5</sup> Edgar V. Lerma,<sup>6</sup> <sup>1</sup>Denver Nephrology, Denver, CO; <sup>2</sup>University Hospitals Leuven, Leuven, Belgium; <sup>3</sup>Northwell Health, Great Neck, New York, NY; <sup>4</sup>Vifor Pharma Ltd, Glattbrugg, Switzerland; <sup>5</sup>Cara Therapeutics Inc, Stamford, CT; <sup>6</sup>University of Illinois at Chicago College of Medicine, Chicago, IL.

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is often reported by hemodialysis (HD) patients, thought to result from inadequate serum phosphate (sP) control, but recent studies refute this. Difelikefalin (DFK) is a selective kappa opioid receptor agonist approved in the United States and Europe for treatment of moderate-to-severe pruritus in adults undergoing HD. DFK significantly reduced itch in the Phase 3 KALM-1 and -2 trials. This analysis determined the correlation of sP to pruritus severity and response to DFK.

**Methods:** The KALM trials enrolled HD patients with moderate-to-severe CKD-aP (mean weekly worst itch numerical rating scale (WI-NRS)  $>4$  [KALM-1] or  $\geq 5$  [KALM-2]). Patients were randomized 1:1 to intravenous DFK 0.5  $\mu\text{g/kg}$  or placebo (PBO) 3 times/week (Wk) for 12 wks. Correlation between sP and WI-NRS at baseline and Wk 12 was assessed, as well as response to DFK in patients with and without hyperphosphatemia ( $\text{sP} \leq 5.5$  vs  $>5.5$  mg/dL) at baseline.

**Results:** In pooled data (DFK and PBO), patients with baseline  $\text{sP} \leq 5.5$  mg/dL ( $N=438$ ) had similar baseline characteristics to patients with  $\text{sP} >5.5$  mg/dL ( $N=407$ ). Baseline WI-NRS ( $7.1 \pm 1.4$  vs  $7.2 \pm 1.5$ ) and anti-itch medication use ( $37.9\%$  vs  $38.1\%$ ) were similar. No correlation was observed between WI-NRS and sP values at baseline ( $p=0.54$ ) [Figure] or Wk 12 ( $p=0.27$ ). Clinically relevant improvement in WI-NRS following DFK treatment was similar in sP subgroups  $\leq 5.5$  vs  $>5.5$  mg/dL ( $39.3\%$  vs  $40.2\%$  for  $\geq 4$ -point improvement;  $51.1\%$  vs  $57.6\%$  for  $\geq 3$ -point improvement) and a significantly higher proportion of patients in the DFK group vs placebo reported a  $\geq 4$ -point improvement in both sP subgroups ( $p \leq 0.017$ ).

**Conclusions:** sP did not correlate with pruritus severity or response to DFK in patients with CKD-aP.

**Funding:** Commercial Support - Vifor Pharma

**Figure:** Correlation of baseline worst itch numerical rating scale score by baseline phosphate value (Intent-to-treat population for pooled difelikefalin and placebo patients)

## SA-PO402

### Implementation of a Nationwide Online Exercise Program in Hemodialysis Patients

Diogo V. Leal,<sup>1</sup> Pedro M. Martins,<sup>1,2</sup> Daniela F. Cardoso,<sup>1</sup> Manuel A. Ferreira,<sup>2,3</sup> Kenneth R. Wilund,<sup>4</sup> Joao L. Viana,<sup>1</sup> <sup>1</sup>Research Center in Sports Sciences, Health Sciences and Human Development (CIDESD), University of Maia, Maia, Portugal; <sup>2</sup>Nephrocare Portugal SA, Lisbon, Portugal; <sup>3</sup>Nova Medical School, Faculdade de Ciências Médicas, Lisbon, Portugal; <sup>4</sup>University of Illinois Urbana-Champaign Department of Kinesiology and Community Health, Champaign, IL.

**Background:** Physical inactivity of HD patients was aggravated during the COVID-19 pandemic due to the imposed lockdown and suspension of ongoing intradialytic exercise program (IDE). To address this, we have developed an online exercise program (OLEP). The aim of this study was to analyze its implementation over a 12-weeks period.

**Methods:** Implementation study based on retrospective analysis using the RE-AIM framework (reach, effectiveness, adoption, implementation, maintenance). OLEP was proposed to 24 HD units previously offering IDE and included live online exercise sessions (3 times/week) led by 2 exercise physiologists via Zoom®. For each RE-AIM dimension specific implementation outcomes were adapted to OLEP. Effectiveness measures included safety (adverse events during exercise sessions) and in-clinic physical function tests (sit-to-stand 5 and 30, 8-foot up and go (8UG), handgrip strength and single leg stance) performed at baseline and 12 weeks in a group of OLEP participants and a group of patients who refused to participate.

**Results:** OLEP was adopted by 16 units (66.7%). Among 2063 patients of these units, 313 (15.2%) were eligible. Of those, 84 accepted to participate in OLEP (4.1% reach of all patients). Compared to refusals, OLEP participants had higher female proportion

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

( $p=0.009$ ), higher education level ( $p<0.001$ ), lower lean tissue index and handgrip strength (both  $p<0.001$ ), and completed less steps/day ( $p=0.008$ ). *Maintenance* in OLEP over the 12 weeks was 59.5%, i.e., 40.5% drop-out – of which 65% were voluntary. *Implementation fidelity* (patient's adherence to exercise sessions) was  $73.1\pm 18.8\%$ , and *implementation dose* was  $2.2\pm 0.6$  exercise sessions/week. *Effectiveness*: OLEP participants improved performance in all physical function measures ( $p<0.05$ ), except in 8UG ( $p=0.677$ ), whilst refusals did not ( $p>0.05$ ); no severe adverse events were reported.

**Conclusions:** Our data suggests that an OLEP is realistic, safe and may improve physical function. Therefore, its applicability may subsist beyond the pandemic and be used to complement IDE. However, strategies to increase proficiency to use mobile health technology may be needed to reach more patients.

**Funding:** Government Support - Non-U.S.

## SA-PO403

### Blood Pressure Changes After Arteriovenous Fistula Creation in Hemodialysis Patients

Juan C. Duque, Karen Manzur-Pineda, Laisel Martinez, Adriana Dejman, Marwan Tabbara, Roberto I. Vazquez-Padron. *University of Miami School of Medicine, Miami, FL.*

**Background:** Hypertension (HTN) is highly prevalent in patients with end stage kidney disease (ESKD), reporting a rate of up to 86%. However, accepted definitions of HTN and blood pressure (BP) targets have not been established. Initiation of HD may impact the management of HTN. In addition, an arteriovenous fistula (AVF) creation poses significant hemodynamic changes. Studies have shown reduction in 24-hour ambulatory BP after a central AVF creation in patients with severe HTN and preserved renal function. We evaluate the effect of an AVF creation for dialysis on BP changes.

**Methods:** Retrospective study from 2019 to 2020 evaluated 159 patients who underwent a hemodialysis AVF creation. Vital signs were recorded by the same clinic staff and using the same equipment at five different time points: vein mapping, surgical creation, first post-surgical follow-up, second surgery (AVF transposition), and last follow-up before AVF is ready for cannulation. Demographic data, comorbidities, and pharmacological antihypertensive regimen were also collected.

**Results:** The mean age at AVF creation was  $58 \pm 13$  years with a BMI average of  $23.9 \pm 5.3$  kg/m<sup>2</sup>. A 56.7% of the cohort were Hispanic, 37.1% African American, and 6.2% Caucasian. HTN was present in (74.2%) and diabetes (40.2%). 96 patients were on HD using a dialysis catheter, and the rest were CKD stage 5 not on HD. A 52.7% were on CCB, Beta blockers in 50.2%, loop diuretics in 31.4%, hydralazine in 21.3%, ACEI/ARBs in 16.9%, clonidine in 10.6%, and isosorbide in 4.4%. Average BP during the vein mapping was  $137.78/76.3 \pm 25.9/12.5$  mmHg with heart rate (HR) of  $84.4 \pm 7.5$ ; at the AVF creation  $134.7/73.1 \pm 24/12.7$  mmHg with HR of  $73.2 \pm 11.8$ ; at the first follow-up  $135.4/71.6 \pm 23.1/11.7$  mmHg with HR of  $80.8 \pm 12$ ; at the second surgical intervention  $132.4/72.8 \pm 21.4/11.7$  mmHg with HR of  $74.3 \pm 11$ ; and last follow-up  $158.3/74 \pm 18/12.7$  mmHg with HR of  $81.8 \pm 13$ . No correlation was found between collected covariates and BP changes, and no improvement in BP was found.

**Conclusions:** Hypertension is highly prevalent in CKD 5 and ESKD patients requiring multipharmacological management. An AVF creation did not improve BP control in the short-term follow-up in our population. Moreover, we can conclude that other comorbid conditions do not correlate with hemodialysis AVF creation and BP control.

### Disruption of the Blood Brain Barrier in ESKD: A Novel Mechanism of Cognitive Impairment

Archana Gautam, Rebecca J. Lepping, William M. Brooks, Kate J. Young, Joseph Donald, Branden W. Comfort, Md Omar Faruque, Neal Montgomery, Alan S. Yu, Aditi Gupta. *The University of Kansas Medical Center, Kansas City, KS.*

**Background:** Cognitive impairment is common in end stage kidney disease (ESKD). Although disruption of blood brain barrier (BBB) integrity is an early biomarker of cognitive impairment and dementia, BBB has not been assessed in ESKD since gadolinium-based contrast-enhanced MRI used to measure BBB is impractical in ESKD.

**Methods:** In this novel single-center cross-sectional pilot study, we used single-photon emission computed tomography (SPECT-CT) with <sup>99m</sup>Tc labelled DTPA to assess BBB integrity in ESKD. We enrolled 7 ESKD patients and 6 healthy controls (without chronic kidney disease). All participants underwent brain SPECT-CT and cognitive assessments. Cohens D was calculated to compare the SPECT-CT standardized uptake values (SUV) between ESKD and controls.

**Results:** Despite the ESKD group being younger ( $50.6 \pm 13.3$  years) than the control group ( $57.7 \pm 5.9$  years), the ESKD group had a higher SUV ( $0.241 \pm 0.034$ ) indicating a greater disruption of BBB integrity than the control group ( $0.161 \pm 0.033$ ). Cohens D (measure of standard deviations between two means) = 2.35. Figure 1 shows the distribution of SUVs. The ESKD group performed worse on neuropsychological tests, in particular tests of verbal fluency, delayed recall, and Trail making B, than the control group.

**Conclusions:** This is the first report demonstrating that BBB integrity is severely disrupted in ESKD patients compared with controls. The association of BBB disruption with cognitive impairment in ESKD suggests that BBB should be further studied as a novel mechanism underlying cognitive impairment in ESKD.

## SA-PO405

### On the Removal of Middle Molecules and Albumin Loss: An Ex Vivo Evaluation of Commercial Dialyzers

Franziska Hagemann, Hannah Roth, John Linkhorst, Matthias Wessling. *Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany.*

**Background:** An improved removal of middle-molecular-weight uremic toxins in hemodialysis treatments is essential for the patient's health. Tailoring the membrane's molecular weight cut off increases the removal of the toxins. However, an undesirable albumin loss is an often associated side effect and a potential concern for clinical use. A narrower pore size distribution counteracts the unwanted albumin loss. This study presents data on clearance and albumin loss at different blood and dialysate flow rates using novel dialyzers.

**Methods:** This study investigates the clearances for middle molecules in four commercial dialyzers with comparable surface areas. Simulated dialysis treatments were conducted using human plasma. The concentrations of the molecules were analyzed during 60min. The albumin loss was evaluated for 4h in a simulated hemodialysis treatment with bovine blood.

**Results:** The size dependent clearance shows the same trend for all dialyzers. The larger the middle molecule the less the impact of increasing blood flow on clearance. Theranova achieves the most elevated clearance results for small and Phylther for large middle-molecules, cf. Tab 1. However, Phylther showed the highest albumin loss during a 4h treatment compared to the investigated dialyzers, cf. Tab 1.

**Conclusions:** Novel dialyzers with extended permeability enable the removal of middle molecules when used in chronic and acute settings. Phylther stands out with higher removal of the middle molecule YKL-40, compared to the other dialyzers but exhibits a significant albumin loss. Theranova demonstrates the best trade-off between low albumin loss and good clearances of middle molecules.

**Funding:** Commercial Support - Baxter Int., Inc., supported the work.

### Comparative Effectiveness in Removing Uremic Toxins Between Hemodialysis With Reuse and Single-Use Super High-Flux Dialyzer

Piyapun Prapunwatana,<sup>1</sup> Pajaree Chariyavilaskul,<sup>2</sup> Paweena Susantiphong,<sup>1</sup> Yingyos Avihingsanon,<sup>1</sup> Somchai Eiam-Ong,<sup>1</sup> Khajohn Tiranathanagul.<sup>1</sup>  
<sup>1</sup>Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; <sup>2</sup>Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Department of Pharmacology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.

**Background:** Although hemodialysis (HD) with single use super high-flux dialyzer (SHF) provided comparable uremic toxin removing efficacy of both small (such as  $\beta_2$ -microglobulin,  $\beta_2$ M) and large (for example  $\lambda$ -free light chain, FLC) middle molecules to high volume post-dilution online hemodiafiltration, the single use SHF is expensive. The

present study was conducted to compare uremic toxin removing effectiveness between HD with reuse SHF and single-use SHF.

**Methods:** In this single center prospective study, 5 stable thrice-a-week HD patients underwent 3 periods of HD with reuse SHF dialyzer (ELISIO-21 HX), reprocessed with peracetic acid. In each period, one SHF dialyzer was maximally reused for 15 times and each patient utilized 2-4 SHF dialyzers for the whole study. The RR values of  $\beta$ 2M and  $\lambda$ -FLC were compared between the 1<sup>st</sup> use and the 2<sup>nd</sup>, 5<sup>th</sup>, 10<sup>th</sup>, and 15<sup>th</sup> use. The 1<sup>st</sup> use of each SHF dialyzer was utilized to represent the single-use SHF dialyzer. Dialysate albumin lost and serum albumin were assessed.

**Results:** A total of 15 dialyzers were analyzed. The RR of  $\beta$ 2M (should be  $\geq 80\%$ ) was comparable between the 1<sup>st</sup> use and 15<sup>th</sup> use ( $85.5 \pm 5.9\%$  vs  $82.5 \pm 3.5\%$ ). The  $\lambda$ -FLC RR (should be  $\geq 40\%$ ) was  $50.4 \pm 4.9\%$  at the 1<sup>st</sup> use which was significantly dropped to  $40.0 \pm 5.8\%$  and  $32.3 \pm 5.5\%$  at the 5<sup>th</sup> and 15<sup>th</sup> use, respectively ( $p < 0.001$ ). Dialysate albumin loss was significantly decreased from 1.01 g at the 1<sup>st</sup> use to 0.19 and 0.06 g at the 2<sup>nd</sup> and 5<sup>th</sup> use and undetectable after the 10<sup>th</sup> use. No statistically significant changes in serum albumin and Kt/V were found.

**Conclusions:** HD with reuse SHF dialyzer provided comparable ability to remove  $\beta$ 2M to single use SHF while the effectiveness in removing  $\lambda$ -FLC was gradually reduced after reuse. The removal of  $\lambda$ -FLC in the 5<sup>th</sup> use SHF was still comparable to high-volume online HDF. In conclusion, HD with reuse SHF dialyzer reprocessed with peracetic acid can be an alternative method to single use SHF with similar efficacy to high-volume online HDF at the 5<sup>th</sup> use.

**Funding:** Private Foundation Support

## SA-PO407

### The Efficacy of Post-Dilution Online Hemodiafiltration and Medium Cut-Off Dialyzer on the Removal of Protein-Bound Uremic Toxins

Ju young Moon,<sup>1</sup> Yang gyun Kim,<sup>1</sup> Su Woong Jung,<sup>1</sup> Dae Kyu Kim,<sup>1</sup> Sangho Lee,<sup>1</sup> Gun Tae Jung,<sup>4</sup> Kwang Pyo Kim,<sup>4,5</sup> Young-Il Jo,<sup>3</sup> Kyubok Jin,<sup>2</sup> Yaerim Kim,<sup>2</sup> <sup>1</sup>Kyung Hee University School of Medicine, Seoul, Republic of Korea; <sup>2</sup>Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; <sup>3</sup>Konkuk University Medical Center, Gwangjin-gu, Seoul, Republic of Korea; <sup>4</sup>Department of Applied Chemistry, Institute of Natural Science, Global Center for Pharmaceutical Ingredient Materials, Kyung Hee University, Seoul, Republic of Korea; <sup>5</sup>Department of Biomedical Science and Technology, Kyung Hee Medical Science Research Institute, Kyung Hee University, Seoul, Republic of Korea.

**Background:** The accumulation of protein-bound uremic toxins(PBUT), which is not easily removed in conventional hemodialysis (HD), is associated with increased cardiovascular outcomes in dialysis patients. High-efficiency HD is known to eliminate uremic toxins more efficiently, but data regarding PBUTs and dialysis modalities, especially medium cut-off (MCO) membrane, is scarce. Therefore, this study was designed to assess the efficacy of PBUTs clearance according to dialysis modalities.

**Methods:** In this prospective cross over multicenter study, dialysis removal of uremic toxins including urea, lambda free light chain( $\lambda$ -FLC), beta 2-microglobulin( $\beta$ 2MG), indoxyl sulfate(IS), and p-cresyl sulfate(pCS) were measured in the 22 HD patients on high-flux HD (HF-HD) with FX CorDiax80, post-dilution online hemodiafiltration (Post-OL-HDF) with Fx CorDiax800, MCO-HD with TheraNova 500 over three weeks each (Figure 1).

**Results:** The average convection volume in Post-OL-HDF was  $21.4 \pm 1.8$  L per session. The reduction rate(RR) of middle-molecular weight uremic toxins was significantly higher in MCO-HD and Post-OL-HDF than in HF-HD. The RR of  $\lambda$ -FLC was higher ( $p=0.001$ ), while the RR of  $\beta$ 2MG was lower ( $p=0.004$ ) in MCO-HD than in Post-OL-HDF. The dialysate albumin was highest in MCO-HD ( $2547.3 \pm 968.3$  mg/session), followed by Post-OL-HDF ( $778.3 \pm 313.2$  mg/session) and HF-HD ( $59.9 \pm 70.8$  mg/session). Post dialysis serum levels of IS (HF-HD:  $15.3 \pm 10.4$  mg/L, Post-OL-HDF:  $12.9 \pm 6.8$  mg/L in, MCO-HD:  $13.1 \pm 7.1$  mg/L) and pCS (HF-HD:  $26.6 \pm 12.3$  mg/L, Post-OL-HDF:  $24.8 \pm 14.1$  mg/L, MCO-HD:  $23.4 \pm 13.7$  mg/L) were not statistically different. Total solute removal of IS (HF-HD:  $95.0 \pm 96.0$  mg, Post-OL-HDF:  $83.6 \pm 13.0$  mg, MCO-HD:  $74.3 \pm 66.8$  mg), pCS (HF-HD:  $114.6 \pm 58.1$  mg, Post-OL-HDF:  $126.2 \pm 69.5$  mg, MCO-HD:  $101.7 \pm 57.4$  mg), and dialytic clearance of IS (HF-HD:  $22.1 \pm 19.9$  mL/min, Post-OL-HDF:  $19.5 \pm 17.2$  mL/min, MCO-HD:  $19.6 \pm 15.8$  mL/min), pCS (HF-HD:  $13.6 \pm 2.8$  mL/min, Post-OL-HDF:  $15.3 \pm 3.2$  mL/min, MCO-HD:  $14.1 \pm 3.9$  mL/min) also did not show a significant difference.

**Conclusions:** This study shows no significant difference in the removal of PBUTs according to three dialysis modalities, even though albumin removal was the highest in MCO-HD.

## SA-PO408

### Combined Hemodialysis or Hemodiafiltration With Hemoperfusion Treatment for Removal of Uremic Toxins

Aglaia Chalkia, Dimitris Kourniotis, Zoi Alexakou, Margarita Mpota, Emelina Stambolliu, Athanasia Kapota, Dimitrios I. Petras. *Nephrology Department, Hippokraton General Hospital, Athens, Greece.*

**Background:** The combination of hemodialysis-hemoperfusion (HDHP) has been proved to be superior to hemodialysis (HD) in eliminating uremic toxins. The optimal prescription is not fully elucidated.

**Methods:** 28 patients with end-stage renal disease were divided into 3 groups. We prescribed in group A hemodialysis (HD) and hemoperfusion (HP) sessions (HDHP), group B only HD and group C hemodiafiltration (HDF) and HP sessions (HDFHP). The

reduction ratio (RR) of targeted uremic toxins (low and medium) for each session was assessed. We used the HA-130 adsorption cartridge.

**Results:** The patients presented median age  $71 \pm 12$  years and median time on HD  $12 \pm 2$  months. We prescribed the HP session once biweekly (for the 1st month) and once monthly (for 11 months) during the first 2H of a regular HD or HDF. After 12 months of this intervention, both HDHP (n=12) and HDFHP (n=8) showed a significant removal of small water-soluble solutes, like urea (HDHP PR  $37 \pm 1$ ,  $p=0.03$ ; HDFHP  $25 \pm 6$ ,  $p=0.034$ ), compared to HD (n=8) (PR  $1 \pm 0.5$ ,  $p=0.09$ ). Regarding middle-sized molecules, HDHP and HDFHP also showed a significant increase in removal of  $\beta$ 2-microglobulin (HDHP PR  $6 \pm 0.7$ ,  $p=0.023$ ; HDFHP  $16.7 \pm 0.2$ ,  $p=0.037$ ) but not for iPTH, compared to HD (PR  $1.2 \pm 0.7$ ,  $p=0.098$ ). As far as safety, we only reported low intradialytic blood pressure at 5% of the patients to whom HP was added.

**Conclusions:** We demonstrated that a combination of hemodialysis or hemodiafiltration and hemoperfusion for 12 months helped efficaciously to reduce low and middle uremic toxins.

## SA-PO409

### Comparison of High-Flux, Super High-Flux, Medium Cut-Off Hemodialysis and Online Hemodiafiltration on the Removal of Uremic Toxins

Mohamed Belmouaz, Guillaume Goussard, Florent Joly, Betous Thomas, Frank Bridoux. *Universite de Poitiers UFR Medecine et Pharmacie, Poitiers, France.*

**Background:** Middle molecules (MM) that are inadequately removed by high-flux (HF) hemodialysis (HD) strategies are thought to contribute to the high morbidity and mortality of HD patients. On-line hemodiafiltration (OL-HDF) and HD using high-performance membranes such as adsorptive, medium cut-off (MCO), super high-flux (SHF) or protein permeable dialyzers have been implemented to enhance the removal of MM. The aim of this study was to compare the efficacy of these dialyzers used under different dialysis strategies on small solutes and MM reduction ratio (RR) and mass removal.

**Methods:** We performed a prospective study in 8 HD patients. Each patient underwent 9 dialysis sessions: seven sessions on HD using either TheraNova 500<sup>TM</sup>, Elisio 21H<sup>TM</sup>, Renak PS-2.0W<sup>TM</sup>, Filtrizer BK-2.1F<sup>TM</sup>, Vie 21X<sup>TM</sup>, TS-2.1UL<sup>TM</sup> or FDY 210-GW<sup>TM</sup> dialyzers and two sessions on OL-HDF using Elisio 21H<sup>TM</sup> or Renak PS-2.0W<sup>TM</sup> dialyzers.

**Results:** Urea mass removal and RR were similar between all dialysis strategies. The lowest beta2-microglobulin RR was achieved with Filtrizer BK-2.1F<sup>TM</sup> HD ( $p < 0.05$ ). Compared to Elisio 21H<sup>TM</sup> HD, Renak PS-2.0W<sup>TM</sup> OL-HDF produced higher beta2-microglobulin mass removal ( $181 \pm 46$  vs  $317 \pm 161$  mg,  $p < 0.05$ ). TheraNova 500<sup>TM</sup> HD, Vie 21X<sup>TM</sup> HD, FDY 210-GW<sup>TM</sup> HD, Elisio 21H<sup>TM</sup> OL-HDF and Renak PS-2.0W<sup>TM</sup> OL-HDF induced higher RR for kappa and lambda FLC, as compared to Elisio 21H<sup>TM</sup> HD and Filtrizer BK-2.1F<sup>TM</sup> HD ( $p < 0.05$ ). TS-2.1UL<sup>TM</sup> HD and Renak PS-2.0W<sup>TM</sup> HD produced higher lambda FLC RR compared to Elisio 21H<sup>TM</sup> HD ( $p < 0.05$ ). Renak PS-2.0W<sup>TM</sup> OL-HDF achieved higher kappa FLC mass removal compared to Elisio 21H<sup>TM</sup> HD ( $563 \pm 515$  vs  $141 \pm 47$  mg,  $p < 0.01$ ) and to Renak PS-2.0W<sup>TM</sup> HD ( $563 \pm 515$  vs  $153 \pm 25$  mg,  $p < 0.05$ ). Albumin loss varied from  $0.02 \pm 0.05$  to  $7.6 \pm 3.8$  g/session with Elisio 21H<sup>TM</sup> HD and Renak PS-2.0W<sup>TM</sup> OL-HDF, respectively. Compared to all other strategies, Renak PS-2.0W<sup>TM</sup> OL-HDF induced a significantly higher albumin loss ( $p < 0.05$ ).

**Conclusions:** This study confirms that albumin loss and the removal of MM, are similar using conventional Elisio 21H<sup>TM</sup> OL-HDF, MCO-HD (TheraNova 500) and SHF type V dialyzers (Vie 21X and FDY 210-GW). Although Renak PS-2.0W<sup>TM</sup> OL-HDF provides high performance for MM depuration, this protein-permeable dialyzer should not be used in post-dilution OL-HDF because of albumin loss exceeding the theoretical acceptable limit of 5 g per session.

## SA-PO410

### Improved Removal of Free Light Chains by Hemodialysis With Medium Cut-Off Dialyzer

Jung eun Lee, Jong Hyun Jhee, Hyeon cheon Park. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

**Background:** Free light chains (FLCs), well known middle molecular uremic toxins, are frequently elevated in patients with renal impairment. They are associated with chronic inflammation and vascular calcification and often elevated FLCs lead to increased morbidity and mortality. Recent studies suggest that middle to large molecules are more efficiently removed by medium cut-off (MCO) dialyzers than high-flux dialyzer. This study aimed to investigate the efficacy of MCO dialyzer on elimination of FLC compared to high-flux dialyzer in patients undergoing hemodialysis.

**Methods:** A randomized prospective study was performed with 68 participants, divided into MCO dialyzer group (n = 34) and high-flux dialyzer group (n = 34). Serum levels of middle to large molecules including kappa and lambda FLCs, and beta-2 microglobulin, and their reduction ratios were measured at baseline and after 6 months, and compared between two groups.

**Results:** Baseline serum levels of albumin, calcium, inorganic phosphate and hemoglobin, and Kt/V did not differ between two groups. After 6 months, Kappa FLCs (from  $354.4 \pm 509.7$  to  $304.7 \pm 401.8$  mg/L, vs. from  $236.7 \pm 73.8$  to  $248.2 \pm 73.8$  mg/L;  $p = 0.016$ ), lambda FLCs (from  $204.9 \pm 60.3$  to  $183.4 \pm 57.8$  mg/L, vs. from  $190.1 \pm 52.0$  to  $198.8 \pm 79.4$  mg/L;  $p = 0.001$ ), and beta-2 microglobulin levels (from  $29.5 \pm 5.8$  to  $25.6 \pm 3.4$  mcg/mL, vs. from  $26.9 \pm 5.7$  to  $26.4 \pm 5.2$  mcg/mL;  $p = 0.019$ ) of MCO dialyzer group were significantly decreased, and while those of high-flux group were increased. The reduction ratios of kappa and lambda FLCs, and beta-2 microglobulin in MCO group were higher than those of high-flux group ( $10.5$  vs.  $-5.3\%$ ,  $11.1$  vs.  $-3\%$ , and  $10.6$  vs.  $-1\%$ , respectively). After 6 months, there was no change in serum albumin levels between two groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Hemodialysis with MCO dialyzer shows better removal of FLCs, with preserved dialysis adequacy and serum albumin. Further studies are needed to establish the long-term effects of using MCO dialyzer on clinical outcome.

Figure 1. Difference between high-flux group and MCO group in reduction ratios of the middle molecule levels

## SA-PO411

### Improved Serum Phosphorous and Small Molecule Removal With Expanded Hemodialysis and Hemodiafiltration vs. Conventional Hemodialysis: A Cross-Over Randomized Clinical Trial

Olynea Vega, Adrián Esteban Caballero-Islas, Noemi Del Toro-Cisneros, Mauricio Arvizu Hernández, Armando Jezael Martínez-Rueda, Diana Camacho, Ricardo Correa-Rotter. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Background:** Expanded hemodialysis (HDx) with medium cut-off dialyzers is expected to provide enhanced permeability to medium sized molecules, selective solute retention, and better internal retrofiltration. The objective of our study was to compare clearance of different size molecules in 3 modalities: conventional hemodialysis (cHD), hemodiafiltration (HDF), and HDx.

**Methods:** A single-center cross-over study was conducted in prevalent hemodialysis. Patients were randomized to determine the initial modality of treatment (Figure 1). Blood samples were taken on the first and last session in each modality and pre and post treatment. We performed ANOVA to compare groups.

**Results:** Twenty-seven stable patients were randomized, 5 were excluded (Figure 1). Twenty-two patients completed the study and were included in the analysis. The removal of small solutes (BUN) was similar in HDF and HDx and less effective in cHD ( $p=0.048$ ). There was no difference in reduction ratios for medium-sized molecules (CRP, IL6, IL10, TNF $\alpha$ ), or in protein-bound p-cresol. We observed a decrease in serum phosphorous (P) in the HDx and HDF periods, contrary to what happened with cHD: (HDx 4.78 vs 3.99, HDF 5.09 vs 4.07, and cHD 4.51 vs 4.62) (Figure 2). There was no decrease in serum albumin in any of the modalities. The most frequent adverse event was intradialytic hypotension, without differences between groups.

**Conclusions:** HDF and HDx were more effective to remove small molecules vs cHD. In addition serum P values were lower in the end of period determination with HDF and HDx, which reflect a better removal of total body P with these two modalities.

### A Randomized, Open-Label, Crossover Clinical Study to Compare the Effect of Hemodialysis Performed With a Medium Cut-Off Membrane vs. That With a High-Flux Membrane on Endothelial Function

Rachel G. Armani, Aluizio B. Carvalho, Monique V. Rocha e Silva, Maria Eugenia F. Canziani. *Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

**Background:** Endothelial dysfunction (ED) is considered a marker of vascular complications, especially in patients with chronic kidney disease (CKD). Inflammation and the uremic state contribute to ED in hemodialysis (HD) patients. Recently, the medium cut-off (MCO) HD membrane has been proposed to efficiently remove inflammatory cytokines and higher molecular weight uremic toxins. The aim of this study was to compare the effect of dialysis with medium cut-off (MCO) or high-flux (HF) membranes on endothelial function of patients on chronic HD.

**Methods:** A prospective, randomized, crossover study in which 32 patients with CKD were dialyzed for 12 weeks with each membrane, including a 4-week washout period between treatments. Endothelial function was assessed by flow-mediated dilation (FMD) using brachial artery ultrasound at weeks 1, 12, 16, and 28.

**Results:** The population consisted of 59% men,  $52.7 \pm 13.4$  years, 16% non-black, on HD for  $8.8(4.1-15.1)$  years, 72% with arteriovenous fistula. Hypertension was the most common etiology of CKD and 34% of patients had previous cardiovascular disease. Patients were grouped, regardless of treatment sequence, into MCO or HF groups, since no carry-over ( $p=0.634$ ) or sequence ( $p=0.998$ ) effects were observed in the FMD assessment. The ANOVA model with repeated measures showed no effects of treatment ( $p=0.426$ ), time ( $p=0.972$ ) or interaction ( $p=0.413$ ) in the comparison of FMD, between the MCO and HF groups. Figure 1 shows mean and respective 95% confidence interval of FMD (%) per treatment, according to evaluation moments.

**Conclusions:** Dialysis performed with MCO or HF membranes did not influence endothelial function in patients undergoing chronic HD.

**Funding:** Commercial Support - Baxter Company

Figure 1 - Mean and respective 95% confidence interval of FMD (%) per treatment, according to evaluation moments.

## SA-PO414

### Expanded Dialysis With TheraNova Compared to Conventional High-Flux Hemodialysis: A Randomized Prospective 12-Month Study

Maggie ming yee Mok,<sup>1,2</sup> Sing-Leung Lui,<sup>1,2</sup> Tak Mao D. Chan,<sup>3,2</sup> Tung Wah Hospital, Hong Kong, Hong Kong; <sup>2</sup>The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong; <sup>3</sup>Queen Mary Hospital, Hong Kong, Hong Kong.

**Background:** Hemodialysis (HD) using medium cut-off (MCO) TheraNova enables enhanced clearance of middle molecules. This study investigated the clinical effects of MCO dialysis compared with conventional HD, in Hong Kong where a significant proportion of patients were on twice-weekly HD.

**Methods:** Adult chronic HD patients were recruited from two HD units. All patients received high-flux HD over a 6-week run-in period, then were randomized (1:1) to receive high-flux HD or MCO-HD for 12 months. Primary outcomes included nutritional indexes measured by body composition monitor (BCM), and patient-reported symptom parameters. Blood parameters related to nutrition, inflammation, and cardiovascular health were also measured.

**Results:** Sixty patients were included (30 in each group) with similar baseline characteristics. Body mass index, lean and fat tissue indexes remained stable throughout within and between groups. Serum albumin in the MCO-HD group showed a significant decrease at 6-month ( $36.23 \pm 3.36$  g/L) compared with baseline ( $37.93 \pm 2.80$  g/L,  $p=0.043$ ), which was significantly lower than that in controls ( $38.44 \pm 3.43$  g/L,  $p=0.024$ ) at this time-point, but the level increased afterwards and the differences were not sustained. At 12-month, measured serum parameters were similar in the two groups (Tab). Symptoms related to sleep quality, appetite, itchiness, and quality of life as measured by KDQOL-SF™ V1.3 showed no between-group difference. The incidence rates of all adverse events and hospitalizations were similar in the two groups, including events related to fluid

status. Overhydration as measured by BCM was not increased in patients on MCO-HD compared with controls, while ultrafiltration was only used in the latter.

**Conclusions:** MCO-HD with TheraNova over 12 months was safe and well tolerated, resulting in similar morphometric and biochemical parameters of nutritional status compared with patients on high-flux HD. Patients treated with MCO-HD showed an initial decrease in serum albumin which returned to prior levels after 6 months.

### Evaluation of VIE-X Filter Performances vs. Medium Cut-Off Dialyzer and High-Flux Dialyzers on Protein Loss and Inflammatory Status of Chronic Hemodialysis Patients

Matteo Marcello,<sup>1,2</sup> Anna Lorenzin,<sup>3,2</sup> Claudio Ronco,<sup>3,2</sup> Monica Zanella,<sup>3,2</sup> <sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Fondazione IRRIV, Vicenza, Italy; <sup>3</sup>Ospedale San Bortolo di Vicenza, Vicenza, Italy.

**Background:** In ESKD there is retention of a wide range of uremic toxins. The identification middle molecular weight toxins, has promoted interest in the development of alternative techniques in order to remove larger solutes. Hemodiafiltration (HDF) has produced some results, although large convective volume, optimal vascular access and strict water quality management are required. A new class of membrane has been recently developed with a cut off (MWCO) close to the molecular weight of albumin and a very high retention onset (MWRO), allowing convective movement of large uremic solutes even in conventional HD. The aim of this study was to evaluate the safety and efficacy of ASAHI new membrane Vie-X, comparing its performance with MCO membranes and HDF treatments.

**Methods:** A longitudinal single-center device study was conducted for 3 months among 18 chronic HD patients afferents to our center. Patients were randomly assigned to either online HDF, HDx with MCO membrane, or HD with Asahi Vie-X. Blood samples, as well as dialytic effluent, were collected during 4 dialysis sessions (T0, T1, T2, T3). The primary goal was to assess albumin loss among the three types of dialyzers.

**Results:** All dialyzers had an albumin loss lower than 5 grams per HD session. We found a greater albumin loss in patients undergoing HD with MCO membrane with a significant difference in comparison to Vie-X and online HDF,  $p=0.003$  (Figure 1). We didn't find any statistical difference in the clearance of middle molecules such as myoglobin between the three dialyzers ( $p=0.22$ ). Clearance of IL-6 was higher in patients undergoing online HDF ( $p<0.001$ ).

**Conclusions:** Vie-X is a polysulfone, vitamin E-interactive membrane with presumed cut-off valued of 60kD allowing advanced sieving profiles and increased internal filtration. In our study we find Vie-X to have a safe albumin loss, comparable to that of online HDF, maintaining clearance for middle molecular weight molecules similar to MCO dialyzer and online HDF.

## SA-PO416

### Safety and Performance of the Clearum™ High Flux Hemodialyzer

Thilo Krueger,<sup>1</sup> Frank Dellanna,<sup>1</sup> Werner Kleophas,<sup>1</sup> Candace Mcclure,<sup>2</sup> Silvia Manfredini,<sup>3</sup> <sup>1</sup>DaVita Clinical Research Deutschland GmbH, Düsseldorf, Germany; <sup>2</sup>North American Science Associates Inc, Northwood, OH; <sup>3</sup>Medtronic Inc, Mirandola, Italy.

**Background:** Clearum™ is a new high flux steam sterilized (HS) dialyzer for treatment of end stage renal disease (ESRD) patients with hemodialysis (HD) or hemodiafiltration (HDF) online. A clinical study was conducted to evaluate the safety and performance of the Clearum HS hemodialyzer in the removal of small and middle-sized uremic toxins.

**Methods:** A prospective, interventional, non-randomized study enrolled twenty (20) ESRD patients undergoing HD. The Clearum HS dialyzer was compared to Fresenius FX-series of dialyzers for a baseline (control) comparison. The duration of the trial was 2 weeks for the FX control dialyzer + 6 weeks with the Clearum HS dialyzer used for 3x weekly high flux hemodialysis.

**Results:** Nineteen (19) of 20 subjects completed the study. The primary objective of mean urea reduction ratio (URR) >65% was met. No significant difference in mean URR between the Clearum HS and Fresenius FX-series of dialyzers ( $p=0.97$ ) was observed. No dialyzer-related adverse events were reported in the study. β<sub>2</sub>-microglobulin (B2M) reduction with the Clearum HS dialyzer was statistically higher than the FX-series dialyzer (67.0% versus 54.1%;  $p<0.0001$ ). Pre-dialysis interleukin-6 (IL6) and C-reactive protein (CRP) concentrations, blood-rest scores and thrombin-anti-thrombin (TAT) were comparable among the Clearum HS and FX-series of dialyzers. Finally, albumin remained at a stable level over the course of the 6 weeks of Clearum HS dialyzer use with no appreciable differences when compared to the Fresenius FX-series of dialyzers.

**Conclusions:** Overall, the Clearum HS dialyzer performed effectively in this post market study and with no reported dialyzer-related adverse events.

**Funding:** Commercial Support - Medtronic

### β<sub>2</sub>-Microglobulin and α<sub>1</sub>-Microglobulin Reduction Ratios and Survival in Prevalent Dialysis Patients

Sonoo Mizuiri,<sup>1</sup> Yoshiko Nishizawa,<sup>1</sup> Toshiki Doi,<sup>1,2</sup> Aiko Okubo,<sup>1,2</sup> Kenichi Morii,<sup>1,2</sup> Kazuomi Yamashita,<sup>1</sup> Kenichiro Shigemoto,<sup>1</sup> Takao Masaki,<sup>2</sup> Ichiyokai Harada Hospital <sup>1</sup>Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; <sup>2</sup>Hiroshima Daigaku Byoin, Hiroshima, Japan.

**Background:** The β<sub>2</sub>-microglobulin (β<sub>2</sub>-MG) and α<sub>1</sub>-microglobulin (α<sub>1</sub>-MG) molecular weights are 11,800 and 33,000 Da. There are several important middle molecules including fibroblast growth factor 23 around α<sub>1</sub>-MG. β<sub>2</sub>-MG and α<sub>1</sub>-MG reduction ratios (RRs) and dialysis patient survival were studied.

**Methods:** Subjects were prevalent dialysis patients (247 predilution online hemodiafiltration [Pre-OL-HDF] and 61 hemodialysis [HD] patients). Clinical data including β<sub>2</sub>-MG and α<sub>1</sub>-MG RRs were assessed at baseline. Kaplan-Meier curves, logistic regression analyses and Cox proportional hazard models were used to assess patient survival.

**Results:** Age, dialysis duration, and diabetes prevalence in all patients ( $n=308$ ) were 67±12 years, 70 (42–140) months, and 47.4%, respectively. Over 450 days, 33 patients died. The mortality cut-off values for β<sub>2</sub>-MG RR and α<sub>1</sub>-MG RR using receiver operating characteristic curves were 78% and 20%, respectively. Patients with β<sub>2</sub>-MG RR ≥78% ( $n=131$ ) showed significantly higher serum albumin ( $3.6±0.4$  vs.  $3.5±0.4$  g/dL) and magnesium levels and Pre-OL-HDF frequency, but a significantly lower age and C-reactive protein levels than in patients with β<sub>2</sub>-MG RR <78% ( $n=177$ ) ( $P<0.05$ ). These differences were observed between patients with α<sub>1</sub>-MG RR ≥20% ( $n=134$ ) and α<sub>1</sub>-MG RR <20% ( $n=174$ ) ( $P<0.05$ ). Kaplan-Meier survival rates were significantly higher in patients with β<sub>2</sub>-MG RR ≥78% than in patients with β<sub>2</sub>-MG RR <78% and in patients with α<sub>1</sub>-MG RR ≥20% than in patients with α<sub>1</sub>-MG RR <20% ( $P<0.05$ ). In unadjusted Cox models, the β<sub>2</sub>-MG RR (hazard ratio [HR] 0.97,  $P<0.01$ ) and α<sub>1</sub>-MG RR (HR 0.97,  $P<0.05$ ) but not HDF were predictors of all-cause mortality. After adjusting for age, sex, diabetes, dialysis duration, C-reactive protein, and normalized protein catabolic rate, the β<sub>2</sub>-MG RR (HR 0.92,  $P<0.01$ ) but not the α<sub>1</sub>-MG RR remained a significant predictor for mortality. α<sub>1</sub>-MG RRs were significantly correlated with β<sub>2</sub>-MG RRs ( $p=0.71$ ,  $P<0.0001$ ) and serum albumin levels ( $p=0.21$ ,  $P<0.001$ ). β<sub>2</sub>-MG RRs were significantly correlated with serum albumin levels ( $p=0.23$ ,  $P<0.0001$ ).

**Conclusions:** In patients on Pre-OL-HDF or HD, higher β<sub>2</sub>-MG and α<sub>1</sub>-MG RRs showed better survival, and the β<sub>2</sub>-MG RRs was a significant determinant for mortality. Higher β<sub>2</sub>-MG and α<sub>1</sub>-MG RRs were not related to lower serum albumin levels.

SA-PO418

**Molecular Sieving via Conformational Flexing During Frictionless Flow in Slippery Carbon Nanotube Membranes for Hemodialysis**  
Piran Kidambi,<sup>1</sup> Peifu Cheng,<sup>1</sup> Nicholas J. Ferrell,<sup>5</sup> Carl M. Öberg,<sup>6</sup> Steven F. Buchsbaum,<sup>3</sup> Melinda L. Jue,<sup>3</sup> Dan Wang,<sup>5</sup> Shuvo Roy,<sup>4</sup> Francesco Fornasiero,<sup>3</sup> William H. Fissell,<sup>2</sup> <sup>1</sup>Vanderbilt University, Nashville, TN; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Lawrence Livermore National Laboratory, Livermore, CA; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>The Ohio State University, Columbus, OH; <sup>6</sup>Lunds Universitet, Lund, Sweden.

**Background:** Size selective molecular separation offer transformative advances in hemodialysis. The classic trade-off between selectivity and permeability necessitates larger membrane areas (larger kits) and high pressures in conventional dialysis membranes, which limits progress towards implantable/wearable alternatives. Here, vertically aligned nanoscale capillaries embedded in a polymer matrix present new possibilities.

**Methods:** Vertically aligned carbon nanotubes (CNTs) forests were synthesized via chemical vapor deposition with precise diameter control via catalyst engineering and the space between was filled with paralyene. A microporous silicon support was used as a backing plate and the membranes mounted into a custom-built filtration cell. Hydraulic permeability was assessed via gravimetric flow rates at different transmembrane pressures. The transport of fluorescently labeled polydisperse Ficoll, either in phosphate-buffered saline (PBS) or bovine blood plasma was used to evaluate the size-selectivity. Ficoll concentrations were analyzed using size-exclusion chromatography.

**Results:** The synthesized CNT membranes membrane exhibited a cut-off ~6nm for Ficoll in PBS as well as bovine blood plasma. We measured a hydraulic permeability ~102.3 ml h<sup>-1</sup> m<sup>-2</sup> mm Hg<sup>-1</sup> in comparison to ~30 ml h<sup>-1</sup> m<sup>-2</sup> mm Hg<sup>-1</sup> reported in the literature for conventional high flux dialyzers. The CNT membranes allow for near complete passage of ~2 nm Ficoll molecules (Figure), which is similar to the approximate size of hemodialysis relevant small/middle molecules, e.g. b<sub>2</sub> microglobulin, while maintain clinically acceptable levels of Albumin loss.

**Conclusions:** The synthesized CNT membranes showed enhanced middle molecule clearance as well as higher hydraulic permeability compared to conventional hemodialysis membranes.

**Funding:** Other U.S. Government Support

SA-PO419

**Auto Flow Feature Reduces Dialysate Use While Maintaining Dialysis Adequacy Among In-Center Hemodialysis (HD) Patients**  
Meijiao Zhou, Linda Ficociello, Claudy Mullon, Michael S. Anger. *Fresenius Medical Care, Waltham, MA.*

**Background:** Adjustment of dialysate flow rate (Qd) as a proportion of blood flow rate (Qb) may lower dialysate consumption. The Auto Flow (AF) feature on Fresenius Medical Care 2008T dialysis machines can make these adjustments automatically. Using real-world data, we investigated the use of the AF feature and its impact on dialysis adequacy among in-center HD patients.

**Methods:** Adult in-center HD patients converting from manual to AF (either 1.5 or 2.0 times the Qb) during 2021 at Renal Research Institute clinics were included. All patients had Kt/V measured 3 months before and after switching to AF and no change in vascular access, dialyzer types or prescribed Qb. Parameters were averaged over each 3-month period before and after switch, and comparisons between time periods were made using paired t-tests.

**Results:** At AF switch, patients (n=48) had mean age of 64 years and vintage of 7 years. Most patients had a fistula (63%) and used Optiflux 180NRe (85%). 46% and 54% patients were switched to AF 1.5 and AF 2.0, respectively. After switch, on average, actual Qd reduced by 37 mL/min; based on the treatment time and actual Qd, we calculated that

8.6 L dialysate volume could be saved per patient per treatment (p<.0001). There was no statistically significant change in mean spKt/V, although there was a numeric increase after switch (table). Sub-analysis by AF 1.5 and 2.0, showed no change in spKt/V among patients switched to AF 1.5 (1.67) and an increase from 1.55 to 1.61 (p=0.06) among those switched to AF 2.0.

**Conclusions:** Use of the Auto Flow feature during HD maintained patients' dialysis adequacy. Based upon actual Qd and treatment time, we can estimate that this would save, on average, 8.6 L of dialysate per patient per treatment (p<0.0001).

**Funding:** Commercial Support - Fresenius Medical Care

Parameters	3-month before switch to AF	3-month after switch to AF	Mean difference	P value

SA-PO420

**The Effect of Hemodiafiltration vs. High-Flux Dialysis on Middle- and Large-Sized Molecules' Reduction and Its Relation to Albumin Loss Using Big Surface-Area Dialyzer 2.6 m2**  
Hesham M. Elsayed, Magdy ElSharkawy, Hayam M. Aref, Waleed A. Abdelmohsen, Abdelrahman N. Khedr, Hussein S. Abdallah, Shaimaa Z. Abdallah, Reem A. Sultan, Mohamed F. Radwan, Aya M. Magdi, Khalid G. Abdelwahab, Abdelrahman A. Elbraky, Ahmed Emara. *Ain Shams University Faculty of Medicine, Cairo, Egypt.*

**Background:** Uremic toxins are classified into small, middle-sized, and protein-bound solutes. Removal of middle-sized molecules with minimal albumin loss is needed. This study assessed different molecules' removal using 2.6m<sup>2</sup> surface area (SA) dialyzer on high-flux haemodialysis (HF-HD) vs. hemodiafiltration (HDF) and its relation to albumin loss

**Methods:** A crossover study included 25 patients, underwent HF-HD followed by online post-dilution HDF using dialyzer; BIOPURE (Biorema) 260 HF (with a SA 2.6 m<sup>2</sup>, High-flux hollow Fiber Hemodialysis membrane with steam sterilization, myoglobin SC 0.7, membrane cutoff value 40 KDa.), with 2-weeks washout period. All patients were subjected to single session assessment of cumulative dialysate albumin loss, and to measurement of pre-post dialysis Reduction values of Kappa and Lambda free light chains (FLC), α-1-microglobulin (MG), IL-6 and procalcitonin by ELISA.

**Results:** There was significant reduction in post-dialysis levels of all molecules in HF-HD and HDF compared to pre-dialysis levels (P<0.001). HDF showed higher post dialysis reduction ratio of kappa and lambda FLC, α 1-MG, IL-6 and procalcitonin (P<0.001). Total dialysate albumin loss on HDF was higher compared to HF-HD with median of 2.46 (1.7 – 2.8 IQR), 0.65 (0.48 – 1.1 IQR) respectively. Maximum albumin loss on HDF was in the first hour with a median of 1.20 (0.77 – 1.3 IQR). Transmembrane pressure was positively correlated with total albumin loss in both modalities.

**Conclusions:** BIOPURE (Biorema) 260 HF, 2.6 m<sup>2</sup> SA, may be effective in medium-sized molecules' removal especially with online post-dilution HDF with acceptable albumin loss

**Funding:** Private Foundation Support

## Clinical Efficacy of Fractionated Plasma Separation and Adsorption Integrated With Continuous Veno-Venous Hemofiltration in Patients With Liver Failure

Jianhua Dong, Li Huang, Wenjing Fan, Yongchun Ge. JinLing Hospital, Nanjing, China.

**Background:** To observe the clinical efficacy and safety of fractionated plasma separation and adsorption integrated with continuous veno-venous hemofiltration (FPSA-CVVH) treatment on patients with liver failure.

**Methods:** In this retrospective study, we enrolled patients with acute or acute-on-chronic liver failure (serum total bilirubin  $>171.0 \mu\text{mol/L}$  or MELD Score  $>18$ ) hospitalized from 2015 to 2021. All patients received the treatment of FPSA-CVVH. The extracorporeal circulation connection is shown in Figure 1. Anticoagulation was provided with LMWH or citrate. The main efficacy evaluation index was bilirubin reduction ratios per session (RRs).

**Results:** 78 patients with acute ( $n=74$ ) or acute-on-chronic ( $n=4$ ) liver failure were enrolled. Total bilirubin at baseline was  $377.0 \pm 101.6 \mu\text{mol/L}$ , direct bilirubin was  $279.3 \pm 78.7 \mu\text{mol/L}$  and indirect bilirubin was  $59.7 \pm 27.4 \mu\text{mol/L}$ . 187 sessions of FPSA-CVVH treatment were performed. After a single session total bilirubin ( $364.8 \pm 104.5 \mu\text{mol/L}$  vs  $170.8 \pm 57.3 \mu\text{mol/L}$ ), direct bilirubin ( $262.4 \pm 86.5 \mu\text{mol/L}$  vs  $102.5 \pm 46.4 \mu\text{mol/L}$ ) and indirect bilirubin ( $62.3 \pm 27.7 \mu\text{mol/L}$  vs  $35.9 \pm 14.8 \mu\text{mol/L}$ ) significantly decreased. RRs was  $52.0 \pm 7.6\%$  for total bilirubin,  $59.4 \pm 13.0\%$  for direct bilirubin and  $36.9 \pm 15.4\%$  for indirect bilirubin. Mean arterial pressure and heart rate remained stable during the treatment. 2 patients changed the filters due to blood coagulation. And another 2 patients exhibited bleeding (gastrointestinal bleeding and Oozing bleeding). 29 patients (37.2%) survived in discharging from hospital, 12 patients had recovered liver function, and the remaining 17 patients still needed intermittent artificial liver support therapy.

**Conclusions:** FPSA-CVVH treatment was a novel and effective artificial liver support therapy in patients with liver failure. Thus, it may be considered as a "bridge technique" to the recovery of liver and renal function in critical ill patients with liver failure.

## SA-PO422

## Standard Addition Method to Analyze Bisphenols in Dialyzers

Zahin S. Haq,<sup>1</sup> Xin Wang,<sup>1</sup> Xiaoling Wang,<sup>1</sup> Gabriela Ferreira Dias,<sup>1</sup> Joann Cheng,<sup>5</sup> Chih-Hu Ho,<sup>4</sup> Hannah-Madeleine Breitwieser,<sup>3</sup> Nadja Grobe,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; <sup>4</sup>Fresenius Medical Care North America, Ogden, UT; <sup>5</sup>Fresenius Medical Care North America, Waltham, MA.

**Background:** Bisphenol A (BPA), a high-volume industrial chemical, has been associated with health risks. Materials made with alternative chemicals such as Bisphenol S (BPS) have been produced, but toxicity concerns were also raised. BPA-containing materials have been used to manufacture dialyzers. Hemodialysis patients' exposure to BPA/BPS can be measured in dialyzer extractables (E) and leachables (L). However, analytical challenges are E/L complexity, matrix effects, and lack of appropriate blank specimen. We propose Standard Addition Method (SAM) as a good choice for accurate quantification of BPA/BPS in E/L.

**Methods:** BPA/BPS extracted from dialyzers in exaggerated (95% EtOH, E) and simulated-use (17.2% EtOH, L) conditions were subjected to tandem liquid chromatography-mass spectrometry. For SAM, unspiked E/L and five diluted, authentic BPA/BPS spiked E/L were run. <sup>13</sup>C<sup>12</sup>-labeled BPA/BPS served as internal standards. MassHunter Quantitative Analysis was used for quantification (Fig. 1A).

**Results:** Concentrations were reported when quality thresholds were met, including repeatable retention time, Q/Q ratio of  $100\% \pm 20$ , correlation coefficient  $> 0.99$ , accuracy and recovery within  $100\% \pm 20$ . Figure 1B shows two types of dialyzers made from BPA/BPS-containing material (Type A) and BPA/BPS-free material (Type B). With the measured BPA/BPS level in E/L, patient exposure can be estimated.

**Conclusions:** SAM is a good quantitation method for analyzing BPA/BPS in E/L. Analytical challenges such as matrix complexity and effects and lack of appropriate blank specimen can be overcome. With the measured concentration of BPA/BPS in E/L,

patient exposure to BPA/BPS can be estimated, and the toxicological risk assessment on hemodialysis-associated BPA/BPS exposure can be performed.

Figure 1A: BPA/<sup>13</sup>C<sub>12</sub> BPA chromatograms and calibration curve for Type A sample. Figure 1B: BPA/BPS levels per device and estimated patient exposure.

## Allo-Hemodialysis Feasibility Study in a Porcine Model of AKI

Xin Wang,<sup>1</sup> Amrith U. Patel,<sup>1</sup> Anil K. Gothi,<sup>2</sup> Dejan Nikolic,<sup>3</sup> Alexander Heide,<sup>3</sup> Jiaming Dong,<sup>4</sup> Vaibhav Maheshwari,<sup>1</sup> Nadja Grobe,<sup>1</sup> K s Nayak,<sup>5</sup> Peter Kotanko.<sup>1,6</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Vivo Bio Tech, Hyderabad, India; <sup>3</sup>Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; <sup>4</sup>Fresenius Medical Care R&D (Shanghai) Co., Ltd, Shanghai, China; <sup>5</sup>Virinchi Hospitals, Hyderabad, India; <sup>6</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Annually, millions of kidney patients, predominantly in low and middle income countries, die prematurely because of lacking access to affordable kidney replacement therapy. Previously (ASN Kidney Week, 2021), we have demonstrated in healthy pigs the technical feasibility of allo-hemodialysis (alloHD), an alternative, low-cost dialysis treatment where the blood of a kidney failure patient flows counter-current to the blood of a healthy subject through the dialyzer. Here we report first results from an alloHD feasibility study in a porcine acute kidney injury (AKI) model.

**Methods:** The protocol was approved by the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), New Delhi, India. We studied four female Yorkshire pigs (weight 30 to 80 kg) with central venous catheter as vascular access. Under general anesthesia, AKI was induced in two pigs (AKI1; AKI2) through ligation of renal blood vessels. AKI pigs were then dialyzed for 4 hours against healthy pigs (H1; H2). AKI and healthy pigs were connected to the dialysate and blood compartments, respectively, of a Nipro Cellentia 17H dialyzer and anticoagulated with heparin (5,000 IU/h). Blood samples were collected before, during, and after alloHD for measurements of blood urea nitrogen (BUN) and creatinine.

**Results:** We performed one alloHD session each in two pig pairs (AKI1 & H1; AKI2 & H2). During alloHD, BUN and creatinine levels declined in the AKI animals and - as expected - transiently increased in the healthy animals and declined in the second half of the dialysis (Fig. 1). We found no indication of hemolysis or dialyzer coagulation.

**Conclusions:** In our feasibility studies in a porcine AKI model, alloHD performed as expected. Studies exploring extended outcomes are underway.

Fig. 1. Dynamics of BUN (panel A) and serum creatinine (panel B) in healthy (blue) and AKI (red) pigs.

## Therapeutic Plasma Exchange for Severe Hypertriglyceridemia

Zachary Drury, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

**Introduction:** Severe hypertriglyceridemia (HTG) can result in significant acute and chronic conditions including pancreatitis and major cardiac adverse events. Early recognition and treatment is imperative to avoid complications. We report a case of severe hypertriglyceridemia incidentally discovered during therapeutic plasma exchange (TPE) for paraneoplastic syndrome with subsequent improvement of severe HTG with TPE.

**Case Description:** A 61 year old man with past medical history of CAD presented with ataxia and vision changes and was found to have Hodgkins lymphoma and anti-Tr antibody associated paraneoplastic syndrome. He was started on chemotherapy with doxorubicin, bleomycin, vinblastine, dacarbazine, and decadron. His paraneoplastic syndrome was treated with corticosteroids, intravenous immunoglobulin and TPE with subsequent improvement in gait and vision. He developed a recurrence of neurologic symptoms and returned for a second course of TPE. His effluent was noted to be white and Triglyceride (TG) levels were obtained that notable for levels of 1503 mg/dl. After third session of TPE a 71.4% reduction in the serum TG (1368 mg/dl to 390 mg/dl) was observed. TPE was then continued for a total of five sessions. At the completion of five sessions of TPE triglycerides had improved to 370 mg/dl. The etiology of HTG was likely undiagnosed diabetes in the setting of high dose corticosteroids for paraneoplastic syndrome and chemotherapy. The patients Hemoglobin A1C was increased at 9.1%. He was started on empagliflozin and insulin with improvement in blood sugar. On his follow up visit his A1C had decreased to 6.7% and his TG improved to 437 mg/dl.

**Discussion:** Severe HTG can have life threatening acute and chronic complications. Severe HTG was incidentally found due to workup of white effluent during TPE. It is reasonable to consider TPE as a therapy for severe hypertriglyceridemia pending evaluation and treatment to avoid complication from elevated triglycerides.

## SA-PO426

## Comparison of Mid and Conventional Dialysate Flow in Critically Ill Patients Undergoing Intermittent Dialysis

Sevag Demirjian, Anne M. Huml, Michael W. George, Matthew Layne, Jonathan J. Taliercio. *Cleveland Clinic, Cleveland, OH.*

**Background:** Conventional dialysis is a water hungry medical procedure where potential savings in consumption and wastage are feasible without compromise in patient care. Kinetic modeling of urea has shown that dialysate flow rates ( $Q_d$ ) of 300 ml/min incur lower urea reduction ratio (URR) compared to conventional rates. We sought to compare urea clearance between mid and conventional flow rates, and the effect of filter size in real life clinical setting.

**Methods:** A retrospective observational study of critically ill patients requiring bedside intermittent dialysis. The study included dialysis treatments with prescribed and completed 4 hr treatments with achieved blood flow rate of 400 ml/min. ANOVA with p value of < .05 was used to compare URRs between 300 and 600 mL/min  $Q_d$  and type of dialyzer use (Optiflux High Flux 160 vs 250).

**Results:** The three groups ( $Q_d$ =300/F160,  $Q_d$ =300/F250, and  $Q_d$ =600/F160) were statistically different in post dialysis BUN, and URR achieved (Table). The mean URR was significantly different between  $Q_d$ =300/F160 and  $Q_d$ =600/F160 groups (.69 vs. .72,  $p$ =.03), but was similar between  $Q_d$ =300/F250 and  $Q_d$ =600/F160 (.71 vs. .72,  $p$ =.17).

**Conclusions:** Small solute clearance represented by URR delivered in critically ill patients was higher in dialysis treatments with  $Q_d$  of 300 vs 600 mL/min. However, this difference was offset by the use of larger dialyzer. The current findings may have implications in hospital settings where water preservation is of priority.

	$Q_d$ =300/F160 (n=51)	$Q_d$ =300/F250 (n=102)	$Q_d$ =600/F160 (n=4019)	p value
Age (yrs)	60 (55, 72)	57 (49, 69)	61 (52, 69)	.06
Weight (kg)	83 (73, 92)	84 (76, 111)	86 (74, 106)	.28
Dialysis duration (min)	240 (235, 240)	240 (235, 240)	240 (235, 240)	.10
BUN pre (mg/dL)	57 (40, 74)	50 (37, 70)	51 (36, 71)	.29
BUN post (mg/dL)	16 (12, 24)	13 (10, 19)	14 (9, 20)	.03
Urea reduction ratio	0.69 (0.64, 0.75)	0.71 (0.63, 0.77)	0.72 (0.67, 0.78)	.01

\*Blood flow rate = 400 ml/min

## SA-PO425

## Reductions in Dialysate Flow Rates Among a Large Cohort of Hemodialysis (HD) Patients and Impacts on Dialysis Adequacy

Linda Ficociello, Brooks E. Rogers, Amanda Stennett, Marcy E. Goldberg, Paul Smith, Kathleen Belmonte, Jeffrey L. Hymes. *Fresenius Medical Care, Waltham, MA.*

**Background:** National shortages of dialysate have led to measures to optimize therapy while conserving dialysate in US dialysis clinics. Dialysis adequacy >1.2 is a major indicator of therapy achievement. The current analysis aimed to assess whether lowering of dialysate flow ( $Q_d$ ) to 500 ml/min was accompanied by changes in dialysis adequacy or changes in other HD prescription parameters.

**Methods:** Included in the analysis were Fresenius Kidney Care HD patients dialyzed 1/21/22-1/22/22 and had their  $Q_d$  set to 500 ml/min at the discretion of the treating physician by 2/25/22-2/26/22. Approximately 30% of patients were not included because their  $Q_d$  remained >500 ml/min. Patients were categorized into the following categories based on dialysis adequacy (based on dialysis machine online clearance): <1.2, 1.2-1.4, >1.4. Changes in delivered treatment parameters were counted, including changing treatment time  $\geq 10$  minutes, blood flow ( $Q_b$ ) by  $\geq 25$  ml/min, or dialyzer size.

**Results:** Patients (n=92,768) were, on average, aged 64 years with 4.5 years dialysis vintage and 43% were women. On average patients'  $Q_d$  was lowered from 687 to 500 ml/min. As shown in Figure, 76% of patients remained in their adequacy category despite reducing  $Q_d$  to 500 ml/min, while 13% and 11% decreased or increased adequacy category, respectively. For those remaining in the same category, the majority achieve this without changes to dialysis prescriptions (64%) where 20% increased time,  $Q_b$ , or dialyzer size. Among the patients who lowered adequacy, 91% had treatment parameters stay the same or decrease.

**Conclusions:** Reductions in  $Q_d$  to 500 ml/min were not accompanied by decreases in dialysis adequacy in 87% of patients. In the 13% of patients with decreases, no increases in HD prescriptions were observed for 91% of patients. An algorithm outlining steps to adjust HD prescriptions when it is necessary to lower  $Q_d$  may need to be developed as part of preparedness plans.

## SA-PO427

## Feasibility of Crit-Line®-Based Estimation of Pre-Dialysis Hemoglobin in Hemodialysis Patients

Ohnmar Thwin,<sup>1</sup> Lin-Chun Wang,<sup>1</sup> Xia Tao,<sup>1</sup> Zahin S. Haq,<sup>1</sup> Xin Wang,<sup>1</sup> Xiaoling Wang,<sup>1</sup> Hanjie Zhang,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Nadja Grobe,<sup>1</sup> Stephan Thijssen,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Most patients on hemodialysis (HD) have renal anemia. Anemia management involves periodic collection of pre-dialysis blood samples for measurement of hemoglobin (Hgb) concentration. Replacing these blood draws by non-invasive measurements with the Crit-Line® Monitor (CLM) would be desirable but requires adjusting the measurements to reflect the customary pre-HD laboratory values. We explored whether such an adjustment is feasible.

**Methods:** Chronic HD patients were studied on up to 3 occasions each. Pre-HD blood was collected, and the mean of 20 repeated Hgb measurements was used as a highly accurate estimate of true Hgb concentration. CLM hematocrit was obtained 3.5 min into HD, converted into Hgb using a conversion factor of 0.322, and adjusted as per Equation 1 (patent app. WO2015/179523 A1). Blood volume was estimated using the Nadler equation, and the saline half-life was estimated to be 25 min.

**Results:** We studied 14 subjects (age 56.7 ± 16 years, 50% males) during a total of 27 HD treatments. The difference between adjusted CLM Hgb and pre-HD laboratory Hgb was -0.05 ± 0.55 g/dL (Figure 1; N = 25; CLM data unavailable for 2 visits).

**Conclusions:** Infusion of the extracorporeal priming fluid into the patient causes initial hemodilution. Equation 1 yields adjusted CLM Hgb values that are on average virtually identical to pre-HD laboratory measurements of Hgb. The observed variability may be due to inaccuracies in anthropometric blood volume assessment and variability in saline extravasation rate.

**Equation 1.** Adjusting early intradialytic CLM hemoglobin concentration to reflect pre-dialysis Hgb concentration.

$$Hgb_{CLM}^{adjusted} = Hgb_{CLM} + (V_{saline} \cdot 0.5^{(t_{CLM}/t_{1/2}^{saline})} - V_{UF(t_0, t_{CLM})}) \cdot \frac{Hgb_{CLM}}{BV}$$

$Hgb_{CLM}$ : Hgb obtained from CLM;  $V_{saline}$ : volume of infused priming solution (saline);  $t_{CLM}$ : elapsed time of HD when CLM Hgb was obtained;  $t_{1/2}^{saline}$ : intravascular half-life of infused saline;  $V_{UF(t_0, t_{CLM})}$ : cumulative ultrafiltration volume at  $t_{CLM}$ ;  $BV$ : pre-HD blood volume

**Figure 1.** Difference between adjusted CLM Hgb and pre-HD laboratory Hgb (25 study visits from 14 subjects). Vertical line denotes average.

## SA-PO428

## Human Factors Validation of the Tablo Hemodialysis System With Health Care Practitioners

Brittany Lim, Cynthia J. D'Alessandri-Silva, Elise Edson, Josh Schumacher, Michael A. Aragon. *Outset Medical, San Jose, CA.*

**Background:** Hemodialysis is a lifesaving treatment warranting extensive training to perform safely and effectively in different use environments. Shortages in nurse staffing due to the COVID 19 pandemic caused a desire to innovate systems that can be safely and effectively used by healthcare professionals (HCPs). The Tablo® Hemodialysis System ("Tablo") is easy-to-learn, indicated for clinic, hospital, and home settings. Features include a simplified user interface, interactive touchscreen GUI coupled with videos to assist users. Prior usability testing of Tablo had a use error rate of 1.5%. Here we report on the results of simulated use human factors validation testing on recent software version of the Tablo® Hemodialysis System ("Tablo") with HCPs in the clinic setting.

**Methods:** HCPs tested the Tablo in a simulated clinic environment to validate safety and usability. HCPs underwent training on all aspects of device operation; including setup, takedown, monitoring, routine maintenance, and alarm resolution. After a decay of at least one hour, HCPs performed tasks without the trainer. Task performance to use errors, close calls, and difficulties were recorded along with interview data.

**Results:** Fifteen (15) HCPs were recruited, consisting of 9 RNs with prior HD experience and 6 dialysis technicians. A total of 7365 tasks were performed, with the use error rate across all tasks less than <1%, with most use errors related to Manual Blood Return. 100% of HCPs reported that they felt they could use Tablo safely and effectively. Summary of user task assessments shown in Figure 1.

**Conclusions:** After standard 3-hour training, HCPs were able to safely and effectively operate Tablo in a simulated use clinic setting. HF testing of this more recent software shows further reduction in Tablo's already low use error rate. This supports prior data regarding the ability of HCPs to easily learn and use Tablo and the device's ability to facilitate expansion of available dialysis nursing staff while increasing the quality and safety of dialysis treatments across the care continuum.

**Funding:** Veterans Affairs Support

## Interventions Required for Use of a Wearable Device in Hemodialysis Patients

Maggie Han,<sup>1</sup> Ohnmar Thwin,<sup>1</sup> Xia Tao,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Amrith U. Patel,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Increased physical activity (PA) is associated with reduced risk of cardiovascular disease, which is prevalent in hemodialysis (HD) patients. Wearable activity trackers (WAT) allow the remote monitoring of PA. We aimed to explore what kinds of interventions are required to maintain use of WAT in a HD population

**Methods:** HD patients from 4 New York City clinics were enrolled on a rolling basis starting June 2018 and followed for up to 1 year. Ambulatory patients ≥18 years, on maintenance HD, and owning a mobile device were included. Each patient was provided with and taught how to use the Fitbit Charge 2. A stepwise intervention plan was used to assess feasibility (Figure 1). Patients were deemed non-compliant if they were withdrawn for non-compliance and patients who completed the 1-year follow up period were deemed compliant.

**Results:** 119 patients were enrolled into the study. Patients were 54±12 years old, 59% African American, 37% lived alone, and 54% had an education level of college and above. 74 patients completed the study, 17 patients were withdrawn for non-compliance, 6 patients passed away, 12 patients were withdrawn due to kidney transplants, and 10 patients were withdrawn for other reasons. Results of the interventions deployed to compliant and non-compliant patients are shown in figure 2.

**Conclusions:** Patients who were non-compliant required a greater proportion of phone calls and in-person meetings, both interventions that cannot be automated, compared to their compliant counterparts. Patients who are more likely to be compliant, can maintain use of their wearable devices with automated text message reminders. When considering implementing a program using WAT in the HD population, an intervention-based program is necessary to guarantee adequate device usage and data collection.

**Funding:** Commercial Support - Renal Research Institute

### Association Between Sleep and COVID-19 Vaccination Response in Hemodialysis Patients

Maggie Han,<sup>1</sup> Xiaoling Wang,<sup>1</sup> Xiaoling Ye,<sup>1</sup> Zijun Dong,<sup>1</sup> Ohnmar Thwin,<sup>1</sup> Amrith U. Patel,<sup>1</sup> Lela Tisdale,<sup>1</sup> Lin-Chun Wang,<sup>1</sup> Sarah Ren,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Hanjie Zhang,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Hemodialysis (HD) patients are less likely to mount a response to the COVID-19 vaccination (CoVac). Poor sleep is associated with blunted vaccination response in the general population. We aim to explore the association between CoVac and sleep quality (SQ) in HD patients.

**Methods:** Patients from 3 HD clinics were enrolled if they were ≥18 years and able to give written consent. Patients were administered the Insomnia Severity Index (ISI) and the Pittsburgh Sleep Quality Index (PSQI). Blood specimen were collected after the primary series of COVID-19 vaccination. SARS-CoV-2 neutralization antibodies (nAB) were assayed using the GenScript SARS-CoV-2 Surrogate Virus Neutralization Test Kit (Cat#L00847-A). nAB titers are presented as Unit/ml on a natural log scale. PSQI scores of >5 were categorized as poor SQ and ≤5 as good SQ. ISI scores were grouped as no clinically significant insomnia (NI; score 0-7), subthreshold insomnia (SI; score 8-14), and clinical insomnia (CI; score 14-28). T-test and ANOVA analysis were performed on PSQI and ISI scores, respectively, to determine the statistical association between SQ and nAB levels.

**Results:** 58 patients were included (60±9 years old, HD vintage 4.7±4.5 years, 62% male, 66% Black, 21% Hispanic). In the PSQI, 72% (n=42) had poor SQ. In the ISI, 52% = NI, 31% = SI, and 17% CI. Box plots of nAB levels with median and IQR are shown in Fig. 1. There is no association between SQ and nAB levels.

**Conclusions:** There is no association between SQ and CoVac response. Given the immune dysfunction in this population, any modifying effect SQ has on CoVac, as observed in the general population, is unlikely. Other methods of improving CoVac response in this vulnerable population should be explored.

### Post-Bilateral Orthotopic Lung Transplant Dual Dialysis

Aniruddha Bhattacharyya,<sup>1</sup> Yani Zhang,<sup>2</sup> Girma M. Ayele.<sup>3</sup> <sup>1</sup>University of Maryland Medical System, Baltimore, MD; <sup>2</sup>MedStar Union Memorial Hospital, Baltimore, MD; <sup>3</sup>Howard University College of Medicine, Washington, DC.

**Introduction:** Hyperammonemia (HA) is a metabolic disorder characterized by an elevated concentration of serum ammonia (NH<sub>3</sub>). It is a complication of Bilateral Orthotopic Lung Transplants (BOLT) befalling 4.1% of patients, with a 75% mortality rate. Opportunistic infections of Ureaplasma are implicated as culprits of HA. Renal replacement therapy (RRT) is the treatment of choice for HA with neurologic symptoms. NH<sub>3</sub> is a small molecule whose clearance mirrors urea in RRT. Intermittent hemodialysis (IHD) clears NH<sub>3</sub> faster than continuous hemodialysis (CHD), though CHD is better tolerated in people with hemodynamic instability. There are few studies comparing IHD vs CHD for treating HA in adults.

**Case Description:** We report a case of a 64-year-old man with new encephalopathy, 1 day after extubation following BOLT. Initial imaging was negative for stroke, and later CT scans showed cerebral edema. Concurrent metabolic workup found an elevated NH<sub>3</sub> of 526 umol/L. PCR assays of bronchial fluid after BOLT found the 16S ribosomal RNA sequence of Ureaplasma species. Soon after developing HA, the patient had hemodynamic instability requiring 3 pressors. While critically ill, we treated his HA with a novel regimen of alternating CHD and IHD. RRT was done via a dialysis catheter placed non-emergently in the right femoral vein. The CHD was prescribed with a blood flow (Q<sub>b</sub>) of 300ml/min, and a dialysate flow (Q<sub>d</sub>) of 7800ml/h. The first 2 hours of IHD had a Q<sub>b</sub> of 200ml/min, and a Q<sub>d</sub> of 400ml/min. The 2nd and 3rd rounds of IHD had respective Q<sub>b</sub> of 300 and 350ml/min, and respective Q<sub>d</sub> of 500 and 600ml/min. The patient's NH<sub>3</sub> was reduced by 95% over 45 hours by our unique RRT protocol, and he survived this highly fatal condition.

**Discussion:** Adult patients after BOLT can develop HA as a rare and deadly complication. Opportunistic infections of urease-producing bacteria like Ureaplasma may play a role in increased NH<sub>3</sub> production. While the ideal RRT regimen for HA after BOLT is unknown, our case shows the combination of IHD and CHD can quickly lower NH<sub>3</sub> levels and limit its expected rebound in such patients.

## SA-PO432

### Single Center Experience: Conversion From Conventional Continuous Renal Replacement Therapy to Tablo Adaptive Dialysis

Tara E. Greenleaf Nichols, Sandy Rowe, Debra M. Dutton, Toni Yurcso, Senthil P. Ramaiyah. *Covenant HealthCare, Saginaw, MI.*

**Background:** Since the advent of the COVID-19 pandemic in March 2020, the ability to provide high quality, cost efficient care in the ICU has been challenged by nursing shortages, increased acuity, patient volumes and higher incidence of AKI requiring dialysis. CRRT typically requires 1:1 nursing support and specialized devices. Here we describe Covenant Healthcare, a 372 acute bed hospital that converted from conventional CRRT model ("Non-Tablo") to an adaptive dialysis model with the Tablo® Hemodialysis System ("Tablo").

**Methods:** A retrospective chart review of extended therapy treatments over six months after transition to Tablo. All Tablo treatments performed in the ICU that met the previous hospital criteria for CRRT were included. Nurse to patient ratio during dialysis was 1:1 and 1:2 when not on therapy. Demographics, COVID status, treatment duration and time off therapy, defined as hours within each 24-hr period where the patient was not on dialysis was recorded. Treatment success was defined as achieving at least 90% of prescribed treatment time.

**Results:** A total of 228 treatments were completed in 60 ICU patients with 60% COVID positive. Mean age was 62 yrs (range, 29-88). Total treatment success was 96% with 4% ending early due to alarms. Figure 1 shows total treatment by time; 0-6 hrs, >6-12, >12-24 hrs with success rates. Total time off therapy compared to a Non-Tablo continuous model was 2299 hrs equating to approximately 1.2 FTE (\$100k) in labor productivity.

**Conclusions:** At Covenant Healthcare, conversion to Tablo adaptive therapy model successfully delivered treatments up to 24 hrs to critically ill patients who would otherwise be on CRRT. Adaptive therapy improved nurse staffing efficiency while reducing cost and patient time off dialysis. Application of this model allows a more individualized approach to ICU patient care without increasing the burden on the ICU or acute hospitals.

### Use of Remote Dielectric Sensing (ReDS) in Hemodialysis Patients

Gessica Sabrina Braga Barbosa, Eduardo d. Valle, Carolina M. Lima, João Lucas M. Gorzoni, Daniela C. Favarato, Ana Teresa P. Vieira, Vinicius V. Sobral, Camila F. Assis, Rayra G. Ribeiro, Igor Smolentsov, Lucia Andrade, Camila E. Rodrigues, Jose M. Vieira Jr.. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

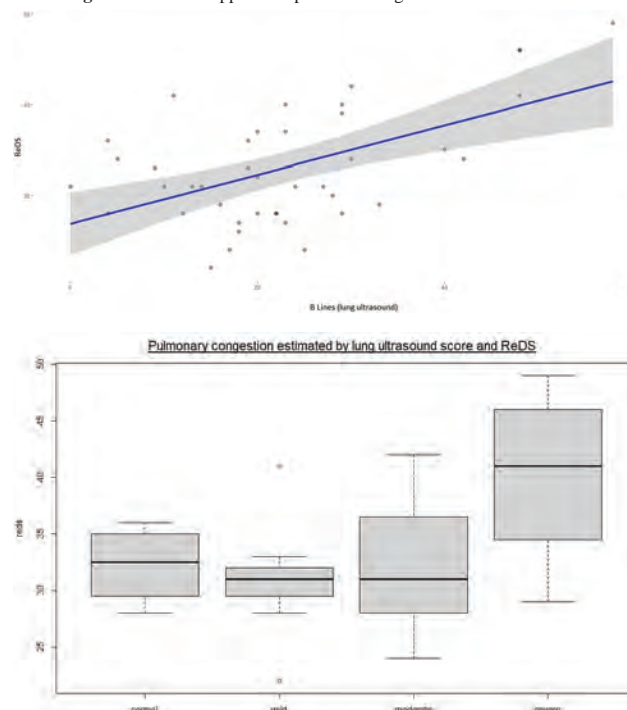

**Background:** New tools are being developed to assess volume status in fluid overload risk patients. The ReDS system is a non-invasive device built from military technology "see through-walls" indicated to assess hypervolemic status represented by pulmonary congestion. There are studies demonstrating an optimal correlation between ReDS and high-resolution chest tomography and invasive hemodynamic monitoring, mostly in heart failure patients. Our aim is to evaluate the use of ReDS in hemodialysis (HD) population.

**Methods:** We enrolled 23 patients under three times per week HD treatment. The fluid status was evaluated before and after dialysis by physical examination, lung ultrasound (LUS) and ReDS. The study was performed for four weeks (ReDS device availability period). Clinical parameters include weight and blood pressure. Degree of pulmonary congestion was evaluated according to B lines number visualized by LUS and percentage of fluid in lung tissue from ReDS (value > 35% is associated to hypervolemic status).

**Results:** The analysis was performed in 41 HD sessions. There is linear correlation between ReDS and LUS especially in cases of severe pulmonary congestion according to LUS degree ( $r = 0.393$ , Spearman's test,  $p < 0.05$ ). There was no difference between blood pressure values and ReDS or LUS results. There was no difference between the assessment before and after HD sessions.

**Conclusions:** ReDS system is a promising tool that can be used to assess fluid status in hemodialysis patients.

## SA-PO434

### Water Smarter: Exploring the Potential to Recycle Reverse Osmosis Reject Water

Keerat Dhatt, Andrew I. Chin. *University of California Davis, Davis, CA.*

**Background:** Water is possibly the most precious resource on the planet, and water conservation has become of increasing concern over the past few years. Opportunities for conservation in hemodialysis (HD) units should be explored. An efficient reverse osmosis (RO) system has an approximate 5% water reject rate. The aim of this study was to assess whether the reject water could be repurposed, rather than wasted.

**Methods:** In July 2021, we tested both the RO product water as well as the RO reject water from a 24 station dialysis center in Sacramento, California as part of routine clinic water testing. We compared the constituents that are tested and regulated by the city of Sacramento in the RO reject water to the levels considered safe by the city.

**Results:** We found that the RO system reject water from our HD clinic is well within the standards put forth by the city of Sacramento for acceptable drinking water. Notably, fluoride is added to the city water, and even this element was within acceptable limits in the RO reject water. See table 1 for these details. Our clinic uses over 176,000 gallons of water each month, even with a standard HD dialysate flow rate of 600 mL/min. Assuming

conservatively that 85% of our water is used to produce product water and a 5% RO reject rate, we estimate that about 7500 gallons of potable water is wasted every month.

**Conclusions:** Our RO reject water is well within the safe standards for drinking water. Differences may be noticed in other cities, depending on the source of the water. However, it is likely that millions of gallons of potable water are wasted by dialysis clinics across the country. As water conservation continues to be of rising concern, municipalities should provide incentives for dialysis providers to repurpose their RO reject water.

## SA-PO435

### Different Modalities of Dialysis for Hyperammonemia Treatment

Ahmed S. Shaih,<sup>1</sup> Moh'd Sharshir,<sup>1</sup> Farah Harasis.<sup>2</sup> <sup>1</sup>Tulane University School of Medicine, New Orleans, LA; <sup>2</sup>Islamic Hospital, Amman, Jordan.

**Introduction:** Hyperammonemia (HA) is a life-threatening condition and can lead to irreversible cerebral damage and death if not treated in a proper way. A Few studies found in literature about the treatment of HA by dialysis in adults. Here, we describe a two cases of acute encephalopathy due HA with different causes. Treated successfully with different modalities of dialysis.

**Case Description: Case 1:** A 23-year-old female presented with altered mental status. Laboratory workups showed ammonia level of 581 (reference value 11 -32) micromol/l with normal lactate, creatinine, and liver enzymes. Brain image showed a cerebral edema. Urea cycle disorder was suspected. Along with medical treatment, Dialysis was initiated using Sustained low efficiency dialysis for 48 hours, Ammonia level decreased to 74. She completely recovered after that and did not need dialysis, ammonia level returned to normal level and discharged without neurological deficit. **Case 2:** A 67-year-old female with liver cirrhosis presented with altered mental status and gastrointestinal bleeding. Laboratory data revealed ammonia level of 263. Intermittent hemodialysis (iHD) was performed for 3 hours then switch to Continuous venovenous hemofiltration (CVVHD) for 24 hours. Level returned to normal, and patient improved then discharged without neurological deficit.

**Discussion:** HA can occur in patients with liver failure, urea cycle defects, inborn errors of metabolism (IEM), post-chemotherapy, toxins exposure or drugs. Management should be started immediately to avoid life threatening consequences. However, there are no specific guidelines about when to start dialysis or which techniques are more appropriate. Generally, the primary goals of dialysis are to rapidly reduce ammonia level and achieve resolution of symptoms. It has been proposed that, when the blood ammonia level is three times greater than the upper limit of normal or encephalopathy, it is worth considering dialysis. Among adult patients, the goal to provide continuous removal of ammonia by performing daily HD and CVVH in between sessions of HD to prevent ammonia rebound as what we did in the second case. If cerebral edema is present as in the first case, we would elect a continuous technique (CVVHD or SLED) to avoid worsening the edema with iHD.

## SA-PO436

### Mathematical Modeling of Allo-Hemodialysis as Acute Treatment for Urea Cycle Disorders

Vaibhav Maheshwari,<sup>1</sup> Guido Filler,<sup>2</sup> Akash Deep,<sup>3</sup> Rasha H. Hussein,<sup>4,5</sup> Maria E. Ferris,<sup>6</sup> Xin Wang,<sup>1</sup> Amrish U. Patel,<sup>1</sup> Peter Kotanko.<sup>1,7</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>London Health Sciences Centre, London, ON, Canada; <sup>3</sup>King's College Hospital, London, United Kingdom; <sup>4</sup>Pontificia Universidade Catolica do Parana, Curitiba, Brazil; <sup>5</sup>Soba University Hospital, Khartoum, Sudan; <sup>6</sup>University of North Carolina System, Chapel Hill, NC; <sup>7</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Urea cycle disorders (UCD) are inborn errors of metabolism characterized by a reduced activity of enzymes that convert nitrogenous waste to urea, resulting in accumulation of ammonia (NH<sub>3</sub>). UCDs can result in neonatal death or severe neurological complications. Clinically, swift reduction of NH<sub>3</sub> levels towards the normal range is key to prevent sequelae. Previously, we have developed allo-hemodialysis (alloHD), a simple extracorporeal dialytic modality where a patient is dialyzed against a healthy subject (buddy) [Maheshwari (2020) KIR 5, S29]. Here, we model alloHD as a treatment for UCD.

**Methods:** We adapted a model of human NH<sub>3</sub> metabolism [Griffin (2019) Theor Biol Med Model 16, 11]. The model considers constant NH<sub>3</sub> absorption, renal excretion, and the activities of key urea cycle enzymes (glutamine synthase, glutaminase, carbamoyl phosphate synthetase I). To simulate UCD, neonate enzyme function was set to 5% of healthy capacity. For alloHD simulation, a mini dialyzer with surface area 0.075 m<sup>2</sup> was used. Neonate and buddy blood flow rates were 15 and 30 mL/min, respectively, ultrafiltration was zero.

**Results:** The NH<sub>3</sub> concentration gradient results in rapid diffusion of NH<sub>3</sub> and glutamine from the neonate to the buddy (Fig.1). Within 60 min of alloHD, the neonate NH<sub>3</sub> plasma concentration drops to around 50%. The subsequent steady state NH<sub>3</sub> is still above normal levels because in our simulations the neonate's NH<sub>3</sub> production is kept unchanged. However, in clinical practice, the UCD patients' protein intake is reduced to zero, which lowers the NH<sub>3</sub> production rate.

**Conclusions:** Our simulations indicate that alloHD is a potential option for the initial, emergency treatment of UCD.

Fig. 1: AlloHD treatment simulation for UCD.

## SA-PO437

### Anaphylaxis From Ethylene Oxide Sterilized Dialysis Tubing and Needles

Clarkson Crane, Robyn A. Cunard, Nicholas Scanlon, Taylor Doherty, O. Alison Potok. University of California San Diego, La Jolla, CA.

**Introduction:** Hypersensitivity reactions to ethylene oxide (EtO) sterilized dialyzers have been described. While EtO is no longer used to sterilize most dialyzers, it is used on other pieces of dialysis equipment. We present a case of dialysis-related anaphylaxis attributed to an IgE-mediated allergy to EtO-sterilized dialysis tubing and needles.

**Case Description:** A 78-year-old male with end stage kidney disease (ESKD) was maintained on hemodialysis (HD) for 3 years without complications. Access was a tunneled dialysis catheter (TDC) then transitioned to an arteriovenous fistula (AVF). Subsequent treatments were complicated by intradialytic hypotension and syncope within minutes of starting HD. Symptoms also included pruritis (no hives), and a throat closure sensation; Labs showed WBC of 11.3 k/uL, of which 2.4 k/uL eosinophils. Differential diagnosis included idiopathic hypereosinophilic syndrome (HES), mastocytosis with eosinophilia, mast cell activation syndrome (MCAS), and type 1 hypersensitivity reaction to ethylene oxide (EtO). Workup showed normal cardiac evaluation, negative D816V mutation, negative FIP1L1-PDGFR, elevated tryptase 28 mcg/L, total IgE >3000 IU/mL, and anti-EtO IgE >100 kU/L. Access was transitioned back to the TDC and a Revaclear dialyzer (polyaryl sulfone) was used with normal saline rinses of dialysis tubing. He was given prednisone and anti-histamines and tolerated subsequent HD treatments. Prednisone was tapered and omalizumab (anti-IgE Fc) was started.

**Discussion:** This case is an example of dialysis-associated anaphylaxis initially presenting as intradialytic hypotension. Upon recognition of the hypereosinophilia, it was noted this was chronic since HD initiation 3 years prior. Previous work-up was negative for parasite infections and malignancy, making mastocytosis less likely. We hypothesize the patient's eosinophilia and hypersensitivity began upon his initial exposure to EtO and HD equipment. While using a TDC, chronic eosinophilia may have been related to the low-level EtO exposure from saline-rinsed tubing. When use of the AVF with EtO-sterilized needles was resumed, he was exposed to a higher "dose" of EtO. This triggered a more robust type 1 hypersensitivity leading to mast cell degranulation and repeated anaphylactic episodes that were overcome by pretreating with steroids, anti-histamines, and anti-IgE Fc monoclonal, omalizumab.

## SA-PO438

### A Bubbly Catastrophe: A Case of Air Embolism Presenting as Ischemic Stroke in a Hemodialysis Patient

Randa Abd algayoum, Tyler Andrea, Kalathil K. Sureshkumar. Allegheny Health Network, Pittsburgh, PA.

**Introduction:** Air embolism is a rare but potentially catastrophic complication and can often be fatal. In humans, a volume of 100–300 mL air is considered fatal. Due to the technological safeguards implemented in hemodialysis machines, symptomatic air embolisms are now exceedingly rare. We present a case of ischemic stroke and cerebral edema due to air embolism in a hemodialysis patient.

**Case Description:** A 76-year old male with history of multiple myeloma, lung cancer, and end-stage kidney disease on hemodialysis through tunneled dialysis catheter, presented for evaluation of stroke symptoms. Patient developed right gaze preference, left hemiparesis and dysarthria at his dialysis center after rinse back. No significant

hemodynamic compromise and no alarms reported. Admission CT angiogram of head and neck revealed no acute intracranial abnormalities or infarct on perfusion imaging. Deemed not a candidate for thrombolytic therapy. MRI brain showed no acute intracranial abnormalities, markedly motion degraded. On the following hospital day, patient developed worsening lethargy and weakness. Follow-up CT head revealed cerebral edema involving the middle cerebral and anterior communicating artery territories on the right side with small focus of air in the right vertex sulcus which was also present on initial head CT scan (figure) consistent with air embolism, not previously reported but commented on in retrospect. Patient underwent emergent hyperbaric oxygen treatments. Following 3 sessions, patient experienced significant improvement in symptoms and was subsequently discharged to a rehabilitation facility.

**Discussion:** Despite the technological safeguards in new hemodialysis machines, though rare air embolism can still occur during hemodialysis nowadays mostly due to human error. Our case highlights the importance of implementing preventative measures, ensuring adequate staff training and the need for high level of vigilance required for early diagnosis and prompt management.

Black arrows pointing to the air embolisms in figure 1 and figure 2, imaging obtained on initial presentation and the following day respectively.

### SA-PO439

#### Comparison Between Incremental and Conventional Hemodialysis in a Single Center

Sehyun Jung,<sup>1</sup> Seunghye Lee,<sup>1</sup> Ha nee Jang,<sup>1,2</sup> Se-Ho Chang,<sup>1,2</sup> Hyun-Jung Kim.<sup>1,2</sup> <sup>1</sup>Gyeongsang National University Hospital, Jinju, Republic of Korea; <sup>2</sup>Gyeongsang National University Graduate School of Medicine, Jinju, Gyeongsangnam-do, Republic of Korea.

**Background:** Residual kidney function (RKF) in dialysis patients contributes to removing body fluids and salts, improving blood pressure, and enhancing middle molecules clearance. According to retrospective data, incremental hemodialysis (HD) may preserve RKF. However, its efficacy and safety are controversial compared to conventional HD.

**Methods:** This was a single-center retrospective study for comparison between incremental and conventional HD for one year. Inclusion criteria of incremental HD were urine output above 600ml/day and residual renal urea clearance (Kru) above 3ml/min/1.73m<sup>2</sup>. Among already maintenance HD patients, 21 patients changed to incremental HD (one or two times a week) and 54 patients maintained conventional HD (three times a week).

**Results:** There were three deaths in incremental HD group. Blood pressure and blood chemistry data at selected time points are shown in Table 1. Study arm between both groups in mixed effect models did not show significant parameters that were blood pressure, serum sodium, potassium, calcium, phosphate, protein, albumin, total cholesterol, glucose, and C-reactive protein. However, serum total CO<sub>2</sub> decreased significantly, and serum chloride was significantly higher in the incremental HD than in the conventional HD (Figure.1).

**Conclusions:** Incremental HD was not inferior to conventional HD. But, serum bicarbonate and chloride can be under-dialysis in the incremental HD, so careful observation is required in this group.

Table 1. Blood pressure and blood chemistry data

#### Case Series of Continuous Venovenous Hemofiltration With Severe Hyponatremia and Acidosis

Kasumi Konishi, Takuya Fujimaru, Kotaro Shimoyama, Nozomi Kadota, Yugo Ito, Fumika Taki, Masahiko Nagahama, Shutaro Isokawa, Toru Hifumi, Norio Otani, Masaaki Nakayama. *St.Luke's International Hospital, Tokyo, Japan.*

**Introduction:** For the patients with anuric acute kidney injury (AKI) and severe hyponatremia, we previously reported “Flex Na” method, which involved flexible adjustment of the sodium concentration using continuous venovenous hemofiltration(CVVH). However the weak point of this methods is the management of severe acidosis. In this case series, we had performed “Flex Na” added on intravenous 1.26% NaHCO<sub>3</sub> and improved severe acidemia and hyponatremia.

**Case Description:** case1 A 57 year-old man admitted to the hospital with bacterial meningitis and AKI due to acute tubular necrosis. The blood test showed sodium 121 mEq/L, potassium 3.6 mEq/L, chloride 84 mEq/L, urea nitrogen 68.8mg/dL, creatinine 4.84 mg/dL. Arterial blood gas analysis showed pH 7.04, PaCO<sub>2</sub> of 37.4mmHg, PaO<sub>2</sub> of 103.0 mmHg, bicarbonate level of 9.6 mEq/L, lactate 10.9 mmol/L. We started Flex Na using the 5% dextrose solution(D5W) infusion and available replacement fluid(Sublood-BSG), which has a sodium concentration of 140 mEq/L as 1.26% NaHCO<sub>3</sub> was infused intravenously. After 48 hours, acidosis was improved. After another 24hours, serum sodium reached 130 mEq/L, and we changed intermittent hemodialysis(IHD). case2 A 48 year-old man with stage 5 chronic kidney injury admitted to hospital with unconsciousness due to uremia. The laboratory data showed sodium 108 mEq/L, potassium 6.0 mEq/L, chloride 78 mEq/L, urea nitrogen 139.3 mg/dL, creatinine, 17.85 mg/dL. Arterial blood gas analysis showed pH 6.8, PaCO<sub>2</sub> of 33.3mmHg, PaO<sub>2</sub> of 43.3 mmHg, bicarbonate level of 5.5 mEq/L, Lactate of 4.10mmol/L. We started “Flex Na” method with continuous infusion of D5W and 1.26% NaHCO<sub>3</sub> intravenously for the additional filtration. After 48 hours treatment, acidosis was improved and we changed IHD for maintenance renal replacement therapy.

**Discussion:** In general, adverse effects of acute metabolic acidosis include decreased cardiac output, arterial dilatation with hypotension, altered oxygen delivery, and impairment of the immune response. Therefore, the patients with severe metabolic acidosis need bicarbonate therapy or dialysis. However, CVVH had slower clearance than IHD. From this case report, Flex Na with intravenous NaHCO<sub>3</sub> infusion could be the optimal tool for the patients with severe hyponatremia and acidosis who require dialysis.

## SA-PO441

**Fatal Systemic Air Embolism From Arteriovenous Fistula During Hemodialysis: A Case Report**

Arturo Peñaloza, Manuel A. Marquez. *Instituto Mexicano del Seguro Social, Tampico, Mexico.*

**Introduction:** We report a case of a Mexican woman diagnosed with end-stage CKD on regular hemodialysis with a left brachiocephalic (BC) arteriovenous fistula (AVF) who presented systemic air embolism during her HD session

**Case Description:** A 59-year-old woman with a ten years history of CKD on HD with a left BC AVF. She attended her scheduled HD session with no symptoms; minutes after the start of her session, she presented dyspnea, hypoxemia, hypotension, and sudden neurological deterioration requiring mechanical ventilation. A non-contrasted head CT demonstrated air embolism in the cortical veins of the bilateral parietal region. Our center had no hyperbaric oxygen therapy chamber, so FiO<sub>2</sub> was increased to 1.0 and continued supportive care. TTE reported dilatation of the right atrium and ventricle, severe tricuspid insufficiency, and pulmonary hypertension. Patent foramen ovale was ruled out. 48 hours after, there was no neurological improvement, so a new head CT was ordered, finding parietal ischemic areas and no evidence of air embolism. Ventilator-associated pneumonia and non-ST elevation myocardial infarction complicated her hospitalization. On her fifth day, she developed VF with a subsequent cardiac arrest that did not respond to resuscitation maneuvers

**Discussion:** Due to the current safety mechanisms in hemodialysis units, such as air traps, a systemic air embolism is an infrequent event. Few cases in patients with AVF with fatal outcomes have been reported in contemporary literature. This case demonstrates the importance of maintaining a high index of suspicion to recognize this clinical entity in patients who present sudden cardiopulmonary and neurological alterations during HD. Alarms in hemodialysis units may not detect the unnoticed passage of air to the patient.

## SA-PO442

**Euglycemic Ketoacidosis: An Underrecognized Complication of Continuous Renal Replacement Therapy**

Joel O. Adewuyi, Jusong Choi, Amir Kazory. *University of Florida, Gainesville, FL.*

**Introduction:** Euglycemic Ketoacidosis (EKA) is a rare presentation of diabetic ketoacidosis in patients with reduced caloric intake and those using newer antidiabetic medications. It is also seen in other settings where the body has to go to a ketogenic state due to reduced available glucose.

**Case Description:** A 52-year-old woman with a history of hypertension and diabetes was admitted for necrotizing soft tissue infection of the lower extremity. Hospital course was complicated by septic shock and oliguric acute kidney injury. Continuous renal replacement therapy (CRRT) was started with a conventional solution leading to gradual improvement in patient's biochemical profile (Day 0). Nutrition was provided with low-glycemic carbohydrate along with intravenous insulin infusion. Two days later, CRRT solution was changed to a phosphate-containing solution to reduce the need for phosphate supplementation. This was followed by an unexplained progressive drop in serum bicarbonate levels in the face of normal serum lactate levels (anion gap metabolic acidosis [AGMA]) (Day 2). Since the phosphate-containing solution is glucose-free, there was a

suspicion for development of ketosis; serum beta hydroxybutyrate was found to be as high as 6.6 mmol/L (normal:  $\leq 0.27$ ) with stable glycemia confirming the diagnosis of EKA. CRRT solution was changed back to a conventional glucose-containing solution leading to a gradual reduction in the level of ketones and normalization of serum bicarbonate concentrations (Day 4).

**Discussion:** Since most patients on CRRT are critically ill and several of their biochemical parameters not within the normal range, EKA may remain unrecognized unless patients are screened for it. The diagnosis should be considered once there is progressive AGMA despite ongoing CRRT, in the absence of lactic acidosis, especially if a glucose-free solution is used.

## SA-PO443

**Evaluation of Bacteriology of Bicarbonate Dialysis Solution (BDS) From Hemodialysis (HD) Clinics That Have Adopted Ferric Pyrophosphate Citrate (FPC; Triferic)**

Helen Currier,<sup>1</sup> Julie Zaleski,<sup>2</sup> Marc L. Hoffman.<sup>1</sup> *<sup>1</sup>Rockwell Medical Inc, Wixom, MI; <sup>2</sup>Ascend Clinical, Redwood City, CA.*

**Background:** Despite broad advocacy in clinical guidelines, concerns remain that intravenous iron may increase the risk of infection by promoting pathogen growth and predisposing patients to infection (Shah, 2021). FPC is an iron (III)-citrate-pyrophosphate oligomeric complex that does not contain a carbohydrate shell and that delivers iron directly to transferrin via BDS. FPC experience at 98+ hemodialysis clinics and over 500 months (mos.) of exposure has not been associated with any report of bacterial growth from the BDS exceeding the Association for the Advancement of Medical Instrumentation (AAMI) standards.

**Methods:** As a quality assurance project evaluating the risk of bacterial growth and to supplement FPC safety data, the bacteriology of conventional BDS from 8 independent HD clinics was evaluated for positive evidence. These microbiological cultures of HD water and fluid are routine safety measures in US HD clinics. Collection is standardized by "clean-catch" and sent out by expedited mail. Permissions were obtained from individual dialysis facility medical directors to use their proprietary data in the analysis. The data was collected from a single clinical laboratory that exclusively provides ESRD services. The 8 FPC user clinics represented rural/urban areas from 4 states. Deidentified Water Analysis Reports collected and reported for routine Quality Assessment Performance Improvement surveillance [Total Viable Microbial Count (CFU/mL) and Limulus Amebocyte Lysate (LAL)] were analyzed for potential microbial growth pre- and post-adoption of FPC. Data included 12 mos. pre-FPC adoption to present. CMS regulations reference AAMI RD62:2006 for maximum allowable levels (MAL) in both culture and endotoxin. The MAL in water used for HD is 200 CFU/mL and 2 endotoxin unit (EU)/mL.

**Results:** Neither cohort of BDS cultures exceeded MALs. One LAL pre-FPC exposure exceeded the MAL.

**Conclusions:** This retrospective analysis demonstrates that FPC delivered in its different form *does not* contribute to microbial growth in the BDS. Shah AA, Donovan K, Seeley C, et al. Risk of infection associated with administration of intravenous iron: a systematic review and meta-analysis. JAMA Netw Open. 2021;4(11):e2133935.

## SA-PO444

**Effect of Cytokine Adsorption on Mortality: A Meta-Analysis**

Bernhard M. Schmidt,<sup>1</sup> Hannah Lang,<sup>1</sup> Clara Vollmer Barbosa,<sup>1</sup> Zhejia Tian,<sup>1</sup> Anette Melk,<sup>2</sup> <sup>1</sup>Department of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; <sup>2</sup>Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.

**Background:** Cytokine adsorption using the CytoSorb® device had been proposed to be beneficial in various clinical settings including sepsis, ARDS, hyperinflammatory syndromes, cardiac surgery or recovery after cardiac arrest. The aim of this analysis was to provide evidence for the efficacy of the CytoSorb® device with regard to mortality in these settings.

**Methods:** We searched Medline, Cochrane Library database and used the database provided by Cytosorbents™. Central Register of Controlled Trials and clinicaltrials.gov for randomized, controlled studies (01.1.2010-28.2.22). We considered randomized controlled trials and observational studies with a control group. The longest reported mortality (30 days-, hospital- or ICU-mortality) was defined as primary endpoint. For analyzing the data we computed risk ratios and 95%-confidence intervals and used DerSimonian and Lairds random effects model (R 4.1). We analysed all studies together and separated in the subgroups sepsis, cardiac surgery, SARS-CoV-2 infection, recovery from cardiac arrest, other severe illness. The meta-analysis was registered in advance (PROSPERO: CRD42022290334).

**Results:** Of initial 1249 publications, 37 trials were found eligible, in total including 1256 patients treated with CytoSorb® and 1230 controls. Concerning the primary endpoint mortality CytoSorb® did not show a positive effect in all studies together 1.10 [0.92; 1.33] RR [95%-CI], in sepsis 1.03 [0.81; 1.31], CPB surgery 0.85 [0.51; 1.44], severe illness 1.05 [0.79; 1.39], SARS-CoV-2 1.58 [0.50; 4.94], and recovery from cardiac arrest 1.22 [1.02; 1.46] (figure). Likewise we did not find significant difference in ICU length of stay, lactate levels, or norepinephrine after treatment.

**Conclusions:** To date there is no evidence for a positive effect of the CytoSorb® adsorber on mortality across a bunch of indications that justifies its widespread use in intensive care medicine.

## SA-PO445

**Incidence Rates of Bleeding Events With Heparin Administration in Chronic Hemodialysis Patients: A Systematic Review and Meta-Analysis**

Jochen G. Raimann,<sup>1</sup> Adelheid Gauly,<sup>2</sup> Joanna Willetts,<sup>3</sup> Suman K. Lama,<sup>3</sup> Derek M. Blankenship,<sup>3</sup> Thomas P. Deluca,<sup>3</sup> Jonathan Chavez,<sup>4</sup> Netzahualpilli Delgado Figueroa,<sup>4</sup> Guillermo Garcia-Garcia,<sup>4</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Fresenius Medical Care Global Medical Office, Bad Homburg, Germany; <sup>3</sup>Fresenius Medical Care Global Medical Office, Waltham, MA; <sup>4</sup>Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.

**Background:** To ensure patency of the extracorporeal circuit and vascular access, anticoagulation by systemic heparinization is usually performed during hemodialysis (HD). Heparin may have adverse effects such as bleeding, heparin-induced thrombocytopenia, and others, which may be a burden to the HD patients, to health care providers and to health care systems. The aim of this systematic literature review and meta-analysis was to provide a comprehensive overview of the incidence of bleeding events in heparinized HD patients and to estimate the variation associated with different types of heparins.

**Methods:** We searched PubMed, Embase, and the Cochrane Central Register of Controlled Trials (CENTRAL) database for English-language articles from January 1, 2000, to DATE. We included prospective, randomized, controlled trials and observational

studies that include chronic HD patients in whom unfractionated heparin (UFH) or low-molecular-weight heparin (LMWH), was used for systemic anticoagulation, and in which adverse effects of heparin as primary or secondary end points were reported. A random intercept Poisson regression model with maximum likelihood estimation was applied to estimate incidence rates. All articles were screened by two reviewers; discrepant assessments were cross-checked by a third reviewer. The detailed methodology has been published as PROSPERO Registration no. 239695.

**Results:** Screening of 3764 articles resulted in 20 articles with data that could be used for our meta-analysis. The incidence rate of minor and major bleeding events per 100 patient years for LMWH was 13.8 (95% CI 4.0 to 47.3) and for UFH was 6.2 (95% CI 2.5 to 15.5). Regional variability and a period effect associated with changes in practice patterns is being subject of additional research.

**Conclusions:** Our research quantified the incidence rates of bleeding associated with heparin administration in HD patients. Differences between the types of heparins need to be appreciated and should be subject of further research. A clear difference of heparin estimates to populations with no heparin administration, emphasizes the need for improvements allowing for minimization of the need for heparin administration.

## SA-PO446

**Recurrent Clotting of the Filter in Home Hemodialysis With NxStage System One: A Case Report**

Dhayanithi Dhayalan, Sharon G. Adler, Tiane Dai. Harbor-UCLA Medical Center, Torrance, CA.

**Introduction:** Clotting of the dialyzer is one complication in home hemodialysis. Recurrent filter clotting without pro-thrombotic factors is relatively uncommon. We report an adult male with recurrent clotting of the venous header of the filter in NxStage System One during home hemodialysis.

**Case Description:** A 60-year-old African American male with end stage renal disease from obstructive nephropathy due to prostate cancer was in remission after radiation therapy. He started on in-center hemodialysis via a tunneled internal jugular catheter. Two years later, he transitioned to home hemodialysis due to uncontrolled blood pressure and phosphorus levels. He was on apixaban for anticoagulation due to a history of paroxysmal atrial fibrillation. Patient did well on home hemodialysis via a right brachiocephalic fistula prior to his hospitalization for bladder bleeding that was attributed to radiation cystitis. Apixaban was temporarily discontinued. After discharge, patient started experiencing recurrent clotting of the venous header of the NxStage System One filter, which did not resolve with restarting Apixaban, changing the blood flow rate, increasing the heparin bolus dose, and adding a heparin infusion or saline flush hourly. He had no history of recurrent thrombosis of his vascular access nor identifiable pro-thrombotic risk factors. The clotting issue did not occur when he received in-center or in-hospital dialysis, where a standard (Fresenius) dialysis machine and high flux dialyzer were used. Clotting appeared to resolve with a combination of: 1) Flushing the dialyzer with at least one liter of saline; 2) Administration of apixaban 5mg one hour prior to dialysis; and 3) Using a higher heparin bolus dose 50units/kg (4,000units) with a supplemental 1,000 unit/hr infusion. The patient now experiences prolonged post-dialysis bleeding time and the AVF requires a careful pressure dressing.

**Discussion:** Dialyzer clotting during home hemodialysis is one of the complications. Recurrent clotting of the filter in the NxStage System One is uncommon but can occur in home hemodialysis patients with no identifiable pro-thrombotic factors. Clotting may be prevented by an increase in anticoagulant dosing. Higher bleeding risk is one of the precautions.

## SA-PO447

**Sodium-Induced Microcirculatory Dysfunction During Hemodialysis**

Lisa Hur,<sup>1</sup> Yanmin Zhang,<sup>1</sup> Barry Janssen,<sup>1</sup> Christopher W. McIntyre,<sup>2</sup> <sup>1</sup>Western University, London, ON, Canada; <sup>2</sup>London Health Sciences Centre London Kidney Clinical Research Unit, London, ON, Canada.

**Background:** Hemodialysis (HD) results in microcirculatory dysfunction (MD) leading to recurrent cardiac ischemia. Endothelial glycocalyx is vulnerable to circulatory and oncotic stress (predominantly Na<sup>+</sup> mediated)- inducing shedding of syndecan-1 (syn1), a transmembrane heparan sulfate proteoglycan. The glycocalyx binds Na<sup>+</sup>, buffering sudden serum Na<sup>+</sup> shifts, and can be damaged with acute changes in Na<sup>+</sup> concentration ([Na<sup>+</sup>]). The aim of this study is to investigate the effects of [Na<sup>+</sup>] dialysate on endothelial cell injury and MD during HD. We hypothesize that avoidance of higher [Na<sup>+</sup>] dialysate would have a direct protective effect on the endothelial glycocalyx and minimize directly observed HD-associated microcirculatory disturbance.

**Methods:** 8 healthy male Wistar Kyoto rats underwent HD: 4 were exposed to a higher dialysate [Na<sup>+</sup>] (140mM) and 4 were exposed to dialysate [Na<sup>+</sup>] below typical rat plasma Na<sup>+</sup> level (hyponatremic-130mM). Throughout HD, intravital microscopy (IVM) was used to image skeletal muscle microvasculature at baseline, during extracorporeal circulation with no dialysate flow ("Sham"), at 1 hr into HD, at 2 hrs into HD, and post HD ("Final"). The IVM images were processed to automatically derive the number of identified intersecting points, to quantify microcirculatory blood flow and observe the change in perfusion index at each timepoint. Blood samples were collected at the same timepoints corresponding to the IVM image acquisitions to measure syn1 and quantify glycocalyx shedding during HD. Continuous BP recordings were made from carotid artery cannulation.

**Results:** BP response to HD was comparable between the two groups. We observed progressive increase in syn1 concentration in blood plasma sampled throughout the duration of the experiment in both groups (Fig 1A). The hyponatremic group demonstrated a consistent trend of lower perfusion index at all timepoints relative to the comparator group (ns, Fig 1B).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Preliminary data in healthy rats suggests that a single HD session results in syn1 release from the vasculature- indicating acute HD-associated endothelial injury. Limiting exposure to intradialytic Na<sup>+</sup> may reduce MD under the stress of HD, despite equivalent systemic hemodynamic response.

#### SA-PO448

##### Microbacterium Sepsis due to an Insufficiently Sterilized Dialyzer

Mark D. Kilpatrick, Jason M. Kidd. *Virginia Commonwealth University School of Medicine, Richmond, VA.*

**Introduction:** Water treatment systems and dialysis machines are susceptible to growth of microorganisms if not sufficiently disinfected. We present a case of *Microbacterium* sepsis related to insufficient sterilization of a hemodialysis machine when brought back into circulation.

**Case Description:** A 45-year-old man with ESKD presented to the emergency department after chills and vomiting during hemodialysis. Earlier in the day, a patient using the same hemodialysis machine, which had just been returned to use, developed similar symptoms and was admitted to the ICU. In the ED, our patient was tachycardic and tachypneic with a leukocyte count of  $7.0 \times 10^9/L$ . Blood cultures were collected in the dialysis unit and ED and he was started on vancomycin and piperacillin-tazobactam empirically. On hospital day 3, cultures grew gram positive rods which later speciated to *Microbacterium*. Repeat cultures yielded no growth and our patient's tunneled dialysis catheter was replaced. He was treated with intravenous vancomycin for a 14-day course. Blood cultures in the patient dialyzed before our patient were also positive for *Microbacterium*. Cultures obtained from the dialysis machine yielded no growth.

**Discussion:** This rare case of hemodialysis-associated *Microbacterium* bacteremia demonstrates the importance of proper hemodialysis machine sterilization. *Microbacterium* are gram positive rods that rarely cause human infection [1]. Given our patient's history and the prior patient's similar history on the same machine, the origin of our patient's bacteremia is presumably the hemodialysis machine, likely either the tubing or dialysate. These two sources are the most common sites of microbial contamination [2]. *Microbacterium* bacteremia is also associated with catheter and port access and has been cultured from direct catheter sampling in an infected patient [1]. Although dialysis facilities have varying sterilization procedures, they adhere to strict contamination and monitoring standards for patient benefit. In our case, it is not known if there was a lapse in cleaning protocol or inadvertent material contamination, but thankfully our patient improved with prompt administration of empiric antibiotics and permacath replacement. [A] Chorost M, et al. 2018. [B] Pontoriero G, et al. 2003.

#### SA-PO449

##### The World Prevalence, Associated Risk Factors, and Mortality of Hepatitis C Virus Infection in Hemodialysis Patients: A Meta-Analysis

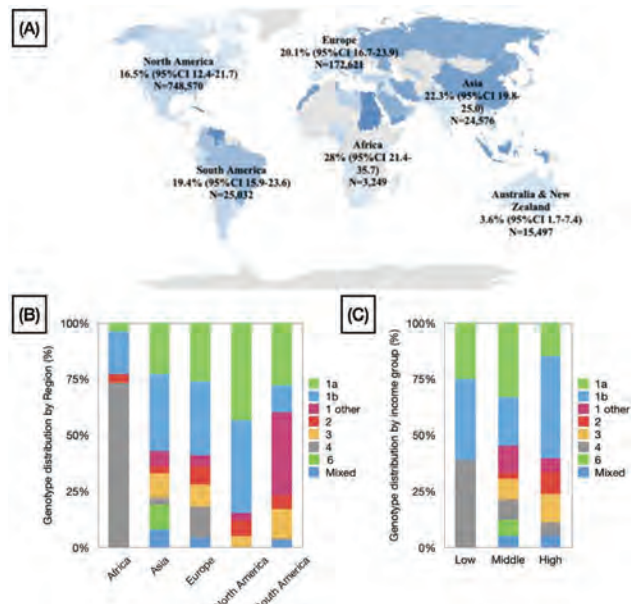

Tanat Lertussavavivat, Primploy Greeviroj, Thana Thongsricome, Kullaya Takkavatakarn, Jeerath Phannajit, Yingyos Avihingsanon, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Paweena Susantitaphong. *Chulalongkorn University Faculty of Medicine, Bangkok, Thailand.*

**Background:** Hemodialysis patients constitute high-risk population for HCV infection. The world burden of HCV infection among hemodialysis patients has not been systematically examined.

**Methods:** A systematic literature search was conducted in MEDLINE and Scopus to determine the world prevalence of HCV infection, risk factors, and outcomes among hemodialysis patients. Random-effect models and meta-regressions were used to generate pooled estimates and assess heterogeneity.

**Results:** Four hundred and seven studies with 1,302,167 participants were analyzed. The pooled prevalence of HCV infection was 21%. The highest prevalence was observed in Africa (28%) and low-income countries (48.5%). A significant prevalence was declined following the publication year and was also inversely related to GDP spent on total health expenditure and total population of each country. The most common HCV genotype was genotype 1b (33.5%), followed by genotype 1a (22.8%), 3 (8.2%), 2 (6%), 4 (5%), and 6 (2.4%). Factors associated with HCV positivity included younger age, longer dialysis duration, more blood transfusions, and dialyzer reuse. The pooled unadjusted HR for all-cause mortality was 1.12 (95%CI 1.03 to 1.22), and the adjusted HR was 1.21 (95%CI 1.12 to 1.30) in HCV-infected relative to non-HCV infected patients. There was significantly higher HCV-associated mortality from infection and malignancy.

**Conclusions:** HCV infection among hemodialysis patients is a shared burden worldwide and is associated with a higher risk of death.

Pooled prevalence of HCV infection among hemodialysis patients (A) by world zones and HCV genotype distribution (B) by regions and (C) country's income

#### SA-PO450

##### Favorable Prognosis in Patients Undergoing Hemodialysis Who Received a 23-Valent Pneumococcal Polysaccharide Vaccine Compared With Those Who Received a 13-Valent Pneumococcal Protein-Conjugate

Kosei Yamaguchi,<sup>1,2</sup> Mineaki Kitamura,<sup>1,2</sup> Satoshi Funakoshi,<sup>1</sup> Tomoya Nishino,<sup>2</sup> <sup>1</sup>Nagasaki Renal Center, Nagasaki, Japan; <sup>2</sup>Nagasaki University School of Medicine, Nagasaki, Japan.

**Background:** Infectious diseases are one of the main causes of death in patients undergoing hemodialysis (HD). Routine pneumococcal vaccination for the older population began in 2014 in Japan. Currently, the 23-valent pneumococcal polysaccharide vaccine (PPSV23), alone or in combination with a 13-valent pneumococcal protein conjugate vaccine (PCV13), is recommended for older patients. However, the efficacy of these two vaccines in patients undergoing HD remains unknown. We aimed to evaluate the prognosis of patients undergoing HD who were vaccinated with only PPSV23 compared with those vaccinated with PCV13.

**Methods:** Patients undergoing HD who were vaccinated with PPSV23 alone (PPSV23 group) or PCV13 (PCV13 group) between 2014 and 2016 were included, and the observation period was three years from the first injection. Patients who underwent HD between 2011 and 2012 were included as controls and observed for three years. The patients did not receive any pneumococcal vaccines during this period. After propensity score matching using age, sex, dialysis vintage, diabetes history, pneumonia history, and serum albumin and creatinine levels, survival analysis was performed.

**Results:** The study included 89 patients in the PPSV23 group (70.0±10.7 years old; 65.2% male; median dialysis vintage, 3.6 years), 98 patients in the PCV13 group (76.6±8.0 years old; 48.0% male; median dialysis vintage, 3.1 years), and 339 patients as controls (67.4±13.3 years old; 57.2% male; median dialysis vintage, 4.6 years). After propensity score matching, the PPSV23 and control groups (81 patients each), and the PCV13 and control groups (76 patients each) were evaluated. Significant differences in the survival rate between the PPSV23 group and controls were observed (P=0.04), but no significant difference was observed between the PCV13 group and controls. The incidence of pneumonia in the PPSV23, PCV13, and control groups did not differ significantly during the observation period.

**Conclusions:** The patients vaccinated with PPSV23 had favorable outcomes; however, the efficacy of PCV13 was limited in older patients who were undergoing HD. Further studies are needed to clarify the mechanisms affecting the prognostic relevance of pneumococcal vaccines and the differences between them.

#### SA-PO451

##### Observations of Infection Prevention and Control Practices in US Outpatient Hemodialysis Clinics, 2015-2018

Nicole Gualandi, Stephanie Hsu, Shannon Novosad, Priti R. Patel. National Dialysis ICAR Implementation Working Group Centers for Disease Control and Prevention, Atlanta, GA.

**Background:** Pandemics have highlighted the need for robust infection prevention and control (IPC) in dialysis clinics to prevent spread of infections. In 2015, public health departments were funded to assess and improve IPC in hemodialysis clinics. We present results of observations performed during these assessments.

**Methods:** A standardized Infection Control Assessment and Response (ICAR) form was developed by IPC experts at a federal public health agency. The form included observations of practice using published tools for 7 different IPC processes. A process was considered successful if all recommended steps were completed. Health department staff selected clinics for assessment and were trained on use of the observation tools. Cross-sectional assessments occurred from March 2015-March 2018. We pooled jurisdictions' aggregate numerator and denominator data and calculated the percent of observed processes successfully completed.

**Results:** In all, 70,288 IPC observations were made in 764 dialysis clinics in 29 jurisdictions. Of 42,642 hand hygiene opportunities observed, 89.5% were successful (Figure). Among injection processes, 82.1% of 3,802 injection preparations and 87.3% of 3,550 injection administrations were successful. Among vascular access processes, 77.3% of 6,688 arteriovenous access connections, 82.0% of 4,061 catheter connection/disconnections, and 65.8% of 2,350 catheter exit site processes were successful. For routine disinfection of dialysis stations, 62.4% of 7,195 observed processes were successful.

**Conclusions:** In a large-scale evaluation of dialysis IPC practices, observed adherence to hand hygiene and injection safety was high. But infrequent, serious errors could have occurred. Important areas for improvement may exist for vascular access care and dialysis station disinfection. Increased attention to routine IPC practice will likely lessen the impact of emerging infections.

**Funding:** Other U.S. Government Support

## SA-PO452

### Characteristics and Outcomes Among Hospitalized Patients With Gram-Negative Bacteremia (GNB) Who Require Kidney Replacement Therapy (KRT)

Matthew R. Sinclair,<sup>1,2</sup> Joshua T. Thaden,<sup>1</sup> Felicia Ruffin,<sup>5</sup> Lawrence Park,<sup>1,3</sup> Michael M. Dagher,<sup>4</sup> Emily Eichenberger,<sup>1</sup> Christina M. Wyatt,<sup>1,2</sup> Vance Fowler,<sup>1,2</sup> <sup>1</sup>Duke University School of Medicine, Durham, NC; <sup>2</sup>Duke Clinical Research Institute, Durham, NC; <sup>3</sup>Duke Global Health Institute, Durham, NC; <sup>4</sup>Duke University Health System, Durham, NC; <sup>5</sup>Duke University Medical Center, Durham, NC.

**Background:** GNB is a common cause of sepsis in patients requiring KRT, and is associated with morbidity and mortality. These adverse outcomes are partially the result of increasing antibiotic-resistant bacterial strains, but other contributing patient and bacterial factors are unclear. Further, it is unknown if patients hospitalized with GNB who develop acute kidney injury (AKI) requiring KRT prior to bacteremia have disparate outcomes compared to patients on maintenance hemodialysis (HD) hospitalized with GNB. We evaluated differences in characteristics and outcomes in hospitalized patients with GNB with AKI requiring KRT vs those on maintenance HD and assessed associations between clinical and bacterial characteristics and outcomes.

**Methods:** Hospitalized, non-neutropenic adults with GNB who required KRT were prospectively enrolled from Jan 1, 2002 to December 31, 2016 (n=185). Clinical and bacterial characteristics and outcomes between groups were evaluated with Mann-Whitney-U or Fisher's Exact test. Associations with outcomes were estimated using logistic regression.

**Results:** Among hospitalized patients with GNB, those patients with AKI requiring KRT (n=38) compared to patients on maintenance HD (n=147) were more acutely ill (Acute Physiology Score, median (APS) 13.0 vs APS 9.0; p=0.03), more likely to be a transplant recipient (44.7% vs 18.4%; p=0.001), less likely to identify as Black race (18.4% vs 67.3%; p<0.001), and more likely to have a multi-drug resistant (MDR) bacterial strain (47.4% vs 27.1%; p=0.02). Additionally, patients with AKI requiring KRT were more likely to have clinical complications (65.8% vs 40.1%; p=0.006) and to die (57.9% vs 24.5%; p<0.001) compared to patients on maintenance HD. Among all patients, MDR bacterial strains and non-vascular source of infection were associated with all-cause mortality (Odds Ratio (OR) 4.36, 95% Confidence Interval (CI) 1.83-11.00 and OR 6.94, 95% CI 2.11-28.48, respectively).

**Conclusions:** Hospitalized patients with GNB and HD-dependence are at significant risk for adverse outcomes. Both clinical and bacterial characteristics contribute to these outcomes, with clinical complications and mortality rates highest among patients who develop AKI requiring KRT.

**Funding:** Other NIH Support - K24-AI093969

## SA-PO453

### Outcomes and Costs of Central Venous Catheter (CVC)-Related Staphylococcus aureus Bloodstream Infections (SA-BSI) in Hemodialysis (HD) Patients (Pts) With SA Nares Colonization (SA-NC) and Diabetes Mellitus (DM)

Nimish Patel,<sup>1</sup> Jamie P. Dwyer,<sup>2</sup> Lynda Berne,<sup>3</sup> Clarence L. Young,<sup>4</sup> Matthew Callahan,<sup>4</sup> Anthony G. Robinson,<sup>4</sup> Thomas P. Lodise,<sup>5</sup> <sup>1</sup>Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego, San Diego, CA; <sup>2</sup>University of Utah Health, Salt Lake City, UT; <sup>3</sup>BAL Pharma Consulting, Princeton, NJ; <sup>4</sup>Botanix Pharmaceuticals Limited, North Perth, WA, Australia; <sup>5</sup>Albany College of Pharmacy and Health Sciences, Albany, NY.

**Background:** The rate of SA-BSIs in pts who start in-center HD with a CVC is estimated to be ~1 cases per 100-person months (PMID: 28663227), with higher rates observed in CVC-HD pts with SA-NC and DM. This study estimated the yearly outcomes and costs attributable to CVC-related SA-BSIs in adult CVC-HD pts with SA-NC and DM who start in-center HD.

**Methods:** A probabilistic model from the US Healthcare Perspective (1-year time horizon) was developed. The study population consisted of ~45,000 pts with DM as primary cause of ESRD who start in-center CVC-HD each year. Markov modeling (4 12-week cycles) was used to simulate the transitions between the different health-related dynamic states of CVC-HD pts with SA-NC and DM and estimate the yearly CVC-related SA-BSI-related outcomes and costs. Time on CVC, prevalence of SA-NC, CVC-related SA-BSI rates, CVC-related SA-BSI re-infection rates, 12-week SA-BSI costs (first episode and re-infections), and CVC-related SA-BSI death rates were identified in comprehensive literature review (Figure 1).

**Results:** Data indicate that 18,000 of the 45,000 annual incident CVC-HD pts with DM have SA-NC. Among CVC-HD pts with SA-NC and DM, the model estimates that there are 3,690 CVC-related SA-BSIs, 720 SA-BSI-related re-infections, and 900 SA-BSI-related deaths annually. Attributable yearly mean (SD) costs are projected to be 229 (51) million USD.

**Conclusions:** The estimated annual incidence of CVC-related SA-BSIs in CVC-HD pts with DM who start in-center HD that is attributable to SA-NC is high, resulting in considerable morbidity, mortality, and healthcare costs. New technologies are needed to prevent CVC-related SA-BSIs in this population.

**Funding:** Commercial Support - Botanix

## Clinician and Patient Support Through Supply Chain Innovation During the COVID-19 Pandemic

Ramnik S. Khangura, Kulwant Sandhu, Cynthia J. D'Alessandri-Silva, Michael A. Aragon. *Outset Medical, San Jose, CA.*

**Background:** Since March 2020, the COVID-19 Pandemic has critically impacted the global supply chain from raw materials to devices and supplies. As a result, many hospitals' and dialysis providers' capacity to provide care for patients in ICUs and dialysis units was materially impacted. To ensure patients received the necessary life-saving dialysis treatments from the ICU to Home with Tablo, it was critical to implement a new, long term global supply chain strategy. Here we report the impact of an innovative supply chain initiative to meet these challenges.

**Methods:** Retrospective analysis of supply chain performance metrics from Dec 2020-Dec 2021 assessed monthly for on-time delivery, inventory, allocation events and overall parts shipped. During March and April of 2020, Outset's supply chain team implemented 3 strategic initiatives aimed at improving risk analysis, upstream sourcing and logistics management. Risk analysis improvements included investment in software analytics and application of AI to improve transparency for rapid decisions. Upstream sourcing developed expertise in the full life cycle of every component and category of the device to secure supplies with methods including dual source or near source. Logistics focused on long term stability and localization of goods by partnering with third party distribution and logistics providers to utilize a wider range of supply transport options.

**Results:** Over the 13 months period, total treatments delivered increased by 125%. The mean On Time Delivery performance over the same period was 96% (min 92%, max 98%), better than the internal target of 95%. (Fig 1) There were no occurrences of delivery interruption or implementation of supply allocation to any hospitals, clinics or home dialysis patients.

**Conclusions:** Sustainable innovation in Tablo's console and cartridge supply chain successfully supported the increased demand for dialysis equipment and supplies and ensured reliable delivery of critically needed treatment related supplies for clinicians and patients using Tablo throughout the peak of the pandemic.

## SA-PO455

## Pandemic Effects on Stability of Goals-of-Care Congruence Between Dialysis Patients and Their Surrogates: A Natural Experiment Study

Mi-Kyung Song, Sudeshna Paul, Jordan L. Pelkmans. *Emory University, Atlanta, GA.*

**Background:** The COVID pandemic has brought fear and uncertainty to all aspects of life and to medical care in particular. This study was to assess the effects of a disaster on the stability of dialysis patients' end-of-life care preferences and dyad congruence on goals of care after an evidence-based advance care planning (ACP) intervention, SPIRIT (Sharing Patient's Illness Representations to Increase Trust).

**Methods:** In an on-going parent study, a pragmatic trial of SPIRIT included 151 patient-surrogate dyads who completed the baseline (T1) and post-intervention assessment (T2), including goals-of-care preferences (asking patient's values in specific scenarios), prior to the pandemic lockdown. Of those, 110 dyads (59 intervention and 52 usual care) consented to be in this natural experimental study during the pandemic and completed the measures 2 additional times, at enrollment (T3) and again 6 months later (T4), along with the COVID Stress Scale. Dyad congruence was measured by comparing patients' and surrogates' responses to the goals-of-care document.

**Results:** The sample included 83% non-White. In general, most patients' goals-of-care preferences and dyad congruence were stable over time. GEE analyses showed a time and pandemic interaction in dyad congruence on goals of care ( $p=0.04$ ): both groups' dyad congruence sharply improved at T2 from T1 but more so in intervention dyads before the pandemic (significant treatment effect,  $p=0.01$ ), and the congruence levels remained stable until T3 during the pandemic followed by an increase in dyads' congruence at T4 (Fig 1). But group difference during the pandemic (T3, T4) was not significant.

**Conclusions:** After the ACP intervention, intervention dyads' congruence was significantly better than controls, but the intervention did not make intervention dyads' congruence more stable than controls' during the pandemic.

## Long-Term SARS-CoV-2 Antibody Titers After mRNA Vaccination in Patients Undergoing Hemodialysis in Japan

Daisuke Kanai,<sup>1</sup> Tatsuya Haze,<sup>1</sup> Hiromichi Wakui,<sup>1</sup> Masaaki Hanaoka,<sup>3</sup> Eriko Abe,<sup>1</sup> Kengo Azushima,<sup>1</sup> Nobuhito Hirawa,<sup>2</sup> Kouichi Tamura.<sup>1</sup> <sup>1</sup>Yokohama Shiritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Yokohama, Japan; <sup>2</sup>Yokohama Shiritsu Daigaku Fuzoku Shimin Sogo Iryo Center, Yokohama, Japan; <sup>3</sup>Iryo Hojin Shadan Kohsaikai Kamioooka Jinsei Clinic, Yokohama, Japan.

**Background:** Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccination is shown to prevent severe illness and death in hemodialysis (HD) patients, but the immune response to vaccines is reduced in this population. This study compares SARS-CoV-2 spike protein antibody titers between HD patients and healthy controls in Japan for up to 6 months following vaccination.

**Methods:** A multi-institutional retrospective study at five clinics in Japan was conducted using 412 HD patients and 156 healthy controls who received two doses of the BNT162b2 (Pfizer-BioNTech) mRNA vaccine. Anti-SARS-CoV-2 spike protein S1 IgG antibody titers were measured at 1, 3, and 6 months after the second dose. The attenuation speed was calculated as slope (i.e., -b) by using a linear mixed-effects model toward the log-transformed antibody titers.

**Results:** The HD group had significantly lower month 1 antibody titers (Ab-titer-1) than the controls, and these remained lower through month 6 (95% CI: 2617.1 (1296.7, 5240.8) vs. 7285.4 (4403.9, 11000.0) AU/mL at Ab-titer-1, and 353.4 (178.4, 656.3) vs. 812.0 (498.3, 1342.7) AU/mL at Ab-titer-6 ( $p < 0.001$ , respectively)). Lower log Ab-titer-1 levels in the HD group were significantly associated with a lower log Ab-titer-6 (0.90 [0.83, 0.97],  $p < 0.001$ ). The -b values in the HD patients and healthy controls were  $-4.7 \pm 1.1$  and  $-4.7 \pm 1.4$  (year<sup>-1</sup>), respectively. In the HD patient group, age, serum albumin level, and hemoglobin level showed a negative correlation with Ab-titer-1, and the use of vitamin D preparation showed a positive correlation. In addition, the lower peak antibody titer contributed to the lower Ab-titer-6.

**Conclusions:** SARS-CoV-2 spike protein antibody titers were significantly lower in HD patients than in healthy controls at 1 (peak) and 6 months after the second vaccination. Low peak antibody titers contributed to low 6-month antibody titers.

## SA-PO457

## Better Anti-Spike IgG Antibody Response to SARS-CoV-2 Vaccine in Patients on Hemodiafiltration Than on Hemodialysis

Fernando Carrera,<sup>1</sup> Stefan H. Jacobson,<sup>2</sup> Joana Costa,<sup>1</sup> Marco A. Marques,<sup>3</sup> Francisco Ferrer.<sup>1</sup> <sup>1</sup>DaVita, Leiria, Portugal; <sup>2</sup>Danderyd Hospital, Stockholm, Sweden; <sup>3</sup>Affidea Laboratory, Lisbon, Portugal.

**Background:** The antibody response to SARS-CoV-2 vaccine in hemodialysis (HD) patients is diminished compared to healthy subjects. The aim of this study was to compare the presence of reactive SARS-CoV-2 antibodies in patients with high-flux HD and on-line hemodiafiltration (HDF) three and six months after the second dose of SARS-CoV-2 vaccine since previous studies indicate that a sustained antibody response correlate with protection from disease.

**Methods:** We included 216 HD patients of which 157 had on-line HDF and 59 high-flux HD and 46 health care workers as controls and studied the presence of reactive anti-spike IgG antibodies three and six months after the second dose of SARS-CoV-2 vaccine. Clinical features between the patient groups were similar, but patients with on-line HDF had significantly higher Kt/V.

**Results:** The percentage of participants with reactive antibodies was significantly lower in patients compared to controls, both three and six months after the second dose of vaccine. Furthermore, the proportion of patients with reactive anti-spike IgG  $\geq 1.0$  six months after the second dose of vaccine was significantly higher in patients with on-line HDF compared to in patients with high-flux HD. In logistic regression analyses

adjusted for several clinical features, the variables associated with presence of reactive anti-spike IgG at three months after the second dose of vaccine were lower age, HDF treatment, not being obese and not having a previous solid organ transplant. The two variables with the strongest influence on the presence of reactive anti-spike IgG levels six months after the second dose of vaccine were treatment with on-line HDF and not having immunosuppressive therapy.

**Conclusions:** This is the first study to show that on-line HDF preserves the antibody response better than high-flux HD after vaccination with SARS-CoV-2 vaccine. Treatment strategies that sustain the vaccine response are essential to apply in this vulnerable group of patients.

**Funding:** Private Foundation Support

### Outcome Study Among Hospitalized Symptomatic COVID-19 Patients Who Required Chronic vs. Acute Hemodialysis (HD)

Phuong-Chi T. Pham,<sup>1</sup> Mohammad S. Alghussein,<sup>1</sup> Svetlana O. Villano,<sup>1</sup> Nisha M. Singh,<sup>1</sup> Susana M. Mendoza,<sup>1</sup> Golriz Jafari,<sup>1</sup> Anita Kamarzarian,<sup>1</sup> Phuong-Thu T. Pham.<sup>2</sup> <sup>1</sup>UCLA Medical Center Olive View, Sylmar, CA; <sup>2</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Background:** Mortality among patients admitted for COVID19 infections who develop acute kidney injury (AKI) and require dialysis support has been reported to be 60-70%. Data are lacking regarding how chronic HD patients with an impaired immune system may: 1) mount an inflammatory response to COVID19 infection and 2) survive the infection compared with those who require acute HD for AKI. We evaluated ferritin levels, hospital length of stay (LOS), and mortality rates among chronic HD patients and those who required acute HD during hospitalization for COVID19-related symptoms.

**Methods:** Inclusion: All patients hospitalized for COVID19-related symptoms who received HD at OV-UCLA Medical Center from January to December 2020. Data collection: Baseline characteristics: age, gender, body mass index (BMI), comorbidities (diabetes mellitus, hypertension, underlying chronic obstructive lung disease or asthma, history of malignancy, and heart failure). Medications: use of any inhibitor of the renin angiotensin aldosterone system. Lab studies: albumin, ferritin, basic chemistry. Hospital LOS and death from any cause. Data analysis: Ferritin levels, hospital LOS, and mortality among chronic and acute HD patients.

**Results:** See Figure

**Conclusions:** Among our hospitalized symptomatic COVID19 patients requiring HD support: 1. Ferritin levels were comparable between chronic HD and previously nondialysis patients who required acute HD support. 2. Chronic HD patients had shorter hospital LOS compared with those requiring acute HD ( $6.2 \pm 5.7$  vs.  $35.3 \pm 31.3$ d). The 2 groups had similar serum sodium, albumin, and ferritin levels. 3. Mortality was <5% (compared with 1.5% for the US population) among chronic HD patients and 58% among those who developed AKI requiring acute HD. 4. Incidentally, BMI among current COVID19 cohort was  $30.6 \pm 8.8$  compared with  $26.4 \pm 5.8$  Kg/m<sup>2</sup> from our 70 non-COVID dialysis patients included in a different study (p-value <0.001).

<sup>1</sup>Baseline Characteristics and Outcomes Among Hospitalized Symptomatic COVID-19 Patients Requiring Hemodialysis Support During the COVID-19 Pandemic (January to December 2020)  
At Olive View-UCLA Medical Center

	<sup>1</sup> Chronic HD	<sup>2</sup> Acute HD	p-value

Age (years)	37.9 ± 31.5	48.3 ± 21.9	0.16
Percent male	78.3	80.6	NS
Body mass index (Kg/m <sup>2</sup> )	28.1 ± 6.9	33.7 ± 9.7	0.02
Number of comorbidities (hypertension, diabetes mellitus, chronic obstructive pulmonary disease, cancer) per patient	2.82	1.39	---
Percentage of patients receiving angiotensin converting enzyme inhibitor or angiotensin receptor blocker prior to COVID diagnosis	69.6	25.8	0.00138
Average sodium concentration (mmol/L)	133.4 ± 3.3	133.6 ± 4.9	0.86
Albumin (g/dL)	3.1 ± 0.5	3.1 ± 0.6	0.72
Highest ferritin level recorded (mcg/L)	3264 ± 2369	3138 ± 3986	0.89
Hospital length of stay (days)	6.2 ± 5.7	35.3 ± 31.3	<0.0001
Percent mortality	4.4	58.1	<0.0001

<sup>1</sup>All data herein pertain to patients admitted specifically for COVID-19 related symptoms.

<sup>2</sup>Chronic HD refers to patients with established need for HD prior to COVID-19 infection; Acute HD refers to HD support for acute kidney injury during COVID-19 related admission. Abbreviations: HD, hemodialysis

## SA-PO459

### An Anuric and Hyperkalemic Patient During the COVID-19 Pandemic Without Access to Dialysis due to Social Protests in a Small Municipality in Colombia: What Can I Do?

Roberto Ramirez Marmolejo,<sup>1,2</sup> Sofia Ramirez Isaza.<sup>3</sup> <sup>1</sup>Universidad Santiago de Cali Facultad de Salud, Cali, Colombia; <sup>2</sup>DaVita Inc, Denver, CO; <sup>3</sup>Pontificia Universidad Javeriana, Cali, Colombia.

**Introduction:** Due to the expenses generated by the pandemic, the Colombian government (image 1) propose raising taxes. This led to a social claim that led to the start of a national strike for several months in Cali city and its small nearby municipalities (Yumbo), indigenous people and other radical groups block main roads into and out of the city (images 2, 3, 4). The blockades prevented the passage of patients to be able to dialyze in Cali. In Yumbo there were no dialysis clinics, since the local hospital only has primary care. We present the case of an anuric patient who, due to lack of dialysis, presented pulmonary edema and hyperkalemia, and who could not be treated in a renal center, but in a small regional hospital and how his life was maintained with a totally alternative protocol.

**Case Description:** A 69y patient, presented pulmonary edema on the fourth day without dialysis, see Table 1, electrocardiogram showing peak T waves. Telephone communication was maintained. Management: Nebulizations with  $\beta$  stimulants, oral nifedipine and minoxidil. The patient persists hypervolemic on the second day, raises potassium to 8.8mEq/L and begins to present oxygen desaturation, a protocol is proposed as a vital emergency: enemas every 15 minutes, for 3. Oral castor oil, one ounce every 12 hours. (first dose assumed as zero hour of the protocol). See evolution in table No. 1. Potassium and pulmonary edema were finally controlled.

**Discussion:** In the history of humanity, there are countless moments where violence causes medical missions to take measures that are not recommended in theory, but have saved lives. This protocol is clearly a desperate measure, but it can be of support in cases of pulmonary edema or hyperkalemia.

### Impact of Inpatient Tele-Nephrology Treatment Outcomes in Rural Alabama

Norman W. Seay, Katie Bean, Arun Rajasekaran, Takamitsu Saigusa, Vinay Narasimha Krishna, Ashlee Chatham, Alicia S. Cole, Eric L. Wallace. UAB Hospital, Birmingham, AL.

**Background:** Access to nephrology care including dialysis in rural Alabama (AL) hospitals is lacking. The University of Alabama at Birmingham (UAB) with Sanderling Inc. started inpatient tele-nephrology (TN) services in 2019 and currently serves 3 rural AL hospitals. Since the COVID-19 pandemic, transfer to TN-equipped hospitals in AL played a pivotal role for patients needing nephrology services when primary referral centers were at capacity.

**Methods:** TN services were 100% virtual and video-based. Consults were completed by UAB nephrology faculty. Home hemodialysis machine (HHD) was used to provide kidney replacement therapy (KRT) in the hospital, with aid of inpatient dialysis technicians supervised remotely by TN dialysis nurses. TN consults were evaluated from Jun 2019 to Dec 2021. Retrospective chart review for pre-defined outcomes was performed and analyzed.

**Results:** There were 694 inpatient TN encounters. Mean age was 64 (18-96) yr. 74% of consultations involved black patients. Mean stay was 6 d. 44% were ICU patients; 18% were COVID-19 positive. AKI and known ESKD patients contributed to 48% and 44% consults, respectively. 11% had AKI necessitating KRT. 20% and 13% of consults involved hyperkalemia and dysnatremias, respectively. 792 dialysis treatments were performed with 11% complicated by intradialytic hypotension (IDH). Patients were discharged 64% and transferred to higher level of care 18% of the time. 90 patients expired. 66% of deaths were attributable to COVID-19. Preliminary economics analysis at the hospital with the most consults showed increase in case-mix index and higher census since implementation of TN services.

**Conclusions:** Inpatient TN in community hospitals in rural AL provided essential nephrology care to underserved populations amidst a pandemic limiting transfer to nephrology-staffed medical centers at capacity. Most patient encounters resulted in discharge without need for transfer to bigger centers thus saving vital time and resources. Dialysis safety was favorable with low IDH prevalence likely given HHD use. TN services can be beneficial for nephrology care in remote community hospitals with further studies warranted.

SA-PO461

**In-Center Hemodialysis Patient Perspectives on Telenephrology**  
Mariam Charkviani, Lagu A. Androga, Priya Ramar, Rachel H. Amundson, Ziad Zoghby, Robert C. Albright. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Telenephrology has gained popularity in various medical specialties, including nephrology. CMS allows its limited use for in-center dialysis rounds but there remains a lack of objective data on patient perceptions on its use as a health care delivery modality. In this study we evaluated in-center hemodialysis patients’ perspectives on care received via telenephrology

**Methods:** We retrospectively studied adults who received telenephrology care in three remote dialysis centers at Mayo Clinic Health System from March 22, 2021 to July 22, 2021. We used a standardized survey methodology to evaluate patient satisfaction and their perspectives on access to their nephrologist, relationship with care provider, their opinions on the telenephrology technology, and their overall assessment of the care received.

**Results:** Overall, 130 in-center dialysis patients received telenephrology care through video visits at three remote dialysis centers. Survey response rate was 62% (n=81). Surveyed patients had favorable perception about care they received via telenephrology. 64% felt a personal connection with their telehealth providers and 94% expressed that most of their questions were answered during the video visits. 86% of survey responders did not have any technical difficulties. 9.2% patients reported poor sound quality. Surprisingly, 67% of patients felt video visits provided them with more time than face-to-face visits with their providers. 90% thought that their video visits were successful. 81% of patients would be comfortable using video for least half or more of their visits, 9% preferred using video for all their visits, and 9% preferred no telenephrology visits at all.

**Conclusions:** Patient satisfaction was high among patients seen via telenephrology. Telenephrology can become valuable tool to fill the gaps in patient care especially in remote dialysis areas.

Patient Views on Video Visit (n=81)

SA-PO462

**Metabolites Associated With Uremic Symptoms in Hemodialysis Patients**  
Leslie Myint,<sup>1</sup> Eugene P. Rhee,<sup>2</sup> Kendra E. Wulczyn,<sup>2</sup> Sahir Kalim,<sup>2</sup> Dorry L. Segev,<sup>3</sup> Mara McAdams-DeMarco,<sup>3</sup> Ravi I. Thadhani,<sup>2</sup> Sharon M. Moe,<sup>4</sup> Ranjani N. Moorthi,<sup>4</sup> Thomas H. Hostetter,<sup>5</sup> Jonathan Himmelfarb,<sup>6</sup> Timothy W. Meyer,<sup>7</sup> Neil R. Powe,<sup>8</sup> Marcello Tonelli,<sup>9</sup> Tariq Shafi.<sup>10</sup> <sup>1</sup>*Macalaster College, St. Paul, MN;* <sup>2</sup>*Massachusetts General Hospital, Boston, MA;* <sup>3</sup>*NYU Langone Health, New York, NY;* <sup>4</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>5</sup>*University of North Carolina System, Chapel Hill, NC;* <sup>6</sup>*University of Washington School of Medicine, Seattle, WA;* <sup>7</sup>*Stanford University School of Medicine, Stanford, CA;* <sup>8</sup>*University of California San Francisco, San Francisco, CA;* <sup>9</sup>*University of Calgary, Calgary, AB, Canada;* <sup>10</sup>*University of Mississippi Medical Center, Jackson, MS.*

**Background:** The specific substances causing uremic symptoms are unknown. We used untargeted metabolomics to identify metabolite markers associated with uremic symptoms in hemodialysis patients.

**Methods:** We profiled 29,591 plasma metabolites (Broad Institute) in 517 Longitudinal US/Canada Incident Dialysis (LUCID) study participants at baseline (discovery) and subset at year 1 (validation). We concurrently assessed uremic symptoms (KDQOL-36; fatigue, pruritus, anorexia, nausea/vomiting, daytime sleepiness, difficulty concentrating, and pain) and investigated demographic- and clinical covariate-adjusted associations using: a) metabolite-wise linear models with empirical Bayesian inference, accounting for multiple testing; b) LASSO; c) random forest (RF) models. We defined robust symptom-metabolite associations if significant in linear models and at least medium importance in both LASSO and RF models.

**Results:** The mean age was 61 years, 80% were male, and mean duration from dialysis initiation was 62 days. We identified several metabolites robustly associated with uremic symptoms; 3 metabolites associated with anorexia, 8 with pruritus, and 1 each with pain, sleepiness, and concentration (Table). Higher levels of 2-hydroxy-3-methylpentanoate/hydroxyisocaproate were linked to higher severity of anorexia, bodily pain, and difficulty concentrating. Lower levels of indoxyl sulfate were associated with higher severity of daytime sleepiness. No metabolites were significantly associated with fatigue or nausea/vomiting.

**Conclusions:** We identified several metabolites associated with uremic symptoms, which could be targeted for future interventions if replicated in other studies.

**Funding:** Other NIH Support - NINR

Symptom		Baseline			Year 1		
		Adjusted Fold Change	Relative Importance		Adjusted Fold Change	Relative Importance	
			High vs. Low*	LASSO <sup>b</sup> RF <sup>c</sup>		High vs. Low*	LASSO <sup>b</sup> RF <sup>c</sup>

**Impact of CKD-Associated Pruritus Relief on Mood and Emotional Distress**  
Sonja Ständer,<sup>1</sup> Steven Fishbane,<sup>2</sup> Thilo Schaufler,<sup>3</sup> Isabelle Morin,<sup>3</sup> Frederique Menzaghi,<sup>4</sup> Warren Wen,<sup>4</sup> Kamyar Kalantar-Zadeh.<sup>5</sup> <sup>1</sup>*Center for Chronic Pruritus, University of Münster, Münster, Germany;* <sup>2</sup>*Northwell Health, Great Neck, New York, NY;* <sup>3</sup>*Vifor Pharma Ltd, Glattbrugg, Switzerland;* <sup>4</sup>*Cara Therapeutics Inc, Stamford, CT;* <sup>5</sup>*University of California Irvine, Irvine, CA.*

**Background:** Chronic kidney disease-associated pruritus (CKD-aP) is a frequent, unpleasant symptom and a cause of suffering in patients undergoing hemodialysis (HD). The aim of this analysis was to assess the impact of itch relief on mood and depression in patients with CKD-aP based on data from clinical trials with difelikefalin (DFK).

**Methods:** DFK studies enrolled HD patients with moderate-to-severe CKD-aP (mean worst itching numerical rating scale [WI-NRS] score >4 [KALM-1] or ≥5 [KALM-2 and 3105]). Patients were randomized 1:1 to intravenous DFK 0.5 µg/kg or placebo (KALM) or received open-label DFK (3105) 3 times/week for 12 weeks. The present analysis reports data from all patients completing the studies irrespective of study drug exposure; data were pooled for patients receiving DFK and placebo from the KALM trials. Change from baseline of the mood and depression sub-domain of Skindex-10 was assessed.

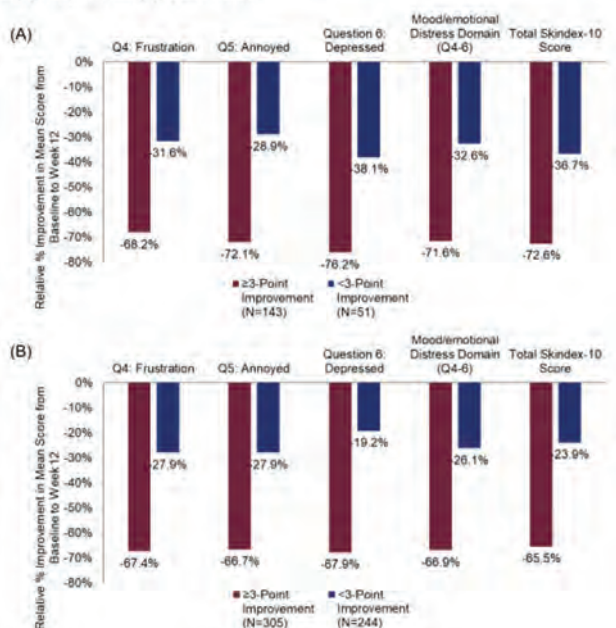

**Results:** Skindex-10 scores were available for 549 patients in KALM and 194 patients in 3105. Patients reporting clinically relevant (≥3-point) change in itch (KALM: n=305; 3105: n=143) reported a corresponding improvement of 72% (3105) and 67% (KALM) in the mood/emotional distress domain of Skindex-10, compared with 33% and 26% for patients with <3-point improvement (KALM: n=244; 3105: n=51) in WI-NRS.

**Conclusions:** In this study we found that achieving clinically meaningful reductions in itch severity to be associated with significantly greater improvements in mood and depression, as well as in overall itch-related quality of life, for patients with CKD-aP.

**Funding:** Commercial Support - Vifor Pharma

**Figure:** Relative percentage change in the mean from baseline to week 12 in Skindex-10 question scores for patients reporting  $\geq 3$ -point vs  $< 3$ -point improvement in worst-itching numerical rating scale in (A) Study 3105 and (B) KALM studies.

#### Efficacy of Regional Citrate Anticoagulation vs. Saline Flushing During Intermittent Hemodialysis on Blood Circuit Clotting Prevention: A Randomized Clinical Trial (The Citra-Saline-IHD)

Suree Yoowannakul, Theerapun Boonsayomphu, Bhumibol Adulyadej Hospital, Bangkok, Thailand.

**Background:** Conventional hemodialysis requires anticoagulation to prevent clotting in the extracorporeal circuit. For patients who unable to receive heparin anticoagulation during hemodialysis, saline flushing technique is a common practice but clots have been found. Regional citrate anticoagulation (RCA) is effective but not routinely use in dialysis unit. We wished to evaluated the efficacy and safety of regional citrate anticoagulation (RCA) for low flux intermittent hemodialysis using with 1.75 mEq/L dialysate calcium compared to saline flushing technique.

**Methods:** A prospective randomized, open label, cross over study on 144 sessions of 72 HD patients was conducted in hemodialysis unit of Bhumibol Adulyadej hospital. Patients were allocated to RCA group and saline group. Citrate was infused and adjusted according to the degree of anticoagulation and level of ionized calcium within the systemic circuit. Assessment of clot formation in dialysis circuit, blood electrolyte, acid-base balance, treatment time and adverse events were evaluated compared between RCA group and saline group.

**Results:** No clotting event in the RCA group while 25% (18 of 72 sessions) of saline group had circuit clots and resulted in early termination of dialysis. The citrate infusion rate was  $41.6 \pm 1.6$  mmol/l/min with using 1.75 mEq/L dialysate calcium and infuse post-filter of 10% calcium gluconate rate 30 ml/hr. No incidence of hypernatremia, hypocalcemia and metabolic alkalosis in RCA group.

**Conclusions:** RCA is safe and more effective for preventing dialysis circuit clots than saline flushing technique. We demonstrated the protocol optimal dose of RCA for low flux hemodialysis with using 1.75 mEq/L dialysate calcium can imply to be the protocol for patients who are contraindicated to the use of heparin anticoagulants in the intermittent hemodialysis.

**Funding:** Government Support - Non-U.S.

#### Parkinson Disease-Induced Cerebral Salt Wasting

Zachary A. Hansen, Adrian J. Baudy, Jing Chen. Tulane University, New Orleans, LA.

**Introduction:** Cerebral salt wasting (CSW) primarily occurs in cerebral hemorrhage but can be caused by any neurologic disease. It is due to renal salt wasting and subsequent volume contraction, but the exact mechanism is unclear. It has many overlapping features with SIADH and distinguishing the two is important as treatment differs drastically. Here, we present a case of hyponatremia and our treatment approach.

**Case Description:** 76-year-old man with Parkinson Disease, neurogenic bladder and suprapubic catheter presented for abdominal pain and altered mental status. He was found to be volume depleted with a serum sodium (Na) of 119 that increased to 122 with 500mL of normal saline (NS). His serum osmolality (S<sub>osm</sub>) was 249, urine osmolality (U<sub>osm</sub>) 421 and urine sodium (Ur Na)  $< 12$ . He received 13 liters of NS over the next few days and repeat labs showed Na 127, S<sub>osm</sub> 127, U<sub>osm</sub> 264, Ur Na 59 and Fractional excretion of Uric Acid (FE Uric Acid) 14%. His sodium dropped when IV hydration was discontinued, raising concern for cerebral salt wasting (CSW). CT head showed no acute changes, but Parkinson's disease remained a possible cause. After more NS, his Na was 128, increasing suspicion for CSW. NS was stopped and Na again dropped to 124 further indicating CSW. To assess this, we measured Ur Na, and U<sub>osm</sub> before and after giving NS. Ur Na went from 88 to 128, U<sub>osm</sub> increased, and FE uric acid remained elevated at 22%. He was still clinically hypovolemic suggesting that he was still losing Na. After the addition of salt tablets, his Na slowly began to improve, and he was discharged.

**Discussion:** To our knowledge, this is the first case of CSW in a patient with chronic idiopathic Parkinson's disease. CSW is a rare disorder usually associated with vascular or traumatic cerebral injury. Its pathogenesis is unclear but may be due to natriuretic peptides that result in renal salt wasting with resulting volume contraction. CSW is a challenging diagnosis and is often mistaken for SIADH early in the disease course. This can affect treatment and delay accurate diagnosis. CSW tends to have high Ur Na and severe volume depletion due to sodium wasting and high urine output. Patients will have a net negative Na balance and high FE Uric Acid. Careful assessment can help differentiate this disorder from SIADH. Patients with SIADH are euvolemic and initially have high FE Uric Acid that drops with improvement of Na.

#### SA-PO466

#### Cisplatin Induced Renal Salt Wasting Syndrome: An Uncommon Diagnostic Distinction

Sharmil Suma Kumaran, Muhammad F. Habib, Metlapalli Venkata Sravanthi, Ramya Bhargava. SUNY Upstate Medical University Hospital, Syracuse, NY.

**Introduction:** Platinum-based chemotherapy is commonly associated with nephrotoxicity and electrolyte imbalances including hyponatremia. The mechanism of hyponatremia in such cases is either syndrome of inappropriate antidiuretic hormone secretion (SIADH) or renal salt wasting syndrome (RSWS). The latter is scarcely reported. We describe a case of RSWS induced by cisplatin.

**Case Description:** A 20-year-old male with nonseminomatous germ cell testicular cancer for which he underwent right orchiectomy, presented with one-week history of abdominal pain, polyuria, and unintentional 15 lbs weight loss after he was initiated on adjuvant BEP (bleomycin, etoposide, cisplatin) chemotherapy. Orthostatic hypotension was noted. He appeared hypovolemic on physical examination. His urine output in the first 24 hours of monitoring was more than 5 L. Pertinent labs include low serum Na 123 mmol/L, high urine Na 173 mmol/L, and normal serum creatinine. His Fractional Na excretion (FeNa) was calculated to be 2.1%. A diagnosis of RSWS was made and he was commenced on intravenous 0.9% saline and salt tablets. His serum Na gradually normalized over two days. Considering his young age and high likelihood of cure, cisplatin was continued although subsequent chemotherapy cycles were completed inpatient with close monitoring of serum and urine sodium. RSWS did not recur on rechallenge with Cisplatin.

**Discussion:** Hyponatremia is a serious complication of platinum-based chemotherapy. Understanding the mechanism of hyponatremia is important as the treatments are distinct—salt supplementation in RSWS and fluid restriction in SIADH. The mechanism of RSWS is thought to be cisplatin-induced inflammation, alteration of solute transport, and apoptosis

in proximal and distal tubular epithelium with preference to the former, thus causing a net sodium excretion. These patients present with hypotonic hyponatremia, polyuria, and hypovolemia. In contrast, SIADH patients are euvolemic and normouric. A high FeNa despite volume depletion helps delineate RSWS further from SIADH. Treatment consists of salt and water replenishment, and recovery is the rule although recurrence is common. While carboplatin is less toxic, cisplatin has unequivocal superiority in most of the cancers in which it is used, making it difficult to replace it, especially when there is realistic curative intent.

## SA-PO467

### Syndrome of Inappropriate Antidiuresis (SIAD): A Clue to a Rare Diagnosis

Amara Sarwal, Sarah Gilligan, Nirupama Ramkumar, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

**Introduction:** Syndrome of inappropriate antidiuresis (SIAD) was first described by Schwartz and Bartter in 1967. Small cell lung cancer is the malignancy most often associated with ectopic ADH release, however extrapulmonary small cell cancers, medications and other pulmonary disease can also be associated with SIAD. SIAD is rarely associated with prostate cancer. We report a case of SIAD with small cell carcinoma of the prostate.

**Case Description:** A 74-year-old man with history of cardiomyopathy, hypertension and left renal cancer with partial nephrectomy presented to our facility due to an irregular heartbeat. Upon further questioning, it was discovered that he had a 2 month history of gait unsteadiness, confusion and fatigue. He denied increased thirst or recent medication changes. He denied use of NSAIDs, PPIs, diuretics, SSRIs, or anti-epileptic medications. He is a former smoker with a 40 pack year history and is a social drinker. During initial workup in the emergency room, a sodium level of 125 mmol/L was discovered. He was initially treated with furosemide and 4 gram salt tabs daily however eventually transferred to the critical care unit for hypertonic saline when his sodium dropped to 115 mmol/L within 72 hours. Further workup revealed a TSH of 1.25 mU/L, morning cortisol of 19 ug/dL, serum osmolality of 236 mOsm/kg with urine osmolality of 500 mOsm/kg and urinary sodium level of 155 mmol/L. MRI brain and CT chest were unrevealing, however his CT abdomen revealed an enlarged prostate with a heterogeneously enhancing large nodule and an enlarged right pelvic lymph node, concerning for metastatic prostate cancer despite a normal prostate specific antigen (PSA) at 0.5 ng/mL. Biopsy revealed small cell carcinoma of the prostate. Radiotherapy as well as chemotherapy with cisplatin and etoposide was initiated. He continued treatment with salt tablets and furosemide with stabilization of his sodium at 130-136 mmol/L.

**Discussion:** Small cell carcinoma of the prostate is rare and accounts for <1% of all patients afflicted with prostate cancer. It is usually diagnosed at an advanced stage and PSA can be disproportionately low compared to conventional adenocarcinoma of the prostate. This case illustrates the need for diligent investigation when patients present with hyponatremia and SIAD.

## SA-PO468

### Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) Secondary to Untreated Parkinson Disease

Najjar Yaseen, Mina Awad, Geovani Faddoul. *Albany Medical Center, Albany, NY.*

**Introduction:** Hyponatremia is the most common electrolyte disorder associated with neurological conditions and is mediated by excess release of antidiuretic hormone. The etiology can range from a straightforward SIADH to the poorly understood mechanism of cerebral salt wasting. Whereas acute intracranial process such as acute stroke, intracranial bleeding or tumor are typical etiologies of SIADH, neurodegenerative diseases such as Parkinson's disease or ALS have not been known to be associated SIADH. However, SIADH has been reported as a side effect of anti-Parkinson medication e.g. Levodopa/Carbidopa. Parkinson's disease per se has not been known to be associated by SIADH and hyponatremia. We present a case of hyponatremia due of SIADH in the setting of untreated Parkinson.

**Case Description:** A 71-yo male patient with DM II and hypothyroidism presented to the hospital with progressive confusion, slow speech and severe fatigue over las few days accompanied with sluggish body movements for few months. On exam, he appeared to be euvolemic. Neurological exam revealed mild arm rigidity, bradykinesia, resting tremors, and stiff gait. Initial blood work showed hypo-osmolar hyponatremia (sodium 122 mEq/L, serum osmolality 275 mOsm/Kg, uric acid 2.3 mg/L, TSH 3.5 UIU/mL, AM cortisol 24 UG/dL). Urine studies showed (urine sodium: 92 mEq/L, osmolality 672 mOsm/Kg). A Brain MRI did not show any structural abnormality. CT chest showed localized infiltrate. Initially SIADH was thought to be due to pulmonary process. After starting him on fluid restriction of 1.5L/day and urea 15 mg BID, sodium improved gradually to 133 mEq/L on discharge. Urine osmolality continued to ranges 700-800 mOsm/Kg. Active pulmonary process was ruled out by pulmonologist. Parkinsonism was confirmed by outpatient neurology who started Carbidopa/Levodopa. As extrapyramidal symptoms improved with Carbidopa/Levodopa, urine osmolality improved to 400 mOsm/Kg. Successfully, sodium level was maintained between 135-137 while being off urea and fluid restriction. He was diagnosed with new-onset SIADH and extrapyramidal symptom.

**Discussion:** This case demonstrated an association of SIADH and untreated Parkinson's disease. In contrary to literature, SIADH resolved with anti-Parkinson treatment which supports Parkinson's disease as a causal mechanism. As dose increased of anti-Parkinson's agent, urine osmolality improved and extrapyramidal symptoms resolved.

## SA-PO469

### Dual Paraneoplastic Syndrome in Small Cell Lung Cancer

Kamil Sardarli, Austin M. Morris, Jamal Abu-Khaled. *BHSH Beaumont Health, Royal Oak, MI.*

**Introduction:** Small cell lung cancer (SCLC) is an aggressive neuroendocrine lung cancer associated with paraneoplastic syndromes – syndrome of inappropriate ADH (SIADH) in 7-16% of cases and Ectopic ACTH Syndrome (EAS) in 3.5-4.3% of cases. Both syndromes are associated with a poor prognosis in patients with SCLC. We describe a patient who presented with SIADH, leading to a diagnosis of SCLC who subsequently developed EAS.

**Case Description:** A 71-year-old female with a past medical history of hypertension, depression, and tobacco use presented with lethargy. She noted headache, but otherwise was unable to provide history due to altered mentation. Per her family, the patient recently had pneumonia treated with antibiotics and steroids and was complicated by hyponatremia. Upon evaluation, our patient was hemodynamically stable, with labs revealing Na 106 mmol/L, K 3.9 mmol/L, Cl 74 mmol/L, BUN 6 mg/dL, and creatinine 0.52 mg/dL. Serum osmolality was 232 mOsm/kg, urine osmolality 543 mOsm/kg, urine Na 130 mmol/L and urine Chloride 128 mmol/L. TSH was within normal limits and random cortisol level was 63.4 mcg/dL. She was managed in ICU with a DDVP clamp and 3% saline. She was discharged on Urea therapy, which was later changed to furosemide and sodium chloride tablets due to cost. At discharge, the etiology of her hyponatremia was most consistent with SIADH. CT scan of the chest followed by PET scan showed multiple enlarged mediastinal lymph nodes that were considered suspicious for malignancy. Lymph node biopsy confirmed metastatic SCLC. Our patient was started on concurrent chemotherapy and radiotherapy. Upon follow up, progression of her cancer was seen, prompting additional chemotherapy with carboplatin, etoposide, and atezolizumab. She was admitted 11 months after her first presentation due to hypernatremia and hypokalemia. She had metabolic alkalosis with a bicarbonate of 36 mmol/L, Na level 146 mmol/L, and K 2.7 mmol/L. Morning cortisol level was 54.2 mcg/dL and ACTH was 63 pg/mL. Cortisol level after low dose dexamethasone suppression test remained elevated at 66.6 mcg/dL. In the setting of active SCLC, findings were most suggestive of ectopic ACTH secretion.

**Discussion:** There are only 8 cases reported in literature with simultaneous or sequential EAS and SIADH. Cortisol and ADH have opposite effects on kidney sodium excretion. This may lead to masking of EAS by SIADH, leading to underdiagnosis.

## SA-PO470

### SIADH Escape or Tolvaptan Resistance in Progressive Small Cell Lung Cancer

Sunny Mandal,<sup>1</sup> Lakshmi Kannan.<sup>2</sup> *<sup>1</sup>University of Pikeville Kentucky College of Osteopathic Medicine, Pikeville, KY; <sup>2</sup>Pikeville Medical Center, Pikeville, KY.*

**Introduction:** Syndrome of inappropriate antidiuretic hormone (SIADH) occurs in 11-15% of patients with small-cell lung cancer. The pathophysiology is through direct tumor secretion, enhanced secretion of ADH from adrenal metastases, chemotherapy, opioids, NSAIDs, or side effects of treatment like nausea, vomiting, stress, and pain. We report a patient with small-cell lung cancer initially managed with tolvaptan but developed resistance to the aquoretic effects of the drug.

**Case Description:** A 61-year-old male with small cell lung cancer and chronic hyponatremia on tolvaptan presented with unsteady gait and weakness. Workup showed serum sodium of 111 mEq/L (baseline 122-125 mEq/L), serum osmolality of 236 mOsm/Kg H<sub>2</sub>O, urine osmolality of 589 mOsm/Kg H<sub>2</sub>O, and urine sodium of 62 mEq/L. The patient was admitted for 3% hypertonic saline for SIADH. His sodium improved to 120 mEq/L with the resolution of symptoms. Reviewing his records, the patient was diagnosed with T3N3 I1IC small cell lung cancer 11 months prior to this admission. He underwent two cycles of cisplatin and etoposide. In a span of 3 months, the patient had four hospitalizations for acute on chronic hyponatremia despite being on tolvaptan as his surveillance CT abdomen/pelvis revealed multiple new liver metastases. The timeline of events is shown in Figure 2.

**Discussion:** Syndrome of inappropriate antidiuretic hormone is characterized by euvolemic hypotonic hyponatremia where tolvaptan has been used since 2009. The first two cases of resistance to tolvaptan therapy were described in 2018 in patients with small-cell lung cancer and this is the third report of SIADH escape to tolvaptan. The possible cause of resistance to the aquoretic effects of the drug is due to extraordinarily high ADH levels from the progression of lung cancer. In these cases, successful treatment of the malignancy will eliminate or reduce the inappropriate ADH secretion. One key factor to consider is the search for new metastasis when patients present with recurrent acute or chronic hyponatremia.

## SA-PO471

## One Not So Salty Lady

Melanie Wanigatunga, Jerald L. Taggart, Adrian J. Baudy, Katherine A. Peacock.  
Tulane University School of Medicine, New Orleans, LA.

**Introduction:** This is unique because it discusses a patient with many episodes of hyponatremia with different etiologies in the same hospitalization. This is important because it emphasizes the significance of physiology in evaluating hyponatremia. Objectives: 1. Develop an approach to hyponatremia 2. See roles of aldosterone and ADH in fluid balance

**Case Description:** A 69-year-old woman with CLL presented with weakness, poor oral intake, and was profoundly hyponatremic to 105 mEq/L with altered mental status. WBC was 160k/uL, serum osmolality 231mOsm/kg, urine osmolality 513mOsm/kg and urine sodium <12mEq/L. Sodium improved with infusions of normal saline but she developed decompensated heart failure and nausea. She was diuresed. Sodium recovered to normal ranges after about one month, yet after fluoxetine was resumed, sodium decreased to 126 mEq/L and was refractory to normal saline. Her studies were: serum osmolality 273 mOsm/kg, urine osmolality 365 mOsm/kg, urine sodium 38 mEq/L. Fluoxetine was stopped and mirtazapine was started for depression. Sodium improved with 1.5 L/day fluid restriction as well. She was discharged to physical rehabilitation with resolution of her mental status to baseline, and lab studies within normal ranges.

**Discussion:** At first, there was concern our patient had pseudohyponatremia from increased WBC in her blood falsely diluting her serum sodium. In CLL, patients can have pseudohyponatremia due to hyperglobulinemia. Hospital machinery is now able to separate the serum electrolytes from other blood elements to measure them properly, ruling out pseudohyponatremia for this patient from CLL. She had hypotonic hypovolemic hyponatremia on admission; her serum osmolality was truly low and her urine sodium showed that aldosterone was increased, trying to increase total body sodium. Urine osmolality was high, showing ADH was working to increase total body water. She improved with appropriate treatment: normal saline. Her re-development of hyponatremia was more complex. Given her nausea and decompensated heart failure, she likely had increased ADH (Sahay & Sahay, 2014). Lab studies were not consistent with SIADH, but improved with treatment for SIADH. It is important to understand the balance of aldosterone and ADH in a patient with hyponatremia as it guides treatment. References Sahay, M., & Sahay, R. (2014). Hyponatremia: A practical approach. Indian journal of endocrinology and metabolism, 18(6), 760–771.

## SA-PO472

## High Urinary Sodium Is Not Always SIADH

Sahar Amin, Neeharika Mettupalli, Alice Chedid. The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

**Introduction:** Cisplatin nephrotoxicity has been well described in the literature. However, renal salt wasting (RSW) is relatively uncommon. We present an interesting case of severe hyponatremia secondary to Cisplatin that mimicked SIADH but improved with administration of IV fluids.

**Case Description:** A 39-year-old AA male with newly diagnosed small cell lung cancer was admitted for induction chemotherapy. Initial physical exam was unremarkable. Vital signs were normal, BP 120/77 mm Hg and HR 85. Laboratory: Na 132 mEq/L with normal creatinine at 0.6 mg/dL. Patient was given Cisplatin 80mg/m<sup>2</sup> x1. Day 2, Na at 128 meq/L. Day 3, Na dropped to 123 meq/L. Further workup: Serum osm 246 mOsm, TSH and cortisol WNL. MRI negative for brain metastases. Urine osmolality at 726 mOsm with urine sodium of 222 mEq/L. Given malignancy concern, patient was treated as SIADH with fluid restriction. Na continued to drop, down to 117 meq/L (graph below). Upon rechecking vitals, patient was orthostatic and was complaining of dizziness. Given hypovolemia, RSW 2/2 cisplatin was suspected. Patient was started on NS infusion with slow and gradual improvement of his serum Na to normal. NS was eventually stopped, and patient was transitioned to salt tablets. Patient was not rechallenged with cisplatin. Graph 1: Sodium Trend

**Discussion:** Renal salt wasting is a rare side effect of Cisplatin that manifests as hypovolemic hyponatremia. Given the clinical and laboratory similarities, it is often misdiagnosed as SIADH. We want to shed light on the importance of recognizing this entity because restoration of intravascular volume is of the essence.

## SA-PO473

## A Severe Case of Cyclophosphamide Induced Hyponatremia

Shawn Alonso,<sup>1,2</sup> Chavely Valdes Sanchez,<sup>1,2</sup> Raman Anam,<sup>1,2</sup> Ahmed A. Waheed.<sup>1,2</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Holy Cross Hospital, Ft. Lauderdale, FL.

**Introduction:** Mild to moderate hyponatremia is a known complication of cyclophosphamide (CY) which has been reported in numerous case reports<sup>2,3</sup> and retrospective analysis.<sup>1</sup> Here we present a case of CY-induced acute severe hyponatremia in a patient with diffuse large B-cell lymphoma.

**Case Description:** Patient is a 37-year-old female with a recent diagnosis of diffuse large B cell lymphoma on etoposide, prednisone, oncovin, cyclophosphamide-hydroxydaunorubicin (EPOCH). After the EPOCH, she received 20mg/kg of intravenous CY and instructions to drink copious amounts of water. The following day, the patient was lethargic with a headache and nausea. Labs revealed sodium of 118mmol/L down from 140mmol/L the day before, with a serum osmolality of 231mOsm/L, urine osmolality of 541mOsm/L, and urine sodium of 175mmol/L. Hypertonic saline was initiated nevertheless the patient suffered a seizure and was taken to the ICU. Despite multiple hypertonic saline boluses, the sodium continued to drop to a nadir of 110mmol/L. Conivaptan was initiated, and the sodium gradually increased to 127mmol/L. The patient was discharged neurologically intact on salt tabs.

**Discussion:** Severe hyponatremia is a life-threatening complication of CY and it can develop rapidly. The potential mechanisms behind this complication may be either a substantial release of antidiuretic hormone (ADH), the enhanced action of ADH on the kidneys, or both. However, more recent studies have reported direct toxic effect of CY metabolites on the collecting tubules, as opposed to an increase in endogenous ADH.<sup>4</sup> Prior reports have also concluded that this adverse effect can occur with both high (>40 mg/kg) and low dose (<20 mg/kg) CY.<sup>1,2,3</sup> The degree of hyponatremia is also likely influenced by an increased free water intake, which is recommended prior to CY administration to reduce the risk of cystitis. Symptoms like pain and nausea which are known to increase the release of endogenous ADH can also contribute to the degree of hyponatremia.<sup>5</sup> This case not only highlights the importance of being aware of this adverse effect but also suggests that there may be a potential need for a standardized protocol to monitor these patients given the danger of acute hyponatremia. The protocol could include patient education, frequent monitoring of serum sodium following the administration of CY, as well as treating any symptoms known to promote ADH release.

## SA-PO474

## Isavuconazonium Sulfate Associated Acute Hyponatremia

Boonyanuth N. Maturostrakul, Abhishek Nimkar, Tanazul T. Pariswala, Hitesh H. Shah. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

**Introduction:** Isavuconazonium sulfate is an azole antifungal agent approved by the US FDA for the treatment of invasive aspergillosis and mucormycosis. Isavuconazonium sulfate has been associated with several electrolyte disorders including hypokalemia and hypomagnesemia. Hyponatremia has rarely been associated with Isavuconazonium sulfate in clinical trials. Here, we present an interesting case of isavuconazonium associated acute hyponatremia

**Case Description:** 72-year-old male with history of liver and kidney transplantation, on immunosuppressives presented to the hospital because of painless mono-ocular vision loss and chronic headache. Pt. was subsequently found to have aspergillus infection of the left cavernous sinus (that was confirmed by tissue biopsy). Mycophenolate mofetil was held in view of active aspergillus infection. Pt. was initially started on amphotericin B treatment but was later switched to intravenous isavuconazonium sulfate (for his invasive fungal infection). Before initiation of isavuconazonium sulfate, serum sodium (SNa) was in normal range at 136 mmol/L. After initiating isavuconazonium sulfate, SNa progressively decreased to 121 mmol/L over the next 10 days. Pt. was clinically euvolemic on exam. Work-up for hyponatremia showed low serum osmolality of 273 mosm/kg, urine sodium of 163 mmol/L and urine osmolality of 484 mosm/kg. Both TSH and AM serum cortisol levels were in normal range. Pt. was initiated on oral salt tablets and fluid restriction. Isavuconazonium sulfate was discontinued for severe hyponatremia and patient was initiated on intravenous voriconazole. SNa progressively improved to 134 mmol/L, 10 days after discontinuation of isavuconazonium sulfate.

**Discussion:** Solid organ transplant recipients are at increased risk for serious bacterial, viral, and fungal infections. Our patient presented with invasive aspergillosis. Treatment with isavuconazonium sulfate, a systemic antifungal medication resulted in acute severe euvolemic hyponatremia. Hyponatremia has shown to be an uncommon adverse effect (<5%) of this agent in clinical trials. While the exact mechanism of isavuconazonium sulfate associated hyponatremia is unknown, serum sodium levels progressively improved in our patient after discontinuation of this agent. Clinicians should be aware of this potential and reversible adverse effect of this agent.

## SA-PO475

## Hyponatremia vs. Pseudohyponatremia: Sodium Measurement in a Patient With a Hematologic Malignancy

Sarah Haeger, Nervik Roy, Sarah E. Young. University of Colorado Denver School of Medicine, Aurora, CO.

**Introduction:** Hyponatremia is an electrolyte disturbance that can portend great morbidity. Once identified, hyponatremia must be confirmed as a true finding and not a laboratory artifact known as “pseudohyponatremia.” Delayed confirmation leads to a

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

lag in treatment. Here we report a case of apparent pseudohyponatremia in a patient with chronic lymphocytic leukemia (CLL), subsequently found to have true hyponatremia due to the syndrome of inappropriate anti-diuretic hormone (SIADH).

**Case Description:** A 73 year old with a history of CLL presented with confusion and nausea. Initial laboratory tests revealed a white blood cell count of  $71.4 \times 10^9$  cells/L and a serum sodium concentration of 110mmol/L. Initial measured serum osmolality was normal (284 mOsm/kg) raising concern for pseudohyponatremia. The patient had no paraprotein gap (total protein 6.0g/dL, albumin 3.3g/dL) and a normal triglyceride concentration (98 mg/dL). Repeat laboratory testing revealed true hyponatremia with a serum sodium concentration 108mmol/L, whole blood sodium concentration 108mmol/L, and serum osmolality 227mOsm/kg. Further testing revealed a diagnosis of SIADH. CT scan revealed new lung nodules concerning for malignancy. The patient's hospital course was prolonged due to refractory hyponatremia despite treatment with hypertonic saline, urea and tolvaptan.

**Discussion:** Serum sodium concentration, obtained on the basic metabolic panel, is routinely measured by indirect ion-selective electrode (ISE) methods which assumes that plasma contains 93% water. Serum sodium measurements using this method may be inaccurate when a patient has increased lipid, protein, or other non-aqueous substances in their blood. In contrast, whole blood sodium concentration is measured by direct ISE methods which does not make a plasma water content assumption. Serum osmolality is used as a surrogate for whole blood sodium concentration. Serum osmolality should be low in true hyponatremia, and if normal identifies pseudohyponatremia. We described a case where initial testing was misleading and delayed the diagnosis and treatment of true hyponatremia. For patients presenting with suspected hyponatremia, but with risk factors for pseudohyponatremia, we suggest repeat testing with serum sodium, whole blood sodium, and serum osmolality to verify the diagnosis of pseudohyponatremia.

### A Case Report on Unusual Idiopathic Central Diabetes Insipidus During the Polyuric Phase of AKI

Omar N. Elhawary,<sup>1,2</sup> Syeda S. Bukhari,<sup>1,2</sup> Isha Puri,<sup>1,2</sup> Mary C. Mallappallil,<sup>1,2</sup> Sonalika Agarwal.<sup>1,2</sup> Nephrology KCH <sup>1</sup>SUNY Downstate Health Sciences University, New York City, NY; <sup>2</sup>Kings County Hospital Center, Brooklyn, NY.

**Introduction:** Historically, classic Acute tubular injury (ATN) goes through an oliguric phase with urine output (UOP)  $\leq 400$  mL/24 hours for 1–2 weeks followed by a non-oliguric phase with UOP  $> 400$  mL/24 hours for 10–14 days with eventual recovery of the kidney functions. Central diabetes insipidus (CDI) is caused by impairment in either the synthesis, transport, or release of antidiuretic hormone (ADH). Clinically, the patient with CDI presents with volume depletion, polyuria, and elevated serum sodium. We usually tend to consider polyuria following AKI as polyuric phase until proven otherwise. In our case the patient had diabetes insipidus that improved with desmopressin, so measuring the urine and serum osmolality in patients developing polyuria post ATN should be considered.

**Case Description:** 75 y/o man with medical history of hypertension was admitted for encephalopathy and hypoxemia. He was found to have anuric ATN secondary to volume depletion complicated with hyperkalemia. The patient was treated with aggressive hydration and electrolyte repletion. A week later he was hemodynamically stable, kidney functions improved without dialysis. As expected, he developed polyuria but surprisingly there was progressive increase in serum sodium despite aggressive free water replacement via the nasogastric tube and intravenous hypotonic fluids. We ordered urine and serum osmolality and serum Na. Labs were significant for serum Na 170, Serum osmolality 363 mOsm/kg, urine osmolality 203 mOsm/kg, therefore diabetes insipidus was highly suspected. Primary polydipsia was ruled out as patient was not conscious enough to drink water by himself. Subcutaneous desmopressin 2 mcg was administered. Diagnosis of CDI was confirmed since urine osmolality doubled at the end of 2 hours. He was started on desmopressin nasal spray and serum Na was checked twice daily. Serum Na improved from 170 to 144. MRI brain did not show pituitary/hypothalamic lesion. Additional diagnostic work up for CDI could not be performed as the patient passed away few days later.

**Discussion:** In cases with Acute Kidney Injury that present with persistent hyponatremia during polyuric phase, other causes should be considered. They should be screened for Diabetes Insipidus by measuring both serum and urine osmolality and a trial of desmopressin can be given if required.

## SA-PO477

### Phenytoin: A Rare Cause of Central Diabetes Insipidus

Muhammad Rawala, Anand Kumar, Shancy Jacob. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Drug-induced electrolyte abnormalities have been increasingly reported and may be associated with considerable morbidity and mortality. In clinical practice, hyponatremia (serum sodium higher than 145 mmol/L) is usually of multifactorial etiology, and drug therapy not infrequently is disregarded as a contributing factor to increased serum sodium concentration. Phenytoin is a commonly used antiepileptic but is rarely associated with hyponatremia in adults. Our case reminds the value of monitoring renal tubular function and electrolytes, especially in the severely neurologically impaired population on this medication.

**Case Description:** A 31-year-old non-verbal male with a history of seizure disorder, traumatic brain injury with right frontotemporal lobectomy, and renal cell carcinoma status post radical nephrectomy presented to the hospital with failure to thrive. The patient presented with mild hyponatremia (146 mmol/L) and intravenous fluids were administered as volume depletion was considered the etiology. The patient had been non-

compliant with phenytoin at home based on undetectable phenytoin levels; however, he was dosed with phenytoin appropriately in the hospital to achieve a therapeutic level. The hyponatremia worsened (161mmol/L-170 mmol/L); further workup revealed a serum osmolality (Osm) of 354 and a urine Osm of 120. The diagnosis was consistent with central diabetes insipidus (DI). After ruling out possible common etiologies of DI, phenytoin was the only medication attributed to DI. Therefore, the patient was treated by switching phenytoin to levetiracetam, and desmopressin was initiated. The patient responded to desmopressin with the resolution of hyponatremia and normalization of serum and urine Osm.

**Discussion:** The reported frequency of hyponatremia in a general hospital population range from 0.3% to 3.5%. We believe this case merits discussion for two reasons. Firstly, to highlight the difficulties encountered in unraveling the etiology of hyponatremia, and secondly, to describe an unusual side effect of a commonly used antiepileptic drug, phenytoin. Our case had a new-onset DI after therapeutically dosing phenytoin. Phenytoin is a rare but recognized cause of central DI, with few cases reported in the literature.

## SA-PO478

### A Rare Case of Methotrexate-Induced Nephrogenic Diabetes Insipidus

Brian Bustos, Soo H. Kae, Chris Dipollina, Eduardo M. Padrao. *University of Connecticut School of Medicine, Farmington, CT.*

**Introduction:** Methotrexate (MTX) is used for several medical conditions, particularly cancers and rheumatologic conditions. High dose MTX is a widely used regimen in malignancies and known to cause renal toxicity. To our knowledge, there has been only one other case report published of methotrexate induced nephrogenic diabetes insipidus (DI).

**Case Description:** 68 year-old male with a history of Burkitt's Lymphoma with CNS involvement (on standard chemotherapy and high dose MTX) presented to the hospital for MTX infusion. He received high dose MTX the day following admission, and subsequently had an elevated MTX level of 10.61 micromoles/L. The nephrology service was consulted 9 days later due to polyuria. He has no history of renal disease and creatinine was unremarkable. Urinalysis on admission revealed a specific gravity of 1.020. He was net negative 8.5 L since admission and had urinated 4.0 L in 24 hours. However, he was being given a D5-100mEq bicarbonate infusion due to elevated MTX level. On the day of consult, urine osmolality was 156 mOsm/kg, raising the possibility of DI. Serum sodium was 144 mmol/L and serum osmolality was 292 mOsm/kg. Glucose and BUN were normal. His intravenous fluids were stopped. The MTX levels declined to 0.09 micromoles/L and urine osmolality increased, eventually reaching 432 mOsm/kg. His sodium levels decreased from the upper limit of normal to 138 mmol/L. His urine appeared more grossly concentrated and urine output slowed.

**Discussion:** Nephrogenic DI as a result of medication use has been seen in a number of different therapies. It is suspected that our patient's polyuria was secondary to methotrexate induced DI. His urinalysis on admission suggested he was able to concentrate his urine. On the day of consult, his urine osmolality could have suggested DI. His glucose and BUN were normal and would not favor osmotic diuresis. He did have serum sodium in the upper limit of normal as well as serum osmolality slightly less than 295 mOsm/kg, which could be due to the bicarbonate infusion lowering his true serum values. In the setting of increasing urinary concentration and decreasing urine output as MTX levels decrease, we can suspect that our patient suffered from methotrexate induced DI, of which has only been reported in one other published case report. Our patient case may contribute to the knowledge of the safety profile of MTX.

## SA-PO479

### Nineteen Liters of Urine Output as a Consequence of Concomitant Use of Extracorporeal Membrane Oxygenation and Tolvaptan

Sri Vibhavari Guntupalli, Frederic F. Rahbari-Oskoui. *Emory University School of Medicine, Atlanta, GA.*

**Introduction:** Tolvaptan (TVP), an oral vasopressin (V2) receptor antagonist, has been used in heart failure patients to increase aquaresis, without evidence on improved long-term or all-cause mortality. Veno-arterial ECMO (VA-ECMO) is a new modality to improve tissue oxygenation in cardiogenic shock. We present the first reported case of massive polyuria in a patient who was on TVP and then started VA-ECMO.

**Case Description:** 31 YO male was transferred from an outside hospital with new onset heart failure (LVEF=15%), ventricular tachycardia and cardiogenic shock. After high dose furosemide, he received 4 doses of TVP 30 mg/d and an additional 60 mg on the day of transfer. Urine output (UOP) increased from 1-2 to 4-7L/day and serum sodium ( $[Na]_s$ ) from 122-123 to 126-130 mmol/L temporarily. VA-ECMO was started at  $[Na]_s$  of 119 mmol/L. UOP increased to 19L over the next 24h with a rise of  $[Na]_s$  by 12 mmol. His urine Na and osmolality were 75 mmol/L and 150 mOsm/Kg respectively. Desmopressin at 2 mcg/day was administered over 2 days and UOP decreased to 11, 9, 5.5 and 3L/day over the next 4 days. Despite 1:1 replacement of free water losses,  $[Na]_s$  continued to rise. His mental status was originally unchanged until his heart failure and overall condition started to deteriorate. His urine output was responsive to loop diuretics but  $[Na]_s$  increased to 147 mmol/L. Unfortunately, he passed away within 2 weeks.

**Discussion:** TVP was used to improve hyponatremia (due to non-osmotic release of ADH observed in heart failure) and cause aquaresis. UOP on TVP is typically around 6+/-2 L in 24h, as originally seen in this case. ECMO can also cause polyuria by increased perfusion of the renal arteries. Effect of TVP on  $[Na]_s$  is unpredictable with overcorrection in 40% of patients [1],  $[Na]_s$  increased with TVP but overcorrected by 12 mmol/day once ECMO was started. His urine Na was elevated with low osmolality. This rapid  $[Na]_s$  rise suggests a residual effect of Tolvaptan administered several days ago combined to the ECMO-induced pressure diuresis. The washout period for tolvaptan should be 5 times

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

the half-life of elimination (12h), which may be prolonged in case of passive hepatic congestion or use of CYP43A inducers. Concomitant use of tolvaptan and VA-ECMO should be avoided under penalty of causing massive polyuria and rapid overcorrection of hyponatremia.

## SA-PO480

### A Surprising Complication Following Immunoglobulin G Therapy: Osmotic Diuresis

Jesus D. Vega-Colon, Maria E. Rivera, Alexis Rivera Gonzalez, Carlos G. Rivera-Bermudez, Krystahl Z. Andujar-Rivera, Ileana E. Ocasio Melendez. *University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.*

**Introduction:** Polyuria is defined as a urine output greater than 3 liters in 24 hours. The differential diagnosis can be classified into osmotic and water diuresis causes. Osmotic diuresis is characterized by an excess of urinary solute with an osmolar excretion rate more than 1,000 mOsm/Day. Elevated urea, resolving acute tubular necrosis and hyperglycemia must be considered as potential triggers. Few cases on literature described the occurrence of immunoglobulin G induced osmotic diuresis in a patient with Pemphigus Vulgaris exacerbation, thus making the diagnosis challenging.

**Case Description:** We report a 52-year-old Puerto Rican female with Pemphigus Vulgaris complaining of recurrent painful blisters in the mouth and chest in the past 5 days. During the initial evaluation patient was started on immunoglobulin G IV therapy. Throughout hospital stay, nephrology service was consulted for persistent polyuria of 6.60 liters/24 hours and hypernatremia of 153 meq/L. No history of diuretics use reported. Renal function was stable with serum creatinine levels on baseline (BUN:19 Scr:0.65 mg/dl). Further workup showed elevated urine osmolality results of 391 mOsm/Kg. To differentiate between osmotic and water diuresis, 24-Hour Osmolar Excretion Rate was calculated multiplying urine output times urine osmolality. Results revealed evidence of 2,580 mOsm/Day indicating osmotic diuresis as the cause of severe polyuria. Typical causes of polyuria were absent leaving recent administration of immunoglobulin G containing maltose as the culprit of osmotic diuresis. Following discontinuation of immunoglobulin G therapy urine output reached normal values of 1.0-1.5 liters/Day.

**Discussion:** This case illustrates a not well-known cause of osmotic diuresis that should be included on the differential diagnosis. Increased awareness of this uncommon side effect will help clinicians recognize and address it early to prevent life-threatening electrolyte disorders. The uniqueness of this case lies on the rarity of this therapy causing osmotic diuresis with only a small percentage of hyperosmolar maltose found on the immunoglobulin G product that led to massive urinary solute loss. Our patient successfully responded after discontinuation of the potential trigger reaching adequate uresis.

## SA-PO481

### A Salty Goodbye to Cardiorenal and Hepatorenal Syndromes: Hypertonic Saline Diuresis

Sean Barnett. *United States Air Force, San Antonio, TX.*

**Introduction:** Diuresis and anti-diuresis are the most pivotal aspects of the cardiovascular system. The pathology of Cardiorenal Syndrome (CRS) and Hepatorenal Syndrome (HRS) are due in large part to a lack of diuresis. The lack of diuresis is due to the Renin Angiotensin Aldosterone System (RAAS) and Antidiuretic Hormone (ADH). The cardiac output, renal perfusion pressure, and neurohormonal controls of diuresis can be accentuated physiologically with 3% Saline to aid in treating this pathophysiology.

**Case Description:** 30 patients with CRS, HRS, CHF or ARDS were treated using 100mL of 3% Saline. 28 patients (93%) responded appropriately and only 2 patients (7%) had no response. Of the responders, 25 (89%) demonstrated a significant change in clinical course within 24 hours. No patient experienced any complications associated with this treatment. No patient experienced hypernatremia.

**Discussion:** Hypertonic Saline, specifically 3% Saline, is the best diuretic adjunct we have in medicine. It is well studied in heart failure and many diverse settings, 3% Saline is a safe and effective way to ensure adequate diuresis while protecting both the heart and the kidneys. In the setting of CRS or HRS, 3% Saline can function as a better adjunct for diuresis and as a diagnostic test in most settings. Physiologically, CRS and HRS arise primarily from poor renal perfusion and excessive activation of RAAS and ADH, with decreased activation or response to ANP and BNP. The urinary evaluation will generally demonstrate a low sodium, high potassium, and high osmolality. Combining physiology with evidence-based medicine, the goal would be a higher urine sodium ( $>50\text{meq/L}$ ), a high urinary sodium to potassium ratio, and a low urine osmolality. This exact situation is achieved by 3% Saline. 3% Saline functions to improve preload, stimulate ANP in the Right Atrium, decrease pulmonary vascular resistance, improve cardiac output, inhibit RAAS (directly and indirectly) and inhibit ADH (directly and indirectly). 3% Saline can be used as a safe and effective treatment for most diuresis. Fortunately, the overall concentration of 3% appears to be the perfect balance of effect without complications. 3% can be given through a peripheral IV at rates under 50mL/hr, 3% can be given outside the ICU, and small amounts of 3% have almost no significant complications in all medical literature.

## SA-PO482

### An Uncommon Case of Liddle Syndrome

Elizabeth Pabon-Vazquez, Jessica Castillo, Jan Paul Rosaly Martinez, Jose Rivera Sepulveda, Bryan L. Pagan Rivera. *Mayaguez Medical Center, Mayaguez, Puerto Rico.*

**Introduction:** Hypertension is a medical condition affecting the population globally. Most of the patients are not aware of this disease until organ damage is present. Misdiagnosis of hypertension's etiology will lead to poorly treated patients and increase risk of medical complications. For this reason, diagnosing and management of hypertension are fundamental in the primary and secondary prevention steps.

**Case Description:** A 52y/o male patient with a past medical history of hypertension. Whom had previously visited multiple physicians due to resistant hypertension. During endocrinologist evaluation, he was found with low potassium levels. However, patient denied any symptoms including weakness, fatigue, muscle cramps or palpitations. Patient has been treated for the past three years with oral potassium replacement. New laboratory bloodwork for secondary causes of hypertension were ordered. At follow up evaluation, patient was found with metabolic alkalosis, normal magnesium levels (2.0mg/dL), normal aldosterone and low renin levels, normal ACTH and cortisol, and normal catecholamines levels. Although, patient had been complaint with oral potassium replacement, he continued with asymptomatic hypokalemia. For this reason, patient was referred to nephrology services. Bloodwork was re-assed and results yield urine potassium spot of 27mmol/L. Since, He was started on amiloride 5mg daily. In the past 2 months for the first time, potassium levels have been between 3.0-3.1, without including potassium replacement. Patient responded successfully to therapy. Abdominal CT-scan was negative for adrenal mass. Genetic studies are under study, but patient's clinical presentation and response behave as Liddle's syndrome.

**Discussion:** Secondary causes of hypertension are medical condition that contributes to elevated blood pressure. Liddle syndrome is a rare genetic condition associated with abnormalities on the epithelial sodium channel (ENaC) at the collecting tubule. Classical presentation is young onset hypertension, associated with hypokalemia and metabolic alkalosis. Usually, a strong family history will lead the work-up and diagnosis. But, as in this case, no family history was relevant. Managing hypertension will require out of the box thinking. Controlling elevated blood pressure with medications, without identifying its etiology is not enough if patient's wellbeing is the priority.

## SA-PO483

### Gitelman-Like Syndrome Associated With Chemotherapy With Cisplatin

Juan D. Diaz Garcia, Mario Alamilla Sanchez, Julio C. Nieto, Irving G. Ramirez, Claudia B. López, Valeria Yanez Salguero, Jose L. Ortega, Martin B. Yama Estrella, Enrique F. Morales Lopez, Francisco Velasco Garcia Lascuain. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

**Introduction:** Gitelman-like or acquired syndrome is a rare salt-losing tubulopathy similar to thiazides, characterized by severe and chronic hypokalemia associated with metabolic alkalosis and secondary hyperaldosteronism, it is also characteristic of hypomagnesemia and hypocalciuria without a defect in the ability to concentrate urine. Cisplatin is the most widely used antineoplastic agent for the treatment of solid tumors and is a well-known cause of nephrotoxicity.

**Case Description:** A 38-year-old female with a history of gastric adenocarcinoma was treated with surgery and 12 cycles of cisplatin, adriamycin, and cyclophosphamide, with no history of taking loop diuretics and thiazides. On hospital admission, her vital signs were normal with stable blood pressure and presence of paresthesias in the extremities. Serum creatinine 0.6 mg/dl, BUN 15 mg/dl, hypokalaemia (2.2 mEq/L) and hypomagnesaemia (0.5 mg/dl), with a venous blood gas analysis that reported a pure metabolic alkalosis with pH 7.52, bicarbonate 32 mEq/L, PCO2 38 mmHg, PO2 82 mmHg. Urinary electrolyte levels were requested in 24 hours, demonstrating urinary losses of potassium with hypocalciuria. He required daily treatment with 20 to 80 mEq of KCl orally, 2000 mg of magnesium oxide and 200 mg of spironolactone to maintain his electrolytes within the normal range., Cisplatin was suspended and chemotherapy was changed. Three months after Cisplatin suspension, the patient reported serum electrolytes within normal limits.

**Discussion:** The mechanism of cisplatin nephrotoxicity remains uncertain, it is believed that cisplatin can cause DNA damage in the NCCT gene and DCT epithelial apoptosis producing Gitelman-like syndrome. Although this syndrome occurs infrequently, cisplatin causes frequent renal dysfunction. Cisplatin administration in divided doses or as a continuous infusion reduces nephrotoxicity. Immediate replacement of magnesium and potassium deficits reduces the risk of adverse effects. This case demonstrates that cisplatin can have permanent effects on tubular function and can cause significant morbidity. This syndrome should be considered in patients with unexplained electrolyte abnormalities and a history of distant therapy for malignancies.

## SA-PO484

### Pregnancy and Gitelman Syndrome

Daniel Gomez, Ursula C. Brewster. *Yale University Department of Internal Medicine, New Haven, CT.*

**Introduction:** Gitelman Syndrome (GS) is a rare genetic tubulopathy resulting in hypokalemia and hypomagnesemia through renal wasting that is caused by a mutation in the SLC12A3 gene that codes for NCC in the Distal convoluted tubule. We present a

case of a pregnant patient with GS and discuss management challenges. The physiologic increase in GFR due to pregnancy, increases potassium/magnesium wasting causing a challenge.

**Case Description:** A 33-year old female with GS presented to nephrology clinic 10 weeks pregnant. She was diagnosed as a teen when routine blood work showed hypokalemia and hypomagnesemia. She previously took KCl 40 mEq four times per day and MgOx 400mg twice a day. She refused sequencing. Blood Pressure was 105/67 mmHg Heart Rate 84/min with normal exam. Initial labs notable for Na 138 mEq/L, K 2.4 mEq/L, HCO<sub>3</sub> 23 mEq/L, Ca 9.4 mg/dL, Cr 0.5 mg/dL, BUN 11 mg/dL, Mg 1.3 mg/dL. A 24 hour urine study showed volume of 3 L, potassium of 285 mmol/24h, Magnesium 134 mg/g Cr and Creatinine 1.44 g/24h. Increase in supplementation didn't substantially increase levels. In an attempt to downregulate the renin angiotensin aldosterone system due to hypovolemia, 1g NaCl tablets three times daily was added and Magnesium oxide was changed to Magnesium lactate for better absorption and lower side effects. Repeat 24 hour urine post salt tablets, showed the potassium dropped to 249 mmol/24h, with no change in Mg. Supplements were titrated up and ultimately she was placed on KCl 200 mEq/24h and 2,672 mg MgLac/24h. On this regimen her labs were Na 136 mEq, K 2.9 mEq, HCO<sub>3</sub> 27 mEq, Mg 1.3 mg/dL stayed throughout the pregnancy, delivering without complications a normokalemic baby. She remained asymptomatic. Her regimen had 21 pills per day, but she never required IV supplementation. She struggled with anxiety and frustration from pill burden and constant monitoring.

**Discussion:** This case illustrates the difficulties that patients with GS face when they become pregnant. Successful pregnancies are possible with close monitoring. GFR increases in pregnancy, increasing K/Mg wasting. Hypokalemia and hypomagnesemia can be treated with high salt diet, oral potassium and magnesium supplementation to achieve adequate electrolyte levels. It is important to understand various Mg preparations available and their side effect profile to aggressively replete orally. Despite the challenges, patients with GS can successfully carry pregnancies with careful monitoring.

## SA-PO485

### Hypokalemia in Pregnancy Concerning for a Masked Renal Tubulopathy

Soumya V. Rajendren, Woojin Ahn. *Columbia University Irving Medical Center, New York, NY.*

**Introduction:** Pregnancy causes many physiologic alterations in fluid and electrolyte balance. Increased progesterone-mediated systemic vasodilation results in hypotension. RAAS upregulation increases renal K secretion. K loss is counteracted by progesterone's inhibition of kaliuresis, protecting the pregnant woman against hypokalemia. GFR rises, increasing proximal tubular K resorption. All of these maintain normokalemia in pregnancy. Hypokalemia in pregnancy therefore may be the first clue to an underlying renal tubulopathy in an otherwise healthy patient.

**Case Description:** A 37 year old asymptomatic G5P4 at 28 weeks gestation with no significant history was referred for hypokalemia to 3.0-3.2 mmol/L. She was mildly hypotensive (93/58). A pre-pregnancy BMP showed serum Na 144 mmol/L, K 3.3 mmol/L, Cl 113 mmol/L, bicarbonate 17 mmol/L and Ca 8.7 mg/dL. During this pregnancy, serum Cl 103-107 mmol/L, bicarbonate 17-22 mmol/L, Ca 8.1-8.7 mg/dL with ionized Ca 1.16 mmol/L and Mg 1.8-2.0 mg/dL. All blood gases were drawn during pregnancy with pH 7.31-7.39 and pCO<sub>2</sub> 32-39 mmHg. Urine pH ranged 5.5-7.0 during this pregnancy and was 6.0-7.0 prior. Urine AG during this pregnancy was 38 mmol/L and TTKG 7 evidenced renal K wasting. There was no nephrocalcinosis, although calcium oxalate crystals were seen on a prior UA. She was given 10 mEq KCl daily with improvement and referred for genetic testing.

**Discussion:** This case demonstrates the challenges in diagnosing renal tubulopathies in pregnancy, as the classic abnormalities may masquerade as normal pregnancy physiology. Scant pre-pregnancy data in these otherwise healthy patients makes accurate diagnoses even harder. Here, the challenge is differentiating a primary NAGMA with respiratory compensation from a physiologic progesterone-mediated respiratory alkalosis with metabolic compensation. Borderline hypocalcemia and questionable hypercalciuria could suggest a type 1 RTA or Bartter Syndrome. Hypotension could be physiologic or suggestive of a tubulopathy like Gitelman or Bartter. And while the absence of an obvious metabolic alkalosis argues against these, the very mild acidosis and correction with a just 10 mEq KCl daily is atypical of a pure type 1 RTA, raising concern for a mixed acid-base disorder. Accurate diagnosis in this population is essential for the prevention of adverse maternal and fetal outcomes, and renal genetic testing may play a key diagnostic role.

## SA-PO486

### A Case of Licorice Root Toxicity With Hypokalemia-Induced Bradycardia and Hypotension

Judy Sakya, Alexander Pennekamp. *Christ Hospital, Cincinnati, OH.*

**Introduction:** Licorice (glycyrrhetic acid) toxicity causes hypertension along with hypokalemia by mimicking a state of hyperaldosteronism. It inhibits type 2 11-beta-hydroxysteroid dehydrogenase and binds to mineralocorticoid receptors.

**Case Description:** A 75-year-old male with a past medical history significant for controlled hypertension, hyperlipidemia, coronary artery disease presented with progressive fatigue and dyspnea on exertion. In the ED, he was hypotensive and bradycardic, hypokalemic with ST-depressions and U-waves on EKG; his troponins were elevated. His medications prior to admission included: losartan, chlorthalidone. Serum Creatinine: 1.4 mg/dL (reference: 0.50 - 1.30 mg/dL) Serum potassium: 1.2 (reference: 3.5 - 5.1 mmol/L) Urine potassium: 50 (reference: 12.0 - 129.0 mmol/L; inappropriately high) Urine creatinine: 128.5 mg/dL (reference: 30 - 310 mg/dL) Fractional excretion of potassium: 45.4% (Renal potassium wasting) Upon further questioning, patient revealed

that he had been taking licorice root extract (glycyrrhetic acid) for the past three weeks to treat his fatigue. He stated that a provider had mentioned that his fatigue may be a result of possible adrenal insufficiency. To intervene with a natural supplement, he was recommended to take the licorice root extract from an online store. The patient's blood pressure normalized with electrolyte correction, licorice discontinuation and supportive care.

**Discussion:** Licorice (glycyrrhetic acid) is a common addition to many candies, gums, and beverages and small amount of consumption poses minimal risk. Ingestion high enough to produce hypermineralocorticoid effects is possible when consumed as a licorice concentrate - a "health supplementation" that is readily accessible to patients without regulation. Interestingly, in our case, the expected hypertension due to overactivation of the renin-angiotensin-aldosterone system was masked by reduced cardiac output from hypokalemia-induced bradycardia. A detailed history was the key to exploring further urine studies, and an inappropriately high urine potassium and high fractional excretion of potassium confirmed the diagnosis.

## SA-PO487

### Unusual Case of Hypokalemia After Gastric Band

Elise Ewing, Hassan N. Ibrahim. *Houston Methodist Hospital, Houston, TX.*

**Introduction:** 55 year old woman with prior laparoscopic gastric band 10 years ago presented to primary care for new onset fatigue, concentration difficulty, and cold intolerance. She also has severe heartburn for the past few years and takes over-the-counter calcium carbonate multiple times per day. She has hypokalemia worsening over the past 3 years and several other metabolic disturbances, and was referred to nephrology clinic.

**Case Description:** Lab results included low potassium 3.0 mmol/L (3.5-5.3), elevated serum bicarbonate 30 mmol/L (20-32), BUN 12 mg/dL, creatinine 0.98 mg/dL, elevated serum calcium 10.4 mg/dL (8.3-10.2) and PTH 21 pg/dL (15-65). VBG revealed pH 7.36, pCO<sub>2</sub> 57mmHg (45-51), and bicarbonate 32 mmol/L (21-28). Hemoglobin was 10.2 g/dL (11.7-15.5) with microcytosis (MCV 82). Serum iron level was 11 mcg/dL (45-160), with 3% iron saturation (16-45). Urine studies indicated renal wasting with random U<sub>Na</sub> 60 mEq/L, U<sub>Cr</sub> 41 mEq/L, U<sub>K</sub> 28 mEq/L and U<sub>Ca</sub> 22 mEq/L. CT scan of the abdomen revealed a significantly dilated esophagus above the gastric band with excessive restriction. The electrolyte disturbances were likely sequelae of this with frequent calcium carbonate intake leading to hypercalcemia, suppressed PTH, and metabolic alkalosis. The metabolic alkalosis induces kaliuresis and intracellular shift of potassium resulting in hypokalemia. She was advised to discontinue calcium carbonate and instead use Esomeprazole 40mg daily for GERD, and to discuss gastric band adjustment with bariatric surgeon. At a 1 month follow-up visit, there was normalization of potassium 3.7 mmol/L, bicarbonate 25 mmol/L, and calcium 9.5 mg/dL. She also received two IV iron infusions and hemoglobin increased to 13.2 g/dL within 2 months. Energy level, concentration, and cold tolerance all improved.

**Discussion:** Milk Alkali syndrome includes a triad of hypercalcemia, metabolic alkalosis, and acute kidney injury. Discontinuing the offending agent usually results in rapid resolution. Calcium carbonate can also impact iron absorption. Typically iron is conjugated within gastric acid and absorbed in the upper gastrointestinal tract. If this process is impaired and iron reaches the alkaline secretions in the proximal jejunum, it is converted to ferric hydroxide and cannot be absorbed. Excess calcium can impair iron absorption. Also since an acidic gastric environment is needed, medications such as PPIs or antacids can decrease iron absorption.

## SA-PO488

### To Kayexalate or Not to Kayexalate

Yahya Al-Yousif, Amenah Al-Juboori, Nitin Behl, Aditya Bansal. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

**Introduction:** Although rare, it is important to consider colon necrosis, ulceration, and perforation in the management of patients with abdominal pain following kayexalate administration. We present a critically ill patient requiring partial hemicolectomy following kayexalate for hyperkalemia.

**Case Description:** A 43-year-old male presented to the ER via EMS after being intubated emergently in the field. Was found to be COVID-19 positive and admitted to the ICU. Creatinine and potassium started trending up after day 5, requiring multiple doses of calcium gluconate, insulin, and dextrose, along with 4 doses of kayexalate 30 g over the second week. On the 10th day, he started spiking fever, having abdominal distention, and continued desaturating. Abdominal x-ray showed a large amount of free intraperitoneal air warranting emergent ex lap with partial right hemicolectomy and end ileostomy. Unfortunately, he was pronounced dead after a lengthy hospital stay of 55 days. The specimen showed perforation, mucosal necrosis, and acute serositis. It also showed Amorphophilic crystals suggesting a diagnosis of kayexalate-induced colon ischemia and necrosis.

**Discussion:** Kayexalate was approved by the FDA in 1958 and has been used to treat hyperkalemia. It can bind intraluminal calcium, leading to bowel obstruction or perforation, with a reported incidence of 0.14-1.8%. The identification of rhomboid or triangular, basophilic crystals with a mosaic pattern on H&E stain is pathognomonic for the presence of kayexalate. We present this case as a reminder of the rare yet devastating complications of kayexalate. For that reason, clinical suspicion should be raised in patients with abdominal pain following kayexalate. Kayexalate should only be used in patients who have life-threatening hyperkalemia where dialysis or newer cation exchangers (ie, patiromer or Lokelma) are not available, and other therapies to remove potassium have failed or are not possible.

**Empagliflozin-Induced Fanconi Syndrome in a Patient With COVID-19**  
Nicole Fernandez, Gilad S. Guez, Edgar R. Escasinas. *LewisGale Medical Center, Salem, VA.*

**Introduction:** Fanconi syndrome is a renal tubular acidosis type 2 that also presents with phosphaturia, renal glucosuria, aminoaciduria, and tubular proteinuria. Etiologies of fanconi syndrome include wilson’s disease, inborn errors of metabolism, type 1 glycogen storage disorders, multiple myeloma, heavy metal toxicity, and medications. While a variety of drugs can lead to fanconi syndrome, there are only 4 published cases due to an SGLT-2 inhibitor, all of which were associated with canagliflozin. Based on our literature review, this is the first reported case of fanconi syndrome due to empagliflozin use.

**Case Description:** 61 year-old female with history of type II diabetes mellitus and rheumatoid arthritis. She had been taking empagliflozin-metformin 12.5 mg-1,000 mg, twice a day for 1.5 years and A1C was 7%. She had covid, and was admitted for severe fatigue and nonanion gap metabolic acidosis. Empagliflozin-metformin was held on admission. Metabolic panel showed bicarbonate 11 mmol/L, phosphate 1.2 mg/dL, magnesium 1.5 mg/dl and potassium 2.7 mmol/L. She required a lot of replacement over the course of 9 days before returning to normal electrolyte levels (table 2).

**Discussion:** Urine studies (table 1) including aminoaciduria also demonstrated that patient had an underlying Fanconi Syndrome. The severe fatigue was exacerbated by Covid infection, but was multifactorial due to low levels of serum electrolytes as well. Fanconi syndrome is a rare form of renal tubular acidosis type II, historically associated with a variety of medications. Some notable drugs include aminoglycosides, cisplatin, valproic acid, tetracyclines, ifosfamide, and tenofovir, as well as heavy metal toxicity. Currently, fanconi syndrome is not a known adverse effect for SGLT 2 inhibitors as there are only 4 previously reported cases. Due to recent emerging data supporting the use of this medication class in diabetes mellitus, especially complicated by congestive heart failure and chronic kidney disease, more data is needed in order to evaluate the benefits of these medications compared to the increasingly growing body of reported complications.

Urine Studies	
Ur Na	76 mmol/L
Ur Phos	46.5 mg/dL
Ur K	31 mmol/L
Ur Protein/Cr Ratio	4.07
Ur Cystine	720 umol/g Cr
Ur Lysine	2,093.2 umol/g Cr
Ur Serine	5,432.9 umol/g Cr
Ur Glycine	11,890.3 umol/g Cr
Ur Histidine	2,973.5 umol/g Cr

(Table 1)

SA-PO490

**Cadmium Toxicity From Cigarettes Causing Proximal Renal Tubular Acidosis and Severe Symptomatic Hypokalemia**  
Lyle W. Baker. *Mayo Clinic, Jacksonville, FL.*

**Introduction:** Heavy metal toxicity is an underrecognized cause of proximal renal tubular acidosis (RTA). Acquired proximal RTA is commonly caused by paraprotein disease, autoimmune disease, & medications. Heavy metals like cadmium can cause proximal RTA. This author presents two cases of cadmium toxicity from cigarette smoking causing proximal RTA and severe hypokalemia presenting as muscle weakness.

**Case Description:** Case 1: 57-year-old female with COPD and >40 pack-year smoking history, admitted for general weakness. She actively smoked 2 packs per day (PPD). Case 2: 66-year-old female with COPD and >50 pack-year smoking history, admitted for lower extremity weakness. She actively smoked 1 PPD. Both patients denied diarrhea, vomiting, and use of laxatives or diuretics. Both patients had unremarkable vitals & exam was significant for 4/5 muscle strength of extremities. Admission labs (Table 1)

revealed severe hypokalemia, hypophosphatemia, & non-anion gap metabolic acidosis. Urine studies (Table 1) including urine potassium-to-creatinine ratio,  $\beta$ 2-microglobulin, & retinol-binding protein-to-creatinine ratio were suggestive of renal potassium wasting, proximal tubulopathy, & RTA. Testing for paraprotein & autoimmune disease was unremarkable. Review of medications did not identify an offending agent. Heavy metals screen in both patients revealed elevated urinary cadmium confirming cadmium toxicity.

**Discussion:** The kidneys are a primary target organ for chronic cadmium toxicity. Inhalation of tobacco smoke is the main source of cadmium exposure in smokers; inhalation from smoking 1 PPD is between 1-3  $\mu$ g. The critical urinary cadmium-creatinine ratio associated with renal tubular injury is 2-10  $\mu$ g/g. These two cases highlight the importance of recognizing chronic cadmium toxicity from cigarette smoking as a rare cause of proximal RTA.

Table 1: Labs

	Case #1	Case #2	Reference
Potassium (mmol/L), serum	<1.5	1.6	3.6-5.2
Phosphorus (mg/dL), serum	1.0	0.9	2.5-4.5
Bicarbonate (mmol/L), serum	20	17	22-29
Serum Anion Gap	11	9	7-15
Urine Anion Gap	9.1	22	
24 Hour Urine Potassium (mEq)	108	-	>30 suggestive of renal potassium wasting in setting of hypokalemia
Urine Potassium-to-Creatinine Ratio (mEq/g)	153	55.9	>13 suggestive of renal potassium wasting in setting of hypokalemia
$\beta$ 2-Microglobulin ( $\mu$ g/L), urine	>20,000	>20,000	<300
Retinol-Binding Protein-to-Creatinine Ratio ( $\mu$ g/g), urine	173,200	178,800	$\leq$ 1190
Cadmium-to-Creatinine Ratio ( $\mu$ g/g), urine	6.2	9.0	<0.6

SA-PO491

**Immune Checkpoint Inhibitor-Induced “Pantubulopathy”**  
Kelly E. Schlotman, Muhammad A. Shahzad, Casey N. Gashti, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

**Introduction:** Immune checkpoint inhibitors (CPI’s) are widely used, effective cancer therapy agents that utilize the body’s natural immune system to destroy cancer cells. Unfortunately, the immune-mediated cellular damage is not limited to malignant cells and can also occur in healthy tissues including the kidneys. Tubulointerstitial nephritis (TIN) is the most common pathology seen on kidney biopsy in patients with AKI due to CPI’s. Here we present a case of CPI-induced interstitial nephritis which resulted in functional defects throughout the entire nephron.

**Case Description:** A 67 yo F w/ PMH of HTN, CKD3b (baseline SCr 1.3-1.6 from previous nephrotoxic exposure to carboplatin and bevacizumab), and metastatic endometrial cancer being treated with pembrolizumab (PD-1 inhibitor), lenvatinib (TK inhibitor), and zoledronic acid presented with a SCr of 3.2 mg/dl, hypokalemia (2.5 mmol/l), hypophosphatemia (1.9 mg/dl), hypomagnesemia (1.3 mg/dl), and a non-anion gap metabolic acidosis with  $[HCO_3^-]$  14 mmol/l and arterial blood pH of 7.18. Her urinalysis had a pH of 6.5, 3+ glucosuria (serum blood glucose of 98 mg/dl), 1+ blood, 1+ protein, and 5 WBC’s. Her urine P/C ratio was 3.8 g/g and urine A/C ratio was 530 mg/g. The fractional excretion of potassium (FEK) and phosphorus (FEPHos) were elevated (FEK 77% and FEPHos 52%) consistent with potassium and phosphorus wasting. The urine osmolar gap was low (28) and urine anion gap was positive (+11), both consistent with a distal renal tubular acidosis. Her severe electrolyte disturbances required aggressive supplementation. Renal biopsy showed acute on chronic interstitial nephritis with acute tubular necrosis and 20% IFTA. She received 40 mg prednisone with improvement in electrolyte disturbances and SCr to baseline.

**Discussion:** CPI’s can cause acute interstitial nephritis leading to AKI and a number of tubular defects. Our case had evidence of 1) proximal tubular defects manifested as Fanconi syndrome with non-albuminuric proteinuria as well as renal K,  $PO_4$ , and glucose wasting 2) a loop of Henle defect with Mg wasting and 3) a distal tubular defect manifested as a distal RTA. While each of these have been reported with CPI’s, we are unaware of a prior case of “pantubulopathy” in which every segment of the nephron was affected by the CPI-induced AIN. Prompt diagnosis and treatment led to complete resolution of AKI and tubular defects.

SA-PO492

**A Novel Form of Renal Tubular Acidosis (RTA) Associated With Immune Checkpoint Inhibitors: A Case Report and Literature Review**  
L. D. Weiner,<sup>1,2</sup> Hyun-Wook Lee,<sup>2</sup> William L. Clapp,<sup>2</sup> Chintan V. Shah.<sup>2</sup>  
<sup>1</sup>Gainesville VAMC, Gainesville, FL; <sup>2</sup>University of Florida College of Medicine, Gainesville, FL.

**Introduction:** Immune checkpoint inhibitors (ICI) are increasingly being used as anti-neoplastic therapy. This report describes a case linking ICI therapy to a novel form of RTA, which we term Type V RTA.

**Case Description:** A 46 yo female with metastatic cancer was treated with Carboplatin-Paclitaxel-Pembrolizumab followed by maintenance pembrolizumab. Three months after starting maintenance pembrolizumab, she developed hypokalemic (K, 3.2 mM) normal-gap metabolic acidosis (tCO<sub>2</sub>, 15 mM). Renal function was preserved (creatinine, 0.6 mg/dl), and the urine pH was 6.0. Urinary ammonia, estimated using urine anion gap (+27 mM) and urine osmole gap (83 mOsmol/kg H<sub>2</sub>O), was not elevated. Urinary citrate in a 24-hour collection was undetectable. A diagnosis of ICI-associated RTA was made, and pembrolizumab was held. A kidney biopsy showed proximal tubule vacuolization but no tubulitis, tubular necrosis, or interstitial nephritis. K-citrate treatment

normalized the acidosis and hypokalemia; urine pH remained 6.0 during therapy. The RTA spontaneously resolved over four months. Immunohistochemistry of the biopsy specimen for key acid-base transporters, NBCe1, H-ATPase, and Rhesus C Glycoprotein, showed normal expression and localization compared to control tissue. Ultrastructural analysis showed proximal tubule apical and basolateral vacuolization. A review of medical literature identified 7 previous cases of RTA associated with PD-1 therapy. Urine pH was 6.0 in 3, 6.3 in one, 6.5 in two, and 6.7 in one case.

**Discussion:** This case represents a novel form of RTA, which we term Type V RTA. Type II (proximal) RTA is excluded given the persistent urine acidification during alkali therapy and undetectable urinary citrate. Intact urine acidification excludes Type I (distal) RTA. The absence of hyperkalemia excludes Type IV (hyperkalemic) RTA. Instead, we postulate that this case represents a novel form of RTA, Type V RTA, which is characterized by normal gap metabolic acidosis, impaired ammonia excretion despite intact urine acidification, the absence of hyperkalemia, and intact ability to decrease urinary citrate. A case review identifies several similar cases, all associated with anti-PD1 therapy. We suggest the etiology is impaired proximal tubule ammonia generation, which may be related to the proximal tubule vacuolization observed.

## SA-PO493

### Metabolic Acidosis in a Patient With Polycystic Ovary Syndrome Taking Oral Contraceptives and Antipsychotics

Renuka Tolani, Palmetto General Hospital, Hialeah, FL.

**Introduction:** Patients with insulin resistance such as with polycystic ovarian syndrome (PCOS) who are on oral contraceptives (OCPs) and antipsychotics, may be at an increased risk for hypertriglyceridemia as a side effect. Lipolysis of triglycerides may increase free fatty acid production and therefore contribute to HAGMA. When there is severe hypertriglyceridemia, then plasmapheresis and dialysis play an important role in resolution.

**Case Description:** An 18 year old female with a past medical history of PCOS, diabetes, and depression presented to the ED with lower abdominal pain. Her home medications included lurasidone, sertraline, ethinyl estradiol-norgestimate, metformin, and insulin. Patient complained of associated dysuria. In the ED patient was found with tachycardia and tachypnea, but normotensive and afebrile. Labs were notable for leukocytosis of 15.7, glucose 252, bicarb 6, anion gap 23, and sodium 128. BUN was 4 and creatinine was 0.6. There was not a significant osmolality gap. Lactic acid was not elevated. Acetaminophen, ethanol, and salicylate levels were negative. UA was significant for leukocyte esterase, protein, glucose, and ketones. Urine culture grew *E. coli*. Blood gas on room air showed pH of 7.028, pCO<sub>2</sub> 10.3, bicarb 5, and pO<sub>2</sub> 130. Lipid panel showed cholesterol of 1,062, LDL < 472, and triglycerides > 2625. Lipase was 431, without findings of pancreatic pathology on CT abdomen. Hemoglobin A1C was found to be 9.81. The patient received a dialysis and plasmapheresis session. She was started on insulin drip, statin, omega and fenofibrate. She received 5 amps of bicarb and was started on a bicarb drip. She was given a course of antibiotics for her UTI. Over a course of 24 hours the acidosis resolved and the anion gap closed. Triglycerides reduced to the 400s by the next day. Trialysis catheter was removed. Psychiatry and internal medicine decided to discontinue antipsychotic and continue sertraline. She was discharged with OCP containing less estrogen, insulin, statin, omega-3 and fenofibrate.

**Discussion:** In patients with hypermetabolic syndrome who have HAGMA on labs, it is important to check for elevated triglycerides and treat based on severity. After plasmapheresis and hemodialysis with reduction of triglyceride levels, our patient's HAGMA resolved. There have been a few cases reported of oral contraception-induced hypertriglyceridemia particularly with estrogen, but requires further research.

## SA-PO494

### L-Arginine-Induced Non-Anion Gap Metabolic Acidosis in a Patient With MELAS Syndrome

Daniel Rechlin, Catherine A. Moore. University of Rochester Medical Center, Rochester, NY.

**Introduction:** MELAS syndrome (Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes) is a rare disorder of mitochondrial DNA manifesting across multiple body systems, including with episodic lactic acidosis. Primary treatment of flares is with L-arginine. This medication has been shown to inhibit proximal renal tubule bicarbonate reabsorption, and we present a complicated case of this known but rare side effect.

**Case Description:** Our patient was a 40 year old male with a history of MELAS syndrome with subsequent seizures, hearing and visual loss, and previous stroke-like episodes; hypertension; and type 2 diabetes mellitus treated with Empagliflozin. He presented to the hospital with 2-3 days of abdominal pain and malaise, with acute onset encephalopathy. Initial workup revealed an anion gap metabolic acidosis (AGMA), with evidence of lactic acidosis and DKA, and concurrent respiratory acidosis. He initially responded to IV fluids, insulin infusion, and mechanical ventilation. On hospital day 2 he was started on IV L-Arginine for suspected MELAS flare. The next day there was recurrence of AGMA, with additional non-anion gap metabolic acidosis (NAGMA). AGMA, attributed to recurrence of euglycemic DKA vs. starvation ketosis, resolved with additional IV fluids and insulin infusion. Given the timeline, and urine labs consistent with type II renal tubular acidosis, his Arginine infusions were felt to be the most likely culprit for his NAGMA. He was treated with temporary bicarbonate supplementation, and with completion of his course of L-Arginine his acidosis resolved.

**Discussion:** This is a case of L-arginine induced non anion gap metabolic acidosis in a patient with MELAS syndrome. Although there have been occasional reports of this phenomenon, there is very little literature on this topic. This patient's case was also

complicated by multiple other sources of metabolic, and respiratory, acidosis. Patients with MELAS syndrome are prone to complicated acid-base disturbances by nature of their disease. NAGMA from L-arginine is a medication side effect peculiar to this combination of therapy and disease process. Because of the multiple potential pitfalls in diagnosis illustrated by this case, it is important to bear this in mind when caring for patients with this rare disease.

## SA-PO495

### Unexplained Metabolic Acidosis: Look for Acetaminophen!

Sriram Sriperumbuduri, Lilia Harris, Uma Mahesh R. Avula, Safa Osman, Carter V. Schwartz, Maria Clarissa Tio. The University of Mississippi Medical Center, Jackson, MS.

**Introduction:** High anion gap metabolic acidosis (HAGMA) is a common clinical scenario and often presents as a diagnostic challenge. We present an often-overlooked etiology of HAGMA in a hospitalised patient.

**Case Description:** A 65-year-old-female with atrophic right kidney and hypertension was referred to our hospital for management of a recently diagnosed urothelial bladder malignancy. She had multiple hospitalisations for urosepsis in the past 3 months. Labs showed low serum albumin of 2.3 mg/dl and serum creatinine of 0.65 mg/dl at the time of current admission. She underwent radical cystectomy and open right nephroureterectomy (for recurrent urosepsis). Post operatively she developed ileus and was started on total parenteral nutrition (TPN). One week later, she developed progressively worsening HAGMA. Initial evaluation at the onset of acidosis showed high blood glucose with normal serum beta hydroxybutyrate (BHB) level. Insulin infusion was started and TPN was held. Despite giving sodium bicarbonate, HAGMA continued to worsen with decline in serum bicarbonate up to 10 mEq/L and increase in anion gap (AG) to 36 mEq/L by post operative day 17. Serum lactate was normal and there was no exposure to salicylates or alcohol. Serum creatinine was 0.9 mg/dl indicating mild acute kidney injury. Chart review showed a cumulative exposure of 49.7 grams to Acetaminophen over 19 days after the surgery. Urine 5-oxoproline was ordered and it was elevated at 1401 mmol/mol of creatinine. Liver function tests remained normal. Acetaminophen was held and intravenous N-Acetyl cysteine (NAC) was given for a total dose of 300 mg/kg over one day. Serum AG normalized after 3 days of NAC to 12 mEq/L and bicarbonate improved to 23 mEq/L after one week.

**Discussion:** This case highlights 5-oxoprolinemia as a differential for HAGMA in a hospitalized patient with chronic acetaminophen exposure. Exposure to high cumulative doses of acetaminophen in patients with predisposing factors (elderly, females, malnutrition, sepsis, chronic acetaminophen exposure) should raise concern for this condition.

## SA-PO496

### Case of Increased Anion Gap Metabolic Acidosis From Acquired Glutathione Deficiency Secondary to Acetaminophen

Hussain A. Karimi,<sup>1</sup> Hoda Kaldas,<sup>1</sup> Mariya Asghar,<sup>2</sup> <sup>1</sup>UPMC, Pittsburgh, PA; <sup>2</sup>Liaquat National Hospital and Medical College, Karachi, Pakistan.

**Introduction:** We describe a case of a 31-year-old female with prolonged hospitalization who had high anion gap metabolic acidosis (HAGMA) secondary to Acetaminophen-induced pyroglutamate excretion.

**Case Description:** 31 y/o F with a past medical history significant for traumatic brain injury secondary to a motor vehicle accident, seizure disorder, bowel perforation status post ileostomy who presented with Pneumonia and UTI (Urinary tract infection) from MDR (multidrug-resistant) organisms, also found to have HAGMA for which Nephrology was consulted. The patient had a very prolonged hospitalization which was met with multiple complications. She was noted to have HAGMA of 26 and a serum bicarbonate level of 12. Her VBG showed a pH of 7.17, PCO<sub>2</sub> of 36, and HCO<sub>3</sub> of 13, her delta gap was 1.16 indicating pure HAGMA. Appropriate workup was done which showed negative ACTH stimulation test, creatine phosphokinase levels <10, Lactic acid at 2.0 mmol/L, beta-hydroxybutyrate levels were 0.27 mmol/L, free valproic acid at 4.7 (4.8-17.3 ug/ml), topiramate levels at 6.8 (5-20 ug/ml), Acetaminophen and aspirin levels were undetectable. Ethanol levels were not checked but she had no exposure to it due to the prolonged hospitalization, all medications were reviewed, and propylene glycol was not used as a solvent in any of the meds. Her renal function showed serum creatinine of 0.3 mg/dl, but it was unreliable as she was severely malnourished, urine anion gap was positive. She was started on sodium bicarbonate tablets 650 mg q 8 hours and then transitioned to a bicarbonate drip with 150 meq/L in 1 L of sterile water. Upon further review, it was noted that she had been getting oral acetaminophen 650 mg every 6 hours as needed intermittently for pain, this prompted us to send serum and urine organic acid panel using gas chromatography/mass spectrometry which revealed massive excretion of pyroglutamate in the urine. Her Acetaminophen was stopped and a week later her serum bicarbonate levels improved to 24 without needing any further NaHCO<sub>3</sub> tablets.

**Discussion:** High anion gap metabolic acidosis due to acquired deficiency of glutathione in malnourished patients who are exposed chronically to Acetaminophen is underinvestigated and underreported. This should be considered as a differential, especially in women with prolonged hospitalization and sepsis when evaluating HAGMA.

## SA-PO497

**Case of Chronic Lactic Acidosis in an Adult Female**

Violeta Alvarez Retamales, Charles W. Heilig. *University of Florida College of Medicine, Jacksonville, FL.*

**Introduction:** Sengers syndrome (SS) is a rare autosomal recessive disorder due to mutations in acylglycerol kinase (AGK) gene. We report a case of an adult female referred to the nephrology clinic with chronic lactic acidosis, diagnosed clinically and undergoing genetic work up for SS.

**Case Description:** 30 y/o F, born of consanguineous parents, with history of chronic myalgias, asthenia, exercise intolerance, open angle glaucoma, and congenital cataracts is found to have chronic lactic acidosis. Her serologies are remarkable for AST at 55 U/L, ALT at 41 U/L, aldolase at 13.4 U/L, lactic acid at 7.6 mmol/L, LDH at 220 U/L, CK at 504 U/L. Urine lactic acid at 92 mmol/mol creat. Echocardiogram (TTE) revealed mild concentric left ventricular hypertrophy but otherwise unremarkable. She has two younger twin brothers, one of them share her symptoms along with cardiomyopathy. No one else in the family has similar symptoms. Her 24 y/o brother has been recently diagnosed with SS. Patient is currently undergoing further genetic workup to confirm SS.

**Discussion:** SS is caused by homozygous or compound heterozygous mutation in the AGK gene on chromosome 7q34. It is an autosomal recessive mitochondrial disorder characterized by congenital cataracts, hypertrophic cardiomyopathy, skeletal myopathy, exercise intolerance, and lactic acidosis. SS is usually diagnosed in infancy yet that is not the case with this patient. Being a very rare disease, its phenotype/genotype is still uncertain. AGK is involved in the synthesis of phosphatidic acid which acts as a second messenger regulating several cellular processes and plays an important role in the synthesis of phospholipids. Multiple studies found oxidative phosphorylation defects in SS and suggested that mitochondrial respiration and metabolism are affected in the absence of AGK. SS can have high mortality rate due to hypertrophic cardiomyopathy, yet in our patient TTE showed only mild hypertrophy. SS can be differentiated from other hypertrophic cardiomyopathy associated genetic disorders by its high incidence of ocular lesions. A distinctive feature is the development of marked lactic acidosis on slight muscular exercise for which our patient has been told to avoid any strenuous activity. Much is still to be understood about SS, yet strong clinical suspicion is needed when a patient presents with ocular lesions, lactic acidosis, muscle weakness and cardiomyopathy clinical features.

## SA-PO498

**Anion Gap Metabolic Acidosis due to Lactate Production in the Setting of Metformin Poisoning**

Nazish Khan,<sup>1,2</sup> John Manllo,<sup>3</sup> Roberto Manllo-Karim.<sup>3,1</sup> *<sup>1</sup>The University of Texas Rio Grande Valley, Edinburg, TX; <sup>2</sup>Knapp Medical Center, Weslaco, TX; <sup>3</sup>South Texas Kidney Specialists, McAllen, TX.*

**Introduction:** We present a case of anion gap metabolic acidosis (AGMA) secondary to severe lactate production due to metformin overdose in an 18-year-old woman, highlighting metabolic derangements ensuing the need for hemodialysis.

**Case Description:** An 18 y/o woman with past medical history of depression and recently diagnosed diabetes mellitus presented to us two hours after attempting suicide by ingesting over a hundred Metformin 1000mg tablets. On evaluation, she reported two episodes of emesis prior to arrival. Physical examination revealed a somnolent yet arousable, tachypneic and depressed young woman. Initial labs were remarkable for serum HCO<sub>3</sub> of 10 mmol/L, anion gap of 19 and a lactic acid level of 6.3 mmol/L. Admission arterial blood gases showed: pH of 7.17, PCO<sub>2</sub> 23.9, PO<sub>2</sub> 126 and HCO<sub>3</sub> 8.5. Urine drug screen, acetaminophen and salicylates level were negative. She received a bolus of isotonic saline and 200 mEq of IV sodium bicarbonate in the ED and was admitted to the ICU for closer monitoring. Within seven hours of ingestion, her lactic acid trended up to 28 mmol/L, serum HCO<sub>3</sub> dropped to < 5 mEq/L and the anion gap rose to 40. Arterial blood pH dropped to 6.811 and she was started on IV sodium bicarbonate infusion. The patient became hypotensive with intractable acidosis and required sustained low-efficiency dialysis. Despite severe tachypnea, the patient did not require intubation. She received two six-hour SLED sessions in 24 hours and 1750 mEq of IV sodium bicarbonate supplementation as infusion and boluses in 48 hours which resolved the AGMA and improved lactic acid to 2.3 mmol/L. No cardiac arrhythmias were recorded. Her symptoms significantly improved with pH correction and she was discharged home after psychiatry consultation.

**Discussion:** Metformin associated lactic acidosis carries a high mortality rate, even higher in cases of overdose. Patients initially have relatively normal labs and the severity of acidosis may not be apparent on presentation. However, as seen in this case, they can rapidly decompensate. Patients with reported or suspected metformin toxicity should be monitored closely with frequent ABG, electrolytes and lactic acid checks for initial 12 hours (two metformin half-lives). Lastly, although metformin has no antidote, its toxicity can be managed with early nephrology consultation and pH correction with sodium bicarbonate and dialysis.

## SA-PO499

**MALA: Surviving Extreme Metformin Toxicity**

Raad B. Chowdhury,<sup>1</sup> Paul M. Palevsky.<sup>2</sup> *<sup>1</sup>UPMC, Pittsburgh, PA; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.*

**Introduction:** Metformin (MET) induced lactic acidosis (MALA) is a potentially life-threatening complication of MET associated with decreased kidney function characterized by a profound type B lactic acidosis with vasoplegia and circulatory

collapse. Management of requires drug removal using kidney replacement therapy. In 2019, close to 90 million prescriptions of metformin were filled. MALA is rare in absence of kidney dysfunction and MET is contraindicated at eGFR < 30 mL/min/1.73 m<sup>2</sup>. MALA. Serum MET levels are important in distinguishing these cases from other causes of lactic acidosis. We describe a case of MALA with one of the highest serum levels reported, in a patient with no prior history of renal disease.

**Case Description:** A 33-year-old female with unknown past medical history presented as a transfer from an outside hospital after ingestion of 90 grams of MET. On initial presentation her lactate was 11 mmol/L, with rapid clinical decompensation and minimal responsiveness. On transfer, her pH was 6.86, HCO<sub>3</sub>- 7 mmol/L, AG 24 mmol/L, lactate 18.3 mmol/L, BUN 18 mg/dL, Cr. 1.1 mg/dL, K+ 5.1 mmol/L, and Posm 348 mOsm/kg. High flux hemodialysis (HD) was initiated for presumed MALA while awaiting pre-HD MET levels. She received kidney hemodialysis for 47.25 hours until her lactate was <3 mmol/L and pH >7.35. Her admission MET level was ultimately reported as 470 mcg/mL. She was discharged from the hospital after 40 days and was HD independent.

**Discussion:** We describe a young female with no prior history of kidney disease who developed MALA associated with one of the highest MET levels reported after massive ingestion who survived after prolonged extracorporeal drug removal. In a systematic review by Yeh et al<sup>2</sup>, the highest reported MET level was 380.0 mcg/mL with a correlation between levels and ingested drug, consistent with our case. In our review of the literature MET levels of >200 mcg/mL were generally fatal. Although MALA is commonly associated with decreased kidney function, this case illustrates that massive MET ingestion can cause MALA independent of other risk factors including presence of kidney disease. In conclusion, we report a case of MALA with a substantial ingestion burden and arguably one of the highest reported levels of metformin who survived after early and prolonged hemodialysis.

## SA-PO500

**Continues Renal Replacement Therapy as a Cause of Euglycemic Diabetic Ketoacidosis**

Hisham N. Abu Farsak, Purnima Kabir, Saba Salem. *Hamilton Medical Center, Dalton, GA.*

**Introduction:** Ketoacidosis occurs when absolute or relative insulin deficiency inhibits the ability of glucose to enter cells for utilization as metabolic fuel, the result being that the liver rapidly breaks down fat into ketones to employ as a fuel source. The overproduction of ketones ensues, causing them to accumulate in the blood and urine and turn the blood acidic. Ketoacidosis is not commonly recognized as a cause for anion gap metabolic acidosis in patients who are on continuous renal replacement therapy (CRRT). We present a case for a patient with acute kidney injury who developed euglycemic diabetic ketoacidosis (EDKA) on CRRT.

**Case Description:** A 78 year-old Caucasian female patient with past medical history significant for diabetes mellitus type 2, chronic kidney disease stage 3, and dementia, who was admitted to the ICU for altered mental status secondary to septic shock presumed secondary to urinary tract infection. Patient was intubated for airway protection. She became hypotensive after intubation and required vasopressors continuously. Patient started to develop oliguric acute kidney injury which required CRRT initiation for hyperkalemia and volume removal after 5 days of her hospitalization. Three days after starting CRRT, her serum bicarbonate level was 14 mEq/L, her anion gap worsened to 22 mEq/L. Her lactate level was normal. Her blood glucose levels were 100-220 mg/dL since admission. Uremia was unlikely with normal serum urea and close-to-normal creatinine while on CRRT. She was not on any drugs known to cause metabolic acidosis. Ketoacidosis was suspected and confirmed by high serum b-hydroxybutyrate level. She was started on glucose and insulin infusions. After 24 hours, her bicarbonate improved to 26 mEq/L, with a significant decrease in b-hydroxybutyrate level.

**Discussion:** EDKA is diagnosed in patients with normoglycemia, wide anion gap metabolic acidosis, and ketonemia. CRRT theoretically may be complicated with EDKA because of potentially compromised caloric intake and increased metabolic demands and stress from underlying critical illness, which may lead to a decrease in endogenous insulin production and a simultaneous increase in glucagon levels, which subsequently leads to lipolysis and ketogenesis. CRRT is an under-recognized etiology of euglycemic DKA which requires early recognition and treatment to avoid catastrophic outcomes.

## SA-PO501

**Persistent Euglycemic Ketoacidosis During Continuous Renal Replacement Therapy Despite IV Insulin Infusion**

Oyintayo Ajiboyé,<sup>1</sup> Pooja D. Amarapurkar,<sup>1,2</sup> Michael J. Connor.<sup>1,2</sup> *<sup>1</sup>Emory University School of Medicine, Atlanta, GA; <sup>2</sup>Grady Memorial Hospital, Atlanta, GA.*

**Introduction:** Euglycemic diabetic ketoacidosis (DKA) is an uncommon, known complication of continuous renal replacement therapy (CRRT) when using dextrose-free CRRT solutions with insulin-dependent diabetics at higher risk. Typically, CRRT-related euglycemic DKA resolves with increased insulin & dextrose exposure. Here we describe a case of euglycemic DKA which did not resolve with insulin administration & only improved after stopping CRRT.

**Case Description:** 73-year-old female with CKD 3aA1, insulin-dependent diabetes, & lung adenocarcinoma admitted for septic shock from empyema & post-obstructive pneumonia, respiratory failure, & anion-gap metabolic acidosis secondary to lactic acidosis & DKA with initial Beta-hydroxybutyrate (BHB) 1.7 mmol/L & glucose 727 mg/dL. She was placed on vasopressors, antibiotics, & an insulin infusion. However, she progressed to anuric acute kidney injury requiring CRRT using our standard phosphorus-containing, dextrose-free solution which improved the metabolic acidosis. Subsequently,

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

developed recurrent anion-gap metabolic acidosis on CRRT day 3 & evaluation revealed recurrence of elevated BHB to 1.38 mmol/L which steadily increased to 5.9 mmol/L on CRRT day 6 despite increased insulin infusion & escalating exposure to IV & enteral dextrose with bicarbonate levels remaining 14-21 meq/L & glucose 142-229 mg/dl on insulin infusion at peak > 5 units/hour. CRRT was stopped on day 6 due to persistent euglycemic DKA with rapid normalization of serum bicarbonate & decrease BHB to 0.78 mmol/L over 12 hours.

**Discussion:** CRRT with dextrose-free solutions results in net glucose loss leading to lower serum glucose levels & decreased insulin requirements in ICU patients. In a patient with impaired endogenous insulin production, this decreased insulin exposure can precipitate ketogenesis leading to euglycemic DKA. In prior case descriptions & our local experience, CRRT-related euglycemic DKA typically resolves with increased insulin dose facilitated by a deliberate increase in exogenous dextrose sources. However, in this case, the DKA did not resolve despite a significant increase in hourly insulin dose & only improved with cessation CRRT. Clinicians should be cognizant of, and alert to, euglycemic DKA as a complication of dextrose-free CRRT solutions. CRRT cessation or change to dextrose-containing solutions may be required when conservative management fails.

## SA-PO502

### A Case of Severe Alcoholic Ketoacidosis and Hyperlactatemia

Benjamin Wooden, Raphael J. Rosen, Woojin Ahn. *Columbia University Irving Medical Center, New York, NY.*

**Introduction:** Alcoholic ketoacidosis is a cause of metabolic acidosis in patients with heavy alcohol use and poor nutrition. We report a case of alcoholic ketoacidosis notable for severe acidemia and hyperlactatemia, which resolved with dextrose administration.

**Case Description:** A 37 year-old woman with alcohol use disorder presented with abdominal pain in the setting of 1 week of heavy alcohol use. She was tachycardic but normotensive. Mental status was normal. Labs showed serum bicarbonate <6 mmol/L and an anion gap of >52. Blood gas revealed pH 6.85 and pCO<sub>2</sub> 18 mm Hg. Venous lactate was 16 mmol/L. She was dosed 25 mEq IV bicarbonate, and subsequent blood gas showed pH 7.05 and pCO<sub>2</sub> 16. Ethanol level was 79 mg/dL, beta-hydroxybutyrate 8.47 mmol/L, AST 253, ALT 54, total bilirubin 0.8, INR 1.1, and serum osmolality 336 mOsm/kg. Calculated osmolality was 301, indicating an osmolal gap of 35. The patient denied ingesting any substances apart from store-bought whiskey. She admitted to poor food intake. She was treated with thiamine and a dextrose infusion, without further bicarbonate. Within 3 hours, her serum bicarbonate increased to 9 mmol/L, and rose to 23 mmol/L less than 18 hours after dextrose was initiated. The hyperlactatemia resolved as well, though it took 3 days to fully normalize. She was stable for discharge on hospital day 4.

**Discussion:** Alcoholic ketoacidosis is the result of disturbed metabolism that occurs with heavy alcohol use and malnutrition. Notable features include a relatively normal mental status (vs. diabetic ketoacidosis of similar metabolic severity), and typically prominent GI symptoms including nausea and pain. Labs show anion gap metabolic acidosis and elevated serum ketones. Serum osmolality is elevated due to accumulation of ketones and ethanol. Lactate elevation can occur (due to NADH accumulation favoring conversion of pyruvate to lactate), but is typically not severe. In our patient, she had a severe hyperlactatemia for which no alternative cause was found, illustrating that alcoholic ketoacidosis should be kept on the differential in alcohol-using patients with anion gap metabolic acidosis and osmolar gap, even in the setting of marked hyperlactatemia. Preserved mental status and normotension, despite severe acidemia, may be clues to the diagnosis. Dextrose administration (with thiamine to protect against Wernicke encephalopathy) can rapidly reverse the acidosis.

## SA-PO503

### Transient Vision Loss From Alcohol Associated Lactic Acidosis

Muhammad A. Monk, Jordan Torres, Krina Viroliya, Ndifreke Ekpa, Junaid M. Alam, Sowmya Puthalapattu. *HCA Houston Kingwood/University of Houston, Kingwood, TX.*

**Introduction:** Lactic Acidosis is a common finding in critically ill patients and can cause a variety of complications. We present a case of reversible blindness caused by ethanol induced lactic acidosis

**Case Description:** A 53-year-old male with PMH of hypertension, type 2 Diabetes, and alcohol abuse presented with acute binocular vision loss, altered mental status, facial droop, and slurred speech. He reported heavy ethanol use and denied any toxic ingestion. The patient had a blood pressure of 206/96 mmHg and respiratory rate of 40/min. Labs were notable for CO<sub>2</sub> of <5, K of 6.1, glucose of 123, lactate of 9.5, and BUN/Creatinine of 73/5.2. ABG showed pH of 6.66, and anion gap of 27. Osmolar gap was found to be 35.5, serum alcohol was 19, and testing for ketones, salicylates, methanol, and ethylene glycol was negative. The patient received TPA, and an IV nicardipine drip was started in the ICU. Vision was restored after receiving IV sodium bicarbonate, and hemodialysis took place 24 hours post TPA. MRI showed small right middle frontal gyrus infarct. Symptoms improved over time, and patient was discharged without residual deficits after removal of dialysis catheter on day 12

**Discussion:** Metabolic Acidosis is known to cause vision loss, and is commonly associated with organic alcohol ingestion. Several cases involving metformin associated lactic acidosis and alcoholic/diabetic ketoacidosis presenting with reversible blindness have also been reported. It is hypothesized that retinal horizontal cells are disrupted in response to severe acidemia. Ethanol use can cause Type B lactic acidosis by altering the NADH/NAD ratio in the liver and increasing metabolism of pyruvate to lactate. Lactic acidosis is a likely cause in this case given that our patient had a history of alcohol abuse and presented with high anion and osmolar gaps, elevated lactate and alcohol, and

negative ketone and organic alcohol levels Though our patient had a frontal stroke on MRI, those are not usually associated with vision loss. Other considered causes include amaurosis fugax, PRES, and hypertensive emergency, though based on negative MRI, and symptom resolution after acid/base correction, lactic acidosis was deemed to be a likely cause Although rare, severe acidosis should be ruled out in cases of acute blindness, and correction of acidosis should take place while investigating other causes

## SA-PO504

### Post-Operative Severe Hypercalcemia: A Tale of Two Patients

Amer A. Belal, Sanaa Badour, Joel O. Adewuyi, Amir Kazory. *University of Florida College of Medicine, Gainesville, FL.*

**Introduction:** Calcium sulfate beads are increasingly used as a means for delivery of local antibiotics in periprosthetic joint infections. Hypercalcemia is an emerging complication after placement of the beads that is poorly characterized. Certain subset of patients (e.g. those with chronic kidney disease [CKD]) seem to be particularly susceptible and need to be risk stratified prior to surgery.

**Case Description:** A 72-year-old woman with a medical history significant for CKD and metastatic papillary thyroid cancer to the right femur was admitted for second revision of right total hip arthroplasty. Her serum calcium (Ca) was noted to rise rapidly from 9.1 mg/dL preoperatively to 11.1 mg/dL on postoperative day (POD) 3. She underwent workup for causes of hypercalcemia with PTH that was appropriately suppressed at 4 pg/m, ionized Ca elevated at 2.0 mmol/L, VitD(25)OH within normal range at 30.65 ng/mL as was VitD(1,25)OH at 25.3 pg/mL. PTHrP was unremarkable at 4 pmol/L, as was Angiotensin Converting Enzyme at 80 U/L. Labs were inconsistent with multiple myeloma. Her serum creatinine (Cr) remained relatively stable at 4 mg/dL during this time. Further investigation revealed that she had insertion of calcium sulfate beads during surgery. Her Ca continued to rise and peaked on POD 7 at 15.8 mg/dL despite medical management including aggressive hydration with 150-200 cc/hour of normal saline, 8 doses of calcitonin, as well as pamidronate on POD 5. Only after 23 days, did her Ca return to a normal level below 10 mg/dL. Contrast this with the case of a 77-year-old woman with normal renal function (Cr 0.7 mg/dL) that was admitted due to prosthetic joint infection of the knee, also with intraoperative placement of calcium sulfate antibiotic eluting beads. Her serum Ca preoperatively was 8.3 mg/dL and rose to 14.1 mg/dL on POD 2, but responded to conventional medical therapy with steady decline and return to normal range of less than 10 mg/dL within 7 days.

**Discussion:** These two cases serve to raise awareness regarding post-operative hypercalcemia that can result from calcium sulfate beads used for local antibiotic therapy. Of note, in patients with advanced CKD, hypercalcemia can be prolonged despite appropriate medical therapy leading to increased morbidity. With increasing use of calcium-eluting beads, we propose that this point needs to be included in pre-operative risk stratification

## SA-PO505

### Paracoccidioides brasiliensis Infection, a Tropical Disease Causing Severe Hypercalcemia and AKI: A Case Report

Renan G. Diniz, Lucia Andrade, Luciana G. Lutf, Fernando L. Strufaldi. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

**Introduction:** Paracoccidioidomycosis is a systemic fungal disease that is prevalent in Brazil. Although it can affect multiple organs, the renal and electrolytic effects are not well known.

**Case Description:** A 30-year-old man from an urban area of the state of São Paulo presented with disseminated papular and nodular skin lesions, some with fistulation and purulent discharge, together with lymph node enlargement, right hypochondrium pain, fever, night sweats, anorexia and weight loss (25 kg). Direct microscopic analysis of the lesions revealed fungal yeast consistent with *Paracoccidioides brasiliensis*. The patient showed normocytic, normochromic anemia (hemoglobin 7.7 mg/dL) and the following: urea 55 mg/dL; creatinine 1.43 mg/dL; sodium 134 mEq/L; potassium 4.2 mEq/L; total calcium (TCa) 12.6 mg/dL; ionized calcium (iCa) 7.3 mg/dL; phosphorus 3.2 mg/dL; parathyroid hormone <6 pg/mL; 25-hydroxy-vitamin D 17 ng/mL; and alkaline phosphatase 596 U/L. Bilirubin, TSH and urinalysis were all normal. Serology for viruses, syphilis and toxoplasmosis were all negative. His 1,25-dihydroxyvitamin D was elevated (94 ng/dL). A CT scan showed no bone lesions. He received intravenous pamidronate 60 mg and saline infusion. Amphotericin B deoxycholate was prescribed but later switched to amphotericin B lipid complex because the clinical profile had improved. On postadmission day 20, creatinine was 0.77 mg/dL, iCa was 5.82 mg/dL and TCa was 10.2 mg/dL. He was discharged on day 49 with significant improvement of the skin lesions, creatinine of 0.7 mg/dL, iCa of 5.03 mg/dL and TCa of 9.4 mg/dL.

**Discussion:** We suggest that the hypercalcemia was associated with endogenous release of 1,25-dihydroxyvitamin D from paracoccidioidomycosis lesions. To our knowledge, this is only the third reported case of paracoccidioidomycosis accompanied by hypercalcemia and the only one in which the patient had a high 1,25-dihydroxyvitamin D level. Although a wide spectrum of neglected tropical diseases are still under investigation, we cannot neglect new findings in this field, given the complexity and peculiarities of this group of diseases. Such findings can allow earlier diagnosis, new discoveries and better treatments.

## SA-PO506

**Chronic Hypercalcemia Secondary to Granulomatous Formation After Buttock Augmentation: Case Report**

Christopher A. Dorizas, Brianna Conte, Anushka Chadha, Desiree Garcia Anton. *University of Miami School of Medicine, Miami, FL.*

**Introduction:** Hypercalcemia is a medical condition often encountered in the clinical setting. While common causes of hypercalcemia include hyperparathyroidism, malignancies, and medications, granulomatous-mediated hypercalcemia from previous cosmetic silicon injections is a rare cause that should be considered.

**Case Description:** A 65-year-old female with hypertension, diabetes mellitus type 2, and recent diagnosis of hypercalcemia of unknown etiology presented to the ED after a syncopal episode from symptomatic hypercalcemia. Vital signs were stable. Physical exam was remarkable for altered mental status. Initial labs showed calcium 17.8 mg/dL, ionized 1.74 mmol/L, normal albumin, PTH 12.8 pg/mL, BUN 46 mg/dL and Cr 2.66 mg/dL, with unknown baseline. Renal ultrasound showed echogenic parenchyma. Intravenous fluids and calcitonin 4 units/kg BID were initiated. PTHrP was negative ( $< 2$  pmol/L) and vitamin D 1,25 dihydroxy was at the upper limit of normal (71.8 nG/mL). Additional workup for sarcoidosis, lymphoma, thyrotoxicosis, and multiple myeloma was unrevealing. The patient noted a history of gluteal silicone injections 10 years ago. PET scan (low level FDG uptake in the subcutaneous tissues of the gluteal regions and proximal thigh) and inguinal lymph node biopsy (granulomatous lymphadenitis) confirmed granulomatous-mediated hypercalcemia. Surgical intervention was not recommended given dissemination. Zoledronic acid 4 mg IV was added along with prednisone 20 mg with taper and Hydroxychloroquine (HCQ) 200 mg daily. Calcium improved to 9.9 mg/dL and creatinine to 1.9 mg/dL.

**Discussion:** Hypercalcemia secondary to cosmetic silicone injections is a rare entity, only about two dozen cases have been reported in the literature. Unfortunately, no definitive therapies exist for this calcitriol-mediated hypercalcemia. Additionally, it carries a significant morbidity burden including lifelong side effects, chronic steroid exposure and development of CKD. HCQ could be a potential treatment option to lower the steroid burden. Awareness must be raised about this disease and clinicians should consider it as a cause of hypercalcemia, especially in an era of increasingly frequent cosmetic procedures.

## SA-PO507

**Hypercalcemia, It's Not Always Cancer: Unique Case of Sarcoidosis Presenting as a Testicular Mass**

Azkaa Zaman, Navkiran Randhawa, Suraj Marwaha, Norhan Elsayed, Ramier J. Lehne, Mohammad H. Wadud, Sunil Patel, James J. Siegert, April Brill, Tauseef A. Sarguroh. *Franciscan Health Inc, Mishawaka, IN.*

**Introduction:** Sarcoidosis is a multi-system disease typically seen in young adults with a prevalence of about 50 to 160 per 100,000 population worldwide. The disease pathology is thought to involve the accumulation of T lymphocytes, mononuclear phagocytes and noncaseating granulomas in the lungs, eyes, skin and lymph nodes. We report a unique case of systemic sarcoidosis in a patient with severe hypercalcemia, acute renal failure and a testicular mass.

**Case Description:** A 44 year old male with history of Hypertension, Type 2 Diabetes, Obesity presented with a painless left testicular mass and 70 pound weight loss over five months. On admission he was noted to have a serum creatinine of 4.6 mg/dL, serum calcium of 17.2 mg/dL with appropriately suppressed intact PTH of 7 pg/mL and an elevated vitamin D 1,25-dihydroxy of 80.2 pg/mL. A kidney biopsy showed acute tubular necrosis with no immune complex deposition or paraprotein mediated disease. CT chest, abdomen and pelvis revealed several bilateral pulmonary nodules and diffuse lymphadenopathy including mediastinal, periaortic and bilateral inguinal chains. A scrotal ultrasound revealed a solid calcified mass lateral to the left testis. Urology performed a left inguino femoral lymph node dissection and a left partial orchiectomy. Frozen section was negative for malignancy and final pathology showed granulomatous lymphadenitis consistent with sarcoidosis. The patient was treated medically for hypercalcemia and discharged on oral corticosteroids.

**Discussion:** Typically, sarcoidosis presents with pulmonary symptoms. This is a rare presentation of severe hypercalcemia in a patient with a testicular mass which emphasizes that physicians should be aware of extrapulmonary manifestations of sarcoidosis when evaluating a patient presenting with hypercalcemia and renal failure.

Calcified mass superior to left testis on ultrasound

## SA-PO508

**Bad to the Bone: Refractory Hypercalcemia due to Limited Bone Marrow Sarcoidosis**

Kaushika Kondragunta, Erin Townsley, Phillip Madonia, Uday Vemulapalli. *Brookwood Baptist Health, Birmingham, AL.*

**Introduction:** Sarcoidosis limited to the bone marrow is a rare diagnosis.

**Case Description:** A 69 y.o. white woman with history of osteoporosis, chronic kidney disease stage 3, silicone breast implants presented with nausea, vomiting, and malaise. Vital signs on admission were stable. Labs were significant for an albumin of 3.3 g/dL, calcium of 14.1 mg/dL (corrected to 14.7mg/dL). She had two prior hospitalizations for volume depletion, with hypercalcemia to a level of 12-13mg/dL, and acute kidney injury which rapidly corrected with IV fluids. However, the recurrence of severe hypercalcemia necessitated further investigation. On admission, parathyroid hormone (PTH) was 55 pg/mL, PTH-related protein was 22 pg/mL, so PTH mediated hypercalcemia was unlikely. Vitamin D 25 level was 35 pg/mL, and angiotensin converting enzyme (ACE) levels were  $<5$ . Urine calcium was not low. Serum cortisol was normal. Mildly elevated vitamin D1,25 at a level of 81 pg/mL was noted. Differential diagnoses included sarcoidosis, multiple myeloma, foreign body granuloma and infectious granulomatosis. Skeletal survey showed no bony lesions. Myeloma panel showed an M spike of 0.5g/dL, immunofixation with IgM lambda, elevation of kappa/lambda light chains 5.12, and 9.19 mg/dL respectively, but total IgM kappa/lambda ratio was normal. A normal PET scan ruled out a silicone granuloma associated with her breast implants. Sarcoidosis was the final diagnosis considered. A bone marrow biopsy was performed, which was negative for polyclonal cells, malignancies, acid fast bacteria, and fungi. It showed scattered deep-seated non caseating granulomas consistent with sarcoidosis. She had complete resolution of hypercalcemia with 60 mg prednisone, tapered over 3 months.

**Discussion:** Diagnosing sarcoidosis from only hypercalcemia and elevated vitamin1,25 D without any other findings on imaging made this diagnosis clinically challenging. The step wise approach to rule out other etiologies led to a bone marrow biopsy, confirming the diagnosis. Chest X-ray and ACE levels are often used to screen for sarcoidosis, but are not very sensitive. Physicians should consider a bone marrow biopsy when there is high suspicion for granulomatous hypercalcemia. The tissue would need to be evaluated for infectious, hematologic, allergic, and other auto immune disorders causing granulomatous lesions.

## SA-PO509

**A Rare Case of Calcium Tartrate Nephrolithiasis**

Madeline S. Chung, Amy Yau. *The Ohio State University Wexner Medical Center, Columbus, OH.*

**Introduction:** Calcium tartrate tetrahydrate nephrolithiasis is rare with only a handful of cases noted in the literature. Initially reported in rats with a high tartrate diet, the stone spectra was later identified in 6% of previously unidentified human kidney stones with a general incidence of 0.007%.

**Case Description:** We present a 39-year-old woman with no significant past medical history who presented with flank pain due to a 5 mm distal left ureteral stone at the ureterovesical junction. She underwent uncomplicated ureteroscopy with basket stone extraction with removal of two kidney stones (2mm and 5mm in diameter). Stone analysis was significant for 50% calcium tartrate tetrahydrate, 30% calcium oxalate monohydrate, and 20% calcium phosphate. Metabolic evaluation was unremarkable with normal 25-OH vitamin D, intact parathyroid hormone, and calcium levels. 24-hour urine samples were significant for low urine volume and hypercalciuria (Table 1). She had no previous history of kidney stones. Upon further questioning, she admitted to consuming 1-2 scoops of Spark energy drink mix daily for the past 5 years. Each scoop of this drink mix contains 10mg of L-carnitine as tartrate and 500mg of choline as bitartrate and citrate. She denied any other supplements nor high consumption of tartrate-containing substances such as wine or free baking powder. She was encouraged to avoid AdvoCare Spark, increase her fluid intake and re-assess hypercalciuria in 6 months.

**Discussion:** This is the fourth reported case of a calcium tartrate tetrahydrate stone with an associated history. The first was a patient in Africa with unknown history. Later retrospective analysis of the Mayo Clinic database revealed 35 stones consistent with calcium tartrate tetrahydrate in 27 unique patients, but only three had available history. All three also consumed AdvoCare Spark energy drink mix regularly. We believe that excessive tartrate intake via the Spark Energy Drink mix is what precipitated the kidney stone in our patient. Her case is a cautious reminder to obtain a full social and dietary history in patients with unknown or rare stone profile and those with or recurrent stones despite appropriate risk factor modification.

Table 1

Date	Vol 24	Ca 24	Ox 24	Cit 24	pH	UA 24	Na 24	Mg 24

## SA-PO510

### A Case of Hypercalcemia Exacerbated by Ectopic 1,25(OH)<sub>2</sub>D Expressed in Post-Transplant Lymphoproliferative Disorder (PTLD) 13 Years After Kidney Transplantation

**Kazumi Kozuka**, Yosuke Nakagawa, Konomi Isozumi, Masahiro Koizumi, Hirotaka Komaba, Takehiko Wada, Masafumi Fukagawa. *Tokai Daigaku Igakubu Jin Naibumpi Taisha Naika, Isehara, Japan.*

**Introduction:** Post-transplant lymphoproliferative disorder (PTLD) develops in 1-3% of kidney transplant recipients. Paraneoplastic hypercalcemia is frequently seen in patients with malignant lymphoma, but is rarely seen in patients with PTLD. Here, we report a case of PTLD presenting with progressive hypercalcemia associated with ectopic calcitriol synthesis at 13 years following deceased donor kidney transplantation.

**Case Description:** A 59-year-old man was admitted to our hospital with a 6-week history of generalized weakness, appetite loss, and extremities edema. He had been on hemodialysis for 23 years and had received a deceased donor kidney transplant 13 years before presentation. He showed no evidence of rejection with immunosuppressants, and his serum creatinine persisted 1.5 to 1.6 mg/dL thereafter. He also had secondary hyperparathyroidism which was well controlled by oral calcimimetics. On examination, he showed severe pitting edema of extremities particularly in the left leg and swollen left knee joint. His serum calcium increased from 10.6 to 15.6 mg/dL for 6 weeks, with suppressed parathyroid hormone (PTH) level (58 pg/mL) and undetectable PTH-related peptide level. Further investigations revealed an increased 1,25(OH)<sub>2</sub>D level of 122 pg/mL (normal range 20-60). Analysis of the knee joint fluid showed atypical lymphocyte infiltration, and flow cytometry revealed a monoclonal lambda-restricted B-cell population, suggesting B cell lymphoma. He was treated with intravenous normal saline and subsequently with a dose of denosumab, but he developed severe acidemia with worsening kidney function and became hemodynamically unstable. Continuous hemodialysis was started on hospital day 2. He underwent R-CHOP treatment, but the lymphoma did not respond to the treatment, and he died on hospital day 6. Autopsy showed massive lymphoma infiltration in iliopsoas muscle, residual kidneys, large and small intestine, and the patient was finally diagnosed as diffuse large B-cell lymphoma. An increased level of 1,25(OH)<sub>2</sub>D suggested ectopic calcitriol synthesis in the lymphoma.

**Discussion:** PTLD should be considered as a differential diagnosis of unexplained hypercalcemia in kidney transplant recipients.

## SA-PO511

### Severe Hypercalcemia due to Hypervitaminosis D

**Kuldeep Lohano**, Sharma S. Prabhakar. *Texas Tech University Health Sciences Center, Lubbock, TX.*

**Introduction:** Hypercalcemia is not an uncommon clinical problem but hypervitaminosis D causing hypercalcemia is very uncommon. We are reporting a patient who presented with this unusual condition.

**Case Description:** A 71 year old frail Caucasian male, presented to ER secondary to a fall. The past medical history was significant for coronary heart disease, hypertension, CHF, COPD, rheumatoid arthritis (on prednisone), right femoral fracture and no history of CKD. A CT scan with contrast on admission revealed a left intertrochanteric fracture and multiple vertebral fractures. On admission, laboratory studies were remarkable for hypercalcemia (14.2 mg/dL), HB: 12.9 g, platelet count of 446k and IWBC count of 33k. Serum Cr was 0.9 mg/dL, albumin 3.9 g/dL, and, BUN: 39 mg/dL. On examination, patient was hypovolemic, confused, chronic RA changes in hands. Diagnostic work up was negative for Multiple myeloma and malignancy. Further interrogation revealed a history of high dose of vitamin D (10,000 IU daily) for a long period which correlated with a vitamin D level of 200 ng/ml and PTH of 16 pg/ml. He was started on IV fluids and calcitonin and furosemide. The hypercalcemia improved on 3rd day while renal function continued to worsen after second day (Scr 1.3 to 2.0 mg/dl) possibly due to contrast induced renal injury. Subsequent course in the hospital was notable for return of calcium levels to 9.5mg/dl and improving renal function on discharge.

**Discussion:** The purpose for reporting this case is two-fold. 1. Vitamin D is rare cause of hypercalcemia, often resulting from prolonged over consumption of vitamin D and calcium supplements without monitoring the serum levels. 2. Consequences of hypercalcemia include dehydration, risk of acute kidney injury, and increased risk of bone fracture. The cause of hypercalcemia in this patient initially was not obvious as hyperparathyroidism, malignancy (multiple myeloma), hyper-thyroidism and adrenal insufficiency were excluded but finally it was narrowed down to hypervitaminosis D.

Initial hemoconcentration due to hypovolemia, was confirmed by normalization of many lab abnormalities after IV fluids. Hypercalcemia could be a contributory factor to AKI (caused by the radio-contrast) as well as to bone fracture by decreased bone turn over due to low PTH and cumulative steroid use. To conclude this case exemplifies how hypercalcemia can result from an usual cause and lead to multiple complications.

## SA-PO512

### Man of Steel: Calcitriol-Mediated Hypercalcemia From Subcutaneous Injection of Vitamin D3 in Sesame Oil

**Anushka Chadha**,<sup>1,2</sup> Efren Chavez.<sup>2,1</sup> *<sup>1</sup>Jackson Memorial Hospital, Miami, FL; <sup>2</sup>University of Miami School of Medicine, Miami, FL.*

**Introduction:** Parathyroid hormone (PTH) independent hypercalcemia in young patients is rare. Differential diagnosis include malignancy, granulomatous diseases, adrenal insufficiency and drug-induced hypercalcemia. We report a case of a young athlete who developed calcitriol-mediated hypercalcemia due to granulomatous disease from oil-based subcutaneous (SQ) injections.

**Case Description:** A 31 year-old male, professional Jiu-jitsu player with no prior history, presented to the ED with worsening nausea, headaches, night sweats and weight loss over several weeks. He just completed a 3 month physician-supervised body building program, taking multiple drugs to increase strength and muscle mass- including daily oral danazol 100 mg, anastrozole 1 mg, DHEA 100 mg, clomiphene citrate 50 mg, bi-weekly intramuscular HCG 10,000 IU and weekly SQ injections of vitamin D3 in sesame oil 100,000 units/mL. On admission, vital signs were stable. Labs with elevated corrected calcium 12.4 mg/dL, ionized calcium 1.97 mmol/L, and acute kidney injury (AKI) with creatinine 4.2 mg/dL (baseline creatinine 0.95 mg/dL). He was initially treated with normal saline, calcitonin and zoledronic acid 3 mcg infusion. On further work up, he had low intact PTH 5.58 pg/mL, undetectable PTH related peptide but elevated 1,25 (OH)<sub>2</sub> Vitamin D 146 pg/mL. Screening for sarcoidosis, tuberculosis and fungal infections was negative. Imaging did not show masses, lymphadenopathy or organomegaly. However, a whole body FDG PET/CT scan had hypermetabolic uptake with skin thickening in the right thigh and anterior pelvic wall, corresponding to areas of administered SQ Vitamin D3. He was treated with oral prednisone, achieving and sustaining resolution of hypercalcemia and AKI.

**Discussion:** Hypercalcemia with suppressed PTH has been attributed to use of cosmetic body fillers- silicone and methyl methacrylate injections. Bodybuilders and athletes similarly use oil-based injections to augment muscle size. Biopsies from those areas demonstrate a foreign body reaction with granuloma formation and express 1 $\alpha$ -hydroxylase activity; this suggests hypercalcemia is due to increased calcitriol synthesis and intestinal calcium absorption. Our case demonstrates the dangers of abusing improper medications for body building and how providers should be vigilant to identify use of oil-based injections and its association with hypercalcemia

## SA-PO513

### A Not So Clear Case of Hypercalcemia

**Andrei Felipe S. Carvalho**, Shawn Alonso, Kara Alcegueire, Ahmed A. Waheed. *University of Miami Health System, Miami, FL.*

**Introduction:** Hypercalcemia is a frequent finding in clinical practice and is most commonly due to primary hyperparathyroidism or an underlying malignancy.<sup>1</sup> Therefore, it is generally recommended that the initial workup begin with determining whether the cause is either parathyroid hormone (PTH)-dependent or independent.<sup>1,2</sup> Although this approach is helpful in most cases, here we present a case where the cause is not quite so clear.

**Case Description:** A 67-year-old woman with a history of hypertension and chronic kidney disease stage 3a, presented with one week of abdominal pain and constipation. On arrival, her vitals were normal, and her exam was notable for mild abdominal tenderness. Initial labs revealed hypercalcemia with a calcium 12.6mg/dL, albumin 3.9g/dL, phosphorus 2.4mg/dL, hemoglobin 9.7g/dL and an elevated creatinine of 2.8mg/dL, with a baseline 1.8mg/dL. Serum PTH was elevated at 677pg/mL, and 25-OH vitamin D was low-normal at 31ng/mL. Imaging showed an 11mm parathyroid mass suspicious for an adenoma, which was presumed to be the cause of the hypercalcemia. However, despite adequate intravenous fluids, the patient's kidney function did not improve as expected, which in addition to the patient's age and the anemia, prompted further workup. The patient was then found to have an IgG-kappa monoclonal gammopathy, which led to a bone marrow biopsy revealing 20% plasma cells. The patient was diagnosed with multiple myeloma.

**Discussion:** Although the hypercalcemia was likely driven by the parathyroid adenoma given the degree of PTH elevation, we suspect that the multiple myeloma was also likely contributing. Interestingly, although the exact mechanism remains unknown, there are numerous case reports, dating back decades, and even a small prospective study describing an association between monoclonal gammopathies, including multiple myeloma, and primary hyperparathyroidism.<sup>3,4,5</sup> Given the prevalence of reported cases, some authors suggest ruling out a coexisting monoclonal gammopathy at the time of diagnosis of primary hyperparathyroidism, particularly in the elderly and those with difficult to control hypercalcemia.<sup>5,6,7</sup> As seen in this case, had it not been for the additional lab abnormalities the diagnosis of myeloma would have likely been delayed. Thus, this case gives us an opportunity to highlight a clinically important association between primary hyperparathyroidism and monoclonal gammopathies.

## SA-PO514

**Hypercalcemia: A Harbinger of Recovery From Rhabdomyolysis?**

Dawn Maldonado, Joseph Guadalupe, Temi-Ete I. Ediale, Cora O. Ogbolu, Maritza Brown, Aaron S. Stern. *Mount Sinai Health System, New York, NY.*

**Introduction:** Hypercalcemia occasionally develops following renal recovery from rhabdomyolysis. We describe a case of hypercalcemia developing just prior to renal recovery. This case suggests that not only can hypercalcemia develop after rhabdomyolysis, but that it can sometimes be a sign of imminent recovery.

**Case Description:** We present a case of a 65-year-old man with a past medical history of hepatitis C who was brought to the emergency department after prolonged cold exposure. He was hypothermic at 30.4 Celsius and had frostbite of multiple digits. Laboratory results were significant for a markedly elevated serum creatine kinase level >22,000 units/L and serum creatinine 4 mg/dL with unknown baseline. He did not respond to aggressive fluid resuscitation; hence dialysis was initiated. Corrected serum calcium was 5.8 mEq/L on hospital day 2, and remained low until it started to rise beyond normal levels on hospital day 28, peaking at 14.4 meq/L on hospital day 41 (table 1). Therapy was initiated with calcitonin and lower calcium dialysate. On hospital day 43 he began making urine, so dialysis was held. Hypercalcemia work-up revealed parathyroid hormone 9.9 pg/mL, vitamin D-25 9 ng/mL, vitamin D1-25 <5 ng/mL, fractional excretion of calcium 0.05, parathyroid-related hormone <2 pg/mL, and alkaline phosphatase 79 U/L – thus ruling out more common causes of hypercalcemia. N-telopeptide/creatinine ratio was 54 (normal 0-62), which ruled out hypercalcemia of immobilization. These results led us to the conclusion that the hypercalcemia was due to recovery from rhabdomyolysis.

**Discussion:** Hypercalcemia can be seen in the setting of recovery from rhabdomyolysis. The mechanism remains unclear, but it is postulated that it is from mobilization of calcium deposits that are sequestered in damaged muscle tissue. We present a case where the patient started developing hypercalcemia shortly before other signs of kidney recovery. Our case suggests that hypercalcemia may at times be the first indication of renal recovery from rhabdomyolysis.

## SA-PO515

**Bones, Groans, and Thyroid Hormones: A Rare Case of Hyperthyroidism Induced Hypercalcemic Crisis**

Neha Siddiqui,<sup>1</sup> Ram Sinha,<sup>1</sup> Jatinder Kohli.<sup>1,2</sup> *<sup>1</sup>AtlantiCare Regional Medical Center, Atlantic City, NJ; <sup>2</sup>Shore Medical Center, Somers Point, NJ.*

**Introduction:** Mild to moderate hypercalcemia can be seen in patients with hyperthyroidism, but serum calcium levels rarely exceed more than 12mg/dL. The mechanism of hyperthyroidism-induced hypercalcemia is not fully understood. However, it is proposed that an elevation in thyroid hormone can stimulate bone turnover and, therefore, cause an increase in serum and urine calcium levels with subsequent suppression of PTH levels.

**Case Description:** A 36-year-old male with a past medical history of IV drug use, hypertension, and untreated hyperthyroidism presented to the emergency department with increasing dyspnea, non-productive cough, dizziness, nausea and vomiting for three days. The patient also endorsed palpitations, hot flashes, and weight loss over the last few months. No known family history of thyroid disease, hypercalcemia, or malignancy. Physical examination was remarkable for tachycardia and tremors. His labs were significant for a corrected calcium of 12.2mg/dl and TSH <0.005. Serum creatinine was within normal limits. UDS was unremarkable, PTH was suppressed, the PTHrP was normal, vitamin D levels were low, and SPEP was unremarkable. The patient received a 2L fluid bolus in the emergency department and was started on maintenance IVF. Upon further investigation, the patient had T3 of >20, elevated free T4 >7.77, Thyroxine (T4) of 23.8, TSIG, and thyroid receptor antibody were positive. NM bone scan showed no osteolytic or osteoblastic lesions. The patient received calcitonin for two days while conducting hypercalcemia workup. The patient was on IV steroids for a brief period of time as treatment for possible thyroid storm. The patient was started on methimazole and propranolol, both of which were continued upon discharge. Serum calcium levels and symptoms responded to treatment.

**Discussion:** To the best of our knowledge, there are four reported cases of hyperthyroidism-induced hypercalcemic crises with a serum calcium level of 12mg/dl (3mmol/dl) or more. We present a case of a 36-year-old male with symptomatic hypercalcemia with a calcium level of 12.2 upon arrival. Although rare, hyperthyroidism should be considered a cause when all other etiologies of hypercalcemic crisis have been ruled out. Immediate volume expansion and treatment with anti-thyroid medications are the mainstay of management of hyperthyroidism-induced hypercalcemia.

## SA-PO516

**Hypercalcemic Crisis as a Presentation of Parathyroid Adenoma: An Atypical Clinical Case Study**

Alexandra Rosario Aulet, Yolanda I. Hidalgo-Hernandez. *Sistema de Salud Episcopal San Lucas, Ponce, Puerto Rico.*

**Introduction:** Hypercalcemia is a common electrolyte disturbance seen in both outpatient and as in patient setting. Normal calcium levels range between 8.6 -10.3mg/dL. Mechanism of hypercalcemia vary in association to the cause, from increase gastrointestinal absorption and bone resorption associated to hypervitaminosis D, to increased bone resorption with tubular reabsorption associated to hyperparathyroidism. Primary hyperparathyroidism and malignancy are the most common causes of hypercalcemia. Primary hyperparathyroidism levels usually elevated but less than 11mg/dL in more rare but severe cases >12mg/dL, levels >13mg/dL usually seen with malignancy and less commonly seen in primary hyperparathyroidism.

**Case Description:** Case of a 69 y/o female patient with a PMHx of alcohol use disorder, peptic ulcer disease, active smoker being work up as outpatient due to a thyroid nodule which presents to the ED due to disorientation, epigastric pain, constipation associated to 30lbs of unintentional weight loss that has been progressing over the last month. During evaluation patient found oriented x2, GCS 14/15, with unstable gait and benign abdominal examination. Laboratory work up noted for a severe hypercalcemia of 18.4md/dL. Symptoms were refractory to medical treatment with IVF and bisphosphonates requiring renal replacement therapy. Work up done reported primary hyperparathyroidism, which FNA biopsy confirmed parathyroid adenoma. ENT was consulted and left parathyroidectomy and left lobe hemithyroidectomy was performed.

**Discussion:** Parathyroid crisis is a rare presentation to a parathyroid adenoma. Seen in 1-2% patient with known primary hyperparathyroidism. Parathyroid crisis presents with severe hypercalcemia associated central nervous system dysfunction like changes in mental status, bone disease, nephrolithiasis, or severe abdominal pain. We want to bring awareness to the medical community about diagnosis and treatment since this could be a rare but fatal endocrinology emergency.

## SA-PO517

**Ogilvie Syndrome: Treatment of Hypokalemia With Amiloride Unmasked Hypercalcemia and Hyperparathyroidism**

Alexa Golbus, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

**Introduction:** Colonic pseudo-obstruction, also called Ogilvie's syndrome, occurs due to impaired intestinal propulsion and is often caused by hypokalemia and some endocrine disorders such as hyperparathyroidism. Additionally, secretory diarrhea due to intestinal pseudo-obstruction can cause hypokalemia. Diuretics such as amiloride can be used to treat hypokalemia in this condition. Amiloride is used to decrease excretion of sodium without increasing reabsorption of calcium, however in our case, we believe that amiloride induced hypercalcemia by unmasking hyperparathyroidism.

**Case Description:** We present a 73-year-old female with a history of hypertension and parathyroid adenoma, presenting with colonic pseudo-obstruction and hypokalemia. She has refused decompression of her pseudo-obstruction. Given concern for Liddle's syndrome based on her chronic hypertension, low plasma aldosterone and renin, and hypokalemia, we treated her hypokalemia with amiloride. This caused hypercalcemia to 14.4 mg/dL and altered mental status. The amiloride was subsequently discontinued with improvement in her symptoms and her primary hyperparathyroidism was treated with cinacalcet.

**Discussion:** Amiloride inhibits sodium reabsorption at the ENaC channel (epithelial sodium channel) in the late distal convoluted tubule, which causes a decreased negative potential in the lumen, resulting in decreased potassium excretion and thus an increase in serum potassium. In our patient, however, this caused an increase in serum calcium. Amiloride is theorized to induce hypercalcemia by increasing calcium reabsorption in the late distal convoluted tubule and the connecting tubule. While the mechanism is not fully known, it is thought that diuretic induced cellular hyperpolarization results in an increased electrical gradient that favors calcium reabsorption. Although our patient's parathyroid hormone level was normal prior to treatment with amiloride, her PTH became elevated with treatment with amiloride. We believe that amiloride unmasked her hyperparathyroidism and induced hypercalcemia.

## SA-PO518

**Platinum Based Chemotherapy Related Hypomagnesemia Treated With Sodium Glucose Cotransporter 2 (SGLT2) Inhibitors in Non-Diabetic Cancer Patients**

Nour Hammad, Arash Rashidi. *University Hospitals, Cleveland, OH.*

**Introduction:** Platinum based chemotherapy, such as cisplatin and carboplatin, is known to cause hypomagnesemia by renal magnesium wasting. Sodium glucose co-transporter 2 (SGLT2) inhibitors are new class of type 2 diabetes drugs with growing popularity because of their renal and heart benefits beside their diabetes indication. This class of medications was found to elevate serum magnesium levels by 0.15-0.24 mg/dl in prior meta-analysis. We present three patients with refractory hypomagnesemia related to cisplatin/carboplatin who were treated with SGLT2 inhibitors with marked improvement in serum magnesium levels.

**Case Description:** Case 1: 75 year old female with history of stage 3C serous ovarian cancer status post debulking procedure and chemotherapy with docetaxol and carboplatin. She had multiple electrolyte abnormalities including hypokalemia and hypomagnesemia that partially improved after ostomy closure. She continued to have refractory hypomagnesemia treated with oral and intravenous magnesium. Case

2 57 year old female with history of stage 3C endothelial varian cancer status post debulking procedure and chemotherapy with carboplatin and docetaxol. She developed hypomagnesemia requiring intravenous and oral magnesium replacements. Case 3: 57 year old male with T2N3M0 left supraglottic cancer treated with cisplatin, 5-fluorouracil, and pembrolizumab. He was noted to have hypokalemia and hypomagnesemia which was dependent on oral and intravenous magnesium. All three patients were later started on amiloride, however continued to be dependent on oral and intravenous magnesium despite increasing amiloride dose. They were later started on dapagliflozin and had normalization of serum magnesium off intravenous supplementation.

**Discussion:** Hypomagnesemia can occur at any time with platinum based chemotherapy and can last after discontinuation of the drug. Our patients developed refractory hypomagnesemia on oral and intravenous magnesium supplementation in addition to incremental doses of amiloride. Dapagliflozin was started and patient had improved magnesium level with discontinuation of intravenous supplementation.

## SA-PO519

### The Dominant Cause of Cramping Muscles

Christina L. Blum, Maura A. Watson, Megha R. Joshi. *Walter Reed National Military Medical Center, Bethesda, MD.*

**Introduction:** Magnesium ( $Mg^{2+}$ ) is the second most abundant intracellular cation. The human body contains about 24g of  $Mg^{2+}$  with normal serum concentration 1.7-2.5mg/dL.  $Mg^{2+}$  influences neuromuscular excitability, mitochondrial function and cellular proliferation. Clinical hypomagnesemia (hypo $Mg^{2+}$ ) ranges from asymptomatic to cramping, seizures and death. Investigating the cause of hypo $Mg^{2+}$  assists prompt management and prevents life threatening complications.

**Case Description:** A 37 year-old male with no significant medical or family history was hospitalized in 2015 for fatigue, profound diarrhea and dehydration. Labs revealed hypo $Mg^{2+}$  and supplementation was started; an extensive workup did not reveal an etiology. He continued to have muscle fasciculation, fatigue, cramping and decreased stamina despite taking  $Mg^{2+}$  1064mg and two Phos-Nak packets twice daily (phos 8mmol/packet). Calcium was 8.9mg/dL, (alb 3.9g/dL),  $Mg^{2+}$  1.1mg/dL, phosphorous 3.1mg/dL, urine calcium <5mg/dL and  $Mg^{2+}$  8.2mg/dL with fractional excretion of Mg 13%. After a trial of amiloride 20mg daily; his  $Mg^{2+}$  remained 1.1mg/dL, potassium 3.5, and phos 2.9. He discontinued amiloride and resumed high dose  $Mg^{2+}$  supplements. Genetic testing revealed a pathogenic variant on gene *FXYD2* c.121G>A, p.Gly41Arg.

**Discussion:** Isolated dominant hypo $Mg^{2+}$ , *FXYD2* c.121G>A, p.Gly41Arg, an autosomal dominant Gitelman-like hypo $Mg^{2+}$ , is a rare genetic cause of hypo $Mg^{2+}$  affecting the subunit of Na<sup>+</sup>-K<sup>+</sup>-ATPase protein of the distal convoluted tubule. The  $\gamma$ -subunit is misrouted and the  $\alpha$ - and  $\beta$ -subunit of the Na<sup>+</sup>-K<sup>+</sup>-ATPase cannot form, resulting in reduction of Na<sup>+</sup>-K<sup>+</sup>-ATPase activity decreasing  $Mg^{2+}$  uptake and increasing renal  $Mg^{2+}$  losses. The average  $Mg^{2+}$  concentration with this mutation is of 1.142mg/dL (0.47mM). Incidence unknown. The gene was discovered in 2000 in 3 Dutch families (29 patients) who presented with tetany, muscle weakness, chondrocalcinosis, excessive thirst, polyuria and less commonly epilepsy, kidney failure, or arrhythmias. Treatment is  $Mg^{2+}$  supplementation. Genetic testing is an important tool for early diagnosis and prompt management. Ongoing research in hereditary hypo $Mg^{2+}$  is needed to further our understanding of *FXYD2* mutations. The views expressed are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, or the United States government.

## SA-PO520

### Rare Co-Existence of Osteogenesis Imperfecta and Familial Renal Phosphorus Wasting

Sidrah Abid, Krishnakumar D. Hongalgi, Kelly H. Beers. *Albany Medical Center, Albany, NY.*

**Introduction:** Osteogenesis imperfecta (OI) is a severe disease with a wide spectrum of presentations depending upon the genetic abnormality. Known as a pure collagen abnormality, co-existence with an electrolyte abnormality such as hypophosphatemia is rarely reported. It could be indicative of multiple genetic abnormalities and may have worsening effect on overall prognosis.

**Case Description:** Our patient is a 35-year-old female with past medical history of severe scoliosis, blue eyes, and OI diagnosed at birth. Patient was referred to nephrology office for low serum phosphorus level after extensive work up done by endocrinology was non-revealing. Urine dipstick was negative for glucose, protein, blood, ketones, and bilirubin. Renal panel was unremarkable except serum phosphorus level of 1.7 mg/dL. Remaining labs showed serum magnesium 2.2 mg/dL, intact parathyroid hormone 27 pg/ml (15-65pg/ml), thyroid stimulating hormone (TSH) 1.850 uIU/ml (0.450-4.5), 24-hour urine phosphorus 0.7gm/day, 24-hour urine calcium 26 mg/day, 24-hour urine creatinine 1.2g/day, urine dipstick was negative for glucose and proteins. Patient was started on calcitriol and oral phosphate supplements. In view of elevated urine phosphorus excretion in the setting of hypophosphatemia, genetic testing was obtained that reported a variant of ALPL gene and SLC34A4 gene. The ALPL gene variant is associated with autosomal recessive and autosomal dominant hypophosphatemia. The SLC34A3 gene variant is associated with autosomal recessive hereditary hypophosphatemic rickets with hypercalciuria. Hence, our patient was kept on oral phosphorus and calcitriol supplements with close monitoring of serum electrolytes.

**Discussion:** Osteogenesis imperfecta is a disease with severe clinical manifestations and while treatment options are only limited to symptomatic management, coexistence of another electrolyte abnormality further worsens the prognosis. These patients should undergo timely genetic counselling along with a multidisciplinary approach for management.

TEST	RESULT	Reference values
Fibroblast growth factor-23	102 RU/ml	< 180 RU/ml
ALPL gene	Heterozygous	
SLC34A3 gene	Heterozygous	
25-hydroxy vitamin D	29.0 ng/ml	30.0-100.0

## SA-PO521

### Isolated Hypophosphatemia due to Renal Phosphorous Wasting in Association With ENPP1 Mutations

Jusong Choi, Gajapathiraju Chamarthi, Dayan Ojeda Damas. *University of Florida, Gainesville, FL.*

**Introduction:** Biallelic mutations in the ecto-nucleotide pyrophosphatase/phosphodiesterase 1 gene is known to cause generalized arterial calcification of infancy or autosomal-recessive hypophosphatemic rickets in humans. We report a case with renal phosphorous wasting syndrome with normal FGF-23 level in a patient with heterozygous variants on ENPP1 c.1798T>C.

**Case Description:** A 38-year-old Caucasian male with refractory bitemporal epilepsy diagnosed in 2012 and status post response neurostimulation implantation in 2020 was referred for evaluation of hypophosphatemia incidentally found during the periods of seizure activity... patient underwent workup for hypophosphatemia. 24 hours urine studies were conducted while the patient was on phosphorus supplement because of concerns of possible breakthrough seizures due to supplementation cessation. 24 hours urine study revealed phosphorus excretion was approximately 800mg per day, serum phosphorus at 2.61 mg/dL and serum creatinine at 1.22mg /dL with eGFR greater than 59 ml. His Fractional excretion of phosphate was greater than 10 percent on different occasions despite serum phosphorus being low at 2.5 while being on phosphorus supplements. Renal wasting was suspected and further work up was pursued. Pertinent labs include FGF 23 level of 27 pg/mL, PTH of 47 pg/mL, vitamin d 25-OH of 36.13 ng/mL, and 1,25-dihydroxy of 69 pg/mL. A genetic test was performed which revealed heterozygous variants on ENPP1 c.1798T>C but of uncertain significance as it has not been reported in literature. Interesting patient endorses some bone mineralization problems with daughter and is currently undergoing evaluation. His low phosphorus checked during the seizure activity was attributed to redistribution.

**Discussion:** Heterozygous mutations in the ENPP1 leading to hypophosphatemia, mildly increased FGF23 have been reported in the literature. The Genetic associations of ARHR2 is thought to enhance the activity or levels of FGF-23 which is the key phosphaturic hormone. Our patient's mutation sequence change replaces the neutral and polar tyrosine with the basic and polar histidine at codon 600 of the ENPP1 protein. This variant has not been reported in literatures of individuals affected with ENPP1-related conditions. Moreover, there are currently insufficient available evidence to determine the role of this variant in the disease.

## SA-PO522

### Injury-Induced DNA Re-Replication Leads to Tubular Cell Polyploidization in FAN1-Deficient Kidneys

Merlin Airik, Amy B. Huynh, Rannar Airik. *University of Pittsburgh, Pittsburgh, PA.*

**Background:** Karyomegalic interstitial nephritis (KIN) is a biopsy-based diagnosis in which the nuclei of the kidney proximal tubule cells (PTECs) appear abnormally enlarged or karyomegalic. Nuclear enlargement in KIN results from increased chromosomal numbers due to a mitotic failure. However, the molecular mechanism responsible for polyploidization has not been identified. Here we show that karyomegaly is caused in *FAN1*-deficient kidney tubular cells by aberrant DNA re-replication induced by failed DNA repair in the preceding S-phase.

**Methods:** KIN was induced in *Fan1* KO kidneys by low dose cisplatin administration (5 weekly injections of 2 mg/kg). Histological analysis was performed using HE and PAS staining. RNA-seq analysis was performed on cisplatin-treated kidneys to identify molecular changes. *FAN1* KO human PTECs were used to monitor changes in cell cycle progression with FUCCI(SA) and FUCCI(CA) probes, and to perform biochemical studies with the p21 inhibitor UC2288.

**Results:** Chronic treatment with low dose cisplatin induced tubular karyomegaly (KIN) in *Fan1* KO kidneys but not in control mice. Marker analysis showed that the karyomegalic cells were arrested in G2. This finding was independently confirmed by RNAseq analysis, which revealed overrepresentation of G2/M checkpoint genes and upregulation of *Cdkn1a* in injured *Fan1* KO kidneys. Unexpectedly, the G2-arrested cells displayed increased DNA replication activity and upregulation of DNA replication licensing factors (RLFs) CDT1 and CDC6 in KIN. *In vitro* assays in PTECs showed that CDT1/CDC6 upregulation and stabilization was triggered by p21 accumulation in cells with DNA damage. Treatment with UC2288 abolished CDT1/CDC6 accumulation in *FAN1* KO PTECs and prevented their polyploidization. Cell cycle analysis with FUCCI probes revealed that karyomegaly leads to irreversible G2 cell cycle exit.

**Conclusions:** Our data show that karyomegaly arises in *FAN1*-deficient tubular epithelial cells through aberrant polyploidization due to DNA re-replication and coincides with p21 upregulation and G2 arrest. Inhibiting p21 blocks upregulation of RLFs and nuclear enlargement, suggesting that p21 may be a therapeutic target to mitigate KIN.

## SA-PO523

**A Novel Pathogenic Mutation in Alström Syndrome Causing CKD**

Jordana Yahr,<sup>1</sup> Mohamed Hassanein,<sup>2</sup> Hernan Rincon-Choles,<sup>1</sup> <sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>University of Mississippi Medical Center, Jackson, MS.

**Introduction:** Alström Syndrome is a rare progressive multi-system disorder caused by mutations in the *ALMS1* gene. It is inherited in an autosomal recessive fashion. It is estimated to occur in 1 of every 1,000,000 live births. The disease is characterized by visual defects (rod-cone dystrophy), sensorineural hearing loss, insulin resistance, cardiomyopathy, nonalcoholic fatty liver disease, and chronic kidney disease (CKD). We present a case of progressive kidney dysfunction in a patient with Alström syndrome due to a novel mutation in the *ALMS1* gene.

**Case Description:** A 21-year-old female patient was referred to the nephrology clinic for evaluation of CKD. Her medical history included obesity, developmental delay in childhood, precocious puberty at age 7, hearing loss, and vision impairment. Genetic testing for Alström syndrome was performed and showed a compound heterozygous finding of c.5166dupA and c.7126dupA in the *ALMS1* gene, both novel pathogenic mutations, resulting in a frameshift mutation with premature protein termination. She eventually developed CKD, hepatic steatosis, and type II diabetes mellitus, all consistent with Alström syndrome. Her brother demonstrated a similar clinical syndrome. Her CKD workup included normal complement levels, negative antinuclear antibody, negative viral hepatitis testing, urinalysis with intermittent microscopic hematuria, protein to creatinine ratio 0.4 g/g, albumin/creatinine ratio 204 mg/g, and structurally normal kidneys on ultrasound. Over the next 8 years, her CKD progressed to stage IIIb with a baseline creatinine of 2.0-2.4 mg/dL. She was treated with aggressive glucose and blood pressure control including an angiotensin receptor blocker and a sodium-glucose cotransporter-2 (SGLT2) inhibitor.

**Discussion:** Alström syndrome is a rare cause of CKD but should be considered in those presenting with consistent features. Kidney impairment is characterized by decreased glomerular filtration rate, microalbuminuria without overt proteinuria, interstitial fibrosis, glomerular hyalinosis, and tubular atrophy. Genetic testing has become the hallmark of diagnosis. We report a novel mutation in the *ALMS1* gene resulting in Alström syndrome. While no specific treatment exists, treatment should be targeted at organ specific complications of the disease.

## SA-PO524

**Unusual Autosomal Dominant Transmission of NPHS2 Variant**

Edoardo La Porta, Gianluca Caridi, Andrea Angeletti, Francesca Lugani. IRCCS Istituto Giannina Gaslini Istituto Giannina Gaslini, Genova, Italy.

**Introduction:** *NPHS2* encodes for podocin, a protein necessary to the structure of the slit diaphragm. *NPHS2* variants are associated with autosomal recessive SRNS. C-terminal part of podocin is responsible for the protein oligomerization (DOI: 10.1007/s10157-016-1331-39) and heterozygous LoF variants of this region can lead to protein retention in the cell cytoplasm, causing a dominant-negative effect similar to the recessive condition. Two families with AD glomerulopathy and C-terminal LoF of the podocin have been described (Seidl, D. Nephrol Dial Transplant 2022 37:suppl3; MO044). We identified a family with a heterozygous frameshift variant of *NPHS2* on exon 8 segregating in all affected members tested.

**Case Description:** A 4 years old male was investigated for proteinuria. Family history underlined 4 generations of affected family members following an AD transmission. Father (III:2) was diagnosed with Minimal Change Disease at 15 years old, and he later developed end stage kidney disease (ESKD). Paternal grandmother (II:1) and great-grandfather (I:2) were affected by ESKD. We also found proteinuria in the sister; after few years she and her brother developed ESKD. We performed exome sequencing in III:1, III:2, IV:1, and IV:2 and we filtered a panel of 388 genes identifying a unique heterozygous variant segregating in all the affected members of *NPHS2* (NM\_014625:c.984del; p. Q328Hfs\*20). Sanger sequencing validated it and revealed the same variant in II:1, therefore it was absent in III:3.

**Discussion:** We presented a tree family supporting the AD transmission of *NPHS2*-related glomerulopathy due to a LoF at the -C terminal. This underlines the importance of the variant itself in the genetic counseling and should point out the necessity of a periodic pipeline revision of the molecular diagnosis of the kidney disease.

## SA-PO525

**Assessing the Allelic Spectrum and Pathogenicity of Novel Variants in NPHS2 in 238 Individuals With Steroid-Resistant Nephrotic Syndrome**

Camille H. Nicolas Frank, Florian Buerger, Nils D. Mertens, Shirlee Shril, Friedhelm Hildebrandt. Boston Children's Hospital, Boston, MA.

**Background:** Recessive variants in *NPHS2* are the second most frequent cause of steroid-resistant nephrotic syndrome (SRNS) and show a wide spectrum of age of onset. There is no well-established loss-of-function screening assay and clinical databases such as ClinVar are insufficient to determine the deleteriousness of newly detected *NPHS2* variants. It was suggested that *in silico* scores can substitute for the lack of high-throughput functional assays. In addition to homozygous variants, specific compound heterozygosity with the common variant R229Q has been described in Tory, Nat Genet 46:299, 2014. We tested the hypothesis, that R229Q variant is only pathogenic when combined with a compound heterozygote variant encoding for an amino acid in the C-terminal domain (residue 124-383).

**Methods:** We re-examined an international cohort of 2,300 individuals with SRNS in whom we had performed exome sequencing and multiplex PCR sequencing (Fluidigm) with a specific emphasis on likely-causative, homozygous missense and compound-heterozygous (in combination with R229Q) variants in *NPHS2*. We generated *in silico* scores (REVEL, EVE) for homozygous missenses *NPHS2* likely causative variants identified in this cohort.

**Results:** Likely causative *NPHS2* variants were identified in 238/2,300 individuals (10%). In 113/238 (47%) individuals, one among 27 different homozygous missense variants was detected. EVE and REVEL scores, calculated for the 27 variants, were plotted to the corresponding individual's median age of onset. Higher REVEL scores negatively correlated with median age of onset ( $p < 0.03$ ), whereas EVE scores did not ( $p = 0.23$ ). 37 out of 238 individuals (15%) with SRNS had a R229Q variant combined with one of 16 different likely causative variants as the alternative allele (in trans). 8 were previously published, whereas we identified 5 new missense variants, and 3 undescribed C-terminal truncating variants. Interestingly, all 16 mapped onto the C-terminal protein domain.

**Conclusions:** In *NPHS2*, we detected a correlation between REVEL deleteriousness score and age of SRNS onset. We confirmed that R229Q is only pathogenic when combined with a variant encoding for an amino acid in the C-terminal domain of podocin (residue 124-383).

## SA-PO526

**Late-Onset Schwannomatosis in Two Unrelated Patients With Peripheral Neuropathy and Focal Segmental Glomerulosclerosis due to INF2 Mutations**

Linh N. Tran,<sup>1</sup> Huong Quynh Tran Thuy,<sup>1</sup> Yoshinori Sato,<sup>2</sup> Hiroyasu Tsukaguchi,<sup>1</sup> <sup>1</sup>Kansai Ika Daigaku Fuzoku Hirakata Byojin, Hirakata, Japan; <sup>2</sup>Showa Daigaku Fujigaoka Byojin, Yokohama, Japan.

**Introduction:** INF2, a member of actin assembly factor formin, is implicated in fundamental biological processes, including maintenance of cell shape, polarity, and migration. Mutations in the extreme N-terminus of INF2 cause peripheral neuropathy of Charcot-Marie-Tooth (CMT) type, in addition to focal segmental glomerulosclerosis

(FSGS). These two disorders are likely ascribed to progressive degeneration through actin dysregulation in podocytes and Schwann cells. Here we report two unrelated patients with CMT and FSGS due to *INF2* mutations manifested schwannomatosis in later clinical course.

**Case Description:** **Case 1** A 12-year female has a heterozygous *INF2* p.G73D variant and had difficulty in walking since childhood, first noticed proteinuria. She showed steppage gait with asymmetric atrophy and weakness in the lower limb muscles and hearing disability. *Pes cavus* deformity was surgically corrected at age 11. At age 14, she developed nephrotic syndrome diagnosed as FSGS. The renal disease was resistant to steroids and progressed into ESRD at age 16. At around age 30, she noticed multiple subcutaneous nodules. A spinal MRI revealed schwannomatosis in the caudal nerves. **Case 2** A 10-year boy has a heterozygous *INF2* p.V108D variant, first noticed walking disability, developed nephrotic syndrome with FSGS at age 14 and progression to ESRD at age 17. Since age around 20, he noticed subcutaneous nodules in his neck, spine, pelvic cavity, and left lower extremity. Biopsy of peroneal nerve revealed degeneration in large myelinated fibers with onion bulb formation. A spine MRI revealed schwannomatosis in the caudal nerves. Histology of biopsied cervical tumors at age 29 revealed schwannomas with a biphasic pattern of mixed hypercellular (Antoni A) and hypocellular (Antoni B) components.

**Discussion:** This report first demonstrated, to our knowledge, multi-focal schwannomatosis development of peripheral neurons in later course of two CMT/FSGS cases with the *INF2* mutations. Our observations shed a light on previously underrecognized, proliferative natures of *INF2* mutations, thereby broadening a phenotypic spectrum of CMT/FSGS mutation that typically leads to cell degeneration. Further study is necessary to clarify the cellular mechanisms by which the CMT/FSGS type *INF2* mutations could accelerate the proliferation in Schwann cells.

## SA-PO527

### Challenges in Diagnosis of Mitochondrial Mutations in Patients With Diabetes and Kidney Disease: A Case Report

Sukhdeep S. Sahi, Sarwat Gilani, Alessia Buglioni, Marie C. Hogan, Lihong Bu, Aleksandra Kukla, Yogish C. Kudva. *Mayo Clinic Minnesota, Rochester, MN.*

**Introduction:** Determining etiology of diabetes may be challenging due to high genetic and phenotypic heterogeneity. Mitochondrial diseases, including “MELAS” (mitochondrial encephalopathy with lactic acidosis and stroke-like episodes) have been associated with maternally inherited diabetes, as well as deafness and kidney disease. We report a case of women diagnosed with mitochondrial disease later in life who initially presented with diabetes.

**Case Description:** A 46 yo woman developed gestational type 2 diabetes at age 30. Family history was positive for maternal diabetes. She was treated with insulin due to her poor tolerance to other anti-diabetic agents. Creatinine had gradually increased from 0.8 mg to 1.3 mg. She reported hearing loss 2 years prior to her diagnosis of mitochondrial disease. Lactate was checked due to the combination of diabetes and deafness and suspicion of mitochondrial etiology. Lactate was abnormal 3.7 mmol/ml (n 0.5-2.2 mmol/ml). There were no other clinical symptoms. Mitochondrial Full Genome Analysis by Next Generation Sequencing (NGS) identified m.3243A>G in MT-TL1 with a heteroplasmy level of 12%. Kidney biopsy showed diffuse mesangial expansion, focal segmental glomerulosclerosis with moderate foot process effacement, and mitochondriopathy with abnormal mitochondria of variable sizes and shapes (Fig), consistent with the dual diagnosis of mitochondrial and diabetic kidney disease. Heteroplasmy was evident in 75% of kidney cells.

**Discussion:** Our case highlights the challenges inherent in diagnosing mitochondrial diseases as the presenting symptoms may vary. Providers should consider mitochondrial etiology when, in addition to diabetes, other systemic symptoms are present. A multidisciplinary approach is necessary to establish diagnosis.

Figure legend: Native kidney biopsy electron microscopy findings of MT-TL1 associated mitochondriopathy, showing dysmorphic mitochondria in proximal tubular epithelial cells. Original magnification (a) x2500 and (b) x6000.

## SA-PO528

### Autosomal Dominant Fanconi Syndrome and CKD Associated With Glycine Amidinotransferase Mutation: A Rare Genetic Syndrome

Ignacio A. Portales Castillo,<sup>1</sup> Patrick Hanna,<sup>1</sup> Andrew L. Lundquist,<sup>1</sup> Harald Jüppner,<sup>1</sup> Avi Traum,<sup>2</sup> Andrew S. Allegretti.<sup>1</sup> *<sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Boston Children's Hospital, Boston, MA.*

**Introduction:** Chronic kidney disease (CKD) secondary to monoallelic mutations in the gene *glycine amidinotransferase (GATM)* was reported in 2018, without subsequent patients published in the literature. We now present the case of a female with hereditary Fanconi syndrome, nephrolithiasis and mild CKD, found with a heterozygous *GATM* mutation.

**Case Description:** A 27 year-old female from Ecuador presented to the adult nephrology clinic for evaluation of renal tubular acidosis (RTA) and CKD. She was first seen at the pediatric nephrology clinic 10 years earlier for a non-anion gap metabolic acidosis (serum bicarbonate 19 mmol/L) and nephrolithiasis. Work-up at that time revealed CKD stage 2 (GFR of ~60 mL/min), hypokalemia at 3.3 mEq/L and low-normal serum phosphate at ~3.5 mg/dL. Urine pH was 7 with glucosuria, amino aciduria, moderately increased phosphate (FePO<sub>4</sub> 27%) and calcium excretion (300 mg calcium/24 hours). At the time, potassium citrate was prescribed for suspected type 2 RTA. During our evaluation at the adult nephrology clinic, serum and urine parameters remained unchanged, except for worsening hypophosphatemia (2.2 mg/dL) with normal 1,25(OH)<sub>2</sub> vitamin D of 44 pg/mL and PTH 28 pg/mL. Her family history was notable for a younger sister with RTA and her father with ESRD at age 30. She was referred to the Massachusetts General Hospital Renal Genetics Clinic with a diagnosis of hereditary Fanconi syndrome. Genetic testing revealed a heterozygous variant of uncertain significance (VUS) in the *GATM* gene (Pro341Leu). In multidisciplinary review, this VUS was strongly suspected to be causative, and was genetically confirmed in her father and sister.

**Discussion:** Fanconi syndrome and CKD in association with heterozygous mutations in *GATM* have been described thus far in a single research study. Using a proximal tubular cell model, pathologic *GATM* mutations caused fibrillary aggregates in the mitochondria, also present in patients' kidney biopsies. Our patient presents with Fanconi syndrome and nephrolithiasis which was not previously associated with variants in this gene. This case illustrates the value of genetic testing, the importance of access to genetic expertise for interpretation of a VUS and the results hold promise for personalized treatment targeting expression of *GATM* with creatine.

## SA-PO529

### A Clinical Workflow for Selection of Patients and Efficient Diagnosis of Genetic Kidney Diseases

Francesca Becherucci,<sup>1</sup> Samuela Landini,<sup>1</sup> Viviana Palazzo,<sup>1</sup> Valentina Raglianti,<sup>1,3</sup> Luigi Cirillo,<sup>1,3</sup> Gianmarco Lugli,<sup>1,3</sup> Benedetta Mazzinghi,<sup>2</sup> Paola Romagnani,<sup>1,3</sup> *<sup>1</sup>Meyer Children's Hospital, Florence, Italy; <sup>2</sup>Ludwig-Maximilians-Universität München, München, Germany; <sup>3</sup>Università degli Studi di Firenze, Firenze, Italy.*

**Background:** The advent of whole-exome sequencing (WES) has been making inherited kidney disorders (IKD) increasingly recognized across all age groups. Accessibility to genetic testing, interpretation of results and cost concerns limit the widespread use of genomic medicine in daily clinical practice. We explored feasibility and diagnostic performance of a service delivery model for patient selection, WES, results interpretation and counseling.

**Methods:** We set-up a multi-step diagnostic workflow based on the application of WES and reverse phenotyping performed by a multidisciplinary team of experts to adult and pediatric patients selected with simple clinical criteria, through a regional network of nephrology and pediatric centers working in close collaboration with a tertiary center for rare kidney diseases. We included all consecutive patients with a clinical picture suggestive of IKD belonging to 8 different clinical categories. We recorded clinical-laboratory-radiological information. We performed a cost-analysis of the diagnostic workflow modelling potential economic savings of a genomic-first approach to the diagnosis of IKD.

**Results:** By applying this workflow to a cohort of 474 pediatric and adult patients, we obtained a global diagnostic yield of 66.9%, with category-specific diagnostic rates ranging from 46% to 87%. Reverse phenotyping performed in patients or family members allowed us to reclassify the clinical diagnosis in 90/317 (28.4%) patients, thus increasing diagnostic accuracy. Disease reclassification encompassed the entire spectrum of IKD. Diagnostic yield was independent on the age at onset of kidney disease. We offered genetic testing as cascade screening to 67 families, providing a genetic diagnosis in 67 family members with previously unsuspected or unspecified kidney disorders. The clinical work-up was redirected in an average of 50% of patients. In 11.5% of patients, the results of genetic testing helped in guiding kidney transplant decisions. Finally, cost-analysis showed that our workflow is efficient enabling to potentially save a mean of 1360 euros per patient.

**Conclusions:** Ordering genetic testing, interpreting results, providing counseling and tailoring clinical management (i.e., personalized nephrology) is feasible and saves costs in a real-world setting.

## SA-PO530

### Incorporating a Renal Genetics Clinic Into Clinical Practice: The Cleveland Clinic Experience

Xin Yee Tan,<sup>1</sup> Chloe Borden,<sup>3</sup> Xiangling Wang,<sup>2,1</sup> *<sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>Cleveland Clinic Genomic Medicine Institute, Cleveland, OH; <sup>3</sup>Cleveland Clinic Lerner Research Institute, Cleveland, OH.*

**Background:** The perceived need for timely diagnoses of genetic kidney diseases to allow multifaceted disease-specific patient care led to the establishment of our Renal Genetics Clinic (RGC) in 2018 which has since been rapidly growing.

**Methods:** A retrospective review was conducted to evaluate the diagnostic yield of available genetic testing modalities and its diagnostic and therapeutic implications among the patients who were referred to our RGC from January 2019 to March 2022.

**Results:** 309 patients from 299 pedigrees including 118 males and 191 females aged 35.1±20.3 years old were seen in our RGC during this period, 292 of whom were recommended for genetic testing and 252 had results available. Presentations were variable comprising mainly of glomerular diseases (33%), cystic kidney diseases (25.2%),

electrolyte disorders(24.9%), congenital anomalies of kidneys and urinary tract(6.5%) and nephrolithiasis/ nephrocalcinosis(3.2%). A tiered testing algorithm was utilized which encompassed single gene panel(SGP), multigene panel(MGP), chromosomal microarray(CMA) and whole exome sequencing(WES). Among patients with results available, 44.8%(113) had a positive result, 25.4%(64) had variant(s) of undetermined significance(VUS), 8.3%(21) were identified as heterozygous carriers, and 21.4%(54) tested negative. The diagnostic yield of different testing modalities is illustrated in **Figure 1**. The majority of positive results in our patients were achieved by MGP(71.7%), followed by SGP(18.6%), WES(8.9%) and CMA(0.9%). The positive results brought about a new diagnosis or a change in diagnosis in 67.3%(76) of patients and confirmed a priori diagnoses in 32.7%(37). Consequently, this has resulted in a change in management including change in medications in 27.4%(31) of patients.

**Conclusions:** As genetic testing becomes increasingly accessible, we have demonstrated compelling benefits of incorporating a specialized RGC into nephrology practice with quantifiable diagnostic and therapeutic impacts.

#### SA-PO531

##### Whole Exome Sequencing (WES) Increases Diagnostic Yield in Renal Genetics Clinic (RGC) Patients With Previously Negative Multi-Gene Panel (MGP) Results

Xin Yee Tan,<sup>1</sup> Chloe Borden,<sup>2</sup> Xiangling Wang,<sup>3,1</sup> <sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>Cleveland Clinic Lerner Research Institute, Cleveland, OH; <sup>3</sup>Cleveland Clinic Genomic Medicine Institute, Cleveland, OH.

**Background:** Genetic testings have been increasingly accessible to patients with kidney diseases. MGP covering up to hundreds of disease-related genes has been frequently used in clinical practice with high diagnostic yield. WES has been valuable in research settings but its utility in clinical setting has not been assessed.

**Methods:** Clinical characteristics and genetic findings of a cohort of patients referred to the Cleveland Clinic RGC who had WES performed in clinical setting were analyzed.

**Results:** From January 2019 to March 2022, 292 patients were evaluated in the RGC. Among these, 54(18.5%) were suggested to have WES, including 33 females and 21 males aged 22.4±18.5 years old. WES was recommended as first tier testing for 23(42.6%) patients and last tier testing after nondiagnostic precedent tests for 31(57.4%) patients. Clinical presentations included electrolyte disorders(25.9%), glomerular diseases(22.2%), cystic kidney diseases(20.4%), congenital anomalies of kidney and urinary tract(16.7%), tubulointerstitial diseases (5.6%), multisystemic diseases(5.6%) and nephrolithiasis/ nephrocalcinosis(2.7%). 50% reported a positive family history and 24.1% had dysmorphic features. 9 patients did not proceed due to denial/lack of insurance coverage and 34 out of 43 patients who proceeded had results available (Figure 1), of which 29.4%(10) had a positive result, 29.4%(10) were found to have variant(s) of undetermined significance (VUS), 5.9%(2) were identified as heterozygote carriers, and 22.2%(12) tested negative. 7 out of 10 patients with positive results received a new or change in diagnosis. When performed as last tier testing after nondiagnostic precedent tests, WES had a diagnostic yield of 13%.

**Conclusions:** This study supports the clinical utility of WES in patients with suspected genetic kidney diseases as it evidently increases the diagnostic yield in patients with previous negative tests results.

#### SA-PO532

##### Electronic Health Record-Based Nephrotic Syndrome Genomic Discovery Using the Mass General Brigham (MGB) Biobank

Janewit Wongboonsin,<sup>1,3</sup> Sagar U. Nigwekar,<sup>2</sup> Matt G. Sampson,<sup>3</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Massachusetts General Hospital, Boston, MA; <sup>3</sup>Boston Children's Hospital, Boston, MA.

**Background:** Published studies demonstrating the value of genetic stratification in nephrotic syndrome (NS) have often focused on children or research cohorts selected for specific characteristics, such as having steroid resistant NS. The prevalence and clinical correlates of known genetic forms of NS in adult patients are less well understood but may have important clinical implications. The EHR-linked Biobank of the MGB, which has enrolled > 130,000 patients and conducted SNP genotyping and exome sequencing on most of them, provides a unique opportunity to identify patients with NS for subsequent genomic discovery.

**Methods:** We used the following strategies to identify all NS patients in the biobank. 1) Screened with ICD-10 diagnosis code of 'nephrotic syndrome.' 2) Applied a published computational phenotype for primary NS consisting of 8 inclusion codes and 87 exclusion codes. 3) Reviewed patients with kidney pathology data and the diagnosis code of 'proteinuria.' 4) Reviewed patients with kidney pathology data, regardless of diagnosis.

**Results:** Strategy 1 identified 558 patients and performed manual chart reviews. The mean age was 60±15 years, and 70% of the cohort were Caucasian. 90.7% of patients had proteinuric kidney disease. Focal segmental glomerulosclerosis (FSGS) was the most common diagnosis (28.1%). Strategy 2 identified 86 patients, 22 of whom had validated diagnoses through chart review. This approach lacked specificity for primary NS as 23% of patients (5/22) did not have NS. Strategy 3 identified 819 patients, 291 of whom had validated diagnoses from strategy 1. 271/291 (93.1%) had pathology reports of native kidney disease confirming the diagnosis. Given the high yield of capturing patients with glomerular diseases through kidney pathology data, we then proceed with strategy 4, reviewing the kidney pathology data from all patients. We obtained additional 1648 patients, 334 of whom have either minimal change disease, FSGS, or membranous nephropathy. The total number of unique NS from these efforts is 564 patients.

**Conclusions:** This EHR-link biobank provided a unique opportunity for genomic discovery for nephrotic syndrome in adults. The kidney pathology data was the key to ensuring that we captured all patients with glomerular disease from the Biobank. Manual adjudication is still required to provide the correct diagnosis.

**Funding:** Private Foundation Support

#### SA-PO533

##### Clinical Utility of Genetic Testing in Kidney Transplant Evaluation

Anshul Bhalla,<sup>1</sup> Darbey Raible,<sup>2</sup> Vasanthi Balaraman,<sup>1</sup> Manish Talwar,<sup>1</sup> <sup>1</sup>James D. Eason Transplant Institute, Memphis, TN; <sup>2</sup>Natera, Inc., Austin, TX.

**Background:** Genetic testing is an emerging tool in kidney transplant (KT) evaluation. We present examples of diagnostic and clinical utility resulting from broad-panel genetic testing in pre- and post-KT settings at an academic transplant center.

**Methods:** Selection criteria for genetic testing included: pre-KT patients with early-onset end stage kidney disease (ESKD), ESKD of unclear etiology or positive family history of ESKD, and post-KT patients with suspected recurrent disease or poor graft function. Patients were tested using a Next-Generation Sequencing (NGS) panel of 385 genes (the Renasight™ Test) associated with isolated or syndromic chronic kidney disease (CKD). Positive results included at least one pathogenic (P) or likely pathogenic (LP) variant in an autosomal dominant or X-linked gene, two P/LP variants in an autosomal recessive gene, or the presence of two *APOL1* risk alleles.

**Results:** This study included 132 patients (pre-KT=98, post-KT=34). The median age was 42 years (range: 21-77) and most (78%) were African American. Overall, 62 patients (47%) received a positive result in at least one panel gene. Hypertensive nephrosclerosis was the most common diagnosis (68%, n=90) at the time of referral for KT evaluation. Genetic findings established a new diagnosis in 57% (n=51/90) of these patients. Genetic testing confirmed the diagnosis for 2 of 36 patients with an established *a priori* clinical diagnosis other than hypertensive nephrosclerosis and led to further delineation of disease origin in 6 (17%) of these patients. Surveillance changes were indicated for 27% of

patients, based on risk for recurrence post-KT (n=11) and/or extrarenal features (n=6) delineated via genetic testing. Significant alterations to treatment were indicated for 2 (unrelated) patients with previously undiagnosed Adenine Phosphoribosyltransferase (APRT) Deficiency, for whom treatment with xanthine oxidase inhibitor was initiated to reduce risk of graft damage and loss.

**Conclusions:** In KT, genetic diagnosis can facilitate personalized prognostication of disease recurrence and changes in management to optimize graft survival. Demonstration of real-world clinical benefits is important for establishing evidence-based guidelines and best practices for integration of genetic testing into KT evaluation.

SA-PO534

**The Clinical Impact of Genetic Testing in Outpatient General and Transplant Nephrology: A Tertiary Centre Experience**  
Lakshna Sankar,<sup>1</sup> Pooja Sanghi,<sup>1</sup> Gurmukteshwar Singh,<sup>1</sup> Prince M. Anand,<sup>2</sup> Kartik Kalra,<sup>1</sup> Alex R. Chang.<sup>1</sup> <sup>1</sup>Geisinger Health, Danville, PA; <sup>2</sup>Medical University of South Carolina, Charleston, SC.

**Background:** Monogenic diseases account for 10-15% of kidney diseases. The impact of clinical genetic testing in real-world nephrology is not well-characterized.

**Methods:** A retrospective study was conducted at Geisinger from June 2020 to April 2022. Patients with suspicion for inherited kidney disease underwent genetic testing. We classified positive finding as having a pathogenic (P) or likely pathogenic (LP) variant in a gene consistent with the clinical phenotype or presence of two apolipoprotein L1 (APO1L) risk alleles. The number of variants of unknown significance (VUS) that matched the clinical phenotype were quantified.

**Results:** Positive genetic diagnoses were obtained in 42 patients (P/LP variants n=36; 2 APO1L risk alleles n=6) encompassing 19 genes. Among those without a genetic diagnosis, 17 patients had a VUS that was consistent with the renal phenotype. The mean number of VUS was 4.8 ± 2.6. 92% of the patients (136/147) had at least 1 VUS. Diagnostic yield of genetic testing in CKD of unknown cause was 28% (Figure 1). Among potential kidney donors, 1/9 (11%) had a positive variant (CFI gene). 28% of the patients (15/53) with positive genetic diagnoses underwent kidney transplant workup. Family testing was done in 6 families confirming 2 genetic diagnoses in 2 relatives who were referred to genetic counseling.

**Conclusions:** Nephrologist-driven use of genetic testing can provide molecular diagnoses influencing management in CKD/ESKD patients. Family testing provides insights that help identify appropriate living donors, refer those with a positive diagnosis to genetics clinic and re-classify VUS as disease causing variants. Our study represents real - world application and utilization of renal genetic testing.

SA-PO535

**African American Kidney Disease Patients Experience Reduced Access to Genetic Testing Compared With White Patients**  
Chloe Borden,<sup>1</sup> Xin Yee Tan,<sup>1,2</sup> Xiangling Wang.<sup>1,2</sup> <sup>1</sup>Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; <sup>2</sup>Cleveland Clinic, Cleveland, OH.

**Background:** African Americans are almost four times as likely as White Americans to develop kidney failure. In the last decade, significant advancements in the diagnosis and management of patients with genetic kidney diseases have been made. Whether disparities in access to genetic testing between racial groups exists has not been previously examined.

**Methods:** A retrospective review of patients referred to the Cleveland Clinic Renal Genetics Clinic (RGC) from January 2019 to March 2022 was conducted. Patient demographics, clinical characteristics, insurance coverage, referring providers, diagnostic modality, and diagnostic yield were collected for comparison.

**Results:** 309 patients from 299 pedigrees including 118 males and 191 females aged 35.1 ± 20.3 years were seen at the RGC from January 2019 to March 2022. 49 African American patients, 232 White patients, 24 patients who were neither White nor African

American, and 4 patients who declined to provide race were seen. African American patients were significantly more likely to be in end stage renal disease (ESRD) at the time of referral compared with White patients (OR = 3.7, p = 0.003). African American patients were additionally more likely to be covered by Medicaid (OR = 1.4, p = 1.4e-5) and less likely to have private insurance (OR = 0.3, p = 3.3e-4). Further, African American patients were more likely to exhibit nonadherence (OR = 3.4, p = 0.003). No differences in referring providers, family history, diagnostic yield, Medicare coverage, eGFR at first visit, and age at first visit between groups were noted.

**Conclusions:** This study suggested inequitable access to genetic testing amongst African American kidney disease patients. As personalized genetic healthcare becomes increasingly prevalent, steps will need to be taken to ensure equitable access for all persons.

Table 1. Patient demographic information				
Factor	African American (N=49)	White (N=232)	Other (N=24)	Total (N=309)
Age (at 1 <sup>st</sup> visit), Mean ± SD	35.4 ± 19.0	36.5 ± 20.2	24.3 ± 19.4	35.1 ± 20.3
Males, No. (%)	28 (57.1)	76 (32.8)	13 (54.2)	118 (38.2)
Females, No. (%)	21 (42.9)	156 (67.2)	11 (54.8)	191 (61.8)
eGFR (at 1 <sup>st</sup> visit), Mean ± SD	79.3 ± 44.4	87.7 ± 43.6	109 ± 59.9	88.6 ± 45.6
Family History, No. (%)	25 (51.0)	125 (53.9)	11 (47.8)	163 (52.8)

SA-PO536

**Diagnostic Yield of Massively Parallel Sequencing in Patients With CKD of Unknown Etiology: The Dutch Nationwide Prospective VARIETY Cohort Study**

Amber de Haan,<sup>1</sup> Mark Eijgelsheim,<sup>1</sup> Liffert Vogt,<sup>2</sup> Ewout J. Hoorn,<sup>3</sup> Joris I. Rotmans,<sup>4</sup> Albertien M. van Eerde,<sup>5</sup> Nine V. Knoers,<sup>1</sup> Martin H. De Borst.<sup>1</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>3</sup>Erasmus MC, Rotterdam, Netherlands; <sup>4</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands; <sup>5</sup>Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.

**Background:** The cause of chronic kidney disease (CKD) remains unknown in at least 20% of patients. While retrospective studies, most in research setting, indicate that massively parallel sequencing (MPS) may lead to a genetic diagnosis in 12-56% of patients with unexplained CKD, the diagnostic yield in clinical practice is unclear. Here, we aimed to determine the diagnostic yield of MPS-based gene panel testing in patients with unexplained CKD in a routine healthcare setting.

**Methods:** A prospective nationwide observational cohort study was conducted in 13 hospitals throughout the Netherlands. Patients with unexplained CKD who had an eGFR <60mL/min/1.73 m<sup>2</sup> before the age of 50 years were included. Informed consent was obtained from all participants. Diagnostic genetic testing was performed using the whole-exome sequencing (WES) based CKD-Y (Chronic Kidney Disease in Young patients; 256 genes) or broad hereditary kidney disease (495 genes) multi-gene panels at the University Medical Center Utrecht.

**Results:** As of May 2022, 370 patients have been included (>90% of the target inclusion, n=400). In an interim analysis involving 233 patients with complete data available, mean age was 44±12 years, mean age at diagnosis CKD was 31±12 years, 39% were female, 62% had proteinuria, 24% had hematuria, 84% had hypertension, 68% had undergone kidney transplantation and 37% reported a positive family history for CKD. A diagnostic variant, defined as (likely) pathogenic variants explaining the clinical phenotype, was identified in 45/233 participants (19%). Most diagnostic variants were identified in *NPH1* (N=12), *COL4A3* (N=7), *COL4A4* (N=5), *COL4A5* (N=4), and *PAX2* (N=3). A genetic diagnosis subsequently led to at least one clinical consequence (e.g. change in therapy, search for extrarenal features, implications for transplantation, family planning/counseling,) in 75% of patients.

**Conclusions:** In this study, WES-based panel testing yielded a genetic diagnosis in 19% of cases, highlighting the relevance of MPS as a tool in the diagnostic workup of adult patients with CKD of unknown origin. Most common genetic diagnoses in this population were nephronophthisis and Alport spectrum disease. Complete data analysis (n=400) is expected by October 2022.

**Funding:** Commercial Support - Sanofi Genzyme, Government Support - Non-U.S.

SA-PO537

**Diagnostic Yield Among Patients With Diabetic Nephropathy and/or Hypertension: Genetic Testing in Kidney Transplant Waitlist Patients**  
David B. Leaser,<sup>1</sup> Karen E. Kennamer,<sup>1</sup> Laurel Kartchner,<sup>2</sup> Margaret M. Romine,<sup>1</sup> Ashley E. Aaron,<sup>1</sup> Kristel J. McLawhorn,<sup>1</sup> Heather Jones,<sup>1</sup> William Irish.<sup>1</sup> <sup>1</sup>*Vidant Transplant Center, Greenville, NC;* <sup>2</sup>*Natera, Inc., Austin, TX.*

**Background:** Diabetes and hypertension (HTN) are common causes of end-stage renal disease (ESRD) in the general population. Studies have shown that ESRD often has a genetic cause. Although diabetes and HTN can have a hereditary component in some cases, recommendations for genetic testing in ESRD typically exclude patients with presumed diabetic nephropathy or HTN. We describe a single-center approach to using genetic testing in patients presenting for renal transplant evaluation, including those whose clinical diagnosis was diabetic nephropathy or HTN.

**Methods:** As part of the initial work-up process, all potential transplant patients were tested to determine cause of original kidney disease, ancestry, diabetes (y/n), and hypertension (y/n). Patients then underwent testing with a panel consisting of >380 genes associated with kidney disease (the Renasight™ test). Positive results included those with pathogenic or likely pathogenic variants, or with the G1 or G2 *APOL1* risk alleles. Results were then stratified based on patient clinical diagnosis.

**Results:** Among the 189 patients tested, 31.7% (n=60) had positive results spanning 14 genes. Six patients were identified as having positive results in >1 gene. At the time of transplant evaluation, diabetic nephropathy or HTN were the most common causes of ESRD. Other causes of ESRD that often are hereditary, such as focal segmental glomerulosclerosis and polycystic kidney disease were highly prevalent among the cohort. Genetic findings were identified in patients whose ESRD was due to diabetic nephropathy (21.7%, 18/83), HTN (34.5%, 19/55), FSGS (66.7%, 6/9), PKD (88.9%, 8/9), and “Other” (27.3%, 9/33).

**Conclusions:** Despite published protocols excluding genetic testing in patients with presumed diabetic nephropathy, this analysis suggests that patients with ESRD caused by diabetes and/or hypertension may have a high diagnostic yield spanning a wide variety of genetic causes.

Common Positive Genetic Findings

Clinical Diagnosis (Cause of ESRD)	Diagnostic yield Genes (# patients)
Diabetic nephropathy at time of KT evaluation (n=83)	21.7% (n=18) <i>APOL1</i> (13), <i>CFH</i> (1), <i>COL4A4</i> (1), <i>HNF4A</i> (1), <i>PKD2</i> (1), <i>SLC7A9</i> (1), <i>TTR</i> (1)
HTN at time of KT evaluation (n=55)	34.5% (n=19) <i>APOL1</i> (12), <i>COL4A3</i> (1), <i>COL4A4</i> (3), <i>COL4A5</i> (1), <i>GLI3</i> (1), <i>MGDR</i> (1), <i>PKD1</i> (1), <i>TTR</i> (2)
Focal segmental glomerulosclerosis (FSGS) (n=9)	66.7% (n=6) <i>APOL1</i> (6)
Polycystic kidney disease (PKD) (n=9)	88.9% (n=8) <i>APOL1</i> (1), <i>PKD1</i> (6), <i>PKD2</i> (1), <i>TTR</i> (1)
Other (n=33)	27.3% (n=9) <i>APOL1</i> (6: lupus, covid, cong renal anomaly, IgAN (2); rheumatoid arthritis), <i>COL4A5</i> (2 GN), <i>PGCRL2</i> (1 solitary kidney), <i>NPH1</i> (1 medullary cystic kidney disease), <i>TTR</i> (1)

SA-PO538

**Copy Number Variation Analysis in 138 Families With Steroid-Resistant Nephrotic Syndrome Identifies Homozygous Causal Deletions in *PLCE1* and *NPHS2* in Two Families**  
Dalia Pantel,<sup>1,2</sup> Nils D. Mertens,<sup>1</sup> Ronen Schneider,<sup>1</sup> Jameela A. Kari,<sup>3</sup> Sherif M. El desoky,<sup>3</sup> Arvind Bagga,<sup>4</sup> Tze Yin Lim,<sup>5</sup> Shirlee Shril,<sup>1</sup> Friedhelm Hildebrandt.<sup>1</sup> <sup>1</sup>*Boston Children's Hospital, Boston, MA;* <sup>2</sup>*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany;* <sup>3</sup>*King Abdulaziz University, Faculty of Medicine, Jeddah, Saudi Arabia;* <sup>4</sup>*Division of Nephrology, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India;* <sup>5</sup>*Division of Nephrology, Columbia University, New York City, NY.*

**Background:** Steroid-resistant nephrotic syndrome (SRNS) is the second most common cause of end-stage renal disease in children and adults under the age of 20 years. Previously, we were able to detect by whole-exome sequencing (WES) a known monogenic cause of SRNS in 25% of affected families (Warejko *CJASN* 13:53, 2018), supporting the indispensable role of WES in uncovering genetic causation of the syndrome. However, WES falls short of detecting copy number variations (CNV) due to technical challenges. We therefore hypothesized that causal CNVs could be detected in a large SRNS cohort.

**Methods:** We performed genome-wide single nucleotide polymorphism (SNP)-based CNV analysis on a cohort of 138 SRNS families, in which we previously did not identify a genetic cause through WES. We evaluated WES and CNV data for variants in 61 known SRNS genes and in 12 genes, in which variants are known to cause a phenocopy of SRNS. We applied previously published, predefined criteria to evaluate and classify the CNVs.

**Results:** In a cohort of 138 families with SRNS, we detected a novel CNV in two genes in two families (2/138 families, 1.5%) after having excluded competing variants by genome-wide WES and CNV analysis. Both CNVs are homozygous deletions: We detected a deletion of 9,670 bp in the *PLCE1* gene and a deletion of 6,790 bp in the *NPHS2* gene. The deletions were confirmed across breakpoint using PCR and Sanger sequencing.

**Conclusions:** This study shows that CNV analysis can identify the genetic cause in families with SRNS in which a genetic cause was not found through WES, though the rate of detected CNVs lies below the one found in other monogenic kidney diseases, like congenital anomalies of the kidneys and urinary tract.

SA-PO539

**Biallelic Variants in *NUP85* Causes Pediatric Steroid Resistant Nephrotic Syndrome**  
Rini Rossanti,<sup>1,2</sup> Dany Hilmanto,<sup>1,2</sup> Tomoko Horinouchi,<sup>1</sup> Nana Sakakibara,<sup>1</sup> China Nagano,<sup>1</sup> Tomohiko Yamamura,<sup>1</sup> Shinya Ishiko,<sup>1</sup> Yuya Aoto,<sup>1</sup> Atsushi Kondo,<sup>1</sup> Kazumoto Iijima,<sup>3,4</sup> Kandai Nozu.<sup>1</sup> <sup>1</sup>*Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan;* <sup>2</sup>*Department of Child Health, Nephrology Division, Dr. Hasan Sadikin General Hospital/ Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia;* <sup>3</sup>*Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan;* <sup>4</sup>*Department of Advanced Paediatric Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.*

**Introduction:** Steroid resistant nephrotic syndrome consistently progressed to end-stage renal disease. Despite the fact that more than 50 monogenic causes of steroid resistant nephrotic syndrome (SRNS) have been identified, a large proportion of SRNS remains unexplained. Nucleoporin 85, a protein encoded by the inner ring subunit of the nuclear pore complex (NPC), has recently been found to cause SRNS. Here we describe a *NUP85* compound heterozygous mutation in a child with focal segmental glomerulosclerosis (FSGS). Although one was a large deletion variant with obvious pathogenicity, another was a novel heterozygous variant which pathogenicity was unknown. To verify the pathogenicity of the missense variant, we conducted *in vitro* protein expression analyses.

**Case Description:** A 9-year-old girl with learning disorder and low vision was diagnosed with SRNS at 3 years old without any history of kidney disease in the family. The histological finding was FSGS. Pre-emptive kidney transplantation was conducted at 9 years-old. Patient harbored 2 novel heterozygous mutations in *NUP85*, c.1379G>A (p.Arg460Gln) in exon 14 by next generation sequencing, and a large deletion straddling from intron 11 of *NUP85* to *GGA3* gene by copy number variant analysis and custom array CGH. The *in vitro* protein expression analysis showed abnormal localization of *NUP85* in cytoplasm with the particle formation by the missense variant.

**Discussion:** In this study we defined the pathogenicity of a very rare missense variant in *NUP85*. This finding can help identifying more variants in this rare form of SRNS.

SA-PO540

**Genomic Sequencing Is Associated With a High Diagnostic Yield in Hospitalized Children With Both Congenital Heart Defects and Congenital Anomalies of the Kidney and Urinary Tract System**  
Erika Allred,<sup>1,2</sup> Elliot Perens.<sup>1,3</sup> <sup>1</sup>*University of California San Diego, La Jolla, CA;* <sup>2</sup>*Rady Children's Institute for Genomic Medicine, San Diego, CA;* <sup>3</sup>*Rady Children's Hospital San Diego, San Diego, CA.*

**Background:** Congenital heart defects (CHD) and congenital anomalies of the kidney and urinary tract (CAKUT) account for significant morbidity and mortality in childhood. Dozens of monogenic causes of anomalies in each organ system have been identified. However, even though 30% of CHD patients (pts) also have a CAKUT and both organs arise from the lateral mesoderm, there is sparse overlap of the genes implicated in the congenital anomalies of each organ system. We sought to determine whether pts with both CAKUT and CHD have a monogenic etiology, with the long term goal of guiding future diagnostic work up and improving outcomes.

**Methods:** Retrospective review identifying patients with both CAKUT and CHD and either whole genome sequencing or whole exome sequencing, admitted to Rady Children's Hospital between January 2015 and July 2020. Demographic information, presenting phenotype, and genetic results were collected, along with the mother's pregnancy history. WGS results were reanalyzed using the CAKUT and CHD phenotype as a primary filter. Genetic results were reviewed to identify causative, candidate, and novel genes for the CAKUT and CHD phenotype. Associated additional structural malformations were identified and categorized.

**Results:** 32 patients were identified. 8 patients had causative variants, 3 patients had candidate variants, and 3 patients had potential novel variants. 5 patients had variants in genes not associated with the CAKUT/CHD phenotype, and 13 patients had no variant identified. Of these, 8 patients were identified as having possible alternative causes for their CHD/CAKUT phenotype. 88% of all CAKUT/CHD patients had at least one additional organ system with a structural malformation.

**Conclusions:** Overall, our study demonstrated a high rate of monogenic etiologies in hospitalized pts with both CHD and CAKUT, with a diagnostic rate of 44%. Thus, physicians should have a high suspicion for genetic disease in this population. Together, these data provide valuable information on how to approach acutely ill pts with CAKUT and CHD, including guiding diagnostic work up for associated phenotypes, as well as novel insights into the genetics of CAKUT and CHD overlap syndromes in hospitalized children.

## SA-PO541

**Barriers to Genetic Testing for Determining Cause of Kidney Disease Among Healthcare Providers**

Michael Spigler, Jemetra Collins, Melanie Paris, Ryan Woolley. *American Kidney Fund, Rockville, MD.*

**Background:** Studies estimate between 5 and 10 percent of cases of kidney disease have an unknown etiology, and that a subset of these unknown designations may be attributable to genetic conditions. Identifying the cause of patients' chronic kidney disease (CKD) is important for informing tailored treatment plans to mitigate or slow disease progression. Genetic testing can also inform patients of any genetic based susceptibility for family members, helps to identify appropriate clinical trials for the advancement of treatment, and remove the feeling of blame for the disease. To identify opportunities for addressing barriers around CKD diagnosis and determining CKD cause, the American Kidney Fund conducted a survey of US-based healthcare providers (HCPs) who treat CKD patients.

**Methods:** An online survey was fielded between January 14-25, 2022, to 300 US-based HCPs, including 105 primary care providers (PCPs), 81 nurse practitioners/physician assistants (NP/PAs), 83 nephrologists, and 31 kidney transplant surgeons who treated 20 or more CKD patients in the previous month.

**Results:** HCPs reported using genetic testing in an average of 8% of their patients with suspected CKD and 25% have never used genetic testing for determining CKD cause. Among those who use genetic testing less frequently (n=198), 50% were not very familiar with genetic testing for kidney disease. PCPs, NPs, and PAs were most likely to see patient out-of-pocket costs (73% and 70%, respectively) and connecting patients with a genetic counselor (57%, and 44%, respectively) as barriers to genetic testing compared to other HCPs. Lastly, after learning more about genetic testing, providers reported an 18% increased likelihood to use it to determine primary cause of CKD.

**Conclusions:** Genetic testing is not widely used among HCPs for determining cause of kidney disease. Cost and coverage, as well as connecting with a genetic counselor appear to be the most challenging aspects of utilizing genetic testing. Additionally, these results demonstrate a notable increase in HCPs likelihood to use genetic testing once presented with the benefits of a definitive diagnosis. With these findings, stakeholders should continue to raise awareness of genetic testing benefits among HCPs and identify policies to address the challenges shared across the kidney community.

## SA-PO542

**Next Generation Sequencing to Determine Etiology of Renal Disease: A Canadian Prospective Cohort Study**

Logan R. Van Nynatten,<sup>1,2</sup> Cadence Baker,<sup>1</sup> Dervla M. Connaughton,<sup>1,2</sup> <sup>1</sup>London Health Sciences Centre University Hospital, London, ON, Canada; <sup>2</sup>Western University Schulich School of Medicine & Dentistry, London, ON, Canada.

**Background:** Recent data suggest that monogenic (single gene) diseases are underestimated in chronic kidney disease (CKD), particularly in adults with CKD of unknown etiology (CKDu). Retrospective research-based studies show that up to 70% pediatric and 30% adult-onset CKD is monogenic. Prospective studies are needed to help guide nephrologists on the integrating next generation sequencing into routine clinical settings.

**Methods:** This study is an ongoing prospective, cohort study to evaluate the diagnostic yield of next generation sequencing testing in a Canadian clinic. The secondary objective is to determine the outcomes following establishment of a genetic diagnosis, to help guide physicians and policymakers on implementation of next generation sequencing diagnostic into routine clinical care. A targeted phenotype driven gene panel was performed if the subtype of CKD was evident at time of presentation. Exome sequencing was utilized for patients with non-diagnostic panels or in whom the subtype of CKD was unknown (i.e. CKDu).

**Results:** To date, 148 families (209 individuals) have been recruited. We report on 72 families with CKD in whom next generation sequencing testing results are currently available. The median age of onset of CKD was 44 years (IQR 35-52). In 55% the subtype of CKD was unknown. A genetic diagnosis was confirmed in 42% of families. Exome sequencing yielded a genetic diagnosis in a further 10% who had a negative phenotype driven gene panel or had CKDu.

**Conclusions:** This is the first study to prospectively characterize monogenic causation of CKD in a Canadian cohort. Genetic sequencing demonstrates a high prevalence of monogenic disease in CKD. Both gene-panel and exome sequencing identified pathogenic mutations associated with renal disease. Genetic sequencing informed prognosis and resolved diagnostic confusion in all positive cases, while in some cases help guide management or facilitate decision making in biologically related living donors.

## SA-PO543

**Genetic Glomerular Disorders Are Associated With Worse Outcomes in CureGN**

Mark Elliott,<sup>1,2</sup> Natalie Vena,<sup>1</sup> Enrico Cocchi,<sup>1,4</sup> Maddalena Marasa,<sup>1</sup> Hila Milo Rasouly,<sup>1</sup> Matthias Kretzler,<sup>3</sup> Krzysztof Kiryluk,<sup>1</sup> Ali G. Gharavi.<sup>1</sup> CureGN Consortium <sup>1</sup>Columbia University Irving Medical Center, New York, NY; <sup>2</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>3</sup>University of Michigan, Ann Arbor, MI; <sup>4</sup>Universita' degli Studi di Torino, Torino, Italy.

**Background:** The true prevalence of monogenic glomerular disease is not known. Prognosis and treatment response may differ between genetic and sporadic forms of disease thus identifying a genetic etiology can have clinical significance in this patient population.

**Methods:** 2018 individuals enrolled in the international, multicenter Cure Glomerulonephropathy Network (CureGN) underwent genome sequencing. 513 with focal segmental glomerulosclerosis (FSGS), 465 with minimal change disease (MCD), 476 with membranous nephropathy (MN), and 564 with IgA nephropathy. Cases with a strong suspicion of a genetic diagnosis and those with kidney failure were excluded prior to enrolment. Variants in 180 genes with glomerular phenotypes were classified per ACMG/AMP guidelines. Pathogenic and likely pathogenic variants consistent with the inheritance pattern and patient phenotype were considered diagnostic. *APOL1* high risk genotypes were evaluated. The risk of immunosuppression resistance and kidney failure, defined by chronic dialysis or transplantation, was determined over a median of 4.3 years of follow-up, adjusted for demographic, clinical and biopsy characteristics.

**Results:** 14 different monogenic glomerular disorders were detected in 42 individuals (2% diagnostic rate): 28 with FSGS (5.4% diagnostic rate), 8 with MCD (1.7% diagnostic rate), 6 with IgAN (1.1% diagnostic rate), and 0 in MN. Over half were due to variants in *NPHS2* (16 variants in 10 individuals) and Alport spectrum disorder genes (18 variants in 18 individuals). 124 individuals have high-risk *APOL1* genotypes, including 3 with Mendelian diagnostic variants. On logistic regression, individuals with monogenic glomerular disease and those with high-risk *APOL1* genotypes were more likely to have immunosuppression resistant disease (OR=4.46, P=7x10<sup>-4</sup>; OR=1.83, P=0.02, respectively), particularly resistance to two or more therapies (OR=3.40, P=0.002; OR=2.19, P=0.003, respectively), and were also at increased risk of kidney failure (Cox proportional hazards OR=2.03, P=0.02; OR=1.88, P=0.002, respectively).

**Conclusions:** Monogenic glomerular diseases were identified in 42 subjects, with the highest diagnostic rate among FSGS cases. Individuals with monogenic disorders and those with high risk *APOL1* genotypes had an increased risk of multidrug resistant disease and kidney failure.

## SA-PO544

**Designing a Protocol for Return of Research Genetic Results to Adult and Pediatric Patients in NEPTUNE: A Multicenter Nephrotic Syndrome Cohort**

Jennifer Fishbein,<sup>1</sup> Chrysta C. Lienczewski,<sup>2</sup> Wendy R. Uhlmann,<sup>2</sup> J. Scott Roberts,<sup>2</sup> Matt G. Sampson.<sup>1,3</sup> NEPTUNE, University of Michigan <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Broad Institute, Cambridge, MA.

**Background:** The Nephrotic Syndrome Study Network (NEPTUNE), an observational cohort study of proteinuric kidney disease, is identifying patients with variants in Mendelian nephrotic syndrome genes. Return of research genetic results may have clinical benefits for participants. However, there is limited literature on how to return results in pediatric and multicenter studies. Some challenges and unanswered questions include returning secondary findings, communicating with patients, involving providers and paying for the process. Here we describe an initial protocol for return of results (ROR) for NEPTUNE.

**Methods:** We determined that only putative pathogenic, monogenic causes of nephrotic syndrome and high-risk *APOL1* genotype will be returned to patients. We conducted a needs assessment of all principal investigators in NEPTUNE (n=29) using an online survey, to understand the levels of expertise and resources across recruitment sites in order to operationalize ROR at each one. We asked about current presence of genetics clinics, use and comfort level with clinical genetic testing, and whom they would like to return results. To support clinicians, we created genetic information sheets and templates for communicating results in the chart and to patients.

**Results:** 27 sites completed the needs assessment. 82% (n=22) have a genetics clinic at their institution and among those, 32% (n=7) have a nephrology specific genetics clinic. 88.9% (n=24) of divisions have providers that already regularly order genetic testing, most commonly kidney genetics panel (n=23). 59% (n=16) of institutions can handle ROR independently. The remaining sites requested counseling and educational support through NEPTUNE. We created templates for a letter to notify patients, telephone script to follow-up with patients, a genetic counseling clinic note, and a family letter to be given to patients.

**Conclusions:** We have created a protocol to return genetic results to patients in NEPTUNE that addresses the unique challenges of a multicenter cohort including pediatric patients. The variability in resources and knowledge about genetic testing amongst nephrology divisions highlighted a need for support for ROR. Our protocol is generalizable to other research studies that aim to implement return of research genetic results.

SA-PO545

Diagnostic Yield of Exome Sequencing in Early Onset Hypertensive Nephropathy in Adults

Justine Serre,<sup>1,3</sup> Alice Doreille,<sup>1</sup> Marine Serveaux Dancer,<sup>2</sup> Laure Raymond,<sup>2</sup> Cedric Rafat,<sup>1</sup> Laurent Mesnard,<sup>1,3</sup> Service de néphrologie Hôpital Tenon <sup>1</sup>Assistance Publique - Hôpitaux de Paris, Paris, France; <sup>2</sup>Eurofins Biomnis Lyon, Lyon, France; <sup>3</sup>INSERM UMRS 1155, Paris, France.

**Background:** Hypertensive nephropathy (HN) is one of the most frequent causes of chronic kidney disease (CKD). However, the very existence of HN has been called into question. Its diagnostic framework is based on non-specific criteria. Next generation sequencing with exome sequencing (ES) has emerged as a comprehensive tool to detect Mendelian diseases in nephrology. ES has yet to be consistently incorporated in the diagnostic workup of patients with presumed HN.

**Methods:** We retrospectively collected the ES performed in the context of HN between September 2018 and February 2021. The diagnosis of HN was established if patients had an eGFR of less than 60ml/min/1.73m2, combined with hypertension, if no other cause of kidney disease could be identified, and a urinary protein to creatinine ratio of less than 2.5 was required.

**Results:** A total of 128 patients (Table 1) were sequenced in the context of HN. We detected pathogenic / likely pathogenic variants in 20 of the 128 patients (16%) encompassing 14 different monogenic disorders with Nephronophthisis and Alport syndrome accounting for more than half of it. Consanguinity and extra-renal disease possibly linked to the renal phenotype were significantly associated with ES positivity. The diagnostic yield of ES was lower in patients of African ancestry (8% versus 30% in non-African ancestry patients, p<0.01). There were significantly more variant of uncertain significance in patients with African (56%) compared to non-African ancestry (22%) (p=0.04) but less co-segregation data, with significantly more ES performed in solo, only proband (96%, compared to 80% in non-African ancestry patients, p<0.01).

**Conclusions:** The high diagnostic yield of ES (16%) in a population of patients thought to have HN casts further doubts on the validity of the existing diagnosis criteria. Our results argue for more consistent implementation of ES in patients supposed to have HN.

Patient characteristics and diagnostic yield

	All patients n = 128	Positive results n = 20	Negative results n = 108	p
Age, median [Q25-75]	41.5 [35.0; 51.0]	40.0 [31.8; 47.5]	42.0 [36.0; 51.0]	0.37
Sex (male), n (%)	99 (77)	13 (65)	86 (80)	0.16
CKD Stage V – Transplanted, n (%)	86 (67)	17 (81)	69 (64)	0.4
First-degree nephropathy, n (%)	38 (30)	9 (45)	29 (27)	0.1
Consanguinity, n (%)	8 (6.3)	4 (20)	4 (3.7)	0.021
Extra-Renal diseases, n (%)	30 (23)	11 (55)	19 (18)	<0.001
African ancestry, n (%)	84 (66)	7 (35)	77 (71)	<0.01

SA-PO546

Whole Genome Sequencing-Based Rare Copy-Number Variation Analysis in Patients With Proteinuric Kidney Disease

Jihoon Yoon,<sup>1,3</sup> Anya Greenberg,<sup>1</sup> Ana C. Onuchic-Whitford,<sup>1,4</sup> Michelle McNulty,<sup>1</sup> Dongwon Lee,<sup>1,2</sup> Matt G. Sampson.<sup>1,2</sup> NEPTUNE <sup>1</sup>Boston Children's Hospital Department of Pediatrics, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>4</sup>Brigham and Women's Hospital Department of Medicine, Boston, MA.

**Background:** Copy-number variants (CNVs), which have relatively larger effects than single nucleotide variants, are major drivers of diverse diseases and phenotypes, including congenital anomalies of the kidney and urinary tract. However, their contributions to nephrotic syndrome (NS) have not been systematically investigated. We addressed this through a whole genome sequence (WGS) based analysis of CNV in 619 pediatric and adult patients enrolled in the Nephrotic Syndrome Study Network (NEPTUNE).

**Methods:** WGS was performed at a depth of 30x. High-confidence CNV in coding regions were identified by integrating multiple detection methods. We used ACMG/ClinGen criteria to identify pathogenic CNV. We selected ancestry-matched controls from putatively healthy controls from the 1000 Genome Project (1KGP) by performing PCA analysis. We assessed the genome-wide distribution of rare (MAF < 0.1%) CNVs in cases and controls. We annotated CNV for the presence of known Mendelian steroid resistant nephrotic syndrome (SRNS) genes and those in the Online Mendelian Inheritance in Man (OMIM) database.

**Results:** There were no CNV (>1kb) impacting coding regions of Mendelian SRNS genes. There were 10 large CNVs (>100 kb) in 9 patients (1.4%) predicted as pathogenic/likely pathogenic based on the ACMG/ClinGen criteria. Case-control analyses revealed no difference in rare CNV burden (MAF < 0.1%). However, NEPTUNE patients had a 1.2x increased burden of coding CNV than controls (1.23 folds, P=0.02). Gene Ontology (GO) analysis of OMIM genes in case-only CNVs, identified enrichment in the lipid metabolism processes, particularly “lipase activity” (GO:0016298, FDR=4.6x10<sup>-3</sup>).

**Conclusions:** CNV impacting known Mendelian SRNS genes do not appear to be a major form of disease-associate genetic architecture. The relevance to NS of the pathogenic CNV detected in these patients needs to be determined. Preliminary case-control analysis suggests that CNV located in genes related to lipid metabolism may contribute to proteinuric kidney disease. Further characterization of these CNVs and expansion to non-coding regions is required.

SA-PO547

Diagnostic Utility of the Targeted Next-Generation Sequencing Panel Test for Suspected Genetic Glomerular Diseases

Ji Hye Kim, Hajeong Lee. Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.

**Background:** A substantial proportion of glomerular diseases has genetic background, but there is no solid guideline concerning genetic work-up. The targeted next-generation sequencing (NGS) gene panel can identify possible mutations causing genetic glomerulopathies. We evaluated the diagnostic utility of targeted NGS panel for glomerular diseases.

**Methods:** Patients who received targeted NGS panel from 2017 to 2021 were included. Our NGS panel covered 23 variants causing genetic glomerulopathies including collagenopathies (COL4A3, COL4A4, COL4A5, and MYH9), genetic nephrotic syndrome (ACTN4, ADCK4, ANLN, COQ2, COQ6, EMP2, INF2, NPHS2, NUP107, PLCE1, and TRPC6), and other syndromic diseases (NPHS1, LAMB2, LCAT, LMX1B, PAX2, SMARCAL1, WDR73, and WT1). Variants were classified according to American College of Medical Genetics and Genomics 2015 guideline. Diagnostic yield was calculated as positivity rate of pathogenic or likely pathogenic variants.

**Results:** A total of 111 patients were included. The median age of disease onset and of receiving test was 9.0 [3.0;22.5] and 17.0 [7.5;33.0] years. Among them, 50 had family history of kidney disease and 3 had congenital anomalies. Seventy-three patients received percutaneous kidney biopsy for their pathologic diagnosis. Overall diagnostic yield of targeted NGS panel was 36% and higher in patients with younger onset age (<18 years) than those older [44.7% vs 17.1%, p=0.03]. It was associated with previous kidney biopsy (adjusted odds ratio (aOR), 6.23; 95% confidence interval (CI), 1.21-32.06), hematuria (aOR, 4.68; 95% CI, 1.32-16.56), systolic blood pressure (aOR, 0.94; 95% CI, 0.88-0.99) and absence of edema (aOR, 0.05; 95% CI, 0-0.66) even after covariate adjustment. Among 40 patients with positive gene test results, 16 changed their diagnosis from initial pathologic diagnosis and 13 patients received new genetic diagnosis.

**Conclusions:** Targeted NGS panel test for genetic glomerular diseases was useful in genetic diagnosis with a modest diagnostic yield of 36%. Previous kidney biopsy, hematuria, low systolic blood pressure and absence of edema were associated with higher positivity rate.

SA-PO548

Genetic Variances in Mesoamerican and Undocumented Immigrant ESRD Patients

Mobolaji A. Obayomi, Jessie C. Fullmer, Henry J. Fan, George N. Coritsidis. Westchester Medical Center, Valhalla, NY.

**Background:** Dialysis clinics in the New York area treat a large population of undocumented immigrants (UIs) who originate or have heritage from Central and Northern South America, where renal failure includes the not yet understood Mesoamerican Nephropathy. Many are in the US for up to 6 years before awareness of CKD, often too late for proper diagnosis of pathogenesis. We were interested to see if certain underlying genetic mutations were more commonly found in UIs.

**Methods:** Patients were recruited prospectively from 5 dialysis units in New York from 2/1/22 focusing on patients whose heritage was from Latin America. Patients' buccal swabs were processed via Renasight genetic screening kits, which looks at 385 different genes related to kidney disease. The test is performed via buccal swab. Results are logged as pathogenic, carriers, or variants of unknown significance (VUS).

**Results:** Of 89 patients screened, 94.6% were UI's and 27.6% were under age 40. Overall positivity for pathogenic genes was 14% and 42% identified as carriers. There was an average of 6.9 VUS in each patient. The most common pathogenic gene was COL4A3 & 4 (8.62%) while the most common VUS genes were CACNA1H (13.4%), FRAS1 (8.6%), and TNS2 (8.6%).

**Conclusions:** An underlying pathologic genetic component that may be tied to patients of Latin American descent was seen at greater frequency in our UI population (14%) than that of the general public (10%). These patients had a multitude of different genetic abnormalities which may play a role in the early presentation and currently unknown origin of Mesoamerican Nephropathy. It is clear that further study of these genes are required.

**Funding:** Commercial Support - Natera

SA-PO549

Underlying Genetic Causes of Adult Patients With ESKD Undergoing Hemodialysis Therapy

Takuya Fujimaru,<sup>1</sup> Takayasu Mori,<sup>1</sup> Motoko Chiga,<sup>1</sup> Shintaro Mandai,<sup>1</sup> Fumiaki Ando,<sup>1</sup> Yutaro Mori,<sup>1</sup> Koichiro Susa,<sup>1</sup> Yuta Nakano,<sup>1</sup> Takao Shoji,<sup>2</sup> Yuichiro Fukudome,<sup>3</sup> Naoto Inaba,<sup>4</sup> Kenichiro Kitamura,<sup>4</sup> Taichi Nakanishi,<sup>4</sup> Toshihiro Kimura,<sup>5</sup> Teiichi Tamura,<sup>5</sup> Kiyoshi Ozawa,<sup>5</sup> Shinichi Uchida,<sup>1</sup> Eisei Sohara.<sup>1</sup> <sup>1</sup>Tokyo Medical and Dental University, Tokyo, Japan; <sup>2</sup>Miura Seaside Clinic, Kanagawa, Japan; <sup>3</sup>Zushi Sakurayama Clinic, Kanagawa, Japan; <sup>4</sup>Kitakurihama Takuchi Clinic, Kanagawa, Japan; <sup>5</sup>Yokosuka Clinic, Kanagawa, Japan.

**Background:** Recent progress of genetic studies gradually reveals true causes of chronic kidney disease (CKD). In the general CKD population, it has become clear that about 10% of patients carry some responsible genetic variants, and further most of them are limited genes such as *PKD1*, *PKD2*, or *COL4As*. End-stage kidney disease (ESKD)

is the ultimate phenotype of CKD, and conducting genetic analysis focusing on the population undergoing hemodialysis leads to the evaluation of key genes that have an influence on ESKD. To clarify underlying true cause of adult patients with ESKD, we performed panel-based comprehensive genetic analysis on hemodialysis patients.

**Methods:** Four dialysis clinics in Japan were included. The study was limited to patients who were introduced to hemodialysis during adulthood between the ages of 20 and 49. Of the 238 patients, the patients with a clear diagnosis of primary disease for ESKD were excluded, and 114 patients were included our study. Comprehensive genetic testing was performed using capture-based next-generation sequencing for 212 genes responsible for hereditary kidney diseases.

**Results:** Eleven patients (12%) out of the 92 were elucidated to have responsible gene variants, leading to definite genetic diagnosis. Of them, 6 and 1 patients carried causal pathogenic variants in *PKD1* and *NPHP1*, respectively. One of the patients with the *PKD1* variant also had the *COL4A4* pathogenic variant. All with *PKD1* variants did not have family history of kidney cysts. In addition, 4 patients, FSGS due to *WT1* variant, ADTKD due to *UMOD* variant, Alport syndrome due to *COL4A3* and *COL4A4* variants, and Fabry disease due to *GLA* variant were included. With the exception of polycystic kidney disease, these diagnoses had not been clinically obtained.

**Conclusions:** Focusing on ESKD patients, the proportion of those with a genetic cause was high. Among the patients who have been introduced to dialysis in adulthood, there are various kinds of undiagnosed hereditary renal diseases. From the viewpoint of genetic counseling and complication management, accurate diagnosis by comprehensive genetic analysis is extremely important.

## SA-PO550

### Korean Cohort of Genetic Kidney Diseases

Hyeon Ah Woo,<sup>1</sup> Hee Gyung Kang,<sup>1</sup> Yo Han Ahn,<sup>1</sup> Jeesu Min,<sup>1</sup> Naye Choi,<sup>1</sup> Hyeonju Lee,<sup>1</sup> Haemin Kang,<sup>1</sup> Seon Hee Lim,<sup>3</sup> Ji hyun Kim,<sup>2</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Bundang Hospital, Seongnam, Gyeonggi, Republic of Korea; <sup>3</sup>The Korean Society of Nephrology, Seoul, Republic of Korea.

**Background:** Genetic causes comprise a significant proportion of chronic kidney diseases (CKD). According to ethnicity, the composition can vary. Here, we report on Korea's nationwide composition of genetic kidney diseases in Korea.

**Methods:** In this multicenter cohort study, we investigated the genetic diagnosis of Korean patients with known or putative genetic kidney diseases and CKD of unknown origin. For known genetic kidney disease patients, clinical information, causative genes, and their responsible variants were collected, and for those without a genetic diagnosis, whole-exome sequencing was applied for genetic diagnosis.

**Results:** Genetic causes were identified in 1040 patients (male:female=1.3:1). Clinical diagnosis of genetic kidney diseases of Korea were as follows. Glomerulonephritis (24.9% of 1040 patients), tubulopathy (24.4%), cystic kidney disease (4.8%), and others (45.9%) including hypophosphatemic rickets or renal glycosuria. 118 genes were identified and the most common causative genes of Korean genetic kidney diseases were as follows. In glomerulonephritis: *COL4A5* (53.7% of glomerulonephritis), *NPHS1* (5.0%), *NUP107* (5.0%), *COL4A4* (4.6%), *WT1* (4.6%), *COL4A3* (4.2%), and others. In tubulopathy: *SLC12A3* (33% of tubulopathy), *AVPR2* (15%) *CLCN5* (15%), *CLCNKB* (11.4%), *OCRL* (11%), and others. In cystic kidney disease: *PKD1* (20% of cystic kidney disease), *PKHD1* (16%), and others. In others: *PHEX* (10% of others), *SLC5A2* (6.9%), and others. For 201 cases of CKD with unknown origin, 71 cases (35.3% of the unknown origin CKD patients) obtained genetic diagnosis using whole-exome sequencing, identifying pathogenic or likely-pathogenic variants in *COL4A5* (n=11, 15.5% of 71 cases), *COL4A4* (n=10), *PAX2* (n=5), *COL4A3* (n=4), *CUBN* (n=3), *NPHS1* (n=3), *WT1* (n=3), and others. Compared to the literature, prevalence of NPHP2 was lower than the reports of Caucasian, and distal renal-tubular acidosis was lower than the reports of Southern Asia.

**Conclusions:** Identifying the characteristics of genetic kidney diseases of a certain ethnicity through establishing a national registry would facilitate early diagnoses and proper management of these rare kidney diseases.

**Funding:** Government Support - Non-U.S.

## SA-PO551

### Biallelic Variants in TULP3 Cause Variable Onset Liver Cirrhosis and Kidney Failure With Defective Ciliary Cargo Composition and DNA Damage Repair

John A. Sayer,<sup>1,2</sup> John Devane,<sup>3</sup> Elisabeth B. Ott,<sup>3</sup> Daniel Epting,<sup>3</sup> Eric G. Olinger,<sup>1</sup> Carsten Bergmann,<sup>3,4</sup> <sup>1</sup>Newcastle University Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom; <sup>2</sup>Freeman Hospital, Newcastle upon Tyne, United Kingdom; <sup>3</sup>Albert-Ludwigs-Universität Freiburg Medizinische Fakultät, Freiburg, Germany; <sup>4</sup>Medizinische Genetik Mainz, Mainz, Germany.

**Background:** Several pathways governed by the primary cilium have been linked to human disease. Among them is autosomal recessive polycystic kidney disease (ARPKD), characterized by early-onset kidney failure in association with ductal plate malformation and hepatic fibrosis. So far, only two ciliary genes have been implicated in the ARPKD spectrum.

**Methods:** We used a combination of massive parallel sequencing with clinical, imaging and histopathological analysis in unsolved patients with features of ARPKD. Mechanistic studies were conducted in different cell models including patient-derived primary cells. This research was made possible through access to the data and findings

generated by the 100,000 Genomes Project (100kGP) (<http://www.genomicsengland.co.uk>).

**Results:** We report a 68-year-old female with a history of liver transplantation (aged 41 years) due to biliary cirrhosis and chronic kidney disease with multiple small cortical and medullary kidney cysts. Through whole genome sequencing analysis, we identified a homozygous missense variant affecting a functionally relevant amino acid in *TULP3*, encoding tubby-like protein 3 implicated in ciliary trafficking of various membrane proteins. Through 100kGP and international collaborators, a further 7 families with matching phenotypes and biallelic *TULP3* variants were detected. Patients (n=15) showed a wide range of disease onset (4-33 years) and presented with progressive liver fibrosis, fibrocystic kidney disease and histologically atypical hypertrophic cardiomyopathy. End-stage liver and kidney disease mostly occurred in adulthood. In several patient-derived cell systems, we identified disrupted ciliary cargo composition, including several proteins previously linked with hepatic fibrosis and cystic kidneys in humans and mice. *Ex vivo* pathway analyses demonstrated aberrant DNA damage repair and upregulation of profibrotic pathways with gene clusters for hypertrophic cardiomyopathy, WNT and TGF- $\beta$  signalling.

**Conclusions:** These findings identify a novel monogenic cause for a recessive progressive degenerative disease of major organs including the kidney in which affected individuals may benefit from early detection and improved clinical management.

## SA-PO552

### Underrecognition and Treatment of Autosomal Dominant Alport Syndrome in a Health System-Based Research Cohort

Kaushal V. Solanki, Bryn S. Moore, Natasha T. Strande, Ion D. Bucaloiu, Alex R. Chang. *Geisinger Health, Danville, PA.*

**Background:** Autosomal Dominant (AD) Alport Syndrome (AS) is increasingly recognized as a cause of chronic kidney disease and end-stage kidney disease (ESKD). It is unknown to what extent patients with ADAS are undiagnosed and whether they may benefit from diagnosis early in the disease course. We sought to assess whether a genetic diagnosis for ADAS was made and whether there were missed opportunities for treatment in a research cohort of participants with whole-exome sequencing data.

**Methods:** We used data from Geisinger MyCode-DiscovEHR, an unselected health system-based cohort with exome sequencing data linked to electronic health records (EHR). We identified participants heterozygous for rare (minor allele frequency <0.001) *COL4A3* pathogenic (P) or likely pathogenic (LP) variants listed in ClinVar. Chart reviews were performed focusing on the diagnosis of ADAS, AS-related features and diagnoses, genetic testing, renal biopsy pathology, treatment with angiotensin-converting enzyme inhibitors (ACEis) or angiotensin receptor blockers (ARBs), urologic workup for hematuria, family history (AS, thin basement membrane disease, and hereditary nephritis).

**Results:** There were a total of 402/174,418 patients heterozygous for P/LP *COL4A3* variants. Mean age was 59 (SD 18.7) years, 64% were female, 56% had ICD-code diagnoses for hypertension, 22% had diabetes, 7.2% had eGFR <30 ml/min/1.73m<sup>2</sup>, and 5.7% had ESKD. Over a median follow-up time of 15 years, only 118 (29%) had quantitative albuminuria testing. Only 4 patients had a clinical diagnosis of AD Alport Syndrome, 5 had documented family history, and 4 had history of kidney biopsy. Among the 338 (84%) who had urinalysis data available, 166 (49%) had trace or greater hematuria. 81 individuals had undergone urologic workup for hematuria. Of the 118 (29%) with albuminuria data, 42% had albuminuria  $\geq$ 30mg/g and 17% had albuminuria  $\geq$ 300 mg/g. ACEi/ARBs were underutilized in the overall population (24.5%), and even for those with hypertension (39.3%), and those with albuminuria (32.4%).

**Conclusions:** Very few patients with AD Alport Syndrome in a large health system-based research cohort had a diagnosis of ADAS, and a minority of patients were receiving guideline-recommended treatment with ACEis. Future studies should examine the benefits vs. risks of early diagnosis of ADAS.

**Funding:** NIDDK Support

## SA-PO553

### Refractory Focal Segmental Glomerulosclerosis: A Presentation of Alport Syndrome

Kenan M. Alrejjal,<sup>1,2</sup> Umayma Abdullatif,<sup>1</sup> Lauren Beretich,<sup>4</sup> Michelle Bloom,<sup>4</sup> Sumit Punj,<sup>4</sup> Abdul A. Abdellatif,<sup>3,1</sup> <sup>1</sup>CLS Health, Houston, TX; <sup>2</sup>MedStar Georgetown University Hospital MedStar Washington Hospital Center Internal Medicine Residency Program, Washington, DC; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>Natera, Inc., Austin, TX.

**Introduction:** Alport syndrome (AS) is a genetic condition caused by variants in the *COL4A3/4/5* genes. While classically characterized by progressive kidney disease, hearing loss, and ocular abnormalities, the use of genetic testing has expanded our understanding of the AS phenotype. Individuals with AS, notably autosomal dominant, are also known to present with benign hematuria, thin basement membrane nephropathy, and focal segmental glomerulosclerosis (FSGS) with or without extrarenal manifestations. The purpose of this study was to describe a case of FSGS refractory to multiple immunosuppressive regimens that was later diagnosed as AS.

**Case Description:** A 38-year-old Caucasian female with a history of biopsy-proven FSGS at 19 years of age with severe nephrotic syndrome. The patient was refractory to multiple lines of immunosuppressive therapy. Furthermore, an eye exam revealed keratoconus. These findings along with her family history of kidney conditions prompted genetic testing with a panel of 385 genes (the Renasight™ test) to help understand the etiology of her renal presentation and to determine further management. Genetic testing identified a heterozygous, likely pathogenic variant (c.1565G>A, p.Trp522\*) in *COL4A4*, associated with AS. This variant is predicted to result in a stop-gain in exon 22 of the

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

*COL4A4* gene. While c.1565G>A (p.Trp522\*) is private to this family, other putative loss-of-function variants downstream of this position have been reported to be pathogenic. The patient's 10 year old daughter was also found to have hematuria, and was subsequently found to have the familial variant in *COL4A4*.

**Discussion:** This case exemplifies the variable presentation of AS and the value of genetic testing for the proband and their family. The patient's condition was reclassified, enabling appropriate intervention, treatment resistance assessment and family testing. In addition, the patient's daughter received an early diagnosis, guiding future treatment plans and options while avoiding unnecessary risk exposure. The family's genetic diagnosis allowed for accurate genetic risk assessment and may increase access to targeted treatments or clinical trials in the future. Ultimately, genetic testing should be considered for individuals with FSGS, given the association with AS and other genetic conditions.

## SA-PO554

### Elucidating the Genetic Architecture of Microscopic Hematuria

Aditi Mhaske, Omid Sadeghi-Alavijeh, Mallory L. Downie, Melanie M. Chan, Daniel P. Gale. *University College London Department of Renal Medicine, London, United Kingdom.*

**Background:** Microscopic hematuria is commonly found during routine urine analysis and may be unrelated to exercise, trauma to the urogenital tract and menstruation. The most common glomerulopathies associated with this finding are IgA nephropathy and type IV collagen defects including Alport syndrome (AS). To elucidate the genetic architecture and identify potential disease-causing variants we used the whole genome sequencing and the phenotypic information from the 100,000 Genomes Project (100KGP) database.

**Methods:** Genome wide association studies (GWAS) were performed on two cohorts. Cohort one represent the 137 probands recruited with familial hematuria, cohort two comprised 3459 patients with hospital episode statistics (HES) data coding for at least one episode of microscopic hematuria. Both cohorts were ancestry matched to ~45,000 controls inclusive of individuals with diverse genetic ancestry. Enrichment of common, low-frequency (minor allele frequency [MAF] > 0.1%) and rare (MAF < 0.1%) single-nucleotide variant (SNV), indel and rare structural variant (SV) alleles on a genome-wide and per-gene basis was sought using a generalised linear mixed model approach to account for population structure.

**Results:** In the gene-based analyses we identified *COL4A4* ( $p=6.21E-10$ ,  $MAF=0.00040$ ) as significantly associated with hematuria. This signal was driven by a stop gain variant that exhibits a founder effect in collagenopathies (rs35138315). The genome wide variant analysis of over 9 million variants in both cohorts did not reveal any statistically significant loci.

**Conclusions:** This study provides insights on the genetic landscape of hematuria in a national health system. The pathogenic rs35138315 mutation in *COL4A4* was also reported recently in a larger cohort of hematuria patients from the UK Biobank. Variants in *COL4A4* account for a large proportion of microscopic hematuria at the population level.

Figure 1 - Rare variant manhattan showing *COL4A4* as being significantly associated with hematuria

## SA-PO555

### Clinical and Diagnostic Utility of Genomic Sequencing for Children With Microscopic Haematuria in a Kidney Genomics Clinic

Josiah Shanks,<sup>1</sup> Catherine Quinlan,<sup>1,2</sup> <sup>1</sup>Department of Nephrology, Royal Children's Hospital, Melbourne, VIC, Australia; <sup>2</sup>Kidney Flagship, Murdoch Children's Research Institute, Melbourne, VIC, Australia.

**Background:** Microscopic haematuria (MH) in children is associated with the risk of progression to chronic kidney disease. Genetic disease including Alport syndrome is an important potential aetiology.

**Methods:** We conducted a retrospective review of the electronic medical records of patients referred to a Kidney Genomics Clinic (KGC) with MH from 2016 to 2021; this period covers both pre- and post-government funded genomic sequencing for MH. Data were collected including demographics, investigations and diagnosis prior to referral, tests undertaken by the clinic, and the diagnostic and clinical utility of these genetic tests.

**Results:** Sixty patients were referred to the KGC with MH over a six-year period. Mean age at referral was 8.8 years and most (73%) were referred for diagnosis of an undifferentiated disease. At time of review, 10 (17%) patients' genetic results were outstanding. Of those with results, 26 (52%) received a genetic diagnosis for their haematuria. The most common diagnosis was X-linked Alport Syndrome (12/26, 46%), followed by Autosomal Dominant Alport Syndrome (10/26, 38%), and two cases each of

Autosomal Recessive Alport Syndrome and Dent's disease. 11/50 (22%) had a variant of uncertain significance (VUS) in a phenotypically concordant gene. The diagnostic yield dropped from 74% to 36% after the introduction of government-funded genomic sequencing for paediatric MH. The average degree of haematuria and proteinuria also decreased after the introduction of government-funding for genomic sequencing suggesting the bar for testing has been lowered. We found a higher diagnostic yield of 54% amongst male patients compared to 28% amongst female patients, despite females being affected twice as often by X-linked disease than males.

**Conclusions:** Our KGC review highlights the substantial clinical utility of genetic analysis for microscopic haematuria in paediatric patients and the important role that government-funded genomic sequencing can play in providing equitable and early access to gold standard testing. The testing is non-invasive and has a high diagnostic yield. A multidisciplinary team including appropriate genetic counselling can help ensure these patients are followed up meaningfully.

## SA-PO556

### New Insights on the Clinical Manifestations of COL4A4 Genetic Variants: A UK Biobank Analysis

Silvia M. Titan,<sup>1</sup> Alexandre da Costa Pereira,<sup>2</sup> <sup>1</sup>Nephrology Division, Sao Paulo University Medical School, Sao Paulo, Brazil; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** The spectrum of clinical manifestations of *COL4A4* is wide, with mutations in this gene being reported to be associated with Alport, thin membrane disease, and no kidney disease. Current literature is largely derived from phenotype-centered analysis but genetic data from population studies offer us the opportunity to investigate the associations of genotypes and phenotypes in an unbiased manner. In this study, we aimed at describing the association of *COL4A4* variants with albuminuria and other phenotypes in a large population study.

**Methods:** We used data from 200,069 UK-Biobank (UKB) participants with WES data to establish the prevalence of coding variants in *COL4A4*. We conducted burden analysis using SAIGE-GENE and WES and albuminuria data from 60,699 individuals adjusting for age and sex. Multiple iterations of conditional adjustment were applied to derive a set of independently associated genetic variants. Associated variants were annotated for their current ACMG classification using the ClinVar database. Finally, we explored other trait associations for selected variants.

**Results:** Of the 2988 unique variants within the *COL4A4* gene region, 1091 were coding: 56 LOF, 720 missense (434 damaging missense), and 315 synonymous. Rare variants in the coding region of *COL4A4* were significantly associated with albuminuria in burden analysis ( $p$ -value =  $8e-22$  for LOF, and  $2e-10$  for missense). Most burden signals for albuminuria at the population level could be explained by only 3 variants: rs35138315 (a stop-gain variant seen in 1:1000 individuals), rs36121515 (a missense variant seen in 1:300 individuals), and rs79143859 (a missense variant seen in 1:300 individuals). While rs35138315 is classified in ClinVar as pathogenic for recessive Alport disease, both rs36121515 and rs79143859 are currently classified as benign. In addition, rs36121515 was significantly associated with hearing-related phenotypes and rs79143859 with eye-related phenotypes, suggesting potentially pleiotropic manifestations of Alport disease.

**Conclusions:** Based on the findings of this large-scale population study, we suggest that rs35138315, rs36121515, and rs79143859 can be disease-modifying variants and should be further characterized regarding pathogenicity.

## SA-PO557

### Immunohistochemistry Staining of Type-4 Collagen Does Not Predict the Expression of COL4A3/4/5 in a Genomic Variant of Focal Segmental Glomerulosclerosis

Suramath Isaranuwatchai,<sup>1,2</sup> Pongpratch Puapatanakul,<sup>1</sup> Jerasit Surintspanont,<sup>1</sup> Koonpong Iampengkhae,<sup>1</sup> Jutamad Makyooy,<sup>1</sup> Thiamjit Chaichana,<sup>1</sup> Ankanee Chanakul,<sup>1</sup> Talerngsak Kanjanabuch,<sup>1</sup> Keartat Praditpornsilpa,<sup>1</sup> <sup>1</sup>Chulalongkorn University, Bangkok, Thailand; <sup>2</sup>Chulabhorn Hospital, Bangkok, Thailand.

**Background:** Focal segmental glomerulosclerosis (FSGS) is one of the kidney diseases with high rate of monogenic mutation. Variants in *COL4A3*, *COL4A4*, and *COL4A5* genes were reported to be the most common cause of FSGS. We conducted an immunohistochemistry (IHC) staining of  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen to see the correlation with the expression of *COL4A3/4/5* and genetic variants of FSGS patients.

**Methods:** Whole-exome sequencing of FSGS patients were analyzed for *COL4A3/4/5* variants and classified by American College of Medical Genetics guideline. Paraffin blocks of FSGS patients with variants in *COL4A3/4/5* genes were recruited and went through IHC staining protocol. We used normal allograft kidney as positive control and confirmed Alport's syndrome case as negative control.

**Results:** Eighteen FSGS patients with variants in *COL4A3/4/5* genes were identified. One patient had a novel pathogenic variant (c.905delG, p.Gly302ValfsTer23) in *COL4A4* gene. Another patient had a known likely pathogenic variant (c.2752G>A, p.Gly918Arg) in *COL4A4* gene. Both of them had positive staining of  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen, which means both patients express  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen in their glomerular basement membrane (GBM), contradicting with our hypothesis that pathogenic variants should result in negative staining. Ten patients had variants of uncertain significance which six of them had positive staining and four of them had equivocal staining. Six patients had benign or likely benign variants in *COL4A3/4/5* genes which four of them had positive staining and two of them had equivocal staining.

**Conclusions:** FSGS patients with COL4A3/4/5 genes variants all had  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen expression in their GBM. The expression of  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen by IHC staining was not correlated with COL4A3/4/5 genes variant classified by ACMG criteria.

**Funding:** Government Support - Non-U.S.

Figure 1: Immunohistochemistry staining of  $\alpha 3(IV)$  and  $\alpha 5(IV)$  collagen

## SA-PO558

### Potentially Clinically Relevant Variant of Uncertain Significance in the COL4A5 Gene

Teresa Trinkka,<sup>1</sup> Kerry Gaj,<sup>3</sup> Quinn P. Stein,<sup>3</sup> Sumit Punj,<sup>3</sup> Mohammed Khurram Faizan.<sup>2,1</sup> <sup>1</sup>The Warren Alpert Medical School at Brown University, Providence, RI; <sup>2</sup>Hasbro Children's Hospital, Providence, RI; <sup>3</sup>Natera, Inc., Austin, TX.

**Introduction:** Genetic testing is an emerging tool for patient management in the field of Nephrology. Numerous studies highlight the benefits of using broad, unbiased genetic panels compared to smaller, targeted panels based on the clinical presentation of the disease, due to the often complex and variable presentation of many renal disorders. Alport syndrome (AS) is an inherited disease caused by pathogenic variants in the COL4A3/4/5 genes that encode collagen IV components respectively. In AS, a spectrum of phenotypes ranging from isolated hematuria with non-progressive renal disease to progressive renal disease with extrarenal abnormalities is observed. Here we report our findings of a variant of uncertain significance (VUS) in the COL4A5 gene in four family members.

**Case Description:** Patient 0 was a 16 y/o female, initially presenting with microscopic hematuria and marginally elevated urine protein to creatinine ratio. The patient's physical exam was unremarkable with normal blood pressure and SCr levels. However, the patient's mother and maternal aunt both had a lifelong history of microscopic hematuria. The maternal grandfather had lifelong kidney disease, for which he received a kidney transplant at the age of 50. All four patients underwent genetic testing with a next generation sequencing (NGS)-based panel consisting of 385 genes associated with kidney disease (the Renasight™ test). No positive genetic findings were identified in the patients; however, a VUS, c.276+2dup, in the COL4A5 gene was identified in all four members.

**Discussion:** In the family presented here, genetic testing provided an intimation of a possible cause and inheritance pattern for kidney disease and hematuria. Genetic testing for Patient 0 gave rise to cascade testing in 3 additional family members to date, with the potential for testing of other affected family members. The VUS identified is predicted to affect the highly conserved splice donor site for exon 4. Functional studies are necessary to determine the impact of this variant and to invoke stronger evidence for reclassification. To our knowledge, this variant has not been reported to be associated with AS and is absent from population databases. However, based on the clinical presentation of these patients and the lack of other positive genetic findings, this VUS is suspicious and warrants further investigations.

## SA-PO559

### Clinical and Genetic Features of Autosomal Dominant Alport Syndrome: A Cohort Study in China

Ningning Hu,<sup>1</sup> Dai Xuantong,<sup>1,2</sup> Fujun Lin,<sup>1,2</sup> Gengru Jiang.<sup>1,2</sup> <sup>1</sup>Shanghai Jiaotong University School of Medicine Xinhua Hospital, Shanghai, China; <sup>2</sup>Centre for Rare Disease, Shanghai, China.

**Background:** Patients carrying pathogenic heterozygous COL4A3 /COL4A4 mutations, considered to have autosomal dominant Alport syndrome (ADAS), account for nearly 1% of the population. ADAS patients show a wide spectrum of disease, extending from familial isolated microscopic hematuria to end-stage renal disease (ESRD). The aim of this study was to evaluate the clinical and genetic spectrum of Chinese ADAS patients.

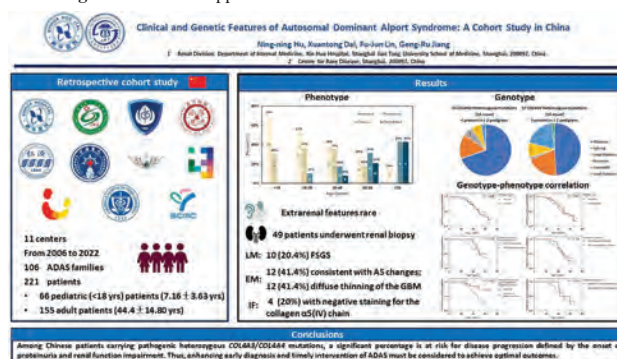

**Methods:** 106 families with ADAS referred from 11 Chinese hospitals between 2006 and 2022 were retrospectively studied. Clinical, genetic, laboratory, and pathological data were collected.

**Results:** Of the cohort of 221 patients, 66 (29.9%) patients were under the age of 18. Microhematuria was present in 98.2% patients, and extrarenal features were rare. 118 (53.4%) patients developed proteinuria [mean age 24.39±16.64 years], 58 (26.2%) with progression toward chronic kidney disease (CKD) 2 and more advanced CKD stages at a mean age of 41.07±13.62 years (22 required kidney replacement therapy at the mean age of 48.05±11.92 years). 49 patients underwent kidney biopsy: findings were consistent

with classic Alport syndrome in 12 cases, with diffuse thin basement membrane in 12 cases and with focal segmental sclerosis in 10 cases. 90 pathogenic heterozygous COL4A3 /COL4A4 mutations were identified and 45 (50%) were Glycine substitution missense mutations. Genotype-phenotype correlation analysis only revealed a significant difference regarding progression toward CKD2 when comparing patients with Glycine mutation located in exons 1-20 and in exons 21 to carboxy terminus ( $P = 0.006$ ).

**Conclusions:** Among Chinese patients carrying pathogenic heterozygous COL4A3 /COL4A4 mutations, a significant percentage is at risk for disease progression defined by the onset of proteinuria and renal function impairment. Thus, enhancing early diagnosis and timely intervention of ADAS must be considered to achieve optimal outcomes.

**Funding:** Government Support - Non-U.S.

## SA-PO560

### Genotype and Renal Outcomes in Alport Syndrome: A Retrospective Cohort Study Using National Registry of Rare Kidney Diseases (RaDaR) Data

Katie Wong,<sup>1</sup> David Pitcher,<sup>1</sup> A. Neil Turner,<sup>4</sup> Kate Bramham,<sup>3</sup> Daniel P. Gale.<sup>2</sup> <sup>1</sup>UK Renal Registry, Bristol, United Kingdom; <sup>2</sup>University College London, London, United Kingdom; <sup>3</sup>King's College London, London, United Kingdom; <sup>4</sup>University of Edinburgh, Edinburgh, United Kingdom.

**Background:** Alport syndrome (AS) is the second commonest cause of inherited kidney failure, resulting from pathogenic variants in COL4A3, COL4A4, and COL4A5 genes. This study investigated the renal outcomes associated with pathogenic variant types in a UK cohort of patients diagnosed with AS.

**Methods:** RaDaR data is linked with the UK Renal Registry for renal outcomes and Regional Genetics hubs for genetics reports. Pathogenic variants were classified into 1) Non-protein length altering 2)Protein length altering. Kaplan-Meier analysis and the log rank statistic were used to compare survival curves, stratified by pathogenic variant type, for a) time between last eGFR  $\geq 90$  and last eGFR  $\geq 30$  ("therapeutic window") b) age at KRT start c) kidney transplant graft survival, censored for death. Analyses were run comparing variant type for 1) COL4A5 males 2) COL4A5 females 3) Heterozygous COL4A3 or COL4A4 variants 4) Homozygous or 2 COL4A3 or COL4A4 variants.

**Results:** Genetic report data were available for 182/914 (20%) AS patients recruited to RaDaR (Figure 1). 167/182 had a detected pathogenic mutation (92%). 46 (25%) underwent kidney transplantation. No significant difference in time to KRT by variant type was observed in males or females with COL4A5 variants ( $p=0.17$ ,  $p=0.06$  respectively). Graft survival and time in therapeutic window were not significantly different between variant type for any group.

**Conclusions:** We did not observe the previously reported correlation between variant type and renal outcomes in males with COL4A5 variants. Linkage of the RaDaR AS cohort with genetic report data is actively ongoing; further correlations may be observed with larger numbers.

Figure 1: RaDaR AS cohort genetic variants

SA-PO561

**Heterogeneity in Electronic Health Record (HER) Phenotype Concepts in Collagen Type IV-Associated Nephropathies**  
Jordan G. Nestor, Krzysztof Kiryluk, Chunhua Weng. *Columbia University, New York, NY.*

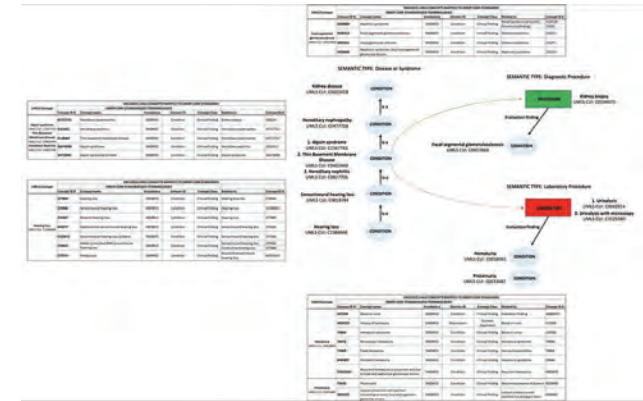

**Background:** Limited appreciation for the full spectrum of disease manifestations of collagen type IV-associated nephropathies (COL4A-AN) contributes to delays in diagnosis. Understanding the diversity of phenotypes is compounded by the heterogeneity of terms used to describe phenotype concepts in the EHR.

**Methods:** We extracted terms from published COL4A-AN case series and mapped them to concept unique identifiers (CUIs) in the Unified Medical Language System (UMLS). We identified 100 exome sequenced Columbia Biobank participants with diagnostic variant(s) in COL4A3/4/5 and performed a heuristic manual chart review. We counted the total number of unique concepts identified across structured (e.g., ICD9/10 and SNOMED-CT codes, etc.) and unstructured (e.g., clinical narratives, raw laboratory values, etc.) formats. Each encoded data element was mapped to standardized terminologies of the OMOP-Common Data Model. Then, we analyzed the diversity of codes used and conducted qualitative interviews with providers on billing practices.

**Results:** Most of the rich descriptions were documented within the text of clinical narratives written by kidney experts. In addition, a review of the raw urinalysis data revealed temporal, diagnostic evidence of hematuria in nearly half the cohort. Across structured data formats, we found numerous billing codes used to document particular concepts, such as hematuria and hearing loss. Through qualitative interviews, we found that nephrologists selected codes that reflected the primary disease addressed in the visit and ones that demonstrated the medical complexity of the patient's disease to maximize reimbursement.

**Conclusions:** EHR data heterogeneity is an obstacle to the development of accurate and valid phenotype algorithms for COL4A-AN and should be accounted for in EHR phenotyping. Extracting concepts from clinical text using natural language processing techniques, in addition to structured data elements like billing codes, may prove useful.

UMLS Concept Map for COL4A-AN

SA-PO562

**Aberrant Splicing Affected by Single Nucleotide Variants Positioned at the Second and Third to the End of Exons in COL4A5 Gene**  
Eri Okada, Yuya Aoto, Tomoko Horinouchi, Tomohiko Yamamura, Kandai Nozu. *Kobe Daigaku, Kobe, Japan.*

**Background:** As it has become more evident that male patients with X-linked Alport Syndrome show obvious genotype-phenotype correlation, it has been of great importance to clarify the impact on aberrant splicing caused by identified variants. We previously reported that single nucleotide variants (SNVs) at the last nucleotide of exons in COL4A5 gene highly cause aberrant splicing. It is generally considered that the 2nd and 3rd to the last nucleotides of exons can also play an important role in the first step of splicing process. The aim of the recent study is to investigate aberrant splicing affected by SNVs positioned at 2nd or 3rd to the last nucleotide of exons in COL4A5 gene.

**Methods:** We selected 8 candidate variants: 6 from Human Gene Mutation Database Professional and 2 from our cohort. We performed in vitro splicing reporter assay and reverse transcription polymerase chain reaction (RT-PCR) for messenger RNA obtained from the patients if available.

**Results:** Initial classification of the candidate variants was as follows: 3 nonsense, 2 missense and 3 synonymous. Splicing reporter assay and RT-PCR for messenger RNA revealed that 6 of 8 variants caused aberrant splicing. Four variants initially assessed as non-truncating variants were revealed to be truncating variants. One variant (No.7, c.685A>T, p.Lys229\*) generated not only normal transcript but also aberrant transcript, which resulting in in-frame deletion.

**Conclusions:** We revealed that exonic SNVs positioned at the 2nd and 3rd to the last nucleotide of exon in COL4A5 gene can highly cause aberrant splicing. Minigene splicing assay is useful to confirm the effect of variants on aberrant splicing especially for genes

that genotype-phenotype correlation is evident like COL4A5 gene to predict the patients' prognosis.

No.	Variant			cDNA analysis (patients' sample)	Minigene splicing reporter assay	
	Exon (bp)	Nucleotide	Protein		splicing outcome	Protein effect
2nd to the last nucleotide						
1	27 (105)	c.2145A>G	p.Lys715=		exon27 skipping	p.[Asp682_Gly716del]
2	29 (151)	c.2394A>T	p.Lys798Asn		exon29 skipping	p.[Gly749Valfs*20]
3		c.2394A>G	p.Lys798=		exon29 skipping	p.[Gly749Valfs*20]

SA-PO563

**Podocalyxin (PODXL) Nonsense Variant in Patients With Atypical Adult-Onset Focal Segmental Glomerulosclerosis (FSGS)**  
Monica Arnaldi, Dervla M. Connaughton. Nephrology Division at Schulich School of Medicine & Dentistry, Western University *Western University, London, ON, Canada.*

**Introduction:** Genetic kidney disease has been the focus of many investigative efforts, particularly in patients with adult-onset chronic kidney disease (CKD) and positive family history. FSGS is a podocyte-driven disease, that is the most frequent cause of CKD worldwide and regularly progresses to end-stage kidney disease (ESKD). The PODXL-encoded podocalyxin is a podocyte protein and a member of the CD34 family of stem cell sialomucins. It has recently been described in families with both recessive (compound heterozygous variants) and dominant forms of familial nephropathies. We detected a novel heterozygous nonsense variant in the PODXL gene c.1048C>T, p.(Arg350\*) in a family with atypical FSGS.

**Case Description:** We detected a novel heterozygous nonsense variant in the PODXL gene c.1048C>T, p.(Arg350\*) in a family with atypical FSGS. This variant was segregated in this family with 3 affected individuals with CKD all carrying the same variant. The patient is a 43-year-old woman, who was first diagnosed 29 years with proteinuria, peripheral edema, and normal creatinine level. A kidney biopsy raised the suspicion of FSGS with patchy podocyte effacement but no definite segmental sclerotic glomerular lesions were identified. There were some areas of thickening of the glomerular basement membranes and mild tubular atrophy and interstitial fibrosis. Initially, she commenced prednisone but had no response, treatment switched to mycophenolate but no response, then started on cyclosporine with low dose prednisone with a complete response followed by relapse. She was later switched to tacrolimus with partial response.

**Discussion:** Next-generation sequencing (NGS) technology can reveal the underlying etiology of disease in patients, where other diagnostic strategies have failed to confirm the diagnosis. In this case, histopathology following kidney biopsy raised the suspicion of FSGS but diagnosis could not be confirmed. Increased utilization of NGS is expected to increase diagnostic efficiency in patients with CKD, especially in patients with positive family history and/or young-onset ESKD. A definitive genetic diagnosis has important prognostic value to help understand these atypical subtypes of disease which may in turn impact treatment strategies for patients carrying particular genetic variants.

SA-PO564

**Genome-Wide Association Study (GWAS) Uncovers Novel Mechanisms and Potential Therapeutic Targets for IgA Vasculitis**  
Lili Liu,<sup>1</sup> Li Zhu,<sup>2</sup> Sara Monteiro-Martins,<sup>3</sup> Francesca Zanon,<sup>1</sup> Francesca Lugani,<sup>4</sup> Krzysztof Mucha,<sup>5</sup> Malgorzata Mizerska-wasiak,<sup>5</sup> Laureline Berthelot,<sup>6</sup> Jan Novak,<sup>7</sup> William E. Smoyer,<sup>8</sup> Robert J. Wyatt,<sup>9</sup> Raoul D. Nelson,<sup>10</sup> Anna Kottgen,<sup>3</sup> Ali G. Gharavi,<sup>1</sup> Hong Zhang,<sup>2</sup> Krzysztof Kiryluk,<sup>1</sup> <sup>1</sup>*Columbia University Irving Medical Center, New York, NY;* <sup>2</sup>*Peking University First Hospital, Beijing, China;* <sup>3</sup>*Albert-Ludwigs-Universitat Freiburg, Freiburg im Breisgau, Germany;* <sup>4</sup>*The Giannina Gaslini Children's Hospital, Genova, Italy;* <sup>5</sup>*Warsaw University Medical Center, Warsaw, Poland;* <sup>6</sup>*INSERM, Paris, France;* <sup>7</sup>*The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL;* <sup>8</sup>*Nationwide Children's Hospital, Columbus, OH;* <sup>9</sup>*The University of Memphis, Memphis, TN;* <sup>10</sup>*University of Utah Health, Salt Lake City, UT.*

**Background:** IgA vasculitis (IgAV) is an immune complex-mediated leukocytoclastic vasculitis characterized by vascular deposition of IgA-containing immune complexes in the skin, gastrointestinal and glomerular capillaries. The exact pathogenic mechanisms of IgAV remain unclear and thus there are presently no targeted treatments.

**Methods:** We conducted a GWAS for IgAV in 8,098 individuals of European and East Asian ancestries including 2,170 IgAV cases and 5,928 controls. We performed

meta-analysis with dense imputation and fine-mapping of significant loci, followed by proteome-wide association studies (PWAS) and transcriptome-wide association studies. Whole blood RNA-seq data from 255 IgAV cases with matched genotype data were used for genome-wide expression QTL (eQTL) mapping. By integrative analysis of genetic and transcriptomic data, we investigated the consequences of IgAV risk alleles on gene function and regulation.

**Results:** In GWAS, we detected 3 genome-wide significant loci for IgAV. We confirmed a strong effect of the *HLA* locus (OR=1.55, P= 1.1x10<sup>-25</sup>) and we identified two novel non-*HLA* loci at chr.19q13.42 (OR=1.51, P=1.0x10<sup>-20</sup>) and chr.2q37.1 (OR=1.34, P= 2.2x10<sup>-09</sup>) loci. The *HLA* fine-mapping identified *HLA-DRB1* as the most likely culprit gene, with amino-acid position 11 conveying the greatest risk. The chr.19q13.42 locus colocalized with the eQTL for *FCAR* (PP4=0.95), encoding the Fc  $\alpha$  IgA receptor (CD89), with the risk allele being associated with increased *FCAR* expression in myeloid cells (P<sub>fidr-adjusted</sub> = 1.6x10<sup>-09</sup>). Blood mRNA levels of *FCAR* in IgAV patients were 1.5-fold higher vs. controls (P=5.1x10<sup>-09</sup>). Four upstream regulators for *FCAR* differentially activated in IgAV cases vs. controls were identified using ARACNe3-based master regulator analysis. By PWAS, we additionally identified a distinct proteome-wide significant signal at the lq21.3 locus that was suggestive in GWAS, and for which the risk allele was associated with increased blood levels of soluble IL6R.

**Conclusions:** Our genetic findings implicate roles for CD89 and IL6R in the pathogenesis of IgAV and nominate these genes and related pathways for future therapeutic targeting.

## SA-PO565

### Familial IgA Glomerulonephritis Is Commonly Caused by Pathogenic Variants Associated With Other Genetic Kidney Diseases

Philip A. Harraka,<sup>1</sup> Khalid Mahmood,<sup>2,3</sup> Heather G. Mack,<sup>4,5</sup> David Barit,<sup>1</sup> David Langsford,<sup>1</sup> Timothy J. Pianta,<sup>6,7</sup> Deb J. Colville,<sup>1</sup> Judith A. Savage.<sup>1</sup>  
<sup>1</sup>The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; <sup>2</sup>Melbourne Bioinformatics, Melbourne, VIC, Australia; <sup>3</sup>The University of Melbourne Department of Clinical Pathology, Melbourne, VIC, Australia; <sup>4</sup>The University of Melbourne Department of Surgery in Ophthalmology, East Melbourne, VIC, Australia; <sup>5</sup>Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia; <sup>6</sup>Department of Medical Education, University of Melbourne, Melbourne, VIC, Australia; <sup>7</sup>Renal Medicine, Northern Health, Melbourne, VIC, Australia.

**Background:** Genetic studies of families with IgA glomerulonephritis have implicated pathogenic variants in *COL4A3-5* and *SPRY2* but in few other genes. We have recently identified retinal drusen in IgA glomerulonephritis which is further evidence for complement activation. This study investigated familial IgA disease for pathogenic variants in five candidate gene lists including those reported in IgA nephropathy (102 genes), the complement system (56), drusen in macular degeneration (46), Alport syndrome (3) and FSGS (47).

**Methods:** Eight unrelated individuals with familial IgA nephropathy were recruited. Family members were examined for haematuria, proteinuria and eGFR. IgA nephropathy was biopsy-proven in the index case and some relatives. Whole exome sequencing of available members in each family was performed and variants curated using the GATK Best Practices pipeline. Variants were examined for a CADD score  $\geq 10$  and a minor allele frequency  $<0.05$  in gnomAD, and pathogenic assessments made according to the ACMG criteria. Assessments included pathogenic features in in-silico prediction algorithms ( $\geq 2$  of PolyPhen-2, SIFT, MutationTaster) and conservation of the affected residue in vertebrates (UCSC Genomics Institute).

**Results:** Damaging variants were identified in four families (50%) consistent with Alport syndrome in two (*COL4A3*, *COL4A5*), Renal Cysts And Diabetes syndrome (*HNF1B*) in one and C9 deficiency (*C9*) in one. The *COL4A3* variant (p.Gly395Glu) was Likely pathogenic (PP5, PM1, PM2, PP2, PP3) and previously associated with AD Alport syndrome and haematuria. The *COL4A5* variant (p.Gly624Asp) is a common hypomorphic variant (PP5, PM1, PM5, PP2, PP3) causing late onset X-linked Alport syndrome. The *HNF1B* variant (p.Pro437Leu) is Likely Pathogenic (PM2, PP2, PP3, PP5) and previously reported in Renal Cysts And Diabetes syndrome. The *C9* (p.Cys54Ter) variant is a Pathogenic nonsense change (PVS1, PP5, PM2, PP3) in a drusen-risk gene associated with a partial C9 complement deficiency.

**Conclusions:** Half the families with IgA nephropathy examined here had another explanation for their genetic kidney disease. Since IgA deposits occur in up to 20% of normal individuals, apparent familial IgA nephropathy may be secondary to another, concurrent, genetic kidney disease.

## SA-PO566

### OXGR1 Is a Candidate Disease Gene for Human Calcium Oxalate Nephrolithiasis

Amar J. Majmudar,<sup>1</sup> Eugen Widmeier,<sup>1</sup> John F. Heneghan,<sup>2</sup> Ankana Daga,<sup>1</sup> Hannah Hugo,<sup>1</sup> Ali Amar,<sup>1,3</sup> Tilman Jobst-Schwan,<sup>1,4</sup> Caleb Nelson,<sup>5</sup> Jan Halbritter,<sup>6,7</sup> John A. Sayer,<sup>8,9</sup> Hanan Fathy,<sup>10</sup> Michelle A. Baum,<sup>1</sup> Shirlee Shril,<sup>1</sup> Shrikant M. Mane,<sup>11</sup> Seth L. Alper,<sup>2</sup> Friedhelm Hildebrandt.<sup>1</sup>  
<sup>1</sup>Division of Nephrology, Department of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; <sup>2</sup>Division of Nephrology, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; <sup>3</sup>Department of Human Genetics and Molecular Biology, University of Health Sciences, Lahore, Pakistan; <sup>4</sup>Department of Nephrology and Hypertension, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; <sup>5</sup>Department of Urology, Boston Children's Hospital and Department of Surgery, Harvard Medical School, Boston, MA; <sup>6</sup>Division of Nephrology, Department of Internal Medicine, University of Leipzig, Leipzig, Germany; <sup>7</sup>Department of Nephrology and Medical Intensive Care, Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>8</sup>Institute of Genetic Medicine, Newcastle University, Newcastle, United Kingdom; <sup>9</sup>The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle, United Kingdom; <sup>10</sup>Pediatric Nephrology Unit, Alexandria University, Alexandria, Egypt; <sup>11</sup>Department of Genetics, Yale University School of Medicine, New Haven, CT.

**Background:** Nephrolithiasis (NL) affects 1 in 11 individuals worldwide. Causative genetic variants are detected in 11-28% of NL and/or associated nephrocalcinosis (NC) (Halbritter *JASN* 2015; Braun *cJASN* 2016; Daga *KI* 2018). *OXGR1* encodes 2-oxoglutarate receptor 1, which is expressed in collecting duct Type B intercalated cells. *OXGR1* mediates cellular Ca<sup>2+</sup> uptake in response to  $\alpha$ -ketoglutarate (AKG) (He *Nature* 2004), a renally excreted metabolite derived from the NL treatment citrate (Krebs *Biochem J* 1938; Coe *Nat Rev Neph* 2016). Genetic inactivation in mice of the *Oxgr1* effector Pendrin leads to hypercalciuria, a risk factor for NL/NC (Tokonami *JCI* 2013; Amlal *AJPCP* 2010; Barone *NDT* 2016).

**Methods:** Exome and targeted sequencing of the *OXGR1* locus was performed in a worldwide NL/NC cohort. Putatively deleterious rare *OXGR1* variants were functionally characterized.

**Results:** A heterozygous missense *OXGR1* variant (c.371T>G, p.L124R) co-segregated with calcium oxalate NL/NC in an autosomal dominant inheritance pattern within a multi-generational family with five affected individuals. Strong amino acid conservation in orthologues and paralogues, severe *in silico* prediction scores (SIFT, PolyPhen2.0, CADD), and extreme rarity in exome/genome population databases suggested the variant was deleterious. Interrogation of the *OXGR1* locus in 1107 NL/NC families identified five additional dominant alleles (p.Ser56Profs\*7, p.Tyr93His, p.Cys217Arg, p.Ser233Arg, p.Ser287Phe) in five families with calcium oxalate NL/NC. All were rare variants ( $<5$  alleles in ExAC,  $<10$  alleles in gnomAD) with multiple severe prediction scores. Rare, potentially deleterious *OXGR1* variants were enriched in NL/NC subjects relative to ExAC controls (0.54% versus 0.16%;  $\chi^2=7.117$ , p=0.0076). Wildtype *OXGR1*-expressing *Xenopus* oocytes exhibited AKG-responsive Ca<sup>2+</sup> uptake. Four of five NL/NC-associated missense variants revealed impaired AKG-dependent Ca<sup>2+</sup> uptake at pH 5 and/or 7.4, demonstrating loss-of-function.

**Conclusions:** Rare, dominant *OXGR1* variants are a candidate etiology of NL/NC, suggesting a novel mechanism for human NL/NC disease.

**Funding:** NIDDK Support, Private Foundation Support

## SA-PO567

### Rare Kidney Stone, Potassium Magnesium Pyrophosphate Pentahydrate Calculi, in Hypophosphatasia

Tariku T. Guduru, Korey Bartolomeo, Xiangling Wang, Cleveland Clinic Cleveland Clinic, Cleveland, OH.

**Introduction:** Hypophosphatasia (HPP) is a rare inherited disorder caused by loss of function mutation of ALPL that encodes tissue nonspecific alkaline phosphatase (TNSALP), characterized by impaired mineralization of bones and teeth in the presence of low activity of serum and bone alkaline phosphatase. Kidney stones and nephrocalcinosis have been reported in some cases and most of the stones are calcium containing. Late diagnosis of hypophosphatasia is not uncommon. Here we present a case of a new diagnosis of hypophosphatasia for a 61 year old man after passing pure potassium magnesium pyrophosphate pentahydrate stones, which is very rare.

**Case Description:** A 61-year-old with history of hypertension, diabetes, premature tooth loss, skeletal fractures and over 10 symptomatic nephrolithiasis since age 20 was sent for genetic evaluation. His most recent serum labs were relevant for creatinine 1.4 mg/dl, alkaline phosphatase (ALP) 6 U/L (40-130), bone specific ALP 1.6  $\mu$ g/ml (6.5-20.1), vitamin B6 1,594.2 nmol/L (20-125), PTH 39 pg/ml (15-65) and 25-vitamin D 69.6 ng/ml (31-80). Calcium and phosphate were within normal lab limits. Urines studies were unremarkable with 24-hour urine protein 480 mg, presumed to be related to diabetic nephropathy or possible tubular injury from recurrent nephrolithiasis. His most recent stone analysis showed 100% potassium magnesium pyrophosphate pentahydrate (PMPP). Family history was significant for short stature and a mechanical fall related wrist fracture in his mother, and kidney stones and color blindness in his 2 nephews. Genetic test showed two heterozygous pathogenic variants, c.1240C>A (p. Leu414Met) and c.407G>A (p. Arg136His), in the ALPL gene confirming the diagnosis of HPP. Parental testing is pending to clarify its inheritance pattern. The patient was started on recombinant human TNSALP.

**Discussion:** Patients with HPP tend to have hypercalciuria with or without hypercalcemia from impaired bone uptake of calcium and phosphorus. This increases risk of nephrocalcinosis and calcium containing kidney stones. Our patient developed pure potassium magnesium pyrophosphate pentahydrate stone, which is very rare, and has not been reported in human beings. Its association with HPP is unclear and deserves further investigation.

## SA-PO568

### Genotype-Phenotype Correlation in Cystinuria

Mohammad D. Hossain,<sup>1</sup> Andrea G. Cogal,<sup>1</sup> Ivan E. Porter,<sup>2</sup> David S. Goldfarb,<sup>3</sup> Peter C. Harris,<sup>1</sup> John C. Lieske.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Mayo Clinic in Florida, Jacksonville, FL; <sup>3</sup>NYU Langone Health, New York, NY.

**Background:** Cystinuria is an autosomal recessive disorder characterized by impaired proximal renal tubular absorption of cystine. To date no clear genotype-phenotype relationship has been established. This study reviewed genetic and clinical data of a large cohort of suspected cystinuric patients in the Rare Kidney Stone Consortium (RKSC) cystinuria registry.

**Methods:** Subjects with suspected cystinuria (n=76) were genotyped either by Sanger sequencing or a targeted next generation sequencing (tNGS) panel that includes the 2 cystinuria genes. Clinical data were abstracted from the RKSC cystinuria registry.

**Results:** Biallelic mutations in *SLC3A1* were found in 50 individuals, biallelic mutations in *SLC7A9* in 21 individuals, and 1 mutation in each gene in 1 individual. Four individuals had a clear cystinuria phenotype with only a single monoallelic change in *SLC3A1* or *SLC7A9* detected. Median (IQR) urinary cystine was 706 (460-848) mg/day. The Table depicts clinical details of participants with disease due to *SLC3A1* and *SLC7A9* mutations. Urinary cystine excretion and other clinical outcomes did not differ by genotype. Patients with *SLC7A9*-related disease more commonly had 2 nontruncating mutations and *SLC3A1*-related disease more commonly had 2 truncating mutations. Multi-exon duplications were common for *SLC3A1*, found in 14 instances. A total of 16 novel, 32 known *SLC3A1* and 12 novel, 12 known *SLC7A9* mutations were detected.

**Conclusions:** The vast majority of cystinuria patients have biallelic disease due to 2 changes in either *SLC3A1* or *SLC7A9*, and not one of each. Cystine excretion and other clinical manifestations did not differ by genotype. Further study is needed to understand genotype-phenotype correlation and the variable outcomes seen in patients with cystinuria.

**Funding:** NIDDK Support

## SA-PO569

### Novel KCNJ1 Mutations Responsible for Adult Bartter Syndrome With Hypocalcemia

Chien-Chou Chen,<sup>1</sup> Chih-Chien Sung,<sup>1</sup> Min-hua Tseng,<sup>2</sup> Shih-Hua P. Lin.<sup>1</sup> Division of Nephrology, Tri-Service General Hospital <sup>1</sup>Tri-Service General Hospital, Taipei, Taiwan; <sup>2</sup>Chang Gung Memorial Hospital, Taoyuan, Taiwan.

**Introduction:** Bartter syndrome (BS) is a rare, autosomal recessive disease, caused by gene mutations of the transporters or channels of thick ascending loop of Henle (LOH) responsible for sodium chloride (NaCl), potassium (K<sup>+</sup>) and calcium (Ca<sup>++</sup>) reabsorption. Accordingly, it is characterized by persistent renal salt wasting with secondary hyperreninemia and hyperaldosteronism, renal K<sup>+</sup> wasting with hypokalemic metabolic alkalosis with renal K<sup>+</sup> wasting, and hypercalciuria with nephrocalcinosis and/or nephrolithiasis. The clinical manifestations of genetic BS vary dramatically from

asymptomatic, polyuria, polydipsia, premature delivery, polyhydramnios and failure to thrive, but usually presenting at antenatal and neonatal period other than adulthood.

**Case Description:** A 28-year-old Chinese female was referred for the evaluation for chronic hypocalcemia, medullary nephrocalcinosis, and hypokalemia. Two years ago, she first presented with severe symmetrical general muscle weakness, muscle tetany, spasm, and polyuria and was found to have moderate hypokalemia with metabolic alkalosis and renal potassium (K<sup>+</sup>) wasting, hypocalcemia (7.0 mg/dl) with an increased serum parathyroid hormone, hypercalciuria and bilateral medullary nephrocalcinosis. A thorough search for the identifiable causes such as autoimmune disorders, inflammation, malignancy, and use of diuretics was non-revealing. Genetic sequencing of calcium sensing receptor (CaSR) was negative. Using next generation sequencing based mutation screening with Sanger sequencing in her family, compound heterozygous mutations c.346\_357del (p.116\_119del) and c.1074 C>A (p.C358X) in *KCNJ1* inherited from her parents was identified. These two *KCNJ1* mutations were novel and pathogenic variants. Treatment with cyclooxigenase-2 (COX2) inhibitor, K<sup>+</sup> and calcium supplementation achieved a remarkable improvement in her clinical feature and laboratory abnormality.

**Discussion:** Although hypercalciuria in the prescene of persisted renal salt wasting, metabolic alkalosis and medullary nephrocalcinosis are the landmark findings for BS, serum calcium, phosphate and PTH may help differentiate between type I/II and V. Genetic form of late or adult BS, albeit rare, should be kept in mind as a cause of chronic hypokalemia with salt wasting and nephrocalcinosis/ nephrolithiasis, even in the presence of hypocalcemia.

## SA-PO570

### Monogenic Forms of Kidney Stone Disease in 841 Adult Kidney Stone Formers From the Bern Kidney Stone Registry

Manuel A. Anderegg,<sup>1</sup> Eric G. Olinger,<sup>2</sup> Robert M. Geraghty,<sup>2</sup> André Schaller,<sup>4</sup> Matteo Bargagli,<sup>1</sup> Lea Pohlmeier,<sup>3</sup> John A. Sayer,<sup>2,3</sup> Daniel G. Fuster.<sup>1</sup> <sup>1</sup>Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; <sup>2</sup>Newcastle University Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom; <sup>3</sup>Renal Services, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; <sup>4</sup>Department of Medical Genetics, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; <sup>5</sup>Interfaculty Bioinformatics Unit, University of Bern, Bern, Switzerland.

**Background:** Kidney stone disease is increasing worldwide, leads to high morbidity and represents a substantial economic burden to health systems. The detection of monogenic forms of kidney stone disease provides crucial pathophysiological insights and enables precision medicine approaches in affected patients. Previous genetic analysis by whole exome sequencing (WES) or kidney stone disease gene panels in relatively small cohorts of selected, mostly pediatric stone formers detected monogenic forms of kidney stone disease in 10-30% of patients studied. Larger studies using WES in well-characterized unselected cohorts of adult kidney stone formers are missing.

**Methods:** We conducted WES in 841 adult kidney stone formers participating in the Bern Kidney Stone Registry (BKSR). The BKSR is an unselected cohort of kidney stone formers with detailed phenotypic data available. Inclusion criteria are: ≥ 1 stone episode and age ≥ 18 years. For the initial analysis, we applied a virtual panel of 33 genes previously implicated in monogenic kidney stone disease. Variants in the 33 genes were filtered according to gnomAD allele frequencies (MAF <1%) and predicted consequence on the canonical transcript and were then curated against in silico pathogenicity tools, variant databases and previously reported modes of inheritance.

**Results:** We detected 184 distinct predicted pathogenic variants in 19 of 33 analyzed genes. Taking into account likely mode of inheritance, this led to a molecular diagnosis for 12.1% of all patients. 30% of the detected variants with predicted pathogenicity have not been previously reported. 70 % of the kidney stone formers with likely monogenic etiology showed monoallelic inheritance, fitting with previous data showing more frequent recessive inheritance of kidney stone disease in children, but more dominant inheritance patterns in adults.

**Conclusions:** In an unselected cohort of adult kidney stone formers, we identified a surprisingly high prevalence of monogenic forms of kidney stone disease. The next steps will include genotype/phenotype correlations of solved individuals. Furthermore, using the detailed phenotypic dataset of the BKSR, we aim to investigate potential multiallelic inheritance patterns and extend the genetic analysis to candidate genes.

## SA-PO571

### Quantification of Oxalate in Human Plasma by Novel Liquid Chromatography-Tandem Mass Spectrometry: Method Development, Validation, and Application in Lumasiran Clinical Trials

Valerie Clausen, Karen H. Cao, John M. Gansner, Gabriel Robbie, Jing-Tao Wu. Alnylam Pharmaceuticals Inc, Cambridge, MA.

**Background:** Primary hyperoxaluria type 1 (PH1) is a rare autosomal recessive genetic disease characterized by hepatic oxalate overproduction. Oxalate is excreted primarily by the kidneys, where it can cause kidney stones and/or nephrocalcinosis, leading to progressive kidney damage. PH1 is characterized by increases in both urinary and plasma oxalate (POx). In PH1 patients with compromised kidney function, POx is monitored. However, measuring POx is challenging due to its intrinsic chemical property and nonenzymatic conversion of ascorbate to oxalate in vitro. We present the development

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

and validation of a novel liquid chromatography-tandem mass spectrometry (LC-MS/MS) assay to determine oxalate concentration in human K<sub>2</sub>EDTA plasma.

**Methods:** A validated LC-MS/MS assay capable of measuring oxalate in 100 µL of K<sub>2</sub>EDTA plasma was developed. Samples were spiked with internal standard (<sup>13</sup>C<sub>2</sub>-labeled oxalic acid), acidified, and extracted by protein precipitation prior to analysis using anion exchange high-performance liquid chromatography with electrospray ionization MS/MS detection. The method was assessed for linearity, sensitivity, accuracy, precision, selectivity, hemolyzed plasma, lipemic plasma, interference, recovery, matrix effect, and stability. The validated LC-MS/MS assay was used to quantify POx in the lumasiran clinical trials.

**Results:** The LC-MS/MS assay was developed and validated successfully with a quantitation range of 0.500-50.0 µg/mL (5.55-555 µmol/L). The validation met acceptance criteria of 15% (20% at the lower limit of quantitation) for accuracy, precision, and other parameters tested. Oxalate was shown to be stable in K<sub>2</sub>EDTA human plasma for 125 days and for 5 freeze/thaw cycles at -20°C and -70°C. Analysis of POx levels in 75 healthy adults indicated the normal range to be 1.71-12.11 µmol/L.

**Conclusions:** A novel LC-MS/MS assay was developed and validated successfully and in accordance with regulatory guidelines. The required sample volume was only 100 µL of K<sub>2</sub>EDTA plasma, which is especially favorable in the pediatric population, and there is no need to acidify blood before processing. The assay accurately determines POx levels, which were used as an efficacy endpoint in the clinical development of lumasiran.

SA-PO572

Detection of X-Linked Variations in SHROOM4 in Four Families With Syndromic Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)

Caroline M. Kolvenbach,<sup>1,2</sup> Tim Felger,<sup>1</sup> Luca M. Schierbaum,<sup>1</sup> Isabelle Thiffault,<sup>6</sup> Marcin Zaniew,<sup>3</sup> Friedhelm Hildebrandt,<sup>2</sup> Phillip Grote,<sup>4</sup> Benjamin Odermatt,<sup>1</sup> Heiko M. Reutter,<sup>5</sup> Gabriel C. Dworschak.<sup>1</sup> <sup>1</sup>Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany; <sup>2</sup>Boston Children's Hospital, Boston, MA; <sup>3</sup>Uniwersytet Zielonogorski, Zielona Gora, Poland; <sup>4</sup>Institut für Tumorbilogie und experimentelle Therapie, Frankfurt am Main, Germany; <sup>5</sup>Universitätsklinikum Erlangen, Erlangen, Germany; <sup>6</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO.

**Background:** SHROOM4 plays an important role in cytoskeletal modification and development of the early nervous system. Previously, single nucleotide variants (SNVs) or copy number variations (CNVs) in SHROOM4 were shown to cause the X-linked neurodevelopmental disorder Stocco dos Santos syndrome (MIM 300434). However, no congenital anomalies of the kidney and the urinary tract (CAKUT), the intestinal, or cardiovascular system have been described in Stocco dos Santos syndrome.

**Methods:** Here, we performed exome sequencing (ES) and CNV analyses to detect further variants, and expression studies and gene knockdown experiments in zebrafish to study the role of SHROOM4 during embryonic development.

**Results:** In a family with two affected individuals with CAKUT, anorectal, cardiovascular, and central nervous system anomalies, we identified by ES a putative disease-causing SNV in SHROOM4 (c.940G>A; p.Glu314Lys). Analysis of 666 CAKUT ES samples revealed no further allele carriers. Through GeneMatcher, one family with a SNV (c.3942+1G>A; p.?) and two families with two different CNVs (chrX:g.49,369,600-50,447,320 and chrX:g.49,375,617-52,838,206) in SHROOM4 were contributed with a matching syndromic CAKUT phenotype. Upon embryonic mouse and zebrafish *in situ* mRNA expression studies we showed Shroom4 expression in the urinary tract, cloaca, heart, and cerebral central nervous system. Knockdown studies in zebrafish larvae using a splice blocking Morpholino revealed pronephric cysts, anomalies of the cloaca and the heart, decreased eye-to-head size ratio, and higher mortality compared to controls. These findings replicate the phenotypic spectrum of the affected individuals with genetic variations in SHROOM4 reported here. Co-injection of human wild-type SHROOM4 mRNA and Morpholino rescued the observed phenotypes.

**Conclusions:** The identified SNVs and CNVs in four families with syndromic CAKUT and embryonic mouse and zebrafish studies suggest functional deleteriousness of SHROOM4. We therefore propose that SHROOM4 plays an important role in the development of several principal organ structures.

**Funding:** Government Support - Non-U.S.

SA-PO573

Trio Whole Exome Sequencing Analysis Reveals PRPF8 as a Potential Ciliopathy Candidate Gene Phenocopying Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)

Lea M. Merz,<sup>1</sup> Tucker J. Carrocci,<sup>4</sup> Nils D. Mertens,<sup>2</sup> Florian Buerger,<sup>2</sup> Heiko M. Reutter,<sup>3</sup> Aaron Hoskins,<sup>4</sup> Shirlee Shril,<sup>2</sup> Friedhelm Hildebrandt.<sup>2</sup> <sup>1</sup>Department of Pediatrics, University Hospital, Leipzig, Germany; <sup>2</sup>Department of Pediatric Nephrology, Boston Children's Hospital & Harvard Medical School, Boston, MA; <sup>3</sup>Department of Neonatology, University Hospital, Erlangen, Germany; <sup>4</sup>Department of Biochemistry, University of Wisconsin - Madison, Madison, WI.

**Background:** Congenital abnormalities of the kidneys and urinary tract (CAKUT) represent the most frequent birth defect. The discovery of ≥45 monogenic causes of CAKUT in humans has generated novel insights into its pathogenesis. PRPF8 is a core component of the spliceosome and was recently shown to be localized at the distal end

of the mother centriole (Shen, *J Cell Biol.* 3;221(1):e202105092, 2022). It functions as receptor for the linear ubiquitin assembly complex, facilitating the removal of CP110 from the mother centriole and promoting ciliogenesis.

**Methods:** We performed whole exome sequencing in 136 trios of children with CAKUT and identified *de novo* variants in 38 different genes. To identify the most likely pathogenic variants, we ranked those 38 *de novo* variants using the following criteria: constraint and prediction scores, absence from the gnomAD control database, number of additional *de novo* variants, and whether a mouse model with CAKUT existed. Since CAKUT-linked mutations occurred at positions that are highly conserved between yeast and human spliceosomes, we are using *S. cerevisiae* (growth and ACT1-CUP1 reporter assays) as a model system to test their impact on aspects of the splicing reaction.

**Results:** Following those criteria, PRPF8 scored highest as a potential new candidate gene for CAKUT. We identified two additional CAKUT families with heterozygous *de novo* missense variants (Reutter, *Current Genomics* 16(999):1-1, 2015, Lei, 40(10):1290-1299, 2020) and 8 further heterozygous missense mutations that were inherited or of unknown mode of inheritance. All three *de novo* variants are positioned in highly conserved regions within the linker and endonuclease domains, including one amino acid residue that was previously shown to impact the catalytic steps of splicing in *S. cerevisiae* (human PRPF8 residue R1681). Using splicing assays, we found that PRPF8 mutants do not impact the splicing at the consensus splice sites. Two mutants showed an altered splicing effect at the non-consensus splice with a potential inhibition of the exon ligation.

**Conclusions:** We generated initial evidence that PRPF8 mutations may represent a novel ciliopathy gene, phenocopying CAKUT.

Clinical Characterization of a Dent Disease-1 Cohort Including Genotype-Phenotype Correlations

Muhammad G. Arnous,<sup>1</sup> Andrea G. Cogal,<sup>1</sup> Jennifer Arroyo,<sup>1</sup> Franca Anglani,<sup>2</sup> Peter C. Harris,<sup>1</sup> John C. Lieske.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Università degli Studi di Padova, Padova, Italy.

**Background:** Dent disease is an X-linked recessive renal disorder associated with Low molecular weight proteinuria, kidney stones, nephrocalcinosis, and kidney failure in the 3<sup>rd</sup> to 5<sup>th</sup> decade. Dent-1 is caused by mutations in the CLCN5 gene and Dent-2 mutations in the OCLRL2 gene. DD-1 accounts for 60% of diagnosed patients

**Methods:** Review of 134 patients from (RKSC) DD Registry (65 unique mutations). CLCN5 variants were assessed for pathogenicity using ACMG guidelines and categorized as truncating (nonsense, frameshift, large deletions, and canonical splice-site mutations) and nontruncating (missense and non-frame mutations). Correlations were analyzed using observational statistics and survival analysis methods.

**Results:** Missense mutations were the most prevalent (37%), followed by frameshift (23%) and nonsense (23%). Overall truncating (65%) were more common than non-truncating (35%) mutations. Patients with truncating mutations had more prevalent nephrocalcinosis, experienced stone events earlier in life, and manifested a higher albumin excretion rate than the non-truncating group. Patients with non-truncating mutations developed hematuria more often. No statistically significant difference between the 2 groups regarding CKD evolution. 24h urine Ca was positively associated with lifetime stone events and CKD evolution among the whole cohort. 24h urine protein was positively associated with CKD evolution but not associated with nephrolithiasis. Stratifying the cohort by mutation type, Lifetime stone events positively correlated with CKD evolution within the truncating group.

**Conclusions:** DD-1 patients with truncating mutations tended to have a more severe disease course compared to those with non-truncating mutations. Functional studies of the effect of specific mutations on intracellular processes and function, and overall renal physiology, may help to elucidate the underlying reasons.

**Funding:** NIDDK Support

Dent Disease Presenting as Night Blindness

Robin Miller,<sup>1,2</sup> Justin J. Arnett,<sup>3</sup> Katayoon Shayan,<sup>1</sup> Shyamanga R. Borooah,<sup>3</sup> Caitlin E. Carter.<sup>1,2</sup> <sup>1</sup>Rady Children's Hospital San Diego, San Diego, CA; <sup>2</sup>University of California San Diego, La Jolla, CA; <sup>3</sup>University of California at San Diego Department of Ophthalmology at the Shiley Eye Institute, La Jolla, CA.

**Introduction:** Dent Disease is an X-linked inherited tubulopathy that results in low molecular weight proteinuria, hypercalciuria, nephrocalcinosis, and progressive kidney dysfunction. Typical clinical manifestations in children include rickets, polyuria, and nephrolithiasis. We report a case of night blindness as the initial presentation of Dent Disease.

**Case Description:** A 16 yo healthy male with no family history of kidney disease presented with progressive night blindness and peripheral vision loss. He was found to have vitamin A deficiency and visual symptoms improved with vitamin A supplementation. Evaluation for underlying causes of vitamin A deficiency revealed renal dysfunction (serum creatinine 1.2 mg/dL, eGFR 65 ml/min by Schwartz 2) and nephrotic range proteinuria (3.5 gm/day). Urinary retinol binding protein to creatinine ratio was markedly elevated at >6667mcg/g (normal <190 mcg/g), suggestive of loss of retinol binding protein as the etiology of his vitamin A deficiency. Kidney biopsy demonstrated fibrous glomerular crescents, glomerulosclerosis, and tubular atrophy with moderate interstitial fibrosis. Evaluation for immunologic and genetic causes of glomerular disease was unrevealing. Genetic testing confirmed a pathogenic mutation in CLCN5, one of the two genes known to cause Dent Disease. The patient was subsequently found to have low bone mineral density by DEXA and hypercalciuria.

**Discussion:** Dent Disease due to CLCN5 mutation results in the inability of the proximal tubule to reabsorb low molecular weight proteins from the glomerular filtrate. This includes retinol binding protein, and vitamin A deficiency is a known sequelae of Dent Disease, however resultant vision loss has not previously been reported as the presenting finding in Dent Disease. In addition, while Dent Disease is typically considered a primarily tubular disorder, our patient had significant glomerular pathology including fibrous and fibrocellular crescents, which are rarely reported manifestations of Dent Disease but may play a role in its progression. Identifying early symptoms of Dent Disease allows for prompt treatment which could limit morbidity and mortality.

## SA-PO576

### Outcome of Atypical Hemolytic Uremic Syndrome (aHUS) Treated With C5-Inhibition, Primary vs. Secondary vs. Idiopathic: Results From the ItalKid-HUS Network

Gianluigi Ardisino,<sup>1</sup> Marianna Tangredi,<sup>4</sup> Valentina Capone,<sup>1</sup> Luigi Porcaro,<sup>3</sup> Massimo Cugno,<sup>2</sup> Brigida Brezzi,<sup>5</sup> Olga Credendino,<sup>6</sup> Lino C. Cirami,<sup>7</sup> Giuseppe Castellano,<sup>4</sup> Federica Ravera,<sup>8</sup> Donata C. Cresseri.<sup>4</sup> ItalKid HUS Network <sup>1</sup>Center for HUS Prevention, Control and Management at Pediatric Nephrology, Dialysis and Transplant Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; <sup>2</sup>Medicina Interna, Dipartimento di Fisiopatologia Medico Chirurgica e dei Trapianti, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Università Degli Studi, Milano, Italy; <sup>3</sup>Medical Genetics Laboratory, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; <sup>4</sup>Nephrology, Dialysis and Transplant Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; <sup>5</sup>Presidio Ospedaliero SS Antonio e Biagio, Alessandria, Italy; <sup>6</sup>Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Napoli, Italy; <sup>7</sup>Ospedale Careggi, Firenze, Italy; <sup>8</sup>Azienda Socio Sanitaria Territoriale Grande Ospedale Metropolitano Niguarda, Milano, Italy.

**Background:** Atypical Hemolytic Uremic Syndrome is a Thrombotic Microangiopathy related to complement abnormalities (genetic or acquired) in 50-60% of cases. The remaining cases may involve unknown genes, but may also be due to coexisting complement over-activating conditions acting as triggers. Based on the presence of complement abnormalities and of specific triggers, 3 groups can be identified: 1. Primary (with complement abnormality), 2. Secondary (trigger only), 3. Idiopathic (neither complement abnormality nor trigger). This approach to aHUS classification may have important drawbacks in the management of patients particularly with regards to C5 inhibition (C5i) as to treatment initiation, discontinuation and response rate.

**Methods:** The case series of aHUS treated or referred to our Center between 2000 and 2021 was analyzed according to the mentioned classification criteria. Response rate (RR), case-fatality rate, frequency of ESKD and relapse rate were compared between C5i and conventional treatment.

**Results:** Out of 240 patients, 150 (62.5%) had Primary aHUS, 55 (22.9%) Secondary aHUS and 35 (14.6%) Idiopathic aHUS. In patients treated with C5i (n:143) RR was higher within all groups (82.7% for Primary, 76.1% for Secondary and 59.1% for Idiopathic aHUS) compared to conventional treatment (38.7%, 55.6% and 53.9%, respectively). The frequency of ESKD was lower after C5i in all groups (Primary 15.7 vs 59.6%; Secondary 14.8 vs 40.4%; Idiopathic 36.0 vs 40.0%). Similarly, case-fatality rate was lower with C5i in all groups compared to conventional treatment (Primary 5.7 vs 9.5%; Secondary 8.5 vs 20.0%; Idiopathic 4.0 vs 13.0%). Among patients who discontinued C5i (n:83) the relapse rate was significantly higher in those with complement dysregulation compared to patients without complement abnormalities (68.6% for Primary and 0% for both Secondary and Idiopathic aHUS).

**Conclusions:** Based on our results and given that aHUS patient can't be correctly classified *a priori*, C5i should be promptly started in all patients meeting the criteria for aHUS. When complement dysregulation workup is available, patients can be better stratified and managed accordingly as to treatment discontinuation.

## SA-PO577

### Rare Cause of Nephrotic Range Proteinuria During Pregnancy: Genetic C3 Nephropathy (C3N) Presenting During Pregnancy

Harshil Fichadiya,<sup>1</sup> Richa Dua,<sup>1</sup> Poorva P. Bhide,<sup>1</sup> Adhithya Rajamohan,<sup>1</sup> Spiros M. Arbes,<sup>1,2</sup> <sup>1</sup>Rutgers Health Monmouth Medical Center, Long Branch, NJ; <sup>2</sup>Hypertension & Nephrology Association, Eatontown, NJ.

**Introduction:** Causes of proteinuria during pregnancy include isolated gestational proteinuria, pre-eclampsia, UTI, pre-existing CKD or denovo glomerular disease. We report a case of genetic C3N presenting with new onset proteinuria during pregnancy. C3N is a very rare cause of MPGN and is more commonly seen as an acquired disease due to formation of C3 Nephric factor (autoantibodies against regulatory proteins of complement pathway) than as inherited disease due to defect in C3 gene leading to abnormal activation of alternate complement pathway. It is associated with monoclonal gammopathy in elderly.

**Case Description:** 30-year-old Caucasian female presented with pedal and periorbital edema with 3+ proteinuria at the end of first trimester of pregnancy. She had normal BP, no recent infection or vaccination, history of IV drug or medication use, known malignancy, hepatitis of HIV infection, diabetes mellitus, no family history of nephrotic syndrome, negative PLA2R Ab, normal C3, C4 level and no gammopathy disease. UPr/Cr ratio at 21 weeks was 1.6g/mg. At 35 weeks her UPr/Cr. ratio ratio worsened to nephrotic range proteinuria 6.1g. Proteinuria was managed with non pharmacological measures during pregnancy. Postpartum her kidney biopsy revealed MPGN with C3 deposits. Genetic testing revealed pathogenic autosomal dominant variant of C3 gene associated with C3N and atypical HUS and carrier variant of NPHS2 gene. ADAMTS13 level were normal. She was enrolled in a clinical trial at a higher center.

**Discussion:** To our knowledge this is the first case of genetic C3N presenting during pregnancy. A case of atypical HUS which involves similar gene defect and pathogenesis has been reported in a one month postpartum female. Our patient like a few other cases of C3N presented with nephrotic range proteinuria, hematuria and normal serum complement level. Treatment of mild disease (normal kidney function with proteinuria <1.5g/day) includes supportive measures while moderate to severe disease (proteinuria >1.5g/day and abnormal renal function) includes glucocorticoid and immunosuppression therapy. Trials have reported benefit with eculizumab (C5 inhibitor). Iptacopan (selective factor B inhibitor) is being studied in an ongoing clinical trial. While the genetic disease is autosomal dominant it presents with incomplete penetrance.

## SA-PO578

### X-Linked Recessive Variants in X-Prolyl Aminopeptidase 2 (XPNPEP2) as a Potential New Cause of Nephrotic Syndrome

Bshara Mansour,<sup>1</sup> Ronen Schneider,<sup>1</sup> Florian Buerger,<sup>1</sup> Katharina Lemberg,<sup>1</sup> Camille H. Nicolas Frank,<sup>1</sup> Kirolos Yousef,<sup>1</sup> Dervla M. Connaughton,<sup>5</sup> Peter J. Conlon,<sup>3</sup> Sevcian A. Bakaloglu,<sup>4</sup> Sherif M. El desoky,<sup>2</sup> Jameela A. Kari,<sup>2</sup> Shirlee Shril,<sup>1</sup> Friedhelm Hildebrandt,<sup>1</sup> <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>King Abdulaziz University, Jeddah, Saudi Arabia; <sup>3</sup>Beaumont Hospital, Dublin, Ireland; <sup>4</sup>Gazi Universitesi, Ankara, Turkey; <sup>5</sup>London Health Sciences Centre, London, ON, Canada.

**Background:** Steroid-resistant nephrotic syndrome (SRNS) is the second most frequent cause of chronic kidney disease in children and young adults. Major insights into its pathogenesis came from the discovery of ~68 monogenic causes, contributing to ~11-30% of SRNS with onset <25 years of age. However, a significant proportion remains without a genetic diagnosis.

**Methods:** To identify novel potential monogenic causes of SRNS, we performed whole-exome sequencing (WES) in a worldwide cohort of individuals with SRNS from 1,285 different families. We evaluated potential pathogenicity of bi-allelic hemizygous genetic variants by *in-silico* prediction scores, evolutionary conservation, and allele frequency in public genome sequencing databases.

**Results:** We discovered, 3 different X-linked recessive, likely deleterious variants in *XPNPEP2* (X-Prolyl Aminopeptidase 2) in unrelated male individuals. Individual A4966\_21 had missense variant: c.346C>T, p.(Arg116Cys), which changes an arginine residue as part of a highly conserved DXRY motif that is important for the enzyme activity. This variant is deemed as likely disease-causing by SIFT, MutTaster, and PolyPhen2 prediction programs. Individual A222\_21 had a nonsense variant c.670C>T, p.(Arg224\*). Individual D\_10382\_21 had an obligatory splice variant c.1107+1G>A. The ages of SRNS onset were 3, 15, and 2-year-old, respectively. All variants were absent hemizygously from the gnomAD database. No extra-renal manifestations were reported. Upon renal biopsy, individuals A4966\_21 and D\_10382\_21 both showed focal segmental glomerulosclerosis, and A222\_21 showed membranoproliferative glomerulonephritis. *XPNPEP2* encodes a membrane-bound isoform of aminopeptidase P (APP2), a widely distributed hydrolase that cleaves N-terminal imido bonds. One of the substrates for APP2 is Bradykinin (BK). We consider *XPNPEP2* a candidate gene for SRNS/FSGS because BK has been shown to play a role in the pathogenesis of FSGS, operating through B1 receptor signaling in a mouse model (Pereira *Kidney Int.* 79:1217, 2011).

**Conclusions:** By WES, we identify X-linked recessive variants in the gene *XPNPEP2* in 3 affected individuals, as a potential novel monogenic cause of SRNS.

**Funding:** Other NIH Support - 5R01DK068306-18

## SA-PO579

## UPLC-MS/MS-Based Plasma Assay for Therapeutic Monitoring in Patients With APRT Deficiency

Unnur A. Thorsteinsdottir,<sup>1</sup> Hrafnhildur L. Runolfsson,<sup>2</sup> Vidar O. Edvardsson,<sup>2,1</sup> Runolfur Palsson,<sup>2,1</sup> Margret Thorsteinsdottir,<sup>1</sup> APRT Deficiency Research Program of the Rare Kidney Stone Consortium 'Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; <sup>2</sup>Landspítali, Reykjavik, Iceland.

**Background:** Adenine phosphoribosyltransferase deficiency (APRTd) is a rare disorder of purine metabolism characterized by urinary excretion of poorly soluble 2,8-dihydroxyadenine (DHA), nephrolithiasis and chronic kidney disease (CKD). Treatment with allopurinol or febuxostat, reduces DHA excretion and slows CKD progression. The aim was to optimize a UPLC-MS/MS method for simultaneous quantification of DHA, adenine, allopurinol, oxypurinol and febuxostat in plasma, utilizing the chemometric approach design of experiments (DoE).

**Methods:** The UPLC-MS/MS quantification method was optimized, employing the chemometric software MODDE Pro 13. Fractional factorial (FF) design was used to reveal significant experimental factors influencing peak area, retention time and resolution of all analytes using partial least square (PLS) regression. Absolute quantification of DHA, adenine, allopurinol, oxypurinol and febuxostat was performed in plasma samples from untreated and treated APRTd patients and healthy controls.

**Results:** For all analytes, accuracy and precision were within the acceptable range of  $\pm 15\%$ . Preliminary data revealed a median (range) plasma concentration of 248 (224-395) ng/mL for DHA and 194 (159-284) ng/mL for adenine, in the untreated patients, and below 50 ng/mL for DHA and 533 (339-1034) ng/mL for adenine, in those on treatment. DHA was not detected in the plasma samples from healthy controls. In patients receiving XOR inhibitor therapy, the median plasma concentration for allopurinol, oxypurinol and febuxostat was 687 (103-2901), 7945 (2199-10943) and 1628 ng/mL, respectively.

**Conclusions:** A UPLC-MS/MS assay for quantification of DHA, adenine, allopurinol, oxypurinol and febuxostat in human plasma was developed and optimized using DoE.

**Funding:** Government Support - Non-U.S.

## SA-PO580

## Dent Disease in Drosophila: Homologous Functions Between the Fly and Human Chloride Transporters

Carmen J. Reynolds,<sup>1</sup> Christopher M. Gillen,<sup>2</sup> Julian A. Dow,<sup>3</sup> Michael F. Romero,<sup>1</sup> <sup>1</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>2</sup>Kenyon College, Gambier, OH; <sup>3</sup>University of Glasgow, Glasgow, United Kingdom.

**Background:** Mutations in the 2Cl<sup>-</sup>/H<sup>+</sup> transporter CLC-5 cause Dent Disease type 1 (DD1) and lead to progressive renal failure by age 20-40. A major characteristic of DD1 is the renal mishandling of Ca<sup>2+</sup> that increases urinary Ca<sup>2+</sup> excretion, calcium oxalate (CaOx) kidney stones, and kidney calcification. Our laboratory has identified *Drosophila* Clc-c as the homolog of CLC-5 with conserved amino acids at DD1 mutation sites. We hypothesize that Clc-c shares functional similarities in Cl<sup>-</sup> transport and Ca<sup>2+</sup> homeostasis.

**Methods:** To determine the function of Clc-c, we assessed Cl<sup>-</sup> transport by Clc-c and Clc-c with homologous DD1 mutations by voltage clamp assays. We then knocked-down expression of Clc-c in the renal Malpighian tubules of flies to assess evaluated crystal formation and cation secretion.

**Results:** Voltage clamp experiments in *Xenopus* oocytes show that Clc-c is electrogenic with similar outward-rectifying currents in Cl<sup>-</sup> solutions as observed with human CLC-5. Chloride transport was decreased by acidic (pH 6.0), but not by alkaline solution (pH 8.5) when compared to the standard solution of pH 7.5. Homologous DD1 mutations S393L, R494W, and Q777x impaired Cl<sup>-</sup> transport activity similar to previous observations for CLC-5 DD1 mutations S244L, R345W, and Q629x (Tang et al, Physiol Rep 4[8], 2016). RNAi knockdown of Clc-c (Clc-c-KD) in the *Drosophila* renal tubules (Malpighian tubules, MT) resulted in 50% Clc-c mRNA expression. Tubule Ca-oxalate crystals in adult anterior MT (7 days after eclosion) were present in all Clc-c-KD and were more abundant (15 $\pm$ 4 crystals per fly) compared to 5 $\pm$ 2 crystals in control flies ( $P=0.02$ ). Using MT-secretion experiments, cations secreted from MT of Clc-c KD flies contained higher concentrations of Ca<sup>2+</sup> while all other ions (Na<sup>+</sup>, NH<sub>4</sub><sup>+</sup>, K<sup>+</sup>, Mg<sup>2+</sup>), and volume were the same as WT.

**Conclusions:** In conclusion, *Drosophila* Clc-c has similarities to human CLC-5 including impaired function with voltage-gated Cl<sup>-</sup> transport, homologous DD1 mutations, increased CaOx crystal formation, and elevated Ca<sup>2+</sup> in urine secretions. Thus, Clc-c has the potential to be an important model for future investigations on the effects Ca<sup>2+</sup> homeostasis in DD1.

## SA-PO581

## Purely Coincidental CLCN5 Variants Identified in Two Patients With IgA Nephropathy

Darby Raible,<sup>1</sup> Sumit Punj,<sup>1</sup> Padam Hirachan,<sup>2</sup> Andrew Lazar,<sup>1,3</sup> <sup>1</sup>Natera, Inc., Austin, TX; <sup>2</sup>Cenla Kidney Specialists, Alexandria, LA; <sup>3</sup>UH Ahuja Medical Center, Beachwood, OH.

**Introduction:** Many monogenic forms of chronic kidney disease (CKD) exhibit phenotypic variability, making clinical diagnosis challenging. An example is Dent disease 1 (DD1), caused by variants in the *CLCN5* gene, which can present with low molecular

weight proteinuria and variable hypercalciuria, nephrocalcinosis, nephrolithiasis, and hyperphosphaturia. While DD1 is primarily a disorder of the proximal tubules, glomerular pathology has been reported and may contribute to CKD progression. Use of broad panel-based genetic testing may improve the ability to identify monogenic disorders and/or reclassify biopsy-based diagnoses. We report two patients with biopsy-confirmed IgA nephropathy (IgAN) in whom likely pathogenic variants in *CLCN5* were identified through broad-panel genetic testing of 385 CKD associated genes (the Renasight™ test).

**Case Description:** Patient 1: a 38-year-old Caucasian male with history of progressive CKD (eGFR 30 mL/min/1.73 m<sup>2</sup>), proteinuria, hematuria, and biopsy-proven IgAN. Family history is significant for hematuria and unspecified diabetes mellitus in the maternal grandfather. Genetic testing revealed a likely pathogenic, hemizygous, frameshift variant in exon 9 that results in a truncation of *CLCN5*. The genetic diagnosis of DD1 informed counseling and prompted management changes to reduce nephrolithiasis risk. Patient 2: a 52-year-old Caucasian male with a history of persistently elevated serum creatinine (2.24 mg/dL), proteinuria, hematuria, nephrolithiasis, and biopsy-confirmed IgAN diagnosed over three decades. Genetic testing identified a likely pathogenic, hemizygous, frameshift variant in exon 8 that results in a truncation of *CLCN5*. The genetic diagnosis of DD1 prompted treatment changes including cessation of hydroxychloroquine and initiation of potassium citrate and an SGLT2 inhibitor.

**Discussion:** These cases demonstrate the clinical utility of broad renal genetic testing in patients with renal dysfunction by identifying an unexpected co-existence of DD1 with IgAN. Cases of co-occurring IgAN with type IV collagen disorders and Fabry disease have been reported, demonstrating that individuals presenting with IgAN can have a variety of monogenic forms of CKD. Further studies are needed to determine any relationship between IgAN and these monogenic conditions, or impact on disease severity or progression.

## SA-PO582

## Prevalence and Phenotypic Spectrum of Heterozygous SLC34A3 Mutations in a Large Genetic Database

Chinedu O. Nwachukwu, Gurmukteshwar Singh, Bryn S. Moore, Natasha T. Strande, Ion D. Bucaloiu, Alex R. Chang, Geisinger Medical Center, Danville, PA.

**Background:** Homozygous or compound heterozygous mutations in *SLC34A3*, encoding the sodium dependent inorganic phosphate cotransport proteins 2c (NPT2c), cause autosomal recessive hypophosphatemic rickets with hypercalciuria. Whether heterozygous carriers of *SLC34A3* pathogenic variants have increased risk of nephrolithiasis or other renal disorders is unknown.

**Methods:** We included participants heterozygous for *SLC34A3* S192L in the Geisinger MyCode/DiscoverEHR study, an unselected health-system-based study with exome sequencing data linked to electronic health records (EHR). We reviewed EHR for nephrolithiasis-related labs, diagnoses in progress notes or imaging, workup, nephrology and urology encounters.

**Results:** Of 174,418 MyCode participants, 238 (0.14%) were heterozygous for *SLC34A3* S192L. We excluded 3 with *SLC34A3* variants of uncertain significance and those without EHR data. Of the 217 remaining (mean age 58.6 years, 63% female), 65 (30%) had evidence of nephrolithiasis, including 13 who had incidental nephrolithiasis on imaging, and 2 had nephrocalcinosis. Only 21/65 with nephrolithiasis had urology visits for nephrolithiasis (15 had urologic procedures) and 13/65 were seen by nephrology for nephrolithiasis. Only 11 (5.5%) participants had family history of nephrolithiasis noted. Nephrolithiasis lab tests were rarely done. Of 88 participants with available serum phosphorus, 34 (39%) had hypophosphatemia <2.5 mg/dL at least once. Among 9 patients who had a completed 24-hour urine risk profile, mean 24-hour urine calcium was 294 mg/d (67% >250 mg/d), mean 24-hour urine phosphorus was 856 mg/d (33% > 1100 mg/d). Kidney stone analysis on 3 patients indicated calcium oxalate stone composition. Prescriptions potentially increasing nephrolithiasis risk included calcium supplements in 12 (6%) and vitamin D supplements in 29 (13%). No participants were taking phosphate supplements.

**Conclusions:** In our unselected EHR-based cohort, approximately 1/3 of *SLC34A3* S192L heterozygotes had evidence of nephrolithiasis. Few were comprehensively evaluated for nephrolithiasis, and many were taking potentially contraindicated medications. Further studies will help determine if personalized management could improve nephrolithiasis risk in this population.

## SA-PO583

## Rapid Detection of Heterozygous Carrier of AGT for Autosomal Recessive Renal Tubular Dysgenesis in Taiwan

Min-hua Tseng,<sup>1</sup> Shih-Hua P. Lin,<sup>2</sup> <sup>1</sup>Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; <sup>2</sup>Tri-Service General Hospital, Taipei, Taiwan.

**Background:** Recurrent mutation of homozygous E3\_E4 del:2870bp deletion+9bp insertion in the *AGT* gene responsible for autosomal recessive renal tubular dysgenesis (ARRTD) is frequently reported in Taiwan, but the exact prevalence of heterozygosity is still unknown. The rapid detection of this mutation may help in the prevention of recurrent ARRTD.

**Methods:** This study was aimed to investigate the prevalence of heterozygosity of E3\_E4 del:2870bp deletion+9bp insertion of *AGT* in Taiwan and develop a simple and rapid method to detect this mutation. Three thousand health, ten heterozygous parents, and five homozygous Taiwanese were enrolled to define this mutation and determine their prevalence by using TaqMan probe-based real-time polymerase chain reaction (RT-PCR). We designed and validated the mutation detection plate, and tested its feasibility in newly diagnosed ARRTD patients.

**Results:** The recurrent mutation-based TaqMan assays were fully validated with excellent sensitivity and specificity in genetic diagnosed patients and healthy subjects. The prevalence of heterozygosity of E3\_E4 del:2870bp deletion+9bp insertion of AGT is 1.27% in Taiwan. The probability that this haplotype occurred independently in all index cases was of 1.52 x10<sup>5</sup>, suggesting a founder effect.

**Conclusions:** The prevalence of heterozygosity of E3\_E4 del:2870bp deletion+9bp insertion of AGT in Taiwan is high and can be rapidly identified by TagMan probe-based RT-PCR.

SA-PO584

**NephroS: Phenotypical Analysis of a Large National Nephrotic Syndrome Cohort: A Multicentre Longitudinal Study From Great Britain**  
Maryam Afzal. Bristol Renal Group *University of Bristol, Bristol, United Kingdom.*

**Background:** Nephrotic Syndrome (NS) is a rare kidney disease diagnosed by the presence of proteinuria, oedema and hypoalbuminemia. The estimated global incidence of NS is 2-7 people per 100,000. The pathological processes that cause NS remain elusive. This novel multicentre longitudinal study aimed to identify the clinical and socio-demographic characteristics of a large NS cohort across Great Britain. Phenotypical analysis of such a large cohort will help understand the natural history and patterns of disease during a patient's lifetime.

**Methods:** A large multicentre longitudinal study was set up in January 2010 in 51 adult and paediatric sites across England, Scotland and Wales. Detailed prospective and retrospective clinical data was captured onto the Rare Renal Diseases Registry (RaDaR) over a period of 12 years from date of diagnosis until the cut-off point in January 2022. Patients were categorised by both their response to steroids and histological diagnoses to identify specific NS subgroups.

**Results:** Over 12 years, a total of 1974 adult and paediatric NS patients were recruited. The results show that NS is a male predominant condition (56%) and more prevalent in South Asian (13%) and African ethnicities (4%). A large proportion of patients were steroid-sensitive (48%), and the main histological diagnosis was Minimal Change Disease (MCD) (50%). Those who reached end stage renal disease (16%) were mainly aged 0 – 17 years old. A high proportion of deaths were noted in 2020/1, and caused by cancer or COVID-19.

**Conclusions:** It can be concluded that NS is dominant in males, and in South Asian and African ethnicities. A large proportion of patients were steroid-sensitive, and the main histological diagnosis was MCD. The data gathered in this study will help transform our understanding of NS. To better understand the implications of these results, future research including international collaboration will facilitate the development of translational research and evidence-based recommendations.

**Clinical Presentation and Management of Nephrotic Syndrome in the First Year of Life: A Report From the Pediatric Nephrology Research Consortium (PNRC)**  
Yu Kamigaki,<sup>1</sup> Alexandru R. Constantinescu,<sup>2,4</sup> Tej K. Mattoo,<sup>3</sup> Larry A. Greenbaum,<sup>5</sup> Melissa A. Muff-Luett,<sup>6</sup> Ali Annaim,<sup>7</sup> Scott E. Wenderfer,<sup>8,9</sup> Emilee Plautz,<sup>10</sup> Michelle N. Rheault,<sup>11</sup> Robert L. Myette,<sup>12,13</sup> Katherine Twombly,<sup>7</sup> Mahmoud Kallash,<sup>1</sup> William E. Smoyer,<sup>1</sup> Tetyana L. Vasylyeva.<sup>14</sup> <sup>1</sup>*Nationwide Children's Hospital, Columbus, OH;* <sup>2</sup>*Joe DiMaggio Children's Hospital, Hollywood, FL;* <sup>3</sup>*Wayne State University School of Medicine, Detroit, MI;* <sup>4</sup>*Florida Atlantic University Charles E Schmidt College of Medicine, Boca Raton, FL;* <sup>5</sup>*Emory University School of Medicine, Atlanta, GA;* <sup>6</sup>*Children's Hospital and Medical Center, Omaha, NE;* <sup>7</sup>*Medical University of South Carolina, Charleston, SC;* <sup>8</sup>*The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada;* <sup>9</sup>*BC Children's Hospital, Vancouver, BC, Canada;* <sup>10</sup>*University of Minnesota, Minneapolis, MN;* <sup>11</sup>*University of Minnesota Masonic Children's Hospital, Minneapolis, MN;* <sup>12</sup>*Children's Hospital of Eastern Ontario, Ottawa, ON, Canada;* <sup>13</sup>*Ottawa Hospital Research Institute, Ottawa, ON, Canada;* <sup>14</sup>*Texas Tech University Health Sciences Center School of Medicine Amarillo, Amarillo, TX.*

**Background:** Nephrotic syndrome (NS) in the first year of life is called congenital (CNS) if diagnosed between 0-3 months, or infantile (INS) if diagnosed between 3-12 months of age. The aim of this study was to determine if there were clinically meaningful differences between CNS vs. INS patients regarding clinical presentation, management, and outcomes.

**Methods:** 11 PNRC sites participated in the study, using IRB-approved retrospective chart reviews of CNS and INS patients born between 1998-2019. Data were collected on patient characteristics, pertinent laboratory tests, need and frequency of albumin infusions, and type and timing of nephrectomy and renal replacement therapy (RRT).

**Results:** The study included 69 patients, 49 with CNS and 20 with INS, median ages at diagnosis of 1 month and 6 months, respectively. Patients were similar with respect to nutrition, thyroxin supplementation, IVIG/SCIG prophylaxis, and thrombosis prophylaxis. Within the first 2 months after diagnosis, daily albumin infusions were more frequently needed in CNS vs. INS (79 vs. 30%; p=0.006), while weekly infusions were more frequently needed in INS vs. CNS (50 vs. 3%; p=0.001). Moreover, within the final

6 months preceding RRT, albumin infusions were more frequently required in CNS vs. INS (51 vs. 15%; p=0.007). Nephrectomy was also performed more frequently in CNS vs. INS (78 vs. 50%; p=0.024). Dialysis was similarly required in CNS vs. INS (73 vs. 55%; p=0.14). Pre-emptive kidney transplantations were similarly performed in CNS vs. INS patients (6% vs. 5%). Notably, management without either nephrectomy or RRT was more frequent in INS vs. CNS (40% vs. 16%; p=0.035). Sequences of interventions (i.e., Nephrectomy->RRT->Transplant [TXP]) were similar between the groups, although RRT->bilateral nephrectomy->TXP tended to occur more frequently in CNS vs. INS (61 vs. 36%; p=0.06).

**Conclusions:** Compared to children with INS, those with CNS had more severe disease courses, requiring more frequent albumin infusions, and earlier onset of RRT. In addition, almost 25% of children with CNS or INS were able to be managed without need for either nephrectomy or RRT.

SA-PO586

**Congenital Nephrotic Syndrome in the Amish and Mennonite Population of Central Pennsylvania**  
Hannah Kim. Penn State Children's Hospital and Division of Pediatric Nephrology and Hypertension *Penn State College of Medicine, Hershey, PA.*

**Background:** Pennsylvania has the largest Amish/Mennonite population in the United States. The Amish/Mennonites accept beliefs that restrict participation in larger American society and thus have increased risk for certain genetic diseases including congenital nephrotic syndrome (CNS). We aim to describe the CNS population at Penn State Children's Hospital.

**Methods:** Clinical characteristics of the known CNS population at Penn State Children's Hospital were assessed using a retrospective electronic medical record review. An individual was defined as being part of, or historically part of, the Amish or Mennonite population by self-disclosure. Characteristics were summarized using medians (interquartile ranges) or proportions. Kaplan-Meier curves and Log-rank tests were used to evaluate time to end-stage kidney disease as defined by time to end-stage kidney disease (ESKD).

**Results:** 25 patients were identified at Penn State Children's Hospital over the last 30 years with a diagnosis of CNS (Table 1). Of those patients, 80% identified as Amish or Mennonite. The majority had either NPHS1 or NPHS2 mutations. The median time to ESKD was at 3 years of age (Figure 1). The median time to ESKD was faster for those with NPHS1 as compared to those with NPHS2 mutations (3 vs. 6 years, p<0.001).

**Conclusions:** The majority of children were of Amish or Mennonite background with ESKD in the first few years of life. Most had associated hypothyroidism, but the incidence of other complications including thromboses and serious bacterial infections was low.

Clinical Characteristics	Characteristic	N (%) or Median (IQR)
Amish/Mennonite (n=25)	Neither	4 (16%)
	Amish	9 (36%)
	Mennonite	11 (44%)
	Either/unknown	1 (4%)
	Gene (n=21)	
	LAMB2	1 (4.8%)
	NPHS1	10 (47.6%)
	NPHS2	9 (42.9%)
	WT1	1 (4.8%)
Gender (n=25)	Male	14 (56%)
	Female	11 (44%)
NICU (n=24)		4 (16.7%)
Ever diuretic use (n=24)		23 (95.8%)
Thrombosis (n=24)		1 (4.2%)
Ever anticoagulation use (n=24)		3 (12.5%)
Ever anti-proteinuric agent use (n=24)		21 (87.5%)
Ever NSAID use (n=24)		1 (4.2%)
Serious bacterial infections		16 (66.7%)
	1	6 (25%)
	2	2 (8.3%)
Ever use of infection prophylaxis (n=24)		19 (79.2%)
Ever levothyroxine use (n=24)		21 (87.5%)
ESKD (n=25)		21 (84%)

Table 1. Clinical Characteristics

### SA-PO587

#### Hyperfiltration and eGFR Equations in the Pediatric NEPTUNE Study Cohort

Eloise Salmon,<sup>1</sup> Yujie Wang,<sup>1</sup> Katherine M. Dell,<sup>2</sup> Kimberly J. Reidy,<sup>3</sup> Pediatric Working Group of the NEPTUNE study <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Cleveland Clinic Children's Hospital, Cleveland, OH; <sup>3</sup>Children's Hospital at Montefiore, Bronx, NY.

**Background:** Hyperfiltration has been reported in nephrotic syndrome. Pediatric GFR estimating equations were developed with data primarily on children with decreased GFRs, and the accuracy of these formulas with elevated GFRs is unknown. Because hyperfiltration may be deleterious, inaccurate estimated GFRs (eGFRs) in this patient population may generate false clinical reassurance. The objectives of this study in the pediatric NEPTUNE cohort were: (1) to examine whether the variance between two pediatric eGFR estimating formulas differs by hyperfiltration status; and (2) to compare the prevalence of hyperfiltration while in first remission in this cohort.

**Methods:** eGFR was calculated using the creatinine based pediatric "bedside" Schwartz formula and the CKID U25 formula. Hyperfiltration was defined as eGFR  $\geq 140$  mL/min/1.73m<sup>2</sup>. First remission was defined as the first urine protein:creatinine (UPC)  $< 0.3$  mg/mg for which there was an available serum creatinine obtained at the same time. For Aim 1, all available serum creatinines obtained on patients 1- <18 years of age were utilized irrespective of proteinuria status. Absolute differences between the two eGFR formulas were calculated and the difference in those with and without hyperfiltration were compared by t-test (two-sample unequal variance). For Aim 2, only the subset of pediatric patients who achieved first remission were included.

**Results:** A total of 3570 serum creatinine values from 320 unique patient with a median age of 6 years (35% minimal change disease, MCD, 20% focal segmental glomerulosclerosis, FSGS, 45% not biopsied) were available for analysis. The median [interquartile range] difference between the eGFRs using the two estimating formulas in patients with vs without hyperfiltration was 23 [16.9-28] vs. 11 [6.8-15.2] mL/min/1.73m<sup>2</sup>, respectively ( $p < 0.001$ ). For children who achieved first remission ( $n=233$ ), 12.5% had hyperfiltration by "bedside" Schwartz vs. 7.7% by the U25 formula.

**Conclusions:** Pediatric NEPTUNE patients with hyperfiltration vs. not demonstrate higher variability in eGFRs using two common pediatric estimating equations, and rates of hyperfiltration (in remission) also vary based on the formula used. These data suggest estimating equations may be less accurate in children with nephrotic syndrome and indicate more research is needed to better refine eGFR estimation formulas for this population.

### SA-PO588

#### Induction Therapy With Mycophenolate Mofetil for Steroid-Sensitive Nephrotic Syndrome in Children: A Prospective Single Center Pilot Study

Alexandra Mazo,<sup>1,2</sup> Tanya E. Pereira,<sup>1,2</sup> Sonia Solomon,<sup>1,2</sup> Dmitry V. Samsonov,<sup>1,2</sup> <sup>1</sup>Westchester Medical Center, Valhalla, NY; <sup>2</sup>New York Medical College, Valhalla, NY.

**Background:** Standard induction therapy for steroid sensitive nephrotic syndrome (SSNS) in children is steroids for 12 weeks. The purpose of this study was to evaluate whether Mycophenolate Mofetil (MMF) can replace steroids to complete the induction phase in SSNS.

**Methods:** Patients 2 to 12 years old with first diagnosis of nephrotic syndrome who achieved remission (UPC  $< 0.3$  mg/mg) within 2 weeks of steroid treatment were recruited. In MMF group (TG) treatment with steroids was stopped on day of enrollment and MMF (1200 mg/m<sup>2</sup>/day) initiated and continued for a total of 10 wks. Control group

(CG) continued standard steroid treatment. Quality of Life (QOL) was assessed by questionnaires at enrollment and in 10 weeks. The primary study outcomes were relapse rate (RR) and relapse free interval (RFI) (time in weeks from enrollment to first relapse). Secondary outcomes included side effects of MMF, steroids, and changes in QOL.

**Results:** Nine patients were in TG and 17 in CG. During induction phase 2 out of 9 patients (22%) in TG developed relapse compare with 1 out of 17 (6%) in CG ( $p = 0.1$ ). During the first year 6 out of 9 patients (67%) in TG and 12 out of 17 (71%) in CG developed relapse ( $p = 1.0$ ). Median RFI was 11 (Q1 5-22) weeks in TG and 17 (Q1 13-31) weeks in CG ( $p = 0.7$ ). Two patients in CG and none in TG required treatment for hypertension. QOL improved in both groups, not statistically significant. No difference in secondary outcomes (weight gain, leukopenia, anemia, infection rate) were seen between the groups.

**Conclusions:** Induction therapy with steroids resulted in less RR during the first 3 months of therapy and prolonged RFI. However, in our small sample data difference between the groups was not statistically significant. Larger randomized study is underway to compare MMF and steroid induction in SSNS (INTENT study).

Relapse free interval by Kaplan-Meier analysis (logrank test  $p=0.72$ )

### SA-PO589

#### Significance of Remission of Proteinuria in Childhood IgA Nephropathy

Yuko Shima,<sup>1</sup> Hironobu Mukaiyama,<sup>1</sup> Yu Tanaka,<sup>1</sup> Wataru Shimabukuro,<sup>2</sup> Hiroshi Kaito,<sup>3</sup> Ryojiro Tanaka,<sup>3</sup> Kandai Nozu,<sup>4</sup> Kazumoto Iijima,<sup>4</sup> Daisuke Tokuhara,<sup>1</sup> Norishige Yoshikawa,<sup>5</sup> Koichi Nakanishi,<sup>2</sup> <sup>1</sup>Wakayama Kenritsu Ika Daigaku, Wakayama, Japan; <sup>2</sup>Ryukyuu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan; <sup>3</sup>Hyogo Kenritsu Kodomo Byoin, Kobe, Japan; <sup>4</sup>Kobe Daigaku, Kobe, Japan; <sup>5</sup>Shakai Iryo Hojin Aijinkai Takatsuki Byoin, Takatsuki, Japan.

**Background:** Remission of proteinuria is the most significant prognostic factor for kidney outcome in IgA nephropathy (IgAN). There is no study investigating the effect of proteinuria remission on long-term outcomes in a large cohort of pediatric IgA nephropathy. The purpose of this study is to clarify the factors for proteinuria remission and their outcomes in childhood IgAN.

**Methods:** In the retrospective analysis of 538 biopsy-proven childhood IgAN between 1976 and 2013, we evaluated clinical and pathological findings of the 309 cases (57.4%) with proteinuria remission and the others.

**Results:** Although there were significant differences in onset age (median 10.3 vs. 11.9 years,  $p < 0.0001$ ), and follow-up period (median 7 vs. 3 years,  $p < 0.0001$ ) between the proteinuria remission and non-remission groups, there was no other significant difference in clinical and pathological findings. In the logistic regression analyses, onset age (OR=0.90,  $p=0.04$ ), initial biopsy year before 1990 (OR=0.41,  $p=0.03$ ), need for immunosuppressive treatment (OR=0.40,  $p=0.03$ ), and follow-up period (OR=1.21,  $p < 0.0001$ ) were significantly related to proteinuria remission. Kaplan-Meier analysis showed a significantly better kidney survival rate in the proteinuria remission group than in the non-proteinuria remission group (97.0 vs 78.7% at 13 years,  $p < 0.001$ ). And, all patients who progressed to kidney failure in the proteinuria remission group had proteinuria relapse.

**Conclusions:** The patients with childhood IgAN were detected by annual school screening early in the disease course in Japan and they were treated according to their clinical and pathological severity. Regardless of clinical and pathological severity at biopsy, risk factors related to proteinuria remission were only onset age, the initial biopsy year before 1990 when extensive treatments began, and the need for immunosuppressive treatment in the course. Not only proteinuria remission but also the continuation of proteinuria remission is important for renal survival.

## SA-PO590

**Cerebral Venous Sinus Thrombosis in a Child With IgA Vasculitis and COVID-19 Infection**

Kayla J. Erspamer,<sup>1</sup> Ethan A. Canty,<sup>1</sup> Bronwyn Baz,<sup>1,2</sup> Abbie R. Bauer,<sup>1</sup> <sup>1</sup>*Oregon Health & Science University Doernbecher Children's Hospital, Portland, OR;* <sup>2</sup>*Kaiser Permanente Sunnyside Medical Center, Clackamas, OR.*

**Introduction:** IgA vasculitis (IgAV) is a common diagnosis in children and includes purpura, and/or petechiae (without thrombocytopenia or coagulopathy) with at least one of the following: abdominal pain, joint pain, AKI, hematuria, proteinuria, or evidence of IgA deposition. Many cases are preceded by upper respiratory tract infections, including COVID-19. The incidence of cerebral venous sinus thrombosis (CVST) in the pediatric population is low (0.6/100,000 per year). We present a case of a 5 year old boy with IgA vasculitis and COVID-19 infection found to have CVST.

**Case Description:** A previously healthy 5 year old boy transferred to our institution with two weeks of intermittent, severe abdominal pain in the setting of COVID-19 infection with new-onset hematochezia, hypertension, and tachycardia. Abdominal ultrasound, abdominal x-ray, chest x-ray, ANA, C3, C4, ANCA, creatinine, electrolytes, and coagulation factors were normal. Urinalysis was significant for hematuria and a urine protein-to-creatinine ratio (UPC) of 2.02 mg/mg. Purpuric and petechial rash appeared the day after admission. UPC trended up to 4.82 mg/mg and a renal biopsy confirmed the diagnosis of IgA nephropathy. Patient was treated with 30mg/kg/day Solu-Medrol for three days and discharged home on 2mg/kg/day prednisolone daily. He was readmitted two days later with severe left frontal headache. UPC was worse at 5.98 mg/mg and mycophenolic mofetil (MMF) was initiated. Imaging revealed an occlusive thrombus of the left transverse sinus with nonocclusive thrombi in the distal portion of the left lateral sinus and posterior superior sagittal sinus. He started 21mg Lovenox twice daily and had minimal residual thrombosis after three months. His UPC peaked at 20.73 mg/mg and eventually normalized with high-dose steroids, Enalapril, and MMF.

**Discussion:** This is the first case, to our knowledge, of CVST in a patient with IgAV associated with COVID-19 infection. Multiple case reports of IgA vasculitis associated with COVID-19 infection have been published in the past two years, and this case may support a more careful approach when it comes to screening for pro-coagulation risk factors.

## SA-PO591

**A Rare Genetic Cause of Steroid Resistant Nephrotic Syndrome**

Jessamyn S. Carter,<sup>1,2</sup> John D. Spencer,<sup>1</sup> <sup>1</sup>*Nationwide Children's Hospital, Columbus, OH;* <sup>2</sup>*The Ohio State University Wexner Medical Center, Columbus, OH.*

**Introduction:** MIRAGE syndrome, named for Myelodysplasia, Infection, growth Restriction, Adrenal hypoplasia, Genital phenotypes, and Enteropathy, is a rare genetic disorder caused by autosomal dominant mutations in *SAMD9* and which is sometimes associated with adaptive monosomy 7 leading to myelodysplasia. However, there is significant genotypic and phenotypic variation with an increase in identified mutations and presentations in recent years. We present here a case of focal segmental glomerulosclerosis in a patient with MIRAGE syndrome associated with a novel *SAMD9* mutation.

**Case Description:** A 3 year old boy with history of intrauterine growth restriction, cryptorchidism, and intermittent thrombocytopenia presented for persistent proteinuria (urine protein:creatinine ratio, or UPCR, of 3.4) with normal serum albumin. Renal biopsy showed segmental sclerosis in 2 out of 20 glomeruli, and he completed a prednisone course with no improvement of proteinuria. He was then started on enalapril and spironolactone with improvement of UPCR to 1 and has remained on renin-angiotensin-aldosterone system blockade since that time for management of his proteinuria. His hematologic course progressed to myelodysplastic syndrome with transient monosomy 7 and he underwent bone marrow transplant at age 8. That year, while on tacrolimus from BMT, he developed edema and hypoalbuminemia prompting repeat renal biopsy which again showed focal segmental glomerulosclerosis. Immunosuppression with curcumin was given with improvement in UPCR from 4.4 to 1.6 initially but with recurrent increase over the next two years. He has since received no other immunosuppression and maintains on lisinopril and spironolactone with variable but persistent proteinuria and intermittent episodes of edema. UPCR was 6.8 during most recent follow up at age 15.

**Discussion:** MIRAGE syndrome is a rare but increasingly recognized genetic disease impacting many organ systems. The immunologic and hematologic manifestations are most notable because of potential lethality, but scattered evidence suggests MIRAGE syndrome can be associated with glomerular disease. Though not definitive, people with MIRAGE syndrome may have structural anomalies in the endosomal system, which could trigger dysfunctional endocytosis in podocytes and lead to proteinuria.

## SA-PO592

**Revealing Complement Regulatory Functions of Thrombospondin-1 as New Potential Mechanism in Renal Disease**

Swagata Konwar,<sup>1,2</sup> Jessika Kleindienst,<sup>1</sup> Eva L. Decker,<sup>2</sup> Martin Pohl,<sup>1</sup> Christian Gorzelanny,<sup>3</sup> Todor A. Tschongov,<sup>1</sup> Karsten Häffner,<sup>1</sup> <sup>1</sup>*AG Pediatric Nephrology <sup>1</sup>Universitätsklinikum Freiburg, Freiburg, Germany;* <sup>2</sup>*Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, Germany;* <sup>3</sup>*Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Overactivation of the complement system can lead to severe kidney and vascular diseases like atypical hemolytic uremic syndrome (aHUS) and ANCA-associated vasculitis. In recent years it is becoming clearer that coagulation,

thrombosis and extracellular matrix are deeply connected with the complement system. Thrombospondin-1 (TSP-1) is a major compound of  $\alpha$ -granules in platelets and also present in Weibel-Palade bodies of endothelial cells. TSP-1 is rapidly released after injury and involved in the regulation of clot formation and platelet aggregation. Binding of complement factor H (FH) to TSP-1 has been reported before, however, no research has examined possible intrinsic TSP-1 complement regulation.

**Methods:** Alternative pathway ELISA, Hemolysis, cofactor, decay acceleration and terminal complement complex (TCC) formation assay were performed as described previously (Michelfelder et. al. JASN, 2018). Factor D inhibition assay was performed as described previously (Edwards et. al. J Biol Chem, 1999) Binding assays: TSP-1 was coated on 96 well plates and incubated with increasing amounts of C3 or C5. Binding was analysed using HRP-coupled antibodies. Cell culture: HUVEC were transfected with TSP-1 siRNA using lipofectamine as instructed. Immune fluorescence staining was performed with specific antibodies against TSP-1 and C3.

**Results:** TSP-1 is able to strongly inhibit the alternative pathway (AP) in normal human and aHUS patient serum. The inhibition is only partly dependent on FH. TSP-1 binds to central complement proteins of the alternative pathway. It has no intrinsic cofactor or decay acceleration activity, but inhibits cleavage of FB and C3. Additionally, TSP-1 prevents formation of TCC. Knockdown of TSP-1 in endothelial cells leads to an increase in C3 deposition on HUVEC. This increase can be ameliorated by adding recombinant TSP-1 back into the system.

**Conclusions:** In several in vitro experiments we have found that TSP-1 directly inhibits the activation of the AP in multiple ways. We believe that TSP-1 can act as a bridge between platelets, extracellular matrix, coagulation and complement system and thereby contribute to pathomechanisms of renal diseases. This knowledge could lead to the development of new treatment strategies for complement mediated diseases in the future.

## SA-PO593

**A Unique Presentation of Dense Deposit Disease**

Golnaz Sadeghiani, Amal G. Ezzaiyani, Ashley E. Rawson. *Our Lady of the Lake Regional Medical Center, Baton Rouge, LA.*

**Introduction:** Diagnosis of dense deposit disease (DDD) is made by renal bx. It has a poor prognosis and treatment remains difficult and varied. Renal bx may be confounding early in the disease process.

**Case Description:** A 14 yo female with no PMH presented to our facility with 4 weeks of progressive edema. Initial evaluation demonstrated UA with 20-50 WBCs, 10-20 RBCs, and >500 protein; serum Cr 1.54; UPCR 13000 mg/G; C3 11; and C4 11. ANA and anti-dsDNA antibodies were positive. Renal bx demonstrated a diffuse proliferative glomerulonephritis (GN) and membranous nephropathy with multiple wire loop lesions. IF showed a full house pattern with diffuse global granular mesangial and capillary loop staining for IgG (3+), IgA (trace-1+), IgM (1+), C3 (3+), C1q (2+), kappa (3+) and lambda (2+). EM revealed occasional subepithelial and intramembranous electron-dense deposits along the basement membranes. She was diagnosed with mixed class IV/V lupus nephritis and met ACR classification criteria for diagnosis of SLE. From 4/2020-4/2021, she was treated with high dose pulse IV steroids, oral steroids, rituximab, mycophenolate mofetil, azathioprine, and cyclophosphamide. Despite aggressive treatment, her response was moderate at best and the C3 did not increase. She underwent a second bx 12 months later due to lack of resolution of renal symptoms. IF on the second bx revealed focal and segmental granular mesangial and capillary loop staining for IgG (1+), kappa (trace) and lambda (trace) and diffuse global granular mesangial and capillary loop staining for C3 (3+). EM revealed extensive electron-dense transformation of the glomerular basement membranes and mesangium. These findings appeared more consistent with DDD. Complement pathway assessment revealed elevated SC5B-9 Level (1,048 ng/ml), C3a (454.5 ng/ml), C5a (28,616 ng/ml), C3 Nephritic Factor (171.0 unit/ml) and complement Bb (3,790 mcg/ml). She was started on eculizumab with significant improvement over the last six months. Her Cr fell from 2.52 to 1.41 and UPCR fell from 5,513 mg/G to 2,117 mg/G.

**Discussion:** GN patients present similarly in many cases and some lupus indicators such as ANA may be nonspecific. This case shows the importance of repeating a renal bx in non-responsive lupus nephritis or GN patients in general as the initial biopsy may not tell the full story. In our case repeat biopsy revealed a new diagnosis leading to different treatment options.

## SA-PO594

**Acute Renal Papillary Necrosis With New-Onset Minimal Change Disease**

Shree Goswami,<sup>1,2</sup> Shunhua Guo,<sup>1,2</sup> Joshua Roth,<sup>1,2</sup> Andrew L. Schwaderer,<sup>1,2</sup> Myda Khalid,<sup>1,2</sup> <sup>1</sup>*Riley Hospital for Children at Indiana University Health, Indianapolis, IN;* <sup>2</sup>*Indiana University School of Medicine, Indianapolis, IN.*

**Introduction:** Acute renal papillary necrosis (RPN) is a rare condition in children characterized by renal sloughing of papillae. We present a case of RPN in a healthy 4-year-old girl with new onset minimal change disease (MCD). To our knowledge, RPN as a complication of new onset MCD has not been previously reported.

**Case Description:** The patient presented with a 4-day history of generalized edema, fatigue and decreased urine output. Pertinent lab findings were albumin of 2.4 mg/dL and UPCR of 27 mg/mg. She had an elevated serum BUN and creatinine of 44 mg/dL and 1.2 mg/dL respectively. Renal bladder ultrasound showed bilateral nephromegaly without hydronephrosis. Upon hospitalization, she received albumin with furosemide overnight. However, she remained anuric and creatinine rose to 2.9 mg/dL the next day. Repeat renal bladder ultrasound demonstrated bilateral circular isoechoic foci in mid-poles of the

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

kidneys with bladder debris, suspicious for RPN. Double J stents were placed urgently with immediate production of urine. Retrograde pyelogram at the time of stent placement demonstrated multiple collections of contrast in bilateral kidney papillae, specific for RPN. A renal biopsy on day 6 of hospitalization revealed MCD. Common risk factors for RPN such as NSAID use were not present and a hemoglobin electrophoresis was negative. She remained on prednisolone for the MCD and entered remission in one month.

**Discussion:** To our knowledge we are not aware of any case reports describing RPN as a complication of minimal change disease. The sloughed renal papillae caused an acute bilateral ureteric obstruction. Due to sudden onset of obstruction hydronephrosis did not develop. We speculate that the intravascular volume depletion from MCD triggered a hypoxic state resulting in RPN which is similar to the pathophysiology of severe dehydration induced RPN.

Retrograde left pyelogram demonstrating central excavation of the papillae typical for papillary necrosis.

A. A "ball on tree appearance" in the upper and lower poles papillae (arrows 1, 2, and 4) and a clubbed calyx appearance in the mid pole papilla (arrow 3).

B. There is progressive filling of the papillae excavations, most severe in the mid pole (arrow).

SA-PO595

### The Difference of Activation Pattern of Complement System Between Pediatric and Adult Lupus Nephritis

Minji Park, Min Hyun Cho. Kyungpook National University Hospital, Daegu, Republic of Korea.

**Background:** Lupus nephritis has an etiopathogenesis caused by activation of the complement system. The purpose of this study is to investigate the differences and clinical implication of the activation pattern of complement system between pediatric and adult lupus nephritis patients.

**Methods:** We retrospectively reviewed medical records of 14 pediatric and 26 adult patients whose tissue specimens were stored among patients diagnosed with lupus nephritis through renal biopsy. The activation of complement system was evaluated by performing IHC staining for C4d (a component of the lectin pathway) and IF staining for C1q (a component of the classical pathway) and C3 (a component of the alternative pathway) in renal tissue.

**Results:** The study enrolled 14 pediatric and 26 adult patients, and the proportion of female was significantly higher in both groups. The average age at diagnosis of pediatric patients was  $11.7 \pm 2.9$  years, and the average age of adult patients was  $37.3 \pm 13.5$  years. Except for age and C3 level, the baseline clinical characteristics of pediatric and adult patients were similar. Age-adjusted mean C3 value were significantly lower in pediatric patients, 33.0mg/dL in pediatric patients and 50.8 mg/dL in adult patients ( $p=0.003$ ). As a result of complement staining of kidney tissue, the C3 and C1q positivity rate in pediatric/adult patients were 92.9/76.9% and 85.7/80.8%, respectively and there was no significant difference. However, the C4d positivity was 35.7% in pediatric patients and 76.9% in adult patients ( $p=0.010$ ), which was significantly higher in adult patients than in pediatric patients. Although there was no correlation between C4d activation and initial laboratory findings and prognosis in both groups, the C4d/C1q(+/+) group among adult patients had poor prognosis (defined as CRF, dialysis or death) than the C4d/C1q(+/-) group (82% vs 33%,  $p=0.027$ ).

**Conclusions:** Pediatric lupus nephritis patients had significantly lower C4d activation compared to adult lupus nephritis patients and the co-positivity for C4d and C1q can be considered as a poor prognostic factor for lupus nephritis patients. Therefore, we conclude that the pattern of complement activation system plays an important role in determining the age difference and prognosis in lupus nephritis.

SA-PO596

### Urine Complement Factor Ba Is an AKI Biomarker in Critically Ill Children

Erin K. Stenson,<sup>1,2</sup> Zhiying You,<sup>1</sup> Charles L. Edelstein,<sup>1</sup> Shinobu Miyazaki-anzai,<sup>1</sup> Joshua M. Thurman,<sup>1</sup> Bradley P. Dixon,<sup>1,2</sup> Michael Zappitelli,<sup>4</sup> Stuart Goldstein,<sup>3</sup> Jessica B. Kendrick,<sup>1</sup> <sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>Children's Hospital Colorado, Aurora, CO; <sup>3</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>4</sup>Sick Kids Foundation, Toronto, ON, Canada.

**Background:** Critically ill children with acute kidney injury (AKI) suffer from high morbidity and mortality and lack treatment options. Complement activation is implicated in AKI pathogenesis, which could potentially be treated with complement-targeted therapeutics. We assessed the association between urine Ba, an activated fragment of the alternative complement pathway, and AKI in a heterogeneous cohort of critically ill children.

**Methods:** A biorepository of critically ill children was leveraged and identified children with pRIFLE criteria AKI (stage 1 eGFR 25% decreased; stage 2 eGFR 50% decreased; stage 3 eGFR 75% decreased). ELISAs quantified urine Ba values. The log value of Ba was used in ANOVA with pairwise comparison by the Tukey method. Logistic regression tested the association between urine Ba and AKI.

**Results:** 73 patients from the original study had urine specimens available. 17 with no AKI, 26 with stage 1, 16 with stage 2, and 14 with stage 3 AKI. Ba was higher in patients with stage 3 AKI compared to all other stages, and higher in patients with stage 2 AKI versus no AKI (Figure 1;  $p<0.05$ ). Multivariate analysis showed the association between urine Ba and AKI (OR 1.40, 95% CI 1.08-1.82,  $p = 0.002$ ) after adjusting for PRISM (an estimate of illness severity).

**Conclusions:** Urine factor Ba levels are increased in patients with AKI compared to patients without AKI. In patients with similar illness severity on admission, a doubling of urine Ba level was associated with a 40% increase in AKI diagnosis. Further studies are needed to investigate the role of complement activation in critically ill children at risk of AKI, to help stratify patients to study complement therapeutics in.

Multivariate logistic regression

Variable	OR (95% CI)	p-value
Urine Ba	1.40 (1.08-1.82)	0.0015
Urine IL-18	1.21 (0.60-2.42)	0.60
PRISM	0.99 (0.91-1.07)	0.78

SA-PO597

### Prospective Cohort Study of Pediatric AKI in Korea

Naye Choi,<sup>1,3</sup> Jeosu Min,<sup>1,3</sup> Ji hyun Kim,<sup>2,3</sup> Haemin Kang,<sup>1</sup> Hee Gyung Kang,<sup>1,3</sup> Yo Han Ahn,<sup>1,3</sup> <sup>1</sup>Seoul National University Children's Hospital, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea; <sup>3</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Acute kidney injury (AKI) is a common complication in pediatric patients with underlying disease, and it is associated with increased length of hospital stay and mortality. Additionally, AKI is a well-known risk factor for chronic kidney disease (CKD). Although studies about AKI in children have been increasingly conducted, there was lack of study on the longitudinal kidney outcomes after AKI. Therefore, we conducted a prospective cohort study to investigate the short- and long-term effects of AKI on kidney function in children with AKI.

**Methods:** A prospective cohort study was performed in hospitalized children who were diagnosed with AKI in Seoul National University Children's Hospital from February 2016 to July 2021. AKI was defined according to Kidney Disease: Improving Global Outcomes (KDIGO) criteria. Kidney function was assessed at 1, 3, 6, and 12 months after the AKI event and annually thereafter from 1 year.

**Results:** A total of 807 children with AKI were enrolled, and 735 (male 58.2%) patients with follow-up data were analyzed. AKI occurred at the median age of 5.6 (interquartile range (IQR) 1.1–12.1) years. The 85.4% of patients had the underlying disease, including hemato-oncological disease 210 (28.6%), preterm birth 115 (15.6%), and kidney disease 74 (10.1%). Hypertension was present in 107 (14.6%) at the time of AKI. Among them, 415 (56.5%) patients were classified as stage 1, 177 (24.1%) and 143 (19.5%) were classified as stage 2 and 3, respectively. Estimated glomerular filtration rate (eGFR) declined from 102.6 (IQR 70.7–136.6) mL/min/1.73m<sup>2</sup> at baseline to 52.8 (IQR 23.9–74.4) mL/min/1.73m<sup>2</sup> at the onset of AKI. At follow-up of 1, 3, 6, 12 months, eGFR were 88.9 (IQR 63.5–119.4), 98.3 (IQR 78.2–121.2), 100.5 (IQR 82.0–121.7), and 95.9 (IQR 77.8–113.2) mL/min/1.73m<sup>2</sup>, respectively. After 12 months, the proportion of eGFR less than 90 and 60 mL/min/1.73m<sup>2</sup> were 39.8 % and 8.4%, respectively. The eGFR at follow-up of 12 months was significantly lower than that at baseline ( $P = 0.007$ ). Older age and hypertension at the AKI event were the risk factors for CKD stage 3.

**Conclusions:** In this study, 8.4% of children progressed to CKD following AKI. Therefore, it is important to monitor the kidney function in children after an AKI event. Further study is needed to validate risk factors for CKD and longer outcomes.

## SA-PO598

## Patient Level Factors Increase Risk of Acute Kidney Disease in Hospitalized Children With AKI

Mital Patel,<sup>1</sup> Christoph Hornik,<sup>1</sup> Clarissa J. Diamantidis,<sup>1</sup> David T. Selewski,<sup>2</sup> Rasheed A. Gbadegesin.<sup>1</sup> <sup>1</sup>Duke University Medical Center, Durham, NC; <sup>2</sup>Medical University of South Carolina, Charleston, SC.

**Background:** Studies in adults have shown that acute kidney disease (AKD [kidney dysfunction  $\geq 7$ -90 days]) may be a better predictor of chronic kidney disease (CKD) and mortality in AKI survivors. However, in the pediatric population, little attention has been paid to the AKI-to-AKD transition and subsequent consequences. The aim of this study is to evaluate the risk factors for progression of AKI to AKD in hospitalized children and determine the incidence of CKD following AKD.

**Methods:** We quantified AKD risk using a retrospective cohort of 528 children admitted with AKI to critical care and general wards at a tertiary care children's hospital between 2015-2019. Exclusion criteria included insufficient creatinine values to evaluate for AKD, chronic dialysis, or previous kidney transplant. AKI and AKD were defined using Kidney Disease Improving Global Outcomes criteria. CKD was defined as new estimated glomerular filtration rate of  $< 60$  ml/min/1.73m<sup>2</sup> for  $> 3$  months after AKI.

**Results:** In this cohort, 297 (56.3%) of hospitalized AKI survivors developed AKD. Univariable analysis showed that there are patient level risk factors for AKD (table 1) including preexisting conditions, iatrogenic factors, and severity of kidney injury. Among children with AKD, 26.3% developed CKD compared to 13.4% in the group without AKD (OR 2.9, 95% CI 1.75-4.77).

**Conclusions:** Our data shows that AKD is extremely common among hospitalized children with AKI and that multiple patient level risk factors are associated with AKD. This study suggests that AKI survivors with AKD are at higher risk of developing CKD than those without AKD, suggesting nephrology follow up is indicated in this group.

**Funding:** NIDDK Support

Table 1: Univariable analysis comparing risk factors in patients with and without AKD

Variable	AKD (n=297)	No AKD (n=231)	p-value
Prematurity < 36 weeks	106 (35.7)	54 (23.4)	0.0026
Malignancy	37 (12.5)	15 (6.5)	0.023

## Neonatal Hyperoxia Contributes to Kidney Injury and Differential Kidney Gene Expression in Adult Rats

Marissa J. Defreitas,<sup>1</sup> Augusto F. Schmidt,<sup>1</sup> Amanda Levine,<sup>1</sup> Shathiyah Kulandavel,<sup>1</sup> Pingping Chen,<sup>1</sup> Runxia Tian,<sup>1</sup> Claudia P. Rojas,<sup>2</sup> Carolyn L. Abitbol,<sup>1</sup> Shu Wu,<sup>1</sup> Karen Young,<sup>1</sup> Merline Benny.<sup>1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Memorial Healthcare System, Hollywood, FL.

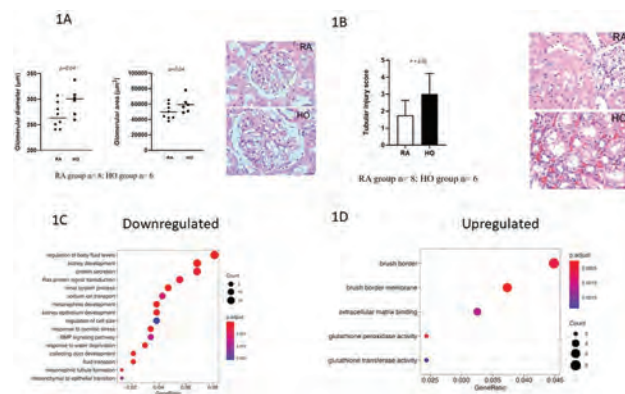

**Background:** Neonatal hyperoxia exposure causes short- and long-term kidney injury and impaired kidney development. However, the mechanisms underlying this programming are largely unknown. Here, we test the hypothesis that neonatal hyperoxia induces renal histomorphometry changes and altered kidney gene expression in adult rats.

**Methods:** Newborn rats (N=14) randomly assigned to normoxia (RA; n=8) or hyperoxia (HO; n=6) (85% O<sub>2</sub>) from postnatal day 1 to 14, were recovered in normoxic conditions until 1 year of life. At 1 year of life, kidney and body weight were measured. Renal histomorphometry was assessed for glomerular size (diameter and area) and tubular injury score. RNA-seq of the whole kidney was done (n=4/group) to assess the transcriptional effects of neonatal hyperoxia at 1 year. Data are expressed as mean  $\pm$  SD and analyzed by Student's T test.

**Results:** At 1 year, kidney weight/body weight was significantly lower in the HO compared to the RA group (1.98  $\pm$  0.57 mg/gm vs 3.99  $\pm$  2.05 mg/gm, respectively, p=0.03). There was significant glomerulomegaly (Figure 1A) and a trend towards increased tubular injury score (Figure 1B) in the HO compared to RA group. Neonatal hyperoxia exposure differentially regulated genes in 1 year old kidneys. Gene set enrichment analysis showed that the most downregulated genes were related to "kidney development" (Figure 1C) while the most upregulated included genes involved in "brush border", "extracellular matrix binding", and "glutathione peroxidase and transferase activity" (Figure 1D).

**Conclusions:** Neonatal HO exposure was associated with sustained glomerular and tubular injury and decreased nephron mass in adult rats. This was accompanied by a downregulation of kidney developmental gene expression and an upregulation of antioxidant and tissue repair gene expression. Further studies to determine how antioxidant therapies could alter the programming of kidney injury after neonatal HO exposure are important.

**Funding:** Other NIH Support - K08, KL2

## SA-PO600

## Predictive Factors of Mortality in Pediatric Patients With AKI Hospitalized in a Tertiary Hospital

Simone Vieira, Maria Fernanda C. Carvalho, Paloma C. Gago, Eduardo F. Hatanaka, Karina M. Macedo, Ana Carolina A. Dos Santos, Pollyanna S. Pacheco, Renata L. Miranda, Paulo C. Koch Nogueira. Hospital Samaritano de Sao Paulo, Sao Paulo, Brazil.

**Background:** Retrospective analysis of risk factors associated with death in pediatric patients hospitalized in the intensive care unit (ICU) of Samaritano Higienópolis Américas Hospital from January 2016 to April 2022, with indication of dialysis, taking into account the etiology of kidney disease, clinical and demographic characteristics.

**Methods:** We evaluated 235 patients (6 on peritoneal dialysis - PD, 102 on continuous hemodialysis - CRRT and 127 on conventional hemodialysis - HDC). The patients were grouped into: survivors and death. To evaluate the predictive factors of death, univariate logistic regression analysis was used with the outcome death, and the following risk variables: age, gender, etiology of kidney disease, Fluid overload, use of diuretics, vasoactive drugs, and time of ICU stay until consultation with nephrologist.

**Results:** Of the 235 patients included in the study, 63 (27%) died and 172 (73%) survived until hospital discharge, 176 (75%) were male, 157 (67%) had kidney disease, 51 (22%) had oncologic disease, 17 (7%) were cardiac. The median age was 5 years (interquartile range 1.4 to 10.0) and the risk factors significantly associated with the outcome death were: Fluid overload (FO%) (OR= 1.07, 95% CI 1.03-1.1, p<0.001), age (OR= 0.91, 95% CI 0.86-0.97, p 0.002), according to the underlying disease: Oncologic (OR= 8.31, 95% CI 4.18- 16.51), p <0.01, cardiac (OR= 26.56, 95%CI 5.87- 120.21, p <0.001), kidney (OR= 0.05, 95% CI 0.02- 0.11, p < 0.001), use of vasoactive drugs (OR = 13.47 95% CI 6.2- 29.28, p < 0.001) and ICU stay to initiate dialysis (OR= 1.1, 95% CI 1.05 - 1.15, p<0.001).

**Conclusions:** In this study the variables that were associated with the highest risk of death were: underlying disease, with a higher chance of death for heart disease (increased risk of death by 26.56 times) and oncological (increased risk of 8 times), patients with Kidney disease had a protective effect for death, age (each year of increase reduces the risk of death by 9%), use of vasoactive drugs (increased death by 13.5 times), ICU stay (each day the most increased the risk of death by 10%) and Fluid overload (each 1% FO increased the risk of death by 7%).

## SA-PO601

## Fluid Balance and Return to Birth Weight Impact Short- and Long-Term Respiratory Outcomes in Premature Neonates

Michelle C. Starr,<sup>1</sup> Katja M. Gist,<sup>4</sup> Jeff L. Segar,<sup>7</sup> Rupesh Raina,<sup>8</sup> Ronnie Guillet,<sup>9</sup> Saudamini Nesargi,<sup>6</sup> Shina Menon,<sup>3</sup> Nekayla Anderson,<sup>2</sup> David J. Askenazi,<sup>2</sup> David T. Selewski.<sup>5</sup> Neonatal Kidney Collaborative

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL; <sup>3</sup>Seattle Children's Hospital, Seattle, WA; <sup>4</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>5</sup>Medical University of South Carolina, Charleston, SC; <sup>6</sup>St. John's Medical College, India, India; <sup>7</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>8</sup>Cleveland Clinic Akron General, Akron, OH; <sup>9</sup>Golisano Children's Hospital, Rochester, NY.

**Background:** Premature neonates are at risk of acute kidney injury (AKI) and disordered fluid balance (FB). Few data exist on association between FB and respiratory outcomes in this population.

**Methods:** We evaluated neonates born 24–27 weeks in the PENUT study, a Phase III randomized, placebo-controlled trial in 30 US NICUs from 2013–16. Primary exposure: peak FB in the first 14 postnatal days. Secondary exposures: FB postnatal day 3 and return to birthweight day. FB was calculated as percent change from birthweight. Primary outcome: mechanical ventilation (MV) on postnatal day 14. Composite secondary outcome: severe bronchopulmonary dysplasia (BPD) or death.

**Results:** 923 preterm neonates were included. Weight was available for 13,394 of 13,845 (96.7%) potential patient-days. 480/923 (53.5%) were MV on postnatal day 14 and 554/923 (60.0%) had severe BPD/death. Neonates with peak FB  $> 5\%$  had 1.75

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

higher odds (95% CI 1.33, 2.31,  $p < 0.0001$ ) of MV on postnatal day 14, and 1.51 higher odds (95% CI 1.11, 2.06,  $p = 0.009$ ) of severe BPD/death. After adjusting for confounding variables, for every 5% increase in peak fluid balance there was 2.21 higher odds of MV on postnatal day 14 (aOR 2.21, 95% CI: 1.61, 2.80,  $p < 0.0001$ ). (Table 1) Median return to birthweight was shorter in neonates who were MV on postnatal day 14 (7d vs. 8d;  $p < 0.0001$ ) and those with severe BPD (7d vs. 8d,  $p = 0.0003$ ) (Figure 1). Neonates who did not drop below their birth weight were more likely to be MV (68% vs. 59%,  $p = 0.0041$ ).

**Conclusions:** Peak FB was associated with MV and severe BPD/death. Time to regain birth weight and 5% fluid overload are actionable markers of poor pulmonary outcomes. Future work should determine if interventions including targeted fluid management or individualized fluid delivery guided improve patient outcomes.

**Funding:** Commercial Support - Nuwellis

Table 1. Fluid balance stratified by the need for mechanical ventilation at postnatal day 14			
Outcome	Mechanically Ventilated at Postnatal 14		p-Value
	Yes (N = 458)	No (N = 415)

### Clearance and Nutrition in Neonatal Continuous Kidney Support Therapy (CKST) Using the CARPEDIEM System

Kimmy T. Vuong,<sup>1,2</sup> Molly R. Vega,<sup>1,2</sup> Pamela Heise,<sup>1,2</sup> Sarah J. Swartz,<sup>1,2</sup> Poyyapakkam Srivaths,<sup>1,2</sup> Scott W. Osborne,<sup>1,2</sup> Christopher J. Rhee,<sup>1,2</sup> Ayse Akcan Arkan,<sup>1,2</sup> Catherine Joseph,<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Texas Children's Hospital, Houston, TX.

**Background:** Improved solute clearance has been associated with improved dietary protein intake estimated by normalized protein catabolic rate (nPCR) and better nutritional status in pediatric CKST. Optimizing nutrition in neonatal CKST to ensure adequate growth can be challenging and requires appropriate clearance. The Cardio-Renal, Pediatric Dialysis Emergency Machine (CARPEDIEM™, Bellco-Medtronic, Mirandola, Italy) was designed as infant CKST with continuous veno-venous hemodialysis (CVVHD). Used in Italy since June 2013 and approved in the United States in April 2020 for infant CKST, we aimed to assess the solute clearance effect on nPCR receiving CKST with CARPEDIEM™ system.

**Methods:** Single center retrospective cohort of 8 patients who received CKST between June to December 2021. Institutional quality improvement dashboard for CKST collected real-world data for circuit characteristics prospectively. Per institutional protocol, filter performance is monitored daily with effluent urea nitrogen. Urea clearance (ml/min) was determined by the effluent rate. nPCR was calculated using the Edefonti equation for the first 5 and last 5 treatments for each patient, with goal nPCR value > 1 g urea nitrogen/kg/day.

**Results:** 8 infants received a total of 272 CKST sessions (162 using 015 filter and 110 using 025 filter) for 31.8 days (IQR 21.9 – 49.6) days CKST. At CKST start, estimated dry weight was 2.61 kg (IQR 2.52 – 3.4) and actual patient weight was 3.27 kg (IQR 3.04 – 4.60). Average filter life was 18.04h, average blood flow rate was 28.36ml/min, average effluent flow rate was 50.57ml/kg/h, and median total effluent volume per day was 6509 mL (IQR 5573-7307) per patient. Urea clearance was 34.3 (IQR 23.1-59.9). Overall median nPCR was 1.20 (IQR 0.95-1.44), with lower median nPCR during the first 5 treatments (median nPCR 1.13 with IQR 0.81-1.35) compared to the last 5 treatments (median nPCR 1.22 with IQR 1.00-1.48).

**Conclusions:** Adequate solute clearance can be achieved using the CARPEDIEM™ system which can allow for optimization of nutritional status and promote growth among critically ill neonates.

## SA-PO603

### High Prevalence of Bone Disease in Children on Prolonged Continuous Kidney Replacement Therapy

Mugdha Rairkar,<sup>1,2</sup> Peace D. Imani,<sup>1,2</sup> Siddharth P. Jadhav,<sup>1,2</sup> Matthew Ditzler,<sup>1,2</sup> Ayse Akcan Arkan,<sup>1,2</sup> Poyyapakkam Srivaths,<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Texas Children's Hospital, Houston, TX.

**Background:** Acute kidney injury (AKI) with/without continuous kidney replacement therapy (CKRT) alters bone metabolism in adults, possibly increasing long term fracture risk. Few studies look at bone disease in AKI on prolonged CKRT with regional citrate anticoagulation in children. We aim to assess osteopenia and bone biomarker changes in pediatric AKI on prolonged CKRT.

**Methods:** Retrospective chart review, ≤ 21 yrs of age with AKI on CKRT ≥ 28 days, including bone markers, without chronic kidney disease/metabolic bone disease. Chest X-ray (CXR) at CKRT initiation, day 14, day 28 evaluated for osteopenia by two independent blinded radiologists.

**Results:** CXR readings (Kappa 58.7%) moderate agreement amongst radiologists. Baseline osteopenia in 17/53 (32%), in 21/53 (40%) by day 28. Among risk factors, acute liver failure (Odds ratio [OR] 3.93, 95% CI: 1.14–13.5,  $p = 0.03$ ), low 25-OH Vitamin D (95% CI: 1.3–0.16,  $p = 0.045$ ), high PTH (95% CI: 0.008–0.39,  $p = 0.003$ ) associated with worsening osteopenia at day 28. Serum calcium, phosphorus, citrate rate, steroid not associated with worsening. Baseline osteopenia associated with higher fracture risk (OR 5.5, 95% CI: 1.4–21,  $p = 0.013$ ), osteopenia day 14 with even higher risk (OR 10.9, 95% CI: 2.2–43.7,  $p = 0.002$ ).

**Conclusions:** Baseline osteopenia present in 1/3 children at CKRT start, which persisted &/or worsened by day 28. Osteopenia associated with increased risk of fracture, risk increasing with increasing days on CKRT. Targeted screening (skeletal survey/DEXA scan) likely warranted for prolonged CKRT, especially in high risk patients as liver failure. Further investigation needed to know if optimal metabolic control in prolonged CKRT will decrease future fracture risk, and to understand underlying pathophysiology.

Table 1: Demographics and Markers of Bone disease

Days on CKRT	Total patient (n)	Age in months (Median [IQR])	Gender (n/F)	Weight at admission in kg (Median [IQR])	Fracture during hospitalization (n)	Total calcium (mg/dL) (Median [IQR])	Ionized calcium (mg/dL) (Median [IQR])	pH (Median [IQR])	Serum bicarbonate (mmol/L) (Median [IQR])	Serum pH (Median [IQR])	Serum 25-OH Vitamin D (pg/mL) (Median [IQR])	Blood urea nitrogen (mg/dL) (Median [IQR])	Calcium infusion rate (mg/kg) (Median [IQR])	Citrate infusion rate (mg/kg) (Median [IQR])	Osteopenia (n)
	53	8.5 (5.4, 12)	23/30	8 (16, 45)	11	8.9 (7.8, 9.7)	1.17 (1.06, 1.29)	7.28 (7.25, 7.31)	23 (19)		80 (105, 120)	80 (105, 120)	55 (115, 180)	125 (185, 200)	29
Day of initiation						8.9 (7.8, 9.7)	1.17 (1.06, 1.29)	7.28 (7.25, 7.31)	23 (19)		80 (105, 120)	80 (105, 120)	55 (115, 180)	125 (185, 200)	29

### Ribonuclease 6 Is a Monocyte and Macrophage Derived Antimicrobial Peptide That Limits Urinary Tract Infection Susceptibility In Vivo

Macie M. Kercsma,<sup>1</sup> Hanna H. Cortado,<sup>1</sup> Birong Li,<sup>1</sup> Christina B. Ching,<sup>1,3</sup> Ashley R. Jackson,<sup>1,2</sup> John D. Spencer,<sup>1,2</sup> Juan de Dios Ruiz-Rosado,<sup>1,2</sup> Brian Becknell,<sup>1,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>Department of Urology, Nationwide Children's Hospital, Columbus, OH.

**Background:** Urinary tract infections (UTI) are common, serious bacterial infections of childhood that originate in the bladder and can ascend to the kidney resulting in acute and chronic injury. Ribonuclease 6 (RNase 6) is an antimicrobial peptide that kills uropathogenic *Escherichia coli* (UPEC). Here, we studied the impact and cellular sources of RNase6 on UTI susceptibility *in vivo*.

**Methods:** To understand the impact of RNase6 on UTI susceptibility, we established humanized *RNASE6* transgenic mice and performed transurethral inoculation of UPEC. We utilized a novel *Rnase6*<sup>EGFP/+</sup> knock-in allele and *Cx3cr1*<sup>GFP/GFP</sup>; *Ccr2*<sup>REDF/REDF</sup> mice to

definitively establish the cellular sources of RNase6. The role of RNase6 in intracellular UPEC killing was identified in a gentamicin protection assay using bone marrow derived macrophages (BMDM).

**Results:** *RNase6* transgenic mice were protected from experimental UTI, with reduced bacterial burden throughout the urinary tract, compared to non-transgenic controls. Mouse *RNase6* and human RNase6 are expressed by resident macrophages and circulating monocytes that are recruited to the infected bladder and kidney. At baseline, these RNase6+ cells localize to the submucosa of the bladder and kidney. Following infection, these cells redistribute to the urothelium in close proximity to intracellular UPEC. Compared to non-transgenic controls, *RNase6* transgenic macrophages are more adept at killing phagocytosed UPEC.

**Conclusions:** RNase6 is a monocyte and macrophage associated antimicrobial peptide that redistributes to the bladder and renal urothelium in the presence of UPEC to effectively limit disseminated infection *in vivo*.

## SA-PO605

### The Human Ribonuclease 3 Antimicrobial Peptide Reduces Urinary Tract Infection Susceptibility *In Vivo*

Hanna H. Cortado,<sup>1</sup> Macie M. Kercsmar,<sup>1</sup> Birong Li,<sup>1</sup> Sudipti Gupta,<sup>1,3</sup> Christina B. Ching,<sup>1,3</sup> Ashley R. Jackson,<sup>1,2</sup> John D. Spencer,<sup>1,2</sup> Juan de Dios Ruiz-Rosado,<sup>1,2</sup> Brian Becknell,<sup>1,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>Department of Urology, Nationwide Children's Hospital, Columbus, OH.

**Background:** Urinary tract infections (UTI) are common, serious bacterial infections of childhood, most often caused by uropathogenic *Escherichia coli* (UPEC). To develop innovative and effective strategies to prevent and treat UTI, we have focused our efforts toward identifying antimicrobial peptides (AMPs) that exhibit potent activity toward UPEC *in vitro* and *in vivo*. Here, we utilized a genetic approach to study the contributions of human Ribonuclease (RNase) 3 to UTI susceptibility in mice.

**Methods:** Urine RNase3 levels were measured by ELISA in females with UTI and compared to unaffected controls. Humanized *RNase3* transgenic mice underwent transurethral inoculation of UPEC, and CFU were enumerated in urinary tract organs. We utilized immunofluorescence microscopy and intracellular flow cytometry to identify the cellular sources of RNase3. The bactericidal activity of RNase3 toward UPEC was investigated through the use of recombinant RNase3 and *RNase3* transgenic neutrophils.

**Results:** Urine RNase3/Cr levels were elevated in patients with UTI compared to controls. RNase 3 amino-terminal peptide exhibited dose-dependent killing of UPEC. *RNase3* transgenic mice were protected from ascending UPEC infection, with reduced upper tract bacterial burden, compared to non-transgenic controls. RNase3 protein is expressed by neutrophils that infiltrate the infected kidney and bladder and release RNase3 following UPEC exposure. Accordingly, compared to non-transgenic controls, *RNase3* transgenic neutrophils are more adept at extracellular UPEC killing.

**Conclusions:** Our data establish that RNase3 is a neutrophil derived antimicrobial peptide induced during human UTI with potent bactericidal activity toward UPEC. Functionally, our *in vitro* and *in vivo* data in *RNase3* transgenic mice and neutrophils establish that RNase3 effectively limits the disseminated UPEC infection.

### Urine Microbiota Analysis and mGWAS in Children With Urinary Tract Infections and Vesicoureteral Reflux

Miguel Verbitsky, Pavan Khosla, Heekuk Park, Yask Gupta, Atlas Khan, Iman Ghavami, Krzysztof Kiryluk, Simone Sanna-Cherchi, Jonathan M. Barasch, Cathy L. Mendelsohn, Anne-Catrin Uhlemann, Ali G. Gharavi. Columbia University, New York, NY.

**Background:** Vesicoureteral reflux (VUR), the retrograde flow of urine from the bladder into the ureters and kidney, accounts for 25-30% of pediatric ESRD worldwide. Urinary tract infections (UTI) are often associated with VUR.

**Methods:** We performed a microbiota analysis based on 16S rRNA gene sequencing from 325 urine samples of children with urinary tract infections with or without VUR from the RIVUR and CUTIE studies' cohorts, and a microbiota GWAS (mGWAS) in 278 of them, with genomic DNA available for genotyping.

**Results:** We found a significant decrease in urine microbiota alpha diversity with VUR ( $P=3 \times 10^{-8}$ ), lack of toilet training ( $P=4 \times 10^{-3}$ ), and younger age ( $P=1 \times 10^{-3}$ ). Our mGWAS identified genome-wide significant associations with zero-truncated relative abundance of *Pseudomonas* on chr10 ( $P=2 \times 10^{-9}$ ) and *Clostridia* on Chr3 ( $P=5 \times 10^{-8}$ ), and a suggestive association with *Bacillales* ( $P=3 \times 10^{-7}$ ) on the same locus as with *Pseudomonas*. Secondary analysis in female participants showed a suggestive association with Gammaproteobacteria on Chr11 ( $P=6 \times 10^{-8}$ ). The top SNPs in these loci were on or near genes associated with immune surveillance, inflammation, and genitourinary tract development and disease (CXCL12, ROBO1, WNT11). We also conducted phenome-wide association studies on the UK Biobank and eMERGE cohorts of the top SNPs showing suggestive associations with UTI and bladder dysfunction.

**Conclusions:** We report the first combined urine microbiota analysis and mGWAS in children with UTI and VUR, showing associations of bacterial taxa's relative abundances with clinical variables and human host genetic factors.

## SA-PO607

### Fundamental Role for the Urothelial Plaque in Gram-Negative Urinary Tract Infections

Birong Li,<sup>1</sup> Hanna H. Cortado,<sup>1</sup> Sudipti Gupta,<sup>1,3</sup> Christina B. Ching,<sup>1,3</sup> Ashley R. Jackson,<sup>1,2</sup> Brian Becknell,<sup>1,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Kidney and Urinary Tract Center, Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>Department of Urology, Nationwide Children's Hospital, Columbus, OH.

**Background:** Over 90% of human urinary tract infections (UTI) are caused by Gram-negative bacteria, most commonly, uropathogenic *Escherichia coli* (UPEC). Superficial cells in the bladder produce Uroplakin (Upk) containing urothelial plaques that bind to type I fimbriae of UPEC in a mannose-dependent manner. The role of the urothelial plaque in bladder epithelial cell invasion and triggering the host inflammatory response remains unclear. We hypothesized that a functional urothelial plaque is absolutely required for Gram-negative cystitis to occur.

**Methods:** We established acute cystitis in urothelial plaque-deficient female *Upk1b*<sup>-/-</sup> and wild-type (*Upk1b*<sup>+/+</sup>) mice by transurethral inoculation of UPEC strain UT189 or *Enterococcus faecalis* strain 0852. Bacterial burden was measured by plating tissue homogenates and enumeration of bacterial CFU. Intracellular bacterial communities were detected on the basis of b-galactosidase activity and immunofluorescence microscopy. Upk protein expression was localized by immunofluorescence microscopy, and plaque ultrastructure was visualized by electron microscopy. UPEC elicitation of cytokines and chemokines was measured by qPCR.

**Results:** *Upk1b* deletion results in failure of superficial bladder epithelial cells to assemble a functional urothelial plaque, as evinced by absence of plaque ultrastructure and increased permeabilization of FITC-Dextran. In response to UPEC inoculation, *Upk1b*<sup>-/-</sup> mice exhibited reduced bacterial burden throughout the urinary tract, absence of intracellular bacterial communities, less cytokine and chemokine mRNA production induction, and decreased neutrophil infiltration, when compared to *Upk1b*<sup>+/+</sup> mice. Conversely, *Upk1b*<sup>-/-</sup> and *Upk1b*<sup>+/+</sup> mice displayed equal susceptibility to infection with *E. faecalis*.

**Conclusions:** The urothelial plaque is essential to facilitate UPEC invasion of the bladder mucosa and establishment of cystitis, but this structure is dispensable for *Enterococcus* infection. This study demonstrates the primacy of the plaque for Gram-negative UTI and further strengthens the rationale for targeted therapies such as mannosides to disrupt UPEC-plaque interaction and serve as anti-infective agents.

## SA-PO608

### $\alpha$ -Defensins 1-3 Gene-Dosage Drives Protection of the Urinary Tract From Uropathogenic Bacterial Challenge

Jorge J. Canas, Andrew L. Schwaderer, David S. Hains. Indiana University School of Medicine, Indianapolis, IN.

**Background:** Antimicrobial peptides (AMPs) are potent innate immune effectors with direct antimicrobial activity against a range of bacteria. The AMP  $\alpha$ -Defensin 1-3 (*DEFA1A3*) is expressed by human neutrophils granules and kidney epithelial cells. Recently, a low DNA copy number of *DEFA1A3* has been associated with increased UTI risk in children (<4 copies versus >6 per diploid genome). Due to the lack of this gene in mice, we utilize a human *DEFA1A3* gene knock-in mouse with a 4 copy gene per haploid genome to study gene-dosage interactions. This study aims to compare bacterial burden and antimicrobial gene expression between human *DEFA1A3* gene knock-in mice under a pyelonephritis model.

**Methods:** Experimental UTIs were induced by transurethral inoculation of uropathogenic *E. coli* strain CFT073 into *DEFA1A3*<sup>+/+</sup> (8 copies), *DEFA1A3*<sup>+/-</sup> (4 copies), and *DEFA1A3*<sup>0/0</sup> (0 copies) littermate mice. Following 6 hours post-infection (6-hpi), kidneys and bladders were homogenized for bacterial colony-forming unit analysis and mRNA isolation.

**Results:** Compared to *DEFA1A3*<sup>0/0</sup>, *DEFA1A3*<sup>+/+</sup> mice had a significant reduction of mean bacterial burden titers in kidneys and bladders (Figure 1). Following gene expression antimicrobial response array and qRT-PCR in *DEFA1A3*<sup>+/+</sup> and *DEFA1A3*<sup>0/0</sup> kidneys, the most significantly differentially expressed genes were *Rac1* and *Lyz2* (Figure 2).

**Conclusions:** The human *DEFA1A3* gene knock-in mouse represents a critical tool to evaluate novel  $\alpha$ -defensins 1-3 gene-immune interactions. Further studies will involve exploring gene-drug interactions under antibiotic prophylaxis settings before UTI challenge.

**Funding:** NIDDK Support

Figure 1. Bacterial titers of kidney (A) and bladders (B) comparing *DEFA1A3*<sup>+/+</sup>, *DEFA1A3*<sup>+/-</sup>, and *DEFA1A3*<sup>0/0</sup> mice. Percentages above the line are clearance rates in kidneys without bacterial growth.

Figure 2. Kidney *DEFA1A3*<sup>+/+</sup> and *DEFA1A3*<sup>+/0</sup> mouse mRNA expression of *Rac* (A) and *Lyz2* (B) relative to *Gapdh* gene.

## SA-PO609

### The PPAR $\gamma$ Signaling Pathway Regulates Urothelial Adaptation During Urinary Tract Obstruction in Mice

Alexa Miehl,<sup>1,2</sup> Kelly Grounds,<sup>1</sup> Birong Li,<sup>1</sup> Macie M. Kerckmar,<sup>1</sup> Brian Becknell,<sup>1,2</sup> Ashley R. Jackson.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Urinary Tract Obstruction (UTO) is a leading cause of chronic kidney disease in children. No treatments can prevent kidney injury, but heterogeneous outcomes implicate unknown protective adaptations. We previously reported that mice with UTO adapt a bladder-like urothelial lining - characterized by the acquisition of terminally differentiated plaque producing uroplakin-expressing cells (UPK-UCs) along the renal urothelium. Depletion of UPK-UCs or the urothelial plaque accelerate UTO-induced structural and functional injury, suggesting that formation of UPK-UCs is protective. The adult tissue repair progenitor, and the molecular program that governs UTO-induced renal urothelium remodeling is unknown. In the bladder, UPK-UCs function as tissue repair progenitors, and the PPAR $\gamma$  signaling pathway drives urothelial differentiation. Thus, we hypothesized that UPK-UCs to activate PPAR $\gamma$  signaling during UTO-induced renal urothelium remodeling.

**Methods:** UTO was modeled using unilateral ureteral obstruction. Lineage analysis was performed using *Upk2*<sup>CreERT2</sup>;R26<sup>DTT</sup> mice. Immunofluorescent localization was used to profile the PPAR $\gamma$  signaling pathway during experimental UTO. We used *Upk2*<sup>CreERT2</sup>;R26<sup>DTT</sup> mice to deplete UPK-UCs during UTO. We conditionally disrupted PPAR $\gamma$  signaling using *Upk*<sup>CreERT2</sup>;Pparg<sup>fl/fl</sup> (Pparg-cKO), and Pparg<sup>fl/fl</sup> mice during UTO.

**Results:** Lineage analysis experiments showed that adult UPK-UCs were the major contributor to UTO-induced renal urothelium remodeling. At post-operative day 7 and 10, renal urothelium expressed *de novo* PPAR $\gamma$  and FABP4 (a direct transcriptional target of PPAR $\gamma$  signaling), which co-localized to UPK-UCs. In mice where UPK-UCs were genetically depleted, we observed diminished PPAR $\gamma$  and FABP4 during UTO. Finally, we found that Pparg-cKOs had fewer UPK-UCs during UTO than Pparg<sup>fl/fl</sup> mice.

**Conclusions:** Our results indicate that UTO-induced urothelial remodeling is achieved through activation of the PPAR $\gamma$  signaling pathway in UPK-UCs. Future studies will investigate the impact of Pparg-cKO and PPAR $\gamma$  gain of function experiments on kidney injury/function during UTO. Altogether, our findings advance our understanding of renal adaptation to UTO, and reveal a potential mechanism with therapeutic utility for mitigating obstructive kidney disease in children.

**Funding:** NIDDK Support

## SA-PO610

### Stat3 May Drive Prevention of Experimental Chronic Urinary Tract Infection

Sudipti Gupta, Evan Alexander, Hanna H. Cortado, Brian Becknell, John D. Spencer, Christina B. Ching. Kidney and Urinary Tract Center Nationwide Children's Hospital, Columbus, OH.

**Background:** Our understanding of the pathogenesis of chronic urinary tract infections (UTIs) is poor. Having previously identified the importance of IL-6 in UTI susceptibility, we sought to identify the role of the downstream transcription factor, Stat3, in UTI susceptibility, particularly in chronic infection. We hypothesize that Stat3 is involved in limiting UTI development and chronicity.

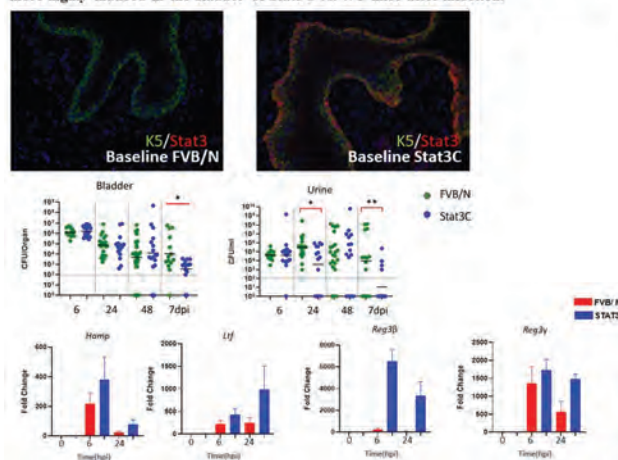

**Methods:** Experimental UPEC UTI (eUTI) was induced in 6-8 weeks old female mice expressing constitutively active Stat3 (Stat3C) and FVB/N wild type controls (WT). Bladder and urine bacterial burden were evaluated at various time points up to 7 days post infection (dpi); and IBCs enumerated. Histopathologic evaluation was performed via H&E and immunofluorescent (IF) staining. qRT-PCR was used for quantification of antimicrobial peptide (AMP) expression. Results were evaluated by Mann-Whitney U test with p<0.05 being significant.

**Results:** Compared to WT, Stat3C mice demonstrated significantly decreased urine bacterial burden at 24 hours post infection (hpi) and 7dpi with bladder burden being significantly less at 7dpi. There was no significant difference in IBC phenotype at 6hpi. H&E of Stat3C bladders at 24hpi showed less inflammation and edema compared to WT. Both uninfected and infected Stat3C urothelium showed Stat3 reactivity by IF with relatively little staining in WT mice. Stat3C and WT urothelium demonstrated induction of pStat3 after infection with apparent persistence of pSTAT3 in Stat3C at 7dpi. Stat3C urothelium showed more Ki67 staining at 24hpi compared to WT. There was significantly higher induction of certain AMPs with eUTI in Stat3C vs. WT mice on qRT-PCR.

**Conclusions:** Stat3 appears significant in protecting against chronic UTI. This could be through differences in urothelial regeneration and turn over as well as through elevated AMP expression.

**Funding:** NIDDK Support

**Figure:** Stat3C mice demonstrate baseline expression of Stat3 on IF and a decrease in bladder and urine bacterial burden by 7dpi. Certain antimicrobial peptide expression is more highly induced in the bladder of Stat3C vs. WT mice after infection.

## SA-PO611

### Dose Vesicoureteral Reflux Increase Risk for Bacteremia in Urinary Tract Infection?

Dabin Kim,<sup>1</sup> Naye Choi,<sup>1,2</sup> Jeeseu Min,<sup>1,2</sup> Hee Gyung Kang,<sup>1,2</sup> Yo Han Ahn.<sup>1,2</sup> <sup>1</sup>Seoul National University Children's Hospital, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Urinary tract infection (UTI) is one of the most common serious bacterial infections in children. During UTI episodes, concurrent bacteremia occurs in 5% to 31% of the cases. UTI accompanied by bacteremia is associated with adverse outcomes such as prolonged admission, shock, bacterial meningitis, and intensive-care unit admission. While it is known that bacteremic UTI had higher CRP, risk factors of concurrent bacteremia is not well investigated yet. Vesicoureteral reflux (VUR) is commonly found in children with UTI. While it is known that bacteremic UTI had higher CRP, DNI, and creatinine level, risk factors of concurrent bacteremia is not well investigated yet.

**Methods:** We reviewed clinical findings of UTI cases from January 2000 to December 2021 in Seoul National University Children's Hospital. To investigate if VUR is a risk factor for bacteremia, the study population was defined as those who had UTIs younger than 24 months and in whom voiding cystourethrogram (VCUG) was performed at the time of UTI. Urine culture, blood culture, and VCUG results were collected in addition to demographic findings. Only when blood culture reported the same pathogens as urine culture, the UTI episodes were considered as concurrent bacteremia.

**Results:** Among a total of 152 (male 78.3%, female 21.7%) cases who had UTI and VCUG tests, 19 patients (12.5%) had concurrent bacteremia during febrile UTI episodes. When comparing these patients with those without concurrent bacteremia (n=133), demographic findings were not statistically different, but the prevalence of high-grade VUR (VUR of grade 3 or higher) was higher in the bacteremia group (47.4%, 9/19) than in the non-bacteremia group (20.3%, 27/133, P=0.018). Patients who have VUR grade 3 or higher had a 3.53-fold increased risk for bacteremia. (95% CI: 1.307-9.554)

**Conclusions:** Children with a VUR of grade 3 or higher are more susceptible to bacteremic UTI. Therefore, concurrent bacteremia might imply the presence of high-grade VUR. On the other hand, managing VUR might reduce the risk of bacteremia in case of UTI.

## SA-PO612

### Spatial Transcriptomics Provides Unique Insights Into the Pathophysiology of Experimental Pyelonephritis

Gregory Ballash,<sup>1</sup> Israel Cotzomi Ortega,<sup>1</sup> Ashley R. Jackson,<sup>1,2</sup> Brian Becknell,<sup>1,2</sup> Juan de Dios Ruiz-Rosado.<sup>1,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Kidney and Urinary Tract Center, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH.

**Background:** Acute pyelonephritis (APN) is considered one of the most significant bacterial infections among young children and is associated with acute kidney injury, renal scarring, and end-stage kidney disease. The molecular mechanisms leading to alterations of tissue homeostasis and long-term sequelae during APN are poorly understood. In this study, we utilized a novel technique, spatially resolved transcriptomics, to define the molecular basis of APN pathology.

**Methods:** Immunocompetent C3H/HeOJ female mice underwent transurethral inoculation with uropathogenic *Escherichia coli* (UPEC). We performed spatial transcriptomics (Visium, 10x Genomics) in kidney sections from infected mice at 0, 7 and 28 days post-infection (dpi), to provide a spatiotemporal context of differential gene expression during UPEC-induced pyelonephritis. Transcriptomic data was spatially integrated using the 10X Space Ranger pipeline. Space Ranger output was investigated for gene expression within tissues via Loupe Browser and across tissue using the *Seurat* package in R.

**Results:** APN kidneys showed unique clustering that localized to geographic regions of the cortex and papilla corresponding to renal abscessation. The acute phase of infection witnessed the emergence of four unique clusters associated with immune response initiation, LPS tolerance, and promoting apoptosis. As infection progressed to a chronic phase, two unique clusters localized to early renal scars that prominently featured genes involved in the adaptive immune response, fibroblast migration, and extracellular matrix formation. By integrating single cell RNA-seq analysis, we identified an enrichment of neutrophils in areas of abscessation, surrounded by macrophages at 7 dpi, and an enrichment of stromal cells in regions of mononuclear inflammation at 28 dpi. Predicted pathways of inflammation thought to instigate renal fibrosis circumscribed renal lesions at both acute and chronic phases of infection.

**Conclusions:** Spatial transcriptomics is a powerful tool to superimpose transcriptional changes onto the landscape of renal pathology. This experimental approach will serve to integrate transcriptional dynamics into a pathophysiological map of the renal response to bacterial infections.

**Funding:** NIDDK Support

## SA-PO613

### Distinct miRNA Profiles Govern the Host Response to Bacterial Cystitis vs. Pyelonephritis

Gregory Ballash,<sup>1</sup> Birong Li,<sup>1</sup> Hanna H. Cortado,<sup>1</sup> Israel Cotzomi Ortega,<sup>1</sup> Ashley R. Jackson,<sup>1,2</sup> Juan de Dios Ruiz-Rosado,<sup>1,2</sup> Brian Becknell.<sup>1,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Kidney and Urinary Tract Center, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Division of Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH.

**Background:** Urinary tract infections (UTIs) are one of the most common bacterial infections of childhood. The innate immune response is essential for pathogen detection and eradication, but excessive inflammation can result in urothelial remodeling that increase risk of subsequent infection and long-term sequelae. MicroRNA are small, non-coding RNA with key roles in regulating renal inflammation and tissue remodeling, but their expression and function in UTI are unknown. Here we investigate miRNA dynamics in the setting of experimental cystitis and pyelonephritis.

**Methods:** Female C3H/HeOJ mice underwent transurethral inoculation with uropathogenic *Escherichia coli* (UPEC) or carrier. Bladders and kidneys were harvested 7 days post infection for miRNA and total RNA sequencing. Transcriptome analysis was performed using GO and Ingenuity. Differential miR expression was validated by qPCR. In certain experiments, miR expression was measured in purified urothelial cells following fluorescence activated cell sorting. The kinetics of miR expression elicited by UPEC was studied in immortalized human urothelial cells.

**Results:** The kidney and bladder miRome varied markedly in response to UPEC infection, with renal miR regulating the proliferative/regenerative response, while bladder miR regulated inflammation and a Tlr4/NF-kB response to Gram-negative bacteria. qPCR validated upregulation of miR-155, -146a, and miR-21, and pathway analysis identified these miR as significant upstream regulators of mRNA expression during cystitis. We determined that a subset of miR were expressed by Upk2+ urothelial cells, and that miR-146a levels increased within this population following UPEC infection. A similar induction of miR-146a occurred in human urothelial cells following UPEC treatment *in vitro*.

**Conclusions:** Distinct miRNA are induced by UPEC during cystitis and pyelonephritis. In the bladder, the targetome of miR-155, miR-146a, and miR-21 suggests their regulatory role in reducing inflammation. Complementary studies in isolated urothelial cells establish this lineage as a source of UPEC-elicited miR *in vivo* and *in vitro*. These observations justify further studies to identify the functional significance and mechanistic properties of miRNA during UTI.

### Cell-Specific Insulin Receptor Deletion Disrupts Urothelial Barrier Integrity Increasing Urinary Tract Susceptibility to Infection

Kristin Bender,<sup>1</sup> Laura Schwartz,<sup>1</sup> Aaron A. Simoni,<sup>1</sup> John D. Spencer.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Individuals with diabetes mellitus have a higher risk for urinary tract infection (UTI), which may increase their risk for kidney injury. The underlying mechanisms of infection remain undefined. During infection, the bladder urothelium acts as a barrier during bacterial attachment and invasion. To investigate the role of insulin signaling on urothelial barrier integrity and infection susceptibility, we genetically deleted the insulin receptor (IR) in the basal or intermediate/superficial cells in the murine urothelium.

**Methods:** IR knock-out mice (IRKO) were generated by crossing mice homozygous for the floxed *Insr* (insulin receptor) gene with transgenic mice that have tamoxifen-inducible Cre recombinase under the Keratin 5 (Krt5) or Uroplakin 2 (Upk2) promoter

expressed in the basal or intermediate/superficial cells, respectively. Littermates lacking the Cre transgene served as controls (IRflox). To determine if IR deletion impacts host defense, female mice were transurethral infected with uropathogenic *E. coli* (UPEC). UPEC burden was enumerated in urine and bladder post infection. To assess bladder barrier permeability, uninfected bladders were mounted in an Ussing chamber, and transepithelial resistance (TER) and radioisotope permeabilities were measured. Cell adhesion markers in isolated urothelium were assessed by qRT-PCR and western blot.

**Results:** Compared to IRflox, IRKO mice exhibit normal development, normoglycemia, and normal bladder histology. Following transurethral UPEC infection, UPK2 IRKO mice have significantly greater UPEC burden in the urine and bladder while barrier studies indicted uninfected UPK2 IRKO mice have lower transepithelial resistance and increased water and urea permeabilities. No differences are observed in Krt5 IRKO in burden. Isolated urothelium from UPK2 IRKO mice expressed lower mRNA levels of several cell adhesion markers compared to IRflox.

**Conclusions:** These results suggest that insulin signaling in the intermediate/superficial cells in the urothelium is critical for the integrity of the urothelial barrier in UTI defense. Disruption of signaling in the basal cells did not impact the bladders defenses during infection. Additional studies to evaluate how IR deletion impacts urothelial defenses.

### PTEN Deletion in the Bladder Superficial Epithelium and Kidney Tubules Enhances Bacterial Burden During Urinary Tract Infections

M. Skye N. Bochter,<sup>1</sup> Kristin Bender,<sup>1</sup> Laura Schwartz,<sup>1</sup> John D. Spencer.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Urinary tract infections (UTI) are one of the most common types of bacterial infections, affecting more than 150 million individuals a year. Previous work from our lab identified a role for PI3K/AKT signaling regulating in the innate immune response in the bladder and kidneys. To further investigate the significance of PI3K/AKT signaling on host defense, we genetically deleted *Pten*, a PI3K/AKT antagonist, in the superficial cells of the bladder urothelium or in the epithelium of the distal nephron and collecting ducts of the kidney.

**Methods:** Mice homozygous for the floxed *Pten* gene were crossed with transgenic mice expressing the Cre recombinase under the control of the Uroplakin2 (Upk2) promoter or cadherin 16 (KSP) promoter to create bladder urothelium-specific or kidney tubule-specific *Pten* knockout (PTEN-KO) mice. PTEN-KO mice and Cre-negative littermate controls (PTENflox) were transurethral infected with uropathogenic *E. coli*. At 16 and 24hrs post infection, *E. coli* burden was quantified in the urine, bladder, and kidney.

**Results:** Upk2-Cre and KSP-Cre PTEN-KO mice showed normal phenotypes and development. PCR confirmed Cre-recombination in PTEN-KO bladders and kidneys. qRT-PCR confirmed *Pten* mRNA deletion. Compared to PTENflox littermate controls, bladder and kidney tissue from Upk2-Cre and KSP-Cre PTEN-KO mice appeared phenotypically normal by light microscopy. Following experimental UTI, Upk2-Cre and KSP-Cre PTEN-KO mice had 1-1.5-fold greater urine and bladder bacterial burden at both 16 and 48hpi compared to PTENflox control mice.

**Conclusions:** These results indicate that PI3K/AKT signaling in the bladder urothelium and kidney tubules impacts UTI susceptibility. They provided added support that the kidney tubules contribute to UTI defense. Additional studies are needed to identify the mechanisms of how PI3K/AKT signaling regulates host defenses and how PI3K/AKT hyper-activation enhances UTI susceptibility.

## SA-PO616

### NOD2 Activates Intercalated Cell Immune Defense During Uropathogenic *Escherichia coli* Infection

Sarah C. Linn,<sup>1,2</sup> Laura Schwartz,<sup>1</sup> John D. Spencer.<sup>1,3</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Veterinary Medicine, Columbus, OH; <sup>3</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Urinary tract infections (UTIs), including pyelonephritis, are frequent infections in women and children often caused by uropathogenic *Escherichia coli* (UPEC). Intercalated cells (ICs), located within the collecting duct, prevent and combat UTIs by recruiting immune cells and secreting antimicrobial peptides (AMPs) into the urine. Mechanisms of UPEC pyelonephritis pathogenesis and the IC immune response are unclear. Here, we challenged ICs *in vitro* with UPEC or bacterial membrane constituents to identify their innate immune responses.

**Methods:** Rabbit ICs (Clone C cells) were challenged with UPEC or the UPEC cell membrane components lipopolysaccharide (LPS), muramyl dipeptide (MDP) and  $\gamma$ -D-Glu-mDAP (iE-DAP). Following infection, cell lysates were obtained and an antimicrobial response PCR array or qRT-PCR were used to determine immune gene activation. Immunoblotting was performed to confirm innate immune pathway activation. Bacterial attachment and invasion assays assessed if exposure to cell membrane components prior to infection impacted IC susceptibility to UPEC.

**Results:** UPEC activated Toll-like receptor (TLR), NfKB, and Nucleotide Binding Oligomerization Domain Containing (NOD)-like receptor (NLR) signaling pathways in ICs, as determined by the antimicrobial response arrays, STRING, and Ingenuity Pathway Analysis. Immunoblotting confirmed activation of both NfKB and MAPK signaling pathways. LPS and the NOD2 agonist, MDP, stimulated NF-kB and MAPK signaling and induced AMP expression, including Lcn2 (NGAL), Ribonuclease 4, and Ribonuclease

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

8. The NOD1 agonist, iE-DAP did not affect AMP expression. Incubation of ICs with LPS and MDP one hour prior to infection protected ICs against UPEC attachment and invasion.

**Conclusions:** In response to UPEC, ICs activate NOD2, TLR4, and the downstream NFkB and MAPK signaling pathways. Stimulation with LPS and MDP activates IC innate immune pathways and increases AMP expression to protect ICs from UPEC. Together, these data indicate NOD2 and downstream NFkB and MAPK signaling may have a role in IC innate immune defenses against UTI.

## SA-PO617

### Notch Signaling Regulates Renal Urothelial Cell Proliferation During Experimental Urinary Tract Obstruction

Kelly Grounds,<sup>1</sup> Alexa Miehs,<sup>1,2</sup> Birong Li,<sup>1</sup> Brian Becknell,<sup>1,2</sup> Ashley R. Jackson.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Urinary Tract Obstruction (UTO) is a leading cause of pediatric chronic kidney disease (CKD). While no interventions can prevent CKD progression, heterogenous outcomes suggest differences in ability of the kidney to adapt to hydrostatic pressure and pelvicalyceal dilatation. Congenital and acquired UTO triggers protective urothelial remodeling. Basal Keratin 5 (K5)-UCs function as age-restricted progenitors, giving rise to protective apical Uroplakin (UPK)-UCs, but the molecular regulation of renal K5-UC progenitors is unknown. The Notch signaling pathway regulates progenitor proliferation and differentiation in other organ systems. Thus, we hypothesize that the Notch signaling pathway governs renal K5-UCs during UTO.

**Methods:** We profiled the expression of members of the Notch signaling pathway using RNAscope (Jag2, Notch1, Dll1), immunohistochemical (ICH) and immunofluorescent (IF) localization (Notch1, NICD, RBPJ, Hes7). We used Megabladder mice (Mgb, congenital lower UTO), and unilateral ureteral obstruction (UUO, acquired upper UTO) to model UTO. We used *K5<sup>CreERT2</sup>;;RBPJ<sup>fl/fl</sup>;;R26<sup>dT/+</sup>* mice (RBPJ-cKO) to inducibly disrupt Notch signaling in K5-UCs and compared to *RBPJ<sup>fl/fl</sup>;;R26<sup>dT/+</sup>* (control). We investigated the impact of Notch loss of function on urothelial integrity using IF (K5, UPK, Ki67).

**Results:** Renal urothelium expresses *Jag2*, *Dll1* (ligands), and *Notch1* (receptor), but low or undetectable levels of NICD (activated Notch) during homeostasis. UTO (both Mgb & UUO) leads to increased NICD in K5-UCs, thus, we proceeded to disrupt Notch during UTO. After validating deletion of RBPJ (loss of Notch function) in K5-UCs, we then performed UUO in RBPJ-cKO and control mice. At post-operative day 2 (peak stage of UTO-induced urothelial proliferation) RBPJ-cKOs exhibited increased Ki67 in K5-UCs compared to controls.

**Conclusions:** Our study suggests renal K5-UC progenitors are regulated by the Notch signaling pathway during UTO. Further studies are warranted to determine whether increased K5-UC proliferation in RBPJ-cKOs leads to impaired renal urothelial remodeling, and whether this impacts renal function. Nevertheless, these findings advance our understanding of renal adaptation to UTO, and implicate a potential signaling pathway with therapeutic utility for mitigating obstructive nephropathy.

## SA-PO618

### Novel Drug Therapy to Prevent Bladder Fibrosis in a Pre-Clinical Model of Posterior Urethral Valves

Kevin X. Cao,<sup>1</sup> Maria K. Joannou,<sup>1</sup> Cheuk Yan Man,<sup>1</sup> Navroop S. Johal,<sup>1</sup> Peter M. Cuckow,<sup>1</sup> Christopher H. Fry,<sup>2</sup> Paul Winyard,<sup>1</sup> David A. Long.<sup>1</sup> David Long - UCL Nephro-Urology <sup>1</sup>UCL Great Ormond Street Institute of Child Health, London, United Kingdom; <sup>2</sup>University of Bristol, Bristol, United Kingdom.

**Background:** Posterior Urethral Valves (PUV) remains one of the most severe paediatric conditions, responsible for most of the demand for renal replacement resources in childhood. We previously showed that excess extra-cellular matrix (ECM) in these bladders may be the pathologic culprit, so finding an anti-fibrotic therapy is a promising means to improve outcomes in this disorder. We performed a pre-clinical trial with both an animal model of PUV and human cell culture experiments with PUV bladder cells, treating both with soluble guanylate cyclase (sGC) modulators to explore the therapeutic potential of this family of drugs.

**Methods:** 8-week old male C57 mice (n=36) were used to create a PUV-analogue surgical model, through partial-ligation of the urethra, which were then orally-administered sGC modulators for two out of three weeks of the experiment. Bladders were stained with picosirius red to allow evaluation of the smooth muscle to connective tissue ratio (SM:CTR). Biomechanical assessments of the stress-strain relationship from these bladders was measured to derive elastic modulus, or stiffness from the steady-state tension (measured in kilopascals, kPa). Furthermore, primary cell cultures were established from children with PUV undergoing bladder surgery or kidney transplant and treated with the same drugs over a 7-day course to determine relative changes in both ECM proteins and changes to gene expression of ECM genes.

**Results:** Our animal model generated a PUV-like morphology, reducing SM:CTR from 1.2 in sham surgery to 0.5 in the model, indicating a greater ECM content (p<0.001), with increase in detrusor stiffness from 50kPa to 170kPa. Treatment with either sGC activator, cinaciguat or sGC stimulator, BAY 41-2272 (10mg/kg) kept both these variables in the same range as sham surgery (p<0.001). Culture of detrusor in a pro-

fibrotic 1% fetal bovine serum milieu resulted in a 20% increase in fibronectin protein and gene expression, compared to control milieu of 10% serum, relative to housekeeping gene/protein GAPDH. Treatment in 1% serum with BAY 41-2272 reduced expression of fibronectin protein by seven-fold and FN1 gene expression by 20%.

**Conclusions:** sGC modulation in an in vivo and in vitro model described here demonstrates prognosis-altering potential for this on-market drug in PUV.

### Are Patients With Renal Anomalies at Risk for Müllerian Anomalies?

Laura E. Walawender, Yueyang F. Fei, Brian Becknell, Daryl J. Mcleod. Nationwide Children's Hospital, Columbus, OH.

**Background:** Patients with Müllerian anomalies have a 30-50% increased prevalence of congenital renal anomalies, but the prevalence of Müllerian anomalies among patients with known congenital renal anomalies is unknown. A delay in diagnosis of obstructive Müllerian anomalies can increase the risk of poor clinical outcomes including pelvic inflammatory disease, abscess, infertility, and endometriosis. The goal of this study was to describe the prevalence of Müllerian anomalies in a cohort of patients with known congenital renal anomalies.

**Methods:** A retrospective electronic medical record review was performed of patients within the Nationwide Children's Hospital system with ICD9 or ICD10 diagnostic codes for both urologic and gynecologic anomalies. Patients with complex urogenital pathology, such as, cloaca, urogenital sinus, or bladder exstrophy were excluded. Renal anomaly diagnosis, Müllerian anomaly diagnosis, reason for pelvic evaluation, type of evaluation, and age of diagnosis of both renal and Müllerian anomalies were evaluated.

**Results:** 136 patients were identified as having both urologic and gynecologic codes; 80 were excluded based on the exclusion criteria. Of the 56 eligible patients, 31 (55%) had a congenital solitary kidney. The type of and reason for pelvic evaluation was determined for 46 patients. Abdominal pain/dysmenorrhea was the most common reason for pelvic evaluation (38%), most often by ultrasound (70%), leading to the diagnosis of a Müllerian anomaly in 41 (73%) patients. Among the 38 patients with renal and Müllerian anomalies, 24 (63%) had an initial diagnosis of a renal anomaly; 6 (16%) had an initial diagnosis of Müllerian anomaly, and 8 (21%) were diagnosed with both simultaneously. 16 patients (39%) had a Müllerian obstruction, and 9 underwent urgent surgical intervention within 2 weeks of the diagnosis.

**Conclusions:** In this study, over half of the patients had a renal anomaly diagnosed before their Müllerian anomaly, which was obstructive in over one-third of instances. Given the primacy of early diagnosis for obstructive Müllerian anomalies, there is a need for a prospective study in patients with congenital renal anomalies to determine if routine pelvic ultrasound at thelarche or around the age of expected menarche could reduce the rate of obstructive Müllerian anomalies presenting acutely.

## SA-PO620

### Altered UBASH3A Expression May Be Involved in Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) Phenotypes of Down Syndrome

Mirela Lozic, Katarina Vukojevic. Sveučiliste u Splitu Medicinski fakultet, Split, Croatia.

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) are considered to be the fourth most common major birth defects in Down syndrome (DS) and are up to 30 times more prevalent than in the general population. Due to the lack of insight into its primary pathogenesis, diagnostic and therapeutic possibilities are limited. The *UBASH3A* gene could be considered a candidate gene for the development of some DS phenotypes as it is mapped to 21q22.3, which is within the critical region for the development of DS. Previously conducted In silico analysis of a database obtained by whole-exome sequencing of patients with CAKUT uncovered *UBASH3A* as a novel protein-coding candidate gene. We also demonstrated the expression of *UBASH3A* in normal developing and adult kidneys. Due to the increased gene dose, established expression pattern, and possible role in renal development, altered *UBASH3A* expression could be involved in the CAKUT DS phenotypes.

**Methods:** For the immunofluorescence study of *UBASH3A* in DS, the tissue of kidneys of premature infants and adults diagnosed with DS and CAKUT, along with healthy controls, were used.

**Results:** *UBASH3A* exhibited positive expression patterns in DS but differed in intensity and distribution compared to the control samples. In DS, the signal was clearly visible only at a magnification of 100x, while in controls it was clearly visible at 40x, which indicates a significantly reduced intensity. However, in DS we could observe a granular, scattered signal within the nucleus in contrast to the control nuclei, which mostly contained a single punctate signal. This could indicate a large number of abnormal gene products and/or apoptotic processes.

**Conclusions:** Because of its expression pattern and its mapping to 21q22.3, *UBASH3A* could be involved in the CAKUT phenotypes of Down syndrome.

**Funding:** Government Support - Non-U.S.

## SA-PO621

### Renal Scintigraphy in the Follow-Up of Patients With Congenital Single Functioning Kidney

Luigi Cirillo,<sup>1,2</sup> Francesca Becherucci,<sup>2</sup> Tommaso Mazzerli,<sup>1</sup> Elisa Buti,<sup>2</sup> Carmela Errichiello,<sup>2</sup> Paola Romagnani.<sup>1,2</sup> <sup>1</sup>Università degli Studi di Firenze Dipartimento di Scienze Biomediche Sperimentali e Cliniche Mario Serio, Firenze, Italy; <sup>2</sup>Meyer Children's Hospital, Firenze, Italy.

**Background:** In the last decade the association between congenital single functional kidney (cSKF) and increased risk of hypertension, proteinuria and kidney injury has become clear. Regarding CKD long-term outcome, kidney hypertrophy at ultrasound (US) in the early months of life is reported as protective. Kidney US measuring renal length (BPL) and renal scintigraphy (RS) measuring GFR (mGFR) are both useful tools for the clinical management. The follow-up is frequently based on local protocols, although clinical recommendations have been proposed recently. The aim of the present study was to assess the utility of RS and to compare it to US in gathering information on kidney function, long term outcome and the appropriate use in the follow-up of patients with cSKF.

**Methods:** Retrospective, monocentric, observational study enrolling pediatric cSKF patients. Demographic, clinical, instrumental and laboratory data were collected from medical records for all the patients included in this study. CKD was considered as composite outcome (at least one: reduced mGFR or eGFR, proteinuria in at least two different examinations, hypertension).

**Results:** 163 cSKF patients were included. The BPL showed a linear increase over time, with curve flattening after 144 months of age. Conversely, mGFR rapidly increased between 0 and 60 months, stabilizing thereafter (Fig.1) and reaching a median value over the threshold of normal function between 24 and 60 months; we observed a slight decrease after 180 months, although not statistically significant. Comparing the trend of BPL and mGFR over time, we observed a significant correlation ( $R^2=0.5$ ,  $p\text{-value}<0.05$ ) between 1 and 60 months of life, that was lost thereafter. Proteinuria, hypertension, impaired eGFR and mGFR were found in 11.7 %, 18.7%, 30.4% and 39.3% patients, respectively, with overall CKD rate of 41.6%. Of note, 25% of these patients were identified only by RS, having no other considered abnormality. Moreover in this subgroup patients only one showed kidney hypertrophy at US before the age of 60 months.

**Conclusions:** RS can be as useful as US in the follow-up of cSKF. It allows to early spot an higher number of CKD patients and probably represent the best option for those with late referral in which early US is not available, to guide the clinicians in defining the risk of CKD and inform prognosis.

## SA-PO622

### Immunohistochemical Expression Pattern of RIP5, FGFR1, and FGFR2 in Normal Human Kidney Development and Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)

Katarina Vukojevic,<sup>1</sup> Anita Racetin,<sup>1</sup> Nela Kelam,<sup>1</sup> Natalija Filipovic,<sup>1</sup> Violeta Soljic.<sup>2</sup> <sup>1</sup>University of Split School of Medicine, Split, Croatia; <sup>2</sup>University of Mostar School of Medicine, Mostar, Bosnia and Herzegovina.

**Background:** RIP5 plays a key role in the urinary tract development, downstream of FGF-signaling and its impairment can lead to congenital anomalies of the kidney and urinary tract (CAKUT).

**Methods:** Human kidney tissues of 16 conceptuses between 22<sup>nd</sup> and 28<sup>th</sup> developmental weeks (dw) were used as a control, in the comparison with 21 CAKUT samples. Sections were stained with the double-immunofluorescence method with RIP5 and FGFR1/FGFR2 markers.

**Results:** RIP5 expression was higher in the collecting tubules (Ct) of CAKUT samples in comparison to control ( $p<0.0001$ ), while in metanephric mesenchyme (mm) (3.5%) and glomeruli (g) (4.15%) was lower than in control ( $p<0.0001$ ). The highest expression of FGFR1 and FGFR2 was observed in the collecting ducts (Cd) of both CAKUT cases and control. Additionally, expression of FGFR1 and FGFR2 was also higher in Ct and g of controls in comparison to CAKUT cases ( $p<0.0001$ ). RIP5 and FGFR1/FGFR2 co-expressed in Cd of controls, while RIP5 and FGFR1 did not co-express in CAKUT samples. In CAKUT cases RIP5 and FGFR2 co-expressed in mm and g.

**Conclusions:** Altered RIP5, FGFR1, and FGFR2 expression pattern in CAKUT cases in comparison to normal human kidney development might indicate its significance in FGF receptor signaling and normal kidney development.

**a-d** Immunofluorescence staining of developing human kidneys and CAKUT cases with RIP5, FGFR1, FGFR2 markers (arrows), and DAPI in different kidney structures (g–glomeruli, Ct–convoluted tubules, Cd–collecting duct, mm–metanephric mesenchyme) between 22<sup>nd</sup> and 28<sup>th</sup> developmental week. Merged pictures reveal co-expression of RIP5 and FGFR1 and RIP5 and FGFR2 in the collecting duct of controls (asterisks) and RIP5 and FGFR2 in the mm and g of CAKUT cases (asterisks). **e-g** Distribution of RIP5, FGFR1 and FGFR2 positive cells in the mm, g, Cd and Ct in human kidney development and CAKUT cases. Data were shown as mean ± SD,  $p<0.05$  (two-way ANOVA with Sidak's multiple comparisons test).

## SA-PO623

### Rapid Development of Severe Nephrolithiasis in Febrile Infection-Related Epilepsy Syndrome

Linda Wang, Sun-Young Ahn. Children's National Hospital, Washington, DC.

**Introduction:** Febrile infection-related epilepsy syndrome (FIRES) is a rare disorder characterized by new onset of refractory status epilepticus, with development of seizures within 24 hours to 2 weeks of febrile illness. Nephrolithiasis has not been previously reported with FIRES.

**Case Description:** A 5-year-old previously healthy boy presented with fever followed by refractory seizures requiring multiple antiepileptics; he was subsequently diagnosed with FIRES. Serum electrolytes, calcium (Ca), phosphorus (P), uric acid, and creatinine were normal, but urinalysis showed blood and protein. Initial renal ultrasound (US) was normal; however, an abdominal US 11 days later showed extensive multiple bilateral kidney stones, largest measuring 10 mm, resulting in pelvicalyceal dilation bilaterally, with bilateral ureteral dilation from calculi and bladder wall calcification. Stone formation was initially attributed to furosemide (given 7 days), topiramate (11 days), and ketogenic diet (1 month). However, the patient continued to form numerous bilateral stones for several months after discontinuation of all 3 factors, requiring repeated lithotripsy, stone extraction, and bilateral ureteral stenting to relieve obstruction. Initial stone analyses revealed carbonate apatite (dahlite, 100%) stones and a stone analysis 3 months later showed Ca hydrogen phosphate (brushite, 100%) stones. A 24-hour urine analysis showed hypercalciuria (4.8 mg/kg Ca,  $nl<4$ ) and phosphaturia (22.5 mg/kg P,  $nl<17$ ). He received intravenous immunoglobulin, steroids, rituximab, anakinra and tocilizumab as treatment for FIRES with improvement in his seizures; hematuria and proteinuria resolved. Oral hydrochlorothiazide was initiated resulting in decreased stone burden on abdominal CT scan.

**Discussion:** Kidney stone formation has been associated with increased expression of molecules involved in inflammatory pathways, such as osteopontin which is detected in stone organic matrix. In addition, serum osteocalcin, elevated in our patient (98.4 ng/ml,  $nl$  7.3-38.5), has been linked to development of renal calcium phosphate deposits. In our patient with possible underlying hypercalciuria, the pro-inflammatory state from FIRES may have triggered the rapid and massive kidney stone formation and bladder calcification. Further investigation is needed to delineate the association between nephrolithiasis and inflammatory conditions such as FIRES.

## SA-PO624

**Nephrocalcinosis in Children: Clinical Outcomes According to Underlying Diseases**

Jinwoon Joun<sup>1,2</sup>, Heeyeon Cho.<sup>1,2</sup> <sup>1</sup>*Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea*; <sup>2</sup>*Sungkyunkwan University School of Medicine, Suwon, Republic of Korea*.

**Background:** Nephrocalcinosis (NC) is defined as calcium deposits in renal tubules and interstitium. Often detected as an incidental finding, NC have been suggested to be caused by factors such as prematurity, metabolic and monogenic disorders. Recently, there was a few reports that NC might be a specific finding of hereditary renal disease of various outcomes. This study aimed to evaluate the risk factors and underlying diseases including genetic causes and assess clinical outcomes of Korean children with NC.

**Methods:** Total 256 children who visited Samsung Medical Center from January 2017 to December 2021 with a confirmative or suspected diagnosis of NC at age under 18 using ultrasonography were enrolled. Medical records including sex, gestational age, underlying disease, medication history, genetic analysis, and ultrasonography were retrospectively reviewed.

**Results:** Male to female ratio was 0.9:1 and the average age at first diagnosis of NC was 598.4 days after birth. One hundred eighty-one children (70.7%) were born as prematurity. Underlying disease of bronchopulmonary dysplasia (BPD) and patent ductus arteriosus (PDA) were found in 34.7 % and 25.0%, respectively. Each of 143 (55.8 %) and 107 (41.7%) of patients had medication history of furosemide and vitamin D. Incidence of BPD, PDA and taking vitamin D were remarkably high in premature group comparing with full term group. Among 142 children in whom the follow-up data were available, NC was spontaneously resolved over time averaging to 310 days in 96 children (67.6 %). Progression to chronic kidney disease (CKD) was noted in 8 (3.1%) patients. For 44 patients without the clinical risk factors, genetic studies were performed and 20 pathogenic variants including *HNF1B*, *SLC25A13*, and *PKHD1* were detected in 22 children. Among the 22 showing genetic mutations, 2 patients with *HNF1B* and *CFH* mutation progressed to CKD.

**Conclusions:** The majority of current study group had histories highly relevant with preterm birth and most of them showed spontaneous resolution of NC within a year. On the other hand, full-term born children without the known risk factors were more likely to have genetic causes and to develop CKD. Therefore, our study suggests that although the children with NC present the favorable outcomes, regular follow-up and genetic analysis are necessary for the patients without the clinical risk factors.

## SA-PO625

**First Post-Natal Screening Study to Detect Primary Hyperoxaluria Types 1 and 3**

Cristina Martin Higuera<sup>1</sup>, Bodo B. Beck,<sup>2</sup> Katharina Hohenfellner,<sup>3</sup> Bernd Hoppe.<sup>1</sup> <sup>1</sup>*German Hyperoxaluria Center, Bonn, Germany*; <sup>2</sup>*Uniklinik Köln, Köln, Germany*; <sup>3</sup>*Kliniken der Stadt und des Landkreises Rosenheim GmbH, Rosenheim, Germany*.

**Background:** The three primary hyperoxalurias (PH) are ultra-rare diseases of the glyoxylate metabolism, at which three specific enzyme defects induce severe endogenous overproduction of oxalate, and thus its massively elevated urinary excretion. Clinical hallmarks are recurrent urolithiasis, progressive nephrocalcinosis and eventually end stage kidney failure. Early diagnosis should be mandatory to achieve better outcome, which is even more important now, as a new treatment option is available for type 1 primary hyperoxaluria.

**Methods:** After parents have signed informed consents, we include all routine newborn-screening cards sent to our screening lab for testing the presence of the most common mutations of the *AGXT* (c.508G>A, PH 1) and *HOGAI* (c.700+5G>T, PH 3) genes in Europe, respectively. We expect to test > 150.000 samples. If patients are homozygous, treatment will be started promptly, and outcome will be compared to historical controls from the German PH registry (OxalGermany). If heterozygous mutations are found, repeated spot urine analysis is performed to exclude hyperoxaluria. In those new-borns with hyperoxaluria, further genetic analysis is done and, if being positive, they start treatment promptly.

**Results:** So far, we have screened 7131 newborns in the routine testing. Out of those, no patient with homozygous mutations for *AGXT* or *HOGAI* have been found. However, we found 24 heterozygous patients each for *AGXT* and *HOGAI* mutations, respectively. One other newborn was heterozygous for *AGXT* and *HOGAI*. In 19 (11 *HOGAI*, 8 *AGXT*) patients urine analysis is already available, all were normal for oxalate and PH-type specific metabolites.

**Conclusions:** This huge newborn screening program will answer multiple questions. First we can better calculate the true prevalence of two PH types in Germany, as genomic data supposes many more patients, as currently known. Secondly, we can promptly treat patients and prevent disastrous outcome. Thirdly, we will compare outcome of different treatments (standard with vitamin B6 compared to new RNAi, Oxlumo, in PH 1). Lastly, the batches of urine analyzed will provide best normative molar creatinine ratios not only for oxalate and related metabolites, but also for other lithogenic substances for the newborn period.

**Single Cell Immune Profiling Reveals Pro-Inflammatory Mechanisms Linked to Dysbiosis and Cardiovascular Disease in Children With CKD**

Johannes Holle<sup>1,6</sup>, Harithaa Anandakumar,<sup>1</sup> Ulrike Löber,<sup>1,7</sup> Anne Dueck,<sup>2</sup> Julia Schlender,<sup>1</sup> Hannes Sallmon,<sup>3</sup> Felix Behrens,<sup>1</sup> Jennifer A. Kirwan,<sup>4</sup> Jun Oh,<sup>5</sup> Stefan Engelhardt,<sup>2</sup> Sofia K. Forslund,<sup>1,7</sup> Dominik Müller,<sup>1</sup> Hendrik Bartolomaeus,<sup>1,6</sup> Nicola Wilck.<sup>6</sup> <sup>1</sup>*Charité Universitätsmedizin Berlin, Berlin, Germany*; <sup>2</sup>*Technische Universität München, München, Germany*; <sup>3</sup>*German Heart Institute Berlin, Berlin, Germany*; <sup>4</sup>*Berlin Institute of Health at Charité, Berlin, Germany*; <sup>5</sup>*Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany*; <sup>6</sup>*German Centre for Cardiovascular Research, partner site Berlin, Berlin, Germany*; <sup>7</sup>*Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany*.

**Background:** Controlling chronic inflammatory processes as a major risk factor for cardiovascular disease (CVD) is of outstanding importance in chronic kidney disease (CKD) to reduce CKD-associated morbidity. The underlying mechanisms of inflammation in CKD are incompletely understood, but may be linked to gut dysbiosis. We aimed to characterize microbiota-immune interactions in pediatric CKD patients, thus independent of confounding comorbidities frequently seen in adult patients.

**Methods:** We analyzed the fecal microbiome, metabolites and immune phenotypes in 48 children (normal kidney function, CKD stage G3-G4, G5 treated by hemodialysis (HD) or kidney transplantation) with a mean age of  $10.6 \pm 3.8$  years. We validated and further expanded our knowledge in a second cohort of 38 patients linking cardiovascular phenotypes to single immune cell transcriptomics.

**Results:** Serum TNF- $\alpha$  and sCD14 were stage-dependently elevated, indicating inflammation, gut barrier dysfunction and endotoxemia. We observed compositional and functional alterations of the microbiome, including a diminished production of short-chain fatty acids. Plasma metabolite analysis revealed a stage-dependent increase of tryptophan metabolites of bacterial origin. Serum from HD patients activated the aryl hydrocarbon receptor and stimulated TNF- $\alpha$  production in monocytes, corresponding to a pro-inflammatory shift from classical to non-classical and intermediate monocytes. Unsupervised analysis of T cells revealed a loss of mucosa-associated invariant T (MAIT) cells and regulatory T cell subtypes in HD patients. Pro-inflammatory immune cell patterns were confirmed and further described using targeted proteomics and CITE-seq in the validation cohort.

**Conclusions:** Gut barrier dysfunction and microbial metabolite imbalance mediate the pro-inflammatory immune phenotype, thereby driving the susceptibility to cardiovascular disease. Thus, the data highlight the importance of the microbiota-immune axis in CKD irrespective of confounding comorbidities. Further investigations are ongoing to highlight the role of microbiome-immune interaction as an emerging treatment target in CKD patients.

## SA-PO627

**Molecular Pathways Underlying Vascular Disease in Children With ESKD**

Maria Bartosova<sup>1</sup>, Julie Bernardor,<sup>1</sup> Conghui Zhang,<sup>1</sup> Rebecca Herzog,<sup>2</sup> Iva Marinovic,<sup>1</sup> Anette Melk,<sup>3</sup> Verena Peters,<sup>1</sup> Klaus Kratochwill,<sup>2</sup> Claus Peter Schmitt.<sup>1</sup> <sup>1</sup>*International Pediatric Peritoneal Biobank* <sup>1</sup>*Universitäts Klinikum Heidelberg, Heidelberg, Germany*; <sup>2</sup>*Medizinische Universität Wien, Wien, Austria*; <sup>3</sup>*Medizinische Hochschule Hannover, Hannover, Germany*.

**Background:** Patients with ESKD suffer from exceedingly high cardiovascular disease. Children, devoid of life-style and aging related CVD risk factors, provide highly sensitive and specific insights in early pathomechanisms of vascular disease.

**Methods:** Arterial tissues from 95 non-CKD and 110 ESKD-children (median age 9.2 years) underwent digital histomorphometry. Omental arterioles microdissected from surrounding fat tissue underwent multi-omics, and untargeted and vascular calcification (VC) targeted GSEA/IPA. Key mechanisms were validated by quantitative immunostaining *ex vivo* and *in vitro*.

**Results:** Significant arteriolar lumen obliteration was present in children with ESKD, intima and media thickness increased, and endothelial telomeres were shorter, independent of underlying diseases and sex. Arteriolar inflammatory (CD68+) and pro-fibrotic (pSMAD2/3) activity was increased. GSEA identified top enriched pathways including telomere extension by telomerase and chromatin histone methylation. IPA cross-omics showed suppression of actin cytoskeleton, tight junction signaling, and focal adhesion. VC pathway analysis identified 30/442 pathways related to actin cytoskeleton, Wnt signaling, extracellular matrix (ECM) organization, complement activation, and osteoblast-like phenotype. In independent age-matched ESKD cohorts, endothelial methylated histone 3 was reduced and complement system activated compared to non-CKD controls. Actin cytoskeleton interacting proteins gamma actin and profilin-1 were reduced, cofilin-1 unchanged. ECM protein fibronectin-1 was reduced. *In vitro*, exposure of endothelial cells to inflammatory cytokines and reactive metabolites reduced transendothelial resistance, increased permeability and impaired sealing junction and cytoskeleton integrity. These effects were prevented by co-incubation with anserine, 3-methylhistidine and alanyl-glutamine, but not by carnosine, L-histidine, L-methylhistidine and methyl- alanine.

**Conclusions:** ESKD results in major vascular aging already in early childhood. We provide a first comprehensive analysis of underlying molecular mechanisms and derive a novel potential therapeutic intervention, *in vitro* preserving endothelial cell barrier integrity.

## SA-PO628

## Variant Load in Childhood Nephrotic Syndrome Is Associated With Pattern of Therapy Response

Rachel K. Cason,<sup>1</sup> Megan Chryst-Stangl,<sup>1</sup> Kinsie Huggins,<sup>1</sup> Brandon M. Lane,<sup>1</sup> Tiffany Tu,<sup>1</sup> Alejandro Ochoa,<sup>1</sup> Rasheed A. Gbadegesin.<sup>1</sup> *Duke University Medical Center, Durham, NC.*

**Background:** Nephrotic syndrome (NS) is the most common glomerular disease seen in pediatric nephrology clinics. Although the etiology for most cases of NS remains unknown, several genetic loci have been associated with Steroid Sensitive NS (SSNS). It is unclear if these loci are also associated with pattern of therapy response. In the present study, we investigated the association between NS risk loci and pattern of therapy response in a large, multi-ethnic cohort of patients with NS.

**Methods:** We enrolled 1058 patients with childhood onset NS comprising of Steroid Resistant NS (SRNS) and SSNS (including Infrequently Relapsing [IFR] and Frequently Relapsing/Steroid Dependent [FR/SD]). Genotyping was done using TaqMan and Direct Sanger Sequencing for 10 childhood NS risk loci: *HLA-DQA1* (rs1129740 & rs1071630), *BTNL2* (rs9348883), *HLA-DR/DQ* (rs4642516 & rs3134996), Intergenic (rs9273371), *CALHM6* (rs2637678), *NPHS1/KIRREL* (rs56117924), *TNFSF15* (rs6478109), and *TNFRSF11A* (rs34213471). We compared the minor allele frequencies (MAF) between NS vs. controls, SRNS vs. SSNS, and IFR vs. FR/SD. Variant load analysis comparison was performed using Wilcoxon (rank sum) 2-sample test.

**Results:** All 10 risk loci were associated with NS compared with controls ( $p=0.006$  to  $<2.2e^{-16}$ ). Variant load was associated with both SRNS and FR/SD (SRNS vs. SSNS  $p=1.98e^{-15}$  and IFR vs. FR/SD  $p=0.002$ ).

**Conclusions:** Our study showed that genetic risk loci for childhood NS are associated with pattern of therapy response and may predict disease outcome.

## SA-PO629

## Proteomic Analysis of Complement Proteins in Glomerulonephritis

Lilian M. Palma,<sup>1</sup> Jason D. Theis,<sup>2</sup> Fernando C. Fervenza,<sup>2</sup> Sanjeev Sethi.<sup>2</sup> *<sup>1</sup>Universidade Estadual de Campinas, Campinas, Brazil; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Complement plays an important role in the pathogenesis of glomerulonephritis (GN). Even though the underlying etiology of GN might be different, complement activation results in glomerular injury and progression of disease in most GN. Routine IF includes staining for only complement proteins C3c and C1q. Therefore, with regards to evaluation of complement pathways the kidney biopsy provides limited information.

**Methods:** We performed laser microdissection of glomeruli in 60 cases of GN that included infection-related GN (IRG), lupus nephritis (LN), IgA nephropathy (IgAN), fibrillary GN (FG), membranous nephropathy (MN), ANCA-GN, C3GN, dense deposit disease (DDD), proliferative GN with monoclonal Ig deposits (PGNMID), monoclonal Ig deposition disease (MIDD) and immunotactoid glomerulopathy (ITG). This was followed by mass spectrometry (MS/MS) to analyze complement proteins and pathways involved in GN.

**Results:** MS/MS shows that C3 followed by C9 are the most abundant complement proteins in GN, indicating activation of classical/lectin/alternative and terminal pathways, either exclusive or with combination of pathways (Figure 1). C3G, IgAN, and ANCA-GN showed alternative pathway activation. Depending on the type of GN, classical/lectin pathway activation with either C4A and/or C4B was present. Thus, MN, FG and IRG showed C4A-dominant pathways while LN, PGNMID, MIDD and ITG show C4B-dominant pathways. Significant deposition of complement regulatory proteins FHR1 and FHR5 is present in most GN.

**Conclusions:** This study shows accumulation of specific complement proteins in GN. The complement proteins, complement pathways and the amount of complement protein deposition is variable in different types of GN. Selective targeting of complement pathways may be a novel option in the treatment of GN.

	IRG	LN	IgAN	FG	ANCA + GN	ANCA - GN	C3 GN	DDD	PGNMID	ITG	MIDD	MN
C3	+++	+++	+++	+++	+	+++	++	+++	+++	+++	+++	+++
C4A	+	-	-	+++	+/+	+/+	-	++	++	-	-	+++

## SA-PO630

## C3 Glomerulonephritis Has a Higher Burden of Complement Proteins Compared to Post-Infectious Glomerulonephritis

Lilian M. Palma,<sup>1</sup> Jason D. Theis,<sup>2</sup> Maria Izabel N. de Holanda,<sup>3</sup> Fernando C. Fervenza,<sup>2</sup> Sanjeev Sethi.<sup>2</sup> *<sup>1</sup>Universidade Estadual de Campinas Faculdade de Ciencias Medicas, Campinas, Brazil; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>3</sup>Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

**Background:** Complement plays an important role in Post Infectious Glomerulonephritis (PIGN) and C3 glomerulonephritis (C3GN). Both PIGN and C3GN are characterized by a proliferative GN on light microscopy and bright staining for C3 on immunofluorescence studies and are difficult to distinguish on kidney biopsy. However, the etiology, pathogenesis and treatment are different for PIGN and C3GN. Given the limitations of routine kidney biopsy, we performed laser microdissection followed by mass spectrometry (MS) analysis to determine whether glomerular complement profiles are different in PIGN and C3GN.

**Methods:** Complement protein profiles were analyzed in patients with PIGN (n=8) and C3GN (n=9). Glomeruli (8-10 per biopsy) were laser microdissected and dissected fragments were digested into tryptic peptides and analyzed by MS. For each case 2 samples were analyzed. A list of proteins was generated and peptide identifications were accepted if greater than 90% probability by the Peptide Prophet algorithm was established. The Total spectral counts (TSC) of complement proteins of the alternative and terminal pathways (C3, C5-C9), regulatory proteins (CFH, CFHR1-5) and classical/lectin pathways (C4A, C4B) were compared between the two groups.

**Results:** Mean TSC of complement proteins for PIGN vs. C3GN were as follows: C3: 35.25 vs. 129.5 ( $p<0.05$ ), C5-C9: 9.6 vs. 66.4 ( $p<0.05$ ), CFH: 0.62 vs. 14.2 ( $p<0.05$ ), CFHR1-5: 5.25 vs. 48.6 ( $p=NS$ ), C4A: 0 vs. 8.11 ( $p=NS$ ) and C4B: 1.25 vs. 11.6 ( $p<0.05$ ). Compared to PIGN, C3 was 3.7-fold higher in patients with C3GN, as was C5-C9 (7-fold), CFH (22-fold), CFHR1-5 (9.3-fold) and C4B (9.3-fold). Only C4A had similar TSC among the two groups.

**Conclusions:** Glomeruli of C3GN express significantly higher levels of C3, C5-C9, and CFH when compared to PIGN. These studies show that burden of alternative and terminal complement pathway proteins is much higher in C3GN compared to PIGN.

## SA-PO631

## Kidney Complement Peptides Are Abundant in Patients With Kidney Disease

Salem Almaani,<sup>1</sup> John P. Shapiro,<sup>1</sup> Sethu M. Madhavan,<sup>1</sup> Anjali A. Satoskar,<sup>1</sup> Michael Merchant,<sup>2</sup> Jon B. Klein,<sup>2</sup> Brad H. Rovin,<sup>1</sup> Samir V. Parikh,<sup>1</sup> Isabelle Ayoub.<sup>1</sup> *<sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>University of Louisville, Louisville, KY.*

**Background:** Activation of the complement system has been observed in many immune and non-immune kidney diseases. Murine models of renal fibrosis demonstrate that targeting the complement system may be useful in slowing renal fibrosis. In previous work using an agnostic proteomics approach, the complement system was one of the top regulated pathways shared by many kidney diseases. In this study, we aimed to further identify patterns of complement involvement in a variety of kidney diseases.

**Methods:** Kidney biopsies from 58 patients across several kidney diseases and 25 controls were used. Glomeruli and tubulointerstitium (TI) were isolated using laser-capture microdissection, processed, and submitted for LC-MS/MS. Peptides were analyzed for spectral count quantitation. Spectral counts of complement pathway components were compared between disease and control samples that were analyzed in the same batch using t tests, a raw  $p$ -value  $<0.05$  and  $|\log_2$  fold change  $>0.58$  were considered significant.

**Results:** An increase in abundance of common and terminal pathway complement components was noted in the glomeruli and TI across all diseases. An increase in glomerular and TI C2 and C4 abundance was noted in patients with MCD and FSGS, suggestive of classical and/or lectin pathway involvement. A decrease in glomerular complement receptor 1 (CR1), which is typically expressed by podocytes, was universally observed.

**Conclusions:** Proteomic analysis of a heterogeneous population of kidney diseases identified an increase in complement pathway peptide abundance. An increase in terminal complement pathway components was universally observed and has the potential to be

leveraged therapeutically, to slow fibrosis, across a variety of kidney diseases in a manner similar to renin-angiotensin-aldosterone blockade.

**Figure 1. Complement protein abundance in glomeruli (left) or tubulointerstitial space (right) in several kidney diseases.**  
 Abbreviations: LN-I: class I IgA nephritis; LN-V: class V IgA nephritis; MN: primary membranous nephropathy; MCD: minimal change disease; PISGS: primary FSGS; sFSGS: secondary FSGS; APOL: APOL1-related nephropathy; IgA: IgA nephropathy; ISV: IgA vasculitis; SAGN: staphylococcus aureus-associated glomerulonephritis; ATN: acute tubular necrosis; VanATN: vancomycin-induced ATN; DKO: diabetic kidney disease; Hy: Hyaline nephropathy.

## SA-PO632

## Identification of Cell-Specific Transcriptomic Changes in Complement Activation and Regulation in Glomerular Microangiopathy Using Single Nuclei RNA Sequencing

Chelsea C. Estrada,<sup>1,2</sup> Nehaben A. Gujarati,<sup>2</sup> Sandeep K. Mallipattu,<sup>2,1</sup>  
<sup>1</sup>Northport VA Medical Center, Northport, NY; <sup>2</sup>Stony Brook University  
 Renaissance School of Medicine, Stony Brook, NY.

**Background:** Kruppel-Like Factor 4 (KLF4), a zinc finger transcription factor, is a key regulator of an anti-inflammatory and anti-thrombotic endothelial cell (EC) phenotype. EC-specific loss of *Klf4* exacerbates glomerular microangiopathy and complement activation in three models of endothelial injury (mice with *Nos3* deficiency, aging and Shiga-Toxin 2). Glomerular expression of the complement regulatory gene *Cd55* was reduced in each of these models. However, the mechanism and cell-specific regulation of complement in thrombotic microangiopathy remains unexplored.

**Methods:** EC-specific *Klf4* knockout mice (*Klf4*<sup>ΔEC</sup>) were generated by crossing *Klf4*<sup>fl/wt</sup> mice with *Cdh5-Cre* mice. *Klf4*<sup>ΔEC</sup> and *Nos3*<sup>-/-</sup> mice were crossed to generate double knockout mice (DKO). Single nucleus (sn)RNA-seq libraries were prepared from kidney cortex using the 10X Chromium System and raw data was processed with Cell Ranger. Quality control and clustering were performed using the R-package, Seurat. Comparisons were made across four groups and between *Klf4*<sup>fl/wt</sup> and *Klf4*<sup>ΔEC</sup>, and *Nos3*<sup>-/-</sup> and DKO to account for the role of EC-*Klf4*.

**Results:** SnRNA-seq generated 26,456 nuclei transcriptomics across four groups of mice (*Klf4<sup>fl/fl</sup>*, *Klf4<sup>ΔEC</sup>*, *Nos3<sup>-/-</sup>* and DKO) and 21 clusters using unsupervised clustering analysis. Enrichment and pathway analyses showed a downregulation of angiogenic pathways across EC clusters in *Klf4<sup>fl/fl</sup>* mice as compared with *Klf4<sup>ΔEC</sup>* as well as in *Nos3<sup>-/-</sup>* mice as compared with DKO. Conversely inflammatory pathways such as STAT3 and NFκB were upregulated in DKO mice compared to *Nos3<sup>-/-</sup>*. A cross-reference of differentially expressed genes (DEGs) in each glomerular cluster with known complement activation genes revealed upregulation of *C8a*, and pro-thrombotic *von Willebrand factor* in the EC cluster in the DKO group, with no significant DEGs in the podocyte or mesangial cluster. Across all groups, differential expression of complement regulatory genes in the glomerulus showed upregulation of *Cd55* and *Cd59* in the podocyte cluster and *Cd46* and *Cfh* in the mesangial cluster without significant basal expression in the EC cluster.

**Conclusions:** SnRNA sequencing identified other potential mechanisms, such as decreased angiogenic signaling, behind the exacerbated microangiopathy and complement activation upon loss of EC-*Klf4*.

**Funding:** NIDDK Support, Veterans Affairs Support, Private Foundation Support

**SA-PO633**

### Kidney C5aR Is Expressed in Resident Macrophages, Tubular Epithelial Cells, and in Association With Fibrosis

Kathleen M. Sullivan, Carolyn Dunlap, Linda Ertl, Zhenhua Miao, Thomas J. Schall. *ChemoCentryx, San Carlos, CA.*

**Background:** TAVNEOS® (avacopan) is a potent inhibitor of C5aR, the pro-inflammatory receptor for complement fragment C5a. Identifying the cellular targets of avacopan is critical for understanding the mechanism of action in kidney disease; however, published reports on C5aR expression in the kidney vary widely (Abe et al., 2001; Yuan et al., 2012). To address this issue, we investigated the mRNA and protein expression of C5aR in human and mouse kidneys.

**Methods:** We performed *in situ* hybridization (ISH) on formalin-fixed, paraffin embedded (FFPE) tissue blocks using mRNA probes for C5aR and C5L2, the alternative C5a receptor that plays a role in dampening C5aR activity (Bamberg et al., 2010). We tested commercial C5aR and C5L2 antibodies for immunohistochemistry (IHC) with control FFPE cell pellets and tissues. Macrophage (CD68) and tubule subpopulation

(CALB1, SLC13A3) antibodies were validated for IHC and a dual IHC-ISH method. Kidney FFPE tissues were from normal human subjects and lupus nephritis patients, or from mouse models, including surgical nephrectomy and the bm12 inducible lupus model, in a human C5aR knock-in (hC5aR KI) strain.

**Results:** Two commercial antibodies specific for human C5aR by IHC had overlapping but distinct expression patterns in interstitial and tubular cells. We confirmed this result by using ISH, and identified the cells expressing C5aR as macrophages and a discrete subpopulation of distal tubule epithelial cells. C5L2 was observed in the same kidney cell types, but at a lower expression level than C5aR. The hC5aR KI mouse kidney had a similar expression pattern for C5aR compared to human. C5aR expressing cells localized to areas of fibrosis in kidney disease models and lupus nephritis biopsies.

**Conclusions:** In both mouse and human kidneys, we observed C5aR expression on macrophages, on a subpopulation of tubular epithelial cells, and in association with fibrosis. The antibody-specific differences in C5aR detection may be due to cell-dependent post-translational modification, since expression of C5aR detected by both antibodies was confirmed by ISH. C5aR expression in the kidney is consistent with its role in inflammation and tissue remodeling, and suggests the hypothesis that treatment with avacopan may reduce inflammation-driven fibrosis in disease.

## SA-PO634

### Naturally Occurring C3-Convertase Antibodies: A Nef Precursor?

Christopher Culek, Richard J. Smith, Carla M. Nester. *University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA.*

**Background:** Pathogenic autoantibodies that bind to and dysregulate the C3-convertase (C3bBb) are called Nephritic Factors (Nefs). Nefs are identified in ~80% of C3 Glomerulopathy patients. Why these antibodies arise is unknown, and there is no consensus on whether analogous antibodies exist in the normal population. We developed a specificity assay to test antibody binding to C3bBb and C3-proconvertase (C3bB) by surface plasmon resonance to explore the prevalence of C3-convertase binding antibodies in the normal population.

**Methods:** IgG from 30 normal donors were tested as well as Nef-containing positive control IgG and an anti-C4b sham control IgG. With C3b as a ligand, specific binding for each sample was determined using diverse sample preparations: purified normal human (NH) IgG alone, FB alone, FB with NH IgG, FD alone, FD with NH IgG, FB+FD, and FB+FD with NH IgG. Binding was measured following injection and after 200 seconds of dissociation. Normalized Decay (ND) was calculated by the following equation: ND= (RU at 200s)/(RU at 0s).

**Results:** Anti-C4b antibody demonstrated no binding and no stabilizing effect on C3bBb or C3bBb. The Nef positive control displayed no nonspecific binding (IgG alone or FcD+IgG) but had significant binding to and stabilization of C3bBb and C3bBb. One NH sample replicated the negative control results while 86.7% of NH samples matched the Nef's specificity for C3bBb and C3bBb. However, the stabilization of these samples was less than the Nef control.

**Conclusions:** Our data suggests that autoreactive C3bB and C3bBb antibodies are highly prevalent in the normal population, but they lack the degree of *stabilization* seen with the Nef control. Considering the different kinetics and the lack of disease in the donor population, these antibodies are technically not Nef. We prefer a C3-Convertase autoantibodies (C3CAbs) nomenclature. C3CAbs in normal sera may inform next steps in determining the origin of the *pathogenic* version of these antibodies (Nef) in C3G.

**SA-PO635**

### Modeling C3 Glomerulopathies on Extracellular Matrix Surface

Sofiya Pisarenka, Yuzhou Zhang, Richard J. Smith. MORL *The University of Iowa, Iowa City, IA.*

**Background:** C3 glomerulopathies (C3G) are ultra-rare complement mediated diseases that lead to end-stage renal failure within 10 years of diagnosis in ~50% of patients. The underlying cause of C3G is dysregulation of the alternative pathway (AP)

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

of complement in the fluid phase (i.e. circulation) and/or the renal glomerulus. The latter is comprised of glomerular fenestrae, which are blanketed by extracellular matrix (ECM) and depend on circulating regulators for complement control in this microenvironment. Here we present an *in vitro* model of ECM-specific AP C3 convertase activation and regulation.

**Methods:** A human ECM substitute (MaxGel) was used as a base upon which AP C3 convertase was reconstituted. Convertase activity and regulation was validated using inhibiting (Factor H) and stabilizing (Properdin) regulators of complement activation. Once validated, we used this model to assess the effect of C3 Nephritic factors (C3Nefs) on C3 convertase activity.

**Results:** AP C3 convertase forms and decays on MaxGel in the expected manner; negative and positive regulation by FH and FP, respectively, was also observed. In the presence of IgGs derived from C3G patients positive for C3Nefs, the rate of decay of C3 convertase was significantly decreased when compared to C3 convertase alone, normal human serum IgGs, and IgGs derived from C3G patients negative for C3Nefs.

**Conclusions:** We conclude that this model of the glycomatrix offers a reliable and replicable method of evaluating various drivers of C3G in an environment similar to that of the glycomatrix. Further, we show that patient-specific assessment of C3 convertase activity and regulation is possible, thus offering an improved understanding of the effect of different disease factors on C3G pathogenesis.

**Figure 1:** C3 convertase decay decreases in presence of IgGs from C3G patients positive for C3Nefs.

##### SYNERGY-1: A Phase 1, First-in-Human, Safety, Tolerability, Immunogenicity, Pharmacokinetics, and Pharmacodynamics Study of KP104 in Escalating Single and Multiple Doses

Paul Wabnitz,<sup>1</sup> Xiang Gao,<sup>2</sup> Jay Ma,<sup>2</sup> Ping Tsui,<sup>2</sup> Martin Rabe,<sup>2</sup> Helen N. Fu,<sup>2</sup> Chaomei He,<sup>2</sup> Jingtao Wu,<sup>2</sup> Brian K. York,<sup>2</sup> Christina Weng,<sup>2,3</sup> Jon Rankin,<sup>4</sup> Frederick C. Beddingfield,<sup>2,5</sup> Wenru Song,<sup>2</sup> Nicholas Farinola,<sup>1</sup> Richard Lee.<sup>2</sup>  
<sup>1</sup>Cancer Research Institute, University of South Australia, Adelaide, SA, Australia; <sup>2</sup>Kira Pharmaceuticals, Cambridge, MA; <sup>3</sup>Massachusetts General Hospital - Harvard Medical School, Boston, MA; <sup>4</sup>Syneos Health Australia, Sydney, NSW, Australia; <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Background:** Glomerular diseases (GD), such as IgA nephropathy and complement (C) 3 glomerulopathy which have limited or no approved therapies, are known to be mediated by aberrant C activation. KP104 is a bi-functional C inhibitor fusion protein comprised of humanized anti-C5 monoclonal antibody fused with truncated C factor H. KP104 fusion design inhibits C5-mediated membrane attack complex formation and alternative pathway (AP) activation.

**Methods:** This is a first-in-human, randomized, double-blind, placebo-controlled, single center study of KP104 in healthy volunteers. Safety, tolerability, anti-drug antibodies (ADA) development, PK, and PD were assessed in single ascending dose (SAD) and multiple ascending dose (MAD) cohorts. At interim analysis, 48 SAD and 8 MAD have completed study assessments. SAD dose levels were 60-1200 mg; MAD was 600 mg IV QW for 5 total doses.

**Results:** Majority of subjects were Caucasian (81.3% SAD and 62.5% MAD), male (26 SAD and 6 MAD), and mean age was 30.5 and 33.6 years for SAD and MAD, respectively. No deaths, DLIs, or severe TEAEs were reported. SAD (n=38/48, 79.2%) reported 126 TEAEs in all cohorts. No dose related trend was observed. MAD (n=8/8, 100%) reported 24 TEAEs. Majority of TEAEs were Grade 1 and resolved without treatment. In SAD cohorts, 3 PD markers, rRBC (AP + terminal pathway [TP]), C3b (AP), and free C5 (TP) all showed substantial inhibition as dose increased. Maximum rRBC, C3b, and free C5 inhibition reached >85%, >90%, and >99.5% (<0.5 µg/mL) respectively, at ≥360 mg and inhibition duration was extended with higher doses. At 1200 mg, inhibition for all 3 PD markers was ≥99%. In the MAD cohort, the 3 PD markers achieved substantial inhibition during entire dosing period. ADAs were detected in 3 SAD and 4 MAD but did not appear to impact subject safety.

**Conclusions:** KP104 was safe, well tolerated, and showed proof of mechanism with potent TP and AP inhibition in the SYNERGY-1 study. Complete data will be available at ASN 2022. The data supports planned future clinical trials in C-mediated GD. To our knowledge, KP104 is the first bifunctional biologic demonstrating successful inhibition of both AP and TP.

##### Analysis of Galnt14 Null Mice Link O-Glycosylation Defects With Elevated IgA Levels via Altered B-Cell Homing

Nicholas J. Steers,<sup>1</sup> Sindhuri Prakash-Polet,<sup>1</sup> Kelsey O. Stevens,<sup>1</sup> Anna Ng,<sup>1</sup> Judy Liang,<sup>1</sup> Jan Novak,<sup>2</sup> Ali G. Gharavi,<sup>1</sup> <sup>1</sup>Columbia University Irving Medical Center, New York, NY; <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL.

**Background:** Defects in O-glycosylation of IgA1 are a characteristic finding in IgA Nephropathy. It is not known if aberrant O-glycosylation can impact other aspects of IgA homeostasis, such as B-cell homing and migration. In humans, up to 20 distinct acetylgalactosaminyltransferases (GALNTs) can initiate O-glycosylation of proteins.

**Methods:** We studied *Galnt14* null mice and compared the circulating and mucosal IgA levels and tissue resident IgA+ B-cells in *Galnt14*<sup>-/-</sup> and *Galnt14*<sup>+/+</sup> mice by ELISA and flow cytometry.

**Results:** GALNT14 is expressed in human and murine lymphoid tissue, including the germinal centers of the spleen and lymph nodes, which are the major sites for B-cell maturation, antibody class switching and proliferation. Serum IgA levels were significantly elevated in the *Galnt14*<sup>-/-</sup> mice compared to the *Galnt14*<sup>+/+</sup> mice (1.73 ± 0.95 mg/mL, 0.84 ± 0.35 mg/mL, P-value < 0.001, respectively). Similarly elevated were mucosal IgA levels in the peritoneal cavity (PC), small intestine (SI), and the colon in *Galnt14*<sup>-/-</sup> mice. Flow cytometric analysis of IgA bound to fecal bacteria also demonstrated enhanced binding of IgA to bacteria derived from *Galnt14*<sup>-/-</sup> mice compared to the *Galnt14*<sup>+/+</sup> mice (mean fluorescence intensity 5721 ± 1028, 4006 ± 480, respectively P-value < 0.01). In addition, the percentage of IgA+ B cells in spleen and peritoneal cavity was significantly increased in *Galnt14*<sup>-/-</sup> mice. No differences in the percentage IgA+ B-cells in the SI, Peyer's patches and peripheral blood mononuclear cells were observed between the genotypes, suggesting non-mucosal tissues as the major site of abnormalities in the distribution of IgA-producing cells. Finally, reciprocal adoptive transfer experiments demonstrated that splenic derived B-cells isolated from *Galnt14*<sup>-/-</sup> mice had a reduced ability to home to the spleen, regardless of the recipient genotype.

**Conclusions:** *Galnt14*<sup>-/-</sup> mice have a defect in B-cells to home and potentially remain in mucosal and lymph tissues, partially explaining the increased number of IgA+ cells in the spleen and PC, and elevated IgA in the serum of *Galnt14*<sup>-/-</sup> mice. We are currently exploring the mechanisms of the alterations observed in B-cell recruitment to mucosal and lymphoid tissue in *Galnt14*<sup>-/-</sup> mice.

##### LIF/JAK2/STAT1 Signaling Enhances Production of Galactose-Deficient IgA1 by IgA1-Producing Cell Lines Derived From Tonsils of Patients With IgA Nephropathy

Koshi Yamada,<sup>1</sup> Zhi qiang Huang,<sup>2</sup> Colin Reily,<sup>2</sup> Hitoshi Suzuki,<sup>1</sup> Jan Novak,<sup>2</sup> Yusuke Suzuki,<sup>1</sup> <sup>1</sup>Juntendo University Faculty of Medicine, Tokyo, Japan; <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL.

**Background:** Galactose-deficient IgA1 (Gd-IgA1) have a key role in the pathogenesis of IgA nephropathy (IgAN). Tonsillectomy is one of the effective treatments and is prospective to reduce serum levels of Gd-IgA1. Thus, abnormal responses of the tonsil-residing B cells in pro-inflammatory condition may be involved in synthesis of Gd-IgA1. However, the mechanisms of production of Gd-IgA1 in tonsils remain unknown. In this study, we used IgA1-producing cell lines derived from tonsils of patients with IgAN and assessed the effects of cytokines, Leukemia inhibitory factor (LIF) and Oncostatin M (OSM), encoded in the Chr.22q12 IgAN-risk locus, on cellular signaling and production of Gd-IgA1.

**Methods:** IgA1-producing cell lines were derived from palatine tonsils of patients with IgAN and patients with chronic tonsillitis (CT) after EBV immortalization. Tonsillar-tissue sections were stained with antibodies specific for components of JAK-STAT pathway. Gd-IgA1 production was measured by lectin ELISA, JAK-STAT signaling in cultured cells was assessed by immunoblotting of cell lysates and validated by using siRNA gene-specific knock-down and small-molecule inhibitors.

**Results:** Staining for JAK2 was observed in the crypt epithelium and germinal center (GC) of palatine tonsils from both IgAN and CT groups. Staining for phospho-STAT1 was enhanced in GC regions of palatine tonsils from IgAN patients compared to CT groups. IgA1-producing cells derived from tonsils of patients with IgAN, compared to those of CT, exhibited enhanced STAT1 phosphorylation and elevated Gd-IgA1 production in response to LIF, but not OSM. JAK2 inhibitor and STAT1 siRNA knock-down blocked these LIF-induced effects.

**Conclusions:** In summary, palatine-tonsil-derived IgA1-producing cells exhibit dysregulation of LIF-mediated signaling resulted in Gd-IgA1 overproduction. These findings indicate that LIF-mediated abnormal mucosal immune responses may be involved in the overproduction of the main autoantigen in IgAN, Gd-IgA1.

## SA-PO639

**IgA+ Plasma Cells Accumulation in Kidneys of IgA Nephropathy Model Mice and Patients**

Yoshihito Nihei, Maiko Nakayama, Yusuke Fukao, Hitoshi Suzuki, Yusuke Suzuki. *Juntendo University, Tokyo, Japan.*

**Background:** Previous studies have suggested that nephritogenic IgA are mainly produced in the bone marrow in IgA nephropathy (IgAN), whereas plasma cells (PCs) are often found in the affected kidneys in autoimmune diseases like systemic lupus erythematosus. In the present study, we evaluated the leukocytes in the kidney of IgA nephropathy model mice (gddY mice) and patients and investigated whether PCs infiltrate in the inflamed kidney.

**Methods:** GddY mice were generated through selectively mating individuals within an early-disease onset group of ddY mice for more than 20 generations. All individual gddY mice exhibit proteinuria and glomerular IgA deposition by 8 weeks of age, followed by obvious renal failure and the pathology being similar to human IgAN. Isolated leukocytes from murine kidney were analysed by flow cytometry. To check whether PCs are present in the patient's kidneys, the kidney biopsy specimens from patients with IgAN were stained with anti-human IgA and CD138 antibodies. To investigate whether the IgA+ PCs in the kidney of gddY mice are generated in T cell-dependent or independent manner, we sequenced the variable region of IgA heavy and light chains from single IgA+ PCs isolated from the kidney of gddY mice.

**Results:** We found that a significant number of IgA+ PCs accumulated in the kidneys of gddY mice. The IgA+ PCs emerge by 8 weeks of age and further increased with age in gddY mice. Immunohistochemical staining of kidney biopsy samples from IgAN patients revealed the presence of IgA+ PCs cells in the tubulointerstitial region of the kidney. Most of the heavy- and light-chain V region genes from IgA+ PCs in the kidney of gddY mice contained significant numbers of somatic mutations that replaced amino-acids, indicating that these PCs were generated in a T-cell-dependent manner through the germinal center.

**Conclusions:** We found that IgA+ PCs accumulate in the kidneys of gddY mice and IgAN patients and these IgA+ PCs are generated in T-cell-dependent manner. We will clarify the role of these IgA+ PCs in the pathogenesis of IgAN.

## SA-PO640

**T-Cell Receptor Repertoire Analysis in Tonsillar Tissues of Patients With IgA Nephropathy**

Kazunori Satokata, Shin Goto, Hiroki Yamaguchi, Hirofumi Watanabe, Suguru Yamamoto, Yoshikatsu Kaneko, Ichiei Narita. *Division of Clinical Nephrology and Rheumatology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

**Background:** Immunoglobulin A nephropathy (IgAN) is the most prevalent primary chronic glomerulonephritis. The aberrant mucosal immune response is considered to be related to the IgAN pathogenesis. However, evidence for the involvement of T-cells in mucosal immunity of IgAN is limited, and we conducted a comprehensive analysis of T-cell receptor repertoire in the tonsillar tissues in patients with IgAN.

**Methods:** 28 patients with biopsy-proven IgAN and 20 patients with recurrent tonsillitis (RT) who had undergone tonsillectomy were included in the study. After total RNA was extracted from each dissected tonsillar crypt, unbiased adaptor-ligation-PCR was carried out as library preparation. Then T cell receptor (TCR) sequencing was performed by the next-generation sequencer. We examined the usages of variable and joining regions and analyzed diversity and similarity in TCRα (TRA) and β (TRB) genes at the tonsillar crypts using bioinformatics software.

**Results:** TCR sequencing obtained an average of 74,761 in-frame reads in TRA gene and 57,163 in TRB gene per sample. Diversity indexes of repertoire in both TRA and TRB were not different between patients with IgAN and RT. Similarity indexes of TRA repertoire, but not TRB, were significantly lower in IgAN than in RT patients ( $p < 0.01$ ), and the sharing of TRA clonotypes by more than two individuals was significantly lower in IgAN patients ( $p < 0.05$ ). In shared TRA sequences, TRAV1-2 and TRAJ33, which belong to invariant TCRs, were significantly shared by RT patients ( $p < 0.01$ ). On the other hand, the relative abundance of shared TRA repertoires in IgAN patients was higher than in RT and significantly increased in shorter CDR3 lengths ( $p < 0.05$ ). TRAV41 was significantly abundant in shorter CDR3 lengths of IgAN patients.

**Conclusions:** Our data suggests that dynamic changes in the T-cell subset are involved in abnormal mucosal immune responses in the tonsils of patients with IgAN.

## SA-PO641

**Biologically Active Circulatory Immune Complexes in IgA Nephropathy Contain Polymeric IgA1, With Galactose-Deficient and Minimally Sialylated O-Glycans, IgG, and Complement C3b and iC3b**

Stacy D. Hall,<sup>1</sup> Sarah Coffee,<sup>1</sup> Zhi qiang Huang,<sup>1</sup> Nicolas Maillard,<sup>1,2</sup> Zina Moldoveanu,<sup>1</sup> Audra A. Hargett,<sup>1</sup> Dana Rizk,<sup>1</sup> Bruce A. Julian,<sup>1</sup> Matthew B. Renfrow,<sup>1</sup> Jan Novak.<sup>1</sup> *<sup>1</sup>The University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.*

**Background:** IgA nephropathy (IgAN) is an autoimmune disease wherein pathogenic immune complexes (IC) are thought to form in the circulation from IgA1 with some hinge-region O-glycans deficient in galactose (galactose-deficient IgA1; Gd-IgA1) bound by IgG autoantibodies. Some of these IC deposit in the glomeruli to induce kidney injury. The glomerular immunodeposits are enriched for Gd-IgA1 and the corresponding IgG autoantibodies. However, the composition of the circulating IC in IgAN is not fully understood.

**Methods:** We isolated different molecular forms of IgA1 from sera of 20 patients with IgAN by lectin-affinity and size-exclusion chromatography (SEC). Isolated monomeric IgA1 (mIgA1), polymeric IgA1 (pIgA1), and IgA1 bound in IC (IgA1-IC) were analyzed for their degree of galactose deficiency by a lectin ELISA performed without and with neuraminidase treatment to remove sialic acid. For assessment of biological activity, IgA1-IC were isolated by SEC directly from serum and tested for proliferation-stimulating and signaling-inducing activities in cultured primary human mesangial cells. SDS-PAGE immunoblotting was used for detection of IgA, IgG, complement C3, and phosphorylated (P-) and total ERK1/2, and P- and total Akt.

**Results:** Molecular forms of serum IgA1 included mIgA1 (~90%), pIgA1 (~9%) and IgA1-IC (<0.4%). Relative degree of galactose deficiency of the IgA1 was highest in IgA1-IC, less in pIgA1, and least in mIgA1. IgA1 in IC had minimally sialylated O-glycans. IgA1-IC isolated by SEC from sera of IgAN patients had molecular mass >700 kDa. These circulatory IC induced signaling (e.g., P-ERK1/2, P-Akt) and cellular proliferation of the mesangial cells. These biologically active IgA1-IC contained pIgA1, IgG, and complement C3b and iC3b.

**Conclusions:** Biologically active circulatory immune complexes in patients with IgAN had molecular mass >700 kDa and contained polymeric Gd-IgA1 with a high degree of galactose deficiency and minimal sialylation, IgG, C3b, and iC3b. Collectively, these findings support the pathogenic role of IgA1-containing immune complexes in IgAN.

**Funding:** NIDDK Support

## SA-PO642

**Inhibition of Platelet-Derived Growth Factor-Induced Signaling and Filopodia Formation in Cultured Human Mesangial Cells by Sheng Ping, a Chinese Herbal Medicine**

Zhi qiang Huang,<sup>1</sup> Lea Novak,<sup>1</sup> Xianwen Zhang,<sup>2</sup> Stacy D. Hall,<sup>1</sup> Lin Wang,<sup>2</sup> Yiping Chen,<sup>2</sup> Bruce A. Julian,<sup>1</sup> Jan Novak.<sup>1</sup> *<sup>1</sup>The University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>Long Hua Hospital, Shanghai, China.*

**Background:** Proliferation of mesangial cells is commonly observed in kidney-biopsy specimens of patients with IgA nephropathy (IgAN). This process is thought to involve several factors, such as platelet-derived growth factor (PDGF) with its corresponding receptors and downstream protein kinases, including a focal-adhesion kinase (FAK) involved in the control of cell migration. Histologically, PDGF induces formation of filopodia, slender cytoplasmic projections, in cultured mesangial cells. Here we assessed the effects of Sheng Ping, a traditional Chinese herbal medicine, on PDGF-induced signaling and filopodia formation in cultured primary human mesangial cells.

**Methods:** Quiescent primary human mesangial cells were activated with PDGF (10 ng/ml) for 15 min at 37°C. Sheng Ping, an inhibitor of FAK (PF 573288), or medium only were added to mesangial cells prior to PDGF addition. Negative control consisted of mesangial cells with medium only. After the incubation with PDGF, cells were washed, and cell lysates were analyzed by SDS-PAGE immunoblotting using antibodies specific for protein kinases and their phosphorylated variants. For imaging analyses, mesangial cells were cultured on 4-chamber glass slides and treated as described above. Then, the cells were washed, fixed, permeabilized, and stained with TRITC-phalloidin (specific for fibrillar actin) and a nuclear stain. To assess formation of filopodia, the stained cells were examined by a fluorescence microscope using 60x objective.

**Results:** Sheng Ping inhibited PDGF-induced formation of filopodia in the cultured mesangial cells, phosphorylation of FAK, extracellular signal-regulated kinase 1/2 (ERK1/2), and a serine/threonine kinase 1 (AKT1). PF 573288, a positive control for FAK inhibition, inhibited filopodia formation as well as phosphorylation of FAK, ERK1/2, and AKT1.

**Conclusions:** Sheng Ping, Chinese herbal medicine, blocked PDGF-induced formation of filopodia and phosphorylation of several proteins in cultured human mesangial cells. The clinical benefit of Sheng Ping for treatment of patients with IgA nephropathy may, in part, be based on its effect to inhibit the signaling pathways in mesangial cells activated by PDGF.

**Funding:** NIDDK Support

## SA-PO643

**Serum IgA1-IgG-Containing Immune Complexes From Patients With IgA Nephropathy Activate Cultured Human Mesangial Cells and Associate With Cellular Integrin  $\beta$ 1**

Zhi qiang Huang,<sup>1</sup> Xianwen Zhang,<sup>2</sup> Stacy D. Hall,<sup>1</sup> Lin Wang,<sup>2</sup> Yiping Chen,<sup>2</sup> Dana Rizk,<sup>1</sup> Bruce A. Julian,<sup>1</sup> Jan Novak.<sup>1</sup> <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>Long Hua Hospital, Shanghai, China.

**Background:** Circulatory IgA1-IgG-containing immune complexes of patients with IgA nephropathy (IgAN) induce cellular proliferation of cultured human mesangial cells. This process involves activation of multiple protein-tyrosine kinases. However, whether IgA1-IgG immune complexes associate with mesangial cells and any role of integrin  $\beta$ 1 in this process are not known.

**Methods:** IgA1-IgG immune complexes were isolated from sera of patients with IgAN by size-exclusion chromatography and added to quiescent human primary mesangial cells in culture. After 15 min incubation at 37°C, with or without different inhibitors, the cells were washed and lysed. Cell lysates or immunoprecipitated products were analyzed by SDS-PAGE immunoblotting. Inhibitors of integrin  $\alpha$ 1 $\beta$ 1 (obustatin) and  $\alpha$ 5 $\beta$ 1 (Arg-Gly-Asp peptide; RGD), and protein-tyrosine kinases (dasatinib) and Sheng Ping (a herbal medicine for treatment of patients with IgAN in China), were tested for their inhibitory effects. Antibodies specific for integrin  $\alpha$ 1 $\beta$ 1, integrin  $\alpha$ 5 $\beta$ 1, or platelet-derived growth factor receptor  $\beta$  (PDGFR- $\beta$ ) were used for immunoprecipitation. Antibodies specific for IgA, IgG, different subtypes of integrins and their associated proteins, several protein-tyrosine kinases and their phosphorylated variants were used for immunoblotting.

**Results:** The mesangial cell lysates contained IgG and IgA, indicating that IgA1-IgG immune complexes associated with the cells, either bound at the surface or within the cells. Immunoprecipitation indicated that the IgA/IgG were associated with integrin  $\alpha$ 1 $\beta$ 1 and  $\alpha$ 5 $\beta$ 1. The complexes induced phosphorylation of ERK1/2, AXL, PDGFR- $\beta$ , and integrin  $\beta$ 1. Analysis of immunoprecipitated products indicated association of integrin  $\beta$ 1 with PDGFR- $\beta$ . Obustatin, RGD, dasatinib, and Sheng Ping inhibited phosphorylation of integrin  $\beta$ 1, PDGFR- $\beta$ , and ERK1/2; all inhibitors except RGD also inhibited phosphorylation of AXL.

**Conclusions:** Thus, IgA1-IgG immune complexes associated with mesangial cells and this process was, at least in part, mediated by integrin  $\alpha$ 1 $\beta$ 1 and  $\alpha$ 5 $\beta$ 1 and involved activation of multiple signaling pathways. A better understanding of the pathways activated by IgA1-IgG immune complexes may provide new therapeutic approaches for IgAN.

**Funding:** NIDDK Support

## SA-PO644

**High-Resolution Imaging Approaches to Assess Colocalization of Immunoglobulin-Component Chains in Glomerular Immunodeposits in IgA Nephropathy**

Lea Novak,<sup>1</sup> Stacy D. Hall,<sup>1</sup> Dana Rizk,<sup>1</sup> Zina Moldoveanu,<sup>1</sup> Bruce A. Julian,<sup>1</sup> Mark Haas,<sup>2</sup> Jan Novak.<sup>1</sup> <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA.

**Background:** Routine immunofluorescence microscopy of glomerular immunodeposits in IgA nephropathy (IgAN) reveals IgA with variable amounts of IgG and/or IgM and usually complement C3. We have developed a new high-resolution confocal-microscopy approach to detect immunoglobulins in biopsy specimens. In earlier studies, we found IgG in all IgAN kidney biopsies, including those IgG-negative by routine immunofluorescence microscopy. This improved visualization of immunoglobulins enables studies of colocalization of their component light chains. Here, we evaluated our imaging approach for assessment of colocalization of IgG with kappa and lambda light chains in IgAN kidney biopsies.

**Methods:** Frozen-tissue sections (4  $\mu$ m) of remnant kidney biopsies from 20 IgAN patients (3 IgG-positive and 17 IgG-negative by routine immunofluorescence) were fixed, blocked, and stained sequentially with IgG-Fc nanobody, mouse monoclonal antibody (mAb) specific for human kappa light chain, mouse mAb specific for human lambda light chain, and a nuclear stain. Using a high-resolution confocal microscope (Nikon A1R/SIM), z-stack images were acquired (objective 60x). For each slide, 60 regions of interest were selected in areas with IgG staining. Using Advanced NIS analysis software, Pearson's correlation coefficient (PCC) and Mander's overlap coefficient (MOC) colocalization data were collected for each slide.

**Results:** IgG was detected in all 20 biopsies. Single-optical-plane images showed colocalization of IgG with kappa and lambda light chains; this finding was confirmed by line-intensity profiles. IgG was not colocalized with only one type of light chain. Colocalization of IgG with kappa or with lambda light chain exhibited variability by PCC and MOC analyses but colocalization for IgG with kappa versus IgG with lambda light chain did not significantly differ.

**Conclusions:** High-resolution confocal microscopy and the use of sensitive immunofluorescence staining are suitable for study of glomerular immunodeposits in IgAN. Colocalization of IgG with kappa and lambda light chains in all IgAN kidney biopsies is consistent with polyclonal origin of these pathogenic IgG autoantibodies.

**Funding:** NIDDK Support

## SA-PO645

**Cell-Surface Glycoprofiling of IgA1-Secreting Cells From Patients With IgA Nephropathy Reveals Subpopulations With Differential Cytokine Responses and Capacity to Produce Galactose-Deficient IgA1**

Colin Reilly,<sup>1</sup> Shigeaki Nakazawa,<sup>2</sup> Bruce A. Julian,<sup>1</sup> Jan Novak.<sup>1</sup> <sup>1</sup>The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; <sup>2</sup>Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu Igaku Senko, Suita, Japan.

**Background:** Galactose-deficient IgA1 (Gd-IgA1) is the main autoantigen in IgA nephropathy (IgAN) and its elevated circulatory levels predict poor kidney outcome. As Gd-IgA1 constitutes a small fraction of total circulatory IgA1, we hypothesize that only a few IgA1-secreting cells may be involved. Moreover, cytokine stimulation can increase Gd-IgA1 production in cultured IgA1-producing cells from IgAN patients. We report here that cell-surface glycoprofiling of immortalized IgA1<sup>+</sup> cells with a GalNAc-Gal-specific lectin (peanut agglutinin, PNA) can identify subsets of cells with differential signaling and O-glycosylation of IgA1.

**Methods:** Immortalized IgA1-producing cells derived from peripheral blood mononuclear cells of healthy controls (HC) and IgAN patients were stimulated with mixture of cytokines (IL-4, IL-6, IL-21, CD40L) for 20 min, followed by cell-surface staining with PNA and IgA-specific antibody and FACS. Non-stimulated cells served as negative controls. The live-sorted cells with distinct PNA binding (low- and high-PNA-binding cells) were cultured and assessed for baseline and cytokine-mediated signaling and Gd-IgA1 production. Gd-IgA1 was determined by lectin ELISA, phosphoproteins by intracellular staining with antibodies and FACS.

**Results:** For both HC- and IgAN-derived IgA1<sup>+</sup> cells without cytokine stimulation (i.e., baseline), high-PNA-binding cells exhibited more phosphorylated (P) ERK1/2, less P-65-NF-kB, and less P-STAT1 compared to low-PNA-binding cells (p<0.01, p=0.02, p<0.01, respectively). Moreover, there was less P-65-NF-kB in HC- vs. IgAN-derived cells, but only for the low-PNA-binding cells (p=0.01). For both HC- and IgAN-derived IgA1<sup>+</sup> cells with cytokine stimulation, P-ERK1/2 was increased in PNA-high cells (p<0.01) and P-65-NF-kB was increased in PNA-low cells (p=0.01). In a pilot experiment, the high-PNA-binding cells from an IgAN patient produced more Gd-IgA1 compared to low-PNA-binding cells.

**Conclusions:** Glycoprofiling of IgA1<sup>+</sup> cells with PNA lectin revealed cells with differential cell-surface glycosylation. These distinct cell types differed in baseline and cytokine-induced cell signaling and Gd-IgA1 production.

**Funding:** NIDDK Support

## SA-PO646

**Experimental Investigation of Exacerbation of IgA Nephropathy by Exposure to Fine Particulate Matter**

Yohan Park, Se-Hee Yoon, Sung-Ro Yun, Won Min Hwang. Konyang University Hospital, Daejeon, Republic of Korea.

**Background:** It is known that exposure to fine particulate matter, which has recently been highlighted as an environmental problem, occurs mainly through the respiratory tract, which increases various inflammatory reactions. This increase in mucosal inflammation is thought to cause aggravation of IgA nephropathy, but no studies have been reported on the relationship between IgA nephropathy and fine particulate matter so far.

**Methods:** The HIGA (high serum IgA) mouse model was used as a spontaneous IgA nephropathy animal model. Using a sealed fine particulate matter exposure cage system, the exposure group was exposed to fine particulate matter for 1 hour at a time, 3 times a week, for a total of 8 weeks. After 8 weeks of exposure to fine particulate matter, blood, urine, lung, and kidney tissues were obtained and analyzed.

**Results:** There was no significant difference in the total IgA concentration in the blood of the exposure group and the control group. However, in the lectin binding assay (Ricinus communis agglutinin I, Sambucus nigra agglutinin), the concentration of glycosylated IgA tended to be higher in the control group. In the lung tissue of the exposure group, interstitial thickening was evident and toll like receptor (TLR)-9 expression was significantly increased. In the kidney tissue of the exposure group, mesangial proliferation and mesangial expansion were increased, and the number of glomerular scleroses were higher in the exposure group compared to the control group. Mesangial IgA deposition in the exposure group was significantly increased compared to the control group in immunofluorescence assay.

**Conclusions:** It was observed that fine particulate matter increased TLR-9 expression in lung tissue, which increased hypoglycosylated IgA, resulting in renal glomerular damage and increased mesangial IgA deposition in HIGA mouse model. This suggests that chronic exposure to high concentrations of fine particulate matter in IgA nephropathy may exacerbate the disease severity.

## SA-PO647

### An Epigenetically Driven Mechanism Triggered by Viral and Bacterial RNA Regulates the IL-6 Levels in IgA Nephropathy

Fabio Sallustio, Claudia Curci, Maria Teresa Cimmarusti, Angela Picerno, Alessandra Stasi, Francesco Pesce, Vincenzo Di Iorio, Loreto Gesualdo. Loreto Gesualdo's research Group *Università degli Studi di Bari Aldo Moro, Bari, Italy*.

**Background:** Recently, the role of IL-6 in IgAN pathogenesis is becoming increasingly important. A possible hypothesis emerges from our recent work on genome-wide DNA methylation screening in patients with IgAN, which identified, among other findings, a hypermethylated region comprising Vault 2-1 RNA (VTRNA2-1), a non-RNA coding also known as a precursor of miR-886 (pre-mi-RNA). Consistently, VTRNA2-1 expression was found downregulated in IgAN patients.

**Methods:** Total RNA were isolated from PBMCs of IgAN patients, transplanted IgAN patients (TP-IgAN), non-IgAN transplanted patients (TP) and healthy subjects (HS). VTRNA2-1, CREB, PKR and IL-6 were evaluated by RT-PCR and by ELISA. Poly (I:C) and Pfizer-BioNTech COVID-19 COMIRNATY vaccine were used to transfect patient PBMCs. PKR inhibitor imoxin (C16) 1  $\mu$ M was used to stimulate patient PBMCs.

**Results:** Here we confirm that VTRNA2-1 is low expressed in IgAN subjects compared to HS and we found that also in TP-IgAN, compared to TP, the VTRNA2-1 transcript was expressed at level very low. We found that in IgAN patients with downregulated VTRNA2-1, PKR is overactivated, coherently with the role of the VTRNA2-1 that binds to PKR and inhibits its phosphorylation. The loss of the VTRNA2-1 natural restrain caused the activation of CREB by PKR, a classical cAMP-inducible CRE-binding factor interacting with a region of the IL-6 promoter and leading to IL-6 production. We found higher CREB phosphorylation levels and IL-6 levels both in IgAN and in TP-IgAN patients. Since PKR is normally activated by bacterial and viral RNA, we hypothesized that these microorganisms can further activate the PKR/CREB/IL-6 pathway leading to an excess of IL-6 production, explaining both the high levels of IL-6, both infection involvement in the disease, both cases of IgAN associated with COVID-19 infection and with COVID-19 RNA-vaccination. Both the RNA poly(I:C) and the COVID-19 RNA-vaccine stimulation significantly increase the IL-6 levels in IgAN patient PBMCs.

**Conclusions:** In conclusion, the discovery of the upregulated VTRNA2-1/PKR/CREB/IL-6 pathway in IgAN patients may provide a new pathogenic mechanism in IgAN and may be useful for the development of novel therapeutic approaches, likely by modulating the VTRNA2-1 methylation level in IgAN patients.

## SA-PO648

### CARD9 Risk Locus for IgA Nephropathy Plays a Dichotomous Role Between Systemic and Mucosal Immunity Mediated by Retinoic Acid

James Gleeson, Eleftheria Theodora Metallinou, Dina Rafah, Harry Sokol, Renato C. Monteiro. *INSERM, Paris, France*.

**Background:** Caspase recruitment domain family member 9 (CARD9) has been identified as a susceptibility gene for IgA nephropathy (IgAN) by genome wide association studies. CARD9 is an adaptor protein involved in innate immune response and intestinal immune homeostasis. We aimed to study CARD9 in the mucosal immune compartment and examine its role in a mouse model of IgAN.

**Methods:** Serum and intestinal immunoglobulins of *wt* and *CARD9*<sup>-/-</sup> mice were measured. Humanised a1KI-CARD9<sup>-/-</sup> mice and a1KI-CD89tg-CARD9<sup>-/-</sup> mice were generated as models of IgAN. Mesenteric lymph nodes (MLNs) and splenocytes were isolated and cultured *ex vivo*. Bone marrow derived dendritic cells (BMDCs) were exposed to 2 $\mu$ M retinoic acid (RA) to induce a mucosal phenotype. Cholera Toxin subunit B (CTB) was administered by oral gavage for mucosal immunization or subcutaneously for systemic immunisation.

**Results:** Compared to *wt* mice, *CARD9*<sup>-/-</sup> mice had higher intestinal IgA and lower serum IgA. RA increased BMDC expression of CARD9. The effect of CARD9 KO on BMDC cytokine response was inverted by RA exposure such that in the absence of RA, CARD9 KO reduced cytokine production but, in the presence of RA CARD9 KO increased cytokine production, resulting in a significant interaction between RA and *CARD9* for IL-10 ( $p < 0.0001$ ), IL-21 ( $p = 0.01$ ) and BAFF ( $p < 0.0001$ ). KO of CARD9 in

a1KI mice caused decreased IgA1 secretion by splenocytes ( $p < 0.05$ ), but increased MLN IgA1 secretion ( $p < 0.01$ ). After mucosal immunization with CTB, CARD9 KO enhanced IgA adaptive response ( $p < 0.0001$ ) and weakened IgG adaptive response ( $< 0.01$ ) while after systemic immunisation no effect of CARD9 was seen. In a spontaneous mouse model of IgAN (a1KI-CD89tg) CARD9 KO mice had more severe glomerulonephritis than controls with greater IgA1 mesangial deposition ( $p < 0.05$ ), proteinuria ( $p < 0.001$ ) and higher serum cystatin C ( $p = ns$ ). Vitamin A (RA) free diet reversed the effect of CARD9 KO on IgAN phenotype.

**Conclusions:** Loss of CARD9 function aggravates IgAN phenotype in a mouse model through increased activity of the mucosal IgA response. The effect of CARD9 in the mucosal compartment is mediated by retinoic acid from dietary vitamin A. These results support a role of mucosal CARD9 dysregulation in the immuno-pathogenesis of IgAN.

## SA-PO649

### Intestinal Dysbiosis of Mucin-Degrading Bacteria Causes IgA Nephropathy

James Gleeson, Jonathan M. Chemouny, Nicolas Benech, Eleftheria Theodora Metallinou, Aurelie Sannier, Eric Dugas, Francois Vrtovnik, Harry Sokol, Renato C. Monteiro. *INSERM, Paris, France*.

**Background:** IgA nephropathy (IgAN) is characterized by glomerular deposition of deglycosylated IgA1 (dg-IgA1) bound by autoreactive antibodies. Genome wide association studies and clinical observations implicate the mucosal immune system in disease pathogenesis. We sought to investigate host-microbiota interactions in IgAN.

**Methods:** Faecal samples from IgAN patients (IgAN,  $n = 33$ ), healthy controls (HC,  $n = 65$ ) and disease controls with other causes of CKD (CKD,  $n = 20$ ) were analysed by 16S rRNA DNA sequencing. CaCo-2 cells were used *in vitro* while C57BL/6J and humanized a1KI-CD89tg mice were used for *in vivo* experiments. Immunofluorescence microscopy quantified IgA and C3 deposition, RT-PCR quantified gene expression, ELISA quantified proteins. IgA1 glycosylation was measured by HAA lectin, dg-IgA1 specific antibody (KM55, IBL) and mass spectrometry.

**Results:** Compared to HC and CKD, the intestinal microbiota of IgAN had altered  $\beta$ -diversity ( $p = 0.001$ ,  $p = 0.02$ ) and increased abundance of *Akkermansia muciniphila* ( $p = 0.001$ ,  $p = 0.03$ ). *A. muciniphila* (AKK) consistently deglycosylated human IgA1 ( $p = 0.0007$ ); dg-IgA1 passed retrogradely from the luminal to systemic side of mucosal tissue both *in vitro* and *in vivo*. Glomerular deposits of IgA1 were found in AKK, but not *E. coli*, colonised *wt* mice after oral gavage with exogenous IgA1 ( $p < 0.001$ ). Colonization of a1KI-CD89tg mice with AKK induced an aggravated IgAN phenotype whereas colonisation with *E. coli* did not ( $p = 0.001$ ). Faecal levels of a-Defensin 6 correlated negatively with faecal AKK ( $p = 0.02$ ). *In vitro* growth assays and electron microscopy showed inhibition of AKK by a-Defensin 6. IgG colocalized with IgA in glomerular deposits of AKK, but not *E. coli*, colonized a1KI-CD89tg mice. Affinity of serum IgG from IgAN patients was much greater for human IgA1 incubated with AKK than for controls.

**Conclusions:** IgA1 is deglycosylated in the intestinal lumen by mucin-degrading bacteria, such as AKK, before passing by retro-transcytosis to the systemic circulation, where it is bound by autoreactive antibodies, and depositing in the mesangium. We provide mechanistic evidence for the causal role of an intestinal dysbiosis in the pathogenesis of autoimmune glomerulonephritis.

## SA-PO650

### Metabolomics Reveals Serum mTOR Signaling Activation in IgA Nephropathy Patients

Hyung Woo Kim,<sup>1</sup> Tae-Joon Park,<sup>2</sup> Jinhwa Kong,<sup>2</sup> Boyoung Nam,<sup>1</sup> Seung Hyek Han,<sup>1</sup> Tae-Hyun Yoo,<sup>1</sup> Shin-Wook Kang,<sup>1</sup> Bong-Jo Kim,<sup>2</sup> Heun-Sik Lee,<sup>2</sup> Jung Tak Park.<sup>1</sup> <sup>1</sup>Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; <sup>2</sup>Division of Genome Science, Department of Precision Medicine, National Institute of Health, Cheongju, Republic of Korea.

**Background:** Circulating metabolites are known to play key roles in the pathophysiology of several diseases. In Immunoglobulin A nephropathy (IgAN), the role of systemic milieu as a risk factor for progression has been reported. However, the serum metabolic profile of IgAN and its role in disease progression is not well known.

**Methods:** Twenty-five patients with IgAN and five controls without IgAN were included in this study. The capillary electrophoresis and time-of-flight mass spectrometry-based metabolomics quantification was applied for the serum metabolic profile. The concentration of each metabolite was log-transformed and scaled. To determine metabolomic differences between IgAN and controls, a principle components analysis (PCA), hierarchical cluster analysis (HCA), and univariate Welch's t-test was performed. Metabolite pathway analysis was performed to find significant disease-pathway associations. Pathway sets were obtained from the Kyoto Encyclopedia of Genes and Genomes and the Ingenuity Pathway Analysis (IPA) database.

**Results:** The mean age of the patients with IgAN was 39.4 years, and 44% were female. The mean eGFR was  $89.7 \pm 27.6$  ml/min per 1.73 m<sup>2</sup> and the median urine protein-to-creatinine ratio was  $1.5 [0.9 \text{ to } 2.8]$  g/g. The mean age of controls was 55.6 years, and 80% were female. The mean eGFR was  $84.7 \pm 11.4$  ml/min per 1.73 m<sup>2</sup>. A total 56 serum metabolites were assessed. PCA and HCA revealed significant metabolic pathway differences between IgAN and controls. Welch's t-test showed that 16 metabolites (3 and 13 metabolites in the anion and cation, respectively) concentrations were significantly higher in IgAN patients after multiple test correction. Pathway enrichment analysis showed that four pathways were associated with these 16 metabolites: Valine, leucine and isoleucine degradation, aminoacyl-tRNA biosynthesis, glyoxylate and dicarboxylate

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

metabolism, and alanine, aspartate and glutamate metabolism. In addition, IPA database revealed mTOR signaling pathway to be related with the 4 metabolites among 16 metabolites.

**Conclusions:** In this metabolomics analysis, 16 metabolites were noticed as those that significantly identify IgAN. The mTOR signaling pathway activation through these metabolites may play a role in IgAN pathophysiology.

**Funding:** Government Support - Non-U.S.

## SA-PO651

**Genome-Wide Methylation in Patients With Primary IgA Nephropathy**  
Qiuxia Wang, Wei Wang. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

**Background:** Methylation gene chip was used to study the pathogenesis of DNA methylation in IgAN.

**Methods:** NimbleGen 3x720K methylation gene chip was used to screen differentially methylation genes (DMGs) in patients with IgA nephropathy and healthy subjects combining with functional enrichment analysis. The mRNA expression of DMGs in peripheral blood lymphocytes was screened by RT-qPCR; the methylation level of DMGs was verified by pyrophosphate sequencing; the relationship between the methylation level of DMGs and mRNA expression level and clinical characteristics were analyzed.

**Results:** 1. 2062 differentially methylation sites and 1839 differentially methylation genes were detected by methylation gene chip. 2. Four differentially methylation genes *CLEC10A*, *ACCS*, *CFHR1* and *TNFRSF17* were screened by functional enrichment analysis. 3. RT-qPCR showed that, in peripheral blood lymphocytes of IgAN group, the mRNA expression level of *TNFRSF17* was higher than that of control group ( $P=0.03$ ). 4. Combined with the clinical data, in peripheral blood lymphocytes of patients with IgAN, the mRNA expression level of *CLEC10A* was negatively correlated with hemoglobin ( $P=0.02$ ,  $r=-0.33$ ); the mRNA expression level of *TNFRSF17* was negatively correlated with high density lipoprotein ( $P=0.04$ ,  $r=-0.33$ ); the mRNA expression level of *CFHR1* was negatively correlated with eGFR level ( $P=0.03$ ,  $r=-0.31$ ) and positively correlated with the level of serum creatinine ( $P=0.06$ ,  $r=0.27$ ). 5. According to the analysis of pathological data, the mRNA expression level of *CLEC10A* in E1 group was higher than that in E0 group, and that in S1 group was higher than that in S0 group ( $P < 0.05$ ). Compared with M0, E0 and C0, the mRNA expression level of *TNFRSF17* increased in M1, E1 and C1~2 groups, but the difference was not statistically significant. 6. In IgAN group, the methylation level of *TNFRSF17* CpG1 site was increased ( $P=0.02$ ), and it was positively correlated with the expression level of *TNFRSF17* mRNA ( $P<0.05$ ,  $r=0.39$ ).

**Conclusions:** 1. Aberrant DNA methylation of *TNFRSF17* may be involved in the pathogenesis of IgAN. 2. *CFHR1* and *CLEC10A* may be related to the disease progression of IgAN.

## SA-PO652

**More Severe Mitochondrial Injury at the Time of Diagnosis Is Associated With Poor Prognosis in IgA Nephropathy**  
Byung chul Yu, Kyung Ho Lee, Soo Jeong Choi, Moo Yong Park, Jin kuk Kim. *Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.*

**Background:** We hypothesized that the degree of mitochondrial injury at the time of diagnosis may serve as a valuable prognostic marker in IgA nephropathy (IgAN).

**Methods:** We prospectively enrolled 52 patients with IgAN. Focusing on the stimulator of interferon genes (STING)-NF- $\kappa$ B pathway activated by mitochondrial injury, the signal intensity of immunohistochemical (IHC) staining for STING and NF- $\kappa$ B was analyzed using kidney tissue at the time of diagnosis. Proteinuria at 6 months after treatment was categorized by conventional definitions of complete ( $<0.3$  g/day) and partial remission ( $<3.5$  g/day and 50% reduction in proteinuria). Time-averaged proteinuria (TA-proteinuria) was calculated as the average of the mean of proteinuria were obtained by 24-hour urine collection every 6 months for each patient.

**Results:** Kidney tissue from 40 patients showed positive IHC staining for STING and NF- $\kappa$ B. Patients were divided into the high ( $n = 21$ ) and low ( $n = 31$ ) intensity subgroups according to the signal intensity of IHC staining for STING and NF- $\kappa$ B based on 2+ and more or less, respectively. Fewer patients achieved complete or partial remission in the high intensity group than in the low intensity group (53.3 vs 94.1%,  $p = 0.013$ ). During a median follow-up of 3.5 years, TA-proteinuria and mean annual rate of estimated glomerular filtration rate decline were higher in the high intensity group than in the low intensity group ( $0.99 \pm 0.78$  vs.  $0.49 \pm 0.32$  g/day,  $p = 0.010$ ; and  $-1.91 \pm 4.71$  vs.  $1.55 \pm 5.82$  mL/min/1.73m<sup>2</sup>/year,  $p = 0.029$ , respectively).

**Conclusions:** More severe mitochondrial injury, as represented by a high signal intensity of IHC stain for STING and NF- $\kappa$ B at the time of diagnosis, could be used as a prognostic marker to predict poor prognosis in IgAN.

**Funding:** Government Support - Non-U.S.

Immunohistochemical (IHC) staining of STING and NF- $\kappa$ B on kidney tissue obtained from patients. Patients were classified into 1+ (A), 2+ (B), and 3+ (C) according to the signal intensity of IHC staining.

## SA-PO653

**A Role for Circulating MicroRNAs in the Pathogenesis of IgA Nephropathy**

Jasraj S. Bhachu, Jonathan Barratt, Izabella Z. Pawluczyk. *University of Leicester, Leicester, United Kingdom.*

**Background:** IgA nephropathy (IgAN) is considered to be a systemic disease with the kidneys being injured as innocent bystanders, therefore investigating circulating mediators as a key to its pathogenesis is well founded. Recently, the emergence of microRNAs (miRs) as negative regulators of gene expression has opened new avenues to understand their role in normal and pathological processes. The aim of this study was to investigate the role of circulating miRs in IgAN.

**Methods:** Next generation sequencing (NGS) was performed by Qiagen (Germany) on sera from patients with IgAN, idiopathic membranous nephropathy (IMN) and healthy subjects (HS). NGS data was validated using independent serum samples from each cohort by RT-qPCR. Extracellular exosomes were also isolated from the sera and urine of patients and controls and miR expression measured by RT-qPCR. MicroRNA expression was also measured in peripheral blood mononuclear cells (PBMCs). Mechanistic studies were subsequently performed using kidney cells *in vitro*.

**Results:** NGS and subsequent validation using RT-qPCR identified miRs -483-5p and -122-5p as being significantly overexpressed in those IgAN patients at high risk of future progression (IgAN-HR) compared to those at low risk of progression (IgAN-LR) and HS, but not compared to IMN. Both miRs were also significantly increased in serum exosomes of IgAN-HR compared to IgAN-LR and HS and this time also compared to IMN. Sera from IgAN-HR patients contained significantly more exosomes than sera from IgAN-LR, HS and IMN. Exosomal miR-483-5p levels correlated with proteinuria and with serum-derived tumour necrosis factor (TNF) super family analytes in IgAN. Having identified that miR-483-5p was enriched in peripheral blood CD19+ cells and in the urine, *in vitro* studies showed that exposing immortalised B cells to TNFR1 resulted in B cell activation and release of B cell-derived exosomes containing high levels of miR-483-5p. Collecting duct epithelial cells (CDECs) exposed to these miR-483-5p-enriched B cell-derived exosomes adopted a pro-inflammatory phenotype which was mediated by the transcription factor SOCS3, a known target of miR-483-5p.

**Conclusions:** This study has identified a potential novel mechanism for the TNF superfamily/B cell-axis in driving tubulointerstitial injury in IgAN.

**Funding:** Private Foundation Support

## SA-PO654

**Treatment With Nefecon Reduces Circulating Levels of Galactose-Deficient IgA1 in Patients With IgA Nephropathy in the NeflgArd Clinical Trial**

Karen Molyneux, Nadia Nawaz, Scott Taylor, Jonathan Barratt. *University of Leicester, Leicester, United Kingdom.*

**Background:** IgA nephropathy (IgAN) is characterized by mesangial accumulation of IgA1-containing immune complexes (IgA1 ICs), which generate a pro-inflammatory and pro-fibrotic glomerular microenvironment, breakdown of the glomerular filtration barrier and progressive tubulointerstitial inflammation and scarring. IgA1 IC formation in the circulation is mainly driven by increased levels of polymeric galactose-deficient IgA1 (Gd-IgA1), thought to be derived from mucosally primed B cells, mostly residing in the gut associated lymphoid tissue (GALT). The therapeutic effect of selectively targeting the GALT was first investigated in the NEFIGAN study (NCT01738035) and results have now been confirmed in the larger NeflgArd clinical trial (NCT03643965).

**Methods:** NeflgArd is a randomized, double-blind, placebo-controlled Phase 3 trial, comprising PART A (9-month treatment and 3-month follow-up period) and PART B (12 month no-treatment follow-up period). Serum samples were collected at screening (placebo  $n=81$ ; 16 mg Nefecon  $n=81$ ), Month 3 (placebo  $n=81$ ; 16 mg Nefecon  $n=81$ ), Month 6 (placebo  $n=81$ ; 16 mg Nefecon  $n=79$ ), and Month 9 (i.e. end of treatment: placebo  $n=79$ ; 16 mg Nefecon  $n=81$ ). Gd-IgA1 levels were measured with an ELISA

using the Gd-IgA1 specific antibody, KM55 (IBL, Japan). Between-group comparisons at each time point were undertaken using unpaired t-tests (significance level = 0.05).

**Results:** 16 mg Nefecon treatment significantly reduced levels of circulating Gd-IgA1. Mean Gd-IgA1 levels fell by 21.4% (p<0.0005) at Month 3, 23.5% (p<0.0017) at Month 6 and 34% (p<0.0001) at Month 9 vs placebo.

**Conclusions:** To date, two large independent studies have shown that targeting the GALT with Nefecon results in a significant reduction in both proteinuria and a critical pathogenic biomarker in IgAN. Gd-IgA1-containing immune complexes have been shown to activate mesangial cells, promote glomerular scarring, and high levels are associated with more severe glomerular injury in kidney biopsies and worse kidney survival in clinical studies. This significant reduction in Gd-IgA1, combined with the proteinuria reduction reported in the NeflgArd trial, are consistent with Nefecon having a direct disease-modifying effect in IgAN.

**Atacicept Reduces Serum Immune Complex Levels in Patients With IgA Nephropathy (IgAN)**  
Jonathan Barratt,<sup>1</sup> Celia J. Lin,<sup>2</sup> Nadia Nawaz,<sup>1</sup> Karen Molyneux,<sup>1</sup> Gerald B. Appel,<sup>3</sup> James A. Tumlin,<sup>4</sup> Yusuke Suzuki.<sup>5</sup> <sup>1</sup>University of Leicester, Leicester, United Kingdom; <sup>2</sup>Vera Therapeutics, Inc, Brisbane, CA; <sup>3</sup>Columbia University Medical Center, New York, NY; <sup>4</sup>Emory University School of Medicine, Atlanta, GA; <sup>5</sup>Juntendo University Faculty of Medicine, Tokyo, Japan.

**Background:** IgAN is an autoimmune disease thought to have a multi-hit mechanism in the inflammatory pathogenic process. Elevated serum Gd-IgA1, which plays a central role in IgAN pathogenesis is the first hit. The second hit is the antibodies that develop against Gd-IgA1 (anti-Gd IgA1) leading to formation of immune complexes (third hit). These circulating immune complexes can then deposit in the kidney and cause injury (fourth hit). The Ph2a JANUS, a randomized placebo-controlled clinical trial, showed that atacicept was the first therapeutic to decrease both circulatory Gd-IgA1 and anti-GdIgA1. This analysis investigates whether atacicept can also reduce serum immune complex levels.

**Methods:** JANUS patients were evaluated for serum IgA-IgG immune complex levels by ELISA at baseline, weeks 4, 12, 24, 48, and 72. Serum samples were normalized using 3 standard serum samples included on all plates.

**Results:** Decrease in serum IgA-IgG immune complex levels was observed in both atacicept 25 mg and 75 mg groups over time. At 24 weeks, mean percent change from baseline was 17% decrease for atacicept 25 mg, 21% decrease for atacicept 75 mg, and 3% decrease for placebo. At 72 weeks, 29% decrease for atacicept 25 mg, 26% decrease for atacicept 75 mg, and 13% decrease for placebo was observed.

**Conclusions:** Atacicept is the first therapeutic to show reduction in serum Gd-IgA1, anti-Gd-IgA1, and now immune complex levels in IgAN patients. Atacicept's ability to mitigate all of the first three hits of the multi-hit hypothesis illustrates its potential to modify the disease. The ongoing Ph2b ORIGIN trial evaluating up to atacicept 150 mg in IgAN pts, will help determine how reduction of these multiple hits translate to renal function.

SA-PO656

**Urinary GADD45G Protein Excretion Predicts IgA Nephropathy Progression**  
Min-Jeong Lee. *Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea.*

**Background:** Growth arrest and DNA damage 45G (GADD45G) is a family of proteins involved in DNA damage response and cell growth arrest. In this study, we show evidence that urinary GADD45G protein is associated with progression of IgA nephropathy.

**Methods:** Patients diagnosed with IgA nephropathy without reversible acute kidney injury at study initiation and with at least one subsequent serum creatinine (SCR) measurement were included. A 50% or greater increase of SCR level was used as an endpoint of deterioration of renal function. Enzyme-linked immunosorbent assay (ELISA) was performed using a Human GADD45G ELISA kit. Renal biopsy tissues were stained with a monoclonal mouse anti-GADD45G antibody.

**Results:** Forty-five patients whose renal biopsy revealed IgA nephropathy were enrolled. Urinary GADD45G and urinary protein concentrations were 1.89 ± 1.82 µg/g and 1.47 ± 1.98 g/g, respectively. Urinary GADD45G showed significant positive correlations with SCR-slopes and urinary protein. The SCR-slope of the highest tertile group of urinary GADD45G (above 1.95 µg/g) was significantly higher than that of the lowest tertile group (below 0.90 µg/g). Univariate Cox regression analysis showed that urinary GADD45G was significantly associated with deterioration of renal function. Kaplan-Meier test showed a significant difference in event-free survival for deterioration of renal function between the highest urinary GADD45G tertile group and other tertile groups. The area under the receiver operating characteristics (ROC) curve indicated urinary GADD45G had a good performance in predicting renal outcome (cut-off point 1.67 µg/g, positive predictive value 36.8%, negative predictive value 100%). Immunohistochemistry showed that GADD45G was expressed across all pathologic grades of IgA nephropathy and mainly detected in the cytoplasm of renal tubules whereas no staining was noted in normal tissues.

**Conclusions:** In the present study, we showed that urinary GADD45G excretion is significantly associated with kidney disease progression in patients with IgA nephropathy. We also found that GADD45G was expressed in renal tubules across all pathologic grades indicating that tubular damage was an early pathogenic process of IgA nephropathy.

SA-PO657

**Persistence of Signs and Symptoms in Treated Patients With IgA Nephropathy: Evidence From Real-World Data**  
Richard A. Lafayette,<sup>1</sup> Michel Kroes,<sup>2</sup> Carolina A. Aldworth,<sup>2</sup> Luis Prieto-Rodriguez,<sup>2</sup> Aneesh T. George,<sup>3</sup> Jonathan J. de Courcy,<sup>6</sup> Keisha J. Golden,<sup>6</sup> Emma Chatterton,<sup>6</sup> Li Yao,<sup>4</sup> Dario Roccatello.<sup>5</sup> <sup>1</sup>Stanford Medicine, Stanford, CA; <sup>2</sup>Novartis AG, Basel, Switzerland; <sup>3</sup>Novartis Healthcare Private Limited, Hyderabad, India; <sup>4</sup>The First Hospital of China Medical University, Shenyang, China; <sup>5</sup>University of Turin, Department of Clinical and Biological Sciences, Turin, Italy; <sup>6</sup>Adelphi Real World, Bollington, United Kingdom.

**Background:** Immunoglobulin A nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide, with an estimated annual incidence of 25 per million. It currently has limited treatment options. This analysis aimed to describe IgAN signs and symptoms (S&S) in treated patients.

**Methods:** The Adelphi IgAN Disease Specific Programme was a point-in-time survey of IgAN-treating nephrologists in the US, EU5 (France, Germany, Italy, Spain, UK) and Asia (China and Japan) between June and October 2021. Nephrologists completed structured online records for successive patients presenting with IgAN, including patient's demographics, IgAN treatment history, and a list of 29 current IgAN S&S.

**Results:** 295 nephrologists completed records for 1376 patients treated for a minimum of one week at time of survey. Mean patient age was 42.6 years, 59% were men. Median time since treatment initiation was 86 weeks (US 61, EU5 121, Asia 76). Despite treatment with standard of care (ACEi, ARB, Statins, Corticosteroids), most patients presented with S&S at time of survey. This was consistent in patients with longer treatment duration. Common S&S experienced were proteinuria, hematuria, hypertension, and fatigue (**Table 1**). A higher proportion of patients in their second year of treatment were at a better CKD stage than those in their first year of treatment or those treated for >2 years. Of those patients treated for more than two years, US 26%, EU5 31%, and Asia 24% had >1g proteinuria/day were reported.

**Conclusions:** Despite treatment, IgAN S&S persist in the majority of patients. Proteinuria persists in many patients, increasing the risk of progression to kidney failure. This shows a need for better treatment options for IgAN.

**Funding:** Commercial Support - Novartis Pharma AG

**The Real-World Diagnostic Pathway in Patients With IgA Nephropathy**  
Richard A. Lafayette,<sup>1</sup> Michel Kroes,<sup>2</sup> Carolina A. Aldworth,<sup>2</sup> Luis Prieto-Rodriguez,<sup>2</sup> Aneesh T. George,<sup>3</sup> Jonathan J. de Courcy,<sup>4</sup> Keisha J. Golden,<sup>4</sup> Emma Chatterton,<sup>4</sup> Li Yao,<sup>3</sup> Dario Roccatello.<sup>6</sup> <sup>1</sup>Stanford University School of Medicine, Stanford, CA; <sup>2</sup>Novartis AG, Basel, Switzerland; <sup>3</sup>Novartis Healthcare Private Limited, Hyderabad, India; <sup>4</sup>Adelphi Real World, Bollington, United Kingdom; <sup>5</sup>The First Hospital of China Medical University, Shenyang, China; <sup>6</sup>University of Turin Department of Clinical and Biological Sciences, Turin, Italy.

**Background:** Although rare (estimated global annual incidence of 25/million) immunoglobulin A nephropathy (IgAN) is the most common form of primary glomerulonephritis. IgAN is associated with a poor prognosis, 30% or more of patients with >1g/day of proteinuria progress to kidney failure within 10 years. Poor prognosis is partly due to delayed diagnosis (Dx). This analysis aims to better understand the diagnostic pathway of IgAN patients.

**Methods:** The Adelphi IgAN Disease Specific Programme was a point-in-time survey of IgAN-treating nephrologists in the EU5 (France, Germany, Italy, Spain, UK), US and Asia (China and Japan) from June to October 2021. Nephrologists completed structured online records for successive patients presenting with IgAN, including demographics, clinical data, and reasons for delay of Dx.

**Results:** A total of 295 nephrologists completed records for 1792 patients in the survey. Mean patient age was 43.6 years, and 59% were men. Median time from symptom onset to the patient consulting a physician was reported for 79% of patients. In the EU5 (n=456) and US (n=233), this was 4.4 weeks (IQR EU5: 0.4-9.3, IQR US: 1.3-12.4) and in Asia (n=734) 4.6 weeks (IQR: 0.7-16.3). Median time from first physician consultation to confirmed IgAN Dx was reported for 86% of patients. Half of the patients received Dx within 4-5 weeks, the top 10% experienced a much longer period (**table 1**). Reasons for a delay >4 weeks between first consultation and Dx were reported for 46% of patients (n=826). Waiting to conduct tests (44% EU5, 30% US, 43% Asia) and waiting for a referral to a specialist (47% EU5, 41% US, 22% Asia) were the most common causes. Where GFR was recorded at Dx (76%, n=1356), 20% of patients were at CKD stages 3b-5 (GFR <45 mL/min/1.73 m<sup>2</sup>), in the US this figure was 32%.

**Conclusions:** While half of IgAN patients receive a relatively quick Dx, for at least one in ten the wait was over 20 weeks. During this time patients may have progressed to later stages of CKD. Improving the diagnostic process may improve prognosis for some patients.

**Funding:** Commercial Support - Novartis Pharma AG

Table 1. Time from 1st consultation to IgAN Dx (weeks)	EU5 (n=491)	US (n=263)	Asia (n=783)
25th percentile	2.4	0.9	1.0
Median	5.3	4.0	4.3

## SA-PO659

### Compartment Specific Analysis of Leukocyte Trans-Endothelial Migration Molecular Signature in IgA Nephropathy

Fengge Zhu,<sup>1,2</sup> Xizhao Chen,<sup>1,2</sup> Guangyan Cai,<sup>1,2</sup> Xiangmei Chen,<sup>1,2</sup> <sup>1</sup>Chinese PLA General Hospital, Beijing, China; <sup>2</sup>State Key Laboratory of Kidney Diseases, Beijing, China.

**Background:** The mechanism of how vascular lesions in IgA nephropathy affect renal disease progress remains unclear. Leukocyte trans-endothelium migration is an important bridge between blood vessels and tissue inflammation. This study analyzes the molecular signature of leukocyte trans-endothelial migration in IgA nephropathy based on the proteomic and the transcriptomic data of glomerulus, renal tubulointerstitium, peripheral blood mononuclear cells and peripheral CD14<sup>+</sup> monocytes of IgA nephropathy.

**Methods:** The renal proteomic data are obtained from a local cohort of 59 IgA nephropathy patients and 19 healthy controls. RNA-seq transcriptomic data of glomerulus, renal tubulointerstitium, PBMCs and peripheral CD14<sup>+</sup> monocytes in patients with IgA nephropathy are accessed from web based GEO database.

**Results:** 1. Canonical molecules related to leukocyte trans-endothelial migration, including molecules in cell adhesion, anchoring and cell deformation are analyzed in IgA nephropathy kidneys. We find that MCAM, ICAM1 and CDH5 are significantly upregulated in IgA nephropathy compared to that of paraneoplastic tissue, and not in membranous nephropathy. 2. Pearson correlation analysis show that the leukocyte trans-endothelial migration molecular signature is not correlated with proteinuria, renal function, hypertension or serum complement level, but had a weak correlation with decreased S score in the Oxford classification. 3. One of the trans-endothelial migration related genes - Integrin  $\alpha$  Subunit L (ITGAL) was significantly upregulated in the tubulointerstitium compartment of IgA nephropathy compared to healthy controls. However, there is no difference between IgA nephropathy and controls within the glomerulus, PBMCs, or peripheral CD14<sup>+</sup> monocyte compartments.

**Conclusions:** The leukocyte trans-endothelial migration signature molecules are significantly upregulated in the renal tubulointerstitium of IgA nephropathy, but not in the glomerulus, PBMCs, or peripheral CD14<sup>+</sup> monocytes. The leukocyte trans-endothelial migration signature is weakly correlated with decreased Oxford S score.

## SA-PO660

### Misdiagnoses and the Impact on Disease Severity in Immunoglobulin A Nephropathy Patients: A Real-World Study

James Jackson, Sarah Bourgeois, Mollie Lowe, Mohammed T. Khan, Muhammad Jamee. *Adelphi Real World, Bollington, United Kingdom.*

**Background:** Physicians may suspect immunoglobulin A nephropathy (IgAN) based on patient history, a physical exam, and urine and blood tests, but the only way to truly diagnose IgAN is by kidney biopsy. Data reporting on misdiagnosis of IgAN are sparse. This study aimed to understand rates of misdiagnosis and the impact on disease severity in a real-world population.

**Methods:** Data were drawn from the Adelphi IgAN Disease Specific Programme (DSP™) conducted in 2021 in France, Germany, Italy, Spain, United Kingdom (EU5), USA, China, and Japan. The DSP was a real-world, point in time survey collecting data from nephrologists and their consulting patients, including demographics, frequency of misdiagnoses, diagnostic delay, reasons for the delay, and physician perceived disease severity. Descriptive analyses were performed.

**Results:** In total, 321 physicians provided data for 1792 patients. The mean age of patients was 43.6 years, 1052 (59%) were male and 726 (44%) patients were white/Caucasian. Overall, 262 (82%) physicians reported managing patients who had been initially misdiagnosed which resulted in a delayed IgAN diagnosis. A higher proportion of misdiagnosed patients was reported in the EU5 and USA compared with, China and Japan (*Figure 1*). In total, 860 (56%) patients experienced a delay of >4 weeks from first consultation to receiving an IgAN diagnosis. In 54 (6%) of these, the reason for delay was diagnosis or suspicion of another condition. A higher proportion of patients who were misdiagnosed were moderate (57%) or severe (22%) when receiving an IgAN diagnosis than those who had not been misdiagnosed (52% moderate; 13% severe).

**Conclusions:** Our study showed that patients diagnosed earlier and without misdiagnosis were less severe at the time of their IgAN diagnosis. Prevalence of IgAN misdiagnosis is high, therefore further research is needed to understand the challenges faced by physicians when diagnosing this rare disease.

Figure 1: Distribution of % physicians who are managing misdiagnosed patients

## SA-PO661

### Investigating the Role of the Complement System in Paediatric Sickle Cell Disease

Daniel Diatlov,<sup>1,2</sup> Arlette Bohorquez,<sup>2</sup> Melanie E. Jackson,<sup>4</sup> Melina Cheong,<sup>4</sup> Christoph Licht,<sup>3,2</sup> <sup>1</sup>University of Toronto Institute of Medical Science, Toronto, ON, Canada; <sup>2</sup>The Hospital for Sick Children Research Institute Cell Biology Program, Toronto, ON, Canada; <sup>3</sup>The Hospital for Sick Children Division of Nephrology, Toronto, ON, Canada; <sup>4</sup>The Hospital for Sick Children Division of Haematology/Oncology, Toronto, ON, Canada.

**Background:** Sickle cell disease (SCD) is one of the most common hereditary red blood cell (RBC) disorders in the world, with an estimated 300,000 infants born with the disease annually. In SCD, a mutation in the gene for  $\beta$ -globin results in rigid sickled RBCs that can form blockages in the micro-vessels within organs, such as the kidney, leading to RBC lysis, endothelial cell (EC) damage, ischemia/reperfusion injury, and extremely painful vaso-occlusive crises (VOC). SCD can give rise to a variety of renal manifestations such as hyperfiltration, microalbuminuria, and AKI. Approximately 16-18% of overall mortality in patients with SCD is ascribed to kidney disease. The complement system – a critical part of the innate immune system – is involved in a myriad of kidney and vascular disorders, and emerging research points to the involvement of complement in SCD, potentially contributing to sickle cell nephropathy (Fig. 1A).

**Methods:** Paediatric patients with SCD (HbSS or HbS/β0) were enrolled during hospital admission with diagnosed VOC or acute chest crisis (ACS) not caused by infection. Patient serum was collected during hospital admission (crisis) and during follow-up (steady state). Complement activity was measured using the WIESLAB Complement System Screen (Svar Life Science). Immunofluorescence (IF) imaging was used to measure the deposition of C3b and C5b-9 on the surface of ECs exposed to patient serum.

**Results:** There is equal classical and alternative pathway activity during disease steady state and crisis, with an interesting trend showing elevated MBL pathway activity during crisis compared to steady state (Fig. 1B). IF assay data shows significantly elevated deposition of C3b and C5b-9 proteins on ECs when comparing crisis samples and healthy controls, with a trend suggesting a potential difference in complement deposition between steady state and crisis patients (Fig. 1C).

**Conclusions:** Our preliminary data shows complement is active in SCD, resulting in elevated C3b and C5b-9 deposition on ECs during SCD crisis. Future work will focus on further quantifying complement activity, and assessing the functional consequences of this on the surface of ECs.

## SA-PO662

## The Characteristics of IgM Nephropathy Compared to Other Glomerular Diseases

Eun-Jeong Kwon,<sup>1</sup> Ho Jun Chin.<sup>1,2</sup> <sup>1</sup>Seoul National University Bundang Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

**Background:** IgM nephropathy (IgMN) is pathologically defined as diffuse deposition of IgM in the mesangium. The definition and characteristics are still unclear. In this study, we explain manifestation of IgMN according to the electron dense deposits (EDD) in mesangium and differences in the clinical feature of IgMN with minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS). Finally, we would like to compare clinical findings between IgA nephropathy (IgAN) and IgMN, which have mainly mesangial lesions.

**Methods:** We enrolled 63 adult IgMN patients with a renal biopsy from May 2003 to June 2017. IgMN was defined as 1+ or more IgM antibody deposition in mesangium which intensity is more than the other antibodies of IgG or IgA. We excluded secondary nephropathy: autoimmune diseases, monoclonal gammopathy, or pathologically proven diabetic nephropathy. We compared the characteristics of IgMN with those of 91 MCD, 103 FSGS, and 469 IgAN. The renal failure was defined as decrease of estimated GFR more than 50% at the time of renal biopsy, less than 15 ml/min/1.73 m<sup>2</sup>, or progressed to end stage renal disease during follow-up period.

**Results:** There were 13 IgMN patients with EDD and 50 IgMN without EDD. Among light microscopic findings, mesangial cellularity and matrix were increased in IgMN with EDD, more frequently. The intensity of immunofluorescent staining for IgG, IgM, IgA, and C3 were more prominent in IgMN with EDD. Diffuse podocyte effacement was found in IgMN with EDD, more frequently. There was no difference of clinical characteristics and renal outcome of IgMN according to presence of EDD. IgMN had similar clinical features to FSGS. IgMN patients had higher blood pressure, lower proteinuria, and lower level of creatinine at renal biopsy, compared to MCD. However, it is greater blood pressure, creatinine and proteinuria, and more frequent incidence of acute kidney injury at renal biopsy in IgMN compared to IgAN patients. The frequency of renal failure in IgMN (46.0%) was similar to FSGS (40.8 %) (p=0.522), although it was higher than that of MCD (18.7 %) or IgAN (26.4 %) (p<0.001 and p=0.001, respectively).

**Conclusions:** Clinical characteristics of IgMN were not different according to the presence of EDD. Therefore, IgMN should be defined by the immunofluorescent findings. IgMN has similar characteristics to FSGS, however, has severe presentation compared to MCD and IgAN.

## SA-PO663

## Injection Heroin Use and AA-Type Renal Amyloidosis: An Underrecognized Etiology?

Jaskiran Mann,<sup>1</sup> Roberto L. Chuapoco,<sup>2</sup> Hoang Anh Nguyen,<sup>1</sup> David C. Wallace,<sup>1</sup> Kevin Yu.<sup>1</sup> Valley Hospital Medical Center <sup>1</sup>Valley Hospital Medical Center, Las Vegas, NV; <sup>2</sup>Touro College & University System, Las Vegas, NV.

**Introduction:** Serum amyloid A (SAA) renal amyloidosis is characterized by the deposition of serum amyloid A protein into renal glomeruli, tubules, and vessels. The AA amyloid proteins are misfolded aggregates derived from acute-phase reactant serum amyloid A protein. Regular injection heroin use has been linked to increased risk of secondary amyloidosis, possibly due to recurrent skin and soft tissue infections.

**Case Description:** Patient is a 40 year-old Caucasian male with history of untreated hepatitis C and daily injection heroin use who presented to the emergency department with cellulitis of bilateral hands, and was found to be septic and bacteremic with *Streptococcus pyogenes*. Patient was started on broad spectrum antibiotics. Transesophageal echocardiogram was negative for vegetations/endocarditis. Nephrology was consulted for worsening non-oliguric acute kidney injury with uprending creatinine. Urine studies notable for protein 176 mg/dL with microalbumin 110.2mg/dL. Workup included renal ultrasound showing echogenic kidneys bilaterally; SPEP and UPEP with no M-spike, but elevated free kappa and lambda chains with normal kappa/lambda ratio; negative immunofixation; and repeat urine studies showing 20,840mg protein per day and UPC 16.4g/dL. Renal biopsy showed mild interstitial fibrosis and tubular atrophy (IFTA) and acute tubular injury, proteinaceous material in gloms and tubules that stained positive with congo red and demonstrated apple green birefringence; no evidence of kappa or lambda light chains on immunofluorescence. Renal function stabilized and patient was advised to follow up outpatient to initiate ACE inhibitor for proteinuria in likely AA renal amyloidosis.

**Discussion:** AA amyloidosis is an under-recognized cause of acute kidney injury. The pathophysiology may be due to inflammation associated with recurrent skin and soft tissue infections associated with injecting heroin, versus local inflammation due to injection heroin use. Case series have demonstrated rapid progression to dialysis-dependent

renal failure and death in these patients. Greater awareness of renal amyloidosis and its complications may help reduce incidence of disease and/or slow its progression.

## SA-PO664

## AL Amyloidosis Following Johnson &amp; Johnson COVID-19 Vaccination

Abhishek Nimkar, Tanazul T. Pariswala, Nupur N. Uppal. Northwell Health, New Hyde Park, NY.

**Introduction:** Amyloidosis is a clinical disorder that results from extracellular tissue deposition of pathogenic, misfolded proteins. Several cases of COVID-19 vaccine associated nephrotic syndrome have been described, here we report a case of AL amyloidosis following Johnson and Johnson (J & J) SARS-CoV-2 vaccine.

**Case Description:** A 76-year-old Haitian male with no past medical history was evaluated for acute kidney injury (AKI) and lower extremity (LE) swelling. Patient mentioned that he started to notice LE swelling on 13th day after receiving J & J SARS-CoV-2 vaccine, with associated presence of foamy urine and weight gain of 13 lbs since the receipt of the vaccine. He denied any rash, joint pains, change in appetite, use of NSAIDs, PPIs, antibiotics or herbal supplements. Lab work showed serum creatinine (Scr) of 2.26 mg/dl (baseline Scr was 1.19 mg/dl, 2 weeks prior to receiving vaccine), low serum albumin (2.1gm/dl), anemia (Hgb 11.4 gm/dl) and hyperlipidemia. Urine analysis revealed >600 mg/dl proteinuria, 37 RBCs with spot urine total protein/creatinine ratio (TP/Cr) elevated to 8.6. Serum immunofixation showed IgA lambda band. He was initiated on oral torsemide. Kidney biopsy revealed renal amyloidosis AL type, lambda light chain restricted with extensive glomerular and vascular deposits (26% of glomeruli obliterated by amyloid). Subsequently, bone marrow biopsy also showed lambda chain amyloidosis. Scr peaked to 4.66 mg/dl, albumin was low at 2 gm/dl and spot urine TP/Cr was elevated at 13.3. He was initiated on treatment with Daratumumab + Cyclophosphamide, Bortezomib and Dexamethasone, 8 months into therapy. Scr and spot urine TP/Cr have decreased to 2.6 mg/dl and 2.8 respectively and serum albumin had normalized to 3.6 gm/dl.

**Discussion:** Vaccination is a recognized trigger for new-onset and relapse of glomerular disease. It appears that our patient had undiagnosed amyloidosis, however the onset of nephrotic syndrome occurred after pt. received the vaccine, likely secondary to enhanced immune response causing the disease to manifest clinically. Further studies are needed to determine whether there is an association or causation between the COVID-19 viral vector vaccines and amyloidosis.

## SA-PO665

## A Curious Case of Immunoglobulin Deposition in C3-Dominant Membranoproliferative Glomerulopathy

Abhishek Nimkar, Purva D. Sharma. Northwell Health, New Hyde Park, NY.

**Introduction:** Eculizumab/Ravulizumab is a humanized murine recombinant monoclonal antibody engineered to minimize immunogenicity and proinflammatory effects by inhibiting the terminal complement component C5 to prevent the generation of the membrane attack complex. We report a case where new immunoglobulin deposits were seen on kidney biopsy in a patient with C3 glomerulopathy following use of ravulizumab.

**Case Description:** A 20 yo male presented with hypertension, foamy urine and hematuria. Lab work showed elevated serum creatinine of 2.9 mg/dl and elevated urine protein to creatinine ratio of 5.8 gms/gm of creatinine. Serological work showed low C3 and rest was unremarkable. Kidney biopsy was performed which showed membranoproliferative glomerulonephritis (GN) with dominant C3 deposits. Work up for low complement mediated GN was unrevealing for atypical HUS. He received 4 doses of Ravulizumab for C3 glomerulopathy but couldn't continue due to insurance issues. Patient initially responded to the treatment, but later serum creatinine started rising again with significant proteinuria. Patient underwent repeat kidney biopsy which revealed C3 GN with strong IgG2/4-Kappa reactivity in glomerular deposits. Patient was resumed on complement blockade and was listed for kidney transplant evaluation.

**Discussion:** Eculizumab/Ravulizumab consists of a hybrid human IgG2 heavy chain hinge region, which does not bind Fc receptors, and the IgG4 heavy chain CH2 and CH3 regions associated with a κ light chain. The tissue deposition of IgG2, IgG4, and κ light chain has been described in literature in patients receiving this drug for C3 glomerulopathy. With the expanded use of eculizumab/ravulizumab for treatment of conditions that could benefit from terminal complement blockade, pathologists are expected to encounter more biopsy specimens with IgG2, IgG4, and κ deposits. Given its low immunogenicity and slow tissue clearance, prolonged tissue deposition of the antibody is expected, which may generate confusing results. Knowledge of this finding is important because the detection of Ig-positive monoclonal deposits in patients with clinically suspected glomerular disease could lead to misdiagnoses, especially if therapy was discontinued a while prior to the biopsy and the pathologist was not informed of antecedent eculizumab/Ravulizumab use and if IgG subclass staining is not performed.

## SA-PO666

## A Rare Cause of Thrombotic Microangiopathy (TMA)

Rama Kethineni, Sarah Gilligan, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

**Introduction:** TMA can occur secondary to systemic autoimmune disorders such as SLE, Scleroderma, and APS. We present a case of TMA secondary to autoimmune myositis.

**Case Description:** A 48-year-old Hispanic female with a history of hypertension presented with headache, blurry vision, chest pain and dyspnea, with blood pressure of

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

230/140 mm hg. Her creatinine worsened from 0.8 mg/dl to 2.6 mg/dl with proteinuria of 1 g/g within a week despite improvement in blood pressure. Her labs were notable for microscopic hematuria and Platelets of 96k/ul and hemoglobin 10 g/dl. She had a troponin-I of 0.26 ng/ml, CK of 995 U/L and an ECHO with EF of 43%. Serologic work-up showed positive ANA of 1:1280 with speckled pattern, SSA-60 of 76 with negative SLE and Systemic sclerosis panel. Her hemolysis labs and SPEP were normal. Her cardiac MRI showed findings of myocarditis. Renal biopsy showed TMA with scattered subendothelial immune complex deposits and acute tubular injury. Immunofluorescence showed show scant capillary and mesangial staining for predominantly IgM and C1q, with scant staining for other antibodies. Creatinine worsened to 11.5 mg/dl over the course of 5 weeks and dialysis was initiated. Two months later she presented with fatigue, weakness, and diffuse muscle pain with CK of 4000 U/L and muscle biopsy showing necrotizing myopathy. She was started on high dose steroids and Cellcept with improvement of CK level. Her clinical course was complicated by bone marrow suppression, CMV viremia, and HLH with elevated ferritin of 25,527, SIL2r elevation of 19K with no response to Anakinra. She had worsening hemodynamic instability and ultimately passed away after her family opted to withdraw care.

**Discussion:** Distinguishing and treating of various causes of TMA can be very challenging especially when limited to the kidney. TMA frequently presents with hypertension, making it difficult to distinguish malignant hypertension from other causes. Literature on autoimmune myositis and TMA is rare. It can be very challenging to diagnose if TMA is caused early in the course of the disease as in our case.

## SA-PO667

### New Onset Anti-GBM Glomerulonephritis on a Background of IgA Nephropathy Post-SARS-CoV-2 Vaccination: A Double Hit Phenomenon?

Ramsha Riaz, Danny Haddad, Marissa M. Sansone, Valentin Marian, Deepika Jain. *Jersey City Medical Center, Jersey City, NJ.*

**Introduction:** Anti-glomerular basement membrane (anti-GBM) nephritis is a rare, but potentially fatal pathology that occurs due to development of IgG autoantibodies against an autoantigen expressed in the basement membrane of kidneys. We present a case of anti-GBM nephritis as an uncommon immune-mediated adverse effect post mRNA Covid-19 vaccination.

**Case Description:** This is a 41-year-old South Asian female with a history of hypothyroidism, who was tested positive for Covid-19 in April 2021. Post-covid, she received the Pfizer-SARS-CoV vaccine in June and July 2021. Few weeks later, she presented with anemia to her primary care physician, and a couple of months after, a urinalysis revealed significant microscopic hematuria and proteinuria. Further workup revealed a blood urea nitrogen (BUN) of 70 mg/dL and serum creatinine of 9.8 mg/dL which subsequently led to hospitalization for workup of acute kidney injury. Her labs were significant for hemoglobin 6.8 g/dL, BUN/Creatinine 81/10.13 mg/dL, potassium of 5.4, metabolic acidosis (HCO<sub>3</sub> 16mmol/L), and a urinalysis showing >50 red blood cells (RBCs) per high power field (HPF) with a protein of 300 mg/dL and 24-hour protein excretion of 5.7 g/dL. Complete review of systems was unremarkable with no signs of extrarenal manifestations and negative chest imaging. Immunological workup was negative except for elevated anti-GBM titer at 4.6 (normal <1) and elevated IgG and IgA serum proteins. A renal biopsy was performed to confirm the diagnosis, which showed acute anti-GBM nephritis - crescentic glomerulonephritis with 2-3+ linear IgG staining with incidental mesangial IgA deposits. She was initiated on IV pulse steroids, plasma exchange therapy, and IV Cyclophosphamide. Renal function gradually improved on this treatment regimen.

**Discussion:** The occurrence of anti-GBM nephritis with concomitant IgA nephropathy post-SARS-CoV-2 mRNA vaccination has been rarely reported in literature. The etiology remains speculative; however, these cases highlight the need to exercise vigilance in patients presenting with symptoms or lab findings suggesting acute kidney injury with a preceding history of recent vaccination. Early identification and intervention may prevent progression of disease.

## SA-PO668

### IgA Vasculitis Nephritis in a Patient With Alport Syndrome: An Association or a Just a Coincidence?

Uma Mahesh R. Avula,<sup>1</sup> Michelle N. Rheault,<sup>2</sup> Lilia Harris,<sup>1</sup> Michael B. Kuperman,<sup>3</sup> Safa Osman,<sup>1</sup> Mohamed Hassanein.<sup>1</sup> <sup>1</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN; <sup>3</sup>Arkana Laboratories, Little Rock, AR.

**Introduction:** Alport syndrome is a rare inherited disorder manifested by persistent microscopic hematuria, nephritis, sensorineural deafness, and ocular abnormalities. IgA nephropathy has been reported in a small percentage of patients with Alport syndrome, however, IgA vasculitis nephritis (IgA-VN) has not been reported. We report a rare case of Alport syndrome with crescentic IgA-VN.

**Case Description:** A 48-year-old male with a history of deep vein thrombosis (on warfarin) was followed by nephrology clinic for chronic kidney disease (CKD). Due to concerns of risks associated with holding warfarin, genetic testing was done in lieu of kidney biopsy which was positive for a hemizygous pathogenic mutation in the X-linked COL4A5 gene for Alport Syndrome. He did not have any sensorineural deafness, ocular abnormalities, or a family history of kidney disease. He was admitted to the hospital for acute kidney injury (creatinine 14.6 mg/dL from a baseline of 2 mg/dL), nephrotic range proteinuria (microalbumin/creatinine ratio: 3,689 mg/g, normal < 200 mg/g) and microscopic hematuria. A full serological workup was unremarkable. He developed new-onset bilateral lower extremity purpura which was biopsied showing leukocytoclastic IgA

Vasculitis. Kidney biopsy showed IgA-dominant glomerulonephritis with 70% interstitial fibrosis and tubular atrophy, 80% crescents, and no electron microscopy findings suggestive of Alport Syndrome. Four days after the kidney biopsy, he was started on dialysis and immunosuppression (IV Methylprednisolone and Cyclophosphamide) after ruling out infection. He was discharged with a plan to continue immunosuppression and dialysis as an outpatient. Unfortunately, he developed COVID-19 prompting a delay in further immunosuppressive therapy.

**Discussion:** Although extremely rare, mutations in the COL4A3, COL4A4, and COL4A5 genes have been implicated in cases of familial IgA Nephropathy and Alport Syndrome. We report a novel patient with IgA-VN and COL4A5 variant. It is unclear whether his underlying COL4A5 variant contributed to his severe presentation with IgA-VN. Genome-wide association studies in patients with coexisting pathologies are needed to discover both diseases' possible common genetic connection.

## SA-PO669

### A Case of an IgA Variant of Anti-Glomerular Basement Membrane Disease

Mairead Hamill, Ian Harrington, Michelle Madden, Francis Ward. *Tallaght University Hospital, Dublin, Ireland.*

**Introduction:** Anti-GBM disease is a rapidly progressive glomerulonephritis. Pathogenesis is generally attributed to circulating IgG autoantibodies against cryptic epitopes in the NC1 domain of the alpha-3 chain of type IV collagen. It is a rare disease with a grave prognosis. Atypical anti-GBM disease has been described as a variant characterised by linear staining of GBM by IgG, IgM or IgA, in the absence of circulating anti-GBM autoantibodies. Here we report a case of an IgA variant of atypical anti-GBM disease.

**Case Description:** A 77-year old Caucasian female presented with malaise, and pyrexia on a background of chronic obstructive pulmonary disease. She had recently recovered from COVID-19. On presentation, she had anuric AKINIII (creatinine: 10.2 mg/dL) with previously normal function. On imaging, chest was clear and there was no obstruction. Urine microscopy revealed microhaematuria and proteinuria was quantified at 288mg/mmol. Complement studies and immunoglobulins were normal. HIV, hepatitis B and C virology were negative. Serum anti-GBM and anti-neutrophil cytoplasmic antibodies (ab) were negative. Kidney biopsy revealed extensive crescentic glomerulonephritis, with moderate interstitial fibrosis. GBM thickening was noted. On IF, linear staining for IgA (2+) and C3 was seen in capillary loops. EM did not identify immune complex deposition disease. Immunosuppression with prednisolone, cyclophosphamide and plasmapheresis was initiated without success. Serum IgA anti-GBM ab was negative. She remains dialysis dependent.

**Discussion:** The limited available literature suggests that biopsy-proven IgA variant anti-GBM disease, with undetectable serum anti-GBM ab, is an extremely rare presentation and that conventional therapies are rarely successful. Early diagnosis has an impact on prognosis in anti-GBM disease and, given widespread use of IgG anti-GBM ab assays, atypical cases may have treatment initiated later with devastating repercussions. This case illustrates the importance of prompt biopsy and need for increased awareness of atypical anti-GBM disease presentations.

## SA-PO670

### Crescentic IgA Nephropathy (cIgAN) in a Patient With COVID-19 Infection

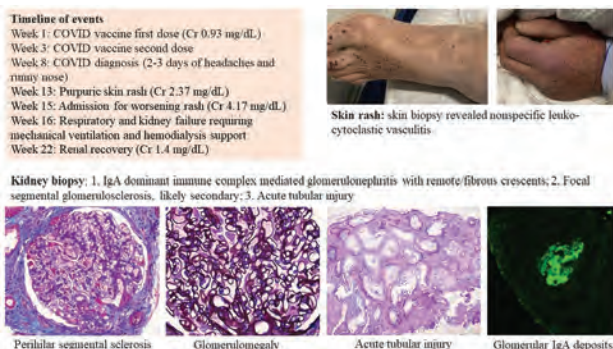

Sally Chau,<sup>1</sup> Svetlana O. Villano,<sup>1</sup> Vinod K. Valluri,<sup>1</sup> Kulwant S. Bath,<sup>1</sup> Masoud Haghi,<sup>1</sup> Nisha M. Singh,<sup>1</sup> Jean Hou,<sup>2</sup> Susana M. Mendoza,<sup>1</sup> Golriz Jafari,<sup>1</sup> Anita Kamarzarian,<sup>1</sup> Phuong-Thu T. Pham,<sup>3</sup> Phuong-Chi T. Pham.<sup>1</sup> <sup>1</sup>UCLA Medical Center Olive View, Sylmar, CA; <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA; <sup>3</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Introduction:** COVID19 infection has been linked to various glomerulonephropathies (GN) including collapsing focal segmental glomerulosclerosis, pauciimmune crescentic glomerulonephritis, and possibly minimal change disease and IgA nephropathy.

**Case Description:** A 57-year-old obese man with hypertension, hyperlipidemia, prediabetes, chronic obstructive pulmonary disease, illicit drug use, status post Pfizer COVID vaccine (1<sup>st</sup> dose 4m prior, 2<sup>nd</sup> dose 3w later), and COVID19 infection 7w prior, presented with an acute onset purpuric rash that began from bilateral hands and

feet and progressed to arms and legs. Patient denied joint pain or abdominal discomfort. Initial studies: Serum creatinine (Cr) 4.17 mg/dL (2.37 mg/dL 2w prior, baseline 0.93 mg/dL 4m prior). Urinalysis: > 50 red blood cells/high power field; Urine protein/Cr 4g/g, albumin/Cr >3g/g; Negative: HIV, ANCA, ANA, antiGBM, complements. Chest CT: Bilateral multifocal consolidative opacities concerning for aspiration, multifocal bacterial or viral pneumonia, or atypical presentation of COVID19 pneumonia. Skin biopsy: Leukocytoclastic vasculitis; No immunoreactants detected. Patient suffered from rapid respiratory deterioration, multiple hypotensive episodes, and acute kidney injury requiring mechanical ventilation and dialysis support. Kidney biopsy: IgA dominant immune complex mediated glomerulonephritis with focal/remote fibrous crescents; acute tubular injury. Treatment: Intravenous methylprednisolone 250 mg x 3d, followed by oral prednisone course. Patient recovered adequate function after 6w and was able to discontinue dialysis.

**Discussion:** COVID19 infection-related inflammatory response may precipitate GN in susceptible individuals. Crescentic IgAN is known to be associated with acute inflammatory conditions involving lungs, gastrointestinal tract, and skin. The timeline for the development of cIgAN herein raises suspicion for COVID19 infection/pneumonia as the inciting event.

Skin rash: skin biopsy revealed nonspecific leukocytoclastic vasculitis.

## SA-PO671

### A Challenging Case of C1q Nephropathy in a 62-Year-Old Man

Nidal Alhosainat, Nicole Hunter, Wajid M. Choudhry. *Rochester Regional Health, Rochester, NY.*

**Introduction:** C1q nephropathy is a rare form of glomerulopathy characterized by mesangial deposition of the complement component C1q, usually affects older children and young adults. We are presenting an unusual case of a 62-year-old male patient with C1q nephropathy

**Case Description:** A 62-year-old man with PMHx of hypothyroidism, diabetes mellitus, admitted with shortness of breath and anuria for 24 hours, on presentation, BP was 104/70. Physical exam was notable for positive JVD, and lower extremity edema. Labs were significant for creatinine 4.82 mg/dl (baseline 1.8), Urinalysis showed RBC casts, +2 proteinuria. Urine protein:creatinine ratio was 821 mg/d. low C3 at 23mg/dl and C4 at < 5mg/dl. ANA, ANCA, RF, anti-RNP, anti-Smith, anti-SSA/SSB, anti-histone, anti-cardiolipin, CCP, myeloperoxidase, proteinase 3, cryoglobulin, SPEP, UPEP, immunofixation, HCV, and HIV all were negative. Renal biopsy revealed proliferative glomerulonephritis with glomerular and extra glomerular IgG and C1q-containing immune complex deposits with organized substructure. Diagnosis of C1q nephropathy was made and the patient was started on prednisone with significant improvement of the kidney function.

**Discussion:** C1q nephropathy is a poorly understood entity characterized by mesangial proliferation, and prominent C1q deposits on immunofluorescence microscopy in a patient with no clinical, laboratory or histopathological evidence of systemic lupus erythematosus (SLE). The prevalence of C1q nephropathy varies from 0.2 to 16% and seems to be higher in children. Clinical presentation is diverse, and ranges from asymptomatic hematuria or proteinuria to frank nephritic or nephrotic syndrome. Light microscopic features can mimic minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), and proliferative glomerulonephritis. The main defining pathology is intense staining for C1q mainly in the mesangium, can be accompanied by IgG and IgM deposition. Corticosteroids are the mainstay of treatment, with immunosuppressive agents reserved for steroid resistant cases. Poor outcomes can be seen if nephrotic syndrome and FSGS present. **Conclusion** C1q nephropathy is a distinct clinicopathologic entity characterized by mesangial C1q deposition, it may carry poor outcomes, therefore, early detection can be vital in the management, treatment usually by steroids, addition of immunosuppressive therapy might be required in resistant cases.

## SA-PO672

### Bartonella Infection-Associated Glomerulonephritis and Recurrent Dense Deposit Disease in a Kidney Transplant

Yuang Chen, Ramya Krishna Velagapudi, Agnes B. Fogo, Paisit Pauksakon, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

**Introduction:** Dense deposit disease (DDD) is caused by dysregulation of the alternative complement pathway, leading to excessive complement activation and complement deposition in the glomerular capillary walls and mesangium. Patients with DDD are at risk to have over-activation of the complement pathway in the setting of

acute infection, and may present with initial features suggesting infection-associated glomerulonephritis (IAGN) that transform to DDD. We present a case of infection-associated trigger of recurrent DDD in a kidney transplant patient with acute bartonella infection.

**Case Description:** A 29 year old man with DDD and subsequent living unrelated kidney transplantation, maintained on tacrolimus, MMF, and prednisone, presented 1 year after transplant with headaches, fevers, diarrhea, and myalgias. He was diagnosed and treated for cat scratch disease (bartonella IgM 1:64). He was readmitted 11 days after initial presentation for neuroretinitis and non-oliguric AKI (Cr 3.5 mg/dL [baseline 1.4 mg/dL], low C3 and normal C4, UA with 89 RBC, 12 WBC, >500 protein, UPCr 1.48). Biopsy revealed diffuse endocapillary hypercellularity with neutrophils, diffuse global chunky mesangial and capillary loop staining for C3+++, IgM++, and EM with mesangial and subendothelial deposits of usual density without hump-type subepithelial deposits. There was ribbon-like staining for C3++ along tubular basement membranes with focal dense TBM transformation by EM, indicative of IAGN transforming to DDD. Factor H autoantibodies were then detected. He was treated with high-dose prednisone, doxycycline/rifabutin, and twice-weekly plasma exchange with FFP for 8 weeks. The bartonella infection resolved and kidney function returned to baseline with resolution of proteinuria and hypocomplementemia. Repeat biopsy 3 months later confirmed resolving IAGN-like features and early recurrent DDD.

**Discussion:** The inherent dysregulation of the alternative complement pathway in our patient likely put him at risk for overactivation of the complement system in the setting of an acute infection, leading to IAGN-like acute lesions and evolution to recurrent DDD in the kidney transplant. Prompt diagnosis and management led to clinical resolution but with persistent morphological changes. More research is needed to further characterize this association.

## SA-PO673

### C3 Glomerulonephritis Triggered by Toxocariasis

Mona Ben m'rad,<sup>1</sup> Alexandre Beaulac,<sup>2</sup> Steven Palanchuck,<sup>1</sup> Veronique Beaunoyer,<sup>1</sup> Me Linh Luong,<sup>3</sup> <sup>1</sup>Hopital du Haut-Richelieu, Saint-Jean-sur-Richelieu, QC, Canada; <sup>2</sup>Centre integre universitaire de sante et de services sociaux de l'Estrie Centre hospitalier universitaire de Sherbrooke du Quebec, Sherbrooke, QC, Canada; <sup>3</sup>Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada.

**Introduction:** C3 glomerulonephritis (C3GN) is a rare disease, triggered by a monoclonal gammopathy or auto-immunity or an infection resulting from the overactivation of the alternative pathway of the complement (APC), with a poor prognosis. We report a case of C3GN triggered by *Toxocara canis* (*T. canis*), a parasitic infection.

**Case Description:** An 83 year-old man was admitted for fever, rash, pruritus, eosinophilia 1600/mm<sup>3</sup> and a serum creatinine of 122 µmol/L. He had repaired a septic tank which required excavation of contaminated soil, 2 weeks prior. He was discharged with no diagnosis and readmitted 4 months later for a recurrent rash, fever, dyspnea, a nephrotic syndrome (NS), hematuria, a peak creatinine of 355 µmol/L, low C3 (0.2 UI/L) and a peak eosinophilia of 2400/mm<sup>3</sup>. A *Staphylococcus aureus* bacteremia was treated with IV cefazolin for 14 days. An extensive NS and eosinophilia work-up including ANCA, ANA, electrophoresis, free light chains, viral serologies, bone marrow biopsy, genetic mutations and autoantibodies against the APC regulators was negative, except for a repeatedly highly positive *Toxocara sp* serology. The kidney biopsy showed a severe diffuse endocapillary glomerulonephritis with C3 deposits. On the basis of the strong positivity of the *T. canis* serology, the marked eosinophilia, a diagnosis of C3GN associated with an active visceral toxocariasis was made. After 3 pulses of Solumedrol 1 g IV followed by prednisone 1 mg/kg/day slowly tapered and albendazole 400 mg twice a day for 28 days, the *T. canis* infection abated. He required dialysis. Within 6 months, a second kidney biopsy showed an important decrease of the inflammation and of the C3 deposits with a lot of scarring tissue and fibrosis confirming end-stage renal disease.

**Discussion:** Toxocariasis, a highly prevalent helminthic zoonosis worldwide, has been reported as a rare cause of NS and eosinophilia both in adults and children. Here, an active infection-related C3GN was probably triggered by a visceral toxocariasis, after exposure to a contaminated soil, suggesting the role of an uncontrolled activation of the APC. The treatment goals were: 1/ eradication of *T. canis*, 2/ control of the glomerular inflammation and prevention of flares after the destruction of the larvae with slowly tapered steroids, 3/ supportive. We suggest to consider toxocariasis as a differential diagnosis for NS and eosinophilia.

## SA-PO674

### Unmasking the C3ulprit

Audai Ma'ayah, Brian Benes, Kathleen Borghoff, Kirk W. Foster, Prasanth Ravipati. *University of Nebraska Medical Center, Omaha, NE.*

**Introduction:** C3 glomerulonephritis (C3GN) is a rare disease with kidney biopsy findings typically showing a proliferative pattern of injury with C3 deposition on immunofluorescence (IF), along with an absence of immunoglobulin (Ig) staining. However, in certain cases, it is important to pursue paraffin IF, which can unmask deposited Ig that is negative on routine IF staining. The aim of this case report is to illuminate the importance of paraffin IF to help distinguish cases of C3GN from immune complex GN.

**Case Description:** A 22-year-old man with no chronic medical history presented with complaints of arthralgias and sore throat and was found to have acute kidney injury. He was without rash, synovitis, or peripheral edema. Serum creatinine was 4.37 mg/dL, urinalysis showed numerous dysmorphic red blood cells, and spot protein to creatinine ratio was 2.5. Serologic evaluation showed low C3, low C4, and a positive

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

anti-nuclear antibody. Additional antibody testing, streptococcal testing, serum protein electrophoresis with immunofixation, and infectious diseases evaluation were negative. Kidney biopsy showed mesangioproliferative glomerulonephritis involving all glomeruli, with IF staining positive only for C3 in the glomerular capillary walls. A preliminary diagnosis of C3GN was made. However, electron microscopy (EM) showed fibrillary-like substructure within subendothelial deposits and intracellular rod-like crystals, which raised suspicion for masked glomerular Ig deposits. Therefore, we performed paraffin IF which showed IgG staining with kappa restriction along the glomerular capillary wall. Serum testing revealed the presence of circulating IgG cryoglobulin. The patient was ultimately diagnosed with type 1 cryoglobulinemic glomerulonephritis.

**Discussion:** In cases of suspected C3GN, paraffin IF is important to ensure the absence of immune complex GN. Patients with paraproteinemia or EM findings of fibrillary or microtubular substructure warrant consideration for paraffin IF to avoid misdiagnosis. This is critical to inform proper clinical management, as paraprotein-related immune complex GN warrants further evaluation for lymphoproliferative disease.

## SA-PO675

### C3 Glomerulonephritis (C3GN) in a Patient With Marginal Zone Lymphoma Responsive to Rituximab Therapy

Mark N. Massoud, Stephen R. Sammons, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

**Introduction:** We present the case of a patient with Marginal Zone Lymphoma diagnosed later with C3GN and treated consequently with Rituximab with complete renal response

**Case Description:** An 81-year-old man was diagnosed with IgM-kappa Monoclonal Gammopathy of Undetermined Significance (MGUS) in 2016 during evaluation for peripheral neuropathy and was found to have a CD5/CD10-negative Marginal Zone Lymphoma. In 2019, microscopic hematuria and proteinuria (UPCR 904 mg/g) were identified which prompted a Nephrology referral. At this time, he was noted to have low serum C3 and C4 levels, kappa-lambda ratio of 2.2 and stable renal function (serum creatinine 1.1-1.2 mg/dL). A renal biopsy was obtained in May 2019 which was significant for focal proliferative glomerulonephritis with dominant C3 deposits and strong IgM staining of capillary loops and mesangial matrix. His proteinuria improved with ACE-I (UPCR < 115 mg/g), and he remained under surveillance for his MGUS/MZL and off any therapy directed at his C3GN until January 2021 when he developed deterioration of renal function (serum creatinine up to 1.7 mg/dL), worsening proteinuria (UPCR 960 mg/g), hypocomplementemia and elevated kappa-lambda ratio of 4.3 with pancytopenia. In March 2021, he underwent 4 weeks of rituximab therapy, after which his proteinuria, complement levels, and renal function improved. These improvements have persisted thus far for a year after his rituximab therapy.

**Discussion:** C3GN is a rare type of GN in which dysregulation of the alternative complement pathway results in deposition of C3 within the glomeruli. C3GN can be associated with monoclonal gammopathy and can lead to renal impairment. Patients usually present with hematuria, proteinuria, variable degree of renal dysfunction and hypocomplementemia. If left untreated, patients could progress to ESRD. Diagnosis is established with a renal biopsy showing glomerular C3 and monoclonal Ig deposits on IF in the kidney. Treatment of C3GN in patients with monoclonal gammopathy should be directed at the underlying clone, and targeted therapy can lead to improved renal survival.

## SA-PO676

### C3 Glomerulonephritis After Vector COVID-19 Vaccination: A Case Report

Akilandanayaki Angamuthu, Zahir Ali Shaikh, Imara Dissanayake, Manjula Balasubramanian, Saurabh Gupta. *Albert Einstein Medical Center, Philadelphia, PA.*

**Introduction:** Mass vaccinations for coronavirus (COVID-19) are being administered worldwide. Even though vaccine is safe and effective, rare adverse events like thrombosis with thrombocytopenia, myocarditis, Guillain barre syndrome have been reported. Renal adverse events such as IgA nephropathy and minimal change disease are reported as well. We report a case of C3 glomerulonephritis (C3 GN) after Johnson & Johnson (J&J) vector COVID-19 vaccine.

**Case Description:** 84-year-old female with history of hypertension, diabetes, and CKD stage 3 presented with fatigue, shortness of breath, leg swelling and poor oral intake. She had received J&J vector vaccine few weeks prior to presentation. Her baseline creatinine was 1.8. Home medications included amlodipine, aspirin, clonidine, coreg, hydralazine, insulin and protonix. In the emergency department, vitals were normal. She had bilateral lower extremities edema. Her labs showed creatinine 5.4 mg/dl, BUN 42 mg/dl, and CPK 167 IU/L. Urine analysis positive for dysmorphic RBCs. 24-hour urine protein was 820 mg. Hepatitis serologies, Anti-dsDNA, SPEP, UPEP, C-ANCA and PR-3 were negative. Her ANA, P-ANCA and MPO titers were positive. Her C3 was low. C4 was normal. Renal biopsy revealed C3 dominant glomerulonephritis with crescents and moderate interstitial fibrosis. C4d was negative. Hydralazine was discontinued. With worsening renal parameters, she was initiated on hemodialysis. Trial of Steroids and CellCept did not show any response and she remains on hemodialysis.

**Discussion:** The C3 glomerulopathies are a group of rare kidney diseases characterized by complement dysregulation occurring in the glomerular microenvironment, which results in prominent complement C3 deposition. Most patients are treated with steroids in combination with either cyclophosphamide or Mycophenolate mofetil. Rituximab has been used in some case reports. To our knowledge, this is the first reported case of C3 GN after receiving the COVID-19 vaccine. In our case, the temporal association suggests an immune response to vaccine as a potential trigger. 1. Lebedev L. and Wechsler

## SA-PO677

### A Heavy Heart and Grieving Kidneys: C3 Glomerulonephritis Complicated With Cardiac Tamponade

Wilfredo M. Pedreira, Charlynn De Jesus Ramos, Jaymilitte Bosques, Carlos Cortes, Mario J. Robles-Franceschini. *VA Caribbean Healthcare System, San Juan, Puerto Rico.*

**Introduction:** C3 glomerulopathies are rare complement-mediated kidney diseases classified as Dense Deposit Disease or C3 Glomerulonephritis (GN) based on structural manifestations on electron microscopy (EM), both which result after complement cascade dysregulation. Most common clinical presentations are proteinuria, hematuria, altered kidney function & hypertension. We herein present a case of C3GN with nephrotic syndrome (NS) & a rare complication.

**Case Description:** 66 y/o man recently hospitalized due to uncontrolled hypertension, new-onset NS, atrial fibrillation, & pneumonia developed involuntary movements, hypoxemia & hypotension days after discharge. Kidney biopsy results were pending & had been started on apixaban at discharge. POCUS: large pericardial effusion with right ventricular collapse during diastole. He was intubated & pericardiocentesis performed. Pericardial fluid: blood & inflammatory cells, other laboratories negative. Serum Cr: 2.58mg/dL BUN: 59.0mg/dL Alb:2.5g/dL Urine Prot/Cr: 6.37g. Kidney biopsy's light microscopy: diffuse mesangial & endocapillary cell proliferative GN with crescents. Immunofluorescence: IgM & kappa light chains: trace, C1q: +1, C3: +2, others: negative. EM: Small sub-endothelial deposits, no sub-epithelial nor mesangial deposits, & foot process effacement. Labs: decreased C3 & C4, increased ESR & CRP, rheumatologic, hematologic (including monoclonal gammopathy) & infectious (except IgG mycoplasma) workup negative. Patient met criteria for C3GN. Patient improved & was later discharged, currently on immunosuppressive therapy.

**Discussion:** Few reports of cardiac tamponade secondary to GN are present in the literature & to our knowledge, none related to C3GN. Although no mechanism has been explained in these patients, one could elucidate that circulatory congestion from NS could lead to formation of a pericardial effusion. Although recently started on apixaban, there is no evidence of increased risk of cardiac tamponade in anticoagulated patients compared with non-anticoagulated. Timely recognition of this unusual & lethal complication of Nephrotic Syndrome may prevent deaths.

## SA-PO678

### Reduced Dose Non-Cyclical Oral Cyclophosphamide and Prednisolone for Membranous Nephropathy

Karppagavalli Subramaniam, Srimathi Ponnusamy, Mangalakumar Veerasamy. *KMCH, Coimbatore, India.*

**Background:** Calcineurin inhibitors, rituximab and cyclic steroid & cyclophosphamide are the main therapeutic options in membranous nephropathy (MN). We describe the effect of non-cyclical reduced dose oral cyclophosphamide/ prednisolone (nCCP) in this group.

**Methods:** Patients were given oral cyclophosphamide (1.5mg/kg body weight/day) and prednisolone (0.5mg/kg body weight/day) for 3 months. At 3 months cyclophosphamide was stopped and prednisolone was tapered over the ensuing 4-7 weeks at a decremental rate of 5mg/week.

**Results:** Patient characteristics are described in table 1. Remission rates are given in figure 1. 3 patients experienced major adverse events (pneumonia -2, zoster-1, hemorrhagic cystitis-1).

**Conclusions:** nCCP regime appears to have comparable effect in inducing proteinuria remission at 6 & 12 months in this retrospective study and it was achieved using lower dose of cyclophosphamide. The latter may help to reduce cumulative cyclophosphamide related toxicities. This regime avoids pulse steroid infusion without losing the efficacy. Corticosteroid and cyclophosphamide were used simultaneously and whether this could help to use lower doses of cyclophosphamide merits further evaluation. Despite using lower dose of cyclophosphamide (1.5mg/kg as opposed to 2mg/kg in RI-CYCLO study) 1 of our patients developed hemorrhagic cystitis raises the important safety question about the use of cytotoxic agents.

### Safety and Efficacy of Felzartamab (MOR202) in Anti-Phospholipase A2 Receptor (PLA2R) Autoantibody-Positive Membranous Nephropathy: The M-PLACE Study

Brad H. Rovin,<sup>1</sup> Pierre M. Ronco,<sup>2,10</sup> Jack F. Wetzels,<sup>3</sup> Sharon G. Adler,<sup>4</sup> Isabelle Ayoub,<sup>1</sup> Philippe Zaoui,<sup>5</sup> Seung Hyeok Han,<sup>6</sup> Julia Jauch-Lembach,<sup>7</sup> Nicola Faulhaber,<sup>7</sup> Jie Cui,<sup>8</sup> Stefan Haertle,<sup>7</sup> Ben Sprangers.<sup>9</sup> <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>Sorbonne Université and INSERM UMRS 1155, Paris, France; <sup>3</sup>Radboud University Medical Center, Nijmegen, Netherlands; <sup>4</sup>Lundquist Research Institute at Harbor UCLA, Torrance, CA; <sup>5</sup>Centre Hospitalier Universitaire Grenoble Alpes, Grenoble, France; <sup>6</sup>Yonsei University College of Medicine, Seoul, Republic of Korea; <sup>7</sup>MorphoSys AG, Planegg, Germany; <sup>8</sup>MorphoSys US Inc., Boston, MA; <sup>9</sup>University Hospitals Leuven, Leuven, Belgium; <sup>10</sup>Centre Hospitalier Le Mans, Le Mans, France.

**Background:** Primary membranous nephropathy (MN) is an autoimmune kidney disease. Depleting CD20-/CD38+ plasma cells, potentially a main source of autoantibodies, may be an effective treatment (Tx) strategy for MN, particularly in patients (pts) with high PLA2R Ab titers. This interim analysis reports proof-of-mechanism data for felzartamab, a fully human IgG1 anti-CD38 mAb.

**Methods:** M-PLACE (NCT04145440) is a Phase Ib/IIa, open-label, multicenter, multinational study of adults with anti-PLA2R Abs-associated MN requiring immunosuppressive therapy (IST). Cohort 1: newly diagnosed and IST-relapsed pts; Cohort 2: IST-refractory pts. Pts received 9 felzartamab infusions (16 mg/kg) over six 28-day cycles, followed by a 28-week follow-up. Primary endpoints are incidence and severity of Tx-emergent adverse events (TEAEs); key secondary endpoint is the immunologic response rate based on anti-PLA2R Ab reductions; exploratory endpoints include the effect of Tx on 24h UPCR reduction.

**Results:** By April 10, 2022, 31 pts were enrolled from 21 sites in N. America, Asia-Pacific, and Europe (Cohort 1, n=18; Cohort 2, n=13); 23 pts have completed the Tx phase (Cohort 2, n=9). Mean (SD) age was 57.5 (11.8) years and 77.4% were male. At baseline, mean circulating anti-PLA2R Ab titer was 247.1 (259.3) U/mL; mean UPCR was 6.4 (2.2) g/g; mean eGFR was 60.2 (20.0) mL/min/1.73m<sup>2</sup>. Overall, 27 pts (87%) had at least one TEAE; TEAEs were mostly mild/moderate in severity and the majority resolved. The most commonly reported TEAE was infusion-related reaction (29% of pts; one Grade 3). Five pts (16%) experienced serious TEAEs. A ≥50% reduction in anti-PLA2R Ab titer from baseline was shown in 26/31 pts (84%). Change in anti-PLA2R Ab titer was generally followed by a timely change in UPCR. At ~12 months, 4/12 pts with EOS data showed >50% reduction in UPCR, including one refractory pt.

**Conclusions:** Longer follow-up of the M-PLACE study shows safety data consistent with the safety profile previously described and as expected in this underlying population. The early and pronounced anti-PLA2R Ab responses observed with felzartamab are encouraging, including in hard-to-treat patients; long-term UPCR responses will be further evaluated.

**Funding:** Commercial Support - MorphoSys AG

## SA-PO680

### PLA2R-Membranous Nephropathy in Black Americans: A Single Center Cohort

Swetha Rani Kanduri, Vipin Varghese, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Medical Center, New Orleans, LA.

**Background:** Phospholipase A2 receptor (PLA2R) antibody-associated membranous nephropathy (PLA2R-MN) is the most common type of MN. Although PLA2R-MN has been well characterized in cohorts in Asia, Europe and North America, description of its phenotype in a predominantly black population is lacking. We hypothesize that PLA2R-MN in black individuals is associated with unique serological or clinical phenotype.

**Methods:** We retrospectively reviewed records of adult patients diagnosed with PLA2R-MN in native kidneys over the last 5 years at a single medical center. Trajectories of anti-PLA2R titers were extracted. Rates of serological remission (SR) (anti-PLA2R < 2 RU/mL), partial remission (PR) [reduction in urine protein-to-creatinine ratio (UPCR) to 0.5 to 3.0 g/g without worsening serum creatinine (sCr)] and complete remission (CR) (UPCR < 0.5 g/g) were assessed at varying time points within a 24-month interval and compared between ethnic groups

**Results:** We included 41 patients, median age 61 years, 39% women, 61% self-identified black, 29% white, 5% Hispanic, and 5% Asian. PLA2R antigen was biopsy-

verified in 30/41 (73%). Median peak anti-PLA2R titer was 269 (21 - >1500) vs 100 (24 - 850) RU/mL for black patients (n=25) and other races (n=16), respectively (p=0.01). Median sCr was 1.0 mg/dL for both groups (p=0.58), whereas the median UPCR were 5.8 g/g in black patients and 5.8 g/g in others (p=0.9). Patients receiving immunosuppression (IST) (cyclophosphamide, rituximab, tacrolimus-based regimens) included 14/25 (56%) black patients and 7/16 (44%) of other races. No patient on either race group achieved SR by 3 months. Although the overall SR rates after 24 months were comparable (52% vs 56%), SR was achieved at a later time for black patients compared to other races [5/13 (38%) vs 8/9 (88%)] achieved SR by 12 months in black and non-black patients, respectively, p=0.022]. Comparable PR and CR rates were observed

**Conclusions:** Individuals of black race with PLA2R-MN present with higher peak anti-PLA2R titers and may take longer to achieve serological remission with IST. The temporal difference in achieving SR was not driven by less common use of IST. Prospective studies will be needed to expand on this observation and its potential implication on harder clinical endpoints

## SA-PO681

### Prognostic Value of Anti-PLA2R-Ab on Long Term Outcomes in Primary Membranous Nephropathy

Omar S. Ragy,<sup>1</sup> Sebastian G. Bate,<sup>2</sup> Samar Qaisera Bukhari,<sup>3</sup> Arif Khwaja,<sup>3</sup> Anirudh Rao,<sup>4</sup> Durga Anil K Kanigicherla.<sup>2</sup> <sup>1</sup>Southmead Hospital, Bristol, United Kingdom; <sup>2</sup>Manchester Metropolitan University, Manchester, United Kingdom; <sup>3</sup>The University of Sheffield, Sheffield, United Kingdom; <sup>4</sup>NHS England and NHS Improvement North West, Manchester, United Kingdom.

**Background:** Better risk prediction tools are needed to improve longer-term outcomes in Primary Membranous Nephropathy (PMN). Studies well established the diagnostic utility of the Anti-PLA2R antibody test in PMN, but its prognostic value in clinical practice remains unclear. We aimed to assess a) the prognostic value of the Anti-PLA2R-Ab and compared its performance to conventional clinical markers of disease activity and b) the impact of testing on disease outcomes compared to outcomes before its discovery.

**Methods:** 222 patients from three centres in the North of England, UK who were diagnosed with PMN from January 2003 to July 2019 and had a serum Anti-PLA2R-Ab test (contemporaneously or retrospectively) were included. Baseline markers including protein creatinine ratio (uPCR), estimated GFR (eGFR), Anti-PLA2R-Ab status (positive and negative), Ab titre (high and low), and time of test (contemporary and retrospective) were assessed for risk with outcomes. The primary outcome was time to progression (composite of doubling of serum creatinine, CKD5, and death). Secondary outcomes were time to partial remission (PR) and time to immunosuppression. Cox proportional hazard (PH) models adjusted for baseline conventional biomarkers were used.

**Results:** Cox PH tests did not show significant correlation between Anti-PLA2R-Ab status (positive vs negative) and both time to progression (aHR 0.93, p=0.71), and time to PR (aHR 0.84, p=0.13). A similar lack of association with time to progression was noted for the Ab titre, High vs Low (aHR 1.07, p=0.77); there was a trend for a longer time to PR in the high Ab titre group (aHR 0.794, p=0.08). There was a strong association between conventional clinical markers: eGFR (HRz 0.767, p<0.05) and uPCR (HRz 1.44, p<0.005) and time to progression among all patients; and eGFR (HRz 0.61 p<0.005), among PLA2R-Ab positive patients. Time to Immunosuppression was significantly shorter in both the positive (HR=1.450, p<0.05) and high titre patients (aHR=1.42, p=0.02).

**Conclusions:** Anti-PLA2R-Ab status or Ab-titres do not outperform baseline conventional markers of eGFR and proteinuria in predicting disease progression in the longer term. Further studies are needed to best harness the utility of antibody testing in predicting disease progression in PMN.

## SA-PO682

### The Clinical Significance of Circulating piRNAs in Extracellular Vesicles in Patients With Idiopathic Membranous Nephropathy

Soonhyo Kwon,<sup>1</sup> In O Sun.<sup>2</sup> <sup>1</sup>Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; <sup>2</sup>Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

**Background:** PIWI-interacting RNAs (piRNAs) are a distinct group of small non coding RNAs that regulate gene expression. Although piRNAs has been studied in predicting prognosis in kidney cancer, little is known about piRNAs in glomerular disease. Therefore, we investigated the clinical significance of piRNAs in nephrotic syndrome.

**Methods:** We prospectively enrolled 60 participants, including those with idiopathic nephrotic syndrome (IMN) (n=19) and idiopathic nephrotic syndrome (INS) (n=21) and healthy volunteers (HVs; n=20) in this study. Using RNA sequencing, we assessed the serum extracellular vesicle (EV)-piRNA profiles of all participants. We investigated whether the piRNAs could be helpful to discriminate IMN from INS and predict the treatment response of patients with IMN. Based on achievement of clinical remission, IMN patients were divided in to two groups [IMN-W (n=9) vs IMN-R (n=10)].

**Results:** We found 11 piRNAs that were upregulated and 6 that were downregulated in patients with IMN when compared to HVs. There were 22 miRNAs that were upregulated and 23 that were downregulated in patients with IMN when compared to the INS. Among these miRNAs, we found 5 piRNAs, whose levels were significantly up- or downregulated in patients with IMN compared to HVs and patients with INS. There were 50 upregulated and 11 downregulated piRNAs in patients with IMN-R when compared to patients with IMN-W. Of these piRNAs, the expression level of piRNA-42775 and piRNA-36743 were found to be inversely correlated with proteinuria on kidney biopsy.

Meanwhile, a positive correlation was observed between renal function and expression of piRNA-43108.

**Conclusions:** Patients with IMN have a distinct EV-piRNA expression profile compared with INS and HVs. In addition, circulating EV-piRNAs could be useful to predict the treatment response of IMN patients.

## SA-PO683

### Is Lupus Podocytopathy Always a Benign Glomerulopathy?

**Cristiane B. Dias,** Lectícia Jorge, Luis Yu, Viktoria Woronik. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

**Background:** The aim of the study is to evaluate the clinical and histological characteristics, as well as evolution of patients with Lupus Podocytopathy (LP). LP is defined as patients with Systemic Lupus Erythematosus (SLE) and nephrotic syndrome whose diagnostic renal biopsy showed light microscopy with normal glomeruli (MCD) or focal segmental glomerulosclerosis (FSGS) or mesangial proliferation (MP), in addition to immunofluorescence with the absence of sub-epithelial or sub-endothelial deposits. For patients with a renal biopsy compatible with FSGS, the nephrotic presentation was not required as long as there was no chronicity on the renal biopsy.

**Methods:** This is a one Center retrospective study with LP patients submitted to renal biopsies from 1994 to 2017. Patients are highly responsive to corticosteroids but relapses are very common thus the impact of long-terms outcomes is unclear in literature.

**Results:** During the study period, 31 patients met the criteria for LP and had a median age of 32 (28-40) years at the time of renal biopsy, median proteinuria of 4.9 (3.7-8.27) g/day and serum albumin of 2.18 (1.57-2.65) g/dl. Only two patients did not have nephrotic syndrome at the time of renal biopsy, in addition, 42% had CKDEPI <60 ml/min/1.73m<sup>2</sup> and 25.8% had serum low C3 complement level. The time between the diagnosis of SLE and LP was 10 (2-33) months in 28 patients, whereas in three the renal diagnosis occurred before SLE. Histological diagnosis comprised 22 FSGS, 7 MCD and 2 MP. On follow-up owing to clinical criteria of progression and/or persistent proteinuria, ten patients underwent renal rebiopsy, highlighting that 5 patients transitioned to other histological class (3 Lupus Nephritis class IV originally one FSGS and two MP while 2 MP were originally MCD), others 5 patients remained as originally (4 FSGS with increased chronicity and 1 MCD). The median of follow-up time was 84 (53-120) months, being that two patients were lost to follow-up, while five patients (17%) had CKDEPI below 60 ml/min/1.73m<sup>2</sup> and one was on dialysis.

**Conclusions:** LP has a variable course with transition to more severe histological classe of Lupus Nephritis (class IV in three patients out of 31) and evolution to chronic kidney disease in approximately 20% of patients.

## SA-PO684

### The Trajectory of Glomerular and Tubulointerstitial Lesions After Treatment of Lupus Nephritis

**Ana Malvar,**<sup>1</sup> Valeria G. Alberton,<sup>1</sup> Bruno J. Lococo,<sup>1</sup> Maria C. Lourenco,<sup>1</sup> Joaquín Martínez,<sup>1</sup> Mauro Elencajaj,<sup>1</sup> Haikady N. Nagaraja,<sup>2</sup> Brad H. Rovin.<sup>2</sup> <sup>1</sup>Hospital Fernandez, Buenos Aires, Argentina; <sup>2</sup>The Ohio State University, Columbus, OH.

**Background:** Proliferative lupus nephritis (LN) is characterized histologically by glomerular and tubulointerstitial (TI) inflammation that presumably must resolve with treatment to achieve remission. Here we sought to document the trajectory of lesion resolution using serial kidney biopsies during LN treatment.

**Methods:** A cohort of proliferative LN patients was prospectively followed during treatment with standard LN therapy. Patients had a diagnostic kidney biopsy (Bx1), a biopsy generally within the first year of treatment (Bx2), and a biopsy after at least 3 years of total immunosuppression (Bx3). The NIH activity and chronicity indices (AI, CI) were calculated at each biopsy.

**Results:** The cohort (n=110) was followed for a median (range) of 109 (34, 202) months. Patients were treated with either MMF or cyclophosphamide initially. Overall, the patients did very well. Only 2 patients developed ESKD by last follow-up and only 9 patients had CKD (eGFR <60 ml/min/1.73m<sup>2</sup>), but this was pre-existing in 4 patients. AI followed an exponential decline after starting treatment. At the time of Bx2 (an average 9.7 months after Bx1), the percent of biopsies positive for cellular crescents (CC), fibrinoid necrosis (FN), and neutrophil infiltration NEU) fell precipitously, while the decline of endocapillary hypercellularity (EH) and hyaline deposits (HD) was more gradual. At Bx3 (an average of 42.6 months after Bx1) fewer than 5% of biopsies had residual CC, FN, NEU, or interstitial inflammation, but 25% still had EH and HD. By immunofluorescence microscopy over 90% of Bx1 biopsies had IgG and complement components C3 and C1q. At Bx3 only 30-40% of biopsies continued to show IF for complement, but IgG was still present in 66% of biopsies. The CI increased after Bx1. The rate of increase of all CI components was greatest from Bx1 to Bx2, slowed between Bx2 and Bx3, and actually declined for fibrous crescents.

**Conclusions:** These data show that the most inflammatory lesions found in proliferative LN are rapidly responsive to immunosuppression, but EH and HD are more resistant. Complement deposition resolves quickly, but IgG is present in glomeruli for a long time. Despite rapid improvement in active inflammation, kidneys sustain chronic damage early in the disease course.

### Feasibility and Safety of Obtaining Kidney Biopsy Research Cores in a Predominantly Black Lupus Nephritis Patient Population

**Jason Cobb,**<sup>1</sup> Alton B. Farris,<sup>1</sup> Ahmad Akhgar,<sup>2</sup> Gabor G. Illei,<sup>2</sup> Dominic P. Sinibaldi,<sup>2</sup> Wendy I. White,<sup>2</sup> S. Sam Lim.<sup>1</sup> <sup>1</sup>Emory University School of Medicine, Atlanta, GA; <sup>2</sup>AstraZeneca Pharmaceuticals LP, Wilmington, DE.

**Background:** Lupus nephritis (LN) occurs in >50% of patients with SLE. Black patients disproportionately suffer from LN with more severe disease. Histologic examination of kidney tissue is required for definitive diagnosis and advancing the science. We are reporting the feasibility and safety of obtaining kidney biopsy research cores in a high-risk group of LN patients as part of a study that was carried out to detect novel biomarkers associated with LN.

**Methods:** Patients suspected of having LN were referred for a diagnostic kidney biopsy, and all had estimated proteinuria >500 mg/g. Patients consented to an extra pass for the obtainment of a research core. Kidney biopsies were performed at three hospitals: Emory University Hospital, Emory University Hospital Midtown, and Grady Memorial Hospital.

**Results:** A total of 47 patients suspected of LN were enrolled from 2014-2017. All patients underwent at least 3 core passes using standard 16 cm, 18 gauge biopsy needles by interventional radiologists (CT guided) or nephrology services (ultrasound guided). A total of 46 LN patients had a kidney biopsy and 40 patients had sufficient research core samples. Standard of care for CT guided kidney biopsy is same-day hospital discharge and an overnight stay after an ultrasound guided biopsy. Patients were 82% female and 90% Black race. The mean systolic blood pressure was 135 ± 17 mmHg. The mean hemoglobin was 10±1.8 g/dL and mean platelet count 219±94 10<sup>3</sup>/mL. Only one LN patient had an adverse outcome requiring hospital admission after a CT guided biopsy and that patient required renal artery embolization but did not receive a blood transfusion.

**Conclusions:** We demonstrated that the obtainment of research core samples in addition to the usual cores needed for a diagnostic kidney biopsy is feasible and overall safe with only 1 patient requiring an unplanned hospital admission. Suspected LN patients were generally agreeable to an extra pass for research purposes, particularly notable in this sample of mostly Black patients. The obtainment of research kidney biopsy cores is a newer discussion topic in nephrology, and this study is even more unique since it was successfully carried out in SLE patients which are likely at higher risk of bleeding due to higher rates of thrombocytopenia and anemia.

## SA-PO686

### Repeated Renal Flares in Lupus Nephritis Are Associated With Decreased Response to Therapy, Progression of Kidney Disease, and Patient Survival

**Sofia E. M. Macedo,**<sup>1,2</sup> Abril A. Pérez Arias,<sup>1,3</sup> María F. Zavala Miranda,<sup>1,2</sup> Cristinoc Cruz,<sup>1,2</sup> Luis E. Morales-Buenrostro,<sup>1,2</sup> Juan M. Mejia-Vilet.<sup>1,2</sup> <sup>1</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; <sup>2</sup>Universidad Nacional Autonoma de Mexico, Mexico City, Mexico; <sup>3</sup>Universidad Autonoma de Baja California, Mexicali, Mexico.

**Background:** Repeated renal flares in lupus nephritis (LN) occur in some patients with systemic lupus erythematosus and have been associated with worse long-term kidney function. This study aimed to assess the impact of repeated LN flares in response to therapy, kidney and patient prognosis.

**Methods:** All patients from a well-characterized biopsy-proven LN cohort between 2008 and 2018 were segregated into three groups according to the number of LN flare when they entered our cohort: first LN flare, second LN flare, or third LN flare. The following outcomes were evaluated by unadjusted and adjusted time-to-event analyses: complete and partial response, disease relapses, progression to decline of 30% of the eGFR, doubling of serum creatinine, end-stage kidney disease, and patient survival.

**Results:** A total of 441 patients were included: 257 (58%) in their first LN flare, 102 (23%) in their second LN flare, and 82 (19%) in their third LN flare. There were significant differences in LN flare presentation in age, eGFR, serum albumin, pyuria, and hematuria among groups. The NIH chronicity indices and the percentage of patients with vascular lesions were higher in groups at progressive LN flares. In the adjusted analyses, complete and partial response rates decreased, as well as kidney and patient survival, at a progressive number of LN flares. No differences in the dynamic course of all surveillance laboratory parameters were observed in the first year after initial therapy among LN flare groups.

**Conclusions:** A progressive number of LN flares is associated with a lower response to therapy and an adverse prognosis for kidney function and patient survival. The history of LN flares should be accounted for in clinical practice and clinical trials in lupus nephritis.

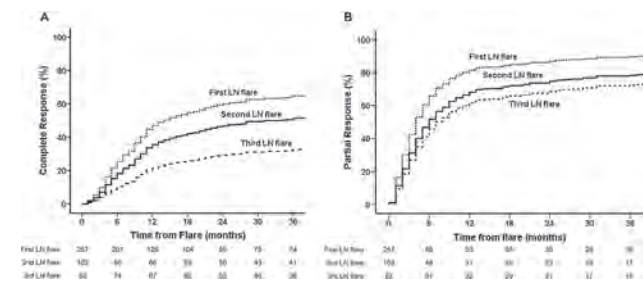

Figure 1. Complete (A) and Partial (B) response rates for lupus nephritis patients in their first, second, or third flare.

SA-PO687

Outcomes of Immunosuppressive Therapy in Lupus Nephritis  
Pamela O. Tan Lim, National Kidney and Transplant Institute, Quezon City, Philippines.

**Background:** Lupus Nephritis (LN) is one of the severe manifestations of Systemic Lupus Erythematosus (SLE). Renal involvement is seen in about >50% of the patients which caused significant morbidity. Over the past decades, the survival rate of patients with LN has improved dramatically because of improvement in the classification of patients, improvement in diagnosis, more intensive treatment with the use of immunosuppressive/ cytotoxic agents, high dose corticosteroid pulse therapy, and advances in the treatment of hypertension, infections and renal failure.

**Methods:** Biopsy proven LN patients, diagnosed from January 2015 to December 2019, and started on immunosuppressive therapy were included. The demographic and clinical characteristics were retrieved from electronic medical records. Laboratory results at baseline, at initiation of treatment, and at time of remission and flare were assessed.

**Results:** Fifty-five biopsy proven LN patients were included. Median age was 27 years at time of biopsy and majority were female (89.09%). Thirty one (56.36%) patients had Class IV LN; the median lupus activity score was 4 (ranging from 0-12), and chronicity score was 2 (ranging from 0-12). Complete remission was observed in 16 (29.09%) patients and partial remission was noted in 31 (56.36%) patients. There was no response in three patients, ESRD in five patients and no deaths. The time to remission is at 6 months on the average and the median time to renal flare was 18 months. The risk of renal flares increases by 2% for every one month increase in the delay between diagnosis and treatment.

**Conclusions:** Among patients diagnosed with LN, treatment with induction therapy followed by maintenance therapy ensured good efficacy. The occurrence of renal flare after initiation of treatment was 18 months. Early response to treatment on diagnosis may lessen risk of renal flares.

Outcomes in lupus nephritis	
	Frequency (%); Median [95% CI]
Remission	47 (85.45)
Complete	16 (29.09)
Partial	31 (56.36)
No response	3 (5.45)
ESRD	5 (9.09)
Death	0
Time to partial or complete remission from start of treatment (months)	6 [5 to 7]
Lupus flare	15 (27.27)
Time to lupus flare from start of treatment (months)	18 [11 to 18]

SA-PO688

Voclosporin Induces Systemic Lipidomic Alterations: Implications in the Remission of Lupus Nephritis  
Farsad Afshinnia,<sup>1</sup> Linda M. Rehaume,<sup>2</sup> Jennifer Cross,<sup>2</sup> Robert B. Huizinga,<sup>2</sup> Subramaniam Pennathur.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

**Background:** Voclosporin is a novel calcineurin inhibitor indicated for the treatment of adults with active lupus nephritis (LN). Cardiovascular disease (CVD) is a major cause of morbidity and mortality in SLE patients, and LN is an independent CVD risk factor. The AURORA 1 trial showed favorable renal clinical response and changes in traditional lipoproteins with voclosporin. We hypothesize that the beneficial therapeutic response is mediated in part by alteration in circulating lipids.

**Methods:** In a lipidomic analysis, 918 serum lipids in 14 classes from baseline and week 52 of randomly selected participants from control (placebo) (N=30) and voclosporin (N=28) arms of the AURORA 1 trial (ClinicalTrials.gov, NCT03021499; EudraCT, 2016-004045-81) were compared. All patients received MMF and low-dose steroids. The difference of lipids at week 52 from baseline was calculated, z-score standardized, and used in mixed linear models.

**Results:** The alterations of lipid class levels were assessed as a function of voclosporin effect and by achievement of either complete renal response (CRR) or partial renal response (PRR) (Table). Voclosporin and renal clinical response (CRR or PRR) contributed to decline in CERs and TAGs and increase in DCERs and PIs independent of each other. Results indicate the additive effects of voclosporin and renal clinical response on alteration of corresponding lipids. Voclosporin, CRR and PRR were independently associated with alteration of PC(C16), PIs, and TAGs. An integrative analysis showed significant correlations between saturated DAGs and MAGs (C>16), TAGs, SMs, CERs, unsaturated PEPs, and palmitoyl PCs(C16) after controlling for CRR or PRR.

**Conclusions:** CERs, DCERs, PIs, and TAGs are altered by voclosporin. Alterations of PC, PI and TAGs correlate with renal outcome independent of voclosporin. Collectively, these findings suggest that voclosporin reduces lipogenesis by decreasing incorporation of fatty acid precursors, and a favorable therapeutic response is mediated in part by promotion of change in corresponding lipid class.

**Funding:** Commercial Support - Aurinia Pharmaceuticals Inc.

Alterations of lipids by main effect of voclosporin, complete renal response (CRR), partial renal response (PRR), and their interaction				
Lipids	Voclosporin effect (N=28 vs N=30 in control)	CRR effect (N=14 with CRR vs N=44 with no CRR)	PRR effect (N=30 with PRR vs N=28 with no PRR)	Interaction between voclosporin and CRR
Ceramides (CER)	Decreased	Decreased	Decreased	Decreased
Dihydroceramides (DCER)	Increased	Increased	Increased	Increased
Monacylglycerol (MAG) (C12-18)	Decreased	Decreased	Decreased	Decreased
Saturated Diacylglycerol (DAG)	Decreased	Decreased	Decreased	Decreased
Lysophosphatidylcholine (LPC) (C14-18)	Decreased	Decreased	Decreased	Decreased
Phosphatidylcholine (PC) (C16)	Decreased	Decreased	Decreased	Decreased
Phosphatidylserine (PS)	Increased	Increased	Increased	Increased
Sphingomyelin (SM)	Decreased	Decreased	Decreased	Decreased
Triacylglycerol (TAG)	Decreased	Decreased	Decreased	Decreased

Note: Each column shows the change in mean of lipid class from baseline to week 52 by the main effects of voclosporin, clinical response and their interactions. Complete renal response assessed at Week 52 was defined as urine protein creatinine ratio (UPCR) <0.5 mg/mg, stable renal function (eGFR >60 mL/min/1.73 m<sup>2</sup> or no decrease >20% from baseline), presence of sustained, low-dose steroids (in the 8 weeks prior to assessment) and no use of rescue medication. Partial renal response defined as >50% reduction from baseline in UPCR. P-values are <0.02.

SA-PO689

Comparison of Clinical Efficacy of Centrifugal-Membranous Hybrid Double Filtration Plasmapheresis and Membranous Double Filtration Plasmapheresis on Severe Lupus Nephritis  
Jianhua Dong, Li Huang, Wenjing Fan, Yongchun Ge. JinLing Hospital, Nanjing, China.

**Background:** The Study delves into the clinical efficacy and safety of centrifugal-Membranous Hybrid double filtration plasmapheresis (C/M hybrid DFPP) on severe lupus nephritis (LN) by comparing it with membranous DFPP (M DFPP).

**Methods:** A retrospective cohort study was conducted in 70 patients who were diagnosed with severe LN and had received DFPP treatment from 2016 to 2021. 51 patients received C/M hybrid DFPP, and 19 patients received M DFPP. The differences in clinical efficacy, vascular access, dosage of anticoagulant, treatment cost and adverse events were compared in the two types of DFPP.

**Results:** A total of 181 DFPPs (133 C/M hybrid DFPPs and 48 M DFPPs) were performed. The ANA, AdsDNA titer, quantitative urinary protein, urinary red blood cell count and serum creatinine decreased and hemoglobin increased after the DFPP treatment and at 3<sup>rd</sup> month after treatment, however, there was no significant difference between the two groups. All patients built the vascular access via the central venous catheter in M DFPP, while 8 patients built the vascular access via puncturing into the peripheral artery and vein in C/M hybrid DFPP. 34 patients (66.7%) received 4% citric acid alone for anticoagulation in C/M hybrid DFPP, the dosage of LMWH was significantly lower than that in M DFPP (1204±286 vs 4106±399IU, P<0.001). M DFPP had a significantly higher cost than C/M hybrid DFPP. 2 patients in M DFPP developed skin ectasis, epistaxis or aggravated alveolar hemorrhage, and 4 patients in C/M hybrid DFPP developed perioral numbness, numbness in distal extremities or tetany.

**Conclusions:** C/M hybrid DFPP could be a cost-effective treatment strategy applied in patients with severe LN.

### Systemic Lupus Erythematosus (SLE) Nephritis and COVID-19

Lakshmi Aishwarya Pavuluri,<sup>1</sup> Venkata A. Yalamanchili,<sup>2</sup> Ram Rapur.<sup>1</sup> Nephrology, SVIMS, Tirupati <sup>1</sup>Sri Venkateswara Institute of Medical Sciences, Tirupati, India; <sup>2</sup>Dallas Nephrology Associates, Dallas, TX.

**Background:** We report the outcomes of renal biopsy proven SLE nephritis patients after COVID-19 infection from Sri Venkateswara Institute of Medical Sciences (SVIMS), a tertiary care referral center and University Hospital in Tirupati, India.

**Methods:** Our Institute has been declared as State COVID-19 hospital in the last week of the March 2020. From then, till now we had admitted and managed COVID-19 patients from several districts of Andhra Pradesh and neighbour states. We collected the data of patients with biopsy proven SLE nephritis contemporaneously from admission to the outcomes on a computerised proforma. We employed the following statistics. For the data of continuous variables and categorical variables, student t test and chi square tests were used respectively. For the risk factors for mortality univariate linear regression was used. We used Medcalc free online software.

**Results:** We had identified sixteen patients of SLE nephritis admitted with COVID-19 disease. Of them fourteen were females and two were males. The mean age was 29.3 years. Out of sixteen patients, seven patients, required mechanical ventilator and dialysis and eventually died during their hospitalization. One more patient expired due to disseminated tuberculosis (50%). We identified the patients who died were of younger age, had higher serum creatinine at presentation, higher CT severity score and lower serum albumin as factors which had significant effect on mortality.

**Conclusions:** Of the more than 20 studies published on SLE patients with COVID-19, none of the studies focussed on the lupus nephritis. Our results suggested that with the approximately 50% mortality the COVID -19 disease had a calamitous effect on SLE nephritis patients.

Parameters related to systemic lupus erythematosus nephritis

Parameter	Result before COVID-19 disease	Result during/after COVID-19 disease
Anti dsDNA titre (reference range: > 40 WHO IU/mL - positive)	163.8 ± 30.3	147.6 ± 23.0
Complement C3 (reference range: 91 - 156 mg/dL)	70.9 ± 8.9	81.0 ± 7.6
Complement C4 (reference range: 20 - 50 mg/dL)	18.4 ± 2.1	21.3 ± 4.5
Serum creatinine (mg/dL) in patients without renal failure (n=8) (mean ± SD) (range)	1.17 ± 0.20 (0.9-1.4)	1.32 ± 0.22 (1.05-1.24)
Serum creatinine (mg/dL) in patients with renal failure (n=8) (mean ± SD) (range)	7.82 ± 3.25 (3.5-12.4)	9.05 ± 0.6 (6.1-11.9)
Renal biopsy in SLE patients admitted with COVID-19 (n=16)	Class IV: 10 Class III+V: 4 Class V: 2	Class VI: 1*
Treatment of SLE nephritis	Steroids, cyclophosphamide and ACE-inhibitors	Steroids

\* A 17-year-girl, SLE nephritis Class IV diagnosed before COVID-19 presented with haematuria after the diagnosis of COVID-19. A repeat renal biopsy done during COVID-19 disease revealed crescents

### The First-Year Course of Urine MCP-1 Is Associated With Response to the Initial Therapy and Long-Term Prognosis

Abriel A. Pérez Arias,<sup>1,2</sup> Sofia E. M. Macedo,<sup>1,3</sup> María F. Zavala Miranda,<sup>1,3</sup> Cristinon Cruz,<sup>1,3</sup> Luis E. Morales-Buenrostro,<sup>1,3</sup> Juan M. Mejia-Vilet.<sup>1,3</sup> <sup>1</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; <sup>2</sup>Universidad Autonoma de Baja California, Mexicali, Mexico; <sup>3</sup>Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

**Background:** There is a need for useful biomarkers in lupus nephritis. The monocyte chemoattractant protein 1 (MCP-1) has been previously proposed as a biomarker of disease activity, however, it has been study at single timepoints and with short follow-up. We aimed to assess the course of uMCP-1 and its association with response to therapy and long-term kidney function in a prospective cohort of adults who received a kidney biopsy for suspicion of active lupus nephritis (LN).

**Methods:** Subjects were segregated into a histologically active LN group and a histologically chronic LN group. Both groups were followed for >36 months and urine were collected at flare, 3-, 6-, and 12-months of follow-up. The association between the

course of uMCP-1, response to treatment, and progression to 30% loss of the eGFR was evaluated by linear mixed models for repeated measures.

**Results:** A kidney biopsy was performed on 125 subjects. In 114 the report was consistent with histologically active LN, and in 11 with chronic LN. Urine MCP-1 levels were significantly higher in the active LN than in the chronic LN group. Urine MCP-1 levels correlated with the histological findings of cellular crescents, endocapillary hypercellularity, interstitial inflammation, glomerular sclerosis, interstitial fibrosis, and tubular atrophy. The mean estimates of uMCP-1 at flare were higher in the non-response group than in the complete response group, and decreased in the complete/partial response groups by the 3<sup>rd</sup> month, while they remained elevated in the non-response group. The mean estimates for uMCP-1 were higher at LN flare and remained elevated in patients who progressed to loss of 30% of the eGFR, while they decreased in patients with stable kidney function.

**Conclusions:** The first-year course of uMCP-1 is associated with response to therapy and kidney survival in lupus nephritis.

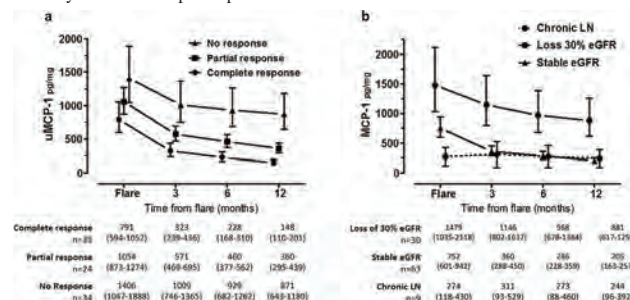

Figure 1. First-year course of urine MCP-1 levels according to response to therapy (a) and long-term kidney prognosis (b).

## SA-PO692

### Low Chronicity Score at Kidney Biopsy Predicts Renal Recovery From Dialysis in Patients With ANCA-Associated Vasculitis With Glomerulonephritis

Dalia Zubidat,<sup>1</sup> Marta I. Casal Moura,<sup>1</sup> Marc Patricio-Liébona,<sup>2</sup> Maria Jose Soler,<sup>2</sup> Fernanda G. Dos Santos,<sup>1</sup> Luca Nardelli,<sup>1</sup> Juan C. León Román,<sup>2</sup> Ciria L. De Sousa,<sup>1</sup> Ladan Zand,<sup>1</sup> Sanjeev Sethi,<sup>1</sup> Ulrich Specks,<sup>1</sup> Fernando C. Fervenza.<sup>1</sup> <sup>1</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>2</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain.

**Background:** Predictors of renal recovery from dialysis after remission-induction therapy in patients with ANCA-associated vasculitis with glomerulonephritis (AAV-GN) are not fully characterized.

**Methods:** We conducted a retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV (MPA and GPA) and active renal disease requiring dialysis followed between 1996-2021 at two tertiary care centers.

**Results:** We analyzed 110 patients that needed dialysis and had undergone kidney biopsy at the time of AAV-GN presentation. Seventy-nine patients (71.8%) remained permanently on dialysis, while 31 patients (28.2%) required dialysis only transiently (16 patients received PLEX). There were no differences in severity of the disease as assessed by BVAS/WG (8vs.8 points, p=0.990) nor in eGFR (9.7vs.9.1mL/min/1.73 m<sup>2</sup>, p=0.902). There were no differences in the activity index on kidney biopsies (assessed by the % of crescents or necrosis/total glomeruli). However, most patients who recovered from dialysis had a minimal/mild chronicity score (64.5vs.39.2%, p<0.0001), whereas patients that remained on dialysis more frequently had moderate/severe chronicity features (60.8vs.35.5%, p<0.0001). There were no differences in the remission-induction immunosuppressants, or use of i.v. methylprednisolone or PLEX. In patients who recovered from dialysis, rituximab was the most frequently used remission-maintenance treatment (42.9vs.10.0%, p=0.005). Mortality was higher in patients who remained on dialysis (35.4vs.12.9%, p=0.019). Minimal/mild scoring of the biopsy was a predictor of recovery from dialysis (OR 2.815; CI95% 1.187-6.675, p=0.019) in univariable analysis. Assuming a p<0.100, we performed a multivariable analysis, and when adjusted to the treatment with PLEX, minimal/mild scoring of the biopsy remained a predictor of recovery from dialysis (OR 2.529; CI95% 1.046-6.118, p=0.040) (Table 1).

**Conclusions:** In patients with AAV-GN, renal recovery from dialysis depends on the chronicity score of the kidney biopsy at the time of diagnosis and not on the use of PLEX.

Recovery from dialysis	Multivariable Logistic Regression	
	OR (95% CI)	p-value
Minimal / Mild grades (MCCS)	2.529 (1.046 - 6.118)	0.040
PLEX	1.701 (0.708 - 4.085)	0.235

**Renal Medullary Angiitis and Arteritis in ANCA Vasculitis: Clinico-Pathologic Features and Outcomes**

Grant Kirby,<sup>1</sup> Alana Dasgupta,<sup>1</sup> Abdulrahman K. Alabdulsalam,<sup>2</sup> Avi Z. Rosenberg,<sup>1</sup> Duvuru Geetha.<sup>1</sup> Johns Hopkins Nephrology <sup>1</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>2</sup>King Abdulaziz Medical City, Riyadh, Saudi Arabia.

**Background:** The hallmark of ANCA associated glomerulonephritis is a pauci-immune glomerulonephritis, with renal medullary angiitis (RMA) and arteritis (AR) reported infrequently. We sought to compare the clinico-pathologic characteristics, renal risk score (RRS) and outcomes of RMA and AR in ANCA-associated vasculitis (AAV) patients who underwent a diagnostic kidney biopsy.

**Methods:** AAV patients with a kidney biopsy diagnosis of RMA and AR were included. RMA was defined by the presence of interstitial hemorrhage in the medulla associated, polymorphonuclear leukocyte infiltrate and karyorrhectic debris. AR was defined by fibrinoid necrosis of the vessel wall and/or inflammatory infiltrate involving the media of the artery. Demographic, clinical and treatment details were extracted by record review. Descriptive statistics were analyzed to evaluate variables of interest.

**Results:** Of 136 AAV biopsies, 13 had RMA and 13 had AR. The mean (SD) age was 65 (19) yrs for RMA and 72 (9) yrs in AR. At entry all had severe disease with eGFR of  $\leq 20$ . There were no differences in ANCA type, entry eGFR, proteinuria or extra-renal vasculitis between the groups. All biopsies included cortex and medulla with a mean (SD) glomeruli of 9 (5) in RMA and 27 (30) in AR. There were no significant differences in the % of normal glomeruli, global sclerosis, glomerular necrosis, or crescents between RMA and RA. RRS was moderate/high in 69% of patients. All patients were treated with glucocorticoids and either cyclophosphamide or rituximab or mycophenolate. All patients with RMA achieved remission while 2 with AR had early mortality secondary to active vasculitis. Similar improvements in eGFR were noted at 12 M in both groups.

**Conclusions:** RMA and AR was seen in 10% of biopsies in our cohort and clinically presents with severely impaired renal function. Glomerular crescents, necrosis and interstitial inflammation with less chronicity are observed in both RMA and AR. Although, majority of RMA patients respond to immunosuppression with good kidney recovery, refractory vasculitis is seen 15% of patients with AR.

**Economic Evaluation of Azathioprine vs. Rituximab in ANCA-Vasculitis in the United States**

Lexy Ehler,<sup>1</sup> Vimal K. Derebail,<sup>1</sup> Susan L. Hogan,<sup>1</sup> Sherrie L. Aspinall,<sup>2,3</sup> Carolyn T. Thorpe.<sup>1,4</sup> <sup>1</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>VA Center for Health Equity Research and Promotion, Pittsburgh, PA; <sup>3</sup>University of Pittsburgh School of Pharmacy, Pittsburgh, PA; <sup>4</sup>Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, PA.

**Background:** Research indicates that rituximab (RTX) is superior to azathioprine (AZA) as a maintenance therapy in preventing relapse among patients in remission for ANCA-vasculitis (AV), including granulomatosis with polyangiitis, microscopic polyangiitis, and renal-limited disease. Some guidelines recommend RTX as first-line therapy, with AZA as second-line therapy. Because RTX is 15.5 times as expensive as AZA, we sought to evaluate the cost-effectiveness of RTX vs. AZA as a maintenance therapy in AV, from a U.S. payer, or health plan, perspective.

**Methods:** We used a 10-year Markov model with a hypothetical cohort of 10,000 patients. In this model, patients moved through four health states (see Figure). Model inputs included health state transition probabilities; probabilities of infection, cancer, and cardiovascular events; costs of treatment and outcomes; health state utility weights; and cost/utility discount rates. We did not include end-stage kidney disease, likely captured by relapse/death. Model outputs were years patients spent in relapse, deaths, costs, and quality-adjusted life-years (QALYs). We conducted a one-way sensitivity analysis to account for wide variation in medication costs.

**Results:** Therapy-specific results are reported in the Table. The incremental cost of RTX treatment was \$171 million. The cost per major relapse year averted was \$63,018 and the cost per death averted was \$142,869. The cost per QALY gained was \$43,936. In our one-way sensitivity analysis, we found that if payers pay 100% of the listed drug price, then the cost per QALY gained is ~\$44,000. If drug costs can be reduced to 50% of current listed price, then the cost per QALY gained is ~\$15,000.

**Conclusions:** Though RTX is associated with better health outcomes in this population, \$44,000/QALY may be above the willingness-to-pay threshold for some U.S. payers. Efforts to reduce RTX cost can help payers stay within their WTP range and decrease overall healthcare spending.

Treatment Arm	Minor Relapse Years	Major Relapse Years	Deaths	QALYs
Azathioprine	4,993	15,530	2,103	53,065
Rituximab	5,043	12,813	904	56,963

## SA-PO695

**Successful Treatment With Eculizumab in Patients With Severe ANCA Vasculitis**

Miguel Uriol Rivera,<sup>1,2</sup> Gemma Arrufat Goterris,<sup>1</sup> Aina Obrador,<sup>1</sup> Angel Garcia-Alvarez,<sup>3</sup> Sonia Jimenez.<sup>1</sup> <sup>1</sup>Hospital Universitari Son Espases, Palma de Mallorca, Spain; <sup>2</sup>Fundacio Institut d'Investigacio Sanitaria Illes Balears, Palma de Mallorca, Spain; <sup>3</sup>Hospital Comarcal d'Inca, Inca, Spain.

**Background:** Severe presentation of ANCA vasculitis is a life-threatening disease despite aggressive immunosuppression therapy. Complement hyperactivation is involved in pathogenesis; thus, the effect of the C5 inhibitor (eculizumab) used in severe forms of ANCA vasculitis may be a treatment option.

**Methods:** This is a retrospective study. Nine patients were included. Period of study: from May 2017 to May 2022. All patients received at least 3 drugs (steroids, rituximab and mycophenolate or cyclophosphamide) before eculizumab. Eculizumab was indicated as an off-label indication due to lack of improvement or clinical worsening.

**Results:** Mean (SD) age: 62 (15) years. Female: 4. Three patients showed serum anti-proteinase 3 antineutrophil cytoplasmic antibody (PR3-ANCA) and 5 (myeloperoxidase: MPO-ANCA) and one was ANCA-negative. Six patients had an estimated glomerular filtration rate (eGFR)  $< 10$  ml/min/1.73 m<sup>2</sup> at presentation. Five patients had pulmonary involvement. The mean (min-max) time of follow-up after the onset of eculizumab was 27 (1-60) months. One patient ANCA-negative microscopic polyangiitis with diffuse alveolar hemorrhage needed orotracheal intubation and had a satisfactory evolution after eculizumab; however, 20 days after, the patient developed a COVID-19 infection and died. One patient who needed urgent dialysis at presentation did not recover renal function and showed a complement factor H mutation. The evolution of the other 7 patients was as follows: the median (p25-p75) eGFR increased from baseline to the end of the follow-up: 9.1(4.8-21.7)ml/min/1.73m<sup>2</sup> to 31(13-45)ml/min/1.73m<sup>2</sup>, respectively (P=0.018) and the mild proteinuria disappeared in all patients. Alveolar hemorrhage improved in all patients within seven days after the first eculizumab administration. The median (p25-p75) doses of eculizumab administered were 1800(1800-3600) mg. One patient required eculizumab for two different periods.

**Conclusions:** One patient died due to a COVID-19 infection, and one remained in chronic renal replacement therapy. Alveolar hemorrhage was well controlled in all patients. The eGFR increased significantly in 7/9 patients, and in 4/6 patients, dialysis could be withdrawn. In severe ANCA vasculitis, eculizumab should be considered for improving outcomes.

## SA-PO696

**Integrated Safety of Avacopan in ANCA-Associated Vasculitis**

David R. Jayne,<sup>1</sup> Pirow Bekker.<sup>2</sup> <sup>1</sup>University of Cambridge, Cambridge, United Kingdom; <sup>2</sup>ChemoCentryx Inc, San Carlos, CA.

**Background:** Avacopan (TAVNEOS®) is approved as adjunctive treatment for adults with ANCA-associated vasculitis (AAV). Integrated safety data from 2 Phase 2 and 1 Phase 3 studies in 439 AAV patients is reported.

**Methods:** In the 3 trials, all groups received background cyclophosphamide followed by azathioprine, or rituximab; control groups received full prednisone regimen (60mg tapered to 0 over 20 weeks) plus placebo. The Phase 2 CLEAR trial (Jayne et al. 2017) had 3 groups: control (N=23), avacopan 30mg twice daily (BID)+low dose prednisone (N=22), and avacopan+no prednisone (N=22). The Phase 2 CLASSIC trial (Merkel et al. 2020) had 3 groups: control (N=13), avacopan 10mg BID (N=13), and 30mg BID (N=16). The Phase 3 trial (ADVOCATE; Jayne et al. 2021) had a control group (N=164) and a 30mg avacopan group with no oral glucocorticoid taper (N=166). The treatment period was 12 weeks in Phase 2 and 52 weeks in Phase 3. Integrated exposure-adjusted adverse event (AE) rates were calculated.

**Results:** 439 patients were treated, 200 controls and 239 avacopan. The AE patient first incidence rate and AE rate, serious AE rate, infection event rate, and WBC count decrease AE rate were statistically lower in the avacopan compared to the prednisone group (see table).

**Conclusions:** In the context of avacopan's demonstrated efficacy profile, these integrated safety results provide support for avacopan's use in the treatment of patients with AAV. Refs: Jayne et al. J Am Soc Nephrol 2017;28:2756; Jayne et al. NEJM 2021;384:599; Merkel et al. ACR Open Rheumatol 2020;2:662.

**Efficacy and Safety of Remission Induction Regimens in Elderly Patients With ANCA-Associated Glomerulonephritis**  
Lillian Xu, Faten F. Aqeel, Yumeng Wen, Duvuru Geetha. *Johns Hopkins Medicine, Baltimore, MD.*

**Background:** Induction regimens using either cyclophosphamide (CYC) or rituximab (RTX) have demonstrated comparable efficacy and adverse event rates in a randomized trial of patients with mean age of 54 years. However, data is sparse on outcomes of older patients with ANCA-associated glomerulonephritis (ANCA GN) receiving such therapies. This study aimed to compare outcomes in elderly ANCA GN patients based on induction regimen (CYC vs. RTX vs. CYC+RTX).

**Methods:** Patients, age 60 and above, diagnosed with ANCA GN were retrospectively identified. Baseline characteristics and outcomes across several clinical parameters were recorded and compared between CYC, RTX, and CYC+RTX groups for significance using Kruskal-Wallis test, Chi-squared test, and multivariate logistic regression as appropriate.

**Results:** Among 75 patients with ANCA GN with a mean (SD) age of 70 (6) years at diagnosis, there were significant differences in age at diagnosis (p=0.018), Caucasian race (p=0.01), entry eGFR (p=0.00009), dialysis at entry (p=0.009), and use of plasmapheresis (p=0.001) between the CYC (n=25), RTX (n=38), and CYC+RTX (n=12) groups. There were no significant differences between the three groups in prednisone dose at 6 months (p=0.06), infections requiring antibiotics (p=0.57), disease remission (p=0.37), and ESKD at 1 year (p=0.999). There was a significant difference in bone marrow suppression (p=0.002) between the CYC (28%), RTX (2.6%), and CYC+RTX (41.6%) groups. Moreover, after adjustment for age at diagnosis, entry eGFR, and prednisone dose at 6 months, use of RTX only was associated with reduced bone marrow suppression (aOR = 0.08, 95% CI = 0-0.6) [Table].

**Conclusions:** CYC, RTX, and CYC+RTX are equally effective in remission induction in elderly patients with ANCA GN. Use of RTX only was associated with a lower risk of bone marrow suppression compared to CYC only. More information is needed on the comparative safety of induction therapy strategies in elderly ANCA GN patients.

**Funding:** Clinical Revenue Support

Outcome			
Treatment group	CYC	RTX	CYC+RTX
Infection (OR)	Reference	0.47 (0.14-1.54)	0.94 (0.21-4.07)
Bone marrow suppression (OR)	Reference	0.08 (0-0.6)	1.63 (0.33-8.04)
Prednisone dose at 6 months (coefficient)	Reference	-2.87 (-5.92-0.17)	0.51 (-3.53-4.56)
GFR at 12 months (coefficient)	Reference	-1.16 (-8.82-6.5)	-4.12 (-14.38-6.14)
ESKD at 12 months (OR)	Reference	7.02 (0.57-162.63)	0.53 (0.02-7.05)

SA-PO698

**Health-Related Quality of Life in ANCA-Vasculitis Patients in Ireland: A National Survey**  
Eithne M. Nic an Riogh,<sup>1</sup> Eoin Gogarty,<sup>2</sup> Alyssa M. Verrelli,<sup>3</sup> Elhussein A. Elhassan,<sup>4</sup> Jennifer Scott,<sup>1</sup> Arthur White,<sup>2</sup> Mark A. Little,<sup>1</sup>  
<sup>1</sup>Tallaght University Hospital, Dublin, Ireland; <sup>2</sup>The University of Dublin Trinity College, Dublin, Ireland; <sup>3</sup>Cork University Hospital, Cork, Ireland; <sup>4</sup>Beaumont Hospital, Dublin, Ireland.

**Background:** Anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) is a debilitating disease that can impact on a patient's quality of life. The aim of this study was to assess longitudinal quality of life among patients with AAV using the EQ-5D instrument.

**Methods:** 343 patients with AAV were recruited from the Irish Rare Kidney Disease Registry. The EQ-5D instrument was used to evaluate the domains of mobility, self-care, usual activities, pain/discomfort, anxiety/depression and to generate an index score. Health was also rated using a visual analogue scale (0-100). Questionnaires were completed during nephrology clinics and through a patient support phone app. Data was screened for missing data and questionnaires with clear inconsistencies in responses were excluded. 2082 episodes and 283 patients were analysed. A random effects model was used to control for multiple entries relating to individual patients.

**Results:** A poorer quality of life was seen amongst those with AAV (median index value 0.80, UK average 0.856). The mean visual analogue scale was 75.6 (UK average 82.8). Pain and discomfort levels were most affected while self-care was least affected. The index score decreased with increasing age with a 1.5% reduction in index score per decade. A 6% reduction in index score was seen during periods of disease activity compared to periods of remission. Patients requiring dialysis had a 5% reduction in index score. Covid-19 lockdown resulted in a 5.5% index score reduction. Using a median survival rate of 6.16 years for patients with small vessel vasculitis, we calculated the QALYs for this population as 4.9 years.

**Conclusions:** We have defined for the first time the EQ-5D index value over the full disease course in patients with AAV. Other studies have demonstrated a reduction in quality of life during active disease using the AAV-PRO and the Medical Outcomes Study Short Form-36. A prior study among Japanese patients reported a mean index value of 0.72. This is lower than our observed index value however a smaller population (n=34) was examined. In conclusion, our research highlights the negative impact of AAV on patients' lives with a further reduction in quality of life seen during periods of increased disease activity, with increasing age and during the Covid-19 pandemic.

SA-PO699

**The Humanistic Burden of Rare Kidney Diseases, Understanding the Impact of Focal Segmental Glomerulosclerosis and IgA Nephropathy on Patients and Caregivers Study (HONUS): Preliminary Results for IgA Nephropathy in the United States**  
Justyna Szklarzewicz. On behalf of HONUS Advisory and Study team members. *Leicester General Hospital, Leicester, United Kingdom.*

**Background:** While immunoglobulin A nephropathy (IgAN) has been shown to be associated with significant clinical and economic burden, less is known about the humanistic burden associated with the disease. The HONUS study aims to quantify the humanistic burden of rare kidney diseases, including IgAN.

**Methods:** HONUS is a multi-national, cross-sectional survey among adult patients, caregivers (care-partners) and parents/care-partners of youth (8-17 years) with focal segmental glomerulosclerosis (FSGS) or IgAN. Information on demographic/clinical characteristics, health-related quality of life (HRQoL, 12-Item Short Form Survey [SF-12]) and disease impact on employment (Work Productivity and Activity Impairment [WPAI]) are being collected. The current analysis focused on information gathered from IgAN adult patients and their care-partners in the US by May 2022. Data were analyzed descriptively.

**Results:** The analysis included 89 adult IgAN patients. Most of them were Caucasian (88%) and 52% were female, with mean age of 37 years. Most patients (67%) were in CKD stage 3/4, and 3% in end-stage renal disease and had received transplant. Commonly reported comorbidities include hypertension (26%), anemia (22%), and depression (17%). The mean SF-12 physical and mental component scores (PCS, MCS) for patients were 46.7 and 39.3, respectively, lower (reflecting worse HRQoL) than previously published mean scores (MCS and PCS of 50) for the US general population. Employed patients (n=63 [71%]) reported 7% absenteeism, 30% presenteeism, 34% overall work productivity loss, and 39% activity impairment due to IgAN-related reasons. Most of the paired care-partners were the patients' partners (89%), with mean age of 39 years. Among them, the mean SF-12 PCS and MCS were 49.9 and 41.5, respectively. The employed care-partners (n=85 [96%]) reported 12% absenteeism, 32% presenteeism, 39% overall work productivity loss, and 37% activity impairment due to IgAN-related reasons.

**Conclusions:** With US general population estimates as a reference, patients with IgAN experience impaired HRQoL and productivity, which also impacts their care-partner's mental health and productivity.

**Funding:** Commercial Support - Traverre Therapeutics, Inc., San Diego, CA

SA-PO700

**Synergistic Effect of Proteinuria on Hematuria-Related Decline in Kidney Function: The Japan Specific Health Checkups (J-SHC) Study**  
Hikari Tasaki,<sup>1</sup> Masahiro Eriguchi,<sup>1</sup> Hisako Yoshida,<sup>2</sup> Takayuki Uemura,<sup>1</sup> Masatoshi Nishimoto,<sup>1</sup> Takaaki Kosugi,<sup>1</sup> Masaru Matsui,<sup>1</sup> Ken-ichi Samejima,<sup>1</sup> Masato Kasahara,<sup>4</sup> Kunitoshi Iseki,<sup>4</sup> Koichi Asahi,<sup>4</sup> Kunihiko Yamagata,<sup>4</sup> Tsuneo Konta,<sup>4</sup> Shouichi Fujimoto,<sup>4</sup> Ichiei Narita,<sup>4</sup> Yugo Shibagaki,<sup>4</sup> Toshiki Moriyama,<sup>4</sup> Tsuyoshi Watanabe,<sup>4</sup> Kazuhiko Tsuruya.<sup>1,4</sup> <sup>1</sup>Nara Kenritsu Ika Daigaku, Kashihara, Japan; <sup>2</sup>Osaka Koritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osaka, Japan; <sup>3</sup>Nara-ken Sogo Iryo Center, Nara, Japan; <sup>4</sup>Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Check, Fukushima, Japan.

**Background:** We hypothesized that proteinuria had an effect modification on hematuria-related kidney function decline.

**Methods:** This is a longitudinal observational study. Participants was 40 to 74 years old and those who received multiple nationwide specific health checks between 2008 and

2014. The exposures of interest were hematuria (presence or absence) and proteinuria (3 categories: none, occasional, and persistent). Using a mixed-effects model, trajectories of eGFR decline adjusted for clinically relevant factors were examined between hematuria categories stratified by proteinuria categories.

**Results:** Among 552,951 subjects, 146,753 (26.5%) had hematuria, and 56,021 (10.1%) and 8,061 (1.5%) had occasional and persistent proteinuria, respectively. During the median follow up of 3.0 years, annual change in eGFR decline in participants with hematuria (median [95% confidence interval]:  $-0.95$  [ $-0.98$  to  $-0.92$ ] mL/min/1.73 m<sup>2</sup>/year) was significantly faster than those without hematuria ( $-0.86$  [ $-0.87$  to  $-0.84$ ] mL/min/1.73 m<sup>2</sup>/year,  $P < 0.001$ ) in the entire cohort. The differences in eGFR decline rate between participants with and without hematuria (mean  $\pm$  standard error) were  $0.036 \pm 0.005$ ,  $0.027 \pm 0.013$ , and  $0.130 \pm 0.048$  mL/min/1.73 m<sup>2</sup>/year in none, occasional, and persistent proteinuria categories, respectively. Proteinuria had synergistic effect on hematuria-related eGFR decline rate ( $P$  for interaction  $< 0.001$ ).

**Conclusions:** Proteinuria has a synergistic effect on the hematuria-related decline in kidney function.

## SA-PO701

### The Irish Rituximab Study (IRIS): A Nationwide Study of Rituximab Prescribing and Effectiveness for the Treatment of Kidney Diseases

**Dearbhla M. Kelly,<sup>1,2</sup>** Dearbhail Ni Cathain,<sup>1</sup> Blathnaid O'Connell,<sup>3</sup> James O'Hanlon,<sup>1</sup> Aislinn E. Hanahoe,<sup>4</sup> Sorcha O'Brien,<sup>5</sup> Omer Ahmed,<sup>6</sup> Raymond S. Piggott,<sup>7</sup> Laura M. Slattery,<sup>1</sup> Eoghan White,<sup>8</sup> Catherine M. Brown,<sup>3</sup> Liam F. Casserly,<sup>6</sup> Amy Hudson,<sup>1</sup> Mark A. Little,<sup>4</sup> Denise M. Sadler,<sup>7</sup> Donal J. Sexton,<sup>6</sup> Sarah M. Moran,<sup>8</sup> Michelle M. O'Shaughnessy,<sup>8</sup> Peter J. Conlon.<sup>1</sup> **IRIS Rituximab Study (IRIS)** <sup>1</sup>Beaumont Hospital, Dublin, Ireland; <sup>2</sup>Massachusetts General Hospital, Boston, MA; <sup>3</sup>University Hospital Waterford, Waterford, Ireland; <sup>4</sup>Tallaght University Hospital, Dublin, Ireland; <sup>5</sup>St. James's Hospital, Dublin, Ireland; <sup>6</sup>University Hospital Limerick, Doonadoyle, Ireland; <sup>7</sup>Mater Misericordiae University Hospital, Dublin, Ireland; <sup>8</sup>Cork University Hospital, Cork, Ireland.

**Background:** Rituximab is increasingly used to treat glomerular diseases, including ANCA-associated vasculitis (AAV), membranous nephropathy, minimal change disease (MCD), and focal segmental glomerulosclerosis (FSGS). However, strong evidence supporting its use in some of these conditions is lacking and it is also costly and potentially toxic. Using nationwide data, we examined prescribing practices and clinical outcomes in Irish patients who received Rituximab for glomerular disease.

**Methods:** All patients attending Irish Nephrology Centres who received Rituximab for glomerular disease between 01/01/13 and 31/12/21 were included in this retrospective observational study. Rituximab dosing, prior and concurrent medications, clinical presentation, and outcomes were extracted from electronic healthcare records. The primary efficacy outcome was complete or partial remission at 12 months. Descriptive statistics are herein presented.

**Results:** From 9 participating centres, we identified 405 patients (median age 55.3 years; 37.3% female), a majority (53%) of whom had AAV, **Table**. The most frequent Rituximab dose was 1g (60%) and the median cumulative dose received was 3g (IQR 2-4g). From patients with available outcome data (n=306), 259 (85%) achieved CR or PR by a median of 5 (IQR 2-10) months. During a median follow-up of 49 (IQR 31-74) months, 71 (23%) patients had disease relapses and 80 (25%) experienced adverse events: 72 (22%) infections, 40 (13%) leucopenia, 18 (9%) infusion reactions, 15 (7%) malignancies, and 12 (3%) episodes of hypogammaglobulinemia.

**Conclusions:** Based on preliminary data, Rituximab was an effective and safe treatment in the majority of Irish adults with glomerular disease who received it.

### A Retrospective Analysis of Cardiovascular Disease (CVD) Events in Prevalent Patients With Focal Segmental Glomerulosclerosis (FSGS) in the United States

**Juan Carlos Q. Velez,<sup>1</sup>** Kamlesh M. Thakker,<sup>2,3</sup> Mark E. Bensink,<sup>2</sup> Edgar V. Lerma,<sup>4,5</sup> Richard M. Lieblich,<sup>6</sup> Martin C. Bunke,<sup>7</sup> Kaijun Wang,<sup>2</sup> David Oliveri,<sup>8</sup> Andrew Rava,<sup>8</sup> Diana T. Amari,<sup>8</sup> David Cork.<sup>9</sup> <sup>1</sup>Ochsner Medical Center, New Orleans, LA; <sup>2</sup>Traverse Therapeutics Inc, San Diego, CA; <sup>3</sup>Notting Hill Consulting LLC, Celebration, FL; <sup>4</sup>University of Illinois Chicago, Chicago, IL; <sup>5</sup>Advocate Christ Medical Center, Oak Lawn, IL; <sup>6</sup>VJA Consulting, Walnut Creek, CA; <sup>7</sup>CM Bunke Consulting, Mt. Pleasant, SC; <sup>8</sup>Genesis Research LLC, Hoboken, NJ; <sup>9</sup>Genesis Research LLC Newcastle, Newcastle upon Tyne, United Kingdom.

**Background:** FSGS is a histologic pattern of glomerular injury with numerous causes, frequently associated with kidney disease progression and kidney failure. Although CVD events are known to be associated with end stage kidney disease (ESKD), there is a paucity of research examining this relationship in the FSGS population. We assessed the impact of baseline proteinuria and eGFR decline to ESKD on CVD event incidence and all-cause mortality.

**Methods:** A descriptive, retrospective analysis using Optum® de-identified Market Clarity and proprietary Natural Language Processed (NLP) Data (2007-2020). Inclusion criteria: Patients ( $\geq 18$ yo) with  $\geq 2$  FSGS ICD-10 codes (N031, N041, N051, N061, N071) and/or  $\geq 2$  FSGS NLP terms within 180 days and  $\geq 30$  days apart without associated negation terms,  $> 6$ mo pre-index activity (exclusion: COVID-19). Post-index CVD events included myocardial infarction (MI), ischemic stroke/transient ischemic attack (TIA), unstable angina, congestive heart failure (CHF), percutaneous coronary intervention (PCI), or coronary artery bypass graft (CABG). All-cause mortality included patients with a death date post-index.

**Results:** Overall (n=7,974), 11.7% of patients with FSGS experienced a CVD event. Post-ESKD, and among patients with higher baseline proteinuria, CVD events and mortality were significantly elevated ( $p < 0.01$ ; Table 1).

**Conclusions:** A significant increase in CVD events and death was associated with elevated proteinuria and progression to ESKD in patients with FSGS. New therapies for FSGS that reduce proteinuria may reduce CVD events and improve overall survival.

**Funding:** Commercial Support - Traverse Therapeutics, Inc

Table 1: CVD Events and Mortality

	Pre-ESKD* (n=4,478)	Post-ESKD* (n=4,934)	p value	Baseline Proteinuria $\leq 1.5$ g/g (n=576)	Baseline Proteinuria $> 1.5$ g/g (n=534)	Baseline Proteinuria $\geq 3.5$ g/g (n=710)	p value

\*Patients could contribute to both pre- and post-ESKD periods based on kidney function.

## SA-PO703

### Minimal Change Disease Management and Outcomes: Observation Over 10 Years From a Single Adult Nephrology Centre

**Anja Oklopčic,<sup>1</sup>** Corrie Bowers,<sup>1</sup> Nithin Balasubramanian,<sup>2</sup> Arif Khwaja,<sup>1</sup> Syazrah Salam.<sup>1</sup> <sup>1</sup>Sheffield Kidney Institute, Sheffield, United Kingdom; <sup>2</sup>The University of Sheffield Medical School, Sheffield, United Kingdom.

**Background:** Minimal change disease (MCD) is one of the causes of nephrotic syndrome. Disease response to corticosteroid varies and time to disease remission and relapse is unknown. We assessed: the remission and relapse rates, time from remission to first relapse, the proportion of patients on adjunct treatment, the proportion of patients with acute kidney injury (AKI) at initial presentation, clinical outcomes.

**Methods:** Single centre service evaluation. Adult patients with diagnosis of MCD. Between 1st January 2010 and 31st December 2019. Follow up data were collected until 31st December 2020. Patients from paediatric nephrology services were excluded.

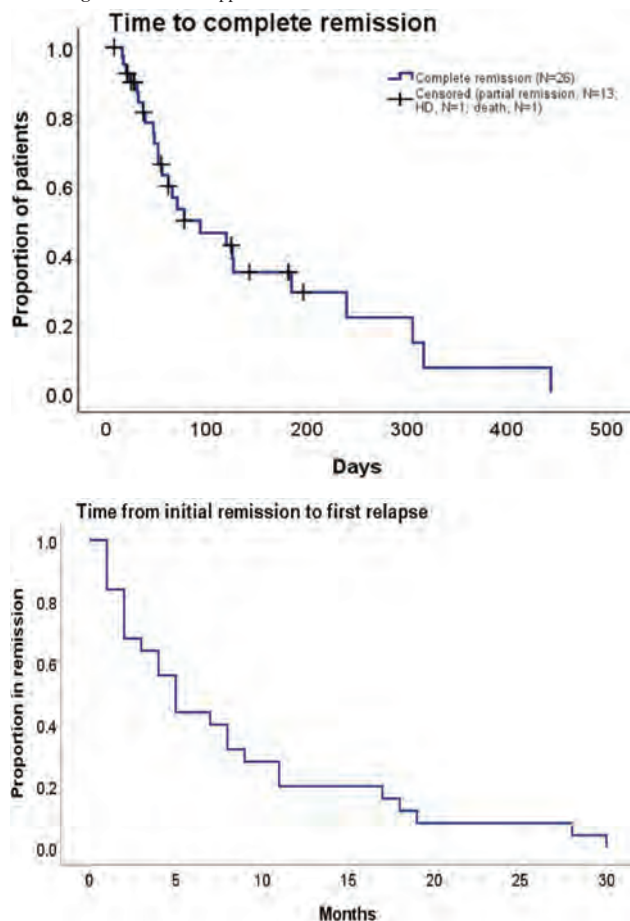

**Results:** 41 patients (26 men, 15 women). All but one had histological diagnosis. Mean age  $49 \pm 17$  years. 11 patients had AKI at presentation. 37/41 patients achieved remission; 26 had complete and 11 had partial remission. 24/37 patients relapsed but all subsequently achieved remission (21 complete and 3 partial remission). The median time from initial remission to first relapse was 168 days (IQR 71 – 327 days). 14/24 patients had a relapse within 6 months from initial remission. All patients received

corticosteroid. Additional immunosuppression was predominantly calcineurin inhibitor (CNI, 22 patients).

**Conclusions:** Majority of MCD patients achieved remission, but over half relapsed within 6 months of initial remission. CNI is the most common adjunct treatment in our centre. Long term dialysis and death are uncommon.

**Funding:** Government Support - Non-U.S.

#### SA-PO704

##### Comparing Outcomes of Patients With and Without Nephrotic Syndrome in Minimal Change Disease

Hyung Eun Son,<sup>1</sup> Seokwoo Park,<sup>2</sup> Ho Jun Chin.<sup>2</sup> <sup>1</sup>Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; <sup>2</sup>Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea.

**Background:** Minimal change lesion (MCD) is characterized by edema, nephrotic ranged proteinuria (NS). However, the fate of MCD without nephrotic proteinuria needs to be defined in more detail.

**Methods:** We enrolled 79 adult MCD patients with the first renal biopsy in a tertiary hospital from May 2003 to June 2017. We did not include patients having any immunosuppressive treatment before renal biopsy, patients with inappropriate biopsy samples (<10 glomeruli/biopsy, any electron dense deposit, and light microscopic findings suggestive secondary causes). Remission of proteinuria was defined as urine protein to creatinine ratio (UPCR) < 0.3 g/g creatinine and relapse of proteinuria as UPCR ≥ 3.0 g/g creatinine. Clinic-pathologic features were compared between patients with and without NS. We followed up with the frequency of flare to nephrotic proteinuria, and renal outcomes such as the decrease of estimated glomerular filtration rate (GFR) over 50% compared to GFR at renal biopsy, GFR < 15 ml/min/1.73 m<sup>2</sup>, or progression to end stage renal disease during follow-up period.

**Results:** There were 3 patients with UPCR < 0.3 g/g creatinine, 17 patients with UPCR 0.3-2.9 g/g creatinine, and 59 patients with UPCR ≥ 3.0 g/g creatinine at admission for renal biopsy. Mean age at renal biopsy was 53.7 ± 19.2 (range:18.5-99.0) years, and there were 38 male patients (48.1%). Each group included 20 patients (Non-NS group), and 59 patients (NS group). Non-NS group had lower UPCR (1.36 ± 0.99 vs 10.2 ± 6.21 g/g creatinine, p<0.001) and higher GFR (98 ± 27 vs 75 ± 36 ml/min/1.73 m<sup>2</sup>, p=0.012) at renal biopsy. Non-NS group had lower frequency of AKI during follow-up period [5.0% vs 59.3%, p < 0.001]. Response rate to steroid treatment was 100 % in Non-NS group and 92.3 % in NS group (p = 1.000). There was no difference in the frequency of the first relapse and the number of relapses. At the final visit, the CR rate was 73.4 %. The eGFR during follow-up was much improved in NS group compared to Non-NS group because

of higher incidence of AKI at renal biopsy. The incidence rate of renal event, ESRD event, or mortality was not different between groups.

**Conclusions:** The adult MCD patients with nephrotic and non-nephrotic ranged proteinuria showed similar outcomes. Therefore, MCD should be paid more attention regardless of the amount of proteinuria at renal biopsy.

#### SA-PO705

##### Preparing a Clinical Outcomes Assessment Set for Nephrotic Syndrome (Prepare-NS): A New Core Set of Clinical Outcome Assessments Focused on Fluid Overload for Nephrotic Syndrome

Eloise Salmon,<sup>1</sup> Debbie Gipson,<sup>1</sup> Noelle E. Carozzi,<sup>1</sup> Jin-Shei Lai,<sup>5</sup> Patrick H. Nachman,<sup>3</sup> David T. Selewski,<sup>2</sup> Richard A. Lafayette,<sup>4</sup> Kelly Helm,<sup>6</sup> Cathie Spino,<sup>1</sup> Courtney N. Hurt,<sup>3</sup> Rebecca Scherr,<sup>1</sup> Vivian Kurtz,<sup>1</sup> Yujie Wang,<sup>1</sup> Daniyal Shamim,<sup>1</sup> John D. Peipert.<sup>5</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Medical University of South Carolina, Charleston, SC; <sup>3</sup>University of Minnesota Academic Health Center, Minneapolis, MN; <sup>4</sup>Stanford University School of Medicine, Stanford, CA; <sup>5</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>6</sup>Nephcure Kidney International, King of Prussia, PA.

**Background:** Individuals with nephrotic syndrome (NS) experience fluid overload (FO). Partnering with FDA, we are creating and validating Clinical Outcome Assessments (COAs) of Patient Reported Outcomes (PRO) and Observer Reported Outcomes (ObsRO) of FO in NS for use in drug development. The initial project phase established a conceptual model, conducted a gap analysis, and assessed available data.

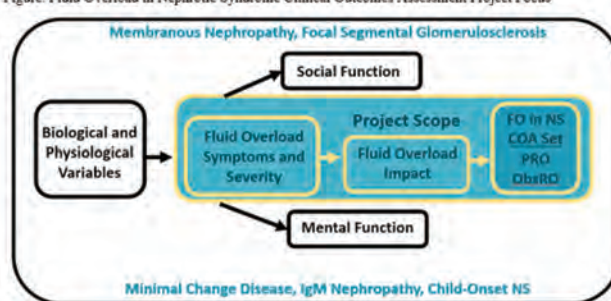

**Methods:** Stakeholder groups met, context of use (COU) was defined, and a scoping literature review was conducted. Analysis of existing PROMIS HRQOL data from the NEPTUNE and CureGN cohort studies estimated mean score differences (25,75 CIs) for participants with current vs past edema.

**Results:** COU includes age ≥ 2 yrs, NS etiology (Figure), persistent or relapsing/remitting NS, and edema, excluding dialysis dependence. 1337 manuscripts were reviewed; 9 met inclusion criteria. Two PROs created for FSGS or FSGS/minimal change disease (MCD) included FO items. No ObsROs identified. Secondary analysis of existing FSGS and MCD qualitative data identified edema location and severity ranges. Pooled cohort analysis showed worse HRQOL with edema in 1,678 participants (1246 adults, 432 children), e.g., adult Physical Function (-5.71 (-8.41, -3.01) and child Mobility (-3.8 (-5.86, -1.73)).

**Conclusions:** No existing PRO or ObsRO focus on assessment of FO and its impact on patients with NS. Scores on generic HRQOL scales vary with edema but do not gather detailed information on FO, making them insufficient for use in drug development. Protocols for concept elicitation and cognitive debriefing are in progress to fill the identified gaps and inform the creation COAs for FO in NS, inclusive of an ObsRO for young children and PRO for self-report for ages 8+. At project end, the final COA set will be publicly available for use as an endpoint in NS trials.

**Funding:** Other U.S. Government Support

##### A Prospective Study to Assess Safety and Efficacy of Bone-Marrow Derived Mesenchymal Stromal Cells for Severe Frequently Relapsing or Steroid-Dependent Idiopathic Nephrotic Syndrome: The MESNEPH Study

Marina Vivarelli,<sup>1</sup> Manuela Colucci,<sup>1</sup> Piero L. Ruggerenti,<sup>2</sup> Federica Casiraghi,<sup>2</sup> Federica Zotta,<sup>1</sup> Francesco Emma,<sup>1</sup> Giuseppe Remuzzi.<sup>2</sup> <sup>1</sup>Division of Nephrology, Bambino Gesù Pediatric Hospital IRCCS, Rome, Italy; <sup>2</sup>Istituto di Ricerche Farmacologiche "Mario Negri" IRCCS, Bergamo, Italy.

**Background:** An immune etiology of idiopathic nephrotic syndrome (INS) has been suggested by the efficacy of steroids and steroid-sparing agents, which present side effects.

**Methods:** This phase I study aimed to assess feasibility, safety and efficacy of autologous bone marrow-derived mesenchymal stromal cells (BM-MSC) in children and young adults (5-40 age years old) with steroid-dependent or multirelapsing INS. Following BM-MSC infusions, oral immunosuppression (IS) was gradually tapered. Safety, efficacy and immunomodulatory effects on different B and T cell subsets *in vivo* were monitored for 12 months.

**Results:** A total of 16 patients (10 children, 6 adults) were enrolled. A sufficient amount of autologous BM-MSC was obtained for all. Infusions were well tolerated.

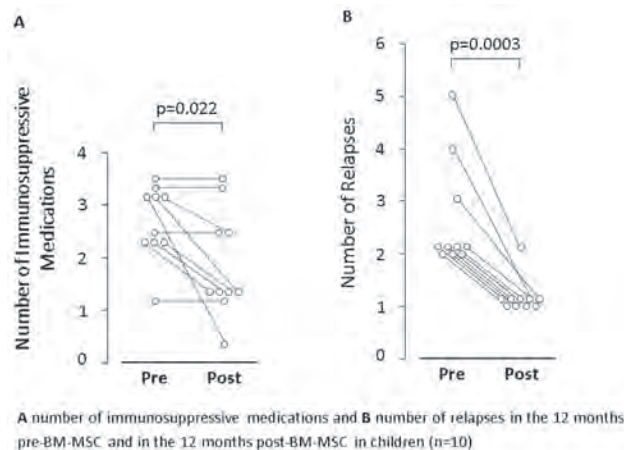

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Adverse events were limited and not reconducable to BM-MSD infusion. At baseline, all patients were on steroids and most were on 1-2 steroid-sparing agents. At the end of the study, the number of required IS was significantly reduced in children ( $p=0.022$ ) but not in adults. Whereas all patients relapsed during the 12-month follow-up, with a mean time of 8.5 months, the median number of relapses was significantly reduced in children (1 [IQR 1-1] vs 2 [IQR 2-3.25] compared to the previous 12 months, ( $p<0.001$ ) but not in adults. Among B and T cell subsets, a significant but transient reduction of total CD19+, mature and switched memory B cells and an increase of transitional B cells and regulatory T cells ( $p<0.05$ ) was observed *in vivo* between 1 and 3 months following BM-MSD infusion, despite the tapering of immunosuppression, especially in children.

**Conclusions:** Infusion of autologous BM-MSD was safe. A significant reduction of number of IS drugs and of relapses was found in children but not in young adults. The immunomodulatory effect of a cycle of autologous BM-MSD infusions on specific B and T cell subsets was transient.

**Funding:** Government Support - Non-U.S.

## SA-PO707

### Rituximab and a Short Course of Corticosteroids for Initial Management of Adult-Onset Minimal Change Disease

Ayotunde Ositelu, Fatmah N. Yamani, Kana R. Amari, Yashpal S. Kanwar, Vikram Aggarwal. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Minimal change disease (MCD) accounts for 10-25 % of adult nephrotic syndrome (NS). Despite corticosteroid (CS) sensitive course of NS in MCD, high doses and prolonged exposure lead to many CS-related adverse effects. Rituximab (RTX) has proven to be effective in frequently relapsing (FR) and CS-dependent (SD) MCD. We report our experience of using RTX and a short course of CS for the initial management of the first episode of adult-onset MCD with the intention to curtail the duration and cumulative dose of CS.

**Methods:** Our series includes 5 adult patients with biopsy-proven MCD from February 2018 to March 2022 at Northwestern Memorial Hospital, Chicago, Illinois. Management plans were based on shared decisions with patients regarding the risks and benefits of various treatment options, the evolution of adverse effects, and the course of NS. All patients were initially treated with high-dose prednisone (1mg/kg/day) and two infusions of RTX (2-4 week intervals). Relapse, partial and complete remission (PR, CR) were defined per the KDIGO 2021 Glomerular Diseases Guideline.

**Results:** The mean age of the patients was 46 years (range 32-79), all females. The mean duration of initial high-dose CS was 3.2 weeks and followed by CS taper. The total mean duration of CS use was 8.6 weeks (range 6-12 weeks). All patients received the first dose of RTX within 4 weeks of CS initiation. CR was achieved in all patients at a mean time of 9.4 weeks (range 2-24 weeks, Figure 1). All patients expressed reluctance to a long duration of CS as per KDIGO as they experienced CS-related adverse events. All patients maintained CR for one year. Only 2 patients had relapsed after 1 year and responded to a single dose of Rituximab alone. No patient experienced severe adverse events from RTX.

**Conclusions:** Our study is promising and indicates that RTX may be a viable candidate as first-line therapy for treating MCD in adults. This approach limits the cumulative dose of CS and maintains remission at 1 year with overall limited side effects and better patient-reported outcomes.

Course of Adult-Onset MCD for Five Patients Over 1 Year

## SA-PO708

### The ACTION (AT1R and CCR2 Targets for Inflammatory Nephrosis) Program in Focal Segmental Glomerulosclerosis

Simon D. Roger,<sup>1</sup> David W. Mudge,<sup>2</sup> Craig L. Nelson,<sup>3</sup> Muh Geot Wong,<sup>4</sup> Robert Shepherd,<sup>5</sup> Alisha J. Smith,<sup>5</sup> David K. Packham,<sup>6</sup> ACTION-FSGS <sup>1</sup>Gosford Hospital, Gosford, NSW, Australia; <sup>2</sup>Princess Alexandra Hospital, Woolloongabba, QLD, Australia; <sup>3</sup>Western Health, Footscray, VIC, Australia; <sup>4</sup>Concord Repatriation General Hospital, Concord, NSW, Australia; <sup>5</sup>Dimerix Bioscience, Melbourne, VIC, Australia; <sup>6</sup>Melbourne Renal Research Group, Melbourne, VIC, Australia.

**Background:** Focal segmental glomerulosclerosis (FSGS) is a disease of podocytes. Complications include nephrotic syndrome and progressive kidney failure. There is no approved treatment. The angiotensin II receptor type 1 (AT1R) and chemokine receptor 2 (CCR2) are G protein coupled receptors that form functional heteromers. Simultaneous antagonism of these receptors demonstrated synergistic renoprotective effects in preclinical models. In a Phase 2a study of 27 patients with proteinuric chronic kidney disease, 25% of patients achieved > 50% reduction in proteinuria with combination of DMX-200 (propagaramanum, a CCR2 antagonist) and irbesartan, an angiotensin receptor blocker (ARB). Proteinuria reduction is a positive prognostic sign for preserving kidney function.

**Methods:** ACTION is a Phase 2a randomised, placebo-controlled, 2-way crossover study in primary FSGS patients receiving ARB, exploring the safety and efficacy of DMX-200 in reducing proteinuria. Patients were randomised to receive DMX-200 240mg daily or placebo for 16 weeks, followed by 6-week washout, then crossed over to the alternate treatment for a further 16 weeks. Eligible patients were aged 18-80 with biopsy-proven primary FSGS. Patients received stable dose of irbesartan 300 mg/day throughout the study. Screening urine protein/creatinine ratio (UPCR) was  $\geq 150$  mg/mmol and eGFR  $\geq 25$  ml/min/1.73m<sup>2</sup>. Exclusion criteria included secondary FSGS and diabetes mellitus.

**Results:** 8 patients were enrolled and completed the study. DMX-200 for 16 weeks demonstrated a safety profile similar to placebo, with no safety concerns associated with combined DMX-200 and irbesartan. The study was not powered for efficacy but greater reduction in UPCR (-84.3 mg/mmol vs -5.1mg/mmol) from baseline was observed with DMX-200 compared with placebo. Mixed model for repeated measures (MMRM) analysis showed placebo-corrected ratio was < 1, indicating a greater reduction in UPCR with DMX-200 vs placebo.

**Conclusions:** These encouraging data suggest that DMX-200 may result in clinically meaningful reduction in proteinuria when added to ARB in patients with primary FSGS. This has led to the initiation of an international Phase 2/3 randomised double-blind, placebo-controlled study (ACTION3) to further evaluate the efficacy of DMX-200 in patients with FSGS receiving an ARB.

**Funding:** Commercial Support - Dimerix Bioscience Ltd

## SA-PO709

### Repetitive Administration of Rituximab to Maintain Clinical Remission in Patients With Minimal Change Disease/Focal Segmental Glomerulosclerosis

Thomas Osterholt, Lucas Kuehne, Franziska Grundmann, Thomas Benzing, Linus A. Volker, Paul T. Brinkkoetter. *Uniklinik Köln, Köln, Germany.*

**Background:** Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are glomerulopathies that present with nephrotic syndrome and show foot process effacement on electron microscopy. Primary forms of these diseases are treated with immunosuppressive drugs such as steroids, calcineurin inhibitors, and cytotoxic agents. Particular problems are frequent relapsing or glucocorticoid-dependent forms of those diseases. A recent metaanalysis provided evidence for the efficacy of B-cell depleting agents such as rituximab (RTX) in such patients. However, there is little evidence for the efficacy of reinduction of remission after initial successful treatment with RTX.

**Methods:** We conducted a single-center retrospective case series to evaluate the efficacy of repeated induction therapies with rituximab in patients with primary minimal change disease and focal segmental glomerulosclerosis. We identified 13 patients who received more than one induction therapy with RTX from our institutions and the ForMe-registry (NCT03949972). Disease status prior to induction and after 3 and 6 months was assessed. Changes in serum creatinine, proteinuria and time to relapse were evaluated. Relapse-free survival was assessed with the cox proportional hazard and Kaplan Meier estimators and compared to previous therapy regimens.

**Results:** Through all additional cycles after the first treatment with RTX, an improvement of disease activity could be shown and led to a complete remission in 71% and partial remission in 27% after 3 ( $p<0.001$ ) and 6 months ( $p<0.001$ ) compared to the disease state before induction. Time to relapse increased from 4.5 months (95%-CI: 3-10 months) to 21 months (95%-CI: 15-32 months) ( $p<0.001$ ) compared to previous immunosuppression regimen. The estimated glomerular filtration rate remained stable through all cycles ( $p=0.53$ ). Compared to continuous B-cell depletion, an individualized relapse based approach led to a significantly reduced rituximab exposure.

**Conclusions:** Repeated administration of RTX in patients with MCD/FSGS with an initial good clinical response did not result in drug tolerance and decreased efficacy at a median follow-up of 93.5 months after the first RTX induction. Thus, reinduction therapies may provide an alternative to continuous B-cell-depletion and reduce long-term side effects of continuous immunosuppression.

**Funding:** Government Support - Non-U.S.

## SA-PO710

### Direct Oral Anticoagulants vs. Warfarin for Venous Thromboembolism Prophylaxis in Patients With Nephrotic Syndrome: A Retrospective Cohort Study

Katerina Stanilova, Aminat A. Tijani, Eric M. Coons, Ashley Casey, Britta Mizuki, Miranda Dermady, Adi Bamnolker, Muhannad Alqudsi, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Medical Center, New Orleans, LA.

**Background:** Hypercoagulability with resultant venous thromboembolism (VTE) is a common feature of nephrotic syndrome (NS). Anticoagulation with warfarin is standard of care for patients with NS and serum albumin  $< 2.5$  g/dL, whereas the evidence supporting the use of direct oral anticoagulants (DOACs) for VTE prophylaxis in NS is mostly limited to case reports. We examined the rates of bleeding and thromboembolic event rates in patients with NS receiving DOACs or warfarin for VTE prophylaxis.

**Methods:** A retrospective cohort study was conducted in adults with NS treated with a DOAC or warfarin for VTE prophylaxis for  $\geq 7$  days and with  $\geq 2$  encounters documented within the Ochsner Health System between January 2013 and July 2021. Patients were excluded if they had a prior VTE within 6 months or had known prior exposure to a study drug. The primary outcome was the composite rate of major and clinically relevant non-major bleeding. Secondary outcomes included time to bleeding events and the rate of new thromboembolic events.

**Results:** Of 171 patients screened, 44 patients were included in the study (25 in the DOAC cohort and 19 in the warfarin cohort); median age 55 (41-64) years, 50% women, 63% self-identified black. Median follow-up was 7.8 (4.6-18.7) months. Median urine protein-to-creatinine ratio, serum albumin and serum creatinine were 8.6 (5.0-11.8) g/g, 1.6 (1.2-2.1) g/dL and 1.3 (0.8-2.1) mg/dL, respectively. The most common etiology of NS was membranous nephropathy: 14 (56%) in the DOAC group [12 of them phospholipase A2 receptor (PLA2R)+] and 9 (47%) in the warfarin group [4 of them PLA2R+]. The primary outcome occurred in 2 patients treated with a DOAC and 5 patients treated with warfarin (8% vs 26%,  $p=0.21$ ). The primary outcome was driven by major bleeding (4% vs 21%,  $p=0.15$ ). There was no difference in time to major bleeding (250 vs 340 days,  $p=1.00$ ). One new VTE event occurred in the DOAC cohort.

**Conclusions:** Bleeding and thromboembolic events were similar in patients with NS treated with a DOAC or warfarin for VTE prophylaxis. This study adds comparative data for VTE prophylaxis in patients with NS. Larger prospective studies are still warranted.

## SA-PO711

### PatchSorter Enables Efficient Digital Glomerular Classification

Akhil Ambekar,<sup>1,2</sup> Tasneem Talawalla,<sup>3</sup> Bangchen Wang,<sup>1</sup> Clarissa A. Cassol,<sup>4</sup> Anant Madabhushi,<sup>3,5</sup> Laura Barisoni,<sup>1,6</sup> Andrew Janowczyk.<sup>3,7</sup> <sup>1</sup>Duke University Department of Pathology, Durham, NC; <sup>2</sup>Duke University, Durham, NC; <sup>3</sup>Case Western Reserve University Department of Biomedical Engineering, Cleveland, OH; <sup>4</sup>Arkana Laboratories, Little Rock, AR; <sup>5</sup>VA Northeast Ohio Healthcare System, Cleveland, OH; <sup>6</sup>Duke University Department of Medicine, Durham, NC; <sup>7</sup>Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

**Background:** Quantification of segmental (SS) and global glomerulosclerosis (GS) has diagnostic and prognostic relevance in kidney disease, which entails laboriously assigning SS, GS, and non-GS/SS labels to individual glomeruli. While deep learning (DL) based tools can automate this task, they require large amounts of categorized glomeruli for training. PatchSorter (PS), an open-source tool (patchsorter.com), can facilitate review and label assignment of glomeruli by grouping those with similar presentational characteristics in a 2-dimensional plot. Within this plot, as PS receives user feedback, separation between categories iteratively increases to facilitate bulk labeling, improving labeling efficiency. This study compares glomerular labeling efficiency of PS versus an un-DL-aided approach, QuickReviewer (QR).

**Methods:** 3446 segmented glomeruli from 241 NEPTUNE PAS whole slide images previously manually categorized as SS, GS, and non-SS/GS were uploaded in PS and QR for labeling by a pathologist. Labels per second (LPS) were calculated for both approaches. Concordance between PS labels and ground truth was calculated.

**Results:** All glomeruli were labeled in 4260 seconds using PS (0.808 LPS), vs 712 glomeruli in 1800 seconds using QR (0.395 LPS), yielding a 105% speed improvement for PS over QR. Concordance of PS labels with manual categorization was 95%, suggesting efficiency improvements did not come at the cost of labeling fidelity.

**Conclusions:** PS is a robust and efficient tool for glomerular classification with potential to aid in overcoming manpower limitations in generating large cohorts of labeled digital kidney biopsies.

**Funding:** NIDDK Support, Other NIH Support - NIH NCI, Veterans Affairs Support, Private Foundation Support

Figure 1: Left image: the user lessons areas of interest in the Cartesian plot (left) which are subsequently presented for review and bulk labeling (right). Right image: as labeling progresses, the feature space is improved, further separating predicted categories in the plot to facilitate improved labeling efficiency.

Figure 2: An upward trend in labeling efficiency is observed after each model iteration, suggesting the potential for a further improvement in labeling times when applied to larger cohorts.

## SA-PO712

### A Phase 3, Multicenter, Randomized, Double-Blind, Placebo-Controlled Study to Evaluate the Efficacy and Safety of Sibeprenlimab Administered Subcutaneously in Patients With IgA Nephropathy

Dana Rizk,<sup>1</sup> Vlado Perkovic,<sup>2</sup> Richard A. Lafayette,<sup>3</sup> Hernan Trimarchi,<sup>4</sup> Jonathan Barratt,<sup>5</sup> Kevin Carroll,<sup>6</sup> Vladimir Tesar,<sup>7</sup> Hong Zhang,<sup>8</sup> Yusuke Suzuki,<sup>9</sup> Adrian Liew,<sup>10</sup> Muh Geot Wong,<sup>11</sup> Bruce R. Leslie,<sup>12</sup> Mohit Mathur,<sup>13</sup> Jeffrey Harkin.<sup>12</sup> <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>University of New South Wales, Sydney, NSW, Australia; <sup>3</sup>Stanford University, Stanford, CA; <sup>4</sup>Hospital Britanico de Buenos Aires, Buenos Aires, Argentina; <sup>5</sup>University of Leicester, Leicester, United Kingdom; <sup>6</sup>KJC Statistics, London, United Kingdom; <sup>7</sup>Charles University, Prague, Czechia; <sup>8</sup>Peking University, Beijing, China; <sup>9</sup>Juntendo Daigaku, Bunkyo-ku, Japan; <sup>10</sup>Mount Elizabeth Novena Hospital, Singapore, Singapore; <sup>11</sup>Concord Repatriation General Hospital, Concord, NSW, Australia; <sup>12</sup>Otsuka Pharmaceuticals Development & Commercialization, Inc., Rockville, MD; <sup>13</sup>Visterra Inc, Boston, MA.

**Background:** IgAN is the leading primary glomerulonephritis worldwide. Up to 40% of patients develop kidney failure within ~20 years of diagnosis. Current treatment consists of optimized supportive care including renin-angiotensin aldosterone system (RAAS) blockade. New therapies targeting the underlying disease pathophysiology are needed. Emerging data suggest that the B cell growth factor, A Proliferation Inducing Ligand (APRIL), plays a key role in the pathogenesis of IgAN and may be an ideal target. Sibeprenlimab (VIS649), a humanized IgG2 monoclonal antibody (mAb) that inhibits APRIL, is being evaluated for the treatment of IgAN.

**Methods:** The VISIONARY Trial (NCT05248646) is a global Phase 3 randomized controlled trial which will assess the efficacy and safety of sibeprenlimab in adult patients with IgAN. Approximately 450 patients with biopsy-confirmed IgAN will be randomized to receive 400mg sibeprenlimab subcutaneously or placebo for 24 months, while continuing to receive standard of care. Key inclusion criteria: on maximally tolerated RAAS blockade, 24 hr uPCR  $\geq 0.75$  g/g or urine protein  $\geq 1.0$  g/day, eGFR  $\geq 30$  mL/min/1.73 m<sup>2</sup>. Patients with secondary IgAN, coexisting kidney disease, IgG  $< 600$  mg/dL, MEST-C score T2 or C2 will not be included in the study. An exploratory cohort of 20 patients with eGFR 20-30 mL/min/1.73 m<sup>2</sup> will also be enrolled. The primary efficacy endpoint is to evaluate the change in 24 hr uPCR at 9 months compared with baseline. Key secondary efficacy endpoint is to evaluate the change in annualized eGFR slope over 24 months. Additional secondary endpoints include clinical remission, safety, pharmacodynamics, and anti-drug Ab. Patients completing the trial will be eligible for a 24-month open label extension study (NCT05248659).

**Results:** Results of study expected later when study is complete.

**Conclusions:** Sibeprenlimab is a mAb that blocks APRIL, a B cell growth factor implicated in the pathogenesis of IgAN. A pivotal phase 3 trial is under way to assess the efficacy and safety of sibeprenlimab for the treatment of IgAN.

**Funding:** Commercial Support - Otsuka Pharmaceuticals Development & Commercialization, Inc.

## SA-PO713

### Evolution in IgA Nephropathy Treatment: How Will SGLT2 Inhibitors, Steroid Regimens, and Experiment Therapies Change the Treatment Landscape?

Chris Dudzenski,<sup>1</sup> Pietro A. Canetta,<sup>2</sup> Denise Foy.<sup>1</sup> <sup>1</sup>Spherix Global Insights, Exton, PA; <sup>2</sup>Columbia University Irving Medical Center, New York, NY.

**Background:** Treatment options for IgA nephropathy (IgAN) are evolving rapidly. The use of SGLT2 inhibitors (SGLT2i) has established efficacy. Other treatment options, including reduced-dose systemic steroid regimens, a recently launched oral targeted budesonide. Agents in development have the potential to continue to improve patient outcomes. Survey data is presented on U.S. nephrologists' clinical practice and expectations regarding the treatment of IgAN.

**Methods:** 907 IgAN patient records were collected in collaboration with more than 200 US nephrologists via a HIPAA-compliant, online chart review tool between Dec 20, 2020 – Feb 16, 2021 and Dec 14, 2021 – Feb 21, 2022. Launch tracking data for

delayed-release budesonide capsules was captured via an online survey fielded to 77 US nephrologists from May 4–7, 2022.

**Results:** SGLT2i use in IgAN patients more than tripled between 2021 and 2022 (from 6% to 21%) after dapagliflozin was approved in the U.S for non-diabetic CKD and sub-analysis data was published on its use in IgAN patients. 75% of nephrologists strongly agreed that SGLT2is may significantly help delay kidney disease progression in glomerular disease patients, and 73% expected to continue to increase their prescribing over the next six months. Despite awareness of the TESTING trial spreading among nephrologists, use of systemic steroids has remained stable at 14% of patients year-over-year. The availability of budesonide capsules has created another option, with nephrologists were predicting up to 13% of their diagnosed IgAN patients may be eligible candidates for this therapy. New agents in the pipeline for IgAN include sparsentan, atrasentan, and iptacopan. Nephrologists have strong awareness of these agents in development (~60% consider themselves moderately to highly familiar with sparsentan and atrasentan, this moves to 42% for iptacopan) and indicate increasing willingness to prescribe if available.

**Conclusions:** Nephrologists treating IgAN patients have significantly increased their use of SGLT2is in the past year, with utilization likely to continue to increase. However, large majority of patients remain untreated with SGLT2i. Systemic steroids, with evolving treatment regimens, continue to have a role in patient management, with the potential for more change following the recent approval of delayed-release budesonide.

Robson,<sup>5</sup> Sven-Jean Tan,<sup>6</sup> Muh Geot Wong,<sup>7</sup> Ashley Frazer-Abel,<sup>8</sup> Qingqing Yang,<sup>9</sup> Lixuan Yin,<sup>9</sup> Terry Barrett,<sup>9</sup> Jon L. Ruckle,<sup>10</sup> Eugene Schneider,<sup>9</sup> Richard Geary,<sup>9</sup> Filippo Canducci,<sup>11</sup> Michael Mccaleb.<sup>9</sup>  
<sup>1</sup>The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; <sup>2</sup>University of Toronto, Sunnybrook, ON, Canada; <sup>3</sup>CDHB, Christchurch, New Zealand; <sup>4</sup>Liverpool Hosp Renal Clinic, Liverpool, NSW, Australia; <sup>5</sup>Christchurch Clinical Studies Trust Ltd, Christchurch, New Zealand; <sup>6</sup>The Royal Melbourne Hospital, Parkville, VIC, Australia; <sup>7</sup>Royal North Shore Hospital, St Leonards, NSW, Australia; <sup>8</sup>Exsera Biolabs, Denver, CO; <sup>9</sup>Ionis Pharmaceuticals Inc, Carlsbad, CA; <sup>10</sup>Pacific Pharma Grp, Tacoma, WA; <sup>11</sup>Roche, Basel, Switzerland.

**Background:** Pathogenesis of IgA nephropathy (IgAN) is known to be dependent upon multiple factors, one being the complement system. Overactivity of the complement Alternative Pathway (AP) has been proposed to be responsible in part for the renal deposition of complement C3 activation-products and subsequent renal sequelae. We sought to test the hypothesis that a reduction of systemic AP would improve proteinuria. This was accomplished by lowering the production of complement factor B (FB), a required component of the AP, using an investigational antisense oligonucleotide that targets FB mRNA in the liver.

**Methods:** An exploratory, single arm, open label Ph 2 study recruited patients with biopsy-confirmed IgAN within 12 months (C3 deposition,  $\leq 50\%$  IFTA,  $\leq 50\%$  crescents), proteinuria  $> 1.5$  g/d, eGFR  $> 45$ , hematuria, despite maximum ACEi/ARB for at least 60 d. Patients received monthly SC administration of IONIS-FB-LRx. Primary outcome was change in 24-hr proteinuria at Wk29 (4 wk after last dose) compared to baseline (BL). Secondary outcome measures included: safety, complement levels and eGFR. (NCT04014335)

**Results:** Study enrolled 10 subjects, 25-59 yr, 40% Female, 6 Asian, and 4 White. There was a selective reduction of plasma complement FB protein levels, serum AP activity and urinary Ba from BL to end of treatment (mean % change of -69%, -39% and -88%, respectively). Median proteinuria (24 hr urine collection) at BL was 2.06 g/d (IQR 1.43, 3.51 g/d). At Wk 29, the change in proteinuria was -1.09 g/d (IQR -1.68, -0.79 g/d), corresponding to a 44% reduction. There was no change in eGFR at Wk 29 compared to BL (mean  $\pm$  SD; BL 68  $\pm$  26; Wk29 69  $\pm$  21 mL/min/1.73m<sup>2</sup>). The drug demonstrated an acceptable safety profile with no Treatment Emergent SAE and the only clinically meaningful safety signal (moderate TEAE) was a reversible elevation of ALT without changes in bilirubin in one subject. All subjects completed the study (wk 29).

**Conclusions:** This Ph 2 open label study provides initial clinical evidence that IONIS-FB-LRx reduces complement and proteinuria in patients with IgAN, supporting further development to determine the potential of IONIS-FB-LRx to reduce the progression of IgA nephropathy.

**Funding:** Commercial Support - Ionis Pharmaceuticals

### Glomerular Transcriptomics Predicts Outcome and Identifies Therapeutic Strategies for Assumed Benign IgA Nephropathy

Mariell Rivedal,<sup>1</sup> Håvard Mikkelsen,<sup>1</sup> Hans-Peter Marti,<sup>1,2</sup> Thomas Knoop,<sup>1,2</sup> Rune Bjoerneklett,<sup>1,2</sup> Yngvar Lunde Haaskjold,<sup>1,2</sup> Jessica Furriol,<sup>1,2</sup> Sabine Leh,<sup>2</sup> Terje Apeland,<sup>4</sup> Flavia T. Paunas,<sup>3</sup> Janka Babickova,<sup>1</sup> Andreas Scherer,<sup>5,6</sup> Oystein Eikrem,<sup>1,2</sup> Philipp Strauss.<sup>1</sup>  
<sup>1</sup>Universitetet i Bergen, Bergen, Norway; <sup>2</sup>Helse Bergen HF, Bergen, Norway; <sup>3</sup>Helse Fonna HF, Haugesund, Norway; <sup>4</sup>Helse Stavanger HF, Stavanger, Norway; <sup>5</sup>Helsingin yliopisto, Helsinki, Finland; <sup>6</sup>Spheromics, Kontiolahti, Finland.

**Background:** In a previous study of patients with IgA nephropathy (IgAN) with assumed benign disease, we have shown that 18.6% of patients develop a progressive clinical course, which was not predicted by any known clinical nor histopathological parameters (Knoop 2017, *Nephrol Dial Transplant*). We aim to differentiate between future progressors and non-progressors with assumed benign IgAN by using glomerular transcriptomics from diagnostic kidney biopsies and to investigate whether this can identify drugs to be used in those patients.

**Methods:** We included adult progressive patients (n=15) and patients with remitting disease (non-progressors, n=21) from our previously reported IgAN cohort, with a mean follow-up time of 21.6 years, and assembled an internal validation cohort. Glomerular laser-capture microdissection was performed from 10µm archival kidney biopsy sections, RNA extracted and sequenced with the SMARTer Stranded Total RNA-Seq kit – Pico Input Mammalian (Clontech Laboratories, California, USA). Expression key results were validated in publicly available cohorts and on the protein level with immunohistochemistry in our internal cohorts.

**Results:** Based on the 1,240 differentially expressed glomerular genes from the initial kidney biopsies, we were able to identify which patients will be IgAN progressors and non-progressors using a two-component classifier. The classifier predicted disease progression with 88% accuracy, 75% sensitivity and 100% specificity (AUC=0.875), more accurate than the recommended International IgAN Prediction Tool. We identified 45 possible drug targets, including angiotensinogen, a target of sparsentan, currently investigated as therapy in IgAN (NCT03762850 and NCT04663204). The findings on upregulation of angiotensinogen, which was independent of blood pressure, were validated in an internal IgAN validation cohort. Interestingly, complement activation did not play a major role in our data.

**Conclusions:** Glomerular mRNA sequencing from diagnostic kidney biopsies from assumed benign IgAN can differentiate between future progressors and non-progressors at the time of biopsy, on average 21.6 years before progressive disease is documented.

### Machine-Learning Based Prediction Model for Prognosis of IgA Nephropathy Patients

Sehoon Park,<sup>1</sup> Eun Sil Koh,<sup>6</sup> Chung Hee Baek,<sup>5</sup> Yong Chul Kim,<sup>1</sup> Jung Pyo Lee,<sup>3</sup> Dong Ki Kim,<sup>1</sup> Seung Hyeok Han,<sup>4</sup> Ho Jun Chin,<sup>2</sup> Kwon Wook Joo,<sup>1</sup> Yon Su Kim,<sup>1</sup> Hajeong Lee.<sup>1</sup>  
<sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea; <sup>3</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>4</sup>Severance Hospital, Seodaemun-gu, Seoul, Republic of Korea; <sup>5</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; <sup>6</sup>Catholic University of Korea School of Medicine, Seoul, Republic of Korea.

**Background:** IgA nephropathy is one of the most common primary glomerulonephritis and the disease shows heterogeneous prognosis. International Risk Score system has been developed to predict the prognosis of IgA nephropathy, however, further investigation for additional prognostic modeling by machine-learning based method may further improve the prediction power.

**Methods:** We screened total of 5387 IgA nephropathy patients from 3 tertiary university hospitals in Korea. The study population was divided into development and validation cohort. Based on the collected electronic health records, CatBoost model was used for machine-learning based modeling for the adverse composite outcome, which included halving of eGFR and end-stage kidney disease. Area under curve (AUC) values for the outcomes within 1, 3, and 5 years were calculated to assess the discriminative power.

**Results:** The constructed model showed good discriminative power in the developmental cohort as the AUC values ranged from 0.94 to 0.99 for the study outcomes. In the developmental cohort, there was some attenuation particularly in the hospitals with small number of samples (AUC 0.65-0.80), however, most AUC values for the study outcomes remained in acceptable range (AUC 0.81-0.97).

**Conclusions:** Machine-learning based prediction model for IgA nephropathy prognosis may provide a valid tool to estimate the kidney failure risk in the patients.

SA-PO717

**Predictors of Bleeding Following Inpatient Percutaneous Kidney Biopsy**  
Tulayla Katmeh,<sup>1</sup> Aran Thanamayooran,<sup>1</sup> Isaac Bai,<sup>2</sup> Geraint C. Berger,<sup>2</sup> Meghan Day,<sup>1</sup> Bright Huo,<sup>2</sup> Amanda J. Vinson,<sup>1,2</sup> Karthik K. Tennankore.<sup>1,2</sup>  
<sup>1</sup>Nova Scotia Health Authority, Halifax, NS, Canada; <sup>2</sup>Dalhousie University, Halifax, NS, Canada.

**Background:** Percutaneous diagnostic kidney biopsy is important in managing kidney disease, but less is known about predictors of bleeding following biopsy. The purpose of this study was to determine clinical risk factors for minor/major bleeding following percutaneous diagnostic kidney biopsy among admitted patients.

**Methods:** We analyzed a cohort of all adults that received an in-patient diagnostic kidney biopsy at a tertiary care center from 2014-2019. Biopsies for the diagnosis of kidney tumors were excluded. Outcomes of interest were minor bleeding (any of hemoglobin drop >10 g/L within 24 hours post biopsy, macrohematuria, hematoma on ultrasound) and major bleeding (need for blood transfusion or surgical intervention post biopsy). Predictors of major bleeding were analyzed using logistic regression; those factors significantly associated with bleeding using a P<0.05 were included in a multivariable model and reported using odds ratios (OR) with 95% confidence intervals (CI).

**Results:** Between 2014-2019, a total of 380 in-patient biopsies were performed. 221 (58.2%) of the patients were male, and mean age of the population was 57.3 ± 15.8 years. A minor bleed occurred in 131 (34.5%) of patients, and a major bleed occurred in 56 (14.7%) of patients. Risk factors for major bleeding are noted in Table 1. Factors significantly associated with major bleed included: creatinine 400-600 (OR. 7.46; 95%CI. 2.13-26.14); creatinine >600 or on dialysis (OR. 13.82; 95%CI. 4.04-47.25); structural heart disease (OR. 9.40; 95%CI. 1.33-66.47) and cerebrovascular disease (OR. 6.62; 95%CI. 1.47-29.78).

**Conclusions:** This study highlights risk factors associated with bleeding after inpatient percutaneous kidney biopsy which is of clinical importance for health care professionals. In future study we will derive and validate a risk prediction model for major and minor bleeding following biopsy.

Table 1. Risk factors for major bleeding following kidney biopsy (adjusted model; N=325)

Variable	Odds ratio	95% Confidence interval

SA-PO718

**Bacterial Infections in Patients With ESKD due to Glomerular Disease in the United States**

Vivek Charu,<sup>1</sup> Jialin Han,<sup>1</sup> Maria E. Montez-Rath,<sup>1</sup> Wolfgang C. Winkelmayr,<sup>2</sup> Michelle M. O'Shaughnessy.<sup>3</sup> <sup>1</sup>Stanford University School of Medicine, Stanford, CA; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>University College Cork, Cork, Ireland.

**Background:** Patients with kidney failure on dialysis are at increased risk for infection. However, whether reported cause of kidney failure associates with infection risk after dialysis initiation has been poorly studied. We quantified rates of infection-related hospitalization (IRH) by cause of kidney failure in patients newly initiated on dialysis in the US.

**Methods:** Using data from the United States Renal Data System (USRDS), we studied all adult patients (≥18 years) with kidney failure attributed to any of six selected glomerular disease subtypes, diabetic nephropathy [DN], or autosomal dominant polycystic kidney disease, who started dialysis as a first kidney failure treatment modality between 2005 and 2014. We used multivariable Prentice, Williams and Peterson (PWP) models to estimate hazard ratios for overall, 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> IRH for each cause of kidney failure.

**Results:** 277,173 patients were included in this analysis. Compared to patients with IgA nephropathy (IgAN), those with MPGN, lupus nephritis (LN), vasculitis, or DN had higher overall IRH rates (20 vs. 30-36 events per 100 person years; p<0.05). Multivariable PWP models demonstrate that after adjustment for demographic and clinical covariates, patients with LN, vasculitis, or DN (vs. those with IgAN) had significantly higher hazards of 1<sup>st</sup>-3<sup>rd</sup> IRHs (adjusted HRs 1.14-1.44, p<0.05; **Figure**).

**Conclusions:** In US patients with kidney failure, the risk of IRH varied by reported cause of kidney failure. Specifically, patients with LN, vasculitis, or DN were at higher risks for IRH compared to patients with IgAN. These findings can inform patient counseling as well as the design of future studies examining pathogenic mechanisms and therapeutic interventions.

Adjusted hazards ratios for 1<sup>st</sup>-3<sup>rd</sup> infection-related hospitalization (IRH), adjusting for adjusted for demographic/clinical characteristics.

SA-PO719

**Epidemiology of Membranoproliferative Glomerulonephritis: A Single Centre Observation Over 20 Years**

Chethana Ramakrishna, Joshua Storrar, Sara Metaoy, Constantina Chrysochou, Francesco Rainone, James Ritchie, Dimitrios J. Poulidakos, Rajkumar Chinnadurai, Philip A. Kalra, Smeeta Sinha. *Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

**Background:** Membranoproliferative glomerulonephritis (MPGN) is a pathological entity seen on light microscopy which represents a pattern of kidney injury characterised by an increase in intraglomerular cells and diffuse thickening of the glomerular capillary walls. MPGN accounts for about 7% -10% of all cases of confirmed glomerulonephritis on biopsy. MPGN includes immune complex mediated MPGN (ICGN) and C3 glomerulopathy (C3G). C3G in turn comprises of dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). The updated classification has enabled a greater understanding of the pathophysiology and facilitated research focusing on targeted therapeutic options and trials particularly targeting the complement system

**Methods:** This is a single centre observational study was conducted on all patients who had a biopsy proven diagnosis of MPGN from our biopsy database between January 2000 and December 2020

**Results:** A total of 41 patients were diagnosed with MPGN over this 20-year period of which 28 patients had immune complex mediated MPGN and 10 patients had C3G. Of the patients with C3G, 8 had C3GN and 2 had DDD. Three patients with MPGN were not classified due to insufficient data. The mean age at diagnosis was 55.7 ±17.6 years. Mean age at diagnosis for ICGN and C3G was 56.8 ± 16.9 years and 48 ± 17.9 years respectively. Mean blood pressure was 147/81 mmHg ±27/11mmHg. Nephrotic

range proteinuria was the presenting feature in 14 patients with ICGN and 7 patients with C3G. MPGN was associated with infections in 8 patients, connective tissue disease in 5 patients and haematological malignancies (lymphoma/leukaemia) in 5 patients. The remaining 23 patients did not have a clear aetiology for MPGN. The mean estimated glomerular filtration rate was  $40.3 \pm 27.8$  mL/min at diagnosis; 80.4% received renin-angiotensin system inhibitors (RASi) and 73.17% received immunosuppression. Twenty patients (50%) progressed to end stage kidney disease and received renal replacement therapy. Two patients underwent renal transplantation of which one developed recurrence of MPGN in the transplant kidney.

**Conclusions:** Our observation has added insights to this rare renal pathological diagnosis which has multiple aetiological factors including complement pathway dysregulation.

## SA-PO720

**Crescentic Glomerulonephritis due to Proteinase 3 (PR3) Anti-Neutrophil Cytoplasmic Autoantibody (ANCA) and IgA Mediated Anti-Glomerular Basement Membrane (GBM) Disease: A Rare Case of Double Identity**  
Melody L. Siff,<sup>1</sup> Mirza S. Baig,<sup>2</sup> Jason M. Kidd.<sup>1</sup> <sup>1</sup>Virginia Commonwealth University Health System, Richmond, VA; <sup>2</sup>Richmond Nephrology Associates, Richmond, VA.

**Introduction:** Crescentic glomerulonephritis due to co-existing ANCA associated vasculitis and Anti-GBM antibody disease is rare and often referred to as “double positive” disease. Most double positive cases involve myeloperoxidase (MPO) ANCA. Furthermore, anti-GBM disease generally manifests with linear staining IgG staining. We present a case of double positive disease with both PR3-ANCA and linear IgA staining of the glomerular basement membranes.

**Case Description:** A 73-year-old female presented to the hospital with acute kidney injury with a serum creatinine of 5.7 mg/dL. She had been treated with antibiotics for mastoiditis intermittently for 3 months. She was admitted to the hospital and underwent kidney biopsy. Serologic work up was significant for elevated PR3 ANCA. Biopsy was significant for crescentic glomerulonephritis and IgA and kappa linear staining along the GBM. No immune complexes were seen on electron microscopy. There was no evidence of diffuse alveolar hemorrhage. She was started on dialysis at presentation. After tissue diagnosis, she was started on glucocorticoids, plasma exchange and plan to begin cyclophosphamide. She has shown some renal recovery and dialysis is currently on hold.

**Discussion:** Double positive ANCA and anti-GBM is rare combination with limited and conflicting data regarding treatment. Literature review revealed approximately one-third of patients with anti-GBM also had an associated ANCA, which was usually MPO and rarely PR3. We believe this is the first described case of atypical anti-GBM (linear IgA) disease with dual positive PR3-ANCA. Due to the rarity of the co-existence, there are no treatment guidelines. Due to the severity of disease presentation, we are treating the patient aggressively with high dose steroids, plasma exchange and cyclophosphamide, which then should be followed by maintenance immunosuppression to prevent relapse of ANCA, especially prevalent in PR3.

## SA-PO721

**Treatment of Membranous Nephropathy With Crescent Nephritis by Rituximab With Corticosteroids**

Fan Zhang, Yiya Yang, Yinyin Chen, Yumei Liang, Xun Luo. Hunan Provincial People's Hospital, Changsha, China.

**Introduction:** Crescent formation is rare in primary membranous nephropathy (MN). Previously reported cases of MN and crescent formation without any signs of vasculitis, lupus, or anti-GBM disease showed unfavorable therapeutic response and tended to have worse renal outcomes. Here, we presented a rare case presented with NS and kidney biopsy-proven MN.

**Case Description:** A 71-year-old female was admitted to hospital with nausea, vomiting and hypouricemia for 20 days. Serum creatinine was 539 μmol/L. Urinary sediment showed 120000 red blood cells per ml, 4+ protein. Serum albumin was 24.99 g/L. Anti-PLA2R antibodies were positive of 415.29(<14) RU/mL. ANCA, anti-GBM antibody, anti-PR3 antibody, ANA antibody were all negative. Kidney biopsy (Fig. 1) contained 11 glomeruli, 1 of them were global sclerosis, 6 of them had crescent formation. GBM thickening and “spike and dome” appearance observed. Immunofluorescence showed granular deposits of IgG++, C3+ and IgM+ along capillary loop. The diagnosis was stage II MN combined with crescentic glomerulonephritis. She was treated with methylprednisolone 500mg per day for 3 days then reduced to 40mg per day, in combination with rituximab 600mg per week for 4 weeks (total dose 2.4mg), combined with intermittent hemodialysis (Figure 2). One month later, her serum creatinine was 139(40–100) μmol/L. Urinary sediment showed no red blood cells, 2+ protein. Glucocorticoids were gradually reduced and the patient got complete remission 3 months later. Anti-PLA2R antibody became negative.

**Discussion:** Now there is no guideline for the treatments to MN with crescents and previously reported cases showed poor response of the therapy. Our case suggests a beneficial effect of rituximab for MN patients with crescentic glomerulonephritis. It provides that there is a pathologic feature of MN and crescents in the absence of known immunologic factors and rituximab could serve as an effective cure and could be considered in serious conditions of MN.

Kidney biopsy examinations.

## SA-PO722

**Probenecid-Induced IgA Nephropathy Is Reversible**

Sreyoshi F. Alam, Spencer Hodgins, Daniel L. Landry, Gregory L. Braden. Div of Nephrology UMass Chan Med School-Baystate, Springfield, MA.

**Introduction:** IgA nephropathy is usually idiopathic in nature but can have a genetic predisposition & it can also be secondary to autoimmune diseases, vasculitis, infections, liver disease, or anti-VEGF drugs like bevacizumab, & covid vaccine. We present a case of probenecid-induced IgA nephropathy.

**Case Description:** A 65-year-old male with chronic gout developed progressive chronic kidney disease over a 3-year period. He had been on probenecid 1 g twice daily for his gout for 15 yrs. His sodium iohalate clearance deteriorated to 58 mL/min, with a serum creatinine of 1.5 mg/dL. All other serologic tests were negative. His 72-hour lead level was also normal. He did not have SLE, granulomatous disease, or systemic rheumatic disorders. Surprisingly he did not have proteinuria or hematuria. Renal biopsy revealed IgA nephropathy, with segmental mesangial hypercellularity, mild arterial sclerosis, & tubular atrophy. Cytoplasmic lipofuscin pigment was noted on PAS stain capillary loops with focal thickening of the glomerular basement membrane, engorged capillary loops, & thickened tubular basement membrane. Immunofluorescence studies showed diffuse segmental paramesangial granules of IgA [3+] & fibrinogen as well as paramesangial granules of IgG [2+], Kappa & lambda. Electron microscopy showed swollen podocytes with increased cytoplasmic organelles and vacuolization, focal foot process effacement, & electron-dense deposits in the paramesangium & mesangium. His MEST score was zero. 6 months after discontinuation of probenecid, the patient's iohalate GFR significantly improved to 79 mL/min, followed by 82 mL/min 6 months later. He never had proteinuria, hematuria, or casts throughout his disease course. Five years later his GFR was 88 mL/min with a serum creatinine of 1.1 mg/dL.

**Discussion:** Probenecid has pleiotropic effects on the human immune system. It inhibits Pannexin-1 channels which are known to modulate T-cell function. Probenecid also regulates TRPV-2 channels as an agonist. These channels are also present on human immune B and T cell lymphocytes. Probenecid inhibits VEGF in retinal endothelial cells, & bevacizumab, an anti-VEGF monoclonal antibody, has been shown to cause IgA nephropathy. We conclude that probenecid can be a cause of IgA nephropathy which is reversible upon drug discontinuation.

## SA-PO723

**Parvovirus B19 and Collapsing Glomerulopathy in a Postpartum Female**  
Elias S. Khazoum, Azkaa Zaman, Norhan Elsayed, Chetachi E. Odelugo, Moudi Hubeishy, Shanaz Azad, Tauseef A. Sarguroh. Franciscan Health Inc, Mishawaka, IN.

**Introduction:** Collapsing glomerulopathy (CG) is a variant of FSGS characterized by rapid onset and progression of renal failure. Interstitial fibrosis (IF), tubular atrophy (TA), entry level serum creatinine (SrCr) and degree of proteinuria have been used as predictors for progression.

**Case Description:** A 36-year-old African American female with a history of obesity reported gradual development of lower extremity edema following delivery of her second child. Her pregnancy was complicated by gestational diabetes and preeclampsia. At four months postpartum, she developed an upper respiratory infection followed by onset of exertional dyspnea, orthopnea, chest pain and worsening edema for which she presented to the hospital. Of note, she mentioned that her newborn was being treated for a rash on her face and scalp. Workup showed a SrCr of 1.0 mg/dL and a urine protein to creatinine ratio of 7.0 g/g. An echocardiogram revealed biventricular systolic dysfunction. Renal biopsy showed CG with moderate IF/TA and sclerosis of 24% of glomeruli. Serologies and HIV were negative, but parvovirus B19 (PvB19) IgM and IgG titers were elevated. Furosemide, losartan and spironolactone were started. Two weeks after discharge her repeat labs demonstrated SrCr of 1.0 mg/dL and proteinuria improved to 1.94 g/g.

**Discussion:** In one study, all CG patients with recovery of renal function had both IF and TA < 25% on biopsy. Another found IF > 20%, SrCr > 2, and proteinuria of > 8 g/day to be strong indicators of progression. A previous case report of CG in a 36-year-old intrapartum female with acute PvB19 infection and little IF/TA on initial biopsy showed rapid progression to ESRD, though she carried two APOL1 risk alleles. Our patient's preserved renal function and improved proteinuria on follow-up, despite risk factors of moderate IFTA on biopsy, may be related to a decreased genetic risk.

#### SA-PO724

##### **Lupus-Like Nephritis Secondary to Non-steroidal Anti-inflammatory Drug (NSAID) Use: Case Report**

Sapna Sharma,<sup>1,2</sup> Angelina Dhani Mohamed,<sup>1,2</sup> Ermias S. Greffie,<sup>1,2</sup> William M. Paredes,<sup>1,2</sup> Jamil Ibrahim,<sup>1,2</sup> Bessy Suyin Flores Chang,<sup>1,2</sup> <sup>1</sup>*St Barnabas Hospital, Bronx, NY;* <sup>2</sup>*The City College of New York, New York, NY.*

**Introduction:** Membranous nephropathy (MN) is a disorder with thickening of the glomerular capillary wall, resulting from immune complex formation on the basement membrane which leads to loss of large amounts of proteins in the urine. MN accounts for 30% of cases of nephrotic syndrome in adults of which 80% are due to primary MN and 20% are secondary to medications such as NSAID and diseases such as systemic lupus erythematosus (SLE), hepatitis B, hepatitis C and malignancies. We present a case of Lupus-like nephritis secondary to NSAID use

**Case Description:** 50-year-old male patient with diabetes, hypertension, asthma and obesity came to the hospital complaining of bilateral lower extremity swelling for 8 months. Physical exam was significant for generalized anasarca, chronic stasis changes in bilateral lower extremities, warmth and erythema of the left leg. His medications included lisinopril, hydrochlorothiazide, omeprazole, diclofenac 100 mg daily for over 8 months for joint pain. Initial serum creatinine was elevated to 9.2 mg/dl, Albumin was decreased to <1 gm/dl. 24-hour total urine protein was 27 g and diagnosis of nephrotic syndrome was made. Extensive workup for infectious causes were negative. Autoimmune workup was negative for antinuclear antibodies, Anti-dsDNA, and rheumatoid factor. This prompted a kidney biopsy which revealed full-house immunofluorescence with focal segmental sclerosing features, diffuse acute tubular injury and moderate interstitial inflammation. He required temporary hemodialysis and was subsequently started on pulse dose steroids for 3 days with subsequent tapering along with lisinopril and albumin. Serum creatinine plateaued around 4.5 mg/dl for which dialysis was discontinued and followed up in clinic

**Discussion:** Membranous nephropathy with full-house immunofluorescence (IgG, IgA, IgM, C1q and C3) has been recently recognized in patients without features of SLE, called lupus-like nephritis. The insidious presentation of renal insufficiency with severe lower extremity edema, nephrotic syndrome and biopsy demonstrating full-house immunofluorescence, diffuse acute tubular injury and acute interstitial inflammation suggested NSAID induced MN in our patient. There are no clear guidelines on treatment for secondary MN due to NSAID use and need to be established along with awareness regarding long term effects

#### SA-PO725

##### **A Case of Concomitant Anti-Glomerular Basement Membrane (Anti-GBM) Disease and Membranous Nephropathy**

Cora O. Ogbolu, Dawn Maldonado, Temi-Ete I. Ediale, Joseph Guadalupe, Stephen C. Ward, Saad A. Bhatti, Aaron S. Stern, Maritza Brown. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Introduction:** There have been few cases of anti-glomerular basement membrane disease co-existing with membranous nephropathy (MN). We present a case of this rare dual pathology.

**Case Description:** A 56-year-old man with hypertension presented to the emergency room with dark urine and oliguria. He denied fever, dyspnea or hemoptysis. He had stable vitals, clear lungs, leg edema, and no rashes. Creatinine was 9.5 mg/dL (0.9 8 months ago).

Urine microscopy showed red blood cell casts. Anti-GBM was 194 U. ANA, ANCA, complements, and anti-PLA2r were normal. Kidney biopsy revealed cellular crescents, and immunofluorescence showed linear IgG and C3 (figure 1). Electron microscopy showed subepithelial and rare intramembranous immune deposits (figure 2). The final diagnosis was anti-GBM and MN. The patient was treated with pulse steroids, cyclophosphamide, and plasma exchange alternating with dialysis. Despite 2 weeks of plasma exchange, anti-GBM remained elevated at 46 U. He remains dialysis-dependent after 3 months.

**Discussion:** Only a few case reports have described the co-existence of anti-GBM and MN. Renal outcomes are worse than in patients with either diagnosis alone, which was the case for our patient. The fact that anti-GBM titers remained elevated despite plasmapheresis suggests that a systemic factor led to its active production. This factor may be related to the MN. This case highlights the need for elucidation of a target antigen that may trigger both diseases.

#### SA-PO726

##### **Ovarian Carcinoma Induced NELL-1 Membranous Nephropathy With Bilateral Renal Vein Thromboses**

Cynthia Contreras, Amit K. Rajput, Cesar E. Abdul-Massih, Antoine L. Samaha. *TriHealth, Cincinnati, OH.*

**Introduction:** Membranous nephropathy (MN) is one of the most common causes of nephritic syndrome in adults, accounting for nearly one-third of all cases. PLA2R, a transmembrane receptor, is the major antigen in primary MN, found in approximately 70% of cases. Neural epidermal growth factor-like 1 (NELL-1) is seen in 16% of PLA2R negative MN. NELL-1 has a high association with underlying malignancy, seen in up to one-third NELL-1 positive MN patients.

**Case Description:** A 70-year-old female with a history of myelofibrosis was admitted by her nephrologist due to an asymptomatic acute kidney injury (AKI) with nephrotic range proteinuria (UPCR 23g). Her Cr increased from 1.1mg/dL to 2.5mg/dL in less than 3 months. Extensive serologic work up was unremarkable, prompting a renal biopsy. The renal biopsy revealed NELL-1 MN with 6/27 glomeruli globally sclerosed and severe arteriosclerosis. Interestingly, the biopsy also demonstrated focal glomeruli with rare intraluminal aggregates of fibrin material and focal glomerular hypercellularity, suggesting renal vein thrombosis. During the work up, the patient was found to have a left renal vein acute thrombosis and no visualization of the right renal vein. A subsequent venogram demonstrated bilateral renal vein thrombosis, as well as thrombosis in the inferior vena cava and hepatic vein. The patient underwent multiple thrombectomies and thrombolytics, which improved her clot burden, but unfortunately was unable to salvage

the right renal vein. The patient was started on long-term anticoagulation. Given the association with NELL-1 MN and malignancy, the patient underwent an extensive work up. She was ultimately found with bilateral ovarian masses, which were consistent with high-grade serous carcinoma of the ovaries.

**Discussion:** NELL-1 membranous nephropathy accounts for approximately 16% of all PLA2R negative MN cases. As seen with this patient, NELL-1 MN has a strong association with underlying malignancy. If diagnosed on biopsy, patients should undergo extensive cancer screening. As our understanding of this association progresses, more research is needed in guiding treatment for NELL-1 MN, especially cases with co-existing malignancies.

## SA-PO727

### A Novel Approach in a Case of Cryoglobulinemic Glomerulonephritis

Pooja Kalantri, Koba A. Lomashvili. Emory University, Atlanta, GA.

**Introduction:** Obinutuzumab, a fully humanized monoclonal anti CD-20 antibody, has been used for the treatment of B-cell malignancies. It is a novel and attractive treatment option in cases of glomerulonephritis, when Rituximab, a chimeric humanized murine monoclonal anti CD-20 antibody is not tolerated.

**Case Description:** A 52-year-old lady had a history of hypertension, Sjogren's disease, and mixed cryoglobulinemia complicated by glomerulonephritis and vasculitis. She reported being diagnosed with this disease in 2008 needing plasmapheresis. She relapsed in summer of 2020, with severe renal and skin manifestation and responded well to Rituximab infusion in August of 2020, achieving full remission with subsequent doses of rituximab at 4 months intervals. Unfortunately, the patient developed severe serum sickness reaction to third dose of Rituximab, requiring intubation. She relapsed again in 7/2021, and was diagnosed with monoclonal paraproteinemia of IgM kappa type with a normal bone marrow biopsy, 29% cryoglobulin levels, worsening proteinuria, AKI and purpuric rash with skin ulcers. She got pulse steroids and was started on monthly IV Cytoxin and oral steroid taper. The patient improved initially, dropping cryoglobulin level to 3%, but relapsed again when prednisone was tapered to 20 mg, while receiving IV Cytoxin. Prednisone was increased back to 60 mg daily. She later got admitted with a large left lower extremity ulcer and worsening skin rash. Her cryoglobulin level was also up to 8%. She was started on pulse dose steroids again and 1000mg Obinutuzumab given IV, with which she went into remission within 3 months. She got her second dose 5 months later on 3/2022, with prednisone completely tapered off currently. She had a healed leg ulcer, resolving purpuric rash, proteinuria of 330 mg/day, negative cryoglobulins, and an improving histopathology as of 3/2022.

**Discussion:** Rituximab is a chimeric antibody with murine and human components in it. Obinutuzumab is a fully humanized form. We believe that our patient had a reaction to the murine component of rituximab, which was not present in Obinutuzumab and hence she tolerated it well. It is a good alternative to explore. Obinutuzumab is currently not FDA approved for the treatment of cryoglobulinemic glomerulonephritis, and is being investigated for the treatment of lupus nephritis and membranous nephropathy.

## SA-PO728

### Glomerulonephritis Following a Streptococcal Infection: Deciding Whether It's Poststreptococcal Glomerulonephritis

Latoya N. Gayle, Alan M. Weinstein, Steven Salvatore. NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.

**Introduction:** Infection related glomerulonephritis (IRGN) was described in children as poststreptococcal glomerulonephritis (PSGN). Diagnostic kidney biopsy findings are subepithelial humps, which stain for C3 and IgG. IRGN is increasingly diagnosed in adults presenting for treatment of other infections. Ambiguity may arise when the biopsy does not display classic findings. We present a case of PSGN in an adult

**Case Description:** A 64-year-old female with hypertension and type 2 diabetes, presented to hospital with dyspnea for 1-2 days. She had a strep throat a week prior and received amoxicillin. She was saturating 86% on room air, with BP 182/90 and leg edema. Serum creatinine (Cr) = 4.68, up from 1.06 a month prior. Urine protein:Cr = 6.2, and urine sediment showed >50 RBC, >50 WBC, and RBC casts. On hospital day 1, urine output was less than 100 ml, despite bumetanide. CXR showed patchy consolidation and edema. She had worsening dyspnea with elevated systolic BP to 200 mmHg. CVVHD was started, and after net removal of 9L, systolic BP improved to 130 and BIPAP was no longer needed. Serologies included C3 = 54 (90-180mg/dl), C4 = 46.8 (12-36mg/dl), antistreptolysin O (ASLO) titre = 544 (<=200iu/mol), ANA positive 1:180, rheumatoid factor positive, ESR 83 and CRP 10. ANCA, dsDNA, MPO, PR3, hepatitis B and C were negative. Renal biopsy on day 4 revealed an exudative GN with no crescents, and IF showing only C3 and no IgG; there was widespread acute tubular injury of moderate severity. The patient received dialysis twice (days 5 and 7), as urine output reached 1.25 L on day 8. She was discharged on day 10 with Cr = 3.4. One-week later Cr = 2.9, with C3 = 118 and ASLO = 198.

**Discussion:** IRGN is often diagnosed in children based on presentation, while in adults biopsy confirmation is recommended. The finding of C3 only on our patient's kidney biopsy suggested possible C3GN. With her history, positive ASLO, and normalization of C3 within 2-3 weeks of presentation, this case was a true IRGN. However, at the time of biopsy there was ambiguity, between true PSGN and C3GN in someone who had a recent strep infection. Further studies into the evolution of IRGN in adults, with respect to the processing of glomerular immune deposits, may help address this ambiguity.

## SA-PO729

### Gonococcal Endocarditis-Associated Glomerulonephritis: Revisiting a Forgotten Enemy

Lillia Harris, Sriram Sriperumbuduri, Bushra Syed. The University of Mississippi Medical Center, Jackson, MS.

**Introduction:** Disseminated gonococcal infection is rare in the post-antibiotic era (0.5-3.0% cases) and can be complicated by infective endocarditis (IE) and glomerulonephritis (GN). We describe a unique case of rapidly progressive GN (RPGN) secondary to gonococcal IE coinciding with complement deficiency.

**Case Description:** A 61-year-old male with migratory polyarthritis, recurrent UTIs and conjunctivitis presented with diarrhea, arthralgia, and skin rash. On physical exam: purpuric rash involving forearms, thighs, nasal tip and cheeks; tenderness and swelling of the right shoulder and small joints of the right foot; bilateral chronic anterior uveitis. On initial workup (Table 1): anemia, leukocytosis, sCr of 2.98 mg/dL from baseline 0.8. Urinalysis showed proteinuria, hematuria, sterile pyuria, WBC casts. Cefepime started for empiric sepsis (Figure 1). A skin biopsy was consistent with leukocytoclastic vasculitis. Steroids were initiated due to suspected RPGN and worsened sCr. On additional workup: elevated UPCr and low C3 complement level; on renal biopsy diffuse crescentic and exudative GN with C3 deposits; favors IRGN. ECHO revealed a multi-lobular mass 1.9x2.6 cm on tricuspid valve (TV). Steroids were held due to concern for IE. Workup for culture-negative IE was unrevealing but metagenomics sequencing of microbial cell free DNA resulted positive for *Neisseria gonorrhea*. Functional testing of the complement pathway revealed normal CH50 and decreased AH50 activity. He received 6-weeks of Ceftriaxone with resolution of the TV vegetation and partial renal recovery with sCr of 1.27 mg/dL.

**Discussion:** Complement deficient patients are highly susceptible to *Neisseria* infections. Dysregulation of complement pathway predisposed to C3 glomerulopathy and concomitant infection provided a second hit contributing to severe GN. Treatment with antibiotics and steroids led to partial renal recovery; further research needed on role of immunosuppression for course and outcome of IRGN.

Admission laboratory results	Admission laboratory results
WBC	13.7 TH/mm (4.0 - 11.0)
Hemoglobin	5.7 g/dL (13.0 - 17.0)
ERS	111 ml/hr (0.0 - 10.0)
CRP	15.6 mg/dL (0.0 - 0.5)
sCr	2.98 mg/dL (0.67 - 1.17)
BUN	59 mg/dL (8-23)

## The Maximal Consequences of Minimal Change Disease

Chris Dipollina, Brian Bustos, Soo H. Kae. *University of Connecticut, Storrs, CT.*

**Introduction:** Minimal change disease (MCD) is a common cause of nephrotic syndrome in children. However, it only accounts for 10-15% of nephrotic syndromes in adults. The exact pathophysiology of MCD still remains unclear. We present a case of adult-onset MCD causing nephrotic syndrome and explore the pathophysiology behind MCD.

**Case Description:** A 38-year-old male presented to the hospital with 2 weeks of lower extremity edema and 3 days of oliguria with outpatient blood work showing creatinine rise to 1.5mg/dL from a baseline of 0.7 mg/dL 4 months ago. He had gross anasarca on exam, hypoalbuminemia with albumin level of 2.0 g/dL, and significant proteinuria (>7g/24 hrs) consistent with nephrotic syndrome. He denied being started on any new medication or using illicit drugs. During admission, his creatinine rose to 2.6mg/dL and he also had hematuria on urinalysis prompting a renal biopsy, which showed findings consistent with acute tubular necrosis (ATN) and diffuse podocytopathy confirming diagnosis of MCD with concurrent ATN. ANA, ANCA, and anti-PLA2R were all negative. Patient was pulsed with IV steroids and discharged on a steroid taper with resolution of his edema and proteinuria and normalization of his creatinine.

**Discussion:** The hallmark of MCD is podocyte effacement that results in protein loss, especially albumin, subsequently causing edema and hyperlipidemia. The exact mechanism as to how the podocyte gets effaced remains unclear although there are some emerging hypotheses. One theory is that T cell dysfunction results in production of glomerular permeability factor, which is thought to affect the glomerular capillary wall and cause proteinuria and foot effacement. More recent studies have shown the presence of deposits of circulating autoantibodies targeting nephrin, an essential component of the glomerular slit diaphragm, in kidney biopsies of patients with MCD. These hypotheses point towards an autoimmune or immune dysregulatory mechanism behind MCD, which can potentially explain why patients with MCD respond to immunosuppressives agents. Although rarer in adults, MCD is a known cause of nephrotic syndrome and carries significant morbidity with nearly 20% of cases necessitating dialysis. Kidney biopsy is the only way to confirm diagnosis. Further studies are needed to identify serological markers that could aid in a more prompt diagnosis of MCD in order to pursue targeted management.

## SA-PO731

## APOL1 Extracellular Translocation: A Possible Role of Microvesicles

Prabhjot K. Johal,<sup>1</sup> Vinod Kumar,<sup>1</sup> Ashwani Malhotra,<sup>2</sup> Pravin C. Singhal.<sup>2</sup>  
<sup>1</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

**Background:** Podocyte expressed APOL1 (pAPOL1) is not secretory compared to the one expressed by liver cells. However, the plasma membrane integration potential of pAPOL1 is well documented, where G0 has maximum membrane penetration than G1 & G2. Presence of pAPOL1 protein in the culture medium and biological fluids is still unclear. Here, we hypothesized that APOL1 secretion in podocyte cells adopt microvesicles (MVs) secretion pathway rather than direct secretion to the medium.

**Methods:** APOL1 and its risk variants were over-expressed in human embryonic kidney (HEK) cells. After 48hr of incubation, the culture medium was collected and processed for MVs isolation by ultracentrifugation and MVs isolation kit. MVs were also isolated from podocytes expressing APOLG0, G1 & G2. Isolated MVs were characterized for the presence of HSP70, CD81, CD63 and absence of Calnexin by Western Blot (WB) and FACS. Size was measured using Nanosize system and Scanning Electron Microscopy. ELISA was used to detect circulating APOL1, while WB used for MVs APOL1. MVs were further incubated with non APOL1 expressing HEK cells and after 48hr HEK cell lysate was analyzed for APOL1 presence by WB.

**Results:** Nanosize & SEM measured size of isolated MVs was in between 90-125nm. These MVs stained positive for the expression of CD63, CD81, and HSP70, but were negative for the expression of calnexin. Thereby, confirming that there was no cytosolic contamination. We observed the presence of APOL1 protein only in the lysed MVs. However, the level of APOL1-G0 (intensity: 1.92±0.01) is much higher compared to Vector (0.11±0.01) G1 (0.12±0.01) and G2 (0.17±0.02) Figure1

**Conclusions:** This preliminary study shows that Podocytes secrete APOL1 through MVs pathway

**Funding:** Government Support - Non-U.S.

**Fig 2. MVs size measured using Nanosize (A&B), SEM (C), expression of MVs protein marker and APOL1 (D), ELISA to detect APOL1 in media and MVs (E). P value \*\*\*p<0.001, #p<0.001 (\*G0 vs V, G1 or G2; #media vs MVs)**

## SA-PO732

## Obesity-Related Glomerulopathy in the Presence of APOL1 Risk Alleles

Nang San Hti Lar Seng,<sup>1,2</sup> Ronald Valdez Imbert,<sup>1,2</sup> Belinda Jim,<sup>1,2</sup> <sup>1</sup>Jacobi Medical Center, Bronx, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.

**Introduction:** Apolipoprotein L1 (APOL1) confers protection from *Trypanosoma brucei* infections are enriched in sub-Saharan African populations. Nephropathic APOL1 risk alleles (G1/G2) have been associated with focal segmental glomerulosclerosis, HIV-associated nephropathy, SLE-associated collapsing glomerulopathy, and other glomerulonephritides. Here, we present a case of obesity-related glomerulopathy (ORG) in the setting of two APOL1 risk alleles.

**Case Description:** A 32-year-old female from Jamaica with a history of hypertension, preeclampsia, hyperlipidemia, and obesity (BMI 32 kg/m<sup>2</sup>) was referred to the nephrology clinic for the evaluation of proteinuria and lower extremity edema. An evaluation for secondary causes of HTN was unrevealing. The patient also denied a history of premature birth or low birth weight for herself, though noted frequent urinary tract infections as a child but was never further evaluated. Her family history was significant for her mother who developed hypertension in the mid-twenties, her maternal grandmother who experienced a cerebrovascular accident at the age of 40, and her maternal grandfather who died of end-stage kidney disease of unknown etiology. Physical examination revealed a blood pressure of 150/100 mmHg, clear lungs, normal cardiac and abdominal exam, but bilateral 2+ lower extremity pitting edema. Labs were significant for estimated glomerular filtration rate 65 (82-137 ml/min/1.73 m<sup>2</sup>) and urine protein creatinine ratio (uPCR) 2368 mg/g. Infectious and autoimmune workup were unremarkable. Kidney biopsy showed mild focal global glomerulosclerosis with glomerulomegaly with mild tubular atrophy and interstitial fibrosis. The findings of glomerulomegaly indicated glomerular hypertension and hyperfiltration, which may be related to obesity, hypertension, and/or reduced nephron number. We referred our patient to the weight management clinic, started her on losartan and atorvastatin. At four-month follow-up, her uPCR decreased to 1618 mg/g.

**Discussion:** Obesity may serve as a "second hit" to develop ORG. Moreover, APOL1 risk alleles may be associated with increased cardiovascular and metabolic derangements. Given the substantial morbidity and mortality from the combination of cardiovascular disease and CKD, knowledge of APOL1 risk allele status may help to better stratify cardiovascular and renal risks to help guide clinical care.

## SA-PO733

## A Case of Lupus Podocytopathy in Transition to Membranous Lupus Nephritis Class V With Positive APOL-1 Gene

Venkata Kishore R. Mukku, Marjan Afrouzian, Tina Kochar. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Lupus podocytopathy (LP) is a glomerular lesion in systemic lupus erythematosus (SLE) patients characterized by diffuse epithelial cell foot process effacement (FPE) without immune complex deposition or with only mesangial immune complex deposition. In SLE, nephrotic syndrome in rare instances, appear as LP, mimicking minimal change disease (MCD) or primary focal segmental glomerulosclerosis (FSGS).

**Case Description:** 21-year-old African American female with a past medical history of eczema, kidney stone, COVID-19, facial rash admitted with persistent shortness of breath, lower extremity swelling with symptomatic anemia. Patient was noted to have nephrotic syndrome with positive serology for SLE and low complements. Renal biopsy

showed lupus podocytopathy with features of collapsing glomerulopathy. The absence of endocapillary proliferation, presence of collapsing features, and lack of sub-endothelial immune complexes on electron microscopy (EM) are features consistent with LP with transition to Membranous lupus nephritis (LN) Class V. Patient was started on steroids, mycophenolate mofetil, and hydroxychloroquine. Voclosporin was added at one month follow-up given persistent nephrotic syndrome. Proteinuria improved significantly to 2 g in 4 weeks and prednisone taper was started. APOL1 gene assay revealed presence of G1, G2 risk alleles.

**Discussion:** The prevalence of LP in LN biopsies is approximately 1% and is diagnosed based on clinical presentation of nephrotic syndrome with SLE and kidney biopsy findings of diffuse and severe FPE on EM, and absence of subendothelial or subepithelial immune deposits on EM. LP is further subclassified as MCD or FSGS subtypes. The MCD forms respond well to treatment with glucocorticoids as induction therapy, adding a nonglucocorticoid immunosuppressive agent only to treat or, in some cases, to avoid relapses. On the other hand, the FSGS forms with collapsing lesions have worse outcomes, progressing to end-stage renal disease in more than 50% of the cases. LP FSGS subtypes are less steroid-responsive and may benefit from initial induction treatment with glucocorticoids and another agent, such as calcineurin inhibitors. APOL1 genotyping of African American patients with SLE might help identify patients at risk for collapsing glomerulopathy, an entity with poor prognosis and resistance to treatment.

SA-PO734

**Human iPSC-Derived Podocytes to Study APOL1 High-Risk Variants**  
Lauren Haines, Uyen Tran, John F. O’Toole, John R. Sedor, Oliver Wessely. *Cleveland Clinic, Cleveland, OH.*

**Background:** Podocytes within the glomerulus are integral to forming the filtration barrier needed for kidney function. The CDC estimates 15% of adults in the US have chronic kidney disease (CKD), but there are no curative treatment options for CKD and patients must resort to time-consuming dialysis or undergo a kidney transplant to maintain a quality of life during disease progression. The African American population of sub-Saharan descent has a 3.5-fold increased risk for end-stage kidney disease compared to populations of European descent. This incidence discrepancy is, in part, due to two pathogenic variants G1 and G2 in the apolipoprotein L1 (*APOL1*) gene. Individuals with the presence of one high-risk allele are resistant to African sleeping sickness, but the presence of two high-risk alleles significantly predisposes to kidney disease.

**Methods:** As *APOL1* is only present in humans and some higher-order primates, to model its biology we have generated a series of isogenic human induced pluripotent stem cell lines (iPSCs) genetically engineered to contain *APOL1* reference (G0) and high-risk (G1, G2) variant genotypes. In addition, the lab has also developed a protocol to directly differentiate iPSCs into pure populations of podocytes. Combined with our new iPSC cell lines, this provides a novel cellular model to study *APOL1* high-risk variants in the cell type affected in human patients. A pure population of human high-risk *APOL1* podocytes will enable additional discovery not feasible through prior means of research.

**Results:** Variant *APOL1* iPSC lines successfully differentiate into pure podocyte populations using our podocyte differentiation protocol. These podocytes robustly express FOXD1, MAFB, and WT1. They form foot process-like cytoplasmic extensions, marked by slit diagram proteins NPHS1 and NPHS2. Upon stimulation with IFN- $\gamma$ , the podocytes express *APOL1*. These podocytes do not demonstrate differential cell death upon induction of *APOL1*.

**Conclusions:** This research allows the integration of human-specific aspects of podocyte biology in a representative and homogenous cell population. It provides an opportunity to gain an understanding of *APOL1* and the mechanism underlying *APOL1*-mediated diseases. Data generated using this model will help to provide directly translatable and desperately needed therapeutic intervention to kidney disease injury and progression.

**Funding:** NIDDK Support

SA-PO735

**Progression of Focal Segmental Glomerulosclerosis in Patients With High Risk APOL1 Genotypes: A CureGN Study**  
Mahmoud Kallash,<sup>1</sup> Yujie Wang,<sup>3</sup> Abigail R. Smith,<sup>3</sup> Howard Trachtman,<sup>3</sup> Carla M. Nester,<sup>4</sup> Rasheed A. Gbadegesin,<sup>6</sup> Pietro A. Canetta,<sup>7</sup> Chen Wang,<sup>7</sup> Tracy E. Hunley,<sup>14</sup> John Sperati,<sup>5</sup> David T. Selewski,<sup>2</sup> Isabelle Ayoub,<sup>8</sup> Tarak Srivastava,<sup>9</sup> Amy K. Mottl,<sup>10</sup> Jeffrey B. Kopp,<sup>11</sup> Virginie Royal,<sup>12</sup> Debbie Gipson,<sup>3</sup> Jason M. Kidd.<sup>13</sup> <sup>1</sup>Nationwide Children’s Hospital, Columbus, OH; <sup>2</sup>University of South Carolina System, Columbia, SC; <sup>3</sup>University of Michigan, Ann Arbor, MI; <sup>4</sup>The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; <sup>5</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>6</sup>Duke University Medical Center, Durham, NC; <sup>7</sup>Columbia University Irving Medical Center, New York, NY; <sup>8</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>9</sup>Mercy Children’s Hospital Springfield, Springfield, MO; <sup>10</sup>Cincinnati Children’s Hospital Medical Center James M Anderson Center for Health Systems Excellence, Cincinnati, OH; <sup>11</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>12</sup>Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; <sup>13</sup>VCU Medical Center Main Hospital, Richmond, VA; <sup>14</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** Polymorphism in *APOL1* is a risk factor for disease progression in FSGS. This study evaluated the association of *APOL1* genotypes on kidney disease progression in patients with FSGS.

**Methods:** Cure Glomerulonephropathy participants with a biopsy diagnosis of FSGS were included. Whole genome sequencing was performed with 150 bp paired end reads on Illumina NovaSeq 6000 instruments targeting 30X read depth. eGFR decline was categorized as  $\leq 5$ , 0 to  $-5$ , and  $>0$ ml/min/yr. Multivariable ordinal logistic regression was used to assess the association with *APOL1* high-risk (HR, 2 risk alleles) vs low risk (LR, 0-1 risk alleles).

**Results:** Of 650 participants, 13% were HR, 60% were LR (*APOL1* status missing for 27%, Table). HR participants’ biopsies showed more collapsing FSGS ( $p<0.001$ ), greater interstitial inflammation ( $p<0.001$ ) and interstitial fibrosis and tubular atrophy ( $p=0.02$ ). The odds of rapid progression was 2.76 times higher in the HR group after adjustment. Proteinuria at biopsy was not associated with progression category, however, within the first year post-enrollment, higher nadir proteinuria (OR=1.09,  $p=0.02$ ), need for multiple immunosuppressive agents (OR=1.35,  $p=0.001$ ) and uncontrolled hypertension (OR=1.61,  $p=0.04$ ) were associated with rapid progression.

**Conclusions:** In addition to *APOL1* genotype, degree of proteinuria reduction, use of multiple immunosuppressive agents and uncontrolled hypertension are additional risk factors for rapid progression of FSGS. A better understanding of the natural history of FSGS in the context of high risk *APOL1* genotypes will improve patient care and inform the design of interventional studies.

Table: Demographic and clinical characteristics of subjects per APOL1 status.

Character	All (N=650)	HR genotype (N=87)	LR genotype (N=389)	P

## SA-PO736

**Testican-2 Alleviates Adriamycin-Induced Podocyte Injury by Modulating Vitronectin-Integrin  $\alpha\beta 3$  Interaction**

Donghai Wen,<sup>1</sup> Ivy A. Rosales,<sup>1</sup> Robert B. Colvin,<sup>1</sup> Sushrut S. Waikar,<sup>2</sup> Wen Zhou,<sup>1</sup> Martin Pollak,<sup>3</sup> Eugene P. Rhee.<sup>1</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Boston University, Boston, MA; <sup>3</sup>Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** Testican-2 is a podocyte-derived glycoprotein encoded by the gene *SPOCK2*. Its circulating levels are associated with higher estimated glomerular filtration rate (eGFR) and slower rate of subsequent eGFR decline in two large racially diverse cohorts. The biological function of testican-2 in podocytes is unknown.

**Methods:** Immortalized cultured human podocytes were treated with adriamycin with or without testican-2, and then actin cytoskeleton disruption was examined to assess podocyte injury. BALB/c male mice were treated with adriamycin together with placebo (eGFP) or *Spock2* adenovirus. Three weeks later, urine spot albumin/creatinine and glomerulosclerosis were examined. To further investigate the underlying mechanisms of testican-2 on podocyte function, immunoprecipitation-mass spectrometry (IP-MS) was utilized to examine the potential binding proteins of testican-2 in the extra-cellular matrix (ECM) of cultured human podocytes. Bio-Layer Interferometry (BLI) was utilized to further confirm their interactions. Finally, glomerular testican-2 expression levels of human kidney biopsy samples from patients with primary focal glomerulosclerosis (FSGS) and normal control subjects were examined by immunofluorescence (IF).

**Results:** Testican-2 significantly reduced adriamycin-induced podocyte actin cytoskeleton disruption. Treatment of *Spock2* adenovirus also improved adriamycin-induced albuminuria and glomerulosclerosis as compared to eGFP adenovirus. IP-MS identified vitronectin as one of the binding partners for testican-2, which was further verified by BLI. In addition, BLI showed that testican-2 inhibits the interaction between vitronectin and integrin  $\alpha\beta 3$ , which is an anchored protein that has been shown to play an important role in podocyte injury. Administration of testican-2 also reduced adriamycin-induced activation of integrin  $\alpha\beta 3$  in cultured human podocytes and mouse glomeruli as examined by IF. Finally, glomerular testican-2 expression was reduced in patients with FSGS as compared to normal control subjects.

**Conclusions:** Testican-2 alleviates adriamycin-induced podocyte injury, likely through modulating vitronectin-integrin  $\alpha\beta 3$  interaction

**Change of Integrin  $\alpha\beta 3$  in Glomerular Diseases and Flow Shear Stress**

Jae seok Kim, Nghia T. Pham, Ji-Hee Kim, Bao T. Dang, Minseob Eom, Jun Young Lee, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi, Seung-Kuy Cha. *Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.*

**Background:** Podocyte and glomerular basement membrane (GBM) are main components of glomerular filtration barrier. Integrins (Itg) play a specific role in the crosstalk of podocyte and GBM under physical stress, but the renal disease-specific expression and context-dependent role of specific Itg remain elusive.

**Methods:** Here we explored disease-specific integrin (Itg  $\alpha\beta 3$ ) expression using human kidney tissues obtained from the patients with trauma (control), membranous nephropathy (MN), and minimal change disease (MCD), and examined the (patho) physiological role of Itg  $\alpha\beta 3$  upon mechanical stress.

**Results:** In immunohistochemical studies, Itg  $\beta 3$  was exclusively expressed in glomerulus. Itg  $\beta 3$  expression was lower in MN and MCD than that of control, while uPAR and fibronectin, an activator of Itg  $\alpha\beta 3$ , were higher in MN and MCD. There were no differences in Itg  $\beta 3$ , uPAR, and fibronectin between MN and MCD groups (Figure 1). Functional experiments revealed that mechanical forces by fluid shear stress (FSS) upregulated Itg  $\beta 3$  activation and induced actin remodeling without affecting total Itg  $\beta 3$  expression in human podocyte. In addition, FSS increased fibronectin supporting that Itg  $\alpha\beta 3$  might be activated in association with fibronectin under FSS (Figure 2).

**Conclusions:** Taken together, this study demonstrates that Itg  $\alpha\beta 3$  may be implicated in the interplay of podocyte and GBM under pathological conditions. In particular, Itg  $\alpha\beta 3$  activation by fibronectin is thought to be important step in the role of Itg  $\alpha\beta 3$ . Our results provide new clues for therapeutic strategies for glomerular diseases. **Discovery of a Novel Podocyte Complex of Nephrotic Syndrome Disease Protein NOS1AP and Dystroglycan Complex (DGC) Component SNTA1**

David A. Ball,<sup>1</sup> Lorin Liang,<sup>1</sup> Vineeta Sharma,<sup>1</sup> Gabrielle L. Wilson,<sup>1</sup> Florian Buerger,<sup>1</sup> Radovan Bogdanovic,<sup>2</sup> Stanley C. Froehner,<sup>3</sup> Marvin Adams,<sup>3</sup> Shirlee Shril,<sup>1</sup> Shrikant M. Mane,<sup>4</sup> Friedhelm Hildebrandt,<sup>1</sup> Amar J. Majumdar.<sup>1</sup> <sup>1</sup>Division of Nephrology, Department of Pediatrics, Boston Children's Hospital, Harvard Medical School, Boston, MA; <sup>2</sup>The Institute of Mother and Child Health Care of Serbia "Dr Vukan Cupic", Belgrade, Serbia; <sup>3</sup>University of Washington Department of Physiology and Biophysics, Seattle, WA; <sup>4</sup>Department of Genetics, Yale University School of Medicine, New Haven, CT.

**Background:** Nephrotic syndrome (NS) is a leading cause of pediatric chronic kidney disease. We discovered recessive mutations in *NOS1AP*, encoding nitric oxide synthase 1 adaptor protein, as a novel cause of NS (Majumdar *Sci Adv* 2021). We aimed to identify podocyte-specific *NOS1AP* interaction partners through which it regulates podocyte homeostasis.

**Methods:** Protein interactions were detected by co-immunoprecipitation (co-IP) assays using tagged cDNA constructs. Immunofluorescence (IF) staining and confocal microscopy were performed. Exome sequencing (ES) data from >800 NS families was analyzed.

**Results:** Of 85 putative *NOS1AP*-interacting proteins from published candidate interaction and proteomics studies, six were co-expressed (% cell expression z-score > 1) with *NOS1AP* in podocyte clusters from at least three of four published kidney single cell mRNA sequencing (scRNAseq) datasets: FYN, PAK1, GSN, SPTAN1, SNTA1, HSPA12A. Upon co-overexpression in immortalized podocytes, *NOS1AP* exhibited bi-directional co-IP with only SNTA1 and HSPA12A and required its PDZ binding domain for the SNTA1 interaction. SNTA1 (syntrophin alpha 1) is an adaptor protein, which recruits other dystroglycan complex (DGC) proteins to the mouse neuromuscular junction (Adams *J Neurosci* 2010). DGC genes *DAG1* and *UTRN1* were co-expressed with *NOS1AP* and *SNTA1* in podocyte clusters from published kidney scRNAseq datasets. By IF, we found that *NOS1AP* and SNTA1 co-localized with podocyte marker nephrin and was adjacent to alpha-dystroglycan in glomeruli from human and rat kidney sections. *NOS1AP*-induced filopodia formation, an NS intermediate phenotype, was reduced by SNTA1 knockdown in immortalized podocytes (32.8% versus 23.1%,  $X^2 = 4.4$ ,  $p = 0.035$ ). Finally, ES data was evaluated under the hypothesis that DGC genes are mutated in human NS. Candidate compound heterozygous variants in *UTRN1* (p.S623F, p.T3177C), with rare prevalence in gnomAD and multiple severe *in silico* prediction scores, were detected in a 16-year-old female F1418 with nephrotic range proteinuria resistant to corticosteroids.

**Conclusions:** Our results suggest that *NOS1AP* and SNTA1 form a complex in glomerular podocytes, which may have implications for actin remodeling and human NS.

**Transcriptomic Analysis of Homozygous CLVS1 H310Y Podocytes Reveals Mechanisms Driving Disease and Corticosteroid Mediated Rescue**

Brandon M. Lane,<sup>1,2</sup> Megan Chryst-Stangl,<sup>1,2</sup> Guanghong Wu,<sup>1,2</sup> Kinsie Huggins,<sup>3,2</sup> Rasheed A. Gbadegesin.<sup>1,2</sup> <sup>1</sup>Duke University School of Medicine, Durham, NC; <sup>2</sup>Duke Molecular Physiology Institute, Durham, NC; <sup>3</sup>Duke University, Durham, NC.

**Background:** We have previously shown that the homozygous CLVS1 H310Y variant is a cause of familial steroid sensitive nephrotic syndrome (SSNS). This variant causes defects in clathrin mediated endocytosis that results in increased generation of reactive oxygen species and decreased viability in conditionally immortalized podocytes. These phenotypes were ameliorated by corticosteroid treatment, mimicking the phenotype in the affected family, however the exact mechanisms involved were unclear.

**Methods:** To identify mechanisms of disease and therapy response, we performed unbiased RNA-seq transcriptomic analysis on conditionally immortalized podocytes with WT CLVS1, homozygous CLVS1 H310Y podocytes, and corticosteroid treated homozygous H310Y podocytes (N=3 each).

**Results:** Among the most significant pathways disrupted by the CLVS1 H310Y variant according to Gene Ontology (GO) analysis is response to virus (p=1.26E-6). Interestingly, other top downregulated pathways including focal adhesion, cell substrate adhesion, actin cytoskeleton regulation, and cell-cell adhesion in H310Y podocytes (p=4.51E-11, 4.34E-11, 2.73E-05, and 0.000395) were also among the most significantly upregulated pathways by corticosteroid treatment (p=7.84E-23, 7.87E-23, 1.26E-05, and 0.001755). Additionally, corticosteroid treatment increased intracellular vesicle transport of proteins to the cell membrane, endoplasmic reticulum, and within mitochondria (p=6.54E-24, 7.92E-23, and 2.54E-05).

**Conclusions:** The results of this study identified disruption of podocyte adhesion and cytoskeletal regulation pathways in podocytes homozygous for the CLVS1 H310Y mutation. Our findings also revealed that glucocorticoid treatments partially correct the dysregulation in these pathways. Corticosteroid treatment also increased expression of vesicle transport processes that could counteract a loss in clathrin mediated endocytosis. Taken together, this data provides valuable insight into mechanisms driving disease and corticosteroid response in SSNS due to defects in CLVS1 gene and highlights pathways that may be potential therapeutic targets.

### Nephrin-Ephrin-B1-Par6 Complex Is Crucial for Slit Diaphragm in Podocytes: Ephrin-B1 Suppresses Tight Junction Formation by Interfering With Par-6-Cdc42 Binding

Yoshiyasu Fukusumi, Ying Zhang, Hidenori Yasuda, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University, Niigata, Japan.*

**Background:** We have reported that ephrin-B1 interacts with nephrin, a key molecule of slit diaphragm at the extra-cellular domain (Fukusumi et al. JASN 2018) and interacts with Par-6, a member of the Par polarity complex, at the cytoplasmic domain in podocyte (Takamura et al. Am J Pathol 2021). However, the precise role of the ephrin-B1-Par-6 interaction in the slit diaphragm is unclear. The binding of Cdc42 with Par-6 is understood to be essential for tight junction formation. Converting to slit diaphragm from pre-mature junctions is an important step in podocyte differentiation, and it is reported that the transition of slit diaphragm to tight junction appears in many nephrotic conditions. Thus, we hypothesize that ephrin-B1-Par-6 interaction contributes to the maintenance of the slit diaphragm by interfering with the binding of Par-6-Cdc42.

**Methods:** To verify the hypothesis, the interactions of ephrin-B1, Par-6 and Cdc42 were analyzed with the HEK cell expression system. The alterations of the interactions in podocyte injury models were investigated with dual-labeling immunofluorescence study.

**Results:** The interaction of Par-6 and Cdc42 was detected with immunoprecipitation techniques with HEK cells transfected with these molecules. However, if ephrin-B1 was co-transfected, Par-6 was dissociated from Cdc42 and interacted with ephrin-B1. Then, if ephrin-B1 was phosphorylated by the treatment of Eph-Fc, the interaction of Par-6 with ephrin-B1 was disrupted and Par-6 interacted with Cdc42. In anti-nephrin antibody-induced nephropathy, a rat nephrotic model, not only nephrin but also ephrin-B1 was phosphorylated, and ephrin-B1 was dissociated from Par-6.

**Conclusions:** Ephrin-B1-Par6 interaction interferes with the Par-6-Cdc42 interaction, and consequently suppresses tight junction formation. The interaction of Par-6 with ephrin-B1 instead of Cdc42 is a critical step for converting the slit diaphragm from the tight junction. In injured podocytes, ephrin-B1 is phosphorylated and dissociated from Par-6, and Par-6 interacts with Cdc42 instead of ephrin-B1. It is conceivable that dissociation of ephrin-B1 from Par-6 is one of the critical events in podocyte injury. The stabilization of ephrin-B1-Par-6 interaction could be a novel therapeutic approach for nephrotic syndrome.

### Disease-Associated Mutant Gain-of-Function Causes INF2-Related Focal Segmental Glomerulosclerosis

Balaji karthick Subramanian,<sup>1,2</sup> Martin Pollak.<sup>1,2</sup> BIDMC-Nephrology <sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Highly penetrant Mendelian forms of Focal Segmental Glomerulosclerosis (FSGS) are rare examples where we can unequivocally say we know the cause of the disease. Inverted Formin 2 (INF2) is one of the 15 members of the formin family of proteins, which share a formin homology domain (FH2) involved in the control of actin polymerization. Missense mutations in INF2 lead to kidney disease characterized by proteinuria, progressive kidney dysfunction, and FSGS with or without Charcot-Marie-Tooth disease (CMT). Prior studies have suggested that INF2 promotes actin polymerization and modulates various cell processes such as mitochondria fission and Rho/mDia signaling. However, the mechanisms underlying kidney disease development remain unclear.

**Methods:** INF2 knock-out and INF2 R218Q knock-in mouse models were compared for their disease phenotype development. Puromycin aminonucleoside (PAN) injury was used as a stress model to compare the disease development between INF2 knock-out and knock-in mice models. Glomerular RNA sequencing analyses were performed to identify the pathways associated with the disease development. Micropatterned podocytes were used to validate the pathways driving the disease development.

**Results:** Neither the INF2 R218Q knock-in mutation nor INF2 knock-out condition impact glomerular development. However, the disease phenotype was higher with PAN injury in heterozygous and homozygous R218Q INF2 knock-in mice. In contrast, heterozygous or homozygous knock-out mice do not develop any significant kidney disease phenotype. RNA sequencing analysis showed changes in the expression of genes that regulate cell adhesion, mitochondria, and trafficking to associate with the disease phenotype. These changes were replicated in micropatterned podocytes, in which heterozygous and homozygous knock-in mice-derived podocytes exhibited disease-associated cell-adhesion (cortactin distribution) and mitochondria (fission/fusion balance) and trafficking (lipid raft recycling) defects.

**Conclusions:** INF2 mutation confers susceptibility to glomerular injury in the mouse, indicating the gain-of-function nature of INF2 mutants and presenting an important model to target for therapeutics development. Processes associated with cell adhesion, trafficking, and mitochondria may be involved in the disease.

### New Mutation in the TNS2 Gene Causes a New Form of Treatable Nephrotic Syndrome

Raquel Martínez Pulleiro,<sup>1,2</sup> Manuel Fidalgo diaz,<sup>3</sup> Angel Carracedo,<sup>2</sup> Cándido D. Rodríguez,<sup>3</sup> Miguel A. Garcia-Gonzalez.<sup>1,2</sup> <sup>1</sup>Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain; <sup>2</sup>Grupo de Medicina Xenómica (GMX), Santiago de Compostela, Spain; <sup>3</sup>Hospital Clínico Universitario de Santiago de Compostela, Servicio de Nefrología, Santiago de Compostela, Spain.

**Background:** Pediatric primary nephrotic syndrome (PNS) is a renal disease characterized by the triad of proteinuria, hypoalbuminemia and edema. Treatment consists of immunosuppressive drugs and corticosteroids and, not in all cases, a satisfactory response is obtained and corticoid dependence or corticoid resistance (SRNS) may develop. Patients may progress to end-stage renal disease (ESRD) and may require dialysis and/or transplantation. In most cases its etiology is unknown, although advances in the molecular genetics of glomerular diseases have shown that single gene defects can affect podocyte structure and function being responsible for one-third or more of all pediatric cases of SRNS. In 2018, Ashraf et al. described a new entity of partially treatment-sensitive SN (pTSNS) and found an underlying genetic cause (six genes involved in the regulation of Rho GTPases in podocytes, including TNS2).

**Methods:** DNA extraction from a blood sample and mutation detection by NGS sequencing of a panel of glomerular genes. Variant filtering was done based on population and eigen frequencies, quality and functional impact parameters. Interpretation with reference to ACMG criteria.

**Results:** In our cohort we have a case of pTSNS with multiple recurrences throughout life, persisting into adulthood. All alternative therapies that were tried to limit the high doses of steroids and their respective toxicities were unsuccessful. Genetic diagnosis revealed a previously undescribed homozygous mutation in the TNS2 gene (Asn1262Ile), in a conserved residue, with interpretation of “disease-causing” given by in silico predictors and with a particular phenotype.

**Conclusions:** The homozygous mutation of the TNS2 gene is responsible for our patient's NS, being the second genetic diagnosis worldwide linking mutations in TNS2 with pathology. Although immunosuppressive treatment achieves disease remission for months, it is not able to prolong it over time. The only way to control relapses is steroids. Knowing the behavior of the SN associated with TNS2 can give the patient a better prognosis of the disease. Regarding genetic diagnosis, there is a need to constantly update the panelized study of genes causing glomerular disease due to the continuous discovery of new genes.

## SA-PO743

### A Missense Mutation in Zinc Finger 4 of WT1 Might Lead to Focal Segmental Glomerular Sclerosis due to Its Mislocalization and Downstream Dysregulation

Toru Kanamori, Tomohiro Udagawa, Miki Murakoshi, Eriko Adachi, Mika Okutsu, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Tokyo, Japan.*

**Background:** Wilms' tumor suppressor gene 1 (*WT1*) is associated with the development of the urogenital system and regulates genes involved in sex differentiation and determination. *WT1* encodes four zinc finger domains (ZF). Inactivation in ZF2 or 3 of *WT1* causes Denys-Drash syndrome (46, XY disorder of sex development [DSD] and renal disorders) and in intron 9 of *WT1* causes Frasier syndrome (genital tract anomalies and focal segmental glomerulosclerosis [FSGS]). Eozenou et al. reported that mutations in ZF4 of *WT1* cause 46, XX DSD (*ProNAS*. 2020, 13680). There is insufficient evidence associating ZF4 variants and nephropathy.

**Methods:** A 15-year-old boy presented with proteinuria, renal dysfunction, and undescended testis. He was diagnosed with FSGS by renal biopsy at 16 years and started hemodialysis at 20 years of age. To analyze the pathogenic mechanism of the mutations (*WT1* R495Q) found in this FSGS patient, we evaluated localization of *WT1* and other podocyte slit-diaphragm proteins by immunofluorescence staining using C-terminal antibodies of a kidney section. HEK293T cells were transfected with expression constructs to encode the wild type or R495Q *WT1* protein. To examine the effect of *WT1* R495Q on the regulation of key podocyte genes, we quantitatively assessed messenger ribonucleic acid (mRNA) expression levels isolated from wild type or mutation-expressing HEK293 cells by qPCR.

**Results:** Immunofluorescence staining showed that in contrast to the cytoplasmic localization of *WT1* in a boy with non-genetic nephrotic syndrome, WT1 was localized to podocyte cytoplasm and nucleus. We found less expression of the *NPHS1* gene in the case of transfection with *WT1* R495Q compared to wild types. *NPHS1* mRNA expressed approximately 25-fold whereas *NPHS* mRNA expressed approximately 10-fold compared to the control. When wild type and mutant WT1 were transfected with the same dose, the expression of *NPHS1* was the same as when only the mutant was transfected.

**Conclusions:** We demonstrate that *WT1* R495Q mutation affects WT1 protein localization and dysregulates *NPHS1* expression in podocytes. Our data suggests the loss of function mutation had a dominant negative effect in podocytes.

**Funding:** Government Support - Non-U.S.

## SA-PO744

### Single Cell RNA Sequencing Revealed Genes That Could Mediate Podocyte Injury in Genetic Podocytopathy

Vidhi Dalal,<sup>1,2</sup> Alexander J. Kula,<sup>1,2</sup> Priya S. Verghese,<sup>1,2</sup> Tomoko Hayashida,<sup>1,2</sup> *Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Up to 30% of pediatric patients with steroid-resistant nephrotic syndrome carry a mutation in genes that are critical for maintaining the podocyte structure. While it is still impractical to mend individual mutation, some patients develop symptoms later in their life, providing a potential therapeutic window. However, a mechanism by which podocyte injury progress in those patients are largely unknown.

**Methods:** Single cell suspension was prepared from a portion of nephrectomized kidney of a patient with ACTN4 and ITGB4 mutations and subjected to single cell RNA sequencing (scRNAseq). The data was compared to a dataset from healthy adult kidney at Kidney Interactive Transcriptomics (KIT).
